LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

Stations in the United States.

U. S. Department of Agriculture.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of *Experiment Station Record* is $1.50 per volume, or 15 cents per number. The prices of other technical publications are given above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XX. SEPTEMBER, 1908. No. 1.

The call for men to carry on the work of the agricultural colleges and experiment stations has continued unabated during the past year. At this season, when changes are being made and new plans put into effect, the demand is especially imperative. It comes with particular stress for men to fill the higher positions in the work of these institutions, notably the advanced work in the experiment stations.

The difficulty of filling positions satisfactorily is increasing as the demand becomes more exacting. Standards have changed materially in the last few years. More and more emphasis is being laid on new appointees having had broad training, in addition to their college course. Less stress than formerly is laid on the practical training and experience, and more upon a thorough grounding in the principles of science and a true conception of the spirit and methods of research. Given the latter, a sufficient familiarity with practice to bring the investigator into touch with its problems may be acquired; but the reverse does not follow.

The change in character of the demand has been gradual but steady. Already it has left behind many who started out in the work originally, or even a decade ago. The development of stations all over the country has presented such differences in standards and in grade of work that in the past men with but little special training beyond the college course have usually been able to find places in the work, if they combined other desirable qualities. Gradually, however, the necessity for more advanced study of agricultural problems has become widespread; and especially since the passage of the Adams Act the attempt to inaugurate more work of that class has been general throughout the country. The latter has exercised an unmistakable influence on the work of the stations as a whole, and has thus made new demands on the personnel, present and prospective. It has directed more attention to investigation and to the necessary preparation for it.

The first effort in inaugurating these investigations was to conduct them mainly with the staff which the station already had. Men who could be added for this purpose were scarce, and furthermore the

actual requirements were not always fully appreciated. It is not surprising therefore that difficulties were encountered. Comparatively few of the men had been educated and trained for thoroughgoing investigation, and hence the number who fully understood the spirit and the meaning of scientific investigation was not large.

Out of any large body of men interested in science only a few are really productive in investigation. This is evidenced by the record of any large scientific society, or even of any large university. While there are many men publishing the results of their work, much of which is of value, especially in cumulative form, there is a comparatively small number whose work is conspicuous for originality of thought and for marking distinct advance. This is in some degree due to the fact that the general average is already higher than formerly, but it is also due to the fact that genuine research ability is rare. Hence in any branch of science a considerable body of workers is essential to a satisfactory output. There must be a quite large number of men engaged before the amount of actually productive research is such as to attract much attention.

This is as true in station work as elsewhere. Out of a comparatively small number who have prepared themselves for original scientific work there will necessarily be but few who will exhibit special aptitude and ability, and not until a considerable number have been developed who have an interest and zeal for agricultural investigation will there be a sufficiently large body of genuine investigators to lead thought and promulgate the spirit of that work. Hence when the Adams fund came there were comparatively few who were able to formulate productive lines of original research—undertakings in which for the time being the consideration of principles predominated over the development of rules for practice.

The result has been that the investigation under that fund has not all been of uniformly high grade. Some has been abandoned or turned over to other funds, and some has been reshaped and strengthened in plan as a result of conference and advice. Much can be done by way of suggestion, but it is becoming evident that no amount of planning will make an undertaking a piece of research unless the guiding hand of the man in charge places it there. The man may be aided by suggestion and counsel in shaping his investigation, but his own genius will determine its ultimate quality. Research is an individual product, an expression not only of the man's technical knowledge but of his mental grasp and acumen.

It is time that the kind of men required for station work was more fully understood. This applies to the stations themselves, as well as to the men electing to enter that field. It applies to the experimental work of the station as a whole, as well as to its research work. The

station is a scientific institution. Its work in every department must be on a basis that will command the respect and confidence of scientific men as well as of the farmers. Moreover, it must be progressive, advancing, going higher and higher as it develops. How can this be the case if it runs against human limitations almost at the outset?

Not all men entering the station work are to become investigators in the scientific sense. It will not be exacted of them. There are various grades of station work which have to be provided for; but the standards for all classes of work are steadily advancing. We can not always be expected to continue comparing varieties of cabbage or strawberries to determine which are best for the market gardener to grow. We shall advance to a grade of work a step higher—perhaps show him how he himself can improve varieties, and then what characters are correlated with certain qualities. We shall lead him and make him more independent, rather than keeping him dependent and allowing his inertia to hold the station back.

Hence the men who now enter the work must be trained so that they can see the real problems and have the right perspective as to values. They must be able to make their work progressive in character and to bring into it more and more real investigation—features which aim at establishing some of the fundamental facts. Then their work will become productive. If the man lacks sufficiently broad training and perspective, he will not be able to do this creative kind of work, no matter how hard he tries. His department will mark time, or the station will have to find someone to take his place. So in selecting their new men, the stations must secure, as far as possible, men who have the desire, the qualifications, and the broad outlook for progressive work, even though circumstances may for awhile keep them at some rather elementary tasks.

For the research work which the station is to enter upon at once it must have broadly educated and mature scientists, men who know what constitutes the essentials of investigation and are able to apply these to agricultural problems. No matter how sincere and earnest a station may be in its desire to carry on advanced investigation, it will fall short of attaining this end unless it has the men suited by taste and preparation. It can not develop a corps of productive investigators out of men who lack this foundation. The man whose fundamental training has not been of such extent and character as to give him the right point of view at the start, will be able to grasp only feebly the kind of work which is wanted of him or to adapt himself efficiently to it. Not only will he not be resourceful in investigation, but he will not have correct ideas of values and can not grow into the position of a directing head of a department. The qualities which fit a man for investigation are not picked up, except to a limited degree. They are distinctly a product of his education, supple-

mented by a natural aptitude. These qualities become a part of his nature as exhibited in his habit of thought, the evidence he requires to satisfy his mind.

We need in some quarters a clearer understanding of what research is and of the methods of science which characterize it. The lack of this knowledge is a stumbling block to some men who have aspired to undertake Adams fund work. It can not be otherwise, and until a proper conception of this grade of work and its requirements becomes more widespread, our investigation will not attain the position which we hope for it.

A great deal of our "research" is not started right and can not lead to definite conclusions of scientific value until different methods are practiced. The accumulation of data, whether analyses or observations, in an indefinite way, in the hope that they will shed light or furnish a clew which will suggest a starting point or give an empirical answer, is expensive and seldom leads up to an investigation.

Research does not spring merely from a desire to further human knowledge. It is conditioned on certain qualities in the man, developed in part through his training and in part inherent in himself. The foundations of it are laid in an attitude which demands a scientific reason for observed phenomena, a knowledge which enables the subject to be approached intelligently, and skill and judgment in the handling and interpretation of data. We may have the desire to know the fundamental reason why a given soil becomes infertile; but unless we have a sufficiently broad training to discern the point of attack, to formulate a plan of investigation, taking advantage of what is already known, and to interpret the results in a logical and scientific manner, research will be out of the question.

An investigator can not be made, even by the most careful attention to his training and preparation. His ultimate success will depend upon something within himself which can not be supplied from the outside. But a great deal can be done in developing the resources he possesses, in directing his study along broad lines, and in inculcating the scientific spirit. These things are a product of special graduate work of university grade. They require a favorable atmosphere for their development.

The recognition of these facts is leading station directors to an increasing degree to require higher qualifications in their new men. They are looking for men who have had substantial graduate courses in science equivalent to the work of the larger universities, which shall have brought them into direct contact with research work and given them not only the technical knowledge and training in methods, but correct discrimination and an inspiration which lie at the very basis of successful investigation.

The idea has been current to some extent that the stations could train their own men, at least in part. This has led to the not unusual practice of taking men direct from the college course and putting them through a sort of apprenticeship in station work, which has been accepted by the men as equivalent to a graduate course in a university. As a matter of fact, this is usually far from being the case. The stations can advise men in their reading, can assist them in getting a clear conception of the spirit of their work, and can stimulate them to secure more adequate preparation through university courses. But it must be left to the colleges and the universities to provide courses of instruction which prepare men to undertake advanced work and give them the proper point of view. They must bring to the station a thorough start in their education for its work.

The stations on their part should stimulate their men to pursue advanced study if they are to rise above the grade of a quite subordinate assistant. It should give them no encouragement to think that in the present status of station work they can get along without it. Indeed, they might well make such graduate study a condition of advancement to a position of independent work, as some have already done.

In the past the stations have had very largely to adapt such men as the market afforded to their special field of work. This must always be the case to some extent. The work is so special that no institution could be looked upon to provide courses of instruction in it. But this is quite different from providing the fundamental education. Education is not only the imbibing of information but the securing of a point of view and an ability to work out problems for one's self. This is the work of the preparatory institution. The value of a scientific fact and the method by which it is established is a part of a man's scientific education. Without it he will have distinct limitations as a station man, and will never be able to progress far in independent work.

The question is already being asked whether the courses of the agricultural colleges provide men with the proper groundwork for station investigators. In some cases, at least, they clearly do not inculcate the point of view which the prospective station man should have. He does not receive a correct idea of values as applied to different classes of experimental work, or a true conception of the relations which science bears to the practical art of agriculture. The means by which science may be made to clear up the mysteries of plant and animal growth are not always brought home to the student, even in an elementary way, and the relative merits of different kinds of experimentation and investigation are rarely presented in such a way as to give him a true perspective or an intelligent discrimination.

In other words, he gathers little of the real spirit of investigation or of the scientific method in settling questions. In the past many of the graduates have left the course with much the same feeling that the farmer has—that practical trials and simple experiments under conditions which imitate practice will be sufficient to determine the best methods and furnish rules for farming. Beyond this they have not had impressed upon them the needs of agriculture in a broad and more fundamental sense.

If one of the main objects of the college education is to teach correct ideas of values, it would seem that this should be extended to the subject which touches the agricultural student most closely. The work of the stations furnishes a great variety of material for such instruction, and it might with advantage be made a part of the required course. Agricultural education is not complete unless it teaches the student the meaning of experiment station work—the significance of investigation as well as of the more immediately practical experiments, and enables him to use the results intelligently and with some discrimination.

The experiment station is one of the fields open to the graduate in agriculture. In the past it has looked to the agricultural college as the source from which to recruit its forces. The station investigator should be the highest product of the agricultural course, and as such may be accorded some special attention in its courses. This does not minimize the position of the farmer graduate, or the man who has gained a new touch with nature through its course, or the agricultural editor whose effort is to lead agricultural thought. But the discoverer of truth, the man who is adding to the store of knowledge, is furnishing the stock in trade of the farmer, the writer, and the teacher. He stands at the head of the system, indispensable to further progress, and marking the highest stage in the application of his education. He is therefore worthy of special care in his training, for potentially he represents the highest type of product.

Formerly when there were only a few State stations the encouragement to young men to spend time and money preparing for a career in that field was quite restricted. The conception of the need of special preparation has rested with the stations, and not until they demanded it and made it a condition of appointment was provision made to meet it. Now the colleges are establishing graduate courses and giving more attention to advanced study. Whether or not they will be able to turn out men with the highest type of preparation is a vital question.

The opportunity for a career in station work is now at hand. The stations in the development of their work have furnished the incentive to young men to prepare themselves thoroughly for this field. The grade of work is steadily advancing throughout the country. The

opportunity for advanced work freed from the distraction of other duties is making the field more attractive. The man of faulty preparation will soon find his limitations, and the discovery may and often will come too late to be rectified. A requirement of broad and thorough preparation is in the ultimate interest of the man as well as of the station.

The effect of the Graduate School of Agriculture the past summer in opening up the field of agricultural investigation and broadening the view of those in attendance regarding the problems and methods of investigation, was perhaps its most important influence. The opportunity for coming into intimate contact with so many leading men in that work was a rare one. It was especially beneficial to young men preparing to enter the experiment stations. It not only served to familiarize them with the present status of knowledge on special subjects, but it inculcated higher ideals as to the character of work to be done and the preparation necessary to undertake it.

The real nature of many intricate problems in agriculture and their relation to the fundamental sciences were brought home with a new force. To many a man this school presented the first real conception of the true scope of the field in which he was working. To some the discovery was well-nigh overwhelming, while to others it was stimulating to a high degree, and inspired them with a desire for further study. To all it was broadening and imparted something more of the spirit of investigation.

53818—No. 1—08——2

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

On the theory of indicators and the reactions of phthaleins and their salts, S. F. Acree (*Amer. Chem. Jour., 39 (1908), No. 4, pp. 528–544*).—The essential point brought out in this discussion is that "the chief cause of this color [in case of phenolphthalein and similar compounds] is not the colored quinone group . . . but the double compound formed by the inter- or intramolecular union of the quinone complex with the free aniline (or aniline hydroxid) groups of the dyestuff."

Note on the determination of potash by the perchlorate method in fertilizers, soils, manures, crops, etc., V. Schenke (*Landw. Vers. Stat., 68 (1908), No. 1–2, pp. 61–65; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 546, II. p. 321; Chem. Ztg., 32 (1908), No. 36, Repert., pp. 238, 239*).—The author calls attention to certain difficulties encountered in applying his method (E. S. R., 19, p. 613) to the determination of potash in soils rich in lime and in solutions containing strong acids, particularly sulphuric acid. To overcome such difficulties he recommends a procedure which is in the main the same as that followed in the modified Finkener platinic chlorid method which he has previously described. In this the sulphuric acid is removed by evaporation and careful heating over a direct flame, the residue taken up in a small amount of 5 per cent hydrochloric acid, the sulphuric acid precipitated with the smallest possible excess of 10 per cent barium chlorid, and other salts removed by the addition of alkali-free milk-of-lime. After standing about one-half hour an aliquot part of the filtrate from these precipitations is acidified with hydrochloric acid and potash precipitated with 20 per cent perchloric acid. A comparison of this method with the ordinary perchlorate method showed that the modified method gave somewhat higher results than the original method.

On the use of nitron for the determination of nitric acid in soils and plants, J. Litzendorff (*Ztschr. Angew. Chem., 20 (1907), No. 51, pp. 2209–2213; abs. in Jour. Soc. Chem. Indus., 27 (1908), No. 2, p. 83; Jour. Chem. Soc. [London], 94 (1908), No. 544, II, pp. 130, 131; Bul. Soc. Chim. France, 4. ser., 4 (1908), No. 5, p. 341*).—In the use of this method for determining nitric acid in soils 2 kg. of the soil is shaken for ½ hour with 4 kg. of water according to the method of Buhlert and Fickendey (E. S. R., 17, p. 832). To 100 cc. of the solution thus obtained, heated to boiling, 5 to 10 cc. of 10 per cent nitron acetate solution is added and the solution kept in ice or ice water until the precipitate separates out. The precipitate is then collected on a Gooch filter, dried at 110° C., and weighed. When the soil contained less than 20 parts per million of nitric nitrogen it was found desirable previously to concentrate the soil extract by evaporation with the addition of a little sodium hydroxid or calcined magnesia.

In the determination of nitric acid in mustard 20 gm. of the dried and fine-ground plant was extracted with 400 gm. of water which was slightly warmed.

A part of the extract was then acidified with acetic acid, the solution filtered, and nitrate precipitated with the nitron solution.

The method was compared with other standard methods of determining nitric acid, such as the Schloesing and the Schulze-Tiemann methods, under varying conditions. The materials examined included compost earth, field soils, and mustard, as already stated. The results show that the method will very accurately determine 2 to 3 mg. of nitrate nitrogen in 100 gm. of soil. In case of soils containing less than this amount of nitrate it is not possible to make accurate determinations on account of the fact that the repeated extraction necessary and the greater concentration required result in increase of substances in the solution which prevent the crystallization of the nitron nitrate. Substances which similarly interfere with the crystallization occur when soil extracts are sterilized by heat. The difficulty due to these substances can be removed by repeatedly adding hydrogen peroxid to the extract during evaporation and by heating the concentrated extract with hydrogen peroxid in boiling water for 6 hours until the color is destroyed. The determinations of nitrate in mustard indicate that the results heretofore obtained by other methods of determining nitrates in plants are often too high.

The determination of ammonia in water, A. Ronchèse (*Jour. Pharm. et Chim., 6. ser., 27 (1908), No. 5, pp. 231–235; Bul. Soc. Chim. France, 4. ser., 3 (1908), No. 6, pp. 362–366*).—The author describes an adaptation of his formaldehyde method (E. S. R., 19, p. 407) to the determination of small amounts of ammonia in waters. He reports tests with water containing varying amounts of ammonia from which he concludes that the method is as exact as the more sensitive methods of determining ammonia in water, as, for example, that of Buisson.

A method for the determination of very small amounts of carbon, especially the carbon of organic substances, in water, N. Popowsky (*Arch. Hyg., 65 (1908), No. 1, pp. 1–16, figs. 2*).—The method with which this article deals is an adaptation of the wet combustion method perfected by Scholz in which the organic matter is converted to carbon dioxid by boiling with potassium bichromate and sulphuric acid. The carbon dioxid is measured by the decolorization of sodium-carbonate solution containing phenolphthalein, the carbon dioxid converting the carbonate to bicarbonate and thus destroying the color.

A new reaction for protein, B. Bardach (*Ztschr. Physiol. Chem., 54 (1908), No. 4, pp. 355–358*).—The presence of albumin hinders the formation of iodoform from iodin or iodid of potassium and acetone. The author studied the reaction with a number of different proteids and concludes that it not only may be useful for the detection of protein but also may be of value in judging of the nature of the proteid present.

Chemistry of flesh. Further studies on the application of Folin's creatin and creatinin method to meats and meat extracts, A. D. Emmett and H. S. Grindley (*Jour. Biol. Chem., 3 (1907), No. 6, pp. 491–516*).—On the basis of an extended chemical study of meat extracts and meats, conclusions were drawn regarding the applicability to such products of the Folin method of determining creatinin and creatin, and suggestions are made regarding details of manipulation, etc.

The authors conclude "that the Folin method when properly modified is as applicable to meat extracts and meats as it is to urine," and that it has given reliable and concordant results in their experience.

Concerning Liebig's meat extract, III, Kutscher (*Zentbl. Physiol., 21 (1907), No. 18, pp. 586, 587*).—A saturated alcoholic solution of cadmium chlorid has proved a useful reagent in the study of meat extract bases.

A trial of the polariscopic method for the determination of gliadin, G. W. SHAW (*Jour. Amer. Chem. Soc., 29 (1907), No. 12, pp. 1747–1750*).—From an experimental study of this method, the author is decidedly of the opinion that it is worthy of much more extended use and that if precautions are taken to make corrections for the effect of other optically active bodies there are fewer opportunities for error than with the ordinary methods of determining nitrogen.

"In our experience with the method it was always found necessary to make two polarization determinations, the first of the original solution, and the second after separating the protein bodies by the use of a concentrated solution of mercuric nitrate, and then making the required correction to give the true gliadin reading."

On the analytical estimation of gliadin, W. E. MATHEWSON (*Jour. Amer. Chem. Soc., 30 (1908), No. 1, pp. 74–81*).—In a comparison of different methods of extracting gliadin it was found that 8 to 17 per cent more nitrogenous matter was extracted when the proportion of material to solvent (cold 70 per cent alcohol) was 4 gm. to 100 cc. than when 4 times as much flour was used.

"After drying 6 hours in the water oven, 10 to 20 per cent less gliadin was obtained by extracting with cold solvent. With the hot water solvent the figures were nearly the same, being slightly lower. Pure gliadin remains soluble in dilute alcohol after the same treatment. No tendency for glutenin to remove gliadin from its alcoholic solutions by absorption or with the production of a solid solution could be demonstrated. Propyl alcohol of constant boiling point (70 per cent by weight) used in an extraction apparatus gave results probably no more accurate than the others. Anhydrous phenol dissolves a high percentage of protein matter from the flour. The dissolved matter is not pure gliadin, however, nor does it seem to consist of gliadin with but one other protein."

Experiments upon Barfoed's acid cupric acetate solution as a means of distinguishing glucose from maltose, lactose, and sucrose, F. C. HINKEL and H. C. SHERMAN (*Jour. Amer. Chem. Soc., 29 (1907), No. 12, pp. 1744–1747*).—In the authors' hands, this method gave good results, being efficient for the detection of 0.0004 gm. glucose, either alone or in the presence of maltose, lactose, or sucrose up to 0.02 gm.

"Reduction due to disaccharid occurs if too much either of sugar or of acid be present, or if the heating be too prolonged. In order to effect complete destruction of the glucose, so that the filtrate might be utilized in testing for maltose or lactose, it was necessary to limit the amount to about 0.002 gm. of glucose to 5 cc. of the reagent. It appears that the test requires very careful regulation as to details of manipulation and amount of sugar tested, but under such restrictions is capable of greater usefulness than has generally been appreciated. . . .

"On account of the difficulty of securing an exact degree of acidity in the cupric-acetate solution, each chemist should demonstrate the efficiency of his reagent, as well as verify his manipulation, by check experiments upon known sugar solutions covering the probable range of composition of the unknown solutions to be tested."

The estimation of starch in potatoes by means of specific gravity, FOTH (*Ztschr. Spiritusindus., 30 (1907), No. 21; abs. in Bul. Assoc. Chim. Sucr. et Distill., 25 (1908), No. 7, pp. 691, 692*).—A modified method of estimating the starch content of potatoes from their specific gravity is proposed.

A new method of determining the water which flour will absorb, J. F. HOFFMANN and R. PLOETZ (*Ztschr. Spiritusindus., 31 (1908), No. 5, pp. 42, 43*).—In the method described the sample, after wetting with water, is pressed

between 2 porcelain slabs. A mathematical formula is proposed for use in calculating from measured data the power of flour to absorb water.

Microscopical examination of wheat flour, especially for the detection of rice and bean flour, J. Bellier (*Ann. Chim. Analyt., 12 (1907), No. 6, pp. 224–228*).—The data reported have to do with the characteristics of different sorts of flour examined with a microscope and are discussed with special reference to the detection of adulteration of wheat flour.

Adulteration of chocolate with potato starch, A. Paladino-Blandini (*Naples, 1907, pp. 3; separate from Gaz. Internaz. Med., 10, 1907*).—The data reported have to do with the detection of potato starch in chocolate.

Concerning the acid content of honey, Utz (*Pharm. Post, 41 (1908), Nos. 6, pp. 69, 70; 7, pp. 81–83*).—The author determined the acid content of 175 samples of honey, most of them of German origin. He found that the acid content, expressed as formic acid, varied decidedly from the values given in the literature of the subject, ranging in the samples analyzed from 0.0644 to 0.3312 per cent. He also concludes that heating honey on a water bath diminishes the amount of free acid present and that this loss is more noticeable if the honey is heated over a free flame.

Concerning the mineral matter in honey, Utz (*Ztschr. Angew. Chem., 20 (1907), No. 51, pp. 2222–2225; 21 (1908), No. 17, pp. 780–781*).—Examination of 131 samples of German honey from different regions showed a range of 0.013 to 0.703 per cent, the mean average value being 0.358 per cent ash. Eighteen samples of honey from other regions contained from 0.051 to 0.306 per cent.

Concerning the mineral matter in honey, F. Schwarz (*Ztschr. Angew. Chem., 21 (1908), No. 10, pp. 436–439*).—The author does not agree with Utz's conclusion regarding the ash content of honey (see above). Basing his conclusions upon the examination of 374 samples he believes that the ash content of pure honey is not less than 0.1 per cent and that when it falls below this value the material is either adulterated or very suspicious. In his opinion, determining the ash content is an important method of judging of the purity of honey.

Biological method for determining the presence of horse meat, Weidanz (*Ztschr. Fleisch u. Milchhyg., 18 (1907), No. 3, pp. 73–78*).—On the basis of investigation, the author concludes that the biological method gives satisfactory results.

A practical method for the detection of beef fat in lard, J. A. Emery (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 132, pp. 9*).—The method described consists in determining the melting point of the solid glycerids of the sample, obtained by crystallization from ether. It depends on the fact that although under like conditions of crystallization there is a uniformity in such value for lard, and also in that for beef tallow or oleostearin, the melting point is lower for the latter than for the former, and for a mixture of the two lies somewhere between the values for the pure fats. The technique of the method and the determination of the melting point are described, possible sources of error are mentioned, and some results of the practical application of the method are given.

In conclusion the author states that the method "has afforded very good results both in his hands and in those of a number of his coworkers and is considerably shorter than the method proposed by Leys.

"The application of both of these methods has proven efficient in detecting added beef in samples of suspected 'pork sausage.' The fat was obtained by subjecting the meat to a temperature of 125° C., and then pouring off and filtering the separated melted fat.

"In samples in which the amount of fat as obtained in this manner was not sufficient, extraction of the fat from the water-free finely minced product by means of ether and evaporation of the solvent was necessary. The subsequent procedure was then carried out as described in the method given.

"Finally it may be said that when the crystallized glycerids of any questionable sample of lard examined by the method described in this paper show a melting point below 63.4° C., the presence of beef fat should be suspected, while a melting point of 63° C., or below, can be regarded as positive evidence that the sample under examination contains beef fat as an adulterant."

The application to solid fats of Renard's test for peanut oil, W. B. SMITH (*Jour. Amer. Chem. Soc., 29 (1907), No. 12, pp. 1756, 1757*).—The results obtained show "that the addition of fats containing large percentages of solid fatty acids to cotton-seed oil or other oils interferes materially with the detection of peanut oil by this method, and in case the presence of peanut oil is suspected in such mixtures, some modifications of the method will be necessary to detect it; either to increase the proportion of 90 per cent alcohol used, which would be objectionable, or to recrystallize the 'arachidic acid' until a melting point higher than that of stearic acid is obtained, when the presence of arachidic acid is established."

The determination of sulphites in wine, C. MENSIO (*Gaz. Chim. Ital., 37 (1907), II, No. 4, pp. 344–355*).—A study of methods.

Examining and judging pepper, F. HÄRTEL and R. WILL (*Ztschr. Untersuch. Nahr. u. Genussmtl., 14 (1907), No. 9, pp. 567–579*).—The analytical and other data reported and discussed have to do with the detection of adulteration in pepper. According to the authors' results, the largest amount of ash permissible under the German pure food regulations, 7 per cent, is too high. They consider that a reduction to at least 6.5 per cent is desirable.

Ginger and extract of ginger, R. REICH (*Ztschr. Untersuch. Nahr. u. Genussmtl., 14 (1907), No. 9, pp. 549–567*).—According to the author's observations the quality of ginger may be learned by determining the volatile and nonvolatile ether extract, the alcohol extract by the Winton method, the alcohol extract after extraction with ether, the petroleum ether and methyl alcohol extract, total ash and sand-free ash, and the sand-free mineral matters insoluble in water. Characteristic differences in various sorts of ginger are pointed out and discussed.

The examination of marzipan and marzipan goods, F. HÄRTEL and P. HASE (*Pharm. Zentralhalle, 48 (1907), No. 50, pp. 1029–1035*).—From the considerable amount of analytical data which is reported, the author concludes that the determination of the water, fat, and sugar, and under some conditions the mineral matter, is essential for judging of the quality of such goods. The use of sweet apricot pits in place of almonds and other questions are also considered with special reference to pure-food laws.

A simple mechanical method for the estimation of casein in cows' milk, E. B. HART (*Wisconsin Sta. Rpt. 1907, pp. 117–133, figs. 3*).—The substance of this article has been noted from Bulletin 156 of the station (E. S. R., 19, p. 707).

Application of the reductase test in judging the hygienic characteristics of milk, C. BARTHEL (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 7, pp. 385–403*).—According to the results of investigations reported, testing the reductase action of milk upon the methylene-blue solution used in the Schardinger reaction may be employed as a means of judging the quality of milk.

To 10 cc. of milk 0.5 cc. of methylene-blue solution is added, the mixture is covered with a few drops of liquid paraffin and placed in a water bath at 40 to 45° C. If the color disappears in a few minutes the milk contains 100,000,000 or more bacteria per cubic centimeter. Even when the color continues

for about an hour the milk must be considered as too impure for food, especially for infants. Milk in which the color disappears within 3 hours is of inferior quality, but that requiring more than 3 hours is good market milk. The test should be made in duplicate.

A very simple means of distinguishing between cooked milk and raw milk, L. Gaucher (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 6, pp. 275, 276*).—A small sample (20 cc.) of milk is colored with 20 drops of a 1 per cent solution of hematein and shaken. If the milk is raw the rose color remains, but if it has been boiled the color quickly fades.

Pentoses in feces and their estimation, A. Jolles (*München. Med. Wchnschr., 55 (1908), No. 3, pp. 117–120*).—In this article, which discusses the pathological occurrence of pentoses, data are supplied regarding the relation of pentoses to different diets.

Miscellaneous chemical analyses, F. W. Woll and G. A. Olson (*Wisconsin Sta. Rpt. 1907, pp. 160–164, 167–170*).—Among the analyses reported are those of a Cheddar cheese 4 years old, skim-milk cheese, salty milk, human milk, and factory by-products.

A new apparatus for determining the condensing power of soils for ammonia, G. Rösing (*Ztschr. Landw. Versuchsw. Österr., 11 (1908), No. 2, pp. 123–127, fig. 1; abs. in Chem. Abs., 2 (1908), No. 11, pp. 1586, 1587*).—A modification by Remy of the apparatus described by Wohltmann and Schneider (E. S. R., 17, p. 537) is described and tests of it on a number of samples of soil are reported. The modification provides for equalization of pressure in the apparatus before and after absorption of the ammonia and thus insures accuracy of measurement.

Determination of the heat of combustion of organic compounds by use of the platinum resistance thermometer, E. Fischer and F. Wrede (*Sitzber. K. Preuss. Akad. Wiss., 1908, No. 5, pp. 129–146; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 545, II, p. 155*).—More accurate results are claimed from the use of a platinum resistance thermometer in place of the mercury thermometer. Values for the heats of combustion of sucrose and benzoic acid are given as 3.954 and 6.328 large calories per gram, respectively.

METEOROLOGY—WATER.

Note on some meteorological uses of the polariscope, L. Bell (*Proc. Amer. Acad. Arts and Sci., 43 (1908), No. 15, pp. 407–412, fig. 1*).—An account is here given of some preliminary observations with a Savart polariscope at the base of Mount Moosilauke, N. H., at an elevation of 1,650 ft., from which the conclusion is drawn that such observations give "a most instructive view of the very early stages of atmospheric nucleation, and especially if combined with rainband observations should have material prognostic value as regards comparatively local conditions."

Equivalent temperature as a unit expression of the climatic factors, air temperature, and atmospheric humidity, W. Knoche and J. Hann (*Met. Ztschr., 24 (1907), Nos. 10, pp. 433–444, figs. 7; 11, pp. 501–504*).—Knoche calculates the equivalent temperature as well as its yearly and daily variations for various climates, and discusses the value of this unit as a combined expression of air temperature and humidity. As defined by von Bezold equivalent temperature is the heat measured by the thermometer plus the latent heat of the aqueous vapor in the air. J. Hann in reviewing Knoche's article asserts that equivalent temperature is of no value as a unit expression for air temperature and humidity, as a climatic factor, or as a factor in the heat economy of man or organisms in general; that is, it is of no biological importance.

The relation of meteorology to horticulture, R. H. Curtis (*Jour. Roy. Hort. Soc. [London], 33 (1908), No. 1, pp. 12–19*).—This is a continuation of a previous article and deals chiefly with atmospheric moisture, particularly the amount, distribution, and character of the rainfall in relation to plant growth.

The development of the German weather service during 1907, Börnstein (*Jahrb. Dent. Landw. Gesell., 22 (1907), No. 4, pp. 761–764*).—This is a brief statement regarding the value of this service to farmers.

The weather of the summer of 1907 in Germany and its influence on the agricultural industry, Kassner and Hillman (*Jahrb. Dent. Landw. Gesell., 22 (1907), No. 4, pp. 765–778, pls. 4*).—The season of 1907 is briefly discussed from the meteorological standpoint as well as with reference to its influence on the agricultural industry.

Climate [of Belgium], (*Exposé de la Situation du Royaume de 1876 à 1900. Brussels: Gort., 1907, vol. 1, pp. 55–84*).—The general climatic conditions are described and meteorological observations which have been made since the establishment of the observatory of Brussels in 1833 are summarized.

Contributions to the study of the meteorology of Cape Verde, J. M. de Macedo (*Rev. Off Missão Agron. Cabo Verde, 1 (1908), Nos. 1, pp. 19–24; 2, pp. 48–51; 3, pp. 85–88*).—The meteorological conditions during 1905–1907 are briefly summarized.

Studies on the climate of Tunis, G. Ginestous (*Études sur le climat de la Tunisie. Tunis, 1906, pp. 428+XI, illus.; rev. in Bul. Dir. Agr. Com. et Colon. [Tunis], 11 (1907), No. 45, p. 577*).—This is a thesis presented for a doctor's degree at the University of Paris. It reviews previous publications on the climate of Tunis and summarizes and discusses the meteorological data obtained at the various stations of the meteorological service of Tunis during more than 20 years. The work is in three parts, (1) general character of the climate of Tunis, (2) study of the climate of Tunis, and (3) natural climatic regions of Tunis.

The climate of São Paulo, Brazil, F. T. de Souza Reis (*Lavoura; Bol. Soc. Nac. Agr. [Brazil], 11 (1907), No. 9, pp. 393–399*).—This is a brief review of the principal meteorological elements for this region.

Lakes and forests as climatic factors, J. Schubert (*Geogr. Ztschr., 13 (1907), No. 12, pp. 688–694, fig. 1*).—Observations bearing on this subject are reviewed with an attempt to explain the climatic influence exerted by lakes and forests.

A new theory of formation of underground water, G. Martinet (*Chron. Agr. Vaud, 21 (1908), No. 1, pp. 13–16*).—The author agrees with Haedicke that in many cases at least atmospheric precipitation is not sufficient to maintain the underground supply of water, and that in such cases the supply is maintained more largely by absorption of aqueous vapor from the air than from precipitation.

Iron in subterranean waters, H. Schwers (*Rev. Hyg. et Pol. Sanit., 30 (1908), Nos. 1, pp. 11–43, fig. 1; 2, pp. 100–126, figs. 8; 3, pp. 185–221; 4, pp. 287–306*).—This is a rather comprehensive discussion of this subject divided into general and special parts. The first part deals with the nature of iron compounds in subterranean waters, the conditions which cause their solution, and the processes of removal of the iron. The second part deals particularly with a study of natural ferruginous deposits (ochers), and tests of methods of removing iron, with practical conclusions arrived at.

Water-supply investigations in Alaska, 1906–7, F. F. Henshaw and C. C. Covert (*U. S. Geol. Survey, Water-Supply Paper 218, pp. 156, pls. 12, figs. 2*).—This report gives the results of stream measurements in the Nome and Kougarok regions of the Seward Peninsula, and the Fairbanks district of the Yukon-Tanana region, as well as meteorological records (rainfall, temperature, and

pressure) for Seward Peninsula and the Fairbanks district during 1906–7, and a summary of observations on precipitation throughout Alaska from 1902 to 1907, inclusive.

Nitrates, nitrites, and ammonia in sea water, W. E. Ringer and I. M. P. Klingen (*Chem. Weekbl., 5 (1908), No. 10, pp. 147–168*).—Previous investigations on this subject are reviewed, and the results of tests by very refined methods of numerous samples of sea water are reported, showing in different cases considerable amounts of the three forms of nitrogen.

The fertilizing value of snow, F. T. Shutt (*Trans. Roy. Soc. Canada, 3. ser., 1 (1907–8), Sec. III, pp. 35–38; Chem. News, 97 (1908), No. 2530, pp. 243, 244*).—Determinations of free and albuminoid ammonia, nitrates, and nitrites in snow collected on the Central Experimental Farm of Canada at intervals from February 21 to May 4, 1907, are reported.

The results show wide fluctuations in the nitrogen content of the samples, but the average for the total nitrogen was 0.471 part per million, of which 0.256 was free ammonia, 0.052 albuminoid ammonia, and 0.163 nitrates and nitrites. It is calculated that with an average snowfall of 90 in. approximately 1 lb. of nitrogen would be supplied to the soil per acre during a season.

On the purification of peaty waters by freezing, F. T. Shutt (*Trans. Roy. Soc. Canada, 3. ser., 1 (1907–8), Sec. III, pp. 31–33*).—Analyses of 2 samples of river water containing considerable amounts of peaty matter are compared with analyses of ice from the same source. The results show that in freezing a very large proportion of the dissolved organic matter was eliminated. The amount of chlorin was also reduced and the mineral matter was entirely eliminated.

On natural filtration of soils, W. Prausnitz (*Ztschr. Hyg. u. Infektionskrank., 59 (1908), pp. 161–224, pl. 1, figs. 10*).—This article gives the results of a large number of observations on the removal of disease germs from waters percolating through soils.

SOILS—FERTILIZERS.

Preliminary report on the agricultural geology of Nebraska, G. E. Condra and A. Keyser (*Ann. Rpt. Nebr. Bd. Agr., 1906–7, pp. 325–350, figs. 7*).—This paper supplements previous articles by E. H. Barbour (E. S. R., 14, p. 646) summarizing the results of a study of the geography and geology of the State in connection with the State and National geological and soil surveys. It briefly describes the climatic, topographic, and geological conditions of the State, as well as soils, drainage, and water supply. Four typical soil areas are distinguished, namely, the loess, sand hill, high plains, and bad land regions. The predominant soil types are Marshall silt loam, Miami silt loam, Marshall fine sandy loam, Marshall loam, Wabash silt loam, meadow, river wash, and dune sand. The agricultural adaptabilities of the different soil areas are briefly discussed.

Drainage conditions in Wisconsin, A. R. Whitson and E. R. Jones (*Wisconsin Sta. Rpt. 1907, pp. 286, 287*).—This is a synopsis of Bulletin 146 of the station (E. S. R., 19, p. 87).

The required capacity of open drainage ditches, E. R. Jones (*Wisconsin Sta. Rpt. 1907, pp. 288–293, fig. 1*).—Observations on rainfall and run-off in a typical marsh land district of the State are recorded.

Some field studies in tile drainage, E. R. Jones and W. C. Schroeder (*Wisconsin Sta. Rpt. 1907, pp. 294–301*).—This is a record of observations in Milwaukee and Racine counties on the extent, methods, and advantages of tile drainage.

Studies on some soils from Saskatchewan, L. L. Clark, R. A. Gortner, and C. E. Vail (*Amer. Chem. Jour., 39 (1908), No. 2, pp. 163–165*).—Analyses of samples of a bowlder clay from southern Saskatchewan to show the vertical distribution of soluble salts in the soil, the composition of the water-soluble portion of the soil, and the chemical composition of the soil particles of different sizes (sand, coarse silt, fine silt, clay) are reported. There was in all cases a steady decline in soluble salts from the first to the sixth foot. The principal constituents of the water-soluble material were sodium, magnesium, sulphuric acid, and chlorin. The percentage of lime was smallest in the clay particles and largest in the coarse silt. The percentage of iron and alumina, potash, and phosphoric acid increased steadily from the sand to the clay.

Soil surveys and agricultural maps in foreign countries and in Denmark, K. Rördam (*Tidsskr. Landökonom., 1907, Nos. 10, pp. 537–563, figs. 4; 11, pp. 608–616*).—An address delivered before the Danish Royal Agricultural Society, February 20, 1907, with discussion of the same. Soil survey work in Denmark, Scandinavia, Germany, Belgium, France, and England is referred to.

Twenty-five years' work of the German Moor Culture Association, Wangenheim and M. Fleischer (*Illus. Landw. Ztg., 28 (1908), Nos. 14, p. 111, figs. 3, map 1; 15, pp. 123, 124*).—Brief reviews of the work of this organization are given, with a map showing the distribution of moor lands in Germany.

The Swedish Moor Culture Association and the Flahult moors, L. Grandeau (*Jour. Agr. Prat., n. ser., 14 (1907), Nos. 47, pp. 649–653, figs. 2; 48, pp. 680–684, figs. 3; 49, pp. 713–716, figs. 2; 50, pp. 745–747; 51, pp. 777–780, fig. 1; 52, pp. 808–810*).—This is a statement regarding the work of this association and an account of a visit to the moor culture station at Flahult, with descriptions of the work in progress there.

First principles of soil fertility, A. Vivian (*New York, 1908, pp. 265, figs. 93; rev. in Amer. Agr., 81 (1908), No. 6, p. 150*).—It is stated that this book is intended primarily for home reading, but since it is made up largely from lecture notes used by the author in a course in soil fertility it is believed that it will be found a suitable text for short courses. It is written in nontechnical language with free use of illustrations. The subjects treated include the atmosphere and soil as sources of plant food, nitrogen as a plant food, origin of the soil, tillage, drainage and irrigation, summer fallowing, humus and green manuring, rotation of crops, manure and its preservation and application, relation of barnyard manure to the maintenance of fertility, nature and use of commercial fertilizers, purchase of fertilizers, and indirect fertilizers.

The productiveness of the soil: Chemical factors, J. Graftiau (*Ann. Gembloux, 18 (1908), No. 2, pp. 89–107, figs. 2*).—This is a general discussion of the chemical factors of soil fertility intended to supplement a previous article by Grégoire on physical properties of soils in their relation to productiveness (E. S. R., 19, p. 1015).

The influence of various salt solutions on the permeability of soils, D. J. Hissink (*Chem. Weekbl., 4 (1907), pp. 663–673; abs. in Chem. Zentbl., 1907, II, No. 26, pp. 2071, 2072, fig. 1; Jour. Chem. Soc. [London], 92 (1907), No. 542, II, p. 984*).—The results of percolation experiments with water, sodium chlorid, potassium chlorid, ammonium chlorid, and calcium chlorid solutions through soil in cylinders are reported. With distilled water and solutions of sodium and potassium chlorids the permeability of the soil was decreased; when treated with solutions of ammonium and potassium chlorids the permeability was increased at first, but finally decreased.

Nitrogen content of soils as affected by methods of farming, A. R. Whitson, C. W. Stoddart, and A. F. McLeod (*Wisconsin Sta. Rpt. 1907, pp. 254–262*).—This article reports a continuation of observations begun in 1906 (E. S.

R., 18, p. 1025) on the changes in the nitrogen content of a number of clay loam soils under the influence of continuous cropping in a general system of farm management. Determinations of nitrogen in the cropped soil and in similar virgin soil are reported.

The results show in general that the largest loss of nitrogen has occurred in those soils which ordinarily contain a rather large percentage of nitrogen. In 16 out of 21 cases in which the virgin soil contained 0.2 per cent of nitrogen or over the loss of nitrogen above that removed by crops, probably due chiefly to denitrification and leaching, exceeded 500 lbs. per acre. In 21 out of 26 cases in which the virgin soil contained less than 0.2 per cent of nitrogen the loss of nitrogen was less than 500 lbs. per acre. The average losses were 29.6 per cent of that removed by crops in 1907 and 22.3 per cent in 1906. The loss of nitrogen above that removed by crops was greater when the soil was manured than when no manure was applied. "This seems to indicate that the nitrogen added in the form of manure, as ordinarily applied, does not accumulate in the soil, and suggests the desirability of a very careful study of the methods of applying farmyard manure to determine whether it should be applied in very small quantities annually, or larger amounts at intervals of 4 to 6 years, as is the customary practice."

The feeding of plants by the free living nitrogen-fixing bacteria of the soil, A. Koch et al. (*Jour. Landw., 55 (1907), No. 4, pp. 355–416, pls. 3; abs. in Deut. Landw. Presse, 35 (1908), No. 6, p. 57; Chem. Zentbl., 1908, I, No. 5, pp. 480, 481; Jour. Chem. Soc. [London], 94 (1908), No. 543, II, pp. 56, 57; Jour. Soc. Chem. Indus., 27 (1908), No. 9, p. 459; Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 13–14, pp. 435–437*).—These investigations have been reviewed from another source (E. S. R., 19, p. 318).

On fixation of nitrogen in cultivated soils, H. Warmbold (*Centbl. Bakt. [etc.], 2. Abt., 20 (1907), No. 4–5, pp. 121–126*).—This is a reply to criticism by Pfeiffer and his collaborators (E. S. R., 18, p. 617) of a previous article by the author, in which data were reported indicating a chemical fixation of nitrogen in sterilized soils. In further experiments with the same samples of soils no gain was observed under such conditions. On the other hand, a decrease in percentage of total nitrogen was observed in all cases. The extent to which these apparent gains or losses are due to analytical errors is discussed.

Fixation of nitrogen by certain hyphomycetes living in dead plants, H. Froehlich (*Jahrb. Wiss. Bot. [Pringsheim], 45 (1907), No. 2, pp. 256–302, figs. 3*).—Studies of nitrogen fixation in pure cultures of *Alternaria tenuis, Macrosporium commune, Hormodendron cladosporioides,* and *Cladosporium herbarum,* derived from dead stems and leaves of various trees and herbaceous plants are reported which showed that these organisms, which occur widely distributed in plant remains, can grow normally on substrata to which no nitrogen compounds have been intentionally added. Careful determination of the nitrogen balance indicates that all four of the organisms assimilate free nitrogen from the air.

Under the cultural conditions of these experiments the relative rates of fixation per 100 cc. of culture solution were as follows: *M. commune* 3.70 mg. of nitrogen, *A. tenuis* 3.34 mg., *C. herbarum* 2.26 mg., and *H. cladosporioides* 1.93 mg. The period covered by the different experiments varied from 39 to 42 days. The maximum nitrogen increase observed was 4.5 mg. in a culture of Macrosporium, the smallest, 1.16 mg., in a culture of Hormodendron. The nitrogen content of the dry matter produced (100 to 200 mg.) was relatively low, but varied with the different cultures. In general it was somewhat less than 1 per cent. All of the organisms required oxygen for their growth and are obligate aerobic organisms. Hormodendron and Cladosporium were able to grow at

temperatures of from 0 to 10°. Dextrose was found to be the most suitable source of carbon. Fermentation processes were not observed in case of any of the organisms. The amount of nitrogen fixed per gram of dextrose assimilated was greater in all cases than with *Clostridium pasteurianum*, being on the average as follows: *M. commune* 8.92 mg., *A. tenuis* 5.02 mg., *C. herbarum* 4.38 mg., and *H. cladosporioides* 2.56 mg.

Incidentally the conclusions of other investigators that *Aspergillus niger* and *Penicillium glaucum* are capable of fixing free nitrogen were confirmed. It was also shown in the culture experiments reported that *Hormodendron cladosporioides* and *Cladosporium herbarum* are two entirely distinct forms and not, as has been often claimed, identical organisms.

On the adaptability of different sources of energy to assimilation of atmospheric nitrogen and the distribution of nitrogen-fixing bacteria in the soil, II. PRINGSHEIM (*Centbl. Bakt. [etc.], 2. Abt., 20 (1908), No. 8–9, pp. 248–256*).—In the investigations reported in this article the power of various Clostridia, but especially *Clostridium americanum*, to assimilate the carbon of cane sugar, starch, milk sugar, and ammonite under different conditions of concentration, etc., was studied. It was found that these carbohydrates were about as efficient as grape sugar as sources of energy in the fixation of nitrogen by *C. americanum*. With concentrations varying from 0.5 to 4 per cent it was found that the utilization of the energy-producing materials was best with the lower concentration. *C. americanum* utilized the different sources of energy more completely than *C. pasteurianum*. The addition of iron salts to the culture solutions did not increase the nitrogen-fixing capacity of the first-named organism.

The fixation of nitrogen by Rhizobium leguminosarum, R. GREIG-SMITH (*Proc. Linn. Soc. N. S. Wales, 31 (1906), pt. 4, pp. 608–615*).—A study of the production of slime in continuation of earlier work (E. S. R., 19, p. 518) and the fixation of nitrogen by Rhizobium from Robinia or lupine alone or in association with *Bacillus levaniformans*, *B. radiobacter*, and Azotobacter on culture media containing no asparagin or other nitrogenous substance, showed that different races of the Rhizobium can fix atmospheric nitrogen under such conditions and that the fixation is coincident with and proportional to the formation of slime. "Under conditions that preclude the formation of slime, there is no fixation. Conditions, such as the presence of another bacterium, which assist the formation of slime, also assist fixation. It is a matter of indifference whether the medium is acid or alkaline."

The author's studies on the structure of Rhizobium indicate that it is a compound micro-organism of coccus type (leuconostoc or streptococcus-like) and his observations on the fixation of nitrogen by the organism confirm and amplify the results obtained by Mazé. The author believes that the slime produced by this organism contains gum and a soluble albuminous constituent which is assimilable by plants and thus makes the plant independent of the supply of soil nitrogen under certain conditions, as for example, in nitrogen-free soils.

"We are now certain of the kind of help which the bacterium gives the plant. There exists a symbiosis; the plant supplies saline and saccharine matter, the latter of which the bacterium converts into gum and at the same time elaborates atmospheric nitrogen into constituents which are partly contained within the bacterial cell and partly diffused in the gum, which by virtue of their presence appears as a slime. Both the nitrogenous and the carbohydrate constituents of the slime are then elaborated by the plant cells into tissue elements."

The fixation of nitrogen by Azotobacter chroococcum, R. GREIG-SMITH (*Proc. Linn. Soc. N. S. Wales, 31 (1906), pt. 4, pp. 616–618*).—The slime pro-

duction and nitrogen fixation of various organisms obtained in the process of isolating *Rhizobium leguminosarum* from a nodule of the blue lupine are briefly reported upon in this article. The organisms experimented with were *A. chroococcum*, *Bacillus radiobacter*, and *B. levaniformans* singly and in various combinations. "The experiment bears out Beijerinck's and Van Delden's results, that the fixation of nitrogen by these bacteria is chiefly, if not entirely, due to *A. chroococcum;* and . . . indicates that the combination of bacteria brings about a quicker and more regular fixation."

A biological method for the determination of alkali carbonates in soils, H. R. Christensen (*Tidsskr. Landbr. Planteavl, 14 (1907), pp. 292–294; Centbl. Bakt.* [*etc.*], *2. Abt., 19 (1907), No. 21–23, pp. 735, 736; abs. in Chem. Zentbl., 1908, I, No. 2, pp. 166, 167*).—This is a preliminary report of investigations in continuation of previous experiments which led to the conclusion that lime in the form of gypsum, calcium chlorid, and tricalcium phosphate can not be utilized by Azotobacter (E. S. R., 18, p. 720).

The later investigations do not bear out this conclusion, but show that in certain soils there is no growth with these salts, in others a limited growth, and in still others as vigorous growth with these salts as with calcium carbonate. This difference in behavior of soils is attributed to the presence in certain of them of substances which are able to convert a small amount of the lime into form suitable for assimilation by Azotobacter.

Experiments are reported which show that alkali carbonates are capable of bringing about such changes, and it is suggested that the growth of Azotobacter in soils supplied with gypsum may be utilized as a measure of their content of alkali carbonates.

The new nitragin, J. Vogel (*Illus. Landw. Ztg., 27 (1907), No 2, pp. 5, 6; abs. in Centbl. Bakt.* [*etc.*], *2. Abt., 20 (1907), No. 6–7, p. 175*).—This article reviews the progress in the practical application of pure cultures for soil inoculation, especially with the improved Hiltner cultures. It is stated that it has been demonstrated that Hiltner's cultures and methods of inoculation give in many cases results of great practical importance. Of 62 tests of pure cultures for serradella reported in 1905, 85 per cent gave beneficial results. Large numbers of cultures for yellow and blue lupines, peas, vetches, and beans were also distributed.

Inoculation as a factor in growing alfalfa, H. A. Harding and J. K. Wilson (*New York State Sta. Bul. 300, pp. 137–164, figs. 2, map 1*).—This bulletin gives the results of experiments on 67 farms in 33 different counties of the State to test the need and most effective means of inoculation for alfalfa.

"The bacteria, *Pseudomonas radicicola*, which enable alfalfa to obtain nitrogen from the air were present, at least in small numbers, in practically all of the 67 experimental fields. They were present in sufficient numbers to produce an inoculation in any considerable number of the young alfalfa plants in only one-third of these fields. An attempt to supply the germs by applying pure cultures of *P. radicicola* to the seed, drying, and sowing, resulted in almost complete failure. Applying soil from an old alfalfa field at the rate of 150 to 300 lbs. per acre invariably produced an abundant inoculation on these experimental fields.

"While but 15 of the 67 experimental plats produced a successful crop without inoculation, 48 adjacent plats where inoculating soil had been applied produced successful crops. Accordingly, alfalfa growing, on 33 of the 67 fields which were tested, was changed from a failure to a success by the application of inoculating soil."

Alfalfa aided by soil inoculation, F. H. Hall (*New York State Sta. Bul. 300, popular ed., pp. 10*).—A popular edition of the above.

How to determine the fertilizer requirements of Ohio soils, C. E. Thorne (*Ohio Sta. Circ. 79, pp. 23, map 1*).—This circular explains the laboratory, pot culture, and field experiment methods of studying the fertilizer requirements of soils, the conclusion being that field experiments furnish the only safe guide for this purpose. The methods of conducting such experiments and of drawing conclusions from the results obtained are explained in detail.

Report on cooperative field experiments in Jutland, 1906 (*Beretning om Lokale Markforsög og Forevisningsmarker i Landboforeningerne i Jylland 1906. Aarhus, 1907, pp. 351, figs. 24*).—The report covers a large amount of field experimentation conducted by farmers' clubs in different parts of Jutland during 1906. Seven hundred and twenty-four different fertilizer trials with winter and spring grains, roots, and hay crops were made, as well as 344 trials with farm crops, variety tests, methods of planting or culture, green manuring, etc., making a total of 1,068 different trials for the year. Detailed information is given in each case as to cultural conditions, fertilizers applied, and results obtained. Data are also given as to economy of the fertilization in each case.

Superphosphate and sodium nitrate produced the best results in case of all crops, except the root crops, with which this combination of fertilizers came second, and sodium nitrate alone first; the complete fertilizer, on the other hand, came third or fourth, potash with one or the other of the ingredients producing the poorest results, and in the case of all the crops, except the mangels, generally at an actual loss. It is suggested that the poor showing of the potash fertilizers may have been partly due to their rather late spring application.

As a general rule, the best and most certain results from the applications of the various fertilizers were obtained with the winter grains and the least certain returns with the spring grains. Owing to the dry September the root crops did not respond to the fertilizers applied in as marked manner as usual. There was considerable uncertainty in the after-effects of the fertilizers on the first-year clover and grass meadow, but many striking examples were obtained showing that it pays to apply potash and phosphates, even if only the total increase in the hay crop is taken into consideration. There was, however, a marked improvement in most cases in the quality of the hay due to an increased growth of leguminous plants and good grasses.

In 158 other field trials tests were made of the adaptability of different regions to a profitable culture of alfalfa; time and method of application of sodium nitrate; distribution and harrowing in of potash salt and superphosphates; different phosphatic fertilizers; lime niter *v.* sodium nitrate; "Kultura" phosphate, marl, and lime; green manuring; barnyard manure and liquid manure; time of sowing spring grains; time of thinning mangels; gray and yellow oats; variety tests of oats, barley, rye, potatoes, and turnips; alfalfa experiments; culture of peas, grown alone and in mixtures; maize for green feeding; crop rotations on sandy soils; picking of mangel leaves; grading of seed oats; cultivation tests; grass-seed mixtures; and prevention of club-root disease.

Cooperative fertilizer trials in Malmöhus County, 1906, M. Weibull, G. Nordin, and G. Thomé (*Malmö. Läns K. Hushåll. Sällsk. Kvrtlsskr., 1907, No. 1, pp. 197–265*).—The trials were conducted in the same manner and along similar lines as during the preceding year. The following special investigations were conducted and are reported in this publication: The best potash fertilization for fodder beets, ruta-bagas, and barley, being comparisons between 37 per cent potash salt and kainit, in which Wagner's results (E. S. R., 16, p. 861) were, in general, corroborated; trials with calcium cyanamid *v.* lime niter for potatoes and sugar beets, showing that the nitrogen in these fertilizers is of equal value; ammonium sulphate *v.* sodium nitrate for potatoes on sandy

soils, in which the former produced 15 per cent higher yields than the latter at a considerably lower cost; and further trials of the effect of artificial fertilizers on the quality of potatoes and root crops. The results of cooperative fertilizer trials similar to those of earlier years on meadows, small grains, peas, potatoes, and root crops are also reported.

The value of the Albert plant food salts for pot cultures, K. Brehmer (*Gartenwelt, 12 (1908), No. 17, pp. 193–197, figs. 9*).—Experiments, mainly with a number of ornamental plants, are reported in which various combinations of these salts were used in solution and also in solid form. The best results were as a rule obtained by two applications per week of 1 gm. each per pot of a solution of mixed salts containing from 6.5 to 12 per cent of phosphoric acid, 13 to 15 per cent of nitrogen, and 3.5 to 11 per cent of potash.

Further experiments with various kinds of nitrate, J. Sebelien (*Jour. Landw., 55 (1907), No. 4, pp. 293–297; abs. in Chem. Zentbl., 1908, 1, No. 3, p. 286; Jour. Chem. Soc. [London], 94 (1908), No. 543, II, p. 61*).—Pot experiments with mustard in 1905 having shown that excessive applications of nitrate of soda slightly depressed the yield while similar applications of basic lime nitrate showed no such injurious effects, pot experiments with still larger applications of basic lime nitrate and sodium nitrate, as well as of "sulphate-nitrate," a mixture of calcium nitrate with ammonium sulphate, were made with the same crop grown in sand in 1906.

The results show that the yields were five times as great with the basic lime nitrate and the sulphate-nitrate mixture as with sodium nitrate.

In similar experiments with oats grown in sand and soil of good quality the basic lime nitrate and sodium nitrate gave equally good results.

It is stated that the object of mixing calcium nitrate with ammonium sulphate is to avoid difficulty in the use of the nitrate due to its deliquescence. The mixing of the two substances results in a recombination producing ammonium nitrate and gypsum.

Should lime nitrogen be applied at the time of seeding and can it be used as a top dressing in spring? A. Stutzer (*Deut. Landw. Presse, 35 (1908), No. 7, p. 65*).—The author criticises adversely the method used by Müntz and Nottin (E. S. R., 19, p. 320) in experiments with lime nitrogen from which they concluded that the germination of seeds is not interfered with by applications of not more than 89 lbs. of calcium cyanamid per acre, and that top-dressing at this rate will give good results. The opinion is expressed that the more carefully controlled investigations of others show that injurious results are very likely to follow the use of calcium cyanamid in the manner indicated.

Citric-acid-soluble phosphoric acid in phosphatic slags, M. de Molinari and O. Ligot (*Bul. Agr. [Brussels], 23 (1907), No. 12, pp. 911–918, figs. 5*).—The authors report here a continuation during 1907 of pot experiments with oats, barley, and spring wheat grown on loam and sandy soils to test the fertilizing efficiency of the phosphoric acid, insoluble in 2 per cent citric acid, of various samples of phosphatic slag. The results obtained confirm those of similar experiments in 1905 and 1906 (E. S. R., 17, p. 953; 18, p. 1113) in showing a decidedly lower fertilizing efficiency for the phosphoric acid insoluble in 2 per cent citric acid in case of the three crops. The authors conclude, therefore, that the content of phosphoric acid soluble in Wagner's reagent is a better basis for purchase of slags than the content of total phosphoric acid.

Comparative tests of Thomas slag and agricultural phosphate, Kuhnert (*Mitt. Deut. Landw. Gesell., 22 (1907), No. 50, p. 422*).—A continuation of previous experiments (E. S. R., 17, p. 649) is briefly reported, in which it was found as in previous years that Thomas slag gave higher yields than the agricultural phosphate.

On the fertilizing value of salts of manganese, L. Grandeau (*Jour. Agr. Prat., n. ser., 14 (1907), No. 52, pp. 808–810; abs. in Rev. Gén. Agron., n. ser., 3 (1908), No. 2, pp. 49, 50*).—Attention is called especially in this article to experiments by von Feilitzen on moor soils at Flahult, near Jönköping, Sweden (E. S. R., 19, p. 1022). The author concludes from his review of this work, as well as that of other investigators, that while interesting results have been obtained with manganese salts, particularly the sulphate, these results are not of sufficient importance to warrant the regular use of such materials as fertilizers.

The American fertilizer handbook (*Philadelphia, 1908, pp. 244, figs. 2*).—This contains articles on National Fertilizer Association, census of the fertilizer industry, the phosphate movement, 1906–7, points for fertilizer salesmen, sulphuric acid catalytic processes, German potassium deposits, American sulphur mines, a study of soils, the "filler" in fertilizers, station analyses of fertilizers, explanations of market quotations, fertilizer materials, Peruvian and other guanos, fish and fish scrap fertilizers, the value of fertilizer, our large rural population, sulphuric acid tables, practical superphosphate manufacture, soluble and insoluble phosphates, the phosphate industry, commercial nitrogen, Chilean nitrate, abattoir by-products, ammonium sulphate, cotton-seed meal, and other sources of nitrogen, as well as fertilizer manufacturers, allied fertilizer trades, and cotton-seed oil meal directories.

Fertilizer materials market (*Oil, Paint, and Drug Reporter, 73 (1908), No. 7, pt. 2, pp. 54–56*).—This is a review of trade in fertilizers during 1907 in the New York, Chicago, Philadelphia, and Charleston markets.

Nitrate of soda in 1907, Maizières (*Engrais, 23 (1908), No. 2, pp. 36–38*).—Statistics of production and consumption of nitrate of soda for many years past are given. The total production in 1907 is stated to have been 1,665,000 metric tons. Of this amount Europe consumed 1,274,000 tons, America 345,000 tons. A comparison with statistics for previous years shows that the European consumption increased 33,000 tons in 1907, while that of America decreased about 10,000 tons.

Nitrate of soda (*Chem. Trade Jour., 42 (1908), No. 1078, pp. 48–51*).—This article gives statistics and discussion of the nitrate of soda industry in 1907. It is reported that the world's consumption of nitrate in 1907 was 1,646,890 tons or only 7,590 tons greater than that of 1906. The organizations and combinations controlling the trade and the outlook for 1908 are also discussed.

Agricultural uses of crude ammonia, E. Bouant (*Sci. XX. Siècle, 5 (1907), No. 60, pp. 356–359, figs. 5; abs. in Sci. Amer. Sup., 65 (1908), No. 1675, p. 95*).—This article summarizes information regarding the manufacture and use of this material as an insecticide, weed destroyer, and fertilizer. See also a previous note (E. S. R., 18, p. 325).

The material has been prepared for many years in all large French gas works by absorbing the nitrogenous compounds in the Laming mixture of slaked lime, ferrous sulphate, and sawdust. It is reported that 13,000 tons of crude ammonia are annually produced in France and 8,000 tons are imported. It is utilized in the manufacture of ammonium sulphate, Prussian blue, pure sulphur, and a mixture known as precipitated sulphur, which is used by grape growers as a remedy for mildew. The greater part of the material, however, is used directly in agriculture as an insecticide, a destroyer of weeds, and a fertilizer. Its value as a fertilizer has not yet been very definitely determined, but it has been shown to be effective as a weed destroyer and insecticide.

On the influence of plant constituents on the physical and chemical properties of peat, V. Zailer and L. Wilk (*Ztschr. Moorkultur u. Torfverwert., 1907, pp. 1–109; Ztschr. Landw. Versuchsw. Österr., 10 (1907), No. 11, pp. 787–

816; abs. in Chem. Zentbl., 1907, II, No. 9, pp. 732–734; 1908, I, No. 3, pp. 283, 284; Jour. Chem. Soc. [London], 94 (1908), No. 543, II, p. 60; Chem. Abs., 2 (1908), No. 6, pp. 878, 879).—The importance of a study of the botanical origin and characteristics of peat deposits as an aid in understanding their chemical and physical properties is emphasized. The characteristic vegetation from which certain Austrian upland and lowland moors have been derived is described and the determining influence of the vegetation on the color, structure, coherence, absorptive power, composition of the organic and inorganic matter, and fuel value of the peat is pointed out.

The Austrian moors are classified as follows with reference to the principal forms of peat which they yield which are of value for cultivation, for litter, and for fuel: Sphagnum, wool-grass moss, Carex, reed, Hypnum, Scheuchzeria, Eriophorum, wood, raw moor humus, and liver peat.

The hygroscopicity of undecomposed peat is higher than that of decomposed, although the latter contains more humus substances which are highly hygroscopic. The absorptive power of peat for ammonia depends less upon the botanical composition than upon the free humic acids and colloids present. The ash content of peat is as a rule higher than its botanical composition would indicate. This is accounted for by admixture of foreign mineral matter. Of the ash constituents of the plants forming peat the easily soluble potash and sodium salts have been almost completely leached out. The phosphoric acid has been removed to a moderate extent and lime and iron have remained almost entirely undissolved. As a result peat is often very rich in these constituents. Scheuchzeria peat is especially rich in phosphoric acid, which appears to be combined with iron.

The nitrogen content of peat depends primarily upon the nitrogen content of the plants from which it has been formed and secondarily upon chemical processes resulting in absorption of ammonia and upon the accumulation of chitin remains of insects, etc. Only very resistant forms of nitrogen accumulate in peat.

Sphagnum moss and undecomposed sphagnum peat has a very strong acid reaction due to free organic acids. This explains in part the high absorptive power of these substances for ammonia.

The heating value of the different peats was found to vary widely (more than 25 per cent) and no close relation was observed between the fuel value and the ash content of the water-free substance.

The nitrification of peat in artificial niter beds, F. Desprez (*Betterave, 18 (1908), No. 443, pp. 10–13*).—A method of constructing a peat niter bed devised and successfully operated for several years by E. Bazin, a sugar manufacturer of Laon, is described. The bed is constructed and operated upon essentially the same principles as those recently described by Müntz and Lainé (E. S. R., 18, pp. 323, 430). It is stated that when nitrification in these beds is in active operation they produce from 350 to 400 gm. per cubic meter of peat every 24 hours.

Report on trials of machinery used in the peat industry, 1906 (*Meddel. K. Landtbr. Styr. [Sweden], 1907, No. 8 (127), pp. 79, figs. 36*).—The methods and apparatus used are described and results of trials of various kinds of machinery at the testing station of the Royal Agricultural Department at Utförd, Sweden, are reported.

The utilization of atmospheric nitrogen in its economic and social relations, P. B. Giovanni (*Riv. Internaz. Sci. Soc., 44 (1907), No. 172, pp. 481–493*).—The importance of devising commercial means of utilizing the nitrogen of the air independently of leguminous plants as security against a shortage of the

nitrogen supply and a consequent bread famine is briefly discussed in this article.

The high-tension arc and the fixation of nitrogen, G. Brion (*Phys. Ztschr., 8 (1907), No. 21, pp. 792–799, figs. 12; abs. in Sci. Abs., Sect. A—Phys., 11 (1908), No. 121, p. 69*).—The author discusses the characteristics of the high-tension arc and the electrochemical relations. He also describes the arrangement which he employed and the results obtained in his studies on this subject. He obtained the same yield per kilowatt for direct and for alternating currents, thus practically confirming Birkeland's figures.

Experimental investigations on the high-tension arc, G. Brion (*Ztschr. Elektrochem., 13 (1907), No. 48, pp. 761–786, figs. 26; abs. in Sci. Abs., Sect. A—Phys., 11 (1908), No. 121, p. 69*).—This is a full account of experiments partly reported in the article noted above.

The manufacture of calcium cyanamid, J. B. C. Kershaw (*Chem. Trade Jour., 42 (1908), No. 1078, pp. 61–64, figs. 4*).—The Frank and Caro process and its modifications are described as well as the progress made in Europe in the commercial application of the process. The probable cost of nitrogen in the product by this process is discussed and suggestions are made regarding the use of the lime nitrogen as a fertilizer. A list is also given of the principal English patents covering the process. It is stated that a factory located at Odde in Norway will during 1908 manufacture a product which will be put on sale in England at about $2.40 per ton cheaper than ammonium sulphate of the same nitrogen content. The present English market price of sulphate of ammonia is about $58.40 per ton.

The action of sulphuric acid on calcium cyanamid, T. Jona (*Gaz. Chim. Ital., 37 (1907), II, No. 6, pp. 558–562; abs. in Jour. Soc. Chem. Indus., 27 (1908), No. 5, p. 224*).—The author concludes from the investigations briefly reported in this article that under the conditions obtaining in his experiments the action of sulphuric acid on calcium cyanamid results in the formation of dicyanodiamidin sulphate corresponding to the formula $(C_2H_6ON_4)_2$. H_2SO_4. $2H_2O$. Further investigations to determine whether this material can be economically produced on a commercial scale are in progress.

Other uses for lime, A. Pardy (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 11, pp. 1369–1372*).—This article briefly discusses the use of lime in the preparation of citrate of lime, calcium cyanamid, and calcium nitrate with a view to the possible introduction of the manufacture of these products into Natal.

The German potash industry, K. Kubierschky (*Die Deutsche Kaliindustrie. Halle, 1907, pp. VIII+122, figs. 8; rev. in Ztschr. Landw. Versuchsw. Österr., 10 (1907), No. 7, p. 648*).—This is the third volume of Wohlgemuth's monographs on chemical-technical methods of manufacture. The mineral salts occurring in the potash deposits are described as well as the processes, products, and by-products of manufacture of these salts.

The manufacture of potash in North Caucasus (*Vyestnik Finansov, 24 (1907), No. 44, pp. 134, 135; abs. in Chem. Ztg., 32 (1908), No. 1, Repert., p. 3; Rev. Sci. [Paris], 5. ser., 9 (1908), No. 4, p. 117*).—The preparation of potash as a by-product of sunflower culture in this region is described. The potash is prepared by lixiviation of ashes of the stalks, steams, leaves, etc., of the sunflower, evaporation of the solution, and calcination of the residue, the methods employed being very primitive.

It is stated that 24 factories in Caucasia produced about 12,600 to 16,200 tons of potash in 1907, valued at $1,133,000. About one-fourth of the product is used in Russia, and the rest is shipped to foreign countries, some being exported to this country. A very pure product is prepared containing 90 per cent

of potassium carbonate and no soda. The medium and better classes of soils produce from 2,600 to 4,000 lbs. of stalks, stems, etc., per acre, containing an average of 3 to 4 per cent of ashes. One acre of sunflowers, therefore, produces about 160 lbs. of ashes and 40 to 53 lbs. of potash. The crude ashes bring from 0.5 to 0.8 cts. per pound.

Phosphate beds [of South Carolina], E. Sloan (*Handbook of South Carolina. Columbia: State Dept. Agr., Com. and Immig., 1907, pp. 125–127*).—Deposits of this material in the State are briefly described.

The phosphate minerals from Elder Rock, D. Mawson and W. T. Cooke (*Trans. Roy. Soc. So. Aust., 31 (1907), pp. 65–70, fig. 1*).—The investigations on this subject are summarized as follows:

"(1) Elder Rock is a prominent, abrupt mass, standing in a level plain in the arid northern districts of South Australia.

"(2) A hard yellow phosphate encrusting the top of the rock is the remnant and more insoluble part of a larger deposit of guano, chiefly bird-derived.

"(3) The soluble salts of the guano have, to some extent, saturated the rock for a depth below; in a favorable spot this impregnation has been effective for at least 46 feet in the vertical. These compounds are chiefly nitrates of ammonia, with some fixed alkali and phosphate. The more soluble compounds have percolated to greater depths.

"(4) The hard yellow phosphate on top of the rock is a mixture of the minerals, chiefly iron and aluminum phosphates, and has no definite composition; it is, however, here referred to as paratooite. Two widely divergent types are described, the commoner near to evansite, and a scarcer globular phosphate related to beraunite.

"(5) Paratooite probably has a wide distribution, as small scattered occurrences in the arid northern parts of South Australia.

"So far as we are aware, no similar phosphate has ever previously been described from Australia."

Phosphatic slags, P. Marsais (*Rev. Vit., 29 (1908), No. 733, pp. 9–12*).—Information regarding the manufacture, composition, and use as a fertilizer of different kinds of phosphatic slags is summarized in this article. Attention is called to the beneficial results obtained from large applications of slag in the Rhine vineyards and it is pointed out that the increasing demand and rising price of the material raises the question of replacing slag by mixtures of superphosphate and mineral phosphates.

Phosphatic fertilizers, G. Fasoli (*Indus. Chim., 7 (1907), pp. 327, 328; abs. in Chem. Zentbl., 1908, I, No. 4, p. 421*).—The preparation of superphosphates is briefly described and the following are given as the best conditions for this purpose: Sulphuric acid of between 50 and 53° Baumé and a temperature not to exceed 110° C. The fertilizer should never be mixed with gypsum, since the latter reduces the solubility of the superphosphate on standing.

On the reversion of phosphoric acid in superphosphates, K. Herbst (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 36 (1907), pp. 645–652; abs. in Chem. Zentbl., 1908, I, No. 3, p. 285*).—The author gives a brief summary of previous investigation on the reversion of phospheric acid. He attributes such reversion in superphosphates to the action of iron salts, particularly ferrous and ferric sulphates, which are formed in the process of treating natural phosphates with sulphuric acid in the manufacture of superphosphate. The calcium and magnesium salts present in superphosphates are practically without effect in this respect. It is explained that by the action of ferrous and ferric salts on monocalcium and monoaluminum phosphates insoluble ferric phosphate ($FePO_4+xH_2O$) is formed. In the presence of free sulphuric acid a double ferric-aluminic phosphate ($Al_2O_3.Fe_2O_3(P_2O_5)_2+H_2O$) is formed. The author

emphasizes the importance in the manufacture of superphosphates of avoiding as far as possible the formation of ferrous and ferric salts or of rendering them harmless.

The world's production of phosphates in 1907, MAIZIÈRES (*Engrais, 23 (1908), No. 7, pp. 156–158*).—The world's production during 1907 is placed at 4,347,107 metric tons as against 4,092,243 tons in 1906. Of this amount the United States furnished 1,917,000 tons in 1907 as against 2,052,000 in 1906.

[South Carolina] marl, E. SLOAN (*Handbook of South Carolina. Columbia: State Dept. Agr., Com. and Immig., 1907, pp. 121, 122*).—A brief account is given of deposits of this material in the State.

Commercial fertilizers, W. J. JONES, Jr., O. C. HAWORTH, and E. G. PROULX (*Indiana Sta. Bul. 125, pp. 63–139, map 1*).—This bulletin gives results of analyses of 793 samples of fertilizers inspected during 1907 with full text of the Indiana fertilizer law and notes on its enforcement, estimated sales of different classes of fertilizers in the State, and a review of results of inspection for the six years 1902 to 1907. It is estimated that 100,791 tons of fertilizer, valued at $2,341,842, was sold in Indiana in 1907.

Commercial fertilizers, J. L. HILLS, and C. H. JONES (*Vermont Sta. Bul. 134, pp. 35–51*).—This is the first report on fertilizer inspection for the season of 1908 and contains analyses of 60 brands of fertilizers.

AGRICULTURAL BOTANY.

The occurrence of rennet in the Papaveraceæ, C. GERBER (*Bul. Soc. Bot. France, 54 (1907), pp. VII–XVI*).—The author describes the occurrence of rennet or a similar substance that coagulates milk in a number of species of plants belonging to the poppy family, and gives the results of experiments with the juices of a number of these plants in the coagulation of milk.

The properties of rennet are found quite marked in *Chelidonium majus* and *Mecconopsis cambrica*, while they are less pronounced in *Papaver rhœas*, *Rœmeria hybrida*, *Hypecoum pendulum*, *Glaucium luteum*, and *G. corniculatum*. In studying these rennet-like substances, the author finds that they fall into two classes, which may be distinguished as the type occurring in the genus Papaver and the type represented in Glaucium.

The presence of a nitrate-reducing enzym in green plants, ANNIE A. IRVING and RITA HANKINSON (*Bio-Chem. Jour., 3 (1908), No. 1–2, pp. 87–96*).—The question as to the form in which nitrogen is most easily assimilated by the green plant has long been under discussion, and various conflicting views have been given regarding it. There appear but few statements in the literature of plant physiology suggesting the presence of a nitrate-reducing enzym, but the authors' investigations seem to show that a general distribution of such an enzym is to be expected if nitrates are utilized in the formation of proteids. The present paper is the outcome of work carried on upon this hypothesis.

Experiments were conducted with a number of water plants, as these offered greater facilities for collecting and examining gases than others. The results obtained were checked up by application to other plants.

The theory of the presence of an enzym capable of reducing nitrates in green plants seems to be established, and the authors report the extraction of such an enzym from grass. Later the same enzym was found present in a number of other plants, including various grasses, iris, *Vicia faba*, etc. In the case of the species of Vicia the enzym was found in all parts of the plant, but the reaction was stronger in starting and slower in progress in the case of the roots when placed in the nitrate and asparagin solution.

So far as their experiments go, the authors claim that there is no reason to doubt the general distribution of such an enzym in green plants. In the normal plant the only conditions necessary for nitrate reduction seem to be the presence of the enzym found in roots, stems, and leaves, and a suitable carbohydrate. The latter condition suggests the green leaf as the center of reduction, and this agrees with the distribution of nitrates in the plant.

The rôle played by proteins and the decomposition products of albuminoids in fermentation, EHRLICH (*Amer. Brewer, 41 (1908), Nos. 1, pp. 10, 11; 2, pp. 61–64*).—This is a paper, read by the author before a brewing association at a meeting in Berlin, in which he describes the rôle played by albuminoids in the process of fermentation. He calls attention to a newly discovered property of proteids in their behavior during fermentation and to a new reaction of yeast cells. This subject is at present believed to be of theoretical interest only, but will undoubtedly prove of considerable application.

"Up to the present time it has been generally accepted that only carbohydrates, maltose, etc., are capable of undergoing alcoholic fermentation through the agency of the yeast. It has now been found, however, that in every fermentation of sugar by living yeast cells the albuminoids in their last stage of decomposition—i. e., in the form of amino acids—suffer decomposition, inasmuch as they are decomposed not only into carbonic acid and others, but also mainly into alcohol, besides some aldehyde and acids of various form, so that we may now justly speak of an alcoholic fermentation of albumen. This hitherto unknown protein fermentation is not limited to the nitrogenous substances of the wort, but extends to the yeast albumen also; it is brought about by a peculiar breaking down and building up of the albumen of the living cell and leads to the formation of a number of nonnitrogenous substances. Up to the present these substances had erroneously been regarded as by-products of the fermentation of sugar."

A study of the rôle and function of mineral salts in the life of the plant, N. T. DELEANO (*Inst. Bot. Univ. Genève [Pub.], 7. ser., 1907, No. 9, pp. 48; abs. in Bot. Centbl., 107 (1908), No. 1, p. 4*).—According to the author, there is a double movement of mineral material during the life of the plant, one from the soil to the plant and the other from the plant to the soil. These movements are termed by him positive and negative migrations. Concerning the latter there appears to be but little information, and it is with this that the author has carried on investigations.

He found under certain conditions that plants could return to the soil mineral matter equal to 50 per cent of the plant's weight. While the nitrogen content of the plant remains fairly constant after once attaining a maximum, and the carbohydrates increase and are stored up, the mineral matter gradually diminishes until the death of the plant. The cause of this negative migration is said to be due to the fact that the mineral matter is not truly assimilated by the plant but is held by the plasma of the cells through its semipermeability. When the vitality of the cell becomes reduced or the cells are dead the plasma becomes permeable and the mineral matter escapes by simple diffusion.

The experiments upon which the author's conclusions were based were conducted with oats fertilized in various ways. He found with these plants that the water content began to diminish after the forty-third day and at the same time the mineral matter began to decrease. In this way the composition of the plant juices remained practically constant.

The possible rôle of light in relation to alpine plants, C. H. SHAW (*Abs. in Science, n. ser., 27 (1908), No. 687, p. 339*).—The author reports that readings of the actinometer and the black bulb thermometer in vacuo in the region about the Selkirk Mountains seem to prove that light at high altitudes is considerably

more intense than on adjacent lowlands, and that the difference is chiefly in the refrangible end of the spectrum.

Cultures of plants were made by the writer, and when additional blue-violet light was allowed to fall on the plants growing in ordinary daylight the plants exhibited a distinct response. The leaves were more hairy and the internodes shorter than in the control series.

It is believed probable that the character of the light at high altitudes may have a morphogenetic value differing materially from that at low altitudes.

The carbon assimilation of Penicillium, H. Hasselbring (*Bot. Gaz., 45 (1908), No. 3, pp. 176–193*).—In order to gain some knowledge of the complex problems of the assimilation of some of the simpler carbon compounds, the author undertook a series of experiments to study the effect of a number of related compounds on the growth of mold fungi. *P. glaucum* was selected on account of its omnivorous habits. To the inorganic medium in which it was cultivated, alcohol, potassium ethyl sulphate, ethyl nitrate, ethyl acetate, potassium acetate, and acetic acid were added. The cultures were all made in Erlenmeyer flasks of 200 cc. capacity, and the growth in the different media determined.

It was found that alcohol, acetic acid, and the substances from which the acetic acid radicle is readily derived are assimilated by *P. glaucum*. In the case of alcohol the addition of mineral acids stimulates growth, but nitric acid produces greater stimulation than hydrochloric. The esters of alcohol with mineral acids were found valueless as sources of carbon, and their lack of nutritive value was not due to any toxic properties. In general the substances which possess the greater food value are those which are most readily oxidized.

A number of interesting observations incidental to the experiments are reported. Among them, it is shown that, contrary to the current belief that substances which permit vigorous growth of mycelia are not suitable for the germination of spores, alcohol was not only very favorable for growth, but permitted an abundant germination of spores. It was further noted that in none of the cultures containing alcohol was there any production of spores by the fungus.

Another fact brought out was the great individual difference of resistance of spores to deleterious agents. "In the lower concentration of all substances favorable for growth, practically all spores germinated, forming a dense matlike growth over the surface of the culture fluid. When, with increase of concentration, the substance becomes deleterious, germination and growth are not stopped abruptly, but the number of colonies becomes fewer and fewer until the final concentration is reached, where germination of even the most resistant spores is inhibited. In most cases, where only a few colonies were formed, these grew with unusual vigor, so that the total weight of the culture was often as great as that of cultures of lower concentrations."

Assimilation of zinc by Sterigmatocystis nigra, M. Javillier (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 7, pp. 365–367*).—The stimulating effect of dilute solutions of zinc when added to culture media in which *S. nigra* is grown has been reported. The author has carried on experiments to determine the amount of zinc assimilated by this fungus, and he has found that where the quantity of the metal does not exceed 1 part to 250,000 of the culture media, all the zinc is taken up by the fungus. Where a greater amount is added there is a proportional diminution in the relative amount of zinc fixed by the fungus. It seems that *S. nigra* is able to assimilate without injury a quantity of zinc equal to 1/1100 of its weight.

Injury to vegetation and animal life by smelter wastes, J. K. Haywood (*U. S. Dept. Agr., Bur. Chem. Bul. 113, pp. 40, pls. 8*).—The results are given of

investigations in regard to the injury to vegetation and animal life observed by the author in the vicinity of certain smelters, particularly one located at Anaconda, Mont. From all the work in the vicinity of Anaconda, the author draws the following conclusions:

"(1) The forests around the smelter appear from actual chemical analysis to be injured for at least 10 miles north of the smelter, 6 miles south of the smelter, and 13 miles west of the smelter.

"(2) This injury to forests by sulphur dioxid undoubtedly extends to a distance of 15 to 20 miles north of the smelter, 8 miles south of the smelter, 15 miles west of the smelter, and perhaps even farther in certain localities, although not proved by chemical analysis.

"(3) The junipers are very resistant to smelter fumes and are able to grow close to the smelter; the red firs are susceptible to the fumes and are badly damaged at distances of about 15 miles or perhaps even farther; the lodgepole pines are intermediate between the other two species of trees, but show damage for at least 10 miles.

"(4) Large quantities of arsenic are discharged from the smelter on the surrounding country, this poison being found in forage crops in large enough quantities to poison cattle.

"(5) The waste from the reduction plant discharged into the Deer Lodge River renders it unfit for irrigation purposes.

"(6) The land irrigated by the Deer Lodge River, containing the waste from the reduction plant, is greatly injured by the copper present in the irrigation water.

"(7) The soils irrigated by the Deer Lodge River which were studied by the writer do not contain enough alkali salts to be injurious to ordinary farm crops."

The methods of analysis are described at length.

FIELD CROPS.

Studies on the improvement of sand, marsh, and heavy clay soils, A. R. Whitson, R. R. Marshall, and E. J. Delwiche (*Wisconsin Sta. Rpt. 1907, pp. 263–285, figs. 4*).—Experiments begun in previous years (E. S. R., 18, p. 1034) for the purpose of improving certain typical sand, marsh, and heavy clay soils of the State by different systems of cropping and manuring were continued in 1907 and the details of the experiments are reported in this article.

Fertilizer experiments with potatoes on sandy soils at Sparta resulted in the heaviest yield from the plat receiving 30,000 lbs. of barnyard manure per acre, the yield consisting of 90.83 bu. of large and 16.33 bu. of small potatoes per acre. The plat treated with 50,000 lbs. of peat, 100 lbs. of potassium sulphate, and 200 lbs. of phosphate stood second with a yield of 55.66 bu. of large and 12.33 bu. of small potatoes per acre. The results in general indicate that the most serious need of the land is nitrogen and that very little benefit is to be derived from the use of commercial fertilizers.

Crimson clover made a fair growth on manured land and developed nodules. Alfalfa made a very poor growth, developed no nodules, and showed practically no benefit from fertilizers. Alsike clover made a fair growth on the manured soil and a very poor growth on other portions of the field. Cowpeas developed nodules quite generally and made a good growth.

At Iron River the largest yield of oat hay on sandy soil was 1,824 lbs., obtained on the plat receiving 20,000 lbs. of manure. The plat receiving peat, rock phosphate, and potassium sulphate and the one treated with ground limestone and sodium nitrate ranked next in yield. These results also plainly show the

need of nitrogen in the soil. Where peas and oats were grown for hay the barnyard manure plat produced 1,360 lbs. of hay per acre and the sodium nitrate and ground limestone plat 1,304 lbs. The largest yield in potato trials at this farm was secured on the plat treated with barnyard manure, followed by the plat receiving acid phosphate, potash, and ground limestone. Ground limestone seems to have been beneficial but not to the same extent as the nitrogenous substances supplied. Hairy vetch sown in the summer of 1906 produced an excellent stand, and the following season the yield of hay was estimated at 1⅛ tons per acre.

On marsh soil at Marinette barley gave a slightly better yield on the plat receiving 30,000 lbs. of barnyard manure per acre, but the use of 300 lbs. of acid phosphate and 2,000 lbs. of wood ashes gave nearly as large a yield, and this is regarded as indicating that for barley the chief need of this soil is for the mineral elements phosphoric acid and potash. Barnyard manure was the most effective fertilizer for potatoes. The use of 10,000 lbs. per acre produced an increase of 50 bu., of 20,000 lbs. an increase of nearly 100 bu., and an application of 30,000 lbs. an increase of 130 bu. per acre. At 30 cts. per bushel this indicates a value on such land of $3 per load for good barnyard manure. The experiments with potatoes indicate in general that the crop is well adapted to this soil when well drained, and that manure where available is probably the best fertilizer but that wood ashes applied at the rate of about 1 ton per acre together with 300 lbs. of acid phosphate per acre, or 50 to 75 lbs. of sulphate of potash with 400 lbs. of acid phosphate, can be substituted for the manure.

At Phillips, where barley, timothy, and alsike clover were grown, the results seemed to show that there is some other difficulty than the lack of available mineral elements or acidity in the soil. It is believed possible that the infertility is due to a slow rate of nitrification, although it is not understood why wood ashes should have a much more marked effect than lime when supplemented with both potash and phosphate on this soil.

At Superior the tile-drained land averaged 20.2 bu. of barley, 12,956 lbs. of sugar beets, 171 bu. of potatoes, and 12,820 lbs. of corn per acre, as compared with 11 bu. of barley, 11,367 lbs. of sugar beets, 170 bu. of potatoes, and 7,862 lbs. of corn per acre on untiled land. This was a dry season and the effect of drainage for this reason was less marked. There was little difference in the crop of corn whether barnyard manure was plowed under or given as a top-dressing, while in the case of potatoes there was a greater difference, the top-dressed plat yielding at the rate of 161.5 bu. per acre as compared with 180.1 bu. on the plat on which the manure was plowed under.

At Ashland there was a difference of 11.6 bu. of barley, 11.42 bu. of oats, 1.33 tons of corn, and 3.87 tons of sugar beets per acre in favor of tiled as compared with untiled land. Fertilizer experiments with these same crops indicate the lack of nitrogen in available form, and it is believed that the growing of clover or some other leguminous crop is necessary to make the soil fertile.

The relation of orchard cover crops to soil moisture and soil freezing, E. J. Delwiche and J. G. Moore (*Wisconsin Sta. Rpt. 1907, pp. 379–385*).—Observations and determinations on a number of different cover crops are reported. The relative rank of the different crops as to ease in getting a catch, obtaining an early cover, resistance to drought, frost, shade, and attacks of fungi, immunity from insect attacks, ability to withstand tramping, efficiency in lowering the moisture content in late summer and early fall, soil moisture-holding capacity, and snow-holding efficiency is recorded.

Oats, rape, rye, and millet were most readily started, cowpeas were the first to form a cover and also ranked first in drought resistance, field peas stood

shade best, soy beans showed the greatest resistance to fungus diseases and cowpeas to insect enemies, hairy vetch stood tramping best, rye was the hardiest crop, turnips were most effective in lowering the moisture content of the soil in late summer and early fall, crimson clover showed the greatest efficiency in holding soil moisture, and Canada peas in holding snow. No choice is made as to protection against deep freezing of the ground. It is stated that a cover crop decreases the depth of freezing by at least one-half. Moisture determinations made in the spring showed that the average moisture content of the covered ground was considerably more than that of the bare ground.

The improvement of mountain meadows, J. S. Cotton (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 127, pp. 29, pls. 4*).—The results reported in this bulletin show that mountain meadows may be greatly improved by reseeding with tame grasses, and that for this purpose timothy and redtop are best. It is stated that the introduction of timothy into a devasted mountain meadow will increase its acre-carrying capacity for a 1,200-pound steer at least 1 month and ordinarily 2 months. The cost of introducing timothy is given at 95 cts. per acre, and the value of the pasturage is estimated at 25 cts. a month for each head of stock. Redtop is valued mainly in reseeding places too wet for timothy. A mixture of the two is considered valuable because timothy gives returns quickly, while redtop is more permanent. These grasses should be sown in the late autumn in order to save the expense of harrowing.

The cost of introducing brome grass, tall fescue, and orchard grass, which have proved well adapted to mountain meadows, is too great for their extensive use. Mountain brome grass readily re-covers the gravelly hillside areas denuded by over-grazing, but other grasses are preferred by the stock. In introducing large-seeded grasses, like brome grass, mountain brome grass, etc., harrowing is almost necessary. Plowing is ordinarily impracticable and sometimes positively injurious. Drainage, partial irrigation, and the filling in of old washouts are sometimes aids to meadow improvement.

Building up a run-down cotton plantation, D. A. Brodie (*U. S. Dept. Agr., Farmers' Bul. 326, pp. 22, figs. 9*).—An account is given of the progress made in 3 years in changing a run-down cotton plantation in Arkansas into a profitable stock and hay farm. In 1905 this farm produced one-fourth of a bale of cotton and 15 bu. of corn per acre; in 1906, after a crop of cowpeas, it produced one-half of a bale of cotton and 37½ bu. of corn per acre, and in 1907, after a crop of cowpeas, it produced one-half of a bale of cotton and 34 bu. of corn per acre. After cowpeas and 300 lbs. of commercial fertilizer it produced nearly three-fourths of a bale of cotton per acre, and after cowpeas and clover continuously for 2 years 1 bale of cotton to the acre.

Deep plowing had no detrimental effect upon the yields, and planting cotton and corn in check rows and cultivating both ways saved seed and labor and did away with chopping and hoeing. Red clover proved successful in this latitude as a soil builder and as a hay and seed crop, but cowpeas were the most important factor in building up the fertility of the soil. Planting the cowpeas in rows 3 ft. 6 in. apart is recommended as saving seed and bringing greater returns in yields of seed and hay.

Crimson clover, bur clover, and the vetches were successful as winter cover crops after inoculation had been thoroughly established, but early planting in the autumn was absolutely necessary for the best results with these winter crops. It is stated that on worn-out soils from 2 to 3 years are required to inoculate the land with the proper bacteria for the different leguminous crops.

Small farms in the corn belt, J. A. Warren (*U. S. Dept. Agr., Farmers' Bul. 325, pp. 29, figs. 3*).—Descriptions are given of two 40-acre farms and one 20-acre farm in Nebraska, with an account of the methods of crop rotation and

cultivation as practiced, and itemized statements of the cost of equipment and production of the crops, with the financial returns for several years.

Annual report of the Porto Rico Experiment Station for 1907 [Field crops], D. W. May (*Porto Rico Sta. Rpt. 1907, pp. 8–12, 16, 17*).—A brief outline of the work with sugar cane, tobacco, fiber crops, and forage crops is given.

The station has a number of seedling canes containing from 15 to 19 per cent of sucrose in the juice, while the average content in the cane now grown on the island is about 10 per cent. These seedling canes are being distributed over the island. Fertilizer experiments at the station seem to indicate the lack of nitrogen in the soil, and in tests to determine how best to supply this element by the growing of leguminous crops the cowpea and the soy bean have given the most promising results. The cowpea will mature in 70 days and can, therefore, be grown between the rows after planting the cane and again after the last plowing. Trials are also in progress as to distance of planting in cane production. In this work the cane is planted in lots 5 by 5 ft. up to 10 by 10 ft., and also in continuous rows. In the first crop the narrow planting gave the heaviest yield. The figures for the rattoon crops could not be given as these crops had not been harvested. Planting the canes in lines and covering entirely with earth has, where the changa is not too bad, proved a better practice than sticking canes in the ground on end as is the usual custom. Numerous suggestions in the line of improved cultural methods are given.

Of the different fiber crops tested sisal seems to be the most promising. Abacá grows well on the island but requires fertile soil, which fact prevents its extension, as land suitable for it can be more profitably employed in growing other plants. The carludovica plant, which furnishes the fiber for genuine Panama hats, has been introduced with a view to distribution. Sea Island cotton is grown to some extent, but as a rule planters are hard to interest in cotton growing. The cotton caterpillar is a great menace to the crop.

Guinea and malojillo grass are the main sources of forage. As forage crops rich in protein, cowpeas and velvet beans have succeeded best at the station. Alfalfa may be grown but is readily choked out by the vigorous native grasses.

In notes on the fermentation of tobacco by O. Loew, it is pointed out that the curing as well as the fermentation of this product is not so carefully conducted in Porto Rico as in the United States. It was observed in Mayaguez that the temperature of re-piled bulks reached only 44.5° C., while such bulks in Florida have reached 55 to 56° C. To prevent excessive after-fermentation in bulk the bales of tobacco in some establishments are now made up in leaves of the royal palm instead of the porous burlap which admits too much air. It is also mentioned that wrapper leaves grown under cheese-cloth when held under light often show green spots after fermentation.

Experiments with grain and forage plants, 1907, R. A. Moore, A. L. Stone, and E. J. Delwiche (*Wisconsin Sta. Rpt. 1907, pp. 386–408, figs. 5*).—At the station 24 varieties of oats, 27 of barley, 4 of winter wheat, 6 of rye, and 1 of buckwheat were tested.

In the test with oats Joannette, a black variety, ranked first with 35 bu. per acre, Kherson second with 33.7 bu., and Sixty Day third with 28 bu. Joannette also ranked first in weight per measured bushel with 30 lbs.

Oderbruck barley ranked first in the barley experiments with a production of 48 bu. per acre. This variety and Manshury have been selected and distributed by the station and constitute at least one-half of the barley crop of the State. Barley breeding work is carried on and of 16 different strains of pedigreed barleys grown at the station this year sufficient seed of each was secured to plant 2 acres in 1908. Of 4 varieties of winter wheat Iowa led in yield with 28.3 bu. per acre, followed by Minnesota No. 695 with 26.6 bu.,

and Minnesota No. 550 and Beloglina with 25 bu. Minnesota No. 2 rye yielded 42.5 bu. per acre, Minnesota No. 1, 41.4 bu., Ivanoff 40.3 bu., Petkus 35.7 bu., and Schlansted 32.8 bu., while Olds Mammoth Spring produced only 20.7 bu. per acre. Two new varieties bred from Schlansted and Petkus foundation will go into the increase plats in 1908.

The varieties of corn under test were Silver King, Golden Glow, Smut Nose flint, and Early Yellow Dent. These varieties were tested by the ear-to-the-row method. Thirty-seven ears of Silver King ranged in seed ear production from 19 lbs. to 61 lbs., and in total yield from 83 lbs. to 276 lbs. A row of the 1906 crop was left standing through the winter to determine its vitality. In the fall the row was thoroughly matured before freezing weather and all ears showed a uniform germination of 100 per cent prior to zero weather. After the thermometer had registered below zero the viability of the corn immediately dropped in all ears with the exception of one, which gave a test of 100 per cent throughout the winter. The progeny of this ear, however, did not show the vigor of the kiln-dried corn nor did it produce any greater number of good seed ears. The general corn field of 18 acres planted with tested seed, the progeny of high-yielding rows from the seed plat of 1906, gave an average yield of 63.8 bu. of seed corn per acre. The approximate cost of production per bushel is estimated at 29.5 cts.

Oderbruck barley tested near the Iron River farm yielded 36 bu. per acre. At Ashland and Superior this barley yielded 20 bu. per acre in an unfavorable season. In trials of brewing barleys, many of which were not acclimated, only low yields were secured, partly because of the dry season.

Swedish Select oats gave 20 bu. per acre at Superior, 12½ bu. at Iron River, and an average of 18 bu. at Ashland. The weight per bushel averaged 38 lbs. at Ashland and Superior and 33 lbs. at Iron River. Sixty Day and Tobolsk stood first in rust resistance but last in yield.

The winter wheat varieties grown at Ashland and Iron River suffered from winter-killing and gave low yields. The best showing was made by Beloglina, Kharkoff, and Padii.

Silver King corn at the Iron River farm gave a yield of 12¾ tons of silage corn and 84 bu. of ear corn per acre, and Early Yellow Dent 10 tons of silage and 55 bu. of ear corn. The corn had matured when frost came on September 25. Several varieties of flint corn tried at Superior and at Ashland did not reach full maturity.

A good stand of alfalfa was secured on the Iron River farm by sowing the seed in the fall of 1906. In 1907 the field was clipped three times and by September 20 the alfalfa was a foot high, apparently well established, and almost of a perfect stand. The field had been inoculated with soil and nodules were abundant on the roots of the plants. Soy beans were ripe September 20 and gave a yield of 12 bu. per acre. Soil inoculation in this case also seemed to have favored the development of the nodules. Thirty-seven strains of medium red clover were sown in the spring of 1907 on the Iron River farm, and on the whole a fair catch was secured, although dry cold weather affected the stand. At Superior alsike clover yielded 5 bu. per acre, and near Ashland 8 bu. of clean seed was secured on a 1-acre tract.

Cooperative alfalfa work for 1908, C. G. Williams and L. H. Goddard (*Ohio Sta. Circ. 80, pp. 4*).—The plan for cooperative alfalfa work for 1908 is briefly described, and cultural notes are given, together with an application blank, for those wishing to cooperate with the station.

Barley culture in the northern Great Plains, M. A. Carleton (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 5, pp. 12*).—The development of barley culture in the United States, and in this particular section, is discussed and tables are

given showing the comparative yields of a number of different varieties of barley at several experiment stations. Notes on two-rowed and six-rowed barley, variety improvement, the maintenance of pure seed, the cultivation and the uses of barley are also given.

Brewing barleys. C. P. Norgord (*Wisconsin Sta. Rpt. 1907, pp. 413–415*).—Among 8 varieties of pedigreed barleys introduced from Svalöf, Sweden, the best yields at the station were secured from Gotland, which yielded 28.7 bu., followed by Svanhals with a yield of 17.1 bu. per acre. Manchuria, a pedigreed variety from Guelph, yielded 26.5 bu. per acre in this experiment. Among a list of common varieties Oderbruck stood first with 32.7 bu., Golden Queen second with 32 bu., Silver King third with 29.5 bu., and Canadian Lake Shore fourth with 29.2 bu. per acre.

The prickly pear as a farm crop. D. Griffiths (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 124, pp. 37, pls. 2*).—The experiments discussed in this bulletin were conducted in a region having a very unevenly distributed annual rainfall, varying from 15.9 to 40.5 in., the average for the past 18 years being 28.4 in. The absolute minimum temperature recorded for the locality is 4° F., this having occurred but once in 18 years. Of the 10 years ended in 1903 in only one was there 7 days with a minimum below 22° F.

It is stated that the plants are best grown from single-joint cuttings planted 2 ft. apart in 6-foot rows. On moist and well prepared ground the cuttings may be distributed on the surface, otherwise they should be placed in a furrow and partially covered. The planting may be done at any time except during the hottest and driest part of summer. Frequent shallow cultivation is given to prevent weed growth and excessive baking of the soil. Plants set in February can be harvested at any time of the year after 20 to 24 months.

Singeing the standing plants has been found most advantageous. It is recommended that a stump of 2 to 4 joints be left in harvesting the plants, and that those most vigorous and most free from disease be selected for planting stock. In the vicinity of San Antonio, Texas, the *Opuntia lindheimeri* best meets these conditions.

An experimental plantation which was made cost nearly $9 an acre, but it is believed that this cost may be reduced to $6 or $7. About 20 varieties of spineless forms are grown at present, but these are considered as practically useless under present Texas conditions except for breeding purposes. It is estimated that the prickly pear under cultivation will produce 22.8 tons of roughage per acre. Eight times as much growth of prickly pear has been secured under cultivation as was obtained without cultivation on ungrazed pastures, and more than six times as much roughage during the past 2 years from prickly pear as from sorghum.

The injuries by the black-spot fungus (*Perisporium wrightii*) and the red spider (*Tetranychus opuntiæ*), to which the prickly pear is subject, are described, but it is believed that both may be controlled by selection of stock and by methods of harvesting. The diseased condition known as dropping of joints is considered as purely climatic.

The soy bean. C. G. Williams (*Ohio Sta. Circ. 78, pp. 8*).—This circular, giving general directions on the culture of this crop, discusses its use for hay, silage, seed, soiling, pasture, and soil improvement, describes the more important varieties, and presents brief cultural notes on soils, fertilizers, seeding, cultivation, harvesting, and thrashing.

The effect of soil inoculation on the distribution of the fertilizer ingredients in soy beans. F. W. Woll and G. A. Olson (*Wisconsin Sta. Rpt. 1907, pp. 164–166*).—Wisconsin black soy beans were grown on inoculated and uninoculated soil. Chemical analyses of the crops indicate that inoculation of the

soil was beneficial by increasing the nitrogen content of the plant, decreasing the percentage of ash constitutents, increasing the percentage of fertilizer ingredients in the roots, increasing the protein content of the beans, and decreasing their oil content. The yield in price per acre of fertilizer ingredients on treated and untreated soils, as calculated on the basis of 15 cts. per pound for nitrogen and 4 cts. per pound for phosphoric acid and potash, shows the value of the phosphoric acid and potash in the beans from the treated and untreated soil to be about the same, but the value of the increase in nitrogen amounted to $2.3½ per acre. These results indicate that soil inoculation not only increases the yield of leguminous crops, but also improves the feeding value since the increased percentage of nitrogen is nearly all in the form of true proteids.

[Fertilizer experiments with sugar beets during the season of 1906], F. W. Woll and C. W. Stoddart (*Wisconsin Sta. Rpt. 1907, pp. 321–336, figs. 3*).—A condensation of Bulletin 150 of the station previously noted (E. S. R., 19, p. 141).

[Fertilizer experiments with sugar beets during the season of 1907], F. W. Woll and R. A. Moore (*Wisconsin Sta. Rpt. 1907, pp. 336–342*).—The fertilizer requirements for sugar beets of the clay loam soil on the agronomy field at the station near Madison, and of the light sandy soil on the substation farm at Iron River, were studied. The Braune Elite sugar beet was grown, and different combinations of the following quantities of fertilizers were applied on tenth-acre plats: Sodium nitrate 20 lbs., potassium sulphate 20 lbs., acid phosphate 40 lbs.

On the agronomy field the beets were planted June 13 and the first samples taken October 18 showed 12.62 per cent of sugar and an average purity of 86 per cent. The beets were harvested November 11, and when analyzed November 15 an increase in the percentage of sugar from the different plats amounted to 4.16 per cent and an increase in the average purity of 3.1 per cent was observed. The average yield obtained during 11 seasons at the station was 17¾ tons of beets and 4,500 lbs. of sugar per acre, but this year the yield on any plat did not much outyield 9 tons of beets and 2,800 lbs. of sugar per acre. As the season was unfavorable no comments or deductions as to the relative influence of various fertilizers seemed warranted. The most pronounced results in the increase of beets and sugar were obtained with phosphoric acid alone or in combination with potash.

At Iron River the average sugar content in the beets was 19.38 per cent and the purity 87.3 per cent. Nitrogen had a more marked influence in improving the yield of beets than any other single fertilizer ingredient, potash ranking next. The quality of the beets was generally improved by the application of phosphoric acid and of nitrogen, while potash had a decidedly depressing influence on the sugar content and the purity. The results in general indicate that in a dry season at least the best fertilizer treatment for sugar beets on the sandy soils of northern Wisconsin consists in the use of nitrogen alone or of nitrogen with potassium or phosphorus.

Sweet potatoes, W. R. Beattie (*U. S. Dept. Agr., Farmers' Bul. 324, pp. 39, figs. 24*).—This bulletin discusses the areas adapted to sweet potato culture, the climatic and soil conditions required, and the latest methods of growing the crop. In addition to giving general cultural directions, the storage, marketing, cost of production, returns, and uses of the plant are considered. The following varieties are described: Big-Stem Jersey, Yellow Jersey, Red Jersey, Southern Queen or Hayman, Pumpkin Yam, Georgia or Split-Leaf Yam, Red Bermuda, Florida, Pierson, Black Spanish, and Shanghai.

Tobacco investigations for 1907, J. G. Moore and A. J. Rogers (*Wisconsin Sta. Rpt. 1907, pp. 365–368*).—Nearly 300 lbs. of seed grown under the direction

of the department of horticulture were distributed in lots from 1 to 6 oz. among approximately 900 growers for the purpose of introducing improved types in place of the older and less valuable varieties now grown.

In the seed breeding work 9 crosses selected from a great many grown during the previous 2 years were used for the selection of plants producing a superior grade of tobacco. Out of approximately 1,000 plants only 5 were deemed worthy of use for further selection.

Fertilizer experiments were conducted on 3 different farms near Janesville. On 2 of the farms no definite results were secured, but on the third where 1,000 lbs. of cotton-seed meal, 750 lbs. of nitrate of soda, 140 lbs. of sulphate of potash, and 1,500 lbs. of bone meal were applied to a 5-acre plat very little rust occurred, while on the check plat a great deal of injury resulted from this disease.

Eradication of farm weeds, R. A. Moore, A. L. Stone, and G. Hutton (*Wisconsin Sta. Rpt. 1907, pp. 411, 412*).—The use of an anti-quackgrass mixture proved to be of no value in eradicating quackgrass. In another test the ground was plowed 6 in. deep in the fall and harrowed to bring the roots of the quackgrass to the surface, which were then raked up and burned. In the spring this same ground was plowed a little deeper than in the previous fall and harrowed again to prevent the growth or the rooting of any of the grass. During a dry period in July the ground was disked and harrowed, and at the last plowing and harrowing in September no more quackgrass roots were found. The grass was entirely eradicated from $\frac{1}{2}$ acre of ground at a cost of $18.

Report of the agronomist, E. M. East (*Connecticut State Sta. Rpt. 1907–8, pt. 7, pp. 397–452, pls. 9*).—This report discusses the prospects of better seed corn in Connecticut, the practical use of Mendelism in corn breeding, inbreeding in corn, some essential points in potato breeding, and extension work in agronomy. In connection with the articles on inbreeding in corn and potato breeding lists of the authors and works cited are given.

In summarizing the article on how Mendel's law may be practically applied in corn breeding, the author makes the following statement to illustrate his principal points: "Let us suppose that a yellow flint has been crossed upon a white flint, and a yellow variety is desired. The crossed kernels are planted and allowed to fertilize naturally in the field. In this season, there will appear about three yellow kernels to one white kernel. The white kernels being the recessive will breed true without further trouble. Of the yellow kernel, on the other hand, there will be one pure yellow to every two hybrid. If only yellow kernels are then planted and a number of resulting ears are self-fertilized, then, wherever a pure yellow kernel has been planted by chance, the kernels of its self-fertilized ear will be pure yellow and will ever after breed true to yellow. The same thing is true of the other dominant characters."

In treating the subject of inbreeding in corn the author reviews the opinions of different investigators, including Shull, who also recently published a paper on the subject, and points out some of the results obtained at experiment stations. The author believes that when the results of inbreeding corn by artificial pollination are not as favorable as those secured by natural pollination this does not necessarily mean that this has been entirely due to inbreeding. He states that in his first year's work with artificial corn pollination he secured poor ears upon both crossed and self-fertilized plants, but in succeeding years he obtained excellent ears by artificial pollination both when the ears were crossed and when they were self-fertilized. Rows grown from ears self-fertilized for 2 or 3 generations were exceedingly uniform in all of their botanical characters, the plants were perfectly healthy and normal, and the

only difference in favor of the crossed rows was the yield. The author further points out that several types of corn plants always appear in the breeding plat, and as these types are intercrossed there are always some of the rows from such crosses so vigorous that they are selected because of the yield and that therefore the odd type remains. In 1905, in a breeding plat of Stowell Evergreen sweet corn two types, one with a smooth full kernel and the other with a thin peaked kernel, were observed. In 1906, some ears of the same type were planted side by side so that they were intercrossed. In 1907, a part of the ears of each type were planted so that they would be fertilized by the same type and a part so that one type would pollinate the other. The rows were selected by yield only and, in every case but one, rows in which the two types had been crossed were the ones selected.

The results of several experiments and investigations made at the station are reported in an article on potato breeding. It is shown that potato varieties may be arbitrarily divided into those the buds of which drop off without opening, varieties in which a few flowers open but immediately fall, varieties the flowers of which persist several days but rarely produce viable pollen, and sorts which under most conditions always produce viable pollen. Of 721 varieties under observation, in 67 per cent the buds fell off before opening, and in about 70 per cent of the remaining varieties the flowers remained on the stems for more than one day. In unselected 2-year old seedlings the percentage of varieties retaining their flowers and those the buds of which fell off was about the same as in named varieties.

In experiments to test the efficiency of stimulating seed production through prevention of tuber formation by removing the earth from around the stolon, it was found that there are characteristic differences in seeding power which are inherited by different varieties and that the fluctuations in these characters are large and may be increased artificially by changing environmental conditions, but that no ordinary treatment will force a variety across its critical point into another biotype. From these results it is concluded that there is no reason to believe that artificial treatment can sufficiently change the natural tendencies of varieties the buds of which fall off to allow their being used as parents in originating new varieties.

It was found that the flowers most easily crossed are not those at the upper end of the plant stem but those at the next lower axils. Of such pollinations on naturally seeding varieties 52 per cent were successful, while of those on the uppermost cymes 28 per cent and of those on the lowest clusters only 18 per cent formed fruit.

A microscopical examination of pollen of different varieties showed a great variation in the character of the pollen produced by each, in addition to considerable fluctuation within the variety. Normally healthy pollen is described as round and about 0.036 mm. in diameter and pollen not producing tubes as seldom over 0.02 mm. in diameter and shriveled and irregular. Pollen grains with a number of slight protuberances were the first to germinate when placed in a 7 per cent sugar solution, and the pollen tubes grew faster and appeared stronger than those from the round grains. A pollen tube germinated from each of the protuberances, showing that several nuclei were present.

From the results of a study to determine the relation between amount and viability of pollen, it is concluded that the percentage of viable pollen should be about 50 and that it is useless to attempt using a variety of which less than 25 per cent of the pollen will grow. No fruit was obtained from varieties producing no multi-nucleate pollen grains, and of those varieties producing fruit with fair readiness all but one yielded above 16 per cent of this kind of pollen. It was observed that in general if less than 50 per cent of the ovules are fer-

tilized the seed berries are dropped in less than 8 days after fertilization, and it is concluded that the persistency of the berries increased directly with an increased percentage of fertilized ovules. A summary of the procedure in hybridizing potatoes is given.

In a study of the correlations between characters, round and oblong shapes, deep and shallow eyes, rough and smooth skins, tall and dwarf plants, and colored and uncolored stems were compared in good pollen and poor pollen varieties. Out of the correlation tables constructed only four showed correlations higher than the probable error, and these were all correlations where color is manifested on different parts of the plant.

The suggestions regarding extension work in agronomy contain outlines of 4 fertilizer experiments, 4 experiments with leguminous crops, 3 in seed selection, and 2 with varieties.

Corn breeding in Minnesota, C. P. Bull (*Minnesota Sta. Bul. 107, pp. 177–256, figs. 45*).—The possibilities of corn improvement in Minnesota are discussed, the need of such work is pointed out, and detailed directions on the methods of corn improvement followed at the station are given. Some of the more important subjects discussed are lack in uniformity of type, pollination and formation of ears, factors influencing yield and quality, principles of breeding, the breeding plat, the registry system, the pedigree chart, and the score card.

Plant breeding for farmers, H. J. Webber (*New York Cornell Sta. Bul. 251, pp. 291–332, figs. 10*).—This bulletin discusses simple methods of plant breeding suitable for the general use of farmers. Some of the factors of plant breeding such as pedigree breeding, variations, principles of selection, transmitting power, control of parentage, and record keeping are described, and methods in detail for breeding corn, wheat, oats, barley, and potatoes are presented.

Cereal production of Europe, F. R. Rutter (*U. S. Dept. Agr., Bur. Statis. Bul. 68, pp. 100*).—This bulletin contains the results of an investigation of the conditions attending the production, supply, and consumption of grain in Europe. The statistics of acreage and production and of imports and exports are given for each country covering a period of 20 years, and the statistics relating to the main progress or decline of grain culture in each country are also presented. The inadequacy of the surplus of eastern Europe to supply western Europe, the extent as well as the limits of grain culture in Europe, and the relation of the grain area to arable land are discussed, and statistics are given to point out existing conditions. Notes and statistics are also given on the average yield of grain, the average size of holdings, and the acre value of crops.

European grain trade, F. R. Rutter (*U. S. Dept. Agr., Bur. Statis. Bul. 69, pp. 63*).—This bulletin presents the results of a thorough investigation of the conditions attending the importation and exportation of grain in Europe during a period of years. The imports and exports of cereals for each country, in nearly all cases covering the period from 1883 to 1905 or 1906, are shown in tables. Brief explanations of the data are given and special features of the cereal trade of each country are pointed out. There are also general notes on the grain deficit in western Europe and on the countries of surplus production.

HORTICULTURE.

Report of the horticulturist, M. J. Iorns (*Porto Rico Sta. Rpt. 1907, pp. 20–30, fig. 1*).—The work for the past year was largely in continuation of work previously reported (E. S. R., 18, p. 1044) and consisted of cultural and variety tests of economic fruits and vegetables. Several new lines were outlined both for the station and for cooperating planters, some of the more important of which are cover crops, treatment of pineapple plantings after the second year,

stock resistance to "mal de goma," effect of stock on scion, pruning, and plant selection and breeding for special purposes. A detailed statement is given of the work being done or planned in the various lines.

In order to emphasize the former work by the station, experiments are being carried on to determine more definitely the special growth seasons for different classes of vegetables. Some of the points thus far brought out from this work are that such vegetables as radishes and lettuce with proper culture grow well at all times of the year, except in periods of excessive rainfall; that many others do have certain seasons in which they grow best; that these seasons are usually during the early winter and spring months; that the insect pests and diseases are, in a large measure, periodic; that tomatoes, melons, cucumbers, and some others can be grown in Porto Rico for a winter or spring market; and that good seed of many classes of vegetables can be home grown and the better native varieties readily improved.

Among the orchard fruits giving promise of sufficient merit to warrant further investigations are the Japanese persimmon, the Peen-to peach, the cherimoyer, the loquat, and several of the imported guavas. With a view of studying in detail cultural methods, diseases, and various other problems of fruit growing, several new plantings have been made, including a new citrus grove and a cacao grove, with rubber for shade, as well as miscellaneous plantings of cocoanuts.

Notes are given on the work with cocoanuts, rubber, mangoes, bananas, and pineapples, as well as brief notes on several miscellaneous fruits, including the Barbados cherry, Otaheite gooseberry, anona, rose apple, guava, avocado, and cacao.

A large number of standard varieties of grapes have been introduced and have made an exceptional growth during the year. It is found that heavy pruning can be done without apparent injury while the vine is in full growth. Pruning semidormant vines caused severe bleeding. By 1 or 2 heavy prunings at the proper time and pinching the buds before the growth fairly begins, it is possible to keep the vines in good bearing condition. Several new varieties of strawberries are being tested, some of which have stood the adverse conditions of drought and excessive rains and give promise of producing excellent fruit. The crop is not heavy at any one time, but the bearing period lasts over several months.

In the cooperative fertilizer experiments, in all the soils thus far tried a complete fertilizer has given a marked increase in growth over no fertilizer or one composed of 1 or 2 elements only. In no case has there been less than from 10 to 15 per cent gain in favor of a complete fertilizer. No injurious effects have been noticed from using chlorids or organic fertilizers in citrus groves. The "mal de goma" present in some groves seems in almost all cases to be due to too deep planting, bad drainage, or some allied cause rather than to the presence of organic matter. In the station orchard fresh manure has been liberally spread with beneficial results.

In the work in plant improvement, practically all of the standard vegetables are under observation, and all the native strains that give any promise of merit are being tested. Special emphasis is being laid on breeding disease-resistant varieties. The tomato, eggplant, cucumber, and muskmelon are being given special attention. Some of the most stubborn diseases, like wilts and mildews, can be overcome by breeding and selection. With choice eggplants grafted on native wild eggplants, the grafts seemed proof against disease and the fruits were large and of excellent quality. The plants bore several successive crops and were destroyed only by a newly appearing insect, which did the damage

before it was discovered. Wild eggplants are also being used as a stock on which to graft tomatoes, with considerable success. A native strain of muskmelon of large size has been found with merit enough to warrant further work. With the use of fertilizers these melons have been grown to a large size and retain an excellent flavor. Another type, locally known as "melón de la China," has been found to rank well with the Rockyford in size and flavor and to excel it in appearance. This melon is to be further tested relative to its shipping qualities, size, productiveness, and flavor. Spanish onions have been planted and will be grown from seed with the view of determining whether they keep better than those grown in the United States or in the Bermudas. An excellent and extra early strain of cowpeas has been developed, and seed is being raised for trial at other points in the island. The breeding crops thus far have matured in from 63 to 68 days.

Influence of "bottom heat" in forcing cucumbers, J. G. Moore (*Wisconsin Sta. Rpt. 1907, pp. 355–364*).—An account of an experiment in forcing cucumbers which has been conducted by the station for the past 3 seasons, the chief object of which was to determine the soil temperature best suited to the production of the crop irrespective of cost. Other factors studied were earliness, relative number of male and female flowers, and relative effect on growth and vigor of plants. Eight benches of plants were grown, 3 each in 1905 and 1906 and 2 in 1907. The range of temperatures from lowest to highest during the entire period was from 68.7° to 83.3° F.

From observations made and data secured during the 3 years, it is concluded that a soil temperature of approximately 74° gives a greater fruitfulness during the same length of time than temperatures ranging either much higher or much lower. Increase in soil temperature increases the earliness of production little if any. Variation of soil temperature shows little influence on flower production, the important factors in this respect being sunshine, atmospheric temperature, and individuality of plants. Higher soil temperature shortens the fruiting period of the plants, and the author believes that the length of fruitfulness in the cucumber is inversely proportional to the amount of soil temperature, within the limits of temperature usually given in producing this crop. The advantages gained by higher soil temperature are not sufficient to warrant the additional cost. Plant individuality is so marked that better results can be obtained by using seed from the best individuals rather than by attempting to influence production by increased soil temperature.

Cranberry investigations, A. R. Whitson and O. G. Malde (*Wisconsin Sta. Rpt. 1907, pp. 302–308, fig. 1*).—A further report on the cranberry investigations being conducted at the station and which have been reported on from year to year (E. S. R., 18, p. 1047).

The general results of the season's investigations further emphasize the influence of drainage and sanding on soil temperature. The observations relative to soil and air temperatures at different depths and heights are to be published in detail in the future. The results secured for the past 4 years relative to the influence of deep, shallow, and absence of drainage on the yield of berries are tabulated and indicate a considerable benefit from drainage. On the plat where the water was held at the surface, the average number of barrels of cranberries secured was 32, whereas on the plat drained to a depth of 14 in., the average number of barrels secured was 39. The roots on the better drained plat showed a tendency to extend deeper and were stronger than those on the undrained plat. Relative to the sanding of plats, it appears that the application of 2 in. of sand at one time on vines already established is very detrimental, as the runners are covered too deeply to prevent the rapid development of more runners. About ½ in. of sand applied to ground already well covered is found to be beneficial.

A table is given showing the yields of cranberries secured on the various fertilizer plats during the period from 1904 to 1907, inclusive. The treatments which have been most beneficial are combinations of phosphate and nitrate and of potash and nitrate. Two cooperative fertilizer tests have been made with growers during the past 2 seasons, the experiment consisting of an application of acid phosphate, sodium nitrate, and potassium sulphate, each alone and in a combination of 2 on areas of one-tenth acre, except that on one of the bogs potash and nitrate were not used singly. The yields of berries together with the treatments are given, although no conclusions are drawn as yet from the work.

A number of plats planted at the station in 1904 produced fruit and gave some indication of the results of different methods of planting as well as the comparative value of a few of the standard varieties of berries. Of 3 plats set with short cuttings by the use of a disk, as described in a previous bulletin (E. S. R., 16, p. 975), the native varieties yielded at the rate of 10 barrels per acre, the Palmeter variety 17 barrels per acre, and the Howe 12 barrels per acre. Another plat, planted with vines from the nursery in 1905 and set with a dibber in rows about 5 in. apart and 1 to 2 in. between vines in the row, yielded at the rate of 26 barrels per acre. McFarland vines planted in 1904 on unsanded peat yielded about 1 barrel per acre.

As a result of work in the moss-killing tests, the application late in May of 2 barrels of air-slaked lime per acre is recommended. This application may be repeated the second year, but the third application should be deferred for at least a year. While this treatment is suitable for sphagnum moss, wood moss is not killed by the lime, and experiments were made to establish some treatment for killing wood moss. Dry salt was first used, but could not be applied in sufficient amounts without injury to the vines. During the past year the salt was applied in solution, giving excellent results. "The application of a mixture of 15 pounds of common salt to 50 gal. of water at the rate of 4 barrels to the acre just before the opening of the terminal buds of the cranberry vines has been found safe and effective for killing the wood moss, which at that time grows rapidly." A second growth of moss usually occurs in the latter part of September and should be given a second application of the treatment at that time.

The relation of weather to the setting of fruit; with blooming data for 866 varieties of fruit, U. P. Hedrick (*New York State Sta. Bul. 299, pp. 59–138*).—In the first part of this bulletin considerable data are given together with references drawn relative to the behavior of fruit crops during the varying weather conditions of past seasons in western New York. Killing frosts, rain, temperature, sunshine, and wind are all discussed in their relation to the setting of fruits. The data are largely based upon a study of the printed records of the fruit crop of the above region found in the Proceedings of the Western New York Horticultural Society, together with an examination of crop reports, weather records, and the agricultural papers for the period under discussion. In connection with the discussion meteorological data, compiled from the records of 96 weather stations in New York, are given for the month of May for the years 1897 to 1906, inclusive.

The author points out that although self-sterility with lack of cross-pollination may be an important cause of the failure to set fruit, unfavorable weather conditions during the blooming period are also important factors in the loss of fruit crops. The conclusions reached from this investigation are that frosts, rain, cold weather, and cold or high winds are the chief agencies in preventing the proper setting of fruit in New York. The damage in the case of light frosts may be prevented to some extent if the proper precautions are taken. Abundance of sunshine and a low percentage of humidity give the most favorable con-

ditions for the setting of fruit. The orchards should be located with reference both to general and to local climate. Varieties of fruit may be selected with reference to time of blooming and with reference to their ability, from one cause or another, so to withstand injurious weather as to escape in some degree injurious climatal agencies. Cultural treatment to induce strong vitality probably helps plants to withstand stresses of harmful weather. The climate changes in short cycles, but such oscillations are not permanent, and it is probably beyond the power of man to change the climate by flooding, draining, planting or destroying forests, etc.

Blooming time is next briefly considered relative to the influences tending to hasten or retard its advent. The dates of blooming for 866 varieties of fruit, including the apple, pear, peach, plum, cherry, and grape, are given. The data were taken from the station orchards and are given for the years 1902 to 1907, inclusive, for the tree fruits and for the years 1892 to 1898 for the grape. The dates are those of the first open blossoms and the full bloom and were taken from trees grown under normal conditions as to pruning, distance apart, and other factors which might influence the blooming period. An examination of the list shows that under normal conditions and during the average season, varieties of any one species overlap sufficiently for the purpose of cross-pollination, with the possible exception of the very early and the very late varieties.

Relative to the belief that early varieties bloom earlier than late ones and that late varieties are less liable to have their blossoms injured by late frosts, the author concludes, after a study of the varieties for which blooming dates are given in connection with the period of ripening given for the same varieties in fruit manuals, that there is no correlation between blooming and fruiting, although there are many apparent exceptions.

The average of data taken for 5 years shows the length of time the several fruits are in bloom as follows: Apples, 9 days; peaches, 8 days; pears, plums, and cherries, 7 days; and grapes, 10 days. The actual length of the blooming period may vary considerably under different weather conditions. An inspection of the dates of blooming of all the fruits shows a variation of several days in most seasons between the appearance of the first blossoms of the different varieties, which can be taken advantage of in selecting sorts to avoid injury from frost. A list is also given showing early and late blooming varieties of apples, pears, peaches, plums, and cherries.

Pruning fruit trees, W. S. Thornber (*Washington Sta. Popular Bul. 3, pp. 4, figs. 8*).—This bulletin contains popular directions for pruning apples, pears, sweet cherries, and peaches.

Notes on the avocado fruit, O. Loew (*Porto Rico Sta. Rpt. 1907, pp. 18, 19*).—A detailed description of the avocado, with a brief note on a study made relative to the softening of the fruit.

Repeated shipments to New York have failed on account of the decay of the fruits, attributed to injuries to the skin, permitting the entrance of fungi. The author found, however, that where perfectly healthy fruit without any injury and with the stem still attached were selected and kept at 35 to 40° C. in a thermostat, the skin commenced to turn brown after 4 days. Two days later the fruit was soft and the skin had begun to shrink. After another 2 days the entire skin was deep brown and showed considerable and irregular shrinkage. The flesh was found to be discolored and sour, but neither microbes nor mycelium were observed. It is believed that not even the most careful packing proposed will stop these changes, but cooling with ice will retard them.

Dry-land olive culture in northern Africa, T. H. Kearney (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 125, pp. 48, pls. 4, figs. 10*).—This bulletin contains an account of the cultivation of olives without irrigation in the vicinity of Sfax in

southern Tunis, in which region the average yearly rainfall is only 9.3 in. The drought-resistant variety of the olive that is grown in Tunis has been introduced with a view to establishing dry-land olive culture in the United States, and it is believed that the present work will be useful not only in directing attention to the type of tree and methods of culture that are likely to give the best results in the olive zone, but also in stimulating as well the cultivation of trees in general in arid and semiarid regions.

A discussion is given of the importance of dry-land arboriculture in ancient Africa, the climate, topography, and soils of the Sfax region, and the cultural methods employed, including propagation, clearing the land, planting, tillage, manuring, pruning, harvesting, and yields. The relation of rainfall to yields, the question of labor, and the utilization of the run-off water in olive culture in other parts of Tunis are also discussed. Only one variety of olive, the Chemlaly, a small-fruited, oil-producing variety, is extensively grown in the Sfax region. It is very productive and the fruit yields an unusually high percentage of oil. Wide planting and thorough cultivation are the most important principles of olive culture at Sfax, the trees being planted 65 to 80 ft. apart in each direction. There appears to be a relation between the yield of the olive and the rainfall of the previous year, but none between the yield and the rainfall of the year in which the crop is made.

The decay of oranges while in transit from California, G. H. Powell et al. (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 123, pp. 79, pls. 9, figs. 26*).—This is the first comprehensive report on the investigations which are being conducted by the Bureau of Plant Industry of this Department in cooperation with the California orange growers relative to the causes and control of the decay in citrus fruits while in transit to eastern markets. The investigations in general have been conducted under commercial conditions with a view to rendering the data secured of practical value in the various phases of the industry. In the experimental investigations it was sought to determine the comparative susceptibility to decay of oranges handled in different ways for shipment, including holding them in the packing houses in California for about 2 weeks, forwarding to New York at short intervals after packing under ventilation, icing, and precooling, and handling in different ways and shipping under different conditions when stored in a common storage room in eastern markets. Technical investigations in refrigeration were also conducted, including the development and testing of various methods of cooling the oranges for shipment and the determination of changes in the temperatures of cars when shipped under different methods. For a proper understanding of the work under discussion, a general account is given of the California citrus fruit business relative to its extent, location, cultural conditions, and methods of picking, packing, and shipping.

The preliminary survey of the winter of 1903–4 showed that the decay varied in extent in different regions and in different packing houses in the same region and that it usually increased in severity as the season advanced. As has been previously noted in a preliminary account of the work (E. S. R., 17, p. 663), it was found that the decay was caused by a blue mold fungus, which enters the orange through mechanical abrasions in the skin. A systematic series of observations and inspections was started in 1905 to determine the amount and severity of mechanical injuries of oranges when delivered to the packing houses and the relations of the methods of handling the fruit to these injuries, and a variation commonly running from 1 to 50 per cent was found in the amount of injury in the fruit of different pickers, growers, and packing houses. Largely as a result of this investigation the relation between mechanical injury to the orange and the chance of decay during shipment is now generally under-

stood by growers and packers, and a determined effort is being made to reduce the trouble. Abundant data have been accumulated to show that with care in instruction and supervision of labor not more than 2 or 3 per cent of the oranges will be injured in handling the fruit on a large commercial scale.

With the oranges handled in different ways and held in the packing houses in California for about 2 weeks previous to shipment, the work of the 3 years from the standpoint of the packing house shows that the least decay develops in sound unbrushed fruit. Brushing increases decay and washing increases it still more. The greatest decay develops in mechanically injured oranges. Little difference was noted in the amount of decay in oranges grown in different sections and handled in the same manner or in oranges picked from the same grove with equal care at different periods from January to May. Curing the orange for a few days before packing wilts the skin and in the early part of the season renders it more pliable. While this process is probably not harmful to uninjured fruit, the blue mold begins to develop more or less in the injured oranges during the curing period, according to the severity of the injury. When fruit is packed promptly after picking and shipped at once in a cool temperature the decay may not develop in transit. Brushing so large a proportion of the oranges as has been the custom is found to be unnecessary, and washing can be avoided by treating the groves properly for scale.

Two hundred and ninety-seven shipments of fruit were made to New York during the last 3 years. Relative to the handling of the fruit, the least decay has developed under all methods of shipment in the sound, carefully handled oranges, and the greatest amount in those mechanically injured. With regard to promptness of shipment after packing, the decay has increased proportionately with delay in shipment. As to the method of shipment the least decay developed in precooled fruit that was loaded in the cars in cold condition. When the fruit is cooled to a temperature of about 40° F. before shipment less re-icing is required en route. The boxes may also be loaded more closely than is safe under regular icing. Precooling retards decay temporarily but does not remove the cause. Decay can be avoided by handling the fruit carefully. In the market-holding tests the greatest loss occurred in mechanically injured oranges.

The temperature of the fruit was found to change slowly in transit. "In ventilated cars there may be extreme changes in the outside air, and if the extremes do not persist long the changes in the temperature of the fruit are relatively slow. In iced cars the temperature falls relatively fast during the first few days, but a train may cover one-third of the trip across the continent before the temperature of the fruit reaches 50° F. The decay develops rapidly during the early part of the trip, while the fruit is warm. In a car in which the fruit is cooled to 40° F. or lower before shipment the temperature remains nearly constant if the car is re-iced regularly in transit. In cool weather it remains fairly constant without additional icing after the car leaves California. In warm weather the re-icing during the first half of the trip can be avoided, but the car may need re-icing during the latter half of the trip."

Nomenclature of the pear; a catalogue-index of the known varieties referred to in American publications from 1804 to 1907, W. H. RAGAN (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 126, pp. 268*).—This bulletin is similar in its scope to the Nomenclature of the Apple (E. S. R., 16, p. 777) and is offered as the second of a contemplated series in which it is hoped to publish the names of all the cultivated fruits. The data collected are based on a careful study of the American literature of the pear, extending back to and including the publication of the Domestic Encyclopedia in 1804. The code of nomenclature of the American Pomological Society has been followed in the naming of the varieties.

The index is arranged in alphabetical order and consists of a fairly complete list of the cultivated varieties of pears, embracing both leading names and their synonyms, together with brief descriptions and histories of varieties, including origin, form, size, color, texture, flavor, quality, and time of maturity. An index to the American literature of the pear from 1804 to 1907 is appended.

Report of the coffee expert, J. W. VAN LEENHOFF (*Porto Rico Sta. Rpt. 1907, pp. 39, 40*).—Storms lasting continuously from November 25 to December 14, 1906, and again from March 26 to March 28, 1907, did much damage to old and young trees, especially in less protected places, and showed the necessity of many more wind-breaks. As a provisional protection plantains were planted between the rows, to be removed as soon as the shade had grown to sufficient height. Although the claim of Porto Rican planters that young coffee wants heavy shade has not been proved, it does appear that many shade trees for wind-breaks may be required.

The experiments in improving an old coffee grove were continued and the yields determined (E. S. R., 18, p. 1049). The crop from 10 acres in 1902 was 3,387 lbs. In the following year the plat was divided into 10 1-acre plats, on each of which a different method of treatment was followed, as has been previously noted (E. S. R., 16, p. 144). In all 1,106 trees were removed and the others trimmed up. In 1903 the yield from the 10 acres was in all 1,623 lbs. The yield has increased each year, and in 1906, 4,349 lbs. was secured. Full details of the experiments are to be published later in bulletin form.

The total cost of gathering and preparing 100 lbs. of coffee for market is estimated at $4.335, and the average price obtained for the same amount as $10.885. Estimates are given of the cost of the new plantings of coffee. The net cost per acre to the end of the third year was $83.70.

The fermentation of cacao and of coffee, O. LOEW (*Porto Rico Sta. Rpt. 1907, pp. 41–55, figs. 2*).—Studies were made by the author relative to the purpose and necessity of, and the kind of action involved in, the fermentation of cacao and coffee. Several investigators are cited to show that a great difference of opinion exists along these lines.

The chief purposes of the fermentation process with cacao are given as the removal or contraction of the pulp surrounding the seeds, the loosening of the connection between the seed and its testa, and the development of the color and the improvement of the taste. The action of the fermentation process in bringing about these changes is discussed.

The author concludes that the fermentation process itself is due primarily to yeast cells, which multiply rapidly in the saccharine juice oozing from the pulped cacao, or slime tissue, and produce alcohol and carbon dioxid. Bacteria also develop rapidly after a certain time and ozidize the alcohol formed by the yeast, either wholly or partly, into acetic acid. These processes cause a rise of temperature and the death of the cells of the seeds and slime tisue, whereupon the juice of the slime tissue, more or less altered, collects at the bottom of the receptacles, together with the acetic acid produced. By thus shrinking the slime tissue the quick drying of the seed is facilitated, the adhesion between the seed and its envelope is loosened, and the envelope is hardened.

Fermentation also acts indirectly in killing the seed cells, thus liberating oxidizing enzyms, which cause the formation of a brown coloration by oxidation of the tannin of the seed. This coloration is increased during the drying process and finally by the roasting. The taste of the raw cacao bean is not only altered by the partial oxidation of tannin during the fermentation or sun drying of the seed, but also by products of roasting. Both the oxidizing enzyms and the final roasting process assist in developing the aroma.

The fermentation of coffee was also investigated, and the author comes to the conclusion that the alcoholic and acetic fermentations are of only indirect benefit, inasmuch as heat is thereby produced which supports the action of a body (enzym) furnished by the bacteria, which dissolves the adhesive substance between parchment envelope and slimy layer.

From 15 to 20 hours is considered sufficient for the fermentation of coffee in Porto Rico, while in some sections of Central America, as Guatemala, it must be carried on for 2 days. Undue prolonging of the fermentation causes a brown coloration of the parchment and of the seeds. The latter also acquire a disagreeable odor.

FORESTRY.

Forests (*Bibliogr. Nat. Suisse, 1907, No. V 9c, Sup., pp. VIII+151–231*).—This is a supplement to a catalogue published in 1894 of literature dealing with the various phases of Swiss forestry. The present supplement comprises a complementary list of works published from 1800–1892, together with the forestry literature from 1893–1900. The scope of the literature is broad, including forest zoology, botany, soil and climatology, instruction, experiments, history, societies, biographies, commerce, statistics, expositions, surveys, management, taxation, administration, politics, and sylviculture. The work is arranged in chronological order and is accompanied with an alphabetical index.

Yearbook of the administration of government and funds property, A. Heidler (*Jahrb. Staats u. Fondsg. Verwalt., 6 (1907), pp. V+263, pls. 6, figs. 47*).—Tabular data are given relative to the constitution and areas of the government and various endowment estates in the different provinces of Austria for the period 1894–1905, inclusive, together with a summarized report on the revenues of these estates for the period 1899–1903, and comparative data of the revenues obtained in the period 1874–1903. Detailed tabular data are also given showing the production of the various forest products, sylvicultural operations, and forest management for the period 1899–1903. Concluding articles deal with an account of the work in combating the nun moth (*Lymantria monacha*) in the Niepolomice principality from 1891 to 1902 by W. Sedlaczek, and an account of forestry operations conducted under the direction of the administrator of the estates of the Bukowinaer oriental religious funds in Czernowitz by J. Opletal.

A statistical review of the forest administration of the Grand Duchy of Baden for the year 1905 (*Statis. Nachw. Forstverw. Baden, 28 (1905), pp. XX+123, dgms. 9*).—A statistical report for the year 1905 of forest areas, planting and cutting operations, yields, and revenue from various forest products in the Grand Duchy of Baden for the year 1905, together with comparative data for the period from 1878 to 1904.

Progress report of forest administration in Baluchistan for 1905–6, S. Singh (*Rpt. Forest Admin. Baluchistan, 1905–6, pp. 41*).—The usual annual report on the forest operations in Baluchistan for the year 1905–6, including notes and tabular data dealing with the constitution and areas of State forests, forest surveys, preparation of working plans, protection from fire, sylvicultural operations, exploitations, and financial results.

A brief report of similar nature is given by E. H. S. James for the Zhob district for the year 1905–6.

Trees and their life histories, P. Groom (*London and New York, 1907, pp. XVI+407, pl. 1, figs. 317*).—A popular account and description of all the more important trees of Great Britain, including analytical tables, diagnosis of families, and numerous illustrations showing the various tree types, structure of the bark and new growth, flowers, and fruits. An explanatory introduction

is given, dealing with the activity and nourishment of trees and a study of the various tree organs, classification, and nomenclature.

The commercial forest trees of Massachusetts, D. A. CLARK (*Boston, 1907, pp. 66, figs. 76*).—This pamphlet, which was prepared by the author under the direction of F. W. Rane, State Forester of Massachusetts, is offered by that State for free distribution with a view of presenting a practical working description of the commercial trees of Massachusetts.

The more important characteristics and distinguishing features of each species are given, together with a brief account of their distribution, range, habit of growth and form, with figures illustrating the winter twigs, leaves, and fruit.

Forestry from a commercial standpoint, F. W. RANE ([*Boston*], *1907, pp. 16*).—A lecture on this subject delivered by the author before the Massachusetts Horticultural Society, and which is here presented in pamphlet form for general distribution to Massachusetts citizens. The subject matter deals particularly with conditions in Massachusetts and several estimates are given showing the profits to be derived from woodlands under present conditions in that State, including second growth white pine, chestnut, and sprout hardwood growth, as well as planted woodlands.

Practical results in basket willow culture, C. D. MELL (*U. S. Dept. Agr., Forest Serv. Circ. 148, pp. 7*).—In this circular results are given of 2 years' tests at the willow holt of the Forest Service, located on the Department experimental farm at Arlington, Va., in growing standard European basket willows under different methods of management. The varieties tested include Welsh or purple, Lemley, patent Lemley, and American green or almond, and have been described in a previous bulletin (E. S. R., 16, p. 161).

Tests were made on two phases of willow culture, spacing and cutting. The results are presented in tabular form and discussed. The following important facts were brought out by the experiments: Wide spacing was found greatly to decrease the number and total weight of rods for a given area and to increase the weight of individual rods; close spacing greatly retards the growth of weeds; spacing has little effect on the proportion of bark to wood or on the length of the best rods, but wide spacing lowers the production of unbranched rods; cutting below the surface of the ground lowers the quality of the rods and decreases the productivity of the stools.

Large samples of bark from all the willows on the experimental farm were analyzed by the Bureau of Chemistry of this Department. The tannin content was found to be comparatively large, ranging from 8.75 per cent in the Welsh variety to 11.38 per cent in the American green, from which it is concluded that willow bark may prove a valuable source of tannin. Brief suggestions are also given relative to the marketing of willow rods.

Yield tables for the spruce and beech of Switzerland, P. FLURY (*Mitt. Schweiz. Centralanst. Forstl. Versuchsw., 9 (1907), pp. VII + 290 + 55, pls. 7, map 1*).—The yield tables here presented are based upon statistical data collected from 356 pure stand experimental areas of spruce and of beech established and directed by the Swiss forestry experiment station and located in various State, communal, corporation, and private forest areas in the hill lands and mountain regions of Switzerland. The first of these experimental areas was established about 18 years ago, and most of them have been thinned for the second or third time.

The first part of the work is devoted to a detailed account, with explanatory tables, relative to the individual experimental areas and methods of gathering the data. Parts 2 and 3 contain detailed tabulated descriptions, and various felling results of the individual experimental areas, together with computed yield and accretion tables for different age and quality classes of spruce and

beech. In the case of the spruce, separate sets of tables are given for the hill lands and mountain areas since the various relations for this species differ considerably in the two regions. Only one set of tables is given for the beach, which species shows practically the same development in both regions. Part 4 discusses the principal results derived from the statistics, together with the application of the yield table.

In an appendix the separate experimental stands are classified relative to the diameter and yield per hectare of stems at the time of the first felling and according to the quality of the locality. A map is given showing the location of the various experimental areas, as well as a catalogue of the yield tables for various species of trees published since 1872, and of all works published since 1881 dealing with the arrangement, testing, results, and investigations in connection with yield tables.

Progress in chestnut pole preservation, H. F. WEISS (*U. S. Dept. Agr., Forest Serv. Circ. 147, pp. 14, figs. 2*).—This circular discusses a number of points relative to pole preservation not brought out in the former publications of the Forest Service on similar subjects (E. S. R., 19, pp. 243, 952), and is based largely upon the results of a series of experiments conducted at Parkton, Md., from August, 1905, to June, 1907, in cooperation with the American Telephone and Telegraph Company.

A comparison of poles cut from sprouts and seed trees showed practically no difference in the taper, but the sprout-grown poles are stronger and hence safer under strain. Furthermore, they require a shorter rotation, thus giving quicker and larger returns on the investment.

The poles were preserved by the brush and open-tank treatments. Under the brush treatment the penetration of carbolineum and creosote was about equal and averaged about one-eighth of an inch. Creosote alone was used in the open-tank treatment, and special studies were made of the effects of long soaking in hot oil and of a rapid change from hot to cold oil, and as to whether poles soaked in water and then seasoñed take better treatment. The conclusion reached is that the sapwood of chestnut, which is a thin layer, should be completely saturated with the preservative. This can be accomplished by heating the poles in oil for 6 hours and leaving them in the cooling oil over night, or by heating them in hot oil for 4 hours and plunging them into cold oil for 2 hours. Soaking poles in water preparatory to preservative treatment is not recommended, since no better absorption or penetration of the oil is obtained thereby. Effectiveness of treatment is independent of the season of cutting, but depends directly upon the moisture content and the width of the sapwood. Chestnut poles cut during the period of maximum rate of diameter growth and thoroughly seasoned admit of best results in preservative treatment. Poles cut in spring and summer reach such a condition more quickly than those cut in autumn and winter.

A table is given showing the length of seasoning period desirable previous to preserving for poles cut at different times of the year. Defects such as cup shakes, frost cracks, or splits from careless cutting may cause serious damage, especially in spring-cut and summer-cut poles. It is advised that such poles be immediately treated with S-irons to prevent them from splitting.

Experiments with railway cross-ties, H. B. EASTMAN (*U. S. Dept. Agr., Forest Serv. Circ. 146, pp. 22, fig. 1, dgms. 2*).—An account is given of an investigation conducted in cooperation with the Northern Pacific Railroad to determine the best and most economical methods of handling tie timbers accessible to that road when manufactured into cross-ties. The timbers used in the experiments were Douglas fir, western hemlock, western tamarack, and giant arborvitæ, and the work was conducted along 3 lines, as follows: Tests to

determine the green weight and rate of seasoning of timbers cut in different months, tests to determine the absorptive power of seasoned timbers cut in different months, and tests to determine the comparative durability of green, seasoned, and treated timbers when laid under similar conditions and with various tie-plates and rail fastenings in a test track. The seasoning and preservative tests, which were conducted at Tacoma and Pasco, Wash., and Sandpoint, Idaho, are described and the results are tabulated and discussed.

The general conclusions reached are that there is practically no difference in the rate of seasoning of 7 by 2 and 8 by 1 forms of piles. The rate of seasoning, as affected by the position of the pile, depends largely upon local conditions.

Hewed ties peeled when cut season much more rapidly during the first 4 months than unpealed ties. The weights of both peeled and unpeeled ties, however, are approximately uniform after a year's seasoning. The oven-dry weight of Douglas fir was 28.3 lbs. per cubic foot, the green weight varying from 41.7 lbs. in February to 37 lbs. in July. The minimum air-seasoned weight reached was 31.9 lbs. per cubic foot.

Two kinds of checks were observed in the timber—radial and small honeycomb. The honeycomb checks were found to cause little damage to the tie, while radial checks are very destructive and often make the tie unfit for service. It is advised that the practice of cutting tie and bridge timbers from Douglas fir and western hemlock during June, July, August, and September should be discontinued, since radial checking is particularly serious during those months. Dimension material over 6 by 6 in. should be partially air seasoned before being shipped east of the Cascade Mountains.

Hewed ties peeled directly before treatment absorb more preservative than those peeled when cut, provided they have seasoned for an equal length of time.

A large number of green, seasoned, and treated ties have been placed in test tracks, one on the west slope of the Cascade Mountains, near Maywood, Wash., and one in western Montana, near Plains. The nature of these tracks is described and illustrated and the scheme of the tests to be conducted is given.

Forest products of the United States, 1906 (*U. S. Dept. Agr., Forest Service Bul. 77, pp. 99*).—This bulletin contains statistical data for 1906 relative to the lumber cut of the United States, the consumption of cross-ties, pulpwood, tanbark, tanning extract, and poles, the production of tight and slack cooperage stock, veneer, and wood used for distillation.

The statistics for each of these products have been previously issued in separate circulars, which are noted (E. S. R., 19, pp. 748, 848, 950).

Wood pulp in Norway, F. S. S. Johnson (*Daily Consular and Trade Rpts. [U. S.], 1907, No. 3062, pp. 9, 10*).—A brief statistical review of the wood pulp industry of Norway. Tables are given showing the quantity and value of wood pulp produced at various periods from 1869 to 1906, as well as the share of the product taken by each country in 1906. The production increased from 60 tons in 1869 to 505,627 tons in 1906, which consisted of mechanical wood pulp, dry, 13,059 tons, and wet, 362,228 tons, chemical wood pulp, dry 122,923 tons, and wet, 7,417 tons. Great Britain, France, and Belgium are the largest buyers of Norwegian pulp wood.

Data are also given relative to the forestry resources of Norway.

The resinous products of the Dipterocarpaceæs of Indo-China, E. Milliau and C. Crevost (*Bul. Écon. Indo-Chine, n. ser., 10 (1907), No. 63, pp. 381–403*).—A key is given to the genera and species of the Dipterocarpaceæ family, including the species of Dipterocarpus, Hopea, Shorea, and Anisoptera, which produce resinous products used in the manufacture of varnish, furniture polishes, etc. The key is prepared for the benefit of exporters and manufacturers. The local and botanical names of the different species are given, together with notes on

their habitat and the nature of the product which they yield. The more important products are resin oil, commonly known as wood oil, damars of Batavia, and copal.

Bamboo as raw material, W. RAITT (*Paper Making, 26 (1907), Nos. 11, pp. 502–508; 12, pp. 539–541*).—This paper, which originally appeared in *Paper Mill*, contains a general discussion as to the probable importance of bamboo as a source of wood pulp, together with notes on laboratory tests made by the author in the production of wood pulp and observations on the growth and behavior of bamboo under various systems of cropping, with estimates on the average weight of the material which might reasonably be expected annually from a given area under rational systems of culture.

The results of the author's experiments in the production of wood pulp from bamboo indicate that the use of 2 or 3-year old growths appears to be the most economical and to differ very slightly in the results. It is concluded that cropping every third year, when the stems are from 28 to 34 months old, will secure an absolute permanence of growth. In making paper pulp the nodes must be removed from the bamboo cane. Fifteen tons of canes per acre every third year is given as the dependable crop to be realized from poor to moderate bamboo stands. According to data secured from laboratory tests it is estimated that 5 tons of air-dry bamboo will produce at least 45 per cent or 45 cwt. of unbleached pulp.

Rubber cultivation in the British Empire, H. WRIGHT (*London, 1907, pp. VII+100, pls. 4*).—A lecture on this subject delivered before the Society of Arts. Introductory considerations deal with the importance of rubber cultivation and the development of the rubber market, including tabular statistics showing the consumption and value of rubber from 1899 to 1906, the relative importance of India rubber, Balata, and gutta-percha, and the capital invested in rubber companies.

The author discusses the various geographical and botanical sources of caoutchouc, briefly describes the important rubber-producing species and varieties, and gives a general account of the development of wild and plantation rubber, with special reference to rubber cultivation in the British Empire. The differences between the laticiferous systems of different genera is discussed, the methods of tapping, collecting, coagulating, and the manufacture of rubber are described, and data are given on yields secured under various conditions. Notes are also given on numerous slides shown at the lecture.

Caoutchouc and gutta plants, H. JUMELLE (*Les Plantes à Caoutchouc et à Gutta. Paris, 1903, pp. XII+542, figs. 57*).—This work is designed to supersede one published in 1898 on the caoutchouc and gutta plants in the French colonies. The present volume has been revised and enlarged with a view of including all the tropical countries where rubber is produced and presenting the more recent information collected on the subject of rubber culture.

Part 1 deals with plants producing caoutchouc, which are discussed in a general way relative to their history, the chemical and physical properties of the rubber and latex, and methods of harvesting and coagulation, after which the important caoutchouc-producing species and varieties are taken up, including their geographic distribution, botany, exploitation, yield in latex and rubber, cultivation, etc. Part 2 deals with plants producing gutta.

India-rubber and its manufacture, H. L. TERRY (*London, 1907, pp. VIII+294, figs. 18*).—This volume is designed for the general reader and the technologist in other branches of industry, with a view to furnishing information relative to the natural history and manufacture of rubber. A brief general and historical account is given of the rubber industry, together with the botanical origin of raw rubber, methods of tapping, coagulation, and principal raw

rubbers of commerce. Succeeding chapters deal with the chemical and physical properties of rubber, vulcanization, India-rubber plantations, India-rubber substitutes, reclaimed rubber, washing, drying, and compounding of rubber, rubber solvents and their recovery, rubber solution, and the various forms of manufactured rubber and the articles made therefrom. Concluding chapters treat of the production and uses of gutta-percha and balata. A brief bibliography is also given of publications dealing with the various phases of rubber cultivation and manufacture.

DISEASES OF PLANTS.

Report of the botanist for 1907, G. P. Clinton (*Connecticut State Sta. Rpt. 1907–8, pt. 6, pp. 339–396, pls. 16*).—General notes are given on a number of diseases of plants that have been previously reported and short accounts presented of a number that have not hitherto been reported as occurring in this State.

The diseases new to the State are taken up under an alphabetical list of host plants, and among the number, attention is called to the blight of the white pine, which, it is said, has been one of the most conspicuous diseases of the year, occurring not only in Connecticut but over most of New England. This disease has been attributed to various causes, but the author thinks the trouble a physiological one, induced by adverse conditions. In some cases winter injury was probably the cause of the trouble, while in others it was apparently due largely to drought and late frosts.

Notes are given on the internal brown spot of potatoes, a diseased condition that proved rather troublesome in potatoes that were imported from Scotland for experimental purposes at the station. The occurrence of scurf on potatoes, due to *Spondylocladium atrovirens*, is also noted.

An account is given of a disease of Sumatra tobacco, which is believed to be possibly of bacterial origin. Attention was first called to this disease in Bulletin 150 of the station (E. S. R., 17, p. 136), in which it was stated that the plants were attacked by a fungus root disease. Subsequent studies seemed to indicate that the trouble may be bacterial in origin. The disease, so far as it has been noticed, has been confined to seed beds.

An account is given of investigations begun in 1906 on the root rot of tobacco, due to *Thielavia basicola*. This fungus, which seems to be rather widely distributed, occurring on a number of plants, has proved very troublesome both in tobacco seed beds and in the fields. Experiments with formaldehyde and steam sterilization in seed beds have given fairly satisfactory results, the steam heated plats producing the best stand, followed by those treated in the fall of the year with formaldehyde at the rate of 1 part formalin to 100 parts water. Formalin diluted and sprinkled over the plants after their growth had begun, injured the plants and resulted in a very poor stand and growth. When the convenience of treatment is considered, the author believes that the formalin treatment is an efficient and convenient method of protecting seed beds against the root rot and possibly the damping off of tobacco. Observations made of the treatment of tobacco fields for the control of this disease seem to indicate that as yet no effective treatment for use in the field has been obtained. Wherever possible the growing of tobacco in land that has become infested should be abandoned for a few years.

The report concludes with an account of studies on heterœcious rusts of Connecticut having a peridermium for their acidial stage. This is a detailed report on investigations which have been previously noted (E. S. R., 19, p. 1149).

Symptoms of disease in plants, F. D. Heald (*Ann. Rpt. Nebr. Hort. Soc., 38 (1907), pp. 231–244*).—The author describes the symptoms of a large number

of plant diseases and gives methods for recognizing their causes. Suggestions are also given for the prevention of the diseases where definite means are known.

The control of plant diseases, H. H. Whetzel and F. C. Stewart (*New York Cornell Sta. Bul. 252, pp. 349–361, figs. 15*).—Brief descriptions are given of the more important fungus diseases attacking alfalfa, apples, asparagus, beans, cabbage, cauliflower, carnations, celery, cherries, chrysanthemums, cucumbers, currants, ginseng, gooseberries, grapes, lettuce, muskmelons, oats, onions, peaches, pears, plums, potatoes, quinces, raspberries, roses, strawberries, tomatoes, turnips, and wheat, together with directions for their control.

Cultures of Uredineæ in 1907, J. C. Arthur (*Abs. in Science, n. ser., 27 (1908), No. 687, p. 340*).—A brief abstract is given of a report on the cultural work carried on by the author during 1907. Thirty species of rust were grown with success, 8 of which are reported for the first time. A rust of Allium was carried through its life cycle, and 3 sedge rusts and 2 species of Gymnosporangium, *G. betheli* and *G. inconspicuum*, were connected with their æcidial stages.

The life history of Puccinia malvacearum, J. B. Dandeno (*Rpt. Mich. Acad. Sci., 9 (1907), pp. 68–73, figs. 5*).—The author calls attention to this parasite, which is of interest on account of the fact that, so far as known, it does not produce any other stage of spores than teleutospores. On account of this peculiarity, the wintering of the fungus and its sudden spread during the late summer have been subjects of considerable study.

The author undertook a series of investigations to discover how the fungus passes the winter, in this way testing the statements of others that the disease might pass the winter in the embryo of infected seeds, or that teleutospores produced late in the season acted as resting spores and then germinated in the spring.

So far as the author's observations have gone, none of the old spores could be induced to germinate, and the author claims that the idea of teleutospores wintering the fungus over will have to be abandoned. On examining some mallows very early in the spring the fungus was found present, and it is believed that it winters over in living portions of such infected plants as withstand the winter. Its slow development in the summer is attributed to the probable fact that the temperature and moisture conditions in the latter part of the summer are best suited for its rapid development and spread.

Blindness in barley (*Jour. Bd. Agr. [London], 14 (1908), No. 11, pp. 670, 671*).—A brief account is given of the experiments carried on by the agricultural department of Cambridge University in treating barley with fungicides to prevent the attack of the disease known as blindness in barley, a disease that is caused by the fungus *Helminthosporium gramineum*.

In the first series of experiments, seeds were treated with a 10 per cent solution of copper sulphate, with formalin, with the mixture known as Sar, and by the hot-water method. The results obtained showed that the copper sulphate, while injuring the seed to some extent, was efficient in preventing the disease, and that formalin was nearly as satisfactory, the other methods being much less effective.

In 1907 formalin was again used in 2 strengths of solution, 1 part in 240 of water and 1 part in 160 of water. For the stronger solution, only 0.9 per cent of diseased plants was observed, while for the weaker solution, 2.5 per cent was found to be attacked by the fungus. The stronger solution had no bad effect upon the crop, while by checking the disease it is believed that the yield of grain was increased by not less than 25 per cent. There was also a decided increase in the proportion of heavy to light grain.

Barley smut investigations, R. A. Moore and A. L. Stone (*Wisconsin Sta. Rpt. 1907, pp. 409, 410*).—In the experiments being conducted by the authors with a view to reducing the loss from barley smut, the modified hot-water treatment was again used during 1907 with practically the same results reported for 1906 (E. S. R., 18, p. 1055). Owing to the cold weather following the seeding, some of the kernels of soaked barley failed to germinate and in some places the stand was thinner than on plats where the seed was not treated.

Data received from 99 members of the experiment association, who conducted cooperative tests in exterminating smut, show an average percentage of smut in untreated seed of 2.93 as compared with an average of only 0.65 per cent of smut in treated seed. The average percentage of the crop saved by the treatment was 2.28. Thirty reported poor germination of treated seed after sowing.

As a result of both the station and cooperative tests, it is concluded that loose smut of barley can be eradicated by the modified hot-water treatment, although the farmer is advised to treat only small areas until further tests have been made with large quantities of seed. The range of temperatures of the hot water at which the treatment will be effective without injury to the seed appears to be limited. Treated barley should be sown immediately, otherwise it will sprout. The ground should have become warm before sowing, to facilitate germination.

Observations upon the prevalence of early potato blight (Alternaria solani) in Wisconsin, J. G. Milward (*Wisconsin Sta. Rpt. 1907, pp. 343–350, figs. 6*).—The potato investigations conducted by the station for the past 4 years have shown the early potato blight (*A. solani*) to be an immediate factor in determining the annual yield of potatoes in Wisconsin. The author points out the need of a correct understanding of the nature and life history of this fungus and a clear correlation of these facts as associated with standard methods of control. The disease is briefly discussed relative to conditions leading to its development and perpetuation, and the important morphological characters of the fungus are brought out by the aid of illustrations.

Potato spraying experiments for 1907, J. G. Milward (*Wisconsin Sta. Rpt. 1907, pp. 351–354, fig. 1*).—The spraying experiments for the prevention of early blight were continued during 1907 with results similar to those reported for 1905 and 1906 (E. S. R., 18, p. 1056).

Bordeaux mixture has proved an efficient preventive where cultural conditions are suited to the growing of the crop, 5 applications of Bordeaux made during the season on each of the 3 test fields at a cost of $4.30 per acre resulting in gains per acre of 27, 30, and 52 bu. of potatoes, respectively, and net profits per acre of $7.70, $9.20, and $21.70, respectively.

The work has been extended to include observations upon blight-resistant varieties and yield tests with 3 varieties of Russian alcohol potatoes. Among the 110 varieties tested a wide variation was shown in regard to disease resistance.

Attention is called to the importance of selection and care of seed potatoes as a factor in maintaining productiveness and vigor in the standard varieties, and to the need of a closer study of the influence of weather conditions upon the prevalence of early blight in Wisconsin.

Diseases affecting rice in Louisiana, H. R. Fulton (*Louisiana Stas. Bul. 105, pp. 3–28, pls. 8*).—Four diseases of rice observed in Louisiana are considered in this bulletin, the blast, brown grain spot, green smut, and black smut.

The first disease, rice blast, is in all probability the same as that known in Italy as brusone, and also known to occur in Japan, and is caused by the fungus *Piricularia oryzæ*. The general effect of the blast is shown in the extensive

paling and drying of the leaf and stem and the poor condition of the head. The most conspicuous lesions are found in the sheath nodes just above the joints of the stem, at the region where the stem becomes the axis of the head. A fungus that does not seem to be distinguishable from the rice blast Piricularia has been found on crab grass, and it is thought probable that this host plant may serve as a source of infection for rice. The results of inoculation experiments and the conditions favoring the occurrence and spread of the disease are given. An account of preventive measures, based largely upon the experiments by the South Carolina Station (E. S. R., 18, p. 244), is presented.

Brown spot of rice grains, which is also called speck and pip, is characterized by the presence of one or more discolored shrunken areas on the grains, the typical spots being regularly circular, about $\frac{1}{16}$ in. in diameter, and bounded by a dark marginal line. The interior portion of the grain under the spot is chalky, opaque, and brittle, and the whole grain is of inferior quality. A careful examination of diseased tissues showed the presence of several kinds of bacteria and fungi and also that the center of each spot contained a minute depression such as might be caused by the prick of a fine needle. This suggested the possibility of insects being the cause of the trouble, and a study pointed to the fact that the primary cause of the disease is *Œbalus pugnax*. This insect was found abundant in the rice fields, and the bacteria and fungi present followed the injury caused by this pest.

The green smut usually affected only a few grains in a head, causing their enlargement, the fungus responsible for this trouble being *Ustilaginoidea virens*. This disease has been known in Japan for a long time, and in Louisiana it has been found on the Honduras and red rice, and less frequently on Japan rice. The life history of the fungus is very poorly known, and at present no definite means of infection have been determined. The treatment of seed with formalin or other fungicides, which have been used with success for similar diseases, it is believed would prove adapted to the prevention of this disease of rice.

The black smut, which, so far as the author's observations have gone, is confined to the Honduras and red rice, is due to *Tilletia horrida*. This may be controlled by treating the seed with any of the better known methods of seed treatment.

[**Fermentation and diseases of tobacco**], O. Loew (*Porto Rico Sta. Rpt. 1907, pp. 16–18, fig. 1*).—Brief notes on the method of fermenting tobacco and the diseases of tobacco in Porto Rico.

The author is of the opinion that the so-called after-fermentation of tobacco proceeds much more energetically in the continuously warm climate of Porto Rico than in the United States, and that it appears unnecessary in the case of the main fermentation to turn over the bulks of tobacco quite so often as in the States, although a temperature of 55 or 56° C. should be reached in each bulk the first time.

Relative to diseases of tobacco the opinion is advanced that the various troubles observed in the United States occur more or less in Porto Rico. The mosaic disease and the wilt disease do not appear to be general.

L. DuBois reports a trouble observed with the tobacco in a certain seciton of the Aibonito district, in which the tobacco several weeks after fermentation acquires such a disagreeable odor as to render it worthless. An examination of some of this tobacco showed the odor to be moldy or musty. The vines were covered here and there with a white mass and many of the stems were so rotten that they easily broke into fragments on being handled. A microscopical examination revealed no fungus mycelium, but numerous bacteria, especially cocci, as well as yeast-like cells. The disease resembles pole burn. The cause is still undetermined.

A peculiar disease, known as "sancochado" in Porto Rico, was observed in tobacco seed beds of Cáguas. This disease spreads from a center in ring-like progression. The circle of dead, bleached seedlings increasing continuously is checked only by removing the soil to some depth and treating the spot with diluted formaldehyde (1 spoonful to 30 gal. of water). A microscopical examination revealed no mycelium, but numerous active nematodes were found, which are thought to cause the disease.

The tobacco flea beetle and the changa are considered the worst enemies of tobacco in Porto Rico. The majority of the insect pests, including the cutworm, are avoided by growing the tobacco under cheese-cloth.

Peach leaf curl, I. B. P. Evans (*Transvaal Agr. Jour., 6 (1908), No. 22, pp. 259, 260, pls. 2*).—The author describes the peach leaf curl caused by *Exoascus deformans*, giving particular attention to its occurrence on nectarines and apricots. When the fungus attacks the fruit of the nectarine it becomes covered with wart-like growths, while apricots are arrested in their development so that they never attain more than half the normal size.

For the prevention of this disease the author recommends thorough spraying with Bordeaux mixture.

Notes on the black knot of plum, J. B. Dandeno (*Rpt. Mich. Acad. Sci., 9 (1907), pp. 74, 75, fig. 1*).—The author reports on successful attempts in obtaining the ascospores from the black knot of plums. Upon careful examination it was found that the perithecia are not produced for about 3 years after infection. After the perithecia are produced the asci are quickly disseminated, and the old knots remain on the twigs. In order to collect material showing the asci and ascospores the third year's growth of the plum knots must be secured.

From inoculation experiments with conidia formed by the fungus, it seems that they are not very active as infecting agents. Only a small proportion of infection with ascospores succeeded in producing the disease, which seemed to indicate that artificial inoculation is not readily accomplished.

Gooseberry black knot (*Jour. Bd. Agr. [London], 14 (1908), No. 11, pp. 680, 681, figs. 4*).—A description is given of a disease of gooseberries and red and black currants that is due to the fungus *Plowrightia ribesia*.

The fungus is a wound parasite, and it seems probable that aphids and scale insects enable it to gain entrance into the living tissues of the plant. The first indication of disease is the wilting and yellowing of the leaves, which fall quite early in the season. As a rule a branch is not killed outright in the first season of the attack, but during the second year the leaf buds remain in half-opened condition and the branch dies, owing to the presence of the fungus mycelium in the water conducting vessels. There is no external evidence of the fungus until the branches are dead or nearly so, when the fruiting bodies burst through the bark, forming elongated or grouped blackish warts.

It is believed that spraying will have little or no effect in controlling this disease, and it is recommended that on its first appearance all branches whose foliage is wilting should be removed and burned.

A combined treatment for the prevention of the powdery and downy mildew of grapes, D. Donon (*Jour. Agr. Prat., n. ser., 15 (1908), No. 5, pp. 146–148*).—A description is given of a fungicide that is said to consist of a copper and sulphur mixture to which formaldehyde is added. This fungicide is claimed to be very efficient in the control of various grape diseases, including the powdery mildew, and its use does away with the necessity of sulphuring the vines. The fungicide is prepared for the trade in a concentrated form, and is said to be of easy application and less expensive than a liquid spray for the prevention of black rot, etc., with a separate application of sulphur for the powdery mildew.

The efficiency of this new fungicide in controlling other plant diseases is to be tested.

Timber fungi, with special reference to the pines, C. G. Bates (*Ann. Rpt. Nebr. Hort. Soc., 38 (1907), pp. 201–208*).—Descriptions are given of fungi causing damping off of the seedlings of pines, pine blister due to *Coleosporium senecionis*, hypertrophy of pine cones, ring scale of pine due to *Tranetes pini*, root rots caused by *Polyporus annosus* and *Armillaria mellea*, and dry rots due to *P. vaporarius* and *Merulius lachrymans*.

The treatment of damping-off in coniferous seedlings, P. Spaulding (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 4, pp. 8*).—Greenhouse tests have been made by the writer for several years relative to the effect of various chemicals upon the damping-off diseases of tender coniferous seedlings. The work was extended to field conditions in 1907, experiments being conducted in several nurseries of the New York Forest, Fish, and Game Commission and of the Vermont State Forestry Commission, located, respectively, at Saranac Inn, N. Y., and Burlington, Vt. The results presented are not considered final, but are offered to nurserymen with the hope that they may prove useful until more conclusive proof of the comparative value of the chemicals tested can be secured.

The plats used were located in seed beds 12 ft. long and 4 ft. wide, each bed being divided into 3 equal parts 4 ft. square. The chemicals were used in the form of fine powders or in solutions. The solutions were applied to the soil with an ordinary sprinkling can before the seeds were sown and again about 5 days after the seedlings had come up. The powders were applied to the beds only after the seedlings had been up for 3 or 4 days, a simple form of duster having a perforated bottom being used. Very light coatings were given, which were renewed promptly after each rain.

Powdered sulphur was used in 3 forms, namely, washed, resublimed, and precipitated, with favorable results, although the first form gave slightly the best result. The preparation of dry Bordeaux mixture was found to be too tedious and time-consuming to be of use in the case of a disease like damping-off and was discarded for a copper sulphate and lime mixture which is easily and quickly made. Powdered sulphate of copper was mixed with fresh slaked lime 1 : 10. No injurious results were noted when this mixture was freely used, even when the seedlings were still wet with dew. Very good results were obtained in checking the damping-off, and it is believed that the mixture may prove of commercial value.

Solutions of potassium sulphid and of potassium permanganate gave no definite results, owing to the absence of the disease in the experimental plats. Commercial 40 per cent formalin, used at the rate of 4 oz. to 3 gal. of water, when applied to the soil before seeding and not afterwards, seemed to have no effect on the disease. When the application was repeated after the seedlings had come up the results were poor, hence it is believed that formalin is of little value with the damping-off diseases of coniferous seedlings unless supplemented after the germination of the seed with some other efficient chemical.

The best results were obtained with dilute sulphuric acid. The soil was thoroughly drenched with a solution of 1 oz. of sulphuric acid to 1 gal. of water several days before sowing the seed, and the treatment was repeated about a week after the seedlings came up. When noted in December, there was a very good stand of fine, healthy seedlings on the treated plat and the soil was entirely free from algæ and moss, while on the check plat there were practically no seedlings left and the soil was green with algæ and moss. Of the several species thus treated, the Norway spruce alone showed ill effects from the treatment. A weaker solution, 1 part sulphuric acid to 500 of water, is recommended in preference to the stronger one used in these experiments.

Fomes pinicola and its host plants, L. H. Pennington (*Rpt. Mich. Acad. Sci., 9 (1907), pp. 80–82*).—This fungus, which is said to be one of the most common of the larger fungi that infect conifers, is reported by the author as being found on a number of broad-leaved species of trees, among them the hard maple, beech, yellow and white birch, and balsam poplar.

Some diseases of rubber plants, C. Bernard (*Bul. Dépt. Agr. Indes Néerland., 1907, No. 12, pp. 79, pls. 2*).—The author gives descriptions of some of the principal fungus diseases and insect enemies of rubber plants, grouping them under the following species of plants: *Hevea brasiliensis*, *Ficus elastica*, *Castilloa elastica*, *Kickxia elastica*, and *Manihot glaziovii*.

Fungicides, H. H. Whetzel and C. S. Wilson (*New York Cornell Sta. Bul. 252, pp. 363–364, fig. 1*).—Popular directions are given for preparing and using the most important fungicides.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Report on rabbit branch, A. Crawford (*Jour. Dept. Agr. West. Aust., 15 (1907), No. 12, pp. 935–938*).—The campaign against rabbits in Western Australia is being pushed vigorously. Complaint is made that many of the individual farmers are disposed to allow the government to bear the whole burden and do not even assist by the destruction of rabbits on their own farms. The methods employed include the use of rabbit-proof fences, encouragement of the natural enemies of rabbits including iguanas, hawks, etc., and killing all doe rabbits which are caught by various trapping devices (the buck rabbits being set free).

Observations on the food of a number of birds, N. Passerini and G. Cecconi (*Bol. Ist. Agr. Scandicci, 2. ser., 7 (1908), No. 1, pp. 12–102*).—The authors studied the kind of food eaten by a large number of wild birds and on the basis of the data obtained classified them in accordance with their food habits.

The locust-destroying birds of the Transvaal, F. W. D'Evelyn (*Condor, 10 (1908), No. 1, pp. 10–14*).—Descriptive notes are given on the habits of various birds which have been observed to feed upon locusts in the Transvaal. Special mention is made of storks, starlings, guinea fowls, and the secretary bird.

Some observations concerning the effects of freezing on insect larvæ, J. S. Hine (*Ohio Nat., 8 (1908), No. 4, pp. 258–260*).—The larvæ of *Bellura obliqua* were placed in water over night and exposed to a temperature of —15° F. This process was repeated for 6 nights, the temperatures ranging from —6 to —16° F. None of the larvæ was injured. The larvæ of the tomato hawk moth were killed by a frost severe enough to kill tomato vines. Similarly with larvæ of the fall cankerworm a frost on May 4 killed a large number of them.

The more important insects injurious to Indian agriculture, H. M. Lefroy (*Mem. Dept. Agr. India, Ent. Ser., 1 (1907), No. 2, pp. V + 113–252, figs. 82*).—A description is given in systematic order of the insects known to be injurious to crops in India. No list of economic insects has previously been published for this territory and it is believed that the bulletin will be of service to economic entomologists. In the case of each insect a brief description is given with notes on its distribution, biology, food plants, and the extent of its injuries.

The Indian surface caterpillars of the genus Agrotis, H. M. Lefroy and C. C. Ghosh (*Mem. Dept. Agr. India, Ent. Ser., 1 (1907), No. 3, pp. 253–274, pl. 1*).—Several species of Agrotis and Euxoa are described in detail and notes are given on their biology. Particular attention is given to a discussion of *Agrotis ypsilon*.

Combating ants and locusts in South America. C. Bolle (*Tropenpflanzer, 11 (1907), No. 6, pp. 392–401*).—A number of leaf-eating ants occur in South America and may cause serious damage. These insects may be controlled to some extent by the use of burrows combined with pits in which the ants are captured. In the control of locusts good results are reported from the introduction of colonies of predaceous ants which feed upon them. It is stated that these ants may easily be transported in whole colonies to cultivated fields or other localities where their help is needed in the control of locusts.

European insect pests in North America. R. Heymons (*Naturw. Ztschr. Forst u. Landw., 6 (1908), No. 1, pp. 6–22*).—A historical statement is given of the introduction and distribution of gipsy moth and brown-tail moth in the United States with particular reference to the use of artificial remedies in controlling the pests and to the importation of their parasites.

[Insect pests]. J. Craig, M. V. Slingerland, and C. R. Crosby (*New York Cornell Sta. Bul. 252, pp. 335–349, figs. 12*).—Attention is called to the underlying principles and economic aspects of spraying in general. Directions are given for preparing insecticides and applying them in the control of the chief insect enemies of apples, plums, cherries, quinces, peaches, pears, nursery stock, grapes, small fruits, roses, potatoes, cucurbits, cabbages, onions, and greenhouse plants.

Report of the entomologist and plant pathologist. W. V. Tower (*Porto Rico Sta. Rpt. 1907, pp. 31–38, pl. 1*).—Notes are presented on the chief pests infesting oranges, tobacco, vegetables, sugar cane, pineapples, and other crops, the use of wind-breaks in checking purple scale, and the preparation of kerosene emulsion.

The "orange dog," a variegated caterpillar belonging to the genus Papilio, was found feeding on the orange during July, and a second brood was observed October 18, at which time the larvæ were half grown. The orange leaf-weevil occurred in great numbers in the latter part of May. Spraying with arsenate of lead was effective for both of these pests. For orange scab, spraying with Bordeaux mixture just as the fruit forms and again after from 10 to 14 days is recommended. Nurseries of rough lemon should not be planted between budded rows of trees, nor should nurseries be planted on the windward side of the groves. Red scale and purple scale are causing much trouble but may be combated by spraying with kerosene emulsion 1:6 and the use of wind-breaks.

The principal tobacco pests were cutworms, changas, flea beetles, hornworms, and nematodes. A Paris green mash made up of a mixture of 20 lbs. bran or corn meal with ½ lb. Paris green made into a thick paste with 1 gal. molasses and 1½ gal. water, and applied in the form of small cones partly below ground and partly above, is recommended for changas and cutworms. *Telenomus monilicornis* was observed as a parasite in the eggs of the hornworm. *Plutella maculipennis* did considerable damage to cabbage, kale, mustard and turnips. For mealy bugs on sugar cane and pineapples, dipping in kerosene emulsion is advocated. Tobacco dust placed in the crown of the pineapple has also given excellent results.

Brief notes are also given on May beetles, brown scale, rust mite, southern cabbage worm, a white fly, plant lice, striped cucumber beetle, the melanconium stage of *Tricosphæra sacchari*, sugar cane weevil, a borer of the genus Xyleborus, rice weevil, *Icerya montserratensis*, *Pulvinaria psidii*, rufous scale, wax scale, mummy disease of guavas, and other pests.

The so-called green bug and other grain aphids in Minnesota in 1907. F. L. Washburn (*Minnesota Sta. Bul. 108, pp. 257–280, pl. 1, figs. 15; Spec. Rpt. State Ent. Minn. 1908, Mar., pp. 21, pl. 1, figs. 15*).—On account of the alarm which prevailed among the grain growers of Minnesota regarding the possible invasion of the State by the green bug, an investigation was made of this insect

and of other related aphids. The green bug occurred sparingly in various parts of Minnesota during 1907 but did not affect the wheat crop appreciably. The author believes that the long cold winters and hot summers of Minnesota are unfavorable for the multiplication of this pest. The most common grain aphid in Minnesota is *Macrosiphum granaria*. This pest is attacked by parasites and is usually held in control by climatic conditions. An account is given of the injury caused by the green bug in the southwestern States and descriptions are presented of the developmental forms of this pest as studied in the insectary.

Peculiar injury to barley by Clorops tæniopus, B. Wahl (*Ztschr. Landw. Versuchsw. Österr., 10 (1907), No. 10, pp. 750–756*).—The author had occasion to observe an unusually severe attack of *Clorops tæniopus* upon barley. In the infested plants the inflorescence appeared to be normal in its early stages but soon showed a pronounced deformation due to the attacks of the insect.

Kafir corn aphis (*Agr. Jour. Cape Good Hope, 32 (1908), No. 1, pp. 27–31*).—*Aphis sorghi* has attracted attention on account of its ravages upon Kafir in South Africa since 1904. The pest is apparently spreading and its eradication is a difficult problem. A description is given of the insect together with a brief account of its natural enemies which thus far seem to include merely lady beetles. Apparently some advantage is to be derived from early sowing of Kafir. According to certain growers, Bushman Kafir is rather more resistant to aphis attacks than other varieties.

The asparagus beetles, F. H. Chittenden (*U. S. Dept. Agr., Bur. Ent. Circ. 102, pp. 12, figs. 6*).—The life history of these insects has been previously studied by the author (E. S. R., 9, p. 569; 10, p. 570; 19, p. 158). In this circular attention is given to the habits, life history, and means of combating *Crioceris asparagi* and *C. 12-punctata*. The present status and distribution of these insects is outlined and recommendations are made regarding the most effective remedies for controlling the pests.

Screening for the protection of cabbage seed beds, W. J. Schoene (*New York State Sta. Bul. 301, pp. 165–174, pl. 1*).—In raising seedling cabbage, great losses have been experienced from attacks of flea beetles (*Phyllotreta vittata* and *Systena hudsonias*) and root maggots (*Pegomya brassicæ* and *P. fusiceps*). The ordinary methods adopted for the control of these pests have not given satisfactory results. Experiments were therefore undertaken to test the value of cheese cloth screenings for the protection of cabbage seed beds from these pests. A bed was sown to cabbage seed on May 15 and covered with cheese cloth on May 20 just as the plants were coming out. On June 20 the screen was removed to harden the plants before transplanting. The hardening process was allowed to continue for 13 days. The total expense for cheese cloth, lumber, laths, wire, and tacks for screening a seed bed 12 by 150 ft. was $20.21 or about 40 cts. per 1,000 cabbage plants.

The results indicate that cabbage plants may be completely protected from root maggots by screening with cheese cloth and that the flea beetles are also prevented from attacking the young plants. The losses in check beds which were not screened were very large.

Protecting cabbage plant beds from maggots, F. H. Hall (*New York State Sta. Bul. 301, popular ed., pp. 4, fig. 1*).—A popular edition of the above.

Report on the study of insects injurious to cranberries during the summer of 1907, C. B. Hardenburg and O. G. Malde (*Wisconsin Sta. Rpt. 1907, pp. 309–320, figs. 2*).—The three most injurious insect pests of the cranberry are the blackheaded vine worm, yellowheaded vine worm, and fruit worm. Biological notes are also given on tip worm, girdler, a species of snout beetle, and other less important cranberry insects.

In controlling the insect pests of cranberries, flooding is recommended for the first brood of the blackheaded or yellowheaded vine worm. Spraying is a safer but more laborious method of control. Two applications are sufficient for vine worms and three for fruit worms. The spray recommended for this purpose is lead arsenate solution and Bordeaux mixture with 5 lbs. of resin soap added for each 50 gal. Arsenate of lead is considered superior to Paris green.

Report on the work of the section for plant protection, 1906–7, C. BRICK (*Stat. Pflanzenschutz Hamburg, Bot. Staatinst., [Ber.] Abl. Pflanzenschutz, 9 (1906–7), pp. 1–18*).—A detailed report is given of the extent of importation of apples and other fruits and living plants from America and other countries.

As in previous years the Baldwin is the chief apple imported from the United States, constituting about 70 per cent of the total importation and coming chiefly from New York and Maine. From a total of about 200,000 packages of these apples about 11,000 or approximately 6 per cent were found to be infested with San José scale. Apples imported from New South Wales were found to be slightly infested with San José scale. Notes are also given on other insect pests and plant diseases found upon this fruit.

A report is also made upon the condition of live plants imported from various countries.

Does it pay to spray Nebraska apple orchards? R. A. EMERSON and F. E. DENNY (*Nebraska Sta. Bul. 106, pp. 3–20*).—Practical tests were made under what were considered average conditions to determine the value of spraying orchards, particularly for the control of codling moth and apple scab. Five applications were made from May 2 to August 20 of combined insecticides and fungicides chiefly Paris green or arsenate of lead and Bordeaux mixture. For the first three applications Paris green and Bordeaux mixture were used while arsenate of lead was used alone in the last 2 sprayings. In one orchard a net gain of $1.70 per tree was produced and in another orchard of $2.56, the increased yield being 1.17 bu. and 2.1 bu. per tree, respectively.

The apple maggot or railroad worm, A. L. QUAINTANCE (*U. S. Dept. Agr., Bur. Ent. Circ. 101, pp. 12, figs. 2*).—The apple maggot is placed among the five chief insect enemies of the apple. It is a native American species and its native food is apparently species of Crataegus. It attacks nearly all varieties of cultivated apples. The spread of the apple maggot when once established in the orchard is very slow. The insect is described in all its stages and notes are given on its life history. There is only one generation annually.

In combating this pest no hope can be entertained of success from the use of arsenicals. All fallen infested fruits should be promptly gathered and fed or otherwise destroyed. If preferred, orchards may be pastured with sheep, hogs, or cattle to destroy the windfall apples promptly. Some success may also be expected from the thorough cultivation of orchards.

The insect pests of peach trees, F. LAFONT (*Prog. Agr. et Vit., 24 (1907), No. 49, pp. 680–685*).—Biological and economic notes are given on *Ceratitis capitata*, codling moth, *Anarsia lineatella*, *Cossus ligniperda*, bark beetles, and other insects injurious to peaches.

State nursery inspection, J. G. MOORE (*Wisconsin Sta. Rpt. 1907, pp. 369–378, figs. 3*).—The law governing nursery inspection in Wisconsin was so amended in 1907 as to provide for the inspection of the premises of all nurseries doing business within the State. The general conditions observed in the nurseries during the past season were somewhat improved. San José scale was found in one nursery only. Mention is also made of the prevalence of oyster-shell bark-louse, woolly aphis, strawberry root louse, cottony maple scale, coxcomb gall of the elm, and anthracnose of raspberries.

Diseases and insect pests [of coffee], J. W. Van Leenhoff (*Porto Rico Sta. Rpt. 1907, p. 40*).—Experiments in fertilizing to overcome losses due to the leaf-miner seemed to give good results, the field described in a former report (E. S. R., 18, p. 1060) having completely recovered and showing very vigorous growth, with a very noticeable decrease of the brown spots on the leaves. A number of old coffee trees have been attacked by a borer which eats its way in a vertical direction through the heart of the trunks and branches. This pest is now under investigation.

Individual and seasonal variations in Helopeltis theivora, with description of a new species of Helopeltis, H. H. Mann (*Mem. Dept. Agr. India, Ent. Ser., 1 (1907), No. 4, pp. 275–337, pl. 1, figs. 5*).—A large number of specimens of *Helopeltis theivora* were obtained from various parts of India and careful observations were made to determine the variations which occur in this species. In this work variations in color were noted and also variations in the size and proportions of the antennæ, legs, rostrum, and other anatomical parts. Particular attention was given to the possible effect of locality, seasons, and food upon variations, but these factors appeared to be of little constant value. A change of food from tea to cinchona led to no modification either in the structure of the insect or in its color. The relationship between *H. theivora* and *H. antonii* is briefly discussed.

The coccidæ attacking the tea plant in India and Ceylon, E. E. Green and H. H. Mann (*Mem. Dept. Agr. India, Ent. Ser., 1 (1907), No. 5, pp. 337–355, pls. 4*).—The information relating to scale insects which attack the tea plant in India and Ceylon has been brought together and summarized in this bulletin. A list including 31 species, three of which are described as new, is given, together with brief notes on the relative importance of these species.

Means of combating cockchafers, Von Tubeuf (*Naturw. Ztschr. Forst u. Landw., 6 (1908), No. 1, pp. 73–75, fig. 1*).—A considerable variety of insecticides was used in spraying foliage to test their effectiveness in the control of cockchafers. Bordeaux mixture, barium chlorid, tobacco decoction, and insect powder had no effect. The use of Paris green, however, was attended with striking success. Attention was called to the apparent wide-spread distribution of a parasitic fungus, *Isaria densa*, upon cockchafers.

On a new phytophagous mite with notes on other species of economic importance, C. G. Hewitt (*Mem. and Proc. Manchester Lit. and Phil. Soc., 52 (1907–8), pt. 1, No. 5, pp. 1–10, pl. 1, figs. 2*).—*Lohmannia insignis dissimilis* is described as a new species of mite attacking tulip bulbs. *Rhizoglyphus echinopus* is also mentioned as an important enemy of the bulbs of tulips, hyacinths, and other liliaceous plants. *Glycyphagus spinipes* has appeared in a number of instances as a serious house pest occurring in large numbers and attacking the horsehair or other material used in upholstered furniture.

Experiments in the control of Tinea pellionella, L. Roussin (*Rev. Serv. Intend. Mil. [Paris], 20 (1907), No. 155, pp. 373–396*).—The appearance of this insect in its different stages is described in detail. A number of insecticides were tested in determining their effectiveness in controlling the pest. From a series of observations and experiments reported by the author it appears that benzine, turpentine, naphthalin, camphor, carbolic acid, and a number of other volatile substances of this class may produce asphyxia of the insect in woolen fabrics. The remedies mentioned give satisfactory results as used against all stages of the insect. Metallic salts such as arsenious acid, corrosive sublimate, and sulphate of copper are only slightly effective, while bitter substances such as aloes and extract of gentian have no effect whatever. The best results are to be obtained from the use of ordinary illuminating gas or bisulphid of carbon. Either of these substances is perfectly effective.

Bee breeding, S. N. Green (*Medina, Ohio, 1907, pp. 12*).—Complaint is made that the subject of bee breeding has not received sufficient attention. It is urged that in the improvement of the honey bee an ideal standard should be set up for which a score of points is suggested. After the ideal has been adopted, the problem consists, in the author's opinion, in improving the environment of bees in all possible ways and selecting those queens and drones which come nearest to the ideal standard.

Queen rearing, E. W. Alexander (*Gleanings Bee Cult., 36 (1908), No. 4, pp. 209, 210*).—The question is often raised whether it is better for the bee raiser to rear his own queens or depend upon professional queen breeders. The author concludes that in most cases the professional breeders will obtain better results than the ordinary bee raiser and that if certain queens in an apiary should develop particularly desirable qualities they may be sent to a breeder for the purpose of producing other queens of similar characteristics.

The digestibility of mulberry leaves with relation to the rational feeding of silkworms, P. Bucci (*Staz. Sper. Agr. Ital., 40 (1907), No. 8–12, pp. 721–798*).—A long series of feeding experiments was carried out with the purpose of determining the digestibility of the leaves of different varieties of mulberries and other matters connected with the feeding of silkworms. Statistical data are presented in a tabular form showing the amount of mulberry leaves eaten under different conditions, the growth and weight of the silkworms, the amount of silk produced and its elasticity and other qualities.

A variety of mulberry obtained from Verona gave the best results both in respect to its digestibility and to the quantity and quality of the silk obtained as a result of feeding. Another variety of mulberry referred to as rosea proved no less digestible but the mortality of silkworms fed upon it was somewhat greater than in the case of the Veronese variety. The leaves of Chinese mulberries were much less digestible than those of the Veronese variety.

Experiments were also conducted in the addition of starch to the diet of mulberry leaves. It was found that this material could easily be sprinkled upon the leaves with a small expense of time and energy. Silkworms fed in this manner did not weigh more at maturity but the cocoons were heavier, the quantity of the silk was slightly greater, its quality was improved, and the mortality of the silkworms was diminished.

The author contends that careful experiments in the feeding of silkworms are as much needed as in the case of higher animals. These insects grow with great rapidity and produce a large amount of silk within a short time. The experiments thus far conducted indicate that the amount and quality of the silk are largely dependent upon a rational system of feeding.

FOODS—HUMAN NUTRITION.

Food chemistry, J. Varges (*Nahrungsmittelchemie. Leipsic, 1907, pp. 298, pls. 3, figs. 178*).—In this handbook of food chemistry the subjects treated have been arranged in alphabetical order. In the discussions of the various animal and vegetable foods, beverages, condiments, and commercial products, special attention has been paid to histological characteristics and microscopical methods, as well as to the more common methods of food examination.

The food chemist as an expert, C. A. Neufeld (*Der Nahrungsmittelchemiker als Sachverständiger. Berlin, 1907, pp. XX+477*).—This volume is designed for the information of public analysts and discusses general questions which have to do with food inspection, with special chapters on milk and other dairy products, fats and oils, fruits, honey, sugar, spices, beverages, etc.

The peacock edible, Martha McC. Williams (*Country Life Amer., 13 (1907), No. 2, pp. 252, 254, 256, fig. 1*).—Directions are given for preparing and cooking pea fowl. Though not commonly eaten, these birds are considered of superior quality and when range bred are very much like game.

Analyses of canned sausage, Balland (*Rev. Serv. Intend. Mil. [Paris], 20 (1907), No. 151, pp. 77, 78*).—Proximate analyses are reported of 4 samples which had been canned several years before.

Analyses of canned fish, Maljean (*Rev. Serv. Intend. Mil. [Paris], 20 (1907), No. 154, pp. 351–357*).—Examination was made of salt water fish when canned and when put up for soups. The canned fish was made up of 164 parts of flesh to 100 of jelly. The proportion of jelly to flesh, as the author points out, is much higher than in the case of canned beef and hence the nutritive value is lower. The fish canned for soup making was rich in fat, but the author believes that it is not suitable for army rations owing to the complicated process required in preparing it for the table.

A new method of preserving meat, H. de Lapparent (*Bul. Soc. Nat. Agr. France, 67 (1907), pp. 280–286; abs. in Hyg. Viande et Lait, 1 (1907), No. 11, pp. 511, 512*).—In the method of preserving described, meat is exposed to sulphur vapor for 24 hours and then stored in an atmosphere of carbon dioxid. Analyses showed that meat so preserved did not contain free sulphuric acid and that the cooked meat showed 22 gm. of sulphites and bisulphites per 100 kg.

Slaughtering and meat packing (*Bur. of the Census [U. S.] Bul. 83, pp. 7–41*).—According to the statistical data summarized and discussed the value of the combined slaughtering and meat packing industry in the United States in 1905 was $913,914,624, an increase of 16.6 per cent over 1900.

Meat inspection, M. Toubeau (*Bul. Mens. Off. Renseig. Agr. [Paris], 6 (1907), No. 11, pp. 1340–1359*).—A summary of French legislation on this subject.

Pasteur's theory applied to diastatic action in bread making, or rational bread making, Serand (*Rev. Serv. Intend. Mil. [Paris], 20 (1907), Nos. 157, pp. 549–590; 159, pp. 777–834*).—Part 1 of this article discusses the processes of bread making. Parts 2 and 3 treat of the biology of the various fermentations with detailed directions for making bread sufficient for 300 rations and explanations of the rationale of each step.

Survival of pathogenic bacteria in bread after baking, J. Roussel (*Rev. Serv. Intend. Mil. [Paris], 20 (1907), No. 152, pp. 122–131; abs. in Rev. Hyg. et Pol. Sanit., 29 (1907), No. 8, pp. 722, 723*).—According to the author's observations the temperature in the crumb of bread during baking ranged from 101 to 103° C. and in the crust from 125 to 140°. The author also studied the effect of such temperatures on tuberculosis bacilli artificially introduced into the dough with special reference to the question of the employment of tubercular subjects in bakeries.

Experimental studies of the character of flour, bread, and Italian pastes sold in Venice, A. Zoso (*Separate from Lab. Chim. Munic. Venezio, 1907; abs. in Chem. Zentbl., 1907, II, No. 21, pp. 1754, 1755*).—A large number of analyses are reported in this study of Venetian flour and flour products, undertaken with a view to studying the relation between composition and quality. Phosphoric acid and other ash constituents are reported in addition to the usual analytical data.

Cultivation of cassava and the manufacture of cassava flour in São Paulo, J. B. Sobrinho (*Rev. Agr. [São Paulo], 13 (1907), No. 147, pp. 479–483*).—Statistical and other data regarding the production of cassava flour are presented, together with an analysis of this material.

Flour and grist mill products, E. K. Ellsworth (*Bur. of the Census [U. S.], Bul. 64, pp. 45–84*).—From an extended summary of data it appears that the total value of the flour and grist mill products produced in the United States in 1905 was $713,033,395, an increase of 42.2 per cent over 1900.

Starch, R. H. Merriam (*Bur. of the Census [U. S.] Bul. 64, pp. 85–92*).—The statistical data reported in this article show that the total value of the starch products produced in the United States in 1905 was $8,082,904, an increase of 12.5 per cent over 1900.

Bacteriological studies of field-grown vegetables from Moscow, M. B. Kozyn (*Vrach [St. Petersb.], 6 (1907), p. 22; abs. in Chem. Ztg., 31 (1907), No. 86, Repert. No. 78, p. 522*).—Examination of a number of samples of vegetables showed that 3 had tetanus bacilli on the surface. Sixty samples showed no typhoid bacteria though the surface was more or less infected with intestinal bacteria. Generally speaking, bacteria were not found in the interior of the vegetables through pus bacteria were finally found in 5 samples.

The soy bean as a feeding stuff in Italy, G. Ruata and G. Testoni (*Bol. Uffic. Min. Agr., Indus. e. Com. [Rome], 6 (1907), VI, No. 6, pp. 698–718, pls. 5*).—In a discussion of the probable value of soy beans as a feeding stuff under Italian conditions data are summarized regarding the culture of this crop and the chemical composition and nutritive value of the beans, and 9 analyses are reported of Italian-grown samples. Determinations of the pentosan content of 5 samples which are quoted showed that it ranged from 2.86 to 3.86 per cent.

Descriptions and analyses of bean curd and other soy-bean products used as food for man are quoted and the possible use of soy beans as a bread stuff and as porridge is discussed. A bibliography is appended.

The nutritive value of the avocado, C. A. Garcia (*Bul. Assoc. Chim. Sucr. et Distill., 25 (1907), No. 5, pp. 516, 517*).—The author analyzed Peruvian-grown avocado and found the following values: Water 38.00 per cent, protein 3.79 per cent, fat 34.10 per cent, cellulose and undetermined material 28.10, and ash 3.50 per cent. The phosphoric acid content of the pulp was 0.817 per cent or 12.9 per cent of the total ash. Neither starch nor sugar were found.

The large proportion of fat, protein, and phosphoric acid, the author concludes, indicates that avocadoes have a high feeding value. On the basis of personal experience he believes that they may be valuable in invalid dietetics, particularly in the case of tuberculous and diabetic patients.

Some observations on the date, A. E. Vinson (*Plant World, 10 (1907), No. 11, pp. 259–262*).—On the basis of his observations, the author briefly discusses the composition of dates with special reference to stages of ripening and related topics.

"The development of the fruit takes place in 3 stages. After fertilization very little change in the fruit itself can be observed for several weeks, but during this period the entire energy seems to be expended in building a long massive stem. When this is nearly completed, the fruit starts to grow and the seed to mature. When the fruit has reached its full size, but is still green, it corresponds very closely in chemical character to any other nonstarchy fruit, and contains about 20 per cent of dry matter. The third stage now begins and additional sugar is heaped into the fruit at a rapid rate without any apparent change in size until upwards of 60 per cent dry matter is present. It then softens, the tannin becomes insoluble with consequent loss of astringency, and the fruit is ripe."

Concerning the quantity of fatty substance in some samples of olive flesh, N. Passerini (*Staz. Sper. Agr. Ital., 40 (1907), No. 6–7, pp. 606–617; Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 4 (1907), No. 3, pp. 322–333*).—Fifty samples were analyzed and the results discussed.

Some Algerian olive oils, II, L. Archibutt (*Jour. Soc. Chem. Indus., 26 (1907), No. 22, pp. 1185, 1186*).—The author reports the examination of 12 samples of Algerian olive oils from different localities in continuation of earlier work (E. S. R., 19, p. 765). It was found that varieties from certain districts showed extremely high iodin values, while oils from other varieties and districts gave normal or nearly normal results.

Investigations on the composition of cocoanut milk and the diastases of the fruit of Cocos nucifera, E. de Kruyff (*Agr. Prat. Pays Chauds, 7 (1907), No. 55, pp. 339–345*).—The conclusion is drawn from the experimental data reported that cocoanut milk contains saccharose, sugar being inverted during the ripening of the nut by means of the diastase sucrase, which is dissolved in the juice present. The diastase is secreted by the albumin cells. In addition to sucrase cocoanut milk contains oxydase and catalase, the 2 last mentioned being absent in the young nuts. The haustorium of the nut contains lipase, a proteolytic diastase, amylase, catalase, and a peroxydase.

Adulteration of cola nut and preserved truffles (*Ann. Soc. Agr. Sci. et Indus. Lyon, 1906, pp. 133, 134*).—Analytical data are reported.

Edible oil from safflower seed, H. E. Houghton and P. R. Mudaliar (*Cent. Agr. Com. Madras Circ. 23, pp. 2*).—A brief note on the use of safflower seed (*Carthamus tinctorius*) and safflower seed oil for culinary purposes and on the experimental manufacture of the oil. The oil cake is used as cattle feed.

Alcohol-free beverages, O. Mezger (*Ztschr. Angew. Chem., 20 (1907), No. 49, pp. 2116–2121*).—The results of the examination of 44 samples are reported and discussed.

Analyses of white wines at the National School of Agriculture, M. Kirschbaum (*Bol. Min. Fomento [Peru], 5 (1907), No. 8, pp. 80–85*).—Detailed analyses are reported of 5 samples.

Statistics of Swiss wines for the year 1906 (*Ann. Agr. Suisse, 8 (1907), No. 5, pp. 247–272*).—Several hundred analyses of Swiss wines from various cantons are reported.

Port wine and the vineyards of the Alto Douro (*Lancet [London], 1907, II, No. 24, pp. 1705–1714*).—A descriptive article with analyses of musts, ports, imitation ports, and brandies used for checking fermentation.

Institutions for the technical examination of foods, condiments, and commercial products in the German Empire, J. König and A. Juckenack (*Die Anstalten zur technischen Untersuchung von Nahrungs- und Genussmitteln sowie Gebrauchsgegenständen. . . im Deutschen Reiche, etc. Berlin, 1907, pp. XV+308*).—Legal and other data regarding the character and extent of the German department of public health and the institutions in different provinces for inspection and analysis.

Food inspection decisions (*U. S. Dept. Agr., Food Insp. Decisions 93–95, pp. 4; 96, pp. 2*).—The questions considered are an amendment to regulation 34, the labeling of medicinal and table waters, the use of neutral spirits distilled from beet sugar molasses in the preparation of whisky compounds and imitation whiskies, and serial number guaranty.

Food and drug inspection, A. E. Leach (*Ann. Rpt. Bd. Health Mass., 38 (1906), pp. 351–409*).—A total of 7,530 samples of food and drugs was examined under the provisions of the State law, of which 5,520 were of good quality, while the remainder did not correspond to the requirements of the statutes. The report contains details of the work.

Housekeeping in Egypt, Emily Williams (*Boston Cooking-School Mag., 12 (1908), No. 7, pp. 317, 336, 337*).—Food and diet of the Egyptian wage-earners and families living in the country are described, as well as methods of preparing bread, meat, rice, and other foods, and related topics.

How a five-cent lunch is cooked and served at the Honolulu Normal School, Marion Bell (*Boston Cooking-School Mag., 12 (1908), No. 6, pp. 292, 293*).—Pupils receive part of their training in preparing and serving a school lunch. The receipts are used for defraying the expenses of the course in cookery and have been adequate for the purpose. The plan, it is stated, has proved very successful.

School lunches (*Ann. Rpt. Women's Ed. and Indus. Union, 29 (1908), pp. 34, 35*).—Hot lunches were supplied to 12 schools. The work is briefly described.

Vegetable products [of northern Nigeria] (*Bul. Imp. Inst., 5 (1907), No. 3, pp. 327–332*).—In an account of northern Nigerian vegetable products in the Indian and Colonial Collections of the Imperial Institute, considerable information is given regarding guinea corn, Indian corn, rice, acha seed (*Digitaria* sp.), and other cereals, and roots, vegetables, vegetable fats, etc., used locally for food, ways in which they are prepared for the table, etc.

Diet in Indo-China, M. Kermorgant (*Ann. Hyg. Pub. et Méd. Lég., 4. ser., 7 (1907), pp. 411–431*).—The author discusses the diet of native and foreign residents of Indo-China, and describes available food supplies, important hygienic measures, and related topics. He states that the natives, as is the case with other races in the far East, live very largely upon rice, pork, fish, and vegetables, rice being eaten in very large quantities. In his opinion, Europeans living in the Tropics should exercise moderation in diet and should avoid an excess of energy-yielding foods, though the energy value of the diet must be proportional to the amount of physical work performed. The article also furnishes considerable data regarding the food plants cultivated and the animals raised in Indo-China.

Diet of the poor and its social significance, M. Rubner (*Rev. Hyg. et Pol. Sanit., 29 (1907), No. 9–10, pp. 854, 855*).—In a paper presented at the Fourteenth International Congress of Hygiene and Demography, the author discusses the results which, in his opinion, follow the long continued use of a diet of low nutritive value and composed largely or exclusively of vegetable foods, such as is commonly noted with the poor in Europe. In his opinion such a diet is responsible for defective physical condition, a lowered ability for work, an increase of morbidity and mortality, a lowered resistance to epidemic diseases, and similar undesirable results.

Hygiene in relation to nutrition and physiology, Reiss (*Hyg. Zentbl., 3 (1907), No. 13–14, pp. 409–414*).—A report of the meeting of the section of hygiene in relation to nutrition and physiology at the Fourteenth International Congress of Hygiene and Demography. Brief abstracts are given of papers presented at the section meeting, including sulphurous acid in foods, by Kerp; the sociological effects of undernutrition, by Rubner (see above), and a paper on the same subject by Blauberg; a paper on minimum protein requirements, by Rubner; a paper on a similar subject by Forster; and a number of others on a variety of topics.

In his discussion of protein requirements Forster expresses the opinion that mineral matter in organic combination as existing in the protein molecule is of great importance. This is shown by the fact that protein from which mineral matter has been removed by dilute hydrochloric acid will not sustain life in animals even if the material thus removed is evaporated, incinerated, and added to the ration.

Influence of food on the progress of experimental tuberculosis, Lannelongue, Achard, and Gaillard (*Compt. Rend. Acad. Sci. [Paris], 145 (1907), No. 20, pp. 785, 786*).—It was found that the progress of experimental tuberculosis in guinea pigs was very much delayed when wheat gluten was added to a

basal ration in comparison with isothermic quantities of butter and sugar. The animals receiving the gluten ration lived 371 days and those fed sugar and butter 87 days and 40 days, respectively.

The authors believe that this experiment demonstrates the importance of nitrogenous material in the diet of tuberculous patients.

Recent dietetic experiments, J. H. KELLOGG (*Lake Placid Conf. Home Econ. Proc., 9 (1907), pp. 118–124*).—Some recent investigations on diet and physiological chemistry are discussed, particularly such phases of the work as in the author's opinion justify the use of a vegetarian diet and low proteid rations.

Physiological economy in nutrition. Is not a different explanation possible? A. HAIG (*Edinb. Med. Jour., n. ser., 22 (1907), No. 6, pp. 501–505*).—The position is taken that uric acid is the harmful substance formed by nitrogen metabolism in the body. Any observed increase in strength and endurance when the amount of proteid food is lowered is therefore due, the author believes, not to this factor but to the diminished uric acid which it involves, since, in his opinion, the lower the uric acid the less the internal friction and hence the greater the amount of energy available for external work. A constant relation, it is claimed, obtains between nitrogen consumed and force produced, so that although a diminished intake of protein may appear beneficial for a time by diminishing the uric acid, a continued lowering of the nitrogen intake leads eventually to breakdown.

On the relation between the output of uric acid and the rate of heat production in the body, E. P. CATHCART and J. B. LEATHES (*Proc. Roy. Soc. [London], Ser. B, 79 (1907), No. B535, pp. 541–545*).—Experiments with a man on uniform diet showed that exposure to cold with and without labor increased the uric acid output materially. If the body was warmly protected exposure to the cold with exercise did not produce such an increase. The results are discussed, but the author considers the available data too limited to furnish an adequate explanation of the observed facts. The total nitrogen and other constituents of the urine were determined also.

Investigations on purin bodies, 1882–1906, E. FISCHER (*Untersuchungen in der Puringruppe (1882–1906). Berlin, 1907, pp. 608; rev. in Brit. Med. Jour., 1907, No. 2448, p. 1592*).—This volume, in which the author has reprinted 47 papers relating to work carried on in his laboratory, constitutes a valuable reference work for those interested in questions of purin and metabolism.

Has a purin-free dietary any special therapeutic value? C. WATSON (*Brit. Med. Jour., 1907, No. 2451, pp. 1759–1761*).—From practical experience the author concludes that there is no special therapeutic effect in a purin-free diet. The benefit derived from such a régime in certain cases, he believes, would be equally obtained by the use of a carefully planned system of feeding, formed without special reference to purin condition. "In some cases the restriction in amount of animal protein food is of special value, in others the diminution in the carbohydrate, and especially the sugars, is equally efficacious, and in others the restriction of various alcoholic liquors will suffice."

The behavior of nonfermentable carbohydrates in the animal body, W. BRASCH (*Ztschr. Biol., 50 (1907), No. 2, pp. 113–162*).—The author studied the question of the assimilation of galactose, pentoses, and other carbohydrates with special reference to the behavior of nonfermenting carbohydrates in diabetes. In harmony with the results of other observers he found that comparatively small quantities of galactose were assimilated by normal man, the upper limit in his experiments being 30 to 40 gm. per day. As shown by experiments with dogs, pentoses can not be regarded as precursors of glycogen. The author

considers it certain that the consumption of pentoses increased nitrogen metabolism.

Concerning the digestion and utilization of crude fiber and cellulose by man and animals, H. Lohrisch (*Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, n. ser., 2 (1907), No. 21, pp. 801–822*).—A critical summary and discussion of the literature of crude fiber and cellulose assimilation, together with the results of the author's own investigations.

In experiments in which a man was fed cellulose specially prepared from cabbage it appeared that it was very largely absorbed in soluble form. Sugar was not formed from it nor did it undergo fermentation. In general, the author believes that the amount of cellulose which a man secures in an ordinary mixed diet is so small and its cleavage value so low that cellulose has practically no value as a feeding stuff for normal man.

The article includes an extended bibliography.

The effect of cocoa on metabolism, Gerlach (*Österr. Chem. Ztg., 10 (1907), No. 22, pp. 310, 311*).—In a paper presented before the meeting of the German Naturalists and Physicians, September, 1907, the author briefly summarizes the results of experiments showing that the use of cocoa, with either large or small amounts of fat, as a part of the diet did not diminish thoroughness of digestion in general.

The mineral matter required by the human body, H. C. Sherman (*Lake Placid Conf. Home Econ. Proc., 9 (1907), pp. 114–118*).—The results of the author's investigations with iron (E. S. R., 19, p. 58) and similar studies with calcium and phosphorus not yet reported in detail are summarized and discussed with special reference to the kinds and amounts of mineral matter required by the body.

From a comparison of the computed amounts of ash constituents supplied by 20 American dietaries with the results of available metabolism experiments it appears that "the amount of iron runs approximately parallel to the amount of protein and there is usually neither greater nor less likelihood of deficiency of the one than of the other. In the case of lime, however, the variations between the different dietaries were much greater, and in nearly half of the cases the diet appeared to furnish less lime than was required for the maintenance of equilibrium in many of the metabolism experiments. In the case of phosphorus, nearly one-third of the dietaries appeared to be deficient when judged by the same standard. From this it would appear that in the selection of food and the planning of dietaries, at least as much attention should be paid to the amounts of calcium, phosphorus, and iron as to the amount of protein. In many cases the dietary may readily be improved with respect to the ash constituents by a substitution of milk or cheese for a part of the meat and a freer use of fruits and vegetables in place of a part of the sugar and starch."

Estimation of water vapor by means of the Jaquet respiration apparatus, R. Staehelin (*Verhandl. Naturf. Gesell. Basel, 19 (1907), No. 1, pp. 100–108*).—The data reported show that the Jaquet respiration apparatus (E. S. R., 16, p. 287) gives accurate results in experiments with men and animals.

Report of progress in food and nutrition, 1906–7, C. F. Langworthy (*Lake Placid Conf. Home Econ. Proc., 9 (1907), pp. 104–112*).—A brief survey of the nutrition investigations carried on during the year 1906–7, particularly those conducted under the auspices of the Office of Experiment Stations.

ANIMAL PRODUCTION.

Fodders and grasses, J. C. Brunnich (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1906–7, pp. 68–70*).—Detailed analyses of sheep's burnett (*Poterium sanguisorba*), rib grass (*Plantago lanceolata*), grasses of different sorts, maize silage, sorghum silage, and mazzagua are reported, together with proximate analyses of the same materials for comparison.

Salvia loca as a forage plant, P. Lavenir (*Bol. Min. Agr. [Buenos Ayres], 8 (1907), No. 3–4, pp. 215–218*).—This plant is said to be a very important forage crop in the Argentine Republic. Proximate and ash analyses of the flowers, leaves, and stems are reported. The leaves are the portion commonly eaten by cattle. In the author's opinion, the plant is comparable with alfalfa for grazing purposes.

The composition and digestibility of dried beet leaves, F. Honcamp, T. Katayama, and O. Kellner (*Deut. Landw. Presse, 34 (1907), No. 101, p. 787*).—On the basis of a large amount of experimental data, which is briefly summarized and discussed, the authors conclude that dried beet tops contain 3.8 per cent total protein, 1.8 per cent digestible protein, and have a starch value of 27 per cent. If the material could be freed from sand before drying, they calculate that the nutritive value would be 20 per cent higher.

Drying beet tops and the use of such material as a feeding stuff, F. Honcamp and T. Katayama (*Landw. Vers. Stat., 67 (1907), No. 5–6, pp. 433–463*).—Data are summarized regarding methods of drying beet tops and the composition and digestibility of the dried material.

Olive pomace as a feeding stuff for farm animals, G. Briganti (*Coltivatore, 53 (1907), No. 47, pp. 653–656*).—Analytical and other data are quoted in a discussion of the value of olive pomace for farm animals.

Maizena feed and homco, F. Barnstein (*Landw. Vers. Stat., 67 (1907), No. 5–6, pp. 419–431, figs. 5*).—A summary of data regarding the manufacture, histological character, composition, and feeding value of these maize by-products.

Concentrated feeding stuffs, C. S. Cathcart, V. J. Carberry, and J. Gaub (*New Jersey Stas. Bul. 212, pp. 3–57*).—Under the provisions of the State law analyses have been made of cotton-seed meal, cotton-seed feed, linseed meal, linseed feed, gluten feeds, corn bran, cerealine and maizeline, hominy meal and feed, distillers' grains, malt sprouts, dried brewers' grains, molasses grains, feed mixtures, alfalfa meal, barley feed, dried beet pulp, cereal breakfast food by-products, ground flax flakes, ground flax seed, ground rice feed, condimental and commercial feeds, millet feed, commercial poultry feeds, meat meals and beef scraps, wheat bran, feeding flours, wheat middlings, wheat feed, rye bran, rye feed, rye middlings, corn meal, corn-and-cob meal, ground oats, corn and oats, a commercial oat feed, mixed grains ground together, buckwheat middlings, buckwheat bran, and buckwheat feed.

Of the 393 samples received at the station which should have been guarantied 5 failed to meet the requirement. In the case of 326 guarantied samples 50 deficiencies in protein and 56 in fat were noted. The authors report no direct adulteration but some of the unguarantied feeds were of inferior quality.

"The cheapest protein feeds this year were of high grade distillers' grains, cotton-seed meal, buckwheat middlings and bran, and dried brewers' grains. . . .

"When purchasing molasses feeds a careful examination should be made for the presence of weed seeds."

Condimental stock foods, F. W. Woll (*Wisconsin Sta. Rpt. 1907, pp. 96–110*).—A summary of Bulletin 151 of the station previously noted (E. S. R., 19, p. 464).

The animal body as a prime motor: Experiments with draft oxen, M. RINGELMANN (*Ann. Inst. Nat. Agron., 2. ser., 6 (1907), No. 2, pp. 243–279, figs. 9*).—The author has reported and discussed his experiments with Limousine and d'Aubrac oxen as draft animals. See also a previous note (E. S. R., 17, p. 1003).

Physiology of the blind intestine of Herbivora, W. USTJANZEW (*Biochem. Ztschr., 4 (1907), No. 2–3, pp. 154–171*).—Experiments which were made with rabbits showed that the blind intestine should be regarded as a specific organ for the digestion and resorption of crude fiber and pentosans. At least this organ exercises a distinct and favorable effect on the digestion of materials containing cellulose.

The value of so-called plant amids in nitrogen metabolism in the animal body, V. HENRIQUES and C. HANSEN (*Ztschr. Physiol. Chem., 54 (1907), No. 2–3, pp. 169–187*).—In the experiments with small animals (rats), which the authors report, asparagin, either alone or in combination with nitrogen-free material, did not prevent a constant loss of nitrogen. Amid substances obtained from 8-day-old etiolated sprouts of vetch, maize, and beans could not replace food protein, but exercised, though in small degree, a sparing effect on the daily proteid requirement. "Amids" obtained from potatoes seemed to possess no value as protein sparers nor could beet amids fed with gelatin peptone satisfy the body needs for protein. The authors call attention to the fact that their results were obtained with an omnivorous animal and that different results might be expected with Herbivora.

The substitution of amids for protein, K. FRIEDLAENDER (*Landw. Vers. Stat., 67 (1907), No. 3–4, pp. 283–312*).—The experiments reported were made with sheep. When amid nitrogen in the form of beet molasses was added to a ration low in protein the loss of body nitrogen was not lessened, although the greater part of the amids contained in molasses are convertible into proteid compounds by the action of bacteria. When asparagin was added to a diet containing low protein it exercised a slight protein-protecting power but was not at all comparable in this respect with a true protein, namely, aleuronat.

Protein metabolism in dogs. I, Protein metabolism on a low nitrogen diet, E. ÖSTERBERG and C. G. L. WOLF (*Biochem. Ztschr., 5 (1907), No. 2–4, pp. 304–343*).—With the exception of urea an increase was noted in all nitrogenous constituents of the urine as compared with total nitrogen on a nitrogen-free diet supplying an abundance of energy. In the case of urea there was a relative decrease in the amount excreted. Doubling the energy value of the diet did not change greatly the proportion of the nitrogenous constituents excreted in the urine. When casein was added to the diet the proportion was materially changed. The absolute quantity of creatinin excreted remained as before, and the absolute quantity of ammonia increased, while a decrease was noted in the proportional amount as compared with total nitrogen. Sulphur excretion was also studied, nitrogen and sulphur metabolism being found to be parallel.

Concerning the nature of the urine of young calves, L. LANGSTEIN and C. NEUBERG (*Biochem. Ztschr., 4 (1907), No. 2–3, pp. 292–298*).—When the urine of calves a few days old was analyzed levulose, milk sugar, and allantoin were identified. The results are discussed with special reference to the origin of the levulose.

A note on the quantities of marsh gas, hydrogen, and carbon dioxid produced in the alimentary canal of goats, A. E. BOYCOTT and G. C. C. DAMANT (*Jour. Physiol., 36 (1907), No. 4–5, pp. 283–287*).—The goats used in the experiments reported were confined in air-tight steel pressure chambers without ventilation and samples of the air were withdrawn at intervals for analysis. It

was found that goats produced from 10 to 30 cc. of hydrogen and methan per hour, which is equivalent to from 3.5 to 6.6 per cent by volume of the total carbon dioxid produced in the same time. "On an average the combustible gases equal 5 per cent of the total CO_2, and an average goat of 20 kg. produces about 9 liters a day. The proportion between H and CH_4 is variable; on an average the CH_4 forms two-thirds of the total combustible gas."

A study of the ratio of carbon dioxid to hydrogen and methan led to the conclusion that it is not unreasonable to assume that at least twice as much carbon dioxid as combustible gas arises from fermentation in the alimentary tract. "Since the combustible gas equals 5 per cent of the total CO_2, it follows that on an average at least 10 per cent of the total observed CO_2 arises from fermentation and not from tissue metabolism. There is little doubt that the bacterial action concerned in these processes goes on anærobically. . . .

"The mean respiratory quotient falls from 0.95 to 0.85 (at most), a figure which is not in accordance with the view that cellulose is dealt with by the tissues as a carbohydrate rather than as a fatty acid arising from the carbohydrate by bacterial action before assimilation.

"It would seem appropriate that the respiratory activity of different animals should, for comparative purposes, be expressed in terms of their 'clean' weight, i. e., the total weight less the contents of the alimentary canal. A number of observations have shown that the contents of the stomach and intestines constitute on an average 18.8 per cent of the total body weight in goats, the extreme figures being 16.4 per cent and 22.7 per cent."

Making corrections for the contents of the intestinal tract, the authors calculate, on the basis of 27 determinations, that the average carbon dioxid production of normal goats is 453 cc. or 0.896 gm. per kilogram body weight per hour.

Yearbook of scientific and practical animal breeding, R. Müller (*Jahrb. Wiss. u Prakt. Tierzucht, 2 (1907), pp. LIV+304, pls. 5, map 1*).—The larger part of this report is occupied with critical reviews of literature relating to the anatomy, physiology, hygiene, feeding, geographical distribution, utilization, and breeding of domestic animals of all kinds. The first part of the report contains special articles on the origin of species in domestic animals, the mutation theory as applied to animals, the development of horns, breeding of horses, hybrids between goats and sheep, and the fertility of mules. In a short article on the last-named subject (pp. LI–LIV), H. W. von Wahl presents evidence of the existence of fertile mules on an estate in Brazil. It is stated that one mare mule has borne colts both from jacks and stallions and that the offspring closely resembled the mother.

Live stock schemes, 1908 (*Dept. Agr. and Tech. Instr. Ireland Jour., 8 (1907), No. 1, pp. 71–87*).—Regulations for registration of stallions and other matters concerned with the improvement of breeds of horses, cattle, and swine are recorded.

The central zootechnic station at São Paulo, H. Raquet (*Ann. Gembloux, 17 (1907), No. 11, pp. 593–621, pls. 21*).—In this article the author describes the equipment of the São Paulo station for animal production, the work in animal breeding and dairying, and related matters.

Annual reports of the live stock associations of the Province of Ontario, 1906 and 1907 (*Ann. Rpts. Live Stock Assocs. Ontario, 1906–7, pp. 272*).—Reports and papers presented at meetings of different provincial live stock associations and similar matters are included.

Animal husbandry in Denmark, 1906, A. Appel (*Tidsskr. Landökonom., 1907, No. 7, pp. 401–417*).—A general survey.

Notes on stable ventilation, Noack (*Deut. Landw. Presse, 34 (1907), No. 103, pp. 811, 812*).—Conditions necessary to proper ventilation and simple means of securing it in stables are briefly discussed in this article.

History of Shorthorn cattle, edited by J. Sinclair (*London, 1907, pp. XIV+895, pls. 62, map 1*).—The object of this volume has been to "place on record as many facts as could be obtained regarding the work of the early breeders, and the development of the breed throughout the wide regions where it is cultivated. No attempt has been made, or, indeed, could have been made, in a single volume of reasonable size to also furnish detailed accounts of existing herds or of those recently broken up. A good many of them have, however, been briefly alluded to, and a list of existing herds in the United Kingdom is also printed."

Feeding blackstrap molasses to young calves, T. E. Woodward and J. G. Lee, Jr. (*Louisiana Stas. Bul. 104, pp. 3–38*).—In this test 13 calves were used, the younger calves being fed 4 to 6 lbs. of skim milk twice daily and the older ones 6 to 8 lbs. Oat hay and crab grass hay were also fed as well as a grain mixture consisting of bran, corn meal, and oil meal 2:2:1, the young calves receiving all the hay and grain they would eat up clean and the older ones about 2 lbs. of grain per head daily. The amount of molasses varied but in no instance did it fail to scour the calves, the amount required to produce this effect varying from 0.05 lb. with very young calves to 0.7 lb. with calves 7 months old. The molasses used at first was slightly sour, but this was not the cause of the scouring as the same effect was noted when fresh molasses heated to a temperature of 180° F. or more was used. Exercise made no difference and granulated sugar produced scouring when an amount equivalent to that contained in the molasses was fed. Milk sugar also proved laxative, but about twice as much as of the cane sugar could be fed without this effect. "When the calves scoured their droppings were sour smelling, but when they did not scour, their droppings did not smell sour."

Several substances were tested as preventives of scouring. Formalin, blood meal, and limewater proved useless. Common salt had a slightly beneficial effect and 50 grains of tannin in some cases permitted the feeding of about one-half more molasses than was possible without it. In other cases it seemed to be without effect. All of these substances, as well as the sugar and molasses, were fed mixed with the milk.

The authors conclude that "on account of its laxative effect, blackstrap molasses can not be used as a supplement to skim milk for calf feeding purposes in sufficient quantity to be of any practical value.

"This laxative effect is due to the sugar content, rather than to any of the other constituents of the blackstrap.

"Scouring is caused by the fermentation of the sugar in the digestive tract.

"Salt and tannin have a beneficial effect, but will not prevent scouring."

The bulletin contains an introduction by W. H. Dalrymple in which the desirability of supplementing skim milk by inexpensive feeds is discussed.

Milk substitute for calf feeding, T. E. Woodward (*Louisiana Stas. Bul. 104, pp. 39, 40*).—Brief statements are made regarding the use on a Louisiana farm of bean soup, with shorts, blood meal, and sometimes cotton-seed meal gradually substituted for milk in calf feeding. The calves were encouraged to eat hay as soon as possible, alfalfa being preferred with peavine hay as second choice.

The method of making the soup which has been found successful is to parboil the beans with soda, drain and boil again until soft. After squeezing the beans through a colander salt is added until the soup has a decidedly brackish taste

and then the shorts, blood meal, cotton-seed meal, and lukewarm water are added. At the end of 10 days the calves received twice daily, in addition to a pint of milk, soup from 4 oz. of navy beans, 3 oz. shorts, 1 oz. blood meal, and about half the time 3 oz. of cotton-seed meal. "The calf receives this ration until it is 6 weeks of age, when the milk is discontinued and the same amount of the substitute fed as before until the calf is 4 months old, when it is weaned, that is, put on dry feed entirely."

Observations on sheep breeding from records of the University flock, G. C. HUMPHREY and F. KLEINHEINZ (*Wisconsin Sta. Rpt. 1907, pp. 25–40*).—From the station records, which have been kept for 240 ewes and which cover a period of 5 years in continuation of previous work (E. S. R., 14, p. 685), the following conclusions were drawn:

"The normal period of gestation, or the time from which a normal ewe is bred to the time of lambing, ranges from 145 to 151 days, and the greatest percentage of ewes will lamb 147 days after service.

"The gestation period appears to be somewhat longer for the male than for the female.

"The percentage of males born is practically the same as that of females.

"The larger percentage of lambs born on or before the 147th day of pregnancy is strong, and after this time the number of weak and dead lambs is greatly increased.

"The number of days a lamb is carried in utero does not seem to have any effect on its size.

"The largest percentage of increase is due to twin lambs, and there is no appreciable difference in the percentage of twins of the different breeds.

"The production of twin and triplet lambs is detrimental to the strength and vitality of lambs at birth.

"Shropshire ewes appear to be more prolific than any other breed.

"Ewes 6 years old produce the largest percentage of increase, while young ewes have the greater percentage of single lambs. The percentage of ram lambs increases and the percentage of ewe lambs decreases as the age of the ewe advances.

"A ram is at his best at 2 and 3 years of age.

"The age of the ram does not have any effect on the sex of the offspring.

"Ram lambs average about one-half pound heavier at birth than ewe lambs.

"The larger the ewe the greater the percentage of increase, while the ram has no effect on the lambs in this respect.

"The size of the ewe and not the size of the ram determines the size of the lamb."

Notes on goat keeping, V. NAUCKHOFF (*Meddel. K. Landtbr. Styr. [Sweden], 1907, No. 10 (129), pp. 28, pl. 1*).—The data reported were collected on a trip to Schleswig-Holstein and North Germany.

The value of different kinds of green forage for hogs, H. J. WATERS (*Missouri Sta. Bul. 79, pp. 3–12, figs. 6*).—Corn meal with rape, alfalfa, red clover, and blue grass was fed in comparison with corn meal and ship stuff 3:2, and corn meal and skim milk 1:3 in a test made with 6 lots of 6 pigs, weighing about 50 lbs. each. The test covered 102 days. The lots were kept in separate pens with a shed for protection and the green forage was given twice daily in a separate trough immediately after cutting.

"It was not expected that in ordinary farm practice the green material would be cut and fed to the hogs in this manner. At the time the experiment was undertaken, however, it was not feasible to fence off areas of each of these forage crops and graze them."

On corn meal and middlings the average daily gain was 0.61 lb. per head, the cost of a pound of gain 3.99 cts., and the grain eaten per pound of gain 4.89 lbs. On corn meal and skim milk the average daily gain was 1.53 lbs. per head, the cost of a pound of gain 2.17 cts., and the grain eaten per pound of gain 1.86 lbs. On the corn meal supplemented by green crops the gain ranged from 0.58 lb. per head on rape to 0.74 lb. on alfalfa. Of these rations, the gain was cheapest on the alfalfa, costing 2.59 cts. per pound, and most expensive on the rape, costing 3.31 cts. per pound. The greatest range in grain per pound of gain was also noted with these lots, being 3.43 lbs. with the alfalfa ration and 4.41 lbs. with the rape ration.

"It is believed to be possible to grow enough alfalfa for hog pasture at least on practically every farm in Missouri. Until, however, alfalfa is an assured success on every farm the farmer ought to arrange for a clover pasture for his hogs every year without fail. . . .

"It is not safe or even desirable to rely upon a single crop, excepting alfalfa where it is an assured success, to furnish pasture for our hogs throughout the entire season. It is better to arrange for a succession of pastures from the beginning of the season until the hogs are ready for market, making the feed richer and more concentrated toward the close of the season and as we approach the finishing or fattening period. For this purpose the following crops are recommended: Red clover or alfalfa, cowpeas, soy beans.

"To provide a crop of cowpeas in the best condition for the hogs, it will be necessary to select some very early maturing sort and sow rather earlier than is advised for a general crop. . . .

"For the best results the hogs should not be turned on the peas until the first pods are turning yellow. They will, however, make good pasture before this time, and if the hogs are needing pasture it is not advised to wait until that stage of maturity. . . .

"As a grain crop to use in connection with corn for crowding the spring crop of pigs to market, the soy bean is a very valuable crop. It is essentially a grain plant, very rich in protein, and while the hogs are running on soy beans they should have access to corn to balance the ration."

The author recommends that medium early corn, which ripens about the same time as soy beans, be fed with them, the two crops being sown together and harvested by the pigs. The pigs should be turned into the field when the first soy bean pods begin to ripen.

"The soy bean is regarded as somewhat better adapted for finishing a bunch of hogs than the cowpea; at the same time if one does not care to bother with so many different crops, the cowpea may be used instead with satisfactory results.

"For brood sows in winter and very early spring, it is always advisable to give them access to a piece of early sown wheat or rye, and to let them have a limited amount of nicely cured clover, alfalfa or cowpea hay by way of variety of feed. Sorghum stalks grown as is customary for the production of sirup, in limited quantity, make an excellent addition to the ration. The main thing to be avoided in carrying hogs of this sort through the winter is a straight corn diet. The greater the variety of cheap materials like these, the better the sows will do."

Pig fattening tests. Hinrichs (*Landw. Wchnbl. Schles. Holst.* 57 (*1907*), *Nos.* 48, *pp.* 797–800; 49, *pp.* 823–825).—A variety of rations, all of which contained potatoes as a prominent constituent, were tested with a number of lots of pigs. The results, in the author's opinion, demonstrate the high value of potatoes for fattening pigs.

Corn to make a pound of pork, G. HENDRICKS (*Breeder's Gaz., 53 (1908), No. 4, p. 177*).—A brief note on the amount of corn required per pound of gain in feeding pigs. A pen of 11 Duroc-Jerseys fed 62 days gained 800 lbs. and required 6.71 lbs. corn per pound of gain. A lot of 15 Poland-Chinas fed 35 days gained 585 lbs. and required 4.96 lbs. of corn per pound of gain. A little skim milk was fed once a day in addition to the corn and the pigs had the run of a pasture.

Meat meal for pigs as compared with ground grain, I. STEFFENS (*Illus. Landw. Ztg., 27 (1907), No. 39, pp. 356, 357*).—Although satisfactory results were obtained in feeding 1.5 to 3 lbs. of meat meal per head per day in comparison with a similar ration without this material, the author concludes that smaller amounts are more desirable and recommends 0.5 lb. per head per day.

Notes on swine management, W. A. LINKLATER (*Washington Sta. Popular Bul. 4, pp. 4, figs. 2*).—Various questions concerned with pig management under local conditions are discussed and especially the use of forage crops, peas, corn, kale, white and Swede turnips, and hairy vetch. The use of artichokes in the drier semiarid regions is also spoken of.

The portable hog house, J. G. FULLER (*Wisconsin Sta. Rpt. 1907, pp. 41–43, fig. 1*).—A summary of data previously noted (E. S. R., 19, p. 774).

The horse book, J. H. S. JOHNSTONE (*Chicago, 1908, pp. 299, pls. 51*).—This volume, which is designed primarily "to be of practical value to those who have in view the production of the types of horses in general request upon the farms and in the market places of the United States," takes up the origin and breeding of horses, the characteristics of the different breeds, hygiene, unsoundness, and disease. An appendix gives the stallion lien laws of all States and Territories where such legislation has been enacted and a list of stud books recognized by the United States Department of Agriculture.

Breeds of horses, C. G. WRANGEL (*Die Rassen des Pferdes. Stuttgart, 1908, vol. 1, pp. VIII+632, pl. 1, figs. 87*).—The origin, history, and characteristics of different breeds of horses are considered in this extended treatise.

Report of the department of horse breeding, A. S. ALEXANDER (*Wisconsin Sta. Rpt. 1907, pp. 44–46*).—A brief summary of data relating to the licensing of stallions and State legislation on the subject, as given in previous publications (E. S. R., 18, p. 764; 19, p. 774).

Horse raising in Denmark, 1906, J. JENSEN (*Tidsskr. Landökonom., 1907, No. 7, pp. 385–400*).—A general discussion of the conditions of the industry during the year.

Economical horse feeding in the brewing industry (*Allg. Brau u. Hopfen Ztg., 48 (1908), No. 9, pp. 85–87*).—The economical feeding of horses is discussed, especially with reference to the substitution of other materials for oats.

Substitutes for oats in horse feeding, H. KÖNIG (*Deut. Landw. Presse, 35 (1908), No. 2, pp. 13–15*).—A summary and discussion of data on the value of oil cakes, meat meal, dried brewers' grains, dried distillers' grains, and other materials as substitutes for oats in horse feeding. A number of rations are suggested in which oats are in part replaced by other concentrated feeds.

Report on the poultry industry in Denmark and Sweden, E. BROWN (*London, 1908, pp. X+112, pls. 16, fig. 1*).—On the basis of information gathered on a tour through Denmark and Sweden, the author discusses poultry breeding, care and management of poultry, and marketing of poultry and eggs in these countries, and related questions. In his judgment, the British poultry raiser has not much to learn from Denmark and Sweden as regards production, and in some instances he considers that the English methods are preferable. "But the main value of these observations is in regard to the widespread and almost

perfect system of marketing, which has been the means of securing for Danish eggs so high a position on the British markets, and is doing the same for Swedish. . . .

"The establishment of breeding centers has had a powerful influence in the improvement of Danish and Swedish poultry, more especially in the direction of economic qualities, and the distribution of eggs for hatching and stock birds from such centers has maintained the character and increased the average productiveness of the fowls kept by farmers. . . . In Denmark and Sweden success has been largely due to adoption of preservation of all eggs produced in the spring beyond those which can then be sold at adequate prices." Generally speaking, the eggs are preserved in limewater.

"These observations in Denmark show the value of maintaining separate central organizations for the promotion of poultry keeping and the sale of eggs and poultry, from those chiefly engaged in the purchase of general agricultural supplies, as the trade requires expert knowledge and undivided attention, but that in local societies the work of collection may be associated with other branches of agricultural produce."

Progressive poultry culture, A. A. BRIGHAM (*Cedar Rapids, Iowa, 1908, pp. 293, pl. 1, figs. 29*).—The author has summarized and discussed data, much of it based on personal experience, regarding the principles and practice of poultry breeding, incubation, brooding, foods and feeding, parasites and diseases, marketing, housing and fencing poultry, and related questions, as well as the exhibiting, scoring, and judging of poultry. A novel feature of the volume is the section devoted to records, accounts, and advertising in relation to the poultry business, and to methods of management of the poultry industry considered as a business enterprise.

The perfected poultry of America, T. F. MCGREW and G. E. HOWARD (*Washington, D. C., 1907, pp. 257, pls. 117*).—As described in the subtitle, this is a concise, illustrated treatise of the recognized breeds of poultry, turkeys, and waterfowl. Information is also included regarding guinea fowl.

Cost of feeding chickens, E. and W. BROWN (*Jour. Bd. Agr. [London], 14 (1908), No. 10, pp. 611–614*).—In a test carried on at the college poultry farm of University College, Reading, 25 White Wyandottes, 4 weeks old, fed for 12 weeks mixed meal, meat, and grit from hoppers, gained on an average 4.1 oz. per week each. The total feed consumed was 171.25 lbs. mixed meal, 63 lbs. meat, and 47 lbs. grit, and its total cost was $6.47.

In comparison with earlier work (E. S. R., 17, p. 797) the feed was expensive, but the added cost was more than compensated for by the increased gain in weight. "Hence it is apparent that the hopper system of feeding and the use of dry mash are worth the attention of poultry breeders and deserve a fair trial. Whether the food supplied could not be cheapened remains to be tested."

The production of table poultry, F. G. PAYNTER (*Country Life [London], 23 (1908), No. 577, pp. 136–138, dyms. 3*).—A brief summary of poultry feeding experiments undertaken on the Farne Islands, which the author discusses in comparison with the University of Reading poultry work.

Notes on the preservation of eggs in water glass, J. HENDRICK (*Aberdeen and No. Scot. Col. Agr. Bul. 8, pp. 12–17*).—A brief account of an investigation noted from another source (E. S. R., 18, p. 1149).

Pheasant farming, G. M. SIMPSON (*Corvallis, Oreg., 1908, pp. 26, figs. 10*).—On the basis of the author's experience in pheasant raising in Oregon the feeding, care, and management of these birds are described.

DAIRY FARMING—DAIRYING.

The university dairy herd, 1906–7, G. C. Humphrey and F. W. Woll (*Wisconsin Sta. Rpt. 1907, pp. 47–75, pl. 1, figs. 13*).—The records of the herd are reported and discussed as in previous years (E. S. R., 18, p. 1076).

The herd included 9 Jerseys, 8 Guernseys, 10 Holsteins, 4 Ayrshires, and 3 Brown Swiss. Descriptions are given of 14 of these cows added to the herd during the year. Data showing the food consumption and yield per cow are given for 23 cows, for which a full year's record was obtained. The average yield of milk per cow was 7,413.9 lbs., containing 308.37 lbs. of butter fat. The average net profit per cow was $44.20, or $3 more than during the preceding year.

A summary of the data comparing the returns from the different breeds shows that the cows ranged in production of milk as follows: Holstein, Brown Swiss, Guernsey, and Jersey; in production of butter fat, Guernsey, Holstein, Jersey, and Brown Swiss; in cost of feed, Jersey (lowest), Guernsey, Brown Swiss, and Holstein (highest); and in average net profit Guernsey, Holstein, Jersey, and Brown Swiss. The analyses of the various feeding stuffs used are recorded.

Tests of dairy cows, 1906–7, F. W. Woll and R. T. Harris (*Wisconsin Sta. Rpt. 1907, pp. 76–82*).—The so-called official and semiofficial tests of dairy cows were continued during 1906–7 as in previous years (E. S. R., 16, p. 813), 213 of the former and 756 of the latter with 345 different cows being conducted. A brief report of the work done in this connection is given.

The records of production made by Colantha 4th's Johanna (H.-F. H. B., 48577), 1906–7, F. W. Woll (*Wisconsin Sta. Rpt. 1907, pp. 83–88, pl. 1*).—The official 7-day, 30-day, and 63-day tests of this cow during the year 1906–7 are given. During the 10 months of the semiofficial record this cow produced 23,981.4 lbs. of milk, with an average fat content of 3.65 per cent, yielding 875.71 lbs. of butter fat.

The Jerseys at the St. Louis Exposition (*New York, 1906, pp. 121, figs. 27*).—An account is given of each cow in the Jersey herd included in the dairy-cow demonstration at the St. Louis Exposition. The productive record and breeding of each cow is reported by R. M. Gow, and the feeding and handling of the cows during the test are described by H. G. Van Pelt. The returns by these and three other herds of different breeds in the same test are summarized and compared.

Bacterial content of machine-drawn and hand-drawn milk, E. G. Hastings and C. Hoffmann (*Wisconsin Sta. Rpt. 1907, pp. 214–223*).—The data reported indicate that if the proper attention is paid to the cleanliness of the milking machine, milk may be produced by machine milking with as low a germ content as, or even lower than, that drawn by hand. To maintain the milking tubes and other parts of the machine in a bacteriologically clean condition the investigators used lime water prepared from fresh unslaked lime.

Distribution of cell elements in milk and their relation to sanitary standards, H. L. Russell and C. Hoffmann (*Wisconsin Sta. Rpt. 1907, pp. 231–253.*)—The purpose of the investigations here reported was to obtain information that would be of use in establishing a rational standard for the leucocyte content of normal milk.

Attention was directed first to the study of the methods of examination. Comparative tests were made of the Doane-Buckley and the Stokes-Stewart methods of quantitative determinations of leucocytes in milk. The results obtained by the former method were considerably higher than those by the latter, and there

was also much more uniformity in the results of duplicate tests. In the data given for 23 tests the percentage variation in duplicates by the Stokes method was very large and averaged 112 per cent, while by the Doane method the largest variation was 20 per cent and the average only 5.6 per cent. A modification of the method introduced by the investigators, which consists in heating the milk sample to 60° or 70° C. previous to centrifugalization, affords even more uniform results, the variations averaging less than 3 per cent. This method as thus modified is therefore recommended in studies of this nature.

In the investigations reported the authors studied the effects of a variety of factors, as physiological conditions of the animal, the period of lactation, the condition of the udder, breed, age, and others, on the cell content of milk of apparently healthy animals.

In summarizing results of their investigations the authors state that much injury may come to the dairy industry through the enforcement of such quantitative standards for leucocyte content as have been hitherto adopted. Their results agree with those of other investigators in showing wide variation in results of examination, depending largely upon the method followed. From the studies according to the method they adopted their conclusion is that "there is a wide range in the cellular content of milks that are apparently normal and perfectly safe for ordinary use. In a number of instances this cell content has been found to be relatively low and constant, while in a large proportion of cases, wide fluctuations have been noted which were frequently much in excess of any standards that have heretofore been accepted. There are undoubtedly factors operative which underlie this peculiarity in the individual animals. From the studies made it appears evident that the milks of older animals are more likely to show a high cell content than younger stock, and that frequently this condition is associated with a previous udder disturbance, which in some instances may leave a more or less marked indurated condition in the udder. These temporary disturbances, which are really gargets of a physiological character, very soon disappear, and the milk becomes wholly normal, although the evidence of such slight inflammatory disturbances may continue for a considerable period of time. So far as we have been able to find, there is no adequate reason why milks from such animals as these should be excluded from ordinary domestic supplies.

"At the present time we do not feel that it is wise to formulate a quantitative standard to be used as a hard and fast line in the inspection of milk supplies. The most that can be said of leucocyte examinations at the present time is that they are suggestive rather than final."

Concerning the bactericidal property of perhydrase milk, H. Much (*Münchcn. Med. Wchnschr., 55 (1908), No. 8, pp. 384–386*).—The experiments reported give evidence of the bactericidal effect of fresh cow's milk in destroying typhus bacilli, *Staphylococcus aureus*, and coli bacilli. They also add experimental evidence to that previously contributed by Much and Römer (E. S. R., 18, p. 368) that the process of producing perhydrase milk does not destroy the antibodies. By this process it is possible to maintain a bactericidal action in the milk for 24 hours, which is not the case with ordinary raw milk.

Medical milk commissions and the production of certified milk in the United States, C. B. Lane (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 104, pp. 43, pls. 6, figs. 11*).—The writer gives a comprehensive account of the work of medical commissions and of the movement that has resulted in their organization in different cities, and he describes in considerable detail the conditions under which certified milk is produced in different parts of the country. A paper prepared by B. D. White shows an economical method for the production of certified milk as practiced several years at a certified dairy in Minnesota.

The variation in the composition of milk, A. LAUDER (*Edinb. and East of Scot. Col. Agr. Bul. 14, pp. 34*).—The present report contains the results obtained from July, 1906, to July, 1907, in continuation of work previously reported (E. S. R., 18, p. 768). Data regarding the yield of 22 cows of the ordinary dairy Shorthorn type, varying in age between 6 and 10 years, are given. On several occasions the mixed milk of the herd contained little more than 3 per cent fat, but it never fell below that standard. The 11 cows that remained in the herd throughout the entire year gave an average yield of 885 gal. of milk, with an average fat content of 3.49 per cent for the morning milking and 3.98 per cent for the evening milking.

Variations in the amount of casein in cows' milk, E. B. HART (*Wisconsin Sta. Rpt. 1907, pp. 111–116*).—This article has been abstracted from another source (E. S. R., 19, p. 776).

The chemistry of milk curdling, J. L. SAMMIS (*Wisconsin Sta. Rpt. 1907, pp. 171–189, figs. 10*).—From the data reported the author draws the following deductions:

"The coagulation of milk by different acids at fixed temperature requires quantities of the acids which are not chemically equivalent to each other.

"The quantity of any acid required to coagulate a given sample of milk is less at high temperature than at low temperature.

"Variations in the proportions of neutral salts, or water, or sugar, as well as acids, present in milk produce variations in the coagulation temperature of the milk. In alkaline milk, neutral salts affect the curdling temperature.

"The reaction of lime-water casein solution with acid, producing a milky white appearance, is shown to be strongly dependent on temperature.

"The theories of Hammarsten, Soeldner, Van Slyke, and Hart, and others to the effect that milk as well as lime-water casein solutions contain a compound of casein with one other milk constituent, as calcium phosphate or oxid, in definite proportions can not be reconciled with these facts.

"The reaction between milk constituents, acids, etc., in solution is reversible and the state of equilibrium among the dissolved substances is affected by changes of temperatures.

"It is easy to correlate all the known facts respecting the curdling of milk, if one accepts the view that chemical attractions hold all of the constituents of milk serum in union with each other.

"Expressed in terms of this theory, milk curdles whenever the chemical attractions of curd constituents for each other and of the whey constituents for each other become relatively stronger than those which bind curd constituents and whey constituents together."

In brief, in the author's opinion the theory that there exists in milk a definite compound of casein with calcium oxid or calcium phosphate, or any other single milk constituent is untenable, and the theory that coagulation depends on the removal of calcium oxid from a definite compound of casein naturally present in milk can not be maintained.

The coagulation of fresh and alkaline milks, J. L. SAMMIS (*Wisconsin Sta. Rpt. 1907, pp. 190–206, figs. 12*).—The data reported present "typical results showing the effect of neutral salts on the coagulation of sweet fresh milk and milk containing caustic alkali." These results resembled those obtained in the previous study with acidulated milk (see preceding abstract). The facts obtained confirm the conclusions there drawn, and "render it very certain that milk curdling does not depend upon the neutralization of lime alone but is a reaction in which all of the constituents of milk take part."

The effect of autolysis on the precipitogenic characteristics of milk, H. DE WAELE (*Biochem. Ztschr., 7 (1908), No. 4–6, pp. 401–406*).—According to the experiments reported the autolysis of milk increases its precipitogenic action.

The influence of the oxygen of the air upon fermentation by typical lactic-acid bacteria, G. KOESTLER (*Centbl. Bakt. [etc.], 2. Abt., 19 (1907), Nos. 1–3, pp. 40–49; 4–6, pp. 128–148; 7–9, pp. 236–255; 13–15, pp. 394–419, figs. 18; abs. in Hyg. Zentbl., 3 (1908), No. 18, p. 558*).—From the results of the investigations reported the author concludes that oxygen had a different effect upon different lactic organisms.

Bacterium güntheri was but slightly sensitive to free oxygen, whereas *Bacillus casei* ε was very sensitive. The effect on this organism varied according to the quantity of oxygen supplied. With an abundant supply fermentation was largely prevented; there was, however, a rich vegetative development of the organisms, but they were not healthy. A scanty oxygen supply was practically without effect. With intermediate aeration there was a maximum acid production and normal cell development. The results indicate that oxygen in large quantities had a toxic effect and in moderate quantities a stimulating effect. This phenomenon can not be explained by Beijerinck's microaerophilus hypothesis, because the same degree of acidity was produced under positive anaerobic conditions as with the free access of air. With controlled aeration the degree of acidity produced depended upon the temperature and the content of the nutrient medium in assimilable nitrogenous compounds. A continuous oxygen supply was not necessary for fermentation, an occasional exposure of the medium to air with shaking being sufficient.

Butter from sweet cream, A. T. CHARRON (*Rpt. Dairymen's Assoc. Prov. Quebec, 25 (1906), pp. 238–246*).—Results of experiments in making butter from sweet cream are discussed. It is claimed that the process is just as advantageous as that with ripened cream, and that the butter made from sweet cream is equally good when fresh and keeps good longer than butter from cream spontaneously fermented.

Influence of metals on the action of rennet, G. A. OLSON (*Wisconsin Sta. Rpt. 1907, pp. 134–159, figs. 7*).—The author summarizes information regarding a number of conditions which influence the action of rennet on milk and reports the results of investigations on the effect of different metals. Milk was kept in contact with copper, zinc, lead, nickel, aluminum, tin, iron, and platinum, and different kinds of glass for different periods of time and afterwards the time required for the coagulation of such milk with a standard solution of rennet under uniform conditions was observed to learn what influence, if any, these substances had on the action of the rennet and whether this was characteristic for each substance.

"The data given show beyond a doubt that metals in some way delay the coagulation of milk with rennet. Different milks respond differently; the most striking retardations were observed with pure nickel. The retardations that are most doubtful are those observed with platinum and tin. It is hardly conceivable that salts of platinum or tin should be formed by the acid of the milk. When tin is treated with lactic acid a slight visible corrosion takes place, while on the other hand platinum remains uncorroded."

The direct cause for retardation of rennet by metal was not ascertained. Practical application of the information obtained in these studies is made in avoiding the use of rusty cans or poorly tinned utensils in the creamery or cheese factory. "The quality of the milk will to a large extent depend upon the condition of utensils in which the milk is kept or hauled to the factory. The degree of influence of iron on milk will depend largely upon the temperature, the length of time kept, and the amount of surface."

The author suggests that the reason for a slow or retarded action of rennet, which cheese makers have often experienced, may be attributed to the action of iron in milk cans in poor condition, and not entirely to the amount of salts present in the milk as was formerly supposed.

Red spots in Emmenthal cheese, J. Thöni and O. Allemann (*Landw. Jahrb. Schweiz, 22 (1908), No. 2, pp. 46–52, pl. 1*).—Several cheeses from 4 to 5 months old showed on the cut surfaces round red spots scattered irregularly throughout the cheese, which were found to be due to *Bacterium acidi propionici* var. *ruber*. Microscopical, cultural, and biological chemical data obtained in the study of this fault in the cheese are given.

Investigation of Gervais cheese, L. Müller (*Molk. Ztg., 22 (1908), No. 18, p. 491*).—Analytical data are given regarding French Gervais cheese and cheese of the same sort made in Germany.

Regarding "short" cheese, F. W. J. Boekhout and J. J. O. de Vries (*Centbl. Bakt. [etc.], 2. Abt., 19 (1907), Nos. 21–23, pp. 690–696; 24–25, pp. 750–754, fig. 1*).—This article has been abstracted from another source (E. S. R., 19, p. 474).

An automatic cheese press, J. W. Moore (*Wisconsin Sta. Rpt. 1907, pp. 207–213, figs. 3*).—This article describes and illustrates a modification of the ordinary cheese press constructed to maintain automatically a constant pressure for any desired length of time. This is accomplished by means of a rope wrapped several times around a pulley attached to the screw of the press, which is horizontal, then passed through another pulley overhead, and having attached on the end a sufficient weight to maintain a desired torsion upon the screw. The press described has been in use for several months. The advantages in the use of this press are summarized as follows:

"By using the proper weight on the rope the cheese can be put under any required pressure.

"By insuring continuous pressure during the night the cheeses are more perfectly closed than is otherwise possible.

"When the continuous pressure device is used there is less loss of fat, because a lower pressure is applied to the warm curd than is required with the ordinary press."

VETERINARY MEDICINE.

Veterinary hygiene, M. Klimmer (*Veterinärhygiene. Berlin, 1908, pp. X+439, figs. 81*).—The purpose of this volume is to show how the principles of scientific hygiene may be so applied to the care and management of domestic animals as to avoid to some extent at least the occurrence and spread of infectious diseases. To this end the author presents a detailed account of the influence of various factors in the environment upon the health of animals, particular attention being given to the conditions under which infection takes place through the air, soil, water, and feeding stuffs. The harmful changes which foods may undergo are discussed in detail. A long list is also given of poisonous plants with notes on the symptoms produced by eating these plants and antidotes which may be used in counteracting their effects.

Wounds: Their treatment and some minor surgical operations, W. Robertson (*Agr. Jour. Cape Good Hope, 31 (1907), No. 5, pp. 534–542, pls. 3, figs. 3*).—Practical suggestions are given regarding methods of casting or otherwise confining animals for surgical operations. A number of simple operations are described, with directions for the treatment of wounds to prevent infection or other serious consequences.

Preventive inoculation of farm stock, W. Robertson (*Agr. Jour. Cape Good Hope, 32 (1908), No. 1, pp. 97–106, figs. 5*).—Detailed directions are given for vaccinating stock against pleuro-pneumonia, anthrax, and blackleg. The principles upon which the effectiveness of vaccination depend are discussed.

Veterinary division, J. A. Gilruth and C. J. Reakes (*New Zeal. Dept. Agr. Ann. Rpt., 15 (1907), pp. 361–397, pls. 4*).—The work of the veterinary staff during the year was largely confined to routine matters and the practical testing of methods for controlling diseases of animals. Brief notes are given on contagious abortion, tuberculosis, anthrax, blackleg, mammitis, renal congestion in lambs, *Strongylus capillaris*, maggot fly, and fluke worms in sheep, tumors, etc. Considerable attention is given to the study of acute stomatitis in lambs. The disease appears to be due to a Staphylococcus which exists in mammary lesions of the ewes. The organism is briefly described and an account is given of its biological characteristics.

Aggressins in barbone and their application as an immunizing agent, F. S. H. Baldrey (*Jour Trop. Vet. Sci., 2 (1907), No. 4, pp. 351–355*).—In a study of the possible value of aggressins in the production of immunity toward barbone, the author found that aggressin fluid could be easily obtained from inoculated rabbits, but that its prophylactic value was very slight. Furthermore, there appears to be great difficulty in obtaining it in large quantities free from contamination.

Granulous colpitis as a cause of sterility, L. Brante (*Svensk Vet. Tidskr., 12 (1907), No. 3, pp. 120–126*).—The occurrence of granulous colpitis as well as of other infections which cause pathological changes in the cervix uteri or ovaries may lead to sterility.

A mycosis affecting man and rats, A. Lutz and A. Splendore (*Centbl. Bakt. [etc.], 1. Abt., Orig., 45 (1907), No. 7, pp. 631–637, pls. 4*).—For several years the author has had opportunity to observe a mycosis which occurs spontaneously in rats and also occasionally in man. In rats the lesions are to be found chiefly on the limbs and tail. Edematous swellings and ulcers appear on the surface, some of them being of a fistulous nature. Infection may be transmitted in rats through the alimentary tract but the progress of the disease is slow. In man the ulcerous lesions appear largely on the hand and arm. The microorganism which produces this disease has been identified as a species of Trichosporium.

Cultivation of trypanosomes and vital coloration of these organisms, C. França (*Bul. Soc. Portugaise Sci. Nat., 1 (1907), No. 1, pp. 5–11, figs. 3*).—Particular attention was given by the author to the typanosomes which occur in frogs. It was found possible to stain these organisms while alive by means of anilin dyes, particularly pyronin. This method, however, was not successful in the case of the trypanosomes of dourine, for these organisms would not take the stain during life.

The trypanolytic power of serum in cases of experimental nagana, A. Rodet and G. Vallet (*Compt. Rend. Acad. Sci. [Paris], 145 (1907), No. 24, pp. 1225–1227*).—In a series of laboratory experiments it was found that in animals which show no crisis during the development of nagana, the trypanolytic power of the serum gradually increased from the time of infection until death. On the other hand, in animals in which a regular crisis occurs during the course of the disease, the trypanolytic power of the serum develops to a high extent at the time of the crisis.

The preventive and curative power of human serum in cases of nagana, O. Goebel (*Ann. Inst. Pasteur, 21 (1907), No. 11, pp. 882–910*).—As had been previously shown by Laveran, Mesnil, and others, human serum in the experiments reported by the author exercised a pronounced preventive and curative

power in mice and guinea pigs infected with *Trypanosoma brucei*. Human serum digested together with the trypanosomes at a temperature of 37° C. did not lose its preventive or curative properties nor did the parasites lose their virulence. The active power of human serum toward the trypanosomes of nagana was destroyed by subjection to a temperature of 64° C.

The treatment of experimental nagana, F. Loeffler and K. Rühs (*Deut. Med. Wchnschr., 34 (1908), No. 1, pp. 5–8*).—In a previous article on this subject (E. S. R., 19, p. 983), the authors reported striking success in the treatment of nagana by the use of arsenious acid. The present article is largely of a controversial nature by way of reply to criticisms of Laveran and Thiroux (E. S. R., 19, pp. 1081, 1182). The authors repeated their experiments and again came to the conclusion that experimental nagana might be certainly cured by the simultaneous use of arsenious acid and atoxyl.

The diagnosis of rabies, S. A. Gryuner (*Arch. Vet. Nauk [St. Petersb.], 37 (1907), No. 11, pp. 964–995*).—A long series of observations was carried out by the author in determining the reliability of various methods in the diagnosis of rabies. In some cases it is found possible to reach a positive diagnosis merely from a post-mortem examination. The presence of sugar in the urine in connection with other evidence may furnish a basis for a positive diagnosis, but the absence of sugar from the urine is not satisfactory proof of the nonexistence of rabies. Negri corpuscles could be recognized with certainty in a certain percentage of cases. The author considers, however, that the only absolutely reliable method is to be found in the inoculation of rabbits or other laboratory animals.

The etiology and diagnosis of rabies, N. Oreste (*Clin. Vet. [Milan], Sez. Prat., 30 (1907), Nos. 50, pp. 805–812; 51, pp. 821–826*).—It is recognized as a great desideratum in the study of rabies to devise a method of rapid diagnosis. The rapidity, however, is no more important than certainty in diagnosis, and in the author's opinion preference should be given to the method of inoculation of guinea pigs.

The effect of various chemicals upon rabies virus, C. Fermi (*Arch. Hyg., 63 (1907), No. 3, pp. 315–330*).—Fixed rabies virus preserved at the Pasteur Institute at Sassari maintained its virulence for 20 days as determined by inoculation of rodents. None of the pieces of rabid brain material preserved in glycerin retained their virulence to the twenty-fifth day. The incubation period of rabies produced from virus preserved in glycerin was 5 or 6 days and was, therefore, not different from ordinary virus.

The theory and practice of anti-rabic immunization, W. F. Harvey and A. McKendrick (*Sci. Mem. Med. and Sanit. Depts. India, n. ser., 1907, No. 30, pp. 43, figs. 7*).—Extended observations were made on the infective power of rabies virus from dried spinal cords as compared with that of fresh virus. Tests were also made to determine the bearing of the rate of desiccaiton of the spinal cord upon the use of such material for immunizing purposes. It was found that there is a direct relation between infectivity and the duration of desiccation of nerve material. No evidence was obtained for the existence of a rabies toxin. There appears to be some advantage in favor of using fresh material in immunization for the reason that this method involves the introduction of less foreign nerve substance.

The action of bile on tetanus toxin, H. Vincent (*Compt. Rend. Soc. Biol. [Paris], 63 (1907), No. 36, pp. 623–625*).—In glass vessels bile exercised a strongly antiseptic effect upon tetanus virus. In guinea pigs, however, the result was far less satisfactory and bile was not capable of protecting the animal against fatal results from the tetanus toxin. It is believed that this fact is to

be explained by the great dilution in which the bile exists in the body of the experimental animal.

Action of the component elements of the bile on tetanus toxin, II. VINCENT (*Compt. Rend. Soc. Biol. [Paris], 63 (1907), No. 37, pp. 695–697*).—In continuation of the work noted above, it appeared desirable to determine the particular elements of the bile upon which its antiseptic property depends. A study of this problem showed that all of the essential elements of the bile possess an antitoxic power toward tetanus toxin. The antitoxic property of cholesterin is somewhat greater than that of lecithin and bile salts.

Experiments in the use of epsom salts in the treatment of tetanus, L. CRUVEILHIER (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 3, pp. 111–113*).—Several investigators have suggested the use of epsom salts in treating tetanus. This drug was tested by the author who administered it hypodermically to mice and guinea pigs in a 2 per cent solution. No beneficial results were obtained and the author concludes that in the treatment of this disease no dependence should be placed upon epsom salts.

Inoculation tuberculosis in cold-blooded animals, G. MORIYA (*Centbl. Bakt. [etc.], I. Abt., Orig., 45 (1907), No. 4, pp. 294–301, pl. 1*).—In a series of inoculation experiments the author found that human tubercle bacilli were by no means easily modified into the form of tubercle bacillus usually found in cold-blooded animals. The author believes that before such transformation can be assumed to be possible it is necessary that further careful experiments be carried out on this line.

Fetal tuberculosis in calves, H. L. ELLERMAN and H. C. DEWAAL (*Tijdschr. Veeartsenijk., 35 (1908), No. 4, pp. 213–217*).—A detailed description is given of the tuberculous lesions observed in a pregnant cow. The disease had become generally distributed throughout the organs of the body and had affected the uterine cotyledons, from which pure cultures of tubercle bacilli were obtained. From these points the infection had spread to the fetus, causing characteristic lesions in various lymphatic glands.

The influence of wounds on the localization of tuberculosis, A. RODET and JEANBRAU (*Compt. Rend. Acad. Sci. [Paris], 145 (1907), No. 26, pp. 1361–1363*).—It has sometimes been assumed that tubercle bacilli possess a tendency to become localized in wounds which exist at the time of infection or arise subsequently. The author's experiments on rabbits led to negative results in this regard. Tubercle bacilli introduced through the alimentary tract led to distinct lesions in the lungs, but did not produce any subsequent lesion in artificial wounds in the joints.

The action of chlorin on the tubercle bacillus, G. MOUSSU and GOUPIL (*Compt. Rend. Acad. Sci. [Paris], 145 (1907), No. 24, pp. 1231, 1232*).—In the opinion of the author it has been shown that the acid-resisting property of the tubercle bacillus depends not alone upon its content of fatty substances, but also upon its protoplasm and other chemical constituents. The author found that if cultures of tubercle bacilli be subjected to the action of chlorin fumes the acid-resisting power of the bacilli disappears rapidly.

The formation of antibodies from the substance of the tubercle, E. BERTARELLI (*Centbl. Bakt. [etc.], I. Abt., Orig., 45 (1907), No. 1, pp. 62–67*).—During the development of the tubercle in susceptible animals the process is not confined to alterations of the tissues as a consequence of necrosis or other pathological changes, but under the influence of the bacterial invasion molecular combinations occur which result in new bodies previously not to be found either in bacterial cultures or in the tissue of the animal organism. These antibodies may possibly prove of some service in the production of immunity.

Tubercle toxin studies, II, A. H. Haentjens (*Ztschr. Tuberkulose, 11 (1907), No. 4, pp. 323–331*).—Suspensions of tubercle bacilli in physiological salt solution, glycerin agar, cultures of tubercle bacilli, and cultures of glycerin and potato were kept in a filter in an autoclave for 14 to 30 days. During this time the filtrate contains the true toxin of the tubercle bacillus. The material is called filtrase by the author and varies in strength according as the cultures are made in physiological salt solution, glycerin agar, or glycerin and potatoes.

This material was tested first on healthy and tuberculous guinea pigs with encouraging results. In healthy guinea pigs it was possible to administer doses of reasonble size without producing either toxic or thermic effects. In larger doses of a stronger filtrate, the material produced only slight toxic reaction. In the case of tuberculous guinea pigs, the use of this material caused an improvement of the general condition or a complete cure.

The material has also been tested on tuberculous human beings with satisfactory results.

Cultures of tubercle bacilli in vivo and vaccination against the disease, G. Moussu (*Rec. Méd. Vét., 84 (1907), Nos. 21, pp. 701–712; 23, pp. 770–776*).—In the investigations reported in this article the author was concerned in obtaining evidence on the influence upon the animal organism of the prolonged cultivation of tubercle bacilli in the peritoneal cavity. In the case of dogs it was found that the cultivation of tubercle bacilli in vivo for a period of 1 to 10 months did not increase the resisting power of the dogs toward inoculation with human tubercle bacilli.

Vaccination against tuberculosis, E. Leclainche (*Rev. Gén. Méd. Vét., 10 (1907), No. 119, pp. 585–597*).—The author reviews in a critical manner the results obtained by other investigators and himself in testing the efficacy and practicability of von Behring's method of vaccination against tuberculosis, and concludes that at the present time the only reliable and well established methods for controlling tuberculosis are the systems of isolation recommended by Bang and Ostertag.

Tuberculosis tests for 1906–7, H. L. Russell (*Wisconsin Sta. Rpt. 1907, pp. 224–230*).—A systematic effort is being put forth by the station to popularize and extend as widely as possible the application of the tuberculin test to dairy herds as a basis for the control of tuberculosis. The number of animals tested is increasing rapidly from year to year. Statistics are given showing the number of herds and number of animals tested from 1901 to 1907. In 1901 the number of cows tested was 425 and in 1907, 10,740. The percentage of tuberculous animals as shown by these tests varied from 2.7 to 19.7. The distribution of tuberculosis is shown by counties and also by regions in the State. The greatest prevalence of the disease is observed in the older dairy regions.

The extent to which the milk yield is affected by subcutaneous injections of tuberculin, E. Bohm (*Svensk Vet. Tidskr., 12 (1907), No. 6, pp. 241–248*).—In the experiments reported in this paper it was found that the milk yield may be considerably lessened as a result of tuberculin injections. With reacting cows the falling off in the milk flow appears within 2 or 3 days after injection and a return to the normal milk yield usually occurs within 1 week. In non-reacting cows there is no diminution in the milk yield, but, on the other hand, there may be a slight temporary increase.

Two new species of nematodes in the alimentary tract of cattle in Sumatra, A. Vryburg (*Centbl. Bakt. [etc.], I. Abt., Orig., 45 (1907), No. 4, pp. 321–332, pls. 5*).—An account is presented of the appearance, life history, and habits of *Strongyloides bovis* and *Agriostomum vryburgi*. Either of these parasites may

be transmitted to healthy cattle through the food and both species may occur simultaneously in the same animal. The symptoms of infestation are not particularly characteristic. In some cases, however, there is a chronic diarrhea which does not yield to treatment with the ordinary remedies. In attempts to treat animals for the parasites thymol, creosote, oil of turpentine, arsenic, and areca nut were used. The results were not satisfactory for either species, but were somewhat more encouraging in the case of *A. rrybnrgi* than with *S. bovis*.

Parturient paresis, Wagner (*Wchnschr. Tierheilk. u. Viehzucht, 51 (1907), No. 51, pp. 1006, 1007*).—In a series of 69 cases of this disease, the author carefully tabulated clinical and physiological data which might be considered of interest in the study of its nature.

The great majority of cases occurred in connection with the fourth or fifth parturition and cases were comparatively rare after the age of 13 years. In nearly all cases of the disease parturition was easy and occurred at the end of the normal term. No lesions occurred during parturition. The nutritive condition was in all cases excellent. In 64 of the 69 cases the udder was well distended with milk. The largest percentage of cases occurred in cows which had been dry for 2 to 3 months previous to parturition.

Poisoning of cattle with tansy. Wessel, Wilster, and Bugge (*Berlin. Tierärztl. Wchnschr., 1907, No. 49, pp. 879–881, fig. 1*).—Descriptive and clinical notes are given on a number of cases of poisoning of cattle with tansy. In one herd 43 per cent were affected and 25 per cent died. From post-mortem examinations it was impossible to observe any constant pathological lesions which were characteristic of the trouble. Notes are given on a number of other cases of this form of poisoning involving in all nearly 200 cattle. The symptoms as a rule are restlessness, irregularity of movement, blindness, twitching of the muscles, and dullness of the special senses. In some cases death resulted within 24 hours. Fairly satisfactory treatment was found in the use of tannin and barium chlorid.

Two undescribed diseases of sheep, T. H. Dale (*Vet. Rec., 20 (1908), No. 1018, pp. 490–492*).—The author has made observations on 2 new diseases of sheep in the Transvaal. The diseases have not been given a characteristic name. In both cases the mortality is very high and the course of the disease short. In one the period of incubation is about 4 days. This disease appears in flocks of sheep without regard to the degree of infestation by parasitic worms. The second disease attacks sheep in excellent condition, causing rapid prostration and death. The pericardium always contains a considerable quantity of fluid stained with blood. This disease is frequently associated with blue-tongue.

The stomach worm of sheep and goats, R. W. Dixon (*Agr. Jour. Cape Good Hope, 31 (1907), No. 6, pp. 637–642, figs. 11*).—The life history of *Strongylus contortus* is briefly outlined. In treating young lambs for infestation with this worm good results were had from the use of copper sulphate in doses from 2 to 4 oz. of a solution containing 1 lb. of copper sulphate and 1 lb. of mustard in 12 gal. of water. Mention is also made of the use of creosote and gasoline.

Ulcerous stomatitis of goats, C. Cadéac (*Jour. Méd. Vet. et Zootech., 58 (1907), Nov., pp. 656–659*).—Ulcerous stomatitis in goats as in other animals may be due to a variety of causes and sometimes appears to be of an infectious nature. A detailed account is given of a serious case occurring in a single goat in a herd, the ulceration in this case being apparently due to some caustic substance which the goat had taken with its food.

Lesions produced in the small intestine of swine by Echinorhynchus gigas, Weinberg and Romanovitch (*Ann. Inst. Pasteur, 21 (1907), No. 12, pp. 960–968, pl. 1, figs. 4*).—By means of gross and microscopic examinations of the

small intestine of swine infested with *Echinorhynchus gigas*, it was found that this parasite by attaching itself to the wall of the intestine may destroy in a mechanical manner the mucous, submucous, and even the muscular layer of the intestinal wall without producing any inflammation. The eosinophilous cells found near the point of attachment of the parasitic worms are apparently not attracted there by the presence of the parasites. *E. gigas* may produce lesions in which pathogenic bacteria find entrance to the host, causing infectious or necrotic enteritis.

Swine erysipelas. E. Césari (*Hyg. Viande et Lait, 1 (1907), No. 12, pp. 544–551*).—A considerable number of cases are cited in which swine erysipelas has been transmitted to man. The characteristic symptoms of the disease as observed in meat inspection are briefly outlined. The bacilli are not destroyed by the ordinary method of preserving hams until after at least 6 months, and the author recommends that pork affected with this disease should not be admitted for human consumption until it has at least been sterilized.

The occurrence of the bacilli of swine erysipelas on the intestinal mucous membrane and in the tonsils in healthy hogs. W. Pitt (*Centbl. Bakt. [etc.], 1. Abt., Orig., 45 (1907), Nos. 1, pp. 33–37; 2, pp. 111–121*).—In an examination of the intestinal mucous membrane in 66, and of tonsils in 50, healthy hogs, undoubted bacilli of swine erysipelas were found in 26 and 28 cases, respectively. The author concludes that the bacilli of swine erysipelas may occur in nearly 50 per cent of healthy hogs and that, therefore, prophylactic measures, such as have been commonly advocated, are of low value. It is, therefore, recommended that protective vaccination be adopted as the only reliable means of controlling this disease.

The behavior of white blood corpuscles in common diseases of the horse. E. Franke (*Monatsh. Prakt. Tierheilk., 19 (1907), No. 2–3, pp. 98–120*).—The variations which occur in the relative proportions of red blood corpuscles and the various kinds of leucocytes are presented in a detailed manner as observed in cases of pneumonia, influenza, petechial fever, tetanus, etc. Attention is called to the fact that in order to obtain reliable results from the examination of the blood the determination of the relative percentages of the different kinds of leucocytes must be made immediately after the blood is withdrawn.

The behavior of red blood corpuscles in surgical diseases of the horse, particularly in purulent inflammations. A. Gasse (*Monatsh. Prakt. Tierheilk., 19 (1907), No. 2–3, pp. 49–98, pl. 1*).—The content of red blood corpuscles in the blood is only slightly affected by the sex of the animal. The white blood corpuscles vary more extensively. The relative percentages of various kinds of white blood corpuscles in normal blood are given in a tabular form. In cases of purulent inflammation a hyperleucocytosis need not be considered especially serious if the relative proportion of the different kinds of leucocytes is not greatly disturbed. If, on the other hand, there is considerable increase in the number of neutrophil cells and a diminution in the number of lymphocytes, prognosis is quite unfavorable. The basophil cells appear in nearly all cases to vary in the same manner as the eosinophils.

Studies on glanders. V. Galtier (*Jour. Méd. Vét. et Zootech., 59 (1908), Jan., pp. 1–5*).—Glanders bacilli in small pieces of infected tissue are rendered entirely sterile by submerging in glycerin for a period of 12 days. The attenuation of the bacilli progresses gradually during this period. Dead glanders bacilli are toxic, and in the author's experiments they were shown to possess considerable toxicity after their virulence had entirely disappeared. No satisfactory results were obtained in immunizing dogs and guinea pigs against glanders.

The toxin of glanders bacillus, R. Turró (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 3, pp. 130, 131*).—The author describes the technique for obtaining a new form of mallein or toxin from the glanders bacillus which acts as an aggressin.

Abscess formation in the hypoglossal glands of horses affected with glanders, E. Lienaux (*Ann. Méd. Vét., 56 (1907), No. 12, pp. 645–648*).—It is commonly stated that the glanderous process in the lymphatic glands of the horse does not lead to formation of abscess. As a rule at least, this statement is true. The author reports, however, one case in which the hypoglossal glands were extensively affected with abscess.

Combating glanders in Dutch East Indies, W. Van der Burg (*Tijdschr. Veeartsenijk., 35 (1907), No. 3, pp. 149–151*).—From a report of the occurrence of glanders in the Dutch East Indies and the methods of control adopted in Java, the author maintains that the system is altogether too lax and that unless mallein is more extensively used as a diagnostic agent and the necessary quarantine measures carried out, it will be impossible to control the disease.

A study of the toxin in ulcerous lymphangitis of the horse, Dassonville (*Bul. Soc. Cent. Méd. Vét., 84 (1907), No. 24, pp. 576–582*).—The author describes the methods used in isolating and studying the toxin of ulcerous lymphangitis. It is found that the bacillus of this disease produces a very active toxin, to which guinea pigs and rabbits are very susceptible, dogs and cats less susceptible, and white mice almost if not quite refractory. The action of the toxin is readily modified by heat or by the use of various acids.

The symptoms and lesions produced by the toxin closely resemble those which occur as a result of diphtheria toxin, and the properties of the toxin as a whole indicate that it is very similar. The similarity is particularly evident from the fact that diphtheria antitoxin greatly modifies or counteracts the toxin of ulcerous lymphangitis.

The treatment of mange in dogs, Dietz (*Berlin. Tierärztl. Wchnschr., 1907, No. 48, p. 867*).—In treating mange due to Acarus mites the author has found it desirable to shear the hair as closely as possible from infected dogs after which a mixture of tincture of iodin and cream is thoroughly rubbed on the affected parts.

Piroplasma canis and its life cycle in the tick, S. R. Christophers (*Sci. Mem. Med. and Sanit. Depts. India, n. ser., 1907, No. 29, pp. 83, pls. 3, figs. 4, charts 7*).—The literature relating to this protozoan parasite and related organisms is critically discussed in connection with an elaborate bibliography (pp. 67–77). In the tick *Rhipicephalus sanguineus* there are at least two means by which transmission may be effected. One is through the egg and the other a stage to stage infection. The latter has not been demonstrated experimentally, but must be assumed to be true from observations which have been made. The parasite passes through the same cycle of development in both methods of infection. In hereditary infection club-shaped forms originating from simple parasites penetrate the ova either in the ovary or in the lower passage of the oviduct.

[A bacterial growth on chickens], D. W. May (*Porto Rico Sta. Rpt. 1907, p. 15*).—A disease, seemingly a bacterial growth, has been noticed which produces lumps on the comb and at the base of the bill. Washing the heads of the fowls with a saturated solution of boric acid gave relief.

The persistence of contagion of fowl cholera, P. V. Sizov (*Arch. Vet. Nauk [St. Petersb.], 37 (1907), No. 10, pp. 847–850*).—It is commonly stated that after the occurrence of this disease an infected condition of the premises may persist for 3 or 4 months. In the author's experiments it was found that the

virus of fowl cholera preserved in glass vessels retained its virulence for 2 years.

Spirochetosis of Sudanese fowls—an after phase, A. Balfour (*Jour. Trop. Mag. and Hyg., 11 (1908), No. 3, p. 37*).—In continuation of his work in spirochetosis of fowls, the author has observed the parasitic organisms entering blood corpuscles. The organisms apparently degenerate after penetrating the corpuscles but the corpuscles also disintegrate. The fact is recorded that after the spirochetes had entirely disappeared from the peripheral blood they reappeared again in considerable quantities.

Some observations on swollen head in turkeys, G. S. Graham-Smith (*Jour. Agr. Sci., 2 (1907), No. 3, pp. 227–243, pls. 2*).—A disease commonly known as swollen head of turkeys is described and notes are given on the symptoms usually observed and on the lesions as determined by an examination of a number of affected turkeys.

The most characteristic symptom is an extensive swelling about the head which becomes so enlarged that the birds are unable to see. The swelling is due to an accumulation of gelatinous substance in the infraorbital cavity. This swelling may disappear in a short time or may persist for several months. The swellings contain a cheesy foul-smelling material and death may take place without regard to the apparent severity of the disease. The lesions are confined to the head except for an occasional distension of the ceca. Bacilli related to the diphtheria bacillus are frequently found in the exudate, but no organism has been definitely shown to be the primary cause of the disease.

RURAL ECONOMICS.

Piece work in agriculture, G. Wasmuth (*Deut. Landw. Presse, 35 (1908), No. 33, pp. 358, 359*).—The author shows that the amount of work done and the wages earned by the average farm day laborer is the correct basis for determining the rate of pay for job workers in many of the operations of agriculture. The various classes of work both by hand and machinery that could be assigned as piece work in agriculture are enumerated, and the author advocates piece work rather than day work for farm laborers. It is maintained that where this class of work has been tried the piece workers accomplish more, earn more, live better than farm laborers paid by the day, and do equally good work. Where laborers are scarce piece work is regarded as a partial solution, because three men on piece work will accomplish as much as four ordinary day laborers. Moreover, the incentives of independence and higher wages as a result of piece work puts the agricultural industry on the same level as other industries so far as wages is concerned, and this is regarded as affording the brightest prospects in the future for retaining the young workers on the land.

The farm labor problem in the Empire State (*Amer. Agr., 81 (1908), No. 21, pp. 583, 584*).—This article contains brief statements from several farmers in different parts of New York State relating to the farm labor problem. The general trend of the replies indicates that good farm labor is scarce, that wages for day labor range from $1.25 to $1.50 per day, and monthly wages from $20 to $33 with board for 10 hours work per day, and that the scarcity of work in cities is bringing back to the farm those who were born and brought up thereon. The encouragement of the immigration of farm labor from the United Kingdom, Germany, Sweden, and other European countries and the greater use of farm machinery are advocated as a remedy.

Emigration to Virginia and the labor question, G. W. Koiner (*Rpt. Va. State Hort. Soc., 12 (1907), pp. 145–155*).—This is an address delivered before

the Virginia State Horticultural Society at its meeting held at Staunton, Va., December 5, 1907.

The paper deals with the personal efforts in northern Europe of the State commissioner of agriculture to induce farm laborers to emigrate to Virginia and of the results of the undertaking. In two seasons some five or six hundred persons had been located on Virginia farms, about 80 per cent of whom were doing well. "There are now a thousand or more applications in my office for farm labor that we can not fill. The work . . . shows a great demand for farm labor in the State of Virginia. We have about 125,000 farmers in Virginia, and about half of them want some help."

The Hungarian farm labor problem (*Wiener Landw. Ztg., 58 (1908), No. 26, p. 269*).—The writer shows that whereas during 1897 there were 14,310 emigrants from Hungary, the year 1906 showed 178,170, and that of the latter about 23,000 were peasant proprietors and 76,000 farm and day laborers. The wages of farm help has doubled during the past 15 years, and even if farm labor were available no remedy could be afforded by offering an increase in wages as they are as high now as the majority of farmers can afford to pay. The recent return of so many emigrants from the United States and other countries brought no remedy to farmers as the majority located and sought employment in industrial centers. The future outlook for agriculture in Hungary, therefore, is regarded as serious.

The agricultural holdings act, 1906, A. P. Poley (*Jour. Roy. Agr. Soc. England, 68 (1907), pp. 1–16*).—This is a discussion of the main provisions of the act which goes into operation on January 1, 1909. The features discussed relate (1) to those alterations in the law which amend preceding agricultural holdings acts, particularly the act of 1900, and (2) to those sections of the act which embody the ideas of the school of agricultural reformers responsible for its inception. The topics of interest to landlords and tenants relate to arbitration, repairs to buildings, record of holding, amendment of market gardeners compensation act, freedom of cropping, compensation for unreasonable disturbance, and compensation for damage by game.

The creation of small holdings under the act of 1907, Mrs. Roland Wilkins (*Jour. Bd. Agr. [London], 15 (1908), No. 1, pp. 1–7*).—This is a discussion of the natural, market, and other conditions which are necessary to the successful extension of small holdings in England.

The cooperative association movement relating to the grain industry in the United States, H. L. Rudloff (*Fühling's Landw. Ztg., 57 (1908), No. 9, pp. 321–334*).—The author discusses the origin, purpose, and development of several associations and cooperative societies in the United States with particular reference to the production, storing, grading, and marketing of wheat. Among the societies historically sketched are the Grange or Patrons of Husbandry, National Grain Dealers' Association, National Farmers' Alliance and Industrial Association, National Grain Growers' Association, Northwestern Independent and Farmers' Elevator Association, and the Cooperative Commission Company.

It is the author's opinion that the farmers of the northwest lack in the spirit of solidarity which has been so helpful in promoting agricultural cooperation in Europe. The spread of cooperation among grain producers it is thought would promote still more the advantages of increased prices already accruing to farmers as a result of this movement.

Agricultural mutual societies, H. Léraillé (*Fermes et Châteaux, 4 (1908), No. 33, pp. 232–234, figs. 7*).—This is a discussion of the origin and progress of mutual insurance and credit societies in France, including the underlying principles of organization, operation, assessment, payment of losses, etc.

The mutual insurance societies were instituted for the insurance of farm buildings against fire and storms, of live stock against loss from diseases or other causes, and of crops against storms, floods, and other natural forces. Since their origin in 1898 the mutual insurance societies have increased to 7,824 in May, 1907. The statistics of mutual credit banks have already been noted from another source (E. S. R., 19, p. 692).

The Utopia of agricultural credit, H. OESTREICHER (*Inaug. Diss., Univ. Freiburg, 1907, pp. 129*).—This is an inaugural dissertation dealing with the history of agricultural credit reform, from the efforts of Rodbertus in 1868 to the present time, with a critical discussion of the different systems and an estimation of their value.

[Cooperative societies in Bombay Presidency], C. S. CAMPBELL and J. E. C. JUKES (*Ann. Rpt. Work. Coop. Credit Soc. Bombay Pres., 1906–7, pp. 45+3, map 1*).—The total number of societies is 70 as compared with 31 in the preceding year, with a membership of 4,845. The maximum rate of interest is 12½ per cent, the lowest 6¼ per cent, and the average per society 8½ per cent.

Summary of the work of the agricultural commission during the year ended October 1, 1907 (*Aperçu des travaux des Commissions agraires pendant la première année de leur fonctionnement (jusqu'au 1-er Octobre 1907). St. Petersburg: Dir. Gen. Organ. Agraire et Agr., 1908, pp. 20*).—This report deals with the new land surveys in Russia, the modification of the rural land-tenure system, and the financial aid afforded the peasantry for improving their holdings under the terms of a royal decree issued March 17, 1906, and the law of May 9, 1906.

The agricultural budget for 1908, E. MARTIN (*Bul. Soc. Agr. France, 1908, May 1, pp. 811–816*).—This is a detailed discussion of the law relating to the government expenditures in France for the different branches of agriculture for the year 1908. The law carries for agriculture the sum of 46,005,594 francs (about $9,200,000), an increase of 850,448 francs over 1907, or 1.17 per cent of the total French budget.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 10 (1908), No. 7, pp. 49–56*).—Crop acreages and conditions in the United States and foreign countries, and the value and prices of the principal agricultural products are reported to July, 1908.

Agricultural production in Russia in 1906 (*Separate from Statis. Empire Russ. 60 (1907), pp. IV+57, charts 13*).—Statistics of crop production are reported.

Agricultural statistics of Bengal for 1906–7 (*Agr. Statis. Bengal, 1906–7, pp. 68*).—Statistical data showing total acreage, classification of areas, crops, current fallows, etc., are reported.

Manual of world economics, edited by E. VON HALLE (*Weltwirtschaft, 2 (1907) pts. 1, pp. VI+368, pls. 2, figs. 8; 2, pp. VIII+284, dgms. 18; 3, pp. VI + 288*).—This publication gives a general review of the world's economic, social, and political conditions during 1906.

Part 1 contains an article by C. Ballod (pp. 64–84), which gives statistics on the production of cereals and other staple crops, meat production and consumption, and other data relating to agricultural products in the chief countries of the world.

Part 2 contains an article by W. von Altrock (pp. 5–63), which discusses the statistics of cereal and fruit production, number of live stock, dairy cooperative societies, agricultural credit societies, etc., in Germany.

Part 3 contains articles reviewing the economic and agricultural conditions in the United States, Europe, and the far east.

Bibliography of the price of cereals, J. A. P. Mackenzie and J. A. Baines (*Jour. Roy. Statis. Soc., 71 (1908), No. 1, pp. 178–206*).—This bibliography was presented by the Royal Statistical Society of London to the International Statistical Institute at the congress held at Copenhagen in August, 1907.

AGRICULTURAL EDUCATION.

Course in agriculture, S. B. McCready (*Ann. Rpt. Ontario Agr. and Expt. Union, 29 (1907), pp. 95–104*).—This is an outline of a two-year course in agriculture suitable for high schools and collegiate institutes. It includes suggestions for instruction in agriculture, physics, chemistry, botany, horticulture, agronomy, animal husbandry, dairy husbandry, poultry keeping, farm carpentry, and farm economics, items of equipment needed and their cost, and regulations to govern agricultural departments in high schools and collegiate institutes.

State facilities for viticultural instruction in Hungary, J. Wortmann (*Landw. Jahrb., 36 (1907), No. 5–6, pp. 788–792*).—An account of the work of the 27 viticultural inspectors in Hungary, the 8 secondary and elementary viticultural schools, the 4 communal viticultural schools, the Royal School for Cellar Masters at Budafok, near Budapest, and the Royal Central Viticultural Institute at Budapest.

French traveling agricultural domestic science schools, A. Ducloux (*Indus. Lait. [Paris], 33 (1908), No. 11, pp. 235–255*).—This article gives a brief history of itinerant instruction in agricultural domestic science in France, and an account of the organization, work of the staff, daily schedule, budget, and qualifications of students of these schools, results obtained in the departments of Oise, Pas-de-Calais, and Nord, and suggestions as to qualifications and preparation of teaching staff necessary to insure the success of this movement, together with the three months' course of study.

The teaching of agriculture, C. C. James (*Ann. Rpt. Ontario Agr. and Expt. Union, 29 (1907), pp. 75–94*).—The author calls attention to the failure of previous attempts at teaching agriculture in the public schools of Ontario in spite of the fact that three good text-books of agriculture have been prepared especially for these schools. He attributes this failure to the lack of rural school teachers having the training that would make them competent to handle the subject even when provided with text-books. He then outlines a new plan, which has recently been put into operation, viz, to start with 6 agricultural college graduates as teachers of agriculture in 6 of the high schools of the province. Reports are given from each of these teachers showing their work not only in the school but also among the farmers in their districts. These reports are followed by a memorandum by the author which was presented to the minister of agriculture in 1906 and which outlines their duties in considerable detail. These young men are not only teachers but local representatives of the department of agriculture, occupying positions very similar to those of departmental professors of agriculture in France.

Agriculture in public schools, A. D. DeWitt (*Cornell Countryman, 5 (1908), No. 6, pp. 187–189*).—This is a description of the 3-year course in agriculture given in the public high school at St. Louis, Mich.

Public school cookery, is it playing fair with the home and taxpayer? Mary B. Hartt (*Good Housekeeping, 46 (1908), No. 2, pp. 123–130, figs. 6*).—A discussion of instruction in cooking in the public schools as to whether it should be in the nature of practical cookery or to give a knowledge of the scientific basis of cooking, and whether or not the principles of cookery should be taught in the grades leaving the science for the high school. A comparison

is made of the fractional recipe or individual method with small amounts of materials and the group method with large amounts. The former method is favored by many. Active teachers agree that the school kitchen should not be expected to produce cooks any more than the manual training school should be expected to turn out fully equipped carpenters or machinists.

School gardening. LUCY R. LATTER (*Trop. Agr. and Mag. Ceylon Agr. Soc., 30 (1908), No. 2, pp. 155–158*).—In considering the place of school gardening in education the author states that a great deal of confusion and disappointment has resulted from the fact that people have not realized the difference between the two points of view from which gardening may be considered, viz, as a direct aim in itself and simply as a means toward a given end. "Experience proves that nature teaching or gardening should be the center point of all the other work of any school children up to at least 9 years of age, and it should certainly have a large place in the work of schools for scholars of more advanced age." The author describes the gardening work at her own school, in which the children are taken in small groups for work. It has been found that 8 or 10 children are all that one teacher can direct advantageously unless it be in such operations as weeding and watering. With 50 or 60 children the work becomes overorganized and its value is lost in drill.

School gardening at Greenville, Ohio. W. S. ROWE (*Ohio Ed. Mo., 57 (1908), No. 2, pp. 49–56, figs. 2*).—An account of the motives prompting the experiment, interest awakened in the homes, provision for ground, tools, and seed, the thoughtful planning and careful direction required, the vacation work (essentially truck gardening), the class of pupils electing the truck gardening, some problems which had to be solved, a device to keep up interest and enthusiasm, the cost of garden and its ample returns, and the economic, educational, and other results.

Arbor day—the American spring festival. W. C. LEE (*Forestry and Irrig., 14 (1908), No. 4, pp. 201–206, figs. 4*).—An account of Arbor Day observance in different States and what it has accomplished.

The farm boys' encampment. S. M. JORDAN (*Mo. Bd. Agr. Spec. Bul., 1907, Dec., pp. 21, figs. 5*).—This is an account of an encampment of farm boys on Glenview Farm, near McCurry, Mo., August 19–23, at which a corn show was held and entertainment and instruction were given. The instruction was on breeding and cultivating corn and demonstration of implements.

Proceedings of the spring meeting of Farmers' Annual Normal Institute and State Board of Agriculture. A. L. MARTIN (*Penn. Dept. Agr. Bul. 157, pp. 210, figs. 9*).—This bulletin includes the addresses and discussions at the meeting of the Pennsylvania State Board of Agriculture, Allentown, Pa., June 4, 1907. Among the addresses relating to agricultural education are the following: The Successful Farmer's Education, by W. S. Owens, and Rural Education, by A. C. True.

Bird life: Its relations to the farmer. T. H. SCHEFFER (*Industrialist, Agr. Ed. Ser., 1 (1907), No. 5, pp. 81–106, figs. 14*).—A study of bird life, in which the following phases are considered: Place of birds in the animal kingdom, their external structure and other structural features, their classification, the object of bird study, birds in their general relations to farm crops, migration, bird diaries, winter birds, some of our useful birds, birds of doubtful value, food habits, birds and the balance of power, natural enemies of birds, man as an enemy, nests and nesting, notes and colors, protecting and encouraging the birds, and how to study a bird. A list of reference material is appended.

The story of cotton. MARY C. BREEN (*Hampton Leaflets, n. ser., 4 (1908), No. 4, pp. 24, figs. 12*).—This circular is intended for the use of teachers and

includes 9 simple exercises on seed testing, depth of planting, some essentials for germination, how plants grow, disposition of surplus water in plants, effect of exclusion of air on plant growth, effect of too much water in soil, and where roots increase in length, as well as a study of the cotton plant in the school garden plat and of its products after it is picked.

Notes on drainage, E. R. JONES (*Madison, Wis., 1908, pp. 166, figs. 25*).—This is a text-book dealing with class-room, field, and laboratory exercises for students of land drainage. Preparatory to the lessons dealing strictly with drainage are a number of chapters on surveying, containing instructions concerning linear and angular measurements, subdivision of land, methods of mapping, the use of different instruments, and problems in surveying.

The lessons relating to drainage deal with moisture and its relations to the soil and methods of artificial drainage and principles governing it. Numerous exercises for practice are given.

MISCELLANEOUS.

Annual Report of Porto Rico Station, 1907 (*Porto Rico Sta. Rpt. 1907, pp. 55*).—This report contains, in addition to a summary by the director of the investigations conducted at the station, separate reports for the physiologist, horticulturist, entomologist and plant pathologist, and coffee expert, and an article on The Fermentation of Cacao and of Coffee. The experimental work reported is abstracted elsewhere in this issue.

Twenty-fourth Annual Report of Wisconsin Station, 1907 (*Wisconsin Sta. Rpt. 1907, pp. VII+137*).—This includes the organization list of the station, a report of the director on the work of the station during the year, numerous articles abstracted elsewhere in this issue, registers of licensed feeding stuffs and fertilizers and their guaranties, lists of exchanges and donations, and a financial statement for the fiscal year ended June 30, 1907.

Laws applicable to the United States Department of Agriculture (*Washington: U. S. Dept. Agr., Office Solicitor, 1908, pp. 255*).—A compilation of the provisions of law pertaining to this Department in force July 1, 1907.

The conservation of natural resources, G. PINCHOT (*U. S. Dept. Agr., Farmers' Bul. 327, pp. 12*).—An address delivered before the National Geographic Society, January 31, 1908, in which attention is directed to the necessity of immediate conservation of the natural resources. The concerted action of forestry associations, waterway associations, irrigation associations, and related bodies is suggested as a means of bringing about a new point of view on the part of the general public to lead to the adoption of a definite policy.

NOTES.

Connecticut College and Storrs Station.—G. H. Lamson, jr., instructor in geology, ornithology, entomology, and physiology in the college, has been appointed entomologist in the station. F. H. Stoneburn, formerly connected with the poultry work of the college and station, has been appointed poultryman, vice C. K. Graham, whose resignation has been previously noted.

Florida Station.—Alfred Dickenson has accepted the position of gardener, vice William Iless, whose resignation has been previously noted.

Georgia College.—The State general assembly has appropriated $105,000 for maintenance and improvements for the college of agriculture for the next biennium. It has also turned over the entire net proceeds from the oil and fertilizer taxes to the district agricultural schools. It is estimated that each school will receive $7,500 from this fund this year.

Guam Station.—In accordance with the current Federal agricultural appropriation act, authorizing the establishment of an experiment station in the Island of Guam, Dr. W. H. Evans of this Office visited the island the past summer and selected a site for the station at Agaña. The station will be conducted under the immediate supervision of this Office, with H. L. V. Costenoble as agent in charge.

Hawaii College.—B. E. Porter, assistant in animal husbandry in the Maryland College, has been elected professor of animal husbandry.

Hawaii Federal Station.—A new insectary, protected against insect pests by screens and by erection on ant-proof pillars, has been completed for use in the breeding work with injurious and beneficial insects. D. T. Fullaway has been appointed assistant entomologist in connection with the breeding work with scale insects and insects injurious to domestic animals, notably sheep maggot and horn fly.

At the urgent request of growers the station is to devote special attention to pineapple and rubber culture. With pineapples the work will include a study of the fertilizer requirements, the soil conditions which lead to yellowing, and pineapple diseases. Experimental plants covering 6 acres have been established on land furnished by two of the leading pineapple companies of the Island of Oahu, and arrangements have been made whereby a plant pathologist from the Sugar Planters' Station will cooperate in a study of pineapple diseases, the results to be published by the Federal Station.

With rubber, extensive investigations are contemplated as to the economics of the industry in the islands, the best methods of tapping, and various other points connected with the fertilization, cultivation, and care of rubber trees. The Board of Commissioners of the Bureau of Agriculture and Forestry has passed a resolution diverting, during the present fiscal year, $1,300 of its funds for the purpose, the work to be under the supervision of the station.

Hawaii Sugar Planters' Station.—C. F. Eckart, director of the division of agriculture and chemistry and business director of the station, has been given a year's leave of absence, during which Noël Deerr will act as director of the division of agriculture and chemistry and L. Lewton-Brain as business director.

The division of pathology and physiology has recently extended the scope of its work, and is investigating a serious disease of the forests of windward Maui. L. D. Larsen, a recent graduate of the Massachusetts College, has been appointed assistant pathologist in connection with this work and has entered upon his duties. W. R. Potter has been appointed illustrator, vice W. E. Chambers, who has accepted a similar appointment with this Department.

Purdue University and Station.—The school of agriculture and the station are planning a mammoth exhibit at the State fair, where a special building has been recently remodeled and equipped for the purpose by the State board of agriculture. Results of experiments will be presented by collections of grains and fruits, photographs, charts, and in similar ways. A special exhibit of stock feeds and fertilizers will be made and demonstrations in making and applying spraying mixtures, judging stock, and seed selection will be given daily. In the dairy division milk testing and separating, cream ripening, and butter making will be carried on throughout the week, and exhibits of butter, cheese, and dairy equipment will be open for inspection. Experts to answer questions and explain the work in detail will be available for each of the exhibits.

Carleton Cutler, of the Vermont Station, has been appointed assistant chemist.

Louisiana University and Stations.—Ernst A. Bessey, pathologist in charge of the Subtropical Laboratory and Gardens of this Department, has been appointed professor of botany in the university. In the Sugar Station H. P. Agee has been appointed assistant director to succeed R. E. Blouin, who has accepted the directorship of an experiment station in Argentina. Dr. Fritz Zerban has resigned as chemist to become director of the Sugar Experiment Station at Lima, Peru. R. E. Graham has been appointed assistant chemist. George Tiebout has accepted the position of assistant horticulturist of the stations and will be located at Roseland.

Massachusetts College.—The main section of the new college barn, erected in 1907 to replace a similar structure destroyed by fire, was burned to the ground on August 15, together with 13 head of live stock, about $4,000 worth of farm machinery, and $4,500 worth of hay. The cattle stable and dairy wing, separated from the main barn by a cement wall, escaped serious injury, as did also the cement silos. The total loss is estimated at about $27,000. The cause of the fire has not been determined.

W. P. B. Lockwood has been appointed assistant professor of dairying.

Michigan College and Station.—As a part of the extensive reorganization of the agricultural work, divisions of animal husbandry, dairy husbandry, soils and farm crops have been established, with H. W. Norton, A. C. Anderson, J. A. Jeffery, and the director in charge respectively of these divisions. H. J. Eustace, expert in fruit storage in the Bureau of Plant Industry of this Department, has been appointed professor of horticulture in the college and horticulturist in the station. Other recent appointments include the following assistants: M. A. Yothers, entomology; F. A. Spragg, farm crops; C. B. Collingwood, chemistry, and Misses Z. Northrop and L. M. Smith, bacteriology.

Mississippi College and Station.—Dr. J. C. Roberts, veterinarian, and Glenn W. Herrick, entomologist, have resigned, their resignations becoming effective September 15.

Missouri University and Station.—C. Stuart Gager, of the New York Botanical Gardens, has been appointed professor of botany in the university and botanist in the station. L. Haseman, assistant entomologist, and C. W. Rine, assistant animal husbandman, have resigned, the former to take up graduate work at Cornell University and the latter to engage in commercial work.

The station veterinarian is meeting with remarkable success in the inoculation of hogs against cholera, the work being done in conjunction with this

Department. The demand from farmers for the antitoxin has far exceeded the supply and efforts are under way to produce it in sufficient quantity. It is found that only limited amounts can be obtained from immune hogs, but it is hoped that other animals, possibly horses, can be utilized for the purpose.

The station correspondence with farmers is larger than ever before. This increase is ascribed to a great extent to the plan now being followed whereby each department has charge of the dissemination of its results through multigraph letters and similar means. The country newspapers of the State are also actively cooperating in the work, showing great willingness to publish notes of interest from the college and station.

Montana Station.—Edmund Burke, assistant chemist and meteorologist, has been appointed chemist, and Reuben M. Pinckney, assistant in chemistry at the University of Nebraska, has been appointed assistant chemist.

Nebraska University and Station.—C. W. Pugsley has been appointed associate professor of animal husbandry in the university and assistant in the station.

New Jersey Stations.—George G. Manning has resigned as field and greenhouse assistant and Arthur J. Farley, a graduate of the Massachusetts College in 1908, has been appointed assistant horticulturist.

Cornell University.—Arrangements have been completed by the extension department whereby a special agricultural train is to be sent out over the lines of the Erie Railroad in the near future.

North Dakota College and Station.—According to a note in *Science*, F. J. Seaver, assistant botanist, has been appointed director of laboratories in the New York Botanical Garden. A $10,000 brick seed house and root cellar and a $2,000 machinery shed 40 by 112 feet have been completed, and the contract has been let for a horticultural green house to cost $6,000.

Oklahoma College and Station.—In accordance with a new State law, representatives from the various country farmers' institutes recently met at the college for the election of a State board of agriculture and the holding of a general round-up institute. The board of agriculture, which acts as the board of regents for the college and station, is now constituted as follows: J. P. Connors (president), Canadian; J. C. Elliott (vice-president), Pauls Valley; E. White (treasurer), McLoud; R. F. Wilson, Valliant; G. T. Bryan, Perry; D. Diehl, Hobart; T. Rice, Hitchcock; R. W. Lindsay, Choteau; A. C. Cobb, Wagoner; J. W. Corley, Howe, and F. Ikard, Chickasha.

W. L. English resigned as director of the station August 24 and B. C. Pittuck has been appointed acting director. W. T. McDonald has resigned as animal husbandman in the college and station and has been succeeded by W. A. Linklater, of the Washington College and Station, as previously noted. Cornelius Beatty has been appointed chemist in the station, vice A. G. Ford resigned, and R. O. Baird has been appointed assistant chemist. The department of botany has been transferred in both the college and station from the department of entomology to that of horticulture, and an additional assistant in horiculure, L. M. Montgomery, of the Colorado College, has been appointed.

The Cotton Conference and Cotton Grading School held at the college during August was largely attended. About 300 delegates and visitors registered for the first week of the conference, and about 100 farmers, merchants, bankers, and cotton buyers were in attendance during the two weeks of the school.

Pennsylvania College and Institute of Animal Nutrition.—Frank D. Gardner, of the Bureau of Soils of this Department, has accepted the professorship of agronomy in the college and has entered upon his duties. In the Institute of Animal Nutrition, John W. Calvin, of the Kansas College has been appointed assistant, vice F. W. Christensen who has been given a year's leave of absence

for study, and D. C. Cochrane and R. C. Jones have been appointed assistants, vice F. S. Putney and W. H. McIntyre, resigned.

Porto Rico Station.—George L. Fawcett, of the Subtropical Laboratory and Garden of this Department, has been appointed assistant in plant pathology and has entered upon his duties.

Clemson College.—D. N. Barrow, who has been engaged in the South in the farmers' cooperative demonstration work of this Department, has been appointed director of the agricultural department and professor of agriculture in accordance with the recent plan of providing separate forces for the instruction and station work in that State. He will enter upon his work at once. According to a note in *Science*, Dr. C. H. Shattuck, of Washburn College, has been appointed to the chair of botany and forestry.

Tennessee University and Station.—The 1908 session of the Summer School of the South, held at the university June 15 to July 25, was extremely successful. About two thousand students, mostly teachers from Tennessee and other southern States, were enrolled. About 125 elected the agricultural work in which for the first time courses were arranged sufficient to occupy the whole time of the students. These courses were conducted throughout the session and included plant life, horticulture, animal life, animal husbandry, and agricultural education, election of four of these courses being required.

J. N. Price has resigned as dairyman and has been succeeded by F. H. Dennis. James Tyler has resigned as poultryman in the station.

Texas College and Station.—R. T. Milner, State commissioner of agriculture, has been elected president of the college to succeed H. H. Harrington, who will devote his entire attention to the directorship of the station. E. R. Kone of San Marcos has been appointed to the commissionership of agriculture, thereby becoming an ex-officio member of the board of directors. It is expected that the next legislature will establish a number of additional substations.

Virginia College and Station.—Dr. W. J. Quick has resigned as dean of the agricultural department in the college, retaining his work in animal husbandry, and has been succeeded as dean by H. L. Price, the horticulturist. Dr. Howard S. Reed of the Bureau of Soils of this Department, has assumed the duties of plant pathologist in the college and station vice Dr. Meade Ferguson, who has accepted the position of bacteriologist to the State board of health. W. D. Saunders has been appointed State dairy and food commissioner. He will retain the superintendency of the college creamery, but will be succeeded as professor of dairying in the college and dairyman in the station by W. K. Brainerd, formerly of the West Virginia University. W. L. Mallory, a 1908 graduate of the college, has been appointed assistant in animal husbandry and agronomy for work on Adams fund projects.

Washington College and Station.—Dr. H. B. Humphrey, recently connected with Leland Stanford Jr. University, has been appointed assistant professor of botany in the college and assistant botanist in the station, assuming these duties September 1. G. A. Olson, of the Wisconsin University and Station, has been appointed assistant chemist in the station, vice H. R. Watkins, whose resignation has been previously noted. W. H. Lawrence, superintendent of the Puyallup Substation, has been appointed plant pathologist in the station and will devote a considerable portion of his time to studies of plant diseases in western Washington. E. E. Elliott has resigned as agriculturist to become dean of agriculture in the University of Idaho. C. H. Goetz, a postgraduate student at the University of Michigan, has been appointed instructor in forestry.

Wyoming University and Station.—T. F. McConnell has resigned as animal husbandman to engage in commercial work and has been succeeded by A. D.

Faville of Wisconsin. Dr. O. L. Prien has assumed the duties of instructor in veterinary science in the university and veterinarian in the station. H. T. Nowell has resigned as irrigation engineer and has been succeeded by J. C. Fitterer.

Prospective Meetings of Agricultural Workers in Washington.—Arrangements have been completed whereby a number of organizations of agricultural workers will hold meetings in Washington in November. The Association of Official Agricultural Chemists will be in session from November 12–16, the Society for the Promotion of Agricultural Science on November 16, the American Association of Farmers' Institute Workers on November 16 and 17, and the Association of American Agricultural Colleges and Experiment Stations from November 17–19.

National Corn Exposition.—The second National Corn Exposition will be held at Omaha in December. As a special feature extensive educational exhibits by a number of agricultural colleges and experiment stations are contemplated, these to be of such a character as to give visitors an idea of the work carried on by these institutions.

Commission on Rural Life.—A commission has been appointed by President Roosevelt to make recommendations touching the betterment of the social, sanitary, and economic conditions of American farm life. Dean L. H. Bailey, of Cornell University, has accepted the chairmanship of the commission, the remaining members of which consist of Henry Wallace, editor of *Wallace's Farmer*, President K. L. Butterfield of the Massachusetts Agricultural College, Gifford Pinchot of the Forest Service of this Department, and Walter H. Page, editor of *World's Work*.

Agricultural High Schools in Oklahoma.—In accordance with the law passed by the first State legislature of Oklahoma providing for the establishment and maintenance of agricultural schools of secondary grade in each supreme court district of the State, 2 schools have been established this year, one known as the Murray State School of Agriculture, located at Tishomingo in Johnston County and the other at Warner in Muskogee County. These State schools will offer no courses of instruction other than industrial courses. Each school has an appropriation for the first year of $20,000 for buildings and $12,000 for maintenance. One-fourth of the maintenance fund for each school must be expended in developing agricultural experiments in the field, barn, orchard, shop, and garden. The Tishomingo School has 120 acres of land and the Warner School, 160 acres.

These and the other similar schools in the State will be under the supervision of the State Commission of Agricultural and Industrial Education, which consists of the State superintendent of public instruction, E. D. Cameron, the president of the State Board of Agriculture, J. P. Connors, and the president of the Agricultural and Mechanical College, J. H. Connell. The Murray School will open this fall and will be in session 8 months.

Smith's Agricultural School.—Plans have been adopted for the main building of this school, which is to be opened during the fall. A two-story red brick structure, with limestone trimmings, 200 by 69 ft., is contemplated, comprising offices and administration rooms, an auditorium, an arena for athletic sports, physical and chemical laboratories, class rooms, etc.

Farmers' Summer School for Negroes.—Clark University, Atlanta, Ga., held from August 3 to 8, a well-attended farmers' summer school especially for the education of the negroes. The instruction consisted of lectures by agricultural experts in the South on the following topics: Farm Garden and Orchards, The Plow—its Care and Adjustment, Fall and Winter Plowing, The Best System of Renting Farm Lands, Management of Farm Labor, Selection of Seed Cotton

and Seed Corn for Planting, Care of the Dairy Herd, Improvement of the Cotton Plant, How to Extend the Rural School Term, Harvesting Corn and Cotton, How to Keep Boys on the Farm, Keeping the Farm Neat and Attractive, Poultry Raising, Insects Injurious to Farm Crops, etc.

Agricultural Education.—The Iowa State Fair and Exposition offered prizes amounting to $500 to the boys and girls of Iowa taking part in contests at the fair August 22. The boys competed for first, second, and third prizes of $200, $100, and $25, respectively, in a corn-judging contest, and the girls for prizes of $100, $50, and $25 for preparing food products and giving reasons for their methods of work.

Prof. W. C. Palmer, who has been at the head of the department of agriculture of the Winona Agricultural Institute, Winona Lake, Ind., has been made dean. He is enlarging the work of the Institute by the addition of new courses and new members to the faculty. The practical 2-year course is being improved, and an advanced 4-year course leading to a degree and a normal course have been added. The courses are modeled after that of the Minnesota School of Agriculture.

According to *Journal d'Agriculture Tropicale* of April 30, 1908, there has been established at Havre, France, by a number of merchants and members of the cotton association of that city a Practical Colonial School, which is designed as a training school for artisans and others in the agricultural, industrial, and commercial exploitation of the French colonies. Lecturers have been chosen from among specialists in colonial affairs who will give instruction in different cultures, particularly that of cotton, and in colonial hygiene and other affairs pertaining to tropical countries. It is expected that about three years will be required for the proper coordination of the different departments of the institution. At present it consists of a collection of cotton ginning and compressing machines of different types, a conference hall, a library of colonial publications, and a colonial museum.

Miscellaneous.—Dr. H. D. House, formerly of the Clemson College and Station, has been appointed associate director in the Biltmore Forest School.

H. H. Cousins has been appointed director of agriculture and island chemist in Jamaica, vice William Fawcett, resigned.

A new fellowship, the Monro Fellowship, has been established at Cambridge, to which T. B. Wood, Drapers' professor of agriculture, has been elected.

W. W. Rawson, prominent as seedsman, market gardener, and writer on horticultural topics, died August 9, at Arlington, Mass., at the age of 61 years.

H. D. Everett, superintendent of the division of forest administration of the Philippine Bureau of Forestry, was murdered by natives in the island of Negros during the early summer. He was 28 years of age.

EXPERIMENT STATION RECORD.

VOL. XX. OCTOBER, 1908. No. 2.

With the expansion of experimental inquiries in agriculture in the United States there is growing interest in investigations dealing with the special needs of particular regions. This is leading to appropriations by State legislatures for substations. To be most effective these substations should be organized to work on definite problems indicated by their local environment. This is especially true in regions where the natural conditions require that agriculture must have a peculiar organization to be successful. This may be illustrated by the conditions existing in the regions in this country where irrigation or drainage is a fundamental requisite of agriculture.

As an example of the organization of experiment stations with reference to peculiar regional conditions, the work being done by the German Government with a view to the reclamation of moor lands is interesting, since it shows a well-directed specialization of experimental inquiries. The attention of our readers is therefore called to some observations on the moor experiment stations of Germany made by Mr. C. G. Elliott, chief of Drainage Investigations of this Office, as the result of a recent visit to these institutions in connection with a study of drainage conditions in Europe.

The moor lands of Germany have long been celebrated in poet's song and upon painted canvas, yet in their natural state they are worthless for growing food plants, a barrier to travel between different sections of the Empire, and forbidding to the prospective home maker. There are more than 5,000,000 acres of these lands, most of them in Government ownership, which yield no revenue and support but few people. Existing as they do in this land of intensive cultivation, and in full view of people of acknowledged industry and scientific attainments, it is a matter of surprise that no greater progress has been made in utilizing them. As an inducement to their settlement, the Government at one time offered immunity from military service to such as would make homes upon the Government moors. Notwithstanding the efforts so far made to reclaim and utilize this vast area of waste land, only about 15,000 acres have been converted into productive fields.

The upland moors are covered with the *Calluna vulgaris*, ordinarily called heather, which, when in bloom, has the appearance of red clover. The plant is an evergreen shrub, growing about a foot high, with foliage like our juniper or red cedar. Scattering birch trees and a few deciduous shrubs, in addition to the attractive bloom of the heather, make a pleasing scene and one which well merits the notice of the artist. The moors are immense beds of decayed mosses, among which the sphagnum genus largely predominates, and are from 6 to 15 feet deep. Underneath them, in some localities, is a stratum of sand, in others clay, and in still others lime rock. The several layers, which are easily traced when a section of the bed is made, indicate that different cycles of climatic conditions have attended the formation of this huge vegetable sponge. The entire mass is filled with water, and is impassable for large animals and nearly so for men. The more solid parts are dug out in brick form, dried in the open air, and used for fuel. The top 4 feet in depth, in many of the moors in northern Germany, is too light and spongy for fuel. When dry this is passed through a machine with two rollers carrying hooks which pull the material to pieces, after which it is baled and shipped abroad to be used as bedding for live stock in barns in the place of straw, and for the manufacture of mattresses, and for other similar purposes.

Some progress in utilizing this land for agriculture has been made in the more favorable localities by individuals, who have shown enterprise and untiring industry. The lands lying in the valley of the Salzach River, near Salzburg, Austria, have been highly productive many years. These moors lie upon limestone, differing in that respect from those in northern Germany. Grasses grow exceedingly thick upon this soil, three good crops being gathered each season. Here fruits are grown to some extent, as well as all the cereal crops. The drainage is accomplished by open ditches, often as deep as 7 feet, placed parallel to each other about 70 feet apart. No lime is required in preparing the raw land for crops, but annual dressings of fertilizers containing potash and phosphoric acid, supplemented by barnyard manure, are a necessary part of their management.

In late years the Government has established experiment stations, having for their sole object the reclamation of moor lands. Notable among them are those at Hude and Ottersberg, in northern Germany, under the direction of Dr. Tacke; in the south, the principal one of which is at Bernau, under the direction of Dr. Baumann; and those in the interior, under the direction of Dr. Schrieber.

A cursory view of some portions of the moors which have been reclaimed in the vicinity of Hude reveals a most unique kind of agriculture. The highway, bordered by birch trees, is built upon the original surface of the land, while upon either side, and 8 feet below, are little meadows of grass, or fields of potatoes growing upon terraces

arranged at various heights, which have been formed in the process of removing the peat for commercial purposes. Large ditches, affording outlets for the drainage of the moors, have been excavated to the layer of sand, and lead directly to the river. It has been learned that any part of the turf can be removed and the place from which it was taken, when drained and treated with suitable fertilizer, can be made productive, that part lying 8 feet below the surface and near the sand base being as valuable as the original surface. The spongy and soft nature of the land requires special methods of management. The field lanes, as well as the public roads, must be well covered with sand to prevent the wheels of vehicles from sinking too deeply into the muck. The horses must have broad footpads clamped to their hoofs whenever they are driven upon the fields. A large part of the cultivation and preparation of the soil for the crops must be performed by hand labor. The farm buildings settle unevenly and soon present a sorry appearance unless their foundations are sunk to the underlying sand or clay.

As a sequence of the experimental work at the Government moor culture stations a great impetus has been given to the development of these lands, which for centuries have lain idle. The results obtained in the several parts of the Empire, and the assistance given to moor farmers, have imparted a confidence in the future of these lands which bids fair to gradually bring them into the agricultural domain. Particular value attaches to the work of the station at Bernau, in Bavaria, bordering the Chiem See, at the foot of the Tyrol Mountains, where 5,000 acres of moor land lies in sight of the King's castle, a mile distant, since it has brought into prominent notice some of the essentials of successful moor culture.

As may be readily inferred, the first step in reclaiming these moor lands is drainage. The land is virtually a bog with water lying at the surface, and held throughout most tenaciously by the vegetable spongy material of which the moor is composed. The usual practice among farmers is to dig ditches 2 feet deep and 45 feet apart, dividing the land into narrow strips which must always thereafter be cultivated as separate fields. The station has shown that the ditches may be made 65 feet apart and 3 feet 8 inches deep, in which drain tile may be placed after the ditches have lain open for two or three months. The ditches are then filled and level culture is practiced, resulting in great economy of labor and in the saving of about one-fortieth of the surface of the land, which in the ordinary method of draining would be occupied by open ditches. It was formerly held by those well versed in moor culture that drain tiles would not remain in alignment because of the continual settling of the land which follows the removal of the water and subsequent cultivation. A careful record of the position of the water table of the drained moors shows

that the earth is always saturated at the level of the drains and that the settling of the earth is limited to that portion which lies above them. Clay tiles 2 inches in diameter are used for all laterals, which are usually planned so as to be not more than 800 feet long. A successful method of measuring the volume of flow from the drains and of determining the position of the water table of the soil between them, and representing it above ground to the eye, has been put in operation at the station. The growing season in this locality is short and the winter long and severe, so that one summer season is required to effect the drainage of the land. Hand labor must be relied upon in all the construction, and also largely in removing the native vegetation previous to seeding the ground.

The proper control of the water content of the soil is considered essential. At the Bernau station good drainage is secured and sufficient moisture conserved by drains placed 3 feet 4 inches to 3 feet 8 inches deep. Rains occur almost every week. The climate is cool, so that evaporation from the land is small. In northern Germany, however, where the strata underlying the turf are sand, somewhat facilitating the natural drainage, stops are sometimes placed in the outlet ditches for the purpose of holding the water within 2 feet of the surface. A considerable portion of this turf is of a less compact character than that previously described. In general a depth of 1 meter (or 39 inches) and lines laid 20 meters (or 65 feet) apart are found to give the best results in moor land.

The cost of draining, even with labor as cheap as it is in that country, is about $35 an acre, and the cost of preparing the land for the first crop is $10 more, making the expense of draining and preparing land for the first crop about $45 an acre. Before improvement the land has a value of about $20 an acre, but after being reclaimed and prepared for the production of crops it is worth $200 an acre. It is reported at Bernau that the produce of the drained land nets $13 per acre annually.

The director of the Bernau station has made the following offer to owners of moor land adjoining the station farm: The Government will drain the land and turn it over to the owners at the end of three years, well seeded to grass, asking only the use of the land during that period and $8 an acre additional to be paid by the owner at the time the land is returned. Thus the owner will give $8 an acre and the use of the land for three years for the reclamation of his moor. This shows the financial side of the question quite clearly and indicates that the owners of these lands may safely undertake their reclamation.

Drainage, though the first essential, is by no means the only requirement of these lands. Those having a sandy substratum require a liberal treatment of lime and also of fertilizers containing potash and phosphoric acid to fit them for producing the first crop. The

latter fertilizers must be applied to the land regularly each year, incurring an annual cost of from $3.50 to $4 an acre.

Another result of these developments is that the speculative value of moor lands has advanced quite materially in nearly all localities. With good drainage the lands may be grazed profitably, though some care is required to keep intact the surface of those portions used for pasture. Meadow grasses, clover, oats, rye, potatoes, beets, and other root crops are grown successfully in the fields, and flowers and vegetables in the garden. It may be said, however, that much remains to be learned regarding the proper fertilization of the land for the economic production of staple crops. The Government is prosecuting this part of the investigation with great care and has attained a reasonable measure of success.

Turning to the moor lands of America, it may be remarked that they are quite different from those in Germany in several important particulars. They are not usually as deep as 16 feet, and many of them have their origin in decayed sedges and grasses, the resulting turf resting upon clay or upon sand only 4 or 5 feet below the surface. The sphagnum moss lands in the north are less compact than the German lands of that class, being apparently of more recent geological formation than those of Europe. Their characteristics, as far as drainage and natural fertility are concerned, are not far different, judging from the few results so far attained in this country. The work on German moors has demonstrated the practicability of making them profitably productive under conditions which exist there, namely, cheap labor, all arable land occupied, and a constant demand for staple crops at good prices. We are approaching these conditions in America, but are still quite distant from such as prevail in Germany. We are beginning, however, to look into the possibilities of our own moor lands. That they are less promising for agriculture than the alluvial swamp and wild lands which we are accustomed to reclaim is acknowledged, yet considering the attention which is now being directed to that portion of our domain, they merit careful examination and experimental treatment.

The acquisition by this country of Hawaii, Porto Rico, and the Philippines has brought to the American people a number of agricultural problems that are pressing for solution. In the past these countries have produced in important amount but one or at most a few crops. In Hawaii sugar, in Porto Rico sugar and coffee, and in the Philippines tobacco and Manila hemp have been the most important agricultural products. Many minor crops are grown, but of as important a crop as rice not enough is produced to meet the requirements and large quantities must be regularly imported.

This is a direct result of the system of agriculture that has been developed in those countries, that of the large holder, either an

individual or a corporation, who employs a large number of peon or contract laborers. In most instances the estate is under the direction of a manager, whose desire is to secure a maximum yield with a minimum outlay. In many cases this has resulted in the continuance of antiquated methods and finally in the utter impoverishment of the soil. There have been some exceptions to this rule, notably in Hawaii, where the methods followed on some of the sugar plantations can be cited as models for the tropical world.

Since these insular regions have become a part of the United States, efforts have been made to develop their agriculture upon more rational lines. In 1901 agricultural experiment stations were established under the direction of the Office of Experiment Stations in Hawaii and in Porto Rico, and a system of agricultural stations is provided for by the local Government in the Philippines. Congress at its last session made an appropriation for the establishment of a station in Guam, and some preliminary work has already been begun on that island. At all of these stations the fundamental idea has been the diversification of agriculture. The single-crop system has in the past been a highly remunerative one to the employer, but it has not contributed very much to the general welfare of the community. It tends to centralization of wealth and power, and the individual ceases to be much of a factor in the economic development of the country as a whole. At all of the experiment stations attempts are being made not only to improve the present agricultural practices, but to introduce new crops and industries. In doing this it is believed that not only will the producing capacity of the countries be increased, but that many small holdings will be developed and made profitable and the islands filled with a more enlightened and contented population.

In the establishment of these stations and the introduction of new crops and improved methods of cultivation, many unexpected difficulties have arisen. In the first place, it has been very difficult to secure and retain qualified men in these new and in many ways strange lands. Naturally the agricultural and other institutions on the mainland were drawn upon to supply the personnel of the new stations, but none of our institutions have courses that are especially adapted to the needs of an investigator in the Tropics. The best that can be done under the circumstances is to get men with good general training along the lines of their various specialties, and allow them sufficient time to become adjusted to their new surroundings. Conditions of living, methods of agricultural practice, kinds of crops, etc., are so at variance with those upon the mainland that some time is required to adapt the old theories to new and unfamiliar conditions.

Under the influence of tropical climates, many factors are wanting that are common in temperate zones. The influence of frost, prolonged hibernation, resting periods, etc., are absent, and in their stead

we find continual growing periods, varied by more or less pronounced dry and rainy seasons. Soils do not react as is often taught, fertilizer requirements vary, insect and fungus pests never cease their depredations, weeds are a greater pest than in temperate climates where annuals are limited in the number of generations within a season and where frost checks for a time the growth of perennials, many and often strange diseases affect farm animals—all these go to perplex the investigator in the Tropics.

Many persons going into tropical regions have made the mistake of attempting radical changes in the methods of agricultural practice. Often the methods in vogue are the result of centuries of unconscious experimentation on the part of the agriculturists. Some things that appear very simple and easy of demonstration fail when put to the test. As an example, it was thought desirable to get away from the oriental method of rice growing that involves so much hand labor in transplanting the crop, and to substitute machinery by which the seed grain was drilled where the crop was to grow. Experiments carried on in Hawaii and in the Philippines have shown that under the existing conditions the oriental method gives the best results. Not only were larger yields secured from transplanted rice, but the cost of production was decidedly less when the added labor of draining the fields, extra amount of seed, cost of machinery, etc., were considered.

A rather discouraging feature of the work in the Tropics is the slowness with which demonstrated results are taken up and applied. For the most part the constituency of the stations are unappreciative and conservative in the extreme. New crops and unusual methods appeal to but a very few individuals, hence the progress noted is not rapid. But, for the time they have been established, the stations have more than met the expectations of those fully acquainted with their organization, aims, and resources, and they have about completed their period of pioneering and are entering upon an era of great usefulness.

Congress at its last session appropriated $5,000 for the establishment of an agricultural experiment station on the Island of Guam. During the past summer Dr. W. H. Evans of this Office visited the island and made preliminary arrangements for opening the station and starting experimental work on the improvement of the agriculture as now practiced.

The Island of Guam is a fertile island of nearly 300 square miles, situated 1,200 miles east of the Philippine Islands, and was acquired as a naval and cable station. Formerly most of the 10,000 or 12,000 people inhabiting the island were engaged in agricultural pursuits. For various reasons, some of which were economic, others agricultural, many cultivators left their plantations and accepted other

employment, until now there is not sufficient food produced to properly sustain the inhabitants. Rice and other foodstuffs are imported from Japan. The internal development work can not be continued on the same scale as formerly, and something must be done to get the people back to their farms. Attempts will be made to introduce new methods of cultivation, new varieties of standard tropical crops, and improved live stock, and to take up breeding and selection in connection with plants and animals. As rapidly as promising material is secured in quantity, the surplus will be distributed for the benefit of the farmers.

While the island is volcanic in origin, the hills are low, none of them exceeding 1,500 feet in elevation, and at least 65 per cent of the land is believed to be capable of cultivation. The remainder is nearly all forested with valuable timber or could be reforested at comparatively little expense. The rainfall of the island averages nearly 100 inches per annum, and while most of it falls during July to November, the so-called rainy season, there are sufficient showers during the other months to permit of crop growing without irrigation. There are now some attempts at growing corn, rice, coffee, cacao, and sugar cane, with extensive plantings of bananas, cocoanut, and breadfruit trees. In a smaller way, some beans, tobacco, sweet potatoes, yams, etc., are grown and it is with these crops that the first work will be done. Considerable introductory work had already been carried on in cooperation with the Hawaii Station, and this will be continued until the best of the agricultural and horticultural products of that Territory are represented in Guam.

There appears to be a woeful lack of cultivated grasses and of pastures, except in the savannas, which are covered with coarse grass that is not palatable to stock except for a short time. Already some of the varieties of grass that have proved especially adapted to the tropical regions of Hawaii and the Philippines have been sent to Guam, and others will be added as fast as possible. The introduction of leguminous plants in cropping will undoubtedly prove of benefit not only for the forage they will produce, but for their renovating power upon lands that have become impoverished by a long-continued cropping without adequate preparation of the soil.

For several years a pest of the cocoanut trees seemed to threaten the most important industry of the island. It is a kind of mealy bug that attacks the young plants within the leaf sheath, and when present in great numbers often destroys the plant. This was thought to be one of the first problems needing attention, but there appears to be evidence that it is not gaining in importance and that either through parasitism or some other cause its threatened invasion is at least temporarily checked. However, studies have been begun upon the insect, and should it again appear in abundance means for its control will probably be at hand.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Joint recommendations of the physiological and biochemical committees on protein nomenclature (*Science, n. ser., 27 (1908), No. 692, pp. 554–556*).—The recommendations adopted are (1) that the word "proteid" be abandoned; (2) that the word "protein" shall be used to designate "that group of substances which consists, so far as at present is known, essentially of combinations of α-amino acids and their derivatives, e. g., α-aminoacetic acid or glycocoll; α-amino propionic acid or alanin; phenyl-α-amino propionic acid or phenylalanin; guanidin-amino valerianic acid or arginin, etc., and are therefore essentially polypeptids;" and (3) that the following terms be used to designate the various groups of proteins: Simple proteins—that is, protein substances which yield only α-amino acids or their derivatives on hydrolysis; conjugated proteins—that is, substances which contain the protein molecule united to some other molecule or molecules otherwise than as a salt; and derived proteins.

The simple proteins would include albumins, globulins, glutelins, alcohol-soluble proteins, albuminoids, histones, and protamins. The conjugated proteins would include nucleoproteins, glycoproteins, phosphoproteins, hemoglobins, and lecithoproteins. The derived proteins would include primary protein derivatives and secondary protein derivatives. In the former group proteans, metaproteins, and coagulated proteins are included and in the latter proteoses, peptones, and peptids.

A suggestion for a new unit of energy, H. P. Armsby (*Proc. Soc. Prom. Agr. Sci., 28 (1907), pp. 164–167*).—The author's proposition for a new unit of energy has been noted from another publication (E. S. R., 19, p. 704).

A supposedly new compound from wheat oil, R. A. Gortner (*Jour. Amer. Chem. Soc., 30 (1908), No. 4, p. 617*).—From wheat oil the author obtained crystals which on recrystallization showed a melting point of 96.5°. The compound, he states, contained nitrogen, but the work was discontinued before its character was determined.

Physical and chemical properties of the fat of the common chestnut, R. Paladino (*Rend. Accad. Sci. Fis. e Mat. Napoli, 3. ser., 13 (1907), pp. 89–93; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 541, II, p. 905*).—Chestnut fat was found to consist of an oily and a solid portion and the physical and other characteristics of the two sorts of fat were studied.

The rotatory power of alcoholic extracts of cereal proteids, Lindet and L. Ammann (*Ann. Inst. Nat. Agron., 2. ser., 6 (1907), No. 2, pp. 233–242*).—The specific rotatory power of proteids from wheat, barley, rye, and maize was measured. According to the author, this property of cereal proteids varies with the concentration of the alcoholic extract. See also a previous note (E. S. R., 19, p. 808).

The relation between refraction and iodin value in pork fat and the non-volatile fatty acids insoluble in water, G. Halfpaap (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 2, pp. 65–72*).—Variations in the iodin value

of fats with the same index of refraction, according to the author's investigations, are due to an abnormally high refraction value. This value is not dependent upon free oxy-acids but is due, the author considers, either to polymerization—that is, lactone formation—or, very probably, to the conversion of normal oleic acid radicals into iso-oleic acid.

Preparing odorless fatty acids from fish oil, A. SANDBERG (*Corps Gras Indus., 32 (1906), pp. 355, 356; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 4, pp. 244, 245*).—In the method described crude fatty acids from fish oil are treated with 20 per cent sulphuric acid at 25 to 40°, being stirred constantly, then allowed to remain for a few hours, washed with water, and distilled. Thus purified the fatty acids solidify at 25 to 36°. According to the author, the disagreeable odor of fish oil depends upon the presence of proteid cleavage products. The purified oil, it is stated, has many technical uses.

Hydrolyzing and oxidizing bacteria of fat, E. DE KRUYFF (*Bul. Dépt. Agr. Indes Néerland., 1907, No. 9, pp. 13, pls. 2*).—Bacteria which induce hydrolysis and oxidation in fat are studied and described and the amount of decomposition which they induce measured.

Contribution to the study of the composition of starch grains, Mme. Z. GATIN-GRUZEWSKA (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 4, pp. 178, 179*).—According to the author's conclusions, amylose constitutes the soluble material in the starch grain and amylopectin the envelope of the starch grain.

Concerning the composition of the starch grain, Mme. Z. GATIN-GRUZEWSKA (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 10, pp. 540–545*).—A contribution to the structure and composition of the starch grain followed by a note by L. Maquenne.

Note on vegetable phosphatids, II, E. WINTERSTEIN and O. HIESTAND (*Ztschr. Physiol. Chem., 54 (1908), No. 4, pp. 288–330*).—Cereals, lupines, vetch, and potatoes were among the materials included in this investigation.

According to the author, different vegetable products contain substances extractable with alcohol and ether which yield carbohydrates on cleavage with acid and for which the name "phosphatid" is proposed. The material obtained from *Pinus cembra* seed, however, was an exception and did not contain carbohydrate. The amount of reducing substance obtained varied greatly in the case of different materials, the phosphatid of a sample of *Triticum vulgare* yielding 16 per cent and a sample from *Lupinus albus* 13 per cent, while only 1 per cent was obtained from material extracted from *L. luteus*.

From the cereal phosphatid pure galactose was obtained and the presence of δ-glucose demonstrated. As yet it is not possible to determine whether these hexoses are present as such or as disaccharids or polysaccharids.

From experimental evidence, the conclusion seems warranted that the phosphatids of wheat contain other nitrogenous components in addition to cholin and it is not impossible that they also contain unknown nitrogen-free material.

Observations on the formation of aldehyde or ketone in acetic fermentation, K. FARNSTEINER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 6, pp. 321–326*).—A study of the volatile reducing bodies of vinegar.

The action of anilin colors on diastase and pepsin, S. SATO (*Jour. Jap. Pharm. Soc., 1907; Pharm. Ztg., 52 (1907), p. 1022; abs. in Jour. Pharm. et Chim., 6. ser., 27 (1908), No. 5, p. 246*).—The anilin colors studied stopped the action of diastase and pepsin.

Coloring matter in apple juice, P. KULISCH (*Ber. Landw. Vers. Stat. Colmar, 1904–1906, pp. 79, 80; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 2, p. 104*).—According to the author, natural apple juice regularly contains a yellow coloring matter which dyes woolen well. The bearing of this fact

upon the analysis of lemonade goods containing apple juice is discussed with special reference to the detection of added coloring matter.

The determination of carbon, I. Pouget and D. Chouchak (*Bul. Soc. Chim. France, 4. ser., 3 (1908), No. 2, pp. 75–80; abs. in Chem. Abs., 2 (1908), No. 8, p. 1105; Analyst, 33 (1908), No. 385, p. 142*).—In the method described carbon is determined in soils by combustion with lead chromate and potassium bichromate, the carbon dioxid and nitrogen evolved being collected in a gas holder over mercury upon which floats a measured quantity of one hundredth-normal barium hydrate, the barium hydrate being finally titrated with one hundredth-normal sulphuric acid.

Determination of phosphoric acid, W. Pawlenko (*Vyestnik Sakh. Promuish., 1906, No. 37, p. 417; abs. in Centbl. Zuckerindus., 16 (1908), No. 21, p. 582*).—Comparative tests are reported which indicate that alkaline magnesia mixture gives as accurate results as the neutral mixture recommended by Järvinen.

Alkalimetric estimation of phosphoric acid by Neumann's method, J. P. Gregersen (*Ztschr. Physiol. Chem., 53 (1907), No. 6, pp. 453–463; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 543, II, p. 64; Ztschr. Angew. Chem., 21 (1908), No. 11, p. 498*).—As a result of his investigations the author prescribes the following precautions as necessary to the best results with the Neumann method: In the destruction of the organic matter and the incineration of the material use 20 cc. of Neumann's acid mixture, adding from time to time during the process small amounts of concentrated nitric acid instead of the mixed acids. In precipitation use 250 cc. of liquid containing 15 per cent of ammonium nitrate, heat to 70 to 80° C., and add a slight excess of 10 per cent ammonium molybdate. In the final titration add a slight excess of standard acid, boil to remove carbon dioxid, and titrate back with one-half normal sodium hydroxid.

Determination of free sulphuric acid in superphosphates, A. Pomaski (*Vyestnik Sakh. Promuish., 1907, No. 50, p. 765; abs. in Centbl. Zuckerindus., 16 (1908), No. 20, p. 552*).—The method is in brief as follows: Shake 30 to 50 gm. of a finely ground superphosphate with 150 cc. of water-free ethyl alcohol for 15 to 20 minutes at room temperature with exclusion of air. Neutralize an aliquot of the solution thus obtained with sodium hydroxid and evaporate to dryness. Take up the residue in a little water, strongly acidify with hydrochloric acid, and determine sulphuric acid with barium chlorid in the usual way.

Industrialization of analysis. Methods and apparatus used in the determination of nitrogen and phosphoric acid in fertilizers, H. Rousset (*Rev. Gén. Chim., 10 (1907), No. 6, pp. 105–113; abs. in Chem. Abs., 1 (1907), No. 12, p. 1601*).—It is stated that the industrial chemist is as a rule interested mainly in matters of routine and desires chiefly knowledge of apparatus and methods. This article gives a general account of apparatus and methods used at the Aisne agricultural station in a large number of routine determinations of nitrogen and phosphoric acid in fertilizers.

On the determination of hardness, as well as free, partly combined, and combined carbon dioxid in waters, H. Noll (*Ztschr. Angew. Chem., 21 (1908), No. 14, pp. 640, 641; abs. in Chem. Abs., 2 (1908), No. 14, p. 1942*).—A comparison is reported of Lunge's method of determining combined carbon dioxid in water by titrating with hydrochloric acid in the cold, using methyl orange as an indicator, with the method in which a given volume of water is boiled with a measured amount of standard sulphuric acid and the carbon dioxid calculated from the amount of unused sulphuric acid. The Lunge method was found to give accurate results for the combined carbon dioxid, while the other method gave results nearly a third too low.

Practical treatise on the analysis of foods, E. Gérard and A. Bonn (*Traité Pratique d'Analyse des Denrées Alimentaires. Paris, 1908, pp. 604, figs. 42; rev. in Brit. Med. Jour., 1908, No. 2458, p. 327*).—Though this handbook of food inspection has been prepared with special reference to the requirements of French analysts, it contains data which will prove useful in other countries. Each chapter concludes with extracts from laws and government regulations regarding the purity of foods dealt with, etc., and French official analytical methods are given in the appendix.

Analytical methods and miscellaneous communications regarding food materials, etc. (*Rev. Internat. Falsif., 21 (1908), No. 1, pp. 4–24, fig. 1*).—A number of papers including among others the following: Vinegar and the Law, by L. Mathieu; Montpellier Milk Standards, by Bertin-Sans, Defrance, and H. Imbert; A Simple Method for Determining Raw and Cooked Milk, by L. Gaucher; and the Dangers of Employing Arsenious Insecticides in Agriculture from the Standpoint of Public Hygiene, by P. Cazeneuve.

Micrographical examination of meat powder, C. N. Peltrisot (*Bul. Sci. Pharmacol., 14 (1907), pp. 19–33; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 4, p. 238*).—Methods of judging of the character and quality of meat powder are described which involve the use of the microscope and various stains.

The estimation of boric acid in liquid eggs, A. E. Parkes (*Brit. Food Jour., 10 (1908), No. 110, pp. 20, 21*).—According to the author, the usual methods employed for the estimation of boric acid were not altogether satisfactory when applied to liquid eggs, and better results may be obtained if protein is first precipitated with alcohol, tannin, or mercurous nitrate, of which the last mentioned is preferable.

The presence of boric acid may then be qualitatively determined by testing with sulphurous acid and turmeric paper. Boric acid is estimated quantitatively with standard sodium hydrate in the presence of phenolphthalein after the separation of protein and phosphates.

The author quotes the results obtained by his method in comparison with other methods and when known quantities of boric acid were used.

The Burstert method of determining fat in cheese, E. Mühlbach (*Milchw. Zentbl., 4 (1908), No. 5, pp. 193–237, figs. 2*).—According to this method cheese is dissolved in an acid solution and the fat is separated centrifugally. The proportion of fat is indicated by the divisions of the scale on the neck of the special bottle used.

Method for the complete analysis of vegetable products, J. M. Albahary (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 7, pp. 336–338*).—The scheme for proximate analysis of vegetable products which the author outlines is more detailed than that usually followed in food analysis, chiefly owing to the determination of a number of the individual constituents making up the nitrogen-free extract group.

The estimation of starch in maize, A. Frank-Kamenetzky (*Chem. Ztg., 32 (1908), Nos. 14, pp. 157–159; 15, pp. 175, 176*).—According to the author, the starch value of maize bears a direct relation to the amount of extract when the latter factor is determined under controlled conditions. In the method which he outlines, a sample of finely ground meal is inverted with diastase, high pressure being avoided, properly diluted, filtered, and the amount of extract material determined with an immersion refractometer or by determining the specific gravity with a pycnometer. The method of calculating the results, the corrections which must be introduced, and similar topics are discussed and the results of a number of determinations reported. The author believes that his method is applicable to other sorts of grain as well as to maize.

Official analysis of Russian high-grade sugars (*Sugar Beet, 29 (1908), No. 4, pp. 320, 321*).—Changes in the method of analysis of standard white sugars adopted by the Imperial Technical Committee in Russia are summarized.

Concerning the Marpmann reaction for distinguishing between separator honey and honey obtained by heating the comb, Utz (*Ztschr. Öffentl. Chem., 14 (1908), No. 2, pp. 21–28*).—The reaction under consideration depends upon the detection of the ferment present in raw honey which is destroyed when it is heated over 50°. Hydrogen peroxid is used as a reagent and *p*-phenylendiamin or other material as an indicator. Methods of manipulation and related topics are discussed and the results of an examination of a large number of samples of German and foreign honeys are reported.

The detection of cherry juice in raspberry juice, Jonscher (*Ztschr. Öffentl. Chem., 14 (1908), No. 2, pp. 29, 30*).—The author criticises the lead-acetate method for the detection of cherry juice, particularly in the case of raspberry juice which has undergone fermentation, and states that he proposes to study this question.

Examination of white wine colored with parched chicory, Popescu (*Ann. Chim. Analyt., 13 (1908), No. 3, p. 101*).—According to the author's investigations, parched chicory coloring matter is insoluble in ether but is extracted by amyl alcohol, which is not the case with the coloring matter of the untreated white wine. Fresh albumin completely precipitates the natural coloring matter of wine, the filtrate being uncolored with natural wine and yellow if chicory has been used. Other characteristic differences are also pointed out.

Ester estimation in wine, G. Austerweil and P. Pacottet (*Chem. Ztg., 32 (1908), No. 10, pp. 112, 113, fig. 1*).—Apparatus is described which, according to the author, facilitates the determination of esters in wines.

Lactic acid in wine, G. Paris (*Staz. Sper. Agr. Ital., 40 (1907), No. 8–12, pp. 689–720, figs. 3*).—A comparison of the author's method with other methods for estimating lactic acid in wine.

The precipitation method for the estimation of oils in flavoring extracts and pharmaceutical preparations, C. D. Howard (*Jour. Amer. Chem. Soc., 30 (1908), No. 4, pp. 608–611*).—The precipitation method, according to the author, affords a direct and valuable check on polarimetric results in addition to providing the material for a refractometric examination. The results which he presents were obtained with solutions of different strength and also with commercial extracts.

The quantitative estimation of total sulphur in urine, H. Schulz (*Arch. Physiol. [Pflüger], 121 (1907), No. 1–2, pp. 114–116*).—In the method described organic matter in the urine is destroyed with fuming nitric acid and the sulphur eventually precipitated as barium sulphate. As shown by duplicate tests, the method gives satisfactory results.

The methods of analysis of raw rubber, D. Spence (*Liverpool Univ., Inst. Com. Research Trop. Quart. Jour., 2 (1907), No. 5, pp. 91–104*).—The author discusses the need of a uniform method of analysis of rubber, and describes a method which in his experience has proved satisfactory.

Miscellaneous analysis, B. L. Hartwell (*Rhode Island Sta. Rpt. 1907, pp. 295–298*).—More or less complete analytical data are given regarding various fertilizer substances, poultry grit, malt sprouts, and materials used in a poultry feeding experiment, and the moisture, nitrogen, phosphoric acid, and potassium oxid content of several samples of hay.

Modification of the Soxhlet extractor, H. C. Wood, Jr. (*Amer. Jour. Pharm., 80 (1908), No. 3, p. 106, fig. 1*).—The modified form of the Soxhlet extractor, which, according to the author, is simple and inexpensive, consists of a narrow percolator, the lower end of which is connected by means of a tightly fitting

cork with a siphon-shaped glass tube, and the upper end closed with a perforated cork into which is fitted a glass T-tube. The rectangular limb of this tube is connected by a short piece of rubber tubing with a glass tube at right angles which passes down to the flask containing the solvent. Additional advantages, according to the author, are the ease with which the apparatus can be cleaned and the fact that by substituting different sizes of percolators it can be adapted with little trouble for use with either large or small quantities.

METEOROLOGY—WATER.

Precipitation, run-off, and evaporation on the earth's surface, R. Fritzsche (*Niederschlag, Abfluss und Verdunstung auf den Landflächen der Erde. Inaug. Diss. Halle, 1906, pp. 55; Ztschr. Gewässerk., 7 (1906), No. 6, pp. 321–370; rev. in Naturw. Rundschau, 22 (1907), p. 111; Mitt. Justus Perthes' Geogr. Anst., 53 (1907), No. 1, Literaturbericht, p. 16; Met. Ztschr., 25 (1908), No. 1, pp. 32–35*).—This dissertation deals with the methods of reckoning mean precipitation, and summarizes and discusses data bearing upon the balance of rainfall, run-off, and evaporation on the earth's surface, distinguishing between the relation of these three factors over water surfaces and land surfaces.

In reviewing this dissertation E. Brückner points out that over the water surface of the earth evaporation exceeds precipitation, but that 92 per cent of the evaporation falls again upon the water surface. On the land surface evaporation is decidedly smaller than precipitation, precipitation being about one and one-half times as great as evaporation. About 70 per cent of the precipitation on the land surface is derived from evaporation from the land.

On the kinds and distribution of viable micro-organisms in the atmosphere, Flemming (*Ztschr. Hyg. u. Infectionskrank., 58 (1908), No. 3, pp. 345–385, figs. 2*).—The results of numerous bacteriological examinations of air collected by means of captive and free balloons at different heights and places over land and sea are reported.

Monthly Weather Review (*Mo. Weather Rev., 36 (1908), Nos. 3, pp. 51–84, fig. 1, charts 17; 4, pp. 85–124, charts 16*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of March and April, 1908, recent papers bearing on meteorology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 3.—Accidental Variations in Atmospheric Pressure in the United States (illus.), by A. J. Henry; Is There a Type of Storm Path, by E. Van Cleef; The Present and Future State of Maritime Meteorology, by H. Hergesell; Abstracts of Russian Meteorological Memoirs, by A. Voeikov; The Study of Evaporation, by A. Voeikov; The Evaporating Power of the Air at the New York Botanical Garden, by C. S. Gager; Radium—Its Properties, Distribution, and Influence on the Atmosphere, by W. W. Strong; and Tornado of January 31, 1908 (illus.), by W. S. Belden.

No. 4.—Chinook Winds in Eastern Colorado During December, 1907, by L. H. Daingerfield; Climate of Kansas, by T. B. Jennings (see 115); Lightning and Powerful Electric Discharges; A Collection of Mean Annual Temperatures for Mexico and Central America, by P. P. Calvert; A Small Cloudburst Near Shasta, Cal., by R. H. McCandless; Local Changes of Climate, by W. C. Devereaux; Ice Columns in Gravelly Soil, by E. D. Bourne; Popof and Erman on the Use of Kites in Meteorology; Forecasting on the Pacific Coast, by A. G. McAdie; Can We Protect Against Tornadoes? The Observatory on Mount Etna; Dustfall in Idaho; Meteorological Education; The Law of the Earth's Nocturnal Cooling, by W. H. Jackson; Early Meteorological Data for Saline,

Mich., by J. E. Buchanan; Excessive Precipitation at Louisville, Ky., by F. J. Walz; A New Formula for Computing the Solar Constant from Pyrheliometric Observations, by H. H. Kimball; and Störmer's Work on the Physics of the Aurora, by P. G. Nutting.

Meteorological work [of the Alaska Stations], C. C. Georgeson (*Alaska Stas. Rpt. 1907, pp. 87–98*).—Tabular summaries are given of the reports of the volunteer weather observers of the Weather Bureau of Alaska on temperature, precipitation, and general weather conditions during the year ended November 30, 1907.

Climate of Kansas, T. B. Jennings (*Mo. Weather Rev., 36 (1908), No. 4, pp. 88–92*).—Extremes and means of temperature and precipitation are given for each month during 20 years, 1887–1906, with notes on frosts, winds, snowfall, thunderstorms, and hailstorms. "The mean annual temperature varies between 51° in the extreme northwestern counties and 57° in the extreme southeastern. . . . The average annual precipitation ranges from 15.37 in. in the extreme western to 44.54 in. in the extreme southeastern part of the State."

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander, T. A. Barry, and R. C. Lindblad (*Massachusetts Sta. Met. Buls. 233, 234, pp. 4 each*).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during May and June, 1908. The data are briefly discussed in general notes on the weather of each month.

Meteorological observations (*Michigan Sta. Rpt. 1907, pp. 123–134*).—Tabulated daily and monthly summaries are given of observations during 1906 on temperature, pressure, precipitation, humidity, cloudiness, wind movement, etc.

Report of meteorologist, N. Helme (*Rhode Island Sta. Rpt. 1907, pp. 381–397*).—Observations at Kingston on temperature, precipitation, prevailing winds, and general character of the weather are given for each month of the year ended June 30, 1907. The mean temperature for that period was 46.5°, the precipitation 48.01 in., and the number of clear days 136.

Weather of the year 1907 in Switzerland, R. Billwiller (*Schweiz. Ztschr. Forstw., 59 (1908), Nos. 2, pp. 46–52; 3, pp. 78–84*).—The meteorological conditions during each month of the year are described, and observations on temperature, precipitation, and sunshine at various stations in Switzerland are summarized.

Meteorological observations in Surinam and Curaçao, 1907 (*Meteorologische Waarnemingen gedaan op de Meteorologische Stations in de Koloniën Suriname en Curaçao in het Jaar 1907. [1907], pp. 16*).—Observations on pressure, temperature, precipitation, etc., at Paramaribo, Surinam, and on precipitation at various places in Surinam and Curaçao and other parts of the Dutch Antilles are given.

The climate of the British Isles, A. Watt (*Scot. Geogr. Mag., 24 (1908), No. 4, pp. 169–186, figs. 9*).—The general climatic conditions are described and the distribution of temperature and rainfall is discussed in some detail. The question of change of climate is also briefly touched upon. It is stated that no definite answer can be made to this question, although there appears to be a very general opinion that the winters in the British Isles have on the whole grown milder.

Climate of the Bahama Islands, O. L. Fassig (*The Bahama Islands. New York, 1905, pp. 111–125, maps 3*).—This is a chapter in a monograph on the Bahama Islands, issued by the Geographical Society of Baltimore. It discusses the climate of the islands as a whole, the temperature, relative humidity, clouds and sunshine, rainfall, winds, thunderstorms, and especially hurricanes.

Forests and rainfall, E. Henry (*Indian Forester, 34 (1908), No. 2, pp. 69–81*).—This is an English translation of the original French article. A previous article in the same series dealt with the levels of underground water in and outside of forests (E. S. R., 18, p. 942).

The present article discusses the moisture content of the air over forests and open land, and the influence of forests upon rainfall and the flow of springs. In the previous article it was shown that the ground water level was much lower under forests than under adjacent open land. The conclusion is drawn from the data reported in this article that the moisture content and the chances of rain are much greater over forests than over open land. It is stated that observations made in various localities show that forests increase the rainfall 8 to 15 per cent above normal. Forests also exert a beneficial influence in maintaining a more uniform flow of springs. The foregoing conclusions, however, apply more particularly to level country. The problem is more complicated in hilly or mountainous areas. It is recognized that the chief factor affecting rainfall is the configuration of the ground, but it is maintained that other conditions being equal wooded hills are better agents for promoting precipitation than bare hills. Experimental data on this point are, however, deficient.

The level of underground water in forests and in the open, P. Ototzky (*Ann. Sci. Agron., 3. ser., 2 (1907), I, pp. 116–119*).—This is a review of the contents of a 2-volume book by Ototzky on Underground Waters, Their Origin, Regime, and Distribution, which contains an account of investigations on the subject of this article made in Gascony in 1902, showing, as many other observations had done, that the level of the ground water is lower under forests than in the open. (See also E. S. R., 16, p. 672.)

The level of subsoil waters with regard to forest, R. S. Pearson (*Ann. Sci. Agron., 3. ser., 2 (1907), I, pp. 104–115*).—A French translation of an article already noted (E. S. R., 18, p. 942).

Recent changes of methods and equipment in the water resources work of the United States Geological Survey, J. C. Hoyt (*Engin. News, 60 (1908), No. 1, pp. 15, 16, figs. 2*).—Several changes in the instruments and methods used in stream gaging by the Water Resources Branch of the U. S. Geological Survey are described.

Effect of low temperature on bacteria in ice, J. C. Sparks (*Sci. Amer. Sup., 65 (1908), No. 1695, pp. 410, 411*).—Tests are reported in this article from which the conclusion is drawn "that ice, even when cut from water which may contain pathogenic bacilli, is utterly incapable of passing on disease if it is stored for some time before being distributed."

Sewage purification works of the State Agricultural School, St. Anthony Park, Minn., F. H. Bass (*Engin. News, 59 (1908), No. 26, pp. 685, 686, figs. 4*).—The construction and efficiency of these works, which consist of a septic tank, a percolating filter, and a sand filter and cost about $9,000, are described.

SOILS—FERTILIZERS.

Soil Studies, II: Acid soils, A. W. Blair and E. J. Macy (*Florida Sta. Bul. 93, pp. 45–69, figs. 2*).—This bulletin reports the results of an investigation which was undertaken to find out to what extent acid soils are distributed in Florida and discusses the origin and nature of Florida soils with reference to the causes of acidity.

Of 189 samples of soils and subsoils, representing 17 counties of the State, 68.22 per cent of the soils and 51.35 per cent of the subsoils were found to be more or less acid when tested by Veitch's limewater method (E. S. R., 16, p. 14). With only one or two exceptions the soils are more acid than the subsoils,

and the cultivated soils are more acid than the virgin soils. With one exception the muck soils examined are extremely acid."

The average lime requirement of the acid soils as determined by the Veitch method was approximately 500 parts per million, equivalent to 1,500 lbs. per acre to a depth of 9 in. There was found to be about three times as much nitrogen in the soils as in the subsoils, slightly more than three times as much in the subsoils as in the second subsoils, and nearly one and one-half times as much in cultivated soils as in virgin soils.

"Experiments by the wire-basket method showed a gain in baskets where lime was used, over baskets where no lime was used, of 17.3 per cent green weight, and of nearly 20 per cent dry weight. With a muck soil which was very acid, the gain in baskets where finely ground limestone was used, over baskets where no limestone was used, was nearly 100 per cent green weight and 120 per cent dry weight."

It is pointed out that Florida soils are composed very largely of sand which has been derived from disintegrated rock, the process of formation being such as to remove to a large extent the basic constituents such as potash, lime, and magnesia. The soils are therefore fundamentally acidic. The acidity is, however, increased by the decomposition of organic matter.

Some notes on soil acidity, F. W. Morse and B. E. Curry (*Abs. in Science, n. ser., 27 (1908), No. 686, p. 298*).—This is an abstract of a paper presented at the Chicago meeting of the American Chemical Society. "The authors report the reactions taking place between a number of clays and some common salts. Also some reactions between the organic matter in soils and some common salts."

A natural model for the formation of dunes, S. Günther (*Sitzber. K. Bayer. Akad. Wiss., Math. Phys. Kl., 1907, No. 2, pp. 139–153, figs. 3*).—This is a discussion of typical forms of seacoast and inland dunes.

Washington soils, R. W. Thatcher (*Washington Sta. Bul. 85, pp. 3–56, figs. 2*).—This is the final report on a soil survey of the State begun in 1893 (E. S. R., 7, p. 375; 15, p. 658) embodying 89 new analyses and summarizing the results of all of the analyses (188) made since the beginning of the survey. The bulletin also contains a statement regarding the objects and methods of the soil survey, and brief discussions of origin and composition of soils and the relation of soil composition to fertility, and the soils of the different districts of the State are fully described. The samples of which analyses are reported represent soils from every county except one and include probably every typical soil of the State. "Practically every type known to soil students is represented somewhere in this State. We have every variation from almost pure sand to pure clay on the one hand and to pure peat on the other. In other localities special types, such as marls, glacial drift of several kinds, etc., are found. These variations in type are accompanied by almost the widest conceivable variations in chemical composition." The extreme variations in the percentages of the several constituents which have been found in the samples of soils analyzed are given as follows:

	Per cent.
Insoluble silica	3.014–90.716
Hydrated silica	.157–18.524
Soluble silica	.002– .938
Potash	.000– .829
Soda	.027– 1.632
Lime	.005–36.009
Magnesia	.000– 4.830
Iron oxid	.181–16.368

	Per cent.
Alumina	0.148–14.898
Phosphorus pentoxid	trace– .409
Sulphur trioxid	.000– .694
Carbon dioxid	.000–28.998
Humus	.084–51.000
Nitrogen	trace– 2.660

Summary of the soil survey of the State, R. W. THATCHER (*Washington Sta. Popular Bul. 7, pp. 8*).—A popular summary of the above.

Analyses of soils [of grass lands], J. W. TAYLOR (*Univ. Col. Reading, Dept. Agr. and Hort. Bul. 3, pp. 24–26*).—Analyses of samples of soil from 21 farms on which fertilizer experiments with grass have been carried on are reported. The samples were taken to a depth of 9 in. The analyses show very low percentages of lime in all except two of the soils. Two of the soils which overlie chalk were found to be practically devoid of lime.

Humid and arid soils of Rio Verde, R. GARCIA OSES (*Las Tierras de Riego y de Temporal en Riovcrde. Mexico, 1907, pp. 24*).—The nature and causes of the differences between the arid and humid soils of this region are discussed.

The origin of the fertile soils of western Morocco, L. GENTIL (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 5, pp. 243–246; abs. in Rev. Sci. [Paris], 5. scr., 9 (1908), No. 7, p. 221*).—The author concludes from his investigations that the very fertile black and red soils of this region are the resultant of decalcification of neogenic calcareous sandstones. Analysis of the black soil shows it to contain 0.15 per cent of nitrogen, 0.25 per cent of phosphoric acid, 0.46 per cent of potash, and 1.39 per cent of calcium carbonate; the red soil 0.2 per cent of nitrogen, 0.08 per cent of phosphoric acid, 0.21 per cent of potash, and 1.79 per cent of calcium carbonate. Chemical analysis does not explain the great fertility of these soils, which is believed to be due mainly to favorable conditions of rainfall and underground water supply.

Notes on Egyptian and Soudan soils, F. HUGHES (*Yearbook Khediv. Agr. Soc. Cairo, 1906, pp. 133–140*).—The variation in the physical character of Nile soils due to variations in the velocity of the flow of the water from which the soil deposits are formed and to admixture of wind-blown desert sand with the alluvial deposits is pointed out.

Analyses of 6 representative alluvial soils from Keneh Province are reported which show that "at least in purely alluvial soils, the amount of plant food contained in the various grades of the finer particles of the soil is practically the same." The availability of the plant food constituents as shown by the Dyer method was also very similar in the different grades of soil particles.

In case of soils with which desert sand has been mixed the plant food constituents decrease with an increase of the added sand.

Analyses of samples of soil from all parts of the Nile Valley show that the alluvial soils in most cases are very similar in composition to Nile silt. Analyses of desert soils not of alluvial origin show that these are much poorer than the Nile soils in mineral constituents and contain only slight traces of nitrogen.

The alluvial soils contain sufficient potash in available form to render the application of potash fertilizers unnecessary. Although the percentages of total and available phosphoric acid are larger than are usually considered sufficient for needs of crops the soils are as a rule benefited by application of phosphatic fertilizers. It is suggested that the inefficiency of the phosphoric acid in these soils may be due to the deficiency of organic matter. In other words, in soils which are naturally poor in organic matter it is necessary to set a somewhat higher figure as the limit below which phosphatic fertilizers may be dispensed with.

Contribution to the knowledge of the lands and the agriculture of Syria, H. AUHAGEN (*Ber. Land u. Forstw. Auslande, 1907, No. 16, pp. 85, figs. 49*).—This is a summary account of the geography, climate, soil, water supply, flora and fauna of agricultural importance, administrative and economic conditions, population, general systems of agriculture in vogue, irrigation, dry farming, animal breeding, and other incidental agricultural industries of this region, which is stated to be about one-half the size of the German Empire.

Soils [of the Malay States] and their analysis, M. K. BAMBER (*Agr. Bul. Straits and Fed. Malay States, 6 (1907), No. 9, pp. 274–277*).—Chemical and physical analyses of 3 samples of alluvial clays and 7 of sandy loams representing typical soils of the Malay States are reported.

It is stated that the soils of the Malay States are roughly divided into two distinct kinds, (1) flat alluvial clays or muds on the banks of the rivers near the seacoast, and (2) undulating low soils a few miles inland, varying from free sandy loams to heavy clays. There are also some peaty soils resting on clay a few miles from the coast.

As a rule the soils are not especially rich in plant food, but their physical properties are exceptionally good. The alluvial clays or muds are generally rich in nitrogen. Potash is frequently deficient, and the proportion of phosphoric acid is variable. The upland soils have a larger proportion of sand and coarser particles and as a result the natural drainage is better. They are richer in nitrogen than the proportion of organic matter would indicate, but are usually slightly deficient in potash and phosphoric acid.

Classification of soils, L. A. REBELLO DA SILVA (*Rev. Agron. [Portugal], 5 (1907), No. 10, pp. 294–301*).—This article briefly describes different types of soils and soil characteristics and gives analyses and a physico-chemical classification of a number of Spanish soils examined by the Schloesing method.

The nomenclature of soils, M. PARDO Y URBINA (*La Nomenclatura de las Tierras. Mexico, 1907, pp. 14*).—This article discusses the necessity for a uniform agricultural classification of the soils of Mexico.

Physiography for high schools, R. D. SALISBURY (*New York, 1908, pp. VIII + 531, pls. 24, figs. 469*).—It is stated in the preface that "this book has been prepared with the purpose of letting the beginner into the method of the science with which the book deals, as well as with the purpose of conveying information to him. It has been prepared with the conviction that the child likes to reason and to follow reasoning, and that reasoning and following reasoning contribute more to his mental growth than the accumulation of great numbers of facts. It has been written with the conviction that the growth of the pupil is more important than facts about physical geography." Directions for laboratory work are not given in the text, it being the author's opinion that such work will be most effective if suggested by the teacher. The book is divided into four parts, the lithosphere, earth relations, the atmosphere, and the ocean. The formation and general characteristics of soils are treated in the first part and climate and weather in the third.

Land ruin compared with soil improvement, C. G. HOPKINS (*Penn. Dept. Agr. Bul. 154, pp. 118–136*).—The results are given of continuous cropping without systematic manuring as compared with a system of soil improvement based upon the use of phosphates in connection with farm manures and green manuring with leguminous crops as applied especially to the soils of the Central West.

On the deep cultivation of soils, STRECKER (*Fühling's Landw. Ztg., 57 (1908), No. 2, pp. 46–64, figs. 14*).—The advantages of deep culture are briefly stated and different methods and appliances used in Germany for the purpose are described.

Methods of soil toxicology, O. Schreiner and E. C. Shorey (*Abs. in Science, n. ser., 27 (1908), No. 686, pp. 295, 296*).—This is an abstract of a paper presented at the Chicago meeting of the American Chemical Society. The importance of working out refined methods for the detection, isolation, and study of the small amounts of toxic organic bodies which are believed to exist in soils is pointed out, and the authors outline "methods of separating the organic matter from the large mass of inorganic material, and further separation of the pure organic body from the extraneous organic matter by methods of extraction, solution, precipitation, distillation, etc. The specific methods by which several harmful organic compounds have already been isolated from unproductive soils are given to illustrate the general principles involved."

The cause of soil sickness (*Mark Lane Express, 98 (1908), No. 3985, p. 145*).—This article reviews briefly the evidence supporting the view that soil sickness is due to poisonous excretions of the roots of plants.

Bacteriological investigations with reference to the drying of soils, O. Rahn (*Centbl. Bakt. [etc.], 2. Abt., 20 (1907), No. 1–3, pp. 38–61, pl. 1, fig. 1; abs. in Chem. Ztg., 32 (1908), No. 9, Repert., p. 47*).—From a large number of studies on the formation of acid in sugar solutions, carbon dioxid in sugar solutions containing calcium carbonate, and ammonia in urea and peptone solution, the conclusion is reached that bacterial changes go on much more rapidly in soils dried at room temperature than in similar samples kept moist or in the original moist soils. The difference in this respect between the dry and moist samples was in the case of garden soil about 60 per cent and in ordinary farm soil 10 to 30 per cent, but in case of a light sandy soil inappreciable. The rapidity with which the drying took place had very little influence on the difference in bacterial change. Since the number of organisms in soil samples was invariably decreased by drying it is difficult to explain the difference in bacterial activity. It can not be explained on the basis of physical properties, since such differences were observed in case of soil samples suspended in water and in extracts of the soils. Neither can decomposition of the soil constituents furnish an explanation, because with the liberal addition of potassium phosphate and asparagin similar differences were observed. Variations in the amount of nitrates in the soil were also without effect on the bacterial activity. Whatever the substances producing the difference it must be undecomposable by boiling and capable of passing through filter paper. It is not clear whether it acts by reducing bacterial activity in the moist soil or accelerating it in the dry soil. Dry soils lose the greater part of their intensified putrefactive power and do not differ materially from the original moist soils after they have been moistened about 24 hours. Mustard plants grew better in soils which had become dry than in those which had been kept moist continuously.

Tests of Remy's method of judging soils indicate that this method may give erroneous results if great care is not taken to prevent the loss of moisture from the cultures.

The influence of the composition of the medium upon the solvent action of certain soil bacteria, C. W. Brown (*Rpt. Mich. Acad. Sci., 9 (1907), pp. 160–162, figs. 3*).—A study of the solvent action of a large number of soil bacteria on rock phosphate, bone, pure tricalcium phosphate, dicalcium phosphate, and calcium carbonate is briefly reported.

The results show that 12 out of 25 bacteria isolated from soil exerted a definite visible solvent action on the substances named when supplied with some form of sugar in the nutrient medium. "One which produces no gas but a larger amount of acid from sugars than any of the others, shows the greatest action upon the calcium carbonate, while other germs which produce gas—largely carbon dioxid—but not as much acid as the former, give an action more

marked than that of the stronger acid producer upon the dicalcium and tricalcium phosphates. These points, with others noticed during the experiments, have led us to believe that, while acid is a great factor in dissolving insoluble phosphates, the carbon dioxid liberated from carbohydrates by the gas producing bacteria must not be overlooked as a solvent agent."

On the activity of bacteria in soils, J. Vogel (*Illus. Landw. Ztg., 27 (1907), No. 20, pp. 175, 176; abs. in Centbl. Bakt. [etc.], 2. Abt., 20 (1908), No. 10, p. 299*).—This is a general explanation of bacterial activities in the soil and the conditions, especially the supply of humus and other energy-yielding material in the soil, favoring such activities. Humus is not considered a very efficient source of energy for the soil organisms, hence the necessity for increasing the supply of readily available energy-yielding materials in the soil if vigorous activity of the soil organisms is to be promoted. The author thinks it is still an open question whether the beneficial results following black fallow are due to increase of nitrogen or to the setting free of latent plant food in the soil. Reference is also made to the favorable results both as regards increase of yield and nitrogen content obtained in field experiments with leguminous plants (serradella, yellow lupines, and soy beans) inoculated with Hiltner's pure cultures of root-tubercle bacteria.

Atmospheric nitrogen, W. J. U. Woolcock (*Sci. Amer. Sup., 65 (1908), No. 1678, p. 143*).—A brief account is given in this article of the results of experiments by Professor Bottomley in England on soil inoculation and also on the possibility of the assimilation of free nitrogen by nonleguminous plants.

Bacteria inoculation in the culture of leguminous plants, J. Simon (*Sächs. Landw. Ztschr., 55 (1907), Nos. 33, pp. 877–881; 34, pp. 901–905*).—This is a general discussion of this subject and of the relative merits of commercial preparations of root-tubercle bacteria (nitragin, nitroculture, etc.) based in part upon experiments at the Tharand experiment station.

The assimilation of free nitrogen by micro-organisms, E. Boullanger (*Bul. Inst. Pasteur, 6 (1908), Nos. 1, pp. 1–12; 2, pp. 49–56; 3, pp. 97–104*).—This is a review of investigations and a critical discussion of the present status of knowledge on this subject, including a bibliography of 84 references to the more important investigations.

Note on de Rossi's article on the organisms which produce the root tubercles of leguminous plants, R. Perotti (*Malpighia, 21 (1907), No. 4–6, pp. 255–262*).—The author cites evidence tending to show that other investigators besides de Rossi have isolated specific organisms from the tubercles of leguminous plants, and calls attention to the fact that although in earlier publications de Rossi casts doubt upon this point, in later reports (E. S. R., 19, p. 519) he is careful to disclaim any specific denial of such isolation by other investigators.

Contribution to the knowledge of denitrification processes, H. Kühl (*Centbl. Bakt. [etc.], 2. Abt., 20 (1908), No. 8–9, pp. 258–261; abs. in Chem. Zentbl., 1908, I, No. 10, pp. 980, 981*).—A series of experiments are reported which show (1) that the activity of denitrifying organisms was greatly increased under anaerobic conditions (covering the culture solutions with oil, paraffin, etc.), (2) the denitrifying power of pure cultures was greatly increased by adding mixed cultures, and (3) that sea slime set up rapid denitrification in culture solutions.

The construction of manure pits and the preservation of manure, P. Cornelius (*Mitt. Deut. Landw. Gesell., 22 (1907), No. 48, pp. 409–413, figs. 3*).—Plans and descriptions are given of manure pits with systems for the collection of the liquid portion and the convenient arrangement of these pits with reference to the cattle stalls and the handling of the manure is explained.

Plans for the construction of manure pits, Friz (*Württemb. Wchnbl. Landw., 1908, No. 1, pp. 4–7, figs. 3*).—Descriptions and plans of various kinds of manure pits are given.

Demonstration experiments with fertilizers in Carinthia during 1905 and 1906, H. Svoboda (*Ztschr. Landw. Versuchsw. Österr., 11 (1908), No. 1, pp. 22–35; abs. in Chem. Zentbl., 1908, I, No. 8, p. 759*).—The cooperative experiments of previous years (E. S. R., 16, p. 761; 17, p. 753) were continued during 1906 and the results of 151 such experiments carried out during that year are reported in detail in this article, a comparison being made of both the direct (first year) and after effect of the various fertilizers on oats, potatoes, and hay meadows.

As in previous experiments, combinations of Thomas slag and potash salts were used on grasses and of superphosphate, potash salts, and nitrate of soda on oats and potatoes. The after effects of the commercial fertilizers were very good, especially on the grasses. In this case not only was the second cut of grasses increased, but the yield the second year after the application of the fertilizers was greater than the first year. It was also observed that under the unfavorable weather conditions of both 1905 and 1906 the meadows which had received fertilizers suffered much less injury than those which had not been fertilized. The results obtained with barnyard manure combined with commercial fertilizers lead to the conclusion that while it is not advisable to completely replace manure with commercial fertilizers, the yield and profit can be greatly increased by judiciously supplementing the manure with such fertilizers.

The results of field experiments with fertilizers on sandy soils in a bad state of cultivation, Clausen (*Deut. Landw. Presse, 35 (1908), Nos. 11, pp. 105, 106; 12, pp. 115, 116*).—Kainit, nitrate of soda, and sulphate of ammonia with superphosphate and Thomas slag were tested in pot and field experiments with oats and potatoes. The effect of the different fertilizers and fertilizer combinations on the yield and nitrogen content of the crop is discussed.

Influence of fertilizers on the composition of wheat, H. Snyder (*Abs. in Science, n. ser., 27 (1908), No. 686, p. 297*).—This is an abstract of a paper presented at the Chicago meeting of the American Chemical Society, the essential features of which have been noted from another source (E. S. R., 19, p. 941).

On nitrogenous fertilizers and their application, P. Lavenir (*Rev. Facult. Agron. y Vet. La Plata, 2. ser., 3 (1907), No. 7–9, pp. 199–217*).—This article discusses the source, value, and use of nitrate of soda, sulphate of ammonia, the artificial compounds prepared from atmospheric nitrogen, and various nitrogenous fertilizers of animal and vegetable origin, as well as green manures.

Nitrates as soil renovators, O. Schreiner and H. S. Reed (*Abs. in Science, n. ser., 27 (1908), No. 686, p. 296*).—This is an abstract of a paper presented at the Chicago meeting of the American Chemical Society. Attention is called in this paper to the possible action of nitrates in aiding in the destruction of harmful organic substances which may be present in unproductive soils. Observations and investigations are reported which indicate that the roots of plants have a strong oxidizing power and that this power is greatly increased by the addition of nitrates, the combined action of the two being sufficient to destroy harmful organic bodies and thus to improve conditions for plant growth. It was shown by chemical analysis that when toxic bodies were used in the experiments they were destroyed by the plant and nitrates.

The nitrogen capacity of cultivated soils with one-sided fertilization with nitrate of soda, T. Pfeiffer (*Fühling's Landw. Ztg., 57 (1908), No. 2, pp. 41–46*).—On the basis of his own previous work and that of other investigators the author argues that the use of nitrate of soda and sulphate of ammonia,

especially the former, as the exclusive sources of nitrogen supply for soils may result in actual impoverishment of the soil in nitrogen. He therefore considers exclusive use of such fertilizers a questionable practice.

On the decomposition of lime nitrogen and nitrogen lime, II, F. Löhnis and A. Sabaschnikoff (*Centbl. Bakt.* [*etc.*], *2. Abt., 20 (1908), No. 11, pp. 322–332, fig. 1*).—In previous experiments (E. S. R., 17, p. 345) Löhnis showed that calcium cyanamid was decomposed and dicyandiamid was produced by the action of water without the intervention of micro-organisms. He also showed that under favorable conditions the nitrogen of the cyanamid was completely transformed into ammonia by the action of various ammonifying bacteria, experiments with pure cultures indicating that urea was an intermediary product in the process of formation of ammonia. This activity of the bacteria was greatly increased by the addition of small amounts of asparagin and grape sugar (about 0.1 per cent). Experiments of similar character showed that in solutions of calcium cyanamid which had been repeatedly heated and in which the formation of ammonia had been started by the action of steam the decomposition resulting from the inoculation of the solution with 10 per cent of soil was as rapid as in case of freshly prepared unheated solutions.

The investigations reported in the present article were undertaken to explain if possible the contradictory results obtained by von Seelhorst, Immendorff, Kappen, and others on the one hand, and by Ulpiani and Perotti on the other, with special reference to the formation and decomposition of dicyandiamid.

Further experiments showed a decided advantage as regards the ammonification of the nitrogen of lime nitrogen and nitrogen lime from the addition of asparagin and grape sugar to the culture solutions in Remy's process. The authors never succeeded in producing ammonia in solutions of dicyandiamid inoculated with soil. When, however, the solutions of lime nitrogen and nitrogen lime were repeatedly heated the nitrogen was rapidly ammonified by a number of soil organisms. In this case it is believed that not dicyandiamid but dicarbimid is produced, which is more easily converted into ammonia.

Of various soil organisms experimented with *Bacterium erythrogenes*, *B. kirchneri*, and *B. lipsiense* were especially active in producing ammonia. A less active organism in this respect was *B. vulgare* var. *zopfii*.

Observations during two years on the influence of season and weather upon the decomposition of lime nitrogen and nitrogen lime in the soil showed that the most active decomposition occurred in May, the least in August, and that there was another period of activity in September, the curves being practically identical for the two seasons, although the first was dry and the second wet.

Nothing was observed in these experiments to indicate that the lime nitrogen or nitrogen lime in any way interfered with the process of nitrification.

Recent investigations on the decomposition and the action of lime nitrogen and nitrogen lime, F. Löhnis and A. Sabaschnikoff (*Fühling's Landw. Ztg., 57 (1908), No. 1, pp. 15–29*).—In this article the authors discuss their own investigations on this subject (see above) as well as the bearing of recent work by Perotti and Kappen (E. S. R., 18, pp. 537, 1028) on their conclusions with reference to the decomposition of calcium cyanamid in the soil and the fertilizing value of the commercial forms of this compound. They maintain that recent investigations have confirmed the conclusion that calcium cyanamid is not converted to any appreciable extent into ammonia in sterile soils and that this transformation is due to the activity of micro-organisms; that under suitable conditions the transformation of the cyanamid as well as the dicyanamid into ammonia by bacterial action is almost complete; and that the transformation into ammonia and ultimately into nitrates which are readily available to crops is

indicated by the action of these materials in increasing the yield of crops in pot experiments, the fertilizing efficiency shown by lime nitrogen, nitrogen lime, and dicyanamid comparing very favorably with that of ammonium sulphate. It is shown that by heating and especially evaporating the solution of lime nitrogen the rapidity of transformation into ammonia by the action of micro-organisms is greatly accelerated.

The authors conclude that while it may be possible under favorable conditions to secure a transformation of 99 per cent of the nitrogen of calcium cyanamid into ammonia and finally into nitrates, it is not likely that such high efficiency as this indicates can be obtained in practice.

Experiments with new nitrogenous fertilizers, L. Malpeaux (*Betterave, 18 (1908), No. 446, pp. 67–70*).—Experiments made at the agricultural school of Berthonval during 1907 with basic lime nitrate and calcium cyanamid on barley and oats are reported. The results obtained with the first were somewhat superior to those obtained in case of nitrate of soda. The second gave results about equal to those obtained with sulphate of ammonia.

Experiments with calcium cyanamid, A. D. Hall (*Jour. Bd. Agr. [London], 14 (1908), No. 11, pp. 652–661*).—The experiments reported deal mainly with the question of the changes which calcium cyanamid is likely to undergo under different conditions. The principal conclusions drawn from the experiments are "that calcium cyanamid as now manufactured can be stored for a reasonable time under ordinary conditions without danger or sensible loss of its fertilizing properties; cyanamid can also be mixed without difficulty or loss with superphosphate, the resulting mixture being as easily handled as any other artificial manure."

Nitrolime, G. L. Ragondet (*Jour. Soc. Agr. Brabant et Hainaut, 53 (1908), No. 9, pp. 219–223*).—The manufacture, properties, composition, keeping quality, and use as a fertilizer of calcium cyanamid are briefly discussed in this article.

The effect of the addition of sodium to deficient amounts of potassium, upon the growth of plants in both water and sand cultures, B. L. Hartwell, H. J. Wheeler, and F. R. Pember (*Rhode Island Sta. Rpt. 1907, pp. 299–357, pl. 1*).—This is an account of investigations carried on in cooperation with the Bureau of Soils of this Department and "gives the results of growing wheat seedlings in complete nutrient solutions containing deficient, and approximately optimum amounts of potassium, and the same supplemented by sodium and again by extra calcium.

"Sodium seemed to cause no increase in growth when an optimum amount of potassium was present, but when the deficiency of potassium was great enough to cause about a 30 per cent depression in the green weight produced, the addition of sodium did give an increase in growth which usually amounted to 10 per cent, or more, within a period of from two to three weeks, under the particular conditions of these experiments.

"The extra calcium did not on the whole increase the growth, either when used with an optimum or a deficient amount of potassium.

"The beneficial effect of sodium, when accompanying a small amount of potassium, is not attributed to the increase in the osmotic pressure of the solution, because the addition of extra calcium, magnesium, phosphorus, or nitrogen failed to cause an increase in growth.

"The increase in transpiration was usually less than that in green weight, when sodium was added, or the potassium increased. This seemed especially marked with the alkali carbonates.

"A larger amount of potassium was left in the solution by the growing seedlings when the potassium in the nutrient medium was supplemented by sodium. In other words, sodium was a conserver of potassium.

"In two experiments by the paraffined wire basket method, with white quartz sand which had been digested with acid, sodium, when supplementing a deficient amount of potassium, affected the growth similarly as in the solution experiments."

The partial substitution of potassium by sodium as a plant food, B. L. Hartwell, H. J. Wheeler, and F. R. Pember (*Abs. in Science, n. ser., 27 (1908), No. 686, pp. 298, 299*).—This is an abstract of a paper presented at the Chicago meeting of the American Chemical Society, the essential features of which are given in the paper noted above.

What is the relation of the increase in yield of barley produced by phosphatic fertilizers to the phosphoric acid content of the soil? F. Pilz (*Ztschr. Landw. Versuchsw. Österr., 11 (1908), No. 1, pp. 36–51; abs. in Chem. Zentbl., 1908, I, No. 8, pp. 759, 760; Jour. Chem. Soc. [London], 94 (1908), No. 547, II, p. 423*).—From the results of a large number of observations on the relation between increased yield of different varieties of barley produced by application of phosphatic fertilizers and the phosphate, nitrogen, and potash contents of the soils the conclusion is drawn that the higher the phosphoric acid content of the soil the greater is the benefit resulting from the application of phosphatic fertilizers. Superphosphates were in general more effective on rich soils (containing over 0.2 per cent each of nitrogen, potash, and phosphoric acid) than on poor soils (containing less than these percentages). This explains the fact often observed in practice that the use of phosphatic fertilizers on poor soils frequently results in a depression in yield and poor ripening of barley.

Phosphorus and humus in relation to Illinois soils, C. G. Hopkins (*Illinois Sta. Circ. 116, pp. 27*).—This is an address which was delivered before the Illinois State Farmers' Institute, and discusses the improvement of the common prairie soils of the Illinois corn belt by means of rotations and the use of fine-ground limestone, rock phosphate, and organic manures, the main object being to increase the phosphorus and humus content of the soils.

On the behavior of minerals in soils, P. Vinassa de Regny (*Staz. Sper. Agr. Ital., 41 (1908), No. 1, pp. 51–77*).—The results of investigations, particularly those of the Bureau of Soils of this Department, and of Delage and Lagatu (E. S. R., 17, pp. 226, 841), bearing on the solubility of various mineralogical constituents of soils are summarized and discussed. A bibliography of 48 references to literature on the subject is given.

Effect of lime and gypsum on the solubility of potassium in feldspars, F. W. Morse and B. E. Curry (*Abs. in Science, n. ser., 27 (1908), No. 686, p. 295*).—This is an abstract of a paper presented at the Chicago meeting of the American Chemical Society. The authors found that lime and gypsum in contact with feldspar increased the solubility of potassium. The fact that this effect was not observed when ordinary clay soils were treated in the same way is attributed to the removal of potassium from solutions by the absorbent power of the clay.

Note on the effect of lime upon the availability of the soil constituents, F. B. Guthrie and L. Cohen (*Agr. Gaz. N. S. Wales, 18 (1907), No. 12, pp. 952–956; Hawaii. Planters' Mo., 27 (1908), No. 1, pp. 32–37*).—Experiments on the solubility in water and 1 per cent citric acid of phosphoric acid and potash in light sandy soil, garden loam, and very stiff clay before and after treatment for one month with 1 per cent of freshly slaked lime, as well as the changes which the nitrogen underwent as a result of such treatment, are reported.

The water-soluble phosphoric acid decreased during the experiment in all of the soils and the potash in the clay soil. The amount of water-soluble plant food, however, was larger in the limed than in the unlimed soils, but only in the sandy soil did the liming increase the proportion of water-soluble phosphoric

acid and potash over that originally present in the soil. Digestion with citric acid showed very little alteration in the amounts of soluble constituents during the experiment, the effect of liming being much less marked in this case than in case of the water-soluble constituents.

The examination of the soils after 8 months with reference to changes in the nitrogen showed a large increase in the proportion of nitrite nitrogen in the limed soil. The total nitrogen as nitrite and nitrate increased in all cases, although the nitrate nitrogen remained almost stationary except in the clay soil. The fact that there was no loss of the very soluble nitrites and nitrates is taken to indicate that the decrease of water-soluble potash and phosphoric acid was not due to percolation through the walls of the pots so much as to conversion into less soluble forms.

Experiments with lime and crushed limestone on a Pennsylvania clay loam soil, W. Frear (*Penn. Dept. Agr. Bul. 154, pp. 79–85*).—This article summarizes briefly the results obtained in a series of experiments at the Pennsylvania Experiment Station which have been continued since 1880. The results show in brief that the use of burnt lime under the conditions of these experiments, namely, in excessive amounts on a soil in no particular need of lime, caused a net decrease rather than a gain in production, whereas with carbonate of lime there was a slight increase in yield, but entirely insufficient to pay the cost of application.

The relation between the effects of liming, and of nutrient solutions containing different amounts of acid, upon the growth of certain cereals, B. L. Hartwell and F. R. Pember (*Rhode Island Sta. Rpt. 1907, pp. 358–380, pls. 2*).—Field experiments having shown that rye and barley are very differently affected by liming, the water cultures with these crops here reported were undertaken to determine "whether varieties of plants which were most benefited by liming were likewise most susceptible to injury by certain acids, when their seedlings were grown in nutrient solutions possessing definite degrees of acidity. . . .

"The water-culture experiments showed that barley seedlings were not more susceptible than rye seedlings to injury from acidified nutrient solutions, even though the field results proved that barley received very much more benefit than rye, from liming.

"While recognizing the caution which should be exercised in drawing conclusions concerning growth in the soil, from results secured by solution cultures, it seems certain, in searching for an explanation of the great differences exhibited by different kinds of plants in respect to liming, that other chemical properties of lime should be prominently studied along with its function as a corrector of acidity, even when attention has been given to the plant-food ingredients.

"According to the method of experimentation employed, the growth of wheat, rye, barley, and oat seedlings was not materially influenced by any degree of alkalinity which is insufficient to cause precipitation from an ordinary nutrient solution.

"The growth of these same seedlings, in nutrient solutions, was likewise scarcely affected by an acidity equal to about $\frac{N}{500}$ or less. A depression in green weight of about 20 per cent resulted when the acidity equalled $\frac{N}{250}$, and an increase in the acidity to about $\frac{N}{170}$ and $\frac{N}{125}$, decreased the production of green weight around 40 and 60 per cent, respectively.

"The very marked property of the seedlings of rendering the nutrient solutions alkaline was measured by titrations against standard acid at the end of the final periods of growth.

"Even if it should be proven beyond question that the so-called acid soils are not injurious to the growth of certain plants because of a noxious degree of acidity, but rather owing to accompanying toxic compounds, it would surely be unwise to discontinue the use of the litmus paper or other tests for soil acidity so long as valuable indications are afforded by them concerning the need of applications of basic material."

The relation between the effects of acid in nutrient solutions, and of liming, B. L. Hartwell and F. R. Pember (*Abs. in Science, n. ser., 27 (1908), No. 686, p. 298*).—This is an abstract of a paper presented at the Chicago meeting of the American Chemical Society, the essential features of which are given in the paper noted above.

Analysis of a sample of synthetic calcium nitrate, N. Passerini (*Bol. Ist. Agr. Scandicci, 2. ser., 7 (1908), No. 1, pp. 108–111*).—The average percentage of total nitrogen found by the Ulsch and Schloesing methods was 12.9. Complete analysis of the material showed calcium oxid 25.7 per cent, nitric anhydrid 49.7 per cent, and water of hydration 23.7 per cent. There were in addition small amounts of nitrous acid, magnesia, and insoluble substances.

Tennessee white phosphate (*Amer. Fert., 28 (1908), No. 2, pp. 5–10, figs. 2*).—This article deals especially with the Wilsdorf deposits, discussing their origin and extent, but also treats briefly of deposits in other parts of the district.

Composition of ashes from Vesuvius, E. Comanducci (*Gaz. Chim. Ital., 36 (1906), II, No. 5–6, pp. 797–812; abs. in Rev. Sci. [Paris], 5. ser., 8 (1907), No. 25, p. 787; Rev. Gen. Agron., n. ser., 3 (1908), No. 1, p. 2*).—The analyses of ashes ejected during the eruption of April 4 and 5, 1906, reported in this article show that Vesuvius is a potassic volcano, the ashes containing 4.66 per cent of potash. They also contain considerable amounts of phosphoric acid (0.75 per cent), and some ammonia (0.03 per cent), nitrous acid (0.001 per cent), and nitric acid (0.0005 per cent). It is reported that the ashes ejected in 1904 contained as high as 1.43 per cent of phosphoric acid. These figures indicate that the ashes have considerable fertilizing value as sources of potash and phosphoric acid. The more important of the other constituents of the ashes reported are soda 4.63 per cent, lime 11.97 per cent, iron sesquioxid 12.29 per cent, iron protoxid 2.72 per cent, alumina 16.75 per cent, and silica 43.69 per cent.

Kainit, Jubartre (*Prog. Agr. y Pecuario, 13 (1907), No. 561; 14 (1908), No. 565, pp. 54–56*).—This article reviews, with numerous references to literature, the investigations relating to the use and value of kainit as a fertilizer, insecticide, and fungicide. The author concludes that it has been clearly demonstrated that the material is of decided value for all these purposes.

Garbage tankage, R. McMurtrie (*Amer. Fert., 28 (1908), Nos. 2, pp. 11–16; 3, pp. 5–10*).—The composition of garbage is given and methods and machinery used in treating it are described, particularly those employed in the preparation of fertilizing material from garbage.

Analyses of fertilizers for consumers, J. S. Burd (*California Sta. Circ. 36, pp. 2*).—The conditions under which consumers may have samples of fertilizers examined by the station, in conformity with the State fertilizer law, are explained in this circular.

Analyses of commercial fertilizers, M. A. Scovell, H. E. Curtis, and G. Roberts (*Kentucky Sta. Bul. 132, pp. 111–195*).—This bulletin reports analyses of 636 samples of fertilizers examined during 1907. Of these "118, representing 101 brands and 29 firms, fell so far below the guarantied analyses in phosphoric acid, nitrogen, or potash, or any two, or all three of these ingredients, that the deficiencies could not be accounted for by variations in sampling or analysis."

Analyses of commercial fertilizers, W. FREAR (*Penn. Dept. Agr. Bul. 159, pp. 69*).—This bulletin reports and discusses the results of analyses of 602 samples of fertilizers examined during the period from January 1 to August 1, 1907.

Licensed commercial fertilizers, 1908, F. W. WOLL and G. A. OLSON (*Wisconsin Sta. Bul. 163, pp. 3–19*).—The results of inspection during the year are reported, with a general discussion of commercial fertilizers and the main principles governing their application.

AGRICULTURAL BOTANY.

The origin of the potato, C. T. DRUERY (*Gard. Chron., 3. ser., 43 (1908), No. 1106, pp. 154, 155, figs. 6*).—An account is given of investigations of A. W. Sutton, which have been carried on for about 20 years to determine the wild species of Solanum that yields the potato of commerce, and also, if possible, to increase the resistant powers of the commercial potato against disease by infusion of a stronger strain. The studies so far have failed to show the origin of the cultivated potato. In every case where the truly wild nature of a species was determined the offspring invariably came perfectly true to the parental type.

In these studies one species, *S. etuberosum*, has been under observation for 20 years, and although its name would imply that it is nontuber bearing, yet tubers have been produced that in the course of the experiment have increased from less than an inch in diameter to tubers of marketable size, while in flavor they do not differ from the ordinary potato. The specific characters of *S. etuberosum* are such as to separate it quite distinctly from the cultivated potato, but it appears promising as a source of edible tubers and of particular value on account of its having proved resistant to the potato disease due to *Phytophthora infestans*. In all the experiments thus far carried on this fungus has never been observed either on the stems or tubers of this species.

Incidental to this investigation, attention is called to the similarity between the variety known as Blue Giant and that described as the Violet variety of *S. commersonii*. These two do not differ in any material character in the foliage, method of branching, flower cluster, seed capsules, or pollen grains, and both differ in common characters from cultivated material of the truly wild species, *S. commersonii*.

Texas honey plants, C. E. SANBORN and E. E. SCHOLL (*Texas Sta. Bul. 102, pp. 31*).—This bulletin contains brief notes on a large number of Texas honey plants, relative to their geographical distribution and honey-producing qualities. In many instances reference is made to the respective quality and yield of pollen and propolis, and data are given concerning the weather conditions and their effects upon the yield of certain plants. The plants are discussed by families, and wherever possible the common name is also given.

The bulletin represents work of the department of entomology for several years past, although the bulk of the work was accomplished by L. H. Scholl, assistant and apiarist from 1902 to 1906.

The poisonous properties of the beans of Phaseolus lunatus, W. R. DUNSTAN and T. A. HENRY (*Jour. Bd. Agr. [London], 14 (1908), No. 12, pp. 722–731*).—Attention is called to the poisonous properties of certain varieties of beans of the species *P. lunatus*. It has usually been stated that the white varieties contain little or none of the glucosid which yields hydrocyanic acid when acted upon by an enzym, and the authors have investigated a number of white and colored varieties which were received from Burma to determine the possibility of their containing glucosids in toxic amount. The red and white varie-

ties of these beans are quite extensively imported into England and other parts of Europe for feeding stock as well as for human food.

An examination of these beans showed that many contained prussic acid in injurious amounts. It has been stated that by cooking them the glucosid is removed, but there appear to be indications that this is not always the case. In view of the interests concerned, the authors think it desirable that an extended investigation be carried on to determine their suitability for use as a feeding material, particularly as many of the white varieties may come into use as a human food, since they closely resemble the small haricot beans in appearance.

A quantitative study of transpiration, Grace L. Clapp (*Bot. Gaz., 45 (1908), No. 4, pp. 254–267, figs. 2, graphs 30*).—A series of studies has been carried on to determine which of the plants available to American teachers are best adapted for the demonstration or investigation of the different physiological processes, and the present paper gives the results of the investigation on the transpiration of 30 species of plants. In this investigation the author determined the actual amount of water lost by the plants growing under ordinary conditions in greenhouses, and at the same time determined the transpiration under various conditions which admit of control and repetition.

The first choice in respect to excellence of material for study falls on *Chrysanthemum frutescens, Tropæolum majus, Pelargonium domesticum, Fuschia speciosa, Senecio petasitis, S. mikanioides, Pelargonium zonale, Heliotropium peruvianum,* and *Pelargonium peltatum.* These were found best since they lose large amounts of water, are easily obtainable at any time of the year, and may be readily grown in houses or in the greenhouse.

In the course of the study it was brought out that there are 2 daily extremes, a maximum about midday, when the sunlight is most intense, heat usually the greatest, and moisture in the atmosphere the least, but with a good supply of water in the soil. The minimum occurs some time during the night, when the temperature is low, the atmospheric moisture approaches saturation, the darkness is complete, and in most plants the stomata are closed.

It was further found that in general the transpiration of ordinary plants grown in greenhouses amounts to about 50 gm. per hour per square meter of surface for the daytime and 10 gm. at night.

The relation between the size of the stomata and photosynthesis in grasses, V. Kolkunov (*Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 8 (1907), No. 4, pp. 369–381*).—In investigations previously noted (E. S. R., 19, p. 225) the author showed that the lowering of evaporation by cultivated plants is brought about by a reduction in the size of the stomata. As a measure of such lowering the author finds it convenient in grasses to consider the length of the stomata.

In connection with these investigations a study was made on the relation of photosynthesis to the size of the stomatic orifices. Experiments were carried on in which leaves of grasses were placed in tubes containing gas of a known carbon dioxid content, then kept for 1½ to 2 hours in the light and the remaining carbon dioxid determined. Experiments were carried on in this way with different varieties of wheat, barley, millet, and other grasses, and in each case the size of the stomata as well as the amount of carbon dioxid assimilated was noted.

The author was led to the general conclusion that the assimilation in grasses varies in proportion to the size of the stomatic orifices.

Incidental to this investigation it was found that the assimilation of different species was differently affected by like intensities of light. In one instance, on a dark rainy day the leaves of millet did not decompose any carbon dioxid, while the leaves of a variety of Turkestan wheat decomposed it as energetically as on bright sunny days.

The physiological function of potash in plants, J. Stoklasa (*Ztschr. Landw. Versuchsw. Österr., 11 (1908), No. 1, pp. 52–61*).—A preliminary account is given of experiments which were conducted with sugar beets and barley, to determine the physiological importance of potash for the growth and development of those plants. A lack of potash was found to interfere seriously with the photosynthesis of the plants. Where plants were grown under control conditions those receiving potash had a much higher content of starch and sugar than those where it was wanting or where the amount was deficient. In both barley and beets the ash from the above-ground or green parts of the plants was much richer in potash than was the ash of the roots. There appears to be an intimate connection between the assimilable potash present and the carbon dioxid assimilation of plants.

The influence of light and of copper on fermentation, J. E. Purvis and W. A. R. Wilks (*Proc. Cambridge Phil. Soc., 14 (1907), No. 4, pp. 361–372; Chem. News, 97 (1908), Nos. 2516, pp. 79–81; 2517, pp. 87–89*).—The results are given of a comparative study of the influence of light and various colors upon fermentation when conducted in unsterilized copper vessels, in sterilized glass vessels, and in unsterilized glass and copper vessels. The effects of the influence were traced in determinations of the optical activity, copper oxid reducing power, nitrogen content, acidity, and specific gravity of the distilled fermented solutions.

It was found that fermentation when carried on under sterilized and unsterilized conditions in glass vessels and under the influence of various colors, as well as of white light and also in darkness, was not seriously affected, as shown by determinations of the optical activities of the fermented solutions.

Fermentation when conducted in copper vessels, but otherwise under the same conditions, was found to be influenced very markedly, as shown by differences in the acidity, optical activity, etc., of the solutions. The light of different colors influenced the changes indirectly. It appears that copper dissolved from fermenting vessels very largely determined the course of fermentation. The results obtained under the influence of blue light proved that the inhibitory effect of this light on the development of acidifying bacteria decreased the amount of acid produced and therefore lessened the amount of copper dissolved. On the other hand, the fermentations under the influence of red light and in darkness gave better facilities for a more vigorous growth of the bacteria. The acid produced under these conditions dissolved a little of the copper, and its inhibitory effect on a normal growth of the yeast and a regular fermentation is evident from the results obtained in the different determinations.

Various contributory causes were noted, among them the influence of temperature, which varied under the different colored lights. It was further found that the original composition of the wort exercises an effect upon the resulting fermentation, a good yeast appearing to resist the action of copper better than a poor one.

On the variation of peroxidase in seeds, Brocq-Rousseu and E. Gain (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 10, pp. 545–548*).—In a previous note (E. S. R., 19, p. 931) the authors report the discovery of the fact that peroxidases do not persist indefinitely in seeds. In the present paper an account is given of an attempt made to determine the length of time that peroxidase could be recognized in seed, the specimens examined varying from 2 to 2,000 years in age.

The oldest seeds to show the presence of peroxidase were *Triticum hybernum* and *T. monococcum*, which were about 208 years old. The seeds of a few other species of plants that were more than 100 years old showed the reaction for

peroxidase, but except in a few cases it was found that peroxidase develops in the seeds only when they are 20 years old or less.

Studies on variegation and some accompanying phenomena, II. LINDEMUTH (*Landw. Jahrb., 36 (1907), No. 5–6, pp. 807–862, pls. 2, figs. 16*).—A report is given of studies made on variegation in a large number of plants, principally species of Malvaceæ. Various theories of variegation are discussed and the results of extended experiments in the transmission of that phenomenon through grafting, cuttings, and seedlings are given.

Recent investigations in plant breeding, C. FRUWIRTH (*Jour. Landw., 56 (1908), No. 1, pp. 89–99*).—Brief summaries are given of some recent contributions to the literature of plant breeding. Most of the investigations reported were carried on in Germany, France, Austria, England, and Italy.

Reports of the plant culture stations in Denmark, 1905–6 and 1906–7 (*Separates from K. Danske Landhusb. Selsk. Aarsber., 1905–6, pp. 57–172; 1906–7, pp. 55–160*).—The reports contain summaries of trials conducted at various Danish State plant culture stations and accounts of other activities of the stations during the years given.

FIELD CROPS.

Thirty years of crop rotations on the common prairie soil of Illinois, C. G. HOPKINS, J. E. READHIMER, and W. G. ECKHARDT (*Illinois Sta. Bul. 125, pp. 323–356, figs. 8*).—This bulletin reports the results of rotation experiments in progress for 13 and 29 years under different systems of farming. The original experiment is described in a previous bulletin (E. S. R., 2, p. 559).

The average corn yields of the last 3 corn crops grown in different cropping systems in both series of experiments are given in the following table:

Average corn yields for the last 3 crops with different crop rotations.

Crop years.	Crop systems.	Average yield per acre.	
		13-year experiments.	29-year experiments.
		Bu.	*Bu.*
1905, 1906, 1907	Corn every year	35	27
1903, 1905, 1907	Corn and oats	62	46
1901, 1904, 1907	Corn, oats, clover	66	58

It was found that in 12 years of growing corn every year the yield became reduced from more than 70 bu. to 35 bu. per acre, and that during the next 16 years the decrease amounted to only 8 bu. During the first 11 years of the rotation of corn and oats the yield decreased from more than 70 bu. to 62 bu., and during the next 16 years a further reduction of 16 bu. occurred. In the 3-year rotation, during the first ten years the yield decreased from more than 70 bu. to 66 bu., and during the next 16 years to 58 bu., the average reduction being only ½ bu. per year.

In a system of grain farming a 3-year rotation of corn, oats, and clover was followed. The cornstalks were disked down and in harvesting the oats as much straw as possible was left in the stubble. The third year the clover was mowed once or twice and left lying on the land. If the clover seed crop was successful it was harvested and the clover straw returned to the soil. In addition, catch crops of annual leguminous plants such as cowpeas were grown between the corn rows. Special treatment was given some of the plats by applying lime at

the rate of ½ ton per acre of ground limestone, phosphorus for 6 years at the rate of 25 lbs. per acre per annum in the form of 200 lbs. of steamed bone meal, and a yearly addition of 42 lbs. of potassium in 100 lbs. of potassium sulphate. The cost per ton was about $2 for the limestone, $25 for the steamed bone meal, and $50 for the potassium sulphate.

Under the system of live stock farming all crops from the land as usually harvested were removed, including the corn and stover, oats and straw, and both first and second crops of clover. The amounts of manure applied were determined by the crop yields during the previous rotation, or the amounts of manure applied were such as could be produced in practice from the crops grown. A summary of the yields of the latest corn crops is given in the following table:

Average of three corn crops in the corn, oats, and clover rotation of thirteen-year experiments.

Crop years.	Special treatment.	Average yield per acre.	
		Grain farming.	Live stock farming.
		Bushels.	*Bushels.*
1905, 1906, 1907	None	69	81
1905, 1906, 1907	Lime	72	85
1905, 1906, 1907	Lime, phosphorus	90	93
1905, 1906, 1907	Lime, phosphorus, potassium	94	96

The results show in general that the fertility of the soil can be maintained or even increased by a proper system of grain farming with leguminous crops in the rotation, and that a good system of live-stock farming will also maintain the fertility of the land. It was observed that barnyard manure gave a net profit in the first 3 crops of $1.30 per ton, or of $7.80 an acre, when 6 tons had been applied. As an average of 18 tests with a rotation of corn, oats, and clover the use of 75 lbs. of phosphorus per acre produced increases in crop yields worth $12.39. Larger yields were secured and phosphorus was nearly twice as effective in the 3-year rotation of corn, oats, and clover as in the 2-year rotation of corn and oats. It is pointed out that while phosphorus is commonly the element that first limits the yield, nitrogen is lost from the soil so much more rapidly under poor systems of farming that this constituent soon becomes the limiting element, after which phosphorus alone has no power to increase the yield.

Field crops [at Copper Center Station in 1907], C. W. H. HEIDEMAN (*Alaska Stas. Rpt. 1907, pp. 53–58*).—In the tests with spring wheat varieties the most promising results were obtained with Early Riga and Velvet Chaff. Velvet Chaff or Blue Stem made the best growth but only a few heads matured, while Early Riga made only a fair growth but ripened uniformly. The most promising barley for future work in Alaska was Pamir No. 18922 from the Himalaya Mountains. Hanna Fall barley, sown April 27, made a good growth, matured, and was harvested August 15. Champion gave most satisfactory results as to yield of straw and grain and was next in earliness to Pamir. An attempt has been made to cross Pamir No. 18922 with Champion. Burt oats from station-grown seed nearly all matured by August 20. Finnish Black oats from station-grown seed produced its earliest matured heads August 15, and the entire field matured August 20, when it was cut for feed. Buckwheat was killed by frost July 4 and millet by frost in June. Wild rice was sown but none of the seed germinated this season. Of the winter grains, Amber winter rye was most resistant to winterkilling. The crop averaged 4 ft. in height.

About 11 acres are devoted to grasses introduced from the States. With the exception of smooth brome grass (*Bromus inermis*) and wheat grass (*Agropyron tenerum*) all have winterkilled badly and have run out. Wheat grass is the most promising of all the introduced grasses at the station. Timothy is not a success in that latitude. Seeds of 46 species of native grasses have been collected for thorough testing under farm conditions.

[Field crops at Rampart Station in 1907], F. E. Rader (*Alaska Stas. Rpt. 1907, pp. 43–47, pl. 1*).—Wheat, barley, rye, and oats were sown as winter grains on August 25, 1906, but the date of this seeding was too late for the latitude. For the first time in the history of the station winter rye failed to live through the winter and Kharkov wheat was the only winter grain to survive. Finnish Black oats, seeded May 24, was cut September 9. It reached an average height of 60 in., but the ground was too rich and the crop grew too tall and lodged badly. The growing season for Romanow wheat, seeded May 24, was about 10 days too short to bring it to maturity. A number of barleys from Abyssinia were grown this year for the first time and seem very promising. Of these, barley No. 362, seeded May 25, was ripe and was cut September 3, its average height being 36 in. A beardless barley, No. 12709, ripened its grain by September 3, but had a very brittle straw, so that when blown to the ground by a storm on August 1 it never straightened up again. Lapland barley this year ripened somewhat unevenly. Heretofore this variety has never failed to mature. Manshury barley has given the best results and has always ripened. This season it grew about 40 in. high and produced very plump heads of good length. Emmer and einkorn failed to mature.

Selected seed was grown of Lapland and Manshury barley and of Burt Extra Early and Finnish Black oats. Lapland barley reached a height of 60 in. and produced heads extra large and plump. The selected Manshury seed grew to a uniform height of 42 in. and the heads were fine and large. Both plats were harvested August 31. Burt Extra Early oats was harvested September 5. This variety has always ripened unevenly, but it is hoped that it may be improved by selection. Finnish Black oats grew to a uniform height of 48 in. and stood up perfectly. This variety is considered the best of those tested at the station.

Among the grasses under test, meadow foxtail (*Alopecurus pratensis*) has proved the earliest in maturity. This season it was ready to cut for hay July 1, when it had reached a height of 36 in. The seed was ripe July 20 and it was harvested for seed August 8. Orchard grass (*Dactylis glomerata*) did not head at all, and timothy (*Phleum pratense*) was also unsuccessful. Smooth brome grass (*Bromus inermis*) promises to be a good grass for hay in that region.

Early Rose potatoes yielded about ninefold and Burbank about eightfold. In yield and size the potatoes this year were inferor to last year's crop. The tubers keep perfectly in the winter.

Report of the Upper Peninsula Substation for the years 1905 and 1906, L. M. Geismar (*Michigan Sta. Spec. Bul. 41, pp. 3–40*).—Meteorological data for the 2 years are given in tables and the yields of different crops tested at the station are reported and discussed in detail.

The yields per acre of the most productive varieties in 1905 were as follows: Early Champion oats 47.5 bu., Mansheuri 6-rowed barley 35 bu., Dawson or Golden Chaff winter wheat 35.67 bu., French June field peas 41 bu., Northwestern corn 27.12 bu., Swedish Brown field beans 51.08 bu., Improved pea 29.04 bu., Earliest Navy bean 27.83 bu., Rye buckwheat 44 bu., broom corn or hog millet 48 bu., Northern Beauty potatoes 358.46 bu., Meyer Friederichswerth Elite sugar beet 37,600 lbs.

In 1906 the leading varieties and their yields were as follows: North Finnish S. P. I. No. 5513 oats 58 bu., Silsolsk No. 89 barley 35 bu., Velvet Chaff spring wheat 17 bu., Black English field peas 33.60 bu., Northwestern corn 68.06 bu., Swedish Brown field beans 43.17 bu., Rye buckwheat 25.83 bu., flax 10.30 bu., einkorn 29.04 bu., Dolsen potatoes 272.25 bu.

Potatoes planted November 5–9, 1904, sprouted and blossomed about 1 week earlier the following spring than potatoes of the same varieties planted May 18 and 20, 1905. A ¼ acre of fall planted potatoes yielded 3,390 lbs., as compared with 3,266 lbs. for a ¼ acre of spring planted tubers.

In 1906, on drained muck land these varieties of potatoes ranged in yield from 123.75 bu. to 284.62 bu. per acre, the leading variety being Northern Beauty. This same year a comparison of fall and spring planting on ⅛ acre plats again favored the fall planted crop in sprouting and blossoming. The yield on this area was in favor of spring planting by 369 lbs. In both years the average differences in yield between level and hill culture and in 1905 between spraying and not spraying were immaterial. In 1906, spraying with Bordeaux mixture gave an average increase at the rate of 22 bu. per acre. A sprayed plat of Delaware potatoes this same season yielded at the rate of 460.8 bu. per acre, while the unsprayed plat produced at the rate of only 358.4 bu.

Kherson oats stood second in 1905 with a yield of 40 bu. per acre. Burt and Sixty Day, two white varieties, and North Finnish, a black oat, are considered promising for that region. French Chevalier 2-rowed barley has given only low yields.

The results of a corn-breeding experiment in 1906 showed that corn will readily adapt itself to new environments and demonstrated the importance of breeding a type sure to ripen in all localities and in all seasons in the Upper Peninsula. Gehu has proved to be the earliest corn of 100 early varieties under test.

The yields of numerous forage crops are given in tables and the growth of these crops is briefly noted.

Forage crops in northwest Texas, A. B. Conner (*Texas Sta. Bul. 103, pp. 5–21, figs. 6, map 1*).—Cooperative forage crop investigations were begun by the Texas Experiment Station and the Bureau of Plant Industry of this Department in 1905 at Chillicothe, and in 1906 at Amarillo, in northwestern Texas, or that part of the State known as the Panhandle. Brief descriptions and cultural directions are given for the different forage crops tested.

Sorghum is by far the most important forage crop of this section. The best forage varieties, according to this report, are Sumac, Orange, Planter, Blackhull Kafir corn, Red Kafir corn, Red Amber, Minnesota Amber, and Milo maize. In 1907, a season not at all favorable to heavy forage production, medium early planting sufficiently thick and regular in the drill to allow the utilization of all available moisture gave the following yields at Chillicothe: Sumac and Orange 5 tons, Blackhull Kafir corn and Red Amber 4½ tons, Minnesota Amber and Planter 4¼ tons, Red Kafir corn 4 tons, and Milo maize 3 tons of thoroughly dried-out forage per acre. Careful seeding was found to control largely the growth and yield of the crop, and the use of a planter with a pack-wheel is recommended. Hand-thrashed seed was found more satisfactory than machine-thrashed seed.

The heaviest yields of forage with most varieties were obtained from drills 21 in. apart with stalks every inch in the drill. Milo maize gave the largest yield of forage in rows 42 in. apart with stalks every inch, and the best yield of seed in rows 3 ft. apart with stalks every 6 in. The yields ranged from 3 to 6 tons per acre at Chillicothe and from 3 to 8 tons at Amarillo.

Alfalfa promised to be valuable in the southeastern part of the section, but through the northwestern portion it had little promise except when grown in depressions known as swales, on beaches around lakes, and especially in canyons. Kansas and Texas grown seed gave the best results. Turkestan alfalfa has so far been a poor yielder.

The cowpea, which is valuable for rotation with sorghum, promises to take the place of alfalfa on the uplands. The moth bean compared favorably with the cowpea in yield of hay and was apparently more drought resistant. The soy bean and the mung bean did not give very satisfactory results.

Grains and forage crops for northern Wisconsin, R. A. Moore and E. J. Delwiche (*Wisconsin Sta. Bul. 161, pp. 3–23, figs. 5*).—The results secured with different grains and forage plants on the substation farms in northern Wisconsin in 1906 and 1907 are reported and discussed. It has been observed in general that the sandy soils of this region are especially adapted to growing sugar beets, corn, oats, soy beans, and clovers when well manured and a proper crop rotation is followed. The clay soils when well worked and drained are suitable for growing winter wheat, barley, oats, peas, clover, and mixed grasses. On heavy clay soil alsike clover has yielded as high as 8 bu. of seed per acre.

The early varieties of corn gave good yields on rich sand and clay loam soils, while the medium dent varieties produced an abundance of fodder but were too late for good yields of well-matured ear corn. Smut Nose and Yellow Flint matured well and seemed to be the preferable varieties for the region at present. Barley was profitable only on old well-subdued clay and loam soils. The heavy, bearded, stiff-strawed, six-rowed varieties have done best.

Wyoming forage plants and their chemical composition, H. G. Knight, F. E. Hepner, and A. Nelson (*Wyoming Sta. Bul. 76, pp. 119, figs. 50*).—These studies are in continuation of work previously reported (E. S. R., 18, p. 229). Of a total of 152 analyses of native and introduced forage plants grown in Wyoming, 72 are included in this bulletin. Heretofore the plants collected for the chemical work were all gathered at about an altitude of 7,000 to 8,000 ft., but for this bulletin the plants were collected from various altitudes ranging from about 4,500 to 11,000 ft.

It was found that the crude fiber in the Wyoming native grasses runs higher on an average than the crude fiber in eastern grasses, but apparently the variations in altitude alone have little or no effect upon this constituent and it is believed that when the crude fiber content is lower in forage grown at low altitudes other causes than altitude must operate to produce this general change.

The forage plants analyzed in general have shown a high percentage of nitrogen, averaging about 9 per cent of the water-free material when calculated as crude protein. Analyses made of soils show on the contrary a marked deficiency in nitrogen content. Thirteen grasses collected at elevations from 10,000 to 11,000 ft. contained on an average 4.85 per cent of ash, 2.64 per cent of crude fat, 32.32 per cent of crude fiber, 10.95 per cent of crude protein, and 49.24 per cent of nitrogen-free extract. This was very close to the average composition of forage plants collected at lower altitudes, but the crude protein was about 2 per cent higher. Downy oat grass, collected at 10,000 ft., contained 9.69 per cent of crude protein, while another sample collected at 11,000 ft. contained 12.20 per cent. Other samples are cited but the number of plants obtained at different altitudes is not considered large enough to warrant general conclusions.

A number of miscellaneous analyses, including analyses of grains, straw, and mixed hay, are also recorded.

Alfalfa studies, P. K. Blinn (*Colorado Sta. Bul. 128, pp. 3–7, pls. 5*).—The station has made a selection of seed from promising alfalfa plants and has established an alfalfa nursery containing 64 different varieties of promising

individual selections. This nursery was planted April 15, 1907, and thinned to single plants about the middle of July. An epitome of the first season's observations is given.

While in previous tests at the station the Turkestan alfalfa has proven the most desirable for hay, it was observed in these tests that although one-half of the plats were sown with Turkestan strains the most leafy and the greatest seed-producing plants were not found in the Turkestan varieties. Six selections of the most promising type for seed and hay were made, and of these the seed production in four ranged from 70 to 118 gm. from 10 plants, one strain produced 18 oz. of clean seed from 50 plants and the remaining strain 11 oz. from 150 plants.

Clover seed in the Connecticut market, E. H. JENKINS and MARY H. JAGGER (*Connecticut Sta. Bul. 160, pp. 3–14, figs. 3*).—This bulletin briefly reports the results of examining 51 samples of clover seed obtained from various sources within the State. The seed of 26 of the samples examined weighed less than 1½ gm. per 1,000 seeds, that of 2 weighing 1.27 gm. or less, being equal to about 363,000 seeds per pound. Two samples weighed 1.92 gm. per 1,000 seeds, which is equal to 236,000 seeds per pound.

The average vitality of the 51 samples was 86.6 per cent, but 20 fell below the minimum of 85 per cent and 4 below 75 per cent, the lowest being 64.2 per cent. The average purity of the seed was 90.5, which is 7.5 per cent lower than the provisional standard of this Department. Disregarding the foreign clover, alfalfa, and timothy seed present, 8 lbs. per acre of any of these samples would plant from 2 to 8 weed seeds per square foot of land.

Three samples were found highly adulterated, the first containing 21.2 per cent, the second 22.6 per cent, and the third 39.1 per cent of black medic (*Medicago lupulina*). In 5 samples the total number of foreign seeds per pound was 78,604, 54,705, 12,458, 28,237, and 44,522, respectively. Only 10 samples were apparently free of dodder seed. In 28 samples tested from 18 to 11,615 dodder seeds were found per pound. With a seeding of 8 lbs. per acre the smaller quantity of dodder would give 1 seed to every 300 sq. ft., while the larger quantity would average 2 dodder seeds for every square foot.

[Experiments in clover and corn selection], F. W. CARD (*Rhode Island Sta. Rpt. 1907, pp. 214–220*).—A test of purple and yellow seeds of red clover showed no material difference in average nitrogen content between the plants grown from the two kinds of seed, but striking differences in the nitrogen content of different individual plants varying from 2.86 per cent in the lowest to 4.62 per cent in the highest, or an increase of over 60 per cent, were observed.

In the corn selection experiments 6 rows of seed from plants bearing 13 ears in 1905 and 13 rows from plants bearing 11 ears in 1905 were planted May 24, 1906. The corn from the 13-ear seed gave an average of 21.3 oz. of ears per plant, 4.6 ears per plant, 3.1 good ears per plant, and with an average weight per ear of 4.6 oz. The corn grown from the 11-ear seed produced 15.6 oz. of ears per plant, 3.5 ears, and 2.3 good ears per plant, while the average weight per ear was 4.5 oz. The highest number of ears per plant borne in 1905 was 13 and in 1906 only 10, but the average number per plant increased. In 1905, 50 per cent of the plants bore less than 4 ears, and in 1906 only 27.5 per cent bore less than 4 ears.

Egyptian cotton in the southwestern United States, T. H. KEARNEY and W. A. PETERSON (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 128, pp. 71, pls. 5, figs. 2*).—A review is given of the cotton trade of Egypt, together with a description of Egyptian cotton, and the results of experiments with this kind of cotton in Arizona are reported.

It is stated that the Colorado River region in southern Arizona and southeastern California, where the climate most nearly resembles that of Egypt, has proved to be well adapted to Egyptian varieties of cotton and that experiments in the Southwest, especially at Yuma, Ariz., during the last 5 years have demonstrated that good yields of high grade can be secured. At first the introduced plants made an excessive growth and produced relatively few bolls, but as the process of acclimatization progressed the plants were reduced in size, the average number of bolls greatly increased, they ripened much earlier and opened wide. Selection was also practiced in order to eliminate inferior individuals. The average length of the fiber of Mit Afifi, the principal variety, was less than 1⅜ in. and lacked strength, fineness, and uniformity as to the characteristic light brown color. In 1907 the length of fiber on the experimental field was practically 1½ in. and the quality had also improved. Two well-marked types were selected, one corresponding to Mit Afifi and the other to Jannovitch. The fiber of the first of these types is about 1½ in. in length, crinkly but fine, and of a pronounced brown color, while the second, which more nearly approaches Sea Island varieties, averages 1⅝ in. in length of fiber, which is silky, lustrous, and of a very light cream color. Mit Afifi yielded at Yuma in 1907 at the rate of 3,300 lbs. of seed cotton per acre, the percentage of lint being about 30. The crop was grown in rows 6 ft. apart and the plants 3 ft. apart in the row. In Egypt the rows average 32 in. apart and the hills 16 in. apart with 2 plants in each hill. The heavier growth in Arizona necessitates wider planting, but as the plants become acclimatized they will probably become smaller and the distance of planting may then be decreased.

Early planting has given much better results than late planting. A level seed bed with flood irrigation seems to be better suited to this section than the furrow method of planting and irrigation practiced in Egypt. The tap root of the plants on the loamy soils of the Yuma Valley penetrate from 6 to 8 ft. and consequently less water is required than for most crops under irrigation. It seems that in a rather light loam soil with the proper cultivation two irrigations after planting will produce a good crop. The fiber of the Egyptian cotton plants in the Colorado River region continues to ripen during several months and 3 or 4 pickings are necessary to harvest the bulk of the crop. Owing to the smaller size of the bolls picking is slower than with our large bolled Upland varieties. All other cultural processes are the same for both types. It is stated that one-fifth of the 600,000 acres of land ultimately to be under irrigation in the Colorado River region yielding 1 bale to the acre could produce the average amount of Egyptian cotton imported into the United States during the last 10 years.

How to make cotton growing pay, G. W. Carver (*Alabama Tuskegee Sta. Bul. 14, pp. 5–14, figs. 2*).—General directions for the profitable culture of cotton are given, and the advantages of special soil preparation are pointed out. The best results in a culture test were obtained on a plat plowed 9 in. deep and thoroughly pulverized by repeated plowing and harrowing until the soil was fine and mellow to that depth. A stalk of cotton grown on this soil had a splendid root growth and produced 12 mature bolls, while stalks on ground not prepared so deep had small root systems and matured fewer bolls.

To show the advantages of shallow surface cultivation, which produces a dust mulch and leaves the feeding roots undisturbed, the results of experiments with the sweet potato are pointed out. Sweet potatoes cultivated 2 in. deep gave much better results than those cultivated 5 and 6 in. deep. The meteorological records for 1906 and 1907 are reported, with brief comments.

Rice investigations: Report of first year's experiments, F. G. Krauss (*Hawaii Sta. Rpt. 1907, pp. 67–90, pls. 5*).—The rice industry in Hawaii is

briefly discussed and the plans, objects, and methods of the experiments reported are noted.

Of more than 100 varieties under test 11 have been selected as suitable for Hawaiian conditions. A number of these are upland rices producing a fair yield with a minimum moisture supply, and the others are promising wet land rices of the short, thick kernel type characteristic of Japan rice. Brief notes on some of these varieties are given. The results of a comparative study made between plats of several varieties are presented in the following table:

Comparison of standard Hawaiian Gold Seed, Japan Seed, and Egyptian varieties of rice.

Name of variety.	Station inventory number.	Date of sowing, 1907.	Date of maturity and harvest, 1907.	Growing period.	Height of plants.	Weight of paddy.	Weight of straw.	Estimated acre yields, paddy.
				Days.	*In.*	*Gms.*	*Gms.*	*Lbs.*
Standard Hawaiian Gold Seed.	148	Feb. 18	July 20	152	42	32	68	3,730
Hawaiian-grown Japan Seed..	153	...do	June 8	110	36	20	54	3,412
Hawaiian-grown Egyptian....	65	...do	July 20	152	48	43	114	4,129

It was found in this work that some varieties which yield well from July planting fail if sown in the early spring, or continue to vegetate until late fall, when they flower and fruit at about the same time as summer plantings. The all-season varieties are considered best for Hawaii. The spring varieties also produce fall crops, while fall varieties are not at all suited to spring culture.

With a view to discovering some of the fertilizer requirements of rice a series of 7 fertilizer experiments was begun July 1, 1906, and continued through a period of about 15 months. The first experiment was made with Hawaiian Gold Seed, and the results secured are summarized in the following table:

Summary of pot experiments with rice, showing effect of fertilizers on growth.

Series No.	Fertilizer used and calculated rate per acre.	Water transpired by 5 plants in total period of growth.	Green weight of 5 plants at end of 30-day period.	Water-free weight of 5 plants at end of 30-day period.	Water transpired per pound of water-free substance.
		Gms.	*Gms.*	*Gms.*	*Lbs.*
1	Check (no fertilizer)	202.0	1.92	0.42	480.95
2	Stable manure .....5 tons..	287.4	2.75	.60	479.00
3	Lime, air-slaked .....1 ton..	296.3	2.75	.57	519.82
4	Nitrate of soda.....200 lbs..	276.1	2.57	.57	484.38
5	Sulphate of potash .....200 lbs..	298.1	2.75	.57	522.98
6	Acid phosphate.....200 lbs..	276.7	2.57	.57	485.44
7	Nitrate of soda and sulphate of potash, 200 lbs. each	299.7	2.47	.60	499.50
8	Nitrate of soda and acid phosphate, 200 lbs. each.....	292.9	2.67	.57	513.86
9	Sulphate of potash and acid phosphate, 200 lbs. cach	235.1	2.37	.50	450.50
10	Nitrate of soda, sulphate of potash, and acid phosphate .....200 lbs. each..	314.6	2.67	.60	524.33
11	Nitrate of soda, sulphate of potash, and acid phosphate, 200 lbs. each, and lime, 2,000 lbs.	273.3	2.50	.55	496.91
12	Nitrate of soda, applied in 10 doses, 3 days apart .....200 lbs..	420.2	4.40	.95	442.10

The most striking result was the superior growth obtained where nitrate of soda was supplied in 10 equal doses, and the second important result was the apparent depreciation of the yield through the application of lime.

The object of the second experiment was to determine as far as possible by means of pot cultures the influence upon the yield of grain and straw of the various elements found in commercial fertilizers used in combination with and without lime. Japan variety No. 153 was used for the test and all fertilizers were mixed with the first 3 in. of soil before planting and applied at the rate of 50 lbs. per acre for each element. One of the striking results in this test was the general depression of the plants when treated with lime, the loss amounting to from 14 to 40 per cent. The general results of the test indicated that nitrogen in the form of sulphate of ammonia is especially suitable for the rice plant. The results with fish guano agreed closely with those obtained with sulphate of ammonia. Next to these two substances acid phosphate seemed to be the most available for the plant. The best combination of two elements was nitrogen and phosphorus in the form of sulphate of ammonia and acid phosphate or fish guano and acid phosphate. Where a complete fertilizer made up of the several forms of these different fertilizers was used practically all the plants were killed within a month.

The relative value of different fertilizers when applied to two widely different types of rice, the Hawaiian Gold Seed and Japan rice, was studied in a third experiment. The fertilizers were supplied in as varied selection as the market afforded and where single constituents were added 40 lbs. of nitrogen, 25 lbs. of phosphoric acid, and 45 lbs. of potash were supplied per acre. The data secured are brought together in the table below:

Relative value of the various commercial forms of nitrogen, phosphoric acid, and potash as fertilizers for the rice crop.

Fertilizers applied per acre.	Check (untreated).	Fertilized before planting.		Limed (750 lbs.) and fertilized before planting.		Fertilized after plants were three-fourths grown.

Complete fertilizer (sulphate of ammonia, fish guano, reverted phosphate, and sulphate of potash), 350 lbs	3.66	7.55	+ 99.73	3.37	−10.8	3.57	− 5.55
Complete fertilizer (nitrate of soda, Thomas slag phosphate, and sulphate of potash and magnesia), 350 lbs	3.30	3.94	+ 4.23	3.00	−20.63	4.31	+14.02

The average production of the 10 untreated plats was 3.78 lbs. of paddy. In a second experiment in which the Hawaiian Gold Seed variety was grown the results were almost identical with those given in the table above.

Plat tests were carried out in a fourth experiment with Japan seed rice fertilized with Chinese peanut cake, fish guano, stable manure, and commercial fertilizers. On some plats lime was used, and as in practically all other tests the addition of this substance seemed to depress the yield except on the plat receiving stable manure at the rate of 5 tons per acre. Fish guano and commercial fertilizer showed a decided gain in the application made before the crop

was sown as compared with the application after the crop had become well advanced. Little difference in this regard was observed with Chinese peanut cake. Stable manure showed an increase of 121 per cent of paddy for an application of 2½ tons, while an application of 5 tons per acre yielded 250 per cent increase over the check plat and over 100 per cent more than where only half as much manure was used. Stable manure also greatly increased the yield of straw in proportion to the amount of grain. Fish guano, which stood next, gave an increased yield of 118 per cent over the check plat, followed by the commercial fertilizer with an average gain of 100 per cent when applied at the rate of 100 lbs. per acre. The same treatment upon the Gold Seed variety produced about the same results.

The object of the fifth experiment was to compare the relative value in economy of several complete fertilizers under different modes of application. The fertilizers were applied April 30, 1907, when the crop was about half grown. The application in one instance was made up of fish guano, acid phosphate, and sulphate of potash and magnesia, and in another of nitrate of soda, sulphate of ammonia, acid phosphate, and muriate of potash. These compounds were used alone, and the one first mentioned was also given in combination with sulphate of ammonia. Where the compound containing the guano was worked into the ground to a depth of several inches a gain of 58.5 per cent, equivalent to a net profit of $29.60 per acre, was obtained, and where the fertilizer was not worked into the ground an increase of 42.5 per cent, representing a net profit of $20.75, was secured.

In the sixth and seventh experiments, conducted in conjunction with the experiment just described, two special nitrogen fertilizing tests were undertaken on a field scale. Sulphate of ammonia at $72 per ton was applied at the rate of 75 and 100 lbs. per acre, and nitrate of soda at $55 per ton at the rate of 100 and 150 lbs. per acre. The applications were made at the same time when the plants were a little more than half grown. The sulphate of ammonia from the 75 and 100 lbs. applications showed increases of 80 and 85 per cent, or net profits of $35.15 and $36.50 per acre, respectively. The larger application barely paid for the extra cost, as compared with the use of 75 lbs. per acre. The 100 lbs. application of nitrate of soda produced a gain of 21 per cent, or a net profit of $12 per acre. These results between the two forms of nitrogen are in practical agreement with those secured in the pot experiments.

The results of culture experiments with reference to age of seedlings at time of transplanting and to broadcasting, drilling, and transplanting are presented in the following tables:

The yield of Japan seed rice (No. 153), as influenced by age of seedlings at time of transplanting.

Topography of the sugars and nonsugars in the sugar-beet root, J. URBAN (*Ztschr. Zuckerindus. Böhmen, 32 (1907), No. 1, pp. 17–24, figs. 2*).—Different parts of the beet root were found to vary not only in sugar content and in crude ash but also in the composition of the pure ash. The organic and inorganic nonsugars increased from the lower toward the upper portion of the root, but the rate of increase was not the same for all substances. In the fresh material, the smallest quantity of potassium oxid was found in the middle portion, while phosphoric acid was about equally distributed throughout the root. The ash from the lower part contained the largest quantities of potassium oxid and phosphoric acid, but these substances decreased toward the crown. Sodium oxid, lime, and chlorin decreased from the crown toward the tip.

A study of the concentric parts of the beet showed that the sugar content is highest and the nonsugars are lowest in the middle portion, that the inner portion contains less sugar, and that the lowest percentage of sugar is found in the youngest layer next the skin. Sodium oxid and chlorin were lowest and calcium oxid, potassium oxid, and phosphoric acid were highest, in the outer portion.

Plant food requirements of seed beets, mother beets, and cuttings, K. ANDRLÍK, J. URBAN, and V. STANĚK (*Ztschr. Zuckerindus. Böhmen, 32 (1907), No. 1, pp. 1–17, figs. 2*).—The composition of seed beets in the early stages of growth, at the time their stems develop, during blossoming and seed formation, and at maturity was determined, and the contents of the different elements at these various stages are recorded and discussed. The results of analyses are given in the table on the following page.

Composition of seed beets in different stages of development during the second year of growth.

An experiment in Swedish turnip culture, F. W. Card (*Rhode Island Sta. Rpt. 1907, pp. 265–273, pls. 10*).—The results of this experiment indicated that the turnip grows best on a garden soil which is sandy rather than silty or clayey. Lime was not beneficial except on a humus soil. Commercial fertilizers increased the tops more than the growth of the roots. Potash was the most advantageous ingredient and when combined with phosphoric acid gave better results than any other combination of commercial fertilizers. The use of sulphate of ammonia gave but a slight increase in yield, and the use of nitrate of soda and dried blood gave no beneficial results. Barnyard manure gave an excellent total yield, but scab was more prevalent than where commercial fertilizers were used. Ashes showed no increase in root growth but apparently increased the growth of the tops about 50 per cent. A moderately dry soil gave better yields than a very wet one. Lime was beneficial when applied with the commercial fertilizers.

HORTICULTURE.

[Horticultural investigations in Alaska], C. C. Georgeson, R. W. De Armond, F. E. Rader, and C. W. H. Heideman (*Alaska Stas. Rpt. 1907, pp. 21–25, 31–41, 47–49, 50–53, 74–87, figs. 3*).—Notes are given on the varieties of fruits, ornamentals, and vegetables being tested at the Sitka Station, fruits and vegetables at the Rampart Station, and vegetables at the Copper Center Station. More than 12,000 fruit trees and shrubs, as well as a large amount of seed, were sent to various parts of the Territory, and the results secured with some of these lots are given in letters from several of the stations' cooperators.

At the Sitka Station, where the work with fruit is more advanced, the Hyslop and Yellow Transparent apples bloomed during the past season, but bore no fruit. These varieties, together with the Whitney crab and the Peerless, give considerable promise. Other varieties are doing poorly. It appears certain that only the so-called summer varieties can mature in Alaska, since in the interior the season is too short, and in the coast region the summers are too cool to mature fall and winter apples. The experiments also indicate that dwarf trees are likely to succeed best.

Of the four varieties of cherries growing, the Early Richmond and English Morello are the best. Currants, gooseberries, and raspberries do well in Alaska. The Cuthbert raspberry has done particularly well in the coast region. The

Downing and Houghton gooseberries have been fairly successful at the Sitka Station, but the Whitesmith, a large English variety, excels them all. Crosses of cultivated varieties of raspberries and strawberries with native varieties are being tested. A native black gooseberry and several native currants have been brought under cultivation.

Trees and plants suffered considerable damage from upheaval during the winter of 1906–7.

Report of the horticulturist, J. E. HIGGINS (*Hawaii Sta. Rpt. 1907, pp. 52–60, pls. 2*).—The chief work of the year consisted in experiments in the shipping of tropical fruits, already noted (E. S. R., 19, p. 338).

The orchard area has been increased by about 4 or 5 acres. In addition to avocados and mangoes, the newer orchard plantings include oranges, pomelos, lemons, papaias, sweet sop (*Anona squamosa*), sour sop (*A. muricata*), cherimoya (*A. cherimolia*), Kafir plum (*Harpephyllum caffrum*), *Spondius lutea*, guava (*Psidium guajava*), and the star apple (*Chrysophyllum cainito*). About 1 acre has been planted to mulberries for experiments in the production of food for silkworms.

Brief descriptive notes are given of the star apple, the fruit of the Anona group, the carambola (*Averrhoa carambola*), which is a Chinese fruit furnishing a drink similar to lemonade, and *Carica quercifolia*, which species of Carica is said to be much richer in papaine, or "vegetable pepsin," than the papaia.

The cultivation of roselle was continued and experiments conducted in the manufacture of jam and jelly. The receipts used are here given. There appears to be nothing gained in planting roselle seed earlier than February in the region of Honolulu. Seed planted before this date produced plants which bore prematurely but did not produce the main crop earlier than plants which were started later. Although the roselle does not require the richest soil, correspondingly better results are secured on good soils. In the experiments conducted at the station the yield averaged from 6,000 to 7,000 lbs. per acre.

The Natal pineapple being tested at the station fruited during the year and is believed to be identical with the Queen. This variety, while not adapted for canning, is of fine quality and may prove of value in markets where a small fruit is demanded.

Report of the South Haven Substation for 1906, L. R. TAFT and F. A. WILKEN (*Michigan Sta. Spec. Bul. 40, pp. 3–37*).—This is the regular annual report of the South Haven Substation, consisting chiefly of brief cultural and descriptive notes on the varieties of strawberries, gooseberries, currants, raspberries, blackberries, cherries, peaches, plums, grapes, pears, apples, crab apples, quinces, and nuts being tested, in connection with which lists are given of cherries, plums, grapes, pears, and apples recommended for planting.

The attempt to grow the English walnut has met with failure thus far. The pecan has made a vigorous growth, but has not yet fruited. The Japanese walnut (*Juglans sieboldiana*) bore a small crop containing many undersized nuts. The trees appear to be failing. Both the Kentish Cob and the Cosford Thin Shell filberts are thrifty growers, but are not productive enough for commercial purposes, although desirable for home use. The chestnuts, of which Paragon is considered the best variety, are the most promising, although the Japanese varieties have failed to fruit.

A test was made between paper and wooden boxes as carriers of strawberries, gooseberries, and currants. The wooden box was found to be superior in picking and packing the fruit and was the one desired by the trade, as the paper boxes were not considered firm enough to stand rough handling. There is little difference in the cost, but the paper box is more attractive. It is suggested

that it may be used for a special trade where care is taken in handling the fruit.

In addition to comparative tests of the various remedies for the San José scale, which have been previously reported (E. S. R., 19, p. 56), cooperative experiments in spraying for the second brood of codling moth were carried on. The plats were injured by the freeze of October 10, thus destroying the chance of getting accurate results, but the evidence secured indicates that the spraying should be done by August 1. It is recommended that in orchards infested with the codling moth the trees should be sprayed with arsenate of lead either the latter part of July or early in August. With varieties subject to the attack of apple scab the addition of Bordeaux mixture is advised.

[Report on horticultural crops of the Upper Peninsula Substation for the years 1905 and 1906], L. M. Geismar (*Michigan Sta. Spec. Bul. 41, pp. 42–59*).—Cultural and varietal notes with tabular data in some instances are given of peas, beans, sweet corn, cucumbers, squashes, pumpkins, muskmelons, onions, tomatoes, radishes, spinach, lettuce, cabbage, celery, pepper, tobacco, and kale, together with several herbs, honey plants, and ornamentals grown at the station in 1905 and 1906. Similar notes are given for strawberries and orchard fruits.

Report of the horticulturist, F. García (*New Mexico Sta. Rpt. 1907, pp. 31–46*).—An outline of the work of the year with data on variety tests of sweet potatoes and the cost of producing sweet potatoes and chillies. The newer work includes variety tests of apples and strawberries, a study of the life history of the codling moth and a test of the lime-sulphur-wash for the San José scale in that region, investigations relative to the best time to plant strawberries and onions, and fertilizer and close-planting celery tests.

The 3 best sweet potatoes relative to yield were the Polo, Fullerton Yellow Yam, and Brazilian. In 1906 on a one-half acre plat of sweet potatoes, the total cost, inclusive of hauling the crop and growing the sets in the cold frame, was $40.67. The total yield was 10,809 lbs., which were sold for $159.36. Partial data are given on similar work with sweet potatoes and chillies for 1907.

Report of the horticultural division, F. W. Card (*Rhode Island Sta. Rpt. 1907, pp. 211–214, 220–265, pls. 7*).—The results for the year are given of various cultural and breeding experiments, including further data on the market garden rotation and lawn experiments (E. S. R., 18, p. 1125).

A large number of crosses have been made between different varieties of raspberries and blackberries during the past years. Some general notes are given on a few of these which are considered promising.

The breeding of beans with a view of increasing their frost-resistant power was continued and the results to date are given. To determine what progress has been made in increasing the hardiness of the beans, seed of the same varieties included in the work was obtained from a seedsman in 1907 and planted with them. From the data obtained the conclusion is reached that this is not a promising line of plant breeding.

Further observations are given on the condition of the various plats in the lawn experiments in which the effects of fertilizers leaving an acid residue and those leaving an alkaline residue are being compared with fertilizers having a neutral effect on the soil. Seven different grasses and grass mixtures were used in this comparison. On other plats different proportions and combinations of fertilizers are being tested, together with special grass mixtures offered by seedsmen.

In the market garden rotation experiment, in which the value of stable manure is being compared with chemicals combined with cover crops, potatoes and early cabbage were used for the early crops, which were followed by beets and

carrots on the ground occupied by early cabbage and by turnips and cabbage on the ground first occupied by potatoes. A detailed account is given of the work together with the results secured. Taking the crops as a whole, the yields from chemicals supplemented by cover crops were equal to those obtained from stable manure. The potatoes were the only crop which gave a slightly larger yield from stable manure. Similar work was continued with onions, spinach, and lettuce in 1907. The season was cold and backward, however, and only the spinach germinated promptly. The spinach grew decidedly quicker on the chemical plats, as may be expected in a cool season unfavorable for the action of the soil organisms in the stable manure.

A test was made of different methods of planting muskmelons with the particular object of seeing whether it was possible to grow a crop in spite of the melon blight. The ground was plowed early in May and lime applied and harrowed in at the rate of 1 ton per acre. The experimental plat was divided into 3 sections. In the first 2 sections stable manure was placed in the partly filled furrows, which were then ridged up, and in section 3 the manure was placed in the bottom of the furrow, after which the soil was leveled off. Seeds were sown on parts of each section and the remainder was planted with potted plants. The tabular results show that the largest melons were obtained from the transplanted plants, and that a larger proportion were obtained somewhat earlier. A better yield was also obtained from the section in which the manure was placed in the bottom of the furrow and covered, leaving the ground level, than from the sections in which the melons were grown on ridges. The number and average diameter of mature and green melons found on each section at the end of the season are given. Taking equal length of row, the yield showed 637 melons from transplanted plants and 799 from seed plants. The transplanted plants, however, were set 2 ft. apart in the row, while the seedling plants were much closer. Blight appeared upon the melons about the end of August and the vines were given 4 successive sprayings a week apart with Bordeaux mixture. Compared with the behavior of melon plants elsewhere the same season, spraying appeared to hold the blight somewhat in check.

Detailed notes were made on the strawberries in fruit during the season. Descriptions and scales of points are given for a few of the most promising seedlings. Very few of the named varieties gave satisfactory yields. The Gowen Seedling and Latest were the best.

An attempt has been made for several years to improve the production of strawberries by selecting and breeding from the most productive parents. A summary is given of the results since 1899. The results have not been satisfactory, however. "The difficulties which have appeared have seemed to more than offset the possible advantage which might accrue by always selecting the most productive parents."

To determine if possible the influence of using scions procured from bearing trees of known quality and productiveness, a number of Northern Spy trees were planted in the spring of 1898 and top grafted in the following year with selected scions of Rhode Island Greening. Comparisons will be made when the trees come into fruiting with ordinary nursery grown trees. Other tests with apples are also being conducted to determine the influence of stock upon scion, and a summary is given of the work to date.

Records are given of the blooming periods of several varieties of apples, pears, peaches, and plums in the station orchard for the years 1904, 1905, and 1907, together with brief notes upon a few varieties of peaches which have fruited on the college grounds. Notes are also given on several miscellaneous breeding experiments with fruits.

Observations were made in the autumn of 1906 on the college vineyard posts, which were variously treated in 1903 with a view of adding to their durability (E. S. R., 16, p. 59). The posts treated with carbolineum were making the best showing. In some cases the outside surface was still quite firm. Charred posts and those treated with coal tar ranked next in their condition and were equally well preserved. Very little difference could be detected in the treatments with pine tar, lime, or copperas and lime. The outer wood ring was more or less decayed in all cases and in the untreated posts was entirely gone. No difference was noted between the posts set with the top end down and those with the bottom end down.

Northern Spy trees were planted in 1898 with a view of testing the influence of methods of pruning at planting time upon the subsequent growth. The trees planted included 2-year whips, 2-year branched trees trimmed to a whip when set, 2-year trees with branches cut back one-half and the leader untouched, 2-year trees untrimmed, and trees with the roots untrimmed, cut back half, and cut back by the Stringfellow method, leaving only a mere stump. In the 3 latter lots the branches were cut back about one-half, leaving the leader untouched. Trees were also planted by the Stringfellow method with the roots cut back to a mere stump 1 or 2 in. long, and the tops cut back to a stub about 1 ft. long. Very little difference has resulted from the different methods of treatment, except in the case of the untrimmed trees cut back to whips when set, in which the tendency has been to develop a tall, leggy growth with small tops. The trees which were not trimmed at all when planted are in good shape, and the results seem to indicate that in the moist Rhode Island climate no more trimming is desirable for apple trees at planting time than is necessary to enable the tree to start into growth well.

The cultivation and handling of goldenseal, Alice Henkel and G. F. Klugh (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 6, pp. 19, figs. 7*).—A revision of Bureau of Plant Industry Bulletin 51, pt. 6 (E. S. R., 16, p. 747), dealing with the identification and geographical distribution of goldenseal, the conditions under which it grows, the collection and preparation of the root, the cultural requirements, and the yield of roots. The question of supply and demand and the possibilities of goldenseal as a cultivated crop are also discussed.

An analysis of roots grown for 6 successive seasons by the Department showed a hydrastin content of 2.98 per cent, whereas the Pharmacopœia calls for only 2.50 per cent. Cultivation appears to influence the hydrastin content principally in the development of a normal high percentage of healthy well-nourished roots.

Marketing the muskmelon, J. W. Lloyd (*Illinois Sta. Bul. 124, pp. 295–322, figs. 15*).—The results are here given of studies conducted by the station for several years relative to the marketing of muskmelons. Consideration is briefly given to the market demands with reference to types of melons and packages, together with a detailed account of the most approved method of handling the crop, including picking, grading, packing, construction of packing sheds, and the organization of the working force. The various methods of selling the crop are also discussed.

Notes on Brassica crosses, A. W. Sutton (*Gard. Chron., 3. ser., 43 (1908), No. 1100, pp. 58, 59, figs. 9*).—Extracts from a paper on this subject read before the Linnean Society, January, 1908, with illustrations and descriptions of various crosses made.

The author commenced a series of experiments in 1900 to determine to what extent different members of the Brassica family could be seeded close to one another without danger of crossing. Various forms of *B. oleracea* were grown side by side and many nondescript hybrids were secured, the majority of which

were discarded as of no practical value. A few, including a Brussels sprout with cabbage head, a curled leaf thousand-headed kale, and a thousand-headed kale with large tender leaf stalks are being perpetuated.

Subsequent attempts to cross various types of *B. oleracea* with different forms of rape, swede, and turnip (*B. napus*, *B. campestris*, and *B. rapa*, respectively) by artificial pollination and under closely controlled conditions lead the author to conclude that *B. oleracea* (cabbage type) will not cross outside of its own class. In cases where the hybrids produced seed, they split up in the second generation into forms resembling the types first cross-fertilized and other intermediate forms.

The rapes, swedes, and turnips crossed with each other and produced hybrids, many of which failed to produce seed, hence were not perpetuated. The deduction is made that as it seems impossible to perpetuate hybrid forms between white and yellow swedes, white and yellow turnips, white turnips and swedes, yellow turnips and swedes, or vice versa, it is probable that these types do not owe their existence to a common wild form.

How new fruits can be made by crossing, S. W. Fletcher (*Gard. Mag. [New York]*, 7 (*1908*), *No. 3, pp. 142–146, figs. 13*).—In this popular article the author aims to present the opinions relative to crossing and the exact methods of practice adopted by the majority of the leading plant breeders in this country. Although the article deals with the crossing of orchard fruits, many of the methods described are considered applicable in the crossing of other plants.

Horticultural districts of the State, G. A. Marshall et al. (*Ann. Rpt. Nebr. Hort. Soc., 38 (1907), pp. 20–34, map 1*).—The Nebraska State Horticultural Society recently divided the State into 19 horticultural districts. A map is given showing these districts, together with a revised list of orchard and small fruits and ornamentals recommended for planting in each.

Fall and early winter injuries to orchard trees and shrubbery by freezing, A. D. Selby (*Ohio Sta. Bul. 192, pp. 129–148, figs. 9*).—Numerous examples of injury to orchard trees and ornamentals from freezing during the fall and winter of 1906–7 were found over the whole State, with the exception of the lake shore district where little damage was done. This bulletin contains a discussion, together with results of studies made relative to the nature and extent of the injury.

The trees and shrubs seriously injured included the apple, Japanese plum, sour cherry, peach, raspberry, weigela, privet, English walnut, and arborvitæ.

The losses were most conspicuous with apple orchards 5 years old or under, and varied considerably with different varieties. In the northern section of the State the Baldwin and in the southern section the Rome Beauty and the Hubbardston suffered severely, the injury in some cases amounting to 90 per cent or more of the young trees. The principal damage is attributed to the October freeze of 1907, which was preceded by a long spell in which the temperature and moisture conditions were above the normal, thus favoring a vigorous growth late in the season. Some damage was also done by warm midwinter weather together with low minimum temperatures. No evidence was secured to show the advantage of one method of orchard practice over another as a means of warding off such winter injury. The loss, however, is regarded as unusual both in time of its occurrence and in the severity with which certain types of trees were injured. The heavy losses with standard commercial varieties suggest the possibility of growing these sorts on hardier stocks.

It is believed that secondary effects upon apple trees injured by freezing may be observed for several years, and observations are to be made along this line.

Second contribution to the experimental study of the forcing of grafted American grape stocks, A. Drago (*Secondo Contributo Sperimentale allo Studio*

della Forzatura Degli Innesti di Viti Americane. Rome, 1908, pp. 72, figs. 20).—An account is given of the work conducted in the propagation and grafting of cuttings of American grape stocks at the experiment grounds of the Royal Agricultural Institute during the season 1907. The various phases considered include the storing of stocks and scions, treatment of the wood previous to grafting, storing of grafted vines previous to forcing, description of the grafting operation, methods of stratification, forcing, planting, and subsequent treatment.

The tropical plants of commercial importance, E. de Wildeman (*Les Plantes Tropicales de Grande Culture. Brussels, 1908, vol. 1, pp. VIII+390, pls. 22, figs. 64*).—This is the first volume of a second edition of this work (E. S. R., 14, p. 870), now revised and enlarged to two volumes.

In the present volume consideration is given to the botany, regions of culture, statistics, preparation, and in some cases the composition of coffee, cacao, vanilla, cola, and bananas. In the opening chapter a brief description is given of the flora of tropical Africa, together with biographical notes on the different botanists who have contributed to the knowledge of the vegetation of the Congo Free State.

Volume 2 is to deal with the rubber-producing plants of tropical Africa.

The date sugar palm (Phœnix sylvestris), N. N. Banerjei (*Dept. Agr. Bengal, Quart. Jour., 1 (1908), No. 3, pp. 161–164*).—A brief account is given of the methods of cultivating and tapping the date sugar palm in Bengal. According to the data here given, the total yield of date sugar for the province is about 15.6 per cent of its total yield of cane sugar.

Ether and the germination of seeds, J. Taubenhaus (*Cornell Countryman, 5 (1908), No. 6, p. 201, fig. 1*).—Tabulated results are given of an experiment conducted to determine the effect of ether on the germination of old and new seeds. The process of etherization was similar to that used by the author in his work with bulbs (E. S. R., 18, p. 938). The seeds tested included tomato, turnip, cucumber, muskmelon, asparagus, cabbage, and wheat.

The conclusion is reached that the ether treatment appears to put new life into old seeds, since, while about half of the old seeds sown germinated when etherized, only about one-third of the check seeds of the same kind started. Etherization appeared to hasten the germination of all the seeds tested. Seedlings from etherized seeds were stronger than those from untreated seeds. The experiment was conducted both in a medium temperature house and in a hothouse with a temperature of 75° F. As no results were secured in the medium house it is concluded that a hot-house temperature is necessary for this process.

A handbook for planning and planting home grounds, W. H. Manning (*North Billerica, Mass., 1907, pp. 74*).—This handbook is issued by the Talbot Mills for the use of its tenants, with a view of creating an interest in the improvement of their premises. In addition to brief practical suggestions relating to the planning and planting of home grounds, a catalogue is given of both wild and garden flowers, shrubs, vines, trees, fruits, and vegetables, including their common and botanical names, and brief notes on their characteristics.

A classified list for ready reference is also given showing herbs, shrubs, trees, and annuals adapted for varying light, soil and moisture conditions, differences in height, climbing, creeping, and thorny plants, and plants with edible fruits. An index is also given of the common names of wild plants, together with localities in which they may be found growing in Billerica.

Laws of Massachusetts relating to public shade trees (*Woodland and Roadside, 6 (1908), No. 8, pp. 89–95*).—The text is given of all the laws relating to shade and ornamental trees, and especially highway trees, which were in force up to January 1, 1908. This supplements a pamphlet on laws relating to Massachusetts forest lands previously noted (E. S. R., 19, p. 545).

FORESTRY.

Forest economy, G. Huffel (*Economie Forestière. Paris, 1904, vol. 1, pp. IX+419; 1905, vol. 2, pp. XIII+484; 1907, vol. 3, pp. VIII+510, figs. 155*).—In this work the author has aimed to bring together both the historical and present information from various sources pertaining to the different phases of forest economy. Each volume consists of a series of detached studies.

Volume 1 deals at length with forest products, influences, ownership, legislation, policy, history, and statistics. The first study in volume 2 is a treatise on dendrometry. Succeeding studies deal with the rôle of man, natural agencies, and forest capital in the development of forests, the relations between capital and revenue, forest estimates and valuations, with a concluding chapter on usufruct and its relations to forestry. The third volume deals with various phases of forest management, including the history and development of different systems of management and methods now in use. Although the work deals primarily with French forestry conditions, much of the subject-matter is of interest to foresters in general.

State forestry development, F. W. Rane (*Proc. Soc. Prom. Agr. Sci., 28 (1907), pp. 129–135*).—In this paper the author discusses the Massachusetts forest policy, with the view of demonstrating what it is hoped will prove a practical State forestry development.

Contribution to the forest statistics of Alsace-Lorraine (*Beitr. Forststatis. Elsass-Lothringen, 1906, No. 25, pp. 127*).—Statistical data are given for the forest year 1906 relative to operations in the state, domain, and public forests of Alsace-Lorraine. The data deal with forest areas, yields in timber and minor products, yields from various species, sylvicultural and improvement operations, expenses, returns, etc. Summarized comparative data are also given for the period from 1870 to 1906.

Forestry in the provinces of Malaga, Grenada, Jaen, and Cordova (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), No. 1, pp. 26–30*).—A brief account by the French consul at Malaga of forest conditions in the above provinces, including their constitution, range, kinds of wood, utilization, returns, and commerce.

Annual progress report on forest administration in the lower provinces of Bengal for the year 1905–6, W. H. Lovegrove (*Rpt. Forest Admin. Bengal, 1905–6, pp. 55*).—This is the customary progress report of the various forest operations for the year 1905–6, including alterations in areas, forest surveys, protection, etc., construction of working plans, sylvicultural operations, and exploitation, together with a financial statement for the year. The important features of the report are presented in tabular form.

Fire conservancy in Burma, F. B. Bryant (*Indian Forester, 33 (1907), No. 12, pp. 537–549, pls. 4*).—In this paper the author presents considerable tabulated data to show that the long continued protection of forests from fire although improving the soil, has tended to cause the younger tree growth to decrease, owing to the heavy growth of bamboos which thrive under fire protection and kill out young teak and other valuable light-demanding species. A classification is given of the teak forests in Burma, and it is suggested that fire conservancy be abandoned in those forests which are overrun with bamboos until young teak growth is established.

Economic thinning of white pine, A. F. Hawes (*Forestry Quart., 5 (1907), No. 4, pp. 368–372*).—The author gives a statement of results secured from improvement thinnings recently made in an 8-acre white pine woodlet in Connecticut. The woodlot is described, and tabulated data are given showing the nature of the stand on representative surveys. The trees were about 50 years

old and averaged 292 to the acre, alive and dead, whereas the average number of trees per acre in a New England white pine grove of this age is estimated at 400. In the improvement thinnings made, 51,800 ft. of lumber and 35 cords of wood were removed, which netted the owners $354.55, or $44.32 per acre. From the data given it appears that after cutting, about 200 trees per acre were left standing.

Condition of cut-over longleaf pine lands in Mississippi. J. S. HOLMES and J. H. FOSTER (*U. S. Dept. Agr., Forest Serv., Circ. 149, pp. 8*).—This circular, which is based on a study of the forest conditions of Mississippi recently jointly conducted by the Forest Service of this Department and the Mississippi State Geological Survey, contains a brief survey of the conditions of cut-over lands in the longleaf pine regions of that State, together with suggestions for the improvement of these lands.

Owing to the wasteful lumbering methods, together with destruction by fire following lumbering, more than half the longleaf pine land of the State has been converted into a blackened and barren waste. It is estimated that the supply in the State will be practically exhausted within a quarter of a century.

Some data are given to show that where fire is kept out, natural reproduction of the pine forests is a comparatively simple process, and the conclusion is reached that the first step in the solution of the problem of reforesting waste cut-over longleaf pine land is to provide a law which shall not only prevent fire, but shall carry with it adequate provisions for its strict enforcement. A statement is given of the provisions which such a law should include.

Mexican timber. A. B. BUTMAN (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3088, pp. 9–12*).—According to data here given there are from 20,000,000 to 25,000,000 acres of first-class timber in Mexico. The heaviest stands of pine and oak are found in the States of Chihuahua, Durango, Jalisco, Michoacan, and Guerrero, and are said to compare favorably with similar stands in this country as regards quality, diameter, and length of clear body. In addition to the open pine stands there are said to occur some 25 varieties of hardwood not well known to the lumber markets. Descriptive notes are given of the wood of many of these varieties, together with data on the chicle industry, transportation developments, rating and prices of wood, cost of logging and manufacturing, and statistics of the lumber trade with the United States for the years 1905 and 1906, and a list of wholesale prices of American lumber f. o. b. Mexican City.

Austria's wood industry and lumber trade. A. VON ENGEL (*Österreichs Holz-Industrie und Holzhandel. Vienna, 1907, vols. 1, pp. X+374; 2, pp. VI+402, pls. 9, figs. 213*).—This work consists of technical, economic, and statistical information for manufacturers in the various wood using industries, lumber dealers, foresters, etc.

In volume 1 an account is given of the methods of exploiting timber in the different regions of Austria, including felling operations, methods of transportation, and the utilization of lumber in the sawmill and factory and in the various industries. Methods of wood preservation are described and a list is given of schools offering courses in the various wood working industries.

Volume 2 gives an account of the local wood industries in different parts of Austria, specifications for the preparation of lumber for various government purposes, numerous considerations relative to the lumber trade, and statistical data relative to forests, lumber production, and the lumber trade in various parts of Austria.

A treatise on the commercial uses of wood, A. MATHEY (*Traité d'Exploitation Commerciale des Bois. Paris, 1906, vol 1, pp. XVIII+492, pls. 8, figs. 377; 1908, vol. 2, pp. XV+835, figs. 429*).—Volume 1 of this work, which was published in 1906, treats of the properties and qualities of wood, conservation, storage, and preservative treatment, methods of exploitation, and transportation.

The present volume contains a detailed account of the uses of wood in various commercial industries, including its use for fuel and for the manufacture of charcoal, paper and fiber, the industries using small sizes of wood, round, unbarked, and square timber, girders, railroad ties, sawed and cleft wood, various small forestry industries, and many other general uses to which wood is put, together with accessory products such as tannin, resin, dyes, wood alcohol, etc.

The arboretum of the National School of Streams and Forests, A. JOLYET (*Rev. Eaux et Forêts, 47 (1908), No. 3, pp. 70–79*).—The arboretum is briefly described and a list is given of the species under observation showing their origin, together with notes on the hardiness of several exotic species.

The evergreen trees of Colorado, B. O. LONGYEAR (*Colorado Sta. Bul. 130, pp. 3–32, figs. 26*).—This bulletin is presented with the view of familiarizing the people of Colorado with the native evergreens of that State and of strengthening the interest in their protection. Keys and descriptions of the Colorado genera and species of evergreens are given, together with suggestions and directions for their use as ornamentals, wind-breaks and screens. The descriptions are accompanied by a series of plates showing the distinguishing characteristics of the various species. Of the 13 evergreens occurring in Colorado which grow to the stature of trees 10 belong in the pine family.

Notes on the bamboos of Indo-China, CREVOST (*Bul. Écon. Indo-Chine, n. ser., 10 (1907), No. 68, pp. 872–893, figs. 4*).—In these notes a general account is given of the various forms of bamboos growing in Indo-China, including their characteristics, range, habitat, and methods of propagation, with descriptive notes by the author and others of the various species and their uses. The local names only are given in most cases, owing to the imperfect botanical classification of the bamboos.

The chestnut tree, J. B. LAVIALLE (*Le Châtaignier. Paris, 1906, pp. III+286, pl. 1, figs. 11*).—Part 1 of this work treats of the botanical and historical classification and description of the chestnut genera and principal species, together with a historical and botanical study of the common and improved varieties of chestnut trees. Succeeding portions deal with the culture and exploitation of chestnut groves, utilization of the wood and other products, the use of the chestnut in ornamental horticulture, revenues from chestnut groves, enumeration of the flora occurring in chestnut groves, insect pests, diseases, and their remedies.

Karité, argan, and some other African sapotaceous trees possessing fatty seeds, E. PERROT and A. CHEVALIER (*Vég. Utiles Afrique Trop. Franç., 1907, No. 2, pp. 194, figs. 32, map 1*).—A botanical, scientific, and economic study of the karité tree (*Butyrospermum parkii*), the argan tree (*Argania sideroxylon*), and other less known African trees of the sapotaceous family possessing fatty seeds. The work consists of extracts from numerous contributions on this subject, together with the scientific observations and botanical investigations of the authors.

Special attention is given to the karité, which abounds in Central Africa. The fruit of this tree yields a butter-like substance which is eaten extensively by the natives and also imported to Europe in considerable quantities under the name of shea-butter and used in the manufacture of soap. Although the coagulated gum is nearly identical in its appearance with gutta-percha, the conclusion is reached that it is of no economic value as a substitute. The argan,

which appears to grow only in Morocco, furnishes an oil similar to olive oil and the wood of the tree is very hard and durable.

The text is accompanied with a map showing the geographic distribution of karité, together with numerous illustrations of the flower parts, fruit, cross-sections of seeds, etc., of the different trees described.

Teak wood, M. Büsgen, C. C. Hosseus and W. Busse (*Tropenpflanzer, Beihefte, 8 (1907), No. 5, pp. 343–399, figs. 11, dgms. 2, map 1*).—This is a series of three papers on teak wood, as follows: The properties and production of Java teak or Djati, by M. Büsgen, an account of the exploitation of teak wood in Siam, by C. C. Hosseus, and an account of teak reforestation in the African colonies, by W. Busse.

Growing wattle bark, R. H. Millward (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3087, pp. 4–6*).—A brief account is given of the wattle bark industry in South Africa, including methods of culture, preparation for market, yields, etc.

Willow culture in Holland, E. Hesseling (*Verslag. en Meded. Dir. Landb. Dept. Landb., Nijv. en Handel, 1907, No. 6, pp. 37–92, figs. 7*).—An account of willow culture in Holland, including general data relative to the importance and extent of the industry, climate, soil, and varieties, together with a description of the extensive and intensive methods of growing 1-year and 3 and 4-year shoots, planting on sandy bottoms, insect pests, and fungus diseases attacking willow wood and their remedies, raw products, and industries.

Several appendixes deal with an account of basket-making and the weaving schools in Austria by E. D. Van Dissel, numerous statistics and graphical diagrams relative to areas devoted to willow culture, yields, prices, etc., and a bibliography on the subject of willow culture.

An effective screen for nurseries, E. J. Zavitz (*Forestry Quart., 5 (1907), No. 4, p. 367, pl. 1*).—An illustrated description is given of a simple and cheap form of screen used for shade in evergreen seedling work in the government nurseries at the Ontario Agricultural College. This screen is made in a fence picket machine out of 4 ft. lath woven with 6 strands of wire. As compared with the old method of nailing lath on frame these screens are much more easy to handle and are considerably cheaper.

The cultivation of Ficus elastica, C. Bald (*Calcutta, 1906, pp. 32, pls. 4*).—This pamphlet is compiled from various periodicals and publications on rubber culture, with a view to assembling in compact form the present information on the plantation culture of *Ficus elastica*. Successive chapters deal with natural conditions, suitable lands, and methods of propagation, planting, culture, and tapping. Some of the methods of culture here recommended are said to be based upon the author's personal experience.

Hevea guyanensis in Surinam, W. A. Van Asbeck (*Inspectie Landb. West-Indië, Bul. 9, pp. 1–27*).—A brief account of the exploitation of this species of rubber, including its botany, tabulated data on tapping experiments with the "V" cut, herring-bone, and spiral methods, and the preparation of the rubber for market.

A new [rubber-producing] forest species of Tonquin, P. Eberhardt (*Bul. Écon. Indo-Chine, n. ser., 10 (1907), No. 65, pp. 576–585, figs. 4*).—A botanical description is given, together with notes on the habitat, methods of exploitation, and production of latex and rubber of a rubber-producing tree occurring in the mountain region of Tonquin and locally known as Teo-Nong. An analysis of the latex gave 67.6 per cent rubber. It is believed that this species, under modern methods of exploitation, may become of great importance.

Recent observations on the rubber-producing tree of Tonquin (Teo-Nong), P. Eberhardt and Bloch (*Bul. Écon. Indo-Chine, n. ser., 10 (1907), No. 67,*

pp. 798–803, figs. 13).—A further botanical study, with illustrations of the floral organs, is given of the rubber-producing tree described by the author and noted above. The tree is said to belong to the ulmaceous family and to be a new species of the genera Streblus de Loureiro.

Recent analyses made of the rubber of this tree show a rubber content of 71.61 per cent. The results are also given of the analyses made of the rubber from the creeper *Bousigonia tonkinensis*, showing the content of rubber to be 77.34 per cent.

DISEASES OF PLANTS.

A contribution to the biology of wood-destroying fungi, Caroline Rumbold (*Naturw. Ztschr. Forst u. Landw., 6 (1908), No. 2, pp. 81–140, pl. 1, figs. 25*).—A contribution is given to the life history of a number of wood-destroying fungi, the studies including species of Merulius, Polyporus, Dædalea, Coniophora, Agaricus, Lenzites, and Schizophyllum. Pure cultures have been made of the various species, and their growth, characteristics, fruiting bodies, reaction to substratum, etc., are described.

Parasitism of Melampyrum pratense, L. Gautier (*Rev. Gén. Bot., 20 (1908), No. 230, pp. 67–84, figs. 21*).—A study has been made of *M. pratense*, which is a semiparasitic plant that is quite specialized in its parasitism. Its preference is for the roots of forest trees, especially the beech, the roots of which are well furnished with mycorrhiza.

The germination of the seed and method of attack were studied at considerable length. The author found that the parasitic state was quickly assumed, the haustoria appearing on the rootlets even before the reserve material in the seed had been used up or the cotyledons had fallen. The truly nonparasitic phase of the life of this plant is very short, although not entirely wanting.

On the existence of Myxomonas betæ, J. Trzebinski (*Ztschr. Pflanzenkrank., 17 (1907), No. 6, pp. 321–334*).—A critical review is given of the work and conclusions of Brzezinski, in which it is claimed that *M. betæ* is the cause of a number of diseases of the sugar beet, among them a root rot of the seedlings, a dry rot of the leaves, and a hypertrophied condition of the roots. The author claims that his studies, made under carefully controlled conditions, have failed to substantiate the conclusions of Brzezinski, and that the reputed new organism does not differ in any way from *Pseudocommis vitis* of Debray.

A study of Aspergillus flavus, D. Brocq-Rousseu (*Rev. Gén. Bot., 20 (1908), No. 231, pp. 102–110, pl. 1*).—In continuation of his studies on the alteration of cereals by various molds (E. S. R., 19, p. 47), the author reports finding *A. flavus* very common on grains, especially on maize. A study was made of this fungus, and its character of growth in various media is described, as are also its morphological and biological characters.

The author found that the fungus varied considerably in its coloration, that it had the power of digesting albuminoid materials, that it secreted amylase, and that it had pathogenic properties. The pathogenic properties of the fungus are to be described in detail in a future publication.

Distorted barley heads, D. von Hegyi (*Ztschr. Pflanzenkrank., 17 (1907), No. 6, pp. 334–337, figs. 2*).—Descriptions are given of distorted heads of barley in which the awns were twisted and matted together and the heads did not fully emerge from the leaf sheath. Two forms of this disease are recognized, one caused by *Siphonophora cerealis*, the other by *Helminthosporium gramineum*.

Dry rot of corn, T. J. Burrill and J. T. Barrett (*Illinois Sta. Circ. 117, pp. 3*).—According to the authors, dry rot of corn is responsible for losses which in

the aggregate are very large. The most common form of dry rot disease is that caused by the fungus *Diplodia maydis*.

Ears infected with this fungus shrivel, darken in color, and become light in weight. The kernels are also shriveled, very brittle, and loosely attached to the cob. The fungus penetrates all portions of the ear, producing many dark brown spores, which serve to propagate it.

There are several other forms of dry rot which are more or less important, some of which at least are due to species of Fusarium.

In the case of the Diplodia disease, and probably the others, the fungus perpetuates itself over winter on old diseased ears and old stalks. It is recommended that all diseased ears be collected and burned, and that where fields are infected to any considerable extent the stalks be deeply plowed under or burned. If the first suggestion is adopted and the second followed wherever necessity demands it, according to the authors, serious losses will be practically prevented.

Diseases of the peach, E. Foex (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 29 (1908), Nos. 5, pp. 134–141, pl. 1; 6, pp. 167–170*).—Descriptions are given of some of the diseases to which the peach and allied plants are subject, with suggestions for their control. Among those described are gummosis, peach leaf curl, a disease caused by *Asterula beyerinckii*, peach powdery mildew, and peach rust.

A spot disease of potatoes, N. H. Swellengrebel (*Arch. Néerland. Sci. Exact. et Nat., 2. ser., 13 (1908), No. 1–2, pp. 151–198, pls. 8*).—A disease of potatoes is described in which the tubers when cut exhibit brownish spots arranged in a circle, corresponding to the distribution of the fibrovascular bundles. About the discolored areas a layer of cork cells is formed. Later the tissues break down, and often cavities are formed within the tubers. When the tubers are fully developed there is no further spread of the cork areas if the potatoes are kept in dry, well-aired places.

No fungi were found associated with the diseased spots when subjected to microscopical examination, but on cultures 3 bacteria were obtained from the diseased tissues: *Bacillus megatherium*, *B. vulgatus*, and *B. mesentericus*. In addition *Bacterium punctatum* was isolated from the cavities. These bacteria are common soil organisms that appear under certain conditions to be able to attack the tissues of the potato. Inoculations with them produced pronounced cork formations, and in some instances there developed a dry form of rot, in others a wet rot.

The different manifestations exhibited by this disease have led to its being confused with other diseases, and the author claims that this accounts for its infrequent mention. He states that the cavities in the tubers are caused either by *Acrostalagmus cinnabarinus* or *Bacterium punctatum*. In the latter case it often results in a wet rot of the tubers.

As precautionary measures for preventing this disease it is recommended that the soil should be well limed, that planting should not be done on infested soils, and that the tubers should not be cut before planting. In order to prevent the destruction of the tubers in the storehouse, they should be kept in cool, dry places and not in pits.

A Fusarium disease of potatoes, O. Appel (*K. Biol. Anst. Land. u. Forstw. Flugbl. 42, pp. 4; Min. Bl. K. Preuss. Verwalt. Landw. Domänen u. Forsten, 4 (1908), No. 2, pp. 51–55, figs. 2*).—A description is given of a Fusarium disease of potatoes, the most striking characteristic of which is the rolling of the leaflets. These roll in toward their midribs and assume a yellowish color. When the attack is late in the season or not very severe but little loss in the crop will be found, but at other times the tubers are so reduced in size that the

yield is very materially diminished. Diseased tubers show discoloration when cut across, and all such should be rejected in planting. The disease is not a new one, but it has only lately become prominent.

A leaf spot disease of sisal in German East Africa, K. Braun (*Ber. Land u. Forstw. Deutsch-Ostafrika, 3 (1908), No. 4, pp. 143–166, pl. 1*).—In 1905 a peculiar spotting of sisal leaves was reported, and in 1906 the author visited a number of plantations and found the spotting more or less common in all localities.

The trouble seems to be due to high temperature and weather conditions, no plant or animal parasite being found to be associated with it. It appears that under certain conditions the sun burns the tissues of the leaves, and that later sunken, discolored areas appear, due to the destruction of the underlying tissues. All leaves do not seem to be equally subject to the spotting, those standing most nearly vertical being less injured than the spreading ones. The author was able by artificial means to produce the spotting without any action of the sun. As would be expected from the nature of the cause, the underside of the leaves is less subject to injury than the upper.

The smuts of sorghum, E. M. Freeman and H. J. C. Umberger (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 8, pp. 9*).—A description is given of the sorghum smuts, 2 forms of which are recognized, the grain, or kernel, smut (*Sphacelotheca sorghi*) and the head smut (*S. reiliana*).

The grain, or kernel, smut is easily distinguished by the fact that only the individual kernels, or grains, are affected, while the head retains its usual form and nearly its usual appearance.

The head smut is quite different in appearance. The whole head just as it emerges from the upper leaf is converted into a single large smut mass, covered by a whitish or grayish membrane, which soon bursts and sets the spores free. In this smut all trace of the individual grain is lost, and the smut mass resembles somewhat that of a smut mass on corn.

Of the 2 forms of smut, only the kernel smut is at present widely distributed, and experiments have shown that this can be readily controlled by treating the seed either with formaldehyde or hot water. Copper sulphate has also given satisfactory results, but is not to be preferred to either of the other treatments.

The head smut at present is known to occur in abundance only in a restricted area in the Panhandle region of Texas, and the only recommendation that can be made at the present time is to keep it away from the farm and the community. In order to do this, care must be exercised to obtain seed from regions where the head smut does not exist.

So far as now known, milo maize has not been reported as subject to either disease, and it may probably be safely grown without treatment.

The field treatment of tobacco root rot, L. J. Briggs (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 7, pp. 8*).—During the past few years a root rot of tobacco, due to *Thielavia basicola*, has been reported from the tobacco districts of Kentucky, Connecticut, Ohio, and Wisconsin (E. S. R., 16, p. 886; 18, p. 1139). The root rot has been successfully checked in the seed bed by the use of formalin and through steam sterilization, but neither of these means is practicable for its control under field conditions. The author carried on some preliminary experiments with fertilizers which seemed to indicate that tobacco is much more severely injured by the fungus in the fields where the soil has been made alkaline by the long-continued use of large amounts of lime, ashes, and fertilizers containing carbonate of potash.

By field and greenhouse experiments it was found that the alkaline condition of the soil favored the development of the root rot, and as a remedy it

is suggested that no lime be used on diseased fields, but that potash be applied in the form of sulphate of potash or double manure salts. Phosphoric acid in the form of acid phosphate or dissolved bone may be used to correct the alkalinity of the soil. Where other land is available for tobacco, diseased fields should be rotated with some other crop.

Investigations on the susceptibility of various varieties of wheat to smut, O. Kirchner (*Fühling's Landw. Ztg., 57 (1908), No. 5, pp. 161–170*).—The results are given of an investigation on a large number of varieties of spring and winter wheats to determine their susceptibility to smut (*Tilletia tritici*).

In connection with this investigation the cause of the resistance was studied, particular attention being paid to the claim that in different varieties a relation exists between their susceptibility and their germinative energy. The author failed to find that a low germinative energy was in any way associated with a strong inclination toward infection by smut, and a high germinative energy was not an unfailing character for the determination of the resistance against this disese.

Wheat nematodes (*Schweiz. Samen Untersuch. u. Versuchsamt. Zürich, Flugbl., 1907, No. 1, pp. 2, figs. 2*).—An account is given of a nematode disease of wheat caused by *Tylenchus tritici*. The presence of the nematode is indicated by a distorted growth of the wheat and the appearance in the heads of swollen and distorted grains.

Where nematodes are believed to be present, it is recommended that the seed wheat should all be submerged in water and the distorted grains rising to the top skimmed off. Where only a slight occurrence of nematodes is noticed the infected plants should be pulled out of the field in the early spring.

So far as known this species of nematode occurs only on wheat, no other plant being subject to its attack.

A contribution to the knowledge of cutting bed fungi, W. Ruhland (*Arb. K. Biol. Anst. Land u. Forstw., 6 (1908), No. 1, pp. 17–76, figs. 3*).—A description is given of *Moniliopsis aderholdii* n. sp. found on cuttings of asparagus, begonia, Tradescantia, etc., in the cutting beds.

A disease of globe artichokes, L. Trabut (*Bul. Agr. Algéria et Tunisie, 14 (1908), No. 2, pp. 35–37, fig. 1*).—A description is given of a disease of globe artichokes which is due to a species of Ramularia.

The infected plants have their inner scales darkened and often more or less rotted. The parasite has not been found in the decayed tissues, but cultures have shown the presence of 2 species of bacteria. It is probable that they are associated with the rotting and follow the injury by the fungus.

Spraying with Bordeaux mixture or some similar fungicide, if done sufficiently early in the season, it is believed would prove efficient in holding this disease in check. The spraying, however, should be discontinued in time to allow the fungicide to be washed from the heads.

A disease of lettuce due to Marsonia panattoniana, O. Appel and F. Laibach (*Arb. K. Biol. Anst. Land. u. Forstw., 6 (1908), No. 1, pp. 28–37, pl. 1*).—A description is given of a serious disease of lettuce that made its appearance in the spring of 1907 and caused great loss to the crop in certain parts of Germany.

The cause of the disease was found to be the fungus *M. panattoniana*, a description of which is given. By means of culture experiments the fungus was isolated and the disease was reproduced by inoculations.

For the control of the disease the author recommends the destruction of all diseased plants, care of the seed beds, spraying the plants in the seed bed, and the rotation of crops, so that lettuce should not follow where a diseased crop of the same plant has been previously grown.

[Apple diseases in Kentucky], H. GARMAN (*Kentucky Sta. Bul. 133, pp. 62–69, pls. 14*).—Notes are given on the occurrence and characteristics of apple twig blight, bitter rot, blotch, brown rot, scab, leaf spot, leaf rust, crown gall, and hairy root, with suggestions for their control where definite means are known.

A disease of olives due to Cylindrosporium olivæ n. sp., L. PETRI (*Ann. Mycol., 5 (1907), No. 4, pp. 320–325, figs. 5; abs. in Bot. Centbl., 107 (1908), No. 10, p. 248*).—According to the author, for the past 2 years there has been prevalent in Tuscany a disease of the olive fruit which resembled in some ways a disease in Portugal caused by *Glœosporium olivarum* and in other ways a disease in Dalmatia due to the fungus *Macrophoma dalmatica*. A study of the fungus, however, showed that it was distinct from either of these and apparently an undescribed species, to which the author has given the name *Cylindrosporium olivæ* n. sp. A technical description is given of the fungus and its effect upon the host.

Yellows and some other important diseases of the peach, J. L. PHILLIPS (*Va. Crop Pest Com. Circ. 4, n. scr., pp. 12, figs. 9*).—The author gives an account of the distribution of peach yellows and some other peach diseases in Virginia, describing their symptoms and methods for control. For peach yellows, peach rosette, and little peach the means for control consist of digging up and destroying the affected trees. In addition an account is given of peach leaf curl, due to *Exoascus deformans*, for the prevention of which thorough spraying with Bordeaux mixture is advised.

Cacao pests of Trinidad, O. W. BARRETT (*Proc. Agr. Soc. Trinidad and Tobago, 7 (1907), pt. 10, pp. 281–304*).—This is a report to the agricultural society of the author's observations regarding the fungus and insect pests of cacao, with some notes upon miscellaneous crops.

The principal destruction of cacao appears to be due to the fungus Lasiodiplodia, although a species of Fusarium, *Phytophthora omnivora*, and other fungi were noted as rather common upon the fruits. A number of insect pests are reported, the most destructive of which is the black and white beetle (*Steirastoma depressum*), the larval stage of which burrows in the trunks and larger branches.

For preventing the fungus diseases, the author recommends the pruning out of all diseased material, which should be burned or deeply buried, and treating the areas cut with some antiseptic. In addition he recommends better attention to cultivation, shade, wind-breaks, pruning, etc.

Cranberry diseases in Wisconsin, C. L. SHEAR ([*Proc.*] *Wis. Cranberry Growers' Assoc., 21 (1908), pp. 17–21*).—According to the author, the scald, rot, and anthracnose, the 3 most injurious fungus diseases of the cranberry in the East, while present in Wisconsin, are not causing very serious loss. Those diseases which are known to be most destructive in the Wisconsin cranberry meadows are Sclerotinia disease, blossom blight or blast, and a disease that is called by some growers false blossom.

The Sclerotinia disease is characterized by the attack of the fungus on the young shoots just as the plants are beginning to blossom. The tips wither and the fungus produces a soft, white, mold-like growth on the stem and leaves. It later attacks the fruit until it is nearly mature without any external evidence of the presence of the fungus. At picking time the diseased berries show a grayish, more or less wrinkled condition of the skin, and the whole berry becomes gray and shriveled. So far as known, it is in these affected berries that the disease is carried over the winter, and all such fruit should be burned or deeply buried.

The blossom blight or blast attacks the young fruit about the time the blossoms fall. The primary cause of the disease is believed to be either a general lack of vigor of the vines or an exhausting of the fruiting power of the plants by excessive stimulation and growth. This disease may be held in check by the sanding of the bogs, a practice commonly followed in the East, or by cutting and thinning the vines by the use of the knife rake. It is believed that better attention to the water supply would also reduce the loss due to this cause.

The false blossom is probably due to a disturbance of the physiological functions of the plant, brought about by abnormal conditions of growth and an excessive amount of nitrogenous plant food. It is characterized by the production of abnormal flowers, the sepals, petals, and stamens of which are frequently changed into leaves or leaf-like bodies. The reduction of the water supply, accompanied by pruning of the vines and liberal sanding of the marshes, it is believed will prevent loss from this cause.

Some diseases of strawberries, F. Laibach (*Arb. K. Biol. Anst. Land u. Forstw., 6 (1908), No. 1, pp. 76–80, figs. 3*).—The author describes diseases of the strawberry caused by *Marsonia potentillæ*, *Leptothyrium macrothecium*, and *Zythia fragariæ* n. sp.

A pine disease (*Bd. Agr. and Fisheries* [*London*], *Leaflet 199, pp. 3, fig. 1*).—A disease of pine trees is described which is due to the fungus *Diplodia pinea*. The disease is confined to terminal shoots and is recognized by the yellowing and subsequent shedding of the leaves, followed by the death of the shoots, which die back for a distance of 6 to 10 in. The dead shoots are persistent, and commencing with the year following infection furnish a crop of spores each season which infect other shoots. Experiments conducted at Kew show that within 2 months after infection the leaves become yellow and begin to twist themselves, due to desiccation, and that at the expiration of 4 months all the leaves have fallen and the shoot is dead.

Inoculation experiments were carried on in which spores were placed on 3-year-old plants of white pine, Scotch pine, spruce, silver fir, and larch. In every instance where the surface of the young shoots was unbroken the spores failed to infect the plant, but where the spores were placed on a drop of moisture that extended from a minute puncture in the bark, they set up an infection which resulted in a dense growth of mycelium, followed by yellowing and falling of the leaves. Successful inoculations were made in the case of the 2 species of pine, but no infection occurred on spruce, fir, or larch.

It is believed that the fungus infects the plants through the action of insects, and this point is to be investigated further.

In the case of nursery stock and young trees the removal of all dead shoots would tend to check the spread of the disease to a considerable extent.

A disease of pine twigs, L. Petri (*Ann. Mycol., 5 (1907), No. 4, pp. 326–332, pl. 1; abs. in Bot. Centbl., 107 (1908), No. 10, p. 248*).—The author describes a disease of young pine trees, in which the terminal branches are destroyed. The cause of the disease is said to be *Cytosporella damnosa* n. sp. and it resembles in some respects a disease of firs due to Cytospora and one of hemlock caused by *Fusicoccum abietinum*.

The fungus has been cultivated and inoculation experiments performed, in which it was found that the spores readily infected the young twigs where they had become injured by any mechanical means. Where there was no previous injury there seemed to be no infection.

Witches' brooms of Pinus sylvestris, K. Müller (*Naturw. Wchnschr., 23 (1908), No. 9, pp. 134–136, figs. 3*).—A description is given of a number of striking forms of witches' brooms that have been observed occurring on *P. syl-*

vestris. The cause of these malformations appears to be unknown, but thus far no fungus hyphæ have been recognized in any of the tissues.

Fungusine as a smut preventive, D. McAlpine (*Jour. Dept. Agr. Victoria, 6 (1908), No. 1, pp. 35, 36*).—An account is given of a comparative trial of Fungusine, a commercial product that is claimed to be more efficient than either copper sulphate or formalin for the prevention of smut of cereals.

When tested it was found that copper sulphate was 100 times more effective than Fungusine in the prevention of stinking smut, and that formalin when used at less than half the strength usually recommended was 30 times more effective.

An analysis of the material is given, from which it appears that it consists principally of burnt lime, white arsenic, and crude carbolic acid.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Report of the ornithologist, H. A. Surface (*Penn. Dept. Agr. Bul. 154, pp. 55–59*).—Unfavorable conditions are said to have caused the death of large numbers of bluebirds which had migrated north rather prematurely. Brief mention is made of the food of a number of the birds of Pennsylvania, including hawks, owls, woodpeckers, grouse, crow, bluejay, chickadee, etc.

The lizards of Pennsylvania, H. A. Surface (*Zool. Bul. Penn. Dept. Agr., 5 (1907), No. 8, pp. 233–264, pls. 4, figs. 3*).—An analytical key is presented for the determination of the species of lizards found in Pennsylvania. Brief notes are given on the habits of these lizards with particular reference to their food and economic relations.

Synopsis of studies in metazoan parasitology in McMane's laboratory of pathology, University of Pennsylvania, A. J. Smith (*Univ. Penn. Med. Bul., 20 (1908), No. 12, pp. 262–282, pls. 10*).—Statistical data are given regarding the occurrence of trematodes, cestodes, nematodes, and other parasites in various animals. The anatomy of some of the parasitic worms was carefully studied and is described in connection with illustrations.

The rôle of arthropods in pathology, G. Marotel (*Ann. Soc. Agr. Sci. et Indus. Lyon, 1906, pp. 279–302, figs. 12*).—The author discusses the agency of mosquitoes, biting flies, and ticks in the transmission of protozoan diseases to animals and man.

International catalogue of scientific literature. L—General Biology (*Internat. Cat. Sci. Lit., 5 (1907), pp. VIII + 141*).—An author and subject catalogue is given of literature in the field of general biology published mainly in 1905, but also to some extent during the years 1901–1904.

Report of the entomologist, D. L. Van Dine (*Hawaii Sta. Rpt. 1907, pp. 25–51, pls. 2, figs. 3*).—A record is given of the routine work of the entomologist in the investigation of injurious insects during the year under report. There is a relatively large amount of insect injury in Hawaii due to the facts that cultural methods of control are little practiced, that sugar cane is the chief crop and offers a large and continuous food supply for insects, that there are no climatic changes to prevent the development of insects, that diversified farming and crop rotation are little practiced, and that many injurious species have been introduced without their natural parasites.

The sweet potato weevil was found on the island of Maui in 1907 and has caused considerable injury. The destruction of the infested crop is recommended for controlling this pest. Attention is also called to the unusually serious outbreaks of the melon fly and fleas. The life history and habits of the melon fly are described together with recommendations for the control of this pest. In cases of bad infestations of fleas it has sometimes become necessary to mow the lawn close, burn the refuse, clean out and destroy refuse from under

infested houses, treat dogs regularly for fleas, and apply insecticides such as buhach, hot soap suds in dwelling houses, etc.

The introduction of top minnow for the control of mosquitoes was successfully accomplished and these fish seem to be serving as an efficient aid in the control of mosquitoes. Apicultural work of the station included a study of Hawaiian honeys and the problem of largely increasing the production of wax. The latter under favorable circumstances is a much more profitable crop than honey. Foul brood has not yet been introduced into Hawaii. Recommendations were made in regard to the encouragement of silk culture by allowing the laboring population on plantations to have small areas for mulberries and sericultural work.

Additions made to the list of injurious insects thus far reported from Hawaii are presented as are also the accessions of books and periodicals relating to Hawaiian entomology.

Report of the entomologist, H. Tryon (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1906–7, pp. 78–81*).—During the year observations were made on the insect pests of sugar cane, corn, cotton, alfalfa, citrus and other fruits, and garden vegetables. A brief report is also made on cattle ticks and on the movement for the protection of native birds.

Report of government entomologist, 1906, H. C. Pratt (*Agr. Bul. Straits and Fed. Malay States, 6 (1907), No. 9, pp. 303–308*).—Notes are given on the habits and life history of *Nonagria inferens* and *Leptocorisa acuta* which caused injury to rice and also on some unidentified insects which seriously defoliated cocoanut trees.

Indian insect pests, H. M. Lefroy (*Calcutta: Govt., 1906, pp. XII+318, figs. 364*).—The present volume on the insects of India is written not so much as a treatise for the scientific entomologist as for the farmer. The chief insect pests with which the Indian farmer has to contend are described and notes are given on their life history and habits. Most of these pests are illustrated. The volume contains a general account of insect anatomy and their habits, insecticides, and special sections on the more important insect pests of cotton, rice, wheat, sugar cane, corn, leguminous crops, miscellaneous garden crops, and fruits, and the insects affecting cattle. In an appendix to the volume information is furnished regarding the cost, preparation, and application of insecticides.

The life history of the carpenter ant, J. L. Pricer (*Biol. Bul. Mar. Biol. Lab. Woods Holl, 14 (1908), No. 3, pp. 177–217, figs. 6*).—The author made a study of two varieties of *Camponotus herculaneus*. Particular attention was given to the life history of the colony, polymorphism observed in individuals, division of labor, the food, relations to light and color, and the instincts of the insect. It is suggested that some of the injuries to wood which have been attributed to this ant are not due primarily to the ant, but rather to other insects which first produced the burrows in the wood in which the ants subsequently came to live.

An automatic trap for night-flying moths, J. Friedrich (*Centbl. Gesam. Forstw., 34 (1908), No. 1, pp. 1–4, figs. 3*).—In connection with illustrations an apparatus is described for the capture of night-flying moths. The apparatus consists essentially of a revolving drum moved by clockwork and illuminated by means of a lamp on the inside. The moths attracted by the light rest upon the drum and are brushed off into a receptacle during the revolution of the drum. The author reports that tests thus far made with this machine indicate that it is very effective.

The control of snout beetles on beets, B. Wahl and K. Philp (*Wiener Landw. Ztg., 58 (1908), No. 1, pp. 3, 4, figs. 2*).—A brief account is presented of the life history and habits of *Cleonus punctiventris* and *C. sulcirostris*. In

combating these pests good results are reported from the use of a solution containing arsenic, blue vitriol, and lime, and from the application of a 2 per cent solution of barium chlorid. A proprietary remedy containing arsenic was also found to be efficient.

The harlequin cabbage bug, F. H. CHITTENDEN (*U. S. Dept. Agr., Bur. Ent. Circ. 103, pp. 10, fig. 1*).—The life history and habits of this insect were carefully studied for the purpose of presenting an economic account of the subject and as a basis for suggesting means of control. The harlequin cabbage bug is quite free from the attack of natural enemies, but an egg parasite (*Trissolcus murgantiæ*) is quite effective. Among artificial methods of control the author suggests clean cultural methods, the use of trap crops and hand methods. Kerosense emulsion and other chemical methods have not proved satisfactory.

The insect enemies of the boll weevil, W. D. HUNTER, W. NEWELL, and W. D. PIERCE (*Crop Pest Com. La. Circ. 20, pp. 7, figs. 3*).—Attention is called to the importance of natural enemies in the control of the cotton boll weevil. Particular mention is made of *Solenopsis geminata* and parasitic insects.

The anatomy and development of galls of Isosoma on Agropyron repens and A. junceum, W. and J. VAN LEEUWEN-REYNVAAN (*Marcellia, 6 (1907), No. 3–4, pp. 68–101, pl. 1, figs. 36*).—Particular attention is given to the life history and formation of galls of *Isosoma graminicola*. Notes are also given on *I. agropyri*, *I. hyalipenne*, and other unidentified species of the genus which form galls on grasses.

Papers on Coccidæ or scale insects. The National collection of Coccidæ, C. L. MARLATT (*U. S. Dept. Agr., Bur. Ent. Bul. 16, tech. ser., pt. 1, pp. 10*).—Much interest has been taken in accumulating a thorough and representative collection of Coccidæ ever since the establishment of a Federal entomological service. Brief notes are given on the contributions made to this collection by various workers in this and other countries. At present the collection includes 1,072 species of Coccidæ. A programme has been worked out for the systematic description of scale insects and a number of convenient devices have been prepared for use in the preservation and study of these insects.

Aspidiotus ostreæformis, R. S. MACDOUGALL (*Jour. Bd. Agr. [London], 14 (1908), No. 10, pp. 614–616*).—The insect is described in its various stages and notes are given on its life history. It is recommended that all infested trees before being planted should be fumigated with hydrocyanic-acid gas and that infestations which may occur later should be treated with resin wash.

San José scale in Oklahoma, J. F. NICHOLSON (*Oklahoma Sta. Bul. 79, pp. 67–88, figs. 12*).—This pest has been found by the author at 9 localities in the State but is largely confined to city fruit trees. Notes are given as to its life history, natural enemies and other means of control, together with extracts from the State law relative to nursery inspection, and an account of spraying experiments at Mulhall to determine the efficiency of the lime-sulphur wash in Oklahoma and to compare it with that of whitewash.

The whitewash proved to have no value as a scab destroyer. Excellent results were secured from the lime-sulphur wash. For summer treatment spraying with whale oil soap solution is recommended.

Apple orchard pests in Kentucky, H. GARMAN (*Kentucky Sta. Bul. 133, pp. 14–62, pls. 13*).—Detailed descriptive and economic notes are given on a variety of apple insects in Kentucky including apple-leaf miner, apple-leaf skeletonizer, apple-leaf crumpler, codling moth, apple-leaf roller, cankerworm, tent caterpillar, fall webworm, tussock moth, bagworm, woolly aphis, San José scale, apple-leaf hopper, periodical cicada, etc.

The codling moth in 1907, A. L. MELANDER and R. E. TRUMBLE (*Washington Sta. Bul. 86, pp. 3–17, figs. 5*).—Experiments carried on in 1907 at Walla Walla

and Wenatchee are reported in continuation of previous work (E. S. R., 19, p. 555).

A dust spray of Paris green and lime 1:20 proved inferior to arsenate of lead and is believed to be unreliable in an excessively wormy orchard. In some cases from 20 to 40 per cent of wormy apples were found after its use, and on other trees completely free from worms there was a large proportion of badly distorted apples, the amount of distortion being directly proportional to the amount of dust applied, and no distortion being apparent on adjacent liquid sprayed trees.

Spraying with arsenate of lead with gasoline power sprayers at 180 to 200 lbs. pressure and with extension rods fitted with Bordeaux nozzles set at an angle of about 45° gave in seriously infested orchards 99 per cent of clean fruit. A test of different brands of arsenate of lead confirmed earlier conclusions that "success depends not so much on a correct formula, nor, with the exception of the first spraying, on the exact timing of the sprayings, but altogether on the manner in which the spraying is done."

Thorough spraying with arsenate of lead 1:50 at high pressure, begun when about 85 per cent of the petals have fallen, with a coarse spray with bent nozzle, followed by a second spraying in one week, is recommended.

Spraying for the codling moth, A. L. MELANDER (*Washington Sta. Popular Bul. 5, pp. 7, fig. 1*).—Popular directions based on the above and earlier publications of the station are given with special reference to spraying materials and spraying outfits, and the time, manner, and rationale of spraying.

Annihilating the codling moth, A. L. MELANDER (*Ent. News, 19 (1908), No. 1, pp. 11–13*).—A brief historical outline is given of the improvements which have been made in the methods for combating the codling moth. In the recent tests at the Washington Station, 98 per cent of the codling moths have been destroyed by spraying alone. The author believes that the best method of operation is to spray only once for the early brood. Arsenate of lead is the best insecticide and should be applied abundantly in a coarse spray with a power sprayer.

Spraying for codling worm, H. A. GOSSARD (*Ohio Sta. Bul. 191, pp. 103–125, pl. 1, figs. 23*).—The experiments reported were conducted chiefly to determine whether the drenching sprays advocated for the Western States could be profitably used in the eastern sections. The economic value of soap and other materials added to the spray as "stickers," the number and time of applications, and the selection of arsenicals were also studied. An orchard of about 325 trees near Amherst was used, the trees averaging 20 ft. or more in height.

When arsenate of lead was compared with Paris green for a first application the proportions of sound fruit were respectively 96.39 and 96.72 per cent, but the results are not deemed conclusive. Substituting 1 qt. sodium arsenite solution for 1½ lbs. arsenate of lead in the solution gave as good results and considerably reduced the cost. No marked advantage was obtained from the use of soap, and it is not believed that the addition of soap or other stickers to lead arsenate solution is profitable for apples.

Slightly more sound apples were obtained by the use of straight spraying rods than by crooked rods, but the latter are considered to promote economy of materials and to be a mechanical convenience. Practically no difference in results was noted from the use of coarse and fine nozzles, but as the former required about 50 per cent more materials their use is not recommended.

The average of picked sound fruit at harvest on all sprayed trees of which records were kept was over 95 per cent, while the same average for the unsprayed trees was less than 58 per cent. "The net profit from spraying an average sized tree from 12 to 20 years old throughout one season at a total

cost of from 30 to 50 cts. is from $3 to $7 or more, when apples are worth $1 per bushel."

Eighth report of the Woburn Experimental Fruit Farm, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt., 8 (1908), pp. IV+129 +XLI*).—This report is occupied with a study of insecticides and fungicides and the results of their application in the eradication of a few insect and fungus pests.

After a thorough study of Bordeaux mixture the conclusion is reached that the chief aim in making this mixture should be to reduce the lime to the lowest possible proportions consistent with the precipitation of all of the copper. In accordance with this principle recommendations are made regarding the preparation of Bordeaux mixture. For preparing 100 gal. of the mixture, it is recommended that 6 lbs., 6½ oz. of copper sulphate be dissolved in 2 or 3 gal. of water. A quantity of lime not less than 2 or 3 lbs. is to be slaked in 120 gal. of soft water, after which the lime and water are to be stirred 2 or 3 times and allowed to settle until the solution becomes quite clear. Then 86 gal. of clear limewater are to be taken for mixture with the copper-sulphate solution and the whole mixture is brought up to the required 100 gal. by the addition of a sufficient quantity of water. The mixture thus prepared contains 1 oz. of copper sulphate in each 134 oz.

In the use of arsenate of lead it was found that a certain amount of scorching of the leaves occurred in some varieties of apples, however carefully the insecticide was applied. The efficiency of this insecticide, however, is very satisfactory. Calcium arsenate was used as a substitute for lead arsenate and gave results almost equal in efficiency and at smaller expense.

In the preparation of emulsions considerable objections have been made to the use of soaps. In most cases even where soft soaps are used the addition of caustic soda changes soft soap into a hard soap which is only sparingly soluble and is consequently thrown out of solution as a flocculent solid. It became desirable, therefore, to select an emulsifying agent which would not be affected by caustic soda. For this purpose the basic sulphates of iron and copper are perhaps the best reagents to be used. Excellent results were obtained from such emulsions. For a caustic winter wash of this sort the authors recommend a formula calling for ½ lb. iron sulphate, ¼ lb. lime, 2 lbs. caustic soda, 5 pts. kerosene, and water to make 10 gal.

In controlling the oyster-shell bark-louse, it was found possible to destroy the eggs by the use of a 2.5 per cent solution of caustic soda. Moss and lichens were readily removed from trees by a 2 per cent solution of the same substance. Brief notes are also given on experiments with apple psylla, caterpillars, aphis, and leaf spot. It is maintained that all insecticides and fungicides exercise some harmful effect upon the tree and for this reason it is believed that two or three thorough applications are better and less liable to cause harm than repeated applications of less strength.

Spraying apple trees, H. GARMAN (*Kentucky Sta. Bul. 133, pp. 3–13*).—An experiment was conducted for the purpose of comparing the value of Paris green and arsenate of lead and the effectiveness of spraying when trees are in full bloom and after the petals have fallen. The experiment was made on an orchard of about 25 acres and involved the use of various combinations of arsenate of lead, Paris green, lime and Bordeaux mixture.

The average injury from codling moth on trees sprayed with arsenate of lead was one-fourth as great as on trees treated with Paris green and lime, and the injury to trees sprayed with arsenate of lead when in full bloom was nearly four times as great as that to trees sprayed after the petals had fallen. With

Paris green and lime the injury was 17.5 per cent when sprayed in full bloom and 10.17 per cent when sprayed after the petals had fallen.

The results obtained in spraying with Bordeaux mixture for the control of codling moth, bitter rot and apple scab were somewhat disappointing. No conclusive evidence was obtained of serious injury to apples from the use of Bordeaux mixture. It is suggested that the apparent injury to Ben Davis apples may be due to spring frosts.

Insecticides and fungicides for use in the apple orchard, H. GARMAN (*Kentucky Sta. Bul. 133, pp. 69–71*).—Formulas are given for the preparation of arsenate of lead, Paris green, kerosene emulsion, miscible oils, Bordeaux mixture, Bordeaux dust, and lime-sulphur-salt wash.

Principles underlying the preparation of insecticides, MANSIER (*Bul. Soc. Agr. France, 40 (1908), Jan. 15, pp. 86–93*).—The success to be obtained in spraying various insecticides upon plants depends in part upon the physical properties of the insecticide solution. The author presents in a tabular form data regarding the number of drops in 5 cc. of various liquids. Data are also given on the solubility of various substances as insecticides. Gratifying results were obtained from the use of two soap mixtures containing 30 gm. of soap and 50 gm. of oil of tar or 10 gm. of formaldehyde per 10 liters of water.

The cranberry insects of Wisconsin, C. B. HARDENBERG (*Wisconsin Sta. Bul. 159, pp. 3–23, pls. 2*).—Life histories are presented of blackhead cranberry worm, yellowhead cranberry worm, cranberry tip worm, false yellowhead vine worm, oblique banded roller, *Archips georgiana?*, yellow cranberry looper, *Physostegania pustularia*, *Diastictis sulfuraria*, *D. inscptata*, cranberry fruit worm, and cranberry weevil.

Treatment of grape roots for phylloxera, H. FAES (*Chron. Agr. Vaud, 20 (1907), Nos. 20, pp. 467–470; 21, pp. 483–485; 22, pp. 499–510; 23, pp. 533–540*).—An elaborate review is given of the methods employed in various countries in combating phylloxera. A large variety of remedies was tried by the author in controlling this pest, including lysol, lysoform, and various mixtures of soap and sulphocarbonate of potash. The best results were obtained by a mixture containing 1 per cent soap and 3 per cent of sulphocarbonate of potash, the roots being immersed in the mixture for 12 hours. A 2 per cent solution of lysol is also found to be very effective.

A revision of the Ixodoidea, or ticks, of the United States, N. BANKS (*U. S. Dept. Agr., Bur. Ent. Bul. 15, tech. ser., pp. 61, pls. 10*).—The great economic importance of ticks as pests of live stock and as carriers of infectious diseases has created a demand for a systematic account of ticks by means of which a species may be easily identified. This task has been accomplished by the author. A description is given of each species known to occur in the United States and references are made to the economic importance, distribution, and hosts of each species. Analytical tables are given for the identification of genera and species and a bibliography of the subject is appended to the bulletin.

The influence of frost on tick life, F. A. VERNEY (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 12, pp. 1550–1552*).—Advantage was taken of residence in a locality subject to changes of temperature for studying the influence of temperature upon the life and fertility of ticks. It appears that as a rule ticks are killed by a succession of heavy frosts but not by single frosts of even great severity. Frosts of less than 10° appear to have little effect upon the life of ticks. The high bench lands of Natal appear to be naturally free from East coast fever and the disease gradually dies out after it has been introduced. The reason for this natural immunity to the disease is apparently to be sought in the destruction of the ticks by frost.

Influence of high temperatures on the eggs of the silkworm, E. Quajat (*Influenza delle alte Temperature sul Seme Bachi. Turin, 1907, pp. 48*).—In a series of observations under carefully controlled conditions it was shown that the indigenous race of silkworms was capable of enduring a temperature of 42° C. for from 6 to 13 hours. The eggs of the Japanese race are somewhat injured by subjection to a very high temperature but may, however, endure a temperature of 50° C. for 30 minutes.

FOODS—HUMAN NUTRITION.

Some of the present-day problems of biological chemistry, R. H. Chittenden (*Science, n. ser., 27 (1908), No. 685, pp. 241–254*).—The structure of proteids, enzyms and their relation to biological problems, and other important biological questions are discussed in this paper presented before the Biological Section of the American Chemical Society at Chicago, January, 1908.

The occurrence of nitrates in vegetable foods, in cured meats and elsewhere, W. D. Richardson (*Jour. Amer. Chem. Soc., 29 (1907), No. 12, pp. 1757–1767*).—The results are reported of the examination of a large number of samples of animal and vegetable foods.

"Nitrates are of general occurrence in plants in all stages of growth, and particularly in the early stages. In the mature parts of plants, such as ripe seeds and fruits, only small quantities of nitrates are found. In some cases notable quantities of nitrates remain in the mature plant—instance ripe beets and turnips. The amounts of nitrates found in vegetables are of the same order but rather more in many instances than those found in cured meats."

In the author's opinion, a diet wholly or largely of fresh vegetables would supply more nitrates than would a mixed diet consisting in part of cured meats.

On certain imported meat foods of questionable wholesomeness, G. S. Buchanan (*Local Govt. Bd. [Gt. Brit.] Med. Dept., Rpts. Insp. Foods, 1908, No. 3, pp. 17*).—The materials discussed in this report are imported boneless scrap meat, imported pork, and tripe, tongues, and kidneys heavily dosed with preservatives. Methods for regulating the importation and trade in such goods are suggested.

The amount of preservatives found in tripe, tongues, and kidneys was very high and, as the author points out, only a portion is removed in preparation for the table.

On inquiries with regard to the wholesomeness of tripe of home and foreign origin, A. W. J. MacFadden (*Local Govt. Bd. [Gt. Brit.], Med. Dept., Rpts. Insp. Foods, 1908, No. 4, pp. 12*).—A discussion of data noted above from another source.

Meat clubs, D. H. Doane (*Breeder's Gaz., 53 (1908), No. 5, pp. 232, 233*).—A cooperative system of slaughtering and distributing meat is outlined, which, according to the author, has been tried with satisfactory results in rural regions where it is usually difficult to obtain a satisfactory supply of fresh meat, particularly during the warm season.

General statistics of the meat consumed and imported, 1902–1906, J. Betancourt (*Sec. Hacienda [Cuba] Estad. Gen. Consumo é Import. Ganado, 1902–1906, pp. XI+66, pl. 1*).—A summary of statistical data.

Powdered eggs, T. H. Norton (*Daily Consular and Trade Rpts [U. S.], 1907, No. 3055, pp. 7, 8*).—A brief note on an Australian process for evaporating eggs. When dried, the eggs are coarsely powdered and it is said will keep for a long period in an ordinary package if stored in a dry place.

Concerning crab extract, IV, D. Ackermann and F. Kutscher (*Ztschr. Untersuch. Nahr. u. Genussmtl., 14 (1907), No. 11, pp. 687–691*).—Betain, pyridin-

methyl-chlorid, a new base for which the name "crangitin" is proposed, and neosin were identified in this study of crab extract. For earlier work see a previous note (E. S. R., 19, p. 358).

The proteolytic enzyms of certain vegetable food stuffs, H. Aron and P. Klempin (*Biochem. Ztschr., 9 (1908), No. 1–2, pp. 163–184*).—In accord with the results of other investigators, the occurrence of proteolytic enzyms in oats, barley, and vetch was demonstrated. The ferment present in oats can be isolated in the form of a glycerin extract and is more active in acid than in alkaline or neutral solution. Its action is rapid. It was found to induce cleavage in milk proteid and a number of plant proteids very readily, as well as in oat proteid, but this was not the case with other animal proteids, egg albumin being not at all affected and serum albumin affected only after cooking. The possible influence of these plant ferments in animal feeding and in human nutrition is discussed. As the authors point out, the ferments in cereals would usually be destroyed by cooking, but the possibility of a favorable effect from the ferments in raw fruits is spoken of.

Milling of wheats, J. C. Brunnich (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1906–7, pp. 62–68*).—The examination of a large number of samples of wheat and wheat milling products is reported, but general conclusions, in the author's opinion, could not be drawn, "particularly for the value of 'strength' on which the commercial value of flour from the baker's point of view is chiefly based. . . . As a matter of fact, so far, no generally satisfactory reasons have been brought forward to explain to which factors the strength of a flour is really due; it seems that strength may vary in the same variety of wheat if grown in a different locality, and in different climatic conditions, and again if milled differently."

The milling quality of Washington wheat, R. W. Thatcher (*Washington Sta. Popular Bul. 6, pp. 4*).—A popular account of investigations which have been noted from an earlier station publication (E. S. R., 19, p. 964).

The effect of nitrogen peroxid upon wheat flour, F. J. Alway and R. M. Pinckney (*Jour. Amer. Chem. Soc., 30 (1908), No. 1, pp. 81–85*).—The experimental data reported have been noted from another publication (E. S. R., 19, p. 666).

[Chemistry of the bleaching of flour], S. Avery (*Jour. Amer. Chem. Soc., 29 (1907), No. 12, p. 1767*).—A correction of data previously published (E. S. R., 19, p. 260).

Studies of the cause of coloration in black bread, G. Bertrand and W. Mutermilch (*Ann. Inst. Pasteur, 21 (1907), No. 11, pp. 833–841; Bul. Soc. Chim. France, 4. ser., 1 (1907), No. 20–21, pp. 1048–1051*).—A fuller account of material noted from another source (E. S. R., 19, p. 965).

Wheat and bread, G. Patouret (*Rev. Sci. [Paris], 5. ser., 9 (1908), No. 5, pp. 135–142*).—Statistical and other data regarding the composition of flour and bread, the bread supply of Paris, and bread making by the Schweitzer system.

Changes in rye flour due to molds, W. A. Arnoldow (*Vyestnīk Obshch. Hig., Sudeb. i Prakt. Med., 43 (1907), p. 1499; abs. in Chem. Ztg., 32 (1908), No. 2, Repert., p. 10*).—When rye flour molds the quality deteriorates rapidly, material change being noticeable in a day. In 60 to 70 days, 60 to 83 per cent of sterile flour was decomposed by mold. Of the carbohydrates, 12 to 24 per cent was lost in 12 to 24 hours, while the nitrogen content and ether extract did not materially diminish.

Comparative nutritive value of bread and zwieback, C. M. Belli (*Pp. 35; separate from Ann. Med. Nav., 13 (1907); abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 2, pp. 96, 97*).—According to the author's investi-

gations, zwieback is less digestible than bread and possesses a lower nutritive value, though judged by composition 100 parts of zwieback were equal to 131 parts of bread. Taking these facts into account, he considers that zwieback should not form a part of rations for soldiers except occasionally when it is not possible to provide fresh bread.

The vermicelli and alimentary pastes of Annam, C. Crevost (*Bul. Écon. Indo-Chine, n. scr., 10 (1907), No. 67, p. 804*).—A brief note on alimentary pastes called hô-tiêu and song-thân, exhibited at Marseille, and the commercial importance of these products in the East.

Studies of fruit pulp called Netté flour, A. Goris and L. Crété (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 4, pp. 187–189*).—Studies of the proximate and ash constituents of the fruit pulp obtained from tropical Africa, which is called "farine de Netté" and is obtained from a legume (*Parkia biglobosa*).

Note on fruit juice statistics, H. Lührig, P. Bohrisch, and A. Hepner (*Pharm. Centralhalle, 48 (1907), pp. 841–847; abs. in Chem. Zentbl., 1907, II, No. 21, p. 1755*).—The authors examined a large number of samples of raspberry, blueberry, and currant juices, which they had themselves made.

Grape juice cordial (*Brit. Med. Jour., 1908, No. 2453, p. 29*).—Brief data are reported regarding the composition of a concentrated unfermented grape juice designed for use as a beverage on dilution with plain or aerated water.

Concerning alcohol-free beverages, O. Mezger (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 1, pp. 14–19*).—Analyses are reported of 44 samples of so-called alcohol-free beverages. All but one of these samples contained less than 1 per cent of alcohol.

Cocoa from the Gold Coast (*Bul. Imp. Inst., 5 (1907), No. 4, pp. 361–369*).—Seven analyses of Gold Coast cocoas, fermented for different lengths of time and washed and unwashed, are reported, as well as other data regarding the cocoas of this region. "The principal defect of these Gold Coast cocoas as a whole is insufficient fermentation, which considerably reduces their market value in comparison with other varieties."

Calorimetric and analytical studies of cocoa, H. Langbein (*Ztschr. Angew. Chem., 21 (1908), No. 6, pp. 241–249*).—A comparative study of commercial brands of cocoa.

Enrilo, a new coffee substitute, A. Beitter (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 1, pp. 21, 22*).—Analyses are reported of a commercial coffee substitute and an infusion made from it. According to the author, it apparently consisted of coarsely ground roasted grains and chicory root. In odor and flavor, the infusion resembled coffee.

Hops, J. C. Brunnich (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1906–7, p. 74*).—Analyses of Queensland-grown and other hops are reported. The results showed that the amount of soft resins and tannins, which are generally considered of special importance in the valuation of hops, are rather low in the local-grown product. "The total resins also give a value indicating the maturation and development of the aromatic and bitter principles, and the total resins are also low in our Downs hop. Otherwise, aroma, appearance, and other physical properties of the sample were very fair."

Food analyses, J. T. Willard (*Bul. Kans. Bd. Health, 4 (1908), No. 1, pp. 4–12*).—Brief statements are made regarding the examination of samples of Hamburg steak, milk, and other food products, and an investigation of the water content of a number of samples of oysters shipped to Kansas under controlled conditions and of the copper content of oysters is reported.

"From the information at hand it would seem that fresh oysters as placed on the market should have very little liquid with them, and the percentage of the solids in the meats should be the best test of adulteration. It is well known

that oysters will absorb by osmotic action a portion of any water in which they may be placed. At the same time oyster solids pass out to a certain extent into the surrounding water. There is no doubt that in this way not only are the juices of the oyster diluted by the water absorbed, but the flavor is still further impaired by the loss of solids. There is a marked difference in flavor between oysters in a natural state and those in the water-soaked, adulterated condition which has been the rule up to recent time."

The average amount of water found in the meats of 22 samples taken directly from the shells and to which no water was added was 16.3 per cent. Considering the solids in the entire samples, that is, meat and liquor together, the water content ranged from 9.38 to 17.79 per cent.

"Taking everything into consideration the standard of 10 per cent of solids established by the State board of health seems abundantly low. Further, it should be recognized that the addition of water to oysters, with percentages of solids large enough to stand dilution, must be treated as an adulteration. The standard is not to be looked upon as one of excellence, but the minimum that will be tolerated. The average should be much higher; that shown by the samples under consideration is 13.58 per cent."

Copper was found in small quantities in the 34 samples examined, the amount varying greatly. The minimum quantity calculated on the dry matter basis was 0.005 per cent, the maximum 0.17 per cent, and the average 0.05 per cent. "Attention may be called to the fact that the liquor accompanying the oysters has, whenever examined, been found to contain copper in quantities of the same order of magnitude as those found in the meats."

"From the data now at hand, however, it seems safe to conclude that copper is a normal constituent of the oyster. It seems not unlikely that samples carrying the larger quantities may be deleterious, at least to individuals especially susceptible to the toxic effect of the metal. The oysters rich in copper have a coppery taste and a greenish-blue color. A green color in oysters has been observed to be caused by algæ upon which the oysters had fed."

For earlier work see a previous note (E. S. R., 18, pp. 1065).

Report on food products for 1907, W. M. Allen and H. M. Card (*Bul. N. C. Dept. Agr., 28 (1907), No. 12, pp. 64*).—During the year 560 samples of foods and beverages have been examined, including meat, fish, and oysters, catsup and sauces, canned goods, condensed milk, baking powders, jams and preserves, pickles, vinegar, alcoholic and nonalcoholic beverages, etc.

Less than 7.5 per cent of the samples of meat examined were adulterated, a marked improvement over conditions the previous year. Boric acid was the adulterant identified.

Codfish was examined to determine whether boric acid used externally as a preservative would be removed by such treatment as is necessary to remove salt before the fish is eaten, a sample being soaked for 12 hours in 4 times its weight of cold water. The water was then poured off and the sample rinsed in fresh water and boiled for 20 minutes in another quantity of water. The fish was then removed and the water evaporated. It was found to contain only a trace of boric acid.

Ice cream thickeners, G. E. Patrick (*Amer. Food Jour., 3 (1908), No. 2, pp. 11, 12*).—The thickeners most commonly used are gelatin, gum tragacanth, starch, dextrin, and rennet. Methods employed in the examination of ice cream for such thickeners and related questions are spoken of on the basis of the author's investigation of the subject. In view of the fact that by the use of thickeners and regulating the speed of freezers the quantity of ice cream may be materially increased, the author is of the opinion that this material should be sold by weight rather than by volume or measure.

Concerning the requirements of the German pure food laws. J. König (*Ztschr. Untersuch. Nahr. u. Genussmtl., 14 (1907), No. 10, pp. 621–636*).—In a paper presented at the Fourteenth International Congress of Hygiene and Demography, Berlin, 1907, the author elucidates and discusses the German pure food laws.

Food law requirements, R. Abel (*Ztschr. Untersuch. Nahr. u. Genussmtl., 14 (1907), No. 10, pp. 613–621*).—In a paper presented at the Fourteenth International Congress of Hygiene and Demography, the author discusses the points which should be taken into consideration in formulating pure food laws.

Notices of judgment (*U. S. Dept. Agr., Notices of Judgment 1, pp. 3; 2, pp. 3; 3, pp. 2; 4, pp. 3*).—The notices of judgment have to do respectively with the misbranding of apple cider, of molasses, of flour, and of coffee.

Hygienic cookery, Henrietta W. Calvin (*Industrialist. Agr. Ed. Ser., 1 (1907), No. 3, pp. 33–58*).—Food and its preparation are discussed in this article, which is designed to meet the needs of rural schools and is included in the agricultural educational series, issued in connection with the college extension work of the Kansas State Agricultural College.

The Rising Sun Household Cookery Book, La Mont and Weedon (*Honolulu, 1907, pp. 285*).—Directions are given in Japanese and English for the preparation of meat, fish, vegetables, desserts, etc., the volume being especially designed for the use of those employing Japanese cooks.

The kitchen manual, 1907, Jennie D. Rees (*Memphis, Tenn., 1907, pp. 372*).—An indexed collection of receipts for cooking meat, fish, vegetables, desserts, etc.

How to cook cowpeas, G. W. Carver (*Alabama Tuskegee Sta. Bul. 13, pp. 12*).—A revised edition of an earlier bulletin on this subject (E. S. R., 15, p. 795).

Saving the wild plum crop, G. W. Carver (*Alabama Tuskegee Sta. Bul. 12, pp. 8*).—Believing that the wild plum crop if generally utilized would be valuable for domestic and commercial purposes the author has collected a large number of receipts for making jams, preserves and similar products from wild plums and for their use in various dishes. The possibilities of improving wild plums by cultivation are also pointed out.

Measuring food values, A. Wilson (*Illus. London News [Amer. Ed.], 42 (1908), No. 1084, p. 234, figs. 5, dgm. 1*).—A brief discussion of the Atwater-Rosa-Benedict respiration calorimeter (E. S. R., 18, p. 1151) and the energetics of nutrition.

Metabolism experiments with 32 children 3 to 6 years old. E. Müller (*Biochem. Ztschr., 5 (1907), No. 2–4, pp. 143–303, tables 18*).—In the metabolism experiments reported special attention was paid to determinations of energy value. According to the author's conclusions, children 3 to 6 years old on an average required 87 calories per day or 16.7 calories per square decimeter of surface area. The average coefficient of digestibility of fat was found to be 94.4 per cent and the amount resorbed per kilogram of body weight 3.26 gm. as compared with a consumption of 3.45 gm.

In the author's opinion, the results do not furnish final data regarding nitrogen values, as the possibility of diminishing nitrogen when nitrogen-free material is present in abundance was not studied. The food consumed by the children studied furnished on an average 0.55 gm. nitrogen per day per kilogram of body weight, of which 0.04 gm. was retained.

Minimum protein requirement, J. Forster (*Münchcn. Med. Wchnschr., 54 (1907), No. 49, pp. 2412–2414*).—In a paper presented at the Fourteenth International Congress of Hygiene and Demography, Berlin, 1907, the author discusses protein requirement. In his opinion, the commonly accepted protein

standards should not be lowered. He believes that protein in generous amounts is required on account of the mineral matter which is bound up with it and on account of the stimulating and similar specific bodies which are formed from protein by cleavage and are essential to body well-being and resistance to disease. Furthermore, he believes that the whole question of proteid metabolism is not yet sufficiently understood to warrant final deductions.

A contribution to the study of calcium metabolism, S. W. Patterson (*Biochem. Jour., 3 (1908), No. 1–2, pp. 39–54*).—In experiments in which rabbits were fed on oatmeal and corn meal, a diet which leads to calcium starvation, the ratio of calcium in the blood to total ash in the blood remained much the same as in a normal animal. The ratio of calcium to total mineral matter in the bones was, however, not constant and showed fairly wide fluctuations even in the normal animal. As the author points out, it has been frequently shown that bones lose calcium when the animal is placed on a diet poor in this constituent. The results which he obtained, however, tend to show "that the bones can lose calcium relatively to the other salts, that is, by a selective autolysis and not by an autolysis of bone in mass."

The results of experiments in which he was himself the subject showed that calcium can be readily stored during nitrogen retention. "More interesting, however, are the experiments with rectal feeding, where calcium was stored despite a continuous drainage of nitrogen from the body. In the latter case, as the proteid absorbed from the food was insufficient, the muscles and glands must have been diminishing in bulk, and yet calcium was retained. This fact rather points to the bones as the seat, in this case, of calcium storage." On a fixed diet the renal excretion of calcium varied only slightly, the variations being parallel with the total amounts of urine excreted.

Studies of the importance of calcium salts for the growing body, H. Aron and R. Sebauer (*Biochem. Ztschr., 8 (1908), No. 1, pp. 1–28, pl. 1, dgms. 2*).—According to the authors' conclusions, the calcium requirement of young and growing animals is equivalent to at least 1.2 per cent of the gains in body weight. Judging by the results of the experiments, which were made with small animals (rabbits and dogs), a deficiency of food calcium does not affect body weight or growth in general provided the deficiency is not too great. The ill effects of such a deficiency are confined almost exclusively to the skeletal system and resemble clinically and anatomically the pathological conditions noted in rickets. Chemical analyses showed that such bones had normal weight but contained a larger proportion of water and less dry matter than normal bones and that the dry matter was deficient in mineral constituents. It was apparent, therefore, that deficiency in food calcium caused the formation of bones with an excess of water and with organic material insufficiently calcified.

The influence of surrounding temperature on carbon dioxid output in subjects at rest without clothing, J. Ignatius, L. Lund, and O. Wärri (*Skand. Arch. Physiol., 20 (1908), No. 3–4, pp. 226–232*).—According to the investigations reported with subjects at rest without clothing, combustion in the body showed a tendency to diminish when the surrounding temperature was moderately high, 31 to 32° C., but the decrease was neither very large nor very marked. The minimum carbon dioxid output was noted at a certain temperature, 26.1 to 29.4°, and increased when the temperature of the surrounding air was lower or higher.

Concerning the rôle of powdered meat, P. Lassablière (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 4, pp. 180–182*).—Experiments are reported in continuation of earlier work (E. S. R., 19, p. 358), and the author concludes that powdered meat acts as a digestive stimulant, though he believes it is valueless

as a nutrient and sometimes dangerous. The experiments were made with dogs.

The biological significance of lecithin, I, W. Glikin (*Biochem. Ztschr., 7 (1907), No. 3, pp. 286–298*).—A comparison of new-born mammals (dogs, rabbits, and cats) with birds featherless when newly hatched showed that there were close resemblances and indicated that helplessness at birth implies a high lecithin content.

The rôle of osmotic pressure in the phenomena of animal life, J. Demoor et al. (*Mém. Acad. Roy. Belg., 2. ser., 2 (1907), pp. 112; abs. in Biochem. Centbl., 7 (1908), No. 1, pp. 8, 9*).—In the investigations reported salt solutions of different concentration were passed through different organs and the changes in volume and rate of passage were noted. The special apparatus used in these experiments is described.

ANIMAL PRODUCTION.

Experiments on the digestibility of prickly pear by cattle, R. F. Hare (*U. S. Dept. Agr., Bur. Animal Indus. Bul. 106, pp. 38, pl. 1, fig. 1*).—Using steers as subjects, five experiments were made to determine the digestibility of prickly pear of different sorts alone and fed with alfalfa and cotton-seed meal in comparison with alfalfa hay alone. The income and outgo of nitrogen was also studied.

According to the author's conclusions—

"The average digestibility of the nutrients of prickly pear as determined in the first experiment where *Opuntia lindheimeri* was used were: Dry matter, 65.86 per cent; ash, 33.68 per cent; protein, 57.47 per cent; fat, 68.38 per cent; crude fiber, 41.32 per cent; nitrogen-free extract, 81.78 per cent.

"In the second experiment where the variety *O. lævis?* was used the coefficients of digestion were: Dry matter, 63.96 per cent; ash, 35.81 per cent; protein, 40.87 per cent; fat, 69.02 per cent; crude fiber, 53.99 per cent; nitrogen-free extract 78.95 per cent.

"In general these results would perhaps show a somewhat low coefficient for protein, a decidedly low coefficient for ash, but a very high coefficient for the nitrogen-free extract. The total digestible nutrients are about equal to those of immature green corn fodder.

"Our experiments seem to show that when prickly pear is fed with cured fodders or grains the digestibility of both is increased. For this reason prickly pear has a greater food value than is shown by its analysis and digestion coefficients.

"The nutritive ratio, i. e., the ratio of proteids to carbohydrates, is very wide for this feed, and in feeding it to all classes of animals, for whatever purpose, much better results should be obtained when it is fed with some substance of a high protein content.

"While the digestibility of the ash was apparently small, as noted above, yet the large amount of ash contained in these plants caused more ash to be assimilated from a ration equivalent to 15 lbs. of dry matter than is ordinarily assimilated from an equal ration of alfalfa, which has a higher coefficient of digestion for its ash.

"The steers seldom drank water when fed prickly pear alone. In fact, in feeding a ration of 100 lbs. of this feed per day the animals obtained from the feed over 8 gal. of water, which is more than was usually drunk by them when fed cured fodders alone.

"While no digestion experiments were made with any of the cacti other than prickly pear, the digestion coefficients of the latter could probably be safely

used for all other members of this family, since their composition and other characteristics are similar."

Concerning the composition and digestibility of hay from sewage meadows, J. Volhard (*Landw. Vers. Stat., 68 (1908), No. 1–2, pp. 11–18*).—Using sheep as subjects, the digestibility of early-cut and late-cut hay from sewage meadows was studied. The author calculated that the early-cut hay had a starch value of 30.5 and the late-cut hay of 29.1.

The composition of hay from sewage meadows and the question of feeding calcium phosphate, P. Ehrenberg (*Landw. Vers. Stat., 68 (1908), No. 1–2, pp. 19–38*).—The author reports results of a number of investigations which he has carried on and summarizes the work of other investigators. According to his analyses, the sewage meadow hay under consideration regularly contained more protein and albumin than ordinary meadow hay from a similar locality. The sewage meadow hay was richer in phosphoric acid and contained on an average less calcium.

The desirability of feeding lime instead of calcium phosphate with sewage meadow hay is discussed but, in the author's opinion, can not be definitely decided on the basis of evidence now available.

German potato flakes, J. E. Kehl (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3122, pp. 5, 6*).—The manufacture of flakes from the surplus potato crop and the commercial importance of such products are considered, and rations containing potato flakes are suggested suitable for calves, cows, pigs, and horses.

"Nsa-Sana" seeds from southern Nigeria (*Bul. Imp. Inst., 5 (1907), No. 4, pp. 369, 370*).—Oil was expressed experimentally from Nsa-Sana seeds (*Ricinodendron africanum*) and the specific gravity and other constants determined. The oil is similar to t'ung oil (Chinese wood oil), which is of importance commercially. It is stated that the cake remaining after the expression of the oil would have a feeding value approximating that of decorticated cotton-seed cake, but as there are indications of the presence of an alkaloid, it would be necessary to study the material thoroughly before it could be recommended for such a purpose. It could, however, be utilized as a fertilizer, since it is rich in nitrogen.

Dried grape marc as a feed for farm animals, Sémichon (*Soc. Aliment. Rationn. Bétail, Compte Rendu 12. Cong., 1907, pp. 144–150*).—A paper with discussion on the feeding value of grape marc.

Experiments on the composition and digestibility of some by-products from ethereal oil manufacture, F. Honcamp and T. Katayama (*Landw. Vers. Stat., 67 (1907), No. 1–2, pp. 105–128; Sächs. Landw. Ztschr., 55 (1907), No. 36, pp. 953–955*).—Studies of the composition and digestibility of the materials remaining when oil is made from ajowan (*Carum ajowan*), celery seed, and coriander seed. The digestion experiments were made with sheep. In general, only about 50 per cent of the protein was assimilated.

Composition of Hawaiian feeding stuffs, Alice R. Thompson (*Hawaii Sta. Rpt. 1907, pp. 63–66*).—Analyses are reported of sorghum, sorghum silage, corn cut for the silo, corn silage, millet roots, hilo grass, Rhodes grass, pili grass, para grass, side oats grama, and other grasses, wheat hay, rice straw, alfalfa, cowpea forage, cassava refuse from starch making, taro waste, *Tacca pinnatifida*, ti root, beets, algeroba beans, algeroba bean meal, Spanish needles, pakana (*Medicago officinalis*), rape, and annual ilima (*Sida* sp.).

Feeding stuff inspection, C. D. Woods and J. M. Bartlett (*Maine Sta. Bul. 156, pp. 157–202*).—Under the provisions of the State law upward of 500 samples of feeding stuffs were examined, including cotton-seed meal, cotton-seed feed, linseed meal, gluten feed, distillers' grains, brewers' grains and malt sprouts, miscellaneous reenforced feeds, molasses and sugar feeds, corn, barley

and oat feed, corn and oat feeds, hominy feeds, rice feed, poultry feeds, wheat offals, and beef scraps. According to the author, in general the cotton-seed meal samples were of good quality. As regards cotton-seed feed, "one pound of choice cotton-seed meal is equal to 2 lbs. of cotton-seed feed." In general the distillers' grains were somewhat below their guaranty in protein.

In connection with the study of gluten meals and feeds the goods and feeds were examined for the presence of foreign coloring matters and for the proportion of acid present, the results being compared with those obtained with corn meal. "All the samples, including the corn meals, exhibited traces of sulphuric acid, but those glutens which gave the highest percentages of total acidity usually seemed to carry more sulphuric acid than the others. The greater part of the acid present in excess, however, was hydrochloric, which varied considerably in the different samples, the variations for the most part agreeing quite closely with the variations in total acidity." In 8 samples coal tar color was detected, in 6 none was found, while the remainder were not examined for such materials.

The feeding stuffs were also examined for the presence of weed seeds and germination tests were made. The nitrogenous feeds were with 2 exceptions free from weed seeds. Such seeds were quite generally found in varying amounts in the miscellaneous reenforced feeds and poultry feeds and in the majority of the wheat offals, though usually weed seeds were reported as few in number in this class of goods. "The most flagrant offenders carrying live weed seeds are the molasses or sugar feeds."

Believing that mold growth might have interfered with germination in the trials which were undertaken, this point was further studied, mold being hindered by treating the seeds with a dilute solution of formaldehyde. It was found "that a number of the brands of feeds which showed no germination in the first test did, under more favorable conditions, sprout numbers of the weed seeds which they contained." The general question of the introduction of weed seeds into feeding stuffs, both whole grains and other feeds, is discussed with reference to State legislation on this matter and the bearing of a decision of the U. S. Board of Food and Drug Inspection on this subject is pointed out.

Commercial feeding stuffs, T. L. Calvert (*Off. Rpt. Sec. Ohio Bd. Agr. on Com. Feed Stuffs, 1907, pp. 26*).—Under the provisions of the State law analyses were made by H. A. Weber of 126 brands of dried distillers' grains, cotton-seed meal, gluten feed, malt sprouts, hominy feed, commercial mixed feeds, including those containing molasses, ground flax flakes, condimental feeds, meat meal, and poultry feeds.

Licensed concentrated feeding stuffs, F. W. Woll and G. A. Olson (*Wisconsin Sta. Bul. 163, pp. 19–31*).—A list is given of the concentrated commercial feeding stuffs which have been registered by manufacturers for the calendar year ending December 31, 1908.

Experiments on the digestion of different quantities of feed by swine, T. Katayama (*Landw. Vers. Stat., 68 (1908), No. 1–2, pp. 1–10*).—The experiments reported show, in the author's opinion, that the quantity of feed taken did not materially affect the digestibility of the different constituents of the ration.

Studies of the nitrogen, phosphorus, and sulphur in organic combination in vegetable products, A. Stutzer (*Biochem. Ztschr., 7 (1908), No. 4–6, pp. 471–487*).—Rye, oats, cocoanut cake, cotton-seed meal, hay, and other vegetable materials were examined and in connection with the work natural and artificial digestion experiments were also made. The view that phosphorus occurs principally in organic forms in plants and especially in the seeds was confirmed

and extended. Sulphur also was found to occur chiefly in organic forms, as has been pointed out by other observers.

The vegetable material insoluble in acid gastric juice contained nitrogen, phosphorus, and sulphur in organic compounds, but no definite relation between these elements or between any two of them could be noted in the different vegetable products studied.

In feeding experiments with sheep, it was found that feces contained a larger amount of organic phosphorus and sulphur than was to be expected from the character of the rations (hay with and without oats). Metabolic products were present in the feces containing the insoluble phosphorus and sulphur compounds, which were also insoluble in acid gastric juice.

According to the author, the nature of the organic sulphur compounds is not known, particularly those which occur in plants and are insoluble in acid gastric juice and also the insoluble organic sulphur compounds remaining in the feces.

Elimination of phosphorus by Herbivora, A. Gouin and P. Andouard (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 3, pp. 133–135*).—The authors studied the effect of different rations on the excretion of phosphorus by Herbivora with special reference to the observed fact that with young animals the urine contains practically all the phosphates excreted, while such is not the case with older animals.

The action of fresh cola nuts on muscular work, J. Chevalier and Alquier (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 2, pp. 86–88*).—Experiments with 2 horses showed that more work was performed on a ration with than without fresh cola nuts. A loss in body weight and increased body temperature were noted during the cola nut period and the authors conclude that the extra work is performed at the expense of body material. Cola nuts are regarded as a stimulant and their use is not considered desirable except when forced work is necessary.

The influence of sexual function on metabolism, F. Tangl (*Landw. Jahrb. 37 (1908) No. 1, pp. 45–50*).—In the studies reported, when a stallion covered a mare the quantity of urine was not increased nor was the renal excretion of nitrogen or phosphorus. This showed, according to the author, that the metabolism of protein and of phosphorus yielding bodies is not materially increased, and so he concludes that it is not necessary to provide stallions with a ration especially rich in phosphorus.

The effects of environment and nutrition upon fertility, F. H. A. Marshall (*Sci. Prog. Twentieth Cent., 2 (1908), No. 7, pp. 369–377*).—The effect of feed on productivity and character of the young and related questions are discussed and data bearing on this subject summarized.

According to the author, the largest percentage of lambs was obtained, in tests which he quotes, from flocks kept on grass during the greater part of the year, but artificially stimulated by feeding the ewes for a time turnips, oats, dried grain, maize, or other similar feed. The data summarized fully confirm the conclusion "that stimulation of the generative organs of sheep by a system of special feeding at the beginning of the breeding season results in an increased crop of lambs at the following lambing season. The twins appear almost invariably to have been born early during lambing, thus showing that the reproductive activity of the ewes is usually greatest at the beginning of the breeding season."

Experiments in calf feeding, A. Gouin and P. Andouard (*Soc. Aliment. Rationn. Bétail, Compte Rendu 11. Cong., 1907, pp. 11–28, 127–130*).—A paper with discussion summarizing the authors' experiments in which rations with and without skim milk were used in calf feeding and potassium phosphates, rock phosphate, sweetbread, thyroid, protylin, and powdered bone were added to the

rations. The digestibility was determined, as well as gains in weight. The results reported emphasize the authors' general conclusion regarding the high efficiency of bone phosphate in calf feeding. That lime is no less necessary than phosphoric acid is also pointed out. For earlier work see previous notes (E. S. R., 16, p. 294; 19, p. 468).

Skim milk for raising and fattening calves, L. Malpeaux (*Soc. Aliment. Rationn. Bétail. Compte Rendu 11. Cong., 1907, pp. 1–10, 126, 127, dgms. 2*).—A paper with discussion. According to the author, 2 calves fed for 84 days on pan-skimmed milk gained on an average 0.945 kg. per head per day as compared with 0.892 kg. in the case of similar calves fed the separator-skimmed milk.

In a comparison of pasteurized with raw sweet milk, it was found that the average daily gain of 2 calves in 112 days on the former was 0.888 kg. per head and on the latter 0.844 kg. In a similar comparison of skim milk and sour milk the average gains were respectively 0.843 kg. and 0.776 kg.

When denatured sugar was used to supplement skim milk in calf feeding the average daily gain in 85 to 112 days was 0.964 kg. per head as compared with 0.867 kg. in a similar test in which starch was used.

Denatured sugar and a decoction of flaxseed were also compared as supplements for skim milk. In 153 days the average daily gain of the 2 calves on the former was 0.250 kg. and on the latter it was 0.225 kg.

As the author points out, the 20 per cent of feeding cake used for denaturing the sugar added to its nutritive value. Forty to 45 gm. of sugar per liter of skim milk is advisable. Large quantities cause scouring.

See also a previous note (E. S. R., 19, p. 171).

Feeding experiments with diastasolin, Reichert (*Molk. Ztg., 22 (1908), No. 4, pp. 77, 78*).—In an article quoted from *Königsberger Land- und Forstwirtschaftliche Zeitung*, the author reports satisfactory results from the use of potato starch inverted with diastasolin as a feeding stuff for calves.

Calf feeding, E. V. Strebel (*Württemb. Wchnbl. Landw., 1908, No. 5, pp. 87–92*).—On the basis of extended experience at Hohenheim, feeding and weaning, cost of rations, and gains in weight of calves up to 2 years old are discussed.

Animal production in Argentina, S. Baldassarre (*La Zootecnia nell' Argentina. Naples, 1906, pp. X+236, pl. 1, figs. 58*).—A general discussion of breeds, feeding, care, and management, slaughtering and marketing, and of dairying in Argentina.

Cattle raising, E. Hnos (*Estac. Agr. Expt. Ciudad Juárez, Chihuahua, Bol. 9, pp. 47, pls. 7*).—The importance of cattle raising, the conditions which affect the local cattle-raising industry, and general topics of breeding, care, and management are discussed.

Cattle, French and foreign, P. Diffloth (*Races Bovines. France—Étranger. Paris, 1908, pp. 426; rev. in Nature [London], 77 (1908), No. 1998, p. 339*).—French and other cattle are described in this volume which is included in the series *Encyclopédie agricole. Zootechnie.*

The improvement of Egyptian cattle, T. P. Goodchild (*Yearbook Khediv. Agr. Soc. Cairo, 1906, pp. 141–157, pls. 6*).—The author believes that the improvement in Egyptian cattle, which is very essential, can be best secured by selection and that crossing with other sorts of cattle would not give satisfactory results. Management of cattle under local conditions, the utilization of Egyptian feeding stuffs, and other matters are considered.

Live and dead weight of Egyptian animals, J. S. J. McCall (*Yearbook Khediv. Agr. Soc. Cairo, 1906, pp. 191–199*).—To secure data on which to calculate the carcass value of the different kinds and breeds of animals slaugh-

tered for market in Egypt, the live and dressed weight of cattle and buffalo of different ages and of camels and sheep of different breeds were determined.

According to European standards, the author points out that the dressed weight of fat steers should equal 58 per cent of the live weight and animals dressing 50 per cent are considered lean and unfit for killing. "If we consider Egyptian animals by this standard we find that very few of the cattle reach it, although many of the sheep exceed 50 per cent."

The article also contains information regarding the prices and use of meat in Egypt and related topics. According to the author, buffalo veal is in great demand and is the most expensive meat sold in Cairo. Camels, particularly Syrian or Shami camels, are slaughtered to some extent and the flesh sold to the poorer people. On an average the dressed weight of Syrian camels is 58 per cent of the live weight.

Sugar for fattening sheep, L. Malpeaux (*Jour. Agr. [Paris], 43 (1908), I, No. 2146, pp. 12–15, dgm. 1; abs. in Illus. Landw. Ztg., 28 (1908), No. 4, p. 22, dgm. 1*).—In a test covering 84 days the average daily gain per head on a ration containing sugar was 202 gm. as compared with 127 gm. per day on a ration without it. When slaughtered the flesh of the sugar-fed sheep was found to be of most excellent quality.

On account of its value as an appetizer and also as a source of nutritive material, the author concludes that denatured sugar is a valuable feeding stuff.

An attempt to acclimatize sheep at Kelantan (*Bul. Écon. Indo-Chine, n. ser., 10 (1907), No. 67, pp. 815–819*).—In general, this attempt to acclimatize sheep in Indo-China has been successful. The report gives some data on the feeding stuffs used, gains in weight, number of lambs born, etc.

Rations for fattening hogs, W. T. McDonald and J. S. Malone (*Oklahoma Sta. Bul. 80, pp. 89–96*).—Meat meal in larger and smaller amounts, cotton-seed meal, alfalfa hay and cowpea hay as supplements to corn meal were compared with corn meal alone in a test made with 6 uniform lots of 5 pigs each. The cotton-seed meal ration, which consisted of 4 parts of corn meal to 1 of cotton-seed meal, was alternated every 2 weeks with corn meal alone. In the 56 days of the test the smallest total gain, 173 lbs. per lot, was noted with the corn meal ration, and the greatest gain, 484 lbs., on corn meal and meat meal 7 : 1. On corn meal and meat meal 11 : 1 it was 473 lbs. On the other rations it ranged from 245 lbs. on corn meal and cotton-seed meal 4 : 1 to about 285 lbs. on corn meal and alfalfa hay ad libitum. The feed eaten per pound of gain ranged from 4.37 lbs. on corn meal and meat meal 11 : 1 to 8.01 lbs. on corn meal alone, and the cost of a pound of gain from 4.73 cts. on corn meal and meat meal 11 : 1 to 8.01 cts. on corn meal alone.

Stock food for pigs, J. W. Wilson and H. G. Skinner (*South Dakota Sta. Bul. 105, pp. 300–317, figs. 9*).—In the first of the two series of tests reported, which included two years, five commercial stock feeds with ground corn and barley were fed in comparison with ground corn and barley, 1 to 1. The feeding period in the first year covered 92 days and in the second 63 days, and the lots included from 8 to 10 pigs. In every case the pigs had access to rape pasture.

On the check ration the average daily gain per pig for the two years was 1.1 lbs., the feed required per pound of gain, 5.19 lbs., and the cost of a pound of gain 4 cts. On the ration including stock feeds the daily gain ranged from 1.17 lbs. per head to 1.34 lbs., the grain eaten per pound of gain from 4.54 to 4.86 lbs., and the cost of a pound of gain from 4.16 to 4.58 cts.

In the second series of tests, corn meal was compared with corn meal and a commercial stock feed, and with corn meal and a home-made stock feed, using three lots of 8 pigs each fed for 61 days. All the lots had the run of blue grass pasture in addition to the grain or grain and stock feed. The total gain was 514

lbs. on corn meal alone, 483 lbs. on corn meal and commercial stock feed, and 551 lbs. on corn meal and home-made stock feed. The feed required per pound of gain in the three cases was 4.91, 5.49, and 5.11 lbs., and the cost of a pound of gain, 3.85, 4.69, and 4.4 cts.

"From the above table it will be seen that it required more pounds of feed for 100 lbs. of gain in this experiment, than it did for the average of the lots in the previous experiment. This can be accounted for from the fact that the rape pasture furnished a more succulent feed than did the blue grass pasture."

"From the data presented in this bulletin the reader must draw his own conclusions as to the value of any of the stock foods tried."

The home-made stock feed, according to the authors was made up as follows:

"Gentian, 2 lbs., cost $0.50; ginger, 1 lb., cost $0.40; sodium bicarbonate, 1 lb., cost $0.10; fenugreek, 0.5 lb., cost $0.10.

"Purchase these materials at a drug store and have them mixed into fine powders. Then mix with 5 lbs. of common salt and 25 lbs. of shorts. This compound will cost about 4½ cts. per pound. For the pig mix 1 lb. with every 48 lbs. of grain.

"This furnishes a comparatively cheap stock food, but even this preparation did not make as cheap a gain as when no stock food was fed."

The composition of the stock feeds used was determined by J. H. Shepard, whose report is included in the bulletin. They were found to consist of such drugs as salt, capsicum, ginger, charcoal, fenugreek, sulphur, etc., with such materials as bran, ground bark, mill refuse, and oil meal.

Some suggestions to farmers who kill their own hogs on the farm or plantation, C. Schuler (*Ann. Rpt. Agr. and Indus. Statis. Bd. Agr. and Immigr. [La.], 1907, pp. 5, 6*).—Directions for the home-curing of ham and other pork products are given.

Notes on horse feeding, E. Vital (*Allg. Brau. u. Hopfen Ztg., 48 (1908), No. 44, pp. 453–455*).—This summary and discussion of horse-feeding problems provides a bibliography of recent work on the subject.

Feeding tests with bran-molasses for horses, L. Pape (*Deut. Landw. Presse, 35 (1908), No. 10, pp. 95, 96*).—On the basis of experience, the author believes that bran-molasses is a satisfactory feeding stuff for horses.

The feeding of the pure blood horse, L. Grandeau (*Paris, 1907, pp. 8, fig. 1; reprinted from Compt. Rend. Cong. Hippique, 1907*).—In a paper presented at the Horse Breeding Congress at Paris, June, 1907, the author discusses the value of dried and ground skim milk as a feeding stuff for horses and gives an account of a horse which was raised on this material supplemented by hay. When about 2 years old 7 kg. of the milk powder was fed per day. At this time the horse weighed some 445 kg. According to the author, he was well developed and in splendid condition.

In a discussion which followed the paper the author states that the Algerians feed their horses exclusively on sheep milk, giving them some 30 liters per day.

The use of dried skim milk for feeding a pure blood horse, Baron Peers (*Soc. Aliment. Rationn. Bétail, Compte Rendu 11. Cong., 1907, pp. 130–133*).—A general discussion of the value of dried skim milk in horse feeding, the author citing the work on this subject noted above.

Proceedings of the Horse Breeding Congress, Paris, 1907, J. M. de Lagorsse (*Compt. Rend. Cong. Hippique, 1907, pp. 160, fig. 1*).—The proceedings, list of members, and other general data are included in this report of the meeting of the Horse Breeders' Association, Paris, June 21 and 22, 1907. Among the reports presented were The Actual Situation and Production of Horses in France, by Viseur; Exportation of French Horses, by Le Gentil, etc.

A paper on the feeding of a pure blood horse with skim milk powder is noted above.

The grade stallion situation in Wisconsin, A. S. Alexander (*Wisconsin Sta. Bul. 158, pp. 3–35, figs. 12, map 1*).—With a desire of improving eixsting conditions, the author discusses the number and character of stallions kept in Wisconsin, pointing out the bad qualities of many of them and making numerous suggestions for betterment. According to the author, there are in the State 1,974 stallions licensed as grades, while there are but 1,286 pure-bred stallions in service. Of those licensed as grades, moreover, 136 were pronounced by their owners as of unknown breeding and 34 were certified to as of mixed breeding. As regards breeds, 43 per cent of the pure-breds were Percherons and 30 per cent trotters.

Safety for new-laid eggs (*Illus. London News* [*Amer. Ed.*], *42* (*1908*), *No. 1088, p. 376*).—A homemade nest is described having a false bottom made of 2 inclined boards with a space between them. These are covered with straw as is also the bottom of the box underneath the opening. The new-laid egg slides down the incline and falls into the lower receptacle where it can not be pecked or broken by the fowls. If a nest egg is used, it may be fastened to the side of the nest or to the false bottom.

The marketing of poultry (*Jour. Bd. Agr.* [*London*], *14* (*1908*), *No. 11, pp. 641–651*).—A summary of data and discussion of market requirements for chickens, ducks, geese, and turkeys in different English markets. It is stated that the demand for high-class poultry in Great Britain has increased very greatly within recent years.

National standard squab book, E. C. Rice (*Boston, 1908, pp. 232, pl. 1, figs. 74*).—Pigeon houses, nest bowls and nests, water and feed, laying and hatching, killing and cooling, the markets, pigeon diseases, and other questions are discussed in this volume, which is designed as a handbook of squab raising.

Breeding for squabs, F. A. Sotter (*Douglassville, Pa., 1908, pp. 75, pls. 14*).—Breeding, feeding, care, and management, diseases, and other matters of importance in squab raising are discussed and a number of receipts are given for cooking squabs.

DAIRY FARMING—DAIRYING—AGROTECHNY.

Sources of bacteria in milk, W. M. Esten and C. J. Mason (*Connecticut Storrs Sta. Bul. 51, pp. 65–109, figs. 8, dgm. 1*).—The significance of kinds rather than of numbers of bacteria in milk is especially emphasized and the different kinds of bacteria that get into milk are classified in groups. These are also tabulated with respect to the source from which they arise, the latter classification depending largely upon the results of investigations discussed by the authors, the purpose of which was to discover the sources of bacteria and means of eliminating them by practical methods from the milk.

According to the authors the cow is the chief source of the bacteria that get into the milk. These come from the interoir of the udder and from the surface of the cow's body. With regard to the udder organisms it is stated that "the flora of bacteria in the normal healthy udder is a rather small one, averaging from 2 to 8 varieties in each udder. The udder is composed of 4 divisions, each separate from the other 3 divisions. There may be one or more different kinds of organisms in each quarter. The number of varieties that come from the udders of a number of cows is a large one. In a herd of about 25 cows there were found to be over 50 varieties of bacteria. Fifty-five per cent of these had no visible effect on sterile milk when inoculated as a pure culture. Thirty-eight per cent turned milk slightly acid, and 7 per cent turned milk to

an alkaline reaction. The micrococci varieties which grow in groups of 4 predominated to the extent of 95 per cent. One variety of micrococci seemed to be dominant and was present in frequency of occurrence 22 times in comparison to other varieties which were present 9, 8, 7, 3, 3, and 2 times, respectively.

"The most abundant source of bacteria that get into milk is the surface of the cow. Some fall on the cow with the dust that settles into the hair. Others accumulate from contamination with cow feces. Organisms from this source are the most serious and most objectionable." A gram of the powder obtained by currying the cow was found to contain 207,000,000 organisms. As to hay as a source of bacteria 28 tests, continuing weekly from October 17 to May 28, were made of the number of bacteria per gram of a hay including timothy, red top, rowen, semiswail, and swamp hay, taken from all parts of the hay loft. The average number of bacteria per gram for all these tests was 16,800,000. "In order to compare the numbers of organisms on hay and on grass from early spring to time of cutting, tests were made of the numbers on grass in the different stages of development. The sources of grass were pasture land, semifertile fields, very fertile fields, and near buildings. Clover and rye were incidentally included. The average number of bacteria per gram for all samples was 15,000,000, a number nearly the same as that found in cured hay."

To ascertain the kinds of bacteria that get into milk from hay "twenty-five of the most abundant kinds were picked out and analyzed. Ten of these, or 40 per cent, were spore-forming bacteria; 18, or 72 per cent, were liquefiers (decay and decomposition bacteria); 22, or 88 per cent, were rod-shaped bacteria, and 12 per cent were cocci or spherical bacteria; 18, or 72 per cent, were motile capable of swimming around in milk and getting into all parts of it, causing much more rapid changes than those that are motionless."

According to the authors, the bacteria found on grass are mostly from soil contamination. To determine whether these grow on the surface of plants "the first spring growth of grass on April 18 was clipped off with sterile shears and a gram was plated for numbers. There were found 455,000 per gram. Over this spot was placed a bell jar, to keep out all contaminations. On the thirtieth of April a gram of grass was taken from under the bell jar and plated for numbers. The number of bacteria now was only 114 per gram, showing that the bacteria on grass are largely bacteria from some other source. If they do multiply on grass it is at a very slow rate. There was no evidence of *Bacterium lactic acidi* present on this sample of grass."

Grain feeds were found to be liberally stocked with organisms. The examinations made show that the percentage of acid organisms is more than twice as large, while that of liquefying organisms is only half as large, as that for hay.

The agency of flies as a source of bacteria was indicated by tests showing that from 414 flies an average of about 1,250,000 bacteria for each fly was obtained. The relation of the prevalence of flies to an increase in intestinal diseases is discussed.

The number of bacteria that could be washed from the hands of a milker who had been working around the farm previous to milking was found to be 45,000,000 before the hands were washed.

Bacterial growth and chemical changes in milk kept at low temperatures, Mary E. Pennington (*Jour. Biol. Chem., 4 (1908), No. 4–5, pp. 353–393; abs. in Science, n. ser., 27 (1908), No. 687, p. 331*).—In milk kept at a temperature of −0.55° C. there was a steady increase in the number of organisms for 5 or 6 weeks. Acid formers were in lower proportion and liquefying organisms in higher proportion than is commonly found. Certain species were especially resistant to cold and frequently were predominating or almost in pure culture at

the end of the experiment. The casein of the milk in cold storage was rapidly digested until more than 50 per cent of it was changed to soluble compounds.

The milk of cows afflicted with foot-and-mouth disease, G. CORNALBA (*Agr. Mod., 14 (1908), No. 8, pp. 103, 104; Indus. Latt. e Zootec., 6 (1908), No. 8, pp. 83, 84*).—A brief summary of information, showing that the quantity of milk given diminishes somewhat according to the gravity of the infection, ranging from a loss of one-third to that of the total amount of milk. The chemical composition is not noticeably altered, but the physical characteristics are somewhat different from those of normal milk. The milk should not be used for food.

Tests of dairy cows, 1906–7, F. W. WOLL and R. T. HARRIS (*Wisconsin Sta. Bul. 160, pp. 3–39, pl. 1, figs. 16*).—The tests previously referred to (E. S. R., 20, p. 77) are here reported in more detail, and photographs of a considerable number of the cows included in the tests are reproduced.

The Kirkee civil dairy, F. FLETCHER (*Dept. Agr. Bombay, Ann. Rpt. Expt. Work Poona Agr. Sta. 1906–7, pp. 20–33*).—The objects of the dairy are stated and the records of the yields and financial returns by several groups of cows and buffaloes of different breeds are given.

The problem of the poor cow, W. J. FRAZER (*Illinois Sta. Circ. 114, pp. 8, figs. 3*).—The records of different cows in the same herd are compared in such a way as to show the wide differences commonly found in productive capacity, the purpose being to interest dairymen in the testing of their cows and increase their profits by weeding out the poor ones.

Why and how to test dairy cows, W. J. FRASER (*Illinois Sta. Circ. 115, pp. 12, figs. 4*).—The improvement accomplished by weighing and testing milk and by other progressive methods in conducting a dairy is described and illustrated by concrete example, and explicit information is given regarding the weighing and testing of milk for the purpose of determining good and poor cows.

Milk supply of Kentucky—Louisville, R. M. ALLEN (*Kentucky Sta. Bul. 134, pp. 75–323, pls. 20, dgm. 1*).—The results of the inspection of a large number of Kentucky dairies supplying milk to Louisville are reported. The introduction to the bulletin comments upon the conditions that were found and the efforts that were made for improvement. Some discussion is also given of tuberculosis in dairy animals, certified milk, and the significance of the score card as a factor in the improvement of market milk.

Dairy practice at Kenai Station, P. H. ROSS (*Alaska Stas. Rpt. 1907, pp. 62–73*).—An account is given of the establishment of a dairy herd at the station and of the methods followed in dairy work, including details regarding the care of the cows and calves, a description of the dairy equipment employed for butter making and for cheese making, and a discussion of dairy practice. The natural advantages of the region for dairying are briefly set forth.

The origin of the turnip taste of butter, H. WEIGMANN (*Landw. Jahrb., 37 (1908), No. 2, pp. 261–309*).—The milk from cows fed on turnips has a peculiar odor and taste. Apparently some volatile product from the turnips gets into the body fluids of the cow and thus affects the milk. This fault may be corrected by warming or aerating the milk. But besides this, certain organisms, as coli bacteria, *Actinomyces odorifer*, *Penicillium brevicaule*, and lactic-acid bacteria, which are found in the feces of cows fed on beets or turnips, also produce the turnip flavor and aroma in butter made from milk or cream in which they are present. The turnip taste of butter may be due to both of these causes together. Butter may have the turnip flavor and aroma, however, even when no turnips are fed, as coli bacteria causing the taste are found also on oats, barley, corn, rape, and other feeding stuffs. Pasteurizing the milk, with subsequent aeration, is recommended as a means of preventing the development of the turnip flavor in butter.

Rusty cans and their effect upon milk for cheesemaking, G. A. Olson (*Wisconsin Sta. Bul. 162, pp. 3–12, figs. 2*).—The author has previously shown (E. S. R., 20, p. 80), that various metals have considerable effect upon the action of rennet. In the experiments reported in the present publication the effect of iron rust on rennet action is shown. "Milk was placed in iron dishes and rusty tin pans and was allowed to stand for definite periods of time. The required time for the coagulation of 50 cc. of such milk with a standard solution of 1 cc. of a 1 per cent commercial rennet extract at a temperature ranging from 87 to 88° F., was then observed. Milks kept in glass beakers were run as controls under similar conditions. The time was noted at the moment the milk just thickened." In these tests "it required from 1 to 16.5 minutes longer for the same milk kept in the rusty pan to coagulate than in case of the milk kept in the glass beaker." The acidity of the control milk was always higher than that kept in the rusty cans, but the difference was not great enough to account for the differences in retardation.

"Milk which had been allowed to stand in iron dishes for several hours had a peculiar bluish grey color, indicating the presence of iron in solution. In several instances the amount of iron dissolved in the milk was determined as iron oxid. The maximum quantities of iron dissolved in the milk ranged from 1 to 1½ lbs. for every 1,000 lbs. of milk." The significance of this is shown by consideration of the conditions of the cans in which milk is brought to the cheese factory, and these conditions in America are contrasted with those prevalent in certain sections of Europe.

Varieties of cheese, C. F. Doane and H. W. Lawson (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 105, pp. 5–72*).—This publication comprises a compilation of descriptions and analyses of those varieties of domestic and foreign cheese about which published information could be found by the authors. A list of publications giving the original sources of analytical data is included.

Investigation of commercial rennet preparations, A. Burr and F. M. Berberich (*Chem. Ztg., 32 (1908), No. 25, pp. 313, 314*).—The chemical composition of a number of samples of liquid and powdered rennet preparations is reported and the data are briefly discussed.

The position of the oleomargarine industry in Sweden, A. Larson (*K. Landtbr. Akad. Handl. och Tidskr., 47 (1908), No. 1–2, pp. 21–29*).—The statistics of the industry during the last 20 years are given and discussed.

The manufacture of oleomargarine in Sweden has gradually increased from 6,000 kg. in 1886 to 14,343,608 kg. in 1906. At the same time the imports decreased from 813,621 kg. in 1885 to 6,296 kg. in 1906, the exports increased from 6,667 kg. to 658,642 kg., and the domestic consumption increased from 806,954 to 13,691,262 kg. The average price obtained for the year has ranged from 72 öre (19.5 cts.) in 1897 to 113 öre (30.5 cts.) in 1902, the mean price for the period given being 91.8 öre (24.8 cts.) per kilo.

The manufacture of starch from sweet potatoes, C. C. McDonnell (*South Carolina Sta. Bul. 136, pp. 7–50, pl. 1, figs. 11*).—The investigations described were undertaken to determine how much starch could be recovered commercially from sweet potatoes and to test the quality of the starch thus obtained for different uses to which starch is put. The discussion includes an account of the method of culture, analyses of the sweet potato, the process of manufacturing starch therefrom and other data. The results are reported of investigations of two years on the manufacture of starch from sweet potatoes and of tests of the starch for commercial purposes in laundry work and in the cotton textile industries.

In the author's opinion "it is practically settled that the starch produced from sweet potatoes is of a high grade and suitable for use in many operations

where a high-grade starch is required. In all of the tests we have had made not a single adverse report has been received."

The pitting or pulping of olives. R. Marcille (*Bul. Agr. Algérie et Tunisie, 14 (1908), Nos. 6, pp. 146–150; 7, pp. 161–168*).—It is stated that removing the pits from the pulp of olives before pressing somewhat improves the quality of the oil, but the increased financial return for such improvement does not pay for the actual cost of the operation.

Vegetable butter, G. Cornalba (*Coltivatore, 54 (1908), No. 16, pp. 487–490*).—Vegetable fat known as karitè, obtained from *Bassia butirracea*, and which is used to some extent as an adulterant in butter, is discussed. The constants given are saponification number 175, iodin number 19, and Reichert-Meissl number 2.6. (See also a note on p. 151 of this issue.)

Extraction of beeswax, F. C. Alford (*Colorado Sta. Bul. 129, pp. 3–14*).—The results of experiments on various methods of extracting beeswax are reported, solar extractors in which the heat of the sun is utilized for melting the wax, three kinds of steam extractors and those employing pressure under water at a temperature sufficiently high to melt the wax, being compared. The latter method was employed using water alone, and also with the addition of diluted sulphuric acid.

Heating with diluted sulphuric acid and pressing under water gave the highest results, the steam extractors giving the next best results and the solar extractors the lowest. The results obtained by the use of the steam extractors were increased somewhat by using artificial heat in connection therewith. In conclusion the author states: "From the results of these experiments and my own experience in handling bees and rendering wax I believe that it is best for the average bee keeper to have a large solar wax extractor, heated by some artificial heat, by means of which most of the wax in the lighter colored combs, cappings, and burr combs may be easily rendered. The dark combs may also be treated in this manner and the slumgum stored in barrels until the bee keeper has time to treat it with dilute sulphuric acid and press under water. This method is quick and efficient. If the wax has to be refined it can be done by heating, while inclosed in a canton flannel sack, with a solution containing 5 per cent of hydrogen peroxid and 2 to 5 per cent of sulphuric acid. Both of these chemicals can be bought at the ordinary drug store. The common kind, commercial, should be used."

Technology of fats and oils, G. Hefter (*Technologie der Fette und Öle. Berlin, 1908, pp. IX+974, pls. 19, figs. 155*).—The second volume of a handbook on the production and preparation of fats, oils, and waxes of plant and animal origin. A rather extensive discussion is included of the history, source, raw materials, preparation, characteristics, uses, and commercial and agricultural importance of these products.

VETERINARY MEDICINE.

Therapeutic technique, W. Schlampp (*Therapeutische Technik. Stuttgart, 1907, vol. 2, pt. 1, pp. 314, figs. 88*).—In the first volume of this work (E. S. R., 17, p. 1111), a discussion was given of the therapeutic methods applicable to the skin of domestic animals. In the present volume a discussion is given of the therapy of the alimentary tract. The subject matter is classified according to the part of the alimentary tract to which the various medicines are to be applied. The methods discussed by the author include washes and applications by means of a brush to the mouth and pharynx and the various means of giving medicines by way of the mouth.

Veterinary hygiene, S. J. Bonansea (*Papers and Rpts. Amer. Pub. Health Assoc., 32 (1906), pt. 1, pp. 320–324*).—Attention is called to the many animal diseases which may be transmitted to man through the agency of milk or other animal products, or by direct contagion. In protecting man against these sources of disease the author recommends the establishment of international laws of veterinary sanitary police and that all countries should take special steps in the strict enforcement of milk and meat inspection and in supervising the traffic in animals.

Annual report of the State board of live stock commissioners of Ohio, T. L. Calvert and P. Fischer (*Ann. Rpt. Bd. Live Stock Comrs. Ohio, 6 (1907), pp. 48, figs. 18*).—During the year under report, attention was given chiefly to glanders, sheep scab, and the control of shipments of southern cattle. In addition to this work, 32 dairy herds were tested for tuberculosis. In a total of 911 cows, 33 per cent proved to be tuberculous. It is known that a large number of animals are privately tested and at present there is no means of ascertaining what is done with cattle found to be tuberculous in these tests. The situation with regard to glanders in Ohio is improving. Attention is called to the great economic importance of this disease in horse-raising localites.

Special statements were given regarding the prevalence and distribution of anthrax, actinomycosis, venereal disease in horses, foot rot, glanders, hog cholera, nodular disease in sheep, rabies, mange, tuberculosis, etc.

Annual report of the civil veterinary department, Bengal, and of the Bengal veterinary college, 1906–7, E. A. Gait (*Ann. Rpt. Civ. Vet. Dept. and Bengal Vet. Col., 1906–7, pp. 14*).—A summary statement is made regarding instruction at the Bengal veterinary college, the work of the bacteriological laboratory, and other veterinary investigations. A collection is being made of the biting flies of Bengal, particularly species of Tabanus, Stomoxys, Lyperosia, and Hippobosca. During the year under report, considerable demonstration work was carried out in the treatment of glanders, rinderpest, hemorrhagic septicemia, and other diseases. An attempt is also being made to improve the quality of native cattle and horses.

Annual report of the imperial bacteriologist, 1906–7 (*Calcutta: Govt., 1907, pp. 27*).—It is stated that rinderpest serum preserved during two hot seasons lost about 60 per cent of its protective power. Serum prepared during an unusually cold winter was much weaker than ordinary serum. The elephant has been shown to be immune to rinderpest.

A test was made of atoxyl in treating horses, mules, and rats for trypanosomiasis. In the Plains region 8 gm. of atoxyl per 400 lbs. of body weight caused only slight symptoms of colic in mules, while at greater altitudes the same quantity of atoxyl sometimes produced fatal results within 85 hours. Extensive tables are given showing the amount of rinderpest serum, mallein, and other preparations made and distributed during the year.

Morphological changes in the spleen after infection in animals passively immunized, A. Jarotzky (*Arch. Path. Anat. u. Physiol. [Virchow], 191 (1908), No. 1, pp. 112–135*).—In the experiments reported in this paper white mice were chosen as the experimental animals and the bacillus of swine erysipelas as the pathogenic organism. The mice received a hypodermic injection of 0.3 cc. serum and culture to which 0.4 cc. physiological salt solution had been added. A parallel series of mice was inoculated with the culture of the bacillus of swine erysipelas without having been treated with serum. In studying the pathological changes in the spleen, microscopic sections were made through the whole structure of this organ. In mice inoculated with the bacillus of swine erysipelas and not treated with serum the cortical layer of the spleen was hyperemic and showed a large number of cells in division and also

giant cells. In addition to these changes the author observed many acidophile granulations and horse-shoe-like free nuclei.

In mice which have been previously treated with serum essentially the same changes were observed but in much less marked form.

The latency of tetanus spores in the animal organism, M. Canfora (*Centbl. Bakt. [etc.], 1. Abt., Orig., 45 (1907), No. 6, pp. 495–501*).—If an infection with tetanus is produced in the animal organism, tetanus cultures may be obtained from the blood after death. This demonstrates that the tetanus bacillus may become widely distributed throughout the organism. If tetanus cultures are heated to a temperature of 70 to 75° C. to destroy the toxin and vegetative form of the bacillus and then inoculated subcutaneously, the spores become distributed throughout the organism and may be found in the blood within a few hours. During the first 10 to 13 days they are found in the blood circulation, after which they may occur in the liver, spleen, kidneys, bone marrow, lymphatic glands, etc., where they persist in a latent state. In the later stage the blood is sterile. The spores may create an infection by coming in contact with a wound produced after inoculation. Apparently the spores are not excreted by the kidneys but are destroyed by the animal organism.

The relation of the mouse typhoid bacillus to the system of typhoid coli bacilli, P. Lotzer (*Über die stellung des mäusetyphusbacillus im system typhus-coli. Inaug. Diss. Univ. Bern, 1907, pp. 33*).—From the experience of the author and other investigators, it appears necessary to observe considerable care in the use of cultures of mouse typhoid bacilli for the purpose of eradicating these animals. In Japan and elsewhere serious consequences have resulted to human beings from the careless use of cultures of mouse typhoid bacilli. In one instance 120 persons were affected and in another 30 suffered a fatal infection from these bacilli. The observations of the author indicate a very close relationship between the bacillus of mouse typhoid, the paratyphoid bacillus, and the bacillus of meat poisoning.

The pathogenic effects of human viruses, L. Cobbett (*Roy. Com. Tuberculosis, Second Interim Rpt., 2 (1907), pt. 2, App., pp. VII + 1217, pls. 26*).—Systematic experiments were carried on with tubercle virus obtained from 63 human patients. During the progress of the experimental work the virus was tested on cattle, rabbits, guinea pigs, goats, pigs, apes, monkeys, dogs, cats, rats, mice, and fowls. The history of each strain of virus is given in detail and the clinical lesions produced in the various experimental animals are elaborately presented. The illustrations used in this connection are of striking excellence. The methods of infection employed included both injection and feeding.

In the majority of cases injections were made both with emulsions of tuberculosis tissue and with cultures. The emulsions were made as a rule from human tuberculous lesions, but when such material was not available in sufficient quantity, guinea pigs were first injected and emulsions were prepared from their tuberculous tissue. Careful estimates were made of the number of tubercle bacilli contained in the doses of emulsion. As a result of the long continued experiments reported by the author, it seems necessary to differentiate quite sharply between two classes of human tubercle bacilli, one of which in doses of the usual size produces rapidly fatal generalized tuberculosis in calves and various other animals, while the other class of virus causes only localized or minute lesions even when injected in large doses. The more virulent type of tubercle bacilli was found capable of producing generalized tuberculosis in cattle, goats, pigs, monkeys, chimpanzee, rabbits, guinea pigs, and dogs. Cats appeared to be somewhat more resistant and no infection was caused by inoculation of fowls.

The pathogenic effects of bovine viruses, A. S. GRIFFITH (*Roy. Com. Tuberculosis, Second Interim Rpt., 1 (1907), pt. 2, App., pp. 711, pls. 17*).—Since 1903, the author has carried on continuous observations in the study of the biology and pathogenic relations of tubercle bacilli of bovine origin. An elaborate system of technique was devised for the estimation of the number of tubercle bacilli present in cultures. In arriving at an estimate of average results along this line, 139 counts were made. The calculation is admittedly imperfect but indicates clearly that the great majority of culture inoculations are richer in tubercle bacilli than inoculations with even the largest doses of tissue emulsions. It is estimated that each cubic millimeter of the culture contains from 4,000,000,000 to 5,000,000,000 tubercle bacilli.

In the experimental work carried on by the author, bovine tubercle bacilli were inoculated into cattle, goats, pigs, apes, monkeys, dogs, cats, rabbits, guinea pigs, etc. Inoculation was accomplished by the intravenous, intraperitoneal, intramammary, and subcutaneous methods and also by feeding. The purpose of the feeding experiments with bovine tubercle bacilli was to ascertain the relative susceptibility of different species of animals to this mode of infection and to study the distribution of tuberculosis lesions thus produced. In these experiments, 318 animals belonging to 15 distinct species were used. The majority of the animals were fed single doses of tubercle bacilli either in the form of a culture or in tuberculous milk. Some of the experimental animals were fed at intervals for varying periods with tuberculous milk.

It appears that in cases where animals are fed a single dose of tubercle bacilli there may be many individual factors which greatly influence the result. For example a catarrh of the mucous membrane of the intestines may protect the animal from infection by hastening the expulsion of the intestinal contents. Tubercle bacilli are readily absorbed from the alimentary canal of pigs but much less rapidly in the case of guinea pigs. Individual susceptibility exercises an important influence on the result. The chimpanzee, baboon, rhesus monkey, lemur, rabbit, and guinea pig are highly susceptible to the action of bovine tubercle bacilli, and infection from however small a dose is almost invariably followed by progressive tuberculosis. In the pig, goat, calf, cat, and dog, on the other hand, with the possible exception of the young pig, tuberculosis produced by feeding may be limited to the glands along the alimentary tract, particularly if the dose of tubercle bacilli is small. In young pigs tuberculosis is usually of a progressive type. Adult swine are, however, somewhat more resistant.

The infection of the organism with general tuberculosis of the lungs from the subcutaneous connective tissue, blood, and alimentary tract, A. D. PAWLOWSKY (*Ztschr. Tuberkulose, 12 (1908), No. 1, pp. 31–45*).—The author's experiments have been carried on since 1903 and have consisted largely in feeding guinea pigs human tubercle bacilli in milk. The guinea pigs were then killed after a lapse of 1 to 3 or more weeks and carefully examined to determine the extent and distribution of tuberculous infection. The experiments show that tuberculosis in the early stages is confined almost entirely to the lymphatic glands while the stomach and intestines are unaffected. The tubercle bacilli pass through the walls of the alimentary tract without causing any lesions in it and remain for some time in the mesenteric glands. From these points they may be carried through the lymphatic system and after a period of from 6 to 8 weeks may appear in the lungs.

Morphological variation in the tubercle bacillus, S. ARLOING (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 3, pp. 100–104, figs. 3*).—Under artificial conditions obtained by modification of the nutrient media, temperature, etc., it was

found possible to cause morphological changes in tubercle bacilli obtained from different sources. Thus the giant branched and club-shaped forms were found not to be characteristic alone of the tubercle bacillus obtained from birds. These forms are found not only in old cultures of mammalian tubercle bacilli but may be observed in fresh cultures subjected to the influence of an elevation of temperature or of the pressure of 2½ atmospheres. The author considers that his work has thrown in question the boundary lines which have been proposed between the forms of tubercle bacilli observed in man, animals, and birds.

Tubercle bacilli in the meat and apparently healthy lymphatic glands of tuberculous animals, J. Y. Swierstra (*Kommen in dem Fleische und in makroskopischen gesunden Lymphdrüsen von tuberkulösen Tieren Tuberkelbazillen vor? Inaug. Diss. Univ. Bern, 1906, pp. 76*).—In testing the meat and macroscopically normal glands of tuberculous animals for the presence of tubercle bacilli, positive results were obtained in a number of cases both in cattle and hogs. On the basis of these experiments the author recommends that the meat of tuberculous animals should be sterilized in all cases showing a high degree of emaciation, extensive soft foci, fresh infection of the blood, or localization of the tuberculous process in the bones.

Ophthalmo-reaction to tuberculin, H. Vallée (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 3, pp. 146–148*).—In experiments with this method of diagnosing tuberculosis the author obtained satisfactory results. The position is taken that by means of the ophthalmo-reaction a rapid test is furnished which will assist greatly in detecting frauds which are attempted in the sale of breeding animals.

The influence of cerebral traumatism on the reaction of the normal guinea pig to tuberculin, A. Slatineano and D. Danielopol (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 2, pp. 89, 90*).—The direct injection of tuberculin into the cerebrum of guinea pigs produces an elevation of temperature to the extent of 1.5 to 2.5° C. within 1 or 2 hours. Experiments in producing slight injuries in the cerebrum indicate that guinea pigs thus treated are highly susceptible to the action of tuberculin applied subcutaneously if the injection is made not less than 6 days after the traumatism.

Immunity toward tuberculosis, S. I. Métalnikoff (*Arch. Sci. Biol. [St. Petersb.] 13 (1907), No. 2, pp. 169–206*).—The experiments of the author with the bee moth have shown that this insect is naturally immune to tuberculosis of warm-blooded animals. Human and bovine tubercle bacilli inoculated into bee moths are quickly surrounded and destroyed by the leucocytes. When bee moths are inoculated with tubercle bacilli from fish the bacilli are rapidly surrounded by the leucocytes but later they begin to multiply inside of the leucocytes and finally escape into the body fluids causing the death of the bee moths within 3 or 4 days.

On the basis of these observations a number of immunization experiments were made chiefly with guinea pigs. It appears necessary in producing immunity to tuberculosis to induce in the blood serum the power of disintegrating the waxy membrane of tubercle bacilli. This may be accomplished to some extent at least by injecting animals with wax obtained from tubercle bacilli after freeing it from other substances. This material possesses immunizing power.

A plan for eradicating animal tuberculosis, B. Rogers (*Manhattan, Kans., [1907], pp. 16*).—In this pamphlet the author presents a statement of the manner in which tuberculosis is ordinarily transmitted from animal to animal and from animal to man. Particular attention is given to the extensive infection of hogs with tuberculosis as shown by recent statistics from meat inspection. Tuberculosis of swine is apparently due to the ingestion of the tuberculous

products of cattle and other animals. It is maintained that the great majority of cases of tuberculous animals are at present produced on not more than 6 per cent of the farms of the country. If animals sent to slaughterhouses were so tagged as to show their origin in all cases, it would be a simple matter to locate these centers of tuberculous infection and apply suitable means for the complete eradication of tuberculosis.

The dissemination and control of tuberculosis as illustrated in the bovine species, V. A. Moore (*Proc. Ann. Conf. Sanit. Off. N. Y., 7 (1907), pp. 34–49*).—A historical review is given of the development of knowledge concerning tuberculosis. Tabular data are presented showing the present status and prevalence of the disease in various parts of New York. Particular attention is devoted to a consideration of the methods of Bang and von Behring in the control of the disease. Von Behring's method is considered as still in the experimental stage. The method has failed in many instances and the duration of immunity is not yet determined with sufficient accuracy.

The diagnosis of blackleg, Warringsholz (*Berlin. Tierärztl. Wchnschr., 1908, No. 4, pp. 65, 66*).—As a rule, diagnosis in the case of blackleg is an easy matter. Occasionally, however, some difficulty is experienced. In a study of the pathological anatomy of blackleg the author found small gray foci in the cortical layer of the kidneys. These structures were sometimes isolated and sometimes in groups. In the center of each structure a minute quantity of gas is accumulated. Blood clots were found in the heart in every case of blackleg.

Bacillus pyogenes bovis and B. pyogenes suis in relation to chronic inflammation of the lungs of cattle, H. C. L. E. Berger (*Vergleichende untersuchungen über den Bacillus pyogenes bovis und den Bacillus pyogenes suis mit beziehung derselben zu den chronischen lungenentzündungen des rindes. Inaug. Diss. Univ. Bern, 1907, pp. 84, figs. 5*).—According to extensive investigations of the author in cultivating and testing the pathogenic properties of *Bacillus pyogenes bovis* and *B. pyogenes suis*, it appears that these organisms commonly occur in chronic cases of broncho-pneumonia of cattle, either alone or associated with other bacteria. *B. pyogenes* is capable of producing both suppurative and metastatic broncho-pneumonia in cattle. The lesions thus produced may lead to a mistaken diagnosis of tuberculosis, in fact the author claims that cattle in which the lungs are infected with *B. pyogenes* may react to tuberculin.

The occurrence and frequency of streptococcic mammitis in cows, G. Rühm (*Wchnschr. Tierheilk. u. Viehzucht, 52 (1908), Nos. 7, pp. 125–130; 8, pp. 147–152*).—It was found possible to detect by the examination of milk the presence of streptococcic mammitis before the disease was apparent from palpation of the udder or from the ordinary methods adopted in milk inspection. The method used by the author in the detection of the disease was that proposed by Trommsdorff for the determination of leucocytes in milk.

Tick fever in cattle, C. J. Pound (*Queensland Agr. Jour., 20 (1908), No. 1, pp. 26–35, pls. 2*).—Detailed directions are given covering the technique of preventive inoculation of cattle in the control of Texas fever and East Coast fever.

Sheep dips, O. Quibell (*Jour. Soc. Chem. Indus., 26 (1907), No. 24, pp. 1266–1268*).—The basis for the present article on sheep dips is the experience of the sheep raisers in the English colonies, particularly Australia and New Zealand, with various kinds of dips in the eradication of scab.

It was found that the lime-sulphur dip is an undoubted cure for scab, although it sometimes fails to cure other parasites of sheep. Australian and New Zealand governments, however, finally came to the conclusion that the low price of their wool was to be ascribed to the use of lime and sulphur. Accordingly the

sheep raisers gave up the use of lime and sulphur in favor of arsenical and carbolic dips.

Arsenical dips when properly prepared are claimed to be very efficient scab remedies and also act as a stimulant to the wool. In the arsenical dips at present used care is exercised to prevent any astringent or caustic properties. It is held that the good effect of arsenical dips upon the quality of the fleece is proved by the high prices which are paid for wool from sheep treated in this manner. Carbolic dips are also effective, but the action of the dip does not persist as long as is the case with arsenical dips.

Bacillus pseudotuberculosis in hogs, Sérès and Guillaume (*Rev. Gén. Méd. Vet., 11 (1908), No. 123, pp. 127–131*).—*Bacillus pseudotuberculosis* is known to have a wide distribution and to cause more or less serious disease in horses, cattle, sheep, and various laboratory animals. According to the authors, however, it has not previously been reported in hogs. A number of cases have been observed by them in abattoirs, but the symptoms of the disease during life have not been studied. In one case it was reported that a hog had symptoms similar to those of rachitis. The characteristic lesions of *B. pseudotuberculosis* were observed in various parts of the body, and cultures were obtained which reproduced the disease in guinea pigs.

The hygiene and internal diseases of the horse, L. Morisot (*L'Hygiène et les Maladies interne du Cheval. Paris, 1907, pp. 472, figs. 49*).—The present treatise on the hygiene and diseases of the horse is written from the standpoint of the practitioner, especially the army veterinarian in the field service. The volume includes an account of the general principles of hygiene as applied to the horse and of the common diseases to which the horse is subject, these being arranged under the organs or parts affected. Special chapters are also devoted to contagious diseases and to the problem of disinfection.

Seborrhoic eczema in horses, H. Bang (*Maanedskr. Dyrlager, 19 (1907), No. 8, pp. 303–317*).—The literature relating to this form of eczema is critically reviewed. The author made a careful study of one case in which the disease was found to consist in a pathological inflammation of the oil glands of the skin. The sweat glands were not affected. In some of the diseased oil glands a leucocytosis was observed, but it is believed that this condition was secondary.

Ophthalmo-reaction in glanders, A. Wladimiroff (*Berlin. Tierärztl. Wchnschr., 1908, No. 3, pp. 50–52*).—As a result of his experience in this method of testing for glanders, the author comes to the conclusion that in large herds of horses the ophthalmo-reaction furnishes a means of quickly eliminating the animals which are beyond suspicion. It is held that all animals which do not react may be considered as healthy and do not require a subcutaneous injection of mallein. A considerable expense is thus saved and the work of eradicating glanders from a herd of horses is rendered more easy.

Hepatic hemorrhage as a result of amyloid degeneration in horses, E. Noyer (*Über Leberblutungen infolge Amyloiddegeneration beim Pferd. Inaug. Diss. Univ. Bern, 1907, pp. 47*).—The literature relating to this subject is critically discussed in connection with bibliographical references. The author had opportunity to follow the clinical history of 8 cases of amyloid degeneration of the liver. These cases all occurred in horses which were used for the preparation of diphtheria antitoxin and the disease appears to be connected with this process. The length of time required for the development of experimental amyloid degeneration has not thus far been determined.

The etiology of fowl plague, S. Prowazek (*München. Med. Wchnschr., 55 (1908), No. 4, pp. 165, 166, figs. 2*).—According to the investigations of a number of authors the virus of fowl plague must be considered as ultramicroscopic. It

is largely thrown out of the blood by subjection to vigorous centrifugalization. After this treatment the virus is found associated with the corpuscular elements of the blood. The virus of fowl plague obtained from the brain is not destroyed by saponin during an exposure of 1 hour. Apparently the virus has the power of passing through the finest filters. In most cases, minute corpuscles were to be observed which may be the organism of the disease.

Coli-septicemia in fowls as a disease which occurs during transportation, L. Claussen (*Über Kolibakteriensepticämie bei Hühnern als Transportkrankheit. Inaug. Diss. Univ. Bern, 1907, pp. 30, pl. 1*).—The coil bacteria which are frequently found in the intestines of healthy fowls may become so modified by unfavorable conditions which occur during transportation as to produce a serious form of septicemia. The virulence of these organisms may be artificially increased by several inoculations of canary birds. The mortality from this form of septicemia is not greater than 50 per cent. The disease may be transmitted by inoculation or by feeding, and the incubation period is about 12 hours.

Infectious inflammation of the air sacs in geese, G. Bugge (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 3 (1908), No. 5, pp. 470–480, fig. 1*).—An outbreak of an apparently new disease among geese was observed by the author and a study was made of the origin and etiology of the disease. It was apparently introduced with geese imported from Russia. Affected birds show a condition of emaciation. The air sacs, particularly those in the body cavity, are of a yellowish color and upon the inner surface whitish yellow masses of exudative origin are to be observed. Similar conditions are noted upon the serous covering of the liver, spleen, intestines, and kidneys. In some cases the outer covering of the stomach is likewise affected. In the blood of diseased birds, bacteria were found and pure cultures were made. The organism in question produces no effect in hens when injected into them and this test may be used as a means of arriving at a differential diagnosis between fowl cholera and infectious inflammation of the air sacs. The latter disease appears to be confined strictly to geese, as ducks and pigeons, as well as common fowls, proved to be refractory. No satisfactory method of treatment or prevention has been devised.

The penetration of toxins from parasitic worms into the body of the host, Weinberg (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 1, pp. 25–27*).—According to the author sclerostomum, esophagostomum, and other parasites may secrete substances which become absorbed by the host and constitute a part of the toxic symptoms observed in cases of infestation by the parasites in question.

Feeding stuffs poisonous or injurious for animals, R. Dumont (*Prog. Agr. et Vit. (Ed. l'Est), 28 (1907), Nos. 48, pp. 658–661; 50, pp. 722–726; 51, pp. 756–760; 52, pp. 778–781*).—Attention is given to a brief consideration of species of Euphorbia, wild mustard, and various other wild plants, including rhododendron, aconite, and digitalis which have been found to be poisonous to stock. Mention is made of the poisonous effects sometimes produced by cultivated plants such as sorghum, lupines, potatoes, tobacco, and various species of beans. The author also discusses briefly the unfavorable results which may follow the use of cotton-seed meal, fermented molasses, and other commercial feeding stuffs.

The effect of digitalis and its glucosids upon various ruminants, A. Salvisberg (*Ueber die wirkung von digitalis und digitalisglykosiden auf den organismus verschiedener wiederkäuer. Inaug. Diss. Univ. Bern, 1907, pp. 46*).—The author's experiments were carried out on sheep, goats, and cattle. In these experiments it was found that the leaves of digitalis could be given to ruminants without producing any apparent effect. Cows received doses which would be fatal for horses without giving any reaction whatever. The conclusion is

reached that the active principles of digitalis are so changed or destroyed in the stomach of ruminants that they have no pharmaceutical action upon the organism. Digitalis given by intravenous injections, however, exercises the same effect as upon other mammals.

RURAL ECONOMICS.

The agrarian question in the German economic system to the middle of the nineteenth century, E. Cronbach (*Das landwirtschaftliche Betriebsproblem in der deutschen Nationalökonomie bis zur Mitte des XIX. Jahrhunderts. Vienna, 1907, pp. XII+338*).—This book gives a historical and critical study of the problems relating to farm management and land ownership in Germany beginning with the sixteenth century.

The agrarian social problem in Spain, del Retamoso (*Crónica del Curso Breve de Cuestiones Sociales Celebrado en Madrid, 1906. Madrid, 1907, pp. 118–161*).—This is a series of three lectures delivered in Madrid in 1906 and entitled as follows: (1) Determination of its distinctive characters in the different districts of Spain; (2) agricultural crises and their causes; and (3) a critical examination of proposed remedies and a study of principal solutions. An extensive bibliography is appended.

[Papers relating to rural economics] (*Rpt. Brit. Assoc. Adv. Sci., 1907, pp. 597–603*).—Summaries of papers on the following subjects read at the annual meeting of the British Association for the Advancement of Science at Leicester, July 31 to August 7, 1907, are reported:

Small occupying ownerships, J. Collings (pp. 597–599).—This is a plea for the establishment of the British land system on the basis of occupying ownership. To facilitate the scheme proposed the author advocates (1) a better system of rural education and (2) the establishment of cooperation among cultivators for both buying and selling. The creation of a class of small owners it is believed would solve the grave social problems of the unemployed, housing, and widespread destitution, and "to pledge the national credit for the purpose of carrying it out would be in accordance with the principles of a sound national and political economy."

The importance of the distinction between (1) subsistence farming and (2) producing for a market in connection with small holdings, W. Cunningham (pp. 599, 600).—As compared with large farming it is believed the small holder who tries to make a living from his land without other source of income is liable to fail. But, if allotments and small holdings can be combined with opportunities of wage-earning, so that the land is used to provide a portion at least of the means of subsistence, it would tend to improve greatly the material welfare of the artisan class.

Some notes on the small holdings of Worcestershire, Kirkaldy (pp. 600, 601).—A brief sketch of the history and methods of working of small holdings in this county which was the pioneer in the movement in England. The results show the value of a committee of practical men to foster the movement, to train the small holder, and to apply the principles of cooperation. The question of assessment requires thorough revision.

Agricultural cooperation in Great Britain, R. A. Yerburgh (pp. 601–603).—Noted from another source (E. S. R., 19, p. 587).

Small holdings in Hampshire, J. C. Newsham (*Jour. Bd. Agr. [London], 15 (1908), No. 2, pp. 83–94*).—This article sets forth the opportunities the county of Hampshire, England, affords to the small holder as regards labor, soil, and markets, gives the economic returns of various types of holdings, and shows that failures occurred "among those who possessed limited capital and a still

more limited knowledge of agriculture, with little or no idea of how to manage the holding."

In view of the government's recent efforts to encourage the increase of small holdings, the author maintains that "the success or failure of additional small holdings in this county will depend to a great extent on the system of cooperation adopted. If an enlightened cooperative movement could be fostered and made a success, there is no doubt that many districts, where produce can not under present conditions be satisfactorily marketed, would become flourishing and prosperous, to the advantage not only of the occupier and the county, but also of the nation as a whole."

The English peasantry and the enclosure of common fields, G. SLATER (*London, 1907, pp. XIII+337, pls. 9*).—This book gives a history of common field enclosure in England, with particular reference to the effects of the movement upon agricultural production, increase of rent, rural depopulation, industrial development, increase of pauperism, national resources, etc.

Some reflections upon the reassignment of small farms, A. RAEYMAECKERS (*Ann. Gembloux, 18 (1908), No. 6, pp. 367–372*).—This article describes how the present system of small farms owned by the peasant classes in Belgium consists generally of a number of small, noncontiguous pieces, and shows how this system in many ways interferes with the effectiveness of agriculture and the welfare of the landowners. The author outlines by means of statistics and discussion derived from the experience of Denmark the economic and social advantages which would accrue to the peasantry as a result of a reassignment of land under government supervision of a single allotment as nearly equal as possible in extent, fertility, and market facilities to the present numerous small parcels.

The law of April 10, 1908, relating to small holdings and cheap houses (*Jour. Agr. Prat., n. ser., 15 (1908), No. 17, pp. 530, 531*).—This is the text of the law which provides for the advancement by the French government of a sum not to exceed 100,000,000 francs for the purpose of enabling the poorer classes of peasants to acquire land, to improve their dwellings or to construct new ones, and to increase the size of their holdings, and for the management of the property in case of the decease of the owner. The funds are advanced at 2 per cent interest to local credit societies, through which the peasants are to transact business, and the societies are prohibited from charging borrowers more than 4 per cent interest.

The holdings of agricultural laborers, F. CONVERT (*Rev. Vit., 29 (1908), No. 749, pp. 467–470*).—This article briefly reviews the efforts of various countries to enable agricultural laborers to become property owners and discusses the law noted above. The author believes the law will enable the poorer classes of peasants to improve the social and economic welfare of their families by increasing their incomes and will greatly encourage the rural population to remain on the land.

The opportunity of acquiring property afforded the agricultural laborer, P. ANTOINE (*Jour. Agr. Prat., n. ser., 15 (1908), No. 17, pp. 528, 529*).—An article similar to the above.

Mutual agricultural credit, P. DECHARME (*Semaine Agr. [Paris], 27 (1908), No. 1399, p. 85*).—This is a review of the development of mutual agricultural credit banks in France, with a discussion of the aims and results of the movement. The mutual credit societies at the beginning of 1908 numbered about 2,000, had 100,000 members, and had advanced in loans to poor peasants during the past 7 years no less than $40,000,000, at interest from 3½ to 4 per cent. The author maintains that there were 33,000 rural communes in France which had not yet put the plan of mutual credit into operation.

Mutual credit and agricultural improvement, F. Virgili (*Bol. Quind. Soc. Agr. Ital., 13 (1908), No. 9–10, pp. 333–343*).—The author gives a brief review of the origin and development of mutual agricultural credit in Italy and discusses its effects upon mortgage indebtedness, statistics of which by provinces, square miles of territory, and per capita are presented. The efforts of the government by legal enactments to improve agricultural conditions by assisting the small farmer to secure credit and to give mutual credit a more economic efficacy and judicial flexibility are also discussed.

Agricultural credit, de Eza (*Crónica del Curso Breve de Cuestiones Sociales Celebrado en Madrid, 1906. Madrid, 1907, pp. 163–217*).—This is a course of three lectures delivered in Madrid in 1906. The article discusses the character and nature of agricultural credit, describes the development of the Schulze-Delitzsch, Raiffeisen, and other mutual credit banks, and gives a brief account of the legal status and present development of agricultural credit in Spain.

Agricultural labor, Hitchins (*Jour. Dept. Agr. West. Aust., 16 (1908), No. 3, pp. 219–221*).—The scarcity of farm labor in Western Australia and the efforts of the government labor bureau to supply the demand are discussed. "The demand at present for experienced farm hands is greater than the supply at wages ranging from 25s. to 30s. per week and keep." The increasing settlement of the country is creating a steady and assured demand for country workers, and work on farms is believed to offer a partial solution of the problem of the unemployed in Perth and other cities of the province.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 10 (1908), No. 8, pp. 57–64*).—The usual statistics and notes on the condition, values, and prices of principal crops in the United States and Europe are reported, including a tabulated statement of the exports from the United States of farm and forest products during the years ended June 30, 1907 and 1908.

[Agricultural statistics of the Netherlands] (*Jaarc. Koninк. Nederlanden, Rijk Europa 1906, pp. 148–162*).—Statistical data for 1906 compared with preceding years of acreage and yields of crops, extent of land cultivated by proprietors and tenants, number and size of farms, live stock, agricultural machinery, etc., are reported.

AGRICULTURAL EDUCATION.

The next step in agricultural education, E. Davenport (*Urbana, Ill., 1907, pp. 22*).—This is primarily an argument against special agricultural high schools and in favor of teaching agriculture in existing high schools. The writer argues that separate schools can never be so good, that they will tend strongly to peasantize farmers, prevent the natural flow of individuals from one profession into another, require students to board and room away from home, and injure the development of existing high schools, and that it is unnecessary to found separate schools in order that agriculture shall be well taught. He believes that agriculture should be given a large and important place in existing high schools, and that as rapidly as sentiment in favor of such teaching crystallizes, the schools will prepare to meet the demand.

The township high schools of Ohio, A. B. Graham (*Agr. Col. Ext. Bul. [Ohio State Univ.], 3 (1908), No. 6, pp. 20, figs. 24, dgms. 2, map 1*).—The author gives a historical sketch of the development of township high schools in the State, with data concerning tuition, classes of high schools, courses of study, equipment, cost of buildings and supplies, and bequests to some of the high schools.

Instruction in practical agriculture upon the university farm at Davis (California) (*California Sta. Circ. 37, pp. 12*).—This is an announcement of

farmers' short courses for 1908 as follows: Dairy manufacture, 8 weeks; irrigation, soils, forage crops, and cereals, 3 weeks; poultry husbandry, 8 days; animal industry and veterinary science, 4 weeks, and horticulture and viticulture, 3 weeks.

Southern agriculture, F. S. EARLE (*New York, 1908, pp. VII+297, pls. 10, figs. 36*).—Under part 1 this book considers climate, soil, cultivation, plant growth, insects and diseases of plants, marketing, and farm management, and under part 2 it gives cultural directions for the chief southern agricultural crops, including discussions on forestry and domestic animals. The book does not confine itself to the agriculture of the Southern States but also treats of tropical and subtropical crops, including fiber plants, coffee, cacao, rubber, nuts, and fruits.

Agriculture for Southern schools, J. F. DUGGAR (*New York, 1908, pp. 355, figs. 188*).—This is an elementary text-book of agriculture which deals with general principles underlying the subject, but uses largely the materials of Southern agriculture for purposes of illustration and study.

Beginning with the plant in flower, the process of pollination, propagation from seeds, and the relations of moisture and plant food to plant growth, the text recurs to the propagation of plants by means of buds, following this with lessons on the improvement of plants, the formation of soil, the relation of the crop to the soil, moisture in the soil, and soil management, including such topics as cultivation, terracing, draining, deterioration and improvement, the use of barnyard manure and commercial fertilizers, and the rotation of crops. The remaining chapters deal in logical order with field and garden crops, the flower garden, forest trees, orchard fruits, plant diseases, insect friends and enemies (with an entire chapter on the cotton-boll weevil, one on insects and health, and one on the honeybee), animal husbandry (horses, cattle, sheep, swine, and poultry), the feeding of animals, the production of milk and butter, farm implements and machinery, roads, and the principal soils and crops of Alabama. Formulas and tabular matter are arranged in an appendix.

Elements of agriculture, W. C. WELBORN (*New York, 1908, pp. XVI+329, pl. 1, figs. 109*).—This is a text-book of elementary agriculture prepared especially for use in the public schools of the South and West. It deals first with the plant and its environment, then with the botany of field crops, propagation, seed selection, and methods of growing crops and maintaining fertility. Special crops are then taken up, like cotton, corn, rice, sweet potatoes, legumes, orchard crops, and truck crops, followed by the feeding of animals, the making of a ration, animal diseases, animal husbandry, raising horses and mules, cattle, sheep, goats, poultry, and bees, and dairying.

An appendix contains a botanical classification of important economic families of plants, a chapter on the treatment of plant diseases with formulas for different spray solutions, a list of harmful insects and remedies, score cards for judging live stock, stock diseases and remedies, and a glossary.

Agriculture in the elementary schools, M. J. ABBEY (*State Normal School, Mayville, N. Dak., Quart. Bul., 5 (1908), No. 4, pp. 48*).—This is an outline course in agriculture for the public schools, beginning with the first grade and extending through the high school. It may be put into the hands of pupils but is more properly a teacher's guide. It is divided into 3 sections, the first dealing with suggestions to the teacher, the second with outlines for the first 6 grades, and the third with outlines for the grammar grades and the high school. In the first 4 grades the work is arranged by years and classified under such headings as plants, animals, weather, machinery, soil and farm problems. In the fifth and sixth grades the more definite study of plants is taken up, together with conditions necessary for plant growth, and this is

followed in the grammar grades and the high school with studies of the soil, the atmosphere, seeds, plant production (wheat, corn, grasses, flax, weeds, horticulture, and plant breeding), farm animals, birds and insects, the school garden, and reference books.

Rural school agriculture, C. W. DAVIS (*New York, 1907, pp. 267, figs. 74*).—This is a series of 142 exercises in agriculture prepared for the use of students of agriculture who expect to become teachers, and for those in rural districts who expect to continue to live on the farm. The exercises are fully illustrated, classified, and arranged in logical sequence. The first group of exercises is intended to familiarize pupils with conditions of matter and changes in matter, and with the meaning of such terms as condensation, absorption, evaporation, assimilation, respiration, solutions, etc. The remaining exercises are arranged in groups relating to plants, soils and fertilizers, corn, wheat and oats, cotton, feeds and feeding, milk, fruits, home grounds, insects, and spraying. A glossary contains definitions of the principal scientific terms, and an appendix contains score cards and tables of values of fertilizers, feeds, weights, etc.

How agriculture can be taught in our schools, C. MANKENBERG (*School Ed., 27 (1908), No. 4, pp. 46, 48, 50*).—An account is given of the writer's experience in arousing an interest in agriculture without the use of the text-book.

Horticultural education, C. P. CLOSE (*Trans. Peninsula Hort. Soc. [Del.], 21 (1908), pp. 94–101*).—An address before the Peninsula Horticultural Society at Salisbury, Md., January 14–16, 1908, in which horticulture is defined and instruction in horticulture, as it is now carried on in different institutions, is discussed.

An elementary course in horticulture for the schools of Michigan, S. W. FLETCHER (*Mich. State Supt. Pub. Instr. Bul. 28, pp. 31, figs. 22*).—This bulletin was prepared at the request of the State superintendent of public instruction in Michigan as an elementary course in horticulture for the public schools. It deals with the propagation of plants, window gardening, fruit growing, landscape and flower gardening, and vegetable gardening, and is intended merely as an outline to be used in connection with a number of manuals to which numerous references are made.

The adornment of rural school surroundings, G. L. CLOTHIER (*Mississippi Sta. Bul. 109, pp. 3–12, figs. 4*).—As preliminary steps to the adornment of rural school grounds the author advises precautionary measures against live stock and trespassers, and enumerates the elements of environment of a country school that are capable of improvement. Directions are then given for handling nursery stock, arranging shrubs, lawns and walks, and planting vines and flowers. An outline plan of a model country school after the execution of the main features of the planting plan is included.

MISCELLANEOUS.

Annual Report of Alaska Stations, 1907 (*Alaska Stas. Rpt. 1907, pp. 98, pls. 7, figs. 3*).—This contains a report of the chief lines of work carried on during the year at the Sitka, Copper Center, Rampart, and Kenai stations with an account of the establishment of an additional station at Fairbanks and of a live stock breeding station at Kodiak Island, and brief notes on live stock operations on a ranch at Kodiak and on an attempt to interest the Indians in gardening, and reports from the seed distribution. Meteorological data, an article on Dairy Practice at Kenai Station, and accounts of extensive tests of field and garden crops are abstracted elsewhere in this issue.

Nineteenth Annual Report of Georgia Station, 1906 (*Georgia Sta. Rpt. 1906, pp. 242–252*).—This contains the organization list, a brief report by the

president of the board of directors, a report of the director on the work of the station during the year, and a financial statement for the fiscal year ended June 30, 1906.

Twentieth Annual Report of Georgia Station, 1907 (*Georgia Sta. Rpt. 1907, pp. 8*).—Data similar to the above are reported for the fiscal year ended June 30, 1907.

Annual Report of Hawaii Station, 1907 (*Hawaii Sta. Rpt. 1907, pp. 90, pls. 9, figs. 3*).—This consists of a general review of the work of the station during the year, and reports of the entomologist, horticulturist, assistant chemist, and expert in charge of rice investigations. Most of the experimental work is abstracted elsewhere in this issue. The report of the assistant chemist also contains analyses of 10 samples of Hawaiian soils and determinations of the salt content of the water from 3 wells to be used in irrigating the rice fields, and of the soils from 4 rice fields.

Twentieth Annual Report of Michigan Station, 1907 (*Michigan Sta. Rpt. 1907, pp. 95–392*).—This contains a financial statement for the fiscal year ended June 30, 1907, reports of the director and heads of departments on the work of the station during the year, meteorological observations noted elsewhere in this issue, and reprints of Bulletins 239–247 and of Special Bulletins 36 and 37 previously noted, together with reports of the South Haven Substation for 1906 and of the Upper Peninsula Substation for 1905 and 1906, noted on pages 133 and 143 of this issue.

Eighteenth Annual Report of New Mexico Station, 1907 (*New Mexico Sta. Rpt. 1907, pp. 56*).—This contains the organization list, a report of the director on the work and publications of the station, departmental reports on the various lines of station work conducted during the year, and a financial statement for the fiscal year ended June 30, 1907. The experimental work in horticulture is noted on page 144 of this issue. The report of the chemist contains analyses of 2 rubber-producing plants from Mexico, and of several samples of sugar beets, soils, and fertilizing materials.

Twentieth Annual Report of Rhode Island Station, 1907 (*Rhode Island Sta. Rpt. 1907, pp. 189–407+X*).—This contains the organization list, a report of the director reviewing briefly the work of the station during the year, departmental reports, the experimental work from which is abstracted for the most part elsewhere in this issue, a financial statement for the fiscal year ended June 30, 1907, a list of exchanges, and meteorological and other data.

Southern California Pathological Laboratory and Citrus Experiment Station, R. E. Smith (*California Sta. Circ. 35, pp. 11, figs. 4*).—This includes the law establishing the Southern California Pathological Laboratory at Whittier and the Citrus Experiment Station in Riverside, together with a description of their buildings and equipment, and an account of their present and proposed lines of work.

NOTES.

Colorado College.—A four-year course in forestry is being offered for the first time, as is also a course in practical and theoretical training in library science and library economy.

Connecticut State Station.—The station is issuing what are called postal-card bulletins, these being similar in form and size to ordinary postal cards. They are not numbered or distributed with the regular bulletin series but consist of brief notes of a popular nature, one recently issued discussing cankerworm.

Harry R. Stevens has resigned as chemist, and has been succeeded by Clarence W. Rodman.

Georgia College and Station.—R. J. H. DeLoach has resigned as botanist in the station to accept the professorship of cotton industry in the college, his resignation becoming effective November 1. A portion of his time is expected to be available for cotton investigations.

Illinois University.—President E. J. James has returned from a tour of inspection of the leading veterinary colleges of Europe, undertaken with special reference to the new State veterinary college to be established in Chicago as a department of the university.

Purdue University.—A course in normal training, in charge of George L. Roberts, has been added to the general curriculum, and is expected to be of special interest to agricultural students.

Kansas College and Station.—Mrs. Mary P. Van Zile has been elected professor of domestic science and dean of women. J. E. Smith has been appointed assistant in botany in the college, O. A. Stevens, assistant botanist in the station, J. C. Cunningham assistant horticulturist, and J. B. Parker assistant entomologist in the college and station.

Louisiana Stations.—Dr. P. A. Yoder, a former chemist and director of the Utah Station, has been appointed research chemist in the Sugar Station, vice Dr. Fritz Zerban, whose resignation has been previously noted.

Maine University and Station.—Recent appointments include F. L. Russell as professor of bacteriology and veterinary science in the university and assistant biologist in the station, V. R. Gardner as assistant professor of horticulture, and W. A. Brown as assistant professor of poultry husbandry.

The station has recently erected, adjacent to and connected with the main building, a small greenhouse for the use of the entomologist and plant pathologists.

Maryland Station.—Nicholas Schmitz, of the Forage Crop Investigations of this Department, has been appointed agronomist, and will enter upon his duties January 1, 1909. The State Live Stock Sanitary Board is to cooperate with the station in a test of the new hog-cholera serum of this Department, and will undertake its distribution if favorable results are obtained.

Missouri Station.—Francis Ward Woodman has been appointed research assistant chemist, and Charles Kenworthy Francis research assistant in agricultural chemistry.

Nebraska Station.—Assistants recently added to the staff include Robert S. Trumbull, agricultural chemistry, Miss Venus W. Pool and W. H. Hein, agricultural botany, Percy B. Barker, soils, and Myron H. Swenk, entomology.

Oklahoma College.—A grant of $62,000 for a domestic science building and girls' dormitory and of $25,000 for a boys' dormitory was made by the last legislature.

Rhode Island College.—Plans have been accepted for the construction of the men's new dormitory and dining hall, for which $55,000 was appropriated by the last general assembly. The number of agricultural students has increased very rapidly in recent years, and the total enrollment is such as to tax the accommodations of the college and village to the utmost.

Vermont Station.—Harry L. Miner, a 1907 graduate of the University of Maine, has been appointed assistant chemist beginning November 1.

Experiment Stations in Portuguese East Africa.—A letter recently received from Mr. O. W. Barrett, director of agricultural experiment stations in Portuguese East Africa, gives additional details regarding the status of these institutions. Grants have been voted by the legislative council of $30,000 for the purchase of agricultural implements, including a steam plow, $13,000 for fencing, $6,700 for live stock, and $6,000 for laboratory equipment.

It is planned to establish a central station and two or three substations, embodying a total area of probably more than 3,000 acres, the substations to be located at Chai-Chai on the Limpopo River, at Inhambane south of and at Quelimane north of the Zambezi River. Plans for the office and laboratories of the central station at Lourenço Marques have been approved and the work of construction has been begun.

Entomology and veterinary sections have been established in charge, respectively, of C. W. Howard and P. Conacher, both of whom were formerly connected with the Transvaal Department of Agriculture. A reconnaissance of the territory and also of the province of Zambezia is expected to be undertaken as soon as possible.

Agricultural Legislation in Mississippi.—At the last session of the Mississippi legislature a number of acts were passed with a view to promoting the agricultural interests of the State. Among these was an act authorizing each county in the State to build an agricultural high school and pledging a State support fund of $1,000 annually for each school meeting certain specified conditions. Fifteen counties have already located schools. The first of these was Noxubee County, which has voted a tax levy of 1 mill upon the taxable property of the county for the support of its county agricultural high school at Mashulaville, an inland village 12 miles west of Macon. This school will have an income of $1,000 from the State, $1,000 from the public schools merged into it, and $5,000 from the county, making an annual income of $7,000.

The legislature also authorized boards of supervisors to appropriate money for premiums to boys engaged in corn-growing contests. Such contests were organized in 5 counties last year and in 23 counties this year, with over 3,000 boys engaged in the work. There are also about 500 girls organized in home culture clubs. Exhibits are first held in the home counties, after which those taking prizes are shown at the State fair.

Other measures passed by the legislature provided for a live stock sanitary board, which is engaged particularly in cooperating with this Department in ridding the State of the cattle tick, for the appointment of county commissioners of agriculture for the protection and fostering of horticulture and fruit growing, and for the regulation of the sale and providing for the inspection of commercial feeding stuffs.

New Agricultural School for Negroes.—An agricultural and industrial school for negroes has been established at Sandy Spring, Montgomery County, Md. The purpose of the institution is to give instruction in agriculture, mechanics, and household arts, and to prepare teachers to teach agriculture in the rural schools. George H. C. Williams, instructor in biology at Armstrong Manual Training School, Washington, D. C., has been selected for the principalship.

New Buildings at Crookston School of Agriculture.—Stephens Hall, the three-story dormitory recently erected at a cost of about $43,000, was dedicated September 17. The speakers included Hon. J. J. Hill, who was the orator of the day, Congressman C. R. Davis, Prof. William Robertson, of the school, P. M. Ringdahl, president of the board of control, State superintendent of public instruction John Olson, and Director Randall, of the Minnesota University and Station. An industrial building, costing about $15,000, and containing a lecture room, creamery, and blacksmith and carpenter shops, is nearing completion.

Country Teachers' Association of Illinois.—This association was organized at a meeting held at Macomb, Ill., July 22 and 23. Its purpose is indicated in resolutions adopted pledging the efforts of its members to increase the usefulness of the country school by improving its physical and social environment, and the enrichment of its course of study in such manner as will bring the child into sympathetic and vital relationship with his environment, by country school extension work through the different educational institutions, offices, and agricultural associations, by consolidating weak country schools, by encouraging more thorough preparation, larger salaries, and longer tenure of positions for teachers, and by the further development in State normal schools of facilities for training country school-teachers.

The Colorado State Fair and Agricultural Education.—The Colorado State fair authorities entered upon a new departure in education this year in the way of offering scholarships as prizes for young people's contests. A scholarship of $125 in any of the regular courses at the State Agricultural College was offered to the boy under 21 years of age who did the best work in judging live stock and corn, and a scholarship of $100 in any college or university in Colorado to the girl doing the best work in the preparation of certain foods and in giving the reasons for the methods employed.

Forestry Work in Massachusetts.—Under a recent act of the State legislature the expenditure of $5,000 in 1908 and $10,000 annually thereafter is authorized for the purchase of lands adapted to forest production. The act permits the repurchase of these lands by the original owners, under certain restrictions, and at any time within 10 years, at the purchase price plus interest at 4 per cent and the amounts expended in improvements and maintenance.

The control and management of these State lands are vested in the State forester, who is also authorized to accept donations of land for the purpose and also to expend not exceeding 20 per cent of the appropriation for the distribution of seeds and seedlings to landowners at not less than cost. It is expected that considerable land will be acquired under this act, especially small tracts held for the control of municipal water supplies, and that these will give opportunity for demonstrations in forest planting and management.

International Congress on Tuberculosis.—The 1908 session of this Congress, held in the new building of the National Museum, Washington, D. C., from September 21 to October 12, was an event of extreme interest and importance from both the scientific and popular standpoint. The speakers included the President of the United States, Secretary Wilson of this Department and others, members of the Cabinet, and a large number of scientific investigators, representatives of the medical and veterinary professions, health officials, and others

prominently identified with various phases of the campaign against the disease. Accredited delegates were in attendance from every civilized country except Japan, and in addition there were hundreds of visitors at the general sessions and the exhibition.

The congress as a whole dealt especially with human tuberculosis, but considerable attention was directed to tuberculosis in domestic animals, and notably to questions dealing with the milk and meat supply and with the inspection of these products. One of the seven sections into which the congress was divided devoted itself especially to these topics, and the general addresses before the congress as a whole included a lecture by Prof. Bernard Bang, of Copenhagen, Denmark, on Studies in Tuberculosis in Domestic Animals and What We May Learn Regarding Human Tuberculosis. An extended discussion followed the reaffirmation by Prof. Dr. Robert Koch, of Berlin, of his theory as to the nonidentity and nontransmissibility of human and bovine tuberculosis, after which a resolution was unanimously adopted recommending "that preventive measures be continued against bovine tuberculosis and that the possibility of the propagation of this to man be recognized."

The very extensive exhibits from the various countries in America and Europe attracted much attention, and presented a vast amount of illustrative material of rare educational value. Phases dealing especially with the prevention and treatment of the disease in its early stages predominated, there being a great variety of models of sanitoria and special appliances, but there were also shown a large number of devices designed to afford better housing, sanitation, and food supply, many of which were of general application to everyday life. A model dairy was operated daily, bacterial counts of about 800 per cubic centimeter being repeatedly obtained under conditions believed to be within easy access of the average producer. The Maryland College and Station exhibited a model of a barn and feeding shed, and the Minnesota Station presented charts and other material pertaining especially to the dissemination of the disease. A collection of pathological material was shown by the Bureau of Animal Industry of this Department, and the University of Wisconsin presented an elaborate exhibit dealing especially with human tuberculosis.

At the close of the congress a tour was made by many of the delegates to the chief cities of the country for the purpose of inspecting the various hygienic methods employed by boards of health, charitable institutions, and hospitals of the various communities. Press reports announce that the exhibition is to be transferred to New York City for an extended period.

The next session of the congress is to be held in Rome in 1911.

Philadelphia Meeting of the American Veterinary Medical Association.—The forty-fifth annual meeting of this association was held at the University of Pennsylvania, September 7–11. A large number of papers were presented on tuberculosis, glanders, Texas fever, cattle and sheep scabies, hog cholera, milk inspection, veterinary education, and other topics. The final day was, as usual, devoted to a surgical clinic, held at the veterinary school of the university, at which a special feature was a lecture and demonstration by Dr. Leonard Pearson on epizootic lymphangitis, a disease hitherto almost unknown in this country.

The officers chosen included J. G. Rutherford, of Ottawa, veterinary director general of the Dominion of Canada, as president; R. P. Lyman, of Hartford, Conn., as secretary; and George R. White, of Nashville, Tenn., as treasurer.

A meeting of the Association of Veterinary Faculties and Examining Boards of North America, an affiliated organization, was also held in Philadelphia September 7, at which after extended discussion a resolution was adopted

endorsing the action of this Department in the appointment of a committee to inquire into the present status of veterinary education in this country.

American Home Economics Association Proposed.—The initial number of a trial series of quarterly bulletins being issued by the Lake Placid Conference on Home Economics announces the appointment at the July meeting of the conference of a committee, of which Dr. C. F. Langworthy of this Office is chairman, to formulate a plan of organization for a national association of those engaged in the solution of home and home economics problems. This committee is to report to the teaching section of the conference at a meeting to be held in Washington, D. C., during the Christmas recess, at which time the question of a national organization will be discussed.

New Journals.—*Zeitschrift für den Ausbau der Entwicklungslehre*, a monthly devoted to the critical discussion of problems in zoology, botany, physiology, psychology, paleontology, biochemistry, and philosophy in their relations to evolution, is being issued at Stuttgart, with R. H. Francé as editor.

Trudni Byuro po Prīkladnoĭ Botanīkye is being issued at St. Petersburg by the Bureau of Applied Botany as a bimonthly. The initial number contains articles in both the Russian and German languages, including papers on Smooth-Awned Barley and Directions for Uniform Sowing of Different Kinds of Grain for Comparative Botanical Investigations.

O Fazendeiro, a monthly review of agriculture, industry, and commerce with special reference to coffee growing, has been established at São Paulo, Brazil. A recent number contains a brief account of a proposed reorganization in the Louis Queiros School of Agriculture, of which C. D. Smith, formerly of the Michigan College and Station, is now director.

Annals of the Entomological Society of America is being published quarterly by the society, with Herbert Osborn as managing editor. An announcement in the initial number states that "the scope of the Annals will be as broad as the interests of the society which it represents, but it may not be out of place to emphasize the point that papers dealing with morphologic, faunistic, and biologic problems, as well as toxonomy in its broadest sense, will be especially welcome." In addition to data as to the constitution, membership, and proceedings of the society, the initial number also contains Notes on Chalcid Infesting Apple Seed, Polymorphism of Ants, and The Habits of Insects as a Factor in Classification.

Miscellaneous.—F. H. A. Marshall has been appointed to the recently established university lectureship in agricultural physiology in Cambridge University.

The retirement of J. H. Hart, superintendent of the Botanical Department of Trinidad, is announced after 34 years' service in the Tropics.

Dr. Francis Huntington Snow, formerly chancellor of the University of Kansas and well known as an entomologist, died at Bellefield, Wis., September 20.

Hermann Settegast died in Berlin August 11 at the age of 90. Among his extensive agricultural writings were Tierzucht (1868, fifth edition 1888), Die Landwirtschaft und ihr Betrieb (1875, third edition 1884), Die deutsche Landwirtschaft vom kulturhistorischen Standpunkt (1884), Der Idealismus and die deutsche Landwirtschaft (1885), and Die deutsche Viehzucht, ihr Werden, Wachsen und gegenwärtiger Standpunkt (1890).

Stations in the United States—Continued.

U. S. Department of Agriculture.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of *Experiment Station Record* is $1.50 per volume, or 15 cents per number. The prices of other technical publications are given above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XX. NOVEMBER, 1908. No. 3.

A report of considerable importance concerning agricultural education in England and Wales has recently been submitted by a special committee appointed by the president of the Board of Agriculture and Fisheries. The report comprises a brief history of agricultural education in England and Wales up to the present time, a more extended view of the progress and development of agricultural education from 1888 to 1908, a description of existing facilities for agricultural education, and recommendations concerning its further development. The inquiry of the committee did not extend to rural secondary and elementary schools since these are under the control of the Board of Education and are not within the province of the Board of Agriculture and Fisheries.

It seems that in England and Wales there are two main sources of financial support for technical and agricultural education. The first includes funds derived from the Excise Act of 1890, which are turned over to local boards known as County Councils to be used for the encouragement of agricultural education, experiments, and demonstrations. These funds are largely used in the counties from which they are derived or are devoted to the support of educational centers which serve two or more counties. These centers may be universities, agricultural colleges, or special institutions deriving their main support from these funds, or they may be special institutions established and maintained by the County Councils. The second source includes funds controlled by the Board of Agriculture and Fisheries which are used for the encouragement of agricultural education by making grants to a selected list of institutions giving instruction in agriculture. In several instances the institutions aided by the Board of Agriculture and Fisheries also derive a part of their support from County Councils.

The committee in its investigations made a study of the work of six universities and university colleges, five agricultural colleges, two dairy institutes, one fruit and cider institute, one veterinary college,

and four agricultural or farm institutes, all of which receive grants from the Board. The committee also sought information from every County Council concerning its provisions for technical and practical instruction in agriculture, from nine colleges and institutions which give instruction in agriculture but are not aided by the Board, from two technical colleges for women, and from many agricultural societies, landowners, farmers, farm managers and others who might have opinions of value concerning the subject of their inquiry. In this way a large mass of information was collected which has been published in Part II of the committee's report, Part I being devoted to its findings and recommendations. The committee also made a considerable study of facilities and methods in teaching agriculture in other countries with a view of recommending such features of instruction as would be applicable to conditions in England and Wales.

In general the committee found that satisfactory progress had been made in practical and scientific instruction in agriculture during the past 20 years, and that farmers now take a keen interest in the work of agricultural institutions. It believes that the establishment of a few more higher agricultural institutions, some of which are now projected, would furnish the country with a sufficient number of collegiate centers, but it found that "the facilities for agricultural instruction of a lower grade are unorganized, unsystematic, and wholly inadequate."

The committee is evidently convinced of the importance of providing a thoroughly equipped staff of specialists for the higher institutions, and well-trained teachers for those of lower grade. With reference to the development of existing facilities the report states that "attention should be given to securing a highly qualified staff. Many institutions employ too few teachers or relegate the teaching of important subjects to junior members of the staff. It is of special importance that higher qualifications should be secured in the teachers of such subjects as agriculture, agricultural chemistry, and agricultural botany. . . . Further developments in agricultural education will be difficult until a greater supply of well-qualified teachers is available." The committee also recommends the employment of itinerant instructors in agriculture, horticulture, farm hygiene, dairying, poultry keeping, and other subjects in every county, and emphasizes the fact that these instructors should be selected from those who have had practical experience. They should have their headquarters at a centrally located agricultural institution, so that arrangements for systematic demonstrations or improved practice can be made. And finally, as regards the teaching force, it recommends "that universities and colleges in receipt of aid from the Board of Agriculture should provide courses of instruction on subjects bearing on agriculture and horticulture for elementary school teachers."

Lack of attention to post-graduate work in agriculture in England and Wales was alluded to by the committee in its recommendation that "the Board of Agriculture provide or encourage the provision of scholarships for post-graduate research, and also traveling fellowships for teachers, enabling them to study foreign systems of agriculture." It also believes that there should be increased provision for original research, field experiments, fruit stations, and demonstration plats, and recommends that the Board of Agriculture collate the results of experiments and publish those directly bearing on the improvement of agricultural practice.

As regards instruction in agriculture of a lower grade, which the committee believes to be of vital importance, the winter agricultural school "appears to be especially adapted to the needs of this country." It is believed that within the next 10 years from 50 to 60 of these schools will be provided and that their course of study should be especially adapted to boys from 17 to 20 years old who have already had some practical instruction in agriculture or horticulture. Short winter courses in colleges have been held with success and should be continued, and this is true also of local winter courses "which should be encouraged until longer and more systematic courses of instruction are available at winter agricultural schools."

The committee calls attention to satisfactory instruction now being given in a number of special subjects, such as forestry, dairying, and veterinary science, and recommends that greater attention be given to such instruction in future.

With regard to the organization of agricultural instruction the committee believes that "agricultural instruction, when provided by universities, university colleges, agricultural colleges, farm institutes and winter schools, or by means of special classes or courses of lectures in agriculture and kindred subjects (e. g., dairying, horticulture), should be under the direction of the Board of Agriculture; while all instruction in agricultural subjects forming part of courses in primary, secondary, or such evening schools as are in definite continuation of the education given in primary schools, should be under the Board of Education."

Credit is given to national agricultural societies for good educational work, but it is stated that local societies have given little aid to either agricultural education or research. Greatly increased funds are needed for agricultural education and these apparently must come mainly from national sources. The committee believes that the Board of Agriculture should first aid existing and projected institutions to strengthen their staff and improve their general equipment and then assist local authorities to make provision for the agricultural work conducted by them.

All members of the committee subscribed to the conclusions and recommendations in this report, but one member, J. C. Medd, believes that certain points of vital importance to the effective organization of a national system of agricultural education have been omitted. One serious defect in the English system which he considers important is the lack of intermediate schools of agriculture corresponding to écoles pratiques d'agriculture de France and to some of the agricultural high schools in this country. He believes that no system of instruction is complete which does not provide for the continuous instruction of boys from the age of 14 to 18. Winter schools will not entirely fill this gap and it can only be filled by the establishment of a few intermediate schools with courses extending over two or three years. He calls attention to the fact that the expense of equipping and conducting such schools is too great for their universal establishment, but believes that they should be established where conditions are favorable and where there is likely to be a demand for them.

Mr. Medd further strongly recommends the holding of conferences of representatives from affiliated or associated counties at their respective university or college centers for the purpose of coordinating and strengthening their work. With reference to the literature published by the Board of Agriculture and Fisheries, he points out that many of the witnesses were unfamiliar with particular reports or leaflets and recommends that all literature issued by the board be distributed, free of cost, to all agricultural and horticultural colleges and schools, farm institutes, chambers of agriculture, farmers' clubs and agricultural or horticultural societies.

The report as a whole indicates that the committee has made an exhaustive and careful study of all the facilities available in England and Wales for promoting technical instruction for its youth along agricultural lines, with the single exception of the public elementary schools in rural districts which are under the administration of the Board of Education. These latter schools are alluded to in Mr. Medd's supplementary statement in a paragraph calling attention to the provisions made by the Board of Education to train teachers along agricultural lines for them. The conclusions of the committee show that there is a strong growth of public sentiment in Great Britain in favor of a complete national system of agricultural education to take the place of the widely varied types of colleges and schools which now afford instruction along agricultural lines. As an indication of the growth of such sentiment it is reported by the committee that agriculture now receives recognition in all the universities in that country and that the Royal Agricultural College at Cirencester, and other agricultural institutions which have hitherto

been operated under private control, are considering the advisability of taking, or have already taken, steps to become public institutions.

The Lake Placid Conference of Home Economics was organized in 1899 for the consideration and study of a variety of problems relating to the home, and particularly for the development of the educational side of the subject. Since its organization the conference has held annual meetings at which papers have been presented, topics have been discussed and plans have been formulated for furthering work in home economics. The conference meetings have been of great benefit to teachers in American agricultural colleges and other educational institutions and have done much to raise the standard of education and efficiency in home economics. It is now generally recognized that the subject can be so taught that it does not simply mean the training of women so that they may be good cooks and housewives. It may be presented in such a way that it is in reality "mentally nutritive," and by properly correlating the different sciences and other subjects around the central idea of the home a course can be provided for women which is logically consistent and high in its ideals. At the same time it may be so related to women's activities that when thus trained they may be efficient workers in their homes and communities, while they will also have a truly liberal education.

Though of wide influence, the Lake Placid Conference has never been a large organization, and the opinion has been generally expressed that the growth of the home economics movement has been so great that a new organization is now needed which will be wide in its scope and unite the many interests which have to do with this subject. With this idea in mind the first steps were taken at the Chautauqua meeting of the Lake Placid Conference last July toward the founding of a body for which the name "American Association of Home Economics" has been proposed. This organization, it is believed, will be to the home economics movement in the United States and Canada what the American Chemical Society, the American Forestry Association, the American Physiological Society, and similar organizations are in their respective fields.

A meeting of the new association will be held in Washington December 31 to January 2 for purposes of organization and for outlining the work. The association will seek to bring together teachers in home economics and related subjects, superintendents of schools and other educators, parents, physicians, investigators, health officers, architects, settlement workers, and students of social and civil affairs, and others who are interested in the study of some phase of the general question. Each of these groups has some valuable contribution to make and some suggestion to offer with reference to the means by which formal and informal educational enterprises may be pro-

moted, for although the home economics movement reaches out in many practical ways into home and community life, it is after all an educational movement. The agricultural experiment stations, the agricultural colleges, and the Department of Agriculture have perhaps contributed more than any other group of educators and investigators to the fund of information on which the subject of home economics is based, and it naturally follows that those who are interested in agricultural education and investigation are interested in home economics as well.

The subject of home economics is already an important one in American agricultural colleges. Some twenty-five of these colleges and similar institutions receiving government aid are now offering courses in this line, and others contemplate the introduction of the work. Their active interest in home economics is also shown by the attempts which are being made to classify and arrange available material related to home economics for educational purposes in the same way that agricultural data have been reduced to pedagogical form.

The experiment stations have already made important contributions to home economics literature and should be interested in the new organization because it should prove a stimulus to further research. Such an organization which aims to bring together investigators, teachers, students, and others whose interests are in considerable part the same should be able to do a great deal for the advancement of home economics throughout the country.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

On the quantitative volatilization of phosphoric acid from phosphates in a current of chlorin and carbon tetrachlorid or of tetrachlorid alone, P. JANNASCH and W. JILKE (*Ber. Deut. Chem. Gesell., 40 (1907), No. 13, pp. 3605–3608, fig. 1; Jour. Prakt. Chem., n. ser., 78 (1908), No. 1, pp. 21–28; abs. in Ztschr. Analyt. Chem., 47 (1908), No. 2–3, p. 162; Chem. Zentbl., 1908, II, No. 4, pp. 348, 349; Chem. Ztg., 32 (1908), No. 65, Repert., p. 417*).—This is an account of a continuation of the work by Jannasch and Heimann (E. S. R., 18, p. 522), who found that phosphoric acid could be quantitatively volatilized by heating with sugar and concentrated sulphuric acid in a stream of chlorin. The later investigations show that the same result can be more easily obtained with all kinds of phosphates by heating in a current of chlorin charged with carbon tetrachlorid or of tetrachlorid alone. The apparatus required in the process is described.

A study of the solubility of potassium chloroplatinate, E. H. ARCHIBALD, W. G. WILCOX, and B. G. BUCKLEY (*Jour. Amer. Chem. Soc., 30 (1908), No. 5, pp. 747–760, figs. 3*).—Studies of the solubility of potassium chloroplatinate in water, potassium and sodium chlorid solutions, and different alcohols are reported. It was found in these studies that:

"(1) Small amounts of potassium chloroplatinate in solution can be estimated colorimetrically with considerable accuracy. This will be true of any salt which gives the $PtCl_6$ anion, provided the color of the cathion is not such as to interfere.

"(2) The chloroplatinate is less soluble in solutions of ethyl alcohol and water than in water solutions of either methyl or isobutyl alcohol. Only 0.0007 gm. of the salt dissolves in 100 cc. of ethyl alcohol at 20°.

"(3) The solubility of the chloroplatinate in potassium chlorid solutions decreases with the increase in concentration of the potassium chlorid until a concentration of 1 gm. molecule per liter is reached. Beyond this point, increasing the concentration of the potassium chlorid has practically no effect.

"(4) The solubility of the chloroplatinate in solutions of sodium chlorid increases rapidly until a concentration of 0.05 gm. molecules per liter is reached. For more concentrated solutions the increase in solubility is small and almost proportional to the increase in concentration of the sodium chlorid."

The destruction of organic matter by electricity in the analysis of foods and agricultural products, F. SCURTI and O. GASPARINA (*Ann. R. Staz. Chim. Agr. Sper. Roma, 2. ser., 1 (1906–7), pp. 150–155*).—The use of electricity for the destruction of organic matter is, according to the authors, simple and gives satisfactory results.

The volumetric determination of hardness in potable waters, U. MILONE (*Atti 6. Cong. Internaz. Chim. Appl., 1 (1906), pp. 258–260*).—A new degree of hardness, viz, centigram of calcium per liter of water, is proposed, and the

strength of the soap solution is modified accordingly. The method is claimed to be more accurate than others because a dilute solution of soap and a burette graduated to tenths of a centimeter are used, quicker because no calculation is necessary, and more modern because hardness is stated in terms of calcium and not carbonate or oxid of calcium.

Studies on direct Nesslerization of Kjeldahl digestates in sewage analysis, G. O. Adams and A. W. Kimball (*Jour. Amer. Chem. Soc., 30 (1908), No. 6, pp. 1034–1037*).—A series of tests made to determine the merits of the claims made for this method is reported. The conclusions reached are as follows:

"The direct Kjeldahl method undoubtedly has its own place in sewage work, but it does not seem as if it should take the place of the distillation method in a permanent sewage laboratory handling many samples because of—

"(1) The greater amount of bothersome and bulky apparatus necessary; (2) the large amount of nitrogen-free water required; (3) the greater chance for error in manipulation; (4) the necessity of having the excess of caustic within narrow limits to avoid turbidity, this practically requiring a rough titration of each determination; (5) the greater length of time required for the determination.

"The method, however, is without doubt an excellent substitute for the distillation method in a temporary laboratory where it is necessary to incur the least possible expense for apparatus or in a small laboratory where but a very few determinations are to be made daily."

On the determination of nitrogen in gas mixtures, A. P. Lidoff (*Atti 6. Cong. Internaz. Chim. Appl., 1 (1906), pp. 35–38, fig. 1*).—The apparatus and method used for this purpose are briefly described.

Determinations of nitric acid in arable soils, M. Weibull (*Svensk Kem. Tidskr., 20 (1908), Nos. 1, pp. 11–13; 2, pp. 22–26*).—A description and discussion of the phenoldisulphonic-acid colorimetric method of determining nitric acid in soils. The method adopted by the author was that of Grandval and Lajoux for determining small amounts of nitric acid in water,[a] modified for use in soil analysis by O. Reitmair.

Note on the Dyer method for the determination of plant food in soils, F. T. Shutt and A. T. Charron (*Jour. Amer. Chem. Soc., 30 (1908), No. 6, pp. 1020–1023*).—In tests of modifications of Dyer's method on a prairie soil well supplied with potash and nitrogen and containing fair amounts of phosphoric acid and lime it was found that "reducing the period of digestion from 7 days to 5 hours materially decreased the amount of phosphoric acid dissolved, but did not similarly affect the potash—the percentages of the latter being practically identical for both periods. The lime falls off but slightly with the shorter digestion. . . . Reducing the volume of solvent used, materially decreases the percentages of phosphoric acid and potash obtained. In the case of lime, the smaller volume extracted but one-half that taken out by the larger volume. Clearly, the influence of volume of solvent is decidedly greater than that of the period of extraction."

A new method for the quantitative determination of diastatic ferments, J. Wohlgemuth (*Biochem. Ztschr., 9 (1908), No. 1–2, pp. 1–9, pl. 1*).—A colorimetric method is described.

The probable chemical constitution of rennet, A. Scala (*Staz. Sper. Agr. Ital., 40 (1907), No. 2, pp. 129–149*).—In the author's opinion rennin is a weak base which consists of an albumose nucleus and amino-side-chains. Upon heating its activity is destroyed and its composition altered. A similar result is

[a] Compt. Rend. Acad. Sci. [Paris], 101 (1885), p. 62; see also U. S. Dept. Agr., Bur. Soils Bul. 22, p. 67.

effected by formaldehyde, the amid-hydrogen being replaced by the methylene group.

Pepsin and rennet, I. Bang (*Ztschr. Physiol. Chem., 54 (1908), No. 4, pp. 359–362*).—The author believes that these two substances are not identical.

Methods of determining the moisture content of butter, G. L. McKay and J. Bower (*Iowa Sta. Bul. 97, pp. 4–39, figs. 8, dgm. 1*).—A description is given of several methods of determining the moisture content of butter, including the official, Gray, Richmond, Patrick, and Irish methods, the Wisconsin high-pressure oven, the Caroll and Geldard testers, the Wagner butter hygrometer, and a new method devised by the station and termed the Ames method. The various methods are discussed with special reference to their use in creameries, their simplicity, the cost of apparatus and of manipulation, and the intelligence of operators being taken into account. Results obtained in tests of several of the methods are reported and compared with those from the official method.

In the Ames method, which is designed to overcome inaccuracies involved in the use of the aluminum beaker methods, due to lack of control of heating temperatures, a 10 gm. sample is weighed into a tared aluminum beaker or other suitable vessel which is then inserted in a vessel containing paraffin at from 150 to 200° C. until foaming ceases, shaking occasionally. The best results are obtained at a temperature approaching 175°. After heating, the beaker is carefully wiped to remove any paraffin that may have adhered, cooled, and reweighed. If preferred, the beaker may be inserted in a slightly larger beaker during the heating, thereby eliminating any error through the adhesion of paraffin. Of 50 analyses by this method 6 only varied 0.2 per cent from the official method, and 1 only was in excess of 0.3 per cent difference.

Directions for the selection and care of scales, sampling butter and preparing the sample, with analyses showing the variation in water content of butter from different parts of the churn, different tubs from the same churning and different parts of the same tub, are given.

German and American lard, E. Seitter (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 8, pp. 485, 486*).—Characteristic differences in German and American lard are discussed with a view to their differentiation in food analysis.

Crystallization experiments with lard and tallow, E. Seitter (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 8, p. 486*).—According to the author, the addition of tallow to lard may be detected by characteristic differences in lard and tallow crystals. In the method described a gram of the fat was dissolved in 15 cc. of chloroform, 30 cc. of absolute alcohol was then added, and the mixture allowed to stand over night in a stoppered flask at medium temperature. The crystals formed were removed by filtration, washed with absolute alcohol, and studied microscopically.

Concerning that portion of meat extract which can not be salted out, K. Micko (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 8, pp. 449–462*).—In the portion of meat extract which can not be salted out the author identified monamino and diamino acids, the present report being taken up with the first-mentioned group. This included glycocoll, alanin, leucin, aspartic acid, and glutaminic acid, as well as taurin. He believes that alanin, glutaminic acid, and taurin are original constituents of the meat extract.

Extract of meat, C. M. W. Grieb (*Pharm. Jour. [London], 4. ser., 26 (1908), No. 1971, pp. 441, 442*).—A note on analytical methods followed in the examination of meat extract for the detection of yeast extract.

Methods for the analysis of vegetable foods, J. Alquier (*Ann. Sci. Agron., 3. ser., 2 (1907), I, pp. 47–103*).—A summary and discussion of methods used for determining the composition of vegetable foods.

A comparison of methods of estimating sugar which depend upon the reducing power of dextrose, T. Kinoshita (*Biochem. Ztschr., 9 (1908), No. 1–2, pp. 208–230, fig. 1*).—A study of methods.

The keeping power of Fehling's solution, and the volumetric process of determining reducing sugars with it, F. Watts and H. A. Tempany (*Jour. Soc. Chem. Indus., 27 (1908), No. 5, pp. 191–193*).—A study of methods with special reference to the analysis of muscovado sugar.

Identification of δ-fructose in the presence of other natural sugar, J. Pieraerts (*Bul. Assoc. Chim. Sucr. et Distill., 25 (1908), No. 9, pp. 830–848*).—According to the author's investigations, by the use of alkaline cupric salt solutions in the manner prescribed it is possible to determine whether or not δ-fructose is present.

The detection of artificial and natural honey, J. Fiehe (*Eine Reaktion zur Erkennung und Unterscheidung von Kunsthonigen und Naturhonigen. 1908, Mar.; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 8, pp. 492, 493*).—The author's method for the detection of artificial honey depends upon the fact that invert sugar gives a characteristic color reaction with resorcin and concentrated hydrochloric acid.

The analysis of waste molasses, H. Johnson (*Hawaii. Planters' Mo., 27 (1908), No. 1, pp. 22–27*).—The apparent purity of molasses was found to range from 33.2 to 36.6 and the true purity from 43.1 to 45.2. "In other words, one is able to obtain nearly any desired purity simply by choice of the clarifying reagent and the amount used in analysis. Evidently, therefore, in order that the results of the analysis of molasses have even a comparative value, it is necessary that all determinations be conducted under exactly the same conditions. The dilution of the molasses should be the same, the same clarifying reagent should be used, and as far as possible the quantity of reagent used should be the same. For control work, the true value of the molasses should be determined by Clerget's method of double polarization, and the total solids by drying."

Analysis of flour (*Rev. Gén. Agron., n. ser., 3 (1908), No. 2, pp. 82–84*).—A summary of data regarding French official methods of analysis.

The decomposition of lecithin-phosphoric acid when alimentary pastes are stored, H. Matthes and O. Hübner (*Chem. Ztg., 32 (1908), No. 16, p. 186*).—The work of other investigators is summarized and some determinations are reported. The authors conclude that since the breaking down of the lecithin-phosphoric acid is apparently influenced by conditions which can not be controlled, data dependent upon the determination of this constituent should be used with caution in judging of the number of eggs which have been used in the preparation of such foods.

Changes in the extractives in the determination of wine extract, T. Roettgen (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 5, pp. 257–262*).—On the basis of analytical data the author discusses the determinations of wine extractives with reference to the German pure food law.

The identification of blueberry juice in fully fermented red wine, W. Plahl (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 5, pp. 262–269*).—The author recommends making the wine slightly alkaline and evaporating to half its volume before lead acetate is added to precipitate the coloring matter.

Determining extract in vinegar, K. Windisch and P. Schmidt (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 5, pp. 269–272*).—A study of methods.

Detection of boric acid in foods, C. Mannich and H. Priess (*Chem. Ztg., 32 (1908), No. 25, pp. 314, 315, fig. 1*).—An improved method of using the flame test for the detection of boric acid is described.

Further observations on the inhibiting effect of fluorids on the action of lipase, together with a method for the detection of fluorids in food products, S. Amberg and A. S. Loevenhart (*Jour. Biol. Chem., 4 (1908), No. 2–3, pp. 149–164*).—Fluorids, it was found, powerfully inhibit the action of lipase and, according to the authors, this property "furnishes an interesting biochemical test for the presence of fluorids in food products and will doubtless prove of considerable value in the work of food inspection."

The quantitative estimation of benzoic acid in catsup, C. H. LaWall and H. A. Bradshaw (*Amer. Jour. Pharm., 80 (1908), No. 4, pp. 171, 172*).—The principle on which the method is based is the use of sodium chlorid and hydrochloric acid to prevent emulsification. The benzoic acid is separated by extraction with chloroform.

The use of the microscope in the detection of food adulteration, B. J. Howard (*U. S. Dept. Agr. Yearbook 1907, pp. 379–384, pls. 4*).—As the author points out, the microscope may be used as an important aid in the detection of food adulteration. Its use in the analysis of starch products, spices, coffee and chocolate preparations, jellies and jams, cream, edible fats and honeys, is discussed, the text being supplemented by reproductions of micro-photographs.

"Though only a few of the more obvious forms of adulteration have been discussed, for the field has as yet been only partly explored, they may serve to illustrate how the microscope comes to the aid of the chemist when he endeavors to detect fraud in foods and food products."

Determining aldehydes with the spectroscope, P. Bruylants (*Acad. Roy. Belg., Bul. Cl. Sci., 1907, No. 11, pp. 955–977*).—The principal subject taken up is the determination of citral in lemon extract.

On a modification of the Schultze-Tiemann apparatus, M. Jacqué (*Atti 6. Cong. Internaz. Chim. Appl., 1 (1906), pp. 264–266, fig. 1*).—A conveniently mounted apparatus somewhat larger than usual is described.

On the general application of the Christomanos carbon dioxid apparatus, A. C. Christomanos (*Atti 6. Cong. Internaz. Chim. Appl., 1 (1906), pp. 56, 57*).—The use of this apparatus for the determination of urea is briefly explained.

Report of the chemical division, R. E. Rose (*Fla. Quart. Bul. Dept. Agr., 18 (1908), No. 1, pp. 152*).—This report includes the result of inspection of fertilizers, feeding stuffs, foods, and drugs during the year 1907, with the laws providing for this work and the rules and regulations adopted under the laws. It is stated that inspection tags covering 124,600 tons of fertilizers and cotton-seed meal and 49,536 tons of commercial feeding stuffs were sold during the year. This represents an increase of 27,600 tons of fertilizers and cotton-seed meal and a decrease of 3,640 tons of feeding stuffs. The inspection yielded a total revenue of $43,535.

METEOROLOGY—WATER.

A search for fluctuations in the sun's thermal radiation through their influence on terrestrial temperature, S. Newcomb (*Trans. Amer. Phil. Soc., n. ser., 21 (1908), No. 5, pp. 309–387; abs. in Amer. Jour. Sci., 4. ser., 26 (1908), No. 151, p. 93*).—The conclusions drawn from a thorough review of this subject are essentially negative in character, "although the observations made by Langley and later at the Astrophysical Observatory at Washington have seemed

to indicate a different result." The author shows "that a careful study of the annual departures of temperature over many regions in equatorial and middle latitudes, indicates a fluctuation corresponding with the period of solar spots. The maximum fluctuation, however, for tropical regions is only 0.13° C., or, in other words, the amplitude of the change is 0.26° C., less than one-half degree Fahrenheit. The corresponding fluctuation of the sun's radiation is, hence, concluded to be 0.2 of 1 per cent on each side of the mean. In addition, there is some inconclusive evidence of changes having a period of about six years, which may be plausibly attributed to changes in solar radiation. Apart from these changes the evidence at hand indicates that solar radiation is subject to no change producing a measurable effect upon terrestrial temperature; the magnetic, electric, and radio-active emanations may be left out of account, as their thermal effect is inappreciable. The ordinary terrestrial phenomena of temperature, rainfall, and winds are thus uninfluenced by changes in the sun's radiation. That wide changes of temperature may occur, as those noted in 1903, when the temperature in Russia and Siberia, for example, was more than 20° F. above the normal, is interesting, but it is argued that these fluctuations can not be attributed to changes in the radiation from the sun, because they do not extend to regions (i. e., the equatorial) where such changes would have their greatest effect."

Anticyclones as aids to long-distance forecasts, H. E. Rawson (*Quart. Jour. Roy. Met. Soc. [London], 33 (1907), No. 144, pp. 309, 310*).—This is a brief summary of a paper recently read before the South African Association for the Advancement of Science which dealt with the progressive seasonal movements of the permanent anticyclones within the high-pressure belt of the Eastern Hemisphere. It is stated that "the cyclic movement of the belt will introduce varying periodicities into the weather of places which are situated differently with respect to the belt, and to the positions occupied in successive years by the systems moving to and fro within it."

Bulletin of the Mount Weather Observatory (*U. S. Dept. Agr., Bul. Mount Weather Observr., 1 (1908), pt. 3, pp. 134–206, figs. 16, charts 4*).—This number contains the following articles: The Luminous Particle a Strong Magnet, and the Consequent Pressure Shift of Spectral Lines, by W. J. Humphreys; Note on the Difference Between Anode and Cathode Arc-spectra, by W. J. Humphreys; Temperature Inversions at the Mount Weather Observatory (illus.), by A. J. Henry; The Change of Phase Due to the Passage of Electric Waves Through Thin Plates and the Index of Refraction of Water for Such Waves, with Applications to the Optics of Thin Films and Prisms, Part II (illus.), by W. R. Blair; and Upper Air Temperatures for January, February, and March (illus.), by W. R. Blair.

The weather of Scotland in 1907, A. Watt (*Trans. Highland and Agr. Soc. Scot., 5. ser., 20 (1908), pp. 330–340*).—"This report consists of (1) a general description of the weather over Scotland from month to month; (2) a selection of rainfall returns, in which each county of Scotland is represented by one or more stations."

The year was unfavorable from an agricultural standpoint. The total rainfall was about normal, but its distribution was unfavorable, excessive rains occurring in May, June, August, and October in several districts. Low temperatures and absence of sunshine prevailed almost continuously from May to August.

Meteorology, P. Boname (*Sta. Agron. Mauritius Bul. 16, pp. 1–15*).—Observations on atmospheric pressure, temperature, precipitation, humidity, and evaporation in Mauritius during 1906 and 1907 are summarized.

Meteorological report for the year ended March 31, 1907 (*Rhodesian Agr. Jour., 4 (1907), No. 6, pp. 602–608*).—This report gives the observations made during the year by 9 barometric, 9 thermometric, and 32 rainfall stations in Rhodesia.

Map-studies of rainfall, H. R. Mill (*Quart. Jour. Roy. Met. Soc. [London], 34 (1908), No. 146, pp. 65–86, pl. 1, figs. 10; abs. in Nature [London], 77 (1908), No. 1995, p. 286*).—The object of this paper is to explain briefly how rainfall maps may be used in the study of the normal annual rainfall of the British Isles in relation to the general configuration of the land, and of the relation of the rainfall of individual years, months, and even showers to the normal. The practical applications of the results of such studies are also indicated.

In this connection emphasis is laid upon the vast national importance of accurate knowledge of the rainfall as related to the flow of streams and the rapidly increasing diversion of the water of streams for irrigation and industrial purposes.

It is stated that "the increasing strenuousness of the struggle for the possession of large water supplies is producing in England, and especially in Wales, a great amount of local jealousy and strife, for the boundaries of parishes and counties coincides but rarely with water-partings, and the argument has been brought forward again and again that the rainfall of one county should not be diverted for the use of the inhabitants of another. The feeling is intensified when the boundary to be crossed is that of a historical division of national importance, like the boundary between England and Wales, but the map study of rainfall can do something to suggest the lines on which such disputes should be settled. . . .

"Care for the water supply of the country, coming as it does from the air that knows no bounds across the land, is by no means a parochial, but in the fullest sense a national matter, and should be dealt with in the interests of the nation as a whole, the units of subdivision, when such are required, being the natural units of river basins."

Hygienic water supplies for farms, B. M. Bolton (*U. S. Dept. Agr. Yearbook 1907, pp. 399–408, pl. 1, figs. 4*).—This article discusses the importance and requirements of a sanitary water supply, sources of water supply, sources of pollution, purification of water in the soil, protection from pollution, abundance of supply, and convenience. It is stated in conclusion "that it is not usually a difficult matter to comply with all the requirements of a sanitary water supply on the farm. It requires only ordinary intelligence in selection of the site and subsequent management, besides a certain expenditure of time and money necessary for the construction of devices for protection and convenience."

SOILS—FERTILIZERS.

Relations between climate and terrestrial deposits, J. Barrell (*Jour. Geol., 16 (1908), Nos. 2, pp. 159–190; 3, pp. 255–295; 4, pp. 363–384*).—This is a series of "studies for students," and consists of a general introduction and chapters on (1) relations of sediments to regions of erosion, (2) relation of sediments to regions of deposition, and (3) relations of climate to stream transportation.

The term terrestrial deposits as used in this article is confined to fluvial and pluvial deposits rather than glacial, lacustrin, and eolian deposits.

The specific topics dealt with are character of rocks supplying sediment; relations of rainfall, temperature, and topography to erosion; separation of topographic and climatic factors and of tectonic and climatic oscillations; influence of nature of surface of deposition; climatic influences in regions of

deposition, including effects of constantly rainy, intermittently rainy, semiarid, and arid climates, and the climatic significance of color; effects of stream transportation; relations of stable climates to transportation; and effects of varying climates upon transportation.

It is shown quite clearly in this discussion that climate is a controlling factor in determining not only quantity but physical and chemical nature of terrestrial deposits, and that the influence of this factor is exerted not only in the weathering of rocks and the original formation of the sediments, but in their transportation and deposition.

It is stated that "varying powers of erosion and transportation giving rise to varying quality and quantity of sediment are seen to be the most delicate stratigraphic indicators of climatic fluctuations. On the other hand the chemical and organic conditions accompanying the deposition of the sediment upon the delta plain are more secure indicators of the stable and average climatic conditions under which the formation as a whole was made."

The fertility of some colonial soils, as influenced by geological conditions, C. F. Juritz (*Separate from Trans. So. African Phil. Soc., 18 (1907), pt. 1, pp. 7–30*).—This is substantially a revised and extended reprint of an article which has already been noted (E. S. R., 19, p. 15).

The loss of water from soil during dry weather, J. W. Leather (*Mem. Dept. Agr. India, Chem. Ser., 1 (1908), No. 6, pp. 75–116, pls. 5, fig. 1*).—Determinations of the water content to a depth of 9 ft. in fallow soil with loose surface are recorded in this paper. Samples of the soil were examined at stated intervals from March, 1906, to May, 1907.

The more important conclusions drawn from the investigations are that during a dry period water moves upward toward the surface from a limited depth only, the maximum depth in the Pusa soil experimented with being slightly over 3 ft. during the whole period of observation. Water is lost from the soil at a rate dependent upon the amount present. That is, it follows the "compound interest law." Therefore, the rate of loss is much greater immediately after rain than subsequently. "The water-retaining power of a soil after drainage has ceased is closely related to the total surface possessed by the solid particles, and it is probable that from a determination of the latter the water-holding capacity of soils may be ascertained."

The upland moor as a water distributor, K. Gangnus and P. Rosenstand-Wöldike (*Mitt. Liv-Estländ. Bur. Landeskult., Jahrb. 1906–7, pp. 42–54, 67–76*).—These articles discuss mainly the question whether the water conditions in upland moors are to any considerable extent influenced or controlled by excessive condensation of dew by the moor mosses.

Report on irrigation dry farming and soil moisture investigations, E. Nelson (*Idaho Sta. Rpt. 1907, pp. 23–46*).—This is a report of investigations made during 1907 on the Boise-Payette reclamation project at Caldwell, Idaho, in cooperation with this Office.

The investigations included studies of the duty of water on wheat, potatoes, and alfalfa, using pumped water. Moisture determinations were made to determine the effect of the different irrigations on the moisture content of the soil and losses by evaporation. These show that "the soil has a maximum moisture capacity of 32.84 per cent of the dry weight. Twenty-four hours after irrigation it rarely contained as much as 28 per cent in the first foot. The extent to which it may dry out ranged from 3.9 to 7.3 per cent in the first foot. In the second and third foot there was rarely as little as 8.7 per cent. At planting time the soil contained an average of about 7.95 per cent of available water or a total of 3.82 in. in 3 ft. of soil. The tests indicate that this is very close to the average amount of available water that the soil may contain. In a

few instances the tests show as high an average as 8.7 per cent. In the first foot it ranged as high as 16 per cent, while in the third foot it was quite often a negligible quantity."

Humus in New Hampshire soils, F. W. MORSE (*New Hampshire Sta. Bul. 138, pp. 191–203, figs. 3*).—The importance of the functions performed by humus in the soil and methods of maintaining and increasing the humus content are discussed, and determinations of the humus content of samples of soils from the station farm and from other places in the State are reported.

The percentages of humus found in typical soils of the station farm were: Sandy loam 1.81; clay loam (upper slopes) 2.1 to 2.57, averaging 2.31; clay loam (lower slopes) 2.81 to 3.09, averaging 2.93; and clay 3.33 to 5.37, averaging 4.5. "Besides these samples of our farm soils, a few lots which were received from time to time from other farms were also analyzed for humus, with the following results: Four loams contained from 2.12 per cent to 2.65 per cent, with an average of 2.32 per cent; two sandy loams contained 1.52 per cent and 1.57 per cent, respectively, and one dark loam contained 3.3 per cent." These results show that "there is a fair average proportion of humus in the soils of this State, and they are by no means worn out when compared with the soils of localities noted for fertility."

Comparisons of the humus in cropped and fallow plats on the station farm show that "continuously tilling the soil on the one hand, or cropping it with hay for a long term of years on the other hand, are unsuitable methods for handling our soils, since the former way destroys humus rapidly, while the latter does not maintain it at the highest point."

It is estimated from the analyses reported that the average loss of humus to a depth of 12 in. in a clay soil which had been frequently tilled amounted to 28,000 lbs. per acre, and in a loam soil similarly treated 22,000 lbs. per acre annually.

On the other hand there were "found in three samples of old grass land on the clay soil, which had been cropped with hay for more than 20 years, percentages of humus ranging from 2.95 to 3.69 and averaging 3.27, while the average of immediately adjoining fields, which had been under tillage for 2 years, reseeded and cropped with hay for 3 or 4 years, was 4.5 per cent. The average difference in humus between these two classes of grass land on the same soil was 1.23 per cent, which, calculated for an acre to the depth of 6 in., would be 18,450 lbs., or over 9 tons per acre.

"The new fields had of course received a dressing of manure at seeding time, but the difference in humus would be equivalent to organic matter in over 35 tons of manure per acre, which is more than is ever applied in the practice of the farm. Therefore a considerable part of the gain must have come from the decay of the turf, roots, and stubble turned under by the plow.

"It is apparent that the marked decrease in the yield of hay after 3 or 4 years' cropping is due in part to the decrease in humus and its accompanying fertilizing constituents."

The conclusion therefore seems warranted that "a rotation of crops by combining periodical rests from tillage, with additions of sod and stubble to the soil, favors the production of humus and promotes its increase."

Soil deterioration and soil humus, J. L. HILLS, C. H. JONES, and C. CUTLER (*Vermont Sta. Bul. 135, pp. 142–177*).—In this article an attempt is made to cover causes and remedies with particular reference to the humus content of soil, its benefits, maintenance, and increase.

"The depletion of the soil humus supply is apt to be a fundamental cause of lowered crop yields. The one-crop system, fallowing, shortage of manure, no green manuring; the nonuse of legumes or grasses in the rotation; deforesta-

tion, fires, the continued use of commercial fertilizers; all these tend unduly to lower the humus content. This complex organic soil ingredient supplies nitrogen and available mineral plant food, augments the water storage capacity, promotes its warmth, betters its texture and permeability, and aids microorganic growth. Seriously to lessen its content in the soil is to lower the crop-producing power of the individual farm and to impair national resources. Its lack may be diagnosed by careful observation, but it is particularly apt to be deficient in the more open and porous soils. The supply is best augmented by adequate crop rotation, using legumes and grass as renovating crops, by the free use of farm manures or by the practice of green manuring."

A short list of references to articles on the subject is given.

What the chemist has found in Pennsylvania soils, and the relation of chemistry to agriculture, W. Frear (*Penn. Dept. Agr. Bul. 157, pp. 77–94*).—This article discusses briefly the origin and general characteristics of the representative soils of Pennsylvania, reports analyses of a number of typical soils of the State, and explains in some detail the fertilizer requirements of the soils as determined by a series of cooperative fertilizer experiments with farmers in different parts of the State.

The three main types of soils considered are sedentary, alluvial, and glacial or drift soils. As measured by solubility in both strong acid and in 1 per cent citric acid, the soils are as a rule abundantly supplied with potash. A number of them, however, are deficient in phosphoric acid. A number of the soil samples examined were from limestone regions and therefore abundantly supplied with lime; others were deficient in this constituent.

The relative merits of different methods of determining the fertilizer requirements of soils are briefly discussed.

On soils derived from carboniferous limestone, A. Grégoire (*Bul. Soc. Chim. Belg., 22 (1908), No. 2, pp. 93–104; Bul. Inst. Chim. et Bact. Gembloux, 1908, No. 75, pp. 99–108; abs. in Chem. Zentbl., 1908, I, No. 17, p. 1642*).—A peculiar unproductive soil of the region of Condroz is described and analyses are reported. This soil, which is locally known as "Flin," is a compact ocherous clay containing a large amount of calcium silicate, limonite, and calcareous fossils and also a high percentage of magnesia. The peculiar character of the soil is believed to be due to decalcification of carboniferous limestone, resulting in a lack of flocculation of the clay produced, and not to an excess of magnesia. In view of the fact that the restoration of the lime would be a difficult operation, the author recommends that the soils can best be utilized and improved by putting them down in grass and liming at frequent intervals.

Where crop yields are curtailed by lack of phosphoric acid and lime in the soil, A. Agee (*Penn. Dept. Agr. Bul. 157, pp. 94–102*).—This article calls attention to the fact that while limestone soils are usually fertile soils, abundantly supplied with both lime and phosphoric acid, there are cases in which such soils are benefited by the application of lime and phosphates. The more general use of ground limestone and of fine ground raw phosphate is recommended, particularly in connection with the growth of leguminous crops.

A contribution to knowledge of the composition of buntersandstein soils, R. Hornberger (*Ztschr. Forst u. Jagdw., 40 (1908), No. 2, pp. 94–102; abs. in Zentbl. Agr. Chem., 37 (1908), No. 9, pp. 577–579*).—Detailed chemical studies of typical soils of this kind are reported.

Some representative soils, H. Ingle (*Transvaal Agr. Jour., 6 (1908), No. 22, pp. 238–243*).—Chemical analyses of several samples from each of three districts of the Transvaal are reported, with brief discussions of their fertilizer requirements.

Analysis of grain soils [of Cape of Good Hope], C. F. Juritz (*Agr. Jour. Cape Good Hope, 32 (1908), No. 2, pp. 228–230*).—Mechanical and chemical

analyses of two typical virgin loam soils from the most productive grain-growing region of the province are reported. The soils contain about the same amount of phosphoric acid (0.04 to 0.05 per cent) found in the ordinary soils of the region, but are much above the average in the amount of lime (0.1 to 0.6 per cent) and potash (0.6 to 0.9 per cent). The mechanical analyses are compared with such analyses of typical wheat soils of the United States as are reported by Snyder. A general agreement is noted.

The development of the modern plow in relation to the chemical and bacteriological theories of soil fertility, C. Hugues (*Bol. Quind. Soc. Agr. Ital., 13 (1908), No. 4, pp. 122–126*).—The history of the development of the plow with special reference to its adaptation to the purpose of putting the soil in the best condition for promoting beneficial chemical and bacterial activities is briefly discussed.

Natural agencies in soil improvement, E. B. Voorhees (*Penn. Dept. Agr. Bul. 157, pp. 63–76*).—This article discusses in a general way what are termed constructive and destructive natural forces and explains practical systems of farm management designed to improve two opposite types of soil, namely, a heavy clay and a light sand, both deficient in vegetable matter and in lime, though with good natural drainage.

The productiveness of the soil: Bacteriological factors, E. Marchal (*Ann. Gembloux, 18 (1908), No. 3, pp. 153–166*).—This article supplements previous articles dealing with the physical and chemical factors of soil fertility (E. S. R., 20, p. 16). It discusses specialization and localization of bacterial functions in the soil and the intervention of micro-organisms in soil fertility, the latter including an account of the efforts which have been made to control and promote by artificial means the bacterial activities which increase soil fertility.

The problem of soil bacteriology, H. Fischer (*Deut. Landw. Presse, 35 (1908), Nos. 20, pp. 215–217; 21, pp. 231, 232*).—The importance of bacteriological activities, especially in fixing and transforming nitrogen, in the soil and the methods of studying and controlling such activities are discussed, but in the author's opinion more fundamental knowledge of soil bacteriological processes is needed before practical applications of value can be made. Of first importance at present is a simple method of determining the bacteriological character of soils.

The microbiochemical processes of ammonization in cultivated soils, R. Perotti (*Atti R. Accad. Lincei. Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 16 (1907), II, No. 10, pp. 704–709; Centbl. Bakt. [etc.], 2. Abt., 20 (1908), No. 15–17, pp. 514–518), abs. in Chem. Zentbl., 1908, I, No. 5, p. 481; Jour. Chem. Soc. [London], 94 (1908), No. 544, II, p. 124*).—The author has shown that calcium cyanamid is ordinarily converted into ammonia in the soil while its derivative, dicyandiamid, does not undergo this change under ordinary conditions. He concludes that the transformation in the first case is a biochemic process resulting from the action of organisms which by the aid of particularly favorable conditions are able to withstand the poisonous properties of the cyanamid. The organisms apparently protect themselves by transforming the poisonous cyanamid into ammonia. In case of the dicyandiamid, on the other hand, the necessity for such transformation does not exist because in ordinary concentrations this substance is not poisonous, and certain of the organisms directly assimilate it. This conclusion is borne out, in the author's opinion, by the results of experiments which he reports in which an increase in concentration of the dicyandiamid solution resulted in ammonization due, it is believed, to the fact that in concentrated solution the diamid became injurious to the organisms. A bibliography of 21 references to literature on this particular phase of the subject is given.

Influence of organic matter on nitrification in impure cultures, A. Karpinski and B. Niklewski (*Bul. Acad. Sci. Cracovie, 1907, pp. 596–615; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 544, II, p. 123; Centbl. Bakt. [etc.], 2. Abt., 20 (1908), No. 18–20, p. 618; Chem. Zentbl., 1908, I, No. 13, p. 1317*).—Small amounts of organic matter such as is furnished by soil extracts, humates, and acetates, and even peptones and sugar, favored nitrification in mixed cultures.

On the production of carbon dioxid in cultivated soil, T. Marr (*Meded. Proefstat. Oost-Java, 4. ser., 1908, No. 38, pp. 503–542, charts 3*).—Detailed studies of carbon dioxid production in manured and unmanured soil are reported. The results in the main substantiate those reported by Stoklasa and Ernest (E. S. R., 18, p. 1024), as showing the very large production of carbon dioxid in cultivated soils.

On the action of carbon bisulphid and similar substances on the soil, K. Störmer (*Centbl. Bakt. [etc.], 2. Abt., 20 (1908), No. 8–9, pp. 282–286; abs. in Chem. Zentbl., 1908, I, No. 10, p. 980*).—Experiments with carbon bisulphid, chloroform, ether, benzol, hydrogen peroxid, arsenic, toluol, xylol, phenol, carbol, and cresol are reported. The fact that higher plants were not killed by the amounts of these poisons which were used is explained as due to evaporation of the volatile poisons and fixation of the metallic poisons. It was found that certain of the organic substances, such as carbol and cresol, were utilized to some extent by the bacteria as a source of carbon, particularly if the substances were not used in too concentrated solution. The assimilation of the carbon was shown by increased production of carbon dioxid. The beneficial effect observed in the case of carbon bisulphid is attributed in part to conversion of the sulphur to SO_3 but mainly to the setting free of nitrogen from the plasma of cells killed by the poison, the nitrogen thus being rendered available for plants.

A denitrification experiment, H. Fischer (*Centbl. Bakt. [etc.], 2. Abt., 20 (1908), No. 8–9, pp. 256, 257; abs. in Chem. Zentbl., 1908, I, No. 10, p. 981*).—The author's observations indicate that continued denitrification in the same medium does not always result in the formation of antibodies which eventually stop the process. He believes that the checking of denitrification under such conditions is sometimes due to the formation of free sulphur. In the experiment which is reported it was found that the addition of citric acid completely prevented denitrification. When, however, the acid was neutralized denitrification went on normally. The addition of sodium citrate to the cultures proved very favorable to denitrification. The addition of asparagin was found to be unnecessary except in the case of certain denitrifying bacteria which can not live on nitrate nitrogen alone but also require amid nitrogen in order to reduce nitrates.

The reduction of nitrates, E. Laurent (*Rec. Inst. Bot. Univ. Bruxelles, 1907; abs. in Bul. Assoc. Chim. Sucr. et Distill., 25 (1908), No. 8, p. 780*).—It is pointed out that under the influence of sunlight nitrates either dry or in solution are reduced to nitrites independently of the influence of the air. Beer yeasts, especially those of Duclaux, reduce nitrates at 20° C. *Penicillium glaucum*, *Mucor racemosus*, and similar organisms also have a reducing power. Germinating seeds and various kinds of tissues produce nitrates when air is excluded.

Note on dialysis of soils, C. V. Garola (*Atti 6. Cong. Internaz. Chim. Appl., 4 (1906), pp. 562–569, fig. 1*).—Verifying Petermann's results it was found that soils yielded to solution in water when subjected to dialysis through parchment paper considerable amounts of potash and phosphoric acid, the amounts

varying, however, with the character of the soil. It is suggested that dialysis may prove a useful method of studying the available plant food in soils. By the use of antiseptics in the soil samples experimented with it was shown that the dialyzable plant food obtained was not due to the solvent action of micro-organisms in the soil.

The analysis of the soil by cultivated plants, A. Proost (*Atti 6. Cong. Internaz. Chim. Appl., 4 (1906), pp. 451–457*).—This is mainly a plea for more thorough study of the physics of plant growth and of the relation of natural flora to the physical properties of the soil.

A simple method of testing the manurial wants of soils (*Dept. Agr. Bengal, Quart. Jour., 1 (1908), No. 3, pp. 140–143, fig. 1*).—A simple arrangement of 8 plats, each 10 yds. square, for testing the need of soils for potash, nitrogen, and phosphoric acid singly and combined is described.

Testing soils for fertilizer needs, F. W. Taylor (*New Hampshire Sta. Circ. 2, pp. 2*).—A simple method of making fertilizer tests is briefly described.

The results of practical fertilizer experiments, P. Wagner (*Chem. Ztg., 32 (1908), No. 19, pp. 233, 234*).—The author summarizes the results of 6 years' cooperative experiments with fertilizers carried out under the auspices of the German Agricultural Society by the agricultural experiment stations of the German Empire and reported from time to time in bulletins of the society (E. S. R., 19, p. 925). It is stated that these experiments have demonstrated, among other things, the proper method of fertilizing grapes, the beneficial effect of potash fertilizers on tobacco, the exhaustion of soil potash by meadow grasses and the beneficial effect of phosphatic and nitrogenous fertilizers on grasses, the determination of the soils and crops on which potash salts rich in chlorin can be used, the resistance of sugar beets to large amounts of chlorids, the special need of potatoes and barley for potash and of leguminous plants for phosphoric acid, and the more rational handling and use of manure.

These experiments have also demonstrated the important fact that all of the factors of production, including soil preparation, selection of varieties, amount of seed, methods of planting, etc., must work together if the optimum production is to be obtained. With an optimum of all these factors the yield may be increased in the case of rye 890 to 1,500 lbs. per acre, with barley 980 to 1,600 lbs. per acre, with oats 1,100 to 1,800 lbs. per acre, and with rye on the poorest land, 440 to 1,100 lbs. per acre.

While fertilizing is not the only factor of production it is one of the most important, but the profit from the use of fertilizers depends largely upon the condition of the fertilizer market. The supply of phosphatic and potassic fertilizers is abundant. The future supply of nitrogenous fertilizers is more uncertain. The author attaches great importance to the utilization of processes of fixation and assimilation of atmospheric nitrogen by means of micro-organisms and also to artificial processes of preparing nitrogen compounds from atmospheric nitrogen. The latter he considers the most important question affecting the fertilizer market at the present time.

Increase and decrease of nitrogen in the soil by manuring (*Armstrong Col., Newcastle-upon-Tyne, Agr. Dept. Bul. 7, pp. 30–32*).—The results of fertilizer experiments during a series of years on hay land are briefly referred to as showing that "the judicious application of phosphatic manures, with the addition of potash manures if needed, is the most economical method of supplying nitrogen to the soil, this being taken indirectly from the air by means of the root nodules of clover plants; and further that the continued application of active nitrogenous manures will ultimately greatly impoverish the soil in nitrogen."

The sources of nitrogen and nitrogen fertilizing, W. Schneidewind (*Die Stickstoffquellen und die Stickstoffdüngung. Berlin, 1908, pp. VII+139; rev. in Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 13–14, pp. 437–440*).—This book summarizes present information on these subjects under the following heads: General considerations relating to gain and loss of nitrogen through natural processes, fallow, green manuring, barnyard manure, nitrogenous fertilizers, nitrogen removed from soils by different crops, and fertilizers for special crops.

The content of combined nitrogen in the air, P. Vageler (*Fühling's Landw. Ztg., 57 (1908), No. 4, pp. 140–151*).—This article gives a very complete summary of data on this subject. The principal deduction drawn from the data is that the amount of nitrogen carried down to the soil in atmospheric precipitation is too small to be of very great practical significance, and for this reason we must look to the soil organisms which fix free nitrogen for any important increase in the nitrogen of the soil from atmospheric sources.

The nitrogen problem in agriculture (*Nature [London], 77 (1908), No. 1997, pp. 330, 331*).—This is a review of a report by W. B. Bottomley on seed and soil inoculation for leguminous crops, which is mainly a summary of practical experiments with the pure cultures prepared and distributed in Great Britain by him. The worthless character of most of these reports from a scientific standpoint is pointed out, as well as the extravagant character of some of the claims made by Professor Bottomley with reference to the benefits which may be obtained from the use of the inoculating material.

Field experiments with different nitrogenous fertilizers, Kleberger (*Illus. Landw. Ztg., 28 (1908), No. 21, pp. 185–187*).—Comparative tests of nitrate of soda, sulphate of ammonia, and nitrogen lime on rape, oats, potatoes, sugar beets, and fodder beets are reported. The effects of applications of barnyard manure and of green manuring were also tested.

Norwegian and Chilean nitrate, H. von Feilitzen and L. Grandeau (*Jour. Agr. Prat., n. ser., 15 (1908), No. 7, pp. 196–198*).—A brief account is here given of comparative tests of these materials at the Swedish Moor Culture Stations at Jönköping and Flahult. See also a previous note (E. S. R., 19, p. 124).

Calcium cyanamid (nitrogen lime or lime nitrogen) as a fertilizer, H. Immendorff and K. Kempski (*Calciumcyanamid (Stickstoffkalk oder Kalkstickstoff) als Düngemittel. Stuttgart, 1907, pp. 123; rev. in Centbl. Bakt. [etc.], 2. Abt., 20 (1908), No. 10, p. 304; Ztschr. Landw. Versuchsw. Osterr., 11 (1908), No. 2, pp 149, 150*).—This is a review of previous investigations and of the present status of knowledge on this subject. Chapters are devoted to consideration of (1) the nitrogen question in general, and the history of investigations relating to the utilization of atmospheric nitrogen through the agency of root tubercles and by oxidation processes; (2) the development of carbid methods; (3) various processes which have been developed for the preparation of lime nitrogen and nitrogen lime and the technical application of these processes in different places; (4) a review of information relating to the chemical and bacteriological characteristics and transformation in the soil of lime nitrogen and nitrogen lime, and of the agricultural use of cyanamid including a consideration of the possible poisonous properties of cyanamid and their influence upon vegetable and animal life; and (5) an elaborate compilation of the results of fertilizer experiments with different crops and soils in various countries.

Some of the more important facts relating to the use of calcium cyanamid as a fertilizer brought out in this discussion are as follows: The material is not suited to acid humus soils nor to light sandy soils of acid reaction. It is

an effective fertilizer on all other soils, particularly on fine clay soils of high absorptive power and rich in lime, especially when such soils are regularly treated with stable manure. Under favorable conditions the cyanamid is considered to be equal to ammonium sulphate in fertilizing efficiency when used at rates of 133.6 to 267.2 lbs. (26.7 to 53.4 lbs. of nitrogen) per acre. It should be applied 2 to 8 days before seeding and well mixed with the soil immediately after application. It should never be applied as a top-dressing and should not be mixed with superphosphates, but may be mixed with potash salts and Thomas slag. The material should be kept dry in storage, otherwise there will be decomposition and loss of nitrogen. If applied with a drill some device should be used which will prevent scattering by the wind. If applied by hand the material should be mixed with double its weight of moist soil.

Results of experiments with calcium cyanamid on horticultural crops and on wheat, R. de Polo (*Asoc. Sal. Propagada, Circ. Trimest. 43, 1908, pp. 151–159*).—The results of a number of experiments made during 1905–6, mainly in Italy, are summarized.

Calcium nitrate and calcium cyanamid, L. Grandeau (*Jour. Agr. Prat., n. ser., 15 (1908), No. 8, pp. 229–231*).—The more important practical information regarding the value and use of these materials as fertilizers is summarized and a brief account is given of tests of the calcium nitrate on potatoes and wheat during the season of 1906–7. The nitrate gave favorable results in both cases.

A danger in the use of nitrogenous fertilizers in the cultivation of grain, D. Cavazza and L. Zerbini (*Ann. Uffic. Prov. Agr. Bologna, 13 (1906), pp. 91–103*).—From the experiments reported the authors conclude that nitrogenous fertilizers, especially the soluble forms, should be used with caution, otherwise there may be great waste.

On the potash fertilizing of tropical and subtropical plants, P. Vageler (*Tropenpflanzer, 12 (1908), No. 2, pp. 69–83*).—This article reviews various investigations which have been made on the potash requirements of tropical and subtropical soils and crops, including a number of references to work by experiment stations of the southern United States. The crops which receive attention include barley, wheat, rice, sugar cane, sweet potatoes, oil plants, tobacco, coffee, cacao, tea, cotton, sisal, and cocoanuts.

The general conclusion reached is that soils of tropical and subtropical regions are frequently deficient in potash and that good results generally follow the use of potash fertilizers on the crops ordinarily grown in such regions. The best forms and methods of use and the profitableness of potash fertilizing depend upon varying conditions which have not yet been thoroughly investigated.

Potash fertilizers, D. Cavazza (*Ann. Uffic. Prov. Agr. Bologna, 13 (1906), pp. 150–159*).—Experiments are reported which indicate that on certain clay soils potash fertilizers are not needed.

The farming of light soils with special reference to the use of potash salts, Kitzinger (*Jahrb. Deut. Landw. Gesell., 22 (1907), No. 4, pp. 741–752*).—This is a popular statement of practical experience in improving light sandy soils by proper rotations and methods of fertilizing, particularly with legumes and potash salts as proposed by Schultz-Lupitz.

The solvent action of soil bacteria upon the insoluble phosphates of raw bone meal and natural raw rock phosphate, W. G. Sackett, A. J. Patten, and C. W. Brown (*Michigan Sta. Spec. Bul. 43, pp. 3–30*).—This is a preliminary report covering 2 years' work and over 500 determinations, the purpose of which was "to demonstrate quantitatively, if possible, the extent to which the

tricalcium phosphate of raw bone meal and the insoluble phosphate of natural raw rock phosphate are made soluble by soil bacteria rather than to attempt any explanation of the processes involved."

It was found that many soil organisms, not specific acid producers, as, for example, *Bacillus subtilis*, *B. mycoides*, *B. proteus vulgaris*, and *B. coli communis*, as well as several agar cultures from garden soil, were capable of dissolving the phosphate of bone and to a less extent that of mineral phosphate. The authors are therefore of the opinion that acid is not the sole solvent in this process, although an important one, as shown by the greatly increased solvent action in cultures of the acid-producing organisms, *B. acidi lactici* and "mother of vinegar," in milk and fermented wort.

The carbon dioxid liberated by the organisms also appear to be an important factor in dissolving the phosphates. The investigations show further that the character of the culture solution has an important bearing upon the solvent action. With the nonacid-producing organisms the greatest solvent effect in case of bone meal was obtained in a culture solution made up of sodium chlorid, potassium sulphate, and ferrous sulphate, with asparagin as the source of nitrogen. Organisms grown in an agar medium containing also magnesium and ammonium sulphates exerted no solvent action on either calcium carbonate, dicalcium or tricalcium phosphate, bone meal, or mineral phosphate. When, however, sugar was added, the phosphates were attacked, as also when meat extract was added, although the action in this case was much reduced.

The solvent action of soil bacteria upon the insoluble phosphates of raw bone meal and natural raw rock phosphate, W. G. Sackett, A. J. Patten, and C. W. Brown (*Centbl. Bakt. [etc.], 2. Abt., 20 (1908), No. 21–23, pp. 688–703; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 547, II, p. 415*).—See abstract above.

On the action of agricultural phosphate, O. Böttcher (*Deut. Landw. Presse, 35 (1908), No. 23, pp. 253, 254*).—Pot and field experiments by the author to test the fertilizing value of this material, which is a fine ground raw phosphate, are reviewed, the general conclusion being that this material can not replace superphosphate as an efficient phosphatic fertilizer and in general confirming the view expressed in the resolution adopted by the Association of Agricultural Experiment Stations of the German Empire at its Dresden meeting to the effect that raw phosphates can not be profitably used on any except acid soils and that their use on other soils is not to be recommended.

Fertilizer experiments with Thomas slag, L. Jozek (*Atti 6. Cong. Internaz. Chim. Appl., 4 (1906), pp. 404–407*).—In experiments with beets no increase in yield was observed when Thomas slag was used alone. There was, however, a considerable increase when nitrate of soda and sulphate of potash were used with the slag. In the case of barley the addition of the nitrate or sulphate did not materially increase the yield produced by Thomas slag alone.

Results of cooperative experiments with fertilizers in swamp soils, R. Harcourt (*Ann. Rpt. Ontario Agr. and Expt. Union, 29 (1907), pp. 48–51*).—A number of such experiments in different parts of the Province of Ontario are reported, the general conclusion being that in the majority of cases lime gave decidedly beneficial results and that potash and phosphoric acid may be profitably used on many of the soils.

The action of lime on the bacterial life in soils, Vogel (*Illus. Landw. Ztg., 28 (1908), No. 21, p. 185; abs. in Chem. Abs., 2 (1908), No. 15, pp. 2119, 2120*).—This is a brief summary of results of some of the more recent investigations regarding the beneficial influence of lime on nitrification, putrefaction, and nitrogen fixation in the soil. The general conclusions are that the activities of all soil micro-organisms are promoted by lime and that this explains the

value of lime as a plant food. The minimum lime requirements of Azotobacter in the soil is estimated to be 0.1 per cent.

The action of various combinations of manganese and particularly of a manganiferous mineral used as a fertilizer for plants, N. Strampelli (*Atti 6. Cong. Internaz. Chim. Appl., 4 (1906), pp. 14–17*).—Plat tests with grain are reported in which manganese carbonate, sulphate, and dioxid, and a manganese ore were used in combination with other fertilizing materials. An increase of yield due to addition of the manganese compounds was observed in all cases, the greatest increase resulting from the use of the sulphate.

The use and increasing production of sulphate of ammonia, T. Collot (*Jour. Agr. Prat., n. scr., 15 (1908), No. 10, pp. 301–304*).—The total production of sulphate of ammonia for the whole world in 1907 is placed at 845,000 metric tons, valued at $50,700,000. Of this amount England produced 361,000 tons and the United States 36,000 tons. The production in Germany has increased from 55,000 tons in 1896 to 287,000 tons in 1907. France produced during the year 53,000 tons and consumed 72,900 tons.

The value of sulphate of ammonia as a fertilizer for various crops, particularly cereals, beets, and potatoes, is discussed, and the importance of increasing the production of this material as a by-product of coke making and by distillation of peat is pointed out.

The utilization of the nitrogen of the air in Germany, Kempski (*Naturw. Wchnschr., 23 (1908), No. 12, pp. 185, 186*).—This note refers to the processes now in actual use and the manufacturing plants in operation in Germany and other European countries for the preparation of nitrogenous compounds from the nitrogen of the air. The processes mentioned are those of Birkeland and Eyde for the preparation of lime nitrate and of Frank and Caro and of Polzenius for the preparation of calcium cyanamid. The plants referred to are those of Piano d'Orta in Italy, Westeregeln, near Stassfurt, in Germany, with an output of about 4,400 tons of nitrogen lime per year, and Brühl, near Cologne, with an output of about 11,000 tons per year. The technical application of Ostwald's process for the conversion of the nitrogen of nitrogen lime into ammonia is also noted.

On the utilization of atmospheric nitrogen by means of calcium and barium, A. Piccinini (*Atti 6. Cong. Internaz. Chim. Appl., 3 (1906), pp. 215–226*).—The history and chemistry of fixation of atmospheric nitrogen by electrical means, especially the calcium cynamid process, is reviewed and a bibliography of 23 references to investigations on the subject is given.

The action of certain fertilizers on calcium cyanamid, G. Fascetti (*Atti 6. Cong. Internaz. Chim. Appl., 4 (1906), pp. 372–378*).—A study of the effects of mixing superphosphates, slag, and mineral phosphates in varying proportions with calcium cyanamid is reported.

On the chlorin content of kainit, J. C. de Ruijter de Wildt (*Cultura, 20 (1908), No. 235, pp. 155–160*).—The percentages of potash and chlorin in 59 samples of commercial kainit are reported. The percentages of lime, magnesia, and sulphuric acid are also given for some of the samples. The chlorin varied from 28 to 50.8 per cent, the potash from 10.8 to 17.1 per cent. As a rule the potash increased with the chlorin content.

Investigations on the composition of Peruvian guano and its value as a fertilizer, J. G. Maschhaupt (*Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat., 1908, No. 3, pp. 5–21*).—This article contains information regarding the origin, formation, and character of the guano deposits, as well as recent analyses and a discussion of the fertilizing value of the guano.

The utilization of locusts as fertilizer, P. Lavenir (*An. Soc. Rural Argentina, 41 (1907), No. 53–54, pp. 179–181*).—Analyses of the whole insect and of its different parts are reported. The dried and ground material (whole insects) was found to contain 9.86 per cent of moisture, 9.94 per cent of fat soluble in benzin, 9.71 per cent of nitrogen and 1.24 per cent of phosphoric acid. The analyses thus indicate a high fertilizing value for the material.

Mineral fertilizer, J. A. Wendel (*Milwaukee, Wis., 1908, pp. 24*).—This pamphlet is practically an abridgment of a book published several years ago under the title Bread from Stones, and advocates the exclusive use of finely ground rocks as a means of maintaining soil fertility.

On the absorptive capacity of peat litter when under high pressure, I. Lugner and H. von Feilitzen (*Svenska Mosskulturför. Tidskr., 22 (1908), No. 1, pp. 36–41, figs. 3*).—Experiments conducted by the authors showed that peat litter with a high absorptive power is able to retain larger quantities of liquids than a poor grade of litter, even if subjected to pressures of 0.8 to 1.6 lbs. per square inch, corresponding to the pressure to which litter is subjected in a manure pile up to a depth of 1 meter.

Fertilizer trade in Hawaii, A. Marquès (*Engrais, 23 (1908), No. 9, p. 209*).—It is reported that fertilizers to the value of $698.241 were imported into Hawaii from the United States during the year 1906–7. This represents 80 to 85 per cent of the total amount used.

Commercial fertilizers; a quarter century of fertilizer inspection, J. L. Hills, C. H. Jones, and C. Cutler (*Vermont Sta. Bul. 135, pp. 59–141, dgms. 10*).—The results of analyses of 130 brands of fertilizers, representing the output of 11 companies, are reported and discussed in this bulletin. A survey of 25 years' fertilizer inspection in Vermont is also given: "A fertilizer control has been conducted in Vermont since 1882. Before the system was inaugurated fertilizers contained no potash, were very irregular and uncertain in composition, were costly, and fraud was rife. To-day the trade is systematized, brands are relatively uniform year after year, and seriously deficient fertilizers are uncommon." The quality of the fertilizers examined during the past year was on the whole good.

Mixing chemical fertilizers on the farm, F. W. Morse (*New Hampshire Sta. Circ. 1, pp. 4*).—It is maintained in this article that "mixing chemical fertilizers is a simple mechanical process and can be done by any farmer," and formulas and methods are given.

AGRICULTURAL BOTANY.

The relation of plant societies to evaporation, E. N. Transeau (*Bot. Gaz., 45 (1908), No. 4, pp. 217–231, figs. 9*).—A study was made at about one dozen stations on Long Island, N. Y., by means of the porous-cup vaporimeter tested and recommended by the Desert Botanical Laboratory at Tucson, Ariz., to determine the relation between evaporation in the soil and the plants occupying any given locality. It was found that the porous-cup vaporimeter is well adapted to the study of habitat conditions. Unlike many forms of instruments, it furnishes data that can be directly related to the plant activity. Comparative readings can be obtained from different habitats by standardizing the instruments at the beginning of the experiments.

Does phosphorus play a part in the production of chlorophyll? J. Stoklasa, V. Brdlik, and J. Just (*Ber. Deut. Bot. Gesell., 26a (1908), No. 1, pp. 69–78*).—The former conclusions of one of the authors on the physiological importance of phosphorus in the formation of chlorophyll (E. S. R., 8, p. 108) having been questioned, the previous experiments, in which leaves were extracted with ben-

zol and the percentage of phosphorus in the extract estimated as magnesium phosphate, have been repeated. The principal experiments were made with *Acer pseudoplatanus*, but the results were confirmed by analysis of 18 other plants. All showed an important phosphorus content in the ash. The authors reassert the previous statement that phosphorus plays an important rôle in the production of chlorophyll.

Lactic and alcoholic fermentation in plant tissues. J. Stoklasa (*Atti 6. Cong. Internaz. Chim. Appl., 3 (1906), pp. 885–890*).—The author gives a brief account of studies on intramolecular respiration of beet roots, potato tubers, beans, cucumbers, cherries, wheat, and barley, in which a lactic and alcoholic fermentation was found to take place. This fermentation, it is claimed, is due to an enzymic action, bacteria having nothing to do with it.

The effect of light on germination, W. Kinzel (*Ber. Deut. Bot. Gesell., 26a (1908), No. 2, pp. 105–115, dgms. 4*).—A study was made to determine the effect of light and darkness, as well as of various colored lights, upon the germination of seeds of a number of species of plants.

In the case of Veronica seeds 100 per cent germinated under clear light and under yellow light in 30 days, while germination was retarded under orange, red, blue, and green light, in some cases less than 50 per cent germinating in 2 months.

Similar investigations were conducted with the seeds of Poa, Nicotiana, Drosera, Allium, Veratrum, and other plants.

The stimulating action on germination of mixtures of colloidal solutions. H. Micheels and P. DeHeen (*Acad. Roy. Belg., Bul. Cl. Sci., 1907, No. 12, pp. 1027, 1028*).—In continuation of previous work on the action of colloidal solutions in stimulating germination (E. S. R., 18, p. 624), results are given of investigations carried on with colloidal solutions of platinum and of magnesium and a mixture of equal parts of the two. The solutions were found to exercise a stimulating effect on the germination of wheat, and the combined solution increased the percentage of germination very materially.

The ascent of water in trees, A. J. Ewart (*Phil. Trans. Roy. Soc. London, Ser. B, 199 (1908), No. 258, pp. 341–392, pl. 1, figs. 7*).—In continuation of previous investigations into the physics of water flow through wood (E. S. R., 17, p. 958), the author has carried on experiments on the ascent of water, measuring it in maple and poplar trees, wistaria, and other plants.

The author states that all his experiments tend to show that the continuous ascent of water is only possible in living wood, the power of conduction being rapidly lost on death, without any mechanical blocking of the vessels being necessarily responsible for the change. From this he concludes that the living cells in tall trees continually restore the conditions for the ascent of water wherever these are affected by the excessive emptying of the vessels, and decrease the resistance to flow as far as possible by maintaining continuous water columns in at least parts of the wood. So long as these are present, a pumping action on the part of the tree becomes necessary only in those trees having a height of over 20 to 50 meters. Suspended columns of water can not be maintained for any length of time in the vessels of tall trees without the aid of the living cells of the wood.

The energy required to pump water upward in the tallest trees is said to represent only a small fraction of that produced by the daily photosynthetic assimilation, and it is this feeble character and diffuseness of the pumping action which renders it so difficult to demonstrate.

Experiments on the suction and exudation of trees at different levels and upon the influence of the entry of air and water under pressure showed that no continuous suspended water columns or high internal tensions existed in

the conducting elements of the maple and poplar trees during their active transpiration. The same was shown by direct measurements of the pressure in vessels of wistaria. This fact, coupled with the high total resistance to flow, shows that this resistance is overcome locally from point to point, and not by any enormous tension from above or pressure from below, neither of which exists nor could be maintained to a sufficient extent to carry on the elevation of water in a tall tree.

The apparent differences of osmotic pressure previously observed between leaves at the base and apex of a tall tree it is claimed are not evidences of the existence of any greater osmotic suction at the higher level, but are the result of the different ages and sizes of the cells and the different conditions to which they have been exposed.

Observations regarding the constancy of mutants and questions regarding the origin of disease resistance in plants. H. L. Bolley (*Amer. Nat., 42 (1908), No. 495, pp. 171–183*).—This is a paper read before the American Breeders' Association at its meeting in January, 1908, in which the author gives his views regarding the constancy of a number of mutating forms of plants, and also outlines the results of his investigations on the resistance to disease of various plants with which he has been experimenting.

The author, in summarizing his results, asserts "(1) that mutants may be so insignificant and numerous as to be unrecognizable and thus fall directly into the class called by DeVries 'fluctuating variations;' or (2) that they may be induced in a mixture of a great number of varieties of a species at one and the same time because of the same environmental causes; or (3) that, in some cases, 'fluctuating variations' are of such nature and worth as to allow results to be obtained in mass breeding of as great importance as any that may be hoped to be obtained by looking for a single mutating type."

In regard to disease resistance the author, while not ready to affirm definitely his position in the matter, believes that the resistance is physiological rather than structural.

The correlation of flower and fruit structure in Carica papaya. P. J. Wester (*Bul. Torrey Bot. Club, 35 (1908), No. 3, pp. 141–146, figs. 2*).—A study has been made of the papaya (*C. papaya*) to determine whether the development and formation of the fruit might be correlated with the structure of the flower. In this study notes were taken on a number of flowers on the same tree. The plant is normally diœcious, but rarely produces perfect flowers. In most instances the bisexual flower buds were bagged with small paper sacks, the sack remaining until the flower had faded and the ovary was beginning to develop.

There was found to be a distinct correlation between the formation and size of the fruit and the flower characters. Where the ovary was small and slender, with rays in the stigma nearly aborted, the fruits grew comparatively small, cylindrical, almost solid, with exceedingly small seed cavity containing few seeds; while where the pistil was normal, or nearly so, the fruit grew large, more or less angular, with the apical end distended, and the cavity containing a large number of seeds.

The author thinks the form with small slender ovaries to be preferable, as it yields a fruit that is much more easily packed. Under the usual methods of propagation a large production of seedlings is not considered profitable, and an attempt to originate a variety of papaya would probably necessitate hand pollination, inbreeding, and rigid selection for several generations.

The nectaries of cotton. F. J. Tyler (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 131, pp. 45–54, pl. 1*).—A study has been made of the nectaries occurring

on the leaves and involucral bracts of cotton to determine whether they can be used as diagnostic characters for the classification of species of Gossypium.

Symbiosis in fern prothallia, D. H. Campbell (*Amer. Nat., 42 (1908), No. 495, pp. 154–165, figs. 3*).—Attention is called to the fact that the author reported in 1895 the presence of an endophytic fungus in the prothallium of *Botrychium virginianum*. Studies have since been made of a number of other species of ferns that show conclusively that an endophytic fungus is normally present in the green prothallia of several additional species, and it is highly probable that further research will show similar fungus endophytes in other ferns.

FIELD CROPS.

Dry farming in Idaho, E. Nelson (*Idaho Sta. Bul. 62, pp. 3–42, figs. 2, map 1*).—Experiments were carried on near Caldwell by the station in cooperation with this Office to determine the best methods of cultivation for different dry-land crops. These experiments were begun in October, 1906, and as the work in 1907 was largely preliminary only few references to results obtained are made. The bulletin treats of dry farming in a general way, giving its history, discussing climatic and soil conditions in regions where dry farming is practiced or is feasible, and describing the advantages of different methods followed in producing crops under dry-land conditions. The monthly precipitation at 46 different points in the State for recent years is given in a table. At Caldwell the yearly precipitation is 10.32 in.

It is stated that the surface soil in the Snake River plains will hold per cubic foot 18.65 lbs. of moisture in the form of capillary water, or 22.46 per cent of the dry weight of the soil. The author observed that a certain deep clay loam had become moist to the depth of only 18 in. during winter. When tested in April it contained 4.85 in. of water in the first 3 ft. of soil, but in the latter part of August it contained only 2.32 in., and this entirely hygroscopic moisture. The rainfall during the period had been 4.53 in., thus making a total of 7.06 in. evaporated in 3 months. The tests were made on unbroken ground. On summer fallow plats at Caldwell, which had been disked and harrowed early, the moisture content in June after plowing and establishing a dry mulch was 7.03 in. in 3 ft. of soil, while late in September it was still 6.55 in., showing a loss of only 0.48 in. The moisture content on new land plowed in spring and cropped in 1907 was 16.63 per cent, 19.20 per cent, and 17.04 per cent for the first, second, and third foot, respectively, at planting time, and 5.98 per cent, 10.88 per cent, and 13.17 per cent for the first, second, and third foot, respectively, at harvest time.

The different varieties enumerated as adapted to southern Idaho dry-land conditions are as follows: Winter wheat, Turkey Red, Forty-fold, Gold Coin, Lofthouse, Jones Fife, Odessa, and Canada Hybrid; spring wheat, Kubanka, Bluestem, Little Club, Red Chaff, Jenkins, Early Wilbur, and Sonora; oats, Sixty Day, Kherson, Big Four, and Black American; barley, Beardless and Smooth Hulless; potatoes, Early Ohio, Early Acme, Six Weeks, and Early Eureka. Rye, emmer, Polish wheat, alfalfa, field peas, Dwarf milo maize, white durra, flint corn, and brome grass are also successfully grown.

On the plains about 15 bu. of wheat per acre may be grown by dry-farming methods. It is estimated that the cost of producing wheat in Idaho, not including thrashing and marketing, is $3 per acre when the work is performed by the farmer, and $5.30 per acre when the work is contracted.

Dry-land farming in the Great Plains area, E. C. Chilcott (*U. S. Dept. Agr. Yearbook 1907, pp. 451–468, figs. 2*).—This article discusses the Great Plains area as a field for investigation, considers the climate of the region and

its effect upon soil conditions, and describes cooperative work of this Department undertaken with State experiment stations.

Outlines and plans of experiments in soil preparation and crop rotation are presented. The object of these experiments is to determine a system of cultivation which will best conserve the soil moisture for the uses of the growing crop. Nine rotations planned are designed for the conservation of humus in the soil, and nine 3-year rotations are designed to give an opportunity for comparing the several rotations considered as units and also for comparing the several crops grown in different rotations under different systems of soil preparation and following different crops.

Notes on dry farming, W. M. JARDINE (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 10, pp. 6*).—These notes include a brief review of dry-land agriculture in Montana, Utah, and Colorado.

In the Yellowstone Valley of Montana at an altitude of 2,500 to 3,000 ft., with an average annual precipitation of 13 to 15 in., yields of 58 bu. of Turkey Red wheat, 2 tons of alfalfa, 250 bu. of potatoes, and 60 bu. of oats per acre are recorded. The two principal varieties of wheat grown are Turkey Red winter wheat and Kubanka durum spring wheat. The winter wheat is reported as yielding 10 to 20 bu. more per acre than the best spring wheat known. Observations made on plowing with gasoline traction engines are reported.

In the Bear River Valley of northern Utah and the Malad Valley of southern Idaho, regions with an annual rainfall of less than 13 in. and with an average of less than 5 in. during the growing season, the author found that a yield of 15 bu. of wheat per acre is secured with only an occasional rotation of the crops or summer fallow.

Orchard management on a dry farm near Denver, Colo., is briefly described. In addition to orchard crops, currants, alfalfa, corn, wheat, and potatoes are also produced. The alfalfa is reported as yielding annually from 1½ to 2½ tons of hay per acre, while in 1907 Turkey Red wheat yielded over 40 bu. per acre. The same season 40 bu. of corn per acre were produced on sod land plowed 9 in. deep. In discussing the cultivation of this farm, the advantage of using the moldboard plow instead of the disk plow in dry-land farming is pointed out.

Cropping systems for stock farms, W. J. SPILLMAN (*U. S. Dept. Agr. Yearbook 1907, pp. 385–398*).—In treating this subject the author gives examples of simple and complex rotations and outlines cropping systems for special types of stock farms, including a Virginia horse farm, a northern dairy farm, a dairy farm in a middle latitude, and a hog farm in a region a little south of middle latitude.

Results of cooperative experiments in agriculture, C. A. ZAVITZ (*Ann. Rpt. Ontario Agr. and Expt. Union, 29 (1907), pp. 14–32*).—A report and discussion of the work in 1907 is presented.

The number of tests made of each crop, the leading variety, and its average yield were as follows: Oats, 102 tests, Imported No. 534, yield 37.44 bu.; Six-rowed barley, 42 tests, No. 21, 30.98 bu.; Two-rowed barley, 3 tests, French Chevalier, 23.88 bu.; Hulless barley, 6 tests, Black Hulless, 18.92 bu.; Spring wheat, 13 tests, Wild Goose, 20.05 bu.; emmer and spelt, 5 tests, common emmer, 44.20 bu.; Winter wheat, 8 tests, Imperial Amber, 22.17 bu.; Winter rye, 2 tests, Mammoth, 26.43 bu.; field peas, 42 tests, Early Britain, 20.53 bu.; field beans, 12 tests, New Prize Winner, 20.59 bu.; corn for grain, 12 tests, Genesee Valley, 33.21 bu.; crop mixtures, 4 tests, Daubeney oats, 34 lbs. and Mandscheuri barley, 48 lbs. per acre, 1,340 lbs. of grain; mangels, 10 tests, Ferry Yellow Leviathan, 36.77 tons; sugar beets, 8 tests, Bruce Giant White Feeding, 25.43 tons; swedes, 4 tests, Carter Invicta, 32.18 tons; fall turnips and kohl-rabi, 3 tests, Redtop White Globe fall turnip, 29.55 tons; carrots and parsnips, 2

tests, Bruce Mammoth Intermediate Smooth White carrot, 20.60 tons; millet, 3 tests, Japanese common, 10.44 tons; grass peas and vetches, 1 test, hairy vetches, 9.20 tons; potatoes, late varieties, 89 tests, Empire State, 157.78 bu., medium varieties, 108 tests, Burpee Extra Early, 151.18 bu., early varieties, 217 tests, Extra Early Eureka, 149.58 bu. Cooperative fertilizer tests with a number of these crops are also described and reported.

[Effects of manures on old land hay], D. A. GILCHRIST (*Armstrong Col., Newcastle-upon-Tyne, Agr. Dept. Bul. 7, pp. 33*).—Cooperative fertilizer experiments were carried on in the counties of Cumberland, Durham, and Northumberland, and the results are here reported, together with suggestions for the manuring of old land hay and pasture.

It is concluded from the results secured that on heavy soils phosphatic manures alone are as a rule most profitable for old land, while on the lighter soils potash should be added to the phosphatic manure. Nitrogenous manures either alone or in combination did not appear profitable. On heavy soils phosphatic manures favored the development of leguminous plants, while on the lighter classes of soils a potash manure was also required to produce this effect. Basic slag was the most effective source of phosphorus, especially on heavy soils. Although bone meal gave good results, it was slower in its action than basic slag.

The botanical history and classification of alfalfa, C. S. SCOFIELD (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 131, pp. 11–19, figs. 2*).—This article discusses the origin of the alfalfa plant and its common names, its early scientific name, the confusion of generic names, the type of the genus Medicago as well as that of the genus Medica, and the seed characters of alfalfa and related genera. An analytical key to the genera is also given.

In summarizing the article the author states that alfalfa was brought into Greece by the Persians about 490 B. C., and that it was known to the Greeks and Romans as "Medike" and "Herba Medica" on account of its supposed Median origin. It is thought probable that the name lucern is derived from the name of the valley of the Luzerne river in northern Italy. The name alfalfa is derived from the Arabian "alfacfacah," meaning the best kind of fodder. The prevalent botanical name, *Medicago sativa*, is considered as being improperly used because the name Medicago belongs to another plant not congeneric with alfalfa and generally known as *Trigonella radiata*. It is stated that the correct botanical name of alfalfa is *Medica sativa*.

Alopecurus agrestis, C. FRUWIRTH (*Arb. Deut. Landw. Gesell., 1908, No. 136, pp. 20, pls. 6, figs. 2*).—The botanical characters of this grass are described and its growth, distribution, prevention, requirements, and uses are discussed.

The period of plant food assimilation and dry matter production in the bush bean under different fertilizer and weather conditions, F. FEST (*Jour. Landw., 56 (1908), No. 1, pp. 1–47, fig. 1, dgms. 6*).—The results of the experiments here reported showed that when phosphoric acid was supplied in excess the potash content was influenced only in the first half of the vegetative period and no other plant food elements were affected. An inadequate supply of potash decreased the percentage of potash and increased the percentage of lime. During the early period of growth a lack of potash increased the percentage of nitrogen, but seemed to have no important effect on the phosphoric acid content. A lack of nitrogen manifested itself during early growth through a decrease in the nitrogen and potash content and an increase in the lime content, while the phosphoric acid content was not modified to any important extent. The percentage content of lime was inversely proportional to the percentage potash content of the plant.

A heavy application of phosphoric acid on the plat receiving a complete fertilizer increased the absolute quantities of dry matter and plant food in the first half of the vegetative period and decreased the same toward the close of the growing period. The lack of potash resulted in a marked decrease in the absolute quantities of dry matter, nitrogen, phosphoric acid, and especially in potash. The quantities of lime, on the other hand, were increased during early growth when there was a lack of lime in the soil, but during the ripening period a reduction took place and the quantity of lime in the crop on this plat was smaller at this time than in the plants on the plat receiving the complete fertilizer. An insufficient supply of nitrogen depressed in nearly all cases the absolute quantities of dry matter, nitrogen, lime, potash, and phosphoric acid.

In studying the influence of weather conditions it was found that the weather had a modifying effect on dry matter production and also to a certain degree on the use the plant made of nitrogen. No definite results with reference to potash, lime, and phosphoric acid in this connection are reported.

The results further indicate that in the early stages of growth, before the root nodules have become active, a small application of nitrogen in a readily soluble form would be very beneficial. Lime and phosphoric acid are needed during the early stage and especially when the plant blooms and forms its fruit. Potash is needed during the entire period of growth. It is stated that the bush bean is adapted to the use of plant food supplied in barnyard manure and that it is capable of using phosphoric acid given in slowly soluble form.

Clover growing on the loess and till soils of southern Iowa, W. H. Stevenson and E. B. Watson (*Iowa Sta. Bul. 98, pp. 44–66, figs. 9*).—Pot culture and field experiments are reported, with suggestions regarding the growing of clover in southern Iowa.

In the pot culture tests 1 gal. pots were filled with soil and the effects of manure and lime were studied. In the pot receiving manure at the rate of 16 tons per acre the weight of the crop was 45.9 gm., as compared with 8.8 gm. from the untreated pot, the number of plants being 13 in each case. It was found that lime was not beneficial on the soil used in the test, for a pot treated with lime at the rate of 1 ton per acre showed little or no advantage over the check test.

The field investigations had reference to the effects of a nurse crop, manure, lime, fertilizing material, time of seeding, and character of soil. Lime was applied as finely ground limestone at the rate of 1,000 lbs. per acre, phosphorus as steamed bone meal at the rate of 200 lbs., and nitrogen as dried blood at the rate of 800 lbs. Mixed barnyard manure was used at the rate of 8 tons per acre. Red clover was seeded at the rate of 8 lbs., alsike clover at the rate of 6 lbs., and oats at the rate of 2 bu. per acre.

Clover when grown alone produced a yield from 2 to 4 times as great as when grown with oats as a nurse crop. The plat seeded April 25 produced the heaviest crop, but all were very satisfactory. Manure was decidedly beneficial, in one case the crop being increased from 2,800 lbs. to 5,120 lbs. per acre. The use of phosphorus gave nearly double the yield, while with potash the crop did not increase either when it was applied alone or in combination with phosphorus. With nitrogen, there was an increase of 1,800 lbs. of clover hay per acre over a plat grown with the minerals without dried blood. It is advised, however, that nitrogen should not be purchased in commercial fertilizing materials but should be supplied in barnyard manure or in green manures.

It was further shown that there is practically no difference in the relation of loess and till soils of southern Iowa to the production of red clover. It was observed that clover seed may be carried to the field by manure in such quantities as to improve the stand. While alsike clover was found well adapted to

the soils under investigation it produced only approximately one-half as much hay as red clover.

The flax plant; its cultivation for seed and fiber, W. SAUNDERS (*Canada Cent. Expt. Farm Bul. 59, pp. 5–13*).—This bulletin contains a general discussion of flax culture under Canadian conditions. Particulars relating to the production of dressed flax as well as the production of flaxseed in Canada are given, and some of the results with flax at the different Canadian experiment stations are reviewed.

Millet, C. G. WILLIAMS (*Ohio Sta. Circ. 81, pp. 6*).—The uses of millet and the culture of the crop are briefly discussed and the different varieties, grouped under foxtail millets (*Chætochloa italica*), broom-corn millets (*Panicum miliaceum*), and the barnyard millets (*P. crus-galli*), are described. In addition, Pearl millet (*Pennisetum spicatum*) and teosinte (*Euchlæna mexicana*) are noted.

The deterioration of Red Texas oats in Kansas, H. F. ROBERTS and G. F. FREEMAN (*Kansas Sta. Bul. 153, pp. 147–164, figs. 5*).—Investigations were made to determine why Red Texas oats growing for 2 or 3 years in Kansas give way to a variety having black chaff. The seed of the Red oats as brought from Texas is always mixed with the black variety, but in that State the black oats does not become preponderant.

A study of the varieties shows them to be distinct. The red variety is low and spreading, tends to stool, and has narrower leaves than the black oats, which is upright, broad leaved, and tillers but little. In nursery plats the red oats averaged 8.6 culms and the black 7 culms per plant. The average number of heads per plant was 4 and 2.6 for the red and black oats respectively, or a superiority of 54 per cent in favor of the red. In average number of spikelets per head the black oats showed a superiority of 83 per cent, in the average number of heads per plant of 19 per cent, in the average weight of each spikelet 20 per cent, and in the average total weight of spikelet per plant a superiority of 43 per cent.

In mixtures of the 2 varieties containing 25, 50, and 75 per cent of red oats grown under usual field conditions, the black oats was superior by 6 per cent in the number of bearing heads and by 8 per cent in the weight of the grains. The black oats showed an increase in every case. Pure lots grown in 40 alternate rows and sown in the way usual in the field yielded at the rate of 1,740 lbs. of straw and 19.4 bu. of grain for the red and 3,000 lbs. of straw and 47 bu. of grain for the black variety. Close-pollinated plants of each sort yielded seed which came true.

While these results show that the black oats are apparently better yielders than the red, it is stated that in practice the Red Texas variety is superior in quality and yield and that this is largely due to the shattering in the black variety. It is concluded that the black oats is an admixture in the imported seed, that it does not originate from the red variety, and that pure-bred red oats free from the black seed can be grown.

Canadian field pea, A. ATKINSON (*Montana Sta. Bul. 68, pp. 83–90, pls. 3*).—Directions for growing Canadian field peas are given and the different uses of the crop are explained. According to the reports of farmers who have grown the crop in Montana on a large scale yields of 29 bu. of seed per acre have been secured.

Cooperative potato experiments for 1908, W. J. GREEN and L. H. GODDARD (*Ohio Sta. Circ. 77, pp. 3*).—Brief outlines of different experiments with potatoes proposed for cooperative work with the station are given, together with a blank to make application for taking part in the work.

Rice book (*Kansas City, Mo. [1908], pp. 32, figs. 16*).—This is a popular treatise in rice culture in the coast counties of Texas and Louisiana. In addition to a general discussion of the subject, the location of a number of rice canals and rice mills is given.

The importance of sodium to the sugar beet, K. ANDRLÍK and J. URBAN (*Ztschr. Zuckerindus. Böhmen, 32 (1908), No. 4, pp. 208–216*).—The results of experiments are presented in tables and briefly discussed.

It was observed that the greater the quantity of potash and nitrogen as compared with the quantity of sodium in the soil, all substances acting simultaneously, the higher the sugar content of the beet. When the quantity of sodium was increased with reference to the other two substances the sugar content was reduced. During the early development of the plant larger quantities of sodium than of potash were present, but after 106 days of growth the quantities of the two substances were about equal, while later and until harvest the quantity of potash continued to increase and was higher than the quantity of sodium. It is stated that in general the more sodium taken up by the beet plant the lower was the sugar content of its root.

The quantity of proteid substance produced in the sugar beet during the first year of its growth, K. ANDRLÍK (*Ztschr. Zuckerindus. Böhmen, 32 (1908), No. 5, pp. 255–262*).—The investigations reported show that the beet plant produced per hectare in dry years from 420 to 700 kg. of proteid substance, the average being 610 kg., and in years with sufficient rainfall from 650 to 900 kg., or an average of 790 kg. Heavy applications of a nitrogenous fertilizer increased the production of proteids to from 800 to 900 kg., and an application of 1,000 to 1,100 kg. per hectare of nitrate of soda showed a proteid production of 900 to 1,040 kg. per hectare. A heavy yield of beets contained from 70 to 74 per cent of the proteids in the leaves, and a lower yield only from 50 to 60 per cent. In general all conditions tending to increase the yield of leaves favored a high production of proteid substances. To obtain a high yield of proteids requires heavy applications of nitrogenous fertilizers.

No relation was apparent between the quantity of total proteid substance produced and the sugar content of the root. In these experiments the proportion of sugar varied from 4.1 to 13.2 parts to 1 part of proteid substances.

Further studies on sugar-beet plants more than one year old, F. STROHMER, H. BRIEM, and A. STIFT (*Mitt. Chem. Tech. Vers. Stat. Cent. Ver. Rübenz. Indus. Österr.-Ungar., No. 194, pp. 15*).—The investigations indicated that the cane-sugar content of the sugar beet in its second or third year, when it is desired that further growth shall be made, must not fall below 5 per cent, but that while a definite quantity of sugar in the beet is necessary to induce growth for further seed production the yield of seed is in no way connected with the sugar content, but is rather the result of the number and the life energy of the healthy cells of the root.

The changes in the composition of the root during growth were along the same line, whether the beet was 1 or 2 years old. The 1-year-old mother beets produced much larger quantities of dry matter than was secured from the 2-year-old mother beets. It was further observed that the quantities of nitrogen, phosphoric acid, and potash in the roots of 1 and 2 year old mother beets were insufficient for the production of new organic substance, and that for this purpose applications of these plant-food elements must be made. Both kinds of beets require larger quantities of nitrogen than of potash, and of potash larger quantities than of phosphoric acid. The quantity of plant food required to produce 100 gm. of additional dry matter in the beet was practically the same for 1 and 2 year old mother beets.

Annual sugar beets, M. Deutsch (*Atti 6. Cong. Internaz. Chim. Appl., 3 (1906), pp. 591–601*).—A paper and discussion are presented on the subject of seed production in sugar beets during the first year of their growth.

After reviewing experiments along this line, together with his own experiences, the author concludes that the beet is a biennial when conditions do not prevent it. It becomes an annual after a cessation of growth caused by cold weather, a prolonged drought, or other unfavorable conditions which may escape our observations. Vigorous plants not only resist this tendency of producing seed the first year better than weaker individuals, but they also are less likely to be attacked by the different beet diseases. The author attributes the phenomenon in a general way to the individuality of the beet, stating that the vigorous plants are resistant while feeble plants are not, and that seed production during the first year is regarded as lack of vigor in the individual.

Growing sugar-beet seed in South Dakota, J. H. Shepard (*South Dakota Sta. Bul. 106, pp. 320–349, figs. 8*).—Experiments in growing sugar-beet seed in cooperation with this Department are reported. Cultural and climatic notes are given, the selection of mother beets is described, and the station work with sugar beets in previous years is briefly reviewed.

Owing to a late spring the beets were planted from May 11 to 17, cultivation was given from June 1 to August 13, and thinning was done from July 2 to 8. The first killing frost on September 27 did little damage to the best varieties, but some of the tenderer sorts and some of the stock beets showed the effect of frost very plainly. The beets were harvested October 14 to 23.

No sugar beet with less than 14 per cent of sugar was saved. The data given in tables show that the best strain was Kleinwanzleben Pioneer, which ranged in sugar content in the beet from 14.2 to 24.8 per cent, with an average of 17.9 per cent. Of the 30 beets analyzed of this variety 13 contained over 18 per cent.

Seedling canes and manurial experiments at Barbados 1905–1907, J. P. d'Albuquerque and J. R. Bovell (*Imp. Dept. Agr. West. Indies Pamphlet 49, pp. 119*).—The manurial experiments were carried on at Dodds botanic station and at five sugar estates situated in typical parts of the island. Five of the stations were on black soils and one on red. The weather conditions were not very favorable and in many instances the average weight of canes per acre was small, especially among the rattoon canes. The root disease was also prevalent and was probably the cause of many of the low yields of canes among the rattoons.

This season on the estates selected variety B 3696 gave the best results on the black soils, with a yield of 2,045 lbs. of sucrose per acre in excess of that given by White Transparent, the standard variety, while B 208 stood next with an increase of 1,494 lbs. These yields represent increased values of $29.61 and $21.63 per acre, respectively. B 147 came third and showed an increased value of $13.34 per acre. On the red soils as plants and rattoons B 1566 again gave the best results, producing 8,394 lbs. of sucrose per acre as plants and 6,645 lbs. as rattoons against 6,006 lbs. per acre from White Transparent as plants and 5,736 lbs. as rattoons, representing a total gain of $47.73. B 3635, D 95, B 1753, B 376, and B 1529 gave good results on black soils, and D 95, B 376, and B 208 on red soils.

The average results of the best varieties for the last 4 years show that on black soils B 3696, B 1753, B 1529, and B 147 gave the best returns as plants, the increases per acre being valued at $34.52, $31.71, $16.18, and $11.64, respectively, as compared with White Transparent. Taking plants and rattoons together, B 208 produced on an average 5,542 lbs. of sucrose per acre as against 5,197 lbs. by White Transparent. On red soils as plant canes B 3405 gave the

best results, and B 3412, B 3390, B 1566, B 208, B 1529, and B 376 gave returns far in excess of those of White Transparent. Taking plants and rattoons together, B 376, D 95, and B 208 gave increased values per acre of $10.84, $10.59, and $8.13, respectively, as compared with the standard variety.

As in previous years the fertilizer experiments showed that large and profitable increases are obtained by the addition of commercial fertilizers supplying nitrogen to the ordinary application of barnyard manure, and that ordinary applications of barnyard manure together with commercial fertilizers gave better results than large quantities of barnyard manure without commercial fertilizers. The use of phosphatic and potassic manures resulted in considerable variation of yield, but in some instances notable increases were obtained.

In 1905, 4,874 seedling canes were planted and of these 118 varieties were selected for replanting at the close of 1907. At the end of 1906, 219 seedlings were obtained, which are now under observation. Five canes produced by artificial hybridization are under experimental cultivation.

Experiments in growing tobacco under shade on the east coast of Sumatra, F. W. T. Hunger (*Meded. Dept. Landb. [Java], 1907, No. 3, pp. 112, pls. 3*).—The shade culture of tobacco in the United States is reviewed, statistics on the importation of Sumatra tobacco into the United States are given, and the results of shade culture experiments in Deli in 1903 are reported. In these experiments it was observed that the leaves of all the different types were much lighter in weight when grown under shade than when grown in the open, that shade culture increased the proportion of the higher grade of leaf and also produced a tobacco much lighter in color than that obtained in the check test, and that the length of the leaves produced in the open was more satisfactory than that of the shade-grown leaves.

When the leaves of the tobacco in the check experiments were taken from the plants at noon no light colored tobacco was produced. Harvesting the shade-grown leaves at noon resulted in the same color of the tobacco as harvesting the open-grown leaves in the morning. These results are considered as affirming the conclusion of Mohr, that under ordinary conditions taking the leaves from the plants in the morning gives a larger percentage of high-grade material than harvesting at noon.

The meteorological observations made in connection with this work are discussed, and the data relating to sunshine, air and soil temperatures, rainfall, and relative humidity are recorded in tables. The average air temperature during the day under the tents was higher and the maximum temperature was lower than in the open. The minimum temperature recorded nights was higher under the tent and the temperature of the covered soil was at all times lower than on the check plats. The relative humidity of the air under the tents was higher than in the open, but the rainfall reaching the covered soil was much less than the rainfall on the unprotected plats.

The prophylaxis of shade growing against mosaic disease of tobacco is discussed, and it is believed that shade growing reduces the prevalence of this malady.

In a general discussion of the results, the author points out that shade growing increases the cost of production 100 per cent under the conditions under which these experiments were made.

The art of seed selection and breeding, A. D. Shamel (*U. S. Dept. Agr. Yearbook 1907, pp. 221–236, pls. 5*).—This article treats of the art of seed selection and breeding as the practical application of methods of breeding to the production of improved varieties of plants for commercial agricultural purposes, and the science of breeding as meaning the work of the investigator in determining by means of experiments the principles relating to the different

problems of breeding. Fields of work for the breeder's art are pointed out and examples of results secured are cited. The work of tobacco breeding in the Connecticut Valley (E. S. R., 18, p. 1042) and of securing by selection a hardy variety of hairy vetch for that region is noted. A brief description of the origin of Whelchel dent corn is given to illustrate the use of crossing in securing an improved variety.

The character and qualifications of the plant breeder and his method of work are discussed, and as illustrations the history of Reid Yellow Dent corn, Triumph cotton, and White Burley tobacco is briefly presented.

Improvement of grasses and other forage crops, B. T. GALLOWAY (*U. S. Dept. Agr. Yearbook 1907, pp. 145–148, pls. 2*).—The work here reported in breeding grasses and other forage crops was begun by the Bureau of Plant Industry of this Department 4 or 5 years ago, and embodies some of the results secured.

As the result of crosses between Kentucky blue grass and Texas blue grass 10 distinct types, 8 of which have rhizomes and all of which are taller than Kentucky blue grass, have been secured. In some the leaves are broader, in others narrower than in Texas blue grass, and the hairy processes which prevent the seed of this grass from being sown broadcast are lessened 75 per cent.

A promising hybrid between a clover from Prince Edward Island and the European zigzag clover (*Trifolium medium*) produces large root stocks and appears perfectly hardy at Washington, D. C. A cross between Peruvian and Turkestan alfalfa, designated as No. 15, has a dark stem, medium-sized leaves, and furnishes a large amount of forage. It is also a good seed producer and is apparently hardy near Washington. A number of crosses between varieties of cowpea have been secured. The cross between the Indian and the Unknown variety excelled all varieties grown in length of vine. About 10 per cent of the seedlings grown came into bearing early and these were upright in growth. It is stated that in many cowpea hybrids the seed was not changed in color in the first, second, and third generations. The Whippoorwill-Iron and Red Ripper-Iron crosses, however, split up into 12 very dissimilar sets of peas in the third generation. The Whippoorwill and Iron crosses are satisfactory at present in earliness and seed production, but so far only a small proportion is of the bushy habit of growth.

Improvement of cereals, A. J. PERKINS and W. J. SPAFFORD (*Jour. Dept. Agr. So. Aust., 11 (1908), No. 6, pp. 540–568, figs. 8*).—This article is a discussion of the work in the improvement of cereals carried on at the Roseworthy Agricultural College. The different varieties of wheat and barley obtained by selection and crossing are described, and the crosses effected in 1907 are enumerated.

Modifications in cereal crops induced by changes in their environment, T. L. LYON (*Proc. Soc. Prom. Agr. Sci., 28 (1907), p. 144–163*).—In discussing this subject this paper reviews some of the experiment station work in this country, furnishing data with reference to whether or not plants adapt themselves to change of climatic or soil influences during the life of an individual and to what extent, if any, this is operative in producing new strains, varieties, or even species.

The germination of vegetable seeds, E. BROWN and W. L. GOSS (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 131, pp. 5–10*).—During the spring of 1907, 2,778 packets of so-called "commission" vegetable seeds were purchased in Maine, Vermont, Massachusetts, Kentucky, Wisconsin, North Dakota, Kansas, and Colorado. These were put up by 27 seedsmen and included seeds of 26 kinds of vegetables. The average germination was found to be 62.2 per cent. The average germination of seeds from one firm was only 37.3 per cent, and from another 44.3 per cent. The variation of germination of different packets of the

same kind of seed from the same firm was in several cases more than 90 per cent. By 21 of the 27 seedsmen represented 200 lots of seed were put up which germinated 10 per cent or less, and by 13 packeting houses 62 lots were put up which entirely failed to germinate. The average germination of the "commission" seeds tested was 25.7 per cent lower than that of the seeds sent out in the Congressional distribution during the past 6 years.

The effect of animal digestion and fermentation of manures on the vitality of seeds, E. I. OSWALD (*Maryland Sta. Bul. 128, pp. 265–291, figs. 3*).—The seeds of 52 species of weeds were placed in piles of horse manure, cow manure, and of horse and cow manure mixed in equal quantities and allowed to remain for 6 months. During the first 60 days the lowest temperature recorded in the piles was 40° F., and the highest 201°, 168°, and 188°, and the average temperature 134°, 120°, and 122° for the horse, cow, and mixed manure, respectively. After 60 days the heat had all passed off and no further readings were taken. At the end of the 6 months, when the buried seeds were sown on sterilized soil, no growth was obtained.

In other tests the seeds were left in the manure for only a month. No seeds germinated after this treatment, but some seeds of rib grass (*Plantago lanceolata*), horse nettle (*Solanum carolinense*), common plantain (*P. major*), large ragweed (*Ambrosia trifida*), bitter dock (*Rumex obtusifolius*), and mallow (*Malva rotundifolia*) were found still hard and firm.

For the purpose of studying the effect of animal digestion on weed seeds 3 healthy yearling calves were fed seeds from a large number of common weeds, and in the germination test in the greenhouse after the seeds had passed through the animals the conditions usually existing when top-dressing with fresh manure, plowing under fresh manure, and pasturing cattle on fields is practiced were approximated. Of the seeds in the manure used as a top-dressing 12.8 per cent, of those in the manure turned under 2.3 per cent, and of those in the manure left as it is found in pastures 3.1 per cent grew. The seeds giving the greatest germination were those of crab grass, Jamestown weed, ragweed, and horse nettle.

HORTICULTURE.

Manuring and fertilizing truck crops, C. P. CLOSE and T. H. WHITE (*Maryland Sta. Bul. 126, pp. 219–242, figs. 4*).—This bulletin contains the results of several manuring and fertilizing experiments with truck crops in which it was sought to bring out the relative values of stable manure and commercial fertilizer, plowing under commercial fertilizer as compared with using it as a top-dressing harrowed into the soil just before planting the crop, heavy and light applications of commercial fertilizers and of fresh and rotted stable manures, rotted manure turned and unturned while in the compost heap, commercial fertilizers derived entirely from mineral sources and those derived entirely from animal and vegetable sources, and the use of stable manure as compared with commercial fertilizer for sweet potatoes.

The tests were conducted on four series of plats. Series D was started in 1899, and series A, B, and C in 1902, 1903, and 1904, respectively. The manures and commercial fertilizers were used in connection with green crops turned under. As near as possible, the same amount of actual plant food was supplied in the chemical fertilizer as was found in the stable manure. A detailed account is given of the work conducted on each series. The results which are tabulated and discussed under their separate headings, are briefly summarized as follows:

"Stable manures always increased the yields, but valued at $2 per ton did not give as much profit as commercial fertilizer.

"Fresh manure spread in winter did not give as much increase as the same amount rotted and plowed down at same date in the spring.

"Turning the manure while rotting was better than leaving it without being turned.

"Commercial fertilizers plowed under in the spring invariably gave larger yields than when sowed on the surface just before planting in the summer.

"About 750 lbs. of commercial fertilizers seemed to be more profitable than three times that amount.

"Continuous crops of sweet potatoes on same land does not appear to be bad practice.

"The quality of the crops, cabbage and potatoes especially, grown upon the check plats, was of very poor grade.

"The soil on plats heavily dressed with mineral fertilizers does not seem to have been changed or injured any more than where the organic fertilizers were applied.

"The seasons through which this work has been followed have all been very moist and some were quite wet."

In the work with sweet potatoes, commercial fertilizer gave the best results for the first three years. The results as a whole, however, appear to favor the use of a combination of stable manure and commercial fertilizer. The smaller quantity of stable manure (5 tons per acre) produced almost as large a crop and gave much greater profits than larger applications of manure.

Truck farming in the Atlantic Coast States, L. C. Corbett (*U. S. Dept. Agr. Yearbook 1907, pp. 425–434, pls. 3*).—The writer points out that the development and extension of truck farming in the Atlantic Coast States has been coincident with the development of transportation facilities throughout that section and briefly discusses the essential differences existing between the methods of growing certain standard crops in various portions of the area. The crops discussed include lettuce, cucumbers, cabbage, potatoes, celery, onions, beans, asparagus, tomatoes, and peas.

Chile culture, F. Garcia (*New Mexico Sta. Bul. 67, pp. 4–32, figs. 10*).—This bulletin contains popular instructions for growing and harvesting chile, including notes on diseases and insect pests. Tabular data are also given on the following chile experiments conducted at the station: Ridge *v.* level culture with field-sown seed, field-sown seed *v.* transplanted plants from seed started in cold frames; yield and cost of production of green and red chile, and the effects of sodium nitrate upon the yield. The results, however, are considered only tentative as the investigations have not been conducted long enough to arrive at definite conclusions.

[Variety tests at Wisley, 1906–7] (*Jour. Roy. Hort. Soc. [London], 33 (1908), No. 1, pp. 184–315*).—Cultural and descriptive notes are given of a large number of varieties of asters, cannas, dahlias, tulips, melons, strawberries, French beans, kales, onions, potatoes, tomatoes, and miscellaneous flowers grown at Wisley during the seasons of 1906 and 1907, together with brief notes on tests of fertilizers, insecticides, implements, etc.

Report of the government horticultural experimental fields in South Holland for 1907, C. H. Claassen et al. (*Verslag Rijkstuinbouwproefvelden Zuid-Holland, 1907, pp. 156*).—This pamphlet embraces the reports from over 150 cooperative cultural, variety, fertilizer, and spraying experiments with a large variety of fruits and vegetables conducted at various localities in South Holland in 1907, under the direction of the professor of horticulture at Boskoop.

Experimental fruit stations of the Province of Quebec, A. Dupuis et al. (*Rpt. Min. Agr. Prov. Quebec, 1907, pp. 139–167*).—Brief reports on orchard and small fruits being grown at nine fruit testing stations in Quebec. A variety

list of fruits which resist the climate and yield good crops, based on the reports of the pomological society of the Province of Quebec and of the horticultural societies, and on the tests of the fruit stations, is also given.

Miscellaneous greenhouse notes, C. P. Close, T. H. White, and W. R. Ballard (*Maryland Sta. Bul. 127, pp. 243–263, figs. 4*).—The results are given of greenhouse investigations which have been conducted during the past 8 years.

In continuation of previous work with fertilizers in solution on chrysanthemums (E. S. R., 14, p. 38), in which cow urine supplemented with phosphates gave good results, tests for 5 years were made of chemical fertilizers in solution containing approximately the amounts of nitrogen, phosphoric acid, and potash found in the urine; muriate of potash, nitrate of soda, and dissolved South Carolina rock being the principal chemical combination used. The urine was used in conjunction with dissolved South Carolina rock. The chemicals gave as good results as, and in some cases slightly better results than, the cow urine. A sheep manure solution was also tried for 3 seasons which appears to have given better results than either of the other mixtures. Lettuce followed the chrysanthemum crop in each case, and the residual fertilizers gave results similar in general to those obtained with the chrysanthemums.

Rye and cowpeas, both alone and combined, and crimson clover were tried as soil formers for greenhouse purposes, the soils on which these were grown being compared with the usual sod and manure compost and white clover sod soil. The test was continued for 5 years, lettuce following chrysanthemums each year, and showed in general that the source of the soil is not a very important consideration for these crops if the soil is properly supplemented with manure or fertilizer. The rye plat soil gave uniformly poorer results than the other cover crop soils tried. From the data secured for several years it also appears that soils enriched with well-rotted manure do not need heavy dressings of phosphate.

Although the necessity of removing greenhouse soils every year or so to avoid disease germs does not appear to be borne out by the work conducted at the station, where one crop of chrysanthemums and two crops of lettuce a year were grown on the same soil for 8 years, it is suggested that the grower who renews his soil annually will probably take the safest course. In a comparison of soil used year after year and of soil annually renewed conducted with carnations for 5 years, the plants on the new soil gave 2 flowers per plant more than those on the continuously used soil.

In an experiment to test the stimulating effect of nitrogen in different forms and amounts, the majority of the plats showed negative results for the 2 seasons tried. On the plats receiving per acre 300 lbs. of nitrate of soda and 500 lbs. of dried blood, respectively, there were more blooms than on the check plat. Dried blood used alone gave the longest stems, while the check plat had the largest flowers.

Tests made relative to the effects of fertilizers upon the stiffness of carnation stems clearly indicate that the use of phosphoric acid gives the stiffest stems, and that potash ranks next. Nitrogen in the form of dried blood gave very weak stems. The plat on which a complete fertilizer was used, however, gave a considerably larger number of flowers per plant and longer stems than any of the other plats, the size of the flowers being as large as the average and larger than those on the phosphoric acid plat.

In a 5 years' test to determine the best time of planting carnations, it appears that of plantings made on July 1, August 1, and September 1, the September planting gave a considerably larger number of blooms per plant. The number of blooms decreased the earlier the planting was made, but the early plantings gave the largest blooms and the longest stems.

The results of tests made of subirrigation *v.* surface watering for lettuce and carnations indicate that any benefit derived from subirrigation does not warrant the extra expense of construction. From the data secured there appears to be no marked difference between tomatoes, carnations, and lettuce grown in solid beds and those grown in benches.

Several ordinary garden varieties of tomatoes were compared with the Lorillard, a commonly used forcing variety. All of the varieties succeeded about equally well under glass, but with some varieties the fruit was too large for the winter trade. Tests were made for 4 seasons of different planting distances for tomatoes. A good average distance apart to set the plants appears to be 1 by 2 ft.

Progress in some of the new work [with vegetables and flowers] of the Bureau of Plant Industry, B. T. Galloway (*U. S. Dept. Agr. Yearbook 1907, pp. 139–145, pls. 3*).—A brief statement of the progress being made in the development of new lettuces and tomatoes for growing under glass and rust-resistant asparagus, and of improvements in lily culture, together with a description of a new summer-blooming dahlia, a hybrid form developed by G. W. Oliver and which has been named the Cosmos.

New hybrid fruits, N. E. Hansen (*South Dakota Sta. Bul. 108, pp. 3–16, figs. 8*).—In this bulletin, a continuation of previous work (E. S. R., 16, pp. 369, 370), brief notes are given on several hybrids resulting from crosses of the native sand cherry (*Prunus besseyi*) and the native plum (*P. americana*) with choicer fruits, including hybrids of the sand cherry with the following plums: Chinese Apricot, Japanese, Sultan, Gold, Bartlett, Climax, native, Persian Purple-leaved, and Pennock Hybrid; the Gold and Red June plums with the sand cherry; and the sand cherry with the peach and the European sweet cherry and apricot. Hybrids are also reported of reciprocal crosses between the native and European plum; *Prunus simoni* with the native plum, and the native plum with the Japanese plum and Chinese Apricot plum. Cuts are given of some of these hybrids, of which the more important are the Hanska and Tokeya, crosses of the native plum with the Chinese Apricot plum and of the native sand cherry with the Chinese Apricot plum, respectively.

The improvement of the native sand cherry by selection from many thousand seedlings is still in progress, and the fourth generation is about to fruit. Several of the third generation, which are an inch in diameter and of good quality, have been sent out for preliminary trial. Only one has been named, the Sioux.

The breeding work thus far shows that the native sand cherry amalgamates readily in hybridizing with other species, and that excellent results may be hoped for, especially with hybrids of the Japanese plums. It has been demonstrated that it is possible to secure fruits combining the hardiness of native stone fruits and at the same time approaching the size and quality of the choice cultivated stone fruits from Europe and Asia.

Promising new fruits, W. A. Taylor (*U. S. Dept. Agr. Yearbook 1907, pp. 305–320, pls. 8*).—Historical notes and descriptions with colored illustrations are given for several recently introduced or little known fruits and nuts that are considered worthy of testing in various sections of the country, including the Delicious and Ensee apples, Lambert cherry, Miller and Ruby persimmons, King orange, Sandersha mango, and Wolford, President, Sovereign, Kincaid, and Mantura pecans.

A study on the volume-increment of fruits, G. Rivière (*Jour. Soc. Nat. Hort. France, 4. ser., 8 (1907), Dec., pp. 747–750*).—Tabulated data are given, together with the conclusions reached, relative to a study made by the author in conjunction with G. Bailhache on the increase in volume through the growing season of the fruit of several varieties of early, medium, and late season

pears. The measurements were taken by entirely submerging the fruit in a special vase filled to the brim with water, the water thus displaced being caught and measured in a graduated glass.

It is concluded from this study that with pears the volume accretion of the fruit is very irregular and differs greatly among different varieties. The late maturing fruits show a maximum growth development during the periods directly preceding the harvest. Summer pears show the greatest increase in growth during the middle of their season. With autumn fruits the greatest increase was made from a month to 6 weeks before the harvest with some varieties to just previous to the harvest with others.

The orchards of Maine, E. F. HITCHINGS (*Bul. [Maine] Dept. Agr., 7 (1908), No. 1, pp. 39, pls. 2, figs. 6*).—Owing to the severe injury to the orchards in some sections of Maine during the winter of 1906–7, the author was called upon to make an investigation relative to the extent and causes of this damage. The present bulletin contains a report of this investigation, together with suggestions for the cultivation and care of fruit, including methods of controlling insect pests and fungus diseases. In all, 950 orchards were inspected with a total of 443,184 trees, of which number 24,613 were killed outright, and it is estimated that about the same number were injured more or less severely.

The orchards investigated included all conditions of location, culture, etc., but where the loss was heavy the conditions were found to be the same. The ground was but slightly frozen, a covering of snow prevented further freezing, and the cells in the cambium layer were destroyed by the sap or moisture being withdrawn quickly by a sudden freeze after the warm weather.

Survey and outlook of the fruit interests of the State (*Wyo. Bd. Hort. Spec. Bul., 1 (1907), No. 1, pp. 32, pl. 1, figs. 12*).—This bulletin contains a general survey of horticultural operations in Wyoming during 1907, including consideration of the operation of the horticultural law, the establishment of home nurseries, nursery and orchard inspection work, the record of the organization of the State horticultural society, and addresses on the future of horticulture in the State of Wyoming by J. M. Carey and on wind-breaks by W. W. Wolfe. The text is accompanied with illustrations of different varieties of apples grown in the State.

The status of the American lemon industry, G. H. POWELL (*U. S. Dept. Agr. Yearbook 1907, pp. 343–360, pls. 5, figs. 2*).—An account of lemon culture in California relative to its history and present development, methods of culture, protection against frost, insect and fungus troubles, and the cost of maintaining a lemon grove. The various phases of handling the crop are also discussed, including picking, washing, coloring, curing and storing. Tabular data are given showing the imports of lemons in the United States for the fiscal years 1900 to 1907 and shipments of lemons from southern California from 1897 to 1907. The annual import of lemons, mostly from Sicily, is given as about 150,000,000 lbs. The annual production in California approximates 100,000,000 lbs. As a result of the recent progress in the industry the demand for the best brands of California lemons is greater than the present supply.

Strawberries for New Hampshire, H. F. HALL (*New Hampshire Sta. Bul. 137, pp. 159–188, figs. 32*).—This bulletin was prepared for the benefit of the amateur as well as the commercial grower. Part one deals with the various cultural phases, including selection and preparation of soil, fertilizing, planting, varieties, cultivation, training, irrigating, mulching, harvesting, selling, renewal of old beds, and the estimated cost of production. Part two consists of descriptive notes, with illustrations in many cases, of varieties tested on the college grounds.

The tabular results are given of a test made to determine the relative value between thick and thin spacing. Plants standing 6 ins. apart in wide matted rows gave the greatest average yield of number one berries. A 2½ ft. wide matted row with alleys 18 to 20 ins. is believed to be the best method for commercial growers to adopt.

A study on the quality and production of several red varieties of grapes, H. Faes and F. Porchet (*Chron. Agr. Vaud, 21 (1908), No. 6, pp. 131–139*).—Tabulated data relative to a test of several varieties of red and white grapes are reported for the years 1902, 1905, 1906, and 1907, circumstances preventing the collection of similar data for 1903 and 1904. The data show the average fruit production and sugar content in grams per plant, as well as the average percentage of sugar and acid in the must of each variety. The different varieties are discussed and one red variety, the Limberger, is especially recommended for the region of Vaud on account of its great resistance to rot and its satisfactory sugar content.

A study relative to the accumulation of sugar and the decrease of acidity in the fruit of Chasselas Doré grape, G. Rivière and G. Bailhache (*Jour. Soc. Nat. Hort. France, 4. ser., 9 (1908), Feb., pp. 125–127*).—In continuation of previous investigations by the authors (E. S. R., 19, p. 844), the progressive accumulation of sugar and the decrease of acidity in the berries from their formation to the period of maturity was traced with fruit growing on both ringed and unringed shoots. Two bunches of grapes were grown to a shoot, and analyses were made on August 5 and 10, September 5 and 19, and October 10 and 22. The effect of ringing the shoots was noticeable in the early stages of growth by both the greater increase in sugar content and decrease in acidity.

Forcing plants with electricity, H. Bos (*Umschau, 12 (1908), No. 12, pp. 228–232, figs. 3*).—An account, including a description of the apparatus used and the results obtained, is given of experiments conducted by the author in forcing flowering shrubs and bulbs with electricity. The operation consisted in passing a weak current through the plants. In most cases the bulbs were seriously damaged by this operation, no positive results being secured. With some of the shrubs a weak current passing through the plant appeared to shorten the resting period of the plant and force it into bloom. In some cases this development appeared to take place in those branches through which the current did not directly flow. The experiments are not considered extensive enough to warrant any definite conclusion as to the value of this method of forcing plants.

Roses; their history, development, and cultivation, J. H. Pemberton (*London and New York, 1908, pp. XXIV+336, pls. 11, figs. 32*).—In part 1 of this popular work consideration is given to the botany of the rose and to descriptions, including notes on the history and development of British wild roses, wild roses of other countries, and summer and autumn flowering roses. Part 2 is devoted to rose cultivation, including the soil and its treatment, manures, planting, pruning, budding, and methods of propagation, together with chapters on the culture of roses for exhibition purposes, exhibiting, judging, growing roses under glass, and insect pests and fungus diseases. A descriptive list is given of selected roses recommended for cultivation, together with the method of pruning each type.

The bibliography of the chrysanthemum, C. H. Payne (*Jour. Soc. Nat. Hort. France, 4. ser., 8 (1907), Dec., pp. 738–747*).—This bibliography is believed to be the most complete on this subject, and includes over 140 general treatises and society publications of various countries, dealing with the history, culture, and classification of the chrysanthemum.

Yard and garden, T. Baker (*Indianapolis, Ind., [1908]*, *pp. 418, pl. 1, figs. 132*).—This popular work is offered as a book of practical information for the amateur gardener in city, town, or suburb. Consideration is given to the planning and treatment of the home grounds, the use and culture of vines, annuals, perennials, bulbous and tuberous rooted plants, shrubs, and trees, varieties recommended for different purposes, seasons, and methods of treatment, soil and fertilizers, insects and diseases, and the indoor winter window garden. An appendix contains planting tables of bulbous plants and annuals for various purposes, together with diagrams illustrating different forms of planting.

FORESTRY.

Report of board of directors of the American Forestry Association for the year 1907 (*Forestry and Irrig., 14 (1908), No. 3, pp. 153–162, figs. 2*).—This report, presented at the last annual meeting of the association, contains a summary of the work of the association for the year, together with an outline of the forest situation and of forestry work in the various States. The advancement in educational work in forestry at different universities and schools is also reviewed, together with instances of increased interest in tree planting and forest conservation on the part of cities, business concerns, and individuals.

Report of the forestry branch for the period July 1, 1906, to June 30, 1907, R. Dalrymple-Hay (*Rpt. Forestry Branch N. S. Wales, 1907, pp. 25, pls. 6*).—This report deals with various forestry operations for the year ending June 30, 1907, including alterations in areas, administrative and sylvicultural work, revenues, expenditures, imports and exports of timber, inspection of timber for export, and general notes on the timber industry.

In a series of appendixes several subjects dealing with forestry in New South Wales are discussed, including forest conservation, the forest survey, a description of state forestry as existing at present, timber supplies of New South Wales and their relation to public works, timber legislation, and the annual report of the government botanist on forestry work for the year. Illustrations are also given of several species of eucalypts.

The causes of timber lines on mountains, C. H. Shaw (*Abs. in Science, n. ser., 27 (1908), No. 687, pp. 339, 340*).—The author describes observations on the timber lines of the White Mountains, Adirondacks, and Selkirk Mountains. In the last-named case it is held that snow, acting as a mechanical agency, plays an important part, either by the direct breaking of the trees under the weight of the snow, or by rendering the small trees and lower branches particularly liable to fungus attacks on account of the late-lying, wet beds of snow.

The author states that when the timber line is restricted by winds, the trees are limited in height and grow thickly in level-topped associations. The upper outposts of the forest are in local depressions or sheltered spots. On the other hand, when the struggle of the trees for existence is with the snow, the forest as altitude increases is resolved into groups of trees. These become more separated and the upper groups occupy ridges and local elevations. The trees injured by the snow possess the spire form, with flourishing upper shoots, but the lower branches and foliage are dying or dead, broken by snow, and attacked by fungi.

Cutting timber on the National Forests and providing for a future supply, R. Zon (*U. S. Dept. Agr. Yearbook 1907, pp. 277–288, pls. 3*).—The author discusses the Government policy of dealing with the timber land on the public domain during three periods as follows: (1) Prior to the act of Congress of June 4, 1897, which gave the Secretary of the Interior authority to sell timber

from the forest reserves; (2) from 1897 to the transfer of these forest reserves to the Forest Service of the Department of Agriculture on February 1, 1905; (3) from 1905 to the present time since the transfer of these forests to the Forest Service. The influence of each of these periods on the condition of the cut-over land and on the kind of forest that such land will produce is discussed and the measures by which the Forest Service aims to establish reproduction on these cut-over areas are briefly stated.

Chestnut oak in the southern Appalachians, H. D. Foster and W. W. Ashe (*U. S. Dept. Agr., Forest Serv. Circ. 135, pp. 5–23*).—This circular deals with the botanical and commercial distribution of the chestnut oak, the extent and character of the present stand, the wood and its uses, sylvical characteristics and requirements, reproduction, susceptibility to injuries and management.

The chestnut oak grows in rocky exposed situations where white oak and other more valuable hardwoods will not thrive, hence aside from its timber value, it is considered important as a protective covering on the steeper slopes. Owing to its sprouting ability and comparatively rapid sprouting growth, it is advised that the chestnut oak be grown as a coppice forest, particularly for the production of ties.

Notes on forest and ornamental trees on the grounds of the Agricultural and Mechanical College of Texas, H. Ness (*Texas Sta. Bul. 105, pp. 3–14, pls. 10*).—The station has grown in its arboretum and on the campus a large number of trees, representing several genera, of which the principal are ash, birch, beech, box elder, catalpa, chestnut, China tree, elm, hackberry, Japan varnish tree, locust, linden, magnolia, maple, mulberry, poplar, sycamore, sweet gum, willow, walnut, arbor vitæ, red cedar, cypress, and pine. Notes are given on the behavior of these various trees under the soil and climatic conditions of that region, together with some general observations on tree growth, transplanting oaks and conifers, and subsequent care.

The greater number of the fast-growing soft-wooded trees, which confine their roots almost exclusively to the surface soil, proved to be failures. Such trees make a continuous, rapid growth under moist conditions in the spring, but this growth is checked by a few weeks of drought before the newly formed tissues have become sufficiently hardened to withstand the strong transpiration, and as a result the leaves fall off prematurely and the extremities of the shoots die in August and September. The hardwood deciduous trees and many of the conifers, which have an intermittent growth, appear to be well adapted to endure in regions with an irregular supply of moisture.

The physical characteristics of the hardwoods of Australia, G. A. Julius (*Perth: Govt., 1907, pp. 6, pls. 21*).—This report, supplementary to the report of some 16,000 tests of Western Australian timber made in 1906 (E. S. R., 19, p. 42), gives results of some 8,800 tests of Eastern Australian hardwoods. The tests were made for cross-bending, end and cross compression and hardness at both 12 per cent moisture and when green, and of direct strength in tension and shearing, being conducted upon the same machinery and in the same manner as those of the previous year. Plates are given representing graphically the strength of the various timbers at all degrees of seasoning, together with comparative data of all the tests conducted during 1905, 1906, and 1907, thus including practically all the commercial hardwoods of Australasia.

In regard to the strength of the hardwoods as compared at 12 per cent moisture, the first 9 species in order of their strength were Yate, Ironbark, Salmon Gum, Tuart, Wandoo, Morrell, York Gum, Grey Box, and Karri. It is pointed out that all of these are native to Western Australia except Ironbark and Grey Box, which were obtained from New South Wales.

The use of wooden poles for overhead power transmission, C. WADE (*Jour. Inst. Elect. Engin. [London], 39 (1907), No. 185, pp. 304–358, pls. 3, figs. 22*).—In this paper, read before the Institution of Electrical Engineers in May, 1907, an account, together with the discussion which followed, is given of experiments dealing with the strength, breaking load, wind pressure, deflection, etc., on single poles and double A-shaped poles. The tests were conducted by the author assisted by Professor Goodman of Leeds University. The methods of procedure are described and illustrated and the tabulated results, together with the method of reducing them, are given in an appendix by Professor Goodman. The discussion which followed is also reported.

In general the results showed the superiority of an A-shaped pole over a single pole for high-tension work, both as regards economy and strength, the "A" pole being shown to be at least four and one-half times as strong as a single pole.

The usual breaking point of a single pole when tested to destruction was about 5 ft. above ground level or about 10 ft. from the butt. Hence, the diameter of the pole at this point is the most important dimension to consider in estimating for certain loads. The weakest point of an "A" pole is at the top, where the stress due to windage and weight takes place. The member of the pole which is under tension tends to elongate and force itself away from the member in compression.

Tests made of different methods of constructing "A" poles are also described. In "A" poles spread to different widths at the bottom, the spread which gives strength combined with cheapness of erection was found to be about 4 ft. on a 32 ft. pole or a taper of about one-eighth.

One advantage of wooden poles in general, as shown by the test, is their great flexibility and recuperative power after severe deflections from the perpendicular caused by abnormal stresses. Some single poles which were projected free for a length of 35 ft. were deflected under pressure from 13 to 15 ft. before breaking, and when released showed a very small permanent set.

Judging from the data secured in these experiments, it is believed that the factor of safety usually required in high-tension work can be greatly reduced.

Treating wood that is refractory to treatment and also subject to decay, D. ALLERTON (*Engin. News, 59 (1908), No. 8, p. 182*).—An abstract of a paper read at the annual meeting of the United States Wood Preservers' Association at Kansas City in January, 1908, and dealing with creosoting experiments with Douglas fir recently conducted for the purpose of deriving a method to secure the maximum penetration of creosote with a specified amount of preservative to the cubic foot.

Three methods were tried in preparing the timber for injection, viz, steaming the timber with dry steam and afterwards applying a vacuum, repeating this method at short intervals, and boiling the timber in creosote. In each case with green timber the excess of water was removed with difficulty, the fiber was injured, and not over 7 lbs. of creosote could be injected to the cubic foot, whereas 10 lbs. per cubic foot is the specified amount for piling. The fiber was also injured when seasoned timber was treated and the same difficulty experienced in injecting the oil.

A method was finally adopted in which seasoned fir is placed in a sealed retort and steam turned into the coil, the creosote being introduced at a temperature of 170° F. A temperature of 175 to 180° is maintained about an hour, when pressure is started gradually in order to allow the injected oil to fill the expanding and heated cells. By gradually increasing the pressure this oil is forced still farther in by the increased pressure of the oil behind. When piling

was treated in this manner a penetration of from 2 to 4½ in. was secured in from 12 to 14 hours. With green fir the open tank method was used, but otherwise the preliminary treatment was the same as for seasoned fir. After 12 hours of pressure, however, the oil was drawn off and the wood and retort cooled for 12 hours, when pressure was again applied for a period of 12 hours. It is found that the most oil is injected in the first 12 hours, but that the greatest penetration takes place in the second 12 hours. The average penetration was from 1 to 2 in. Both processes are said to require skilled help in order to produce satisfactory results.

Preservation of wood against decay from soil, fungus diseases, and insects. E. Henry (*Préservation des Bois contre la Pourriture par le Sol, les Champignons et les Insectes. Paris and Nancy, 1907, pp. 96, pls. 10*).—Noted from another source (E. S. R., 19, p. 441).

The Ceara rubber tree in Hawaii. J. G. Smith and Q. Q. Bradford (*Hawaii Sta. Bul. 16, pp. 7–30, pls. 4*).—An account of the Ceara rubber tree (*Manihot glaziovii*) with special reference to its culture in Hawaii. The tree is discussed relative to its habit of growth, root system, latex system, and seed. Suggestions are given for its culture including seed bed and planting practices, cultivation and subsequent treatment, harvesting and preparing the rubber for market, in which special attention is paid to methods of tapping the tree and coagulating the latex. The bulletin also contains the results of one year's experiments in tapping rubber trees together with a discussion of the future of plantation rubber and notes, by D. L. Van Dine, on the insect enemies of the Ceara rubber in Hawaii.

The tapping experiments were conducted in two small groves of Ceara trees on the island of Kauai. One of these groves was about fourteen years old and the other nine years old. Detailed data are given of the tapping operations in each grove. Tapping experiments thus far indicate that there is a wide variation in the amount and quality of the latex yield by individual trees, hence it is advised that each tree should be tested relative to the quality and quantity of its latex before the tree is two years old and that inferior trees in this respect should be taken up. There appears to be some relation between atmospheric conditions and the flow of latex, although this relation has not thus far been determined. Double the amount of rubber was procured by trickling water containing ammonia over the tapping area over that by tapping without the use of water. For this purpose a water bag holding about a quart of water made with alternating narrow strips of porous oiled cloth or canvas was tied around the tree 6 or 7 ft. above the ground, just above the tapping area. The bag was left on the tree during the whole tapping season. It is believed that the use of water will cheapen the cost of production and will practically do away with the production of scrap or waste rubber. The opinion is advanced that daily tappings for a period of two to four weeks or more will yield much better results than tapping on alternate days or longer intervals over a period of several months. In the present experiments daily tappings for a period of nine days gave better results than tapping on alternate days for double the time, and the recovery of the tree was more rapid. Trees tapped either just before or during the resting period did not leaf out as quickly as trees which had not been tapped.

Relative to planting operations in Hawaii, it is stated that by January, 1908, 400,000 rubber trees had been planted of which upwards of 90 per cent were *M. glaziovii*. The remainder are *Castilloa elastica* and *Hevea brasiliensis* in about equal proportions. It is expected that tapping operations will soon commence on some of these plantations.

The rubber plant of southern Europe, Mattei and G. Van den Kerckhove (*India Rubber World, 37 (1908), No. 6, pp. 177–179, fig. 1, map 1*).—An account, including historical notes, botanical description, geographical distribution, and uses, is given of a gum-yielding species of plant, *Atractylis gummifera*, native to the Mediterranean region both in Europe and Africa. Several analyses were made of this gum and show a rubber content of from 22.96 to 36.46 per cent, with about double that amount of resin. The plant, which appears to have been known from remote times, grows mostly underground in the shape of a large cylindrical trunk, often weighing from 20 to 40 lbs. The leaves grow close to the ground. The Sicilians are said to free the rubber from the resin by chewing the gum. The rubber is then dissolved in spirits of turpentine in order to make a sort of bird lime for catching birds.

Although it is not believed that the gum of Atractylis can take the place of rubber, it is thought that it may be adapted to mixing with it in the same manner as the gums of guayule and pontianak.

Hints on the cultivation of Para rubber, A. W. Bartlett (*Separate from Off. Gaz. [British Guiana], 1907, April 17, pp. 3*).—Brief practical suggestions are given relative to the methods of packing Para seed for shipment, sowing, planting operations and distances, shade and protection from wind, intercrops and catch crops, green manuring, and pruning.

DISEASES OF PLANTS.

Notes on some plant diseases, L. Savastano (*Bol. Arbor. Ital., 4 (1908), No. 1, pp. 21–32*).—Descriptions are given of a number of obscure diseases of citrus trees and fruits, among them a retardation of the growth of orange trees following transplanting, drying of oranges and lemons on the trees, lemon scald, sunburn of the fruit, etc. Notes are also given on vine chlorosis, a disease of alder trees, the biology of the downy mildew of the grape, grape powdery mildew, etc.

Fasciations of known causation, H. Hus (*Amer. Nat., 42 (1908), No. 494, pp. 81–97, figs. 2*).—A description is given of a number of forms of fasciation, the causes of which are grouped under four heads: Mechanical causes, cases where no injury can be traced, the action of fungi, and the action of insects.

Experiments in combating plant diseases, F. K. Ravn and A. Madsen-Mygdal (*Samvirk. Landbofor. Fyens Stift, 1906, pp. 24*).—The report covers experiments on the prevention of smut in spring grains by the hot-water and the formaldehyde methods, studies on barnyard manure as a carrier of contagion of the club-root disease, and experiments on the application of lime as a remedy against the club-root disease. The work along these lines will be continued.

Texas root rot of cotton: Field experiments in 1907, C. L. Shear and G. F. Miles (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 9, pp. 3–7, fig. 1*).—In a previous publication (E. S. R., 19, p. 247) an account is given of the beneficial effect of deep fall plowing and a rotation of crops for the control of the root rot of cotton, due to *Ozonium omnivorum*. In the present publication a more detailed statement is given of further experiments in cultivation and rotation of crops for the control of this disease. It is stated that by rotation with immune crops, a field which in 1904 was planted to cotton with a loss of 95 per cent from the root rot, was, after two seasons with corn and wheat, again planted to cotton in 1907, when the crop was but slightly affected by the root rot. It seems probable that a combination of rotation of crops and deep fall plowing will prove a satisfactory, efficient, and practicable means of control.

Hollow potatoes, G. MASSEE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., 1908, No. 3, pp. 139, 140, fig. 1*).—During the past autumn some diseased potatoes were submitted to Kew for investigation. The potatoes were well grown and externally showed no trace of injury, but when cut open were found to be hollow, only an external shell, varying from a quarter to half an inch in thickness, remaining. In some specimens the cavity was empty, dry, and lined with a shriveled mass, while in other cases the cavity was more or less filled with an unpleasant smelling pulp, which on examination was found to be teeming with nematodes. A series of sections showed that the nematodes gained entrance to the tuber through the original point of attachment to its branch. They then gradually used up the substance of the tuber, working from the center outward until their progress was checked by the vascular zone, which lies at some distance within the potato.

The nematode appears to be *Aphelenchus pyri*, a species originally found in decaying pears. It is believed to be a wound parasite that gains entrance through the minute openings formed by the decay of the tissue at the point where the vascular ring enters the tuber.

Experiments in infecting tubers were carried on, and where the slime described above was placed on the scar formed by the detachment of the tuber, the tubers when cut open after 10 days revealed cavities an inch in diameter. In a second experiment where the nematodes were applied to the eyes of the tubers no infection took place.

On the existence of Myxomonas betæ, F. C. VON FABER (*Ber. Deut. Bot. Gesell., 26a (1908), No. 2, pp. 177–182*).—A careful study has been made of the diseases of beets which, according to Brzezinski, are due to *M. betæ*. The author claims that he was unable to discover any organism resembling in any way that described by Brzezinski, and he concludes that there is no myxomycete associated with these diseases of the beet.

The distribution and control of cucurbit mildew, G. KÖCK and K. KORNAUTH (*Ztschr. Landw. Versuchsw. Osterr., 11 (1908), No. 2, pp. 128–145, pl. 1*).—An attempt has been made to determine the extent to which the cucurbit mildew (*Plasmopara cubensis*) is present in the principal regions of Austria, the relative resistance of varieties, and means for the control of the disease.

The mildew was found quite common in all centers where cucumbers and other cucurbits are extensively grown. Marked differences were noted in the susceptibility of cucumbers, melons, and squashes, cucumbers being much more subject to attack by the fungus, the others seeming to be protected to some extent by their stronger leaf structure.

Experiments were made with about 70 varieties of cucumbers and marked differences in susceptibility to mildew were observed. All the varieties of climbing cucumbers proved quite resistant.

In experiments for the control of the disease, soil sterilization was found worthless, but frequent spraying with a 1 per cent solution of Bordeaux mixture reduced the amount of loss very materially. The addition of potassium permanganate to the Bordeaux mixture was found to be without any particular advantage. Rain and a sudden falling in the temperature were found to favor the rapid spread of the mildew. Where cucumbers are grown under glass, it is recommended that the interior of the house be disinfected with formaldehyde before planting and the plants protected with Bordeaux mixture during the growing season.

Infection experiments with cucurbit mildew, G. M. REED (*Trans. Wis. Acad. Sci., Arts, and Letters, 15 (1907), pt. 2, pp. 527–547*).—Experiments were carried on with the mildew of cucurbits (*Erysiphe cichoraccarum*) to determine

whether this fungus is specialized on particular species or varieties of cucurbitaceous plants.

In the course of the experiments 23 varieties of common cultivated cucurbits were used, which represented 5 different species and 3 genera. Each of the types was readily infected when inoculated with the conidia taken from any other. Young plants were used in all the experiments, and the great susceptibility of young plants to the disease was questioned. In this connection several vines of squashes and ornamental gourds grew to maturity in the greenhouse and the mildew spread over all of them. At first the spread was slow on the gourds, but later they were covered with white patches of mycelium and produced immense quantities of conidia.

As a result of the experiments there appears to be no indication of specialization of this mildew on any genus or species of cucurbits.

The same species of mildew is reported as occurring on golden-rod and asters. The author transferred conidia from squashes to these plants, without causing any infection. This line of investigation is being continued.

A brief bibliography is appended to the article.

The cross-inoculation of fruit trees and shrubs with crown-gall, G. G. Hedgcock (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 131, pp. 21–23*).—An account is given of experiments with apple and pear seedlings, in which the author attempted to determine the susceptibility of these plants to infection by the soft and hard gall forms from other host plants. Three series of experiments have been carried on, involving several thousand seedlings, and as a result of these and other investigations the author has arrived at the following conclusions:

"The soft galls from the almond, apricot, blackberry, cherry, peach, plum, prune, and raspberry have been transferred easily to seedlings of the almond, apricot, peach, and raspberry; less readily to those of the blackberry, cherry, plum, prune, and pear; and with great difficulty to seedlings of the apple, chestnut, walnut, and rose.

"The soft galls of the apple, chestnut, walnut, rose, and pear, as a rule, have not been transferred readily to any of the plants mentioned. Evidence has been obtained of a wide range of susceptibility in different varieties of the same plant. This has been noted in varieties of the apple, blackberry, cherry, chestnut, pear, and rose."

A new cherry disease, E. S. Salmon (*Gard. Chron., 3. ser., 43 (1908), No. 1110, pp. 209, 210, figs. 3*).—During 1907 a fungus disease of cultivated sweet cherries was observed which, according to the author, does not appear to have been hitherto recorded in England.

The general appearance of the affected branches shows the leaves curled and of a pinkish-red color. Soon a delicate whitish bloom becomes visible, spreading over the greater part of the under surface of the leaf. The leaves then turn brown, blacken, and decay. Frequently only a single leaf on a branch shows the disease, in other cases 2 or 3 scattered here and there are affected, while in rare cases most of the leaves on a branch are attacked. In large old trees seldom more than a few branches are attacked, but young trees may become seriously infested.

The disease is due to the fungus *Exoascus minor*. It is said to be closely allied to *E. deformans*, which causes the leaf curl of peaches, etc., and also to *E. cerasi*, the cause of the witches' brooms of cherry.

As the fungus is perennial, the mycelium living from year to year in the buds and young wood, the affected branches should be pruned and destroyed. The pruning should be followed by thorough spraying with Bordeaux mixture.

Severe pruning and spraying as directed, it is said, will completely restore the life of a tree in a single season.

A description is also given of the witches' brooms of cherry, due to *E. cerasi*.

Recent studies of the olive-tubercle organism, E. F. Smith (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 131, pp. 25–43*).—On account of apparent confusion as to the true cause of the disease of olives known as tuberculosis, olive knot, tumor, etc., the author has reviewed the work of a number of investigators and has made studies of material secured from California, Italy, and other countries. He has found that apparently mixed cultures have been used by a number of former experimenters and that the true cause of the olive tuberculosis is a white, nonliquefying bacterium, which is found in the olive tubercle and develops in many culture media as a short rod with rounded ends, occurring singly or in pairs. The yellow organism and others that have been described from time to time as causing the disease are believed to be present saprophytically.

A description is given of the organism, which for nomenclatorial reasons the author calls *Bacterium savastanoi*, together with an account of studies made with it in different media.

The disease is known to occur in Italy, France, Spain, Algeria, Tunis, and California, injuring the olive trees and sometimes destroying them. The organism enters the plants, so far as known, exclusively through wounds. Some varieties of olives seem more subject to the disease than others, and these should be discarded. Skillful pruning, particularly if accompanied by sterilization, will help hold the disease in check, and it is thought probable that the application of some of the better fungicides would aid in its control.

Investigations and trials relating to the appearance of the gooseberry mildew, and measures for its eradication, J. Lind and F. K. Ravn (*Separate from Gart. Tid., 1908, No. 1, pp. 15*).—Spraying with Bordeaux mixture and potassium sulphid solution and dusting with sulphur was found to decrease, but not to prevent entirely, attacks of the fungus disease. The winter treatment recommended consists in (1) pruning the bushes and burning all cut branches and berries, (2) raking together fallen leaves, berries, twigs, etc., and burying them in the ground, and (3) disinfecting the bushes by spraying with acid Bordeaux solution (100 parts water, 8 lbs. copper sulphate, and 1 lb. quicklime or 1½ lbs. slaked lime). This treatment should be followed by spraying with potassium sulphid solution, common Bordeaux mixture, or sulphur every 8 to 10 days from the beginning of May to the beginning of July. The cutting and removal of all diseased branches and berries should be continued throughout the season.

Notes on the treatment of mildew, L. Degrully (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 29 (1908), No. 14, pp. 419–427, pl. 1, fig. 1*).—Attention is called to the necessity of preventive treatments in combating the downy mildew of the grape, and a discussion is given of the quantity of fungicide required in spraying and the relative adhesiveness of different mixtures. Formulas are given for the preparation of about one dozen fungicides.

The black rot of the grape, and its control, D. Reddick and C. S. Wilson (*New York Cornell Sta. Bul. 253, pp. 367–388, figs. 11*).—An account is given of the fungus (*Guignardia bidwellii*) that causes the black rot of grapes, the different stages of the fungus being described in considerable detail.

A report is given of experiments conducted during 1906 and 1907 for the control of the black rot, in which Bordeaux mixture of different strengths, supplemented by treatments with other fungicides, was tested. The experiments in 1907 were undertaken on a considerable scale in a commercial vineyard, and as

a result of the spraying, a net increase of $32.95 per acre was secured. The season was comparatively dry and not favorable to the development of the disease, but from the good results obtained, it seems probable that when the black rot is prevalent to a moderate degree, spraying will completely control it.

A demonstration experiment for the control of black rot was carried on in another region in 1907, in which 4 treatments of Bordeaux mixture and 1 of ammoniacal copper carbonate were applied to the graperines. From the treated rows 1,322 lbs. of grapes were gathered, 97 per cent of which were of commercial grade, while from the unsprayed rows 606 lbs. of grapes were secured, 93 per cent of which were marketable.

On account of the belief that bagging grapes secures considerable protection from rot, a limited experiment was carried on in 2 different vineyards, with results which were decidedly unfavorable to the practice of bagging.

In conclusion, the authors recommend the collection and destruction of all the old mummified grapes, thorough cultivation, the growth of cover crops sown early in July, and spraying with Bordeaux mixture at such intervals as the weather requires.

A disease of chestnut trees, H. Sangier (*Bul. Soc. Nat. Agr. France, 68 (1908), No. 2, pp. 92, 93*).—A brief note is given on a disease of chestnut trees in Portugal that is said to be due to a lack of nitrification in the soil. When this is corrected by drainage and the addition of lime about the trees, the vigor of the trees is restored and the diseased condition disappears. The drainage and application of lime about the trees should be done during their resting period.

The possibility of the control of walnut blight by the use of immune varieties, H. J. Ramsey (*Pacific Rural Press, 75 (1908), Nos. 14, pp. 212, 213; 15, pp. 228, 229*).—Attention is called to the fact that among the walnut orchards of California there are frequently to be found individuals that are more or less resistant to the walnut blight. Some of these have very superior qualities, and the author recommends that they be rapidly propagated by grafting upon resistant stock. A method of grafting that has proved very successful is described.

Diseases of ornamental trees, H. Metcalf (*U. S. Dept. Agr. Yearbook 1907, pp. 483–494, pls. 3, fig. 1*).—A popular account is given of some of the more common diseases to which shade and ornamental trees are subject, with suggestions as to possible means for combating or controlling them. The diseases are grouped into 2 categories, those due to unfavorable surroundings, such as starvation, lack of aeration, gas poisoning, drying and freezing, smoke, dust, etc., and those due to parasitic fungi. As most of the fungi gain entrance through wounds, attention should be paid to these and cut or injured surfaces protected as much as possible.

Rose mildew, E. Prillieux (*Bul. Soc. Nat. Agr. France, 68 (1908), No. 2, p. 94*).—The author calls attention to the rose mildew (*Sphærotheca pannosa*), which is said to be particularly troublesome to the Bengal and hybrid roses. For combating this disease it is recommended that the shoots showing the perithecia of the fungus should be cut off during winter and burned and the remaining portions of the plant sprayed with lysol or concentrated solutions of iron sulphate or copper sulphate.

Fungicides, insecticides, and spraying directions, G. E. Stone and H. T. Fernald (*Massachusetts Sta. Bul. 123, pp. 3–32*).—Formulas are given for the preparation of fungicides and insecticides, with directions for their use in the prevention and control of fungus and insect pests. The authors give specific directions for the treatment of greenhouse, field, and garden plants for the control of their principal enemies. A brief note is given in conclusion on the treatment of weeds on lawns, tennis courts, walks, etc.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

The game resources of Alaska, W. H. Osgood (*U. S. Dept. Agr. Yearbook 1907, pp. 469–482, pls. 2, maps 3*).—Among Alaska's game animals are some of the largest and finest in the world, as the giant moose and the huge brown bears. Its game resources compare favorably with the western part of the United States in early days and at the present time is one of the most important game regions in the world. So far no species have been exterminated, but the traffic in wild game already is a matter of serious moment and difficult to regulate. The several kinds of game resident in Alaska are considered, and a description of their number, habits, and recent history, and of the nature of the country is given. Three maps are given showing the distribution of moose, deer, caribou, mountain goats, and mountain sheep in Alaska.

Destruction of wolves and coyotes, V. Bailey (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 63, pp. 11, fig. 1*).—According to supervisors' reports of the Forest Service, here summarized, there were killed in or near National forests in 1907 1,723 wolves and 23,208 coyotes. Notes are given as to the dates of breeding and number of pups per litter in Wyoming, New Mexico, Michigan, Wisconsin, Minnesota, and Arkansas. It is reported that elk have been found to protect stock in pastures from dogs and wolves, and it is suggested that this may become an important use for elk. Directions for destroying wolves are republished, with slight change, from Circular 55 of the Biological Survey previously noted (E. S. R., 19, p. 51).

The rabbit as a farm and orchard pest, D. E. Lantz (*U. S. Dept. Agr. Yearbook 1907, pp. 329–342, pls. 2, fig. 1*).—A general account is given of the distribution of rabbits in the United States, their protective powers, breeding and feeding habits. The damage they inflict on field crops, gardens, trees, nurseries, and forest plantings is considered. Means of repression, including natural enemies, hunting, drives, trapping, and poisoning, and the protection of crops and trees by rabbit-proof fences and other means are discussed.

Rabbits and the western flora, R. W. Peacock (*Agr. Gaz. N. S. Wales, 19 (1908), No. 1, pp. 46–48, figs. 2*).—The flora of the western grazing regions of New South Wales has been greatly influenced by the ravages of rabbits. Not only are grasses and small shrubs attacked but even trees up to a diameter of 7 in. are said to have been felled and leaves, branches, and trunks devoured by hungry rabbits.

Destruction of the cotton boll weevil by birds in winter, A. H. Howell (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 64, pp. 5, map 1*).—A continuation of the investigation conducted by the Biological Survey (E. S. R., 19, p. 551), on the food habits of birds in relation to their destruction of the boll weevil. Collections were made of birds found in and about cotton fields in central and northwestern Louisiana during January and February, 1908. Six hundred specimens, representing 50 species, were secured, of which 20 species and 81 individuals, or 13.5 per cent, were found to have eaten boll weevils. It was found that more birds were feeding upon the weevils and that many more weevils were being destroyed by them than in any of the more western localities where birds have been collected at a corresponding season. A record is given of the birds examined which had eaten boll weevils with brief notes on the status of the more important winter birds. The relatively greater importance of weevil destruction in winter is mentioned and emphasis is placed upon the need for rigid protection of each and every species of bird known to feed upon the pest.

Food habits of wood pigeons, W. E. Winton (*Jour. Bd. Agr. [London], 14 (1908), No. 11, p. 686*).—Observations were made on the food habits of wood

pigeons during winter and spring. These birds were found to feed largely upon oak galls, the seeds of turnips and rape, wild berries, and the succulent roots of *Potentilla anserina* exposed in plowing fields infested with this weed.

Does it pay the farmer to protect birds? H. W. Henshaw (*U. S. Dept. Agr. Yearbook 1907, pp. 165–178, pls. 4*).—The insectivorous and vegetarian birds and their food habits are discussed by the writer, and their importance as destroyers of insects is emphasized. Directions for the protection of birds from man, and means of attracting them to the farm and of protecting crops from their attacks are given.

An account of the Biological Survey of the Department of Agriculture, H. W. Henshaw (*Nat. Geogr. Mag., 19 (1908), No. 2, pp. 79–118, figs. 38*).—A popular account is presented of the relation of birds and other animals to agriculture, with particular reference to the work of the Biological Survey of this Department and its study of the agricultural relations of birds and mammals. The author also mentions the establishment of game preserves and the means of guarding against the importation of dangerous animals.

Index-catalogue of medical and veterinary zoology, C. W. Stiles and A. Hassal (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 39, pts. 20, pp. 1493–1574; 21, pp. 1575–1624*).—A continuation of the index catalogue of medical and veterinary zoology, part 20, containing the names of authors from Naab to Nystrom and part 21, names from Obenaus to Ozzard.

Sixth report of the state entomologist and plant pathologist of Virginia, J. L. Phillips (*Rept. Va. State Ent. and Plant Path., 6 (1906–7), pp. 99, pls. 3*).—In this report a general account is given of the work of the entomologist during 1906–7 with particular reference to nursery and orchard inspection. Methods of treatment are suggested for nursery stock, together with brief statements of the requirements of various States regarding the shipment of nursery stock. A detailed report is made of the work of orchard inspection in the various counties of the State.

Proceedings of the twentieth annual meeting of the Association of Economic Entomologists (*Jour. Econ. Ent., 1 (1908), No. 1, pp. 1–76*).—At the twentieth annual meeting of the Association of Economic Entomologists held in Chicago, December 27 and 28, 1907, a number of papers were read, the more important of which are noted in the following paragraphs.

President H. A. Morgan in his annual address discussed The Relation of the Economic Entomologist to Agriculture (pp. 11–15). Particular attention was given to the recognition of the importance of economic entomology in the work of the land-grant colleges, and in the recent State and Federal operations in controlling the insect pests of the Southern States.

The relation between Cultivation and Susceptibility to Insect Attack was considered by J. B. Smith (pp. 15, 16). It is stated that as a rule vigorous sappy growth is more generally infested and injured by scale insects than slow hardy growth and that trees in well cultivated orchards and highly fertilized are more susceptible to attack than trees in sod or under cultural neglect. It has also been observed that infestation of young trees is of more serious consequence than that of older trees and that trees which have been persistently treated for years without success often clean themselves of scale after being abandoned and thereafter remain practically free.

Observations on the Biology and Food Habits of the Cecidomyiidæ were given by E. P. Felt (pp. 18–21). The author gave biological notes on a number of gall insects on various wild species of plants.

W. Newell discussed the habits and economic importance of *Iridomyrmex humilis* (pp. 21–34). This ant, commonly known as the New Orleans ant, has proved to be one of the most serious household pests wherever it has become

established. It also attacks the predaceous ant which feeds upon the boll weevil. The New Orleans ant feeds upon meat, lard, honey, sugars, cakes, and nearly all the food products, and multiplies to such an extent that great difficulty is experienced in preventing its injuries. The insect is described in all its stages.

W. A. Hooker called attention to habits and methods of study of ticks (pp. 34–51), discussing such matters as host relationship, adaptations as factors in this relationship, geographical distribution, and life history of ticks and methods used in breeding ticks. He also gave A Review of the Present Knowledge of the Rôle of Ticks in the Transmission of Disease (pp. 65–76), in which the literature of this subject is briefly discussed in connection with a bibliography and tables are presented showing the zoological position of parasites transmitted by ticks and also the classification of ticks.

W. D. Hunter announced A Tentative Law on the Incubation of the Eggs of the Cattle Tick (pp. 51–55). It appears that the total effective temperature required for hatching the eggs of the cattle ticks varied from 840 to 1510° F. In about one-half of the tick-infested area eggs deposited after the middle of September do not hatch until spring.

The Relation of Temperature to the Hibernation of Insects is considered by E. D. Sanderson (pp. 56–65). The thermal-constant for insects is defined as "that accumulation of the mean daily temperature above the critical point of the species which will cause it to emerge from hibernation or to transform from any given stage." The observations reported by the author were made on tent caterpillar, brown-tail moth, and codling moth.

Thirty-eighth annual report of the Entomological Society of Ontario (*Ann. Rpt. Ent. Soc. Ontario, 38 (1907), pp. 136, pls. 4, figs. 47*).—At the forty-fourth annual meeting of the society held in Guelph, October 31 and November 1, 1907, a number of papers were read the more important of which are noted below.

President J. Fletcher in his annual address (pp. 9–15) called attention to some of the tangible results which have been accomplished by economic entomology and discussed the liberality of the United States in providing funds for entomological research.

A conference was held on fruit-tree insects (pp. 15–22) at which a number of pests were considered including fruit-tree bark beetle, codling moth, oyster-shell bark-louse, terrapin scale, San José scale, and woolly aphis.

Brief reports were made on the insects of the year by C. H. Young (pp. 22–27); on The Gipsy and Brown-Tail Moths in Massachusetts, by A. H. Kirkland (pp. 27–31); on nocturnal insects, by T. W. Fyles (pp. 31–34); and on the collection and rearing of dragon flies, by E. M. Walker (pp. 43–50).

T. D. Jarvis presented A Preliminary List of the Scale Insects of Ontario (pp. 50–72), in which remedies are suggested for the more important species of scale insects. The preparation of lime-sulphur wash was discussed by L. Caesar (pp. 72–82). The minimum strength of this wash is considered to be 20 lbs. lime and 15 lbs. sulphur per 40 gals. of water. It is recommended that the mixture be boiled vigorously for 1 hour. It is an effective wash not only against scale insects and plant lice but is also of value in the control of peach-leaf curl, gooseberry mildew, plum rot, and pear scab. Among the other papers presented at this meeting the following may be mentioned: An Unusual Outbreak of Halisidota Caterpillars, by A. Gibson (pp. 82–85); Insect Galls of Ontario, by T. D. Jarvis (pp. 85–94); Injurious Insects in Ontario in 1907, and An Outbreak of the Variegated Cutworm, by C. J. S. Bethune (pp. 95–102); and Entomological Record for 1907, by J. Fletcher and A. Gibson (pp. 113, 114).

Some factors influencing insect development, C. Hennings (*Biol. Centbl., 27 (1907), pp. 324–337, pl. 1*).—The experiments reported in this paper were carried out chiefly on *Tomicus typographus*. It was found that the deposition of the eggs could be delayed at least 2 days by lowering the temperature 3 or 4° C., or by increasing the moisture content of the area. The same modification of these factors also prolonged the period of egg laying sometimes to the extent of 5 days. Similarly the larval and pupal stages were considerably elongated by increasing the moisture content or reducing the temperature.

Increase in the weight of pupæ kept in an atmosphere with a high content of carbon dioxid, Countess von Linden (*Sitzber. Naturhist. Ver. Preuss. Rheinlande u. Westfalens, 1907, I, pt. A, pp. 1–11*).—Pupæ of a number of species of lepidoptera were kept in an atmosphere containing 5 per cent or more of carbon dioxid. By means of careful weighings and gas analyses, it was determined that the pupæ absorb carbon dioxid from the atmosphere and utilize it directly in the formation of carbohydrates, thus increasing their weight.

Some critical observations on the European species of the genus Chermes, E. R. Burdon (*Jour. Econ. Biol., 2 (1908), No. 4, pp. 119–148, pls. 2*).—The author gives a detailed account of the various developmental forms observed in 10 species of this genus. In discussing material for the identification of species he takes up the characters furnished by the insects themselves and also the characters furnished by the galls produced by the insects.

Intercortical scale formation and the development of Diaspis fallax, H. Morstatt (*Centbl. Bakt. [etc.], 2. Abt., 20 (1907), No. 4–5, pp. 150–153*).—According to the author's observations the scale of the female of *Diaspis fallax* and certain other scale insects of this group is partly composed of the extreme outer layer of cork tissue of the host plants upon which the scales are found.

The biology of plant lice, A. Mordwilko (*Biol. Centbl., 27 (1907), pp. 529–550; 561–575; 747–767; 769–816, figs. 25*).—The author discusses the whole cycle of the biology of plant lice with particular reference to heterogony, especially as observed in plant lice and in the alternation of generations which characterizes a large number of species of this group.

The interrelations of ants and plant lice, A. Mordwilko (*Biol. Centbl., 27 (1907), pp. 212–224; 233–252, figs. 5*).—An elaborate description is given of the mutual relations between various species of ants and the plant lice which they attend. Particular attention is given by the author to a discussion of the theories for explaining the origin of this relation and its economic significance.

The polymorphism of ants, with an account of some singular abnormalities due to parasitism, W. M. Wheeler (*Bul. Amer. Mus. Nat. Hist., 23 (1907), pp. 1–93, pls. 6*).—Detailed observations were made on *Orasema viridis* and a species of Mermis as parasites in ant colonies and on the effects produced upon the ants by these parasites. A large portion of the paper is occupied with a general discussion of the origin of parasitism of ants as related to the polymorphism observed in this group of insects.

The fungus-growing ants of North America, W. M. Wheeler (*Bul. Amer. Mus. Nat. Hist., 23 (1907), pp. 669–807, pls. 5*).—Detailed descriptions are given of a number of species of Atta and other genera of this family of ants which are distinguished by their habit of cultivating fungi for food. The theories which have been proposed for explaining the origin of this habit are critically discussed by the author.

Wild bees, wasps, and ants, E. Saunders (*London, [1907], pp. XIII+144, pls. 4, figs. 28*).—The purpose of this volume is to present in a simple form an account of the wild species of bees, wasps, ants, and other related hymenoptera

belonging to the group Aculeata of which about 400 species are known in Great Britain. The author discusses the habits and life history of a number of these insects, particularly solitary bees, digger wasps, solitary wasps, social wasps, bumblebees, and ants.

The book of garden pests, R. H. Pearson (*London, 1908, pp. XIII+214, pls. 17, figs. 51*).—In the present volume the author attempts to cover the subject of insect pests and fungus diseases affecting garden plants in Great Britain, but not including the pests of forest trees, shrubs, and field crops. Special chapters are devoted to insecticides, fungicides, and the pests of tuberous plants, fruit-trees, vegetables, etc.

Practical remedies for insect pests, H. M. Lefroy (*Agr. Jour. India, 2 (1907), No. 4, pp. 356–363*).—There are a number of important insect pests in India requiring the application of the best modern sanitary methods for their control. It is practically impossible, however, to apply these methods at present for the reason that most of the natives do not appreciate the necessity of them. Fortunately a number of simple methods are known for certain pests and these may be applied with good results if the cooperation of a considerable neighborhood is secured. The stem borer of cotton may be held in check by removing and burning withered plants. Similarly with another cotton pest known as the dusky bug, successful treatment is found in removing the affected bolls.

Insects injurious to seeds, P. Bargagli (*Agr. Colon. [Italy], 1 (1907), No. 2, pp. 143–148, pls. 2*).—Brief biological notes are given on grain weevils and other insects injurious to wheat, barley, corn, Kafir corn, flat pea, chick-pea, etc. Particular attention is given to the life history of *Caryoborus pallidus*.

The frit fly (*Schweiz. Samen Untersuch. u. Versuchsanst. Zürich Flugbl., 1908, No. 3, pp. 2, figs. 2*).—In the region of Zürich the frit fly is considered the most important insect enemy of oats. Brief notes are given on the life history of the pest. It may be controlled by early sowing, deep seeding, the liberal use of fertilizers, fall plowing, and the selection of slender stemmed varieties of oats.

The codling moth or apple worm, A. L. Quaintance (*U. S. Dept. Agr. Yearbook 1907, pp. 435–450, pls. 4*).—An estimated shrinkage in the value of the apple crop of approximately $12,000,000 annually, and an additional sum of not less than $3,000,000 or $4,000,000 for expenses incurred in its control, is charged to the presence of this insect in the apple orchards of the country. The character of the injury, and the life history and habits of the pest, with variations in the number of generations are given. Its natural enemies, artificial methods of control, and benefits obtained therefrom are described.

The woolly aphis of the pear tree, P. Passy (*Rev. Hort. [Paris], 80 (1908), No. 4, pp. 82, 83, fig. 1*).—A brief description is given of the injury caused by woolly aphis to pear trees. The best results in destroying this pest have been obtained from the use of insecticides containing some alcohol, the alcohol being of advantage by intensifying the penetration of the insecticide into the body of the aphis.

The scale insects of citrus trees, C. W. Howard (*Transvaal Agr. Jour., 6 (1908), No. 22, pp. 265–277, pls. 3, figs. 2*).—Descriptive and biological notes are given on a number of scale insects affecting oranges and other citrus trees in the Transvaal. Particular mention is made of *Chrysomphalus aonidum, Lepidosaphes beckii, L. gloverii, Icerya purchasi*, orange aphis, and orange psylla. In suggesting remedies for these pests the author presents formulas for the preparation of resin wash, castor-oil emulsion, soap wash, and kerosene emulsion.

The San José scale, H. A. Surface (*Zool. Bul. Penn. Dept. Agr., 5 (1908), No. 9, pp. 267–296*).—It is proposed to establish a number of demonstration orchards in the fruit-growing regions of Pennsylvania for the purpose of applying standard remedies for San José scale for the benefit of orchardists who may

wish to observe modern methods in this work. A statement is given of the plan under which this work will be carried out. Notes are also given on nursery inspection and on commercial and homemade insecticides.

Spraying experiments for 1907. L. F. HENDERSON (*Idaho Sta. Bul. 61, pp. 3–15*).—The author finds that scalecide at the strength of 1:15 kills San José scale as well as any spray, but that it is not effective when used 1:20. Salt added to lime-sulphur sprays was found to be of no value, and large amounts of sulphur added do not appear to increase the effectiveness of the spray. A late fall and an early spring application for the scale is recommended. Spraying at the time of flowering with Bordeaux mixture injures the fruit, causing a russet appearance at the time of picking. A dust spray gave as good results for codling moth as liquid spray, and the weaker sprays of arsenate of lead gave as good results as the stronger. The author considers salt essential to the efficiency of the Niagara, Rex, and Piper sprays for peach leaf-curl.

Spraying in an off year. F. E. DENNY (*Bul. Nebr. State Hort. Soc., No. 16, pp. 7*).—As some doubt is often entertained regarding the profitableness of spraying, especially in the seasons when insect pests and fungus diseases are not particularly in evidence, the economic aspect of spraying was carefully studied by the author, especially during 1906–7. The combination of Paris green or lead arsenate and Bordeaux mixture was used in protecting apple trees against codling moth and apple scab. It was found that the average gain per tree due to spraying was $2.13, or about $85 per acre.

Lime-sulphur for use against San José scale. J. L. PHILLIPS (*Va. Crop Pest Com. Circ. 5, n. ser., pp. 12, figs. 10*).—The formula recommended for lime-sulphur wash calls for 15 lbs. each of lime and sulphur per 50 gal. of water, the mixture to be boiled for 40 minutes and then strained. Directions are given for the preparation of cooking appliances and for the application of the wash.

Dipping of nursery stock in the lime-sulphur wash. P. J. PARROTT, H. E. HODGKISS, and W. J. SCHOENE (*New York State Sta. Bul. 302, pp. 175–202, pls. 2*).—Experiments were made to determine the value of lime-sulphur wash as a dip in disinfecting nursery stock for such pests as the San José scale, woolly aphis, and other destructive insects. Tests were made of the standard lime-sulphur wash at temperatures of 60°, 100°, 120°, and 212° F. The stock used consisted of Bartlett pears, Ben Davis and Mann apples, Satsuma plums, and Fitzgerald peaches. The time period of the immersion varied from instantaneous up to 10 minutes.

The results of these experiments indicate that dipping nursery trees in the standard lime-sulphur wash for the purpose of destroying the San José scale is a doubtful practice. Nurserymen are advised to continue the use of fumigation with hydrocyanic-acid gas.

The currant bud mite and the hazel bud mite. R. S. MACDOUGALL (*Jour. Bd. Agr. [London], 14 (1908), No. 11, pp. 676–679*).—Both *Eriophyes ribis* and *E. avellanæ* live in the buds of their host plants, causing them to swell greatly. These species have sometimes been confused, and the author therefore presents in parallel columns their distinguishing characteristics. Most species of this genus feed upon only one species of plant or in a few instances upon more than one species of the same genus.

Mosquito blight of tea. C. M. HUTCHINSON (*Planters' Chron., 3 (1908), No. 1, pp. 21, 22*).—During the year 1907 the mosquito blight was unusually severe in tea plantations. It had previously been shown that kerosene emulsion is an effective remedy against this insect, but that it is too expensive. Experiments were therefore undertaken to devise an equally effective but cheaper remedy. This purpose was achieved in a simple soap mixture containing 1 lb. of soap

per 20 gal. of water. This mixture may be applied at the rate of 300 gal. per acre at a cost of less than one-half that of the application of the kerosene emulsion.

Thrips on cocoa, H. A. Ballou (*Bul. Dept. Agr. Jamaica, 6 (1908), No. 1, pp. 8–11*).—A brief account is given of the nature of the injury by thrips to the leaves and pods of cacao. Directions are given for the preparation and application of rosin wash, kerosene emulsion, and rosin and whale-oil soap compounds.

On the structural characters of three species of Coccidæ affecting cocoa, rubber, and other plants in Western Africa, R. Newstead (*Jour. Econ. Biol., 2 (1908), No. 4, pp. 149–157, figs. 3*).—The species discussed by the author include *Stictococcus sjostedti*, *Pulvinaria jacksonii*, and *Palæococcus theobromæ*, the last two being described as new species.

Notable depredations by forest insects, A. D. Hopkins (*U. S. Dept. Agr. Yearbook 1907, pp. 149–164*).—A history is given of the depredations in Europe and America by the defoliating and bark-boring insects.

For Europe, the "nonne" moth (*Liparis monacha*), pine spinner (*Dendrolimus pini*), gipsy moth (*Porthetria dispar*), false caterpillars, and the eight-tooth pine bark beetle (*Tomicus typographus*) are mentioned and attention is called to the danger of their introduction into this country. An account follows of the depredations in America by the larch worm, pine butterfly (*Neophasia menapia*), gipsy moth, spruce-destroying beetle (*Dendroctonus piceaperda*), Englemann spruce beetle, Black Hills beetle (*D. ponderosæ*), western pine beetle (*D. brevicornis*), destructive pine beetle (*D. frontalis*), hickory bark-borer (*Scolytus quadrispinosus*), and locust borer (*Cyllene robiniæ*).

It is stated that nearly all great invasions by forest insects in Europe and this country have been more or less of a periodical nature, which is explained as due to various natural causes that operate only after the greatest damage has been done. Most of the bark beetles can be kept under complete control with little or no expense by proper adjustments in forest management and lumbering operations.

Experiments in using various species of trees as trap trees for bark beetles, W. Sedlaczek (*Centbl. Gesam. Forstw., 34 (1908), No. 2, pp. 45–73*).—The trees used in these experiments included silver fir, larch, Norway spruce, and Austrian pine. Reasonably satisfactory results in attracting bark beetles were obtained by ringing these trees in various ways or felling them. Later the trunks may be treated in such a way as to destroy the beetles.

Insects injurious to loco weeds, F. H. Chittenden (*U. S. Dept. Agr., Bur. Ent. Bul. 64, pt. 5, pp. 33–42, figs. 7*).—An account is given of the insects instrumental in reducing the abundance of stock-poisoning loco weeds in the semi-arid regions of the West. The false-indigo gall-moth (*Walshia amorphella*), which as a caterpillar feeds at the roots and crowns of locos, is apparently the principal insect destroyer. Other insects mentioned as attacking loco weeds, particularly *Astragalus mollissimus* and *Aragallus lamberti*, are the loco root-maggot (*Pegomya lupini*), fickle midge (*Sciara inconstans*), four-lined loco weevil (*Cleonus quadrilineatus*), yellow loco fly (*Tritoxa incurva*), spotted root fly (*Euxesta notata*), bur-clover aphis (*Aphis medicaginis*), and meal snout-moth (*Pyralis farinalis*), as well as plant bugs, leaf hoppers, and miscellaneous insects. Some of these insects are considered as highly beneficial, since they have completely rid large areas of loco weeds.

The value of insect parasitism to the American farmer, F. M. Webster (*U. S. Dept. Agr. Yearbook 1907, pp. 237–256, figs. 24*).—An account is given of the great value of parasites in reducing the amount of injury due to several destructive insects, notably the spring grain-aphis (*Toxoptera graminum*) by

Lysiphlebus tritici, the Hessian fly by *Polygnotus hiemalis*, the army worm (*Heliophila unipuncta*) by *Winthemia quadripustulata*, and grasshoppers by parasitic flies as *Melanoptus differentialis* by *Sarcophaga georgina*. The perpetual benefits derived from parasites and their artificial introduction and diffusion are related.

Fruit fly parasites, G. C. Baker (*Jour. Dept. Agr. West. Aust., 16 (1908), No. 1, pp. 27, 28, pl. 1*).—It is stated that after three unsuccessful attempts to establish in Western Australia a parasite of the fruit fly, success has at last been achieved, one generation of parasites having already been bred there. The attempt will be made to breed other parasites to assist in controlling fruit flies.

Anatomy, biology, and pathogenicity of Ixodes reduvius, V. E. Vorontzov (*Anatomiya, Biologiya, i Patogennost Kleshtshei vida Ixodes redurius. St. Petersburg: Govt., 1907, pp. 41, pls. 3*).—The author discusses in detail the anatomy and biology of *Ixodes redurius* with particular reference to its agency in carrying hemoglobinuria of cattle. This disease has definitely been shown to depend upon the ticks for its transmission. The eggs of *I. reduvius* may retain their vitality under water in swampy areas from fall until spring.

The tsetse fly in India, H. M. Lefroy (*Agr. Jour. India, 2 (1907), No. 4, pp. 374–376*).—On account of the importance of the tsetse fly as a carrier of animal and human diseases an investigation was made to determine whether this fly occurs in India. According to the evidence thus far accumulated it does not appear to be found in India, and in the author's opinion the likelihood of accidental importation is quite remote.

Apiculture, E. Chavez (*Apicultura. Mexico: Govt., 1907, pp. 12*).—This pamphlet contains an account of the conference of apiculture held at the agricultural and industrial fair at San Luis Potosi. The chief subjects discussed were the necessity of studying local bee plants and the influence of insects, particularly bees, on the fertilization of plants.

Bee diseases in Massachusetts, B. N. Gates (*U. S. Dept. Agr., Bur. Ent. Bul. 75, pt. 3, pp. 23–32, map 1*).—Both American and European foul brood have been found to exist in practically every quarter of Massachusetts and Connecticut as well as in the other New England States. There seems to be undeniable proof that their introduction is not recent, and that there are fewer bees kept on the farms than there were 50 years ago seems to be due in part to the effect of these diseases. A map is given showing the distribution of the two diseases in Massachusetts and the possible sources of infection from neighboring States.

FOODS—HUMAN NUTRITION.

Changes taking place in chickens in cold storage, Mary E. Pennington (*U. S. Dept. Agr. Yearbook 1907, pp. 197–206, pls. 7*).—A summary and discussion of data obtained in a study of the appearance and characteristics of freshly killed fowls and poultry stored respectively ten months, two years, and three years.

In the stored poultry changes in appearance and character were noticeable, being much greater in the samples stored for a long period than in those in storage for a shorter time. In the case of chickens in storage for three years, changes in the texture and color of both muscles and fat were striking. There was a very considerable drying out, particularly in the muscles of the upper breast and between the muscles the bands of fat were shrunken and of a deep brown-orange color. "No feature of the entire chicken was more striking by comparison with the fresh fowl than this change in the color of the fat.

"The most striking difference between this chicken stored for three years and those stored for shorter periods or those which are fresh is this pronounced inflexibility and the general green tint of the skin. The whole appearance of the bird was unpleasant in the extreme. The odor was not that of putrefaction, but was of a sharp, penetrating, unpleasant character having a biting property, which suggested the effect of acrolein on the eyes and nostrils. While this was plainly detected in the unopened bird, the muscles and the viscera gave it far more distinctly, and a decided increase in its intensity was noticed while the study was progressing."

Other differences in the chickens examined are also pointed out and refrigeration and refrigerator methods are discussed.

"The changes in the chickens which have been described are not the most pronounced of their kind, other specimens exhibiting more marked degenerations and some showing better conditions. These were, rather, alterations representing as nearly as possible the mean.

"Such being the case, the dictum of the warehousemen that there is no change in cold-storage poultry and that it may be kept for an indefinite period can not be accepted in its entirety. Both microscopic study and the taste of the cooked fowl confirm the fact that macroscopically visible degeneration does take place.

"Considering the enormous growth and the wide extent of the refrigeration of foodstuffs, as well as the absolute lack of authoritative supervision of such frozen products before they are offered for sale, it seems most desirable that a careful study should be made to determine whether such alterations as have been noted affect the appearance and histological integrity of the flesh only, or whether, as has been asserted by some, the consumption of poultry after long periods of cold storage is not responsible for some of the obscure intestinal disorders and the imperfect metabolism from which modern humanity, especially the dwellers in large cities, are so apt to suffer."

The grades of wheat in the Manitoba inspection division, crop of 1907 (*Canada Cent. Expt. Farm Bul. 60, pp. 7–21*).—This bulletin consists of two articles.

(1) *The milling and baking qualities of the grades of wheat in the Manitoba inspection division, crop of 1907, by C. E. Saunders* (pp. 7–11).—Manitoba hard, Manitoba northern, and commercial grade wheats of the crop of 1907 were studied in comparison with the results of earlier work, milling tests and baking tests being made. The majority of the samples showed the effects of water and frost.

"The crop of 1904 [see a previous note (E. S. R., 17, p. 379)] was of an unusual character owing to the prevalence of rust. It was therefore to be expected that the grades of the past season would show some points of difference from those of 1904. The flours from the grades of 1904 showed a lower water absorption and a lower protein content than those of 1907 . . . but gave bread of larger volume, especially in the lower grades. These observations perhaps justify the conclusion that wheat which is lacking in plumpness on account of the action of rust will produce better flour than wheat, of about the same degree of plumpness, which has been injured by frost."

(2) *A chemical study of the grain and flour of the grades of wheat, 1907, by F. T. Shutt* (pp. 12–21).—In general the samples were characterized by a decidedly high protein content which it is pointed out might indicate superior rank for bread-making purposes, though according to the author it might in some degree be due to immaturity and so not necessarily be an indication of greater strength as applied to bread making, though it might imply higher value from

a nutritive standpoint. "Frosted wheat, as we have frequently shown, is possessed of a higher percentage of protein than similar wheat that has come to a normal ripeness without frost; it is, in other words, immature wheat. It might be argued that this explanation would only apply in a consideration of the lower grades—those showing the effects of frost—but it is not improbable owing to the backward season last year that in some districts at least a considerable amount of wheat was cut in a 'greener' condition than usual and that this failed to thoroughly ripen in the stook."

The relationship of the weight of the kernel to wheat per bushel and the percentage of straight grade flour was not as obvious, according to the author, as in earlier work, and the same was true of the relationship between protein, gliadin and dry gluten, observed in normally ripened wheats. "The absence of this relationship probably results from the effect of frost, so observable in the lower grades.

"No differentiation of the flours can be made from their protein content; throughout the series there is no marked departure from the average (12.24 per cent).

"The flours of the first three grades give somewhat higher results for gliadin and gliadin ratio than do those of the lower grades. This may point to some relation between maturity and gliadin content, the more fully ripened wheat containing the larger proportion of gliadin. . . .

"The percentages of water-soluble constituents in the flours increase from the first to the last of the series, the increase being chiefly in the nitrogen and ash-free extract or carbohydrates. This agrees in a measure with the sugar results as obtained from both aqueous and alcoholic solutions, but does not fall into line with the data for the volume of loaf produced. There is here no confirmation of Wood's theory [E. S. R., 19, p. 457] that volume of loaf increases with the percentage of sugar present; indeed the evidence is directly to the contrary. It is, however, only right to add that in this series there may be a disturbing influence from the presence of immature or frosted grain.

"The exact nature of the water-soluble carbohydrates of the flours is unknown but is evidently worthy of study. As the volume of loaf is seen to decrease with the increase of this component it seems more than probable that volume is influenced by the amount of soluble constituents, or at all events that such is the case in flours from immature or frosted wheats.

"The results of the present series lend some confirmation to Wood's theory that the shape of loaf is influenced by the ratio to the protein (or total nitrogen) of the soluble ash constituents."

The chemistry of strength of wheat flour, II, T. B. Wood (*Jour. Agr. Sci., 2 (1907), No. 3, pp. 267–277, pls. 2*).—The experiments reported were made in continuation of earlier work (E. S. R., 19, p. 457).

The author studied especially the influence of variations in acidity and the amount of soluble salts in flours upon baking quality and the general effect of acids and salt solutions upon the character of gluten. It was found that gluten immersed in distilled water would retain its coherence for some time, probably until bacterial changes occurred, or if the water were frequently changed, until all acids and salts had been removed. In dilute acid solutions, however, gluten began to disintegrate and lose its coherence, while strong acid solutions produced coherence. Common salt added to the solutions tended to maintain the coherence of the gluten, and this relation was studied with different proportions of several salts.

The experiments reported, according to the author, "show quite clearly that the physical properties of gluten are entirely altered by changing its surround-

ings." In general, "the properties of gluten depend on the nature and concentration of acid and salts in the solution with which it is in contact, and the connection between the properties of gluten and the concentration of acid and salts is a peculiar one which would not be made evident by comparison of analytical figures with bakers' marks. . . .

"The properties of gluten which vary with concentration of acid and salt are coherence, elasticity, and water content, and it is suggested that these properties have an important bearing on the shape of the loaf, and that a knowledge of the acidity and soluble salt content of a flour gives a clue to the factor of strength which decides whether the flour will make a good-shaped loaf.

"Finally, it is suggested that the method of investigation adopted may be expected to throw light on all problems depending on the manipulation of proteids, cheese making being especially mentioned."

Report on the manufacture and sale of vermicelli, called song-thân and hô-tiêu, SANDRÉ (*Bul. Écon. Indo-Chine, n. scr., 10 (1907), No. 67, pp. 805–808, figs. 13*).—These 2 sorts of vermicelli are made by natives in Indo-China, the first from green beans (*Phaseolus radiatus*), white beans (*Dolichos albus*), and rice, and the second from manioc. The processes followed are briefly described.

Hawaiian honeys (*Hawaii Sta. Bul. 17, pp. 7–21, pl. 1*).—The bulletin is made up of two articles.

(1) *The source and characteristics of Hawaiian honeys, by D. L. Van Dine* (pp. 7–12).—In connection with a study of apiculture in Hawaii the author has studied the source and characteristics of Hawaiian honeys. It is pointed out that Hawaiian honeys are of two distinct types: A floral honey "which compares very favorably with the official definition of honey and is derived mainly from the flowers of algeroba, and a honeydew product very decidedly abnormal in its chemical composition." Between these two types, and partaking of some of the characteristics of each, are natural honeys that are the result of some of the bees in a hive visiting flowers where floral nectar is gathered and others visiting sugar cane where honeydew is collected, the character of the product being determined by the relative proportion of the nectar and honeydew gathered and stored. "So long as there is an abundance of flowers, the honey produced will be wholly of the first type, but as the supply of floral nectar decreases the bees visit the cane fields, where they collect honeydew, and when there is a dearth of flowers honeydew alone is collected. This condition results in natural combinations of the two types, which show every gradation from the pure floral product to that derived wholly from honeydew."

As the author points out, algeroba honey does not depart from the requirements of the official standard except in its high ash content (0.44 per cent).

"Algeroba honey is nearly water white in color and solidifies soon after extraction. Its delicate flavor recommends the product for table use.

"Honeydew honey is noncrystalline and usually of a very dark color. The aroma is very similar to that of molasses and the taste insipid. The product is abnormally high in ash, the amount ranging from 1 to 2 per cent, and it has a decided right-handed polarization.

"On account of its wide variation, Hawaiian honey can not be sold on sample. Polarization is necessary to determine whether or not the product is optically right or left handed.

"The algeroba and other natural honeys produced in Hawaii which polarize to the left essentially come within the standard definition of honey, since they meet all the requirements, with the exception of the ash content. The honeydew honey and other natural Hawaiian honeys which polarize to the right should be designated by a modifying term, such as is included in the phrase 'honeydew

honey.' Such honey may further be described as a natural product containing no added glucose or other added sugars. It is a product gathered and stored by the honeybee and as such is unadulterated.

"The present official definition of honey is based on examinations of types of well-known floral honeys and represents honey sold and used for table consumption. For this trade, color and aroma are all-important. On the other hand, more than 50 per cent of the honey produced in the United States is used in the baking and confectionery trade. For this trade, color and aroma are of less importance. The value of honey for baking purposes depends on its baking and boiling properties. Honey is used in bakestuffs and candies for the reason that it imparts a texture and degree of moisture that other sugars will not give. Buyers assert that Hawaiian honeydew honey has better baking and boiling properties than the higher grade algeroba honey, and one local company received from one-half cent to 1 cent more per pound for their honeydew honey than they did for the algeroba product of the 1906 crop."

(2) *Chemical composition of Hawaiian honeys, by Alice R. Thompson* (pp. 13–21).—Analyses are reported of 49 Hawaiian honeys of known origin which were collected by the station entomologist, and were of two types, namely, floral honeys and honeydew products, and natural mixtures of the two types. The methods followed are described.

Concerning coffee, K. Gorter (*Bul. Dépt. Agr. Indes Néerland., 1907, No. 14, pp. 62; Liebig's Ann. Chem., 358 (1908), No. 3, pp. 327–348; 359 (1908), No. 1–2, pp. 217–244*).—Extended chemical studies of coffee led the author to conclude that its chief constituent is the caffein potassium salt of chlorogenic acid, a dibasic acid with a melting point of 206° to 207°. By means of its salts and cleavage products the character of this acid was studied and a structural formula is proposed. A pectin body was found in coffee beans which gave mucic acid on oxidation with nitric acid and galactose and pentose when hydrolyzed. A new acid was isolated from coffee in crystalline form, having the formula $C_{34}H_{54}O_{15}$ and a melting point of 255°, for which the name "coffalic acid" is proposed. On cleavage with acid and alkali it gave isovaleric acid.

An oxidase was identified in Liberian coffee beans which produced color with the potassium caffein salt of chlorogenic acid. The caffetanic acid of earlier investigators is not a distinct chemical compound, according to the author, but a mixture of chlorogenic acid, coffalic acid, and other substances.

On the preparation and sale of vinegar, in relation to the administration of the sale of food and drugs acts, J. M. Hamill (*Local Govt. Bd. [Gt. Brit.], Med. Dept., Rpts. Insp. Foods, 1908, No. 5, pp. 28*).—On the basis of personal observation and data collected from a variety of sources, the author discusses the manufacture of malt and other brewed vinegars, distilled vinegar, wine, spirit, and other vinegars, artificial vinegars, and concentrated and fortified vinegars, the possible vinegar impurities, and related questions with special reference to the food and drugs acts of Great Britain.

An appendix by A. Harden contains a summary of the results of the examination of vinegar by public analysts and a compilation of legislation regarding vinegar in the United States, Italy, and certain of the British dominions.

Fruit juice statistics, 1907, A. Bömer (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 3, pp. 129, 130*).—A summary of data reported in the following studies.

Concerning fruit juices for the year 1907, A. Behre, F. Grosse, and K. Thimme (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 3, pp. 131–139*).—The authors expressed and examined a number of samples of different sorts of fruit juices.

Concerning the composition of fruits and berries and the value of chemical analyses in judging marmalade, together with fruit statistics for the year 1907, E. Baier and P. Hasse (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 3, pp. 140–143*).—The analyses of fruit and fruit juices reported were made with a view to securing data for the use of food chemists.

Concerning fruit juices and marmalades for the year 1907, K. Fischer and K. Alpers (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 3, pp. 144–147*).—A number of analyses of fruit juices and marmalades are reported, which were undertaken to secure data for judging of the quality of fruit products.

Fruit juice statistics for the year 1907, F. Schwarz and O. Weber (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 3, pp. 147, 148*).—Analyses are reported of 14 samples of raspberry juice.

Concentrated fruit juice, A. Rönrig (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 3, pp. 148–152*).—Analyses are reported of fruit juices made by a special process in which the aromatic principles are extracted with chloroform, the remaining juice concentrated, and the aromatic principles again added after freeing from chloroform.

Hungarian fruit juices, J. Halmi (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 3, pp. 153–160*).—A large number of analyses are reported and discussed.

The detail of the enforcement of the Food and Drugs Act, W. D. Bigelow (*U. S. Dept. Agr. Yearbook 1907, pp. 321–328*).—This paper discusses the administration and application of the Federal Food and Drugs Act of June 30, 1906. The enforcement of the law naturally proceeds along two lines, namely, the inspection of imported foods and drugs, and the inspection of domestic products. Such questions as invoices and certification, procedure, prosecution, and seizure and confiscation of illegal goods are considered.

"While it is plainly the purpose of the majority of the manufacturers and dealers to comply with the law, and the character of the foods and drugs on the American market has been greatly improved since its enactment, the prosecution of those who seek to evade it will doubtless cause still further improvement."

The nutrition of man, R. H. Chittenden (*New York, 1907, pp. XII+324, figs. 29*).—In this volume "the attempt has been made to give a systematic account of our knowledge regarding some of the more important processes of nutrition, with special reference to the needs of the body for food." In his discussions the author has incorporated the results of observations and experiments carried on during recent years by himself and his associates, and summarized and discussed this and other data, with special reference to modern physiological views. The subjects treated include foods and their digestion, absorption, assimilation and the processes of metabolism, the balance of nutrition, the source of energy of muscular work, with some theories of proteid metabolism, dietary habits and true food requirements, further experiments and observations bearing on true food requirements, the effect of low proteid diet on high proteid animals, and practical applications of the theories and deductions presented.

The author upholds the position advanced in earlier writings (E. S. R., 16, p. 685) that the protein intake may be materially less than the usual dietary standards require, and in his discussion of this question he quotes the results of a number of experiments with dogs on what he considers a low proteid diet in which the subjects maintained nitrogen equilibrium and body weight, or in some cases made slight gains. For instance, one of the dogs lived for ten

months "with perfect comfort and in good condition on an average daily intake of 0.26 gm. of nitrogen per kilogram of body weight, and with an average fuel value of 70.3 calories per kilogram," while another animal as shown by a twelve months' test required 0.31 to 0.33 gm. nitrogen per kilogram of body weight. For a third dog under observation for nine months "proteid consumption equaling 0.30 gm. of nitrogen per kilogram with a total fuel value in the day's food of 66 to 70 calories per kilogram, was clearly quite sufficient to maintain nitrogen equilibrium and body weight." Data for 3 other dogs are also quoted. In general, the diet contained only small amounts of animal food. According to the author's observations, the digestion of fat under these circumstances was normal.

In general, the author concludes that "the nutrition of man, if it is to be carried out by the individual in a manner adapted to obtaining the best results, involves an intelligent appreciation of the needs of the body under different conditions of life, and a willingness to accept and put in practice the principles that scientific research has brought to light, even though such principles stand opposed to old-time traditions and customs. The master words which promise help in the carrying out of an intelligent plan of living are moderation and simplicity; moderation in the amount of food consumed daily, simplicity in the character of the dietary, in harmony with the old saying that man eats to live and not lives to eat. In so doing there is promise of health, strength, and longevity, with increased efficiency, as the reward of obedience to Nature's laws."

Food and diet in the United States, C. F. LANGWORTHY (*U. S. Dept. Agr. Yearbook 1907, pp. 361–378*).—Popular ideas regarding diet, the object of dietary studies, methods of interpreting results of such investigations and similar questions are discussed with special reference to the dietary work which has been carried on in the United States. A brief summary is given of the results of American and other dietary studies, and it is pointed out that in the interpretation of results of such studies age, sex, muscular work, and similar factors must be taken into account. The dietary standards suggested for man in full vigor at moderate muscular work follow:

Dietary standard for man in full vigor at moderate muscular work.

	Protein.	Energy.
	Grams.	*Calories.*
Food as purchased	115	3,800
Food eaten	105	3,500
Food digested	95	3,200

Estimations of the amount of mineral matter required per man per day are also given, the values quoted being deduced from a summary of available data.

Estimated amount of mineral matter required per man per day.

	Grams.		Grams.
Phosphoric acid (P_2O_5)	3–4	Calcium oxid	0.7 –1.0
Sulphuric acid (SO_3)	2–3.5	Magnesium oxid	.3 –0.5
Potassium oxid	2–3	Iron	.006–0.012
Sodium oxid	4–6	Chlorin	6 –8

The differences between so-called dietary standards and physiological requirements are discussed as well as the adequacy of the American diet, kind of food eaten in American homes, and similar questions.

"An extended survey of the literature of food supply and the food habits of many races makes it plain that in no country is there a greater variety of readily accessible foods of good quality than in the United States and in none is there a more general use of a wide range of articles. Thanks to our varied climate, our ready means of transportation, and our facilities for marketing and handling food products, the contributions of any given locality are readily accessible in other regions. Skill in selecting from this great variety of food products and in the preparation of foods after they are purchased is essential if out of our abundance a diet is to be secured which is best suited to the needs of the American people. The dietary studies herein summarized and other similar reliable data seem to show that the people of the United States as a whole are adequately nourished as compared with other races. The acknowledged energy and achievement of the American people, together with their general good health and physical well being, certainly indicate that we have in the main used our food resources advantageously."

ANIMAL PRODUCTION.

Chemical studies on growth. I, The inverting enzyms of the alimentary tract, especially in the embryo. L. B. Mendel and P. H. Mitchell (*Amer. Jour. Physiol., 20 (1908), No. 1, pp. 81–96*).—The conclusions drawn from the authors' investigations with pigs, dogs, and chickens follow:

"The early appearance of inverting enzyms in the intestine of the embryo corresponds with the relatively early specialization and histological development of the portion of the alimentary tract here investigated. The alimentary proteolytic enzyms, like the special glands which elaborate them, come into evidence at a comparatively late period. Maltase is the most universally distributed of all inverting enzyms. In the embryo pig maltase and lactase are found in the intestine, while sucrase is missing. After birth all three enzyms are present. In the full-grown pig lactase is not regularly found in all portions of the small intestine. In the newly born puppy all the enzyms are found.

"In birds other conditions prevail. Lactase is not found at any period; sucrase, on the other hand, is uniformly present in the newly hatched chick and the adult hen. One might be inclined toward a teleological explanation for the absence of lactase from the intestine of nonmammalian animals, and similarly for the absence of sucrase from the embryos of the pig, sheep, and cattle. Such considerations apply with less force, however, to the subsequent formation of sucrase, or its embryonic occurrence in birds. For the present, the statistics of the occurrence of the alimentary inverting enzyms must await a more adequate interpretation with respect to their functional significance. At any rate, it is safe to conclude that the alimentary tract of the young mammal is, as a rule, even more adequately equipped to digest and utilize the sugar of the milk than are the adults of the same species."

Chemical studies on growth. II, The enzyms involved in purin metabolism in the embryo. L. B. Mendel and P. H. Mitchell (*Amer. Jour. Physiol., 20 (1908), No. 1, pp. 97–116*).—The authors summarize the results of their investigations as follows:

"The nucleic acid of the liver of the embryo pig probably contains only two purin complexes—adenin and guanin.

"The liver is capable of undergoing autolytic changes at an early age. Nucleases are present which liberate purin bases from the nucleic acid complexes.

"The liver of the embryo pig contains adenase, even in its early stage of development, but no guanase. In this respect it shows the specific character of the liver of the adult animal.

"An extract of embryo viscera, other than the liver, readily gives indication of the presence of guanase at an early age.

"The unlike distribution of these two enzym reactions under comparable conditions of experiment give further evidence in favor of the existence of two distinct and specific deamidizing enzyms.

"It has not been possible to demonstrate the formation of uric acid from preformed or added purin bases (adenin or hypoxanthin) by extracts of embryonic tissues. The preliminary oxidative transformation of hypoxanthin to xanthin is likewise doubtful. Xantho-oxidase is not present in the embryo visceral organs of the pig; it is found, however, in the livers of the full-grown and suckling animals of the same species. The latter readily form uric acid from purins under suitable conditions.

"The uricolytic enzym has not been found in extracts of embryo pig tissues under conditions in which it is readily identified in the adult organs. The enzym appears either shortly before or after birth. These observations speak in favor of the specific uricolytic power of tissue extracts, and indicate that the destruction of uric acid in such solutions is not solely due to the alkalin reaction, etc., of the digesting medium.

"The tardy appearance of the oxidative and katabolic enzyms concerned in the transformation of the purins is suggestive as a characteristic of growing, synthetic organisms."

Chemical studies on growth. III, The occurrence of glycogen in the embryo pig, L. B. Mendel and C. S. Leavenworth (*Amer. Jour. Physiol., 20 (1908), No. 1, pp. 117–126*).—Quotations from the authors' summary of their paper follow:

"The . . . experiments [reported] can not be interpreted as giving evidence that a large glycogen content is a characteristic of embryonic structures or developing tissues; for the tissues, examined by adequate methods, show no unusual richness in this carbohydrate. The distribution is not markedly different from what pertains in the adult animal, except that the liver does not assume its glycogen-storing function early, at least in the pig. This conclusion seems as reasonable, in the absence of direct contradictory evidence, as to attribute the uniformly noted poverty in hepatic glycogen entirely to the deficient nutrition of the maternal animal. . . . The metabolism of glycogen in the embryo is doubtless comparable with its rôle in the nutrition of the adult; and it seems unnecessary to postulate any special formative property to account for its presence. Glycogen may thus be regarded simply as a store of nutrient energy rather than as a peculiar mark of histogenesis."

Chemical studies on growth. IV, The transformation of glycogen by the enzyms of embryonic tissues, L. B. Mendel and T. Saiki (*Amer. Jour. Physiol., 21 (1908), No. 1, pp. 64–68*).—Liver muscle and blood from pig embryos and liver from adult pigs were studied. The developing muscle tissue, which contains glycogen during embryonic life, gave evidence during the early stages of this period of a relatively greater glycogen-digesting power than that of liver tissue, which is free from glycogen.

"The principal feature to be emphasized in the present experiments is the variable equipment of amylolytic enzyms in the embryonic tissues and its correlation with developmental changes. The embryo liver, which is early free from glycogen, only gradually acquires its characteristic digestive capacity, the amylolytic efficiency increasing with growth."

Chemical studies on growth. V, The autolysis of embryonic tissues, L. B. MENDEL and C. S. LEAVENWORTH (*Amer. Jour. Physiol., 21 (1908), No. 1, pp. 69–76*).—Using tissues from pigs and pig embryos, a number of studies were made. "The equipment for autolytic tissue disintegration is present early in the embryo, even if it is held in check by the normal environment and reaction of the animal cells. . . . With the contention of certain investigators that these enzyms play no part in metabolism during life we are not at present concerned."

Chemical studies on growth. VI, Changes in the purin, pentose, and cholesterol content of the developing egg, L. B. MENDEL and C. S. LEAVENWORTH (*Amer. Jour. Physiol., 21 (1908), No. 1, pp. 77–84*).—Both hens' and ducks' eggs were used in the investigation undertaken to study the question of purin synthesis in developing eggs. It was found that purin increased during incubation, but not materially after hatching, in tests in which chicks were fed for 2 weeks on a practically purin-free diet of bread crumbs.

Determinations of the guanin, adenin, and hypoxanthin gave "further evidence of the progressive synthesis of purins taking place during the growth of the embryo, and they show that, as in the adult and embryo organs already examined, guanin and adenin are the predominating bases involved."

The proportion of pentoses was also found to increase during the incubation period, while the total ether extract and cholesterol diminished. The studies of fat constituents gave "no evidence of a synthesis of cholesterol in the processes incidental to the development of the chick. On the contrary, the cholesterol appears to disappear in part in company with the rest of the lipoid yoke substances which act here as sources of energy in growth."

Earlier work has been noted (E. S. R., 18, p. 660).

Chemical studies on growth. VII, The catalase of animal embryonic tissues, L. B. MENDEL and C. S. LEAVENWORTH (*Amer. Jour. Physiol., 21 (1908), No. 1, pp. 85–94*).—As in earlier studies of growth, material was obtained from embryonic and adult pigs. The experimental data show the early presence of the catalytic power in embryonic tissues, though considerable variations in the catalytic power of different organs were noted.

Chemical studies on growth. VIII, The occurrence of lipase in embryonic animal tissues, L. B. MENDEL and C. S. LEAVENWORTH (*Amer. Jour. Physiol., 21 (1908), No. 1, pp. 95–98*).—The results obtained in the studies of material from embryonic and adult pigs "gives evidence of the early presence of lipase in the liver and intestine of the embryo; but the activity of the extracts of these tissues is decidedly less pronounced than that of the comparable material from the full-grown animal."

Chemical studies on growth. IX, Notes on the composition of embryonic muscular and nervous tissues, L. B. MENDEL and C. S. LEAVENWORTH (*Amer. Jour. Physiol., 21 (1908), No. 1, pp. 99–104*).—According to the authors, the analytical data presented give further evidence of the comparatively high water content of embryonic tissues.

"Creatin is present in the embryonic muscle, the content being considerably lower than in full-grown animals.

"Among the purin bases obtainable from embryonic muscular structures, adenin and guanin preponderate as in other organs. Hypoxanthin is found free in the tissue, as in adult life.

"Lactic acid can be separated from embryonic muscular tissue, but in exceedingly small amount.

"The distribution of lipoids in the embryonic brain resembles that in 'gray' matter. Cholesterol is present at the earliest periods, while cerebrins are entirely absent."

The materials studied were obtained from embryonic and adult pigs.

The effect of drinking and salting food upon body weight and the water content of the organs, K. FARKAS (*Landw. Jahrb., 37 (1908), No. 1, pp. 51–105*).—The author's experiments were made with sheep, were numerous, and were carried out under a variety of conditions. The total body weight before and after slaughtering, the weight of blood, organs, etc., hourly variations in weight after the water was taken, and other questions were considered.

According to the conclusions reached, when sheep drank so much water that the body weight was increased 8 to 10 per cent it did not after 2 to 5 hours surpass the normal weight by more than 1 per cent. When a normal amount of water was taken the increase in weight was never more than 1 per cent and usually not more than 0.5 per cent. The effects of overdrinking were not noticeable after 5 hours.

If a sheep was given a large amount of salt and was then allowed to drink an excessive amount of water the body weight would be no more than 2.5 to 4.3 per cent greater than in the case of a sheep given no feed or water for 12 hours and not more than 1 per cent greater than that of a sheep given a normal amount of feed and water before slaughtering. These facts are of importance to the buyer, as, if a sheep is sold 10 or 12 hours after salting and watering, an appreciable part of the weight paid for is water contained in the body and not flesh.

The analytical data reported led to the conclusion that simple overdrinking without salt did not affect the water content of the organs even if it was continued for a long time. On the other hand, overdrinking when much salt was taken increased the water content of the lungs and heart and the fatty tissues more or less, and probably the weight of the muscles.

In the author's opinion, the digestive disturbances, loss of appetite, etc., noted when cattle are fed very succulent or wet feed is not so much due to the excessive water content as to the considerable amount of salt which is commonly supplied also.

Digestion experiments, G. S. FRAPS (*Texas Sta. Bul. No. 104, pp. 33*).—The digestibility of Kafir corn, milo maize and molasses, with a basal ration of cotton-seed meal and hulls, was studied with steers as subjects. In addition to the usual constituents the digestibility of the sugars, starches, and pentosans was determined, as was also the fertilizer value of the manure.

The average coefficient of digestibility of the basal ration and the feeds especially studied is shown in the following table:

Average coefficient of digestibility of feeding stuffs—Experiments with steers.

Kind of feed.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Cotton-seed meal and hulls (basal ration)	52.5	94.6	66.5	51.2	43.2
Kafir corn	63.9	78.1	85.4	.....	68.5
Milo maize	65.9	90.2	84.5	.....	.....
Molasses	56.7	.....	104.6	.....	104.4

The following table shows the values which were obtained for the digestibility of the crude fiber, the nitrogen-free extract, and the constituents of the nitrogen-free extract in the different materials studied:

Coefficients of digestibility of nitrogen-free extract and crude fiber.

Kind of feed.	Steer used.	Length of period.	Coefficients of digestibility.					
			Sugar.	Starch.	Pentosans.	Residue of nitrogen-free extract.	Total nitrogen-free extract.	Crude fiber.
Cotton-seed hulls and meals:	*No.*	*Days.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Percent.*
Period 1	1	3	95.4	29.8	86.5	54.0	69.0	54.6
Do	2	6	92.0	12.3	71.9	53.1	64.5	44.9
Period 4	2	8	95.7	28.0	82.9	49.2	65.2	52.1
Do	3	8	96.4	23.6	83.4	54.0	67.2	54.1
Kafir corn:								
Period 2	2	9	86.2	98.0	.....	(a)	82.4	.....
Do	3	3	78.3	96.6	.....	(a)	85.2	.....
Do	3	8	86.2	97.4	.....	(a)	81.3	.....
Milo maize:								
Period 2	2	8	116.3	99.8	.....	(a)	85.9	.....
Do	3	4	103.3	99.7	.....	(a)	83.2	.....
Do	3	8	93.7	99.6	.....	(a)	83.1	.....

[a] The quantity of residue digested was less than the quantity digested from the basal ration.

The author studied the material removed by cold water from the feces in three of his experimental periods and found that something over 3 per cent was soluble, "of which approximately one-third was ash, something over one-third was protein, and less than one-third nonprotein organic matter. About 10 per cent of the total protein, 20 per cent of the total ash, and 3 per cent of the nitrogen-free extract were soluble in water.

"While the above facts are of some interest it was not considered of importance to pursue the investigation further."

The author's summary and conclusions follow:

"The ration of cotton-seed meal and hulls fed in this experiment was digested to a much greater extent than the calculated digestion from average figures.

"The nutrients of the grain of Kafir corn and milo maize are somewhat less digestible than the corresponding nutrients in Indian corn.

"Indian corn has about 10 per cent greater value for feeding than Kafir corn or milo maize.

"The nitrogen-free extract of molasses is highly digestible.

"The productive value of different classes of feeds as measured by the fat produced, is not in proportion to their digestible constituents.

"Increase in crude fiber in a feed means a decrease in productive value.

"Sugars are digested 92 to 100 per cent, even when the reducing materials in the excrement are considered to be sugars.

"The apparent starch of cotton-seed hulls, which can not be true starch, though dissolved by diastase, has a low digestibility.

"The starch of Kafir corn and milo maize is almost completely digested.

"Although the nitrogen-free extract of milo maize and Kafir corn is composed almost entirely of starch, the nitrogen-free extract was digested to a much less extent than the starch. This difference is probably due to a depression of digestibility of the nitrogen-free extract of the meal and hulls. It appears possible that the nitrogen-free extract of starchy feeds is digested to a greater extent than is shown by digestion coefficients.

"It appears possible that crude fiber undergoes changes within the animal which render it soluble in acid or alkali and therefore a portion of the nitrogen-free extract.

"Forty per cent of the phosphoric acid, 25 per cent of the potash, and 48 per cent of the nitrogen, being 42 per cent of the fertilizing value of the feeding stuff, were excreted in the solid excrement.

"About 53 per cent of the total fertilizer value of these feeding stuffs passes into the urine.

"In feeding a ton of cotton-seed meal having a fertilizer valuation of $29.50 to fattening animals, that portion of its fertility which passes into the solid excrement has a valuation of about $12.40, and that which passes into the urine of about $15."

Silage for fattening cattle, B. E. CARMICHAEL (*Ohio Sta. Bul. 193, pp. 149–166*).—A test of the relative merits of corn silage and corn stover was carried on with five lots of seven each and one lot of six steers. On full feed the three lots fed silage received 25 lbs. per head per day, with 17 lbs. of corn and 2.5 lbs. of cotton-seed meal, and the dry-fed lots received 20 lbs. of shelled corn and 2.5 lbs. of cotton-seed meal. The steers were given all the dry coarse fodder they would eat up clean, corn stover being used in the early part of the test and hay of different sorts later. In the 140 days of the test the average daily gain of the steers on silage was 2.333 lbs. and on dry feed 2.313 lbs., the cost of a pound of gain being 9.04 cts. and 10.21 cts., respectively.

Data are recorded regarding the shrinkage in shipment and the manure production of the lots. From two to four pigs followed each lot of cattle, the average gain of those following the silage-fed steers being 1.027 lbs. per head and of those following the dry-fed steers 1.187 lbs. Some of the lots were fed one-third of a pound of tankage per day per pig. The average daily gain in these cases was 1.406 lbs.

"The results of this experiment indicate that silage may be used to good advantage in the fattening of cattle, when stover and hay are high in price. . . .

"No difference in the finish of the two sets of cattle was apparent. This was shown by the fact that, although when the cattle were at market one pen contained only silage-fed cattle and another only dry-fed cattle, a buyer of wide experience, without knowing how the cattle had been fed, purchased both lots at the same price. Other expert cattlemen failed to note any difference between the two lots of cattle.

"It is not to be expected that silage alone or silage and other rough feed will produce a high finish in a short feeding period, since not enough grain is present in the silage for this purpose. Less shelled corn was required, however, by the steers that received silage than by the ones that received only dry feed."

"High-priced feeds do not always prevent fair profits from being secured from feeding operations. Besides, the valuable by-product, manure, remains for use on the farm."

The results are not regarded as final and the experiments will be continued.

Feeding experiments with molasses, S. WEISER and A. ZAITSCHEK (*Landw. Jahrb., 37 (1908), No. 1, pp. 130–149*).—In experiments with steers, the authors conclude that satisfactory results were obtained when 7.64 to 8 kg. of molasses per 1,000 kg. live weight was fed as an addition to a basal ration of 4 kg. alfalfa hay, 2 kg. meadow hay, 3 kg. wheat chaff, and 5 kg. of clover or alfalfa seed screenings. The digestibility of the ration was studied.

In tests with horses, 2.3 kg. molasses fed in addition to 3.25 kg. maize, 3.2 kg. clover, and hay ad libitum gave very satisfactory results. The authors state that the animals remained in the best of condition and left nothing to be desired with respect to work performed. They did not sweat much even in the hot summer months. Four kg. of molasses per 1,000 kg. live weight was also well tolerated. When 5 to 5.5 kg. was fed for a long time no disturbance

in health or in ability to work was noted, but such large amounts of molasses rendered the feed sticky and therefore the animals did not learn to eat the feed so readily or like it so well.

Concerning the nutritive value of different sorts of screenings, F. Tangl and S. Weiser (*Landw. Jahrb., 37 (1908), No. 1, pp. 106–129*).—The authors studied the botanical composition of screenings from clover, alfalfa, and flax seed, and the digestibility of such material by farm animals. As larger coefficients of digestibility were obtained with steers than with sheep or pigs, the authors conclude that the sort of screenings studied can be more satisfactorily fed to the steers than to the other animals.

Concerning blood meal, A. Zaitschek (*Landw. Jahrb., 37 (1908), No. 1, pp. 172–180*).—From the experimental data reported the author concludes that pigs digested the crude fiber and nitrogen-free material of maize fed with blood meal less well than is the case when maize is fed alone. From the summary of data, however, he concludes that blood meal may be profitably used in fattening pigs on account of the relative cheapness of the protein which it supplies.

Kansas concentrated feeding stuffs law (*Kansas Sta. [Pamphlet], 1908, pp. 17*).—The text of the Kansas feeding stuffs law is quoted, the objects, scope and application of the law, the inspection tax, registration of feeding stuffs, analyses of samples and rulings under the law are discussed. The application of the law to condimental or medicinal stock foods is also considered.

The range problem in New Mexico, E. O. Wooton (*New Mexico Sta. Bul. 66, pp. 3–46, pls. 10*).—Physical features of New Mexico range lands, the financial value of such areas and their possibilities, are discussed, with suggestions for rational range management. Of the total area of the Territory, which is about 78,500,000 acres, "more than 90 per cent [is] now valuable for stock raising only and will probably always remain so."

The distribution of the main grass societies on the range is shown, those of most importance being the blue grama, black grama, Colorado blue stem, Arizona fescue, water grass, and salt grass societies. Weeds of different sorts are characteristic of particular kinds of overstocked ranges and a number of poisonous plants are present.

The present carrying capacity for the Territory is estimated as approximately 35 acres per head of cattle per year. The financial value of the range is estimated at from 2.5 to 5 cts. per acre per year, about the prices ordinarily paid. As the range is now run down and not so productive as it might be, or even as it once was, the author recommends that public grazing lands be placed under official control, preferably in his judgment under a cabinet officer and "a system of permits or leases be established under rules adapted to each separate region and governed by the conditions obtaining in the region. The fees should be large enough to support the staff necessary to carry the plan into effect. Some of the objections to this plan are considered. Points which must be covered by the regulations are submitted. These are largely based upon the experience of others."

Poultry work at the Maine Station, C. D. Woods (*Maine Sta. Bul. 157, pp. 203–218*).—The poultry investigations now under way at the station are described, the plans for future work are outlined and the principal lines of work which have been followed in the past discussed and some of the results obtained pointed out, particularly those which pertain to the use of curtain-front houses, dry mash feeding, crate fattening, methods of rearing chickens, and the collection of egg records and their use in breeding up laying strains.

In the discussion of the breeding experiments and the conclusions which may be drawn from the annual egg records it is pointed out that the amount of

variation in regard to egg yield is practically the same at the end as at the beginning of the work, namely from 0 to approximately 250 eggs per hen per year. "That is to say, after 9 years of selection with respect to egg production the birds breed no truer to a definite type of egg production than they did at the beginning. It will be recognized by every stock breeder that this is an important fact to be taken into consideration in passing opinion on the value of the method of breeding poultry which was tried in the experiment."

When the average egg yield is considered year by year there is no evidence of any increase in the egg production of the individual, that is, by selective breeding the average egg production has not been increased, and as a whole the results show "that the quality of high productiveness can not be regarded as any more a fixed characteristic of the station's strain of Barred Plymouth Rocks now than it was at the beginning of the experiment." The author points out that the records show no special change in the proportion of hens with very low egg yield to high producers in the flock, there being relatively few of the low egg producers at any time. Attention is called to the fact that the conclusions now presented differ somewhat from those presented earlier, owing to the fact that some sources of error have been found in the summaries previously published.

"The practical conclusion to be drawn from the results of this breeding experiment seems to the authors to be clear. It is that the improvement of a strain of hens in egg-producing ability by selective breeding is not so simple a matter as it has been supposed to be. Nothing could be simpler than breeding from high producers to get high producers. But if this method of breeding totally fails to get high producers—in other words, if the daughters prove not to be like the mothers in egg production—it can not fail to excite wonder as to whether the simplicity of the method is not its chief (possibly its only) recommendation. Anyone who makes a thorough, first-hand study of an extensive selection experiment carried out, as was this one, by the so-called German method without testing of the centgener power of the individual organisms, can not fail to be impressed, we believe, with the fact that the improvement of a race by selective breeding is a vastly more complicated matter than it is assumed to be by those who maintain that one need only to breed from the best to insure improvement. The supposed 'facts' of heredity on which the practical stock breeder (working for utility points) operates are in very large part inferences rather than facts. What is needed more than anything else for the advancement of the stock-breeding industry in all its phases is an accumulation of definite knowledge of the fundamental principles of the hereditary process. All breeding operations must be based on the laws of inheritance in organisms. The practical stock breeder is able to work out the applications of these laws for himself. What he most needs is broader and deeper knowledge of the laws themselves. This knowledge must come from thoroughgoing, purely scientific investigations."

Poultry keeping for egg production, W. P. Brooks (*Massachusetts Sta. Bul. 122, pp. 3–64, figs. 9*).—In this bulletin, which is designed as a guide to poultry keeping for egg production, houses for growing birds and for laying stock, questions of breeds, incubation, and brooding, and the general management and feeding of both chickens and laying stock are discussed. On the basis of personal experience and experiments made at the station and elsewhere, a summary is also presented of the 13 years' poultry experiments at the station, from which the following conclusions are drawn:

The regular use of condition powder is unlikely to increase the egg product and is unnecessary as a means of insuring health. Cabbages given in moderation are superior to cut clover rowen as winter food for egg production, but if

the amount given is large, the flavor of the eggs is injuriously affected. The number of eggs produced is not affected by the presence of the male, but the average weight of the egg is increased.

"Concentrated vegetable foods such as soy bean meal, linseed meal, gluten meals, etc., should not be used to replace all or even a very large part of animal foods, such as meat or animal meals, beef scraps, cut bone, [illegible] etc. The dry prepared animal foods such as beef scraps and animal or meat meals, if of good quality are cheaper and safer feeds than cut fresh meat and bone and can be so used as to produce an equal egg yield.

"Feeding the mash in the morning, with care not to give too large a quantity, is preferable to feeding it at night. The differences in egg yield on the two systems are small, but giving the mash at night especially in winter must mean empty crops and gizzards long before morning.

"Corn may safely be largely used in rations for laying hens, but its use requires unusual care not to overfeed for best results, and it must be supplemented by a liberal proportion of animal food. With such care and so supplemented, the use chiefly of corn, whole or cracked, and corn meal rather than much wheat and wheat or corn by-products is attended with the following advantages: Lower food cost both per day and per egg, rather more eggs, higher average weight of fowls and better market quality when dressed and an earlier and better molt.

"Buckwheat in any large proportion is a less desirable food for laying fowls than corn . . . Under otherwise similar conditions the less [hard tough] fiber in the ration, the better will be the egg product. Oats, barley, buckwheat and by-products containing the husks of these grains should be sparingly used."

The relative live weight of the organs in chickens, A. Zaitschek (*Landw. Jahrb., 37 (1908), No. 1, pp. 150–171*).—No regular differences in weight were noted in the organs of chickens grouped according to the amount of gains made. The percentage amount of blood, however, was noticeably lower in the case of chickens which had been most quickly, that is, most satisfactorily fattened. In general, the author concludes from the large number of weighings which were made, that the gain in weight is proportionally distributed among the several organs regardless of the method of fattening. In the case of 131 Hungarian chickens, the average dressed weight was 79 per cent of the live weight.

DAIRY FARMING—DAIRYING—AGROTECHNY.

Conditions affecting the proportions of fat and proteins in cow's milk, L. L. Van Slyke (*Jour. Amer. Chem. Soc., 30 (1908), No. 7, pp. 1166–1186*).—The summary of this article as presented by the author is chiefly as follows:

The deductions presented are based upon: (1) 300 analyses of the mixed milk of numerous herds, obtained at cheese factories such as are common in the dairy regions of New York State; (2) 650 analyses of milk of 50 separate herds of cows, covering a period of about six months; and (3) several thousand analyses of milk of individual cows, representing seven different breeds of cows (American Holderness, Ayrshire, Devon, Guernsey, Holstein Friesian, Jersey, Shorthorn), covering several lactation periods for each individual, and an aggregate of about 100 periods of lactation.

General range of variation in the percentage of fat and proteins in milk.—(1) In single milkings of individual cows, the fat varied from 2.25 to 9 per cent, the total proteins from 2.19 to 8.56 per cent, the casein from 1.59 to 4.49 per cent, and the albumin from 0.31 to 5.32 per cent. The highest percentages are found in case of cows far along in lactation. (2) In the case of individ-

ual herds of cows, such as are common in dairy regions of New York State, the fat varied from 2.90 to 5.50 per cent, the total proteins from 2.31 to 3.71 per cent, the casein from 1.70 to 3.02 per cent, and the albumin from 0.41 to 0.97 per cent. (3) In the case of milk consisting of a mixture of the milk of many different herds of cows, the fat varied from 3.04 to 4.60 per cent, total proteins from 2.53 to 3.76 per cent, casein from 1.93 to 3 per cent, and albumin from 0.47 to 0.88 per cent.

Conditions affecting variations of fat and proteins in milk.—The following conditions are considered as of special prominence: (1) Individuality, (2) breed, (3) stage of lactation, (4) food, (5) season, (6) time and manner of milking, including fractional milkings, milk from different quarters of udder, and relative order of milking a quarter of udder.

Conditions affecting the relation of fat to total proteins and to casein in milk.—(1) The breeds studied fall into two general groups; in one case, the ratio of fat to proteins is relatively high (Guernsey and Jersey); in the other, relatively lower. Individuals of the same breed may vary considerably in this respect. (2) The ratio of fat to proteins is very uniform through the lactation period until about the ninth month, when the total proteins increase quite rapidly in relation to fat. The ratio of fat to casein is very uniform throughout the entire period of lactation, there being a slight increase of casein in relation to fat about the ninth month. (3) Variations in composition of milk due to manner of milking affect the fat more or less extensively but the proteins very little.

Conditions affecting the relation of casein to albumin.—Albumin in milk varies quite widely in relation to casein. The relation varies (1) with different breeds, (2) with different individuals of the same breed, (3) with time and manner of milking, (4) the relation is quite uniform during the first eight or nine months of lactation, after which the albumin increases relatively more than the casein.

Methods of calculating casein and total proteins in normal milk.—In the case of herd milk containing 3 to 4.50 per cent of fat, the following formula for calculating the amount of casein has been found to give, in most cases, quite satisfactory results:

$(F-3) \times 0.4 + 2.1 =$ percentage of casein in milk (F equals number representing percentage of fat in milk). Total proteins in milk can be roughly estimated by the following modification of the preceding formula: $(F-3) \times 0.4 + 2.8 =$ percentage of proteins in milk.

The relation of fat and casein in milk to yield of cheese.—In milk of average composition (3.6 to 3.8 per cent of fat) the yield of fresh cheese from 100 lbs. of milk may be ascertained by multiplying the number representing the percentage of fat in milk by 2.7. The yield of cheese may be calculated more closely for milks containing fat below 3.6 or above 3.8 per cent, when the percentage of both fat and of casein in milk is known, as follows: (Casein $\times 2.5$) + (Fat $\times 1.1$) = pounds of fresh cheese made from 100 lbs. of milk.

The relation of fat and casein in milk to composition and quality of cheese.—Cheese made from milk in which fat is high relative to casein is superior in quality to cheese made from milk in which fat is low relative to casein. Skim-milk cheese, whole-milk cheese and cream cheese owe their difference in quality to the difference in relation of fat to casein in milk.

The relation of fat to proteins in milk as a basis for detecting skimmed milk and skimmed-milk cheese.—In the case of herd milk as commonly found in New York State, the milk is open to the suspicion of being skimmed when the percentage of fat is less than that of proteins. Cheese of the Cheddar type which

contains more than 1 part of proteins for 1.2 parts of fat is made from skimmed milk.

The reducing properties of milk, P. Sommerfeld (*Hyg. Zentbl., 4 (1908), No. 1, pp. 1, 2*).—From tests with the use of a 0.5 per cent solution of neutral red in sterile water the author concludes that the reducing properties of milk are not due to preformed reducing ferments but are of bacterial nature.

Bacteria in milk, L. A. Rogers (*U. S. Dept. Agr. Yearbook 1907, pp. 179–196, figs. 6*).—Bacteria in milk, milk flavors, souring of milk, sweet curdling and digestion, bitter milk, stringy or ropy milk, disease-producing bacteria in milk, care and handling of milk, and related questions are discussed in this general summary of micro-organisms in relation to milk.

"While bacteria are in no way essential to milk, they may be considered as normally present in milk, cream, ice cream, butter, and cheese. They may even occur in milk or its products in very large numbers without making it an unsafe food or in any way decreasing its food value.

"Bacteria known to produce disease are seldom isolated from or counted in milk, and bacteriological counts should be taken merely as an indication of the way in which milk has been collected or the temperature at which it has been held. High numbers usually indicate insanitary conditions, careless handling, or old milk. However, milk may be collected under very poor conditions and the bacterial count held down by a liberal use of ice. On the other hand, milk collected in the most sanitary manner may in a few hours contain a large number of bacteria if it is held at a high temperature. Low counts may be due not to clean stables and low temperatures, but to the use of antiseptics.

"Every effort should be made by legitimate means to secure milk with a small number of bacteria, but milk or foods made from milk should not be indiscriminately condemned because they sometimes contain bacteria in numbers which are startling to those not familiar with the nature of these indispensable plants."

Bacterial associations in the souring of milk, C. E. Marshall and Belle Farrand (*Mich. Sta. Spec. Bul. 42, pp. 3–63*).—Studies were made of the entire microbial content of a number of samples of milk in continuation of earlier work (E. S. R., 17, p. 496), in which investigations were confined to selected micro-organisms. "In this work, the micro-organisms isolated from a definite sample of milk are employed for purposes of association with the lactic micro-organism also isolated from the same sample."

The conclusions drawn from the investigations follow:

"Bacteria, ordinarily found in milk, may or may not facilitate the growth of lactic micro-organisms.

"About 57 per cent of the associate micro-organisms when grown in combination with the specific lactic micro-organisms accelerate their growth and action.

"The relative number of each micro-organism introduced into the combination may or may not have a decided influence upon the acceleration of the growth of the lactic micro-organisms of lactic fermentation.

"Acceleration may occur at the beginning of the fermentation, or at the end, or at any stage between.

"The means by which this acceleration of lactic fermentation is produced is not the same in all cases. It appears to be due to products manufactured by the associate micro-organisms, sometimes stable to heat, sometimes unstable; sometimes under alkaline conditions, sometimes under acid conditions; sometimes with apparent digestion, sometimes with no apparent digestion.

"It is very doubtful whether these products combine with the inorganic or casein constituents of milk, as is the case of lactic acid, so as to permit the lactic micro-organisms to grow more freely.

"The period at the beginning of lactic fermentation during which no lactic acid formation can be determined, and during which the number of bacteria is continually increasing, may be greatly shortened by vigorous associate bacteria influencing the lactic micro-organisms.

"Usually the associate micro-organisms disappear with the formation of appreciable amounts of lactic acid; yet the associate micro-organisms may continue or persist, causing an abnormal lactic fermentation.

"Associate micro-organisms may influence lactic fermentation by producing 'off flavors,' 'off aromas,' and an unusual high degree of acidity. Even the character of the acid may be completely changed.

"It follows that the elimination of 'fifth' bacteria is the only means of eliminating the product causing lactic acceleration, inasmuch as the products may be so stable as not to be destroyed by ordinary means of milk treatment."

Bacterial associations in the souring of milk, C. E. MARSHALL and BELLE FARRAND (*Centbl. Bakt.* [*etc.*], *2. Abt., 21 (1908), No. 1–3, pp. 7–59*).—See abstract above.

Variation in the chemical composition of butter, C. CROWTHER (*Univ. Leeds and Yorkshire Council, Agr. Ed.* [*Pamphlet*] *66, 1907, pp. 3–23*).—Data are reported regarding the percentage composition and the Reichert-Wollny number of 126 samples of butter prepared from cream produced on one farm during two years, and these are discussed in considerable detail with reference to the results of studies made on the causes of variation in the water content of the butter and in the proportion of volatile acids. The water content of butter, according to the author, is very largely determined by the nature and amount of working to which the butter is subjected, though a considerable number of other factors also affect it, as the degree of softness of the butter fat, the average size of the butter grains, the temperature of churning and of the water used for washing, the intervals between two workings, the use of dry or moist salt in working, and others. The chief factors affecting the proportion of volatile acids present are the stage of lactation of the cows, the climatic and other conditions affecting their comfort, and the character of their food.

On the relation between clean skimming and clean churning, J. JONAS (*Maelkeritid., 21 (1908), No. 11, pp. 195–202*).—In experiments conducted at Ladelund Dairy School (Denmark) cream containing principally small fat globules gave a buttermilk richer in fat than cream with mostly large globules, and though with very clean skimming (0.05 to 0.07 per cent by the Gottlieb method) the buttermilk was richer in fat than when more fat was left in the skim milk, the yield of butter was increased to a much larger extent. It is therefore important that the milk be skimmed as clean as possible.

Babcock test for butter fat, J. H. FRANDSON (*Idaho Sta. Bul. 63, pp. 6, figs. 4*).—General information regarding the method of operating the Babcock test, prepared in response to inquiries from teachers and farmers.

Researches into some of the chemical changes involved in hard cheese production, T. A. COWARD (*Univ. Leeds and Yorkshire Council, Agr. Ed.* [*Pamphlet*] *68, 1907, pp. 3–23*).—From the results of investigations considered in more or less detail the author concludes that "hard cheese manufacture depends in part, at least, on rennet-enzyms-acid proteolysis, whereby physical and chemical changes are brought about in the curd. In practice, however, it will evidently be necessary to gage all the agents concerned in both these series of changes rather than any selected one, for, from the foregoing experiments

and studies, it follows that the quantity and type, especially of the unorganized ferments added with the rennet; the condition of the proteid when the enzyms are added; the rate as well as the amount of acid development; the condition of the curd when weighting is done, and the extent to which in young cheeses the organisms other than the lactic bacteria exceed the 3:97 proportion; is each able to cause physical and chemical divergencies, which divergencies, if not observed and dealt with during the process of cheese manufacture, will render unattainable the ideal permanent characteristics assumed to be the ultimate aim of the hard-cheese-maker's art."

Butter, cheese, and condensed milk, E. C. BULLOCK (*Bur. of the Census [U. S.], Manfr. 1905, pt. 3, pp. 305–339; Bul. 64, pp. 9–43*).—"This report contains (1) a statistical discussion of the manufacture of butter, cheese, and condensed milk in the United States and in the various States, and the foreign trade in butter and cheese; (2) a discussion of milk products and by-products."

Dairying industry (*Off. Yearbook N. S. Wales, 1905–6, pp. 405–416, pl. 1*).—Statistics regarding the production of milk, butter, and cheese in New South Wales are given.

Report of the dairy test associations of Östergötland County, Sweden, 1906–7, K. A. WESTMAN (*Östergötlands Läns Hushåll. Sällsk. Handl. 1908, No. 1, pp. 72, fig. 1*).—The report shows that 40 test associations, with 454 different herds and 16,897 cows, were in operation during the year or a greater portion thereof. Detailed statements of the average production per herd are given, with kinds and quantities of feed given, the production of milk, butter, fat, and butter per 100 feed units, and also the production price per kilogram of milk, butter fat, and butter.

Milk records, J. SPIER (*Trans. Highland and Agr. Soc. Scot., 5. scr., 20 (1908), pp. 235–258*).—Statistics are given regarding the yield in milk and butter fat of 3,931 cows tested by 7 agricultural societies during the year 1907.

The results discussed clearly indicate the immense improvement in milking stock obtained by judicious breeding. It is also pointed out that "cows producing a large quantity of milk of good quality do so at a much less cost for food per gallon of milk than those yielding half the produce."

Milk and butter tests at the Lincoln show, 1907, E. MATHEWS (*Jour. Roy. Agr. Soc. England, 68 (1907), pp. 138–152*).—A considerable amount of statistics is reported and briefly discussed.

Fat in milk (*Jour. Brit. Dairy Farmers' Assoc., 22 (1908), pp. 83–90*).—The percentages of fat in both morning and evening milk are given for each day except Sunday for an entire year for two herds, one entirely Shorthorns and one mostly this breed with a few Jerseys.

Dairy supervision branch (*Rpt. Dept. Agr. [Victoria], 1905–1907, pp. 38–68, figs. 13*).—The results of the administration during 1907 of the milk and dairy supervision act of 1905 are reported.

Official laboratory of the Province of Quebec, A. L. TOURCHOT (*Rpt. Min. Agr. Prov. Quebec, 1907, pp. 287–375*).—An account of the operations of the laboratory during the year 1907, including a report of tests of 2,087 pieces of apparatus for use in the dairy industry, 350 analyses of milk, a study comprising analyses and bacteriological examinations of 18 samples of rennets from different sources, 96 analyses of butter, and 25 analyses and 36 bacteriological examinations of cheese.

Report of the dairy institution at Memmingen, 1907, K. TEICHERT (*Jahresber. Milchw. Untersuch. Anst. Memmingen, 1907, pp. 15*).—The activities of the institute during the year are summarized.

Investigations on dairy science and dairy practice in the year 1907, II. semester, R. W. RAUDNITZ (*Separate from Monatsschr. Kinderheilk., 6 (1907),*

No. 11, pp. 36, fig. 1).—This includes a list of references to the literature and brief reviews of the important results of the investigations.

Milking machines. I. LINDSTRÖM (*K. Landtbr. Akad. Handl. och Tidskr., 47 (1908), Nos. 1–2, pp. 6–20, figs. 14*).—An historical sketch and general discussion of the problem of machine milking, with illustrations of the more important machines.

Vinification. P. PACOTTET (*Vinification. Paris, 1908, pp. XII+568, figs. 125*).—An extended treatise on the subject of wine making, considering the results of both scientific experiments and practical experience.

The technical manufacture of chemically pure levulose. S. STEIN (*Internat. Sugar Jour., 10 (1908), No. 113, pp. 218–221*).—The author points out the possibility of producing levulose on a commercial scale from inulin. As a source of the latter substance he suggests the use of either dahlia bulbs, which contain 10 to 12 per cent, or chicory root, which contains 6 to 11 per cent, either of which can be produced on a large scale. According to his calculations the levulose could be made from them and sold at a profit at 12 cts. a pound.

VETERINARY MEDICINE.

Proceedings of the American Veterinary Medical Association (*Proc. Amer. Vet. Med. Assoc., 44 (1907), pp. 563, figs. 75*).—A general acount of the forty-fourth annual convention of the association at Kansas City has already been given together with abstracts of the papers read at the meetings (E. S. R., 19, pp. 198–200). The following notes refer to articles not read at the meetings or matters not considered in the previous abstract.

M. E. Knowles describes the symptoms and occurrence of infectious lip and leg ulceration of sheep (pp. 419–424). This disease is quite widely distributed in Montana, occurring on high prairies far away from swampy areas. Sheep of all ages are susceptible. In some cases 60 per cent of the herd has become infected. The chief symptom is necrosis of the tissue about the hoof and upon the lips. If neglected these lesions may become serious. The disease is apparently due to the necrosis bacillus. Ordinarily all cases ultimately recover in the spring, particularly if well fed and cared for.

L. E. Willyoung drew attention to the importance of preventive medicine in army veterinary work (pp. 425–429). The army veterinarian is in a position to apply preventive measures very effectively and under the strictest discipline. Some of the general orders for the regulations of army veterinarians, however, are not based on scientific principles.

An account of the French-Canadian breed of horses was presented by J. A. Couture (pp. 467–471). The history of the development of this breed of horses is briefly outlined and a statement is given of its distinguishing characteristics.

A complete list is given by L. R. Baker of the pathological exhibit prepared by the inspectors of the Bureau of Animal Industry for demonstration purposes. A number of papers were also presented on the educational phases of veterinary medicine. G. H. Roberts made a plea for more cordial intercollegiate relations between the different veterinary schools (pp. 493–501). W. L. Williams gave an outline discussion of subjects which should be taken as preparatory work for veterinary medicine (pp. 502–516).

Report and recommendations regarding veterinary colleges in the United States (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 133, pp. 13*).—A report is given by a committee of five veterinarians appointed by the Secretary of Agriculture for the purpose of obtaining information regarding the course of instruction now

offered at the various veterinary colleges in this country and Canada. Nineteen veterinary colleges were inspected. Recommendations are made as to the matriculation examination and course of instruction necessary to qualify graduates for admission to the civil service examination for the position of veterinary inspector in the Bureau of Animal Industry.

Proceedings of the zootechnic council. G. Gorio (*Ann. Agr. [Italy], 1907, No. 253, pp. 444*).—A complete account is given of the proceedings of the council appointed by the King of Italy for the improvement of domesticated animals in that country. At the various meetings of this council discussions were held regarding the methods of improving cattle, sheep, and the other domesticated animals of Italy.

The practice of immunization, O. Schreiber (*Deut. Tierärztl. Wchnschr., 15 (1907), No. 49, pp. 689–691*).—With the discovery of the possibility of immunization by means of blood serum a great amount of interest was awakened on this subject and numerous experiments have been carried on by various investigators. Preliminary results announced in the treatment of animal diseases by means of blood serum have frequently led to disappointment. The author calls attention to the necessity of further work, particularly in the study of the antagonistic action between the sera of different animals.

The theory of serum activity. O. Bail and E. Hoke (*Arch. Hyg., 64 (1908), No. 4, pp. 313–426*).—The purpose of the investigations which are reported in this paper and which were continued for a period of 2 years was to determine the nature and the action of serum on bacteria. The authors come to the conclusion that the precipitating and bacteriolytic action of serum are one and the same, for the reason that both of these properties are lost by heat. Ordinary sera retain their precipitating power at slightly higher temperatures than their bacteriolytic power. The difference, however, is simply one of degree. Both of these properties are destroyed by treating the serum with cultures of living vibrio or with extracts from cultures of cholera vibrio.

Is acquired immunity inherited? D. Konrádi (*Centbl. Bakt. [etc.], 1. Abt., Orig., 46 (1908), Nos. 1, pp. 41–48; 2, pp. 139–148*).—The author tested the possibility of hereditary immunity in dogs which were vaccinated for rabies. It was found that both the mother and the developing young became immune simultaneously, but that the immunity in the young animals after birth persisted for a longer time than in the mother. The vaccine is in such cases probably transmitted to the young through the placenta rather than through the milk after birth. When the mother dog was immunized some time before becoming pregnant some of the young showed an immunity to rabies while others did not.

The prevention and eradication of stock diseases in South Africa. A. Theiler (*Transvaal Agr. Jour., 6 (1908), No. 22, pp. 217–233, pl. 1*).—A historical statement is given regarding the introduction of animal plagues into South Africa. The first to appear in epizootic form were contagious pleuropneumonia, rinderpest, Texas fever, and East Coast fever. These are still the most important diseases among cattle. Glanders is widely prevalent among horses and mules. Animal industry in South Africa is particularly afflicted with diseases due to animal parasites. In the eradication of piroplasmoses it is possible to proceed either by way of destroying the ticks which carry these diseases or by immunization of all susceptible animals. The destruction of ticks is of no avail unless the work is organized on an extensive plan in which all stockmen affected cooperate.

Carbolic acid in the treatment of bacterial diseases, J. W. Pollock (*Vet. Rec., 20 (1908), No. 1025, pp. 611, 612*).—Satisfactory results are reported from the internal use of carbolic acid in cases of tetanus, septicemia, contagious abortion, cattle plague, and septic conditions of the stomach in cattle and dogs.

Spore formation and other biological processes of the anthrax bacillus, V. Růžička (*Arch. Hyg., 64 (1908), No. 3, pp. 219-294, pls. 3*).—As a result of an extended study of the minute anatomy and staining reactions of the anthrax bacillus the author comes to the conclusion that this bacillus corresponds to a naked nucleus as compared with the usual structure of a protozoan organism.

The action of anthrax serum, A. Ascoli (*Centbl. Bakt. [etc.], 1. Abt., Orig., 46 (1908), No. 2, pp. 178–188, pls. 2*).—The physiological action of anthrax serum can not be explained by the hypotheses which have been proposed for explaining the effect of other vaccinating sera. The active substance of anthrax serum is apparently derived from amboceptors and the serum itself does not hasten the destruction of anthrax bacilli either in vitro or in the living animal. In the experiments reported by the author a constant parallelism was found between the protective and bactericidal action of the serum.

Combating anthrax and blackleg by protective vaccination, Warringsholz (*Berlin. Tierärztl. Wchnschr., 1908, No. 6, pp. 93–95*).—The general application of methods of vaccination in the control of anthrax and blackleg is not recommended except in localities where these diseases are known to prevail extensively. The results of vaccination thus far reported are very satisfactory.

The value of the Straus symptom in the diagnosis of glanders, Liénaux (*Ann. Méd. Vét., 57 (1908), No. 2, pp. 65–69*).—In a number of cases reported by the author great difficulty was experienced in reaching a rapid diagnosis of glanders. The pus that comes from suspected cases does not always produce infection in guinea pigs and the reaction from mallein is not always decisive. The Straus reaction is considered as of great importance.

On some nonspecific reactions of mallein, H. J. Südmersen and A. T. Glenny (*Jour. Hyg. [Cambridge], 8 (1908), No. 1, pp. 14–36, charts 8*).—A series of experiments was carried on to determine whether other bacterial products injected hypodermically into immune horses may cause local reactions similar to those which follow the administration of mallein. The bacterial products used in these experiments included tuberculin and filtrates or toxins from coli bacillus, typhoid bacillus, *Bacillus enteritidis*, streptococci, staphylococci, diphtheria bacillus, proteus, lactic-acid bacilli, etc. It was found that bacterial products from these sources act similarly to mallein in giving large local reactions in certain immune horses. There appeared to be no connection between the reaction and the interval of time since the last injection received by the horse in the course of immunization.

Opportunity was had to test the effect of repeated doses of mallein. In this experiment the conclusion was reached that a glanderous horse may be injected with mallein within a few days after the first injection and still give a reaction, even when the dose is not increased in size. Healthy horses may give increasing reactions upon repeating the dose at short intervals from 4 to 5 times, but the reactions resemble those obtained in immune horses rather than those upon glanderous animals. No temperature reaction was obtained in either glanderous or healthy horses after the second dose of mallein.

The authors find that many horses immunized against other bacteria or bacterial products may give a large local reaction to mallein, but that this reaction is not associated with a rise in temperature, and disappears more rapidly than in a typical mallein reaction.

Barium, a cause of the loco-weed disease, A. C. Crawford (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 129, pp. 9–87*).—An account is given of the distribution of the loco weeds, symptoms of the disease, and an extended historical sketch of loco investigation with references to the literature. It is stated that condi-

tions analogous to those met with in locoed animals occur in other portions of the world, especially Australia.

Experiments with rabbits and sheep were carried on. It was found that the main symptoms described in stock on the range can be reproduced in rabbits by feeding extracts from the loco plants *Astragalus mollissimus* and *Aragallus lamberti*. Inorganic constituents, especially barium, are held to be responsible for this action, at least in the plants collected at Hugo, Colo., though it is suggested that in other portions of the country other poisonous principles may yet be found. Barium acetate was fed to rabbits, the results indicating that small doses of barium salts may be administered to rabbits without apparent effect, but that suddenly acute symptoms set in analogous to what is reported on the range.

"Loco plants grown on certain soils are inactive pharmacologically and contain no barium. In drying certain loco plants the barium apparently is rendered insoluble so that it is not extracted by water, but can usually be extracted by digestion with the digestive ferments. The barium to be harmful must be in such a form as to be dissolved out by digestion.

"In deciding whether plants are poisonous it is desirable not merely to test the aqueous or alcoholic extract, but also the extracts obtained by digesting these plants with the ferments which occur in the gastro-intestinal tract.

"It is important that the ash of plants, especially those grown on uncultivated soil, as on our unirrigated plains, be examined for various metals, using methods similar to those by which rocks are now analyzed in the laboratory of the United States Geological Survey.

"It is desirable to study various obscure chronic conditions, such as lathyrism, with a view to determine the inorganic constituents of lathyrus and other families of plants."

At present it seems best to rely on preventive measures rather than on antidotal treatment.

The diagnosis of rabies, Anna W. Williams (*Amer. Jour. Pub. Hyg., 18 (1908), No. 1, pp. 10–15*).—The smear method for the diagnosis of rabies was used in 487 cases, of which 260 were obtained from the street and 227 were experimental. Of the 260 street cases 185 showed typical Negri bodies. In the laboratory work carried on by the author no brains were virulent in which Negri bodies could not be discovered. Other investigators, however, have reported the determination of virulence in nerve material not showing Negri bodies and it therefore appears to be still necessary to make animal inoculations in order to be sure of the diagnosis.

The histological diagnosis of rabies, V. Babes (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 6, pp. 284–286*).—In diagnosing rabies in dead dogs the author prefers to examine the medulla rather than the hippocampus, for the reason that the former is more easily dissected out. Rabid lesions are more easily recognized than Negri corpuscles and the author prefers to depend upon the former in making a rapid diagnosis of the disease.

Penetration of the toxin and antitoxin of tetanus through the mucous membrane of the large intestine, M. Breton, G. Petit, and H. Vincent (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 4, pp. 160–163*).—It was found that tetanus toxin is so modified or destroyed in large part by the bacterial flora of the rectum that only a minute quantity passes through the mucous membrane of this organ. On the other hand, the antitoxin of tetanus readily penetrates through the mucous membrane of the large intestine. It is also maintained that the intestinal juices are decidedly antitoxic in their effect upon tetanus toxin.

Investigations on the development of trypanosomes in tsetse flies and other diptera, E. A. Minchin (*Quart. Jour. Micros. Sci. [London], n. ser., 52 (1908), No. 206, pp. 159–260, pls. 6, figs. 2*).—In the experiments reported by the author attention was given particularly to the natural transmission of sleeping sickness. The only point of interest to the veterinarian concerns the development of trypanosomes in tsetse flies. The trypanosomes were found to begin but not to complete their developmental cycle in the tsetse fly or other biting insets. It is suggested that the life cycles of different trypanosomes may not all follow the same course.

Baleri, a trypanosomiasis affecting animals along the Nile, G. Bouffard (*Ann. Inst. Pasteur, 22 (1908), No. 1, pp. 1–25*).—Baleri is a trypanosomiasis which affects horses, asses, and dogs, and is due to infection with *Trypanosoma pecaudi*. It is widely distributed along the bend of the Nile. Since this disease is transmitted by tsetse flies the question arises whether it is possible to exterminate these insects. *Glossina palpalis* in the region in question occurs only along those parts of the river where the banks are abundantly overgrown with vegetation and brush.. While the removal of this material would be a serious undertaking it is regarded as practicable.

Studies on tuberculosis (*Arch. Path. Anat. u. Physiol. [Virchow], 190 (1907), Beiheft, pp. 544, pls. 29, figs. 3*).—Immunization of warm-blooded animals against tuberculosis by means of the tubercle bacilli of cold-blooded animals is discussed upon a historical and experimental basis, by J. Orth and Lydia Rabinowitsch (pp. 1–58). It was found that injections of tubercle bacilli from cold-blooded animals were not always harmless to warm-blooded animals and that the immunity thus produced was of little value. A more or less generalized infection took place in some cases, the development of the disease being slow.

H. Beitzke gives a report on experiments and observations in the infection of man with bovine tuberculosis. In an examination of 25 generalized cases of tuberculosis in children, 2, or 8 per cent, were found to be due to the bovine tubercle bacillus. There appear to be a number of transition stages in tubercle bacilli lying on the border line of one or the other of the two main types or between the characteristics of these types. Such atypical human tubercle bacilli may be transformed into typical bovine tubercle bacilli by inoculation into cattle.

E. Klebs discusses in detail the problem of immunization against tuberculosis (pp. 134–195). In attempts to produce immunity in experimental animals by inoculation with tubercle bacilli of low virulence it was found that the weak infection thus produced might entirely disappear, together with all trace of tubercle bacilli. Similar results, however, may ultimately come about from natural infection, for it is occasionally observed that experimental animals inoculated by inhalation of tubercle bacilli ultimately become entirely free from tuberculosis by healing of tuberculous lesions through the natural resisting powers of the animal body. Some beneficial results are also reported from the use of a product called tubercle-sozin, which is said to contain the active principles of the tubercle bacillus without any toxin.

Spontaneous tuberculosis in monkeys was studied by Lydia Rabinowitsch (pp. 196–245). Experiments were made with a considerable variety of apes, using human tubercle bacilli. In nearly all cases the human tubercle bacilli produced typical tuberculous lesions of a generalized character.

M. Koch and Lydia Rabinowitsch give an extended report on their studies of the relationship between avian and mammalian tuberculosis (pp. 246–541). In the course of this study the authors came to the conclusion that mammalian and avian tubercle bacilli are not distinct species but are varieties of a single species adapted to the two groups of the animal kingdom. Avian tuberculosis in general

is characterized by lesions of the abdominal viscera. Infection ordinarily takes place by means of the alimentary tract and the lesions are notable for the extraordinary number of bacteria which they contain. Quite serious and extensive infections were produced in guinea pigs, rabbits, mice, and even in cattle and goats by means of inoculation with avian tubercle bacilli.

The present status of the question regarding the relationship between human and animal tuberculosis, Dammann (*Deut. Tierärztl. Wchnschr., 16 (1908), No. 6, pp. 77–82*).—The two fairly distinct types of tubercle bacilli which have been commonly referred to as bovine and human have been more and more connected in recent years by the finding of a number of intermediate forms which can not be readily classified with either type. The results of recent investigations are unfavorable to the assumption of specific difference between these types.

The chemical constitution and biological properties of the protoplasm of the tubercle bacillus, J. Auclair and L. Paris (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 6, pp. 301–303*).—Of the substances thus far obtained from the tubercle bacillus, tuberculin exercises a general effect, while the fat substance of the bacillus is local in its effects. By means of fractional extraction the authors isolated a form of casein which is believed to be the chief cause of the formation of the tubercle in the progress of tuberculosis.

Intestinal tuberculosis in calves kept in infected stables, A. Ceradini and A. Fiorentini (*Centbl. Bakt. [etc.], 1. Abt., Orig., 46 (1908), No. 2, pp. 104–108*).—The purpose of the experiments reported in this paper was to determine the susceptibility of young calves to tuberculous infection in stables which were known to be infected with this disease. It was found that tuberculosis in sucking calves occurs only exceptionally. In adult cattle the disease appears more frequently as a result of exposure in infected stables. The mesenteric glands of adult cattle may contain virulent tubercle bacilli without showing visible alterations. These glands are very effective in catching tubercle bacilli and other organisms, particularly those of infectious pneumoenteritis in calves.

Clinical diagnosis of tuberculosis of the peritoneum and abdominal lymph glands by means of rectal examination, Storch (*Berlin. Tierärztl. Wchnschr., 1908, No. 8, pp. 141–143*).—Attention is called to the fact that serious cases of tuberculosis of the peritoneum may exist without showing recognizable external symptoms. The author has tested the value of rectal examination in such cases and finds it possible to palpate the tuberculous lesions upon the peritoneum or the tuberculous lymph glands and thus to reach a diagnosis.

Tuberculosis in dairy cows, with special reference to the udder and the tuberculin test, A. Wilson (*Vet. Rec., 20 (1908), No. 1024, pp. 591–596*).—A general account is presented of the nature of tuberculin, the temperature reactions observed in making the tuberculin test, and the importance of this test in putting into practice any scheme for the eradication of tuberculosis. Statistics were collected and are presented in a summarized form regarding the source of tubercle bacilli in milk and the percentage of tuberculous udders in cows.

The absorption of tuberculin by the rectum, A. Calmette and M. Breton (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 4, pp. 163–165*).—In tuberculous rabbits and guinea pigs it was found that intrarectal injection of tuberculin produced the same effects as subcutaneous injection. In healthy rabbits and guinea pigs a single intrarectal injection of large doses or of repeated small doses of tuberculin produces a gradual intoxication which nearly always ends fatally.

Tuberculin, H. E. Reeser (*Centbl. Bakt. [etc.], 1. Abt., Orig., 46 (1908), Nos. 1, pp. 56–67; 2, pp. 149–167*).—In most cases a reaction may be obtained from an injection of tuberculin made only a few days after a previous injection. The

dose need not be increased in order to obtain the reaction. The reaction to the second dose of tuberculin, however, is not constant and the reason for the irregularity observed in such cases is not well understood. As a rule, the second reaction appears more promptly than the first and is somewhat less intense.

With regard to the temperature reaction from tuberculin it appears impossible to fix a minimum under which we may know with certainty that tuberculosis does not exist. In general a temperature of at least 40° C. in animals which showed a maximum of 39.5° C. before injection may be relied upon as indicating the presence of tuberculosis.

Ophthalmo-tuberculin reaction in cattle, E. F. McCampbell and D. S. White (*Jour. Expt. Med., 10 (1908), No. 2, pp. 232–237*).—Tests of the ophthalmo-tuberculin reaction carried out by the authors on cattle indicate that this method is of some value for diagnostic purposes. A characteristic conjunctivitis appears within 6 or 8 hours in tuberculous animals, disappearing after 48 hours. The reaction is more pronounced in cattle which have not been recently tested with tuberculin, but is only slightly reduced in intensity as a result of a previous subcutaneous injection.

Administration of the tuberculin test by stable helpers, A. Van Leeuwen (*Tijdschr. Vecartsenijk., 35 (1908), No. 5, pp. 269–276*).—In the opinion of the author the ordinary attendants about cattle barns are not capable of giving the tuberculin test in a satisfactory way. It is recommended that the test be applied only by qualified veterinarians.

Dangers from the use of tuberculous animal products. Treatment of tuberculosis with strychnin, V. Galtier (*Jour. Méd. Vét. et Zootech., 58 (1907), Dec., pp. 705–712*).—Feeding experiments with the meat of tuberculous animals indicated that this material ordinarily does not contain tubercle bacilli. It is recommended, however, that such meat should always be sterilized by thorough cooking before being used as human food.

Somewhat beneficial effects were observed in experimental tuberculosis as a result of treatment with arsenic or iodid of sodium combined with strychnin or by the use of strychnin alone. Strychnin appeared to increase the resistance of the animal to tuberculosis, to prevent to some degree the generalization of the disease, and to lead to a more hasty healing of lesions.

Chronic pseudotuberculosis in Norway, H. Horne (*Norsk Vet. Tidsskr., 20 (1908), No. 3, pp. 72–77, fig. 1*).—Pseudotuberculous enteritis, or Johne's disease, occurs quite frequently in Norway. The lesions produced in the alimentary tract are described. The author believes that this disease has not been shown to be identical with tuberculosis.

Protective vaccination of cattle against hemoglobinuria, Bugge (*Berlin. Tierärztl. Wchnschr., 1908, No. 6, pp. 95, 96*).—Among 138 cattle vaccinated against hemoglobinuria, 7 subsequently became affected with the disease and 2 died. It is believed that the vaccine used in these cases was somewhat too virulent. The suggestion is therefore made that in future experiments along this line a vaccine be used of lower virulence or in smaller doses.

Bacilliform piroplasmosis of cattle in Algeria, H. Soulié and G. Roig (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 4, pp. 192, 193*).—A piroplasmosis occurs in Algeria under two or three forms, the symptoms of which forms are described by the authors. It is not certain whether the bacilliform piroplasmosis thus identified is an atypical form of Texas fever or a distinct disease.

Post-partum paralysis of cows, A. Zehl (*Berlin. Tierärztl. Wchnschr., 1908, No. 7, pp. 117–121*).—Not all cases in which cows are unable to rise after parturition are to be classified as parturient paresis. The symptoms, however, are strikingly similar in most respects and cases of either disease are readily cured by infusion of air into the udder.

Cattle quarantine law in Nebraska, G. W. Hervey (*Twentieth Cent. Farmer, 1908, No. 376, pp. 6, 7*).—Cattle mange has persisted in western Nebraska for more than 15 years and ranchmen have, for some time, made regular dippings of stock for curative and preventive purposes. The present cattle quarantine law of Nebraska is considered defective, for though it appears to be quite rigid there is no adequate provision for enforcing its various features. For this reason, Federal aid is believed to be required in the control of cattle mange.

Construction of cattle dips, P. Cowley (*Agr. Gaz. N. S. Wales, 18 (1907), No. 9, pp. 756–761, pl. 1*).—Detailed directions are given for the construction of dipping vats of brick and concrete. Cement draining yards and settling tanks are also included in the specifications.

Bovine bilharziosis in France, G. Marotel (*Bul. Soc. Cent. Méd. Vét., 85 (1908), No. 4, pp. 119–122, figs. 2*).—The occurrence of *Schistosomum bomfordi* is reported in cattle in France. A detailed description is given of the anatomy of this worm.

Schistosomum bovis and the alterations produced by it, G. Bertolini (*Clin. Vet. [Milan], Sez. Sci., 31 (1908), No. 1, pp. 1–64, pls. 3*).—*Schistosomum bovis* in the cattle examined by the author occurs in about 9 per cent of cases. The adult parasites are found in largest numbers in the portal circulation, especially in the ramifications of this system in the liver. The location of the parasites, however, varies greatly in different cases. Eggs are laid chiefly in the small intestines but also to some extent in the large intestines. In the small intestines the effect of parasitism include catarrhal enteritis and the formation of nodules under the mucous membrane.

Sheep scab, E. L. Moore (*South Dakota Sta. Bul. 107, pp. 355–382, figs. 4*).—This bulletin gives an account of the forms and symptoms of the disease, the biology of the mites producing it, manner of transmission, remedies, and Federal and State regulations to prevent the spread of scabies in sheep.

The use of communal funds in organizing a system of vaccination against swine erysipelas, Bartels (*Deut. Tierärztl. Wchnschr., 16 (1908), No. 7, pp. 93, 94*).—The authors had occasion to test the feasibility of using district communal funds for defraying the expense of vaccination for swine erysipelas. It is recommended that where this plan is adopted, vaccination should not be carried out in communities in which swine erysipelas rarely occurs but only in the permanently infected localities.

Hog cholera, Carré, E. Leclainche, and H. Vallée (*Rev. Gén. Méd. Vét., 11 (1908), No. 125, pp. 241–246*).—A study of hog cholera in France has convinced the authors that the disease in that country as in the United States, England, and Germany is due to a filterable virus and not to the hog-cholera bacillus.

The possibility of utilizing the horse for the production of an immune serum against hog cholera, W. Koops (*Berlin. Tierärztl. Wchnschr., 1908, No. 7, p. 117*).—Difficulties were experienced in obtaining an immune serum against hog cholera from hogs and resort was therefore had to the horse for this purpose. It was soon found, however, that the resistance of the horse could not be raised sufficiently high for the reason that these animals soon showed a supersensitiveness to hog serum. In order to avoid this trouble a method of precipitation was devised by means of which the red blood corpuscles and protein are extracted from the blood before using the material for the hyperimmunization of horses. Further experiments will be required before it is known how effective a serum can be obtained from horses thus treated.

The horse; its treatment in health and disease, J. W. Axe (*London [1907], vol. 9, pp. X+413–610, pls. 12, figs. 47*).—In this volume the author continues the discussion of warranty of soundness of condition of horses at the time of

sale. The general principles of horseshoeing are presented in connection with a description of the anatomy and physiology of the foot, preparation of the feet for shoeing, the various kinds of shoes, and the possible injuries from defective shoeing. The problems connected with the transportation of horses by sea and land are also discussed. Considerable attention is given to the geological and recent history of the horse and related species.

A glossary of technical terms is appended to the volume and also a general index of the nine volumes.

The Borna horse disease, H. Raebiger (*Landw. Wchnschr. Sachsen, 10 (1908), No. 8, pp. 75, 76*).—The so-called Borna horse disease persists in various localities of Saxony. The means suggested by the author for controlling the disease include a sanitary supervision of the water and food and better care of the horses.

Etiology of infectious pneumonia of horses, E. Tabusso (*Rev. Gén. Méd. Vét., 11 (1908), No. 124, pp. 177–186*).—In four cases of infectious pneumonia in horses the author found *Pasteurella equi* to be the pathogenic organism. It is not maintained, however, that this is the only organism which may produce an infectious pneumonia in horses.

The treatment of foal lameness, Beck (*Wchnschr. Tierheilk. u. Viehzucht, 52 (1908), No. 8, pp. 145–147*).—The administration of iodid of potash directly to young colts affected with lameness of bacterial origin was unsatisfactory. Far better results, however, were obtained from the indirect use of the drug by giving it to the mares. The milk then contains a sufficient quantity of iodid of potash to bring about satisfactory results in the majority of cases. In 14 cases thus treated 12 recovered entirely. The umbilical cord was treated with an antiseptic solution in all of these cases. In 6 other cases in which no attention was given to the umbilical cord but in which the mares received the iodid of potash in doses of 10 gm. daily, 5 of the colts recovered after a few days.

Experimental leukemia in fowls, V. Ellermann and O. Bang (*Centbl. Bakt. [etc.]. 1. Abt., Orig., 46 (1908), No. 1, pp. 4, 5*).—Much difference of opinion has prevailed regarding the nature of leukemia in animals and man. The authors had occasion to carry on some experiments with this disease in fowls. It was found that during the progress of leukemia, the number of leucocytes may be half as great as that of the red blood corpuscles. True leukemia in contrast with so-called infectious leukemia runs a chronic course. The modification of the formula for the blood elements is not due merely to an increase of the white corpuscles in general. The mononuclear forms are greatly increased in numbers while the polynuclear leucocytes are present in relatively diminished numbers. If healthy fowls are inoculated intravenously with an organic emulsion containing these leucocytes a typical case of leukemia is produced within 3 months. The authors are disposed to believe that leukemia will prove to be infectious but the organism has not yet been determined.

Avian diphtheria and contagious epithelioma, V. Fally (*Ann. Méd. Vét., 57 (1908), No. 2, pp. 69–75*).—In the experiments reported in this paper the author attempted to reach a differential diagnosis between these diseases or to obtain evidence as to their identity or dual nature. It is admitted that a fowl may have both diseases at the same time but that recovery from roup does not protect the fowl against epithelioma or vice versa. The author believes, therefore, that the two diseases are distinct.

The parasitic amebæ of the intestinal tract of man and other animals, E. L. Walker (*Jour. Med. Research, 17 (1908), No. 4, pp. 379–459, pls. 4*).—An elaborate review is given of the development of our knowledge regarding parasitic amebæ. The author also discusses methods of cultivation of amebæ,

the reproductive processes which occur in the genus, the nomenclature and the biology of these forms. Detailed descriptions are presented of 38 species of parasitic amebæ which have been found in animals and man. A bibliography relating to the subject is also given.

RURAL ENGINEERING.

Progress report on irrigation experiments in Willamette Valley, Oregon, A. P. Stover (*U. S. Dept. Agr., Office Expt. Stas. Circ. 78, pp. 25, figs. 7*).—This circular describes experiments in irrigation in the Willamette Valley and gives tentative results of the first season's work. While this valley has a rainfall of approximately 44 in. per annum, that which occurs during the summer months is very small, the average for the three months' period from the middle of June to the middle of September being only about 2½ in. This valley has been under cultivation for more than half a century and has been a great wheat-growing region, this crop maturing before the summer drought, but the land has ceased to produce profitable crops of wheat and diversification has become necessary. In order that the crops may be grown throughout the dry summer irrigation is required and the experiments undertaken are for the purpose of determining methods, cost, and returns. The returns reported from the single season indicate large profits from the use of water during the summer months.

The use of small water supplies for irrigation, S. Fortier (*U. S. Dept. Agr. Yearbook 1907, pp. 409–424, figs. 6*).—"From an agricultural standpoint the greatest need of the arid and semiarid regions is a larger water supply. Out of a total of about 900,000,000 acres less than 1⅛ per cent is artificially watered. When all of the available water supplies are utilized it is doubtful if more than 7 or 8 per cent of the total area can be irrigated." The importance of utilizing every available source of water for irrigation is, therefore, evident. This article calls attention to the possibilities of developing small water supplies and shows the methods of using them to the best advantage. It describes typical plants for storing water from springs, and for pumping water from wells by windmills, engines, and electric motors. Methods of construction and cost of plants, methods of using water and returns from the lands are given.

Irrigation with household waste water, H. Selkirk (*Agr. Gaz. N. S. Wales, 19 (1908), No. 3, pp. 223, 224, fig. 1*).—A simple system of pipes and drains for utilizing the house sewage in irrigating vegetables and fruit trees and the benefits derived from such irrigation are briefly described.

Drainage in New York, E. O. Fippin (*New York Cornell Sta. Bul. 254, pp. 391–428, figs. 29*).—The large area in New York requiring drainage includes the marsh or swamp land and the heavy clay soils. The marshes, scattered throughout the State in irregular areas but extensive in the aggregate, are practically useless for agricultural purposes without drainage. The heavy clay soils are in cultivation but their crop value has been greatly reduced by the loss of vegetable matter in the soil, followed by pronounced physical changes whereby the soil has become harder and more compact, the rainfall moving over the land rather than through it, and the subsequent rapid drying causing it to become dense and impervious. These physical changes have given rise to extremes of wetness and drought. Such soil can be reclaimed only by drainage and better methods of cultivation, and thorough tile drainage is recommended as the best means of reclamation.

A brief account is given of the first tile drains used in America, these being laid near Geneva by John Johnston in 1837. The effects of tile drainage and the benefits that accrue to the soil are set forth.

A discussion is given of the practical details of tile drainage, showing how the work should be planned to meet different conditions, and describing the instruments used in laying out the systems and the tools and methods employed in digging the ditches and laying the tile. The use of machines for digging tile ditches is considered, with data as to the relative cost of machine and hand labor. Tables are given showing the number and size of tile required to drain a given area under specific conditions and also the cost of the various sizes of tile in common use.

The value of open ditches and the efficiency of stone drains, such as are used in some parts of the State, are discussed. An appendix presents an abstract of the New York law relative to agricultural drainage and a list of tile manufacturers in the State.

Dust preventives, L. W. PAGE (*U. S. Dept. Agr. Yearbook 1907, pp. 257–266, pls. 4*).—A discussion of the problem of preservation of road surfaces under automobile traffic and of the use of dust preventives, with an account of the results obtained from the use of mineral oils, coal tar, sea water, magnesium chlorid, sodium chlorid, water-gas tar, and a number of proprietary emulsions.

It is stated that up to the present time no method of building an economical dust-proof country road has been devised. As to the relative values of different substances for the treatment of existing roads, "in certain localities the use of one of these materials is often claimed to be more satisfactory than others. Whether this is due to skill in treatment or to local physical conditions, it is impossible at present to say. In estimating the relative cost of dust prevention by various materials, it must be borne in mind that any substance which prevents the formation of dust, and holds that already formed on a road surface, greatly lengthens the life of a road and consequently lowers the cost of maintenance. This precludes the obtaining of accurate cost data at present, as it can only be had after a sufficient length of time has elapsed to determine the saving in repairs to the road from the use of dust preventives. The entire subject is still in an experimental stage, and where a community wishes to have work of this kind carried on, the advice of some experienced person, familiar not only with one preparation but with many, should be sought in order to avoid costly mistakes and the repetition of failures made in other places."

The effect of alkali on Portland cement, E. T. TANNATT and E. BURKE (*Montana Sta. Bul. 69, pp. 93–120, pls. 5, figs. 4*).—Examinations of cement structures, particularly sewers at Great Falls, Mont., which had been disintegrated by the action of alkali, are reported and discussed in this bulletin.

"Just how the alkali in the soil acts upon the cement is a matter for investigation. It is possible that the action is similar to the action of the salts in sea water . . . or it may be that the cements behave in a manner similar to the soils containing zeolites. Zeolites being hydro-silicates contain as bases chiefly lime and alumina with some potash and soda, which have the power of absorbing alkali salts and exchanging bases with them."

The authors conclude from the investigations that the use of cement construction for sewers is inadvisable in alkali soils unless it is possible to drain all ground water from the exterior of the sewer. Sandstone and concrete foundations for buildings are subject to the same objections.

Conditions affecting the production of denatured alcohol in the Northwest, J. S. JONES (*Idaho Sta. Bul. 60, pp. 3–21*).—A popular discussion is given of the present situation in the Northwest, with excerpts from the Federal laws relating to the production of denatured alcohol, an exposition of some of the regulations of the Commissioner of Internal Revenue, and data as to the efficiency of denatured alcohol for light, heat, and power. Although no denatured alcohol

is now produced in the Northwest and its general use is prohibited by the high price ($1 per gallon) at which it is sold, and by the lack of suitable burners, engines, and other appliances, the author believes that it will eventually become an active competitor of gasoline in the region, and that special farm crops will be grown for its production for local use.

RURAL ECONOMICS.

Land reform: Occupying ownership, peasant proprietary, and rural education, J. COLLINGS (*London, 1908, pp. XXIX+452*).—This book is a history of the land-tenure system of England. It proposes as a remedy for rural depopulation, scarcity of trained farm labor, the pauper system, the unemployed in cities, and other rural, economic, and social problems, "a measure of land reform based on the principle of occupying ownership," the creation of a peasant proprietary, and a system of agricultural education that will initiate the children in rural subjects during the most impressionable period of their lives. If this policy could be carried out the author believes "it gives some hope of a remedy for the present deplorable condition of rural life in England."

The agrarian problem in England, G. LECARPENTIER (*Rev. Écon. Internat., 5 (1908), II, No. 2, pp. 403–417*).—This is a historical review of the agricultural land problem in England, including a discussion of the land-tenure system, the inclosure acts relating to common fields, and their effects on rural depopulation. Particular attention is given to the Small Holdings Act of 1907, which is held to correct the defects of a similar act passed by Parliament in 1892. The benefits of the new law relate to the government's interest in making it easier for the small farmer to acquire land and the necessary capital to exploit it.

The farm labor of rural England, F. RYZIGER (*Ann. Gembloux, 18 (1908), No. 7, pp. 403–431*).—The author by personal inquiry and a study of the literature on the subject sets forth in this article a review of the conditions which have brought about rural depopulation in England and considers the governmental and other proposed remedies to counteract the movement toward the cities.

To improve rural labor conditions in England the author believes (1) that information should be procured and presented to farm laborers comparing the actual wage conditions of city and farm laborers, the advantage being easily shown to be with the latter, (2) that farm laborers be given practical instruction especially relating to the advantages offered in rural life, and (3) that they then be left to develop naturally the power of individual initiative.

The farmer and the laborer, T. P. GILL (*Dept. Agr. and Tech. Instr. Ireland Jour., 8 (1908), Nos. 3, pp. 409–422; 4, pp. 635–650*).—These are two addresses delivered before societies of farmers and farm laborers of County Tipperary in February and May, 1908.

The author discusses the existing relations between these classes in Ireland and points out some ways in which improvement could be effected. Among these are mentioned the development of intensive culture, the more regular employment of labor, the raising of first-class dairy, poultry, and other products, the recognition of merit in farm hands by better remuneration, the development of cooperation and mutual credit banks, improvement in the farm laborer's dietary, more efficient training for laborers, a better system of education, and fair facilities for the provident farm laborer to acquire a farm of his own.

Report of the Irish Agricultural Organization Society, Limited, N. T. EVERARD and R. A. ANDERSON (*Rpt. Irish Agr. Organ. Soc., 1907, pp. 79, map 1*).—Detailed statistical data with discussion of the work of the affiliated agricultural cooperative and credit societies for the year ended June 30, 1907. On December

31, 1906, the societies numbered 873, a net gain of 38, and had conducted a business exceeding £2,000,000 during the year. Of this number the cooperative creameries and branches numbered 340 and the mutual credit societies 246.

An uplifting negro cooperative society, R. L. SMITH (*World's Work, 16 (1908), No. 3, pp. 10462–10466*).—This is an account of the development of the Farmers' Improvement Society of Texas from 1890 to 1907, and of the economic and social improvement brought about among negro farmers by means of this cooperative organization which was fostered by the author. From a state of general poverty among farmers due to the prevailing credit system, the society has established a class of negro farmers who are self-reliant, progressive, and property owners. The returns to October, 1907, are as follows: Number of groups 475, with 9,256 members; acres owned by members 71,439, valued at $1,071,585; value of live stock owned by members $275,000; and value of improvements made during the year ended October, 1907, $58,148.

Jews as farmers (*Amer. Cult., 70 (1908), No. 28, p. 2*).—It is estimated that about 5,000 Jews are engaged in agriculture in the United States, and the farm colonies started in many parts of the country, particularly in New Jersey, are briefly described. The Jewish Agricultural Society of New York received 1,345 applications in 1907 from Jews wishing to engage in agriculture and since its organization has assisted 764 farmers in 19 States with loans aggregating nearly $500,000. About one-fourth of this amount has already been repaid, and the farmers assisted now own property with a valuation of about $1,250,000.

Agricultural colonies in Palestine (*Economist, 66 (1908), No. 3380, pp. 1189, 1190*).—This article describes the revival of agriculture in Palestine, largely by Jewish colonists from Russia and Roumania, who have adopted modern implements and methods of culture. The crops raised are oranges, olives, almonds, grapes, and cereal crops, the bulk of which is exported, chiefly to England.

The internal colonization of Prussia and its application to the agrarian problem in Mexico, H. J. LUDEWIG (*Bol. Soc. Fomento [Mexico], 7 (1908), No. 6, pp. 7–83, map 1*).—This bulletin discusses the causes of rural depopulation which took place in Prussia during the last part of the nineteenth century, gives the results of the work of the colonization commission in the establishment of small farms which in 20 years amounted to 18,870, with houses accommodating 75,500 occupants, and points out in what ways such a commission would be helpful to native and immigrant farm laborers in Mexico.

[The relation of the government to agriculture in Russia], TORNE (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), No. 5, pp. 592–601*).—The author describes the methods of securing and publishing agricultural statistics in Russia, the government measures for encouraging the exportation of agricultural products and assisting the industry as a whole, the territorial, administrative, and communal organization of the rural population, and the establishment of schools for the teaching of agriculture.

The assistance rendered by the government to the agricultural population consists in aiding colonists by advancing money, seed, instruments, lumber, and other forms of capital, in encouraging the peasants to become landowners, and in so redividing and reassigning the communal lands as to assign to each peasant a single piece of land equal in extent to the many separate parcels formerly held by individuals or families under the old communal system of land tenure.

State aid to agriculture in foreign and colonial countries, W. E. BEAR (*Trans. Highland and Agr. Soc. Scot., 5. ser., 20 (1908), pp. 1–36*).—The amount of money expended by various governments for different lines of work relating to agriculture are tabulated and discussed.

Some computed returns of farms in Switzerland (*Landw. Ztschr. Rheinprovinz, 9 (1908), No. 24, pp. 329, 330*).—This article is summarized from a report by Dr. E. Laur on the returns from 916 different-size farms in Switzerland for the years 1901–1906, inclusive. The statistics are believed to indicate that intensive rather than extensive farming gives the better returns. A judicious combination of different branches of farming, with about 50 per cent of the land, labor, and capital devoted to dairying, is believed to offer the best prospects to farmers in Switzerland.

Agriculture in Siam, Dilock (*Die Landwirtschaft in Siam. Leipsic, 1908, pp. 215*).—This book describes the conditions of agriculture in Siam and is a contribution to the economic history of the kingdom from the agricultural point of view.

Traffic on Chesapeake Bay and Tennessee River, F. Andrews (*U. S. Dept. Agr. Yearbook 1907, pp. 289–304*).—This article discusses the advantages and disadvantages of water transportation of agricultural products, the Chesapeake Bay and Tennessee River traffic being taken as typical of the methods of handling crops. The amount and kind of crops shipped, and the freight rates for water transportation as compared with rates on railroads competing in these regions, are discussed. Freight rates by water transportation are shown to be very much lower than railroad rates, but certain kinds of truck and fruit crops are better and more quickly handled by the railroads. The possibility of improving the methods of loading and unloading agricultural freight carried by steamboats, the need of longer and more regular seasons of navigation, and the importance of making the channels of rivers more navigable for the regular movement of farm produce are particularly emphasized.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 10 (1908), No. 9, pp. 65–72*).—Notes are given on the crop conditions in the United States and foreign countries, with statistics of the farm values and prices of agricultural products and the principal groups of farm and forest products imported into the United States during the years ended June 30, 1907 and 1908.

AGRICULTURAL EDUCATION.

Education [agricultural] (*Encyclopædia of Agriculture. Edinburgh and London, 1908, vol. 2, pp. 9–18*).—Contains a rather full discussion of agricultural education in the British Islands, beginning with the first attempt to institute systematic instruction in the theory and science of agriculture in 1790, when a chair of agriculture was established in the University of Edinburgh. In Ireland the first state-supported school of agriculture was established in 1838, and in England the first agricultural college was founded at Cirencester in 1845. The development and present status of agricultural education in England, Ireland, and Scotland, and the part taken by state and local governments in this educational work are described.

The New York State Agricultural College at Ovid, N. Y., and higher agricultural education, D. Willers (*Varick, N. Y., 1907, pp. 27, pl. 1*).—A historical paper containing data concerning the act of the New York State legislature incorporating the New York State Agricultural College, which was first located at Fayette in Seneca County, and later at Ovid, and subsequent acts relating to Cornell University and the funds derived from the several acts of Congress in aid of agricultural education.

It appears that the New York State Agricultural College at Ovid was opened for the reception of students December 5, 1860, when a class of 27 young men

entered the institution, and was closed in the spring of 1862. Dr. William H. Brewer was appointed professor of agricultural chemistry, but resigned before the college was opened.

Training courses for teachers of agriculture, D. J. Crosby (*U. S. Dept. Agr. Yearbook 1907, pp. 207–220*).—The results are set forth of an inquiry conducted by this Office concerning courses for teachers of agriculture, in agricultural colleges, State normal schools, privately endowed colleges and schools, and county normal training schools in the United States, together with a discussion of the essentials of training for teachers of agriculture and lines of future development in this work.

Course in cereal foods and their preparation for movable schools of agriculture, Margaret J. Mitchell (*U. S. Dept. Agr., Office Expt. Stas. Bul. 200, pp. 11–78*).—This bulletin contains a syllabus of a course of 15 lectures covering quite fully the use, preparation and nutritive value of cereal foods. The subjects of the lectures are as follows: The composition of vegetable foods; composition of the body and the uses of food compounds in the body; digestion, assimilation, excretion; a study of starch; cereals used as breakfast foods; cereals which are used as vegetables; bread; yeast and molds; a study of wheat flour; a study of rye, corn, buckwheat, and other flours; changes produced in the constituents of bread; cost of bread, causes of imperfections, fancy breads; bread raised by other agents than yeast; cooking in deep fat; and dough raised with eggs, and icing for cake. Each lecture is accompanied by suggestions for practical work and experiments. An appendix contains references to literature and a list of apparatus and materials needed.

Agriculture, industries, and home economics in our public schools, W. M. Hays (*Chicago, 1908, pp. 37, figs. 37*).—An address delivered before the department of superintendence of the National Education Association, in Washington, D. C., February 25, 1908. The paper is profusely illustrated with half-tones, maps, and diagrams showing features of industrial education in secondary schools, the distribution of land-grant colleges and State normal schools, schemes for districting States for secondary agricultural schools, and plans of school buildings and grounds.

A course of study in agriculture for the public schools; what it should be and how to teach it, B. Youngblood (*Okla. School Herald, 16 (1908), No. 4, pp. 17, 18*).—This deals more especially with suggestions for practice work and excursions.

The Weather Bureau and the public schools, J. R. Weeks (*U. S. Dept. Agr. Yearbook 1907, pp. 267–276, figs. 3*).—The author describes some features of public school instruction relating to the weather, particularly in the elementary schools of New York State, discusses the purpose and value of the study of meteorology in schools, and describes simple homemade instruments used in making observations.

The school and its grounds, D. A. Clark (*Fruit-Grower, 19 (1908), No. 5, pp. 16, 17, figs. 2, dgm. 1*).—A discussion of the educational and esthetic value of trees, shrubs, and flowers in the vicinity of the schoolhouse, with suggestions for laying out and planting school grounds.

The school garden, II, O. W. Caldwell ([*East. Ill. State*] *Normal School Bul. 20, pp. 35, pls. 10*).—This is a progress report on school gardens begun at the Eastern Illinois State Normal School in 1902, with an interpretation of the value of school gardens in the scheme of instruction. The author speaks of the way the garden is conducted, taking the individual garden and individual ownership as the basis and discussing somewhat the advantages of this plan. He also discusses such matters as keeping up the interest in garden work in

the summer, the garden as a center of natural history work, and the garden as a means for studying agriculture and forestry and bringing about a better organization of the nature-study and natural-history work.

Home nature-study course, Anna B. Comstock and J. W. Spencer (*Home Nature-Study Course [Cornell Univ., State Col. Agr.], n. ser., 4 (1908), No. 4, pp. 28, figs. 11*).—Suggestions for the work of third-year pupils as outlined in the Syllabus of Nature Study and Agriculture issued by the New York State Education Department. Lessons are given on the trillium plant and its habits, the eggs of frogs and toads, tadpoles, a tadpole aquarium, the toad and its habits, the frog, the tree frog, how to make an aquarium, the strawberry plant, and its flowers, fruits, diseases and insect enemies, and blackbirds and their habits.

Agriculture: Its fundamental principles, A. M. Soule and E. H. L. Turpin (*Atlanta, Richmond, and Dallas, 1907, pp. 320, pls. 4, figs. 219*).—This text-book of elementary agriculture is intended for use in the public schools. It deals successively with the soil, its formation and physical characteristics, the plant in its life cycle, soil improvement, and field, orchard, and garden crops and their enemies and friends. One chapter is devoted to domestic animals, including cattle, horses, sheep, goats, hogs, poultry, and bees, and another to miscellaneous topics, such as trees, farm tools, good roads, the help of science, and school gardens. An appendix contains formulas for fertilizers and spraying mixtures, tables of feed and feeding standards, and lists of Farmers' Bulletins and agricultural experiment stations.

MISCELLANEOUS.

Yearbook of the Department of Agriculture, 1907 (*U. S. Dept. Agr. Yearbook 1907, pp. 798, pls. 65, figs. 56*).—The Yearbook for 1907 contains a report of the Secretary on the work of the Department during the year, a brief account by J. A. Arnold of the life and work of the late James Wallace Pinchot, 26 other special articles abstracted elsewhere in this issue, and an appendix consisting of an agricultural directory, a review of weather and crop conditions, the principal injurious insects and plant diseases of the year, progress in food and drug inspection and in forestry, soil areas surveyed and mapped, improvements in farm practice, game protection, bounty laws in force and road laws enacted in 1907, and agricultural statistics.

Annual Report of Idaho Station, 1907 (*Idaho Sta. Rpt. 1907, pp. 46, pls. 2*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1907, a report of the director, and departmental reports, of which that on dry farming and soil moisture investigations is noted on page 214 of this issue.

Fourteenth Annual Report of Montana Station, 1907 (*Montana Sta. Rpt. 1907, pp. 155–185*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1907, a report of the director on the work of the station during the year, lists of station publications, exchanges, donations, and loans, and a meteorological summary of air and soil temperatures, precipitation, wind velocity and direction, sunshine, cloudiness, and frost during 1907.

Encyclopædia of agriculture, edited by C. E. Green and D. Young (*Edinburgh and London, 1908, vol. 2, pp. VII+536, pls. 11, figs. 101*).—This is the second volume of the general encyclopedia of agriculture and contains articles on topics arranged alphabetically from Drills to Joint-ill. An article on agricultural education is abstracted on p. 291 of this issue.

NOTES.

Arkansas University and Station.—W. G. Vincenheller has resigned as dean and director and C. F. Adams, entomologist, has been appointed acting dean and director.

Colorado College and Station.—C. W. Gay, professor of animal husbandry in the Veterinary College of the University of Pennsylvania, has been appointed agriculturist, vice W. L. Carlyle. Alvin Keyser, in charge of soils work at the Nebraska University and Station, has been appointed agronomist, vice W. H. Olin.

Connecticut Storrs Station.—F. R. Thompson, cheese maker in the cooperative experiments with the Dairy Division of this Department, has resigned to engage in commercial work, and has been succeeded by Clinton Grant.

Florida University.—A free correspondence course in agriculture for teachers has been inaugurated, beginning November 1. This course is offered as a result of the recent announcement of the State superintendent of public instruction that in June, 1909, applicants for first and second grade certificates will be required to pass examinations in agriculture. Up to October 27, 70 teachers had enrolled for this course, and applications were coming in at the rate of from 15 to 25 a day.

Georgia College and Station.—J. M. Johnson, professor of agriculture in the college, has accepted the associate editorship of *The Cotton Journal*. Dr. T. H. McHatton has resigned as horticulturist of the station to become adjunct professor in charge of the horticultural department in the college and has been succeeded by H. P. Stuckey, who has been teacher of elementary agriculture in the Winthrop (S. C.) Normal and Industrial College. C. A. McLendon, a 1908 graduate of Clemson College, has been appointed botanist in the station and J. C. Temple, of the North Carolina College and Station, bacteriologist. Beginning January 1, 1909, the station is to undertake dairy extension work in cooperation with the Dairy Division of this Department, with J. H. McClain in charge.

Illinois University and Station.—As a part of the extension work of the College of Agriculture summer courses in agriculture were offered at the Chautauqua assemblies at Streator, Lovington, and Greenfield. A special tent was provided for the exhibition of illustrative material and as an assembly place for farmers and their families. Lectures were given daily and there were frequent demonstrations and trips of observation to nearby farms. At Lovington a woman's course was also offered by the department of household science, tents being erected and furnished as a series of model rooms.

New courses are announced in floriculture and in concrete construction for agricultural purposes.

According to a note in *Science*, James T. Barrett has resigned as assistant in botany in the station to accept a fellowship in botany at Cornell University.

Purdue University.—The second annual fruit show to be held at the university during the week of the farmers' short course, January 11–16, is reported to be arousing great interest among fruit growers of the State.

Iowa College and Station.—M. Mortensen, who has served as instructor during the short courses in dairying for several years, has been appointed acting head of the dairy department, and H. C. Horneman has been appointed extension worker in dairying.

Louisiana University and Stations.—According to a note in *Demeter*, the university has been organized into six colleges, among which are a college of agriculture and the Audubon Sugar School. The agricultural courses have been rearranged to provide additional electives and greater opportunity for specialization. There has also been added a two-year preparatory school of agriculture with A. F. Kidder as principal.

B. F. Hochenedel has resigned as assistant chemist in the Sugar Station to engage in commercial work.

Michigan Station.—A grant to the bacteriological laboratory of $1,500 has been made from state funds for the purpose of manufacturing hog-cholera serum according to the method suggested by the Bureau of Animal Industy of this Department. About 80 liters of serum have been manufactured and 1,819 animals, representing 33 herds, have been treated with a subsequent mortality of about 12 per cent. A charge of 1 ct. per cubic centimeter for virus and 2 cts. per cubic centimeter for serum is made, which covers the cost of production other than that of buildings and permanent equipment.

Mississippi Station.—J. A. McLean, of the Iowa College and Station, has accepted the position of animal husbandman.

Nebraska University and Station.—Martin Nelson has resigned as adjunct professor of field crops in the university and assistant in field crops in the station to accept the position of agriculturist in the Arkansas University and Station. W. W. Burr has been appointed assistant in soils and crops at the North Platte Substation in connection with the coöperative work with the Bureau of Plant Industry of this Department.

Cornell University and Station.—The work of the College of Agriculture in rural economy, hitherto under the immediate direction of the dean as professor of rural economics, has been formally organized as a separate department in charge of G. N. Lauman, who has relinquished his secretaryship to the faculty.

A biological station has been erected in the marshes at the head of Cayuga Lake with water gardens and other facilities for the study of problems in limnology. The research work now under way in this department deals chiefly with the study and development of the forage food of fishes as the beginning of an effort to develop water agriculture.

C. S. Wilson has been appointed assistant professor of pomology, thereby bringing about a further differentiation of the horticultural department, and C. A. Rogers has been appointed assistant professor of poultry husbandry. Other recent appointments include the following: As instructors, E. S. Guthrie, of Ohio State University, in butter making, Milton Pratt Jones, in extension teaching, and George E. Burnap in rural art; as assistants in the College of Agriculture, Lewis J. Cross in agricultural chemistry in its relation to agriculture, Leonard Haseman in entomology, and M. M. McCool and M. F. Barrus in plant pathology; as research assistant, Scott H. Perky in rural economy; as fellow in agriculture, Arthur W. Gilbert in plant breeding; and as assistants in the station, Fred J. Pritchard, Harry H. Love, and Eugene P. Humbert in plant breeding, and J. O. Morgan and Harold J. Conn in soil investigations.

North Carolina College and Station.—Dr. W. A. Syme has been promoted to the assistant professorship of chemistry in the college, and Hubert Hill has been appointed instructor in chemistry. J. K. Plummer has been appointed assistant chemist in the station.

North Carolina State Station.—Hon. Samuel L. Patterson, as State Commissioner of Agriculture chairman of the board of control of the station, and a former member of the governing board of the North Carolina College and College Station, died September 14, aged 58 years.

North Dakota College and Station.—In succession to F. J. Seaver and J. C. McDowell, whose resignations have been previously noted, Herbert F. Bergman, of the Kansas College and Station, has been appointed assistant botanist and R. C. Doneghue, of the Missouri University and Station, assistant agronomist. Dr. H. P. Bassett, assistant chemist, has resigned to engage in commercial work. H. A. Wood, assistant chemist, died October 3.

A severe hailstorm occurred August 29, and although most of the crops on the college and station grounds had been harvested much damage resulted.

A substation has been established at Langdon, where a quarter section of land has been donated for the purpose by the citizens of Cavalier County. Building operations are under way, and it is hoped to begin experimental work in the spring of 1909.

Texas College.—The college cooperated with the Dairy Division of this Department in an extensive dairy exhibit at the recent State fair which attracted much attention. A complete model creamery equipped with separators, pasteurizers, starter cans, ripening vats, churns, and other machinery was in operation daily for the manufacture of butter and ice cream. A class of students from the college gave practical demonstrations in butter making and milk testing, and also competed for prizes in butter making and the judging of dairy cattle.

Vermont University.—Under the provisions of the Nelson amendment a department of teaching has been established, the work of recent years in the form of educational conferences and a summer school in elementary agriculture having prepared the way for this larger development. A course of lectures coupled with practical work is being given with an enrollment of over 100 students, and a summer school for teachers is announced for next summer to include courses in domestic science, manual training, and elementary agriculture. Dr. L. R. Jones, professor of botany, has been appointed dean of the new department and it is expected to provide additional teaching force in 1909.

Washington College and Station.—W. T. McDonald, whose resignation from the Oklahoma College and Station has been previously noted, has been appointed assistant professor of animal husbandry in the college and assistant animal husbandman in the station. George Severance, professor of agronomy, has been appointed acting head of the department of agriculture in the college, and Director Thatcher acting superintendent of farmers' institutes. Oscar M. Olson, formerly connected with farmers' institute work in Minnesota, has been appointed instructor in farmers' institutes.

West Virginia Station.—N. J. Giddings, of the Vermont Station, has been appointed bacteriologist, and Arthur L. Dacy assistant horticulturist.

Wisconsin University and Station.—The new animal husbandry building and judging pavilion is well under way, and is expected to be ready for use about February 1, 1909. The cost is estimated at about $75,000. Registration in the College of Agriculture at the beginning of the current academic year showed an increase of 63 per cent.

Arrangements have been made to conduct systematic demonstration work at the farm of the State Insane Asylum at Viroqua. It is planned to extend the work to the farms of other State institutions, with a view to providing object lessons for near-by farmers, as well as establishing distributing centers for improved seeds and other material sent out from the college and station. The

work is to be under the general supervision of C. P. Norgard, who has recently been elected assistant agronomist.

Other recent additions to the college and station staff include J. C. Marquis, editor, C. S. Hean, librarian, and the following assistants: W. A. Brannon, fertilizer and feed inspection; B. W. Hammer, agricultural bacteriology; R. R. Marshall and H. L. Walster, soils; and H. Steenbock, agricultural chemistry.

President C. R. Van Hise recently received the degree of LL. D. from Williams College.

Wyoming Station.—Alkali investigations have been taken up by the station with reference to the removal of the injurious alkali salts from the farm recently acquired, combined with a study of the underlying principles of alkali poisoning. F. S. Burrage has been appointed secretary to the board of trustees, vice Dr. Grace Raymond Hebard, who retains the secretaryship of the station council.

Experimental Work in Forestry.—It is announced that the Forest Service of this Department is to establish experimental forests in typical forest regions of the West for the investigation of forest problems. A tract already set aside at Flagstaff, Ariz., in the Coconino National Forest is to be devoted to a study of the reproduction of western yellow pine, which is not now making a satisfactory second growth.

A comprehensive study of the use and effect of wind-breaks and shelter belts is also contemplated, this to be in part in cooperation with the State experiment stations.

Commission on Country Life.—President Roosevelt has appointed two additional members of the commission, Chas. S. Barrett of Union City, Ga., president of the Farmers' Educational and Cooperative Union of America, and Wm. A. Beard of Sacramento, Cal. Dr. E. W. Allen of this Office is acting as executive secretary of the commission.

Farmers' National Congress.—The 1908 session of this body was especially noteworthy as the first to be held at an agricultural college, the meetings taking place at the University of Wisconsin, September 24–30. Over eleven hundred delegates and visitors were in attendance, the largest number ever registered. Among the speakers were Hons. W. H. Taft, W. J. Bryan, and J. J. Hill. President C. R. Van Hise, of the university, gave an address on The Conservation of the National Resources, and there were numerous demonstrations and lectures by Dean Russell, Professors Moore, Humphrey, and Alexander, and other members of the faculty. Among the resolutions adopted by the congress may be noted those endorsing the work of the agricultural colleges and urging the State legislatures to supply adequate financial support, favoring the movement for the conservation of the national resources, and approving the provisions of the Davis bill for the development of secondary agricultural education.

Conservation League of America.—The Conservation League of America has recently been organized with President Roosevelt as honorary president, and Hons. W. H. Taft and W. J. Bryan as honorary vice-presidents, and Walter L. Fisher as president. The league has chosen for its statement of principles the declaration adopted by the Conference of Governors, convened by the President May 13–15. Its purpose is announced to be "the bringing into closer relation and more intelligent cooperation the unofficial associations which have a common interest in the broader aspects of the conservation movement."

American Association for the Advancement of Science.—At the invitation of the Johns Hopkins University, the sixtieth meeting of this association will be held in Baltimore, from December 28, 1908, to January 2, 1909. In addition to the usual section programmes a symposium on public health will be held

December 31, in conjunction with the American Health League, and on January 1, under the general auspices of the association and the American Society of Naturalists there will be a celebration of the one hundredth anniversary of the birth of Charles Darwin and of the fiftieth anniversary of the publication of the first edition of the Origin of Species.

The affiliated societies of the association which have thus far indicated their intention to meet during convocation week include the American Society of Naturalists, American Mathematical Society, Association of American Geographers, Geological Society of America, Association of Economic Entomologists, American Nature-Study Society, Association of American Anatomists, American Chemical Society, American Society of Vertebrate Paleontologists, American Society of Zoologists, American Physical Society, American Psychological Society, American Physiological Society, American Philosophical Association, Southern Society for Philosophy and Psychology, American Anthropological Association, Entomological Society of America, American Folk-Lore Society, American Federation of Teachers of the Mathematical and the Natural Sciences, American Society of Biological Chemists, Sullivant Moss Society, Botanical Society of America, Society of American Bacteriologists, and Wild Flower Preservation Society of America.

First International Congress of Agricultural Associations and Vital Statistics.—The Office is in receipt of an announcement and a preliminary programme of this assembly, to be held at Brussels, Belgium, in September, 1910. The congress is to be divided into 10 sections for the consideration of topics relating to the economic and social organizations of farmers and farm laborers; societies for animal and plant production; associations for the manufacture, purchase, exportation, sale, and consumption of farm products; mutual agricultural credit and insurance societies; vital statistics and sanitation in rural districts; the promotion of the welfare of agricultural laborers; the transportation of agricultural products; measures for the improvement of country life in general; and organizations dealing with agricultural education, agricultural expositions, etc.

Those interested in the objects of this congress may obtain more complete information by communicating with P. De Vuyst, 22 avenue des Germains, Brussels, Belgium.

Agriculture at the British Association.—At the meeting of the British Association for the Advancement of Science, held in Dublin, September 2–9, the subsection of agriculture was reestablished after a lapse of several years, becoming a branch of the section of economics.

Sir Horace Plunkett served as president and in his address called attention to the marked disparity accorded to urban and rural life by those engaged in the application of science to the advancement of mankind, and advocated a more adequate recognition of agriculture by the association. He summarized the three-fold character of the construction work needed in rural life as embodying better farming, better business, and better living. The sciences were deemed most valuable to each of these three divisions, the natural sciences, especially to the first, economic science to the second and third, and educational science to all three; in other words, for rural reconstruction, research, economic investigations, and education were necessary.

Sir Oliver Lodge and J. H. Priestley presented an account of some experiments which are being made on a large scale near Worcester, England, on the effects of a high-tension electrical discharge over a growing crop. J. R. Campbell, of the Irish Department of Agriculture, explained the educational work of that department, and Dr. Carroll Dunham of Harvard University, discussed the systems of agricultural education prevailing in this country.

The second day of the association was devoted to numerous papers and discussions on plant and animal breeding. On the final day economic phases were again discussed. Several papers dealing especially with small holdings were presented, together with papers of more general scope by Dr. Graham Brooks on the moral effects of cooperation upon the workers, and Dr. Moritz Bonn, of Munich, on the status of the Irish tenant, and statistical papers by J. Wilson and W. G. Adams.

Smith's Agricultural School and Northampton School of Technology.—This institution has been opened to students, and at the close of the first week the enrollment was 114, of whom 30 were girls in the household economics course, 30 boys in the agricultural course, and 54 boys in the mechanic arts course. The agricultural course for the first year includes soils and plant life, physical geography, elementary science, practical arithmetic, bookkeeping, freehand drawing, English, algebra, American history, civil government, and mechanical work; for the second year, animal husbandry, botany, farm chemistry, farm physics, plane geometry, English, general history, and mechanical work. The course in mechanic arts during the first 2 years is the same as that of the agricultural course except that chemistry, mechanical drawing, and shop practice take the place of soils, plant life, and animal husbandry, and the household economics course differs from the agricultural course only in offering sewing or cookery in place of soils, plant life, and animal husbandry. Applicants for admission to this school who are graduates of rural schools, or who have passed the ninth grade in other schools, and are 14 years of age or older, may be admitted without examination.

Secondary School Agriculture.—The North Adams High School, North Adams, Mich., has added an agricultural course to its curriculum, in charge of R. C. Carr, a graduate of the Michigan Agricultural College. A nearby field is available for practical and experimental work.

A new agricultural high school has been established at Montague, Mass., with J. R. Parker, a 1908 graduate of the Massachusetts Agricultural College, as teacher of agriculture.

Adam Phillips, a graduate of the New York State College of Agriculture, has been elected principal of the Farragut School, Concord, Tenn., and will give considerable attention to the development of the agricultural features of instruction.

Thorntown, Ind., is a village of 2,000 inhabitants, having a high-school enrollment of 85 pupils. Nearly 60 per cent of these come from the surrounding farms and about 60 per cent are boys. All third-year pupils take agriculture as a required subject, 5 hours a week for text-book work and about 2 periods a week for laboratory work and field exercises.

Agriculture in the Elementary Schools of England.—According to a recent note in The Journal of the Board of Agriculture, instruction in rural subjects in public elementary schools of England is fostered by a system of special grants, and it appears from the report of the board of education for 1906–7 that considerable progress is being made in the teaching of gardening, fruit culture, and dairy work. Gardening is taught in every English county except two, and the number of schools which applied for grants in 1906–7 was over 900, as compared with 371 earning grants in 1903–4. The increase is almost entirely confined to counties in which a horticultural lecturer has been appointed, a part of whose duties it is to organize and supervise school gardening and to train teachers to teach it. Fruit culture is coming to be one of the important features of school gardening, and bee keeping is sometimes associated with it.

Dairying has been reintroduced into the code as a special subject for which grants may be given. It is looked upon as a subject especially valuable for girls, not only as an important branch of domestic work, but also as a means of education and as a practical means of giving instruction in the principles of hygiene.

Agricultural Education in Scotland.—A lecturer on agriculture and rural economy has been appointed in the United College of St. Salvator and St. Leonard of St. Andrews University, the oldest university in Scotland. A course of 50 lectures on the principles of agriculture will be given during the 1908–9 session. The course has been arranged to meet the requirements of candidates for the national diploma in agriculture, and will consist of illustrated lectures supplemented by demonstrations in the field, practical work in the laboratory, and in excursions to some of the best farms in the neighborhood.

A German Trade High School.—The Trade High School opened in Mannheim on May 1, 1908, is the first of such technical institutions for southern Germany. It is under the direction of the minister of justice and public instruction of the Duchy of Baden, and has for its object the provision of instruction in political economy, sociology, and agricultural science as they are related to trade and manufacturing industries.

The course consists of 4 semesters of 6 months each, the hours of instruction being mostly in the evening, as the school is intended to provide an education for those who can not devote their whole time thereto. The subjects taught are as follows: (1) Production and trade—hunting, hunting laws, and fur trade, inland and sea fisheries and trade in fishery products, forestry and lumber trade, stock raising, meat, dairy products, trade in stock, wool, hides, leather, farm and grain production, grain trade, agricultural by-products and distilling, plantations and sugar and cotton trade; (2) mining and metal industries; (3) international economy and colonial politics; (4) banks and banking; (5) science of finance; (6) life insurance; (7) protection of laborers. Special lectures will be given on State and private railway systems, the economic workings of railways and railway traffic, fundamental principles of political economy, securities, exchange and settlement of accounts, etc.

Miscellaneous.—Dr. Eric A. Nobbs, agricultural assistant to the Cape Government, has been appointed director of agriculture in Rhodesia.

The death is noted on June 3 of Dr. J. Hazard, agronomist at the Royal Agricultural Experiment Station at Möckern.

A brief description of the equipment and work of the Menominee County School of Agriculture, Menominee, Mich., is given in the *Northwestern Farmer* for October.

Farm Life (London) of August 1 contains a brief description of the location, equipment, and course of study of the Dookie Agricultural College, Dookie, Victoria, Australia.

A recent number of *Wiener Landwirtschaftliche Zeitung* gives an illustrated account of the machinery-testing station of the Agricultural High School of Vienna.

The New Brunswick legislature has established a commission consisting of the commissioner of agriculture and two others to investigate agricultural immigration and colonization conditions and possibilities of the province.

An intercollegiate stock-judging contest held at the American Royal Live Stock Show at Kansas City, Mo., was won by the Kansas College, with the Iowa College second and the Missouri University third.

EXPERIMENT STATION RECORD.

VOL. XX. DECEMBER, 1908. No. 4.

The proceedings of the recent convention of the Association of American Agricultural Colleges and Experiment Stations at Washington developed remarkable clearness of conception as to the ideals which should obtain in agricultural research and the ways and means by which these ideals may be attained. The formulation of such ideals as a basis for the administration and work of our agricultural experiment stations was most definitely made in the reports of the Commission on Agricultural Research and the standing committee on station organization and policy.

The Commission on Agricultural Research, which was appointed under resolution of the 1906 convention of the association, consisted of David Starr Jordan, Stanford University, California, chairman; Whitman Howard Jordan, of Geneva, N. Y. (elected as secretary); Henry Prentiss Armsby, State College, Pennsylvania; Gifford Pinchot, Washington, D. C.; and Carroll Davidson Wright, Clark College, Worcester, Mass.

The commission was instructed "to inquire into and report to the association the organization and policy that in the opinion of the commission should prevail in the expenditure of public moneys provided for scientific experimentation and research in the interests of agriculture, to the end that such funds shall be applied in the most economical, efficient, and worthy manner to the production of results of permanent value." It will be observed that the instructions are specific as to the scope and purpose of the inquiry, and limits it to matters pertaining to "scientific experimentation and research" having as an object "the production of results of permanent value." The commission, therefore, was not concerned with general administrative and educational questions, except in so far as they affected scientific investigation and related to the training of men to undertake such investigation. In fact, the report makes very clear the importance of differentiating as fully as practicable between scientific research and teaching, promotion, and propaganda work.

That portion of the report of the commission which relates more particularly to the research work of the experiment stations points out that:

"(1) The development of research effort has not been symmetrical and logical. Adequately trained men have not been provided in sufficient numbers to expend in the way of capable investigation the entire amounts of national and state appropriations that have been applied to agricultural research. This is one of the reasons why the more difficult agricultural problems have so largely remained untouched. . . .

"(2) Many persons nominally holding research positions have been investigators only in name, for their time and energy have been absorbed by other duties. . . .

"(3) The persistent and widespread promotion of popular education and of public good will has unquestionably had a profound, and not always immediately healthful, influence on the extent and character of . . . agricultural research. . . .

"(4) The urgent and natural call for results that would produce an immediate and favorable reaction upon the public mind has not only brought about an era of the diffusion, rather than of the acquisition, of knowledge, but has, quite generally, led to the study of problems admitting of prompt conclusions, more particularly problems of a business character directly related to financial benefit, rather than those that are fundamental. . . .

" (5) As one result of the close association of scientific inquiry and popular education a true conception of real and efficient research has not been fully maintained in the minds of all those engaged in the work of agricultural investigation. The effect of such a situation upon the progress of agricultural knowledge is obvious."

Among the recommendations which in the judgment of the commission "should guide in the promotion, organization, and prosecution of research in agriculture " and which are regarded " as essential to bringing about the conditions that all friends of agricultural progress desire to see established," are the following:

"(1) Every effort should be made to promote the training of competent investigators in agriculture both in the agricultural, and, so far as practicable, in the nonagricultural, colleges and universities, and their training should be as broad and severe as for any other field of research.

"(2) The progress of agricultural knowledge now demands that agricultural research agencies shall deal as largely as possible with fundamental problems, confining attention to such as can be adequately studied with the means available.

"(3) The work of research in agriculture should be differentiated as fully as practicable, both in the form of organization and in the relations of the individual investigator, from executive work, routine teaching, promotion, and propaganda, and should be under the imme-

diate direction of an executive trained in the methods of science who should not be hampered by other duties of an entirely unlike character.

"(4) The investigator should be free from all coercion whatever. In reaching his conclusions he should be equally free from the prescription of received opinion and the temptation to exploit his results for the purpose of obtaining future support. . . .

"(5) Any research agency charged with a single main line of investigation should be so organized that it may employ within itself all necessary processes in any branch of science. The cooperation of any or all of the departments of an experiment station on a single problem, when necessary, should be a fundamental requirement."

In the discussion that followed the presentation of the report there was a frank acknowledgment of the present difficulty of attaining such ideals, but it was also made clear that American investigators in agricultural science have made great progress in the clear comprehension of the conditions, organization, and means necessary to their attainment. A long step in advance has been made if substantial agreement can be reached as to ideals even though conditions may be such that in many cases progress toward their full realization must necessarily be slow. On this point Dr. W. H. Jordan expressed himself as follows: "It seems to me that the thing for this association to do is to establish its standards in accordance with its best judgment. These standards need not be binding upon any institution, but they may be worked on as rapidly as possible. The adoption of such standards would not mean any reflection upon any institution that is unable, because of circumstances, to entirely conform to the ideal."

The formulation of such ideals and the announcement of a purpose to work toward them as rapidly as is practicable under the circumstances prevailing in each particular case will in itself have a far-reaching influence in securing for agricultural research in this country and for those engaged in it the scientific standing and recognition they should have and in increasing the scientific efficiency as well as the practical usefulness of agricultural research by laying for it broad and enduring foundations.

The report of the standing committee of the association on station organization and policy dealt with several of the matters discussed in the commission's report, but in a somewhat more specific way. Like those of previous years, it was to a large extent based upon the consensus of opinion of station men as to the most practicable means of securing the highest efficiency in station work.

The report points out certain defects of administrative organization which still prevail to some extent, and defines the functions of administration as related to research, as follows:

"(a) To help to determine in advance whether the proposed research is profitable and altogether advisable from the standpoint of the public, whose representative for the time being the administrative officer must be.

"(b) To assist in determining what lines of experimentation are calculated to throw profitable light upon the problem.

"(c) To help determine whether the work is best carried on by one individual representing a single line of inquiry or by two or more working in conjunction, and if the latter, to secure in advance a complete understanding as to mutual duties, rights, and responsibilities. Upon all these points the judgment and the point of view of the administrative officer is not only likely to be broader but certain to be freer from personal bias than is that of the professional investigator.

"(d) The experiment once decided upon, however, and funds provided, administration is over until results are due, when it begins again and does not cease till reports are published and circulated. The less administration during the progress of the work the better for all interests, and if the need of it becomes clear, it is the best of evidence that administration was remiss at the outset. Your committee can not too strongly point out the necessity of the entire freedom as to methods of investigation on the part of the staff worker who has been employed because of his expert knowledge of the matter and methods of work in a highly specialized field."

The ideal thus presented by the committee is "administrative efficiency and sympathetic helpfulness without interference," requiring "for administrative officers men not only of good business methods and large outlook, but also with the highest obtainable training along some important line of science as related to agriculture."

The committee favors an organization "strong enough to recognize the interests of the whole station as above those of any department or separate interest and strong enough to enable the entire influence of the whole body to be exerted in any desired direction on short notice."

As regards lack of permanency and continuity of work and resulting decreased efficiency, the committee enumerates a number of causes, but is of the opinion "that the interference of teaching and extension work, and the paying of poor salaries, are among the prominent causes of unsatisfactory work and of frequent change."

The committee "reaffirms the recommendation of last year to the effect that there should be concentration on a few lines of research, and further recommends that there be close adherence to thoroughly considered, definite, and well-planned projects; that every effort be made to retain experienced and well-trained men; that an associate be appointed in each important department who shall be capable at any time of taking up the work of the chief; that the finances of the

stations be so administered as to insure the supply of all suitable facilities for work; and that the integrity of long-established experimental fields should be maintained."

In its inquiries regarding the relation of inspection work to other forms of station activity the committee finds that "the consensus of opinion leans toward an ideal station established for the purpose of research work, where little or no inspection work should impose a burden on the station; but that special conditions arise in many of the States making it of advantage to both the station and the State for the former to undertake such work."

The committee recommends that "where it seems best that the station should undertake to do inspection work (1) special funds should be provided to cover fully all expenses of such work; (2) where any considerable amount of inspection work is to be done, a separate division or department of the station be organized for carrying on the work; (3) with the exception of the administrative officers, the work be done by an independent force, paid wholly from the special funds appropriated for inspection; (4) special laboratories for carrying out the analytical work in connection with inspection work be provided."

With regard to the relation of station men to instruction, the committee finds that "the opinion is almost unanimous that research work conduces to effective teaching, so long as it does not become so engrossing as to cause the teacher to neglect his classes."

The committee therefore recommends "as an ideal policy, to be adopted as rapidly as the conditions of the various stations will permit, that those charged with research be completely freed from all responsibility for routine class-room teaching; and that as a step in this direction the teaching required of the investigator be limited to a maximum of three hours per week during one semester annually, to be given along the line of his specialty."

The recommendations of the committee will thus be seen to emphasize particularly the necessity, from the standpoint of scientific research in agriculture, for the sharp differentiation of such research work from educational propaganda and police duties and give full recognition to the fact that to secure a high order of this research work, the station organization and policy must be such that the investigator for at least the greater part of his time is free to devote undivided thought and effort to the work of investigation.

Practically, the greatest difficulty in attaining the ideals set forth in these reports grows out of the fact that in many cases our stations as organized under state laws are composite institutions. They are required to carry on control work, demonstrations, farmers' institutes, and the general diffusion of agricultural information. There will, therefore, be need of more or less reorganization of the stations, as

more exclusively research institutions. The opportunity for this is now afforded by the growing recognition of extension work as a legitimate function of the agricultural colleges. As soon as the extension departments of the colleges are efficiently organized and provided with adequate funds it should be comparatively easy to transfer to them a considerable share of the business now performed by the stations.

As far as the federal funds given to the stations are concerned, it will be the effort of this Department to confine work under the Hatch Act more strickly than ever before to experimental work of a substantial kind, and no longer to permit expenditures from that fund for farmers' institute work, extension teaching, or the preparation of compilations. The Adams fund will, of course, be restricted to "original research."

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

On the determination of phosphoric acid, U. Milone (*Atti. 6. Cong. Internaz. Chim. Appl., 1 (1906), pp. 63, 64*).—A comparison of the methods of Bongartz, Leconte and Pincus (modified Neubauer), and Sonnenschein is reported, the results indicating that the method of Bongartz [a] is quick and reliable. This method is based on that of Thomson,[b] in which phosphoric acid is determined by titration first with normal sulphuric acid using methyl orange as an indicator, and then after boiling and cooling with the same acid using phenolphthalein as an indicator.

Standardization of uranium solution for determining phosphoric acid, F. Repiton (*Monit. Sci., 4. ser., 21 (1907), II, No. 792, pp. 815, 816; abs. in Chem. Zentbl., 1908, I, No. 3, p. 295; Jour. Chem. Soc. [London], 94 (1908), No. 547, II, p. 428*).—In applying the uranium method to the determination of phosphoric acid in calcium phosphate it is advisable to standardize the uranium solution with a solution of calcium phosphate containing an accurately known amount of phosphoric anhydrid. For the accurate determination of the phosphoric anhydrid the author recommends the iron method in which phosphoric acid is precipitated by a solution of ferric nitrate of known strength and the excess of iron precipitated by boiling with ammonium acetate. The combined weight of the two precipitates less the amount or iron oxid used equals the weight of phosphoric anhydrid.

The determination of potash by the platinum chlorid method, H. J. F. de Vries (*Chem. Weekbl., 4 (1907), pp. 231–242; 333–343; 455–462; 5 (1908), pp. 176–184; 261–269; abs. in Chem. Zentbl., 1908, I, No. 17, p. 1647; Jour. Chem. Soc. [London], 94 (1908), No. 508, II, p. 534*).—In this article the author reviews the various investigations which bear upon the causes of error in this method of determining potash and gives his own views as to the best means of avoiding them.

He concludes that the best results with both pure potassium chlorid and mixtures of potassium chlorid with either sodium chlorid or magnesium chlorid, or both, are obtained with the use of 96 per cent alcohol. With both 80 per cent and 96 per cent alcohol much better results were obtained by employing the empirical factor 0.3056 than by using the theoretical factor 0.3071 based upon the latest international atomic weights. The wide variation in results, sometimes amounting to as much as 4 per cent, can not, however, be explained by the kind of alcohol used or the method of calculation, but is due primarily to the presence of sulphuric acid. In the presence of sulphuric acid 96 per cent alcohol gives uniformly too high results and 80 per cent alcohol to low.

On the volumetric determination of potassium as the cobalti-nitrite, W. A. Drushel (*Chem. News, 97 (1908), No. 2520, pp. 124–126; abs. in Science, n. ser., 28 (1908), No. 711, p. 219*).—See a previous note (E. S. R., 19, p. 808).

---

[a] Arch. Pharm., 3. ser., 22 (1884), p. 846.

[b] Chem. News, 47 (1883), p. 186.

A volumetric method for the simultaneous determination of carbon dioxid and other acids in the air, H. Henriet and M. Bouyssy (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 21, pp. 1100, 1101; abs. in Rev. Sci. [Paris], 5. ser., 9 (1908), No. 23, p. 731; Chem. Zentbl., 1908, II, No. 2, p. 196*).—By thoroughly washing the current of air in a soda solution of known strength the carbon dioxid and other acids are absorbed and may be determined by titration with acetic acid, using phenolphthalein as indicator, then adding barium chlorid and titrating a second time, as is done in the determination of free soda in the commercial product.

The detection of small quantities of carbon monoxid in the air, J. Ogier and E. Kohn-Abrest (*Ann. Chim. Analyt., 13 (1908), Nos. 5, pp. 169–173, fig. 1; 6, pp. 218–224, figs. 2*).—The apparatus and procedure for methods based upon the absorption of carbon monoxid in blood and the spectroscopic examination of the blood after the fixation of the oxid are described in some detail in this article. The author believes that such methods are of great value and that the reactions observed are such as are produced by carbon monoxid alone and not by any hydrocarbon gas.

A new method of enumerating bacteria in air, C. E. A. Winslow (*Science, n. ser., 28 (1908), No. 705, pp. 28–31, figs. 2*).—The method described is a modification of that used by Hesse, in which the bacteria are collected by slowly aspirating air through a long roll-tube, the walls of which are covered with melted gelatin. The modification consists mainly in an increase in the size of the culture vessel relative to the sample of air. This is accomplished by drawing the air in succession through two 1½ liter bottles, on the bottom of each of which is a layer of nutrient gelatin.

Tests are reported which indicate that the method "seems to offer a more accurate procedure for bacterial examination of air than any yet available," although it is not so convenient as the sand filter method commonly used.

Determination of nitric acid in water, L. Grünhut (*Ztschr. Analyt. Chem., 47 (1908), No. 5, pp. 324–327*).—This is a review of a number of recent contributions to the subject, namely, those of R. Woy (E. S. R., 14, p. 328), A. Müller (E. S. R., 15, p. 336), P. Drawe (E. S. R., 18, p. 7), H. Noll, H. Grosse-Bohle (E. S. R., 15, p. 851), and A. F. Dokuchayev (E. S. R., 15, p. 1052).

Observations on hardness in water and its removal, E. E. Basch (*Ztschr. Öffentl. Chem., 14 (1908), No. 7, pp. 124–133*).—This is a discussion of the value for technical purposes of various methods of determining and removing hardness in water, especially the method proposed by Hundeshagen (E. S. R., 19, p. 809).

Lead in drinking water, its harmfulness and methods of determination, H. W. Woudstra (*Chem. Weekbl., 5 (1908), Nos. 12, pp. 185–204; 13, pp. 207–216*).—The literature of investigations on the poisonous properties of lead in water is reviewed and gravimetric and volumetric methods of determination are described.

Süchting's improved method of determining the acidity of soils, A. J. van Schermbeek (*Jour. Prakt. Chem., n. ser., 77 (1908), No. 10–11, pp. 489–497; abs. in Jour. Soc. Chem. Indus., 27 (1908), No. 11, p. 581; Jour. Chem. Soc. [London], 94 (1908), No. 550, II, pp. 743, 744*).—The author criticises Süchting's modification of Tacke's method (E. S. R., 19, p. 1009), asserting that the modified method does not determine the amount of acid in the soil but that which accumulates in a mixture of finely divided soil and calcium carbonate stirred up with a considerable amount of water and allowed to stand for several hours. If the mixture is not sterilized considerable acid may be formed by the decomposition of the organic matter.

Süchting's improved method of determining acidity in soils, B. Tacke and H. Süchting (*Jour. Prakt. Chem., n. ser., 78 (1908), No. 15–16, pp. 139–142*).—This is a defense of the method against the above criticisms of A. J. Van Schermbeck.

Estimation of sugar by the Allihn or Meissl method, H. Schaumann (*Ztschr. Analyt. Chem., 47 (1908), No. 4, pp. 235–237, fig. 1*).—Apparatus is described which, according to the author, greatly facilitates the determination of sugar by the Allihn or Meissl method. The improvement consists in drawing into the filter tube, by means of suction, the solution containing the cuprous oxid instead of pouring it in.

The volumetric determination of reducing sugars, A. R. Ling et al. (*Analyst, 33 (1908), No. 386, pp. 160–173*).—A critical examination of methods. The paper is followed by a discussion. For earlier work see a previous note (E. S. R., 17, p. 335).

Critical studies of quantitative estimation of glycogen by means of inversion with acids, W. Grebe (*Arch. Physiol. [Pflüger], 121 (1908), No. 11–12, pp. 604–635*).—A critical study of methods.

Methods for preparing lecithin and other phosphatids from seed, E. Schulze (*Ztschr. Physiol. Chem., 55 (1908), No. 3–4, pp. 338–351*).—In this discussion of methods data are reported regarding the phosphatids of wheat embryo and a number of other seeds.

Observations on the stability of lecithin, J. H. Long (*Jour. Amer. Chem. Soc., 30 (1908), No. 5, pp. 881–895*).—That emulsions of egg and brain lecithin are comparatively stable with respect to temperature is the conclusion drawn from the author's investigations. The characteristics of such lecithin emulsions were studied.

On the oxidation of olive oil, A. H. Gill (*Jour. Amer. Chem. Soc., 30 (1908), No. 5, pp. 874–876*).—In connection with a study of so-called wool oil employed in the manufacture of "tops," i. e., wool roving or wool which has been partially spun, the oxidation of olive oil under different conditions was studied. In harmony with earlier work, the author concludes that "except when spread out in a finely divided condition as upon cotton, olive oil changes but little on exposure to the air or heat."

Note on honey analysis, F. Schaffer (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 10, pp. 604–606*).—Analyses of honey made from Coniferæ are reported and discussed with reference to honey standards.

Honey, A. Reinsch (*Ber. Chem. Untersuch. Amt. Altona, 1907, pp. 25–29; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 8, p. 493*).—Four samples of pure honey showed an ash content of 0.06 to 0.17 per cent, the sample with the lowest ash content being a mixture of clover and linden honey. In the author's opinion, the minimum value for the ash content required under the German pure-food law should be changed from 0.1 per cent to 0.05 per cent.

Has the estimation of the ash content and the Ley reaction value in honey analysis? Utz (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 10, pp. 607–609*).—A controversial article.

Judging marmalades, F. Härtel (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 8, pp. 462–472*).—Recipes for a number of sorts of marmalade are given and the questions of definitions, the use of starch sirup, artificial coloring matters, etc., with reference to marmalade making, and the determining of its character with respect to the requirements of pure-food laws are discussed.

Sampling and judging ground white pepper, E. Spaeth (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 8, pp. 472–484*).—According to the results of the author's investigations, 4 per cent mineral matter and 7.5 per cent crude

fiber are satisfactory standard values for judging of the quality of ground pepper. The idea that the perisperm of the unripe black pepper has a higher content of crude fiber than the ripe white peppercorn is, according to the author, erroneous. The best method for the detection of the addition of hulls, in his judgment, is the determination of the crude fiber content.

A new pepper adulterant, N. Petkoff (*Ztschr. Offentl. Chem., 14 (1908), No. 7, p. 133*).—The author found that powdered graphite was used for coloring black pepper. It was apparently mixed with some sort of gum solution. The ash content of such peppers was high, ranging from 12 to 12.6 per cent. The alkalinity, on the other hand, was about normal, ranging from 50 to 51 per cent.

Lead in cream of tartar, tartaric acid, and citric acid, R. R. Tatlock and R. T. Thomson (*Analyst, 33 (1908), No. 386, pp. 173–178*).—The authors state that in their experience the average amount of lead found in cream of tartar has been 0.005 per cent, in tartaric acid 0.0005 to 0.012 per cent, and practically the same amount in citric acid. The paper, which is followed by a discussion, also takes up the question of analytical methods.

The copper content of cocoa shells, E. Tisza (*Schweiz. Wchnschr. Chem. u. Pharm., 45 (1907), p. 526; abs. in Hyg. Zentbl., 4 (1908), No. 1, p. 16*).—Copper was determined by the electrolytic method, the highest amount found being 0.01 per cent. In half the samples no copper was found and the author believes that when it occurs in minute quantities it is naturally present.

The detection of cocoa shell in cocoa goods, G. Devin and H. Strunk (*Apoth. Ztg., 23 (1908), No. 33, p. 302*).—The authors discuss their analyses with reference to the detection of cocoa shell and conclude that removing the hexoses before determining the pentosans is to be recommended. The addition of 10 per cent cocoa shell can be detected by determining the amount of silicic acid in the ash.

The chemical standardization of foods and drinks, with special reference to cider and perry, H. E. Durham (*Jour. Roy. Inst. Pub. Health, 16 (1908), No. 5, pp. 287–295*).—French and German laws are discussed with special reference to cider and perry in Great Britain, and analytical work is reported which has to do with the amount of alcohol, ash, and other constituents, and the relation of these constituents to standards.

The legislation of different countries regarding the sulphuring of wine, H. Mastbaum (*Chem. Ztg., 33 (1908), No. 34, pp. 427, 428*).—A summary of legal data.

The detection of formic acid in foods, A. G. Woodman and A. L. Burwell (*Technol. Quart., 21 (1908), No. 1, pp. 1–3*).—In the method outlined the formic acid is converted into calcium formate, which is subjected to dry distillation and treated with standard fuchsin-aldehyde, the resulting color being compared with a standard color. From their own experience, which is briefly summarized, the authors consider that the method is very delicate.

The quantitative estimation of rice hulls in feeding stuffs, F. Schröder (*Arb. K. Gsndhtsamt., 28 (1908), p. 213; abs. in Chem. Ztg., 32 (1908), No. 30, Repert., p. 200*).—The presence of rice hulls, according to the author, may be detected with a microscope. The method for estimating the quantity present depends upon the proportion of silicic acid and the ratio of this material in the feeding stuffs to the amount normally present in rice hulls.

Regarding the methods of investigations of butter and other fats, Grimmer (*Milch Ztg., 37 (1908), Nos. 11, pp. 121–132; 12, pp. 133–144; 13, pp. 487, 488*).—By the use of the method of Wijsman and Reijst in examination of and chemical constants of butter commonly considered are summarized.

Detection of cocoanut oil in butter by means of the "silver value," C. Barthel (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 8, pp. 487, 488*).—By the use of the method of Wijsman and Reijst in examination of pure butters and mixtures of butter and cocoanut oil the author at first obtained results which gave indication that the method could be used for detecting the presence of cocoanut oil in butter, but in later experiments with pure butters the method appeared to be unreliable. Butter produced by cows fed on sour beet roots yielded a second "silver value" that was appreciably higher than the first.

Notes regarding cacao butter, F. Strube and D. Sohne (*Ztschr. Öffentl. Chem., 14 (1908), No. 4, pp. 67–70*).—The author reports certain chemical and physical data obtained in the examination of cacao butter from different sources. He found that different methods of separation of the cacao butter had no appreciable effect upon the constants of the substance. For the detection of foreign fats employed in the adulteration of cacao butter the author recommends the method of Cohn.

Digestion and distillation apparatus for nitrogen determination, G. Jakob (*German Patent No. 204262; Ztschr. Chem. Apparatenk., 3 (1908), No. 5, pp. 122, 123, fig. 1*).—A convenient and compact device for digestion and distillation in the same set of flasks is described.

The determination of nitrogen according to Dumas, H. Leeman (*Chem. Ztg., 32 (1908), No. 41, p. 496, fig. 1; abs. in Analyst, 33 (1908), No. 388, pp. 296, 297*).—A device for controlling the flow of carbon dioxid through the combustion tube is described.

Flask for fat determination, W. L. Dubois (*Jour. Amer. Chem. Soc., 30 (1908), No. 5, pp. 797, 798, figs. 2*).—A flask for use in fat extraction is described, which, according to the author, may be readily cleaned.

Report on the most important progress in agricultural chemistry during the last year, A. Stutzer (*Chem. Ztg., 32 (1908), No. 38, pp. 466–468*).—The most important scientific contributions to the assimilation of plant food through the roots of plants, fertilizers, and animal nutrition are briefly referred to.

Annual report for 1907 of the consulting chemist, J. A. Voelcker (*Jour. Roy. Agr. Soc. England, 68 (1907), pp. 210–220*).—Analyses of a number of feeding stuffs and of fertilizers and miscellaneous materials are reported.

METEOROLOGY—WATER.

Wireless telegraphy and meteorological information (*Rev. Sci. [Paris], 5. ser., 9 (1908), No. 17, p. 527*).—This is a brief statement regarding the extent to which wireless telegraphy has been used in Great Britain and the United States for the dissemination of meteorological information.

The application of wireless telegraphy to the improvement of storm warnings, G. Bigourdan (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 17, pp. 885–887; abs. in Rev. Sci. [Paris], 5. ser., 9 (1908), No. 19, p. 603*).—The advantage of a knowledge of the meteorological conditions at sea which can be attained by means of wireless telegraphy is pointed out.

The development of meteorological observations in Africa (*Rev. Sci. [Paris], 5. ser., 9 (1908), No. 19, p. 594*).—This is a brief account of progress made in establishing systematic meteorological observations in different parts of Africa.

Weather observations in connection with cultural and fertilizer experiments, Grohmann (*Fühling's Landw. Ztg., 57 (1908), No. 8, pp. 290–298*).—The value and importance of such observations are pointed out.

Temperature conditions of the earth. M. Hottinger (*Gesundhts. Ingen., 31 (1908), No. 24, pp. 375–379, figs. 4*).—This article discusses the relation of altitude, latitude, depth in the soil, and other conditions on temperature, particularly in its bearing on habitableness.

Monthly Weather Review (*Mo. Weather Rev., 36 (1908), Nos. 5, pp. 125–160, figs. 9, charts 7; 6, pp. 161–196, figs. 4, charts 6*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of May and June, 1908, recent papers bearing on meteorology and seismology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 5.—Weather Influences Preceding the Evacuation of Boston, Mass. (illus.), by W. N. Lacy; The Work of Prof. Carl Störmer on Birkeland's Theory of the Aurora Borealis, by J. A. Anderson; The Warm Stratum in the Atmosphere, by A. L. Rotch; Tornadoes in Louisiana, April 24, 1908 (illus.), by I. M. Cline; Tornadoes in Mississippi, April 24, 1908, by W. S. Belden; Tornadoes in Alabama, April 24 and 30, 1908 (illus.), by F. P. Chaffee; Tornado at Dora and Bergens, Ala., April 24, 1908 (illus.), by W. F. Lehman; Observations of a Tornado near Fort Worth, Tex., by D. S. Landis; Tornadoes in Minnesota on May 24, 1908; Severe Local Storm in Florida; A Hurricane in the West Indies in March, 1908, by J. T. Quin; Tornado at Pekin, Ill., March 27, 1908, by D. A. Seeley; Windstorm at Peoria, Ill., May 5, 1908, by D. A. Seeley; Ice Conditions on the Great Lakes, Winter of 1907–8, by N. B. Conger; Early Meteorology at Harvard College, by B. M. Varney; The Meteor of October 5, 1907, Over New Jersey and Pennsylvania, by H. A. Peck; Some Meteorological Uses of the Polariscope, by L. Bell (E. S. R., 20, p. 13); Ice Movements and Currents in Bering Strait; An Elementary Method of Deriving the Deflecting Force Due to the Earth's Rotation (illus.), by T. Okada; and biographical note on William M. Husson.

No. 6.—A Graduate School of Meteorology; Progressive Climatic Variations on the Isthmus of Panama (illus.), by H. L. Abbot; Severe Windstorms in Ohio, June 19, 1908 (illus.), by J. W. Smith; Severe Windstorm in South Dakota, by S. W. Glenn; Tides of the Solid Earth, Observed by Doctor Hecker (illus.), by R. L. Faris; Some Climatic Influences in American History, by W. N. Lacy; Damage by Frost at Middlebranch, Ohio (illus.); The Climate of Spokane, Wash., by C. Stewart; The Climate of the Canadian Yukon; The Study of English [for Meteorologists]; The Smithsonian Meteorological Tables; National Conservation Commission; Where and How Can Our Observers Pursue the Study of Modern Science? Weather Bureau Men as University Students, by J. K. Hooper; and An Annotated Bibliography of Evaporation, by Mrs. G. J. Livingston.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander and R. C. Lindblad (*Massachusetts Sta. Met. Buls. 235, 236, pp. 4 each*).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during July and August, 1908. The data are briefly discussed in general notes on the weather of each month.

Meteorology, F. W. Christensen and H. D. Edmiston (*Pennsylvania Sta. Rpt. 1907, pp. 28–39, 175–198*).—The observations here recorded are of the same character as those reported in previous years (E. S. R., 19, p. 814). Monthly summaries of observations are given in the body of the report and the detailed record in an appendix. The summary for 1906 is as follows:

Summary of meteorological observations, 1906.

	1906.	Growing season (Apr.–Sept.).
Barometer (inches): Mean	30.049	
Temperature (° F.):		
Mean	49.5	63.8.
Highest	99 (June 9 and 30)	90 (June 9 and 30).
Lowest	−8 (Feb. 6)	23 (Apr. 1).
Greatest daily range	38 (Oct. 13)	37 (Apr. 26).
Least daily range	3 (Oct. 23)	
Mean daily relative humidity (per cent)	83.6	79.1.
Rainfall (inches)	34.15	18.99.
Number of days on which 0.01 in. or more of rain fell	141	64.
Mean percentage of cloudiness	5.4	5.2.
Number of days on which cloudiness averaged 80 per cent or more.	125	48.
Last frost in spring		May 29.
First frost in fall		Nov. 2.

Meteorological statistics, R. F. Stupart (*Irrigation in the Provinces of Alberta and Saskatchewan, 1906 and 1907. Ottawa: Dept. Int., 1908, pp. 5, 6, 28–38*).—Observations on rainfall and temperature at Calgary, Chaplin, Swift Current, Medicine Hat, and Macleod are given for 1906 and previous years, in some cases as far back as 1883.

How much rain does the earth receive annually? (*Rev. Sci. [Paris], 5. ser., 9 (1908), No. 22, pp. 688, 689*).—This article briefly summarizes the various estimates which have been made on this point. The average total annual rainfall of the earth is placed at 465,000 cu. km., of which 112,000 cu. km. falls on land and 353,000 cu. km. on sea.

The damage done by cyclones (*Rev. Sci. [Paris], 5. ser., 9 (1908), No. 19, p. 594*).—Statistics of persons killed and buildings destroyed by the principal cyclones from 1722 to 1900 are reported.

On hail protection appliances, J. Violle (*Rev. Sci. [Paris], 5. ser., 9 (1908), No. 11, pp. 346, 347*).—Experiments with explosives discharged from captive balloons are reported, but it is thought that the experiments were too few in number to give conclusive results. It is believed that more extensive and systematic experiments should be made.

The underground waters of Cape Colony, C. F. Juritz (*Agr. Jour. Cape Good Hope, 32 (1908), Nos. 5, pp. 634–647; 6, pp. 749–771; 33 (1908), No. 1, pp. 85–98*).—A large number of analyses are reported and the character of the waters is discussed.

Chemical analyses of water from dew ponds, S. Skinner (*Nature [London], 78 (1908), No. 2011, p. 30*).—Determinations of calcium carbonate and chlorin in samples of water from dew ponds in limestone regions as compared with similar determinations in water from a spring near one of the ponds are reported to show that the water of the ponds is low in calcium carbonate, thus indicating that the ponds "are simply water butts in which rain water is stored." The influence of the proximity of the sea is shown by a considerable increase in the proportion of chlorin in the water.

The drinking water supply of cities from a chemical standpoint, W. Hempel (*Umschau, 12 (1908), No. 27, pp. 523–527*).—The great importance of a suitable supply of drinking water for cities is pointed out. The author believes that the best results can be obtained by supplying soft water for laundry purposes, steam engines, etc., and hard water derived from deep underground sources for drinking purposes. He condemns the use of surface waters for drinking purposes.

SOILS—FERTILIZERS.

Soil surveys in the United States (*Jour. Bd. Agr. [London], 15 (1908), No. 1, pp. 48, 49*).—The progress, character, and uses of the soil surveys of the Bureau of Soils of this Department are briefly described, and the need in Great Britain of more systematic work of this kind than has heretofore been undertaken is pointed out.

Cartography of southwestern Louisiana with special reference to the Jennings sheet, G. D. Harris (*Geol. Survey La. Bul. 6, pp. 3–24, maps 2*).—This is one of the series of reports of the Geological Survey of Louisiana which has been carried on for several years under the direction of the State experiment stations. A map showing 5-foot contours of a portion of Calcasieu and Acadia Parishes, which it is believed will be of much service in rice culture and canal and levee construction, is given.

Results of analyses of soils, F. F. Villaseñor (*Mem. y Rev. Soc. Cien. "Antonio Alzate," 26 (1907), Nos. 4, pp. 109–114; 5, pp. 159–170*).—Notes on the general character and physical and chemical analyses of a number of samples of cultivated soils from different parts of Mexico are reported in this article.

Soil analysis (*Rhodesian Agr. Jour., 4 (1907), No. 6, pp. 596–601*).—Chemical and mechanical analyses of 6 samples of soils from the Gwelo district of Rhodesia are reported.

Manuring of Rhodesian soils (*Rhodesian Agr. Jour., 4 (1907), No. 6, pp. 541–552*).—Analyses of a number of samples of Rhodesian soils are reported, with suggestions as to their fertilizer requirements. The analyses show that as a rule the soils are somewhat deficient in lime and phosphoric acid.

Contribution to the study of the Amur region, S. V. Sichusev (*Pochvovyedyenie [Pédologie], 1906, pp. 81–89; abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), No. 5, p. 548*).

Tea soils of the Black Sea coast of the Caucasus and of some districts of China and Japan, Zemyatchenskiĭ and Adamov (*Selsk. Khoz. Sborn. Udyel. Vyed., 1 (1905), pp. 147–224; abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), No. 5, pp. 534, 535*).

Contribution to the study of soils, P. de Sornay (*Sta. Agron. Mauritius Bul. 17, 1908, pp. 79*).—The sampling and physical and chemical analysis of soils are discussed with special reference to the applicability and importance of such methods of examination in the case of Mauritius soils. The methods of analysis adopted and used in some preliminary study of the soils of Mauritius are described. The character of these soils as compared with soils of similar islands on which sugar cane is grown is also discussed. It is shown that while the soils of Mauritius are as a rule quite rich in fertilizing materials, they produce less sugar than, for example, those of Hawaii. This is attributed to the fact that the soils have not been thoroughly studied and the use of fertilizers systematically undertaken.

The productiveness of the soil: Geological and climatological factors, A. Grégoire (*Ann. Gembloux, 18 (1908), No. 4, pp. 225–241, figs. 2*).—This is the fourth of a series of articles discussing in a broad way the factors of soil fertility (E. S. R., 20, p. 216). The general conclusion reached in the present discussion is that the study of climatic and geologic factors is of great importance in agrology. They give valuable indications of the phenomena occurring in the soil and furnish a guide for the preparation of agronomic charts, i. e., for the comparative study of soils.

Oroclimatic basis of classification of soils, G. N. Vysotski (*Pochvovyedyenie [Pédologie], 1906, pp. 1–18; abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), 5, pp. 536–538*).

Investigations on processes of weathering, K. D. Glinka (*Trav. Soc. Imp. Nat. St. Petersb., Sect. Géol. et Min., 34 (1906), No. 5, pp. 1–178; abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), No. 5, pp. 546, 547*).—This treatise contains a detailed review of the literature of the subject and original investigations, most of which have already been published by the author (E. S. R., 19, p. 315).

In the last part of this treatise he discusses the subject of types of weathering, holding that in the future it will be possible to establish the types of weathering according to the chemical processes taking place in a given case. He indicates as the chief agents of weathering, carbonated water, weak salt solutions, humic acids and akali humates, and alkali carbonates, the participation of these or other agents depending mainly on the climatic conditions of the locality. The chief climatic factor is moisture, hence he suggests a possible soil classification based upon the degree of moisture as follows: (1) Soils with optimum humidity—laterites, red earths; (2) soils with medium humidity—podzols, forest soils; (3) soils with moderate humidity—chernozems, regurs; (4) soils with insufficient humidity—brown, gray, lamellar-columnar soils of semideserts; (5) soils with excessive humidity—marshy, semimarshy; (6) soils with temporarily excessive humidity—alkali lands.

On the nature of clay soils according to old and recent investigations, A. Atterberg (*K. Landtbr. Akad. Handl. och Tidskr., 46 (1907), No. 6, pp. 385–424; abs. in Zentbl. Agr. Chem., 37 (1908), No. 9, pp. 579, 580*).—This is a critical study of different systems of classification of clays, and of our present knowledge of their nature and characteristics, with an account of the author's views based on original investigations. The subject is discussed under the following headings: The external characteristics of clay soils; their classification; is kaolin a characteristic component of clays; the absorption phenomena; zeolitic substances as components of clay; the properties of the colloidal substances; on the nature of the colloids; are clay substances actual colloids; the composition of the decomposition silicates soluble in hydrochloric acid in northern clays; the Russian black soils and North American soils; and composition of the difficultly soluble decomposition silicates; and the inert components of clay soils.

The author is of the opinion that kaolin is not a characteristic component of clays. What has previously been taken for kaolin in northern clays is apparently composed of fine mica particles. The most characteristic ingredients of clays appear to be particles of the fineness of the colloids, while the zeolitic colloids are the most important component of clays, agriculturally speaking, as they are of other types of soils. The zeolites and other components soluble in hydrochloric acid ("decomposition silicates") differ greatly in composition according to the course of the decomposition processes under different climatic conditions, the end products being either mixtures of kaolin, aluminum hydroxid, and iron oxid, or zeolite-like double silicates of aluminum and iron oxids, with a high content of monoxids, besides gravel and sand. In the northern clays kaolin and aluminum hydroxid appear to play only a minor part or no part, but where kaolin and bauxite occur in quantities in the older formations they may also be expected in the sedimentary clays.

On the eolian origin of the soil salts, J. J. Pivovarov (*Pochrovycdyenie [Pédologie], 1906, pp. 67–80; abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), No. 5, pp. 547, 548*).—The article gives a survey of the literature of the subject in connection with the hypothesis of Vysotski concerning the formation of alkali lands.

Denudation of the steppe, A. IVCHENKO (*Zhegh. Ghcol. Min. Rossii, 1905, pp. 216–240; 1906, pp. 135–197; abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), No. 5, p. 550*).—Contains among other things a very detailed classification of alkali lands.

Humus, R. MCMURTRIE (*Amer. Fert., 28 (1908), No. 4, pp. 5–11*).—This is a summary of information regarding the composition and functions of humus in the soil.

On changes of availability of nitrogen in soils, II, O. LOEW and K. ASO (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1908), No. 5, pp. 567–574; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 549, II, p. 621*).—In an earlier article on this subject (E. S. R., 19, p. 119) attention was called to "the existence of bacteriolytic enzyms which probably play a rôle in the soils when the nitrogen of bacteria is rendered available for the roots."

This article reports culture experiments with *Bacillus pyocyaneus*, *B. mycoides*, *B. megatherium*, *B. subtilis*, *B. fluorescens liquefaciens*, and *Proteus vulgaris* to determine whether these common soil bacteria produce bacteriolytic enzyms. The results showed that the organisms under suitable conditions produce bacteriolytic enzyms which gradually render new bacterial growth difficult. "Since this may happen also in the soil, some explanation can be furnished for the fact that bacterial life does not increase infinitely in organically manured soils." Other investigations bearing on this subject are briefly reviewed.

The enrichment of soil in nitrogen by bacteria and its significance for plant nutrition, J. STOKLASA (*Deut. Landw. Presse, 35 (1908), Nos. 25, pp. 274, 275; 26, pp. 286, 287; 27, pp. 297, 298*).—This is a review of an article by Koch and others (E. S. R., 20, p. 17), with a brief account of the author's recent experiments with different organisms on oats, beets, and potatoes, the results of which confirm his former conclusions. In soils inoculated with *Azotobacter chroococcum* adequately supplied with mannite or grape sugar and lime the number of organisms was increased and both the yield and quality of the crops were improved.

The biology of root tubercle bacteria of leguminous plants in the light of recent investigation, F. FUHRMANN (*Mitt. Naturw. Ver. Steiermark, 1907, pp. 34–36; abs. Centbl. Bakt. [etc.], 2. Abt., 20 (1908), No. 18–20, p. 618*).—The article briefly reviews the more important contributions to this subject. It is stated that the fixation of atmospheric nitrogen by the root-tubercle organisms begins when the bacteroids have reached a stage when they are colored brown-red by addition of tincture of iodin. This occurs only when the organisms are feeding almost exclusively upon carbohydrates and the available nitrogen compounds have been almost completely exhausted. The question of whether the process of assimilation is the result of symbiosis or parasitism is also discussed.

Experiments on the accumulation of green manure nitrogen in light sandy soils, C. VON SEELHORST (*Mitt. Deut. Landw. Gesell., 23 (1908), No. 10, pp. 83–89*).—The results here reported confirm those of earlier experiments (E. S. R., 18, p. 538) in showing as a rule a decided decline in soil nitrogen from green manured soil as a result of growth of crops and loss in drainage.

On observation of the continuous growth of peas on the same soil, S. SUZUKI (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1908), No. 5, pp. 575–577*).—The results of four years' continuous culture of peas grown in pots on humus loam soil unfertilized and fertilized in various ways are reported. These show that no trace of soil "weariness" or "sickness" appeared when the soil was liberally fertilized. The author therefore is inclined to accept the view that soil sickness may in some cases be due simply to deficiency of available plant food.

Maximum productiveness of soils in pots, K. K. Gedroiz (*Trudui Selsk. Khoz. Khim. Lab. St. Peterb., 4 (1905), pp. 103–112; abs. in Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *8 (1907), No. 5, p. 583*).—Experiments made in vegetation pots with oats and mustard on 13 soils of different character showed that the maximum productiveness of the soils, i. e., the yield when fully provided with nutritive substances, was not alike under like conditions and varied for oats and mustard.

Need of fertilizing by Russian soils of various localities according to the vegetation method, K. K. Gedroiz (*Trudui Selsk. Khoz. Khim. Lab. St. Peterb., 4 (1905), pp. 1–64; abs. in Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *8 (1907), No. 5, pp. 582, 583*).—Results are given of investigation, by the vegetation method, of the need of 22 soils for fertilizers, with chemical analyses of the soils. From indirect indications obtained in these investigations and from theoretical considerations the author concludes that this method is altogether inapplicable to the determination of the need of soils for nitrogenous fertilizers and that its suitability in the case of other fertlizers is more than doubtful.

Available phosphoric acid in chernozem soils, A. S. Kudashev (*Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *8 (1907), No. 5, pp. 481–510, fig. 1; abs. in Zentbl. Agr. Chem., 37 (1908), No. 8, pp. 505–507*).—The object of this investigation was to find out whether extraction with oxalic acid is suitable for the determination of the phosphoric acid available to plants. The investigations included (1) vegetation experiments with oats, using all fertilizers except phosphoric acid, and (2) treating the soils with 0.5 per cent solution of oxalic acid and estimating the phosphoric acid in the extract.

Experiments were made with 49 soils from the various governments of the chernozem region of European Russia. The extraction was made by treating 200 gm. of soil during 3 hours with 800 cc. of 0.5 per cent solution of oxalic acid, shaking repeatedly, and then allowing to settle for 1 hour after the addition of 4 gm. of potassium chlorid.

Although the experiments, as the author states, were not carried out under favorable conditions, they seem to strongly indicate (1) that in soils of the same type the yields of oats, when phosphoric acid is in the minimum, increase nearly proportionately to the quantity of phosphoric acid extracted by 0.5 per cent solution of oxalic acid, and consequently this phosphoric acid is approximately proportional to the phosphoric acid assimilated by oats, and (2) that in soils of different types, e. g., in the eastern soils (richer in clay and humus) and the western soils (more sandy) of the chernozem region the phosphoric acid extracted by a 0.5 per cent solution of oxalic acid multiplied by the loss on ignition (which is approximately proportional to the amount of clay, humus, and carbon dioxid in a soil) is approximately equal or proportional to the phosphoric acid assimilated from the soil.

Washing of soils and methods of prevention, J. G. Mosier (*Illinois Sta. Circ. 119, pp. 16, fig. 1*).—This circular briefly discusses the relation of rainfall and run-off to surface washing, and explains that the washing produced by the run-off is of two kinds, sheet washing or general surface washing and gullying. Four methods of preventing sheet washing are explained, namely, the growing of cover crops, increasing the organic matter in the soil, tillage, and terracing and hillside ditching. Various methods of preventing and checking gullying are also described.

The Bremen moor culture station, B. Tacke (*Illus. Landw. Ztg., 28 (1908), No. 14, pp. 112–115, figs. 7*).—This article describes the methods employed and reviews the progress made by the Bremen moor station in reclaiming moor lands.

Examinations of barnyard manure and liquid manure on Danish farms, R. K. KRISTENSEN and F. HANSEN (*Tidsskr. Landbr. Planteavl, 14 (1907), pp. 515–570, figs. 3*).—Experiments were conducted on 6 different farms for the purpose of studying the accuracy of methods of sampling manure heaps. Three or four samples were taken at each place and analyzed for nitrogen, dry matter, and ash. The samples were taken by cutting at least 6 square holes in the manure pile by means of a hay knife, and uniting the columns of manure thus obtained, making a sample of about 50 lbs. weight, which was then worked over thoroughly and about 3 lbs. taken for analysis. Prior to drying the samples in the laboratory, tartaric-acid solution was added to prevent loss of volatile nitrogen compounds. When the manure was sampled as hauled out, a forkful of each load was placed in a tightly covered box, and from the lot of about 600 lbs. of manure a 3-lb. sample was secured for analysis. This method of sampling gave very satisfactory results, especially where the manure was of a rather uniform composition, agreeing within 0.05 per cent for nitrogen and within 1 to 2 per cent for dry matter. Greater variations occurred in the ash, owing to frequent admixtures of foreign inorganic materials like dirt from roots, yard sweepings, etc.

The influence of the feed on the nitrogen content of the liquid manure was studied in a series of experiments. Samples of cow urine from 45 different Danish farms were examined and their composition studied with reference to the influence of the system of feeding practiced. The influence of heavy or light feeding of oil cakes, concentrates, straw, or roots could not be traced to any marked degree in the nitrogen content of the urine. On the other hand the urine obtained on heavy feeding of hay contained on the average 0.498 per cent of nitrogen against 0.429 per cent in that from light hay feeding (averages for 23 and 22 farms, respectively). The differences in the case of the other feeds mentioned were within a few hundredths of 1 per cent when a heavy or a light system of feeding of a particular feed was practiced.

The manner of covering liquid-manure tanks was found of great importance with regard to the losses of nitrogen, cow urine kept in carefully covered tanks containing on the average 0.615 per cent of nitrogen while that from poorly covered tanks contained only 0.285 per cent. The maximum in samples from carefully covered tanks was 0.836 per cent and the minimum from poorly covered tanks 0.169 per cent. A relatively high specific gravity with a low nitrogen content shows that ammonia has been lost by evaporation.

Determinations of potash in liquid manure in 18 different cisterns showed variations in this constituent of from 0.50 to 1.24 per cent, the average being 0.79 per cent, with an average production of urine per cow of 39.4 cu. ft. Similar determinations of phosphoric acid showed variations in the case of four cisterns of from 0.006 to 0.008 per cent, average 0.007 per cent. Complete statistical data as to the methods of construction and covering of the cisterns, production of liquid manure, method of feeding, etc., with the analyses of the contents of the cisterns on 70 different farms, are given at the close of the report.

Experiments with liquid manure, especially as to loss of nitrogen during storage, R. K. KRISTENSEN (*Tidsskr. Landbr. Planteavl, 14 (1907), pp. 276–291, figs. 7*).—The experiments were conducted during 1906–7 largely according to the plan followed during the preceding year (E. S. R., 19, p. 218). The content of nitrogen and of ammonia was highest in the lowest portion of the liquid-manure tank in these trials as in the tests of the preceding year, there being a gradual increase from 0.197 per cent of nitrogen and 8.172 per cent of ammonia at 8.5 ft. from the bottom of the cistern, to 0.609 and 0.545 per cent of nitrogen and ammonia, respectively, 0.5 ft. from the bottom, while the

specific gravity of the liquid manure ranged from 1.0143 to 1.0229 at the two depths given.

Experiments on the storage of liquid manure in a round cistern 9.5 ft. deep and 17 ft. wide were conducted during a period of 8 months. The nitrogen content of the liquid during this period decreased from 0.447 to 0.350 per cent, a loss of 21.7 per cent. At the same time the specific gravity of the liquid went down from 1.0263 to 1.0241 (8.4 per cent). The loss in nitrogen is largely explained by the fact that there was an opening 3 in. wide and 6 in. long in the cover of the cistern, through which the pump projected.

Manure statistics, M. RINGELMANN (*Jour. Agr. Prat., n. scr., 14 (1907), Nos. 48, pp. 696–699; 49, pp. 718–723*).—This article gives detailed data regarding the manure produced by animals of different kinds with varying feed, litter, etc., as well as the weight per unit volume of manure managed in different ways.

Experiments with new nitrogenous fertilizers, H. VON FEILITZEN (*Svenska Mosskulturför. Tidskr., 22 (1908), No. 2, pp. 91–105, figs. 3*).—The experiments were made with two kinds of "Norway nitrate" (calcium nitrate from Notodden, Norway, containing 11.59 and 12.53 per cent of nitrogen respectively), and calcium cyanamid manufactured by three different processes, viz., those of Frank and Caro, Polzenius, and Carlson, these fertilizers containing, respectively, 18.76, 10.19, and 16.69 per cent of nitrogen. For the sake of comparison, experiments were also conducted with sodium nitrate or ammonium sulphate in the different series. Seven series of trials were conducted.

The calcium nitrate produced a somewhat higher increase in yield of potatoes and oats on a peaty soil than the corresponding amount of nitrogen in sodium nitrate. The results of the last three years' trials with this fertilizer by the author have thus agreed in showing that it is fully as effective as sodium nitrate for peaty soils low in nitrogen, as well as for other soils. The calcium cyanamid applied on sandy soils for potatoes, on a good peaty soil for timothy or potatoes, and for sanded white-moor soil, as a top-dressing on grassland, had a fertilizing effect of 60 to 80 per cent of that obtained with corresponding amounts of nitrogen in sodium nitrate. The two German cyanamids produced similar results, while the Swedish product in two series of trials was found to possess a somewhat lower fertilizer effect than the two other cyanamids.

Results of trials with nitrogenous fertilizers, 1907, H. G. SÖDERBAUM (*K. Landtbr. Akad. Handl. och Tidskr., 47 (1908), No. 1–2, pp. 104–110, fig. 1*).—Experiments were made with the following nitrogenous fertilizers: Calcium cyanamid, manufactured according to the Frank, Polzenius, and Carlson processes, sodium or calcium nitrate, and ammonium sulphate. The effect of the fertilizers for oats grown in sandy soil in glass cylinders of about 500 sq. cm. surface, holding about 25 kg. of soil) was studied, the fertilizers being added in the proportions of 0.25, 0.50, and 0.75 gm. of nitrogen per cylinder, with similar quantities of other fertilizing ingredients in all cases.

The results of the trials were remarkable in showing calcium nitrate decidedly inferior in its action to sodium nitrate, especially in the case of the heaviest applications, with ammonium sulphate much more effective than this fertilizer. No marked differences were observed in the case of the low and the medium applications of nitrogen for the three kinds of calcium cyanamid, these being all inferior in their action to sodium nitrate in the former case, and superior to it in the latter case. In the cylinders with the heaviest application of nitrogen, the Carlson cyanamid produced nearly as high results as ammonium sulphate, with the Polzenius cyanamid 12 per cent better than sodium nitrate, and Frank's cyanamid 12 per cent below. The abnormal climatic conditions of the season of 1907 are doubtless largely responsible for the

results obtained. The average temperature throughout the growing period was 2 to 3° C. below normal, and the vegetation period of the crop 111 days, against 88 days in 1906, 89 days in 1905, and 101 in 1904.

Tests of the new nitrogenous fertilizers on potatoes and turnips in 1907, L. Bauwens (*Jour. Soc. Cent. Agr. Belg., 55 (1908), Nos. 5, pp. 169–172; 6, pp. 191–193*).—These tests, which were made on sandy and clay soil, show that sulphate of ammonia and nitrate of soda were about equally effective, with possibly a slight difference in favor of the sulphate, which is attributed to the unusually favorable season. Calcium cyanamid and basic lime nitrate, although giving good results, were not quite as effective as the nitrate of soda and sulphate of ammonia.

On the efficacy of calcium cyanamid under different manuring conditions, I. Namba and C. Kanomata (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1908), No. 5, pp. 631–634, pl. 1; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 549, II, p. 623*).—In pot experiments with oats, onions, and *Brassica chinensis* it was observed that lime nitrogen gave better results when used in connection with superphosphates than when used with neutral phosphate. It, however, does not depress the availability of bone dust, its action in this respect being similar to that of ammonium sulphate rather than to that of sodium nitrate.

Fertilizer experiments with phosphates on Finnish moor land, A. Rindell (*Finska Mosskulturför. Årsbok, 1906–7, No. 3, pp. 182–191*).—Experiments were conducted during 1903–1906 for the study of the effect of different phosphates—bone meal, Thomas slag, and Algiers phosphate—for oats and hay with and without liming. The relative value of the three phosphates for the growing of these crops on moor soils was as follows, for 50 and 100 kg. of phosphoric acid, respectively (Thomas slag=100) : Bone meal 118.1 and 111.7, Algiers phosphate 49.7 and 67.4. Simultaneous applications of lime hardly changed the effect of the Thomas slag, while it decreased greatly the effect of the bone meal, and especially that of the Algiers phosphate.

Comparative fertilizer experiments with high-percentage and low-percentage Thomas slag, Schweickert (*Landw. Ztschr. Rheinprovinz, 9 (1908), Nos. 11, pp. 146–148; 12, pp. 161–163*).—A series of experiments on meadows and with rye and oats are reported. The slags were used with and without the addition of lime. The general result was that the high-grade slag was as a rule more profitable than the low-grade.

On the value of refuse lime from sulphate-cellulose factories as an amendment on moor soils low in lime, H. von Feilitzen (*Svenska Mosskulturför. Tidskr., 22 (1908), No. 1, pp. 42–48, figs. 2*).—Pot experiments with red clover gave results indicating that this material can fully replace slaked lime on peaty soils low in lime if added in air-dry condition.

Gypsum as a manure, T. Takeuchi (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1908), No. 5, pp. 583–597*).—Pot experiments with peas, beans, oats, rice, and spinach in which gypsum was used in connection with ammonium sulphate, sodium nitrate, lime nitrogen, potassium sulphate, and different forms of phosphoric acid are reported.

It was observed that as a rule gypsum decreased the yield when used in connection with acidic fertilizers and increased the yield when used with alkaline fertilizers. Gypsum therefore appears to be a valuable addition to fertilizers containing sodium nitrate or other substances which produce an alkaline reaction in the soil. If, however, acidic fertilizers such as superphosphate and ammonium sulphate are used gypsum is likely to decrease the yield.

It was also found in these experiments that gypsum exerts a favorable influence in overcoming the injurious effect on plants of an excess of magnesia in the soil. In case of spinach it was observed that applications of carbonate of

lime were injurious while the gypsum was beneficial provided the reaction of soil and of fertilizer was not acid.

Why are poor sandy soils often easily injured by liming? H. Yokoyama (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1908), No. 5, pp. 615–617; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 549, II, p. 621*).—From pot experiments with oats the conclusion is drawn that the injurious effect of liming on poor sandy soils is due to the fact that an improper ratio of lime to magnesia is thus produced in such soils. It is recommended that in order to avoid such an unfavorable ratio these soils should be limed only with dolomitic limestone.

On the depression of growth by large doses of lime, C. Kanomata (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1908), No. 5, pp. 599–607, pl. 1*).—The results of pot experiments with varying amounts of lime on a number of different crops are summarized as follows: "When the amount of lime is increased in undue proportion to the amount of magnesia present, the yield of oats is considerably depressed. In sand culture, there was a decrease of 39 per cent of the weight of shoots before flowering time, when the amounts of limestone and magnesite differed so much that the ratio of lime to magnesia was changed from 1 : 1 to 100 : 1.

"In soil culture the decrease was 48 per cent some time after the flowering, when that ratio was changed from 1 : 1 to 10 : 1.

"Corresponding observations were made with upland rice, barley, buckwheat, mustard, and onion. If by proper increase of magnesia in the overlimed sand again the ratio 1 : 1 is produced, there is again a considerable increase of yield.

"These experiments form an analogy to those of Maki and Tanaka who regenerated the overlimed soil by application of magnesium sulphate [E. S. R., 18, p. 14].

"It is certainly not the absolute amount of magnesite or of limestone which comes in consideration but the ratio of lime to magnesia which determines—ceteris paribus—the height of the harvest."

On the absorption of varying amounts of lime and magnesia by plants, T. Takeuchi (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1908), No. 5, pp. 579–581*).—This article reports briefly the results of experiments made to determine the effect of varying ratios of lime and magnesia in the soil, upon the ratios of these elements in leaves, roots, and seeds of oats.

It was found that an increase of lime in the soil from 0.6 to 5 per cent resulted in a relative increase of lime from 1 to 2.1 in the roots and from 1 to 1.7 in the leaves. With a ratio of 1.2 parts of lime to 1 of magnesia the roots absorbed twice as much lime as magnesia, while the leaves contained 2.5 times as much lime as magnesia. By changing this ratio in the soil to 10 : 1 the ratio in the roots increased to only 1.7 : 1 and in the leaf to 1.5 : 1. This small increase, however, was accompanied by a considerable reduction in the development of the plant.

On the agronomical equivalent of artificial magnesium carbonate, S. Kanamori (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1908), No. 5, pp. 609–612, pl. 1*).—From pot experiments with barley and oats the conclusion is drawn that applications of 0.1 to 0.6 gm. of magnesium carbonate are agronomically equivalent to 5 gm. of magnesite. A further increase of the magnesium carbonate, however, decreases the yield.

Top-dressing with magnesium sulphate, J. N. Sirker (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1908), No. 5, pp. 613, 614*).—Pot experiments with barley are reported which show that top-dressing with 10 kg. per hectare (8.9 lbs. per acre) of magnesium sulphate increased the yield 31 per cent on soil containing an excessive proportion of lime to magnesia.

Manganese compounds as fertilizers for maize, W. F. Sutherst and H. Ingle (*Transvaal Agr. Jour., 6 (1908), No. 28, pp. 437, 438, pl. 1*).—This article briefly reviews investigations on this subject in Japan and Holland (E. S. R., 16, p. 43; 18, p. 434; 19, p. 523), and reports the results of pot experiments made by the authors with manganese chlorid, black oxid of manganese (pyrolusite), and manganese sulphate. All of the manganese compounds increased the yield, the most marked results being obtained with the pyrolusite. The benefit derived from the use of the manganese salts is attributed to their stimulating effect.

Do manganese salts stimulate plant growth? S. Rhodin (*K. Landtbr. Akad. Handl. och Tidskr., 47 (1908), No. 1–2, pp. 30–33*).—The author gives a brief discussion of earlier work done with regard to a possible stimulating effect of manganese salts on plant life, and describes experiments conducted by himself during the period 1902 to 1906. The results of these experiments were negative.

Modern niter beds (*Nature [London], 77 (1908), No. 2005, pp. 513, 514*).—This article discusses briefly the economic possibilities of the process proposed by Müntz and Lainé (E. S. R., 19, p. 524).

Crude ammonia, Sévegrand (*Rev. Vit., 29 (1908), No. 746, pp. 380–385*).—This article summarizes information regarding the value and use of this material as a fertilizer, weed destroyer, and insecticide. Of the three uses named the most important is as a fertilizer on account of the low price of nitrogen in the material.

On the manufacture and application of peat litter, A. E. Rautakoski (*Finska Mosskulturför. Arsbok, 1906–7, No. 3, pp. 192–207*).—A general account.

The extraction of potash from feldspathic rock, A. S. Cushman and P. Hubbard (*Jour. Amer. Chem. Soc., 30 (1908), No. 5, pp. 779–797, figs. 7*).—This paper presents the results of a continuation of investigations which have already been noted (E. S. R., 18, p. 717; 19, p. 322), and deals especially with more exact studies of the influence of the fineness of grinding on the electrolytic decomposition of the feldspars. The results are summarized as follows:

"(1) Fine grinding of feldspar renders the potash partly available under the action of water. The addition of certain substances, such as ammonium salts, lime, and gypsum, increases this effect.

"(2) It is possible to completely extract potash by an electrolytic method either with or without the addition of hydrofluoric acid, but it is probable that this method could not be used commercially on account of its cost.

"(3) The effect of fineness of grinding has been studied and data given showing the relation of surface area to rate of decomposition.

"(4) It is shown that there are numerous fusion methods which could be used successfully if the cost were not too high. The attack on the silicates by means of potash or its compounds yields some interesting reaction products which might possibly be made use of.

"(5) The attack with hydrofluoric acid is suggested as a possible method that deserves further study."

The commercial fertilizer industry, Stange (*Vrtljschr. Bayer. Landw. Rat., 12 (1907), No. 4, pp. 503–518*).—Statistics of production and consumption of fertilizer materials of different kinds in the German Empire are briefly summarized.

The development of the superphosphate industry in Italy, Maizières (*Engrais, 23 (1908), No. 14, pp. 324–325*).—It is stated that the amounts of phosphates imported by Italy in 1907 for the manufacture of superphosphates were 338,000 metric tons from Africa and 92,000 tons from America.

Lime and its relation to agriculture, P. G. WICKEN (*Jour. Dept. Agr. West. Aust., 16 (1908), No. 2, pp. 130–134*).—This article briefly describes methods of burning lime, different forms of lime, and methods of application adapted to conditions in Western Australia.

Vegetable ash as a manure, W. GUERRERO (*Chem. Trade Jour., 42 (1908), No. 1090, p. 350*).—Attention is called to the beneficial effect of applications of ashes both as a direct source of plant food and as a means of rendering other fertilizing materials more available. The extensive use of ashes on the Continent of Europe is illustrated by the fact that 22,000 to 24,000 tons of ashes are used per annum in the olive industry alone.

Fertilizer and oil, M. C. MARSH and J. N. COBB (*U. S. Dept. Com. and Labor, Bur. Fisheries Doc. 632, p. 55*).—This is a brief note included in a report on the fisheries of Alaska in 1907, giving statistics of production of fish fertilizer and oil in that Territory. It is stated that there is only one fertilizer plant now in operation in Alaska. This is located at Killisnoo. The amount of fertilizer prepared during 1907 at this factory was "502 tons from herring, valued at $17,020, and 88 tons from salmon, valued at $2,980; while the oil extracted amounted to 80,877 gal. from herring, valued at $16,175, and 14,123 gal. from salmon, valued at $2,825."

Inspection of commercial fertilizers, P. F. TROWBRIDGE (*Missouri Sta. Bul. 80, pp. 3–14*).—This bulletin gives the results of inspection of fertilizers in Missouri during the spring of 1908. Analyses of 69 samples are reported. Attention is called to the fact that a large number of fertilizers failed to meet the guaranty of the manufacturers.

Analyses of commercial fertilizers, H. M. STACKHOUSE and M. B. HARDIN (*South Carolina Sta. Bul. 138, pp. 3–40*).—This is a report in the usual form of the results of the inspection of 744 samples of fertilizers collected during the season of 1907–8.

Comments upon the State fertilizer law, A. L. KNISELY (*Oregon Sta. Bul. 97, pp. 3–11*).—This law took effect June 1, 1907. It requires that all fertilizing materials (except land plaster and lime) selling for more than $5 per ton shall be sold under guarantied analysis, that the source of the fertilizing ingredients must be plainly stated on each package or lot, and that certificates must be filed with the experiment station, the director of which is empowered to enforce the law. Violations of the law are punishable by confiscation of the goods. A license fee of $20 for each brand is required.

AGRICULTURAL BOTANY.

Report of the department of botanical research, D. T. MACDOUGAL (*Carnegie Inst. Washington Year Book, 6 (1907), pp. 57–68, pls. 3, fig. 1*).—A summary is given of the investigations carried on at the botanical research laboratory near Tucson, Ariz., an outline of which has been previously noted (E. S. R., 18, p. 726). Among the leading investigations are studies of the advance and resession of vegetation in the depressed basins of the Colorado River and the inductive influence of physical factors on vegetation.

In the Colorado Delta a number of stations have been located where the advance and recession of plants will be studied. This region has been subject to recent overflow, and a sample of the water taken June 3 showed on analysis that it contained 364.8 parts soluble solids in 100,000. The proportions of sodium, chlorin, and sulphates are high, and the restoration of plant covering must be preceded by leaching and capillary action. Exact observations on the changes in the soil and vegetation are expected to offer evidence of value bearing on the distributional movements of plants.

In the investigations on the influence of physical factors on vegetation 4 stations have been located, one at the Desert Laboratory, a second on a small irrigated farm, a third at an elevation of 6,100 feet, and the fourth an alpine station at 8,000 feet. At these different stations observations are being carried on in which measurements are made of the factors which go to make up the climate of a region. It has been determined by the methods pursued that a meadow received 78,836 hour-degree units of heat in a year, while the floor of a hemlock forest near by received but 68,596 hour-degree units, indicating a season practically 11 days shorter than that in the meadow. In the application of this method to plants having a resting season the exposure is calculated from the time of planting the seeds until their maturity or until the attainment of some stage of development.

A number of correlated problems are under observation, some of which will be reported upon in the publications of the institution.

A new form of automatic rain meter is figured and described.

The physiological constant for the germinating stage of cress, F. A. Waugh and C. S. Pomeroy (*Massachusetts Sta. Rpt. 1907, pp. 71–80, dgms. 3*).—A study was made of the germination of cress to determine the physiological constant or the amount of heat required for the germination of the seed of this plant. These investigations have been carried on for some time at the station, and the authors have employed a recording thermograph in order to secure greater accuracy in the data.

During the period reported upon, 77 thermograph records were obtained showing the sum temperatures above 32°. In these records the sum temperatures varied from 2,714 to 4,286, and the time occupied for the completion of the stage of germination from 70 to 210 hours. By means of formulas the authors have determined the critical temperature of the germination phase of cress to be 38.2°. With this temperature known, the germination period of cress can be computed within rather close limits.

The transpiration current in plants, J. M. Janse (*Jahrb. Wiss. Bot. [Pringsheim], 45 (1908), No. 3, pp. 305–350, figs. 13*).—The author has made a study of the movement of water in plants, paying particular attention to transpiration. He claims that the movement of water in plants in so far as it is caused by transpiration is to be regarded exclusively as an isothermic operation for which all the energy is furnished by the temperature of the environment. If the leaf cells assist in moving the transpiration current, their effect is so small as to be only theoretical.

Molecular activities, such as capillary, imbibition, cohesion, etc., are incapable of promoting the water movement.

The course of the transpiration current is through the vessels when they conduct water only, the spiral vessels, even when containing air, and through the tracheids which are filled with water or which may contain air bubbles. In the case of the tracheids containing air bubbles, the water passes upward between the wall and the bubble, and it is probable that it filters sidewise into the next higher tracheid. Where the vessels are contiguous to the tracheids the water contained in them may enter the transpiratory current even if air bubbles are present, but then only by sidewise filtration from the vessels into the tracheids.

Where the vessels are separated from the tracheids by wood-parenchyma cells the water held in them can not enter the transpiratory stream directly, but it seems probable that it can act as a reserve supply when transpiration is suddenly increased.

The resistance encountered by the transpiratory stream under these conditions is so great that water can be moved for only relatively short distances.

The chemical nature of root secretions, J. Stoklasa and A. Ernest (*Jahrb. Wiss. Bot.* [*Pringsheim*], *46* (*1908*), *No. 1, pp. 55–102, pls. 5*).—Reviewing at some length the investigations on this subject, and summarizing their own experiments, the authors arrive at the general conclusion that the most important if not the only active agent excreted by roots is carbon dioxid, but that both carbon dioxid and organic acids are produced by soil bacteria in considerable amounts.

The structure of root tubercles in leguminous and other plants, W. B. Bottomley (*Rpt. Brit. Assoc. Adv. Sci., 1907, p. 693*).—According to the author, the root tubercles of all leguminous plants examined appear to arise endogenously from the cortical cells just outside of the endodermis of the roots. These cells are stimulated by the infection thread, which grows almost straight from the infected root hair toward the vascular cylinder of the roots, and a conical mass of cells develops which forms the young tubercle. In fully developed tubercles the bacteroid tissues are situated entirely within the vascular strands.

The root tubercles of alder, Elæagnus, and Cycas are to be morphologically considered as lateral roots, showing a central vascular cylinder and well-marked endodermis, completely surrounded by bacteroid tissues. These tubercles branch dichotomously and are perennial, thus differing from leguminous tubercles, which are of limited growth.

The assimilation of free atmospheric nitrogen through the fungus of Lolium temulentum, E. Hannig (*Ber. Deut. Bot. Gesell., 26a* (*1908*), *No. 3, pp. 238–246, fig. 1*).—By means of cultures of *L. temulentum*, in which fungus-infested seed and seed free from the fungus were used, the author has undertaken to determine the possibility of the assimilation of atmospheric nitrogen by this plant in symbiosis with the fungus.

It was found that the seed containing the fungus were considerably richer in nitrogen than those not so infested, but in the cultures comparatively little difference was shown in the growth of the plants from the different lots of seed. As a result of the analyses the author confirms the observation of Hiltner (E. S. R., 11, p. 1016) that there is a slight assimilation of atmospheric nitrogen by infested *L. temulentum*.

Heredity in plants and animals, T. B. Wood and R. C. Punnett (*Trans. Highland Agr. Soc. Scot., 5. ser., 20* (*1908*), *pp. 36–86, figs. 11*).—This is a discussion of Mendel's principles and their bearing on agricultural problems, the data discussed being drawn from investigations of Mendel, Hurst, Johannsen, De Vries, Bateson, Biffen, and others.

A critical review of the known cases of bud variation, P. J. S. Cramer (*Natuurk. Verhandel. Holland. Maatsch. Wetensch. Haarlem, 3. ser., 6* (*1907*), *No. 3, pp. XVIII+474*).—After a general review of the subject of variation, the author takes up and critically discusses a large number of bud variations and attempts to classify them according to their most striking characters.

Suggestions concerning certain bud variations, E. M. East (*Plant World, 11* (*1908*), *No. 4, pp. 77–83*).—The author gives an analysis of a number of bud variations of potatoes, tomatoes, and other plants, most of the variations being changes of color. In the majority of cases he holds that bud variation is simply a loss of a dominant character, and hence the appearance of a related recessive character. This he claims will explain fully 75 per cent of the recorded bud variations, and it is believed that an increasing knowledge of Mendelism will extend the proportion of cases to which it is applicable.

Variation in peas, F. A. Waugh and C. S. Pomeroy (*Massachusetts Sta. Rpt. 1907, pp. 65–70, dgms. 3*).—For several years past the horticultural division of the station has been carrying on investigations with peas to study the so-called

Mendel's law of variation and the application of statistical methods in studying variation and heredity. In the present report an account is given of the results of an examination of a row of peas in the field, in which the length of the vines, number of pods per vine and peas per pod, and length of vines to production of pods were determined, and the range in variation is shown. In connection with these studies the subject of correlation came up, and it was found that the length of vines and number of pods per vine were found to be closely correlated.

Gray's new manual of botany, B. L. Robinson and M. L. Fernald (*New York, 1908, 7. ed., pp. 926, figs. 1036*).—This is a seventh edition of the well-known manual of the botany of the central and northeastern United States and adjacent Canada, the area now covered being that between 48° north latitude and the southern borders of Virginia, Kentucky, Missouri, and Kansas, and from the eastern shores of the continent westward to the Dakotas and eastern Nebraska and Kansas, or to the parallel of 96° west longitude.

The material of the old manual has been rearranged and almost wholly rewritten, and in its preparation various specialists have revised different orders. The sequence of orders and genera is that of Eichler as elaborated by Engler and Prantl. The system of nomenclature is that adopted by the International Botanical Congress at Vienna in 1905. In order to make the manual as convenient as possible to the users, synonyms are freely inserted showing the equivalent names that are not sanctioned by the International Rules. The insertion of small text figures will aid the student at arriving at the determination of some of the more difficult species. In the present edition the Hepaticæ are omitted and the range is restricted in its western extension, but the whole number of species and varieties of plants treated shows a decided increase over previous editions, the actual number described being 4,885 as compared with 3,298 in the sixth edition.

Handbook of flowerpollination, P. Knuth, trans. by J. R. A. Davis (*Oxford, 1908, vol. 2, pp. VIII+703, pl. 1, figs. 210*).—This is the second volume of this work (E. S. R., 18, p. 128), and is based upon Müller's work on the fertilization of flowers by insects. The present volume gives observations on flower pollination made in Europe and in the Arctic regions. 1,686 species of 504 genera belonging to the natural orders Ranunculaceæ to Stylidieæ being reported upon.

FIELD CROPS.

A lesson in intensive farming, R. H. Forbes (*Arizona Sta. Bul. 57, pp. 267–274*).—In this experiment intensive culture was practiced between the rows of date palms in a newly established orchard 7.2 acres in size. The outcome is shown in the following table:

Financial results of intensive cropping on the basis of net cash returns to the small farmer.

Crop.	Acreage.	Marketable crop.	Gross receipts.	Expenditures.	Net returns.	Days labor.		
						Men.	Women and boys.	Team.
White Bermuda onions	0.47	3,916 lbs.	$73.24	$8.94	$64.30	31.5	0.5	1.0
Early Rose potatoes	.84	2,615 lbs.	70.00	12.85	57.15	42.0	----------	4.5
Dwarf tomatoes	.52	13,531 lbs.	624.60	72.72	551.88	85.0	38.0	10.0
Rockyford cantaloupes	1.00	780 doz.	144.60	9.00	135.60	31.0	8.0	2.0
Watermelons	.20	----------	15.65	2.00	13.65	3.0	----------	--------
Alfalfa	1.70	20 tons.	----------	22.41	--------	14.0	----------	9.0
Total	4.73	----------	928.09	127.92	800.17	206.5	46.5	26.5

The alfalfa, estimated to be worth $120, was fed to a team. By way of contrast it is shown that 110 acres of barley grown under extensive farming produced 138.8 tons of grain and 7 tons of barley hay, netting $12.21 per acre.

Report of the agriculturist, W. P. Brooks, E. S. Fulton, and E. F. Gaskill (*Massachusetts Sta. Rpt. 1907, pp. 29–57*).—Previous results of this series of experiments have been noted heretofore (E. S. R., 19, p. 226). The work was conducted on 318 field plats, 153 closed plats, and 330 pots in vegetation experiments.

The relative rank in value as sources of nitrogen on the basis of total yield of the materials under comparison in 1907 was nitrate of soda, dried blood, barnyard manure, and sulphate of ammonia. The average percentage basis for all results secured since 1890 is as follows: Nitrate of soda 100, barnyard manure 85.92, dried blood 70.21, and sulphate of ammonia 45.36.

The use of sulphate of potash gave larger crops of raspberries and blackberries than the use of muriate of potash, which was slightly the more effective in the production of cabbages, rhubarb, corn, and squashes. Asparagus gave much better yields where the muriate was used than where the sulphate was applied. In the production of marketable potatoes the potash salts under comparison ranked as follows: Low-grade sulphate, muriate, nitrate, high-grade sulphate, silicate, carbonate, and kainit, but the differences were relatively small except with the kainit. The plat treated with carbonate of potash was much more infested with scab than the plats receiving the other potash salts.

The plats receiving a special corn fertilizer supplying 42.6 lbs. of nitrogen, 180 lbs. of phosphoric acid, and 77.4 lbs. of potash per acre yielded 58.75 bu. of sound corn, 5 bu. of soft corn, and 6,580 lbs. of stover, while the plats receiving a fertilizer application supplying 47 lbs. of nitrogen, 50 lbs. of phosphoric acid, and 125 lbs. of potash produced 54 bu. of sound corn, 7.68 bu. of soft corn, and 6,890 lbs. of stover per acre. Plats of corn treated with manure alone gave a slightly higher yield of sound corn than plats receiving a smaller quantity of manure with a moderate amount of sulphate of potash which gave the higher yields of soft corn and stover.

In the experiments with different phosphates mixed hay was grown this season. The yields on the plats treated with the different phosphates varied but little. The plats which had received no phosphates during 11 years gave an average of about 4 tons to the acre for the first crop, while the highest yield obtained on any of the phosphate plats at first cutting was only 9,240 lbs. per acre.

The results of soil tests now in progress for 19 years show the great importance of a liberal supply of potash in growing corn.

In the test in which barnyard manure, wood ashes, and a combination of fine ground bone and potash is applied in rotation for the production of grass, the average yield per acre for this year was 5,005 lbs. of hay. The average yield for the 15 years the test has continued is 6,296 lbs. per acre.

In the experiment with winter and spring application of manure on a slope no manure was applied this year, but the crop of mixed grass and clover was extremely heavy and lodged considerably. The differences in yield between the two methods of application were small. Owing to a deficiency of rainfall, nitrate of soda applied for rowen did not repay the cost.

Seeding mowings, W. P. Brooks (*Massachusetts Sta. Circ. 16, pp. 8, figs. 3*).—This circular in discussing seeding down to grass or mixed grass and clover considers especially preparatory fertilization, time and methods of seeding, preparatory tillage, and the varieties of grasses and clover to be used.

[Early Amber sorghum and alfalfa], J. B. Lindsey (*Massachusetts Sta. Rpt. 1907; pp. 101–103*).—The results of 2 years' observations indicate that 50

to 60 lbs. of seed of early Amber sorghum per acre are sufficient when this crop is sown broadcast for forage.

Three cuttings from a one-sixth acre plat of alfalfa amounted to a yield of 3.65 tons of dry hay per acre in 1906. In 1907, nearly 4½ tons per acre were secured on the same plat.

Observations on nurse crops for alfalfa, V. A. Clark (*Arizona Sta. Bul. 57, pp. 284–287*).—In the fall of 1905 alfalfa was planted in pure culture, and with rye, wheat, barley, and oats as nurse crops. The following March the height of the plants in the pure culture was from 15 to 17 in., while in the nurse crops the alfalfa varied from 12 in. down, being generally not more than 6 or 8 in. high. The plants grown with nurse crops uniformly had few shoots as compared with those grown alone. The weights of 10 average alfalfa plants from the various plats were as follows: Pure culture, ordinary stand, 75 gm.; pure culture, stand too thick, 21.3 gm.; rye, two-thirds stand, 10.2 gm.; wheat, one-half stand, 12.5 gm.; wheat, full stand, 2 gm. Alfalfa roots in pure culture had reached a depth of about 18 in., when those grown with nurse crops had reached to a depth of only 12 in. These results were confirmed in a field test.

It was observed that the cereals grown as nurse crops or as intercultures did not tiller, making only one stem from each seed, while rye growing as pure culture stooled abundantly, one ordinary stool being found with 23 and another with 39 stalks.

Disk-harrowing alfalfa, R. H. Forbes (*Arizona Sta. Bul. 57, pp. 256–260, fig. 1*).—The principal benefits of disking alfalfa are enumerated as splitting and spreading the crowns, thereby causing new growth, destroying the egg deposits and larvæ of injurious insects, destroying weeds, and breaking up dense soils and especially the silt-blanket deposited by muddy irrigating water. It is estimated that disking will increase the average crop in Arizona 10 to 20 per cent.

Observations were made on the reduction of the yield resulting from the silt-blankets, which are often 3 to 4 in. thick. A field near Yuma showed a depreciation of 6.3 per cent in the second cutting, one near Phoenix of 9.7 per cent in the third cutting, and one near Solomonville of 27.6 per cent in the second cutting.

Alfalfa, R. S. Shaw (*Michigan Sta. Circ. 1, pp. 4*).—Notes are given relating to suitability of soils for alfalfa, and its cultivation, fertilizing, seeding, and harvesting.

Dodder in alfalfa seed, F. C. Stewart and G. T. French (*New York State Sta. Circ. 8, pp. 4, pls. 2*).—The injuries resulting from dodder in alfalfa seed are pointed out and directions for removing the dodder seed are given. For this purpose a wooden frame 12 in. square by 3 in. deep with the bottom covered with 20 by 20 mesh steel-wire cloth of No. 34 Washburn and Moen gage wire is recommended. When brass or copper wire cloth is used the wire should be No. 32 English gage. By shaking ¼ to ½ lb. of seed vigorously for ½ minute in this sieve the dodder seed may be separated from the alfalfa seed. If but little dodder is present one sifting will do, but if there is much dodder, especially of the large-seeded kind, two siftings should be made.

Culture tests with varieties of barley in 1905 and 1906, A. Boonstra (*Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], 1908, No. 3, pp. 75–118*).—In 1905 cooperative experiments were conducted with Landgerste, Goldthorpe, Primus, Princess, and Hannchen brewing barley, and in 1906 with only Goldthorpe, Princess, and Hannchen.

The results led to the conclusion that in the Netherlands the climate is a great obstacle to the production of good brewing barleys. The yield is seldom very high and most of the varieties are very flinty. Even after soaking the

grain the degree of flintiness is higher than is consistent with the quality of a good barley for brewing purposes. Much damage is also sustained by lodging, and in this particular the variety Princess was the least satisfactory, although in every other way the best variety tested.

Irrigation of barley, H. T. Nowell (*Wyoming Sta. Bul. 77, pp. 3–20, pls. 3, dgm. 1*).—The value of barley as a feed and for brewing purposes is discussed, and the results of experiments on the amount and method of applying water in irrigating barley are reported.

About 12 acres were divided into 6 plats and planted by a press drill with approximately 90 lbs. per acre of Chevalier brewing barley on May 9 and 10. The quantities of water used and the results are shown in the following table:

Quantity of water applied and results secured in growing brewing barley.

Plat No.	Area.	Number of irrigations.	Total depth.	Average depth per irrigation.	Length of irrigating season.	Yield per acre.
	Acres.		*In.*	*In.*	*Days.*	*Bu.*
1	1.267	0			0	1.97
2	1.297	1	8.41	8.41	1	6.31
3	2.339	2	10.83	5.42	24	19.13
4	1.947	3	19.56	6.52	43	35.32
5	2.363	4	26.29	6.57	46	20.96
6	2.289	6	34.67	5.78	43	30.58

Each application of water appeared very slightly to delay the growth of the crop, and this is thought as probably due to the lowering of the soil temperature through the use of cold water or to the displacement of the air from the soil as it becomes saturated.

The following table shows an approximate estimate of the complete cost of growing Chevalier brewing barley:

Estimate of cost and profit of growing brewing barley.

Plat No.	Water per acre.	Total cost per acre.	Cost of harvesting, thrashing, and hauling.	Total cost per acre.	Return per acre.	Profit (+) or loss (−) per acre.
1			$0.22	$6.07	$1.89	−$4.18
2	$0.22	$1.10	.71	7.66	6.06	− 1.60
3	.26	1.30	2.14	9.29	18.36	+ 9.07
4	.49	2.45	3.97	12.27	33.90	+21.63
5	.68	3.40	2.35	11.60	20.14	+ 8.54
6	.89	4.45	3.43	13.73	29.36	+15.63

In a series of experiments to compare the methods of irrigating barley one plat was laid out for irrigation by the check method, a second for irrigation by the furrow method, and a third was prepared for flood irrigation. Furrow irrigation used less water and maintained the surface soil in a much looser condition than either of the other methods. Under the check irrigation method and the flood method the surface soil had a tendency to bake to a hard crust. The initial cost of furrow irrigation was higher but the labor of irrigation less than with the other methods. It is recommended that the furrows be not less than 16 in. apart. At 8 in. apart the first cost is considered too large for the practical farmer.

Contributions to the biochemistry of barley, J. S. Ford and J. M. Guthrie (*Jour. Inst. Brew., 14 (1908), No. 1, pp. 60–87*).—The paper here presented

treats of the amylase of resting barley. The results secured by different investigators are briefly noted and the data obtained in experiments conducted by the authors are shown in tables and discussed. Brief details of isolated observations are given in a summary.

Ordinary aqueous extraction does not indicate the actual amount of amylase present nor does it show the relative amounts contained in the separated structural parts of the grain. When the entire seed is ground up and extracted the amylolytic activity observed is not considered a true measure of the ferment present but simply as indicating the resulting balance of limited solution and destruction. Although extraction by digestion with papain preparations in excess prevents to a great extent the destruction and facilitates the liberation of active ferment, it is regarded questionable as being a correct index of the latent or active amylase present.

A barley digested first with passive and then with active papain does not yield the same activity as when directly treated with active papain. A sample so treated gave an activity equalling 11.4 gm. of maltose per gram of barley as compared with 13.3 gm. by direct treatment. Treating barley with active papain after autodigestion lowered the activity as compared with direct proteolysis, the results of such a test being 10.4 and 14.6 gm. maltose per gram of barley. Even a short aqueous extraction destroyed some amylase and the action of water at higher temperatures caused rapid destruction.

The authors found a distinct increase in the amount of soluble nitrogen in autodigestions as compared with the amount found in an aqueous extract. In aqueous extracts of 2 barleys 28 and 30 mg. of salts, and in autodigestions of the same samples 42 and 46 mg. per 100 cc. were found.

Crude protein obtained from barley and treated with active papain showed no amylolytic activity. A test of the residue from an alcoholic extraction showed that considerable destruction had taken place as no active enzym was found present.

Edestin was extracted by a 10 per cent solution of sodium chlorid and precipitated by ammonium sulphate. The precipitate was redissolved in 10 per cent sodium chlorid and dialysed for some days against distilled water, and the separated edestin filtered off, dissolved in salt, and again dialysed to remove traces of soluble amylase. This edestin dissolved in a minimum of salt solution was partly treated with active papain and in part directly but in neither case was amylolytic activity observed. Crude translocation amylase precipitated from the first filtrate with 70 per cent alcohol was soluble in water and very active. After being dry for a few days it was no longer soluble in water but dissolved readily in the presence of salts and gave an active solution. The barley residue from the sodium chlorid solution exhibited a strong amylohydrolytic power when treated with papain.

The more violent chemical methods of differentiation of proteins are considered inapplicable in this connection. In general the results obtained indicate that the higher amylolytic activity as a result of papain treatment is due to liberation and solution of the colloidal ferment and to its protection from destruction.

Cotton culture, A. Veauvy and J. Coste (*Bul. Agr. Algérie et Tunisie, 14 (1908), No. 5, pp. 116–118*).—Abassi, Yanovitch, and Mit-Affifi Egyptian long-staple cottons were grown in Algeria. An average yield of 1,617 kg. per hectare (1,440 lbs. per acre) of seed cotton was secured. By taking this yield and the price offered for the cotton as a basis, it was found that the net returns amounted to 670.80 francs per hectare ($54.30 per acre).

Some conditions influencing cotton production, C. L. Newman (*South Carolina Sta. Bul. 140, pp. 3–31*).—This bulletin points out the principal conditions

to which the low average yield per acre of lint cotton is due, and reports the results of experiments with cotton by the station.

From about 40,000 stalks several hundred were selected as foundation stock, the seed from them being planted in 1907. The soil selected for the test, typical of the uplands of Anderson, Oconee, and Pickens counties of the State, was well prepared and fertilized and thorough level cultivation was given to the crop. Among 46 varieties the following ranked highest in yield of lint per acre: Toole 736.40 lbs., Cook Improved 622.27 lbs., Corley 620.81 lbs., Gold Standard 618.04 lbs., Big Boll White Seeded Prolific 598.82 lbs., Pride of Georgia 590.24 lbs., Columbia 589.22 lbs., Excelsior Prolific 539.92 lbs., Shank High 538.11 lbs., and Sunflower 533.28 lbs.

In percentage of lint Toole stood first with 40 per cent, followed by an unknown variety with 39 per cent, Evans and Reimproved Toole with 38 per cent, Brooks Improved, Pullnot, Cook Improved, Corley, and Gold Standard with 37.5 per cent, and Excelsior Prolific and Moss Improved with 36.2 per cent. The acre value of seed and lint of the varieties ranking highest as based on prices early in 1908 was as follows: Toole $110.45, Columbia $101.62, Sunflower $101.48, Cook Improved $98.08, Black Seeded Blue Ribbon $95.61, Pride of Georgia $94.45, Gold Standard $93.95, Accidental Hybrid $90.82, Corley $87.94, Big Boll White Seeded Prolific $86.57.

Estimates of the value of the cotton produced were given by three experts, and their statements are reported. Attention is called to the fact that grading as based on these reports would have increased the net returns by $18.66 per acre in one case and by $20 per bale in another.

It is pointed out that the highest acre value credited to one variety was $92.05 and the lowest $36.99, the varieties having been given the same treatment throughout. The highest and lowest yields secured from varieties of like characters in 5 years' trials showed variations from 448 lbs. to 171 lbs. of lint per acre, from 412 lbs. to 140 lbs., from 474 lbs. to 135 lbs., from 637 lbs. to 381 lbs., and from 736 lbs. to 469 lbs. It was also observed that a wide variation in the relative yields of the same varieties in different years often occurs. In a one-year test King and Peerless each gave 566 lbs. of lint per acre, whereas another year King gave 297 lbs. and Peerless 408 lbs. One year Bates Improved gave 164 lbs. more than Jackson Limbless, and in another 76 lbs. less. As these irregularities are not uncommon it is pointed out that one year's test can not prove or disprove the value of a variety. Ways and means for individual cotton growers to secure the best variety are discussed.

A study made by W. J. Roach of the susceptibility of varieties to anthracnose showed a variation from 24.4 per cent in the unknown variety to 2.7 per cent in Harden Prolific.

The nitrogen contents of Egyptian cotton, A. Schindler (*Jour. Soc. Dyers and Colourists, 24 (1908), No. 4, pp. 106, 107*).—Experiments with brown Egyptian cotton on the determination of nitrogen in raw cotton and in cotton after boiling in caustic soda of different strengths are briefly noted. The raw cotton contained from 0.250 to 0.256 per cent of nitrogen. By boiling in the caustic soda the nitrogen content was considerably reduced.

In a discussion of the article, E. Knecht reports further determinations showing that Grey American cotton yarn contained 0.138 per cent of nitrogen, Texas raw, cleaned cotton 0.150 per cent, and Red Peruvian 0.280 per cent.

The cultivation of potatoes, A. M. Soule and P. O. Vanatter (*Virginia Sta. Bul. 174, pp. 125–139, figs. 8*).—Variety, fertilizer, and selection tests are reported.

In 1906 the leading varieties and their yields per acre were as follows: Burbank 262.08 bu., Early Rose 258.53 bu., and Beauty of Hebron 243.36 bu.

Of these yields 230, 227.91, and 224.16 bu., respectively, were marketable. Of the very early varieties Bliss Triumph and Crown Jewel gave the best yields. In 1907, when the season was unfavorable, the best yielding varieties were Burbank with 132.5 bu., Early Rose with 112.91 bu., and Crown Jewel with 108.33 bu. of marketable potatoes. The average for both years showed Burbank in the lead with 181.25 bu., followed by Early Rose with 170.41 bu., Beauty of Hebron with 156.24 bu., Crown Jewel with 151.24 bu., and Gold Coin with 146.04 bu. Of the very early varieties Bliss Triumph led in yield with an average for the 2 years of 97.91 bu.

The influence of the time of digging was studied in 1906, when the crop was dug 80, 93, and 100 days after planting. The results showed that a delay of 21 days in the time of digging made an increase of 136.25 bu. per acre in the case of Beauty of Hebron, 126.25 bu. in the case of Burbank, and 118.75 bu. in the case of Early Rose.

On land where cowpeas had been plowed under and barnyard manure applied at the rate of 15 tons per acre an increase of 51.67 bu. was obtained. Barnyard manure and sulphate of potash at the rate of 100 lbs. gave an increase of 63.34 bu., while sulphate of potash alone at the rate of 100 lbs. gave an increase of 20 bu., high-grade acid phosphate at the rate of 300 lbs. an increase of 25.42 bu., and the sulphate of potash and acid phosphate combined an increase of 29.66 bu. per acre. A complete fertilizer gave an increase of 10.84 bu. in one instance and of 39.59 bu. in another. The best results were secured on the plats on which cowpeas were plowed under. On the other plats the crop followed spring oats and it was observed that these plats receiving barnyard manure produced a larger yield than where commercial fertilizers alone were used. This is considered evidence that the humus added through manure enabled the soil to retain moisture to better advantage.

Work in the improvement of the potato crop was undertaken in 1906 and 1907, and the results obtained showed clearly that some strains are from two to three times as prolific as others, and they indicate that both yield and quality of potatoes may be materially improved by selection. On the basis of the yielding power of the progeny of No. 29 a planting of 25 bu. per acre of this variety would equal 275.75 bu. per acre. Many potatoes produced only about 5 lbs. of tubers from each pound of seed planted and on this basis would yield only 125 bu. per acre. In connection with these tests it was observed that where the seed potato was cut into 2 pieces the number of marketable potatoes varied from 3 to 7 for each set planted, where cut into 3 pieces from 1.33 to 5.66, and where it was cut into 4 pieces from 2.50 to 7.25 potatoes.

The skin of different potato varieties and the influence of soil conditions, moisture, and fertilization upon the same, W. Kreitz (*Arb. K. Biol. Anst. Land u. Forstw., 6 (1908), No. 1, pp. 2–27, pls. 2, figs. 10*).—The results of different investigations on the potato and its diseases are reviewed, and the examination of different varieties grown on the experimental field of the Imperial Biological Institute of Dahlem is noted. In 1905, 23 different varieties were grown and measurements of the thickness of the skin and the cork cells were made and the form and size of the parenchyma cells and cell layers were studied.

It was found that the thickness of the potato skin is most readily determined by Tison's method. The skin thickness of individual varieties was not constant, but was apparently influenced by the location of the plant and climatic conditions. Under otherwise similar conditions a dry season produced a thinner skin than a season with adequate rainfall. Changing the locality of the plant also caused the skin thickness to vary, but when the varieties were brought back to the same kind of soil the differences in this particular soon disappeared.

It is stated that when a variety is grown for a considerable time on the same soil special strains with regard to skin thickness are developed, and when these are then grown on a different kind of soil this character is more or less lasting. Kainit, common salt, and nitrate of soda exerted an unfavorable influence, and superphosphate a favorable influence on the development of the skin.

The stone cells occurring in many varieties are not regarded as indicating a high degree of maturity, but as a variety characteristic pointing to the origin of the strain from a variety containing these cells or as being the result of hybridization. In order that thick-skinned potato varieties may be secured it is recommended that the seed be obtained from those localities in which varieties with thick skin have been grown for a considerable length of time. It was observed that on soils which produced thin-skinned potatoes the use of phosphoric acid as a fertilizer increased the resistance of the skin. In addition to the absolute thickness of the skin in determining its resistant quality, the arrangement of the cork cell layers is also of importance.

The influence of cross- and self-fertilization on the sugar content in the sugar beet, K. Andrlík, V. Bartoš, and J. Urban (*Ztschr. Zuckerindus. Böhmen, 32 (1908), No. 7, pp. 373–387*).—In a series of experiments here reported the influence of cross-fertilization on the sugar content of the progeny was observed in numerous cases. The progeny of self-fertilized plants showed in part a tendency to degenerate, many individuals having yellow and red spots. The progeny of self-fertilized rich beets was lower in weight than the progeny from self-fertilized beets low in sugar. The beets resulting from cross-fertilization stood in average weight about halfway between the beets derived from rich and poor mother beets.

The essential mineral constituents of the sugar cane, T. Murakami (*Internat. Sugar Jour., 10 (1908), No. 112, pp. 172–175*).—A chemical study of sugar cane is reported.

The relative results indicate that the nitrogen content decreases and the total ash increases as the cane grows. Phosphoric acid and potash appeared to decrease per 100 parts of ash but were always constant per 100 parts of cane. The ratio of soda to potash was found to be constant. The only ingredients that increased were oxid of iron, alumina, sulphuric acid, and perhaps silica. A certain ratio was observed between lime and magnesia, but this varied slightly as the cane matured. The ratio between phosphoric acid and potash is determined as 1 : 26, which does not change during the growth of the plant.

The results further indicate that a maximum crop and a maximum sugar content are obtained on a rich soil in which the essential ingredients are distributed in an available form. It is recommended that lime be applied with nitrogen, phosphoric acid, and potash in order to maintain the proper ratio between lime and magnesia.

Cultivation of the sugar cane in Peru (*Internat. Sugar Jour., 10 (1908), No. 112, pp. 177–185*).—This article is a translation of a treatise on sugar cane culture in Peru by F. T. Sedgwick.

Virginia tobacco experiments, E. H. Mathewson, B. G. Anderson, and R. P. Cocke (*Virginia Sta. Bul. 175, pp. 145–171, figs. 9*).—These experiments are carried on cooperatively by the Bureau of Plant Industry of this Department and the Virginia Experiment Station. An earlier report on this work has already been noted (E. S. R., 19, p. 335).

The bulletin outlines a crop rotation for the dark tobacco belt of the State and reports the results obtained in an unfinished rotation. The succession of crops suggested is based upon tobacco as the leading crop, being followed by wheat, which in turn gives place to grass. After the grass crop corn is grown,

which is followed by cowpeas. This may be made a 5 or 6 year rotation by leaving the land in grass either 1 or 2 years.

As described in the previous abstract the tobacco grown received different quantities of fertilizers. In 1906, wheat after a highly fertilized crop of tobacco yielded 21 bu. to the acre, while after the tobacco fertilized with 400 lbs. of 3–8–3 fertilizer it yielded 8 bu. In 1907 the yield of wheat after a heavy fertilized crop of tobacco was 29 bu. per acre, and after a poorly fertilized crop only 12 bu. No fertilizer was applied to the wheat except that the fields were limed for the benefit of the succeeding grass crop.

In 1906 the wheat stubble was disked during the summer and a heavy seeding of grass sown September 3. One part of the field received a mixture of timothy, redtop, and clover, and another clover alone. April 5 a top-dressing of 300 lbs. of nitrate of soda per acre was applied just before a rain. Where the nitrate was used on the clover the yield of field-cured hay was 2.8 tons, and where it was not used 2.09 tons per acre. The increase in yield failed to pay for the nitrate applied per acre by $1.61. The mixed grasses receiving nitrate gave a yield of 5.06 tons per acre of first-class hay, while where the nitrate was not used the yield was only 3.3 tons. The hay was sold for $13 per ton, so that the gain from the use of the nitrate was $22.88 per acre, the cost of the nitrate being $8.

The successful points with grass in the dark tobacco district, as indicated by this work, are a fine mellow seed bed 2 or 3 in. deep, a heavy seeding of mixed grasses, and a liberal top-dressing with nitrate of soda in the spring. The corn and the cowpeas have not yet been grown, but from 40 to 60 bu. per acre of corn and 1 ton or more of cowpea hay are expected.

Notes are given on the home growing of tobacco seed, and the improvement of tobacco by seed selection and breeding.

Results of seed investigations for 1907. L. H. Pammel and Charlotte M. King (*Iowa Sta. Bul. 99, pp. 71–91, figs. 22*).—The results of analyses of seed samples sent in by farmers and others, and also of some purchased in the open market in 1907, are reported.

Of 134 samples of red clover examined the average purity was 96.6 per cent and the average vitality, grown in sand, 86 per cent. Medium red clover showed an average germination of 86.6 per cent in 41 samples examined, and 28 samples showed a purity of 99 per cent or more. In 14 samples of mammoth clover tested the average germination was 88.5 per cent. Ten samples had a purity of 99 per cent or more and 14 of 97 per cent or more. Five samples of white clover were all above 98 per cent in purity, with an average germination of 76.6 per cent. Alsike clover in 40 samples received contained impurities of 1.14 per cent on the average. The average vitality of all samples was 81.6 per cent. One sample had a vitality of 95 per cent, 5 of about 75 per cent, while some ran as low as 22 per cent.

The average vitality of 44 samples of alfalfa seed was 69.2 per cent and the average purity 91.1 per cent. The different samples ranged from 90 to 38 per cent in vitality. The impurities found in 44 samples of timothy were not very pronounced except in a few cases. The purity in 34 samples was 99 per cent or more and the average of all samples was 98.9 per cent. The purity of 21 out of 24 samples of flax ranged from 96 to 100 per cent. The average vitality in sand was only 66 per cent, but in the incubator the average rose to 98 per cent. The percentage of purity in 28 samples of millet was 95 per cent or more. In 3 samples it ranged from 85 to about 95 per cent, and in 2 samples it was under 85 per cent.

The purity of 7 samples of blue grass was 99.7 per cent, with an average germination of only 17 per cent. The percentage of germination in the best

sample was 70 per cent, while in the other 6 samples it was below 45 per cent. One sample of redtop examined had a purity of 99.8 per cent, and 3 samples of *Bromus inermis* had an average purity of 99.7 per cent and an average germination of 73 per cent.

A list of weeds reported as introduced with clover seed is presented and brief directions for removing noxious weed seeds from agricultural seeds are given. The results of purity and germination tests with seeds of garden and field crops by the station and other experiment and seed control stations are given in tables and briefly discussed.

Pure seed investigations, C. V. GREGORY (*Iowa Sta. Bul. 99, popular ed., pp. 3–14, figs. 22*).—This is a popular edition of the bulletin noted above.

Seed work, G. E. STONE (*Massachusetts Sta. Rpt. 1907, pp. 122, 123*).—During the year 359 samples of seeds were tested and separated, as compared with 231 in 1906. The average germination of onion seed for 1907 was 86 per cent, as compared with 79 per cent the year before. White pine seed had a germination of 59 per cent. Only 4 per cent was discarded from the best tobacco seed, as compared with 33 per cent for the poorest sample. From the best onion seed 1.6 per cent was discarded and from the poorest sample 43.3 per cent.

The development and organization of plant breeding in Denmark, Sweden, and Probstei, HOLTMEIER (*Landw. Jahrb., 37 (1908), No. 2, pp. 311–380*).—This article discusses the history, progress, and present status of plant breeding, especially that of field crops, in Denmark, Sweden, and the locality known as Probstei and situated in the eastern portion of Holstein in Germany, in the vicinity of Kiel. The area of Probstei is limited to only a few square miles, but seed growing has been carried on for so long a time and such good seed is produced that the locality has become very well known. The methods employed by prominent plant breeders are described and the particular varieties originated are mentioned. A bibliography of 24 references is given.

HORTICULTURE.

Experiments in drug plant cultivation, S. C. HOOD (*Vermont Sta. Rpt. 1907, pp. 371–386*).—An account with the results to date is given of experiments, conducted jointly by the Vermont Experiment Station and this Department during the seasons of 1903 to 1906, in the cultivation of several drug plants, including yellow dock, burdock, poppies, Seneca snakeroot, summer savory, digitalis, belladonna, sage, and several common herbs.

The results show that root drugs such as burdock and yellow dock can be profitably grown in Vermont providing the land is low priced. It was demonstrated that Seneca snakeroot can be successfully grown under cultivation. Belladonna fails to mature in the short season, and sage, digitalis, and lovage will not survive the winter even though they make a good growth the first season. The culture of such herbs as catnip, thyme, lobelia, pennyroyal, and of seed such as caraway, fennel, and coriander, is not likely to prove profitable. Although the cultivation of poppies for the capsules and seed is not considered promising for Vermont, it is believed that they may be successfully cultivated in the future for the direct production of morphin. Further work is to be done along this line. From fertilizer experiments and variety tests made, it appears that the production of strong healthy plants is more important for the morphin content than the use of large amounts of any particular chemical.

The Montreal market muskmelon industry, W. STUART (*Vermont Sta. Rpt. 1907, pp. 358–366*).—An account, based on the personal investigations of the author, is given of the muskmelon industry on the island of Montreal. The phases considered include cultural methods, size and types of melons, seed

saving, and style of package. With a view of ascertaining the possibilities of growing Montreal muskmelons in Vermont, experimental plantings were made at the station and by a cooperative grower in 1907. The work was unsuccessful from a commercial standpoint, but considerable information was secured which it is believed will lead to success in future work.

Tomato notes, W. M. MUNSON (*West Virginia Sta. Bul. 117, pp. 251–262, pls. 2*).—Popular notes treating of the history of the tomato, the development of modern forms, breeding new varieties, field culture, tomato growing in winter, and financial returns. The notes are based principally on observations made and data secured by the author in previous experiment station work.

Moisture and decay loss of Hubbard squash in storage, W. STUART (*Vermont Sta. Rpt. 1907, pp. 367–369*).—With a view to determining the amount of loss in storing Hubbard squash till midwinter, a ton, weighed as taken from the field, was stored on October 3 in a dry and medium warm room where the temperature was between 50° and 60° F. Moisture determinations were made at different intervals during the winter.

At the time of the final observations on February 3, 4 months from the harvest, the sound squash weighed 1,488 lbs., the total moisture loss was 20.8 per cent, and the loss from decay 4.8 per cent. When the squash were put in storage, they were wholesaling at a cent per pound. At the conclusion of the experiment the 1,488 lbs. of squash were sold for $53, an average of over $0.03½ per pound, the net gain by storage being $33 per ton. Although prices received that season were exceptional, it is concluded that squash properly grown and handled may be held in storage till midwinter or later with a reasonable assurance that the moisture and decay loss will be amply covered by the increased price received. Brief suggestions are given indicating conditions insuring minimum loss in storage.

Fruit list for 1908 (*Proc. N. J. Hort. Soc., 33 (1908), pp. 183–188*).—This list, revised by the executive committee of the New Jersey State Horticultural Society, shows the orchard and small fruits that are most satisfactory to growers for market and home use in the northern, central, and southern sections of the State.

Orchard survey of Wasco County, C. I. LEWIS and R. W. ALLEN (*Oregon Sta. Bul. 99, pp. 3–56, figs. 13*).—The station conducted orchard surveys in Wasco and Jackson counties in 1907, and the data secured in Wasco County, which comprises the fruit-growing districts known as Hood River, Mosier, and The Dalles, are given in the present bulletin.

The survey included every place having at least 4 acres in fruits. The phases reported on include climate and soil, elevation, general aspect, kinds and varieties of fruits, number and age of trees, planting distances, irrigation, drainage, cultivation, fertilizers, pruning, harvesting, packing, yield, selling price and cost of production, past and present condition of orchards, fungus diseases, and insect pests.

Apples, strawberries, pears, peaches, and cherries are grown in the Hood River district, although the first two fruits are the more generally grown. At The Dalles, the important fruits are peaches, cherries, and prunes, while grapes, apples, and pears are grown to some extent. At Mosier, apples and prunes are the leading kinds of fruit. The total orchard acreage of Wasco County was 7,598.7 acres, in addition to which there were 802.9 acres of strawberries and 100 acres of grapes.

Feeding the orchard, H. J. WATERS (*Missouri Sta. Circ. Inform. 22, pp. 32, pls. 3*).—A popular discussion based upon work conducted at the different experiment stations, with deductions and suggestions relative to fertilizing orchards in Missouri.

Tillage v. sod-mulch, U. P. Hedrick (*West. N. Y. Hort. Soc. Proc., 53 (1908), pp. 20–32*).—The New York State Station is conducting two experiments to determine whether an apple orchard will thrive and fruit better under tillage or in sod with the grass used as a mulch. This paper contains an account of one of these experiments, together with the results secured during the seasons from 1904 to 1907, inclusive. Introductory discussions are given of the objects of tillage and the philosophy of the sod-mulch.

In this experiment, which is to be conducted for a period of 10 years, the tilled plat was plowed in the spring and cultivated from 4 to 6 times, cultivation ending about August 1, when a cover crop of barley, oats, or clover was sown. On the sod-mulch plats the grass was cut once or twice during the season and allowed to lie where cut and decay into a mulch.

The results for the 4 years show an average yield per acre on the sod plats of 66.6 bbls., and of 91.3 bbls. on the tillage plats. The average expense per acre for the 4-year period was $15.78 for the sod and $22.18 for the tillage. Although no measurements were taken of the leaf area, inspection of the orchard showed that there were more and larger leaves on the tilled plat and the foliage was a darker and richer green. The mulched trees dropped their foliage about a week or 10 days earlier and the new wood produced was less than half that produced on the tilled trees and was less satisfactory in color. The size of the fruit averaged considerably larger on the tilled plats, while the number of fruits under both forms of culture appeared to be about the same. The mulched plats produced much more highly colored fruits, although the difference was not sufficient to bring any higher price in the general market. The fruit from mulched trees ripened from 1 to 2 weeks earlier than that from the tilled trees, and the difference in color was much less when the season was sufficiently mild to allow the fruit on the tilled plats to remain on the trees several days after that on mulched plats was picked.

The relative keeping qualities of the fruit from both plats was tested under the direction of G. H. Powell of this Department, who reported that the difference in the two methods of culture in this respect appeared to be more important with early maturing varieties such as Wealthy, Alexander, and Fameuse than with the slow ripening later varieties. With the early varieties the fruit from the sod land usually kept better than fruit picked from the tilled land at the same time, although there was practically no difference with well-colored fruit.

No difference was noted with reference to the eating quality of the fruit from the two plats. The causes of the differences noted with the two systems are further discussed.

Notes on the propagation of apples, F. A. Waugh (*Massachusetts Sta. Rpt. 1907, pp. 61–64, figs. 3*).—The station has conducted experiments on the propagation of fruit trees for several years with the two principal objects of determining the effects of stock on scion and the practical merits of different methods of propagation with special reference to the production of dwarf fruit trees. Three stocks were used, the Standard, Doucin and Paradise. Data are given showing the differences in growth of the Baldwin grafted on these three stocks and the variations are further indicated by diagrams. The average height and ratio of height to diameter was greatest where the Standard stock was used and least with the Paradise stock. These differences held with other varieties, including the Wealthy, McIntosh, Greening, etc., and agree with the common belief regarding the influences of the different stocks tested.

A study relative to the progressive increase of sugar and the corresponding decrease in acidity in the fruits of pears from the time of their formation to their maturity, G. Rivière and G. Bailhache (*Jour. Soc. Nat. Hort. France, 4. ser., 9 (1908), May, pp. 284–289*).—In a previous investigation

(E. S. R., 20, p. 241) the authors found that in the Chasselas Doré grape the sugar content increases and the acid content decreases progressively from the time of setting to the maturity of the berries. A similar investigation was conducted with 6 varieties of pears, the results of which are here tabulated and discussed. A portion of the fruit was bagged during the growing period and the remainder grew unprotected.

The sugar content was found to increase without interruption both in the bagged and unbagged fruit. The total sugar content of the pears grown in bags is somewhat higher than those grown without protection, the excess amounting in the case of the Passe-Crassane variety to 19 gm. per 1,000 parts of pulp. The investigation appears to demonstrate the value of growing table pears in paper bags to increase their sugar content. Bagging the fruit does not appear either to hasten or retard maturity. The acidity was found to decrease both with the bagged and unbagged fruit as the fruit approached maturity, although the bagged fruit showed a higher acid content at maturity than the fruit grown without protection. In all cases the density of the pears was found to decrease progressively throughout the period of development, approaching the density of water at maturity. The density appears to diminish in proportion to the increase in volume, and does not appear to differ materially in the bagged and unbagged fruit.

Manurial experiments with limes, R. H. A. A. Nicholls and F. Watts (*Proc. Agr. Soc. Trinidad and Tobago, 8 (1908), No. 2, pp. 73–76*).—This is an abstract of the authors' report on experimental plats in Dominica started in 1903 to determine the fertilizer requirements of lime trees. There were 5 plats included in the experiment, the control plat receiving no fertilizer. The results thus far indicate that the use of nitrogen and potash together increases the yield of fruit. The use of nitrogen alone improved the foliage but did not increase the yield. No conclusions have been deduced thus far relative to the use of phosphoric acid.

It is recommended in a general way that where limes are to be manured both nitrogen and potash, and probably phosphoric acid, should be employed and that care should be taken to maintain the supply of humus in the soil either by the use of pen manures or of green mulches.

Cacao manurial plots [in Dominica] F. Watts (*Proc. Agr. Soc. Trinidad and Tobago, 8 (1908), No. 2, pp. 53–71*).—A further report is given of the fertilizer experiments which have been conducted at the Dominica Botanic Station since 1900 (E. S. R., 18, p. 549), together with the results of fertilizer experiments conducted in several country districts.

As indicated by the yields for the past 5 years at the station, all of the fertilized plats have produced greater yields than the plat receiving no fertilizer. With phosphate and potash combined the annual yield of dry cured cacao was increased by 219 lbs. per acre, with dried blood by 187 lbs., and with a complete fertilizer consisting of phosphate, potash, and dried blood by 374 lbs. The mulched plat showed the greatest gain, with an increased yield of 402 lbs., and was also in the lead relative to the general health and growth of the trees and the soil texture. This plat is well covered by trees planted at the rate of 108 per acre, whereas the plat receiving no fertilizer required 178 trees per acre. The complete fertilizer plat was next in general health and condition as well as in yield. The results of the experiments in the country districts show the value of the phosphatic and nitrogenous fertilizers, but there appears to be little need of potash.

As a general result of these experiments planters are recommended to manure their cacao trees, giving preference to organic manures such as pen manure and liberal mulchings. Where these can not be obtained the use of fertilizers

containing nitrogen and phosphoric acid are advised, and it is further recommended that in many cases mulching be supplemented with moderate applications of nitrogen and phosphoric acid.

Small fruits in 1906, J. P. Pillsbury (*Pennsylvania Sta. Rpt. 1907, pp. 162–170*).—Tabular data with brief notes are given relative to the flowering and fruiting of a large number of varieties of strawberries, raspberries, blackberries, dewberries, currants, and gooseberries being tested at the station. Unpromising novelties and inferior varieties have been discarded from the test. The susceptibility of the different varieties to disease is also indicated.

Cranberry substations, W. P. Brooks (*Massachusetts Sta. Rpt. 1907, pp. 17, 18*).—As a result of the season's work the knowledge relative to cranberry insects has been greatly extended and the tentative conclusions reached as a result of the first year's work (E. S. R., 18, p. 954) have been in many cases confirmed.

The fertilizer experiments being conducted at Falmouth show thus far that nitrate of soda greatly stimulates the growth of vines and increases the size of the berries. Acid phosphate appears to favor early maturity of the fruit, accompanied apparently by decrease in size. Potash exercised the most favorable influence on the yield of fruit and appears favorable to the development of a bright color. The plats to which muriate of potash and acid phosphate were applied produced exceptionally solid, heavy, and fine appearing fruit. Lime appears to have been unfavorable to fruitfulness.

Through the vineyards of the Spanish Peninsula, M. Poirier (*Ann. Inst. Nat. Agron., 2. ser., 7 (1908), No. 1, pp. 135–183, figs. 6*).—A general account and discussion of viticultural conditions in the grape growing provinces of Spain.

Seasonal influence in carnation crossing relative to seed production, W. Stuart (*Vermont Sta. Rpt. 1907, pp. 355–358*).—Tabular results are given and discussed relative to limited studies made during the past 4 seasons. The results, which are in accord with those secured by Rudd (E. S. R., 16, p. 978), lead to the conclusion that crosses made early in the indoor season, as in November and December, give a considerably higher percentage of successes, a much larger number of seeds per capsule, and a higher percentage of germination than crosses made late in the season as in February. The author is of the opinion that the better results secured by early crosses are due principally to the greater vigor of the plants. The weather conditions also appear to be more favorable early in the season.

FORESTRY.

Georgia's forest resources, R. M. Harper (*South. Woodlands, 1 (1907), Nos. 3, pp. 4–23; 4, pp. 1–19; 5, pp. 3–19; 6, pp. 15–32, pls. 4, maps 13*).—A systematic catalogue of Georgia trees, showing the distribution and uses of each species as far as known. There are enumerated 134 species known to occur in Georgia and the probable occurrence of about 20 more is suggested. Introductory statements deal with the factors determining the distribution of forest types in Georgia and the natural subdivisions of the State, with the character of the forests of each. The text is accompanied with a series of maps showing the range of the more important species. The work is based upon previous botanical investigations in the State, together with extensive field investigations made by the author.

Report on an examination of certain swamp lands belonging to the State, W. W. Ashe (*N. C. Geol. Survey, Bien. Rpt. 1905–6, pp. 40–50*).—This report embraces the results of an examination of the most promising portions of

swamp timber lands in North Carolina. These lands are a part of 500,000 acres belonging to the State and held for the benefit of the public schools. Three areas lying in different portions of the coastal plain were selected for examination, comprising Angola Bay in Pender and Duplin counties, open ground of Carteret county, and Newport Pocosin in Craven county. These areas are described with reference to soil formation, topography, timber growth, etc., and recommendations are made for their future treatment.

Suggestions for arbor day planting, J. J. THORNBER (*Arizona Sta. Bul. 57, pp. 260–266, figs. 2*).—The successful trees which are commonly planted in southern Arizona, including extremely drought-resistant species, are enumerated, and attention is called to several desirable evergreen species for park and home planting, including the true cedars, the Monterey, Italian, and Arizona cypresses, the Chinese arborvitae, and two resistant eucalypts, *Eucalyptus polyanthema* and *E. rudis*.

The trees of Great Britain and Ireland, H. J. ELWES and A. HENRY (*Edinburgh, 1908, vol. 3, pp. VI+451–711, pls. 88*).—This is volume 3 of an extensive treatise which is being issued on the trees either native to or cultivated in Great Britain and Ireland (E. S. R., 19, p. 544). The arrangement of the present volume is similar to that of the previous volumes.

In part 1 the varieties and species of 16 genera are considered relative to their history, botany, distribution, cultural requirements, uses of the timber, etc. Descriptions are also given of specimen trees growing in Great Britain. Part 2 consists of illustrations and botanical drawings of the trees discussed in part 1.

Report on the forests of Kenia, D. E. HUTCHINS (*Colon. Rpts., Misc. [Gt. Brit.], No. 41, pp. 40*).—This report embraces the results of a study of the technical and climatic value of the Kenia forests in the East Africa Protectorate, and treats of the kind, quantity, quality, and accessibility of the timber, together with data relative to climate and labor, conditions of lease proposed for working the forests, and the climatic value of the forests as a source of water supply. It is estimated that there is approximately 1,000,000 acres of timber forests, as well as 600,000 acres of bamboo forests in this region. The timber has been valued at £23,000,000.

Edibles trees and shrubs, R. W. PEACOCK (*Agr. Gaz. N. S. Wales, 19 (1908), No. 2, pp. 101–114, figs. 25*).—An illustrative and descriptive account is given of a large number of edible trees and shrubs growing in the central portion of Australia. Many of these plants are extremely drought resistant and a valuable source of food for stock during droughty periods.

List of jungle products used by the poor during the famine, 1896–7, T. E. D. INNES (*Indian Forester, 34 (1908), No. 2, App., pp. 20*).—This list includes a large number of shrubs, trees, creepers, grasses, weeds, water plants, and fungi growing in the jungles of Balrampur which were utilized by the poor as a source of food during the famine of 1896 and 1897. Botanical names are given in most cases, together with notes showing how the different products were prepared for food and what portion of the plant was utilized.

The growth of pines raised from native and northern seed in the Eberswalde forest, DENGLER (*Ztschr. Forst u. Jagdw., 40 (1908), Nos. 3, pp. 137–152; 4, pp. 206–219, pl. 1*).—Comparative studies were made of 21-year old pine trees growing at Eberswalde and raised from native seed grown near Eberswalde as well as from seed grown in Finland, Russia, and Norway. Tabulated data are given showing the measurements of height, diameter, and stem growth, and specific density of the various trees studied, as well as on the complete canopy and branch development, foliage, and needle structure.

The data show the trees grown from northern seed to be far behind the native trees both in height and diameter growth, and that this difference is maintained from the early life of the trees. The development of the trees from northern-grown seed was also inferior to the native trees as regards the canopy and branch growth and the stem form. The wood of the foreign trees, however, showed a greater specific weight, the total foliage was less, and the needles were shorter but broader and thicker than with the native trees.

Breaking tests with twenty-one of the most important species of Surinam woods, together with notes relative to their botanical classification, characteristics, use, etc., E. K. Plasschaert and J. F. Ligtenberg (*Inspectie Landb. West-Indië, Bul. 11, pp. 29*).—Several tests were conducted with each species of wood, and the results are presented in tabular form showing both the moduli of rupture and elasticity. Comparative data are also given of earlier tests of several kinds of British-Guiana woods by the French marine engineer Dumonteil, as well as bending, shearing, and compression tests made with various specimens of woods at the State testing station at Brussels under the direction of E. Roussel.

Transverse tests of jarrah made at Sydney Technical College, J. Nangle (*Jour. and Proc. Roy. Soc. N. S. Wales, 40 (1906), pp. CI–CV, pls. 3*).—Tabulated results are given of tests made for moduli of rupture and elasticity on 20 pieces of West Australian jarrah. The test pieces were 2 in. square and in all but two cases 24 in. long. In most cases a 22 in. span was used. The tables show the breaking-load in pounds, failure under tension and compression, the duration of the test, rate of load applied in pounds per minute, and the moduli of rupture and elasticity, as well as the deflections under varying loads. Notes are also given on the author's exhibit of microscopic sections of Australian timber.

The relation of forests to stream control, G. Pinchot (*Ann. Amer. Acad. Polit. and Soc. Sci., 31 (1908), No. 1, pp. 219–227*).—The author discusses the increasing tendency of our streams to become less navigable both through soil erosion and lack of water, and outlines the engineering methods which are being tried to remedy this trouble.

It is believed that only by conserving and restoring the forest can the inland waterways become permanently improved. Experience and scientific investigation have shown that the two functions exercised by the forest in relation to stream flow are its tendency to reduce the difference between high and low water and its value as a surface protection against soil erosion. These two functions are discussed. Examples are given of typical streams flowing through forested and timbered watersheds, as well as of work being conducted by European countries in the reforestation of watersheds.

The sources of fumes in the Kingdom of Saxony and their influence upon forestry, F. Schröter (*Tharand. Forstl. Jahrb., 57 (1907), No. 2, pp. 211–430, maps 3*).—Investigations were conducted by the chemical division of the Tharandt Forestry Experiment Station in 1906, in continuation of previous work relative to the presence of sulphurous acid in the forest air and the injurious effects of fumes and gases on the trees. The present account is based upon this investigation and consists of a summary of the present scientific and practical knowledge dealing with the causes and effects of damage from fumes, together with a detailed account of the sources and extent of fume and gas damage in the various forest districts of Saxony. Remedial measures both from the standpoint of the forester and the industrialist, together with the various legal length.

The text is accompanied with a map showing the location of the industries liberating fumes and gases in Saxony, and indicating the extent of fume damage in various districts. A more detailed map is given of the forest district of Schwarzenberg.

Popular bulletins of the Swedish Forestry Association (*Skogsvårdsför. Folskr., Nos. 9, pp. 1–32, figs. 11; 10, pp. 1–32, figs. 11; 11, pp. 1–32, figs. 22; 12, pp. 1–32, figs. 14*).—These bulletins deal respectively with the following subjects: Forest Pastures, by C. Björkbom; Charcoal Burning, by E. Andersson; Draining in Forest Regions, by W. Ekman, and The Care and Utilization of Forests, by F. Aminoff.

A summary of the results of forest administration in Saxony for the year 1906 (*Tharand. Forstl. Jahrb., 57 (1907), No. 2, pp. 129–134*).—The summarized data given show the alteration in forest areas, the present condition of the domain funds, yields in timber and other forest products, and revenues and expenditures of various kinds, together with the net returns for the various forest districts to the secretary of agriculture for the year 1906.

Report on Norwegian forestry, 1906, M. Saxlund (*Indberetning om det Norske Skogvæsen. Christiania, 1908, pp. XVII+158*).—Report of the state forester to the secretary of agriculture for the year 1906.

Annual of streams and forests for 1908 (*Ann. Eaux et Forêts, 47 (1908), pp. 369*).—This annual contains the customary statistics complete to January, 1908, relative to the personnel of the forest administration of France and Algeria, together with a list of promotions from the national school of streams and forests and secondary school of professional instruction, and numerous statistical data relative to forest operations.

Review of forest administration in British India for the year 1905–6, S. Eardley-Wilmot (*Rev. Forest Admin. Brit. India, 1905–6, pp. 58, map 1*).—A summarized review of forest operations in the various provinces of British India for the year 1905–6, relative to alterations in areas, forest settlements, demarcations and surveys, the development of working plans, forest protection, sylvicultural operations, experimental work, and exploitation, together with a financial statement for the year.

Tabulated statements are given of all the important data, together with a map showing progress of forest surveys on September 30, 1906. During the year 713 sq. miles were added to the reserves, making a total of 233,651 sq. miles. Surveys were made of 3,608 sq. miles. The total number of square miles under working plans was 39,922. The cut of timber and fuel wood was 246,334,840 cu. ft., together with 210,173,780 bamboos and minor produce to the value of 5,512,819 rupees (about $1,764,100). There was a falling off in output of over 5,000,000 cu. ft. of timber and fuel, and of more than 5,000,000 bamboos from the previous year.

A table is given showing the gross revenue, expenditure, surplus, and proportion of expenditure to gross revenue of the previous 33 financial years. The gross revenue and surplus for 1905–6 are the highest recorded. The total value for the whole year was 30,170,666 rupees (about $9,654,500) and the surplus directly chargeable to revenue 17,919,178 rupees (about $5,734,100).

Annual report on the forest administration in Ajmer-Merwara for 1906–7, M. Prasad (*Ann. Rpt. Forest Admin. Ajmer-Merwara, 1906–7, pp. 40*).—The usual report relative to alterations in forest areas, forest settlements, working plans, forest protection, sylvicultural operations and exploitation, together with a financial statement for the year. The important features of the work are summarized in tabular form.

Progress report on forest administration in Coorg for 1906–7, C. McCarthy, (*Rpt. Forest Admin. Coorg, 1906–7, pp. 14*).—Data similar to the above are presented relative to operations in Coorg.

Annual administration report of the forest department of the Madras presidency, 1906-7 (*Admin. Rpt. Forest Dept. Madras, 1907, pp. 50+CXXVI +5*).—Data similar to the above are presented relative to forest operations in the northern, central, and southern circles of the Madras presidency.

Progress report on forest administration in the Punjab for 1906–7, C. P. Fisher (*Rpt. Forest Admin. Punjab, 1906–7, pp. 66*).—Data similar to the above are presented relative to the administration of the State forests in the Punjab.

Annual progress report of forest administration in the western and eastern circles of the United Provinces for the forest year 1906-7, W. H. Lovegrove and H. Jackson (*Ann. Rpt. Forest Admin. West. and East. Circles [India], 1906–7, pp. 120*).—Data similar to the above are presented relative to the administration of State forests in the eastern and western circles of the United Provinces.

Progress report of the Imperial Forest Research Institute for 1906–7 (*Rpt. Imp. Forest Research Inst., 1906–7, pp. 13*).—An outline is given of the progress made during the year 1906–7 in the various branches of forestry, including administration, investigation, and research, working plans, forest botany, zoology, and economics, together with a summary of revenues and expenditures for the year.

Forest service of Indo-China, G. Capus (*Bul Écon. Indo-Chine, n. ser., 10 (1907), No. 69, pp. 949–984*).—An account of the history, development, organization, direction, work, and purposes of the forest service of Indo-China.

Note on experimental rubber cultivation in the Bombay presidency, G. A. Gammie (*Proc. Agr. Conf. Ahmedabad, 1907, pp. 25, 26*).—Brief notes on cultural and tapping experiments being made by the Bombay presidency with *Cryptostegia grandiflora, Ficus elastica, Manihot glaziorii, Castilloa elastica,* and *Hevea brasiliensis.*

From the results thus far secured the author considers ceara rubber (*M. glaziorii*) the only rubber plant worth growing under general conditions in the Bombay presidency. It is believed that Cryptostegia may yield a little revenue as an adjunct to village resources.

Cultivation of rubber plants on the Malay Peninsula, E. Carle (*Bul. Econ. Indo-Chine, n. ser., 10 (1907), No. 67, pp. 761–782, figs. 4*).—An extract of a report on the rubber industry of the Malay Peninsula, in which some general information is given relative to the cultivation and production of rubber, tapioca, and lemon oil, together with a more detailed account of the production of Para rubber, including a study of the soils, methods of soil preparation, planting, planting distances, the condition of the trees, tapping operations and implements, the age at which the trees are tapped, yields, subsequent treatment of plantation enemies of Hevea and their control, labor, and value of plantations.

On the extraction of rubber from dried rubber plants, P. Alexander and K. Bing (*Tropenpflanzer, 12 (1908), No. 2, pp. 57–68*).—An account, together with tabulated results, is given of some extraction tests made with a view of determining the feasibility of producing rubber from dried rubber plant material. The material used consisted principally of the leaves, branches, bark, and wood of *Kickxia elastica* trees of various ages. The experiments showed that there was only an inconsiderable quantity of rubber in the material tested. The largest amount secured was with the bark of the 7 and 8 year old trees, from which 2.7 per cent of rubber was obtained.

Although the results were not satisfactory, it is suggested that greater rubber returns may be procured from similar tests with other rubber-producing species.

DISEASES OF PLANTS.

Report of the botanists, G. E. Stone and G. H. Chapman (*Massachusetts Sta. Rpt. 1907, pp. 120–150*).—An outline is given of the investigations carried on during the season, particular attention being paid to the study of mosaic diseases of tobacco and other crops, the testing of banding substances for trees, investigations of tomato rot, spraying experiments with potatoes, and a study of the meteorological conditions affecting plant diseases and the development of crops. A brief report of seed investigations is noted on page 335 of this issue.

Among some of the diseases investigated, attention is called to an apparently new fungus trouble affecting asparagus. This is due to a species of Fusarium, and when attacked the young slender shoots are rotted off near the surface of the ground. A disease of peonies has been under observation for some time, but while microscopic examination of the material has shown fungi, bacteria, and nematodes present, they are apparently secondary or accompanying factors of decay. Further investigations are being conducted on this disease.

In experiments with fungicides for the control of diseases of potatoes, Bordeaux mixture and Paris green were tested in comparison with Bordeaux mixture and Disparene, Bordeaux mixture and sodium benzoate, soda Bordeaux mixture and Paris green, and copper phosphate and Disparene. Three applications of the fungicides were made to all the plats. The results showed that soda Bordeaux and Paris green proved the best in reducing the amount of disease, with Bordeaux mixture and sodium benzoate a close second in effectiveness. Bordeaux mixture and Disparene seemed to produce fairly good results and held the blight and insects in check, but did not prove as efficient as either of the other two fungicides. Bordeaux mixture and Paris green did not seem to hold disease in check as well as the others, but was productive of good results, while copper phosphate and Disparene seemed to have no appreciable effect on checking disease, so far as the results of this year's work were concerned.

The influence of various potash salts on potato scab was tested, potatoes being fertilized with 7 different potash compounds and grown in plats previously planted to potatoes and in which the scab organism had become more and more troublesome. Of the forms of potash used, kainit, sulphate, muriate, nitrate, and silicate of potash gave little increase in the development of scab, while the plats receiving carbonate of potash were badly affected by the disease. As the seed tubers in every case were treated with corrosive sublimate before planting, the results obtained showed that this treatment is of little value when the soil conditions are especially favorable for the scab fungus.

Work on the mosaic disease of tomatoes and tobacco was begun at the station in 1907, but it was too late in the season to observe the seed beds and the transplanting of field-grown tobacco, and the work was confined largely to verifying the results of previous investigators. During the coming year the work will be renewed and the disease studied under field conditions. In connection with field work, experiments will be carried on in the laboratory to determine the effects which different enzyms have on the production of the disease.

Tomatoes are especially subject to the mosaic disease, particularly when grown under glass, and healthy and diseased leaves of tomato plants grown

under such conditions were examined for the presence of catalase. Both the α and β forms of catalase were present in the tomato leaves, although there appeared to be a decided deficiency of insoluble catalase in the leaves of the tomato when affected with the mosaic disease.

A study was made to determine the effect of light, heat, and moisture as factors in the susceptibility and immunity to disease.

The occurrence of plant diseases in 1907, N. J. Giddings (*Vermont Sta. Rpt. 1907, pp. 328–334*).—Notes are given on a number of plant diseases which were under observation during 1907. These include several diseases of potatoes, some orchard diseases, and diseases of garden crops.

Among the diseases of garden crops not hitherto reported was a muskmelon rot which developed toward the close of the season and caused considerable loss. The rot usually appeared on the lower side of the fruit, and when attacked the interior flesh was completely decayed around the point of infection and possessed a disagreeable odor. An examination showed that the disease was due to bacteria. The organisms were isolated and transfers and inoculations made, the inoculations resulting almost always in complete decay of the fruit within from 3 to 5 days. In addition to muskmelons, the organism, which is a wound parasite, seems to be able to infest cucumbers, but the action is much slower, only about one-third of those inoculated giving evidence of the disease.

Report of the vegetable pathologist, D. McAlpine (*Rpt. Dept. Agr. [Victoria], 1905–1907, pp. 26–37, figs. 12*).—This is a brief account of the various investigations carried on by the author during the period covered by the report, and includes notes on flax rust, alfalfa rust, flag smut of wheat, potato scab, brown spot of potatoes, etc.

In the investigations with flax rust a decided difference in susceptibility to disease was noted, Russian and Japanese flax apparently being quite free from the fungus, while plants grown from Calcutta seed were almost entirely destroyed.

The flag smut of wheat (probably due to *Urocystis occulta*) is said to be a serious disease, and in certain districts of Victoria considerably reduces the yield in seasons favorable for its development. Pot experiments were conducted to determine the manner in which this smut is carried over from year to year, and it was shown that the smut developed only when the seed was dusted with spores, indicating that it is through the young seedlings that the attack is made and that there is no infection through the above-ground parts of the plant.

An account is given of successful experiments in the prevention of potato scab through the treatment of the seed with corrosive sublimate. Notes are also given on a disease of potatoes called brown ring, which is particularly liable to occur in the variety Beauty of Hebron, and on brown spot. The cause of neither of these diseases is definitely known.

Rusts of cereals and other plants, E. W. Olive (*South Dakota Sta. Bul. 109, pp. 3–20, figs. 5*).—The life histories of a number of the more common species of rusts are described and attention is called to the losses due to the presence of these fungi, particularly upon cereals. Suggestions based on life history studies are given concerning means by which the losses may be greatly reduced.

Cotton wilt in the Central Provinces, G. Evans (*Agr. Jour. India, 3 (1908), No. 1, pp. 78–80*).—The presence of cotton wilt, due to *Neocosmospora vasinfecta*, on the experimental farm at Nagpur is noted. A local variety, Bani, of rather fine staple was first attacked, the signs of the disease appearing toward the end of August, and the attacked plants often being completely destroyed within 24 hours.

An examination of the diseased material showed that it was due to the above-named fungus. A number of other Indian varieties were attacked to a greater

or less extent, but American upland varieties growing around the edge of the infected plats were not attacked, nor was any instance found in which the American cotton was suffering from the disease.

Upon an extended inquiry it was found that this disease had been noticed occasionally for the past 3 or 4 years, but only became serious during 1907. All replies to inquiries indicated that only the Indian varieties were attacked.

The presence in Germany of Pseudoperonospora cubensis tweriensis, a parasite of cucurbits, R. EWERT (*Internat. Phytopath. Dienst (Beigabe Ztschr. Pflanzenkrank.), 1 (1908), No. 1, pp. 8–11*).—The author reports the presence in several localities in Germany of a form of the cucurbit mildew, which was described a few years since by Rostowzew as occurring in Russia. This form of the mildew differs from the species in the larger size of the conidia.

Leaf spot disease of eggplants, P. VOGLINO (*Malpighia, 21 (1907), No. 7–8, pp. 353–363, pl. 1*).—The author claims that the form of leaf spot, to which the name fumagine is sometimes given and which has been variously reported as caused by *Phoma solani* and *Phyllosticta hortorum*, should be referred to *Ascochyta hortorum*. To this species should also be referred *Ascochyta lycopersici*, *A. solanicola*, *A. atropæ*, *A. alkekengi*, *A. physalicola*, and possibly *A. pinzolensis*.

The spores of *A. hortorum* germinate readily in moisture on the leaves of the eggplant, tomato, other species of Solanum, such as *S. nigrum* and *S. dulcamara*, and on *Physalis alkekengi*, *Datura metal*, and *Atropa belladonna*.

In their morphological characters there is a close agreement between *A. hortorum* and *A. pisi*, but from inoculation experiments they seem to be biologically distinct.

Potato spraying experiments, L. R. JONES and N. J. GIDDINGS (*Vermont Sta. Rpt. 1907, pp. 334–342*).—Experimental trials with fungicides upon potatoes have been carried on at the station for the past 17 years. Those in 1907 were designed particularly to determine the relative gain from spraying potatoes with Bordeaux mixture and Paris green, comparing the results from 2, 3, and 4 applications, and the relative gains from the use of commercial compounds, such as Boxal and Bug Death, as compared with Bordeaux mixture and with Paris green.

The experiments with 2, 3, and 4 applications of Bordeaux mixture and Paris green gave results that were in the main in harmony with those obtained in previous years' investigations. The 2 applications of Bordeaux mixture made in August proved less efficient in checking the flea beetle and early blight than where other applications were made, particularly the spraying made early in July. The increase in marketable tubers for the sprayed over the unsprayed lots varied from 52 to 172 per cent.

In experiments in spraying late potatoes with Bordeaux mixture the results were similar, although the season was apparently not one in which large crops were obtained. A tabulation is given showing the average gains due to spraying obtained for the last 17 years as 113 bu., or 68 per cent increase per acre.

The experiments to test the value of Boxal and Bug Death, showed that neither was any improvement over a freshly prepared Bordeaux mixture to which Paris green was added. Both the proprietary compounds had insecticidal and fungicidal value, but they were more costly and less efficient than the Bordeaux mixture.

A new tomato disease, H. T. GÜSSOW (*Jour. Bd. Agr. [London], 15 (1908), No. 2, pp. 111–115, fig. 1*).—An account is given of a disease of tomatoes caused by *Septoria lycopersici*, which until 1907 had been unreported in England. During that year the entire crop was destroyed in one of the principal tomato districts of England.

The characteristics of the disease are pointed out, and the author recommends early spraying with a 3 per cent solution of Bordeaux mixture, the cutting out and burning of all diseased plants, and the use of lime in the soil and scattered about the stems.

Experiments on the control of gooseberry mildew, A. Vasilev (*Zhur. Bolyczni Rast., 1 (1907), No. 3–4, pp. 103–105, German Summary, pp. XIX, XX*).—A brief account is given of the successful use of potassium sulphate for the control of the gooseberry mildew (*Sphærotheca mors-uvæ*).

Fruit tree diseases and fungicides, F. M. Rolfs (*Missouri Fruit Sta. Bul. 16, pp. 3–39*).—An account is given of various fungus diseases which are common to cultivated fruits in the Ozark region of Missouri together with directions for most efficiently and economically combating them. The diseases are grouped according to the host plants, and a bibliography is given of some of the more important station and Departmental publications relating to them. While most of the remedies suggested consist of spraying with fungicides, attention is called to the fact that spraying is merely preventive, and that in order to be effective it must be thoroughly done.

Notes on a cherry disease in Western Germany, R. Ewert (*Proskau. Obstbau Ztg., 13 (1908), No. 1, pp. 2–8, fig. 1*).—An investigation has been made of a disease of cherry trees which has proved quite destructive in the Rhine provinces. Other investigators have attributed the loss to attacks of *Cytospora rubescens* or *Valsa leucostoma* (E. S. R., 15, p. 270).

The author claims that the main cause of the trouble is due to the planting of cherry trees in unsuitable soils and locations, resulting in an unfavorable growth, and that the fungus attacks the trees only after they have been weakened by the environmental conditions. Just what conditions of soil, moisture, and exposure are best adapted to the growth of cherry trees have not been determined, and investigations are desired along those lines.

Preliminary report on dust spraying experiments in Georgia, W. W. Chase (*Ga. Bd. Ent. Bul. 25, pp. 129–135*).—A preliminary account is given of tests of 4 dust fungicides for the control of brown rot of peaches. Directions are given for the making and application of these compounds, and, so far as known, the formulas for preparation are given.

The different dust sprays were applied to 3 varieties of peaches, but, so far as testing the fungicidal value was concerned, the experiments proved a failure, as there was no rot developed on any of the trees. The season was an exceptionally dry one and the conditions were unfavorable for the development of rot, even on the untreated trees. As shown by the defoliation of the trees and the effect on the fruit, marked variations in susceptibility to the treatment were indicated between different varieties. Some difference was also noted in the effect of the various compounds themselves.

The cocoanut stem disease, T. Petch (*Trop. Agr. and Mag. Ceylon Agr. Soc., 30 (1908), No. 3, pp. 285–289*).—The author reviews the conditions surrounding the stem disease of cocoanut palms, which he claims is of fungus origin (E. S. R., 19, p. 1051).

One of the most prominent symptoms of this disease is the bleeding from decaying tissues. The results are given of inoculation experiments with spores from cultures, as well as material from diseased trees, showing that the disease is rapidly transmitted. Where cultures of the fungus were used, there was no bleeding from the wounds at the end of 3 months, but when the infected spots were cut open it was found that the disease had spread over an area of about 12 sq. in., and the bleeding began in another wound a little later.

The disease does not seem to attack old trees, the stems of which have become hard, and in combating it on young trees the author recommends

spraying with Bordeaux mixture. The cutting out of diseased tissues and the scorching of the wounds, after which they are covered with hot coal tar, has proved successful in a number of instances.

The biology of Polystictus versicolor, JESSIE S. BAYLISS (*Jour. Econ. Biol., 3 (1908), No. 1, pp. 1–24, pls. 2*).—A study of bilology of *P. versicolor* is reported and the fungus is said to be a pure saprophyte, whose natural habitat is moist dead wood. The author has found it growing on *Quercus robur*, *Fraxinus excelsior*, *Pyrus aucuparia*, *Salix alba*, *Betula alba*, *Pyrus malus*, *Ligustrum vulgare*, and *Crataegus oxyacantha*, and has been able to infect without difficulty small blocks of *Fraxinus excelsior*, *Ulmus campestris*, *Prunus avium*, *Alnus glutinosa*, *Acer pseudoplatanus*, *Æsculus hippocastanum*, and *Betula alba*. She has also successfully cultivated the fungus from spore to spore. It seems probable from the investigations reported that it will grow on almost any kind of wood except that of conifers.

The spores and their germination are described, after which an account is given of the method by which the destruction of wood takes place. The chemical changes seem to indicate that it attacks and destroys the wood gum, which constitutes a large percentage of the wood of most trees except conifers.

The sporophore of the fungus and the relations of the fruiting body to light, gravity, etc., are described, and attention is called to the fact that under natural conditions the pileus lasts but a comparatively short time, being specially subject to the ravages of a small beetle. The spores retain their vitality for a considerable period even when dried or when exposed to high or low temperatures.

In connection with the investigations the author made the usual tests for enzyms and demonstrated the presence of laccase, rennetase, cytase, invertase, diastase, coagulase, ereptase, and a fibrin-digesting protease. Only negative results were obtained on testing for emulsion, lipase, maltase, and hadromase.

The chestnut canker, W. A. MURRILL (*Torreya, 8 (1908), No. 5, pp. 111, 112*).—A brief account is given of the author's investigations on the occurrence and spread of the chestnut canker, caused by *Diaporthe parasitica* (E. S. R., 19, p. 250), and it is stated that the disease is spreading rapidly. The author claims that not only the native species of chestnut, but also the European and Japanese, which are frequently planted in this country, are subject to attack.

Experiments in pruning trees have shown that this is futile as a means for preventing the further spread of the disease. At the present time the author thinks that planting any species of chestnut in an affected area would be attended with great risk. The owners of chestnut timber are advised to make use of their timber at once, thus clearing the woodlands of the sources of infection and giving young trees of other varieties opportunity to develop.

The bleeding and yellowing of poplars, J. W. BLANKINSHIP (*Ztschr. Pflanzenkrank., 18 (1908), No. 1, pp. 26–28*).—Further notes are given on 2 diseases of poplars termed by the author bleeding and yellowing, of which preliminary accounts have already been given (E. S. R., 17, p. 451). These diseases are said to attack various species of poplar, particularly *Populus angustifolia*, *P. balsamifera*, *P. trichocarpa*, and *P. deltoides*.

The principal characteristic of the bleeding is the exudation of sap from the wounds in the affected tissues. This disease the author believes is due to bacteria, since the sap is full of bacteria, and the inner wood cells of diseased tissues are also found filled with them. Cultures have been made of these bacteria, but further investigations are needed to determine whether the bacteria are the cause of the disease, and also the rôle of ants and flies in its distribution.

Associated with the bleeding disease is another, which is called the yellows or yellowing. This disease has been attributed to an increase in the alkali content of ground water following continued irrigation. The bleeding disease may attack a few twigs of a tree, while the yellowing affects the entire tree and causes its destruction much more quickly than the bleeding.

The author believes that the diseases are due to different causes and that the bleeding may follow a weakened condition caused by the yellowing disease.

Cutting out diseased twigs and coating the fresh wounds with tar or paint is recommended for the prevention of the bleeding disease. If the yellowing disease is due to the presence of alkali, drainage would doubtless correct this trouble.

The damping off of coniferous seedlings, L. R. Jones (*Vermont Sta. Rpt. 1907, pp. 342–347*).—The damping off of coniferous seedlings is said to be a serious hindrance to success in raising seedlings of pine or other conifers in the nursery, and was the cause of considerable loss experienced in 1906 and 1907. Examinations made of plants from local seed beds showed the presence of a Fusarium-like fungus similar to the one described in Europe as parasitic on pine and spruce seedlings. The author thinks, from the circumstances surrounding the location of the seed beds, etc., that the fungus not only is a widespread one, but also is probably a native rather than an introduced species.

In order to determine what could be done to check the loss, investigations were carried on on methods of handling seed beds, sterilization of the soil, and the use of fungicides during certain periods of growth. The investigations showed that the surface of the seed beds should be kept as dry as practicable. It early became apparent that the fungus content of the soil at the time of planting is an important factor, and experiments were carried on in sterilizing the soil by the use of a 1 per cent and a one-half per cent solution of formalin, the seeds being sown 5 days after the application of the fungicide. As a result of the spraying with the one-half per cent formalin solution the stand was reduced by 25 per cent as compared with the check lot, and where the one per cent solution of formalin was used the stand was reduced by nearly the 1 per cent solution of formalin was used the stand was reduced by nearly the treated and untreated lots, practically 90 per cent of the seedlings where no formalin was used having been destroyed, while only 7½ per cent were damped off where the 1 per cent solution was used and 9 per cent where the one-half per cent solution was used.

The possibility of the control of this disease by the application of fungicides during the critical period is being investigated.

The sprinkling of the surface of the seed bed with sand immediately following germination was tested, and was found to be quite efficient in lowering the amount of loss. In this case clean sand, of rather coarse texture, should be used and applied as hot as it can be handled, sprinkling it over the surface of the bed to a depth of about $\frac{1}{16}$ in.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Deer farming in the United States, D. E. Lantz (*U. S. Dept. Agr., Farmers' Bul. 330, pp. 5–20, figs. 2*).—This bulletin discusses briefly the economic possibilities of raising deer and elk in the United States.

"The wapiti and the Virginia deer can be raised successfully and cheaply under many different conditions of food and climate. The production of venison and the rearing of both species for stocking parks may be made profitable industries in the United States.

"Instead of hampering breeders by restrictions, as at present, State laws should be so modified as to encourage the raising of deer, elk, and other animals as a source of profit to the individual and to the State.

"Safeguards against the destruction and sale of wild deer in place of domesticated deer are not difficult to enforce. For this purpose a system of licensing private parks, and of tagging deer or carcasses sold or shipped, so that they may be easily identified, is recommended.

"It is believed that with favorable legislation much otherwise waste land in the United States may be utilized for the production of venison so as to yield profitable returns, and also that this excellent and nutritious meat, instead of being denied to 99 per cent of the population of the country, may become as common and as cheap in our markets as mutton."

Silver fox farming. W. H. Osgood (*U. S. Dept. Agr., Farmers' Bul. 328, pp. 5–22, figs. 10*).—The Biological Survey of this Department has made a study of the silver or silver-black fox raising and here furnishes information as to the possibilities of their propagation and the best methods of conducting the business. The history of silver fox breeding and the area suited for fox farming, with the character of location and space required, and equipment necessary, life history, and habits are considered.

"The number of persons now engaged in the business is relatively small, and the work is still experimental, yet many of the initial difficulties already have been overcome. Numerous minor failures seem explainable in large measure, and are offset by several conspicuous successes. It is therefore probable that under proper management fox raising will be developed into a profitable industry, and it is perhaps not too much to expect that a domestic breed of foxes will be produced. Only time can show how far such expectations will be realized, but present indications must be regarded as very encouraging."

A study of the food habits of birds. W. Leisewitz (*Verhandl. Ornithol. Gesell. Bayern, 7 (1906), pp. 265–275*).—A detailed account is presented of the nature of the food found in the stomachs of various species of hawks and owls including *Buteo buteo*, *Archibuteo lagopus*, *Astur palumbarius*, *Asio otus*, etc. These birds were found to feed upon hare, rabbits, pheasants, grouse, mice, marmots, moles, small birds, and to a less extent insects and frogs. On the whole it is believed that their feeding habits make these birds of some economic importance to the farmer.

Bird preservation. Spraying. H. A. Surface (*Zool. Bul. Penn. Dept. Agr., 5 (1908), Nos. 10, pp. 299–328, pls. 4, figs. 8; 11, pp. 329–360*).—An account is given of the preparation and erection of nesting boxes and of the economic value and food habits of birds, together with a brief report of a study of the economic relations of birds during the year.

Popular notes are also given on the methods of preparing and applying various insecticides in the control of injurious insects.

Report of the entomologists. C. H. and H. T. Fernald and J. N. Summers (*Massachusetts Sta. Rpt. 1907, pp. 151–155*).—It is stated that the resistance of cucumbers when fumigated with hydrocyanic-acid gas has been determined. The leopard moth (*Zeuzera pyrina*) has appeared around Boston and the brown-tail moth has continued to spread over the State. The elm-leaf beetle is again becoming a serious pest. A "blight" of onions due to thrips caused a large loss in the Connecticut River Valley. A marked decrease was noted in the abundance of root maggots and cutworms, while the spruce gall louse, squash bug, and several kinds of caterpillars were unusually abundant.

Insects of 1907. R. H. Pettit (*Michigan Sta. Bul. 251, pp. 113–123, figs. 12*).—*Anaphothrips striatus* was the source of considerable injury to oats. This

was thought to be due to the unusually late spring which was followed by a hot, dry spell. Rains came in time to check the injury by killing many of the thrips and thus saved the greater part of the crop. A pentatomid (*Perillus claudus*) was frequently found piercing larvæ of the potato beetles and sucking them dry. Several farmers reported their work as so effective that it was not necessary to spray. The larvæ of the tussock moth was a source of considerable injury to apples shortly after the fruit had set.

The clover hay worm (*Pyralis costalis*) occasioned considerable loss as stock will not eat hay when badly webbed. It is recommended that the mows be cleaned out and that old hay be destroyed before the moths appear in early June.

The bean maggot (*Pegomyia fusciceps*) made its first appearance at the college in a field of beans. The rose chafer continued to injure grapes. In experiments made, best results were obtained from the application of arsenate of lead.

A small beetle (*Anomala binotata*) was found in one locality injuring young apple trees by feeding on the foliage. The strawberry crown girdler (*Otiorhynchus ovatus*) was reported for the first time as feeding on peach foliage.

Fifth annual report of the State entomologist of Montana, R. A. Cooley (*Montana Sta. Bul. 71, pp. 136–152, figs. 3*).—In this report the entomologist discusses the principal entomological features of the year. The army cutworm, which has been the source of great injury to crops in the spring, especially to wheat, has been given particular attention. This species has been determined as *Chorizagrotis auxiliaris*, the two forms *C. agrestis* and *C. introfercus* apparently being the same species. The life history and habits have been worked out and are described. The factors in natural control are also discussed. Considerable information was gained through a series of questions sent out to those whose fields were infested.

Other insects noted are the eye-spotted bud-moth (*Tmetocera ocellana*), oyster-shell bark-louse (*Lepidosaphes ulmi*), spotted blister beetle (*Epicauta maculata*), and the codling moth (*Cydia pomonella*).

Report on the injurious insects and other animals observed in the midland counties during 1907, W. E. Collinge (*Birmingham, 1908, pp. 60, figs. 13, map 1*).—The work of the year was largely concerned with a study of the habits, life history, and means of combating various insect pests and the preparation and application of insecticides. On the whole the season of 1907 was characterized by less extensive insect injuries to the crops and animals than that of 1906. It was found that the black-currant gall mite may be effectively controlled by the application of a mixture of lime and sulphur in either the dry or liquid form. A proprietary substance has been used in fumigating soil infested with various nematode worms and larvæ of insects which is said to give better results than carbon bisulphid or any other insecticide thus far tested.

The greater part of the report is taken up with specific accounts of injurious insects, including thrips, gall mites, bud mites, weevils, cockchafers, leopard moth, frit fly, carrot rust fly, woolly aphis, etc. The woolly aphis has been successfully controlled by application of contact insecticides to the soil about infested trees.

Papers on coccidæ or scale insects. New species of Diaspine scale insects, C. L. Marlatt (*U. S. Dept. Agr., Bur. Ent. Bul. 16, tech. ser., pt. 2, pp. 11–32, pls. 9*).—Seventeen species of scale insects mostly of economic importance are described as new to science. Ten species belong to the genus Aspidiotus, viz, *A. comperei*, *A. meyeri*, *A. cocotiphagus*, *A. africanus*, *A. coursetiæ*, *A. transcaspiensis*, *A. epigææ*, *A. mitchelli*, *A. popularum*, and *A. chenopodii*, and the

seven remaining are described as *Aonidia juniperi*, *Chionaspis micropori*, *Leucaspis indica*, *Mytilaspis chilopsidis*, *Parlatoria mangiferæ*, *P. pyri*, and *P. chinensis*.

Four species are apparently native to this continent while of the others five species have been found on living plants recently imported. *Leucaspis indica* and *Parlatoria mangiferæ* attack the mango, the former being established in mango plantings in Florida and Porto Rico, while the latter is found more or less generally infesting nursery stock in the Department greenhouses. A vigorous attempt is being made to exterminate both of these scales. Attention is called to the danger of accidentally introducing some of these foreign species.

Photomicrographs are given of the anal plates of the species described.

The scale insects of Argentina, E. Autran (*An. Soc. Rural Argentina, 42 (1908), No. 55, pp. 111–119, figs. 10*).—The distribution and injurious effects of scale insects of Argentina are briefly discussed. Particular mention is made of *Ceroplastes bergi*, *Margarodes vitium*, *Chionaspis citri*, and *Aulacaspis pentagona*.

Scale insects from Amani, L. Lindinger (*Pflanzer, 3 (1907), No. 23, pp. 353–360*).—Particular attention is given to an account of *Aspidiotus destructor* which causes serious injury to cocoanut palms. The author recommends that attempts be made to encourage the multiplication of the natural enemies of this insect. The use of emulsions was not attended with satisfactory results, since these insecticides caused injury to the plants. Notes are also given on *Chrysomphalus aurantii*, *Ceroplastes ceriferus*, and other species.

Remedies for the San José scale and directions for their use, P. J. Parrott (*New York State Sta. Circ. 9, pp. 12, figs. 2*).—Formulæ for sprays for San José scale and directions for their preparation and application are given. Brief notes are included on the thinning out and pruning of old apple orchards.

The Argentine ant in California, C. W. Woodworth (*California Sta. Circ. 38, pp. 11, figs. 2*).—This destructive ant has been found in the State for the first time. In several widely separated localities colonies appear to have become established. Attention is called to the injury by this insect in Louisiana to food supplies, stored products, field crops, fruit trees, etc. Remedial measures are described and methods of eradication suggested.

The mound-building prairie ant, T. J. Headlee and G. A. Dean (*Kansas Sta. Bul. 154, pp. 165–180, figs. 12*).—This ant (*Pogonomyrmex occidentalis*) is distributed throughout western Kansas and over a large part of the eastern plains of the United States.

"They live in large colonies in gravel-covered mounds, each located in a cleared circular space, and beneath these mounds in chambers and galleries that penetrate the earth as far as 10 ft. These chambers and galleries serve them as storerooms, nurseries, and workshops.

"While it is true they destroy a small percentage of cultivated crops, their substantial claim to the title of injurious insects lies in the annoyance caused the farmer in cultivating and harvesting his crops and in the discomfort resulting from their efforts to protect their habitations when occupying public streets, sidewalks, much-used paths, dooryards, and corrals.

"Large numbers of experiments have shown that thorough fumigation with carbon bisulphid is at once the easiest and most successful method of destroying them known at the present time."

The gipsy moth in Connecticut, W. E. Britton (*Ann. Rpt. Conn. Bd. Agr., 40 (1906), pp. 140–152, figs. 5*).—A historical statement is given of the introduction and distribution of the gipsy moth in this country. Particular attention is devoted in the present article to an account of the work thus far done in

attempting to eradicate the colony of gipsy moths which became established at Stonington, Conn.

Phylonactus abdeus, A. Schulz (*Rev. Secc. Agron. Univ. Montevideo, 1907, No. 2, pp. 132–138, pl. 1*).—This pest is closely related in biology and habits to the cockchafers and May beetles. The larvæ remain for a greater part of the time in the soil at a depth of 5 to 6 cm. In this position they cause considerable damage to wheat, barley, and other cultivated crops.

The insect pests of cardoon, P. Lesne (*Rev. Hort. [Paris], 80 (1908), No. 7, pp. 154–157, pl. 1*).—In the experience of the author the most important insect pests of the cardoon are crane flies, species of Gortyna, *Cassida deflorata*, etc.

The frit fly (*Bd. Agr. and Fisheries [London], Leaflet 202, pp. 4, fig. 1*).—The life history of this insect is briefly outlined. In controlling the pest it is recommended that oats be sown early, that heavy applications of fertilizers be made, and that badly infested fields be plowed under.

Spraying apple orchards for insects and fungi, B. S. Pickett (*Illinois Sta. Circ. 120, pp. 3–36, figs. 18*).—This circular is a compendium of information on spraying for insect and fungus enemies of the apple, as derived from experiments by various entomologists and the experience of practical orchardists as well as that of the author. Formulæ of standard spraying mixtures with directions for their application are given and the apparatus and methods of application are explained and illustrated. A spray calendar for the State is appended.

Demonstration spraying for bitter rot and codling moth, F. W. Faurot (*Missouri Fruit Sta. Bul. 15, pp. 3–17, pls. 10*).—Results of demonstration sprayings conducted in cooperation with the Bureau of Plant Industry of this Department are reported. Attention is called to the enormous percentage of the apple crop damaged by the apple scab and codling moth in the Ozarks.

An account is given of bitter rot, apple scab, and the codling moth. "To successfully control bitter rot, 4 applications of standard Bordeaux mixture made at intervals of 2 to 3 weeks, between the middle of June and the middle of August, are usually necessary."

"The time for treatment for codling moth coincides very well with the time of the treatments for scab and bitter rot and is made in connection with them. The first treatment is made with the second spraying for scab, just as the bloom has fallen; the second with the third for scab; the third should be on the trees by not later than the first of July and should be followed by about two others at intervals of 2 or 3 weeks. The last 3 applications are made with the sprayings for bitter rot."

Owing to the season being unfavorable to the development of scab, the results are omitted. Directions are given for the preparation of sprays, and spray machinery is discussed.

Suggestions for the control of the codling moth, J. J. Thornber (*Arizona Sta. Bul. 57, pp. 275–279*).—An account is given in concise form of the biology of this insect and the nature of its injury to fruit, with directions for combating it.

An olive pest, D. L. Navarro (*Prog. Agr. y Pecuario, 14 (1908), No. 563, pp. 22–24*).—The habits and life history of *Phlœothrips oleæ* are briefly discussed. This insect has recently caused serious damage to olives but may be controlled by spraying with contact insecticides.

Insects and diseases of the orange, M. T. Cook and W. T. Horne (*Estac. Cent. Agron. Cuba Bul. 9, pp. 40, pls. 19, figs. 2*).—This bulletin is in the nature of a preliminary report upon the important insects and diseases affecting the orange. The insect pests noted include *Atta insularis*, *Solenopsis geminata*, *Pachnæus litus*, orange dog, red spiders, rust mite, gall insects, plant lice, and

various species of scale insects. The authors also describe wither tip, scab, gummosis, seed-bed disease, blight, and other less important diseases.

Combating Tortrix ambiguella and Eudemis botrana, J. Dewitz (*Landw. Jahrb., 36 (1907), No. 5–6, pp. 959–996, pls. 2, figs. 14*).—Throughout a large portion of the grape-growing regions of Europe these two pests are serious enemies of grapes. No single remedy which has thus far been recommended is sufficient to control either of the insects. A combination of remedies must, therefore, be adopted according to the circumstances of each vineyard. In some vineyards *T. pilleriana* is also an important grape pest.

The remedies which have been tested by the author include the use of sticky shingles for catching the moths, lantern traps, destruction of the eggs with contact insecticides, the use of arsenical poisons for caterpillars, the destruction of pupæ with contact insecticides and with boiling water, removal of the loose bark from the trunks of grapevines, etc. Insecticide methods applied in winter are not so likely to give satisfactory results as similar work in summer.

Experiments in combating the grape-berry moth, J. Capus and Feytaud (*Rev. Vit., 29 (1908), Nos. 741, pp. 231–234; 742, pp. 257–259; 743, pp. 285–290*).—The author experimented with various solutions of arsenic, nicotine, and barium chlorid in controlling grape-berry moth. On the whole the arsenical preparations and barium chlorid gave better results than nicotine or other contact insecticides. Among the arsenicals preference is given to arsenate of lead, but barium chlorid, used in solutions of 2, 4, or 6 per cent, gave perhaps the most satisfactory results.

Zeuzera pyrina on cork oak in Algeria, P. Lesne (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 9, pp. 493–496*).—*Z. pyrina* is reported as causing great damage to cork oaks in certain parts of Algeria. The galleries produced by this insect in the trunks of the trees are of rather simple form and it appears possible to destroy the larvæ by injecting bisulphid of carbon into the burrows.

The Douglas spruce cone moth, R. A. Cooley (*Montana Sta. Bul. 70, pp. 125–130, pl. 1*).—The author's attention was first called to the work of the cone moth (*Cydia pseudotsugana*) in the spring of 1900, when thousands of the moths were observed flying about a Douglas spruce or red fir (*Pseudotsuga mucronata*). Observations have since been continued and studies of the life history which have been made are here reported.

This insect is so widespread in the portion of the State in which observations were made that it is very unusual to find an uninfected tree. It is estimated that under 5 per cent of the seeds escape injury. No other parts of the trees and only this species appear to be attacked. The eggs are deposited on the young cones during the last week of June. Upon emerging the larvæ enter the cone. Feeding is completed by the time the cone is fully hardened. The adult larva which is about ¾ in. in length resembles that of the codling moth in general appearance and motions. The winter is passed in the pupal stage, the greater number of moths emerging during the month of June.

Pebrine and related Microsporidia, A. Lutz and A. Splendore (*Centbl. Bakt. [etc.], 1. Abt., Orig., 46 (1908), No. 4, pp. 311–315, figs. 13*).—In a continued study of the genus Nosema, the authors found that a number of species of this genus live in various arthropods, worms, and fish. In addition to the species which causes pebrine in silkworms a description is given of a number of new species of this genus.

Fixation and multiplication of pathogenic trypanosomes in the proboscis of the tsetse fly, E. Roubaud (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 8, pp. 423–425*).—A study of the biological relations of trypanosomes in the proboscis of tsetse flies indicated that these parasites are able to fix themselves to the walls of the proboscis by means of their flagella and to multiply to a

considerable extent in this situation. This phenomenon was observed not only in the trypanosome of sleeping sickness but also in the trypanosomes of various animal diseases.

The use of arsenicals, L. Degrully (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 29 (1908), No. 10, pp. 288–293*).—During the past few years many objections have been raised against the use of arsenicals on the ground that injurious effects might be produced in man and animals from eating plants treated with these insecticides. This idea has become so firmly rooted in the minds of some investigators that dealers have been prevailed upon to refuse to sell arsenical poisons. In the author's opinion the danger from arsenicals has been greatly exaggerated.

Attention is called to the satisfactory results obtained in spraying various plants with arsenicals for the destruction of leaf-eating caterpillars.

The choice of arsenicals for insecticide purposes, H. Grosjean (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 29 (1908), No. 11, pp. 325–328*).—The insoluble arsenical salts are considered quite superior to those which are more readily soluble. In the opinion of the author these salts may be applied to nearly all kinds of vegetables and fruits in their early stages of growth without danger to the plants or to human beings who may consume the treated plants.

Fungicides, insecticides, and spray calendar, E. H. Favor (*Missouri Sta. Circ. Inform. 23, pp. 3–19, figs. 5*).—Directions for the preparation and application of fungicides and insecticides are given in this circular.

Spray calendar, A. F. Conradi (*Texas Sta. Circ. 10, folio*).—Formulæ of various insecticides and fungicides have been prepared for ready reference in the form of a calendar, together with general directions for their use.

Fumigation with hydrocyanic-acid gas (*Bd. Agr. and Fisheries [London], Leaflet 188, p. 3*).—In fumigating commercial stock it is recommended that one part of potassium cyanid and 1½ parts of sulphuric acid be taken for each 3¾ parts of water. The quantity of potassium cyanid per 100 cu. ft. of space to be fumigated may be varied somewhat, depending upon the nature and hardiness of the plants.

The queen of honey bees. A case of atavism, R. Demoll (*Biol. Centbl., 28 (1908), No. 8, pp. 271–278, figs. 2*).—A theoretical consideration of the different forms of individuals observed in a swarm of bees has convinced the author that there are only two original forms of individuals, the drone and the queen, while the workers are more highly specialized individuals based upon the original queen type. An examination of the anatomical structures of the queen as compared with those of the worker bee indicates quite clearly that the queen is the older type phylogenetically and that the worker is anatomically constructed on the same plan with a specialized development as the result of the division of labor in the colony.

Apiculture, L. Iches (*An. Soc. Rural Argentina, 42 (1908), No. 55, pp. 20–36, figs. 16*).—A general account is presented of the business aspects of apiculture with particular reference to the relationship of this industry to agriculture in general. A statement is given showing the expenses which would be incurred in establishing an apiary of the average size. A list is presented of the more important honey-producing plants.

Bee keeping in North Carolina, F. Sherman, Jr. (*Bul. N. C. Dept. Agr., 29 (1908), No. 1, pp. 27, figs. 5*).—Reports received from 360 bee keepers in the State, owning more than 10,400 colonies of bees, indicate that nearly all sections of the State are well adapted to bee keeping. Thus far bee keepers have given too little attention to the style of hive and to the breed of bees. It is recommended that black and hybrid bees be replaced by Italians, and the

old plank hives by modern ones. The three most important bee plants in the State are sourwood, tulip tree, and clover.

Bee keeping in Ontario (*Ontario Dept. Agr. Bul. 166, pp. 8*).—This report has been compiled from the answers to questions sent out in a circular to the bee keepers of the province. Of the answers received only 10 per cent reported that the industry was carried on at all extensively. Losses of the past 2 years were noted as having made a material change, few large apiaries being left, while many smaller ones were wiped out entirely. It is concluded that this will tend to keep up prices for the better quality of honey, and keepers are advised to give the work special attention.

"Very little disease was reported. While the percentage of dysentery seems high, in every case the correspondent stated that the attack was slight, generally occurring in only 1 or 2 hives in an apiary. Of the instances where foul brood was reported, in only 2 cases was the attack a severe one. European foul brood has appeared in the vicinity of Trenton in rather a virulent form, and has caused heavy losses in two apiaries."

As a result of work by 6 inspectors appointed in the spring a decrease in foul brood has been noted. A large territory in which little is known of the prevalence of this disease is to be inspected.

A large number of the reports received from apiarists having 100 or more colonies are given.

Bee diseases in Massachusetts, B. N. GATES (*Massachusetts Sta. Bul. 124, pp. 3–12, map 1*).—This is a reprint of Bulletin 75, part 3, of the Bureau of Entomology of this Department, previously noted (E. S. R., 20, p. 258).

A new method of controlling flaccidity of silkworms, P. GASPARINI (*Coltivatore, 54 (1908), No. 11, pp. 327–329*).—The best results thus far obtained in controlling flaccidity in silkworms have followed the use of a mixture of chlorin, formaldehyde, sulphur, corrosive sublimate, and phenol for fumigating infected apparatus.

FOODS—HUMAN NUTRITION.

The amount of extractive material in dark and light meat, M. ADLER (*Berlin. Klin. Wchnschr., 45 (1908), No. 8, pp. 393–396*).—Using analytical methods which he believes are more accurate, the author studied the amount and character of the nitrogen in red and white meat and discusses his results in comparison with those of earlier investigators. (See E. S. R., 13, p. 478.)

The following table summarizes the principal results:

Amount and character of nitrogen in meat and fish.

Kind of food.	Total nitrogen.	Extractive nitrogen.	Nitrogen of organic bases.	Kind of food.	Total nitrogen.	Extractive nitrogen.	Nitrogen of organic bases.
	P. ct.	*P. ct.*	*P. ct.*		*P. ct.*	*P. ct.*	*P. ct.*
Beef, raw	3.52	0.4599	0.129	Chicken (leg), roasted	4.97	0.1100	0.034
Beef, roasted	3.60	.4290	.031	Ham, lean, lightly smoked, boiled	.....	.1500	.....
Beef, boiled	.....	.4200	.....	Ham, well smoked, raw	.....	.5100	.....
Veal, raw	3.44	.3700	.014	Carp, raw	3.24	.3120	.156
Veal, roasted	.....	.0630	.025	Carp, boiled	.....	.0690	.....
Veal, boiled	.....	.0570	.....	Cod, boiled	.....	.3200	.....
Pork, very lean, raw	3.87	.4500	.015				
Pork, very lean, boiled	.....	.0900	.....				

According to the author's results, beef and veal showed differences in the amount of extractive nitrogen present which justified the classification into

red and white meat. In the case of white meats, boiling removes more extractive nitrogen than roasting. The results obtained are discussed with special reference to invalid dietetics.

Commercial cuts of meat on the block (*Breeder's Gaz., 53 (1908), No. 11, pp. 599, 600, figs. 4*).—The system of cutting meat followed in the Chicago market is described and a large number of photographs of market cuts reproduced.

The native oysters of the west coast, R. E. C. Stearns (*Nat. Geogr. Mag., 19 (1908), No. 3, pp. 224–226*).—Statistical and other data regarding the oysters and oyster beds on the Pacific Coast of the United States.

Milling qualities of wheat, R. Stewart and J. E. Greaves (*Utah Sta. Bul. 103, pp. 243–276, figs. 2*).—Using 21 samples of Utah wheats grown under irrigated conditions and 70 samples grown under arid conditions, the milling qualities and character of locally grown wheats were studied, including both the common bread varieties and durum wheats.

The average weight of 100 kernels of the common bread variety tested was 3.0417 gm. and of 100 kernels of durum wheat 3.7258 gm. The wheats were ground in an experimental mill, the bread variety yielding on an average 53.21 per cent flour, 35.11 per cent bran, and 10.91 per cent shorts, and the durum varieties, 50.23 per cent flour, 31.97 per cent bran, and 17.27 per cent shorts.

The durum wheats on an average contained 8.89 per cent water and the bread varieties, 8.46 per cent. The average protein contents were respectively 18.82 per cent and 18.44 per cent, using the factor 6.25, or 17.14 per cent and 16.76 per cent, respectively, if the factor 5.7 is used. The water and protein content of the flour, bran, and shorts of the different kinds of wheat are reported. The proportion of wet gluten, dry gluten, the ratio of wet to dry gluten, the gliadin content, the glutenin content, the proportion of protein in the form of gliadin, the acidity, and the ash content of the different samples of flour were also studied.

According to the authors' summary, the Utah wheats are characterized by a low water content and a protein content much above the average. The percentage of protein in wheat grown on irrigated lands was lower than that of wheat grown on arid farms. The Gold Coin wheat showed the lowest protein content of any variety studied.

"The theory that the heavier weight per 100 kernels the greater the yield of flour obtained does not receive any support from our work. The statement that spring varieties of wheat have a higher percentage of protein is confirmed by our results.

"The protein content of the common bread varieties is nearly equal to that of the durum varieties, the difference being only 0.5 per cent. The durum wheats are heavier, kernel for kernel, than the bread varieties.

"There are noticeable variations in the yield, milling, and chemical characteristics of the same varieties of wheat grown on the various arid farms of the State. The moist and dry gluten content of Utah wheats is very high. The bran and shorts produced from the common bread varieties of wheat are fully as nutritious as the bran and shorts produced from the hard varieties of wheat.

"If the gluten content determines the value of durum wheats for the making of macaroni, the common bread varieties grown in Utah should be just as valuable for this purpose.

"The gliadin content of durum wheats is slightly higher than that of the soft varieties.

"No single variety now possesses, combined, the desired characteristics of yield, protein content, flour yield, weight per bushel, and the most desirable milling qualities. However, sufficient evidence is presented to indicate those varie-

ties which it will be most profitable to use for selection in order to obtain the desired results."

The baking quality and the bleaching of flour, J. F. HOFFMANN (*Wchnschr. Brau., 25 (1908), No. 7, pp. 108–110, fig. 1*).—According to the author's conclusions, the physiological condition of the proteids, which influences in large measure the germinating power and bread-making quality of grain, is dependent upon the weather conditions under which the grain ripens. The baking quality can be improved either by drying the grain or by the addition of malt flour. Bleaching with chemical reagents, the author considers, does not permanently improve baking quality.

Bread used by peasants, E. GRÜNER (*Agr. Mod., 14 (1908), No. 6, pp. 71, 72*).—Data are given regarding a bread made of corn meal and wheat, which the author considers more satisfactory than the corn bread which is so commonly eaten in many regions in Italy.

Breakfast foods, W. FREAR (*Penn. Dept. Agr. Bul. 162, pp. 40*).—The general characteristics and chemical composition were determined of a number of samples of cereal breakfast foods and pancake flours on sale in Pennsylvania.

The results obtained "show clearly that the materials used in preparing the cereal breakfast foods are wholesome grains or some of their more valuable products, and that the addition of bran, corncob, cornstalk, etc., sometimes said to be used as adulterants, is purely imaginary. Furthermore, the samples exhibited a good condition of dryness, but many were wormy when received. In general, they exhibited no evidence of the use of bleaching agents, except in the case of a few pancake flours.

"The test for tonic materials, such as strychnin, and also for morphin, were negative. On the other hand, the net weights contained in the packages were most variable. The representations concerning the chemical composition and nutritive value of the preparations were often very highly misleading, and sometimes utterly reckless.

"The cost of these foods was low if they are regarded as confections to please the taste, but very high if they be treated as substitutes for the ordinary domestic cereal products."

Examination of a new preparation, "ice cream powder," F. FERRARI-LELLI (*Arch. Farmacol. Sper. e Sci. Aff., 7 (1908), No. 1, pp. 1–4*).—The ice cream powder examined, according to the author, contained oat and wheat starch and Mars yellow.

The proteins of rice, O. ROSENHEIM and S. KAJIURA (*Jour. Physiol., 36 (1908), No. 6, pp. LIV, LV*).—In a preliminary communication the authors report studies of proteins of rice, the work being undertaken to determine whether the presence or absence of certain proteins or their cleavage products might possibly have any relation to the apparent fact that a diet mainly of rice is a predisposing factor in the causation of beriberi. Rice globulin, rice albumin, and a protein for which the name "oryzenin" is proposed were the bodies identified, the last-named representing the bulk of the rice proteins. It is insoluble in water, salt solutions, and dilute alcohol, but is soluble in dilute alkali (0.2 per cent potassium hydroxid) and is isolated by means of this solvent. When dried it is in the form of a white powder and gives all the usual protein color reactions.

"The absence of any protein soluble in alcohol is a characteristic feature of rice. . . . This fact obviously explains the unsuitability of rice for bread making, for both an alcohol-soluble protein (gliadin) and an alcohol-insoluble protein (glutenin) appear to be necessary for the formation of gluten, the essential constituent of dough. All our attempts to obtain gluten from rice have up to the present been unsuccessful.

It is said that the addition of barley to a rice diet prevents the occurrence of beriberi. This cereal and some others contain gliadins and are characterized by high percentages of glutaminic acid among their cleavage products. The authors propose to study the questions suggested by these facts with reference to beriberi.

Comparison of potatoes and rice, Louise Shipman (*Ill. Agr., 12 (1908), No. 5, pp. 149, 150, fig. 1*).—Data are summarized regarding the nutrients, energy value, and cost of equivalent amounts of raw and cooked potatoes and rice. According to the author, rice takes up about 5 times its weight of water when cooked.

The uses and composition of tamarind seeds, D. Hooper (*Agr. Ledger, 1907, No. 2 (Veg. Prod. Ser., No. 101), pp. 13–16, fig. 1*).—Tamarind seeds, it is stated, are universally eaten by the poorer people of India during times of scarcity and famine and are occasionally eaten at other times. Seeds with and without the outer hull were analyzed and a study of the fat of tamarind seeds was also made. The amount of fat present is small. The principal constituents are protein and carbohydrates, the proportions present in the kernel without the brown covering being 18.06 and 62.88 per cent, respectively.

"There is a decided difference in the composition of the shelled and unshelled seeds. The shells contain the undesirable constituents, namely, the tannin matter and fiber, and the kernels represent a nutritious food, white in appearance and with no disagreeable odor and taste."

The staff tree (Celastrus scandens) as a former food supply of starving Indians, F. T. Dillingham (*Amer. Nat., 41 (1907), pp. 391–393; abs. in Chem. Abs., 2 (1908), No. 5, p. 674*).—The food value of this product is attributed to the presence of mannan.

Strained honey, A. McGill (*Lab. Inland Rev. Dept. [Canada], Bul. 145, pp. 29*).—Of 253 samples of so-called strained honey collected throughout the Dominion of Canada, 219 samples were genuine, 31 of them showing a high water content. Of the remaining samples 4 were doubtful, 16 apparently adulterated, and 14 sold as compound.

According to the author, "the highest amount of water found in any of these samples is 31.4 per cent. . . . The ash of honey is due almost entirely to the accidental occurrence of dust, which sticks to the nectar, or other saccharin fluid, gathered by the bees. It is usually a mere trace, but exceptional instances are on record when it has reached 0.3 per cent."

In the author's opinion, a high ash content in honey is due to carelessness in handling with consequent access of dust, and he does not believe that the ash content is valuable for detecting adulterated honey.

Various other questions connected with honey and honey adulteration are briefly considered.

Sophistication of honey, J. Zimmermann (*Honigfälschungen und Honigfälscher [1908], pp. 80; rev. in Chem. Ztg., 32 (1908), No. 14, p. 165*).—A discussion of the importance of pure food laws with reference to the honey industry and related topics.

New preserved fruit products, J. Halmi (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 5, pp. 277–280*).—Hungarian products are described, including so-called plum bread, plum jelly, plum flour, and similar products made from apricots and apples.

The composition of fresh avocado fruit, E. A. Patrault (*Bul. Assoc. Chim. Sucr. et Distill., 25 (1908), No. 8, pp. 777, 778*).—According to the analytical data presented, the edible portion of the avocado has the following percentage composition: Water 82.1, protein 1.2, fat 8.7, sugar 2.9, cellulose and undetermined material 4.6, and ash 0.5 per cent. Starch and tannin were not present.

The fat, it is stated, is a green aromatic oil with an odor recalling that of laurel oil, which solidifies at 15° C. The sugar present was not completely identified. It reduced Fehling's solution, and hence is not the same as that which has been identified in the avocado seed.

Dried bananas from Queensland (*Epicure, 15 (1908), No. 171, p. 94*).—Brief statistical and other data regarding the manufacture and use of dried bananas and banana flour.

Hydrolytic and catalytic enzyms in relation to the ripening of fruit, G. TALLARICO (*Arch. Farmacol. Sper. e Sci. Aff., 7 (1908), Nos. 1, pp. 27–48; 2, pp. 49–68*).—In the experiments reported the different sorts of ferment activity were measured with bananas of varying degrees of ripeness ranging from unripe to overripe.

Vitis opaca and chemical investigation of its enlarged rootstock, R. T. BAKER and H. G. SMITH (*Jour. Proc. Roy. Soc. N. S. Wales, 40 (1906), p. 52; abs. in Chem. Abs., 2 (1908), No. 5, p. 674*).—The data reported include the chemical composition and a discussion of the use as food by the aborigines of tubers produced on the roots of this native Australian grape.

Examination of an oil-yielding fruit "Njore-Njole" from Kamerun, BRIEGER and M. KRAUSE (*Tropenpflanzer, 12 (1908), No. 2, pp. 83, 84, fig. 1*).—A study of Njore-Njole oil and report of determinations of its physical constants in comparison with olive oil and peanut oil. The authors believe that it has a decided agricultural value. The fruit and seed from which the oil is obtained are described.

Concerning the oil content of different olive samples, N. PASSERINI (*Bol. Ist. Agr. Scandicci, 2. ser., 7 (1908), No. 1, pp. 1–11*).—The analytical data reported are discussed on the basis of different methods of obtaining olive oil.

Examination of fruit juices, E. SUNDE (*Tidskr. Kemi Farm. og Ter., 1907, No. 13, pp. 202–204; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 6, p. 363*).—Of 35 samples of Norwegian commercial fruit juices only 12 were found to be unadulterated.

Concerning barberry juice, F. SCHULZE (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 5, pp. 289, 290*).—Three samples of barberry juice were analyzed.

Concerning orange juice, W. STÜBER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 5, pp. 273–276*).—Samples of fermented and unfermented orange juice prepared by the author were analyzed, together with commerical goods.

Studies of the organic phosphorus compounds in wine, A. FUNARO and A. RASTELLI (*Ann. R. Accad. Agr. Torino, 49 (1906), pp. 33–57*).—The proportion of phosphoric acid in organic and in inorganic combination in a number of samples of wine is reported and the general question of phosphorus compounds in wine is discussed.

Composition of wine from Urbino, A. AGRESTINI (*Staz. Sper. Agr. Ital., 41 (1908), No. 1, pp. 35–50*).—Data are reported and discussed regarding the composition of 25 samples of wine.

Bilberry wine, W. DONSELT (*Pure Products, 4 (1908), No. 3, pp. 126–129*).—The manufacture of bilberry wine, a material which was formerly considerably used for blending claret, is described.

Kafir beer, A. C. CHAPMAN and F. G. S. BAKER (*Jour. Inst. Brew., 13 (1907), No. 7, pp. 638–645*).—Anaylses of 2 sorts of Kafir beer are reported and these beers and other similar beverages are discussed with reference to lactic-acid content and other characteristics.

The manufacture of cocoa with definite fat content, R. BÖHME (*Chem. Ztg., 32 (1908), Nos. 9, pp. 97–99; 10, pp. 110–112*).—The problem of manufac-

turing cocoa of definite fat content which will correspond with the requirements of the pure-food law is discussed and analytical data summarized.

The aroma of black tea, T. KATAYAMA (*Bul. Imp. Cent. Agr. Expt. Sta. Japan, 1 (1907), No. 2, pp. 149–152; abs. in Chem. Ztg., 32 (1908), No. 21, Report., p. 135*).—According to the author's observations, the aroma is due to an enzym acting upon a glucosid present in the tea. The experimental work is not yet concluded.

Gulasch extract, F. SCHULZE (*Ztschr. Untersuch Nahr. u. Genussmtl., 15 (1908), No. 5, pp. 287, 288*).—A commercial Gulasch extract is described and data regarding its composition reported. Apparently this material consisted of onion, paprika, and animal fat.

Economical preservation of food, LEONA B. GARRETT (*Ill. Agr., 12, 1908*), *No. 5, pp. 139–141*).—In a comparison of the cost of home-canned fruit and vegetables with commercial products of the same grade, it was found that in every case the homemade product was cheaper as well as of superior quality.

Preserving wild mushrooms, E. F. PERNOT (*Oregon Sta. Bul. 98, pp. 3–6.*—According to the author mushrooms may be readily canned in their own liquor in either tin or glass by household methods, the young mushrooms being best for the purpose. Sterilizing the cans at intervals for several days is recommended. The author also states that mushrooms may be readily canned if cooked in milk or in any other way which is preferred.

When older mushrooms are used for canning they reduce very much in quality, turning black and becoming mushy. The flavor is not injured, though the appearance is not so attractive as that of young mushrooms. The author therefore recommends that the older mushrooms be dried and powdered. "Mushroom powder keeps very well and it is one of the most delicious flavoring condiments of the kitchen. The powder should at once be placed into well-stoppered dry bottles or fruit jars well sealed and kept in a warm, dry place. Mushrooms that are wet can not be successfully dried. The best are those which grow and are gathered dry."

Directions are also given for making mushroom catsup.

Different methods of preserving meat, P. RAZOUS and R. NOURISSÉ (*Les divers procédés de conservation des viandes. Paris, 1907, pp. II+79, figs. 11*).—This volume contains chapters on preservation of meat by antiseptics, cooking and sterilization, low temperature, and desiccation, and a special chapter on the preparation and preservation of pork products.

The fireless cooker, WITT (*Österr. Molk. Ztg., 15 (1908), No. 5, pp. 60–63, figs. 11*).—So-called fireless cookers of different sorts are described and this method of cooking briefly discussed.

General results of the investigations showing the effect of benzoic acid and benzoates upon digestion and health, H. W. WILEY (*U. S. Dept. Agr., Bur. Chem. Circ. 39, pp. 15, figs. 2*).—Using healthy young men as subjects the effects of benzoic acid and benzoate of soda were studied to secure data which would be of use in judging these materials as food preservatives. Variations in body weight, the composition and character of the excretory products, the balance of income and outgo of sulphur, nitrogen, and phosphoric acid, the characteristics of the blood and urine as shown by the microscope and similar data were recorded.

Quotations from the general conclusions follow:

"From a careful study of the data in the individual cases and of the summaries of the results, it is evident that the administration of benzoic acid, either as such or in the form of benzoate of soda, is highly objectionable and produces a very serious disturbance of the metabolic functions, attended with injury to digestion and health.

"As in the case of boric acid, salicylic acid, and sulphurous acid, this injury manifests itself in a number of different ways, both in the production of unfavorable symptoms and in the disturbance of metabolism. These injurious effects are evident in the medical and clinical data, which show grave disturbances of digestion, attended by phenomena which are clearly indicative of irritation, nausea, headache, and, in a few cases, vomiting. These symptoms were not only well marked, but they were produced upon healthy individuals, receiving good and nourishing food and living under proper sanitary conditions. It is only fair to conclude, therefore, that under similar conditions of administration of benzoic acid or benzoate of soda in the case of weaker systems, or less resistant conditions of health, much more serious and lasting injury would be produced.

"It was also noticed that the administration of benzoic acid and benzoate of soda was attended with a distinct loss of weight, indicative of either a disturbance of assimilation or an increased activity in those processes of the body which result in destruction of tissue. The production of a loss of weight in this kind must be regarded as indicative of injurious effects.

"The influence of the benzoic acid and benzoate of soda upon metabolism was never of a character indicative of a favorable change therein. While often the metabolic changes were not strongly marked, such changes as were established were of an injurious nature. It is evident that the administration of these bodies, therefore, in the food tends to derange metabolism in an injurious way.

"An important fact in connection with the administration of these bodies is found in the efforts which nature makes to eliminate them from the system. In so far as possible the benzoic acid is converted into hippuric acid. There is a tendency usually manifested, however, to retain the benzoic acid in the body for a notable length of time, and this is much more marked in the case of benzoate of soda than in the case of benzoic acid.

"While the administration of both these bodies, therefore, is undoubtedly harmful, the injurious effects are produced more rapidly in the case of benzoic acid than they are in the case of benzoate of soda; the data, however, will show that the total harmful effect produced in the end is practically the same in both cases; hence there appears to be no reason for supposing that the administration of the preservative in the form of benzoate of soda can be justified by any argument relating to the less injurious effect thereof upon health.

"The occurrence of microscopic bodies in the urine is undoubtedly increased under the administration of benzoic acid in both forms, thus showing conclusively the tendency to stimulate the destructive activities of the body.

"Coming to the final consideration of all of these different phases of the subject, there is only one conclusion to be drawn from the data which have been presented, and that is that in the interests of health both benzoic acid and benzoate of soda should be excluded from food products."

Preservatives in food and the effect thereof on the public health, H. W. WILEY (*Amer. Jour. Pub. Hyg., 18 (1908), No. 1, pp. 27–30*).—Information collected from some 250 physiologists, hygienists, health officers, and physicians showed that the majority were not in favor of the use of preservatives other than the usual condimental preservatives sugar, salt, alcohol, vinegar, spices, and wood smoke, and believe that other preservatives as a class are injurious to health and not essential. The metabolism and excretion of chemical preservatives and other similar topics are briefly discussed.

[Food and dairy laws] (*Penn. Dept. Agr. Bul. 160, pp. 69*).—The law creating the State department of agriculture, the legislative acts pertaining to the

dairy and food division, and a digest of numerous court cases relating to these laws are included in this bulletin.

Food of a large city. Sources and average food supply of Paris, É. PAYEN (*Rev. Écon. Internat., 5 (1908), I, No. 2, pp. 370–391*).—A summary of statistical and other data regarding the food supply of Paris.

Food and fare in Italy, LUCY M. YATES (*Epicure, 15 (1908), No. 171, pp. 72, 73*).—Typical foods, methods of cooking, and character of the meals served in Italian families, and similar questions are discussed.

Diet and hygiene in Korea, J. H. WELLS (*Dietet. and Hyg. Gaz., 24 (1908), No. 3, pp. 154, 155*).—On the basis of personal experience the author discusses diet and hygiene in Korea with special reference to disease.

The composition and energy value of the food of the soldier, M. S. PEMBREY and L. E. L. PARKER (*Jour. Physiol., 36 (1908), No. 6, pp. XLIX, L*).—The reported data show the calculated nutrients and energy supplied per man per day by the peace ration and messing allowance of 4 regiments of the British army. The average protein ranged from 123 to 142 gm. per man per day and the energy from 3,248 to 3,478 calories. Soldiers purchase some food in addition to the ration supplied. This is not taken into account in the above estimates.

According to the authors, there is little doubt "that the minimum diet of the soldier is above 100 gm. of protein, 100 gm. of fat, and 400 gm. of carbohydrate and possesses an energy value above 3,000 calories."

Some figures [regarding the nutritive value and cost of food served in a student boarding club], AGNES HUNT (*Ill. Agr., 12 (1908), No. 5, pp. 146–148*).—It is stated that a successful attempt was made to furnish a satisfactory diet to a club averaging 26 faculty and student members at a cost of 50 cts. per person per day, which sum included the cost of raw materials, cooking, and serving. The diet was fairly varied. Meat or eggs were served each day at 2 meals only. A liberal use was made of milk, chiefly as an addition to cereal foods and puddings and in the preparation of various dishes. Potatoes and cereals were also supplied in abundance.

It was found that 53.3 per cent of the total food expenditure went for animal foods and 46.7 per cent for vegetable foods. Meat was the most expensive item, 16.5 per cent of the total being expended for meat exclusive of chicken. The sum expended for chicken and eggs was 12.6 per cent, for butter 11 per cent, and for bakers' goods 9 per cent of the total.

A day's ration with student valuations, NELLE M. DICKINSON (*Ill. Agr., 12 (1908), No. 5, pp. 142–145*).—The data reported include menus and food values, prepared with a view to meeting the requirements of dietary standards and not to exceed a definite amount as regards cost.

The provision of meals for school children, R. H. CROWLEY (*Pub. Health [London], 20 (1908), No. 5, pp. 325–335, chart 1*).—The plan tried experimentally in Bradford, England, of furnishing breakfast and dinner to children in the poor quarters of the city is outlined. The meals supplied are described and some of the principal results secured are reported. The meals were inexpensive, costing a little over 2.5 cts. per child per day, or including administrative expenses about 4 cts. per day. Gains in weight and improvement in condition of the children were observed. The experiment was so planned that it might have educational value.

The author believes that, provided the scientific and educational aspects of such public feeding of school children are taken into account, very great benefits to the children will undoubtedly follow the adoption of such a plan.

Lessons in practical hygiene for use in schools, ALICE RAVENHILL (*London [1907], pp. 744; rev. in Pub. Health [London], 20 (1908), No. 4, pp. 274,*

275).—This volume deals with various branches of general and special hygiene and gives a series of illustrative experiments for each branch taken up. Food constituents, action of cooking on food, beverages, and tests for the quality of food stuffs are among the subjects included.

The elements of the chemical physiology of digestion, S. Schmidt-Nielsen (*Elementerna af Matsmaltningens Komisha Fysiologi Upsala, 1907, pp. 13*).—A syllabus of lectures delivered at the summer course at Upsala University, 1907.

Progress in proteid chemistry with special reference to biological problems, E. Abderhalden (*Naturw. Wchnschr., 23 (1908), No. 8, pp. 113–121, fig. 1*).—A summary of results of recent investigations in proteid chemistry with special reference to the structure of the proteid molecule, the synthesis of proteids from amino acids, the food value of different proteids as dependent upon their structure, the importance of ferments in body processes, and related questions.

Protein synthesis in the animal body, V. Henriques (*Ztschr. Physiol. Chem., 54 (1908), No. 5–6, pp. 406–422*).—The experiments reported, the author believes, show that with albumin cleavage products as the sole source of nitrogen it is possible not only to maintain body weight but also to make substantial gains in nitrogen. Cleavage products obtained by the action of trypsin and erepsin retain this property even if heated on a water bath for 6 hours with 20 per cent sulphuric acid at a temperature of boiling water. When heated for 17 hours, the products no longer suffice to maintain nitrogen equilibrium. Apparently this had some connection with the ability to give the tryptophan reaction, as this was plainly noticeable with the cleavage products with which nitrogen equilibrium could be maintained and was absent when nitrogen equilibrium was not possible. The experiments reported were made with small animals.

Experiments on the influence of an excess of fat in the diet on the digestive tract and on metabolism, E. Biernacki (*Reprinted from Poln. Arch. Biol. u. Med. Wiss., 3 (1907), pp. 272–313; Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, n. ser., 2 (1907), No. 11, pp. 401–414*).—The chief effect noted from an excess of fat in the diet was a lowering of the oxidation of protein, which was manifested as a decrease in the amount of urea excreted and an increase in the urine constituents called amido acids. An excess of sugar also caused a lowering of the urea coefficient but starch did not have this effect. The experiments reported were made with dogs.

Cotton-seed oil taken in food and injected, K. Lendrich (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 6, pp. 326–334*).—In experiments with rabbits it was found that only a limited amount of cotton-seed oil constituents appeared in the body fat though the feeding was continued for a long time. When the cotton-seed oil was injected into the digestive tract phytosterin was rapidly resorbed but not the other constituents.

Carbohydrate metabolism, H. McGuigan (*Science, n. ser., 27 (1908), No. 689, pp. 429, 430*).—The author studied carbohydrate metabolism by means of perfusion experiments with surviving tissue. According to his results, both dextrose and levulose are directly attacked by living tissues and the amount diminished. "If there be a conversion of either into glycogen it takes place in the muscle as it is oxidized, which is highly improbable.

"Maltose is not used directly by the muscle. There is some loss of sugar, but if we assume that the dextrose in the blood is utilized in preference to maltose, no reduction of the quantity of maltose takes place. If we grant that both are used equally there could be at most only a slight reduction of the maltose. . . .

"Investigation of the other sugars has not been concluded."

Sugar in the ration during military maneuvers, Joly (*Arch. Méd. et Pharm. Mil., 49 (1907), p. 241; abs. in Hyg. Zentbl., 3 (1908), No. 21, pp. 674, 675*).—For 3 weeks 60 to 165 gm. of sugar replaced half of the meat ration of 2 companies of French soldiers. The sugar was taken readily in wine, water, or coffee and no digestive disturbances were noted. Five soldiers for 3 days took a larger amount of sugar, namely, 300 gm., in the place of the entire meat ration. In the author's opinion, the men were in better physical condition and had more endurance than on their ordinary ration.

Cleavage in metabolism, Pütter (*Med. Naturw. Arch., vol. 1, No. 1, p. 61; abs. in Zentbl. Physiol., 21 (1908), No. 24, pp. 815, 816*).—According to the author's deductions, the oxidation processes play a smaller part and anærobic cleavage processes a much greater part in metabolism in the animal body than is ordinarily supposed.

Concerning the extractives of muscular tissue. IX, The constitution of carnitin, R. Krimberg (*Ztschr. Physiol. Chem., 53 (1907), No. 6, pp. 514–525*).—According to the author, carnitin is a γ-trimethyl-oxy-butyro-betain.

For earlier work see a previous note (E. S. R., 18, p. 960).

Creatin and creatinin, E. Mellanby (*Jour. Physiol., 36 (1908), No. 6, pp. 447–487, figs. 3*).—Methods of estimation, the stability of creatin in muscles, the effect of glycocyamin feeding on the creatin in chickens' muscle, the effects of creatin and creatinin on the percentage of creatin in muscles, and other questions were considered in connection with the investigations reported.

According to the author's conclusions, the muscle plays a small part in the formation of creatinin, while the liver is intimately connected with the production of creatin and the excretion of creatinin. He believes that muscle creatin is formed from creatinin, the principal reasons for this opinion being that "the feeding experiments on young chickens yield some slight evidence that food creatinin can be changed to creatin and stored. In no physiological experiment in this research has creatin ever been changed to creatinin. Creatinin is not excreted by chickens until about a week after hatching, i. e., not until the muscles are saturated with creatin. . . .

"The change from creatinin to creatin is from every point of view more likely than the change from creatin to creatinin. From a chemical consideration it is more probable that the ring formation of creatinin comes direct from a tissue breakdown, and that this ring is then hydrated to a creatin chain by muscle, rather than that the creatin chain is dehydrated to form the creatinin ring.

"From a physiological point of view it can not be thought that tissues would make an innocuous neutral substance like creatin into a strongly basic substance like creatinin. Such a change would be contrary to all that is known of the changes undergone by chemical substances in the organism."

Studies of the cholesterin group, A. Menozzi (*Atti. R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 17 (1908), I, No. 3, pp. 91–94*).—Chemical studies of cholesterin from hens' eggs led to the conclusion that it is identical with the cholesterin of bile.

Body temperature and periodicity, W. A. Osborne (*Jour. Physiol., 36 (1908), No. 6, pp. XXXIX–XLI*).—The body temperature records kept on a journey from Melbourne to London, which the author presents, tend to prove, in his opinion, that the time of evening maximum takes place with regard to local time and not the time of the starting point. "They do not, however, disprove the existence of body periodicity nor prove that the evening maximum is determined solely by the hours of sleep, the activities of the day and the diurnal variations of light and heat, for a true periodicity might have been present

but adjusted to the new conditions owing to the very gradual manner these were introduced."

Work under pressure and in great heat. J. S. HALDANE (*Sci. Prog. Twentieth Cent., 2 (1908), No. 7, pp. 378–398, figs. 4*).—The author summarizes and discusses the results of his own investigations and other data regarding atmospheric moisture, heat, atmospheric pressure, and other conditions with special reference to their effect on muscular work.

ANIMAL PRODUCTION.

Inspection of feeding stuffs (*New York State Sta. Bul. 303, pp. 203–254*).—Of 297 samples of cotton-seed meal, linseed meal, gluten feed, corn bran, dried distillers' grains, malt sprouts, dried brewers' grains, hominy feed, barley and oat by-products, beet-sugar wastes, meat meals and other animal products, poultry foods, and other feeding stuffs analyzed, 28 were materially below guaranty, which is 41 less than the number found a year ago. Tables of analyses are given.

"With reference to the proprietary feeds, not only have the percentages of protein, fat, and fiber been determined, but these mixtures have been studied with reference to the ingredients from which they were compounded. This was done by a microscopic examination of 38 brands.

"Nearly all of these compounded feeds contain either oat hulls greatly in excess of what belong to the ground oats present, or ground corncobs.

"The molasses feeds . . . nearly all contained a great variety of weed seeds, some of which are noxious weeds such as mustard, charlock, wild carrot, and English plantain (narrow-leaved plantain, buckhorn). Germination tests show that in several cases these seeds have not lost the power of germination."

It is stated that these weed seeds have an unknown nutritive value and that many pass through the animals undigested, thus becoming a menace not only to the land but also to the productiveness of the animals which receive a smaller quantity of digestible nutrients than has been assumed by the feeder who buys these feeding stuffs for pure sound grains.

Twelve gluten feeds examined for acids and artificial coloring matter were found to have a total acidity equivalent to from 0.09 to 0.91 per cent hydrochloric acid. Sulphuric acid was present only in traces, except in one sample which showed 0.18 per cent of SO_3. The acidity was much higher in the 7 samples found artificially colored and it is suggested that the acids may be added to fix the coloring matter.

Feed stuffs, R. E. ROSE (*Fla. Quart. Bul. Dept. Agr., 18 (1908), No. 1, pp. 17–21, 36–39, 96–121*).—According to the results of 223 analyses, "the general average of all the commercial feed sold in the State was slightly above the guaranty." The valuation of feeding stuffs and related questions are spoken of.

The materials examined included bran, middlings, shorts, mill feed, ship stuff, ground ear corn, hominy feed, cotton-seed meal, cotton-seed hulls, gluten feed, cocoanut meal, commercial or proprietary feeds, sugar or molasses feeds, beet pulp, commercial poultry feeds, Natal grass hay, and Japanese Kudzoo vine hay.

The composition of Natal grass hay was as follows: Protein 7.45, fat 1.80, nitrogen-free extract 39.23, crude fiber 36.75, and ash 5.02 per cent, and of Japanese Kudzoo vine hay—protein 16.59, fat 1.68, nitrogen-free extract 32.81, crude fiber 40.09, and ash 8.83 per cent.

Execution of the [Massachusetts] feed law, J. B. LINDSEY (*Massachusetts Sta. Rpt. 1907, pp. 90, 91*).—The chief result of inspection was the discovery

of numerous lots of inferior cotton-seed meal due in part to heavy rainfalls in the autumn of 1906, when large quantities of cotton seed were damaged. One new feed was found, known as flax feed, and consisting substantially of one-third imperfectly developed flax seed and two-thirds of a variety of ground weed seeds. It has an extremely bitter taste and cows ate it rather grudgingly when fed by itself, though consuming it readily when mixed with other grains.

German meadows and the estimation of the value of meadow hay, A. NAUMANN (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 4 (1908), No. 1–2, pp. 50–101, pls. 2, figs. 9*).—A discussion of typical meadow lands and other grass areas found in different countries, a classification of the meadow areas of Germany, and a summary of classified data regarding the botanical distribution, chemical composition, and other characteristics of grasses and other plants found on such areas. Micro-organisms which occur on meadow plants and hay are described and illustrated and the question of poisonous plants found in meadows is also taken up.

The composition and digestibility of hay from sewage meadows (*Agr. Mod., 14 (1908), No. 14, pp. 184, 185*).—Analytical and other data are summarized and discussed.

The native fodder plants of New South Wales, J. H. MAIDEN (*Off. Yearbook N. S. Wales, 1905–6, pp. 754–759*).—A description of grasses, saltbushes, and other fodder plants native to New South Wales with some notes on their use and palatability.

Ensiled beet pulp and its by-products, J. GIELE (*Jour. Soc. Cent. Agr. Belg., 55 (1908), No. 4, pp. 110–112*).—Analytical and other data regarding the composition of ensiled beet pulp are reported and discussed.

Buckwheat feed, F. W. WOLL (*Hoard's Dairyman, 39 (1908), No. 10, p. 300*).—This discussion of buckwheat feeds of different kinds quotes analyses made at the Wisconsin Experiment Station.

Experiments on the nutritive value of nonproteid nitrogenous constituents of hay, O. KELLNER (*Jour. Landw., 56 (1908), No. 1, pp. 49–52*).—A critical discussion.

The value of glutaminic acid and aspartic acid as nutrients, K. ANDRLÍK and K. VELICH (*Ztschr. Zuckerindus. Böhmen, 32 (1908), No. 6, pp. 313–342*).—In the experiments with sheep which are reported 96 to 98 per cent of both glutaminic acid and aspartic acid, taken as sodium salts, were resorbed. The urine did not contain any appreciable quantity of these acids, nor of simpler amino acids. Both acids were retained in the body, the proportion of aspartic acid thus retained being the greater. The resorbed material was in part used for the formation of protein and in part as a source of energy. When glutaminic acid was taken only 43 per cent of the food protein was resorbed as compared with 54 per cent in the case of the aspartic acid ration and 49 per cent with the normal ration.

Fat formation from protein and methods of estimating fat, E. A. BOGDANOW (*Jour. Landw., 56 (1908), No. 1, pp. 53–87*).—According to the author's experience, it is possible to find pigs, though the proportion is small, capable of taking large quantities of protein without disturbing general good health, and with such animals the utilization of casein and meat meal containing little fat was studied.

It was found that a ration very rich in protein induced only small gains in fat even when the feed was eaten in quantity with a good appetite. The author considers it probable, however, that fat was formed from protein under such conditions though the quantity was not large. He calls attention to the fact that this is in accord with the view that at least certain proteins contain pre-

formed carbohydrates and that glycogen formation from protein has been noted by other observers. His method of fat estimation depends upon double extraction and subsequent determination of the fatty acids, a method which, in his opinion, gives particularly satisfactory results in studies of fat formation in the body.

Studies of the digestibility of dried potatoes, O. KELLNER ET AL. (*Landw. Vers. Stat., 68 (1908), No. 1–2, pp. 39–60*).—In experiments with pigs the average coefficients of digestibility of 6 sorts of dried potatoes were as follows: Organic matter 91.3, protein 58.8, nitrogen-free extract 94.5, and crude fiber 73.2 per cent. In experiments with sheep the average values were organic matter 86.5, protein 31.9, nitrogen-free extract 94.4, and crude fiber 16.1 per cent.

Digestion experiments, II, H. G. KNIGHT, F. E. HEPNER, and T. F. MCCONNELL (*Wyoming Sta. Bul. 78, pp. 3–44, figs. 4*).—A continuation of previous work (E. S. R., 18, p. 262). Native hay, oat straw, pea hay, and sweet clover, and alfalfa from different cuttings were fed to sheep. The digestion coefficients found in this and the previous work were as follows:

Digestibility of native hay, oat straw, pea hay, sweet clover hay, and alfalfa hay.

	Dry matter.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Native hay (wire grass)	53.27	38.76	54.19	54.31	58.30	33.81
Native hay (wheat grasses)	63.64	57.12	47.04	66.46	67.49	38.90
Oat straw	54.83	25.72	49.97	57.21	54.13	48.79
Pea hay	67.10	78.24	49.55	79.27	50.73	33.39
Sweet clover hay	60.88	75.46	30.94	72.04	33.63	65.79
Alfalfa hay (first cutting)	61.95	77.56	38.46	73.29	46.04	47.04
Alfalfa hay (second cutting)	64.25	79.55	44.75	75.60	46.12	55.33

The western sedges (Carex) and rushes (Juncus), grown for hay throughout the irrigated regions of the Laramie Plains, were found to be nutritious, although the eastern species are supposed to have little value for stock. Oat straw is deemed more nutritious than eastern workers have found it to be. Canadian pea hay is believed to be one of the most important hays for fattening lambs. White sweet clover (*Melilotus alba*), one of the few alkali-resisting plants, has a peculiar taste which stock do not seem to relish, but if cut early, placed in the stack and salted, it is quite palatable.

The forage plants which composed the native hay (wire grass), arranged in the order of their predominance, were as follows: *Juncus balticus* (Baltic rush), *J. longistylis* (long-style rush), *Deschampsia cæspitosa* (tufted hair grass), *Carex nebraskensis* (Nebraska sedge), *Astragalus bodini* (Bodin vetch), *Triglochin palustris* and *T. maritima* (weeds), *Agropyron occidentale* (western wheat grass), and small amounts of many others. The first 6 species comprised fully 90 per cent of the whole.

The forage plants in the native hay in which wheat grasses predominate included *Agropyron* sp. (species of wheat grasses), *Deschampsia cæspitosa*, *Puccinellia airoides* (alkali meadow grass), *Juncus balticus*, *J. longistylis*, *Elcocharis palustris* (spike rush), and small amounts of several others. About 75 per cent of the whole consisted of the true grasses, mainly wheat grasses, the balance being rushes and sedges.

A feeding experiment with hay, turnips, and cut straw for sheep, J. SÄLAND (*Ber. Norges Landbr. Höiskoles Virks., 1906–7, pp. 225–240*).—A test

with 3 ewes and their 5 lambs showing that turnips may make a profitable sheep feed under the agricultural conditions of eastern Norway.

Fertility in Scottish sheep, F. H. A. Marshall (*Trans. Highland and Agr. Soc. Scot., 5. ser., 20 (1908), pp. 139–151*).—A series of statistics based upon inquiries made by sheep breeders was compiled by the author for the purpose of showing some of the principles involved in determining fertility in sheep. The percentage of lambs per 100 ewes and the percentage of barren ewes in various flocks of different breeds and kept under different conditions are shown in tabular form. It was found that certain changes of weather during the breeding season may have an unfavorable effect upon the percentage of lambs and that the practice of flushing ewes almost invariably has the effect of increasing the percentage of twin lambs and triplets. Considerable evidence was obtained to show that a high fertility is ordinarily hereditary.

Caracul sheep, E. Meuleman (*Le Mouton Karakul. Brussels, 1908, pp. 20, figs. 8*).—An account of raising Persian, caracul, and similar sheep which yield the fur known as Persian lamb, broadtail, astrakhan, etc. The author believes that raising such sheep might be advantageously carried on in parts of Belgium.

Caracul sheep and their possible use in the sandy regions of Germany, J. Kühn (*Illus. Landw. Ztg., 28 (1908), No. 24, pp. 213, 214, figs. 4*).—The author does not believe that caracul sheep would be suited to German conditions, as they apparently require their usual environment in order to produce lambs with the characteristic pelts.

Raising and fattening calves on skim milk with and without supplementary feeds, P. Dornic and P. Daire (*Indus. Lait. [Paris], 33 (1908), No. 10, pp. 183–187*).—Barley flour, rice flour, and linseed oil were used as supplements to skim milk and in the tests which are briefly cited the calves gained from 0.6 to 1 kg. per head per day. The addition of oil to the ration did not materially improve the quality of meat nor influence the gains in weight.

Beef production. II, Methods of beef production in Indiana. III, Factors influencing the value and cost of feeders, J. H. Skinner and W. A. Cochel (*Indiana Sta. Circs. 12, pp. 32; 14, pp. 23, figs. 22*).—Circular 12 is a summary of replies received from 929 successful feeders of Indiana to a list of 100 questions submitted relative to the extent of the business of feeding cattle, the equipment used, and the methods of feeding in vogue. Circular 14 discusses the conformation, quality and breeding, age, condition and weight of steers, market conditions, and other factors influencing the value and cost of feeders.

Fifty years among Shorthorns, R. Bruce (*London, 1907, pp. 214, pls. 21*).—On the basis of personal knowledge the author describes a very large number of notable Shorthorn animals of Great Britain.

Congo cattle, E. Meuleman (*Le Betail du Congo. Brussels, 1907, pp. 23, figs. 13*).—A summary of data on the zebras and the cattle in the Congo. The advantages of introducing improved breeds of cattle and related questions are considered.

Inverted starch in pig feeding, S. S. Sevenster (*Milch Ztg., 37 (1908), No. 8, p. 88*).—A brief note on the use of diastasolin for inverting starch. The use of smaller amounts than usual of the ferment is to be preferred, according to the author's experience.

Supplements to corn for fattening hogs in dry lot, J. H. Skinner and W. A. Cochel (*Indiana Sta. Bul. 126, pp. 143–159*).—Tankage, linseed meal, and soybean meal were compared as supplements to corn meal for fattening hogs. The tests were conducted at different seasons of the year with hogs of various ages and conditions of finish. The results are shown in the following table:

Comparison of tankage, linseed meal, and soy beans as supplements to corn for fattening hogs.

	Ratio of supplementary ration to basal ration (corn meal).[a]	Number of days fed.	Number of pigs.	Daily gain per head.	Amount of feed per pound gain.	Cost per pound gain.
				Pounds.	*Pounds.*	*Cents.*
Experiment 1:						
Period 1—						
Lot 1	Tankage 1:10	35	8	1.57	3.58	3.68
Lot 2	Linseed meal 2:10	35	8	1.48	3.82	3.89
Period 2—						
Lot 1	Tankage 1:10	48	8	1.60	4.33	4.35
Lot 2	Linseed meal 2:10	48	8	1.36	4.68	4.68
Experiment 2:						
Period 1—						
Lot 1	Tankage 1:16	30	9	1.65	3.76	3.62
Lot 2	Linseed meal 1:8	30	10	1.42	3.86	3.76
Period 2—						
Lot 1	Tankage 1:32	21	9	1.12	4.00	3.73
Lot 2	Linseed meal 1:16	21	10	1.20	3.79	3.54
Experiment 3:						
Lot 1	Tankage 1:20	29	7	1.53	3.75	3.57
Lot 2	Linseed meal 1:10	29	7	1.38	4.22	4.02
Experiment 4:						
Lot 1	Tankage 1:15	60	5	1.83	3.83	3.70
Lot 2	Linseed meal 1:8	60	5	1.75	3.75	3.62
Experiment 5:						
Lot 1	Linseed meal 1:5	39	4	1.23	3.82	3.82
Lot 2	Soy-bean meal 1:5	39	4	1.33	3.46	3.46
Experiment 6:						
Lot 1	Linseed meal 1:8	60	5	1.75	3.75	3.62
Lot 2	Soy-bean meal 1:7	60	5	1.82	3.68	3.59
Summary of experiments 1, 2, 3, and 4.	Tankage			1.61		3.82
	Linseed meal			1.49		3.96
Summary of experiments 5 and 6.	Linseed meal			1.48	3.78	3.71
	Soy-bean meal			1.56	3.60	3.55

[a] In the first period of the first experiment 5 parts of middlings were added to the ration.

It is concluded that the tests with soy-bean meal indicate that it is possible to grow in Indiana a feed which is equal in value to linseed meal as a supplement to corn for fattening growing hogs in a dry lot. Corn should be the basis of all rations for fattening hogs, but a larger proportion may be used with tankage than when linseed meal is used as a supplement. With tankage the hogs consumed more feed, made a more rapid gain, and were better finished than when linseed meal was used. Soy-bean meal proved to be a more efficient supplement than linseed meal both as regards the rate and cost of gain.

Hog feeding, W. J. Quick and A. P. Spencer (*Virginia Sta. Bul. 176, pp. 3–14, figs. 2*).—In 70-day tests with 4 lots of 5 Berkshire hogs, 5 months of age, skim milk was compared with blood meal as a supplement to corn, and well-seasoned, hard, and flinty corn was compared with new corn coming directly from the shock. With a basal ration of skim milk and middlings, the lot receiving new corn made an average daily gain of 1.47 lbs. per day at a cost of 5.99 cts. per pound of gain, whereas the lot receiving old corn made an average daily gain of 1.5 lbs. at a cost of 5.6 cts. per pound of gain. With blood meal and middlings for a basal ration, the average daily gain of the lot receiving new corn was 1.37 lbs. at a cost of 5.9 cts. per pound, whereas the lot receiving old corn made a daily gain of 1.4 lbs., costing 5.7 cts. per pound of gain. Analyses of the feeds are given.

"The profit made during the entire experiment differs less than one dollar. From this data we concluded that blood meal and skimmed milk have a similar feeding value when fed on the basis of an equal number of pounds of protein, and as supplements to either old or new corn."

Paddock feeding of pigs, E. R. Sawer (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 7, pp. 701, 702*).—Peanuts, sweet potatoes, beans, and arrowroot were compared as pasturage for pigs at the Winkel Spruit Experiment Farm, the pasturage being supplemented by small amounts of other feed. The total gain made by 12 pigs on peanuts was 69.7 lbs. per week and on sweet potatoes 101.5 lbs. The experimental periods covered from 2 to 3 weeks.

Fattening pigs, Brandt (*Deut. Landw. Presse, 35 (1908), No. 6, pp. 55, 56*).—In an article quoted from *Hannoversche Land- und Forstwirthschaftliche Zeitung* data are summarized regarding the feeding of pigs in accordance with theoretical requirements.

Standardizing breed characteristics, W. J. Spillman (*Proc. Soc. Prom. Agr. Sci., 28 (1907), pp. 115–121, figs. 3*).—Attention is devoted to the recurrence of black specimens among pure-bred Hampshire swine. Since a distinct white band is required in this breed, various attempts have been made to eliminate the tendency to produce black specimens. From a consideration of the inheritance of Mendelian characters it is believed that the desired result may best be brought about by testing all male breeding animals. If a male when bred to a recessive female produces any young showing recessive characters, he should be discarded. The same result may be brought about by discarding all male and female Hampshire hogs which show the recessive character of white feet. If this course is adopted, it will be unnecessary to use black breeding animals to eliminate the white feet.

Breeds of horses, P. Diffloth (*Races Chevalines. Paris, 1908, pp. VIII+467; rev. in Nature [London], 77 (1908), No. 1998, p. 339*).—A classification and discussion of breeds of horses, together with statistics of the number of horses in the world and short chapters on the ass and mule. Data are also presented regarding the government efforts in France to encourage horse breeding. This volume is included in the series Encyclopédie Agricole.

The horses of the British Empire, edited by H. F. de Trafford et al. (*London, 1907, vols. 1, pp. VIII+286, pls. 18, figs. 203; 2, pp. VIII+245, pls. 10, figs. 551*).—The origin and history of domestic horses and the principal breeds of horses, particularly those of importance in the British Empire, are discussed and a large amount of data on horses and horse breeding is summarized. The chapters are contributed by different authors and the work is very fully illustrated.

Types and breeds of horses in the Russian Empire, edited by N. A. Goulkevich ([*1907*], *pp. IV+30, pls. 68*).—By means of illustrations and text the author describes the principal types of Russian horses. The text of the volume appears in Russian, English, German, and French.

Horse feeding with saccharin substances (*Sugar Beet, 29 (1908), No. 4, pp. 295, 296*).—Experiments carried on by Latschenberger and S. Polansky at the Vienna Veterinary School are summarized. When lump sugar was fed to 2 horses, the maximum amount being 4 kg. per day for a horse weighing 475 kg., the animals remained in a satisfactory condition, gained somewhat in weight, and did not drink excessive amounts of water. The basal ration consisted of 3.6 kg. of oats and 4.5 kg. of hay.

Tests were also summarized in which peat molasses was fed in addition to oats and hay, a kilogram per head per day giving very satisfactory results.

The use of bonnets for horses, B. d'Anchald (*Bul. Soc. Nat. Agr. France, 67 (1907), No. 10, pp. 880–883; abs. in Rev. Gén. Agron., 17 (1908), No. 2, pp. 76, 77*).—Studies of body temperatures of horses with and without bonnets showed the animals were cooler without them. The author considers that bonnets are neither necessary nor desirable.

Market classes of mules and breeding them (*Breeder's Gaz., 53 (1908), No. 10, pp. 535, 536, figs. 2*).—This general discussion is based on the experience of a practical mule raiser.

Animal food for chickens, F. Houssay (*Arch. Zool. Expt. et Gén., 4. scr., 6 (1907), pp. 137–332, figs. 47; abs. in Rev. Gén. Agron., 17 (1908), No. 2, pp. 81, 82*).—Experiments which included 6 successive generations of chickens were made in which exclusively animal and vegetable rations were compared.

It was found that during the period of growth the chickens fed the animal food developed very rapidly. Under favorable conditions certain parts of the body, for instance, the epidermis of the foot, made vigorous growth and after several generations a tendency to produce feathered feet was noticeable. The fat of chickens fed animal food was the more firm, but the egg production was smaller and abnormal eggs, for instance, infertile or double-yolked eggs were more commonly produced. As a practical deduction, the author concludes that chickens may receive animal food with profit during the period of growth but that it is not habitually needed afterwards.

Poultry experiments, W. P. Brooks, E. S. Fulton, and E. F. Gaskill (*Massachusetts Sta. Rpt. 1907, pp. 57–59*).—The practical conclusions here reported have for the most part been noted from another source (E. S. R., 20, p. 272).

The poultry export trade, A. Hart (*Jour. Dept. Agr. Victoria, 6 (1908), No. 1, pp. 49–53, figs. 3*).—In the feeding test briefly summarized in connection with a discussion of the importance of properly fattened birds for export trade and related questions, it was found that extra gains in weight cost about 7 cts. per pound with chickens and about 5 cts. with ducklings.

Some suggestions are made regarding poultry feeding and some results obtained by other investigators are summarized.

Poultry culture, C. K. Graham (*Connecticut Storrs Sta. Bul. 52, pp. 115–134, figs. 24*).—A revised and enlarged edition of Bulletin 36 of the station (E. S. R., 17, p. 388). Notes regarding methods of preparing poultry for market have been added. A hook used to hold birds for plucking is figured and described.

Practical poultry houses and fixtures, A. F. Hunter (*Syracuse, N. Y., 1907, pp. 96, pl. 1, figs. 66*).—Poultry houses and poultry house construction, nests, feed, hoppers, and other similar topics are discussed, the descriptions being supplemented by illustrations and plans.

Experiments with ostriches. V. Scaliness and unopened feathers in the ostrich, J. E. Duerden (*Agr. Jour. Cape Good Hope, 32 (1908), No. 3, pp. 355–359, fig. 1*).—Marked scaliness of the skin and nonremoval of the outer feather sheath, which is normally done by preening, are regarded as indications of poor health, a condition likely to interfere with the production of well-grown feathers free from defects. The remedy for the trouble is the general improvement of the health of the ostriches, particularly by attention to the feed.

Farmer's cyclopedia of live stock, E. V. Wilcox and C. B. Smith (*New York and London, 1908, pp. X+745, pls. 6, figs. 450*).—In encyclopedic form the authors have summarized information on the history, anatomy and physiology, and breeding of domestic animals, principles of stock feeding, diseases of animals, business aspects of stock farming, animal products, and the different kinds and groups of farm animals.

The authors state it has been their endeavor "to present all the important facts in their logical bearing on each problem of animal production. The selection of material has been made from the viewpoint of its value to the practical stock raiser in solving the almost innumerable specific problems which he finds.

"The basis of this volume is to be sought in the bulletins and reports of the agricultural experiment stations, Federal and State departments of agriculture, live-stock periodicals, other publications of this and foreign countries, and in our own personal experience. The book, therefore, embodies those experimentally established facts and principles of animal husbandry which at present are our most reliable guides to profitable practice.

"American stock raisers are in a position to produce economically the finest of animal products of all sorts. The recent meat inspection law has enabled the Bureau of Animal Industry to devise and put in operation the most efficient system of meat inspection known to the world. This book is designed to encourage the stockman to do his part in increasing the national resources."

Animal husbandry in Denmark, 1907, A. Appel (*Maelkeritid., 21 (1908), No. 3, pp. 43–58*).—A discussion of the conditions of the industry during 1907.

Pastoral industry (*Off. Yearbook N. S. Wales, 1905–6, pp. 373–401, pls. 2*).—Statistics of the sheep and other farm animals in New South Wales and their value, the meat export trade, and related topics.

DAIRY FARMING—DAIRYING—AGROTECHNY.

A test of soiling crops for dairy cows, T. L. Mairs and F. S. Putney (*Pennsylvania Sta. Rpt. 1907, pp. 73–85*).—Further feeding tests of soiling crops (E. S. R., 19, p. 877) were made, leguminous plants being used as far as possible. The crops tested during the year were alfalfa, clover and timothy, field corn, cowpeas, rye, field peas and oats, Kafir corn and cowpeas. The saccharin sorghums fed in former years were abandoned in favor of Kafir corn, which seemed to be more palatable and furnished a better support for the cowpeas with which it was planted. Tables are given showing the yields of green forage, air-dry matter and protein, the length of time required for maturity, and the amounts fed per cow daily.

During the 3 years that alfalfa has been grown it has yielded an average of 1,328 lbs. of protein per acre. During the periods that alfalfa was fed there was a decrease in milk flow, although there was an increase in digestible protein fed. The greatest proportion of increase in the milk flow was noted when dry matter and green forage were increased but the protein diminished. "It can not be said that milk production depends upon the quantity of any one of the three—protein, dry matter, and green forage. The amount fed does not seem to bear any definite relation to the amount refused. An attempt was made to feed the cows according to their appetite, and except in the case of rye and of corn the amount refused was so small as to be of little importance."

Cooperative dairy investigations, P. N. Flint and J. E. Dorman (*Georgia Sta. Bul. 80, pp. 143–172, figs. 13*).—A report of the records of four herds as obtained on dairy farms of the State in cooperative work with the Dairy Division of this Department.

"The best cow produced in 1 year 9,257 lbs. of milk and 544.39 lbs. of butter. The poorest cow produced in 1 year 1,589 lbs. of milk and 88.02 lbs. of butter.

"The best herd produced an average of 4,873 lbs. of milk and 319.02 lbs. of butter per cow. The poorest herd produced an average of 3,653 lbs. of milk and 221.36 lbs. of butter per cow. The average production of all herds recorded was 4,385 lbs. of milk and 276.03 lbs. of butter per cow.

"The cost of producing a pound of butter varied from 10.07 cts. in the case of herd D to 15.3 cts. in the case of herd C. The cost of producing 100 lbs. of milk varied from 65.9 cts. in case of herd D to 94.2 cts. in the case of hered C. The average value of the product of the herds was $889.77, cost of feed $35.88, and profit $53.89."

Milk Production. I, Herd improvement. II, Feeding, H. A. HOPPER (*Indiana Sta. Circs. 11, pp. 8, figs. 4; 13, pp. 21, figs. 3*).—Circular 11 presents popular suggestions with reference to means of improving the dairy herd. Circular 13 is a discussion of facts and principles thus far found useful in profitable milk production.

Cows v. cows, W. J. FRASER (*Illinois Sta. Circ. 118, pp. 3–26, figs. 14*).—An address given at various dairy meetings. The author thinks that profits on an average dairy farm to-day can easily be doubled by keeping better cows. This can be done by selling off the poorest cows and raising heifers from the best stock instead of buying stock of doubtful ancestry.

Improving dairy conditions, J. M. TRUEMAN (*Connecticut Storrs Sta. Bul. 53, pp. 139–164, figs. 20*).—This is written for the milk producer, and discusses the characteristics of good dairy stock, how to feed and care for it, the sanitation and ventilation of dairy buildings, and the best methods of handling milk. There are tables showing the cost of feeding heifers at the college and the cost of milk produced by cows in the college herd under 5 years of age.

Reconstruction of dairy barns (*Bul. [Maine] Dept. Agr., 7 (1908), No. 2, pp. 41–63, figs. 13*).—The principal features of this publication are a discussion of the King system of ventilation, and hints for reconstructing the tie-up, light in dairy barns and features in all dairy barns that should receive special attention, such as stalls, mangers, floors, gutters, storage of feed, etc.

Amyl alcohol in testing [cream,] C. H. ECKLES and H. S. WAYMAN (*Chicago Dairy Produce, 15 (1908), No. 7, p. 20.*)—A small quantity of amyl alcohol colored bright red by the addition of an anilin color is dropped on the top of the column of butter fat in the test flask. Being lighter than the fat, it floats above it and thus removes the meniscus from the fat and leaves a straight line across the top of the column, thereby allowing more accurate reading of the fat than when measurement is made to the bottom of the meniscus. The readings thus made compare very closely with the results of the gravimetric determination of fat.

The Babcock test, W. B. LIVERANCE (*Michigan Sta. Circ. 2, pp. 7–16, figs. 6*).—Directions are given for using the Babcock test to determine the percentage of fat in whole milk, skim milk, buttermilk, cream, cheese, and whey.

The cost of testing pure-bred cows, J. B. LINDSEY (*Massachusetts Sta. Circ. 15, pp. 2*).—This is a supplement to Circular 9 (E. S. R., 19, p. 879), and contains a schedule of prices adopted by the Massachusetts Station for making tests for dairymen.

Standard for Babcock glassware, E. B. HOLLAND (*Massachusetts Sta. Rpt. 1907, pp. 113–119*).—A State law which took effect July 1, 1901, requires that Babcock glassware should be tested for accuracy. Up to December 1, 1907, 18,855 pieces of glassware had been tested, of which 1,770 pieces, or 9.39 per cent, were condemned. It is found that manufacturers of glassware do not use the same standard of graduation, and upon the request of the station a tentative standard of graduation has been proposed by the U. S. Bureau of Standards, which recommends that a true cubic centimeter at 20° C., equivalent to 0.998877 gm. of water at 4° C., be used for the graduation of all Babcock glassware. Suggestions are also made as to methods of testing and the limit of error.

Supervision of the milk supply (*Rpt. Bd. Health Montclair, N. J., 13 (1907), pp. 42–47*).—Some details regarding the methods and results of controlling the milk supply in Montclair, N. J., are given. According to the account presented considerable improvement has been made in the quality of the milk delivered in the city.

Fourth International Dairy Congress, 1909 (*Indus. Lait. [Paris], 33 (1908), No. 24, pp. 457–460*).—This gives the rules and programme adopted by

the Hungarian Committee of the International Dairy Convention for the Fourth International Dairy Congress to be held in Budapest in June, 1909. As in the previous congress, the first section will be devoted to dairy legislation and regulations, the second to dairy hygiene and veterinary science, and the third to dairy industry.

The National Creamery Buttermakers' Association, 1908 (*Nat. Cream. Buttermakers' Assoc. Rpt., 1908, pp. 5–119, fig. 1*).—This report includes an account of the proceedings of The National Creamery Buttermakers' Association and a number of addresses on various subjects such as starters and cream ripening, how can the buttermaker hold his patronage against unwholesome competition, how to control uniform overrun and quality in butter, creamery records, creamery employees, and others, most of the addresses being followed by considerable discussion.

The chemical composition of milk. J. B. LINDSEY (*Massachusetts Sta. Rpt. 1907, pp. 104–108*).—This contains tables showing analyses of milk from the principal dairy breeds, as compiled from various American and European sources.

The effect of food upon the composition of milk and butter fat, and upon the consistency or body of butter. J. B. LINDSEY (*Massachusetts Sta. Rpt. 1907, pp. 109–112*).—The results of a long series of experiments are summarized as follows:

"(*a*) *Effect on the milk.*—Different amounts of protein in the daily ration derived from linseed, cotton-seed, soy-bean, and corn-gluten meals do not seem to have any pronounced effect in changing the relative proportions of the several milk ingredients.

"Linseed oil in flaxseed meal, when fed in considerable quantities (1.4 lbs. digestible oil daily), increased the fat percentage from 5 to 5.56 and slightly decreased the nitrogenous matter of the milk. This fat increase was only temporary, the milk gradually returning (in 4 or 5 weeks) to its normal fat content. The nitrogenous matter also gradually returned to normal, but more slowly than did the fat.

"Three lbs. of cotton-seed meal with minimum oil (8 per cent), when fed daily to each animal, had no noticeable influence on the composition of the milk.

"The addition of 0.5 to 0.75 lb. of cotton-seed oil to the cotton-seed meal ration appeared to increase the fat percentage of the milk about 0.4 per cent (5 to 5.4), and this increase was maintained during the 6 weeks of the feeding period.

"The substitution of linseed meal with a minimum percentage of oil (3 per cent) in place of the cotton-seed meal and cotton-seed oil resulted in a decline of the fat in the milk to its normal percentage. This change probably was due to the removal of the cotton-seed oil from the ration, and not to the influence of the linseed meal.

"The addition of 0.6 lb. of corn oil to a ration made up of a mixture of grains low in fat increased the fat percentage of the milk 0.23 per cent (5.17 to 5.40). At the end of 2 weeks the effect of the corn oil had disappeared and the milk had returned to its normal fat content.

"The sudden removal of the corn oil from the daily ration caused a drop of 0.54 per cent in the fat (4.97 to 4.43), but after the first week the normal fat percentage was again present.

"Corn oil appeared to have depressed the nitrogen percentage of the milk by 0.034 per cent (0.610 to 0.576). The nitrogen gradually returned to its normal percentage after the feeding of the corn oil had ceased.

"Corn meal (a carbohydrate feed) was without effect on the composition of the milk.

"Two to 3 lbs. of soy-bean meal with a minimum oil percentage (8 per cent), fed daily to each animal, did not appear to in any way modify the proportions of the several milk constituents.

"The addition of 0.5 to 1 lb. daily of soy-bean oil to a basal ration of grain and hay very slightly increased the fat percentage in the milk during the first 2 or 3 weeks (0.1 per cent). No other variation was noted.

"The sudden removal of the soy-bean oil from the ration caused a drop of 0.25 per cent of the fat percentage of the milk. At the end of 3 weeks the milk had not regained its normal fat percentage.

"(*b*) *Effect on butter fat.*—Corn gluten and linseed meals with a minimum percentage of oil (3 per cent) produced a normal butter fat. Cotton-seed and soy-bean meals with a minimum oil percentage (8 per cent) likewise effected little change in the composition of the butter fat. Corn meal was without noticeable influence on the composition of the butter fat.

"Linseed oil (1.4 lbs. digestible oil per head daily) produced a noticeable change in the composition of the butter fat, causing a decrease in the volatile acids and an increase in the melting point and olein percentage (soft fat).

"Cotton-seed oil (0.5 lb. daily per head) increased the melting point and the olein percentage of the butter fat.

"Corn oil (0.6 lb. per head daily) decreased the volatile fats and increased the percentage of olein; the melting point of the fat remained unchanged.

"Soy-bean oil (0.5 to 1 lb. daily per head) caused a drop in the saponification number of some 10 points, a decrease in the soluble fatty acids and in the volatile fatty acids (Reichert-Meissl number), an increase in the iodin number (percentage of olein) from 32 to 40, while little or no change was noted in the melting point of the butter fat.

"A rise in the iodin number (increase in olein) is a reasonably sure indication of a soft-bodied butter which will lack in firmness at a temperature of 70° F. An increase in the melting point of the butter fat is not a sure indication of a harder, firmer butter. It seems evident that the proportions of the several fats is more or less changed by an excess of oil in the feed and that this change of proportions varies the melting point in the fat in some such way as the melting point of a mixture of metals is changed by the resulting amalgamation.

"(*c*) *Effect on butter.*—The effect of linseed meal with a minimum percentage of oil (3 per cent) on the general character of the butter was not positively identified.

"Cotton-seed meal with a relatively high oil percentage (12.6 per cent) produced butter that was rather crumbly when hard, and slightly salvy to the taste. Cotton-seed meal with a minimum percentage of oil (8 per cent) likewise produced a hard, firm butter.

"Corn gluten meal with a minimum percentage of oil (2 to 3 per cent) produced a rather soft, yielding butter.

"Soy-bean meal with minimum oil (8 per cent) produced butter that was rather softer and more yielding to the touch than that derived from a grain ration composed entirely of bran, ground corn and oats, gluten feed and cotton-seed meal.

"An excess of linseed oil (1.4 lbs. digestible oil per head daily) produced a very soft, salvy butter, with an inferior flavor.

"The addition of cotton-seed oil (0.5 lb. per head daily) to a normal ration, or to one containing 3 lbs. of cotton-seed meal in oil, produced a softer, more yielding butter than that produced by the ration with the oil omitted.

"The addition of corn oil (0.6 lb. daily per head) to a normal ration containing 2 lbs. of corn gluten meal low in oil produced a noticeably softer butter than when the oil was omitted.

"Corn meal tended to produce a reasonably hard, firm butter, of an agreeable flavor.

"Soy-bean oil (0.5 to 1 lb. daily per head) added to a grain ration produced a butter that was noticeably soft and yielding to the touch, and that would not stand up well at 70° F. and above."

The following general conclusions are drawn:

"Neither the proteid nor the carbohydrate groups, when fed in normal amount, have any noticeable influence in changing the proportions of the several milk ingredients, nor in modifying to any marked degree the character of the butter fat as revealed by the ordinary chemical tests; such changes, so far as they are the result of food, are due to the presence of oil in the feed stuff.

"Some proteids produce a harder, firmer butter than others, while the tendency of starchy foods is to produce a firm-bodied butter. Vegetable oils in excess of the normal amount produce a noticeably soft-bodied butter.

"It is not considered advisable to feed large quantities of oil to cows, it having a tendency to derange the digestive and milk-secreting organs.

"The flavor of butter depends primarily on the cleanliness of the milk, stage of lactation of the animal, skill and care of the butter maker, and especially upon the character of the starter employed. Normal feed stuffs must be considered of secondary importance in establishing butter flavor."

The action of Bacillus casei ϵ and Mycoderma thöni in the manufacture of Grana cheese, G. Fascetti (*Rev. Gén. Lait, 6 (1907), No. 23, pp. 529–533, pl. 1*).—Under the influence of these two organisms cheeses prepared according to the method of making Grana cheese, but sown with these organisms during the course of preparation, had at the end of 3 months acquired the character of Gruyère cheese as regards structure and savor, while other cheeses made at the same time but not ripened under the influence of these organisms developed as characteristic Grana cheese.

Olmützer cheese, J. V. Pavelka (*Abs. in Rev. Gén. Lait, 6 (1907), No. 23, pp. 538–545, figs. 4*).—The method of making this kind of cheese in the village of Olmütz, in Moravia, is described and illustrated.

Cheese making in Cuba, N. S. Mayo and C. G. Elling (*Estac. Cent. Agron. Cuba Bul. 2, pp. 3–28, pls. 6, figs. 9*).—This publication describes in more or less detail the processes which the authors believe best adapted for making cheese in Cuba.

Mannitic fermentation in apple and pear cider, Truelle (*Bul. Soc. Nat. Agr. France, 68 (1908), No. 4, pp. 263–267*).—This is an extract from a report of investigations by Müller-Thurgau, published elsewhere. Special attention is called to the conclusions of this investigator that mannitic fermentation appears quite frequently in apple and pear cider prepared from fruits slightly acid, from sweet apples or from ripe pears, and is always accompanied by the formation of a large quantity of lactic and acetic acids as well as their ethers. These defects result from the action of certain bacteria or ferments which develop, when slightly acid juice from very ripe fruit has a relatively high temperature. Various methods of preventing the fermentation are suggested, as selecting proper fruit, using potassium metabisulphite or sulphurous acid, and other ways.

Honey vinegar, A. E. Vinson (*Arizona Sta. Bul. 57, pp. 247–255, fig. 1*).—The crude methods of making honey vinegar now in use often result in a great loss of saccharin material. As honey diluted with ordinary well water is deficient in mineral and nitrogenous matter, the effect of adding ammonium chlorid and potassium phosphate on the activity of the yeast cells was studied. Honey was diluted 1:5 with well water supplying sufficient lime and mag-

nesia, and 250 cc. portions were inoculated with a yeast culture. Two flasks receiving no additional mineral matter showed an average total carbon dioxid loss of 10.17 gm. in 3 weeks, 14.12 gm. in 6 weeks, and 17.73 gm. in 13 weeks, at which time the wine produced contained 7.23 per cent of alcohol by weight. Two flasks receiving each 0.25 gm. of ammonium chlorid lost on an average 13.58 gm. carbon dioxid in 3 weeks, 16.01 gm. in 6 weeks, and 17.66 gm. in 13 weeks, the wine containing 6.89 per cent of alcohol. In two flasks each receiving 0.25 gm. ammonium chlorid and the same amount of potassium phosphate there was an average loss of 17.82 gm. carbon dioxid in 3 weeks and 18.26 gm. in 6 weeks, and an alcohol content of 7.5 per cent. It is concluded that ammonium chlorid accelerates fermentation in the early stages. Where both ammonium chlorid and potassium phosphate were used the fermentation was practically complete at the end of the third week.

A comparison of wild yeasts with commercial yeasts showed that although fermentation was nearly as complete at the end of 2 weeks with wild yeasts the percentage of alcohol was lower and other fermentation products were contained in the wine. It is deemed advisable to add a little pure yeast as a starter. It is stated that a very palatable cider may be produced from fermented honey, but the cask must be thoroughly cleansed by steam or hot water.

Full directions are given for making honey vinegar by the following formula: Strained honey 40 to 45 lbs., water 30 gal., ammonium chlorid 4 oz., potassium bicarbonate 2 oz., sodium phosphate 2 oz., and one quarter cake dry yeast softened in lukewarm water. A modification devised by the station of a French generator for making small amounts of vinegar is described.

Vinegar from whey, F. Marre (*Indus. Lait. [Paris], 33 (1908), Nos. 24, pp. 467–468; 25, pp. 477–478*).—In the author's opinion vinegar can be made from whey with a considerable margin of profit, but special attention must be given to the use of proper ferments and to the conditions under which the whey is fermented.

VETERINARY MEDICINE.

Annual report on progress in the study of pathogenic micro-organisms, P. von Baumgarten and F. Tangl (*Jahresber. Path. Mikroorgan., 21 (1905), 1. Abt., pp. 1–400; 2. Abt., pp. XII+401–941*).—Bibliographical lists are given together with abstracts of the more important articles published during the year 1905 on parasitic protozoa, fungi, and bacteria affecting animals and man. An account is also given of the progress made during the year in the field of general micro-biology and technique and practice of disinfection.

The poisonous effects of blood of different species, G. Lefmann (*Beitr. Chem. Physiol. u. Path., 11 (1908), No. 7–9, pp. 255–273*).—The intravenous injection of lipoid substances from the blood of another species of animal introduced in dogs, cats, and rabbits causes symptoms which consist largely in the lowering of the blood pressure, an increase in the rate of respiration and heart beat, and paralysis and narcosis. Lipoid substances from the blood corpuscles of other individuals of the same species are not poisonous for dogs and rabbits, but are slightly so for cats. The poisonous substances were found to be soluble in ether and alcohol but insoluble in chloroform.

Immunization against calf dysentery, swine plague, etc., Bugge (*Landw. Wchnbl. Schles. Holst., 58 (1908), No. 18, pp. 353–356*).—A general account is given of the significance of natural acquired immunity and active immunity in relation to calf dysentery, calf pneumonia, and swine plague.

Injurious fodder and poisonous plants, H. T. Güssow (*Jour. Roy. Agr. Soc. England, 68 (1907), pp. 32–63, figs. 11*).—Among the harmful conditions

which may arise in fodder, mention is made of ergot, smuts, molds, and other parasitic fungi. A rather extensive list of poisonous plants is given with brief notes on the physiological effects of these plants and the means of combating them.

Report of the veterinarian, S. B. Nelson (*Washington Sta. Rpt. 1905, pp. 16–20*).—In an investigation of a disease affecting new-born animals, especially pigs, in the central part of the State, water taken from the section where the disease prevailed was analyzed by the station chemist and found deficient in mineral salts. The disease is attributed to malnutrition, due to this cause, and recommendations are made that pregnant sows be fed precipitated calcium phosphate.

Two experiments were conducted to determine the effect of treatment of decayed teeth of horses, in which the amount of hay wasted and the weight of the animal were recorded during a period prior to the operation upon the teeth, during the period of recovery, and following recovery.

In the first experiment, "with the same amount of hay fed during the first period of 14 days, with 280 lbs. fed and 66 lbs. wasted, the horse averaged 998.7 lbs. During the second period of 11 days after the operation with 220 lbs. fed, and a waste of 83 lbs., the average weight was 995.3, or 3.4 lbs. less than during the first period.

"The third period of 14 days, with 280 lbs. of hay fed, and 9 lbs. of waste, the average weight was 1,013 lbs., a gain over the first period of 14.3 lbs. and on the second of 17.7 lbs. The waste during the first period was 2.43 per cent; second period, 33.33 per cent; and the third, only 3.2 per cent of the hay fed."

A second horse operated on gave an average weight of 1,099 lbs. for the 15 days prior to the operation, and an average of 1,112 lbs. for the 14 days following, or an average gain of 13 lbs.

Annual report for 1907 of the principal of the royal veterinary college, J. McFadyean (*Jour. Roy. Agr. Soc. England, 68 (1907), pp. 201–210*).—In this report the author compares the conditions observed during the year with those observed in other years with respect to anthrax, glanders, swine fever, Johne's disease, and redwater in cattle. With regard to the transmissibility of bovine tuberculosis to man the results obtained by recent investigations are considered as indicating the correctness of the conclusion that such transmission may and does take place.

The standardization of tetanus antitoxin, M. J. Rosenau and J. F. Anderson (*Pub. Health and Mar. Hosp. Serv. U. S., Hyg. Lab. Bul. 43, pp. 59*).—An American unit for the standardization of tetanus antitoxin was officially defined in 1907. According to this definition "the immunity unit for measuring the strength of tetanus antitoxin shall be 10 times the least quantity of antitetanic serum necessary to save the life of a 350-gm. guinea pig for 96 hours against the official test dose of a standard toxin furnished by the Hygienic Laboratory of the Public Health and Marine Hospital Service." In the present bulletin a historical view is given of previous work on tetanus toxin and antitoxin, on the methods of standardization which have been adopted, and on the necessity for the present standard. Descriptions are also given of German, Italian, and French methods for standardizing tetanus antitoxin together with tables for guidance in diluting the toxin and antitoxin.

The cause of milk sickness or trembles, E. O. Jordan and N. M. Harris (*Jour. Amer. Med. Assoc., 50 (1908), No. 21, pp. 1665–1673*).—A brief historical account is given of the occurrence of this disease in various parts of the United States. The authors had opportunity to study the disease in New Mexico and Texas at points far removed from the region where it has ordinarily been

reported. The symptoms of milk sickness were studied in man, cattle, and horses and experimentally the disease was produced in laboratory animals by inoculation.

The chief lesions which were observed in cases of milk sickness in animals were in the liver, heart, musculature, kidneys, and small intestines. These lesions were of a parenchymatous nature such as is usually produced by the action of a toxin. Particularly in the liver, cloudy swelling and fatty metamorphosis were very pronounced. A micro-organism, referred to as *Bacillus lactimorbi*, was isolated and its behavior studied in a number of nutrient media. The symptoms of milk sickness were reproduced in rabbits, guinea pigs, dogs, and calves by inoculation with *B. lactimorbi*.

The problems involved in determining the pathology and etiology of this disease will be studied more elaborately. The cases observed by the authors occurred in a region where *Eupatorium ageratoides* does not grow. This plant, therefore, can not be considered as the cause of the disease.

The properties of races of trypanosomes resistant to atoxyl and sera, F. Mesnil and E. Brimont (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 14, pp. 637–640*).—Experiments in the inoculation of laboratory animals for the trypanosomes of surra and nagana indicate that there are races of these trypanosomes which are decidedly resistant to the action of atoxyl. It was also shown that in some cases resistance of trypanosomes to immune sera is hereditary.

The relation between human and bovine tuberculosis, A. Eber (*Verhandl. Deut. Path. Gesell., 1907, pp. 191–194*).—Human tuberculosis material proved in experiments to be highly virulent for 7 cattle and 1 goat and less virulent for 7 other cattle, while 3 cattle and 1 goat were quite resistant. In corresponding experiments with tuberculosis material of bovine origin, a similar variation in virulence was observed in inoculated cattle. The author concludes from his experiments that tuberculosis material from children or from adult persons, particularly those who are suffering from pulmonary tuberculosis, may be virulent for cattle.

Points of entrance of tuberculosis, G. Railliet (*Rev. Tuberculose, 2. ser., 5 (1908), No. 2, pp. 107–156*).—An elaborate review is presented of the results obtained by various investigators in a study of the modes of tuberculosis infection. It is argued that the results thus far obtained indicate that the penetration of the tubercle bacillus through the conjunctiva, genital mucous membranes, healthy skin, or slight skin abrasions must be considered of rare occurrence or of slight importance. The two chief modes of entrance of the tubercle bacillus into susceptible organisms are by means of air into the lungs and by food into the alimentary tract. The relative importance of these two means of infection varies according to age, individual resistance, and various other factors.

Mode of infection and immunity in tuberculosis, Klebs (*Verhandl. Deut. Path. Gesell., 1907, pp. 183–188*).—In carrying on experiments in the artificial inhalation of tubercle bacilli much care is necessary in order to imitate as closely as possible the conditions of natural inhalation, otherwise the results obtained will have little bearing upon the problem of determining the frequency of this method of infection. In the course of the author's experiments a special form of tuberculin has been prepared which in an impure state has the effect of causing a pronounced contraction of the arterial walls, especially in the lungs and liver. When, however, the toxin which causes contraction of the blood vessels is separated from the tuberculin the latter has the effect of increasing the avidity with which the wandering leucocytes take up tubercle bacilli. The leucocytes which are chiefly concerned in the destruction of tubercle bacilli are

multinuclear and are believed by the author to be derived chiefly from the spleen.

Hematogenous tuberculosis, Morpurgo (*Verhandl. Deut. Path. Gesell., 1907, pp. 189–191*).—In experiments with rabbits and guinea pigs it was found that when only a few tubercle bacilli gain entrance to the circulating blood the primary lesions will appear in various parts, the degree of progressiveness depending upon special susceptibility of the animal. If the animal is particularly susceptible, infection progresses rapidly, assuming in most cases the form of miliary tuberculosis with almost constant localization in the lymphatic organs.

The occurrence of latent tubercle bacilli in the lymphatic glands of cattle and hogs, Joest (*Verhandl. Deut. Path. Gesell., 1907, pp. 195–209*).—The literature relating to the occurrence of tubercle bacilli in the lymphatic glands is critically reviewed. The author maintains on the basis of his investigation that from a histological standpoint there is no latent tuberculosis of the lymphatic glands. It is necessary to make a microscopic examination of suspected lymphatic glands in order to determine whether or not tubercle bacilli are present. The investigations reported by the author were made on cattle, hogs, and goats, and led the author to conclude that there is never any latent tuberculous lesion in the lymphatic glands of cattle or hogs affected with generalized tuberculosis.

Eradication of tuberculosis, J. Niven (*Vet. Rec., 20 (1908), No. 1033, pp. 762–769*).—A brief tabular statement is given showing the results of the inspection of dairy cows with respect to the percentage of mammary tuberculosis, clinical tuberculosis, and incipient forms of the disease recognizable only by the tuberculin test. For the control and eradication of tuberculosis among dairy herds the plans suggested by the author include the division of the country into administrative areas each provided with a veterinary staff, the registration and marking of all dairy cows, isolation of tuberculous cows, immediate slaughter of all advanced cases, sterilization of milk from all tuberculous cows, and compensation to owners for slaughtered cattle, at least for a period of 1 or 2 years.

Contagious abortion in cattle, F. W. Wilson (*Arizona Sta. Bul. 57, pp. 279–283*).—Several cases of this disease are reported from different localities in the State. In the station herd the disease is thought to have been communicated to 5 cows through the medium of the sire. Later, under strict sanitary conditions, one of the affected animals was served from this sire and dropped a living calf. A number of cows on neighboring farms have recently been served by this sire and showed no signs of abortion. The cause of the disease and its treatment are discussed.

Retention of the afterbirth in cattle, C. Pomayer (*Das Zurückhalten der Nachgeburt beim Rind. Berlin, 1908, pp. 64, figs. 9*).—The literature relating to the retention of the afterbirth is critically reviewed and a brief bibliography of the subject is given. The author discusses the processes involved in the natural separation of the fetal membranes from the uterine wall, and reports observations made chiefly on microscopic sections showing the connection between the fetal and uterine tissues at different stages in the development of the fetus. According to these observations the afterbirth is retained for an unusual period or there is total inability to expel it in cases in which the process of parturition is unusually long or in which excessive weakness of the animal was brought about by defective nutrition, distention of the rumen, excessive heat, or the presence of disease.

With regard to the prognosis in cases of retention of the afterbirth any evidence of septic infection must be looked upon seriously since such infection is

very difficult or impossible to check. The author criticizes unfavorably the view that retention of the afterbirth may be due to an insufficient amount of lime in the ration. It is held that a ration deficient in lime may lead to a general state of malnutrition in the animal but that in such cases the mere addition of lime to the ration will not bring about a normal parturition with the expulsion of the afterbirth within the usual period.

Hook-worm disease of cattle, A. F. Conrad and E. Barnett (*South Carolina Sta. Bul. 137, pp. 5–23, figs. 8*).—From post-mortem examinations made upon 4 heifers taken from the college herd it was found that these animals were seriously infested with the hook worm of cattle (*Monodontus phlebotomus*) previously known to occur in Texas and Florida. In two of these cases other parasites were almost entirely absent, while in two stomach worms (*Hæmonchus contortus*) were fairly numerous.

Thymol did not appear to affect the worms greatly, as in a post-mortem examination made on the third day following a dose of 150 grains, numerous stomach worms were found in the fourth stomach, myriads of hook worms in the duodenum, and many inflated bowel worms (*Œsophagostoma inflatum*) in the cecum. The results of fecal examinations, made in each animal, are given in tabular form. Life-history studies of hook worms were made and are reported.

Experiments were made to determine the extent to which the worms may be eliminated by moving 2 heifers from the infested herd to a disinfected shed known to be free from infestation. One of the animals gradually improved, while the other continued to become weaker until the condition became such that it was killed. The authors considered the principal method of host infestation to be through the mouth.

In examinations of the pasture in which the experimental herd was kept, larvæ were only found in material from the lowland and about the barn. In March the larvæ were very numerous in the bottom lands, while it was difficult to find any upon the upland. There appeared to be little development in the feces dropped on a hill during the drought of summer and little danger from infestation in running water.

At present the outlook for a cure is not encouraging. To reduce infestation, drainage, plowing, and burning are suggested. "It is recommended that on hook worm infested farms annual crop rotation be practiced as far as possible. The manure should be removed from stables occupied by infested animals daily and air-slaked lime used liberally to dry up the floors. The greatest precaution should be exercised to prevent the spread of this parasite into localities where it does not yet occur, either by shipments of infested cattle or otherwise."

Notes are also given on *Cooperia punctata* and *Œsophagostoma inflatum*.

Milk fever: Its prevention and successful treatment (*South Carolina Sta. Bul. 139, pp. 3–13 figs. 6*).—Considerable loss of cattle in the State has been due to this disease about which most cattle owners know very little. The author describes the cause of the disease, the symptoms, and methods of treatment. Attention is called to the importance of preventive treatment. The use of drugs is considered and the oxygen and sterile air treatments are described. The results obtained by the station from the use of oxygen and sterile air in 2 cases are given in tabular form. All of these recovered, with the exception of one that had been drenched, which died from gangrene of the lungs.

Notes on the cattle tick and tick fever of cattle, R. R. Dinwiddie (*Arkansas Sta. Bul. 101, pp. 185–210*).—These notes contain observations and experiments on the local life history of cattle ticks with reference to the problem of tick eradication in north Arkansas, experiments on the natural and artificial transmission of tick fever, and tests of treatment by hyperimmune serum and by in-

travenous medication. Following are some of the conclusions arrived at by the author:

"Tick infestation in the northern counties of Arkansas is due partly to yearly importation from farther south (and west in the case of Washington and Benton counties) and partly to overwintering. Larval forms (seed ticks) survived without host from October to April and probably later, but did not survive till June.

"Perpetuation of tick infestation in north Arkansas is largely due to the periods of unseasonable weather common in this region—periods of summer weather during winter season. For the purpose of tick eradication quarantine of ticky cattle should therefore be enforced in winter also.

"Adult female cattle ticks do not survive over winter in this region but may deposit eggs even in midwinter during warm spells of weather and thus perpetuate the species.

"Larval forms and ova of the cattle tick both failed to produce infection when injected subcutaneously into susceptible cattle. The blood of the adult female tick was found to be uncertain in its action but probably infectious only during the first few days after reaching maturity.

"Quinin has no specific action in this disease. Intravenous injection of Lugol's iodin solution was effective in destroying the infective property in the blood in one case but merely delayed its action in another. The maximum dose for yearlings is about 30 cc."

Tick eradication in Arkansas in 1907, W. Lenton (*Arkansas Sta. Bul. 101, pp. 211–220*).—Attention is called to the great loss due to the cattle tick and the benefits to be derived from its eradication. An act passed in May, 1907, made it possible to cooperate actively with the Bureau of Animal Industry of this Department and the work of eradication was commenced toward the end of May. The author describes in detail the methods used.

As a result of this work, on April 1, 1908, six counties were released from quarantine and admitted to the free area. State funds having become exhausted, the amount necessary to guarantee protection to the quarantine line was raised by popular subscription. At present the expense of maintaining a quarantine line in the State falls on the people of the six counties (Benton, Carrol, Clay, Randolph, Lawrence, and Green) below which the line runs. It is expected, however, that the next legislature will appropriate funds to protect the quarantine line and also for tick eradication in other counties.

The cattle tick, L. L. Lewis (*Oklahoma Sta. Circ. Inform. 11, folio*).—Attention is called to the importance of eradicating the cattle tick in Oklahoma, and an account is given of the methods by which this may be accomplished.

Cattle dipping, W. M. Power (*Natal Agr. Jour., 11 (1908), No. 3, pp. 322–324*).—Dipping is believed to be a very valuable means of ridding cattle of ticks, but, in the author's opinion, if adopted, it is necessary to have tick-free pastures on which to turn the cattle, otherwise they become reinfested and the work counts for little. The author argues against compulsory dipping laws in localities in which there are many natives who do not believe in the effectiveness of dipping.

A specific lung disease of calves, L. E. W. Bevan (*Jour. Compar. Path. and Ther., 21 (1908), No. 1, pp. 35–43*).—During the past 8 years a number of outbreaks of a lung disease have appeared in Rhodesia with a mortality of 50 per cent or greater. The most characteristic symptom of the disease is a short cough, the other symptoms being scarcely characteristic. Affected animals do not lose their appetite. The principal post-mortem lesions are found in the lungs which are studded with small nodules appearing upon the surface or in

the tissue of the lungs. In advanced cases the nodules become densely clustered together.

The symptoms and post-mortem lesions are carefully outlined for the purpose of assisting in a differential diagnosis between the disease and white scour, pleuro-pneumonia, and other diseases with similar symptoms. The disease in question appears to be able to remain in a latent condition in the animals and breaks out in acute form when, for any reason, the resisting power of the animal is lowered. Treatment of the disease is for the most part without avail.

Scab: Its nature, cause, symptoms, and treatment, D. HUTCHEON (*Agr. Jour. Cape Good Hope, 32 (1908), No. 4, pp. 433–448, figs. 11*).—The symptoms of scab in various animals are outlined and notes are given on the different species of mites which cause scabies of different sorts, together with a brief discussion of the complaints which have been raised by wool dealers as to the injury caused to wool by the use of certain dips. Wool dealers are by no means of the same opinion on this point.

The author considers that in the treatment of scab no other remedy can compete with a mixture containing sulphur, and recommends a lime-sulphur dip containing 25 lbs. of sulphur and 18 lbs. of lime in 100 gal. of water. A formula is also given for the preparation of a sulphur and caustic soda dip for sheep and goats.

Anemia and pasteurelloses, J. LIGNIÈRES (*Bul. Soc. Cent. Méd. Vét., 85 (1908), No. 8, pp. 187–190*).—Since evidence has been furnished that hog cholera may be produced by a filterable virus independently of the so-called hog cholera bacillus it has been suggested that perhaps other bacteria which have been referred to the pasteurella group may be of secondary pathogenic importance. The author combats this theory and argues that the hog-cholera bacillus differs in many respects from the other members of the pasteurella group.

Swine erysipelas, H. HOLTH (*Norsk Vet. Tidsskr., 20 (1908), No. 5, pp. 113–126*).—The present status of swine erysipelas in various European countries is outlined and statistical data are given regarding the prevalence of the disease and the percentage of mortality. In localities where preventive vaccination has been thoroughly applied the prevalence of swine erysipelas has been greatly reduced.

The occurrence of the bacilli of swine erysipelas in the gall bladder of hogs which have recovered from the disease, W. PITT (*Centbl. Bakt. [etc.], 1. Abt., Orig., 46 (1908), No. 5, pp. 400–405*).—From the observations and experiments thus far made it appears that the bacilli of swine erysipelas persist longest in the gall bladder of recovered animals and may be found in that organ after they have disappeared from all other parts of the body. The bacilli may be found in recovered hogs after attacks from mild or acute cases of the disease. The bacilli found in the gall bladder are viable and virulent.

A germ-free extract for the prevention of swine plague, PFEIL (*Berlin. Tierärztl. Wchnschr., 1908, No. 17, pp. 301, 302*).—On an estate badly infected with swine plague the author inoculated 45 hogs with a mixture of polyvalent swine-plague serum and a germ-free extract of the bacillus of swine plague. All of these animals were immunized by this treatment and remained healthy, while check animals living under the same conditions became infected in a large percentage of cases.

The poisoning of hogs by kitchen swill, H. FRESENIUS (*Atti 6. Cong. Internaz. Chim. Appl., 4 (1906), pp. 457–461*).—An account is given of an outbreak of poisoning among a herd of hogs fed on the swill from the kitchen.

Chemical examination of the stomach contents in one case indicated the presence of traces of mercury, copper, and lead. Attention is called to the fact that

acid food materials preserved in tin utensils or other receptacles soldered with lead preparation may ultimately dissolve and contain some lead. In the case under discussion, however, it was not certain that the poisonous effects were not partly due to ptomaine poisoning since there was a large amount of fragments of lobster, crabs, oysters, and fish in the swill.

The horse: Ailments and accidents, F. T. BARTON (*Philadelphia, Pa., 1908, pp. 192*).—The purpose of this volume is to supply the amateur horse raiser with information regarding the common ailments and accidents which affect the horse and to indicate the symptoms and nature of serious diseases which require the service of a trained veterinarian.

Cutaneous and conjunctival reaction in glanders, DIETRICH (*Arch. Wiss. u. Prakt. Tierheilk., 34 (1908), No. 3, pp. 246–257*).—Neither the cutaneous nor conjunctival method of applying mallein gave the correct indication in the case of 10 glanderous and 6 healthy guinea pigs. With glanderous horses the conjunctival reaction was positive in only 46 per cent and the cutaneous reaction was negative in every instance. Neither of these methods of applying mallein is considered reliable.

Mallein reaction, MIESSNER (*Arch. Wiss. u. Prakt. Tierheilk., 34 (1908), No. 3, pp. 233–245*).—In experiments carried on by the author it was found that in certain cases healthy horses react to mallein and that sometimes glanderous horses do not react. Mallein is, therefore, considered an unreliable diagnostic reagent. A reaction is considered reliable if the elevation of temperature is 2° C. or more and if other local and general symptoms of reaction appear. An injection of mallein into a healthy horse has no effect upon a subsequent injection, but in case of diseased horses it reduces the intensity of the second reaction.

Intratracheal injection of iodin for joint-ill in foals, W. LOTHIAN (*Vet. Rec., 20 (1908), No. 1034, pp. 777, 778*).—Very satisfactory results are reported in treating joint-ill in foals by intratracheal injection of 3 drams of a solution containing 2½ grains of iodin and 5 grains of iodid of potash to the ounce of water. The injection is repeated daily for 2 or 3 days and then every other day until decided improvement is manifest. As a rule, 5 or 6 injections are sufficient.

A preliminary report on the so-called cerebro-spinal meningitis of horses, H. J. MILKS (*Louisiana Stas. Bul. 106, pp. 3–17, pls. 4*).—This disease was prevalent in certain parts of the State during the fall of 1906 and the summer of 1907. It was not confined to any particular locality, occurring in lowlands and in the hill and bluff districts. Animals of all ages were attacked and horses apparently more than mules, and cases appearing in rather widely separated localities. An account is given of the symptoms and post-mortem appearance. Inoculations of rabbits, guinea pigs, and of a horse were made, but none of the animals showed any effect therefrom. The cause of the disease or of its infective nature was not determined by the investigations. No microorganism was encountered that would account for the disease. It is stated that if the statements made by different owners regarding materials consumed by different animals be accepted as accurate, the theory of food contamination does not seem well founded. However, until the exact nature of the agent producing the disease, as well as a possible remedy, has been discovered, it is recommended that upon first symptoms the feeding materials be changed. References to literature are given.

A new method of vaccination against strangles, L. BARUCHELLO (*Rev. Gén. Méd. Vét., 11 (1908), No. 129, pp. 497–509*).—The methods which have been commonly used in vaccinating horses against strangles are critically reviewed by the author.

An essentially new method of vaccination is proposed which consists in using the pleural exudate of rabbits and guinea pigs killed by inoculation with the streptococcus of strangles. The pleural exudate thus obtained is employed in a hyper-immunizing process, the exudate being used first only after sterilization and filtration and later without sterilization. Horses thus treated require a high degree of immunity and furnish a vaccine which has given good results in the several hundred cases in which it has been tried.

Statistical data on dog distemper, D. Wirth (*Tierärztl. Zentbl., 31 (1908), No. 13, pp. 200–205*).—Opportunity was had to make numerous observations on dog distemper at the veterinary high school in Vienna. The data thus collected are presented in tabular form. It appears that the disease is not influenced by the race of dog. Female dogs show a tendency to develop the nervous form of the disease in a higher percentage than do male dogs. The mortality was no higher in pups than in adult dogs.

Report of the veterinarian, J. B. Paige (*Massachusetts Sta. Rpt. 1907, pp. 156–163*).—European fowl cholera of a mild type broke out on two farms in one locality during the year. In one case the disease was stamped out by destroying the flock, thoroughly cleansing the houses, and using disinfectants. In the other case, cleaning the houses and the use of disinfectants appear to have been efficient. While the source of contamination could not be determined, the disease is supposed to have been introduced through fowls purchased from traveling dealers in live poultry.

A disease broke out in brooder chicks in one locality on Cape Cod, in which the mortality ranged from 90 to 100 per cent, but never made its appearance among adult fowls or young chickens aside from those brooded in brooders. Numerous remedies employed proved of no avail and analysis of the soil for suspected irritating poisonous substances yielded negative results, but in experiments made upon chicks by concentrating the sun's rays upon the legs and feet by a lens, lesions were produced identical with those on brooder chicks. The removal of all chicks to a location with vegetation sufficient to protect the featherless and tender portions of the body from the heat of the sun, as recommended, has apparently prevented the trouble.

Fatal septicemia in young chickens or white diarrhea, L. F. Rettger and S. C. Harvey (*Jour. Med. Research, 18 (1908), No. 2, pp. 277–290*).—The disease commonly known as white diarrhea has been confused with fowl cholera and also with ordinary diarrhea which may be due to changes of climate and improper rations. The virulent form of white diarrhea, however, according to the investigations of the authors, is due to a bacillus which is closely related to the coli bacillus, hog-cholera bacillus, and typhoid bacillus. The behavior of the micro-organism on various nutrient media is described. When an infection has once become established it appears to be a difficult matter to eradicate it, and it is likely to appear on the same premises for 2 or 3 years in succession. There appears to be no cure for the disease, but a spread of infection may be largely checked by thorough cleansing and disinfection of incubators, brooders, and inclosures in which chicks are kept.

Spirochetosis of fowls in southern Rhodesia, L. E. W. Bevan (*Jour. Compar. Path. and Ther., 21 (1908), No. 1, pp. 43–49, figs. 2*).—The literature relating to this disease is briefly reviewed.

As a rule, fowls affected with spirochetosis die within a few hours. They suffer from thirst and pronounced weakness from the time of appearance of the first symptoms. The chief post-mortem lesion is anemia. Apparently the disease is associated with *Argas persicus*, which may be instrumental in transmitting it. In preventing infestation of the premises with this tick it is recommended that adult fowls be inspected and quarantined before admitting them to

the premises and that all infested coops or crates be thoroughly treated with a suitable insecticide. Somewhat encouraging results were obtained in treating affected fowls with atoxyl and quinin.

RURAL ENGINEERING.

Practical irrigation; its value and cost. A. J. Bowie, Jr., (*New York, 1908, pp. VIII+232, figs. 53*).—This book deals with certain phases of the subject of water supply for irrigation rather than with the use of water in irrigation, and the greater part of it is devoted to wells, pumps and pumping machinery, and storage reservoirs.

About one-third of the space is given to artificial reservoirs made entirely in embankments. Such reservoirs are not in general use, but in the author's opinion there is a large field for their use in storing water where natural reservoir sites are not available. Formulas, curves and tables for computing water holding capacity, cubic contents of embankments, and cost are given.

In addition to the subjects treated at length, mentioned above, there are brief discussions of methods of irrigation, evaporation, flow of water in ditches, methods of charging for water, and irrigation near Bakersfield, Cal. In general, the book consists of miscellaneous observations on the subjects discussed. The treatment of all subjects is mathematical, the book containing many hydraulic formulas and tables.

Reports upon the administration of the irrigation services in Egypt and in the Sudan for the year 1906 (*Cairo: Govt., 1907, pp. 58, pls. 4, dgms. 2, charts 2*).—This report consists of a general report by Sir William Garstin, adviser to the ministry of public works, and detailed administrative reports by A. L. Webb, under secretary of state for irrigation in Egypt, and C. E. Dupuis, inspector-general of irrigation in the Sudan.

The report shows large increases in the area devoted to cotton and the statement is made that this increase will continue so long as the present prices of cotton are maintained. This increase is made possible by the change from the basin system to perennial irrigation depending upon the Assuan dam. It is now estimated that the conversion works in Middle Egypt will, when completed, provide perennial irrigation for about 420,000 acres, formerly included in basins, at a total cost of about $21,000,000, or approximately $50 per acre. On the basis of work so far done this will increase the rental value of the lands about $21 per acre and the selling value about $275 per acre. The author states that while these figures may seem large they are in no way exaggerated.

It has been found that the floods discharged by the Assuan dam have eroded the channel below the dam, the pits in some cases going below the foundation of the dam and rendering it unsafe. This damage has been repaired by blasting out the rotten rock, filling the holes with masonry, and constructing an apron below the dam which modifies the discharge of the water from the sluice in such a way that no erosion takes place. It is considered that since these repairs there is no danger to the dam from this source.

The work done in the Sudan consisted entirely of surveys preliminary to the making of plans for the improvement of the headwaters of the Nile. The object to be attained is the prevention of losses into the marshes during low water without destroying their usefulness as an escape for flood water. The surveys have not proceeded far enough to allow the formulation of any definite plans for accomplishing this.

Experiments in irrigation, Gerlach and Krüger (*Arb. Deut. Landw. Gesell., 1908, No. 141, pp. 52, pls. 8, figs. 2*).—This is an account of experiments carried on at the Kaiser Wilhelm Institute at Bromberg during the dry year of 1906

and the wet year of 1907 on fertilized and unfertilized plats of corn, oats, beets, and carrots, using 5.9 in. and 11.8 in. of water. Irrigation was decidedly beneficial in the dry year and the beneficial effect was increased by the addition of fertilizers, but in the wet year irrigation not only was not beneficial but even resulted in a decreased yield, due, it is thought, to a leaching out of the fertilizing matter from the soil.

Measurement of water, E. T. TANNATT and R. D. KNEALE (*Montana Sta. Bul. 72, pp. 3–40, pls. 7, figs. 7*).—This is a revision and extension of Bulletin 34 of the station (E. S. R., 14, p. 94), describing the various units employed in measurements of water, and the construction and proper use of weirs and flumes, and also including tables for calculating the discharge over weirs. The use of the second-foot is strongly advised in order to avoid misunderstandings. Common errors made in measuring devices and reasons for failure are pointed out in the text and illustrated by photographs of weirs actually constructed. Mention is made of an automatic measuring instrument patented by E. B. Howell for accurately measuring the depth of water on a weir.

Preliminary tests of sugarhouse machinery, E. W. KERR (*Louisiana Stas. Bul. 107, pp. 3–16, figs. 6*).—This contains results of preliminary tests made to get information as to the relation of capacity to energy consumed and as to the efficiency of machinery peculiar to sugarhouses.

The methods of testing sugar-mill work are discussed. That of determining the volume of juice in the bagasse per unit weight of fiber in the bagasse is deemed impracticable because of difficulty in determining the density of the juice. The method of using percentage of weight of moisture in the bagasse is considered accurate enough for practical purposes.

Tests were made on a mill of the 6-roller type in which the mill rolls were 34 by 84 in., and there was a pressure of 330 tons on the front mill and 390 tons on the back mill supplied by the hydraulics. The indicated horsepower of the engine, when operating the mill, is compared with its rated capacity and also with its indicated horsepower when under no load. The friction of the mill as thus determined shows a probable loss of but 5 per cent in mill friction.

Tests were also made of a cane carrier operated by direct current electric motor. The carrier was 600 ft. long, the vertical lift 27 ft., and the cane was being carried at the rate of 49.26 tons per hour during the tests. The horsepower figured from measurements by voltameter and ammeter, compared with the useful work done, shows an efficiency of 13.7 per cent, 86.3 per cent being lost in friction.

A set of four 30 in. centrifugals of '97 model of Weston type, used for drying second sugars, and a set of five 40 in. Weston centrifugals, used for drying first sugars, were tested to determine the power required both for starting and running. Power for the 30 in. centrifugals was supplied by direct current electric motor and for the 40 in. by an automatic high-speed engine. The starting power of the motor was measured by noting the maximum ammeter reading, and the running power by the reading when the needle came to rest. The results show that the running power is about 25 per cent of the starting power. The power required to start indicates the capacity of the source of power, but not the energy necessary to be supplied by the boiler in the case of a steam engine.

It was attempted to measure the horsepower of the engine by means of a steam-engine indicator and a speed indicator, but this method proved unsatisfactory because of irregularities "due to the fact that the speed counter could not be depended upon to indicate accurately the speed at the moment of starting. A tachometer will be procured for future use."

Applications of electricity to agriculture, D. Hermenegildo Gorria (*Mem. R. Acad. Cien. y Artes Barcelona, 3. ser., 6 (1908), No. 33, pp. 57*).—This article discusses at some length the utilization of natural supplies of power in the production of electricity and the applications of electricity in electro-culture, in the destruction of insects, in assisting the germination of seed and the fixation of nitrogen in soils and plants, the production of nitrogenous fertilizers by means of electricity, and the use of electricity in various farm operations—heat, light, power, and communication. It is shown that there are a great many useful applications of electricity in agriculture which might be profitably employed through cooperation or associations of farmers, if not by the individual farmer.

The equipment of farms and country houses with electricity, P. A. Bates (*Jour. Franklin Inst., 166 (1908), No. 1, pp. 47–49, figs. 45*).—This article discusses various kinds of machinery and appliances used in the equipment of farms and country houses with electricity.

RURAL ECONOMICS.

The mistakes of farm management as determined by bookkeeping (*Landw. Ztschr. Rheinprovinz, 9 (1908), No. 26, pp. 354, 355*).—The net returns of 8 farms differently managed as to the extent of field culture, number of live stock, fertilizers purchased, etc., show a range from a loss of 0.18 mark to a gain of 30.7 marks per hectare, as compared with the average net returns of 57 well-managed farms of 48.9 marks per hectare. The management of each of the 8 farms is described.

Piecework in agriculture, Stieger (*Mitt. Deut. Landw. Gesell., 23 (1908), No. 29, pp. 241–250; Bl. Zuckerrübenbau, 15 (1908), Nos. 14, pp. 213–222; 15, pp. 235–243*).—The author discusses the influence of piecework on the agricultural labor problem in Germany, with particular reference to the benefits accruing both to the farmer and to the laborer from this form of agreement.

Piecework in the place of a day wage is advocated as a means of counteracting the effects of rural depopulation by accomplishing a greater amount of work with a given number of laborers. The benefit to the farmer of piecework lies in hastening the work of the farm and relieving him of overseeing to a great extent; the benefit to the laborer lies in his greater independence, larger income, and development of character.

What influence has piecework upon the agricultural labor problem and how can its most important features be carried out? T. Römer (*Illus. Landw. Ztg., 28 (1908), No. 76, pp. 651–661, figs. 5*).—The author discusses the reasons for introducing piecework into agriculture, the terms of agreement, the greater amount of work accomplished by this form of employment, the practicability of piecework in the agricultural industry, its effects upon the worker, and the general results. The author concludes that "piecework in agriculture operates very favorably upon the labor situation, being advantageous to both the laborer and the employing farmer; that, on account of his greater income, it raises the economic condition of the farm laborer and improves his character; and that these results are undoubtedly to be credited to the operation of piecework."

The Belgian migratory laborer, F. Ryziger (*Ann. Gembloux, 18 (1908), No. 8, pp. 470–478*).—This is a critical dissertation on a work by J. Frost entitled Belgische Wanderarbeiter. The author sets forth certain facts regarding the farm laborer's mode of life, the causes of emigration, number of farm laborers migrating to Holland, France, and Germany, the wages paid in the different countries as compared with the wages paid in Belgium, and the kind and length of service. Suggestions are made looking to the economic and social improvement of this class of laborers.

The second congress of mutual credit and agricultural cooperative societies, F. Lesourd (*Jour. Agr. Prat., n. scr., 16 (1908), No. 28, pp. 51–54*).—A summarized account of the topics discussed at the meetings of this congress. These topics related in general to the limitations of mutual agricultural credit banks, the utilization of agricultural credit in relation to forest conservation, agricultural credit in nature, credit based on word of honor, security for the future of mutual agricultural credit, agricultural insurance in relation to mutual credit, etc.

Mutual agricultural insurance societies in 1908 (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), Nos. 8, pp. 953–964; 9, pp. 1087–1098; Rev. Vit., 30 (1908), No. 763, pp. 128, 129; Semaine Agr. [Paris], 27 (1908), No. 1419, p. 242; Jour. Agr. Prat., n. scr., 16 (1908), No. 31, pp. 133, 134*).—The number of societies in France was 8,780 in June, 1908. Of this number there were 7,241 societies insuring live stock with 53 banks, 1,442 against fire with 16 banks, and 24 against hail. The live stock insurance societies had 398,375 members and the cattle insured were worth 429,209,667 francs. The fire insurance societies had 31,964 members with property insured valued at 277,556,706 francs.

Annual report on the working of cooperative societies in the Punjab for the fifteen months ending June 30, 1907, S. Wilberforce (*Ann. Rpt. Work. Coop. Soc. Punjab, 1907, pp. 24+VII*).—Detailed statistics of number of cooperative credit societies, memberships, receipts, disbursements, loans, etc., are presented and discussed. At the close of the period the societies numbered 174 as compared with 28 at the beginning, the corresponding figures of membership being 17,254 and 1,525, respectively. The financial standing of the societies was equally flourishing.

International agricultural institute, L. C. Griscom (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3252, pp. 6, 7*).—A brief report is given of the first session of the permanent committee of the International Institute of Agriculture held at Rome from May 23 to June 6, 1908. The general desire was to create an international statistical bureau for the compilation of the world's agricultural products. The permanent committee was to meet again on November 10 and the general assembly on November 20.

The modern state and agriculture, A. Gomes Carmo (*O Estado Moderno e a Agricultura. Rio de Janeiro: Govt., 1908, pp. LXXXV+419, pls. 4, figs. 62*).—This volume presents statistics and other data relating to the development, condition, and government aid of agriculture in the United States, Canada, Mexico, Argentina, Switzerland, France, Belgium, Portugal, Denmark, and some of the British colonies, with lists of the publications consulted in the compilation of the work.

America's amazing agricultural advance (*Manfrs.' Rec., 54 (1908), No. 5, pp. 41, 42*).—Statistics of agricultural wealth production, value of farm property, and of population engaged in agriculture during the years 1870 to 1908, inclusive, are presented and discussed in this article.

The increase in value of farm products is shown by the statement that "in the 20-year period between 1870 and 1890 the gain was only $500,000,000; in the 30-year period between 1870 and 1900 the gain was only $2,800,000,000; whereas in the 8-year period from 1900 to 1908 the gain was $3,300,000,000, or $500,000,000 more than for the 30 years from 1870 to 1900." In 1907 the value of farm products raised was $7,412,000,000, the value of all farm property $28,077,000,000, and the number of people engaged in or dependent on agriculture 11,991,000. The great increase in wealth production is attributed to the rapid growth in scientific farming.

The American farmer feeding the world, W. M. Hays (*World's Work, 16 (1908), No. 4, pp. 10597–10603, figs. 27*).—Statistics of the quantity, value, and

destination of the exports of the main agricultural products are discussed and diagrammatically illustrated in this article.

The author calls attention to the fact that the grains and oil cakes exported contain large quantities of nitrogen, phosphoric acid, and potash and could be more profitably utilized on the farms in the United States by being fed to live stock, etc. In this way there would be returned "to our own soils the tens of millions of dollars' worth of fertilizer ingredients and in addition several million tons of humus-making substances other than nitrogen, phosphoric acid, and potash. We would induce the change of the crops of more of our farm areas to grasses and annual forage crops, which both rest the soil and add to it organic matter which adds greatly to the profits from crops."

Settlement and agricultural development of the northwest provinces of Canada, E. H. Godfrey (*Jour. Roy. Statis. Soc., 71 (1908), No. 2, pp. 397–404*).—The information contained in this article is largely summarized from a publication previously noted (E. S. R., 19, p. 1191).

Agriculture in Denmark, Tisserand (*Bul. Soc. Nat. Agr. France, 68 (1908), No. 6, pp. 376–414; Jour. Soc. Statis. Paris, 49 (1908), Nos. 8, pp. 264–275; 9, pp. 296–308*).—This is a general review of the progress made in all branches of agriculture in Denmark from 1855 to 1907, including data on agricultural production, conditions of farm labor, size of farms, etc. The chief causes of progress are given as scientific investigations and government aid, the chief directions in which these forces have operated being pointed out. Data are also presented and discussed relating to agricultural organizations and cooperative societies.

Notes on agriculture in South Australia, W. L. Summers (*Adelaide: Govt., 1908, pp. 61, figs. 55*).—This brochure gives information concerning agricultural conditions and opportunities in South Australia and is finely illustrated with scenes typical of the agriculture in different sections of the country.

[Agricultural statistics of Australia], G. H. Knibbs (*Off. Yearbook Aust., 1908, pp. 219–385, dgms. 7*).—These chapters, dealing respectively with land tenure and settlement, pastoral production, agricultural production, farmyard and dairy production, and forests, forestry, and forestal products of Australia, give statistical information with discussion relating to these topics from 1787 to 1906, inclusive. They comprise a historical sketch of agricultural development in Australia for more than a century.

Agriculture in Japan, H. Sharp (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3255, pp. 9–12*).—A brief account is given of agricultural conditions in Japan, including notes on land areas, implements used, extent of fertilizer importation, irrigation practices, and agricultural exports and imports for 1906 and preceding years.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 10 (1908), No. 10, pp. 73–80*).—The condition of crops in the United States and foreign countries, data on the farm values of principal crops and range of prices of agricultural products in the United States, and a summary of the crop acreage and live stock in the United Kingdom are reported to October 1, 1908.

AGRICULTURAL EDUCATION.

Agriculture the basis of education, O. F. Cook (*Reprint from Monist, July, 1907, pp. 347–364*).—In this paper the author develops his thesis on the long recognized fact that agriculture furnishes the material basis for civilization, and proceeds to show that while this fact has been recognized, educators seem to have forgotten that agriculture is just as truly the basis of intellectual and social development. He believes that "the mental conditions of agriculture

are just as essential to the normal development of the human mind as air, food, and exercise for the development of the body," and that "by no system or method of formal education can children confined to city houses, doorsteps, paved streets, and schools be brought to their full mental stature."

The mission of the Christian college, E. E. Reed (*Lenox Col. Bul., 4 (1907), No. 10, pp. 22*).—This is the inaugural address of Pres. E. E. Reed, of Lenox College, Hopkinton, Iowa, and consists largely of an argument in favor of teaching agriculture in denominational colleges, especially in the 3 years preparatory to the college course.

Development of agricultural education, E. E. Brown (*Jour. Ed. [Boston], 67 (1908), No. 24, pp. 648–650*).—A brief account of the development of agricultural education in the United States.

The agricultural college and its relationship to the scheme of national education, E. J. Wickson (*Addresses and Proc. Nat. Ed. Assoc., 45 (1907), pp. 1041–1048*).—Previously noted as Circular 31 of the California Station (E. S. R. 19, p. 993).

What has been done by normal schools and agricultural colleges for popular education in agriculture, E. E. Balcomb (*Addresses and Proc. Nat. Ed. Assoc., 45 (1907), pp. 1069–1075*).—This paper, presented at the 1907 convention of the National Education Association, is a compilation of information secured by correspondence from the different State normal schools and agricultural colleges concerning their efforts to extend popular education in agriculture.

Agriculture in normal schools: Courses of instruction and financial support, E. E. Balcomb (*Addresses and Proc. Nat. Ed. Assoc., 45 (1907), pp. 752–758*).—A paper presented at the 1907 convention of the National Education Association.

On the training of persons to teach agriculture in the public schools, L. H. Bailey (*Bur. of Ed. [U. S.] Bul. 1, 1908, pp. 53*).—This paper was prepared at the request of the United States Commissioner of Education and is divided into three parts: (1) The nature of the problem, which contains a discussion of the problems of the elementary schools, high schools, and special schools of agriculture; (2) the means of training the teachers, among which are aids to teachers, such as summer schools, regular teachers' institutes, lectures, correspondence and leaflet work, short courses in agricultural colleges, peripatetic teachers, and the educational work of this Department, and courses for the training of new teachers in normal schools, training classes, separate agricultural schools, special foundations, education departments and teachers' colleges, and colleges of agriculture, and (3) the general outlook and the significance of normal work in the colleges of agriculture, in which the writer includes information on some of the work now undertaken for the training of teachers in some of the agricultural colleges.

The work of the National Government in extending agricultural education through the public schools, D. J. Crosby (*Addresses and Proc. Nat. Ed. Assoc., 45 (1907), pp. 1063–1069*).—This is a paper presented at the 1907 convention of the National Education Association, in which the discussion is limited to two main considerations: (1) Financial aid from the Federal Government, and (2) expert assistance from Federal Executive Departments.

Report of the committee on industrial education in schools for rural communities (*Addresses and Proc. Nat. Ed. Assoc., 45 (1907), pp. 409–446*).—This report, which was submitted at the 1907 convention of the National Education Association, is the second report of this committee and supplements that submitted at the 1905 meeting (E. S. R., 17, p. 196). The report was written by L. H. Bailey, and includes (1) a discussion of the general problem of the

rural school and the importance of articulating it with the activities of life, description of new types of rural school buildings, discussion of school gardens, manual training, and separate agricultural schools, mention of agencies which contribute to the nationalizing of the work, and the author's opinion concerning the kinds of schools in which agriculture may be taught; (2) data concerning the present status of industrial work in rural schools in New England, New Jersey, Pennsylvania, and New York; (3) experiences and opinions of individual teachers in the territory mentioned; and (4) a discussion by the author on the preparation of teachers for industrial schools in rural communities.

Agricultural instruction for soldiers. F. MAIER-BODE (*Fühlings Landw. Ztg., 57 (1908), No. 6, pp. 201–210*).—An account is presented of the first course of instruction in agriculture given to subalterns and privates in the German army at Augsburg, beginning January 15, 1907, and extending over 20 days. Instruction was given on the origin, formation, and management of soils, the composition and use of manures and fertilizers, plant life, farm crops, diseases and insect pests of plants, grasses and forage crops, care of the orchard, animal husbandry and nutrition, milk and its utilization, farm management, and farm accounts. The work of the first course was attended with such success that courses have since been given in 14 other places with a total attendance of 2,970.

School gardens. J. VERCIER (*Jour. Soc. Nat. Hort. France, 4. ser., 9 (1908), April, pp. 243–261, dgm. 1*).—This article contains brief statements regarding the condition of agricultural instruction in the primary and normal schools of France and the part taken by the teacher, the need of developing a taste for agriculture in the child and the methods employed in accomplishing it, the necessity of introducing practical work in the present agricultural instruction in the primary school, school gardens in Cote-d'Or, an outline plan for a garden, a school nursery, results obtained during 8 years' experience, and suggestions for the future development of the work.

Farm bacteriology. W. C. PALMER (*Winona Lake, Ind., 1908, pp. 18*).—This deals with bacteria in their relation to the decay of organic matter, nitrogen in soils, changes in milk, cream, butter, and cheese, preservation of food, and diseases of animals. There is also a brief discussion of disinfection and disinfectants.

Hints for eastern Oregon farmers. J. WITHYCOMBE ET AL. (*Oregon Sta. Circ. Bul. 2, pp. 24*).—A circular of information concerning agronomy, horticulture, chemistry, and animal husbandry prepared for distribution among farmers attending meetings on a farming demonstration train.

MISCELLANEOUS.

Twentieth Annual Report of Massachusetts Station, 1907 (*Massachusetts Sta. Rpt. 1907, pp. 172*).—This contains the organization list of the station, a report of the director, which includes lists of the publications during 1907, and of the bulletins and reports available for distribution, a financial statement for the fiscal year ended June 30, 1907, a report of the meteorologist, and other departmental reports, parts of which are abstracted elsewhere in this issue.

Annual Report of Pennsylvania Station, 1907 (*Pennsylvania Sta. Rpt. 1907, pp. III+236*).—This contains the organization list of the station, a financial statement for the fiscal year ended June 30, 1907, a report of the director on the work of the station during the year, together with a synopsis of its work

since 1887, and other departmental reports, of which that of the meteorologist is abstracted elsewhere in this issue. The report also contains reprints of Bulletins 82, 83, and 85 previously noted and of an article on The Available Energy of Red Clover Hay (E. S. R., 19, p. 866), and articles reporting A Test of Soiling Crops for Dairy Cows, and on Small Fruits in 1906, abstracted elsewhere in this issue. An appendix to the report of the librarian presents a check list of the official publications of the Pennsylvania State College.

Nineteenth Annual Report of Tennessee Station, 1906 (*Tennessee Sta. Rpt. 1906, pp. 91–108, figs. 2*).—This contains the organization list, reports of the director and members of the station staff, and a financial statement for the fiscal year ended June 30, 1906.

Seventeenth Annual Report of Utah Station, 1906 (*Utah Sta. Rpt. 1906, pp. XLIX*).—This includes the organization list, reports of the director and heads of departments, reviews of the publications issued during the year, a list of bulletins and circulars issued up to January, 1907, and a financial statement for the fiscal year ended June 30, 1906.

Twentieth Annual Report of Vermont Station, 1907 (*Vermont Sta. Rpt. 1907, pp. 299–518*).—This contains the organization list, a brief announcement concerning the station, a financial statement for the fiscal year ended June 30, 1907, a report of the director containing a list of publications of the station available for distribution, abstracts of Bulletins 124–130 of the station issued during the year, results of miscellaneous analyses, a report on the Vermont State nursery for forest tree seedlings, and numerous other articles abstracted elsewhere in this issue. A special feature is the presentation of condensed outlines, arranged by subjects, of articles published in Annual Reports 1–19 and Bulletins 1–133, comprising the publications of the station from its establishment in 1887 to 1907.

Abstract Twentieth Report, 1906–7 (*Vermont Sta. Buls. 136, pp. 187–222; 137, pp. 227–264*).—These bulletins give a brief résumé of the annual report of the station noted above. Bulletin 136 includes plant diseases, horticulture, weeds, and insects, and Bulletin 137 crops, forestry, stock feeding, and dairy husbandry.

Thirteenth Annual Report of Washington Station, 1903 (*Washington Sta. Rpt. 1903, pp. 28*).—This includes the organization list, a report of the director and heads of departments, and a financial statement for the fiscal year ended June 30, 1903.

Fourteenth Annual Report of Washington Station, 1904 (*Washington Sta. Rpt. 1904, pp. 20*).—Data similar to the above are given for the fiscal year ended June 30, 1904.

Fifteenth Annual Report of Washington Station, 1905 (*Washington Sta. Rpt. 1905, pp. 31*).—Data similar to the above are given for the fiscal year ended June 30, 1905. The report of the veterinarian is abstracted on page 379 of this issue.

[Index to Volume IV of Arizona Station publications], W. O. Hayes (*Arizona Sta. [Index] Bul. 1902–1905, pp. 557–590*).—An index to Bulletins 41–51 and the Annual Reports from 1902–1904.

Experiment Station Work, XLVII (*U. S. Dept. Agr., Farmers' Bul. 329, pp. 32, figs. 4*).—This number contains articles on the following subjects: Low-grade *v.* high-grade fertilizers, improvement of sandy soils, dry farming, seed selection, evergreens—uses and culture, nut growing in Maryland, "hogging off" corn, mineral matter in feeding stuffs, preparation of miscible oils, an automatic cheese press, and cane sugar and beet sugar.

NOTES.

Hawaii Station.—The station has planned a set of breeding experiments with Sea Island, Caravonica and Egyptian cottons covering 5 acres of land and a fertilizer experiment covering 10 acres. As a result of experiments already under way a marked revival in interest in cotton growing is reported, and it is expected that within the near future about 10,000 acres will be planted. Requests have been made for the selected Sea Island and Caravonica seed greatly in excess of the station supply. The climatic and other conditions of the islands appear to be very favorable for the growth of cotton of a high grade.

Kansas College and Station.—E. H. Webster, Chief of the Dairy Division of this Department, has accepted the position of dean of agriculture in the college and director of the station to take effect January 1, 1909.

New Hampshire Station.—The station has adopted the plan of reprinting the scientific articles based on work done at the station and contributed by members of its staff to periodicals, as a numbered series to be known as Scientific Contributions of the New Hampshire Agricultural Experiment Station. The series is to be sent to the libraries of the agricultural colleges and experiment stations, and to this Department, but is not to be available for general distribution. Scientific Contributions Nos. 1 and 2, already issued, contain, respectively, reprints of The Influence of Minimum Temperatures in Limiting the Northern Distribution of Insects, from the *Journal of Economic Entomology*, and The Fruit Spot of Apples, from the *Bulletin of the Torrey Botanical Club*.

Nebraska University and Station.—W. H. Hein has resigned as adjunct professor of agricultural botany and assistant botanist and has been succeeded as adjunct professor by R. E. Stone of the Alabama College. M. H. Swenk, whose appointment as assistant entomologist in the station has been previously noted, has also been appointed adjunct professor of entomology. Robert F. Howard has been appointed assistant horticulturist in the station, beginning December 10.

Wisconsin University.—The first sessions of a bakers' institute organized by the university extension department were held in Milwaukee, October 26–28, and were attended by about 170 bakers. The course included lectures by professors in the university, specialists of this Department, and others, concerning raw materials and products used by bakers, bacteria and yeasts, methods of baking, food values, bakeshop hygiene and sanitation, and other related subjects.

Association of Official Agricultural Chemists.—This association held its twenty-fifth annual convention in Washington, D. C., November 12–16, 1908. Over 200 delegates and visitors were in attendance, the largest in its history, the number being considerably augmented by the meetings of other agricultural organizations in the city. On invitation of the association a brief address was given by Secretary Wilson of this Department in which he directed attention to the questions of soil improvement and pure foods, and to the opportunity open to the association in these lines. During the sessions opportunity was afforded for an inspection of the workings of the denatured alcohol plant of the Bureau of Chemistry.

The address of the president, Prof. Harry Snyder of the Minnesota University and Station, was entitled The Training of the Agricultural Chemist. In this address was emphasized the necessity for the maintenance of high ideals to be developed by a special technical training in agricultural chemistry, coupled with a broad equipment in other lines so that the worker may "outline an investigation, plan intricate details, carry the work to a satisfactory conclusion, and correctly interpret the results." The speaker advocated the establishment in some of our institutions of courses of study having for their specific object the training of agricultural chemists, these courses to present a correlation of the different sciences blended with general and technical chemistry. The development of correct methods was regarded as fundamental, though not always fully appreciated in the desire for immediate results. A knowledge of technical processes of manufacture was deemed essential in the inspection of agricultural products. The position of the agricultural chemist was regarded as in a transition stage, but with the tendency toward larger opportunities, better compensation, and greater recognition, although research work was still handicapped by inadequate preparation and lack of equipment and intelligent support. The field of the association was also discussed, its special province being considered the study and perfection of methods of analysis.

The initial day of the convention was, as usual, devoted largely to papers on food adulteration. A general report was submitted by H. E. Barnard, referee, together with more detailed reports by the associate referees. J. Hortvet, associate referee on wine, discussed the determination of volatile and fixed acids and reducing sugars, and called attention to the necessity of a special study of the determination of glycerol and the examination of the natural coloring matter in wines. H. E. Barnard reported on beer analysis a necessity for the refinement of the present analytical methods and additional differentiation of the various types of beer. Considerable progress was reported in the study of methods for brewing materials, especially on the determination of fat and gluten. L. M. Tolman, associate referee on distilled liquors, presented modifications of the Allen-Marquardt method for fusel oil.

The associate referee on vinegar, C. H. Hickey, presented a study of the lead number for pure cider vinegar. E. M. Chace, associate referee on flavoring extracts, reported that highly satisfactory results had been obtained by collaborators using the provisional methods, except with that for citral, which needs further study. The work with spices, reported by A. L. Winton, was restricted to a study of the adulteration of paprika with olive oil and its detection. The report of H. M. Loomis, associate referee on colors, indicated that the vegetable coloring matters are not sufficiently well understood and the methods of identification inadequate, and that study of the separation and identification of colors is desirable.

The associate referee on dairy products, H. C. Lythgoe, reported a study of methods for the preparation of milk serum and the detection of calcium sucrate in cream. A report of progress on work in cereal products, especially fat determinations in flour, was submitted by E. F. Ladd. W. L. Dubois, associate referee on vegetables, presented a study of the water content of fresh and soaked canned peas. A report on meat and fish was made by F. C. Weber. The work on preservatives, reported by W. D. Bigelow, discussed an attempt to simplify the quantitative estimation of salicylic and benzoic acids and the study of cinnamic acid, which is said to be coming into use by reason of its antiseptic properties. A. G. Woodman, associate referee on tea, coffee, and cocoa, reported cooperative work on caffein and tannic acid in coffee, sugar in tea, crude fiber and starch in chocolate and sugars in milk chocolate, and a special

study, made jointly with W. C. Taylor, was presented on the Estimation of Caffetannic Acid and Caffein in Coffee.

An unusual amount of attention was devoted by the association to the subject of medicinal plants and drugs. L. F. Kebler made an extended report as referee, followed by a paper by B. J. Howard, discussing Microchemical Methods for the Identification of Alkaloids in Drugs, and W. O. Emery outlined methods for the separation of caffein, acetanilid, and sodium bicarbonate. A paper on Pharmalogical Investigations on Effects of Drugs was presented by W. Salant, and Dr. H. H. Rusby gave an illustrated lecture on simple methods of detecting common drug adulterants.

The work of the year on meat proteids, presented by P. F. Trowbridge, took the form of the preparation and analysis of cold water extracts from different wholesale cuts of fresh beef from steers slaughtered in connection with feeding investigations at the Missouri Station. L. L. Van Slyke, referee, submitted a report on the separation of nitrogenous bodies (milk and cheese proteids), presenting cooperative work on a volumetric method of determining milk casein.

The referee on nitrogen, C. L. Penny, reported cooperative work on the determination of nitrate nitrogen. The report of the referee on inorganic plant constituents, H. D. Haskins, dealt with the development of a method for the determination of iron and aluminum in ash. C. C. McDonnell reported on insecticides and fungicides.

S. D. Averitt, referee on soils, reported cooperative work with reference to the determination of total potash and phosphorus, and J. G. Lipman, associate referee, submitted a report on the determination of calcium carbonate in soils. The work on potash reported by B. B. Ross, referee, included cooperative tests of the official method in comparison with the phospho-molybdic volumetric method with some cooperative work on special methods.

J. M. McCandless, referee on potash, reported cooperative work on the examination of basic slag, the determination of iron and aluminum in rock phosphate, and an examination of ammonium citrate solutions as to neutrality. Papers were submitted by J. B. Lindsey on Thomas slag, and by H. D. Haskins on The Valuation of Phosphoric Acid in Basic Slag, the latter recommending a study of Wagner's method.

The work on dairy products reported by the referee, J. M. Bartlett, was in continuation of that of the previous year on analytical methods of condensed milks. E. B. Holland submitted a paper on a Standard for Babcock Glassware, noted on p. 374 of this issue. F. W. Morse, associate referee on cattle foods, reported a study of a modification of Ellet's method for methyl pentosan. A paper was read by J. P. Street on The Determination of Acidity in Cattle Feeds, in which the need for further study of acidity, especially that due to protein bodies, was pointed out, and T. B. Wagner discussed the processes of manufacture of gluten feed with particular reference to color and acidity.

The work on sugar was reported by A. H. Bryan, referee, and Fritz Zerban, associate referee. Cooperative studies were presented on methods of moisture determination and the effect of clarifying agents on the polarization. The referee also submitted a subreport on The Use of the Refractometer in Determining Dry Substances, and papers on the detection of small quantities of glucose in sirups and honey and The Determination of Total Sulphur Dioxid in Molasses.

An innovation in the meetings was the setting aside of the final day of the convention for the reading of special papers and their discussion. The following papers were presented: Methods Relating to the Rate of Decomposition of

Organic Matter in the Soil, J. G. Lipman; Determination of Sulphurous Acid and Sulphites or Sulphur Dioxid in Food Products, E. Gudeman; The Possibilities of Muscovado Sugar as an Adulterant for Maple Products, R. E. Doolittle and A. F. Seeker; Notes on the Winton Lead Number of Mixtures of Cane and Maple Sirup, R. E. Doolittle and A. F. Seeker; A Discussion of Methods for Determining the Availability of Phosphoric Acid in Thomas Phosphate Powder (Basic Slag Phosphate), G. D. Leavens; The Determination of Fusel Oil in Distilled Liquors, A. S. Mitchell; Distilled Liquors, L. M. Tolman and W. E. Hillyer; Composition of Paprika, R. E. Doolittle and A. W. Ogden; Determination of the Iodin Number of the Nonvolatile Ether Extract of Paprika, W. Denis; Determination of Starch in Cocoa Products, W. L. Dubois; Examination of Oysters, W. D. Bigelow; Some Simple Methods for the Detection of Blended and Bleached Flours, A. L. Winton; Moisture Determinations without Heat, P. F. Trowbridge; The Unification of Polarimetric Observations, C. A. Browne; The Influence of Glycerin and Acetanilid in the Estimation of Alcohol in Pharmaceutical Preparations, L. E. Warren and H. C. Fuller; Citral Methods, C. O. Dodge; Citral and its Analysis in Terpeneless Oil of Lemon, S. H. Baer; The Identification of Coal Tar Colors, C. B. Cochran.

Reports of standing committees were presented by L. F. Kebler on testing chemical reagents and W. Frear on food standards, together with a subreport on Methods of Assaying Opium, by C. F. Parker. A report of progress was submitted by H. W. Wiley on fertilizer legislation, recommending postponement of further action until the next meeting. J. K. Haywood made a final report for the committee on revision of methods, stating that Bulletin 107 of the Bureau of Chemistry had been issued embodying such changes as were deemed necessary. A resolution was reported from the committee on resolutions by L. L. Van Slyke, advocating the enactment of Federal legislation regulating the composition and sale of insecticides and fungicides, and adopted by the association.

An amendment to the constitution proposed at the 1907 meeting was adopted, extending membership in the association to delegates from Canada and Mexico. The appointment of a committee of three to cooperate with similar committees from other organizations in this country in unifying methods for the analysis of fats and oils with a view to the establishment of an international commission for this purpose was authorized, but the membership of the committee has not as yet been announced. A referee and associate referee were authorized on waters, to study methods for the analysis of mineral, sanitary, irrigation and technical waters, an associate referee to consider the definition of the term "available potash," and two associate referees on drugs.

In accordance with a decision of the previous year a standing committee on recommendations and revision of methods was elected as follows: For three years, B. B. Ross, E. M. Chace, C. D. Howard; for two years, J. P. Street, F. W. Woll, A. L. Winton; and for one year, J. K. Haywood (chairman), F. P. Veitch, L. M. Tolman. The question of the adoption and printing of conversion tables was also referred to this committee. L. M. Tolman, M. E. Jaffa, A. B. Adams, R. J. Davidson, and H. E. Barnard were appointed a committee on the standardization of alcohol tables.

Officers were elected for the ensuing year as follows: President, W. D. Bigelow, Washington, D. C.; vice-president, W. A. Withers, Raleigh, N. C.; secretary, H. W. Wiley, Washington, D. C.; and additional members of the executive committee, E. F. Ladd, Fargo, N. Dak., and E. B. Holland, Amherst, Mass.

American Association of Farmers' Institute Workers.—The thirteenth annual meeting of this association was held in Washington, D. C., November 16 and 17. There were 257 delegates and visitors registered, representing 42 States, 1

Territory, and 3 provinces of Canada, besides one visitor each from New Zealand and the Transvaal. Secretary Wilson, of this Department, made a brief address, in which he described the sending out by the Department of demonstrators in different lines of farm practice, stating that "my experience in the Iowa Agricultural College of six years, my experience in the Department of Agriculture of twelve years has brought me back around again to the cap-sheaf of agriculture—the sending out of people to lecture to the farmers." The Commission on Country Life was in attendance at one of the sessions, and Chairman L. H. Bailey, of the commission, explained its object and invited suggestions for the betterment of country conditions. By invitation, the association attended as a body a meeting of the National Grange, which was then in session in Washington.

The annual presidential address, made by Dr. Tait Butler, in discussing the ways in which the institutes had been of service, affirmed that "the carrying of agricultural knowledge to the adult farmer and the instruction of the adult members of his family in household economy is naturally and unquestionably the true and legitimate field which should be chiefly if not exclusively cultivated by the farmers' institutes." The speaker strongly advocated increased Federal appropriations for the dissemination of agricultural information in this way. He also declared it to be "the duty of the farmers' institutes to give their aid and moral support to every institution, organization, and force that has for its object the upbuilding of a better agricultural civilization," and commended the women's institutes as a means to this end.

An address was also made by Dr. James W. Robertson, president of MacDonald College, on The MacDonald Movement for the Improvement of Rural Conditions in Canada, in which attention was directed to the immediate need for teachers of agriculture for the rural schools. President Robertson explained in some detail the method employed in Canada for supplying this need through the education of teachers in MacDonald College.

The reports of the standing committees showed that the institutes were rapidly developing, particularly in the direction of movable schools of agriculture, and of boys', girls', and women's institutes. The committee on movable schools reported that these schools were held during the year in 10 States and 5 Canadian provinces. In the opinion of the committee, "wherever movable schools have been held they have met with favor, and it seems that the time is now ripe for the very general adoption of this form of extension teaching."

The committee on boys' and girls' institutes called attention to the remarkable growth of this form of extension work, but expressed a belief that the first work of the institute in behalf of the boy and the girl is to be done with the parents. Among the new features developed during the year was the "farm encampment," where the boys live in tents and are taught in classes in such subjects as corn and live-stock judging, seed identification and tile draining. At one of these encampments a tented school of household science for girls was introduced, which proved a most interesting feature.

Women's institutes were strongly indorsed by the committee on that subject as having demonstrated, in localities where they have been long established, their great practical value in the refinement of farm homes and in the betterment of rural conditions in general.

The subjects in the general programme were mainly directed toward defining the status of the farmers' institute in its relation to other forms of agricultural education, Dean Davenport discussing the agricultural college, Director Burnett the experiment station, F. H. Hall the normal school, F. L. Stevens the agricultural high school, A. B. Graham the rural public schools, President J. H. Connell the agricultural journals, and Alva Agee the agricultural fair associations.

The papers and discussions in the main were to the effect that the farmers' institute occupies the position of field agent for agricultural education, that it provides a most effective channel for carrying agricultural information directly to the farmer who is unable to leave his occupation to go to school, and that it should broaden its work until it embraces other more advanced forms of extension work, and extend its efforts until all rural people have opportunity to enjoy its benefits.

The general progress of the farmers' institute movement in the United States was shown by the reports presented by the various State directors and by the Farmers' Institute Specialist of this Department. The latter report showed the number of sessions held by the regular institutes in 43 States and Territories to have been 14,059, with an attendance at regular and special institutes of 2,215,690. The appropriations to institutes in 46 States and Territories were $320,564, and the total number of institute lecturers in the employ of the State directors in 47 States and Territories was 1,118. In four of the provinces of Canada—Alberta, Quebec, Saskatchewan, and Ontario—the number of half-day sessions was 7,266, with a total attendance of 321,963. A remarkable development of institutes for women in Canada was shown by the report of the Province of Ontario, where 3,978 sessions were held with 93,951 in attendance.

A resolution was adopted indorsing the work already done in forwarding the interests of farmers' institutes by this Department through the Farmers' Institute Specialist, and requesting the executive committee of this association to confer as soon as practicable with the Secretary of Agriculture and with this Office relative to the needs of this work, and to urge upon Congress the appropriation of a sum sufficient to enable the Department adequately to develop it.

The officers elected for the ensuing year were: President, J. L. Ellsworth, Boston, Mass.; vice-president, G. A. Putnam, Toronto, Ontario; secretary-treasurer, John Hamilton, Washington, D. C.; executive committee, the president and the secretary ex-officio; A. M. Soule, Athens, Ga.; H. T. French, Moscow, Idaho; F. H. Hall, Aurora, Ill.

First International Congress for the Repression of Adulteration of Alimentary and Pharmaceutical Products.—This congress was held in Geneva, September 8–12, 1908. About 400 delegates were in attendance, 250 from France and the remainder representing 28 other nations. The chief business of the congress was the formulating of definitions of food and drug products for adoption as an international "codex alimentarius." The second congress will be held in Paris in 1909.

Miscellaneous.—Wm. Fawcett, Director of Public Gardens and Plantations, Jamaica, has retired.

Botanisches Centralblatt of August 11, 1908, records the death of Dr. F. Noll, professor of botany at the University of Halle, at the age of 50 years.

Sir Daniel Morris retired from the post of Imperial Commissioner of Agriculture for the West Indies, November 30.

Philippe de Vilmorin, the present head of the seed firm, Vilmorin, Andrieux et Cie., and well known among horticulturists and plant breeders of this country, has been nominated as Chevalier of the Legion of Honor of France.

LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

Stations in the United States.

Stations in the United States—Cont'd.

U. S. Department of Agriculture.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of *Experiment Station Record* is $1.50 per volume, or 15 cents per number. The prices of other technical publications are given above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XX. JANUARY, 1909. No. 5.

The recent convention of the Association of American Agricultural Colleges and Experiment Stations, of which a brief account is given in the present number of the Record, brought out very clearly the growing tendency to confine the functions of this association to matters relative to the more general problems connected with the organization and management of the institutions represented in the association. The great growth of these institutions and the expansion of the scope and variety of the educational and research enterprises under their control have greatly complicated their organization and brought to their managers many problems which in detail at least are different from those of other educational and scientific institutions. It is therefore very important that these institutions shall have a common meeting ground where the general principles governing the solution of these newer problems of education and research may be thoroughly discussed with a view to the establishment of standards, the differentiation of the local and common characteristics of the problems, and the elucidation of the various difficulties in the light of experience from many sources. As a delegate body, consisting chiefly of the presidents of colleges and directors of experiment stations, the association is especially qualified for work in this field. This has further been facilitated by the changes in the organization of the association which has limited the number of sections and committed so much important work to standing committees. Recent experience has indicated the desirability of carrying the plan involved in this organization further toward its logical conclusion. It has become clearer that papers of a technical character dealing with the methods and results of special researches are out of place in such an association. Care should therefore be taken in arranging the programmes so to word the questions to be discussed that the presentation of such technical matters will clearly be out of order. It also seems desirable further to restrict the number of matters to be brought forward at any one meeting. Considering the wide territory covered by the institutions and the consequent difference in point of view on many questions, it is very desirable that there should be opportunity for full discussion so that the con-

clusions reached will really represent the best judgment of the association. It is also very desirable that the members of the association should be able to give their undivided time and attention to the questions before the association at any one meeting.

There has of late been great activity in the organization of societies of agricultural specialists in various lines for the discussion of the problems in agricultural science relating to these specialties. This movement has progressed so far that naturally a desire has arisen for the affiliation of these organizations in order that provision may be made to promote their general interests and to permit the general discussion of matters in which all or several of them have a common interest. In the discussion of plans for affiliation one fundamental distinction needs to be kept ever in mind. Societies for the discussion of technical and scientific matters do well as a rule to reduce the amount of their administrative business to a minimum. Such business is apt to interfere with strict attention to the more important problems for which these societies are organized. Their times of meeting and their programmes should, therefore, be arranged so that their members can give undivided attention for the time being to the technical and scientific problems before them. It seems probable that the various societies representing branches of agricultural science can profitably arrange some plan of affiliation. It is much more doubtful whether the center of such affiliation should be the Association of American Agricultural Colleges and Experiment Stations. This association is so far devoted to the discussion of administrative questions that it has little in common with the scientific societies, and any close affiliation of the two kinds of organizations might easily prove disadvantageous to both. At any rate discussion of affiliation should recognize the difference of function dividing administrative and scientific organizations.

The growing importance of extension work in agriculture was emphasized at the recent convention of the Association of American Agricultural Colleges and Experiment Stations. Evidently the rapid expansion of this work is bringing new problems to the agricultural colleges and stations. The complicated structure of these institutions and the somewhat confused legislation under which many of them are organized will make the task of properly organizing and administering extension work a delicate and difficult one. There is therefore great need of careful study of the problems involved in such work, and particularly of its relation to the research and inside educational work. Without doubt the association will do well to make a thorough study of this matter. Its action at the recent convention was timely, and it is to be hoped that much attention will be given to the study of this question at the various institutions prior to the next meeting

of the association, when much discussion of extension problems may be expected.

The growing sentiment in favor of better utilization of all available agencies for promoting agricultural education was strongly emphasized in the prominence given to strictly educational features at the Second National Corn Exposition, held at Omaha, December 9–19, which is enthusiastically declared by an agricultural journal to have been "the most elaborate demonstration of farm products ever held in this country." Nearly ten thousand different exhibits relating more particularly to the production and utilization of farm crops and representing twenty-eight States, scattered from Connecticut to Washington, and from Minnesota to Texas, besides entries from Hawaii, Canada, Mexico, England, and Argentina, filled to overflowing the two hundred and fifty thousand square feet of floor space of the large auditorium and the special structures erected for the occasion. The prizes offered in the various contests aggregated in value over fifty thousand dollars. It is estimated that the total attendance was one hundred thousand, an average of ten thousand each day.

The magnitude of the exposition was alone such as to bring prominently to public notice the important position of American agriculture, but, as expressed by another farm journal, the exposition "was far more than a mere display of specimens. It was a short course of study." The more popular and spectacular features, together with those more directly for business purposes, were by no means disregarded, but a notable circumstance was the unusual attention devoted to educational phases, thereby making the exposition an educational agency, especially in the realm of farm crops, such as the International Live Stock Exposition has become in the field of animal production.

Although in name this was the second national corn exposition, the first having been held in Chicago, in October, 1907, the Omaha show was the first to be developed to so elaborate a degree. Like its predecessor, it was in name an exposition of corn, and maize and its products easily predominated, but the term was broadly interpreted to include other cereals, grasses, an alfalfa palace, special exhibits of the work of the agricultural colleges and experiment stations, a large exhibit of farm machinery, a model kitchen, a students' judging contest, and many other features of interest and value. A complete distillery plant for the production of denatured alcohol was in operation, under the auspices of the Bureau of Chemistry of this Department.

Over half of the entries were in what was known as the Junior Industrial Section. This consisted of exhibits from young people, and included displays of articles made from corn and other grains

by the pupils of both rural and city schools, and samples of the corn grown by boys' corn clubs and similar organizations, as well as by individuals. Many of these entries were extremely suggestive as indicative that appeal is being made with success to the farmer of the future as well as of the present.

The educational value of the corn exhibit was much enhanced by an ingenious arrangement through which the racks were so constructed as to make it possible to see every ear entered. Significant, indeed, was the very evident improvement in quality which has been brought about during the past few years. Hundreds of entries of large, well-matured, uniform samples, of rich color and high proportion of kernel to cob, met the eye in bewildering profusion and rendered extremely difficult the rating of the samples by the judges. In the wheat section there was not only an exhibit of improved types and strains, but the judging of the various samples themselves was also supplemented by milling and baking tests, thereby acquainting the grower in a practical way with the requirements and point of view of the miller and the consumer.

The object lessons from the exhibits were explained and emphasized anew by a large corps of lecturers and demonstrators. The speakers included men prominent in state and national affairs, a long list of scientists from this Department and the agricultural colleges and experiment stations, and many experts engaged in various commercial phases of the industries. Not infrequently the audience taxed the capacity of the two lecture halls which were available. A special feature was a two-day session of the Commission on Country Life, in which farmers, agricultural editors, professional and business men and many others participated.

The third day of the exposition was set aside by the management as Agricultural College Day, and special trains brought several hundreds of students from the nearby States for the occasion. But to a large degree the name might well have been applied to each and every day of the exposition, so prominent was the influence of these institutions and so apparent the confidence and esteem with which their work was regarded. In the main auditorium a prominent section was reserved for their special exhibits, twelve institutions presenting illustrative material with reference to their work both in general and with particular reference to those phases relating to crop improvement. Thus, Illinois showed that the protein content of corn could be increased by selection; Ohio that wheat must be improved by selection and not by the fanning mill; Indiana compared the results of continuous cropping with rotation in wheat growing; and Wisconsin showed how through the State Experiment Association improved seed has been distributed in the State. The Iowa and

Nebraska exhibits were especially elaborate, the former giving prominence to cultural methods and the latter to feeding problems and cereal diseases and insect pests.

A novel and instructive feature for women was what was known as the Model Kitchen. This was in reality a school of domestic science, and was under the management of the head of the domestic science department of the Iowa College, assisted by teachers of home economics from the Illinois and Missouri universities and elsewhere. Here a ten-day course was given to a class of young women numbering sixty, with daily demonstrations and lectures which were open to the general public.

For the farmers and experts in embryo—the students in the agricultural colleges—a special incentive was offered in the form of a judging contest. In this, teams from the Iowa and Kansas colleges and the Missouri University struggled in a keen but good-natured competition, finally won by the Iowa College, for the possession of prizes aggregating several thousand dollars in value. Among these were the grand sweepstakes trophy—a silver cup valued at fifteen hundred dollars and presented under the auspices of the Mexican Government to stimulate interest in corn judging—and a thousand-dollar trophy offered by the Western Grain Dealers' Association for the judging of oats. The contests involved the grading of selected and commercial samples of the different grains, and also a statement of the reasons for the judgments made; and there were public lectures by representatives of boards of trade and grain exchanges as to the methods of grading, buying, and selling. Thus the opportunities open to the students were much extended, and they gained both experience and training of a sort to stimulate and develop subsequent work in the class room.

A national exposition of this sort, if closely held to the educational purpose, presents very considerable possibilities in that field. Like most of the other forms of extension work, it is still in the experimental stage and now possesses the temporary advantage of novelty, which must soon to some extent be lost. Much of the instruction it imparts is admittedly more or less superficial in degree and ephemeral in effect, needing subsequent and continued stimulation through other channels to effect its greatest and most lasting value. As a means of arousing interest, however, of pointing out in a practical way the need of individual improvement, and in revealing the opportunities which scientific effort is developing, it may easily become a factor well worthy of consideration in the work of popularizing the results of agricultural research.

CONVENTION OF ASSOCIATION OF AMERICAN AGRICULTURAL COLLEGES AND EXPERIMENT STATIONS, 1908.

The twenty-second annual convention of the association, held at Washington November 18–20, 1908, was characterized by good attendance and by an unusually interesting programme of papers, addresses, reports, and discussions. Over 200 delegates and visitors representing 48 States and Territories were in attendance. Among the visitors in attendance to whom the privileges of the floor were granted were F. B. Smith, Director of the Department of Agriculture of the Transvaal, Pretoria, South Africa; G. C. Creelman and C. A. Zavitz, of the Ontario Agricultural College, Guelph, Ontario, Canada; J. W. Robertson, of McDonald College, Ste. Anne de Bellevue, Province of Quebec, Canada; Edwin Hall, Secretary Auckland Agricultural Association, Auckland, New Zealand; and M. C. Rankin, Acting Commissioner of Agriculture of Kentucky. The large attendance was due in part to the fact that a number of other agricultural organizations, including Farmers' Institute Workers, National Association of State Universities, Society for the Promotion of Agricultural Science, American Society of Agronomy, and National Grange, were in session, and that the Country Life Commission held several hearings in Washington at the same time.

GENERAL SESSIONS.

The general sessions were presided over by President J. L. Snyder, who, in his presidential address, discussed Agriculture and Democracy, laying emphasis especially upon the relation of agriculture to other productive industries and the dependence of other industries upon agriculture. He pointed out that agriculture fosters a spirit of true democracy and developes character and provides conditions which are the true measure of the greatness of a nation. The growing needs of the future must be met by increased production by lands already under cultivation, not by increase of productive area. With the present rate of increase of population every State in the Union must practically double production within 50 years. Our democracy depends upon thus increasing production. Provisions for the maintenance of agencies for promoting agricultural production are therefore contributions to democracy, and this does not concern the farmer alone but every citizen of the Commonwealth. The scope and activities of educational agencies such as the agricultural colleges and the Department of Agriculture should be enlarged to meet the needs indi-

cated. It is not only incumbent upon the agricultural college to enlarge its own courses in various ways, but to take the leadership in securing improved rural education and better economic conditions in general. For example, production is increasing faster than transportation, therefore the improvement of the navigable waterways is of vital importance, and in this as in the conservation of the natural resources of the nation the agricultural colleges may profitably take an active part and must train more men for the greater demands of the future.

In accordance with suggestions contained in this address a committee consisting of J. L. Snyder, chairman, C. R. Van Hise, and R. W. Silvester was appointed to represent the association in its cooperative relations with the National Conservation Commission.

The report of the executive committee, presented by its chairman, H. C. White, briefly reviewed the work of the committee during the year, calling attention particularly to the appearance of the committee before committees of Congress in regard to matters affecting the association and this Office, and to conferences with the President of the Carnegie Foundation for the Advancement of Teaching, with a view to the admission of the land-grant colleges to the benefits of the foundation. Progress in bringing about a better understanding on this point was reported. At the invitation of the committee Dr. Henry S. Pritchett, president of the foundation, addressed the association, explaining frankly and fully the conditions under which the benefits of the foundation may be secured. By formal resolution the association expressed its profound appreciation of the great value to higher education of Mr. Carnegie's act in admitting tax-supported, State-controlled institutions to the benefits of the foundation, and its sense of gratitude for the benefits thus conferred upon American teachers. The resolution also conveyed "to the trustees of the foundation, and especially to its honored president, Dr. Henry S. Pritchett, its grateful acknowledgment of their sympathetic and helpful consideration of the land-grant colleges." Dr. H. C. White was requested to continue efforts to secure general recognition of the land-grant colleges by the foundation.

The report of the committee on graduate study dealt mainly with the Graduate School of Agriculture, the last session of which was held at Cornell University in July, 1908. The need of still more general support of this school on the part of the institutions represented in the association was especially emphasized. It was stated that "it is evident that the meaning of the school is becoming better appreciated by the colleges of agriculture. While the registration in the three successive schools has regularly increased and there is every reason to expect this increase to continue, yet it is the judgment of the committee that many of the institutions owe it to the cause of educa-

tion to take more active and appreciative interest in the Graduate School of Agriculture. This school is setting standards and developing ideals. These standards should be propagated everywhere. They are capable of greatly increasing the effectiveness of education by means of agriculture, and of extending its application. The committee thinks that every land-grant institution must accept the responsibility of furthering this enterprise. Moreover, it is also convinced that no land-grant institution can now expect to do the best work in education unless at least some of its staff actively participate in these graduate schools; and the administration of the institution must also officially recognize the type of work for which the graduate school stands. If for no other reason, the colleges should feel the obligation of cooperating in these schools for the purpose of increasing the supply of available teachers of agriculture.

"In short, the committee feels that the graduate school idea is now established, and far beyond the experimental stage. All the land-grant colleges must now recognize it."

Attention was also called to the injury which may result to the school by the holding of any considerable number of meetings of other organizations during the period of its sessions, a tendency toward which was apparent at the last session. The report of the dean of the school, A. C. True, showed that the last session of the school was very successful in point of attendance, breadth and interest of programme, and general results. An editorial account of the school has already appeared in the Record (E. S. R., 19, p. 1101).

Cordial invitations were received to hold the next school at St. Anthony Park, Minn., and Ames, Iowa.

An important feature of the proceedings was an address by Major-General J. Franklin Bell, Chief of Staff, U. S. Army, on Military Instruction in the Land-grant Colleges, emphasizing the importance of utilizing military instruction at these colleges as fully as possible as an aid in preparing for national defense. On the invitation of General Bell, the members of the convention took lunch at the War College and inspected the work of this institution. The thanks of the association were tendered General Bell, and the executive committee was instructed, if practicable, so to arrange the programme of the next meeting of the association "as to give one session in conference with the War College in relation to military instruction in the land-grant colleges, as suggested and requested by General Bell."

Commissioner E. E. Brown, of the U. S. Bureau of Education, addressed the convention briefly on the importance of enlarging the scope of the activities of the National Government with relation to agricultural education and of more perfect coordination of such instruction with the general work of education. He emphasized the importance of considering agricultural education as an essential

part of our general educational system. The desirability of enlarging the work of the Bureau of Education in its relation to the land-grant colleges was urged and the need of a central office for the promotion of various forms of vocational education was pointed out.

On invitation of the association, T. C. Atkeson, representing the National Grange, addressed the convention, discussing rural conditions in general and the relation of the work of the association and the Grange to the improvement of these conditions. A committee of three, consisting of J. L. Snyder, D. W. Working, and H. T. French, was appointed to visit the Grange, then in session in Washington.

A. C. True of this Office submitted a brief report for the special committee on history of agriculture, reporting progress in collecting data on this subject and asking the cooperation of the agricultural colleges.

The chief feature of the report of the bibliographer, A. C. True, was a statement by the Superintendent of Documents, W. L. Post, on the volume and character, and his methods of handling, cataloguing, and distributing government documents. The unfortunate confusion and lack of permanency as regards designated depositories for such documents was explained. Sale, at moderate prices, rather than gratuitous distribution of government documents, except to libraries, institutions of learning, and collaborators, was advocated. "We want all the libraries, colleges, and schools to understand that we stand ready to assist them in procuring either the information contained or the public document itself; that our services to them are entirely free and willingly bestowed, as are also the books when in stock; and that their interest in our methods and their friendly cooperation are what we need in order to continue to develop our plan of a clearing house for government publications, and a bureau of information regarding their contents."

The standing committee on instruction in agriculture reported progress of its subcommittee on domestic economy and gave an outline of a course in rural engineering prepared by another subcommittee.

The report of the standing committee on extension work made the following recommendations, which were approved by the association: (1) "That each institution represented in this association organize as soon as possible a definite scheme of extension work in agriculture;" (2) "that the association favor increased appropriations for the United States Department of Agriculture for the purpose of making investigations into all phases of the work of disseminating agricultural information, and of assisting the States in every practicable way to organize the work under the best auspices;" (3) "we strongly urge

that specific authority be granted by the association to this standing committee on extension work to make a study of this subject, and to report on it at a future meeting of the association." The recommendation that the association organize a section to be known as the section on extension work was indefinitely postponed, but C. F. Curtiss gave notice of a proposed amendment to the constitution, to lie over and be discussed and acted upon at the next convention, permitting the organization of such a section. The recommendations of the committee "that the association place itself on record in favor of a moderate Federal appropriation to be made to the land-grant colleges for the purpose of carrying on extension work in agriculture, under a plan which requires the States also to make appropriations for the work," and "that the association request Congress to extend the franking privilege to bona fide extension publications issued by the land-grant colleges," were referred to the section on college work and administration for approval as required by the constitution, but no action was reported by that section at this meeting.

The report of the standing committee on station organization and policy made important suggestions and recommendations regarding (1) the relation between the work of research and that of administration in experiment station policy, (2) permanence and continuity as prime essentials in station work, (3) inspection work in relation to other lines of station activity, and (4) relation of the working staff of the station to instruction in the college. The essential features of these recommendations have already been discussed editorially in the Record (E. S. R., 20, p. 303) and will not be further considered here.

Assistant Secretary Hays explained a system of project records which has been used with success in this Department and in several of the experiment stations. He thought that some such system as this might be made a useful means of adjusting administrative relations between different institutions and of securing better and more uniform methods, and might ultimately become, if generally adopted, something of a clearing house for administrative work.

A feature of the proceedings of great interest and importance was the report of the Commission on Agricultural Research appointed at the 1906 convention of the association "to inquire into and report to the association the organization and policy that in the opinion of the commission should prevail in the expenditure of public moneys provided for scientific experimentation and research in the interests of agriculture, to the end that such funds shall be applied in the most economical, efficient, and worthy manner to the production of results of permanent value." David Starr Jordan, Stanford University, California, as chairman, submitted a carefully prepared report embodying (1) a statement of present conditions affecting the efficiency of agricultural research, taking this term to mean "the scientific

investigation of unsolved problems that have a direct or indirect relation to agricultural practices or conditions," and not "academic or popular instruction or agricultural propaganda;" and (2) a series of recommendations which in the opinion of the commission "should guide in the promotion, organization and prosecution of research in agriculture." These recommendations, as far as they directly affect the work of the experiment stations, have already been reviewed editorially in the Record (E. S. R., 20, p. 301).

The executive committee was instructed to wait upon the Secretary of Agriculture and confer with him regarding the suggestion of the commission that an advisory board consisting of members appointed by the Secretary of Agriculture and by the association be formed to consider the mutual interests of the Department and the stations as well as agricultural investigation in general.

In accordance with a resolution of the association, a committee consisting of L. H. Bailey, H. C. White, C. R. Van Hise, T. F. Hunt, and L. G. Carpenter, was appointed to wait upon the President elect of the United States with reference to the future relations of the institutions represented in the association with this Department.

The high appreciation in which the services of Secretary Wilson as administrative head of the United States Department of Agriculture are held by the association was expressed in the following resolution adopted by the convention: "That we extend to Secretary Wilson the highest praise for his remarkable services as leader in the development of public efforts to improve the conditions of the American farmer and to place research and education in their relation to the farm, the farmer's home, and to our country life generally on a high plane and extend their influence very broadly among the masses of our agricultural people."

In accordance with a suggestion contained in the report of the chairman of the executive committee and a resolution introduced by K. L. Butterfield, of Massachusetts, the executive committee was instructed to take into consideration the matter of preparing for proper commemoration in 1912 of the fiftieth anniversary of the passage of the first Morrill Act and the fundamental law of the Department of Agriculture and the twenty-fifth anniversary of the passage of the Hatch Act.

The very general and active interest in the matter of affiliating various organizations dealing with agricultural science, which has been evidenced by the recent efforts of a number of these organizations to agree upon a satisfactory plan of affiliation, was indorsed by the association in the following resolution: "That this association heartily approves of the proposed affiliation of the various existing societies and associations organized for the consideration of subjects relating to agricultural science with a view of bringing all such efforts into

greater harmony and efficiency." The appointment of a committee of three to confer with the representatives of other organizations with regard to the formulation of a plan of affiliation was authorized. The committee appointed in accordance with this authorization consists of H. J. Waters, chairman, T. F. Hunt, and H. J. Wheeler.

The executive committee was instructed to give attention to the bill before Congress providing for the establishment of engineering experiment stations.

The officers chosen for the ensuing year were: President, M. A. Scovell, of Kentucky; vice-presidents, W. J. Kerr, of Oregon; C. E. Thorne, of Ohio; H. T. French, of Idaho; W. D. Gibbs, of New Hampshire; and A. B. Storms, of Iowa; secretary and treasurer, J. L. Hills, of Vermont; bibliographer, A. C. True, of this Office; executive committee, W. O. Thompson, of Ohio, chairman; J. L. Snyder, of Michigan; W. E. Stone, of Indiana; W. H. Jordan, of New York; and C. F. Curtiss, of Iowa.

P. H. Mell, of South Carolina, was chosen chairman of the section on college work and administration; W. J. Kerr, of Oregon, secretary. In the section on experiment station work, P. H. Rolfs, of Florida, was chosen chairman; E. J. Wickson, of California, vice-chairman; and F. B. Linfield, of Montana, secretary.

The vacancies in the committees occurring through the expiration of terms were filled by the following appointments: Committee on instruction in agriculture, A. C. True, of this Office, and T. F. Hunt, of Pennsylvania; committee on graduate study, H. P. Armsby, of Pennsylvania, and Howard Edwards, of Rhode Island; committee on extension work, K. L. Butterfield, of Massachusetts, and C. R. Van Hise, of Wisconsin; committee on experiment station organization and policy, E. Davenport, of Illinois, and C. D. Woods, of Maine.

Cordial invitations were received to hold the next convention of the association at Denver, Colorado, and Portland, Oregon.

SECTION ON COLLEGE WORK AND ADMINISTRATION.

Four topics, educational policy, the value of general culture in technical courses, administrative methods, and military discipline, were considered in the college section.

One of the most interesting and valuable discussions of the meeting was that opened by Andrew Sledd with a paper on Rural *v.* Urban Conditions in the Determination of Educational Policy. President Sledd maintained that educational policy should be adapted to meet the specialized needs of different communities. He believes that the first object of an education is to raise standards of living on a purely physical basis. In rural communities, therefore, instruction in agriculture should be provided for first of all. But education should also give to life a satisfying content. For the farmer it is

desirable not only that the physical standard of living be raised but also that he be given training which will give him poise and contentment. The farmer should be a patriotic, high-thinking man, yet contented with life on the farm. To be this he must have opportunity for gaining a livelihood and also for society, recreation, and mental activity. This opportunity must come largely through a multiplication of educational centers. As against the establishment of one large, strong university or college in a State, democratic policy would favor a number of good smaller schools distributed over the State.

In any school system President Sledd believes that moderate specialization should begin early, but full specialization should not be reached till after the close of the college course. In the high schools the curve of specialization for the student who does not expect to go to college should rise sharply until it covers two-thirds of the course, but for the student who looks forward to a college course it should rise more slowly and cover at the end only about one-third of the course.

In discussing this paper H. C. White called attention to the fact that in this country communal environment is not fixed and argued from this that the matter of first importance in education is to provide the fundamentals in character building and mental development. He would also prefer one good institution of learning to ten less good. W. O. Thompson believed that education which is not utilitarian has no excuse for being—is not education, and called attention to some of the difficulties of providing proper instruction in rural schools, chief among which is that of securing competent teachers.

In the absence of C. C. Thach the discussion of The Value of General Culture in Technical Courses in the Land-grant Colleges was opened informally by G. E. Fellows, who argued that culture may be obtained from any subject which is so thoroughly taught as to make students efficient. He would introduce into the college course only so much of cultural studies as will fit graduates to associate with others and present their ideas effectively. J. K. Patterson argued strongly against cutting loose from traditions concerning the cultural value of classical studies.

A paper on Administrative Methods in American Colleges was presented by P. H. Mell, who outlined briefly four forms of college administration: (1) That form in which the whole college community takes part in government but which is applicable only to conditions in Europe, (2) government by trustees, (3) government by faculty, and (4) presidential government. He did not believe that the trustees should enter actively into the details of college administration but should manage the larger affairs of the college, provide and look after its finances, and fill vacancies, subject to the recommendation of the president. Government by faculty he considered too slow and

cumbersome for modern educational institutions and he therefore favored presidential government. The president should be a good business man but more than a money getter. He should be a good man, strong intellectually, broad minded, able to appear before men, patient and sympathetic, a ruler of men. The college is a business corporation engaged in educational enterprises and it should have at the head of it a single man of ability, who should represent the trustees on the one hand, the faculty on the other. He should have general supervision over discipline but should leave the details of it to others.

In discussing this paper W. E. Stone emphasized the points already brought out and called attention to the fact that the business of teachers in colleges is largely to give instruction and conduct research and they should, therefore, be relieved largely of administrative affairs. In the land-grant colleges and State universities there are many great problems which are not primarily educational and these should be left to the president. M. H. Buckham believed that members of boards of trustees should be impressed with the fact that they have no power except as members of the board, no individual relations to the colleges. W. E. Garrison maintained that the president should be held responsible for results but that he should have the advice of at least one man on his faculty occupying such a position as dean which would bring him in view of the whole field of college work. W. H. S. Demarest held that the discussion thus far tended to put the board of trustees too far away from the college and that the board should give some cognizance to details, in fact should let it be known that in very rare occasions it would consider grievances of students or faculties.

In the absence of H. H. Harrington and K. C. Babcock, the discussion of the extent to which military discipline should be applied in agricultural colleges was opened by W. J. Kerr, who held that many institutions, owing to difficulties arising from large attendance and lack of dormitory facilities which would hold the college community together, have been unable fully to meet the requirements of the War Department in this respect. He believed, however, that the minimum requirement of the War Department was not too great for institutions having suitable facilities for meeting this requirement. W. E. Stone, J. H. Connell, and John Hamilton of this Office thought that more attention should be given to the study of larger problems in military tactics, to sanitation, cookery, and other things which will come under the administration of army officers, and less attention to the manual features of military tactics. Presidents Nichols, Patterson, and Edwards were of the opinion that the value of the manual exercises should not be lost sight of, and the latter called attention to the fact that if the military drill during the full

four-year college course were condensed into ten-hour days it would amount to less than a month of actual drill.

SECTION ON EXPERIMENT STATION WORK.

The general subjects (chosen at the last convention) discussed in this section were: (1) Bovine tuberculosis and methods for its control, and (2) relation of the experiment station to work in instruction with special reference to its popular phase.

The general subject of spread and control of bovine tuberculosis was discussed by V. A. Moore, who pointed out that conditions favoring the spread of the disease are increasing and that even the most reliable test for the disease, viz, tuberculin, can not be depended upon except in progressive cases of the disease. The Bang method of handling the disease was commended, but efficient control in this country would involve (1) a widespread campaign of education, (2) the enactment of special laws and regulations to control the spread of the disease, (3) the utilization of infected herds, (4) the breeding up of healthy herds, and (5) sterilization of dairy by-products. It was stated that by judicious use of the means indicated the disease can be eliminated, but this end can be only slowly attained.

In discussing the relation of dairy by-products to the spread of tuberculosis, H. L. Russell called attention especially to the rapid spread of tuberculosis in calves and hogs by feeding infected milk and dairy by-products, hogs being especially susceptible. The use of the home separator to obviate the use of creamery skim milk and pasteurization of dairy by-products used for feeding stock were suggested as preventive measures. He urged a campaign of education as a necessary preliminary to effective legislation.

H. A. Harding discussed the practical application of the Bang method in this country. He was of the opinion that while the method may be successfully employed, it may not always be practicable. Cheap means of pasteurization are especially needed. Present methods are only applicable in high-priced herds.

In general discussion following the more formal presentation of the above phases of the subject, attention was called to the futility of attempts to eliminate the disease from herds where liberal compensation for destroyed animals is allowed and the matter is not closely followed up. Compulsory pasteurization of dairy by-products used as feed and compulsory testing with tuberculin of breeding stock were suggested as preventive measures. The successful introduction of the Bang method through breeders' associations in North Dakota was referred to by J. H. Shepperd.

In discussing the relation of the station to popular instruction, C. F. Curtiss stated that in some cases station men have had a multiplicity of duties, including (1) instruction, (2) investigation, and

(3) extension work, but that these should be separately and distinctly organized and adequately provided for. There is no advantage in mixing the three lines, and the day of the combination of teacher, investigator, institute worker, and popular writer is happily passing.

W. R. Dodson presented a consensus of opinion of station directors, showing a general approval of and tendency toward a rather sharp differentiation of investigation and instruction in all forms, although it is considered well for station men to do a limited amount of teaching and popular work in their special lines. Research only should be done under Federal funds, while extension work should be provided for by State funds, and the organization may be adjusted on this basis.

W. H. Jordan thought stations should be feeders and supply material for instruction, but that the efficient station worker can not engage to any large extent in popular work. There should be separate agencies for popular work.

E. D. Ball thought the combination college and station man still a necessity in some stations, but that certain lines of work are better suited to the mixed function than others.

L. G. Carpenter thought it was mainly a question of how far the ideal can be attained. There are at present many difficulties of organization to be overcome in certain institutions, particularly in the far West, where a wider scope is required under present conditions.

H. P. Armsby emphasized the fact that to secure the highest efficiency in research the conditions must be kept favorable to creative work. Station men must have opportunity to incubate ideas as well as to put them into execution.

J. L. Hills had found that conditions for research work may be improved by concentrating the various lines of work in different periods of the year.

C. D. Woods thought research should be strictly divorced from instruction and limited to a few of the most important problems.

E. A. Burnett believed in a separate force for publicity work and a limited number of lines of investigation.

F. B. Linfield considered a clear differentiation an ideal to be worked toward as fast as conditions would permit, but thought that this ideal is not at present attainable in some of the newer States.

E. D. Sanderson favored Federal appropriation for extension work.

The topics selected for discussion by the section at the next convention were (1) The Relation of Problems in Irrigation, Drainage, and Engineering, and (2) The Relation of Station Directors to Other Members of the Staff. The programme committee was authorized to change the first topic if in its judgment this should for any reason become desirable.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Determination of sodium and potassium in silicates, J. E. THOMSEN (*Jour. Amer. Chem. Soc., 30 (1908), No. 3, pp. 420, 421; abs. in Chem. Abs., 2 (1908), No. 17, pp. 2354, 2355*).—It is stated that the following method has been found rapid and satisfactory for the determination of sodium and potassium in clay and silicates which can be decomposed by sulphuric and hydrofluoric acid:

"One gm. of clay is decomposed by means of sulphuric and hydrofluoric acids, and the excess of sulphuric acid expelled in a hot-air bath. The residue is then dissolved in water and powdered barium hydroxid added to the boiling liquid to alkaline reaction. The solution is decanted and filtered, and the residue boiled again with water and thoroughly washed. Carbon dioxid is passed into the filtrate in excess, the solution evaporated to 50 cc., 25 cc. of alcohol (96 per cent) added, and the solution filtered and the residue washed with 50 per cent alcohol. A measured excess of tenth-normal hydrochloric acid is then added to the filtrate and the solution boiled to expel the carbon dioxid, litmus being used as an indicator and more acid being added, if necessary, to give a permanent acid reaction after boiling. The titration is then finished with tenth-normal sodium hydroxid. The solution is evaporated to dryness in platinum, dried at 110° and finally at very faint redness, and the residue of potassium and sodium chlorids weighed. The amount of each metal can be calculated on the following principle:

Let a=No. of cc. of tenth-normal HCl used less the No. of cc. of tenth-normal NaOH.
b=a×A 0.00585=weight of NaCl equivalent to sum of NaCl+KCl.
c=weight of NaCl+KCl formed less the weight of NaCl corresponding to the weight of NaOH used.
x=weight of Na.
y=weight of K.

Then $b=\frac{58.5}{23.05}x+\frac{58.5}{39.15}y.$

$c=\frac{58.5}{23.05}x+\frac{74.6}{39.15}y.$

$y=2.432\ (c-b).$

$x=\frac{23.05}{58.5}\left(c-\frac{74.6}{39.15}y\right)=0.3937\ c-0.75\ y.$

Determination of potash in soils, L. RONNET (*Ann. Chim. Analyt., 13 (1908), No. 4, pp. 141–143*).—The method proposed is as follows: Treat 25 gm. of the soil in a porcelain dish with a flat bottom 11 cm. in diameter with nitric acid until effervescence ceases. Add 25 cc. more of the acid and heat for 5 hours on a sand bath. Precipitate sulphuric acid with a few drops of saturated solution of barium nitrate. Evaporate to dryness and heat in a muffle at a low red heat until nitrous vapors disappear, the nitrates of iron and aluminum are completely decomposed, and the nitrates of calcium and magnesium partially decomposed. Take up in a little water and precipitate lime with 10 to 20 gm. of oxalic acid according to the lime content of the soil. Warm under cover

of a funnel in a sand bath. Evaporate to dryness and heat in a muffle at a low red heat until oxalic acid is completely removed. Pulverize the residue and wash with hot water into a 250 cc. flask. Allow the solution to stand over night, shaking from time to time. Make the volume to 250 cc. plus 10 cc. for volume of soil. Filter and evaporate 200 cc. of the solution, corresponding to 20 gm. of soil, and again treat the residue with oxalic acid. Filter and determine potash by adding hydrochloric acid and platinum chlorid or nitric acid and perchloric acid in the usual way. If it is desired to determine potash by weighing the reduced platinum, the method may be simplified by evaporating the 200 cc. directly with hydrochloric acid and platinum chlorid.

On a volumetric method for the determination of phosphoric acid in superphosphates, S. Kohn (*Chem. Ztg., 32 (1908), No. 39, pp. 475, 476; abs. in Chem. Zentbl., 1908, I, No. 26, p. 2205; Analyst, 33 (1908), No. 390, p. 376; Chem. Abs., 2 (1908), No. 18, p. 2529*).—The essential features of the method are titration of the water extract (20 gm. of superphosphate to 350 cc. of water) with sodium hydroxid solution, using methyl orange as indicator; addition of a large excess of neutral calcium chlorid solution; and further titration with the soda solution, using phenolphthalein as indicator. The results obtained agree well with those obtained with the citrate method.

The volumetric determination of water-soluble phosphoric acid in superphosphates, W. Moeller (*Chem. Ztg., 32 (1908), No. 53, pp. 631, 632; abs. in Chem. Zentbl., 1908, II, No. 5, p. 444; Chem. Abs., 2 (1908), No. 18, p. 2529*).—The author questions the accuracy of the Kohn method described above.

On the titration of phosphoric acid in superphosphate solutions, S. Kohn and L. Schucht (*Chem. Ztg., 32 (1908), No. 61, pp. 718, 719; abs. in Chem. Abs., 2 (1908), No. 20, p. 2767*).—In this article Kohn briefly discusses the contributions of Schucht and Littman to this subject and replies to criticisms of his method referred to above. The weaknesses of Kohn's method are commented upon by Schucht.

The systematic investigation of drinking waters, G. Romijn (*Pharm. Weekbl., 45 (1908), No. 15, pp. 402–412, fig. 1*).—The apparatus and procedure adapted to the systematic determination of chlorin, sulphuric acid, carbon dioxid, alkaline earths, nitrates, permanganate consumption, calcium and magnesium ions, and alkali ions are described.

Determination of combined carbonic acid in water, G. Lunge (*Ztschr. Angew. Chem., 21 (1908), No. 18, p. 833; abs. in Chem. Abs., 2 (1908), No. 14, p. 1942*).—The error of 33 per cent in temporary hardness reported by Noll in his tests of Lunge's method is attributed to the presence of a large amount of iron in the water. The author maintains that in ordinary waters containing small amounts of iron there is no appreciable error in the determination of temporary hardness.

The determination of combined carbon dioxid in water, H. Noll (*Ztschr. Angew. Chem., 21 (1908), No. 27, pp. 1455, 1456*).—A reply to the above statement of Lunge, maintaining that even with waters containing comparatively small amounts of iron the results by Lunge's method are too high.

Examination of eggs with colored shells, K. Borchmann (*Ztschr. Fleisch u. Milchhyg., 18 (1908), No. 6, pp. 182–184*).—The data reported have to do with the examination of wild birds' eggs marketed for food purposes. According to the author, water gave better results than salt solution in judging eggs by their specific gravity.

The formic acid content of honey, K. Farnsteiner (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 10, pp. 598–604*).—The studies reported of the acid content of honey led to the conclusion that if formic acid is present it exists only in minute quantities, and the author recommends that for the

present free acid in honey be designated malic acid, and that the acidity be expressed in cubic centimeters of normal alkali solution per 100 gm. honey.

Methods for the analysis of maple products and the detection of adulterants, together with the interpretation of the results obtained, A. H. BRYAN (*U. S. Dept. Agr., Bur. Chem. Circ. 40, pp. 13*).—This compilation of methods of analysis of maple products has been prepared for the convenience of food analysts. The use and interpretation of analytical results in the detection of adulteration are discussed.

Amount of soluble silicic acid in cocoa beans, H. MATTHES and O. ROHDICH (*Ztschr. Öffentl. Chem., 14 (1908), No. 9, pp. 166–169*).—In the determinations reported the silicic acid content of different sorts of cocoa was found to vary considerably and the authors do not believe that quality can be judged by this constituent.

Plant fats and fat mixtures used in chocolate manufacture in the place of cocoa butter, O. SACHS (*Chem. Rev. Fett u. Harz Indus., 15 (1908), Nos. 1, pp. 9, 10; 2 pp. 30–33*).—The physical constants and other characteristics of different fats used in place of cocoa butter in chocolate manufacture are described and other data summarized with a view to the detection of such substitution.

Comparative tests of different methods of measuring fat in milk, E. DEHAYE (*Indus. Lait. [Paris], 33 (1908), No. 22, pp. 425–431*).—In the studies reported the author obtained larger results from chemical methods, such as the Adams method of fat extraction, than from the mechanical-chemical methods, such as the Gerber acid or salt method. In the case of fresh milk, or slightly acid homogenized milk, or milk partly skimmed, the results by the Adams method were slightly smaller than those by the Röse-Gottlieb method. In the author's opinion the latter method is to be preferred for exact determinations.

A milk constant as a basis of judgment, G. CORNALBA (*Indus. Lait. [Paris], 33 (1908), No. 26, pp. 495–499*).—In the data presented the soluble matter in milk has a fairly constant value, ranging from a minimum of 5.94 to a maximum of 6.44 per cent, while the insoluble matter in the same samples ranged from 5.05 to 8.58 per cent. In the author's opinion such a constant value offers the surest and most precise means of judging of the purity of milk, especially with respect to the addition of water.

Study of recent methods of analysis of butter, M. F. JEAN (*Indus. Lait. [Paris], 33 (1908), No. 22, pp. 431–434*).—Some methods recently proposed for detecting adulteration of butter were tested by use of pure butter alone and mixed with animal and vegetable fats. Several revealed adulteration when the latter equaled 10 per cent, but they failed to give positive evidence when it was not over 5 per cent. The method of Robin (E. S. R., 18, p. 709) is mentioned as of considerable value.

Regarding the nonsaponifying constituents of cocoa butter and their detection in mixture with butter, H. MATTHES and E. ACKERMANN (*Ber. Deut. Chem. Gesell., 41 (1908), No. 10, pp. 2000, 2001*).—This is a preliminary notice of investigations on a method of detecting the presence of cocoa fat in butter, depending on the facts stated by the authors that cocoa butter contains a phytosterin which gives customary color reactions but combines with 2 molecules of bromid and forms an acetattetrabromid, whereas butter does not form the latter compound. According to the method described, 1 kg. of cocoa butter upon repeated saponification and solution in ether yields 1.25 gm. of crude phytosterin with a melting point of 135 to 140° and 0.25 gm. of volatile constituents. The acetilized crude phytosterin (melting point 126 to 128°) is bromidized in ether and glacial acetic acid. Upon standing, thin plates with a melting point of 180 to 183° separate. From the filtrate after evaporation and recrystallization of

alcohol there is obtained a microcrystalline aggregate with melting point 132 to 135°, which is the melting point of phytosterinacetatdibromid.

Refractometric analysis of cognac, A. Frank (*Ztschr. Öffentl. Chem., 14 (1908), No. 10, pp. 185–194*).—The author describes a method of determining the alcohol and extract content of cognac from data for specific gravity and refraction, and gives a table showing the percentage of volume of alcohol corresponding to these values. He concludes that the refractometer method is to be recommended on the grounds of accuracy and simplicity.

Examination of feces for nitrogen of metabolic products, A. Stutzer, E. Merres, and L. Seidler (*Biochem. Ztschr., 9 (1908), No. 3–4, pp. 310–317*).—According to the reported data, sheep, goat, and rabbit feces may be preserved for analysis with carbon disulphid in the proportion of 1 cc. to 100 gm. feces. Fairly satisfactory results are also obtained when the feces are spread out and dried at ordinary room temperature. The dry material is extracted for 12 hours with specially prepared gastric juice and hydrochloric acid and the nitrogen determined in the undissolved residue and in the original material. The difference between these values gives the nitrogen of metabolic products.

The analysis of coal-tar creosote and cresylic acid sheep dips, R. M. Chapin (*U. S. Dept. Agr., Bur. Animal Indus. Bul. 107, pp. 7–35, fig. 1*).—This paper deals with methods of determining the various constituents of dips prepared from coal-tar derivatives. The commercial methods in use while rapid were found untrustworthy, undecomposed rosin being distilled along with the hydrocarbon and phenols even at 200° C. The scientific method requires many extractions and re-extractions and under certain conditions is also unreliable. In the method devised by the Bureau hydrocarbons are estimated by difference, water, soda, and pyridin bases, phenols, rosin acids, and other ingredients being determined by fairly simple volumetric processes. Result of tests made by the Bureau are reported.

"Methods exactly parallel to the methods employed in the analysis of dips may be applied to the valuation of creosote oil and cresylic acid which are to be used in making dips. . . .

"The agreement between the analysis of a dip made from analyzed materials with its calculated composition indicates that it is actually possible for a manufacturer to place on the market a dip of practically unvarying composition."

The analysis of turpentine by fractional distillation with steam, W. C. Geer (*U. S. Dept. Agr., Forest Serv. Circ. 152, pp. 5–29, figs. 17*).—A description of important changes in methods previously employed (E. S. R., 19, p. 682). By means of a new form of still-head, which is described, fractionations by dephlegmation are readily obtained. By using steam distillation the temperature can also be more easily regulated.

Results of the application of this method to 4 turpentines of different kinds are shown in graphical form. The color, odor, and maximum boiling temperature of all fractions were noted and specific gravity and index of refraction were determined.

"By introducing the principle of dephlegmation the separation of the constituents is made much more complete. . . .

"The low temperature at which the distillation is carried out reduces the danger of alteration of the sample during the analysis.

"The distillation is similar to certain technical distilling processes which have been found to give excellent results in practice and suggests the possible results of applying such methods to the refining of turpentines."

The examination of turpentine and turpentine substitutes, J. H. Coste (*Analyst, 33 (1908), No. 387, pp. 219–234*).—The author reports a study of

methods of examination of turpentine and describes processes which, while not novel, have been found useful in aiding the investigator to form an opinion as to the nature and quality of turpentine examined.

Proceedings of the Sixth International Congress of Applied Chemistry (*Atti 6. Cong. Internaz. Chim. Appl., 1906. Vols. 1, pp. XV+[413]+752, pls. 8, figs. 108, maps 2; 2, pp. XI+949, pls. 16, figs. 70; 3, pp. XII+919, figs. 19; 4, pp. XII+697, figs. 25; 5, pp. XV+844, figs. 13; 6, pp. XII+537, figs. 60; 7, pp. XX+812, figs. 3*).—A full report of the proceedings of the Sixth International Congress of Applied Chemistry at Rome, April 26 to March 3, 1906, with papers presented, discussions, and reports of committees.

Of special interest are the proceedings of the sections of organic chemistry and allied industries, fermentation and starches, wine making, agricultural chemistry, medical, pharmaceutical, and food chemistry, and the reports of the international committee on the analysis of commercial fertilizers and feeding stuffs, and the committee for the unification of methods for the analysis of food products. Several of the papers have been noted (E. S. R., 20, pp. 207, 208, 211, 218, 219, 222, 223, 225, 307, 384, and 456.

Report on progress in industrial inorganic chemistry, V. Hölbling and J. Preiss (*Chem. Indus. [Berlin], 31 (1908), Nos. 2, pp. 57–66; 3, pp. 83–96; 4, pp. 120–134*).—The feature of this article of greatest agricultural importance is the rather complete review of literature relating to the oxidation of atmospheric nitrogen and to ammonia and ammonium salts.

METEOROLOGY—WATER.

Annals of the Astrophysical Observatory of the Smithsonian Institution, C. G. Abbot and F. E. Fowle, Jr. (*Ann. Astrophys. Observ. Smithsn. Inst. 2 (1908), pp. XI+245, pls. 29, fig. 1*).—This volume reports "a continuation of the work on the relations of the sun to climate and life upon the earth" begun by Secretary Langley in "the hope that careful study of the radiation of the sun might eventually lead to the discovery of means of forecasting climatic conditions for some time in advance. It is believed that the present volume will aid materially to show how far that hope may be justified, for it contains careful and comparable measurements of the solar radiation, extending over several years. These indicate that the sun's radiation alters in its intensity from time to time, and that these alterations are sufficient to affect the temperature of the earth very appreciably. . . .

"From a comparison, extending over thirty years, of the temperatures of 47 stations well distributed over the land surface of the earth, it appears possible that changes of solar radiation do produce, not infrequently, well-marked and recognizable changes of temperature over the continental areas of the world. Such changes of temperature would be predictable if accurate measurements of the solar radiation were systematically continued at a few favorable stations."

The introductory part of the report gives annals of the Astrophysical Observatory 1900–1907. Part I deals with determination of the intensity of the solar radiation outside the earth's atmosphere, otherwise termed "the solar constant of radiation," including chapters on methods of determining the "solar constant of radiation," apparatus for "solar-constant" determinations, sample observations and computation of solar radiation outside the atmosphere, investigation of sources of error in the determination of the "solar constant," results of measurements of the intensity of solar radiation, applications of solar radiation measurements, and the causes of disagreement between the "solar-constant" determinations of different observers; Part II with radiation and terrestrial temperature, including chapters on the effect of the atmosphere on the direct

beam of the sun, the reflecting power of clouds, indirect solar radiation, income and outgo of heat from the earth and the dependence of its temperature thereon, and variations of solar radiation and their effects on the temperature of the earth; and Part III with the radiation of different parts of the sun's disk, including chapters of the phenomenon of varying brightness of the solar disk and possible explanations of it, arrangements for observing the distribution of radiation over the sun's disk, and results of observations of the brightness of the solar disk.

Solar heat received by the surface of the soil, J. Loisel (*Bul. Soc. Astron. France, 1908, May, pp. 229–232, figs. 2; abs. in Nature [London], 78 (1908), No. 2012, p. 66*).—This article discusses the relationships between the activity of various solar phenomena and the amount of heat received at the earth's surface. The discussion is based upon observations made at Montpellier during the period 1883 to 1901. "Plotting the actinometric results obtained at Montpellier, together with the frequency curves for sun spots, faculæ, and prominences, Doctor Loisel shows that they are distinctly analogous, but the terrestrial variation is an inversion of the solar variations."

On the origin of atmospheric ozone and the causes of variations in the carbon dioxid of the air, H. Henriet and M. Bouyssy (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 19, pp. 977, 978*).—This is a summary of results of extensive investigations which have been reported in other journals.

The investigations led to the conclusion that the ozone of the air results from the action of ultra-violet rays of the sun on the oxygen of the upper atmosphere, and is brought to the lower layers of the air by the winds and rains. When the air is very calm and clear a certain amount of ozone is formed in the lower layers of the air by the action of the sun's rays. All variations of the carbon dioxid below the normal are due to the upper air, the carbon dioxid thus varying inversely as the ozone. Variations above the normal are due to local causes such as respiration of men and animals in large cities, fires, exhalations from soils, and the like.

Meteorological observations at Storrs for the years 1905 and 1906, W. M. Esten (*Connecticut Storrs Sta. Rpt. 1907, pp. 163–179*).—This is a record of observations on temperature and precipitation during each month of 1905 and 1906 at Storrs, the rainfall during the six months ended October 31, 1905, and for the same period in 1906, at 20 places in Connecticut, a summary of rainfall for the six months ended October 31 for 20 places in Connecticut during the 17 years 1889–1905, the monthly mean temperature and monthly precipitation for 18 years (1888–1905), and dates of last and first killing frosts for 18 years.

Meteorological summary for 1906, C. A. Patton (*Ohio Sta. Bul. 185, pp. 295–310*).—This summary includes as usual notes on the weather of each month and tabulated daily and monthly records of observations at the station at Wooster, Ohio, on temperature, precipitation, cloudiness, direction of the wind, etc., and for comparison, similar data for 19 previous years (1888–1906) at the station and for 24 years (1883–1906) in other parts of the State.

The mean temperature for the year at the station was 50.7° F.; for the State 51.6°; the highest temperature at the station 92°, June 29; for the State 101°, August 21; the lowest temperature at the station —14, February 7; for the State —23°, February 6. The annual rainfall at the station was 42.8 in., for the State 36.87 in. The number of rainy days at the station was 142, for the State 124. The prevailing direction of the wind was south at the station and southwest for the State.

The weather during the agricultural year, 1906–7, F. J. Brodie (*Jour. Roy. Agr. Soc. England, 68 (1907), pp. 289–296*).—Data are given for rainfall, temperature, and sunshine at various points in the United Kingdom during 1906–7

as compared with previous years, and the general seasonal conditions are discussed. The meteorological conditions of the year are reported as on the whole favorable from an agricultural standpoint.

Climatology (*Bul. Off. État Indépend. Congo, 24 (1908), No. 5, Sup., pp. 167–190, dgms. 11, map 1*).—The mean annual and monthly rainfall and number of rainy days as observed during a number of years at various places in the Congo Free State are shown in diagrams and the distribution of rainfall during each month is shown on colored maps.

Present trend of investigation on underground waters, J. F. Kemp (*Abs. in Science, n. ser., 28 (1908), No. 715, p. 352*).—This is an abstract of a paper presented before the New York Academy of Sciences in which the author states that "within a few years there has been a marked change of views upon the sources, distribution, and extent of underground waters. . . . Now a very large number of geologists have come to regard the underground water as limited to a comparatively shallow zone; to refer uprising heated waters from deeper zones to magmatic sources in cooling and consolidating bodies of igneous rock; and to attribute some part of the underground waters to the same place of origin. In the interpretation of ore bodies magmatic waters have been found to be much more reasonable agents of deposition, in many cases, than are the meteoric."

The author presents figures from which he concludes "that meteoric sources and underground amounts have been much overestimated."

A study of the waters of Rio Verde from the standpoint of potability and agricultural value, M. P. Urbina (*Estac. Agr. Expt. Rio Verde, San Luis Potosí, Bol. 2, pp. 63, pls. 9*).—Detailed examinations of a number of samples are reported and discussed from the standpoint of suitability for drinking purposes and for use in irrigation. The waters are not as a rule suitable for drinking purposes. They are generally very clear, but contain considerable amounts of soluble salts. For these reasons little benefit is derived by the soil from use of the waters in warping, and soils receiving liberal applications of the water should be well drained to prevent accumulation of alkali.

Water supply for villages, W. Pitelps (*Jour. Bd. Agr. [London], 15 (1908), No. 5, pp. 350–355*).—The importance of giving more attention to providing an adequate, wholesome, and cheap water supply for rural towns and villages is pointed out. The number of dairy cows kept in a given locality is suggested as a basis for estimating the amount of water required.

A comparison is made of the consumption and cost of water with and without the use of meters. It was found in many cases that where the meter system was not in use 10 to 20 gal. of water per head of stock was used. With the meter system, however, the amount was greatly reduced.

The broad irrigation sewage farm at Fresno, California (*Engin. Rec., 58 (1908), No. 8, pp. 207, 208, figs. 3*).—This is a brief account of a sewage disposal plant consisting of a septic tank and a tract of 812 acres of land suitable for broad irrigation, which has been in quite satisfactory operation at Fresno, California, since December 28, 1907. The plant disposes of the sewage of a population of 30,000.

Elements of water bacteriology, with special reference to sanitary water analysis, S. C. Prescott and C. E. A. Winslow (*New York and London, 1908, 2. ed., pp. XII+258, fig. 1*).—It is stated that the aim of the author in preparing this new edition was "to include the results of the work of the last four years which bear on the practical investigation of sanitary questions connected with water supply." Considerable additions have been made to the treatment of the problems of self-purification, the description of methods for the isolation of the typhoid bacillus, the treatment of the interpretation of the colon test, an account of the newer presumptive tests for *Bacillus coli*, and the discussion of

the significance of intestinal bacteria other than *B. coli*. "A new chapter has been introduced on the bacteriology of sewage and sewage effluents, in recognition of the growing importance of this branch of the subject."

SOILS—FERTILIZERS.

The production of active nitrogen in the soil, G. S. Fraps (*Texas Sta. Bul. 106, pp. 4–31, figs. 5*).—This bulletin reports the results of laboratory studies of the rate of ammonification and nitrification in different kinds of Texas soils under varying conditions of basicity, acidity, fertilization, and moisture, as well as of pot experiments to determine the relation of the rate of production of active nitrogen to plant growth. The sum of ammonia and nitrates is considered active nitrogen.

The method of procedure in the laboratory studies was in general as follows:

"Five hundred gm. of air-dry soil, which had been sifted through a 3 mm. sieve, was mixed with 20 gm. of fresh garden earth, an amount of nitrogenous substance containing 0.3 gm. nitrogen, and water equal to one-third of the saturation capacity of the soil. The nitrogenous substance and the garden earth were first mixed together, then these were incorporated with the dry soil, the water added, and the whole mixed thoroughly until the mass was uniform.

"The mixture was then placed in 500 cc. precipitating jars, shaking it down by tapping gently against a wooden block. A test tube, with a small perforation in the end, was inserted to a depth of about 1 in., and the jar, with its contents, was weighed and placed in a water bath kept as nearly as possible at 35° C. . . .

"Every Monday, Wednesday, and Friday each jar was placed on a coarse balance and water added slowly through the test tube until its original weight was restored. This method of supplying the water retains the surface of the soil in an open, porous condition.

"After 4 weeks the contents of the jar were mixed thoroughly. One hundred gm. were placed in a funnel on a perforated porcelain disc, and washed with water until the volume of the filtrate was about 100 cc. Nitrates were then determined in the filtrate by the Tiemann-Schulze method and calculated to the original, air-dry weight of the mixture.

"For the ammonia determination, an amount equal to 200 gm. of the dry soil was placed in a flask with dilute hydrochloric acid (1:25) in quantity sufficient to make 500 cc. with the water already present in the sample. The mixture of soil and acid was shaken thoroughly, filtered after standing over night, and 250 cc. of the filtrate distilled with magnesia. The ammonia was caught in standard acid and the solution titrated back with ammonia. Correction was made for the ammonia in the reagents. Both nitric and ammonical nitrogen were corrected from the quantity present in the original soil. . . .

"The saturation capacity of the soil was estimated as follows: Fifty gm. soil are placed in a 1¾ in. carbon filter on a perforated porcelain plate, weighed, and water added until the soil is saturated. After the soil has drained 15 minutes, protected from evaporation, the apparatus is weighed again. The gain in weight is the saturation capacity, and is expressed in percentage of the original soil."

Basicity of the soils was determined by three methods as follows:

"(1) Ten gm. of soil were digested with 100 cc. fifth-normal nitric acid for 12 hours, and 10 cc. of the filtrate was titrated with caustic soda and phenolphthalein. Since salts of iron and aluminum are acid to this indicator and the corresponding hydroxids are precipitated during the titration, this method does

not include the basicity due to bases of iron and aluminum. The basicity measured is due to carbonate and easily decomposed silicates of lime, magnesia, and the alkalis.

"(2) Fifty gm. of soil were digested with 100 cc. tenth-normal nitric acid for one-half hour, and 20 cc. of the filtrate titrated with caustic soda and methyl orange.

"(3) After the titration in (2) phenolphthalein was added and the titration continued until the solution became slightly colored. The difference between methods (2) and (3) consists in the fact that (2) includes basicity due to iron and aluminum in addition to lime, magnesia, and alkalis, while (3) includes only lime, magnesia, and alkalis."

In connection with the pot experiments the method of procedure was as follows:

"Five hundred gm. of the soil were placed in a 500 cc. precipitating jar and 100 cc. of water poured on the surface of the soil. A test tube perforated at the bottom reached to the bottom of each jar. The soil was thus ventilated at the bottom, as in the pot experiments. The jars were kept in a dark cupboard at the room temperature and did not receive any further addition of water during the period of experiment. At the end of the time they were weighed, mixed thoroughly, and portions taken for analysis. . . . The results of the analysis were calculated to the original weight of the soil.

"Vegetation experiments were made on the same soil in galvanized iron pots 8 in. in diameter and 8 in. deep with a 1-in. side tube (Wagner pot). The pot was ventilated from the bottom, a layer of gravel was first introduced, and 5 kg. of soil were weighed into each pot. Each pot received 2.5 gm. acid phosphate and 1 gm. potassium sulphate. The corn planted was grown for various periods in the different soils. The period of growth was the same, however, as the length of time during which the soil was allowed to nitrify in the jars. The effect on plant growth of other additions to the soil was studied at the same time. Most of the tests with nitrogen were made in duplicate.

"At the end of about 9 weeks the corn was harvested, dried, and subjected to analysis."

It was found in these experiments that soils vary considerably in ability to produce nitrates, but to a much less extent in their capacity to produce active nitrogen. While an excess of water may entirely prevent nitrification, it retarded the production of active nitrogen to a much less extent.

"No relation could be observed between the increased production of nitrates due to calcium carbonate, and the acidity or basicity of the soils estimated by the methods described, though the greatest increase was effected on the most acid soil.

"Although the addition of carbonate of lime increased the production of nitrates in most of the soils, the production of active nitrogen was affected thereby only to a slight extent.

"Magnesium carbonate was less favorable to nitrification in the soil tested than calcium carbonate.

"Nitrification was much greater in a limed acid soil than in the unlimed acid soil.

"Phosphoric acid and potash had little effect upon the production of active nitrogen, though in some cases nitrification was affected considerably.

"The formation of ammonia begins rapidly, and a large proportion of the change takes place the first week, under Texas conditions. Nitrification began the second week and reached its maximum in the third.

"At the end of 56 days, under very favorable conditions, a large portion of the active nitrogen produced from cotton-seed meal was still in the form of ammonia.

"While the rank of nitrogenous fertilizers measured by the nitrates formed varies according to the nature of the soil, the relative production of active nitrogen is much less variable and depends upon the nature of the material. This offers a method for comparing the values of different nitrogenous fertilizers. . . . In most cases a greater quantity of nitrogen was taken up by the plants than would be produced in the jars, due to more favorable conditions in the pots for the transformation of nitrogen to active forms.

"Nitrogen content of the crop, as a rule, increased with the active nitrogen produced in the soil.

"All soils yielding less than 7 parts per million of nitric nitrogen, or 9 parts of active nitrogen in the jars, were highly deficient in the pot tests. In no case was the crop larger than 8 gm., and the addition of nitrates increased the crop four-fold or more.

"Soils yielding 7 to 22 parts per million of nitric nitrogen, or 9 to 27 parts of active nitrogen, appear to be deficient in nitrogen.

"Of nine soils yielding 27 parts per million of active nitrogen in the jars, four appeared to supply sufficient nitrogen to the crop, two responded slightly to nitrates, while three responded considerably.

"The soils containing 0.02 per cent nitrogen were very deficient in nitrogen and produced the smallest quantities of active nitrogen. On an average, the production of active nitrogen increased with the nitrogen content of the soil, though the results with individual soils were irregular.

"Six soils containing an average of 0.12 per cent total nitrogen contained an average of 59 parts per million of active nitrogen, this being 5 per cent of the total. Six soils, with an average nitrogen content of 0.8 per cent, and five with an average of 0.026 per cent, contained 21 and 7 parts per million of active nitrogen, being 2.5 and 2.7 per cent of the total. The nitrogen of soils containing high percentages appears to be more available than that containing low percentages.

"The production of active nitrogen in the soil can probably be developed into a method for the determination of the needs of the soil for nitrogenous fertilizers.

"Certain of the soils subjected to study contained a considerable proportion of their active nitrogen in the form of ammonia. . . .

"At the end of 4 or even 8 weeks a large portion of the active nitrogen produced from organic nitrogen fertilizers was present as ammonia, even though the conditions were very favorable for their conversion into nitrates. It appears that ammonia must play a not insignificant part in plant nutrition, when fertilizer or manure is applied."

Absorption by soils, H. E. Patton and W. H. Waggaman (*U. S. Dept. Agr., Bur. Soils Bul. 52, pp. 95, figs. 8*).—This bulletin summarizes the literature relating to the absorption of solids from solution, and reports results of investigations carried on in the laboratory of the Bureau of Soils in continuation of the general work on soil absorption which has been under way for several years.

After a résumé of earlier work, the bulletin takes up in detail the results of investigations on selective absorption with carbon, gelatin, soil, paper, cotton, barium sulphate, kaolin, clay, copper hydroxid, dyes, etc.; absorption by soils of picric acid and dyes from various solvents; distribution of different soluble salts between absorbent and solvent; rate of absorption (formulas); energy changes (heat evolved); condition of the absorbed sub-

stance; effect of absorption upon the physical condition of the soil; and percolation, including reclamation of black alkali soil by leaching, efficiency of calcium sulphate in removing black alkali, and absorption of potassium from carbonate solution.

"The principal object of this work has been to determine how absorption controls the concentration of the soil solution, which is the great nutrient medium upon which plants feed, and, further, to determine the effect of absorption upon the structure of the solid portion of the soil in modifying its power to hold and maintain the soil solution for the continued use of the plant. As a result of this work it has been shown that a number of modifying factors enter into each particular case, which makes it impracticable to formulate a simple general law which will account quantitatively for the distribution of a dissolved substance between the liquid solution and the absorbing medium, although it is brought out very clearly that under the ideal conditions, where there is no change in the surface of the absorbing medium, a simple mathematical law can be predicated a priori, which law is approximately realized in practice in those cases where it is known that the least amount of change takes place in the absorbing surface. . . .

"In the experiments described the materials used are not always fertilizer salts or constituents of the soil itself, since other substances, particularly certain dyestuffs, are better adapted to obtaining a more detailed knowledge of the mechanism of absorption. In general, it may now be stated that where disturbing influences are not great the mathematical formulation may be made both of the time rate and of the absorption and distribution of the material between the solid and the liquid. The disturbing influences, however, are quite important in most cases actually met in practice, and therefore a detailed study of some of them was undertaken. The most important of these is the change in the physical character of the soil itself, consequent upon the absorption of the dissolved materials. In some cases, notably with acids and with lime, the soils assume a 'flocculated' structure, i. e., a great many of the ultimate grains form larger aggregates or 'ball together;' and in other cases, especially with alkalis, the soils are deflocculated, each grain standing out separate and distinct from the others. This change in the structure of the soil is of the utmost importance in influencing the physical condition of the soil, which in turn influences the drainage condition, the aeration of the soil, its capacity to hold the soil solution and control its movement through the soil, the composition of the soil solution, the character and rate of the chemical changes taking place in the soil solution; and, in fact, in influencing directly both the physical and chemical factors which are the most important in governing the proper growth of plants."

The results of experiments with alkali soils from Yakima, Wash., and Fresno, Cal., indicate that "neutral salts, such as chlorids, in the presence of carbonates are comparatively easy to leach from the soil. With continued leaching of the soils containing 'black alkali' there is an increase in the rate at which percolation takes place, due probably to the reduction of the amount of alkali present and to a consequent effect on the physical structure of the soil. With continued leaching there is a comparatively rapid reduction of normal carbonates in the soil water, due in large measure to conversion to bicarbonates. Bicarbonates are rapidly removed at first and then continue to be slowly removed in the soil water in very small quantities, diminishing for an indefinite period. The leaching curves conform fairly well to the rate equation, $\frac{dy}{dr}=K\ (A-y)$, proposed by Schreiner and Failyer. Soils containing 'black alkali' can be reclaimed by leaching (i. e., flooding with underdrainage), but

the time and amount of water required is probably much greater than in the case of 'white alkali.'"

The results of the experiments with these soils also "indicate that the use of gypsum facilitates the removal of black alkali from soil, although at the same time it adds to the total quantity of alkali present."

Seven years' soil investigation in southern Illinois, C. G. HOPKINS, J. H. PETTIT, and J. E. READHIMER (*Illinois Sta. Circ. 122, pp. 4*).—The results of experiments with various methods of improving the soil are briefly summarized.

The maintenance of fertility (*Ohio Sta. Bul. 184, pp. 229–305*).—This bulletin contains in full data previously reported in Bulletins 110, 182, and 183 of the station (E. S. R., 12, p. 127; 19, pp. 315, 720) covering statistics of field experiments on this subject from 1894 to 1906 inclusive.

Plans and summary tables of the experiments at the central farm, Wooster, on the maintenance of soil fertility arranged for reference in the field (*Ohio Sta. Circ. 83, pp. 24, dgms. 6*).—A brief summary and explanation of experiments in continuation of those previously noted (see above), giving data for the season of 1907.

Farmyard manure, A. D. HALL (*Jour. Bd. Agr. [London], 15 (1908), Nos. 1, pp. 7–21; 3, pp. 161–176*).—This is a discussion of the losses during making and storage of manure and its value as a fertilizer, based upon practical observations and investigations at Rothamsted and elsewhere. The economy of manuring and of the supplemental use of commercial fertilizers under various conditions of British farming receives particular attention.

Contribution to the knowledge of the microflora of barnyard manure, F. LÖHNIS and W. KUNTZE (*Centbl. Bakt. [etc.]. 2. Abt., 20 (1908), No. 21–23, pp. 676–687*).—Investigations as to the number, character, and activity of various organisms found in manure are reported.

Green manuring experiments, A. ZIMMERMANN (*Pflanzer, 3 (1907), No. 10, pp. 152–156; 4 (1908), No. 3, pp. 33–36*).—Experiments with lupines, Japan clover, and a number of native plants, including species of Crotalaria, Desmodium, Melilotus, and Indigofera, are reported. Of the less common plants tested certain of the Crotalaria and Desmodium gave good results as green manures. The Crotalaria, however, was worthless as a feed, while the Desmodium apparently possessed considerable value for this purpose.

The nitrogen question, A. GRÉGOIRE (*Rev. Econ. Internat., 5 (1908), II, No. 2, pp. 431–446*).—This article discusses the various sources of nitrogen for agricultural purposes and urges especially the more careful utilization of the nitrogen supplies of the farm.

Experiments with nitrogenous fertilizers, C. SCHREIBER (*Rev. Gén. Agron., n. ser., 3 (1908), Nos. 3, pp. 97–105, fig. 1; 4, pp. 145–153, figs. 3*).—The fertilizing values of nitrate of soda, sulphate of ammonia, and calcium cyanamid on oats, corn, and carrots grown in pots containing 6 kg. of loam soil are reported.

In these experiments the average fertilizing effect of the sulphate of ammonia was 77.8 per cent of that of nitrate of soda in experiments in which calcium carbonate was not used, and 81.5 per cent in experiments in which calcium carbonate was applied. The addition of calcium carbonate was beneficial even in case of soils containing a sufficent amount of lime. The results obtained with sulphate of ammonia were much higher in this series of experiments than in an earlier series, due to the fact that the climatic conditions were more favorable, sulphate of ammonia being much more sensitive to such conditions than nitrate of soda.

The average fertilizing effect of the calcium cyanamid was 69.7 per cent of that of nitrate of soda when calcium carbonate was not used and 67.7 per cent

when the carbonate was applied. The injurious effect of the additional application of lime was especially marked in case of oats in the early stages of growth. In some of the experiments in which calcium carbonate was not used the cyanamid was used in much larger amounts than would be employed in practice without evidence of injury to the plants at any period of their growth.

Investigations on the action of sulphate of ammonia and nitrate of soda as fertilizers, E. Blobel (*Untersuchungen über den Wirkungswert von schwefelsaurem Ammoniak und Chilisalpeter als Düngemittel. Inaug. Diss. Leipsic, 1908, pp. 100; abs. in Chem. Ztg., 32 (1908), No. 42, Repert., p. 274*).—From numerous investigations made on the subject the author concludes that the normal fertilizing value of the nitrogen of ammonium sulphate is equal to that of nitrate of soda and not 90 per cent of it, as stated by Wagner. It is impossible, however, to state a normal for the effect in the field, because of the various modifying and uncontrolled influences there. Averages of results of field experiments are, therefore, unreliable. The author claims that the nitrification of the ammonium sulphate is complete and not accompanied by any loss of nitrogen, as maintained by Wagner, and that, contrary to Wagner's assertion, serious loss of ammonia by evaporation seldom occurs.

It should be borne in mind in comparing the fertilizing value of the two materials that the ammonium salt must first be converted into nitrate and that in this process more or less of the nitrogen is fixed for a time by bacterial action in organic form. For this reason the nitrate gives quicker results than the sulphate and is better suited for top-dressing and certain other purposes. On the other hand, the nitrate is more subject to loss by leaching.

Nitrate of soda and sulphate of ammonia, A. Damseaux (*Ann. Gembloux, 18 (1908), No. 6, pp. 354–360*).—A brief review is given of Wagner's investigations on this subject.

On the properties and action of sulphate of ammonia containing a large amount of free sulphuric acid, Lemmermann (*Fühling's Landw. Ztg., 57 (1908), No. 9, pp. 334–339*).—No injurious effects were observed in experiments on barley with sulphate of ammonia containing 3 per cent of free sulphuric acid. The average amount of free sulphuric acid in German sulphate of ammonia is said not to exceed 0.8 per cent.

The effect of the new nitrogenous fertilizers on hemp, V. Stöhr (*Hospodar Moravsky, Brünn, 9 (1907), No. 20; abs. in Zentbl. Agr. Chem., 37 (1908), No. 4, pp. 229–233; Jour. Chem. Soc. [London], 94 (1908), No. 547, II, p. 421*).—In pot tests basic lime nitrate was as effective as sodium nitrate and ammonium sulphate. Lime nitrogen and nitrogen lime were less effective.

Comparative fertilizer experiments with nitrogen lime and nitrate of soda, R. Kuhnert (*Landw. Wchnbl. Schles. Holst., 58 (1908), No. 19, pp. 366–368*).—In these experiments the use of nitrogen lime resulted in a financial loss in the case of beets. With rye and oats somewhat better results were obtained, but the increased yield barely covered the expense of the fertilizer. Profitable returns were obtained in all cases with the nitrate of soda.

Nitrogen fertilizers, especially lime niter, lime nitrogen, and nitrogen lime, A. Stutzer (*Jahrb. Deut. Landw. Gesell., 23 (1908), No. 1, pp. 41–50*).—This article discusses the relative efficiency of these forms of nitrogenous fertilizers on different kinds of soils and crops.

On the influence of sterilization on the solubility of lime nitrogen, H. Kappen (*Centbl. Bakt. [etc.], 2. Abt., 20 (1908), No. 21–23, pp. 704–715; abs. in Chem. Ztg., 32 (1908), No. 50, Repert., p. 323; Chem. Zentbl., 1908, I, No. 26, p. 2198; Jour. Chem. Soc. [London], 94 (1908), No. 547, II, p. 414*).—It is maintained in this article that the sterilization of lime-nitrogen solutions brings about pronounced changes which may materially modify bacterial action in such

solutions. Instead of attempting to sterilize such solutions the solid substances should be sterilized by dry heat.

The behavior of lime nitrogen in storage, H. von Feilitzen (*Chem. Ztg., 32 (1908), No. 45, p. 542; abs. in Jour. Soc. Chem. Indus., 27 (1908), No. 13, p. 696*).—Data are reported which indicate that "calcium cyanamid, when carefully packed in wooden barrels, lined with paper, may be kept for many months in good condition, and almost unchanged in composition."

Experiments with calcium cyanamid, 1907 (*Agr. Students' Gaz., n. ser., 13 (1908), No. 6, pp. 186, 187*).—Comparative tests of ammonium sulphate, sodium nitrate, and calcium cyanamid on barley and mangel-wurzels are briefly reported. The conclusion drawn from the results of these tests "is that calcium cyanamid judiciously applied, is a good nitrogenous manure on this soil."

The fertilizing action of calcium cyanamid, S. de Grazia (*Rend. Soc. Chim. Roma, 5 (1907), No. 19, pp. 244, 245*).—The author studied the effect of varying amounts of water in the soil on the fertilizing value of the cyanamid. The best results were obtained with the larger amounts of water. This is thought to be due to the fact that dicyandiamid is formed from the cyanamid in relatively concentrated solutions.

The manufacture of calcium cyanamid, J. B. C. Kershaw (*Electrical World, 51 (1908), No. 19, pp. 979–982, figs. 5*).—The main features of the principal processes which have been used in the manufacture of this material are briefly described.

The actual state of the nitrate of lime industry in Norway (*Rev. Sci. [Paris], 5. ser., 9 (1908), No. 17, pp. 532, 533*).—Data are given as to the extent to which Norwegian water power is being utilized in the manufacture of basic lime nitrate.

Phosphates, R. McMurtrie (*Amer. Fert., 28 (1908), No. 6, pp. 8–13*).—This is a summary of information regarding the classification, mining, and handling of mineral phosphates, the preparation of superphosphates, and the relative fertilizing value of mineral phosphates, superphosphates, reverted phosphates, and phosphatic slag.

Tunisian phosphates, E. Bertainchand (*Bul. Dir. Agr. Com. et Colon. [Tunis], 12 (1908), No. 46, pp. 55–81; Bul. Agr. Algérie et Tunisie, 14 (1908), Nos. 9, pp. 225–232; 10, pp. 254–265*).—The phosphate deposits of Tunis which have been developed up to the present time are described, with analyses of samples of the various phosphates. It is stated that the exportation of these phosphates in 1907 amounted to 1,058,700 tons, derived from four different deposits. It is estimated that the exportations during 1908 will be considerably larger.

Attention is called to the fact that Tunisian soils are generally naturally deficient in phosphates and are further impoverished by the growth and export of products which exhaust the phosphate supply of the soil. The more extended and systematic use of phosphates in Tunis is therefore recommended.

The chemical methods used in examining the phosphates are briefly described.

[Phosphate deposits in Tahiti] (*Mark Lane Express, 98 (1908), No. 4001, p. 645*).—The British consul at Tahiti reports the discovery on the Society Islands "of enormous deposits of phosphate of lime of an extremely rich character. It is estimated that on one island alone there are at least 30,000,000 tons of the material, the analysis of which has shown from 65 to 85, and even 90 per cent of pure phosphate of lime."

Increased production of phosphate rock in 1907 (*Tradesman, 59 (1908), No. 9, pp. 918, 919*).—It is stated that "the production of phosphate rock in the United States in 1907 amounted to 2,265,343 long tons, valued at $10,653,558, an increase over the production of 1906 of 184,386 long tons in quantity and of

$2,074,121 in value. The average price per ton in 1907—$4.70—was 58 cents greater than in 1906, an increase of 14 per cent." The production from Florida was greater than in any previous year of the history of the phosphate industry. There was also a large increase in the production from South Carolina and Tennessee.

Potash in granitic soils, J. del Campo (*Prog. Agr. y Pecuario, 14 (1908), No. 374, pp. 197–200, figs. 2*).—In this article data are presented to show that although granitic soils contain considerable percentages of potash they are often benefited by applications of potash fertilizers, thus indicating that the potash of feldspar, the characteristic potassic constituent of granite, is rendered available in the soil very slowly.

On the utilization of leucite, C. Manuelli (*Gaz. Chim. Ital., 38 (1908), I, No. 2, pp. 143–152; abs. in Chem. Zentbl., 1908, I, No. 22, p. 1945*).—Comparative tests of various technical processes for obtaining potash salts from leucite are reported. Heating a mixture of the leucite with powdered charcoal and alum to a dull red glow for one-half hour and extracting with boiling water and steam gave good results in the author's experiments.

The industrial treatment of leucite and leucitic materials, G. Gallo (*Rend. Soc. Chim. Roma, 6 (1908), No. 1, pp. 29, 30*).—A process of treating the materials for the recovery of the potash in an electric furnace with dry chlorin gas is briefly described.

The potash industry (*Saaten, Dünger u. Futtermarkt, 1908, No. 24, pp. 651–658*).—The present status of this industry is reviewed.

[Fertilizers in connection with the beet-sugar industry] (*Sugar Beet, 29 (1908), No. 1, pp. 23–26*).—Brief notes are given on the utilization of the nitrogen of distillers' wash, the transformation in the soil of lime nitrogen, filter press scums as fertilizers, the increased yield of beets due to stimulants such as potassium iodid and sodium fluorid, and the fertilizer consumption of mother beets.

Fertilizer experiments with sulphur water, H. E. Müller and K. Störmer (*Deut. Landw. Presse, 35 (1908), No. 34, p. 369*).—This material, which is an ammoniacal liquor obtained as a by-product in the manufacture of paraffin by the destructive distillation of coal, and is very similar in composition and general character to ordinary gashouse liquor, was used with good results on sandy and sandy loam soils. On cultivated soil it should be applied about 14 days before planting. As a top-dressing it should be applied not earlier than 4 weeks after the plants begin growth. On well-drained meadows it may be applied at frequent intervals to an aggregate amount of 160 gal. per acre annually.

Fertilizer analyses, A. J. Patten, S. L. Jodidi, and C. B. Collingwood (*Michigan Sta. Bul. 252, pp. 3–32*).—This is a report in the usual form of the results of the inspection of 275 samples of fertilizers collected during the months of April, May, and June, 1908.

Analyses of fertilizers—fall season, 1907, B. W. Kilgore (*Bul. N. C. Dept. Agr., 29 (1908), No. 3, pp. 51*).—The analyses here reported are of samples collected by the fertilizer inspectors of the State department of agriculture during the fall of 1907. A list is given of brands of fertilizers registered for sale in 1908.

Analyses of fertilizers—spring season, 1908, B. W. Kilgore (*Bul. N. C. Dept. Agr., 29 (1908), No. 4, pp. 50*).—The analyses here reported are of samples collected by the fertilizer inspectors of the State department of agriculture during the spring of 1908. A list is given of brands of fertilizers registered for sale in 1908.

Analyses of commercial fertilizers, W. Frear (*Penn. Dept. Agr. Bul. 163, pp. 51*).—This is a report of inspection of fertilizers in the State from August 1

to December 31, 1907, and includes analyses of 468 samples of fertilizing materials.

Commercial fertilizers and poisonous insecticides in 1907–8, G. S. FRAPS (*Texas Sta. Bul. 107, pp. 5–16*).—Analyses and valuations of fertilizers examined during the season are given in this bulletin, with brief statements regarding the amount of fertilizers sold in the State and their average value per ton, and the general provisions of the State fertilizer law.

It is reported that 21,850 tons of commercial fertilizers, exclusive of cottonseed meal, was sold in the State from September 1, 1907, to May 1, 1908. The average differences between selling price and valuation were $4 per ton in case of acid phosphate, $8 in case of kainit, $20 in case of sulphate and muriate of potash, and $7 in case of mixed fertilizers.

A list of insecticides registered under the State law during the year ended April 30, 1908, is given.

Standard fertilizers, 1908, A. MCGILL (*Lab. Inland Rev. Dept. [Canada] Bul. 151, pp. 27*).—This bulletin reports the results of analyses of 199 samples of fertilizers registered for sale in Canada in 1908.

AGRICULTURAL BOTANY.

Mushrooms, edible and otherwise, M. E. HARD (*Columbus, Ohio, 1908, pp. XII+609, figs. 504*).—This is a popular guide to the study of mushrooms, about 800 species being described and many illustrated by half-tone prints. The aim of the author in preparing this book has been "to describe the species, as far as possible, in terms that will be readily understood by the general reader; and it is hoped that the large number of illustrations will make the book helpful to those who are anxious to become acquainted with a part of botany so little studied in our schools and colleges."

Notes are given regarding the habitat and time of growth of the different species and also on their edibility. Chapters are included giving directions for cooking mushrooms and on how to grow them.

The yeast fungi, F. G. KOHL (*Die Hefepilze. Leipsic, 1908, pp. VIII+343, pls. 8, figs. 59*).—This is a study on the organization, physiology, biology, systematic classification, importance, and bearing on fermentation of yeasts and yeast-like fungi. Among the yeast-like fungi, the author includes the Schizosaccharomycetes and such genera of fungi as Torula, Mycoderma, Monilia, Oïdium, Dematium, etc.

Acclimatization of plants, H. F. MACMILLAN (*Circs. and Agr. Jour. Roy. Bot. Gard. Ceylon, 4 (1908), No. 9, pp. 55–73*).—In a paper read before the Ceylon Agricultural Society, the author gives an account of what has been done in Ceylon in the acclimatization of plants, and calls attention to the necessity for care in the introduction of plants, as it is usually the most worthless ones that are generally most readily acclimatized. Lists are given of plants which have been introduced into Ceylon from other parts of the world, showing the dates of introduction, so far as known, and the elevation or district best suited to their growth.

On the effect of a partial removal of roots and leaves upon the development of flowers, M. SHIGA (*Jour. Col. Sci., Imp. Univ. Tokyo, 23 (1907), Art. 4, pp. 15*).—The author carried on a series of experiments with peas of different kinds, horse beans, Japanese morning glories and buckwheat in water and pot cultures to determine whether a partial removal of leaves, roots, etc., has any effect upon the formation of flowers.

When the main root and most of the lateral roots were removed, flowering was promoted, except with buckwheat. When all the lateral roots were

successively removed, flowering was prevented, and the leaves and stems became smaller than in the control experiments.

When the removal of the lateral roots was done at intervals of 4 days for a month and after that once a week, the growth of the leaves and stems was not affected, and flowering was promoted. The removal of lateral roots once every week for the first month and once every 2 weeks during the second month resulted in the advance of flowering, but the total number of flowers was not increased.

When the lateral roots were removed, the main root was always greatly lengthened, while the stems of the plants were shorter than in the control. When the main root was removed, leaving a few lateral roots, the stems were not affected.

In the morning glories, peas, and horse beans, the removal of the main root and some of the lateral roots, leaving only a few laterals, caused the flowers to appear earlier than usual and more abundantly. When all the lateral roots were removed, some varieties of peas and the horse beans bloomed earlier, but others were so injured that blooming was not accelerated.

Where the leaves were removed in the morning glory and buckwheat, the plants failed to flower. In the peas, blooming was not promoted, but the bracts seemed to serve as assimilatory organs.

Rapid transformation of starch into sucrose during the ripening of some tropical fruits, H. C. P. Geerligs (*Internat. Sugar Jour., 10 (1908), No. 116, pp. 372–380*).—On account of the fact that many tropical fruits are as a rule gathered in a green and immature state and allowed to ripen afterwards, the ripening process taking place so rapidly that within a few days they become tender and well-flavored, they are said to offer a good opportunity for studying the somewhat obscure problem of the after-ripening of fruits. Investigations were carried on by the author with bananas, mangoes, tamarinds, and sapodillas to determine the changes taking place during ripening after being removed from the plant. A considerable amount of carbon dioxid was given off during this period of after-ripening and important chemical changes were shown to have taken place.

In the case of the banana the starch is rather suddenly transformed into sucrose, and during this process a little dextrin is formed. In the ripe fruits the sucrose becomes partly inverted or consumed as such or as products of its inversion.

With the mango, during the process of ripening yellow coloring matter is produced that resembles in every respect carrotin. During the after-ripening the starch is transformed into sucrose, which later on becomes hydrolyzed and splits up into glucose and fructose. The citric acid present in the fruit is vigorously attacked, and the decrease in the acid taste is not due to an increase in sugar content, nor to the neutralization of the acid, but to the destruction of the citric acid itself.

In the ripening of the tamarinds, the starch is transformed into sugar, but in this case it is not changed into sucrose, but into a mixture of glucose and fructose. The increase in the percentage of sugar after the period of maturity is due to the strong concentration by evaporation, as there is no fresh formation of sugar possible in so dry a fruit.

In the sapodilla the most important change is not due to the saccharification of starch, but to the changes brought about in the tannin and gutta-percha. The amount of sugar before and after ripening is the same, but the fruit becomes palatable by the softening of the hard pectin and by the deposit of tannin and gutta-percha in an insoluble form.

While studying the ripening of the fruits, the author found a rather sudden transformation of starch into sucrose, followed in a later stage by inversion

and partial degradation of the products of inversion. When the fruits were placed in nitrogen and air, it was found that after-ripening in the air proceeded uninterruptedly, while fruits kept in nitrogen remained unchanged and preserved their starch content. This indicates that a free access of oxygen is indispensable for the saccharification of the starch in the fruit.

In studying the cause of the transformation in the case of the mango, it was found that the juice contained a diastatic body with power to transform starch into dextrin and into sugar.

Further investigations showed that the rapid transformation of starch into sucrose during the after-ripening of some fruits is a vital process and not a consequence of the presence of some ferment contained in the fruit.

The hydrolytic and catalytic ferments acting during the process of ripening of fruit, G. Tallarico (*Arch. Farmacol. Sper. e Sci. Aff.*, 7 (*1908*), *Nos. 1, pp. 27–48; 2, pp. 49–68; abs. in Chem. Zentbl., 1908, 1, No. 16, pp. 1563, 1564; Jour. Chem. Soc. [London], 94 (1908), No. 550, II, p. 724*).—The author made a study of bananas to determine the changes taking place during the process of ripening of the fruit. "From this fruit, gathered in different stages of ripening, extracts were made. The catalytic action was determined by investigating the action of the extract on hydrogen peroxid; the amolytic, by its action on starch; the proteolytic, by the action on gelatin; and the inverting, by the action on sucrose. The following enzyms were present: Catalase, invertase, amylase, tyrosinase, and a proteolytic enzym. The catalytic action is very intense so long as the fruit is green and during ripening; it weakens as the fruit gets black. The amylolytic action takes place when the fruit is green or at the beginning of the stage of ripening; it then disappears. The inverting action is almost entirely absent during the green stage, is intense during ripening, and then gradualy disappears. The proteolytic action manifests itself during ripening, and then probably gets weaker."

Transitory presence of hydrogen cyanid in ferns, M. Greshoff (*Pharm. Weekbl., 45 (1908), No. 26, pp. 770–773; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 550, II, p. 725*).—The author reports the detection of hydrocyanic acid in ferns, such as *Gymnogramme aurea*, *G. lastrea*, and *G. athyrium*. The percentage varied from 0.056 in very young fronds to 0.006 in old ones, the content always diminishing with the increase in age of the material examined.

On the effects of certain poisonous gases on plants, W. J. V. Osterhout (*Univ. Cal. Pubs., Bot., 3 (1908), No. 4, pp. 339, 340*).—The author has carried on some experiments to determine a method of distinguishing the effect on plants of smelter fumes and other poisonous gases from that of drought and similar natural causes.

In some experiments on transpiration carried on some time ago, it was noticed that in the case of drought the oldest leaves were the first to succumb, while the youngest held out until the last. This was repeatedly confirmed with cultures of the common wandering jew.

When the problem of smelter fumes was called to his attention, it occurred to the author that probably the effect of poisonous gases would be the reverse of that of drought, in that the younger leaves would be affected before the older ones. Experiments with wandering jew showed that the young leaves were the first to be killed by sulphur dioxid, and these were afterwards confirmed by experiments on fruit trees, grapevines, and other plants. Field observations have since borne out the results of the experiments.

It is believed possible, therefore, to distinguish between the effects of poisonous fumes and natural agencies, such as drought and injury to the roots, in a clear and definite manner.

International catalogue of scientific literature. M—Botany (*Internat. Cat. Sci. Lit., 5 (1908), pp. VIII+1210*).—This is the fifth annual issue of the catalogue of scientific papers compiled and published by the International Council of the Royal Society of England, the arrangement and grouping being essentially the same as in previous issues (E. S. R., 18, p. 435). The number of papers noted is about 7,000, the literature included being mainly that of 1905. As in the previous numbers, the American literature is inadequately catalogued, the publications of this Department and the experiment stations being almost wholly neglected. In the section listing titles realting to the treatment of plant diseases, not a single reference to American literature is given.

FIELD CROPS.

The rotation of crops, W. M. Hays et al. (*Minnesota Sta. Bul. 109, pp. 281–358, figs. 12*).—The plan of this experiment, together with earlier results, has been previously noted (E. S. R., 7, p. 122). This bulletin reports the results of 10 years' work.

Of the different cropping systems tried those in which corn, small grains, and timothy and clover for 1 to 4 years were arranged in a 4 to a 7 year rotation with light manuring once during the course, gave large net profits. The standard 5-year rotation was as follows: First year corn following the application of 8 tons of manure per acre, second year wheat, third and fourth years meadow, and fifth year oats. The average gross income per year from this rotation based on average farm prices was $14.08 per acre and the cost of production, including $3.50 land rental, was $9.05. The best rotations yielded a product worth from $4 to $6 per acre more than is obtained on the average farm throughout Minnesota. All systems of cropping which provided for the maintenance of vegetable matter in the soil either by manuring or by growing pasture or meadow crops gave profitable returns.

The plats growing hoed crops such as corn, potatoes, and mangels continuously without manure gave poorer returns than the plats growing grain continuously without manure. It is believed that the intertillage given these crops caused a more rapid depletion of vegetable matter than took place in the continued grain fields. The 4-year rotation, millet, barley, corn, and oats, gave no better returns than wheat grown continuously. All these crops are considered exhaustive as they decrease rather than increase the supply of vegetable matter in the soil. Sowing grass seed with grain on corn land that is disked in the spring, in place of fall plowing, proved to be the surest method of obtaining a grass stand at the university farm.

In studying the influence of crop rotation and continuous cultivation upon the composition and fertility of soils at the beginning and close of the 10-year period on the 44 experimental plats, it was found that when wheat, corn, potatoes, and mangels were grown continuously the average loss of nitrogen amounted to 0.034 per cent, or 1,100 lbs. per acre. The maximum amount of nitrogen was lost in the continuous cultivation of these crops. In the case of wheat two-thirds of the nitrogen removed was not utilized as plant food but was lost by the rapid decay of the humus with the formation of soluble and volatile nitrogen compounds. When the crops were grown continuously the soils lost 0.5 per cent of carbon, representing over 1 per cent of humus or 20,000 lbs., equivalent to an annual loss of 1 ton per acre. On the plats growing the standard rotations there was an average gain of 0.014 per cent of nitrogen, equivalent to about 300 lbs. per acre. The results show that the nitrogen content is maintained when clover is grown 2 years in a 5-course rotation. The data also indicate that any substitution of crops in the rotation could be made without mate-

rially affecting the nitrogen content of the soil, provided clover was retained. Rotation maintained the carbon and humus content of the soil and in some cases slightly increased it. The substitution of timothy and other nonleguminous plants for clover caused a loss of nitrogen, but the carbon and humus content was kept up. The conservation of the humus prevented rapid nitrification and the loss of soil nitrogen only slightly exceeded that removed by the crops.

The potash compounds of the soil were less soluble at the close of the 10-year period than at the beginning. The formation of soluble potash compounds did not keep pace with the amount removed as plant food and that lost in the drain waters.

Report of the work at the Holly Springs Station for 1907, C. T. AMES (*Mississippi Sta. Bul. 110, pp. 7*).—This bulletin reports briefly the results of fertilizer experiments on cotton, corn, and cowpeas, with notes on grasses and forage crops.

The work of the San Antonio experiment farm in 1907, F. B. HEADLEY and S. H. HASTINGS (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 13, pp. 3–16*).—This circular contains a description of the farm and the lines of work undertaken.

In experiments with cotton and corn in 1907, 4 plats plowed and subsoiled to a depth of 12 in. or more yielded more in every case than an equal number of plats not subsoiled. In October, 1907, part of a field of sorghum was plowed and the other part left unplowed until December. In the meantime, 7 in. of rain fell and soil moisture determinations made in December showed 24.9 per cent of water in the first 3 ft. of the land plowed in October, as compared with 22.6 per cent for the land plowed in December, or a difference equivalent to 1.1 in. of rain.

It is pointed out that on the heavy soil of San Antonio a light rain of 0.1 to 0.4 in. may reduce rather than increase the total amount of soil water. Soil moisture determinations were made in an orchard and a cornfield cultivated on June 5 and 6, 1907, respectively, to illustrate the effect of early tillage after rain. On May 29, 1.2 in. of rain fell and 7 days after, in the absence of a dust mulch, the moisture content of the first 3 ft. in the orchard was 0.6 per cent less than it had been before the rain. In the near-by cornfield, which was cultivated 2 days earlier, an increase of 0.6 per cent of moisture over what was in the soil May 28 was determined.

Soil moisture determinations were also made on March 12, 1908, on two fields, one of which was fall plowed and well tilled throughout the winter and the other plowed in February. The upper foot of soil of the winter tilled plat retained 3.4 per cent more moisture than the plat left without cultivation until February.

Two methods of eradicating Johnson grass were tried. In September, 1906, a 6-acre Johnson grass meadow was plowed 4 to 5 in. deep with a disk plow. Two acres were left fallow during the winter, cultivation was given during February, March, and April at a cost of $10.84 per acre and in May, when the eradication was nearly complete, the field was sown to German millet. The other 4 acres were sown to oats in November. The growth of Johnson grass in the spring in this field was weak and but few plants headed out before harvesting early in May. The cost of cultivation to eradicate Johnson grass after plowing was only $1.12 per acre.

In 1907 a field of sorghum sown broadcast yielded 1.68 tons per acre, while the same variety drilled in rows 4 ft. apart in an adjoining plat yielded at the rate of 2.9 tons of cured fodder. A plat of 1.28 acres planted in alfalfa varieties in double-drilled rows 2 ft. apart to permit cultivation survived the severe drought of the summer of 1907 and in March, 1908, yielded from the first cutting 1,236 lbs. of cured hay from the field, equivalent to 957 lbs. per acre. Ad-

jacent plats sown in drills 6 in. apart yielded at the rate of only 318 lbs. per acre.

Notes on work with cotton, crops for forage, green manure and grain, and on horticultural work are given and the sterility of sorghum due to the activities of *Diplosis sorghicola* is described.

Change of vegetation on the south Texas prairies, O. F. Cook (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 14, pp. 7*).—Attention is called to the fact that regions formerly grassy, open prairies are now covered with a dense growth of mesquite, prickly-pear cactus, and other shrubby plants of intermediate size. The influence of fires on the change of vegetation is discussed. It is stated that mesquite alone works little injury to the grazing industry, but that the huisach (*Acacia farnesiana*), and smaller shrubs and cacti may become numerous enough to kill out the grass and diminish the pasturage rapidly. It is believed that the shrubby vegetation in south Texas will continue to advance and multiply wherever the land is not cleared and cultivated. The mesquites, cacti, chaparral, and sagebrush are considered by the author only as an episode of the bionomic history of the region and not as its original or normal condition or an index to its agricultural possibility. It is believed that they are merely the forerunners of a larger forest growth.

Dry-land agriculture (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 130, pp 7–90, figs. 4*).—This bulletin contains the following papers, read at the second annual meeting of the cooperative experiment association of the Great Plains area, held at Manhattan, Kans., June 26–27, 1907: The Development of Dry-land Farming, by E. A. Burnett; Some Soil Studies in Dry-land Regions, by F. J. Alway; Crop Production under Humid and Dry Conditions, by E. G. Montgomery; Blowing Soils, by L. E. Hazen; Plant Breeding in Conjunction with Dry-land Agriculture, by L. R. Waldron; Rate of Sowing Durum Wheat, by L. R. Waldron; Fruit Growing on the Plains, by J. E. Payne; Oklahoma Rotations and their Relation to Soil Culture Work, by L. A. Moorhouse; and Dry-land Plant Breeding, by J. H. Shepperd.

Dry-land grains, W. M. Jardine (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 12, pp. 3–14*).—An address delivered at the Trans-Missouri Dry-Farming Congress at Salt Lake City, Utah, January 23, 1908.

The different grains adapted to dry-land culture are enumerated, and the great wheat groups, hard spring, hard winter, semisoft white, and soft white wheats are discussed. The hulless types of barley, Tennessee Winter barley, and Sixty Day, Kherson, Burt, and Swedish Select oats are considered promising for dry-land conditions, and the grain sorghums, milo maize, black hull Kafir corn, and red Kafir corn are recommended as valuable for the arid region.

The regions where the different wheat groups are grown under dry farming are pointed out. The durum wheats have proved themselves drought-resistant and rust-resistant, and it is believed that they will ultimately become the leading spring type in dry-land agriculture. It is stated that the durum wheat crop of 1907 exceeded 50,000,000 bu. The hard winter or Crimean group of wheats has shown a wide adaptability and excellent drought resistance. It is thought that the only possible way to obtain a steady and permanent market for grains, especially in the intermountain area, is to concentrate on as few varieties as possible.

Alfalfa (*Kansas Sta. Bul. 155, pp. 183–345, figs. 60*).—This bulletin consists of the following series of papers on alfalfa: History and varieties, alfalfa breeding, and diseases of alfalfa by G. F. Freeman; the seeding of alfalfa, management of alfalfa in the field, the alfalfa seed crop, alfalfa hay—its making, handling and marketing, and handling and treating alfalfa land by A. M. Ten Eyck; the adulterants, substitutes and impurities of alfalfa seed and their

detection by H. F. Roberts; the relation of bacteria to alfalfa by W. E. King; the composition and digestibility of alfalfa and its relation to soil fertility by J. T. Willard; alfalfa feeding by R. J. Kinzer and G. C. Wheeler; alfalfa for a dairy farm by J. C. Kendall; and insects and other animals injurious to alfalfa by T. J. Headlee. In these papers the history, culture, improvement, and uses of alfalfa are discussed. The Turkestan, German, American, Arabian, and Peruvian types are noted, the inoculation of soils for alfalfa culture described, and the composition and digestibility of alfalfa considered. The uses of alfalfa for the different kinds of live stock are pointed out, and the methods of improving the plant by breeding and selection are discussed. A number of the papers report experimental results.

On June 18, 1903, 1,133 alfalfa plants were counted in a plat seeded the fall before and containing 100 sq. ft. On June 29, 1906, this field showed only 670 plants and on August 9, 1907, 403 plants. The decrease in the number of plants during a period of 50 months was 730, or a loss of 64.4 per cent. Another plat seeded in the spring of 1904 contained 1,130 plants on June 20, on an area of 5 ft. square. May 1, 1905, the number of plants had been reduced to 403, and May 25, 1908, to 148 plants. Only 13 per cent of the plants counted in the original seeding survived 4 years after seeding. Although the number of plants was greatly reduced in these plats the stand of alfalfa was apparently as good as ever, because the plants which remained increased in size and sent out more shoots or stems.

Disking alfalfa with the common disk harrow in 1903, 1904, and 1905, gave an average yield of 9,922 lbs. of cured hay, as compared with 10,269 lbs. where no disking was done. An experiment in manuring alfalfa at the rate of about 10 tons of well-rotted barnyard manure per acre, applied to the winter wheat crop immediately preceding the alfalfa, produced 63.7 plants per square foot averaging 13 in. high, while on similar land not manured 50.4 plants, 4½ in. high were produced per square foot.

In germination tests at the station the average germination from brown, blackened, and green immature seed in 21 samples was 65 per cent, the range lying between 39 and 80 per cent. The average germination of 5 high grade samples was 98 per cent. The apparently bad seed from these high grade samples gave an average germination of 70 per cent, while an average from 4 low grade samples gave a germination of 75 per cent and 46 per cent for the whole sample and for the apparently bad seed, respectively. In one sample the dead and defective seed reached 60 per cent of the total, from 5 to 10 per cent being very common in the samples under test. One of the best samples analyzed 95.6 per cent pure, while a germination test showed but 63.9 per cent of pure good alfalfa seed, the impurities amounting to 36.1 per cent and consisting of dead and decayed seed 28.1 per cent, foreign seed 7.1, and inert matter 0.9. Attention is called to the fact that a pound of this sample would have contained 135,053 good alfalfa seed capable of germination, 59,389 dead and defective alfalfa seed incapable of germinating, and 20,593 foreign seeds.

In studying the analyses of alfalfa seed made at the station it was found that about 97 per cent contained from zero to 10 per cent of both inert matter and foreign seed. While 60 per cent of the samples analyzed contained from zero to 10 per cent of foreign seed, 50 per cent of these samples contained from zero to 10 per cent of inert matter. In 35.2 per cent of the samples subjected to analysis the seed failing to germinate ranged from 15 to 25 per cent, and a germination percentage of not more than 64 was found in 30 per cent of the total number of samples, while the mean germination percentage of all of the 253 samples was 75.4 per cent. A table is given showing that with the poorest 10 samples the cost of seeding 1 acre ranged from $3.75 to $34, while the cost

of seeding 1 acre with the best 10 samples ranged from $1.95 to $2.10. A comparison of the results of analyses during the years 1906, 1907, and 1908 shows practically no improvement in the total impurities present in the seed, but the percentage of foreign seed shows a gradual decline.

Cutting alfalfa at different stages of maturity gave the following yields at the first cutting: First bloom, May 16, 1.36 tons of hay, one-tenth bloom, May 29, 1.76 tons, one-half bloom, May 31, 1.81 tons, and at full bloom, June 7, 2.04 tons per acre.

In 1902, A. L. Cottrell found that 223 plants examined contained 6,335 stems, or an average of 28.4 stems per plant. On the average 55 per cent by weight of matured hay was found to be stems and 45 per cent leaves. This relation showed some variations, however, as one group selected for leaf characteristics had 49 per cent leaves and 51 per cent stems, while another selected for stem characteristics contained 41 per cent leaves and 59 per cent stems.

In 1905 the station hauled green alfalfa hay into a small shed above an elevated, well-ventilated bottom, the hay being piled loosely from 4 to 5 ft. thick but not tramped. A second cutting was later placed upon the first in a similar manner. While alfalfa left in the field was very badly spoiled by the rains, this green alfalfa cured out almost perfectly, showing only a little moldy hay in the center of the mow. Directions and plans for the construction of hay sheds adapted to this method of curing and storing alfalfa hay are given.

As an average for 4 seasons the yields per acre of several hay crops compared as follows: Common alfalfa 7,345 lbs., Turkestan alfalfa 6,080 lbs., Medium Red clover 5,490 lbs., *Bromus inermis* and alfalfa 5,473 lbs., timothy 4,779 lbs., timothy and red clover 4,604 lbs., Mammoth clover 4,148 lbs., *B. inermis* and red clover 4,133 lbs., *B. inermis*, orchard grass and red clover 3,825 lbs., timothy, red clover and *B. inermis* 3,560 lbs., timothy and redtop 3,060 lbs., *B. inermis* 2,892 lbs., tall oat grass 1,707 lbs., meadow fescue (English bluegrass) 1,666 lbs., orchard grass 1,414 lbs.

Moisture determinations of green alfalfa cut at different stages of maturity in 1906 showed the following total moisture content: Cut at the time of first bloom, May 16, 74.64 per cent, cut at one-half bloom, May 31, 69.72 per cent, and cut in full bloom, June 7, 64.18 per cent. Other determinations showed a moisture content ranging above 80 per cent.

Winter bur clover, W. C. Welborn (*Texas Sta. Bul. 108, pp. 3–6*).—The culture and uses of bur clover are described.

Cotton experiments, 1907, W. R. Perkins (*Mississippi Sta. Bul. 113, pp. 7, chart 1*).—In comparison of 11 varieties of cotton, Cleveland Big Boll ranked first in lint production with 630 lbs. per acre and first in total value per acre with $69.73. Russell Big Boll ranked first in seed production with 1,280 lbs. of seed per acre. Russell Big Boll and World Wonder produced the longest staple, 1⅛ in. Topping cotton on August 3 and 26 gave inconclusive results. Cotton plowed the last time on August 3 did not keep up its growth as late nor was the number of late blossoms nearly so large as in cotton cultivated twice later than this date, on August 13 and 27. The plat cultivated last on August 3 yielded 1,126 lbs. of seed cotton, while the plat cultivated last on August 27 yielded 1,236 lbs. per acre.

Breeding work with cotton is briefly described. The work was begun in 1904 with a few selected stocks of Cook Improved, but although selection has been carefully continued considerable variation is still found.

Danger in judging cotton varieties by lint percentages, O. F. Cook (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 11, pp. 3–16*).—This circular points out the danger of too persistently basing the selection of cotton upon the single character of lint percentages, shows how smaller or lighter seeds raise the lint

percentage, describes the advantage of large seeds, heavy seeds and large-seeded varieties, and calls attention to the higher lint percentages that diminish fertility, to the large yields without high percentages, and to the high quality with low percentages.

It is shown that smaller or lighter seeds increase the percentages of lint quite as effectively as an additional amount of fiber. A Mexican cotton with 27 per cent of lint hybridized by Egyptian cotton having a somewhat higher percentage gave a progeny with a percentage of only 22.9, while the lint increased from 4.05 gm. to 4.45 gm. per 100 seeds. The seeds, however, increased from 10.95 to 14.75 gm. per 100 seeds. In order that a higher lint percentage may be accompanied by an increased amount of lint it is necessary that the weight of the seeds does not decline either by reduction in size or by change of texture or compactness.

The size of the seed is of practical importance apart from the question of lint, mainly for the reason that there is an increased demand for cotton seed for oil and other uses and that the presence of the boll weevil gives large seeds a definite advantage. The large seed as a rule gives the young plant a better start than a small seed and the more vigorous the seedlings the earlier the varieties should be. It is shown that some of the early varieties like the King, which has small seeds, small bolls, and short lint, may afford no better protection against the weevils than some of the large-seeded big-boll varieties. Early opening of the bolls is not considered the best index of the amount of protection obtained by early development. As long as the bolls are matured they are beyond the reach of weevil injury and a variety setting bolls early and carrying them past the danger of weevil infection may produce a larger crop in the presence of the weevils than the variety which ripens the first bolls. "The ideal habit of earliness would be met by a variety which could develop a large number of bolls past the point of weevil injury early in the season. Delay in the date of opening might be an advantage if all the bolls would open together and thus avoid the need of making several pickings of the same field." Other advantages of big-boll over small-boll varieties are pointed out.

The author states that lint percentages can not be substituted for actual tests of yield and that selection by lint percentages instead of increasing the agricultural value of a variety may actually diminish it. On the other hand, it is shown that large yields may be secured without high percentages. No necessary connection between lint percentages and yields seems to exist, as very high yields are obtained from varieties with relatively low percentages of lint. It is pointed out that in Sea Island and Egyptian cottons the percentages fall below those reached in some of our Upland varieties, but that high yields are not prevented by lower percentages of lint. "Other things being equal, the high percentage varieties would always yield more lint, but it is evident that the other things are often unequal and that the high percentages have no fixed connection with vigor and fertility. Lint percentage is important as long as the other features are not left out of account, but persistent selection for lint percentage alone would be as likely to reduce the crop as to increase it." High lint percentages are not considered as insuring high yields or high quality. With greater length the percentage falls rapidly as the lint of carefully selected varieties becomes longer.

In discussing the true standard of yield in cotton the author points out that the most direct indication of productiveness is not the proportion between the lint and the seed but the proportion of the lint to the plant as a whole. A comparison of the weight of the lint with the weight of the plant would determine how much in the way of other tissues the plant has formed in producing a given

amount of lint. It is proposed that a lint index in the weight of the lint itself instead of a less important proportion between the lint and the seeds be used for judging varieties. "The lint from 100 seeds of Upland cottons ranges in weight from 6 gm. or less to 9 gm. and upward, and these figures can be directly applied as a standard in judging varieties in place of the lint percentages." A lint index on this basis would mean something actually accomplished, and an unintentional discrimination between small seeds and small bolls would be avoided.

The relation between large seeds and large amounts of lint, or a high lint index, was tested by D. N. Shoemaker by a study of weights of 73 samples of seeds and lint in a series of selections of Triumph cotton, and the results are here briefly noted. The average weight of 100 seeds was 12.37 gm., and their average weight of lint 7.38 gm. Of 44 plants whose lint was above the average only 4 fell below the average in weight of seed, and of 29 plants which fell below the average in weight of lint only 4 were above the average in weight of seed, and these exceeded the average only a little. No such evidence of correlation was found when the same data were arranged according to size of seed and percentage of lint. Of the 28 plants showing lint percentages above the average of 37.7, 15 had seeds below the average weight while the other 13 had seeds above the average. The author points out that the selection of a plant with the highest percentage of lint, which was 42.8, would have meant the rejection of no less than 41 plants whose seeds produced larger amounts of lint; that is, the plant with the highest percentage would have ranked as No. 42 in the series of 73 plants if arranged by lint indexes. The plant with the highest percentage of lint had only seven-eighths as much lint as the plant showing the highest lint index, and this is used as an illustration to indicate the extent of the practical difference in this variety between the lint index and the lint percentage as the basis of selection.

Progress of the beet-sugar industry in the United States in 1907 (*U. S. Dept. Agr. Rpt. 86, pp. 7–88*).—As in previous reports a general review of the beet-sugar industry is given for the year 1907, by C. F. Saylor, together with discussions with reference to the influence of the beet-sugar industry, the costs and profits of sugar beet growing, the use and value of by-products, the labor problem and labor-saving devices, and the development of conditions and prospects for extending the beet-sugar industry in the different States, with statistics of sugar production in this country and the world at large.

In 1907, 63 factories were in operation, 370,984 acres of beets were harvested, 3,767,871 tons of beets were worked into 463,628 tons of sugar, the average sugar content of the beets was 15.8 per cent, the average purity coefficient 83.6 per cent, and the estimated abstraction of sugar 12.30 per cent. The average yield of beets was 10.16 tons per acre, exceeded only in 1904 and 1906, and being 5 per cent greater than the 6-year average for 1901–1906. The average length of the campaign was 89 days.

The work of the Bureau of Plant Industry with sugar beets is briefly outlined by B. T. Galloway.

Sugar beets in Virginia. W. B. Ellett (*Virginia Sta. Circ. 1, pp. 4, fig. 1*).—Culture tests with sugar beets in Virginia are briefly reported. The first experiments were conducted by this Department from 1897 to 1900, inclusive, and 132 samples analyzed contained an average of 10 per cent of sugar and a purity of 74 per cent. All but one of the samples were grown in Piedmont and Tidewater, Virginia.

The results of 3 years' experiments begun in 1900 by the Virginia Experiment Station in cooperation with this Department have been previously noted (E. S. R., 17, p. 549). The results of 1904 were a little better than the 3-year

average, the yield being 13.3 tons per acre, the sugar content 13.9 per cent, and the purity 81.2 per cent.

It is believed that equally good results may be secured throughout a large part of the Valley of Virginia, the southwestern part of the State, and possibly in some of the higher sections of Piedmont Virginia.

Varieties of cane, with special reference to nomenclature, N. Deerr and C. F. Eckart (*Hawaiian Sugar Planters' Sta., Div. Agr. and Chem. Bul. 26, pp. 5–25*).—This bulletin records results with reference to nomenclature of varieties of cane secured by a study of all the literature available, as well as the personal observations of the authors. An outline of the history of different varietal groups is presented, and synonyms of the varieties treated are given in a summary. The different varieties discussed are the Yellow Otaheite, Batavian or Transparent, Yellow Caledonia and Tanna, Salangore, Cavengerie, Bamboo, Red, Stripedtip, Elephant, Green Rose Ribbon, Uba, and Daniel Dupont canes.

Cooperative wheat variety work (*Ohio Sta. Circ. 84, pp. 4*).—This circular describes the object of the test and the methods to be followed by each cooperator in conducting the work.

HORTICULTURE.

Handbook of fruit culture, N. Gaucher (*Handbuch der Obstkultur. Berlin, 1908, 4. ed., rev. and enl., pp. XX+1030, pls. 16, figs. 630*).—This work, which is offered as a book of practical experience for practical use, first appeared in 1888, and has been considerably revised and enlarged in the succeeding editions. The first 2 parts deal with the development of the nursery and nursery practices. The succeeding parts of the work treat of the history, importance, and profit of fruit culture, with hints for further development of the industry; fruit culture in the field and on the roadside; planning fruit orchards and gardens; formal fruit gardens and their arrangement; the function of the leaves, purposes of pruning, and the physiological fundamentals of rational fruit culture; pruning methods; the care of artificial tree forms; harvesting, storing, and packing; diseases of fruit trees and shrubs; and the friends and enemies of fruit trees.

The text is fully illustrated, and a monthly working calendar, together with several plans for the development of formal fruit gardens and views of specimen fruit trees grown at the author's horticultural establishment at Stuttgart, are appended.

On the virgin fertility of fruit trees, A. Glatz (*Proskau. Obstbau Ztg., 13 (1908), No. 7, pp. 100–106*).—The occurrence is reported of an apple tree producing seedless fruit. The tree is said to be a heavy bearer and fruit buds are formed on the one-year wood, thus enabling the tree to bear annually. The flowers have neither petals nor stamens. Although the pistils have a weak development, they produce seed when artificially pollinated. The tree comes into full bloom before the leaves begin to develop, from which it appears that the fruit buds, unimpeded by the growing leaves, may be able to develop at the expense of the reserved food supply in the tree. The core development varies in the individual fruits, and in some is almost lacking.

The author is of the opinion that the method devised by Ewert (E. S. R., 19, p. 142) for artificially pollinating nonfertile varieties of fruits will be found to be of little value for practical orchard culture. He suggests that an attempt should be made by judicious breeding so to develop the existing seedless varieties, as to render the production of satisfactory fruit possible in years when the weather and other conditions are unfavorable for pollination.

The grape in the various stages of maturity. W. Kelhofer, trans. by E. Zardetti (*Gior. Vin. Ital., 34 (1908), No. 30, pp. 475–477*).—Tabulated results are given and discussed relative to the determination of the weight of seeds, density of the must, and content of sugar, acid, tannin, nitrogen, and ash in grapes at various stages previous to maturity. Nine determinations were made from August 24 to October 28, inclusive.

The sugar content increased from 0.77 per cent on the first date to 14.76 per cent on the latter date. There was a corresponding decrease in acidity from 31.7 per cent to 13.1 per cent, and of tannin from 0.88 per cent to 0.25 per cent.

On some experience in hybridizing grapes. C. Grimaldi (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 17 (1908), I, Nos. 10, pp. 653–661; 11, pp. 745–751*).—A list is given of 207 hybrid grapes originated by the author since 1889, together with a brief outline of the method of procedure, the results secured, and descriptions of several hybrids recommended for trial.

Viticultural notes, H. Blin (*Semaine Agr. [Paris], 27 (1908), No. 1394, pp. 44, 45*).—A study of the hybrid grape Portuguese Blue×*Rupestris phénomène du Lot* relative to its characters, qualities, and advantages.

Basing his conclusions on single observations as well as on practical tests in numerous situations, the author recommends this hybrid for planting in central France. It is said to be a very productive variety, resistant to cryptogamic maladies, and capable of adapting itself to various soils. The grapes are black, produce a highly colored wine rich in alcohol, and stand shipment well. The bunches are from 15 to 20 cm. long and weigh from 200 to 250 gm. The crop matures about the first of August. It is further claimed that this hybrid is remarkably resistant to frost.

The influence of grafting on the quality of wines in Anjou, Marquis de Dreux-Brézé (*Rev. Vit., 30 (1908), No. 760, pp. 29–32*).—In the course of reconstituting the vineyards in Anjou special attention was paid to the selection of vines suitable for heavy limy soils. A large number of experimental fields were planted in 1893 and 1894 with all of the prominent grape stocks of that time. These were later grafted to healthy scions of known origin. A summary is here given of the author's experience and observations, combined with those of several cooperators, relative to the influence of grafting and of the grape stock on the products of the vine.

Contrary to the opinion of J. Capus, who in the same line of investigation in the department of Gironde found that grafting does not appear to have produced anything new (E. S. R., 19, p. 739), the general conclusions reached from the present investigation are that, other conditions being equal, grafting augments the quality, grade, and value of Anjou wines. On the other hand, the grafted vines are more delicate and require more care. Grafting does not appear to interfere with the special characteristics of local wines. The grape stock, however, has a very great influence on the quality of the wine. White wines appear to be more affected than red wines. The stocks are classed in 3 groups, those which improve the quality, those which elevate it slightly, and those which modify it.

Bearing hybrids (grapes) and their wines in 1907, E. Pée-Laby (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 29 (1908), Nos. 23, pp. 687–689; 24, pp. 707–717; 25, pp. 753–755; 26, pp. 775–782*).—A committee report to the Central Society of Agriculture of Haute-Garonne relative to observations made in 1907 on the cultural value of the direct bearing grape hybrids, together with the results of an analytical study of wines obtained by making various mixtures of the wines of hybrids with the common wines of the country. The older hybrids in the experimental vineyards of the Montpellier agricultural school were studied to determine whether they had deteriorated in quality or not, and observations

were made in several other vineyards in the region. Notes are given on the various hybrids studied with special reference to their resistance to phylloxera and the affinity of hybrids grafted on various stocks.

Although the ideal hybrid direct bearer has not yet been secured, it is believed that progress is being made in this direction. Several hybrids have been found which produce a wine of the right flavor. While they show lack of affinity for the old grape stocks in many instances, it is thought that satisfactory stocks may be found among the Franco-American hybrids. After a lapse of 9 or 10 years some of the direct bearers are as productive and vigorous as those which are grafted, although they are not as yet recommended for general planting. The wines of certain hybrid bearers are found to improve the quality of the ordinary wines when judiciously employed. They increase the selling price of most of the common wines and give them a much richer color. It is also believed that the hybrids will furnish a good grade of wine for general consumption.

Statistics on grape and olive products for the year 1907 (*Estadística de las Producciones Viticola y Olivarera en el Año 1907. Madrid: Junta Agronómica, 1908, pp. 7*).—In this pamphlet tables are given showing the approximate production of grapes, wine, olives, and olive oil as reported by the directors of the Provincial Agronomic Service for the various regions and provinces in Spain.

The total estimated area of vineyards in the Spanish provinces is 1,367,455 hectares (about 3,378,000 acres). The total production of grapes was 3,171,566,500 kg. (about 3,489,000 tons), of which 2,898,222,100 kg. (3,188,000 tons) were converted into wine. The total production of wine was 18,384,337 hectoliters (about 484,346,500 gal.).

The total area devoted to olive culture is estimated at 1,353,196 hectares (about 3,344,000 acres), and the total olive crop was 1,608,361,300 kg. (about 1,769,200 tons), of which 1,534,459,900 kg. (about 1,688,000 tons) were used in the manufacture of olive oil. The total quantity of olive oil produced was 3,330,606 hectoliters (about 87,928,000 gal.).

Observations on the various forms of fig (Ficus carica). Leclerc du Sablon (*Rev. Gén. Bot., 20 (1908), Nos. 232, pp. 129–150, figs. 13; 233, pp. 207–216, figs. 2*).—A comparative study of the flower and fruit of *Ficus carica*, based upon the work of previous investigators as well as the author's personal observations.

All figs are classed according to the morphological characters of the flower under two general types, (1) the male figs, which have in their successive crops during the year female flowers with short styles adapted for symbiosis with the Blastophaga and which have in addition male flowers in the summer crop; (2) the female figs, which have only female flowers with long styles and which in some cases must be fertilized and in others need not be fertilized for the development of the fig. These two types are considered as the male and female flowers of a dicœcious species, and are further divided into 16 groups, according to the characters of the mature fig and the season of ripening. With certain varieties of female figs grown in France the autumn figs are found to mature either with or without fertilization. The fertilized figs contain seeds, are larger, more watery, and have a more pronounced flavor, but contain less sugar than the unfertilized figs. The latter contain no seeds.

A brief bibliography is appended.

Observations on change of sex in Carica papaya, M. J. Iorns (*Science, n. scr., 28 (1908), No. 708, pp. 125, 126*).—The author here reports for discussion the change of sex recently observed in some trees of *C. papaya*, brought about apparently by the removal of the terminal bud.

As found in Porto Rico this species is distinctly diœcious, the monœcious form being very rare. The change of sex in the first tree noted was brought about accidentally. A staminate tree having its terminal bud injured produced shortly afterwards pistillate as well as staminate flowers. The former flowers set and developed good-sized fruits, which bore all the characteristics of normal fruits except that they were not quite so well filled out. The seeds, which are somewhat smaller than normal, have not as yet been tested for germination. Later developing clusters also contained pistillate flowers in the same position as those in the first cluster.

Investigations thus far made lead to the conclusion that the removal of the terminal bud causes the change. In the attempt to disprove native claims that the removal of the terminal bud in the new of the moon would usually cause this transformation, the author finds that although the moon's phase does not appear to have any control, those trees treated at a fairly definite recurring period are the ones that show change. It is suggested that the plant has definite short cyclic periods of growth, and that it may be necessary to remove the tip at some definite phase of this cycle in order to produce the development of fertile flowers. Further data are being collected in connection with this subject.

The cacao fermentation and the preparation of cacao from harvest to shipping, together with studies on the fermentation of coffee and tobacco, A. Schulte (*Die Kakao-Fermentation und die Verarbeitung des Kakaos von der Ernte bis zum Versand sowie Kaffee- und Tabak-Fermentations-Studien. Berlin, 1908, pp. 35*).—A summarized account is given of cacao fermentation studies started by the author in Kamerun in 1899 and later continued in Germany, together with the application of the results on a cacao plantation on St. Thomas in 1903. Directions are given for harvesting, fermenting, drying, and shipping cacao, and suggestions relative to the practical application, without important changes, of the processes used by the author in his experiments. Brief studies relative to the fermentation of coffee and tobacco are also reported.

As a result of his investigations, the author divides cacao fermentation into 2 stages, (1) the alcohol and acetic acid fermentation, and (2) oxidation. He bases the production of good cacao upon a correct execution of both stages. During the alcohol and acetic acid fermentation, the seeds are freed from the pulp and the shells softened, thus favoring oxidation. The oxidation of the astringent substances is the important feature of cacao fermentation. An oxidation temperature of from 40 to 45° appears to be most favorable for the quality of the product, and a moisture content of 15 per cent was found to be most favorable to oxidation and at the same time unfavorable to butyric acid fermentation and the formation of mold. When the oxidation process is conducted satisfactorily a delicate white efflorescence forms on the beans, which may be taken as an indication that the cacao has been oxidized. Oxidation should be continued only until the majority of the beans have taken on a brown color, as if the oxidation is continued until all the beans are brown, the flavor and aroma are weakened. The proper length of time for oxidation can only be determined by experience and may vary in different cacao districts and with different kinds of cacao as well as with different harvesting methods.

As a result of his brief studies on the fermentation of coffee and tobacco, the author concludes that oxidation is as important with them as in the fermentation of indigo, tea, and cacao.

The unheated greenhouse, K. L. Davidson (*London, 1907, pp. VIII+248, pls. 46*).—In this popular work the author makes a plea for a more frequent use of the unheated types of greenhouses by amateur gardeners and gives considerable information, based on many years of practical experience, relative to the management of these houses and to suitable plants and their cultural treatment.

The introductory discussion deals with the advantages of typical forms of unheated greenhouses, hints on construction, regulation of temperature, and plants suitable and unsuitable. The suitable plants discussed include alpine plants, foliage plants for grouping, hardy and half-hardy species of bulbs and tubers, lillies, flowering shrubs, hard-wooded plants, roses, hardy perennials for spring, autumn perennials, annuals and biennials, hardy orchids, and succulent plants.

An extensive appendix is made up of lists of these various forms of plants, containing data relative to their height and color, habitat and season under glass, soil requirements, and general remarks.

FORESTRY.

North American trees, N. L. Britton and J. A. Shafer (*New York, 1908, pp. X+894, figs. 781*).—This work is one of an extensive series known as the American Nature Series, which is to be produced under the guaranty of American experts and from the American point of view. The present work contains systematic descriptions and illustrations of all species of trees known to be indigenous in North America north of Mexico and the West Indies, including all species which are known to become trees, even though they are almost always shrubs. The relationships of the native and naturalized trees of North America to those of other parts of the world are discussed, and the products of trees useful in the arts, sciences, and industries are mentioned or described. The illustrations show the character of the foliage, flowers, and fruit, and a number of photographs illustrate the general aspect of certain species. A glossary of special terms employed is appended.

Wayside and woodland trees, E. Step (*London, 1907, pp. 182, pls. 127, figs. 58*).—A popular pocket guide to the British sylva, designed for the rural rambler and nature lover. Part 1 includes species generally considered indigenous to the British Islands, with brief notes on closely related introduced species. Part 2 is devoted to species of foreign origin. In addition to the common and botanical name, the distinguishing characters of each species are pointed out, together with notes on distribution, habitat, economic uses, etc. The photographs are an important feature of the work. The deciduous trees are shown in both their summer and winter aspects, and illustrations are also given of floral organs and in many cases of the bole.

The conifers and other gymnosperms, F. W. Neger (*Die Nadelhölzer (Koniferen) und übrigen Gymnospermen. Leipsic, 1907, pp. 185, figs. 85; maps 4*).—This work contains systematic descriptions of the various genera and species of gymnosperms, together with brief notes on their anatomy, morphology, characteristics, distribution, and economic value. In an appendix the various trees are grouped together according to the nature of their wood, seeds, and seedlings, and maps are also given showing the geographic distribution of the more important species.

Observations on the species grown by the Section of Streams and Forests, F. Albert (*Algunas Observaciones sobre las Especies Cultivadas en la Seccion de Aguas i Bosques. Santiago de Chile: Sec. Aguas i Bosques, Min. Indus., 1908, pp. 68, figs. 19; An. Agron. [Santiago de Chile], 2 (1907), No. 4, pp. 585–650, figs. 19*).—Notes are given on a large number of trees being tested by the Section of Streams and Forests in Chile, including their origin, general characteristics, and adaptability for different purposes.

The manna gum (Eucalyptus viminalis), F. Albert (*An. Agron. [Santiago de Chile], 2 (1907), No. 3, pp. 318–349, figs. 14*).—A monograph on this species of eucalyptus, including a botanical description with common names and

synonyms, range and distribution, soil and climatic adaptability, seed collection, methods of propagation, planting, and subsequent care with special reference to its culture in Chile, and notes on the timber and its uses.

The red gum (Eucalyptus resinifera). F. ALBERT (*An. Agron. [Santiago de Chile], 2 (1907), No. 1–2, pp. 100–131, figs. 11*).—A monograph on this species of eucalyptus similar to that noted above for *E. viminalis*.

The Australian blackwood (Acacia melanoxylon). F. ALBERT (*El Aromo de Australia o Acacia melanoxylon. Santiago de Chile: Soc. Aguas i Bosques, Min. Indus., 1908, pp. 41, figs. 18; An. Agron. [Santiago de Chile], 2 (1907), No. 4, pp. 651–689, figs. 18*).—A monograph on this species treated in similar manner to those above noted.

Shelter planting, with special reference to the Acacia and Eucalyptus families and their raising. J. E. BARRETT (*New Zeal. Dept. Agr., Dir. Live Stock and Agr. Bul. 1, pp. 10, dgms. 2*).—Popular directions are given for the cultivation of acacia and eucalyptus trees for use as shelter belts. The trees specially recommended for this purpose, owing to the value of the timber and other products in addition to their usefulness as shelter, are the black wattle (*Acacia decurrens*), blackwood (*A. melanoxylon*), *Eucalyptus amygdalina*, and *E. rostrata*.

Type and variability in the annual wood increment of Acer rubrum. A. DACHNOWSKI (*Ohio Nat., 8 (1908), No. 7, pp. 343–349, fig. 1*).—To obtain direct evidence relative to the influence of habitat on the annual accretion of wood, measurements were taken of the width of the annual rings of several red maple trees recently felled, both in a bog and on the shores near by. These data are presented in tabular form, and the author briefly discusses the value of a biometric study in differentiating habitats. The conclusion is reached that a biometric record of secondary growth in trees furnishes a very valuable criterion for the comparison of the conditions of different plant habitats. The text is accompanied with a brief bibliography of works in which biometric methods are discussed.

A preliminary note on the development of the sal in volume and in money value. A. M. F. CACCIA (*Indian Forest Rec., 1 (1908), No. 2, pp. 238, pl. 1, dgms. 4, map 1*).—The author has aimed to bring together the statistical data at present available regarding the development of sal trees and sal woods in volume and in money value.

In part 1 the sal-bearing regions of India are briefly outlined and a table is given showing the distribution of the government sal forest reserves within those regions. Part 2 deals with the development of the stem of single sal trees, including height, girth, and volume increment, stem shape and stem form factors, volume tables, and volume increment percentage. An extensive list is given of all existing sample plats of sal maintained by the forest department in the Bengal Presidency for the purpose of determining the rate of girth increment, the results of measurements thus far recorded being given. Succeeding parts of the work deal with the development of the different parts of a sal tree, the stem development of whole stands, and the development of the money value of single trees and whole stands. In Appendix A the more important sylvicultural problems relating to the sal are outlined, and a further appendix contains data on the growth of some of the companion trees of the sal. A list is given of the literature consulted, together with a map showing the distribution of sal reserved forests in 1907 in the Bengal Presidency.

Native and planted timber of Iowa. H. P. BAKER (*U. S. Dept. Agr., Forest Serv. Circ. 154, pp. 5–24, fig. 1*).—Investigations were made during 1905 by the Forest Service to determine the extent, character, and value of the native farm wood lots and planted groves in Iowa, with a view of aiding in the movement

toward practical forestry in that State. Results of the investigations are embodied in this circular. The adaptability of the State to tree growth is discussed relative to its topography, soil, climate, and drainage, and an account is given of the native timber relative to its distribution, natural extension, condition, utilization, management, fire, insects, and fungi. The planted timber is also discussed with regard to the species, purpose of planting, and probable causes of success or failure, and suggestions are given for the planting and care of wind-breaks, and planting for commercial purposes. A table based upon typical groves in different parts of the State shows the returns which have been obtained from various species under ordinary conditions of treatment.

Cooperative forestry work, W. J. GREEN and E. SECREST (*Ohio Sta. Circ. 82, pp. 9, figs. 4*).—A popular circular discussing several phases of wood-lot management as well as artificial plantings for special purposes, such as wind-breaks, the utilization of waste lands, and for the prevention of erosion. A brief account is also given of the cooperative plan of the forestry work of the station. The text is accompanied with a county map of the State showing the number of cooperators and number of trees planted in each county.

During the past 4 years the station has undertaken cooperative forestry work with 544 landowners in 86 counties of the State. In all 645,274 trees were distributed for demonstration and experimental purposes.

National forests with related projects and data (*U. S. Dept. Agr., Forest Service, map, pts. 4, July 1, 1908*).—This is a base map of the United States, including Alaska, Porto Rico, and the Philippine Islands, compiled by the Drafting Division of the General Land Office, Department of the Interior, and reissued to show the National forests and related projects and data, by the Office of Geography in the Forest Service. The information was furnished by the U. S. Reclamation Service, the Weather Bureau of this Department, and the Inland Waterways Commission. In addition to the National forests the proposed Appalachian and White Mountain National Forests, the Reclamation Service irrigation projects, private irrigated areas, canals and proposed waterways, overflowed lands of lower Mississippi River, principal watersheds, and lines of equal precipitation are indicated.

Report of the departmental committee on Irish forestry, T. P. GILL ET AL. (*Dept. Agr. and Tech. Instr. Ireland, Rpt. Dept. Com. Irish Forestry, 1908, pp. V+60*).—An investigation was made under the direction of the Department of Agriculture and Technical Instruction for Ireland relative to the present provision for State aid to forestry in Ireland, the means whereby, in connection with the operation of the land-purchase acts, existing woods may be preserved and land suitable for forestry acquired for public purposes, and the financial and other provisions necessary for a comprehensive scheme of afforestation in Ireland. The present report embraces the results of this investigation.

Departmental committee on Irish forestry (*Dept. Agr. and Tech. Instr. Ireland, [Rpt.] Dept. Com. Irish Forestry, Minutes of Evidence, etc., 1908, pp. VII+484, maps 4*).—This volume contains the minutes of evidence secured by the departmental committee in the investigation above noted, together with a large number of appendixes consisting of minor reports and data collected in connection with the investigation.

Progress report of forest administration in Baluchistan for 1906–7, S. SINGH ET AL. (*Rpt. Forest Admin. Baluchistan, 1906–7, pp. 41*).—A statement of forest operations for the year relative to alterations in forest areas, forest settlements, surveys, protection, sylvicultural operations, exploitation, financial results, and administration. The important features of the work are presented in tabular form.

Administration report of the forest circles in the Bombay Presidency, including Sind, for the year 1906–7 (*Admin. Rpt. Forest Circles Bombay, 1906–7, pp. 197*).—Data similar to the above are presented relative to the administration of the State forests in the Northern, Central, and Southern circles of the Bombay Presidency and Sind.

Reports of the forest administration in Burma for the year 1906–7 (*Rpts. Forest Admin. Burma, 1906–7, pp. 177*).—Data similar to the above are presented relative to forest operations in the Pegu, Tenasserim, Northern, and Southern forest circles.

The preservative treatment of loblolly pine cross-arms, W. F. Sherfesee (*U. S. Dept. Agr., Forest Serv. Circ. 151, pp. 5–29, figs. 9*).—A detailed account is given of experiments conducted by the Forest Service in cooperation with the American Telephone and Telegraph Company and the Norfolk Creosoting Company to demonstrate the inequality of the treatment received by different classes of loblolly pine cross-arms and to furnish a basis for the development of more uniform and economical treatments.

The results of the entire study are summarized in substance as follows. Cross-arms should be graded during manufacture into 3 classes: Class A consisting of arms containing 75 per cent or more of heartwood, class B 75 per cent or more of sapwood, and class C less than 75 per cent of either heartwood or sapwood. The arms should be piled in the seasoning yard until they have approached an air-dry condition, when they should be shipped direct to the treating plant and unloaded on the cylinder buggies. Each class of arms should be treated separately, the usual preliminary bath of live steam being omitted and a vacuum applied only sufficient to draw the oil from the storage tanks into the treating cylinder. If necessary, additional pressure should be applied to force the oil into the heartwood portions of the arms. The exact amount of oil absorbed should be noted, and surplus oil blown back into the storage tanks and a vacuum drawn and continued in the treating cylinder until only the desired amount of oil is left in the timber. Heartwood arms should finally contain about 6 lbs. of oil per cubic foot, sapwood arms about 10 lbs., and intermediate arms about 8 lbs.

The total duration of the average treatment is estimated as considerably under 2 hours.

Exports and imports of forest products: 1907, A. H. Pierson (*U. S. Dept. Agr., Forest Serv. Circ. 153, pp. 3–26*).—Statistical summaries and detailed data are given relative to the exports and imports of forest products including both raw and manufactured material of various kinds for 1907. The data are taken chiefly from the report of the Bureau of Statistics of the Department of Commerce and Labor upon The Foreign Commerce and Navigation of the United States for the year ending June 30, 1907. The summaries of the exports and imports of forest products from and to the United States for the years 1903 to 1907 inclusive show an increase in value of 48.6 per cent for the exports and 69.8 per cent for the imports. In some cases the increase is due to higher prices and in others to larger quantities.

Turpentine and rosin (*Bur. of the Census [U. S.], Manfrs., 1905, pt. 3, pp. 647–657*).—A statistical discussion of the manufacturing of turpentine and rosin as reported at the census of 1905, including comparisons with previous censusses, and a discussion relative to the immediate future of the industry.

Investigation of Manihot rubber, W. Schellmann (*Pflanzer, 4 (1908), No. 3, pp. 39–45*).—Analyses were made of the rubber taken from 48 trees of *Manihot glaziovii*, varying in age from less than 1 year up to 11 years, with the view of determining whether increasing age has a deteriorating effect on the

rubber. The results are tabulated and discussed. Up to 11 years of age the composition of the rubber is not materially altered.

The author is of the opinion that in a climate generally suitable for the culture of Manihot, profitable quantities of rubber may be procured from trees growing either at high or low altitudes and either remote from or adjacent to the coast. To support this opinion, analyses are given of samples of rubber from 27 trees growing in various parts of German East Africa and in altitudes ranging from 50 to 1,350 meters above sea level. Allowing for difference in the age of trees, no great variation was noted in the amount of rubber produced from trees grown in the different sections.

DISEASES OF PLANTS.

Seed treatment for the smuts of winter barley, F. D. Heald (*Nebraska Sta. Rpt. 1907, pp. 45–53, figs. 4*).—Winter barley has been grown at the experiment station for the past 3 years, and has been found to be badly infected with smut, the plat grown in 1905 showing 10 per cent of smut and that in 1906, 15 per cent. Since seed treatment for barley smuts has not been as satisfactory as with some other cereals, it was considered advisable to compare some of the different methods and to try a number of modifications. The barley was affected by 2 species of smuts, the covered smut (*Ustilago hordei*) and the naked smut (*U. nuda*).

The treatments consisted of seed treatment with formalin, hot water, corrosive sublimate, and copper sulphate. The formalin solutions were of strengths varying from 1 pt. to 10 gal. of water to 1 pt. to 25 gal. The hot-water treatment consisted of a preliminary soaking of the seed in cold water for 4 hours, after which it was set away in the wet sack for 4 hours more. It was then warmed by submerging in water at 110 to 120° F. for a few minutes, after which it was immersed in hot water, 126 to 130°, for 5 minutes, and then spread to dry. The corrosive sublimate treatment consisted of solutions of 3 parts corrosive sublimate in 1,000 parts of water, and half strength of the above. With the copper sulphate treatment, one lot was immersed in copper solution (1 lb. to 24 gal. of water) for 12 hours, then in lime water for 5 minutes, after which it was spread to dry. With the other lot, the treatment consisted of soaking the seed in water for 6 hours, then in copper solution (1 lb. to 18 gal. of water) for 6 hours, followed by a lime water treatment and drying as usual.

The results of the different treatments are shown, from which it appears that barley smuts can be very greatly lessened by the use of any of the treatments employed. The more effective treatments and those recommended are formalin solution, using 1 pt. to 20 to 25 gal. of water, the hot-water treatment, and the copper sulphate treatment.

Cotton wilt, W. A. Orton (*U. S. Dept. Agr., Farmers' Bul. 333, pp. 5–24, figs. 11*).—A popular account is given of the disease of cotton variously known as wilt, blackheart, frenching, etc., due to *Neocosmospora vasinfecta*. The field characters of the disease are described, and the various factors which influence its development are discussed. An account is given of experiments in breeding resistant plants, and some varieties of upland cotton that have proved nearly resistant to this disease are described.

The potato rot, G. Gándara (*Estac. Agr. Cent. [Mexico] Bol. 2, pp. 20, figs. 19*).—A description is given of the potato rot due to *Phytophthora infestans*, with suggestions for its control by the use of fungicides.

Spongospora solani, or corky scab, T. Johnson (*Econ. Proc. Roy. Dublin Soc., 1 (1908), No. 12, XX, pp. 453–464, pl. 1*).—While investigating the yellow

blight of potatoes in the west of Ireland, the author was struck with the common occurrence of scabbiness in the potato tubers, and upon examination he found that the trouble was due to the fungus *S. solani*, which had been hitherto considered as rare and apparently of only biological interest. In investigating this trouble, the author found nearly every plat of potatoes in the district visited affected by the scab, the tubers being greatly reduced in market value, as well as being made almost worthless for seed purposes.

This disease may be recognized with the aid of a low-power lens, showing on the damaged skin of the tubers yellowish-brown particles resembling grains of sand. These are spore-balls of the fungus, and in the first stage of the disease the tuber skin is raised above the general surface, the patches being ⅛ to ¼ in. in diameter. Later the surface of the skin becomes ruptured and the spore-balls liberated. The elevations then become depressions, and gradually the depressions become deeper and wider, the parasite literally gnawing away the substance of the tuber. In some cases, however, the tuber successfully resists the fungus by the formation of protective cork layers.

A description is given of the fungus and its action in various media, after which the author suggests means for its control. He regards the fungus as a dangerous parasite, allied to the slime fungi Ceratiomyxa and Plasmodiophora. The potato crop becomes scabby, either through the planting of healthy tubers in scabby soil or by planting scabby tubers. Want of drainage and aeration of the soil tend to increase the virulence of attack. Crop rotation, the treating of seed tubers with Bordeaux mixture or a 2 per cent solution of copper sulphate before planting, the planting of uncut tubers, soil treatment with sulphur, and thorough cultivation are recommended as remedial measures.

A disease of sea-kale, E. S. Salmon (*Gard. Chron., 3. ser., 44 (1908), No. 1123, pp. 1–3, figs. 3*).—During the autumn of 1906 sea-kale was observed to be badly damaged by the fungus *Rhizoctonia violacea*. This fungus attacked the roots, reducing the crop to a considerable extent. So serious were the effects of the disease that in 1907 experiments were carried on to determine the possibility of preventing it by treatment of the seed beds.

Just before planting in March, 1907, beds were prepared and treated with solutions of copper sulphate, iron sulphate, corrosive sublimate, carbolic acid, formalin, and petroleum, and dusted with sulphur and quicklime, which were worked into the soil. The effect of the different treatments is shown. Copper sulphate and corrosive sublimate reduced the disease to some extent, while the plat receiving the carbolic acid at the rate of 1 oz. to 1 gal. of water was practically free from the disease. The other treatments were without definite effect.

Some tomato fruit rots during 1907, Venus W. Pool (*Nebraska Sta. Rpt. 1907, pp. 1–33, figs. 33*).—Studies are reported on various diseases of the tomato, among them the black rot due to *Alternaria fasciculata*, a Rhizoctonia disease, the anthracnose caused by *Colletotrichum lycopersici*, a Fusarium disease due to an undetermined species, and a disease due to *Fusarium solani*.

The anthracnose was found on nearly all the late tomatoes, while the peculiar blackened condition produced by *Fusarium* sp. occurred on at least half of the earlier fruits. The other rots occurred in greater or less abundance during the main part of the season. Plants which have an upright position of growth with smooth, thick-skinned fruits, such as the Dwarf Champion, were found freer from disease than the trailing thin-skinned varieties, as the Stone.

The employment of proper sanitary measures and spraying with Bordeaux mixtures are recommended for the control of these diseases.

A bibliography is appended.

A root rot of grapes due to Pestalozzia uvicola, F. A. Wolf (*Nebraska Sta. Rpt. 1907, pp. 69–72, fig. 1*).—A report is given on studies made of ripe grapes

brought to the laboratory in 1907 that were covered with numerous black pustules. A microscopical examination of the material showed that the spores were those which characterize the genus Pestalozzia, and further studies indicated that the species was *P. uricola*, of which no record of occurrence in America had been previously reported.

Arsenical poisoning of fruit trees, W. P. HEADDEN (*Colorado Sta. Bul. 131, pp. 3–27, pls. 7*).—The author was called upon to investigate some shade and ornamental trees, the bad condition of which was claimed to be due to arsenic and lead. Subsequently other investigations were carried on to determine whether the arsenic used so extensively as calcic arsenite and lead arsenate for the control of insect pests is responsible for the rapid destruction of trees in a number of the principal fruit districts of the State.

The author made analyses of soils, different parts of trees, etc., and in samples of trees he found present from 1.25 to 12.77 parts of arsenic per million of woody tissue. While the arsenic is generally in an insoluble form, soluble arsenic was found present in the soil in amounts that are believed dangerous to the life of the tree.

In addition to arsenical poisoning, the author discusses briefly lead poisoning and the effect of lime, which in some regions seems to have an unquestionably injurious influence on the trees. In one instance, where the sap had exuded from the tree and dried, he found that the air-dry material contained 24.93 per cent of lime.

In conclusion, the author states that there are a large number of fruit trees in the State suffering from an affection of the trunk and root, the trouble beginning in the greater number of cases at the crown of the tree and subsequently involving both trunk and roots. The first marked symptom is an early ripening of the foliage, usually followed by the death of the tree about midsummer of the ensuing year. The crown of the tree is found to be girdled, the bark on portions of the trunk dead and sunken, and most of the roots dead, the bark destroyed, and the woody tissue discolored. Experiments showed that soluble arsenical compounds will effect the destruction of the bark, the staining of the wood, the production of the so-called blackheart, and the speedy death of the tree.

Arsenical poisons have been extensively used in the orchards under investigation and these compounds have accumulated in the soil. While the accumulation of arsenic in the soil is usually in an insoluble form, it has probably passed beyond the limit of danger in a soluble form, the alkalis, such as sodium carbonate, sodium sulphate, and sodium chlorid rendering the arsenic soluble. The lime salts do not appear to protect effectively the arsenical compounds from the solvent action of the alkalis. It is thought that systematic poisoning may take place, and probably does, by the absorption of the arsenic with the nutritive solutions taken up by the feeding roots, but the greater portion of the trouble appears to be due to local irritant poisoning.

The arsenic in the arsenate of lime is more readily brought into solution than that of the lead arsenate. Arsenical poisoning it is believed is in many cases complicated by lime poisoning, the lime or marl in the soil and subsoil acting conjointly with the arsenic in producing some of the injury.

The Fusicladium disease of the pear and apple, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope, 33 (1908), No. 1, pp. 16–32, figs. 10*).—An account is given of the disease of apples and pears known in this country as apple and pear scab, due to *Fusicladium dendriticum* and *F. pyrinum*. Both these diseases have made their appearance in South Africa and are causing considerable injury. The effect of the fungus on the host plants and the conditions which favor the spread of the disease are described, and suggestions given for preventing the

attacks of the fungi by the use of Bordeaux mixture or other fungicides. The author calls attention to the copper soda spray as a substitute for Bordeaux mixture, but where fresh lime is available, he thinks that the Bordeaux mixture as commonly made with lime is to be preferred.

Notes are also given on bitter pit disease of apples, which seems to be due to physical conditions in the environment of the tree which are unfavorable to a perfect development of the fruit, and on Entomosporium spot disease.

Notes on some diseases of apple trees, E. Prillieux (*Bul. Soc. Nat. Agr. France, 68 (1908), No. 5, pp. 286–291*).—An examination was made of twigs from apple trees which were submitted to the station of plant pathology, from which it was found that they were in most cases attacked by *Nectria ditissima*, causing cankers.

The effect of the fungus on the twigs is described, and the author states that the disease is not a new one, as was feared by the owners of the orchard, but was mostly caused by the presence of the Nectria mentioned above. In addition he found some other fungi present, particularly Monilia.

For preventing the injury, the author recommends the use of resistant varieties, better drainage of the soil, the burning of diseased twigs, and winter treatment with fungicides.

A new form of Sphæropsis on apples, Leva B. Walker (*Nebraska Sta. Rpt. 1907, pp. 34–44, figs. 10*).—Two forms of Sphæropsis have been observed which are capable of producing a severe black rot of the apple. In macroscopic appearance the rots are very much alike, the principal differences in the 2 forms being the size of the spore, the size and thickness of the pycnidium, and the absence of the ostiole in the new form. The new form has decidedly longer spores than is commonly described for *S. malorum*, and it seems to be a much more vigorous grower and to do more damage than the common form. Whether the long-spored form should be considered a new species or a form of *S. malorum*, is not determined. A bibliography is given.

Studies on the genus Gymnosporangium, F. D. Kern (*Bul. Torrey Bot. Club, 35 (1908), No. 10, pp. 499–511*).—A study has been made of the so-called cedar apples and rusts associated with them for the purpose of bringing together data in such a manner as to be of material assistance in the determination of the North American species. A key is presented involving the more evident diagnostic characters and indicating the host plants for each. Preceding the key, notes are given on some of the species, explanatory of their nomenclature, extension in range, and other interesting features which have been revealed in the investigations.

A disease of cloves, H. N. Ridley (*Agr. Bul. Straits and Fed. Malay States, 7 (1908), No. 7, pp. 263, 264*).—The cultivation of clove trees is said to have been an extensive industry at one time in Singapore, but it has almost ceased to be of importance owing to disease. An old tree in the Singapore Botanic Gardens gave the author an opportunity for studying the cause of the trouble, and he found the tree affected by a red-spot fungus.

The fungus forms dark red spots on both surfaces of the leaves, the spots increasing in size until they attain a diameter of 0.2 in. or more. The leaf is often attacked when just opened, before it has attained its full green coloring, and the author is inclined to think that the attack most commonly begins in the bud. The fungus has not been definitely determined, but it appears to belong to the Peronosporaceæ.

The author believes that the fungus destroys many seedlings through attacking the buds, and that spraying with a weak solution of Bordeaux mixture would protect them from attack.

Report on cocoanut palm disease in Travancore, E. J. Butler (*Agr. Research Inst. Pusa [India] Bul. 9, 1908, p. 23; noted in Agr. Jour. India, 3 (1908), No. 2, pp. 177–179*).—A serious disease of cocoanut trees has been spreading in Travancore and materially reducing the yield of nuts. The first indication of the disease is the yellowing of the leaves, as though the trees did not get sufficient water. A year or two after the first appearance of the disease, all the leaves turn yellow and dry up at the tips. When this happens the bunches of nuts become affected. Some do not ripen properly, but fall to the ground in an immature condition, and after a few years none at all are borne. After from 5 to 10 years the diseased palm dries up altogether.

The cause of the disease appears to be a minute fungus, which attacks the roots in the soil, causing them to rot. In addition to cocoanut palms a number of other species of palm are subject to attack. As the parasite which is the probable cause of this disease enters the roots, it is out of reach of direct treatment, but in order to eradicate the disease the author recommends the destruction of all diseased material, cultivating land where diseased cocoanuts have been grown, the application of manure, generally stimulating the health of trees, and the use of disease-resistant varieties.

In conclusion the author briefly describes the leaf disease of cocoanut palms due to *Pestalozzia palmarum* and the bud rot caused by *Pythium palmivorum*.

A disease of rubber trees in Puak, E. Smith (*Agr. Bul. Straits and Fed. Malay States, 7 (1908), No. 3, pp. 90–92, fig. 1*).—The author describes a disease of rubber trees that is apparently of fungus origin. Thus far he has been unable to complete the identification of the fungus, which seems to cause a disintegration of the cells of the bark and in some cases the cambium layer of the trees. In addition to the fungus a spore-bearing bacillus was present. The fungus bears a strong resemblance to Helicobasidium, and the disease is to be given further study.

The effects of Oïdium quercinum on different species of oak, E. Bureau (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 13, pp. 571–574*).—In the summer of 1907 oak trees in parts of France were badly attacked by *O. quercinum*, in some cases the old forests taking on an unusual gray color.

A study was made of the fungus causing the trouble, from which it was determined to be the species mentioned above. It was further found that some species of oak were less subject to attack than others, and in addition that the beech was liable to be attacked by the fungus when grown in coppice. The chestnut, which botanically is much more nearly related to the oak than the beech, seems to be absolutely resistant to attacks of the parasite.

The timber rot fungus (Merulius lachrymans), C. Mez (*Der Hausschwamm und die übrigen holzzerstörenden Pilze der menschlichen Wohnungen. Dresden, 1908, pp. VII+260, pl. 1, figs. 90*).—A study is given of the timber dry-rot fungus and a number of related species that attack construction timber in dwellings, etc. The relation of these fungi to health is discussed, and suggestions are given for preventing their occurrence. About 40 species belonging to the genera Merulius, Polyporus, Lenzites, Dædalea, Hypholoma, Armillaria, Hydnum, and Corticium are described, all of which are not equally destructive.

For the prevention of dry-rot injury, it is recommended that special attention be paid to the general conditions about buildings in relation to moisture, choice of construction materials, use of preservative agents, etc.

The mold of maple sirup, F. D. Heald and Venus W. Pool (*Nebraska Sta. Rpt. 1907, pp. 54–68, figs. 7*).—During the past few years a mold has been frequently observed growing on maple sirup exposed in various containers to the air of the household, and even in the original container if a small amount

of the sirup had been removed. Studies were made of this mold, and it was found to be a species of Torula closely related to *T. saccchari-lactis*, from which it differs in the average size and color of the spores and the ultimate branchlets and in the absence of the delicate prickles. The fungus is supposed to be an undescribed species and is named *T. saccharina*. The characters of the fungus grown in various cultures are described at length.

Analyses were made of various sirups to determine whether the molding of the different kinds of sirup was due to the low sugar content. It was found that by increasing the total sugar content the growth of the Torula was nearly inhibited, and it is evident that market products should be made more concentrated than is the common practice.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

The Alaska game law and regulations of the Department of Agriculture, 1908 (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 66, pp. 8*).—"Under the new law, approved May 11, 1908, Alaska is divided at latitude 62° into two game districts, with special seasons for each district. Caribou on the Kenai peninsula are protected until 1912. Nonresidents hunting big game other than deer or goats and residents desiring to export heads or hides of big game from Alaska are required to obtain licenses. Authorization is also given for the employment of wardens and registration of guides. All matters relating to the issue of licenses, employment of wardens, and the registration of guides are placed in charge of the governor of Alaska. . . . The Department of Agriculture will continue as heretofore to issue permits for the collection and shipment of specimens for scientific purposes and for live animals and birds for exhibition or propagation."

The text of the new law and the regulations prescribed by this Department to take effect October 1, 1908, are given.

Directory of officials and organizations concerned with the protection of birds and game, 1908, T. S. Palmer (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 65, pp. 16*).—This circular presents in convenient form the names of persons to whom application may be made for information respecting game laws. It also shows the date of establishment of each State commission or wardenship, the changes which occur in such offices, and the publications issued by game officials. The addresses are grouped under the headings State officials, National organizations, State organizations, and Audubon societies.

The use of bacteria in destroying rats, Xylander (*Ztschr. Fleisch u. Milchhyg., 18 (1908), No. 8, pp. 241–245*).—The literature relating to the various bacterial cultures which have been used in destroying rats is critically reviewed. The author considers that at the present time it has not been demonstrated that any of these cultures are invariably harmless for animals other than rats.

Exterminating field mice with barium carbonate, L. Hiltner and G. Korff (*Prakt. Bl. Pflanzenbau u. Schutz., n. ser., 6 (1908), No. 4, pp. 37–40*).—A number of experiments were made with two kinds of virus designed for the destruction of mice. The results were fairly satisfactory. Samples of virus were distributed to various individuals but only two reports were received both of which were favorable. On the whole, however, the method of using poisoned baits is more efficient. The best results were obtained from the use of barium carbonate in an attractive bait. This remedy was tried in various localities with good success.

The dissociation of specific characters in hybrids between certain birds, A. Ghigi (*Atti R. Accad. Lincei Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 17 (1908)*.

I, No. 7, pp. 453–451).—Details are presented regarding the characters observed in hybrids between distinct species of Gennæus, Phasianus, and Numida. In all of these hybrids the characters in the first generation were not those of either parent but were intermediate between those of the parent forms.

Wild birds, useful and injurious, C. F. Archibald (*Jour. Roy. Agr. Soc. England, 63 (1907), pp. 17–32, figs. 7*).—Attention is called to the lack of specific information among farmers regarding the economic status of various common species of birds. In order to assist in a better understanding of the relationship of birds notes are given on the feeding habits of the starling, rook, magpie, martin, cuckoo, ringdove, pheasants, sea gulls, etc.

Some common birds of Oregon, W. L. Finley (*Leaflets Listing and Describing Birds of Oregon, No. 2, pp. 16, figs. 10*).—A popular discussion was presented of the feeding habits and economic relations of a number of the common birds of Oregon, including the red-shafted woodpecker, western robin, western bluebird, California jay, crow, kingfisher, western meadow lark, etc.

The locust plague in Hortobágy in 1907, and birds, J. Schenk (*Aquila, 14 (1907), No. 1–4, pp. 223–275, pl. 1, figs. 4*).—A description was given of a serious outbreak of locusts which occurred in 1907. The species chiefly concerned was *Stauronotus maroccanus*. As the plague of locusts increased in extent and numbers various insect-eating birds were observed feeding upon the locusts. The habits of a number of species of birds on this occasion are described by the author. The starling and stork proved to be particularly instrumental in destroying the locusts.

A report on Trox suberosus, L. Ichies (*Bol. Min. Agr. [Buenos Ayres], 9 (1908), No. 1–2, pp. 36–44*).—Reports have been repeatedly received that *T. suberosus* feeds upon the eggs of locusts and should, therefore, be considered as an important help in the control of locusts. Careful observation of the beetle in cages specially prepared for this purpose failed to produce any evidence that the beetle feeds upon the eggs of the locust.

The destruction of Melolontha vulgaris, A. Vivien (*Atti 6. Cong. Internaz. Chim. Appl., 4 (1906), pp. 342–347*).—Statistical data are given showing the number of cockchafers which have been collected by school children and others. Encouraging results have been obtained in the dissemination of fungus disease among the cockchafers. It is not certain whether the fungus concerned is *Botrytis bassiana* or *Isaria densa*.

Miscellaneous papers. A record of results from rearings and dissections of Tachinidæ, C. H. T. Townsend (*U. S. Dept. Agr., Bur. Ent. Bul. 12, tech. ser., pt. 6, pp. 95–118, figs. 6*).—The author here reports the results of bionomic studies of tachinids made in connection with investigations by the Bureau of Entomology of this Department of the parasites of the gipsy and brown-tail moths. It is predicted that *Blepharipa scutellata*, *Palcs parida*, *Zenillia libatrix*, and an undetermined species of Crossocosmia will be found to deposit their eggs upon the leaves and be taken into the bodies of the caterpillars with the food. From dissections, 14 American and 5 European species have been determined to have the habit of depositing their eggs in this manner.

Eupelcteria magnicornis was found to larviposition on green shoots, leaf stems, leaf ribs, and occasionally on the surface of leaves near caterpillars to which the larvæ readily attach as the host passes. From dissections, 13 species have been determined to larviposit. *Dexodes nigripes* and *Compsilura concinnata* have the habit of depositing the living maggots inside the skin of caterpillars. *Parexorista cheloniæ*, *Parasetigena segregata*, *Tricholyga grandis*, *Tachina larvarum*, *T. utilis*, and *T. clisiocampæ* deposit eggs upon the caterpillars. It was found that in the leaf-oviposition species, the eggs and first

larval stage are much smaller than in the other tachinids and that as a result there is, in all probability, an additional maggot stage. While *T. elisiocampæ* oviposits very freely on large gipsy moth caterpillars, but few are parasitized, due to the inability of the young larvæ to penetrate the tough skin of the large *Porthetria dispar* caterpillars.

Parasetigena segregata is apparently a single-brooded species, *Palcs pavida*, *Zenillia libatrix*, and the species of Tachina are reported to be at least double-brooded, while *Compsilura concinnata*, *Dexodes nigripes*, and *Tricholyga grandis* appear to be at least three-brooded. It was found by dissecting the flies and examining the uterine eggs that the reproductive habit could be determined. This is also shown to be of taxonomic importance. Eggs from 70 species have thus been obtained and studied. Dissections show a variation in the reproductive capacity of the species of from 100 to 5,000 eggs. The late summer generations of several species were found to oviposit profusely on newly hatched fall webworms as an alternate host.

An account is given of the methods and apparatus used.

"The results of all this work on European, Japanese, and American tachinids point to the very great importance of *Blepharipa scutellata* and *Crossocosmia* sp. as parasites of *Porthetria dispar*. The great capacity for reproduction, possessed by these species, and the fact that all of their eggs must be eaten by the caterpillars wherever *P. dispar* is abundant, place them in the lead of parasites.

"No two species can be so relied upon as parasites of *Euproctis chrysorrhœa*, but the Japanese Tachinas, *Tricholyga grandis*, *Compsilura concinnata*, *Dexodes nigripes*, and *Parexorista cheloniæ* seem to be among the most important here.

"All of the other imported species mentioned will prove of much importance as aids in the control of one or both of these moths. The great majority of them are parasitic on both hosts."

The formation of the colonies of parasitic ants, H. Viehmeyer (*Biol. Centbl., 28 (1908), No. 1, pp. 18–32*).—In agreement with W. M. Wheeler (E. S. R., 20, p. 254), the position is taken on the basis of experimental work that in many species of ants, particularly *Formica truncicola*, *F. sanguinea*, and *Polyergus rufescens*, the so-called slave-making habit is more properly a form of parasitism.

Annual report for 1907 of the zoologist, C. Warburton (*Jour. Roy. Agr. Soc. England, 68 (1907), pp. 229–241, figs. 4*).—During the year 1907, *Atomaria linearis* was particularly injurious to mangels. The beetle attacks the seed while it is germinating in the ground and later feeds upon the seed, leaves, roots, and other parts of the plant. It attacks both mangels and beets. Mention is also made of the injuries caused by various granary insects, cheese mite, Mediterranean flour moth, nematode worms, snails, slugs, *Tephritis onopordinis* on celery, and other insects.

Insects of the year 1907, R. S. Macdougall (*Trans. Highland and Agr. Soc. Scot., 5. ser., 20 (1908), pp. 305–308*).—An emulsion soda wash has given good results in combating oyster-shell bark-louse. The formula used in the preparation of the wash called for ½ lb. sulphate of iron, ¾ lb. lime, 2 lbs. caustic soda, and 5 pts. of kerosene per 10 gal. of water. Economic and biological notes are also given on *Cryptococcus fagi*, woolly aphis, spruce gall aphis, ox warble flies, gooseberry sawfly, and *Abraxas grossulariata*.

[Notes on economic zoology], Rörig, Börner, and Moritz (*Mitt. K. Biol. Anst. Land u. Forstw., 3 (1908), No. 6, pp. 31–52, figs. 4*).—A study was made of the life history of phylloxera. The biology of this insect was found to be somewhat simpler than has usually been represented, the insect proving to be diecious with five types of generations.

A brief report is given on the results obtained from the use of various proprietary mixtures for preventing injuries to fruit trees by rodents. Brief accounts are also presented of the habits of *Arricola ratticeps* and on nematodes, woolly aphis, earwigs, and foul brood of bees.

Report of committee on entomology, H. A. Gossard (*Ohio Dept. Agr., Div. Hort. Bul. 1, pp. 53–67*).—Mention is made of spraying experiments carried on for the purpose of controlling the grape-berry moth. This moth caused the destruction of about 50 per cent of the grape crop in infested localities. The usual arsenicals were applied with good results. A brief account is also presented of spraying experiments for controlling codling moth and on the use of proprietary insecticides.

Some insect enemies of garden crops, R. I. Smith (*North Carolina Sta. Bul. 197, pp. 5–64, figs. 38*).—An account is given of the more common insect enemies of garden crops. Emphasis is placed upon the fact that even in the home garden success may depend upon the intelligent application of preventive and remedial measures. Under each insect considered a brief description is given of its life history and habits and of the particular remedial treatment necessary. Formulas and directions for preparing spray mixtures are appended.

The weeviling of maize in West Africa, R. Newstead (*Liverpool Univ., Inst. Com. Research Trop. Quart. Jour., 2 (1907), No. 4, pp. 27–31*).—The beetles chiefly concerned in the injuring of maize on the west coast of Africa are rice weevil, granary weevil, and an undescribed species of Bruchus. The biology and economic relations of rice weevil and granary weevil are described in some detail. For the control of these pests fumigation with hydrocyanic-acid gas or carbon bisulphid is recommended.

Sugar-cane borer, A. Ferreyros (*Bol. Min. Fomento [Peru], Dir. Fomento, 6 (1908), No. 1, pp. 57–68*).—The present status of the sugar-cane borer, particularly in Louisiana, is briefly outlined with notes on its habits and life history and the amount of damage caused by it. Natural enemies assist to a slight extent in controlling this pest. One of the most effective remedies is planting the cane so deeply as to prevent the emergence of borers.

The tobacco stem borer, H. M. Lefroy (*Agr. Jour. India, 3 (1908), No. 1, pp. 65–68, pl. 1*).—*Gnorimoschema heliopa*, so far as has yet been determined, feeds only upon cultivated and wild tobacco. The life history of the insect is described in detail. Its attacks are most serious upon the better varieties of cultivated tobacco. In controlling the pest it is recommended that wild tobacco in the vicinity of tobacco fields be destroyed and that the larvæ be cut out of the swellings in the stems in which they live.

The larvæ of the cabbage butterfly, G. Paoli (*Bul. R. Soc. Toscana Ort., 3. ser., 13 (1908), No. 4, pp. 100–103, figs. 3*).—The life history of *Pieris brassicæ* is briefly described with particular reference to the injuries caused by the larvæ of this species and the usual methods applied in controlling it.

Plutella cruciferarum, H. M. Quanjer (*Tijdschr. Plantenziekten, 12 (1906), No. 1–3, pp. 62–70, pls. 2, fig. 1*).—The habits and life history of the diamondback moth are described in some detail. In combating this pest satisfactory results have been obtained from brushing the caterpillars from cabbage leaves and immediately covering them in the soil with a shovel. The caterpillars may also be dislodged by a spray of water.

The blackberry leaf-miner, C. O. Houghton (*Ent. News, 19 (1908), No. 5, pp. 213–216*).—*Scolioneura capitalis* was observed injuring dewberries near Dover, Delaware, in 1905, and was found in considerable numbers during the following year. This species was first described in 1867. A technical description of the insect is given together with notes on its distribution. The insect is apparently parasitized by a species of Rhysipolis.

A new enemy of the strawberry in Germany, H. Morstatt (*Deut. Landw. Presse, 35 (1908), No. 35, p. 379, figs. 9*).—*Tarsonemus fragariæ* is reported as having caused great injury to strawberry plants by attacking the leaves. A brief account is given of the appearance and habits of this mite. Most of the insecticides which have been tested for controlling it have proved to be of little avail, and it has, therefore, been lately recommended that infested plants be removed early in the season and destroyed. It is believed, however, that frequent sprinkling of the plants with water alone or with a dilute solution of ammonia might be beneficial.

The use of arsenical compounds in the treatment of vineyards, H. Bertinsans and V. Ros (*Rev. Hyg. et Pol. Sanit., 30 (1908), No. 4, pp. 281–286*).—A lively controversy has recently developed especially in France regarding the possible dangers from the use of arsenicals in spraying vineyards. The fear has been entertained that such treatment might result in the passage of some of the arsenic into the wine. The experiments reported by the author indicate that the danger from the application of arsenicals in the early part of the season is practically none, but it is considered advisable to prohibit the use of arsenical insecticides after the grapes are in bloom.

Combating the olive fly, A. Berlese (*Bol. Quind. Soc. Agr. Ital., 13 (1908), No. 8, pp. 261–265*).—Brief mention is made of the damage done to olives by *Dacus oleæ*, together with a historical account of the development of the method of using a mixture of molasses, honey, and an arsenical in combating this pest. It has been found that if 2 per cent of arsenic be added to a mixture of equal parts of molasses and honey the mixture may then be diluted with water and sprayed on olive trees with good results.

The cocoanut beetle in Batticaloa, Ceylon, E. E. Green (*Proc. Agr. Soc. Trinidad and Tobago, 8 (1908), No. 3, pp. 105–109*).—The cocoanut beetle is extending its range rather rapidly as shown by the numbers captured by superintendents of cocoanut plantations and by the examination of cocoanut trees. Considerable work has been done in combating this pest by cutting out and burning the crowns and a few feet of the upper part of the stems of infested trees. The trunks of trees destroyed for any purpose may be used temporarily for fencing purposes, but as soon as they become decayed it should be understood that they furnish excellent breeding grounds for the cocoanut beetle.

The more important insects affecting Ohio shade trees, J. S. Houser (*Ohio Sta. Bul. 194, pp. 169–243, figs. 47*).—A general account of the insect enemies of shade trees of the State with directions for the preparation and application of insecticides. Accompanying the account are numerous illustrations of the insects considered, of the injury caused by them, and of spraying apparatus used in their control.

Forest injuries from insects, Hanff (*Jahrb. Schlesischen Forstver., 1907, pp. 39–52*).—The insect injuries which attracted most attention during the year were due to *Gastropacha pini*, *Nematus abietum*, cockchafers, *Pissodes piceæ*, gipsy moth, etc. The larvæ of *G. pini* infested trees in some cases to the extent of 3,000 or 4,000 per tree. In such cases the use of sticky bands was very advantageous.

Injury to Abies nobilis by Chermes piceæ bouvieri, E. Molz (*Naturw. Ztschr. Forst u. Landw., 6 (1908), No. 2, pp. 151–154, figs. 4*).—*Chermes piceæ bouvieri* attacks the tips of growing shoots of *Abies nobilis* causing extensive malformations in the form of galls. The injury thus produced is quite serious, in some cases causing the death of the affected trees.

Some coleoptera affecting the honey locust, C. O. Houghton (*Canad. Ent., 40 (1908), No. 5, pp. 160–162*).—Large numbers of *Agrilus fallax* were observed feeding upon the leaves of the honey locust. Among the other coleop-

tera observed were *Xyleborus erythrocephalus*, *Xylonola punctipennis*, and *Macrobasis unicolor*.

A note on the lac insect, its life history, propagation, and collection, E. P. Stebbing (*Indian Forest Rec., 1 (1908), No. 1, pp. 84, pls. 2*).—The increased use of shellac in electrical work and in the manufacture of phonograph records has led to an increase in the price of the substance. Some attention has, therefore, been given to the method of collecting the crude material and to the artificial encouragement of the lac insect. Detailed notes are given on the growth of the industry from a historical standpoint, the life history of the lac insect, its food plants, enemies, and the injuries which it causes to forest trees. It is recommended that lac should be collected either before or after the swarming of the larvæ. A bibliography of the subject is appended to the article.

The life history of house flies, A. Griffith (*Pub. Health [London], 21 (1908), No. 3, pp. 122–127*).—The life history of house flies was followed through practically the whole cycle in order to determine more accurately those points which may be of value in formulating a campaign against these insects. It was shown by experiment that flies required water frequently. The egg hatches within about 24 hours after being laid and the larval stage lasts 4 days. On an average four layings of eggs are done by each female fly. In combating the house fly reliance must be placed chiefly on the frequent removal and destruction of manure and other rubbish in which flies may breed.

The bot fly (Gastrophilus equi), W. W. Froggatt (*Agr. Gaz. N. S. Wales, 19 (1908), No. 3, pp. 229–233, pl. 1*).—The life history of this insect is described by way of comparison with bot flies, which infest other animals and have different habits. Various chemical remedies have been suggested for destroying bots in the stomach of horses or for expelling bots. As a rule, the results obtained from this line of treatment are not promising. It is suggested that some benefit may be derived from careful grooming of the horses during a period when the eggs of the bot fly are deposited upon the hair.

The rôle of arthropods in the dissemination of diseases, B. Galli-Valerio (*Centbl. Bakt. [etc.], 1. Abt., Ref., 41 (1908), No. 11–13, pp. 353–360*).—A summarized statement is given regarding the agency of arthropods in disseminating various diseases. The arthropods which are concerned in carrying diseases may be classified into 3 groups—those which are simply carrying agents, those which produce direct inoculation, and those which serve as intermediate hosts of the pathogenic parasite.

Sericultural experiments, B. C. Basu Bahadur (*Ann. Rpt. Agr. Stas. East. Bengal and Assam, 1907, pp. 78–86*).—The experience of 4 years has shown that the winter climate of Shillong is cool enough for proper hibernation of eggs of European breeds of silkworms. It was found possible to secure a very even hatching of silkworm eggs by enclosing them in a cloth which was worn under the clothes of one of the workmen, the process of hatching by this method requiring 5 days. Two species of mulberries were tested (*Morus atropurpurea* and *M. indica*). The cocoons from silkworms raised on the latter species were heavier and contained more silk. Little or no trouble was experienced from pebrine or grasserie.

Silk culture and the silk industry in Turkey, N. N. Shavrov (*Shelkovodstvo i Shelkovaya Promuishlennost v Turtzii. Tiflis, 1907, pt. 1, pp. 302, pls. 11, figs. 45*).—An elaborate account is presented of the status of silkworm growing and silk manufacturing in various parts of Turkey and Syria. Attention is chiefly given to the statistics of production, the culture of mulberries, the breeds of silkworms used in various parts of Turkey, the management of silkworms, and the measures which have been taken for promoting this industry.

FOODS—HUMAN NUTRITION.

Food of man studies, L. H. MERRILL (*Maine Sta. Bul. 158, pp. 219–238*).—Analyses of tropical fruits and vegetables and miscellaneous food products are reported as well as studies of the effects of popping on the composition of corn and the digestibility of hulled corn and the results of an examination of graham flours with a view to determining whether the material submitted was true to name. Among the foods analyzed were yautia, air potato (*Dioscorea bulbifera*), avocado, papaya, tayote, sour sop, yams of different sorts, green pepper, egg fruit, sapodilla, yuquilla, and several kinds of candied, dried, and preserved nuts and fruits, and cereal breakfast foods.

The analyses of corn before and after popping showed that "the corn seems to suffer little chemical change beyond that resulting from a loss of water, the loss amounting to from one-half to two-thirds of the total water content. . . . A determination of the water soluble carbohydrates in the corn would probably have shown a gain in every case."

In eight of the digestion experiments with hulled corn this material and milk were the sole articles of diet. In eight additional experiments the hulled corn and milk were supplemented by bread, butter, milk, and candied peaches. The average results of these tests and the calculated digestibility of the hulled corn alone are shown in the table which follows:

Digestibility of hulled corn: Experiments with man.

Kind of food.	Protein.	Carbohydrates.	Heat of combustion.
	Per cent.	*Per cent.*	*Per cent.*
Hulled corn and milk	81.7	97.3	91.8
Hulled corn with mixed diet	90.9	97.0	95.5
Hulled corn alone	61.2	96.4	86.7

As the author points out, the digestibility of the protein and the availability of the energy of hulled corn are low in comparison with results which have been obtained with white bread. The simple mixed diet containing hulled corn was much more completely utilized than the diet of hulled corn and milk.

The comparative study of graham flour reported led the author to conclude that the suspicious sample was not true to name but a made-up product carrying a considerable proportion of low-grade flour.

Some unusual Japanese food products, O. LOEW (*Mitt. Deut. Gesell. Natur. u. Völkerk. Ostasiens, 11 (1906), No. 1, pp. 109–111*).—The use of young sprouts from a number of sorts of plants, of blossoms of several kinds, of fresh-water algæ, and of several insects as food in Japan is discussed. According to the author, a sort of chrysanthemum blossoms sold in the form of compressed tablets contain 3.8 per cent cane sugar and 20.6 per cent invert sugar, a portion of which is perhaps added during the process of manufacture. One of the fresh-water algæ, a species of *Nostoc phylloderma*, when thoroughly dried is said to contain 25 per cent protein.

The article also contains some general data regarding the use of soy-bean products and other Japanese food customs.

New Zealand boned beef, A. M. WRIGHT (*Chem. News, 97 (1908), No. 2514, p. 50*).—Analyses of canned boned veal and of beef from steers and cows are reported and discussed in connection with average figures. The cans from which the samples were taken had been in cold storage for 6 to 8 weeks and represent the average product as it reaches the market.

According to the author, with the exception of cow beef the composition was practically identical with that of the flesh of the average animal. Cow beef contained considerable more fat than the average, but he considers this a favorable characteristic.

Brown spots on beef, E. KLEIN (*Meat Trades' Jour., 26 (1907), Nos. 1002, p. 56; 1003, p. 62; 1004, p. 90; abs. in Vet. Rec., 20 (1907), No. 1000, pp. 168, 169; Hyg. Rundschau, 18 (1908), No. 7, pp. 414, 415*).—Brown spots on frozen meat were found to be induced by a variety of yeast. Experiments with animals showed that the yeast was not harmful. If meat is handled carefully and wrapped up in a cleanly way the author believes that such a discoloration will not occur.

The cuts of a hog carcass, W. DINSMORE (*Breeder's Gaz., 53 (1908), No. 9, pp. 474, 475, figs. 4*).—The division of the carcass in accordance with the trade requirements for standard mess pork is described.

Studies of the chemical composition of fish with reference to growth and environment, H. REUSS (*Ber. K. Bayer. Biol. Vers. Stat. München, vol. 1, pp. 185–220; abs. in Chem. Zentbl., 1908, I, No. 12, p. 1193*).—The analytical data include determinations of lecithin and calcium in addition to the usual proximate constituents. According to the author, the water in which fish are found has an effect upon their growth and nutrition.

Digestibility of milk products, R. BRUYNOGHE (*Rev. Gén. Lait, 6 (1907), Nos. 19, pp. 441–449; 20, pp. 464–472, figs. 2; 21, pp. 489–499, figs. 3; 22, pp. 512–522, figs. 3*).—A study of the digestibility of milk and milk products is reported in which the stomach contents were removed and examined at different intervals after the food was ingested. In general, the major portion of the milk had left the stomach in an hour to an hour and a half. Different phases of the question studied are discused in detail.

Lard, A. MCGILL (*Lab. Inland Rev. Dept. [Canada] Bul. 147, pp. 17*).—Of 140 samples of lard collected in the different Canadian inspection districts, 129 were genuine, 7 doubtful, 2 adulterated, and 2 compound.

Meat extract and similar preparations including studies of the methods of analysis employed, W. D. BIGELOW and F. C. COOK (*U. S. Dept. Agr., Bur. Chem. Bul. 114, pp. 7–56*).—Results of analyses of a large number of samples of meat extracts, meat juices, yeast extracts and similar goods are reported and the analytical results discussed.

The following conclusions were drawn regarding the use and value of this class of food products:

"It is commonly assumed that proteids, gelatinoids, and the similar amids have very different nutritive values, and, while all authorities would agree in assigning the highest value to the first of these, there is probably no small difference of opinion as to the order in which the second and third should be rated. In considering such a question, there should be separately taken into account relative digestibility or solubility, capability of undergoing osmotic absorption, and oxidizabilty for the production of energy. At present, no definite numerical statement of the relative nutritive values of nitrogenous bodies of these three classes can be made. It seems much to be desired that more extended experiments than have so far been recorded should be made upon living animals (as far as possible upon human beings) to determine the utilization of both the gelatinoids and the simpler amids. The latter no doubt undergo oxidation to some extent in the animal body, and produce some energy in consequence. It is probably true of these simpler amidic substances that much larger quantities than analysis exhibits as constituents of the food consumed, or than analysis detects among the residue of food rejected from the body without having undergone complete oxidation, may be constantly formed

among the earlier products of the metabolism of the proteids, and afterwards themselves undergo further change into the simpler and more stable forms of carbon dioxid, water, and urea.

"In the animal body the amido acids are acted upon in two ways; that is, they are converted into the corresponding fixed acids or carbonic acid is split off, leading to the formation of Brieger's diamins, or it is possible for both of these processes to take place. Usually the albumins are converted in the alimentary tract by the four proteolytic ferments (pepšin, trypsin, erepsin, and arginase) into primary crystalline dissociation products, namely, the amido acids, which are absorbed in this form. Whether a part of the albumin taken as food can or can not be absorbed in the form of albumoses, peptones, and peptids remains to be determined.

"Meat preparations of the sort included in this report are largely used by the sick and the young. Their use is recommended frequently by physicians who may not have taken the trouble to ascertain the true nutritive value of the product prescribed. It seems to be the general consensus of opinion among scientific investigators who have studied this question that the food value of these meat extracts is rather limited, and although they are a source of energy to the body they must not be looked upon as representing in any notable degree the food value of the beef or other meat from which they are derived. When prepared under the best possible conditions a commercial meat extract is, of necessity, in order that it may not spoil, deprived of the greater part of the coagulable proteids, which constitute the chief nutritious elements of the juice. It is fair to state that many manufacturers make no claim as to the food value of their preparations, only a comparatively few making extravagant statements as to the nutritive value of these products.

"Preparations of this character are not wholly valueless in the sick room, for they possess stimulating qualities, and in the kitchen they are useful on account of their flavoring properties. They are not, however, concentrated foods, having on the contrary but comparatively little nutritive value. The meat juice prepared from fresh meat, in the home or hospital, by continued heating at a low temperature, is far superior as a food to the commercial meat extracts and so-called meat juices."

Observation on army bread. H. Bischoff (*Ztschr. Hyg. u. Infectionskrank., 59 (1908), pp. 154–160*).—From a consideration of composition, digestibility, wholesomeness, and related questions the author believes that for making army bread it is more economical and satisfactory to use flour with less than the usual content of bran.

The influence of flour and yeast improvers on bread fermentation. A. J. J. Vandevelde and J. Masson (*Separate from Verslag. en Meded. K. Vlaam. Acad. Taal en Letterk., 1907, pp. 29, figs. 2; abs. in Chem. Zentbl., 1908, I, No. 3, p. 282*).—The authors studied several commercial products which are said by manufacturers to assist fermentation and improve the quality of bread. The results indicated that the use of such materials increased the amount of moisture in the bread, hindered rapid drying, and assisted yeast fermentation. So far as artificial digestion experiments showed, bread made with the addition of the materials tested did not differ in digestibility from ordinary bread.

Honey. A. McGill (*Lab. Inland Rev. Dept. [Canada] Bul. 148, pp. 17*).—Of 141 samples collected in December, 1907, 135 were found to be genuine, 3 doubtful, and 2 adulterated, while 1 was sold as compound. "The report now submitted shows that strained honey, as found throughout Canada, is mainly a genuine article, true to name."

The fig. Lucy Doggett (*Amer. Food Jour., 3 (1908), No. 3, pp. 20, 21*).—According to the author's laboratory experience, it is possible to secure dried

figs free from dirt, insects, etc., and the desirability of clean figs is discussed as well as the food value and uses of figs and related topics.

Nuts and their uses as food. M. E. JAFFA (*U. S. Dept. Agr., Farmers' Bul. 332, pp. 7–8, fig. 1*).—This bulletin is a revision and extension of an earlier publication (E. S. R., 19, p. 258). In its present form the bulletin constitutes a summary of available data on the flavor, composition, and digestibility of nuts and nut products and the general subject of nuts and their uses as food.

Olive oil and its adulteration. A. BLAVIA (*Abonos Químicos, 7 (1907), Nos. 80, pp. 193–197; 81, pp. 214–218; 82, pp. 238–243, figs. 2; 83, pp. 262–266, fig. 1; 84, pp. 287–292; 8 (1908), Nos. 85, pp. 4–8; 86, pp. 28–32*).—A summary and discussion of data regarding olive oil and its adulteration.

On the chemical composition of some Australian wines. M. BLUNNO and L. A. MUSSO (*Agr. Gaz. N. S. Wales, 19 (1908), No. 2, pp. 140–145*).—The analytical data reported cover 149 samples. In many cases the ash constituents were determined as a part of the work.

Organic phosphorus in wine. M. SOAVE (*Ann. R. Accad. Agr. Torino, 49 (1906), pp. 109–114*).—A summary and discussion of data on the character of the organic phosphorus compounds of wine.

Lemon extract. T. J. BRYAN (*Amer. Food Jour., 3 (1908), No. 3, pp. 21, 22*).—The author discusses the adulteration of lemon extract and related questions, gives household tests which he considers useful for the detection of such adulteration, and briefly notes the results of the examination of such goods under the State pure-food law.

Salicylic acid for preserving fruit juices. F. W. DAFERT and B. HAAS (*Arch. Chem. Micros., 1 (1908), p. 24; abs. in Chem. Ztg., 32 (1908), No. 27, Report., p. 174*).—In studies of the minimum amount of salicylic acid required as a preservative it was found that 50 gm. per hectoliter of raspberry juice was sufficient.

Influence of food preservatives and artificial colors on digestion and health. IV, Benzoic acid and benzoates. H. W. WILEY (*U. S. Dept. Agr., Bur. Chem. Bul. 84, pt. 4, pp. 1043–1294, figs. 2*).—Full analytical data and other details are reported of investigations on benzoic acid and benzoates. The conclusions have been noted from a previous summary (E. S. R., 20, p. 361).

The social condition of working-class families in Dublin (*Brit. Med. Jour., 1908, No. 2466, pp. 833, 834*).—A summary of investigations carried on by T. J. Stafford and C. D. La Touche into the social conditions and domestic economy of a number of families. Considering 21 families, the average expenditure for food was about $3.20 per week, which provided on an average 98.52 gm. of protein per man per day. Considering only families of unskilled laborers, the amount expended for food was $2.48 per week and the amount of protein obtained 80.6 gm. per man per day. The authors believe that the systematic study of such questions is of the greatest importance.

Dietetics in tuberculosis: Principles and economics. N. D. BARDSWELL and J. E. CHAPMAN (*Proc. Roy. Soc. [London], Ser. B, 80 (1908), No. B538, pp. 151–160*).—In connection with a study of the diet of tuberculosis patients with special reference to the value of animal and vegetable protein, the authors report figures obtained with families under normal conditions which are used for purposes of comparison. They found that the diet of 100 working-class families, regarded as physiologically adequate, furnished 119 gm. protein, 114 gm. fat, 417 gm. carbohydrates, and 3,687 calories of energy per person per day at a cost of 20 cents.

An explanation of the specific dynamic effect of protein. G. LUSK (*Zentbl. Physiol., 21 (1907), No. 26, pp. 861, 862*).—On theoretical grounds the author believes that the specific dynamic affect of protein is due to cleavage which involves the breaking down of the amid radical. If protein is resorbed rather

than broken down such cleavage does not take place and no specific dynamic effect is noted.

Experiments on the effect of gastric and intestinal enzyms on vegetable protein. A. STUTZER and E. MERRES (*Biochem. Ztschr., 9 (1908), No. 1–2, pp. 127–162*).—The experiments reported led to the conclusion that the best results were obtained in artificial digestion when digestibility was measured with a satisfactory pepsin solution. Subsequent treatment with alkaline trypsin solution is not regarded as necessary or desirable.

The action of gastric and intestinal enzyms on vegetable protein, A. STUTZER and E. MERRES (*Biochem. Ztschr., 9 (1908), No. 3–4, pp. 244–254*).—A continuation of the authors' comparison of the results of natural and artificial digestion.

According to the data reported, if the feces in natural digestion experiments are subsequently digested with gastric juice the total digestibility agrees very closely with the results obtained in artificial digestion experiments when the feeding stuff is treated with such acid gastric juice. This method, in the authors' opinion, gives without doubt the most reliable data as to the proportion of digestible nitrogenous material in foods and feeding stuffs.

The utilization of different amid bodies by Carnivora, W. VÖLTZ and G. YAKUWA (*Arch. Physiol. [Pflüger], 121 (1908), No. 3–4, pp. 117–149, chart 1*).—According to the authors' experiments with dogs, ammonium acetate, acetamid, glycocoll, and a mixture of these bodies and asparagin increased the resorption of nitrogen, while asparagin alone diminished it slightly or was without effect. The results are also discussed with reference to the gains in nitrogen and the nitrogen balance and the authors conclude that the character of the amid substances exercises a decided influence upon nitrogen metabolism.

The direct utilization of the common sugars by the tissues, H. MCGUIGAN (*Amer. Jour. Physiol., 21 (1908), No. 3, pp. 334–350*).—The living muscles of an animal, according to the author's experiments, when perfused with dextrose, levulose, or galactose cause a rapid oxidation of these sugars. The results obtained with maltose did not indicate any direct oxidation by the muscles. The perfusion of dead muscles showed practically no loss of sugar.

Other questions were also considered in this experimental inquiry, which is a contribution to the question of the way in which the animal body utilizes a carbohydrate food supply.

Studies of diastase, J. WOHLGEMUTH (*Biochem. Ztschr., 9 (1908), No. 1–2, pp. 10–43*).—The following are some of the conclusions drawn from the author's experimental work: The quantity of diastatic ferment in human saliva varies markedly. Usually more diastase is present after taking food than otherwise but sometimes these conditions are reversed. The kind of food seems to be without effect on the quantity of diastase present. On an average, sodium chlorid was found to increase the diastatic power of saliva about ten times in a 24-hour digestion period.

Metabolism experiments with healthy children and children with rickets with special reference to mineral metabolism, W. CRONHEIM and E. MÜLLER (*Biochem. Ztschr., 9 (1908), No. 1–2, pp. 76–126*).—The results, which have to do with the metabolism of nitrogen and fat in healthy children, were favorable to sterilized milk. In the case of calcium no better results were noted with raw than with sterilized milk. The authors believe that the unfavorable results sometimes noted with sterilized milk are due to conditions not yet understood.

Experiments on the metabolism of calcium, magnesium, and phosphorus in fasting animals, O. WELLMANN (*Arch. Physiol. [Pflüger], 121 (1908), No. 8–10, pp. 508–533*).—The authors studied the metabolism of mineral matter with Herbivora (rabbits) and found that bones lost about 14 per cent of their weight

during fasting, of which about half was fat. Analyses of the bone showed that practically all the calcium and phosphorus lost during the fasting period came from bone substance.

The utilization by the growing animal of calcium in different forms, H. Aron and K. Frese (*Biochem. Ztschr., 9 (1908), No. 1–2, pp. 185–207*).—Growing dogs, it was found, utilized calcium in the form of tertiary calcium phosphate, which is difficultly soluble, as readily as in the form occurring in milk. Sterilizing milk was found to be without influence on calcium metabolism and gains. In general, over 80 per cent of the calcium supplied was utilized.

Observations on the rectal temperature after muscular exercise, M. Flack (*Brit. Med. Jour., 1908, No. 2468, pp. 921, 922*).—A marked rise in temperature was noted in a number of subjects after muscular exercise.

ANIMAL PRODUCTION.

The composition of green maize and of the silage produced therefrom, H. E. Annett and E. J. Russell (*Jour. Agr. Sci., 2 (1908), No. 4, pp. 382–391*).—Analyses of fresh green fodder and silage were made with a view to studying the changes brought about by ensiling. The crude fiber content was found to be practically unchanged and this opinion was confirmed by microscopical analysis. The epidermal cells, according to the author, had undergone no change in the silo beyond a certain amount of shrinkage, even the stomata being unaltered. The vascular bundles were also intact. The greatest change was noted in the nitrogen-free extract, direct tests showing that the sugar disappears almost entirely.

The observed decrease in furfurol "indicates a decrease in the amount of cellulose, i. e., the less resistant cellulose, which alone falls into this group; this was confirmed by microscopic examination which showed that many of the cells of the mesophyll were completely disintegrated.

"The protein suffers considerably, though not in reality as much as the nitrogen-free extract. Hydrolytic decomposition complicated by bacterial action takes place, and although there is not much, if any, loss of free nitrogen the new nitrogenous compounds are less valuable as food than the protein.

"The figures show an absolute loss of nitrogen, but we are satisfied that a certain amount of ammonia is given off during sampling, and we have no evidence to show how or to what extent losses of nitrogen occur in the silo. In laboratory experiments on silage made in bottles we only observed losses of nitrogen when air was admitted, and this did not happen in the silo."

The values obtained for ether extract the authors consider influenced by accidental variation, since this constituent contains a number of soluble acids which obviously wash downward in the silo. A similar factor influences the soluble ash content though not the insoluble ash constituents. During the process of ensiling carbon dioxid is evolved and a number of acids appear which were not present at the beginning of the process. According to the authors the general nature of the losses outlined is probably the same in all silos though the actual amount varies. "Our losses are higher than those observed by American investigators, but there is considerable difference between American and English maize at the time of cutting; ours is much less mature, and contains a lower proportion of nitrogen-free extract."

The chemical changes taking place during the ensilage of maize, E. J. Russell (*Jour. Agr. Sci., 2 (1908), No. 4, pp. 395–410*).—The author summarizes the results of investigations as follows:

"The main groups of compounds found in maize silage are fatty acids, hydroxy acids, amino acids, basic diamino acids, purin bases, and other bases,

besides the ordinary constituents of the plant cell, the celluloses, protein, etc. The nonnitrogenous acids are not found in maize at the time of cutting, and the nitrogenous acids, though they are found, occur to a smaller extent than in silage.

"The characteristic silage changes are the disappearance of sugar, of some less resistant celluloses, and of part of the protein, and the formation of the bodies enumerated above.

"Three agents appear to be involved in making silage—the living maize cell, the enzyms, and micro-organisms. It is considered that the two former bring about the primary and essential changes, the latter only secondary and nonessential changes.

"The formation of acetic and butyric acids appears to be a respiration effect, and comes about when the living cell is deprived of oxygen. Sugar disappears during the process.

"The decomposition of the protein and nucleo-protein is effected by enzyms present at the time of cutting the maize, which can go on acting in the silo even after the cell is dead. Characteristic products of protein hydrolysis were identified in the silage.

"These are regarded as the primary and essential changes.

"Bacteria are, however, always present, and attack the less resistant celluloses, the products of protein hydrolysis, and no doubt other substances as well, but not the resistant fiber. Typical products of bacterial activity were found—formic acid, higher fatty acids, humus, and amins.

"The growth of mold is inhibited except at the surface layer where air gets in. Here the changes are fundamentally different; there is no development of acetic or butyric acids, the mass is alkaline, nonprotein material already existing in the maize is converted into protein, and there is also a loss of nitrogen."

Analyses of a mixture of red clover and timothy forage, A. Grégoire and E. Carpiaux (*Bul. Inst. Chim. et Bact. Gembloux, 1908, No. 75, pp. 109, 110*).—A proximate and ash analysis is reported.

On the composition of rice straw, T. Takeuchi (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1908), No. 5, pp. 619–621*).—From the analyses reported, the conclusion is drawn that straw from rice plants producing a poor crop is somewhat richer in protein, fat, and carbohydrates than is the case when the yield is better.

Fodders and their nutrient values, C. F. Juritz (*Agr. Jour. Cape Good Hope, 32 (1908), No. 1, pp. 99–101*).—Analyses of Vlei grass, ground corncob and corn are reported. As the author points out, the food value of the corncob is about one-third that of the corn analyzed and is also inferior to wheat bran.

Examination of feeding stuffs, C. Aumann (*Ber. Landw. Vers. Stat. Hildesheim, 1907, pp. 6–11, 14*).—A brief report of the examination of a large number of samples of commercial by-products, cereal grains, meat meal, and other feeding stuffs.

Examination of feeding stuffs, H. Immendorff (*Ber. Landw. Vers. Stat. Univ. Jena, 1907, pp. 10–14*).—A brief report of the examination of a number of samples of concentrated feeds and other feeding stuffs, of "futterkalk" and similar materials.

Brief statements are also made regarding samples of milk and dairy products which were analyzed at the station.

Feeding stuff analyses, E. Haselhoff (*Jahresber. Landw. Vers. Stat. Marburg, 1907–8, pp. 10–16*).—Data are reported regarding the composition of feeding stuffs examined at the station.

New feeding stuffs, J. V. de Paula Nogueria (*Gas. Aldeias, 1908, No. 657; abs. in Bol. R. Assoc. Cent. Agr. Portuguesa, 10 (1908), No. 8, pp. 487–495*).—

Analyses of two commercial feeds, one a molasses feed, are reported and discussed with reference to Portuguese conditions.

The digestibility of dried beet pulp, E. Baeck (*Sucr. Indig. et Colon., 71 (1908), No. 17, p. 451*).—In a paper presented at the Second International Congress of Sugar and Fermentation Industries, the author summarizes experimental data which in his opinion show that drying increases the digestibility of the pulp.

The use of olive marc for cattle feeding, A. Guyader (*Bul. Dir. Agr. Com. et Colon. [Tunis], 12 (1908), No. 46, pp. 122–126*).—On the basis of analytical data reported in comparison with other feeding stuffs, the author believes that olive marc is a valuable feed. The olive marc may be readily dried and ground.

Patent horsebread, H. H. Morgan (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3282, p. 11*).—A brief account of a patent feed for horses which is marketed in cake form and is said to be particularly rich in phosphoric acid and lime in addition to the usual feed constituents.

Beer yeast as a feeding stuff, E. Pott (*Illus. Landw. Ztg., 28 (1908), No. 33, pp. 295, 296*).—Data regarding the composition and feeding value of yeast and yeast feeds are summarized and discussed.

Notes from the chemical laboratories, H. Ingle (*Transvaal Agr. Jour., 6 (1908), No. 23, pp. 426–428*).—Ground nut cake, wild plums, pearl millet, and sunflower seed were analyzed with special reference to oil making in the case of the plums and sunflower seed. The plum pits, if dried, would, according to the author, contain 38.1 per cent oil.

Concerning spoiled peanut cake, A. Grégoire, Hendrick, and E. Carpiaux (*Bul. Inst. Chim. et Bact. Gembloux, 1908, No. 75, pp. 44–65*).—In all the spoiled peanut cakes examined sugar was less than 6 per cent of the total organic matter exclusive of fat, and acidity was greater than 60 per cent measured as oleic acid.

Do ptomaines and toxins occur in animal meal? Haefcke (*Ztschr. Fleisch u. Milchhyg., 18 (1908), No. 8, pp. 245–253*).—Although the author was able to identify, in decomposed meat and bone, ptomaines which have previously been found, as well as new amino bases not hitherto reported, he was not able to identify any specific ptomaine in such animal material which had been sterilized after spoiling.

[Sex and birth weight of calves], C. L. Beach (*Connecticut Storrs Sta. Rpt. 1907, pp. 146, 147*).—A table shows the yearly proportion of sexes in the college herd. "During the 10 years, from 1897 to 1906, 201 calves were dropped, of which 41.3 per cent were female and 58.7 per cent were male." In a small flock of Dorset sheep the number of ram lambs was largely in excess. The weight of the calves at birth was, in general, proportioned to the weight of the dams. The average daily foetal growth ranged from 0.38 lb. with Holstein calves to 0.22 lb. with calves from Jersey heifers.

Calf raising, B. R. Jonas (*Wiener Landw. Ztg., 58 (1908), No. 42, p. 436*).—The author studied the body development of calves fed with and without access to pasture, taking into account body measurements and gains in weight. His conclusion is that calves with pasture show the most satisfactory development.

Whole milk compared with skim milk alone and supplemented by other feeds in calf feeding, G. Fingerling (*Landw. Vers. Stat., 68 (1908), No. 3–4, pp. 141–188*).—In the experiments reported the gains in weight and the metabolism in nitrogen were the same on skim milk as on whole milk but the skim milk did not have the same satisfactory dietetic properties as the whole milk. In the author's opinion, milk fat is of value not only as a nutrient but also for its dietetic properties.

Peanut oil emulsion, flaxseed, and starch were used for supplementing skim milk and the best results, according to the author, were obtained with flaxseed, though good results were also obtained with the peanut oil emulsion provided the quantity was not too large. When the skim milk was supplemented by cooked starch the digestive disturbances were as great as noted on skim milk alone.

No conclusions could be drawn from the experimental data regarding the effect of different rations on the quality of the meat produced.

Feeding of the Angus steer Andy, A. Boss (*Breeder's Gaz., 53 (1908), No. 18, pp. 1005, 1006, figs. 4*).—A summary of data regarding the feeding of this champion steer at the Minnesota Agricultural College.

In general the amount of grain was smaller than is recommended by many feeders and large amounts of succulent feed were supplied, roots or silage being used when the steer was not on grass. No molasses or condimental stock feed was used at any time. The average gain in the 2 years was in one 4 week period as high as 3.57 lbs. per day. The steer weighed 1,780 lbs. when slaughtered, the dressed weight after a month in cold storage being 68.6 per cent of the live weight. The flavor of the meat was excellent and the carcass was of fine texture and marbling throughout.

Study of draft oxen in Tunis. G. Barrion and R. Gagey (*Bul. Dir. Agr. Com. et Colon. [Tunis], 12 (1908), No. 46, pp. 103–111*).—The studies reported are not favorable to the draft oxen used locally and the authors recommend raising improved breeds.

A dynamometer for experiments with steers, R. Gagey (*Bul. Dir. Agr. Com. et Colon. [Tunis], 12 (1908), No. 46, pp. 112, 113, fig. 1*).—The author describes a dynamometer used in tests with draft oxen.

Studies of the milk secretion of pigs and the feeding of young pigs, R. Ostertag and N. Nuntz et al. (*Landw. Jahrb., 37 (1908), No. 2, pp. 201–260*).—Some of the conclusions which were drawn from the extended series of investigations reported follow: The milk yield and the fat and protein content of swine milk are much greater than has been hitherto supposed, a sow weighing 150 kg. yielding 4 to 8 liters of milk per day, containing 45 to 90 gm. nitrogen and having an energy value of 7,000 to 14,000 calories.

The food requirement of sows is not greater than the maintenance requirement plus the material necessary for the milk yield. The work of the milk glands apparently does not require any considerable energy expenditure.

Nursing pigs utilize 60 to 80 per cent of the energy of the milk eaten and as much as 70 per cent of the nitrogen content. Gains in nitrogen diminish more than gains in fat as the period of lactation progresses. When the same amount of nitrogenous material is taken after weaning as before, pigs make as large gains in weight, the protein gains being even greater than during the latter part of the period before weaning. To secure the greatest gains after weaning, the nitrogen ratio must not be greater than 1:4 and the proportion of easily digestible carbohydrates must be much greater than fat. Inverting part of the carbohydrates with diastase did not have a favorable effect except immediately after weaning. Homogenized milk was found to be as satisfactory as whole milk and cheaper.

No conclusions could be drawn regarding the effect of the different rations on resistance to infection.

Forage crops for hogs in Kansas and Oklahoma, C. E. Quinn (*U. S. Dept. Agr., Farmers' Bul. 331, pp. 5–24*).—A revision of an article previously noted (E. S. R., 19, p. 569).

Potatoes supplemented by different quantities of protein for pig feeding, Münzinger (*Deut. Landw. Presse, 35 (1908), Nos. 8, pp. 75, 76; 9, pp. 87, 88, figs.*

4).—Greater gains were made on the ration containing the larger amount of protein. Differences in quality of the meat produced were not noted.

Different quantities of skim milk with supplementary feeds for pigs, J. KLEIN (*Milchw. Zentbl., 3 (1907), No. 4, pp. 137–149*).—Four lots of 2 pigs each were used in a test covering 21 weeks, in which varying amounts of skim milk were fed with barley and dried beet pulp or potato flakes, one of the lots receiving some fish meal also. Marked differences were not noted with the several lots with respect to the gains in weight, the ratio of the dressed weight to live weight, the quality of the meat, or the character of the fat.

Construction of pig-sty buildings, A. BROOKS (*Agr. Gaz. N. S. Wales, 18 (1907), Nos. 8, pp. 663–667, figs. 5; 11, pp. 856–862, figs. 11; 19 (1908), No. 1, pp. 30–36, figs. 11*).—The construction and equipment of pig sties are discussed with special reference to local conditions and requirements.

Feeding work horses. A comparison of corn and oats, B. E. CARMICHAEL (*Ohio Sta. Bul. 195, pp. 245–263, figs. 9, dgms. 2*).—The tests reported were undertaken to test the widespread belief that oats are superior to other grain as a feed for horses. Six mature grade Percheron geldings were fed on a basal ration of clover and timothy hay, three receiving oats and three corn as a supplementary ration. Estimating corn to be worth 40 cts. per bushel, oats 30 cts. per bushel, and the hay $8 per ton it was found that the average cost of food per hour of work was 3.3 cts. for the corn-fed horses and 4.54 cts. for those fed oats.

The use of corn to the exclusion of other grain for a period of 48 weeks was not found detrimental to the health of work horses and they endured hard work during the hot weather as well as those receiving oats. When mixed (clover and timothy) hay was fed to mature geldings at general farm work, ear corn was practically as efficient, pound for pound, as oats. On the basis of the results of this experiment and statistical records of farm values of grains, corn has since 1866 been cheaper than oats as a grain feed for work horses.

A drop in weight of the corn-fed horses coincident with the beginning of the use of shelled corn indicates that ear corn is to be preferred above shelled corn for work horses.

Saving corn fodder as horse feed (*Breeder's Gaz., 54 (1908), No. 11, p. 437*).—Corn fodder, it is stated, may be fed to horses, but one-third of the bulk of the ration should be made up of some other material, preferably red clover or alfalfa. Care must be taken to avoid soft corn, which is injurious to horses, therefore stripping off the ears before feeding is recommended. Shredding is not regarded as necessary or desirable.

The metacarpus of carriage and draft horses with particular reference to its strength, A. WOLTER (*Landw. Jahrb., 36 (1907), No. 3, pp. 485–568, figs. 34*).—The author made measurements and tested the strength of the metacarpal bones of the front legs of carriage and heavy horses. The absolute weight of the metacarpal bone in heavy horses is 30 per cent greater than that in light horses and its volume 23 per cent greater. The metacarpus of the heavy type of horse is somewhat flatter than that of the race horse. The relative measurements of the metacarpus show such a great individual variation that no racial distinctions can be set up. The absolute carrying strength of the metacarpus in draft horses is 31 per cent greater than in carriage horses.

Horses—breeding to color, W. GILBEY (*London, 1907, pp. VI+45, pls. 6*).—The author has endeavored to explain the cause of different colors in horses and the reason for the increasing frequency of some colors and the decrease of others. Suggestions are also offered as to how horses may be bred to color.

Feeding experiments with chickens, cockerels, and turkeys, J. W. BOLTÉ (*Rhode Island Sta. Bul. 126, pp. 125–139, pls. 3*).—To compare the effect of

different concentrates with and without bone-forming constituents for winter chickens, 7 lots each consisting of 34 White Wyandottes 2 weeks old were fed a basal ration of mixed grain, clover, and grit, supplemented by animal meal, cotton-seed meal, gluten feed, or granulated milk. Three of these lots also received bone ash and pure calcium carbonate sufficient to bring up the calcium and phosphorus content essentially to that in the ration including animal meal. The test was divided into two periods, the first lasting 28 days and the second 35 days.

During the first period the food required per pound of gain was as follows: On animal meal 3.29 lbs., on cotton-seed meal 9.8 lbs., on cotton-seed meal plus the bone-ash and lime 5.3 lbs., on Buffalo gluten feed 9.92 lbs., on Buffalo gluten feed plus bone-ash and lime 4.39 lbs., on granulated milk 4.1 lbs., and on granulated milk plus bone-ash and lime 3.18 lbs. During the second period the amounts required were respectively 4.52, 9.87, 5.74, 9.05, 5.16, 5.78, and 4.19 lbs. The percentages of deaths from digestive troubles were respectively as follows: 12, 62, 50, 59, 3, 9, and 6. The author states that the data seem to indicate that phosphorus and lime appear to be as necessary as protein, and that cotton-seed meal can not be recommended as a food for chickens in any considerable proportion.

Twenty-four cross-bred Plymouth Rock cockerels were used to test the advisability of fattening late hatched chickens by feeding with a machine. During a period of 21 days those trough-fed made an average gain of 0.61 lb. at a cost of 17.4 cts. per pound. Those trough and machine fed gained 0.75 lb. at a cost of 15.9 cts. per pound. It is concluded that late hatched staggy cockerels confined in slatted coops can be fed a fattening ration for 3 weeks with profit.

"A combination of trough and machine feeding proved superior to trough feeding alone. Chickens fed in this manner gained, on the average, 23 per cent more, and at 9 per cent less cost for feed per pound of gain, than when fed wholly in the trough. The cost of labor, however, is doubled while using the cramming machine for small numbers of chicks.

"In the absence of skim milk to mix with the grain, some other animal concentrate should be supplied. The ration containing 10 per cent of animal meal gave a much greater gain than rations containing either no animal meal or 20 per cent of animal meal. The cost of feed per pound of gain was lessened one-third under the same conditions."

A turkey fattening experiment is reported as seeming to indicate that:

"For a short feeding period there is not sufficient advantage in using a wet mash of mixed grains, at the prices quoted, to warrant the turkey fattener in adopting the ration.

"While the feeding of a mash partly in the trough and partly with the cramming machine gave the greatest average gains at the least cost for feed, the added outlay for labor over feeding corn on the range would make the latter method more profitable.

"Heavy feeding may hasten the development of the 'blackhead' disease, if it is already present in the system."

The experiment was terminated at the end of 10 days by the appearance of "blackhead."

Experiments on the metabolism of matter and energy during incubation of hens' eggs, F. Tangl and A. von Mituch (*Arch. Physiol. [Pflüger], 121 (1908), No. 8–10, pp. 437–458*).—According to the authors' observations an egg weighing 54.2 gm. contained before incubation 36.8 gm. water, 12.14 gm. dry matter, 5.68 gm. fat, and 0.929 gm. nitrogen, and had an energy value of 86.85 calories. At the time of hatching the chick weighed 28.8 gm. and 6.9 gm. egg yolk remained unused.

According to the analytical studies reported, 61 calories, or two-thirds of the energy value of the total egg was required in the incubation process, of which 23 calories was used for the development of the chick and measurable as heat, and 38 calories was represented by the material in the chick's body. The egg yolk remaining unused at the time of hatching had an energy value of 26 calories or about one-third of the amount originally present.

The values, therefore, per gram body weight of the chick would be 0.805 calorie manifested as heat, that is, "relative energy of development," and 3.6 calories per gram dry matter, for body development, that is, "specific energy of development."

The energy required for development is largely supplied by the egg fat. No nitrogen is lost during incubation, according to the authors, at least none could be measured in their experiments.

The assimilation of phosphorus and calcium by the chicken embryo, E. Carpiaux (*Acad. Roy. Belg., Bul. Cl. Sci., 1908, No. 3, pp. 283–295; abs. in Chem. Zentbl., 1908, II, No. 4, p. 337*).—In continuation of earlier work (E. S. R., 15, p. 64) the author studied the calcium and organic and inorganic phosphorus content of eggs at different stages of incubation and found that as the embryo develops the calcium and inorganic phosphorus of the egg increases while the lecithin is correspondingly diminished. According to the observed data the chicken uses almost entirely the phosphorus of lecithin for building its body and does not make use of the phosphorus in the egg-shell. On the other hand, the shell furnishes more than 80 per cent of the necessary calcium.

Carbon dioxid under sitting hens, H. D. Edmond (*Connecticut Storrs Sta. Rpt. 1907, pp. 157–162*).—Using a modification of Pettenköfer's titration method, the author found that the carbon dioxid under hens sitting on good eggs in March ranged from 3.8 to 22.5 parts by weight in 10,000 parts of air while the proportions in the air of the barn ranged from 2.8 to 5.2. Under a hen sitting on china eggs the range was from 3.4 to 8.5. In tests in July, made by a somewhat different method, the percentages of carbon dioxid under hens were much higher than in March, ranging from 5.3 to 12.0 with china eggs and from 9.0 to 80.1 parts per 10,000 of air with good eggs.

In an incubator samples of air were drawn by an aspirator from over the egg tray, the parts of carbon dioxid ranging from 4.8 to 29.5. Oats was sown in one pan to test the effect on the air of the incubator of the carbon dioxid given off by sprouting seed, but no noticeable difference was found.

"Whether carbon dioxid is essential to a perfect hatch and vitality in a chick is still an open question. This work is not complete enough to settle the question and there is very little data to be found on this subject. It is true that there is a much larger percentage of carbon dioxid under sitting hens than in an incubator. It is also true that hens hatch chickens with greater vitality than an incubator."

Incubation experiments, J. Dryden (*Oregon Sta. Bul. 100, pp. 3–32, figs. 6*).—A series of investigations was started to test the relative efficiency of natural and artificial incubation and to discover improvements in incubation and brooding.

"From 879 eggs set, incubators hatched 533 chicks, or 60.6 per cent. From 279 eggs, hens hatched 219 chicks, or 78.8 per cent. Eliminating eggs broken in nests, the hens hatched 88.2 per cent of eggs set. The incubators hatched 78.5 per cent of 'fertile' eggs, and the hens hatched 96.5 per cent.

"Eggs incubated artificially tested out 22.7 per cent as infertile, while those incubated by hens tested out 11.8 per cent. The incubators showed 16.6 per cent of chicks 'dead in the shell,' and the hens 2.8 per cent.

"Chicks hatched under hens weighed heavier than chicks hatched in incubators.

"The mortality of hen-hatched chicks brooded in brooders was 10.8 per cent in four weeks, and of incubator-hatched chicks 33.5 per cent. The mortality in hen-hatched chicks brooded under hens was 2.2 per cent, and of incubator chicks 49.2 per cent. In other tests the mortality was 46.5 per cent for incubator chicks brooded by hens and 58.4 brooded in brooders.

"Hen-hatched chicks made greater gain in weight than incubator chicks, whether brooded by hens or brooders."

Moisture tests were made in which incubators were operated according to the directions of the makers with the exception that moisture was used in different amounts. In the machines with "no moisture" a tray of dry sand, corresponding to the tray in the "maximum moisture" machines was kept under the egg tray. The sand in the "maximum moisture" machines was kept wet all the time, or as wet as it could be kept without the water standing on top of the sand. The "medium moisture" machines had a tray of sand half the size of the other trays.

"There was an increase in number of chicks hatched of 32.6 per cent by using moisture in incubators.

"The wet-bulb thermometer may be used to advantage as an indicator of the proper degree of humidity in the incubator. An average wet-bulb temperature of 87.6 gave 32.6 per cent better hatches than one of 84.5, and slightly better than one of 91.

"The lack of moisture does not alone explain the great mortality in incubator chicks, but it is responsible for a large percentage of the losses in hatching."

The amount of oil on egg shells was determined by washing the surface of the shell with a jet of ether and evaporating. The residue was dried in a dessicator and weighed, with the following results: 12 fresh hen eggs, 3 mg. oil; 12 china eggs, 2 weeks under hen, 3 mg.; 12 hen eggs, 2 weeks under hen, 28 mg.; 12 hen eggs, 2 weeks in incubator, 4.6 mg. This oil is considered a natural secretion from the hen, but its function has not been determined.

Appliance and methods for pedigree poultry breeding, R. Pearl and F. M. Surface (*Maine Sta. Bul. 159, pp. 239–274, figs. 13*).—Descriptions are given of a trap nest, an egg distributing and turning table, pedigree incubator baskets, a chick leg band bender, and a system of keeping pedigree records, devised by the station. It is stated that by making slight changes in detail the system of pedigree records can be adapted to keeping pedigree records in breeding work with either plants or animals.

Chicks: Hatching and rearing, H. A. Nourse et al. (*St. Paul, Minn., 1907, pp. 126, pl. 1, figs. 44*).—Incubation, brooding, feeding, housing, fattening, killing and marketing chickens, and other questions are discussed in this popular summary.

Egg money: How to increase it, H. A. Nourse et al. (*St. Paul, Minn., 1907, pp. 128, pl. 1, figs. 44*).—A summary of information on raising poultry for egg production in cities and villages, as well as under farm conditions.

Experiments with ostriches, J. E. Duerden (*Agr. Jour. Cape Good Hope, 32 (1908), No. 6, pp. 713–721*).—The best time in which to quill ostriches, the author concludes, involves considerations of the age of the bird, its physical condition, and climatic conditions.

"The first quilling must be carried out when the chicks are about eight months old, otherwise irregularities will be introduced by the uneven growth of the new second crop, some feathers of which can not be kept back by allowing the quills to remain in their follicle.

"The extraction of a quill at once stimulates the growth of a new feather, quite irrespective of any natural order of appearance of the feather, and thus evenness of growth can be secured by simultaneous quilling.

"The second quilling may take place at about sixteen months, at which time the quills are ripe; but under certain conditions the operation can be delayed for several months longer.

"The quills of the second and later quillings may be left for many months within the socket, even after they are ripe, provided the birds are not in a high nutritive condition; otherwise some feathers of the new crop will appear and thus produce irregularities.

"Eight month and twelve month systems of quilling are very largely practiced according to climatic conditions, though both systems admit of considerable variations."

For earlier work, see E. S. R., 19, p. 1072.

Egg-laying records of ostriches, J. E. DUERDEN (*Agr. Jour. Cape Good Hope, 32 (1908), No. 4, pp. 449–453*).—Four series of egg-laying records for lots of 1 cock and 2 hen ostriches are given, extending over a period of 4 months. The eggs were removed daily and artificially incubated. The maximum per hen was 100 eggs in 122 days.

"The numbers show that ostriches, like poultry, will go on laying almost continuously during the breeding season if the eggs are removed as laid, and the birds are not allowed to sit. The records afford very clear proof that breeding birds are adversely influenced by inclement climatic conditions to such a degree that the laying of eggs may cease entirely for a time."

The influence of environment generally upon egg-production and also the possibility of an increased yield are briefly discussed.

DAIRY FARMING—DAIRYING.

Experiments in feeding dairy cows, J. S. MOORE (*Mississippi Sta. Bul. 111, pp. 6*).—This bulletin gives results of a number of experiments in the care and feeding of dairy cows. Experiments lasting 16 and 10 weeks, respectively, were undertaken to see if it paid to feed cotton-seed meal when cows had an abundance of green feed. In the former test the cotton-seed meal gave 5 per cent better returns, but this was not enough to pay for the extra cost of the meal. In the second test there was no increase in the yield of milk.

Using cows pastured at night but kept up during the day, cotton-seed meal was fed at the barn in comparison with the soiling crops, alfalfa, sorghum, and Johnson grass. In a 10 weeks' test it was found that 41 lbs. of green feed gave an average daily yield of 14.9 lbs. of milk for each cow, while the lot fed 3.4 lbs. of cotton-seed meal gave 14.2 lbs. The difference in favor of green feed would have been greater if the cows had had no access to pasture.

In a comparison of large, medium, and small rations with three lots of cows, receiving respectively 13 lbs., 10 lbs., and 6 lbs. of a grain ration consisting of wheat bran and cotton-seed meal 2:1, the average weekly yields were 833, 873, and 743 lbs. In the last case there was also some loss of body weight. A second test with three lots of 9 cows each showed that 9 lbs. of the mixture yielded better results than 11 lbs.

In a test for 4 months with 30 cows it was found that silage resulted in a saving of $100 over a feed of wheat bran, cotton-seed meal, and Johnson grass hay.

During hot weather it was found to be of no advantage to protect cows from the heat by keeping them in the barn, as they were more contented in a shady pasture.

Shelter was found to be unnecessary for dairy cows during the month of February, 1906. It is stated, however, that during this test the weather was extremely mild for that season of the year.

Silage v. hulls and meal. A. K. RISSER and R. R. WELCH (*Mississippi Sta. Bul. 112, pp. 2–8*).—In order to present results obtained from the use of silos, herd records of several farms were collected by the station in cooperation with the Dairy Division of this Department. All cows in the test had practically the same ration in the summer months of May, June, and July, i. e., pasture supplemented with cotton-seed meal. During the winter months of November, December, and January 7 herds containing a total of 247 cows were fed a dry ration, principally hulls and cotton-seed meal, with some bran, shorts, and alfalfa, while the eighth herd of 23 cows was fed corn silage and cotton-seed meal.

Milk and butter fat production with silage and dry feeds.

	Average pounds of milk per cow per month.		Average pounds of butter fat per cow per month.		Average cost of feed per cow per month.	Average cost of 1 gal. of milk.	Average cost of 1 lb. of butter fat.
	Summer.	Winter.	Summer.	Winter.			
Dry-fed herds	357.9	240.4	[a]17.12	[a]12.09	$4.10	$0.1468	[a]$0.2993
Silage-fed herds	364.9	335.9	17.58	16.70	3.50	.0895	.2098
Differences	7.0	95.5	.46	4.61	.60	.0573	.0895

[a] Average of 149 cows.

Notes relative to the construction of silos are given.

Modern feeding standards for milch cows. N. HANSSON (*K. Landtbr. Akad. Handl. och Tidskr., 47 (1908), No. 1–2, pp. 57–73*).—A discussion of the feeding standards of Wolff (1874), Julius Kühn (1897), C. Lehmann (1899), Maercker (1902), Pott (1904), Kellner (1905 and 1906), and those of the author (1902), founded on the experience of Swedish dairy test associations. The author has devised a system of feed units for the use of Swedish dairymen, which he discusses in detail.

Report of dairy test associations in Norway, 1906–7. L. FUNDER (*Christiania, 1908, pp. 78*).—The report shows that 132 different associations were in existence during the year, including 22,764 cows in the aggregate. The average production of milk was 2,026 kg. per cow, 100 kg. being produced for every 70.3 feed units (each equal to 1 kg. hay) eaten. Fat determinations in the milk of the cows were made in the case of only 38 associations. The average fat content in the milk, according to the results obtained at the milk control stations for 1906, was 3.48 per cent.

Milk and butter yields of heifers compared with mature cows. C. L. BEACH (*Connecticut Storrs Sta. Rpt. 1907, pp. 142–145*).—Tables are given summarizing official records of 3,098 Holstein-Friesians and 400 Guernseys, classified according to the age of the animals. In the Holsteins "the quality of milk is quite uniform for animals of different ages. The milk of 2-year-old heifers contained 0.2 per cent less of butter fat than that of cows in the mature 5-year-old form." The calculated butter fat yield in 7 days at even age of 2 years is 9.05 lbs., at 3 years 11.31 lbs., at 4 years 13.22 lbs., and at 5 years 14.35 lbs. The average yearly yield of butter fat of the Guernseys for the 2-year-old class was 352.8 lbs., the 3-year-old class 403.9 lbs., and the 4-year-old class 433.5 lbs. The mature form class (5 years old and over) averaged 455.7 lbs.

Milk from different breeds (*Connecticut Storrs Sta. Rpt. 1907, pp. 152–156*).—Analyses are reported of the milk of 23 cows, representing 4 different breeds, for the first 10 months of lactation.

Cattle of the Oldenburger Wesermarsch, P. Cornelius (*Das Oldenburger Wesermarschrind. Hannover, 1908, pp. VIII+140, pls. 7, figs. 56, maps 2*).—An account of the development of the cattle industry in this region. Special attention is devoted to dairy cattle and the dairy industry.

Studies of the dairy industry in France, England, Belgium, Denmark, Sweden, and Holland, A. Reitz (*Milchwirtschaftliche Studien über Frankreich, England, Belgien, Dänemark, Schweden, Holland. Stuttgart, 1907, pp. 228, pls. 7, figs. 48*).—The basis of this information was statistics and travels of the author.

Establishment and management of the dairy farm, G. K. Kelkar (*Dept. Agr. Bombay Bul. 31, pp. 12*).—A bulletin of general information on the cost of equipping and methods of managing an Indian dairy farm. Tables show the rations fed and the cost of feeding buffaloes and the dairy breeds of India.

Dairying in the Argentine, L. T. MacInnes (*Agr. Gaz. N. S. Wales, 19 (1908), No. 8, pp. 673–677; N. Y. Produce Rev. and Amer. Cream., 1908, Oct. 7, p. 902*).—Dairying is an adjunct to stock raising and by the large owner is done on the share system. Modern methods are of recent growth. Skim milk is manufactured into casein and exported to England to be made into knife handles, buttons, and other products. An increase in Argentine dairy exports is not expected until present methods are changed.

Report of Alnarp Agricultural and Dairy Institute and of Alnarp Agricultural School and Farm, 1907 (*Berättelse om Verksamheten vid Alnarps Landtbruks och Mejeriinstitut samt Alnarps Landtbruksskola och Egendom år 1907. Malmö, 1908, pp. 49+XVIII, fig. 1*).—A report of the operations of this institution during 1907.

Handling and marketing of milk and cream, J. Michels (*North Carolina Sta. Bul. 198, pp. 4–24, figs. 13*).—This bulletin treats of cream shipping cans, sterilizers, ice boxes, and other appliances used in handling and marketing milk and cream, together with plans for dairy houses and some general information on producing sanitary milk and cream.

In comparing different types of cream shipping cans the results obtained show that so far as maintaining temperature was concerned there was practically no difference in the 20 gal. insulated metallic, the 20 gal. insulated wood jacketed, and the 10 gal. felt jacketed can. Where low temperatures are to be maintained for 9 or more hours during warm weather the ordinary 10 gal. can placed inside of a covered ice-cream shipping tub that allows ice to be packed around the can, including the neck, is deemed the most satisfactory. The ice should be left coarse, and the amount needed will vary with the outside temperature and length of time in transit. The wooden tub without ice has practically the same insulating effect as the felt jacketed.

The bulk of the milk in the State is sold to consumers without any cooling whatever. To show what cooling will do, tables are given showing the acidity of milk at different ages. When milk was kept at a temperature ranging between 42 and 45° F. there was only a slight development of acidity. The morning milk kept at these temperatures showed an average increase of acidity of only 0.05 per cent during 24 hours.

A cheap and effective ice box is described. The author has also devised an effective sterilizer for cleansing vessels and appliances used in handling milk that costs only one-third as much as those commonly used. An improved cooling arrangement is described, wherein the ice water from the cooler is pumped

back into the ice water storage, thereby resulting in a saving of water, ice, and time. It took 35 lbs. of ice 41 minutes to cool 42 gal. of milk to 45° F. when the pump was used, as compared with 89 lbs. of ice and 88 minutes without the pump.

The preservation of milk, L. Eberlein (*Pure Products, 4 (1908), Nos. 9, pp. 390–394; 10, pp. 442–446*).—A discussion of the bacterial content of milk under different conditions, with tables showing the number of bacteria per cubic centimeter. By strict attention to cleanliness a milk containing few germs may be obtained. Various methods of handling milk are described, together with methods of preserving milk by chemical means, including the Budde method of using hydrogen peroxid.

On the changes occurring in milk on heating, O. Jensen (*Malkeritid., 21 (1908), No. 19, pp. 365–368; Norsk Landmandsblad, 27 (1908), No. 28, pp. 337–339*).—A discussion of results previously noted (E. S. R., 17, p. 289).

Investigations on milk serum, F. Landolf (*Biochem. Ztschr., 10 (1908), No. 4–6 pp. 486–489*).—From the results obtained in investigations in continuation of earlier work (E. S. R., 19, p. 175) the author is convinced that lactose exists in milk not in three or four different modifications, the so-called α, β, γ, and δ forms, as given by other authors, but rather as carbohydrates united in various ways, which can be separated quite easily by fractional precipitation and subsequent fractional crystallization.

"Cieddu," F. Samarani (*Ann. R. Staz. Sper. Caseif. Lodi, 1907, pp. 95–98*).—Bacteriological examination of fresh "Cieddu" (Sardinian fermented milk) showed the presence of only two forms of micro-organisms, one a variety of *Bacterium lactis acidi* and the other a variety of *Bacillus casei* of Freudenreich.

Investigations on the tubercle bacillus content of milk and milk products sold in Leipzig, A. Eber (*Ztschr. Fleisch u. Milchhyg., 18 (1908), No. 10, pp. 309–319*).—In these investigations 19 out of 70 milk establishments supplied milk containing tubercle bacilli. Out of 210 samples of milk 22, or 15 per cent, contained these organisms, of 150 samples of butter 12 per cent, of 50 samples of cream 6 per cent, and of 50 samples of curds 4 per cent. No tubercle bacilli were found in 150 samples of margarin tested.

New cream bottle for Babcock test, J. W. Mitchell (*Ann. Rpts. Dairymen's Assocs. Ontario, 1907, p. 183*).—The author has devised a new style of bottle, which has a small neck graduated to read the percentage of fat for 9 gm. instead of 18 gm. of sample. This allows more room for readily mixing the contents.

Theoretical interpretation of the law of Crismer regarding the acidity of butter, G. Gesaro (*Bul. Soc. Chim. Belg., 22 (1908), No. 6, pp. 221–223*).—A mathematical demonstration of Crismer's statement that adding to the critical temperature of butter the number of cubic centimeters of twentieth-normal potassium hydroxid necessary to neutralize 2 cc. of the melted butter gives very approximately the critical temperature of the butter after neutralization.

Renovated butter, Loock (*Ztschr. Öffentl. Chem., 14 (1908), No. 10, pp. 195–198*).—Determinations of some of the usual constants are reported for spoiled butter before and after renovation. The renovating process consisted in removing the casein, salt, and water by melting, neutralizing the acidity by acid, filtering the fat, and freeing it from objectionable flavor by treatment with steam by a special apparatus. The fat thus obtained is put on the market in this condition, or after churning with milk and working, or mixed with good butter.

Report of the Finnish butter exhibits, 1906, G. A. Bredenberg and L. Sandberg (*Landtbr. Styr. Meddel., 1907, No. 57, pp. 39*).—From 222 creameries

taking part in the exhibits during the year, a total of 1,065 tubs were scored. These contained on the average 13.82 per cent water (ranging from 10.30 to 19.53 per cent), with an average refractive index of 51.2 (ranging from 49 to 54.2) that of the volatile acids ranging from 20.85 to 32.90. The former figure for volatile acids was obtained with butter from the herd milk of a well-known Finnish dairy farm, the output of which was doubtless unadulterated.

Report of the Swedish butter exhibits, 1907 (*Meddel. K. Landtbr. Styr. [Sweden], 1908, No. 4 (133), pp. 48*).—From 516 creameries participating in the exhibits during the year, a total of 2,074 tubs were scored. Chemical analyses showed that the average moisture content of the butter was 13.8 per cent (ranging from 10.3 to 18.5 per cent), and the refractive index 51.16 (ranging from 49 to 53.9). A paper giving directions for regulating the moisture content of butter, by L. F. Rosengren, is included in the report.

Report of the cheese experiment station at Lodi, C. Besana (*Ann. R. Staz. Sper. Casecif. Lodi, 1907, pp. 15–64*).—In addition to the account of the work of the station during the year and some reports of investigations, this publication includes an article on the Third International Dairy Congress at The Hague in September, 1907.

Chemical study of the ripening of soft cheese, R. Sanfelici (*Ann. R. Staz. Sper. Casecif. Lodi, 1907, pp. 65–94*).—The experimental data reported include determinations of the chemical composition and distribution of the nitrogenous substances and acidity in 5 samples of Quartirola and 4 samples of Crescenza cheese.

From the data reported the author concludes that in Crescenza cheese ripened at a low temperature (5 to 10° C.) the solubility of the casein is greater than in Quartirola cheese ripened at a somewhat higher temperature (15 to 20° C.). In these two types of soft cheeses the solubility of the casein and consequently the ripening is due to unorganized ferments or enzyms and very probably to the galactase of the milk and the pepsin of rennet. In Crescenza cheese the production of peptones is greater than in Quartirola cheese. The fat in these types of soft cheese does not undergo any appreciable alteration and does not participate in the ripening.

On paraffining of cheese and convenient appliances for same, L. F. Rosengren (*Nord. Mejeri Tidn., 23 (1908), No. 24, pp. 280–282, figs. 3*).—The paper deals with the advantages of paraffining cheese and describes apparatus for the purpose.

VETERINARY MEDICINE.

Annual report of the veterinary department, 1906–7, R. J. Stordy (*Colon. Rpts., Misc. [Gt. Brit.], No. 49, pp. 1–21, pls. 2, figs. 2*).—The veterinary staff of the East Africa Protectorate has been considerably enlarged, with the result that a great improvement has been observed in the work of controlling dangerous diseases. Statements are given of the present condition of African coast fever, pleuro-pneumonia, gangrenous ergotism, glanders, trypanosomiasis, intestinal parasites of horses, sheep scab, various parasitic worms in sheep, pleuro-pneumonia in goats, and diseases of dogs. *Buphaga erythrorhyncha*, locally known as the tick bird, is said to be of some benefit in feeding upon cattle ticks but has become a nuisance on account of its habit of attacking skin wounds of cattle.

Piroplasmosis, trypanosomiasis, and rinderpest, E. Meuleman (*Piroplasmoses, Trypanosomiases, et Peste Bovine. Brussels, 1907, pp. 176, pls. 4, map 1*).—An elaborate account is presented of the distribution, symptoms, etiology, pathological lesions, and means of preventing Texas fever, African coast fever,

nagana, surra, galziekte, trypanosomiasis of goats, and rinderpest. A bibliography relating to these diseases is appended to the volume.

Complication of rinderpest with piroplasmosis, J. KOWALEWSKY (*Jour. Méd. Vét. et Zootech., 59 (1908), Mar., pp. 146–150*).—The author describes the symptoms and pathological lesions produced in cattle simultaneously infected with rinderpest and piroplasmosis. A number of other instances are known in which two diseases may affect the same animal simultaneously.

Alterations in the blood of animals affected with experimental trypanosomiases, V. L. YAKIMOFF (*Arch. Sci. Biol. [St. Petersb.], 13 (1908), No. 3, pp. 243–276, pls. 2*).—The experiments reported by the author were made on various laboratory animals with cultures of the trypanosomes of nagana and mal de caderas.

With regard to the effect of experimental inoculation of trypanosomes upon the blood, three periods may be differentiated. In the first period there is an increase in the total number of leucocytes, particularly the polynuclear cells, and a decrease in the number of lymphocytes. In the second period the trypanosomes appear in the blood and simultaneously there is a decrease in the total number of leucocytes and an increase in the number of lymphocytes. The third period which in fatal cases occurs shortly before death is characterized by an increase in the number of polynuclear leucocytes and irregular variations in the relative proportions of the different forms of leucocytes.

A bibliography is appended.

The biology of the pathogenic organism of hemorrhagic septicemia, R. OSTERTAG (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 4 (1908), No. 1–2, pp. 1–4*).—The purpose of the study reported in this paper was to determine the importance of certain practical methods for controlling hemorrhagic septicemia. It appears that the organism of this disease is quite readily destroyed by desiccation, even in pure cultures being killed by desiccation for 7 days under the influence of diffuse sunlight. Experiments also indicated that under ordinary treatment the bacillus becomes completely nonvirulent on the skins of animals affected with the disease. On the other hand, the bacillus shows high resisting power toward decomposition, retaining its virulence for 100 days or more in decomposing blood and meat.

Lecithinophilous property of the tubercle bacillus and tuberculin, A. CALMETTE, L. MASSOL, and M. BRETON (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 13, pp. 676–679*).—In a series of experiments carried on by the authors it was found that serums which contain lecithin revealed its presence by their power of rendering cobra poison more active in disintegrating washed red blood corpuscles. In fact this method may be used for estimating quite closely the quantity of lecithin in sera, merely measuring the quantity of the serum which is capable of rendering active a certain weight of the cobra poison. It was found that the blood sera of tuberculous animals and man contain a considerable amount of lecithin while normal serum shows none of this substance.

The etiology of tuberculosis, M. P. RAVENEL (*Berlin. Klin. Wchnschr., 45 (1908), No. 16, pp. 788–793*).—A brief review is given of the literature on tuberculosis, particularly that relating to the point of origin of tuberculous infection. The feeding experiments and observations of the author along this line are summarized.

The conclusion is reached that the tubercle bacillus frequently gains entrance to the body through the alimentary canal and that such infection may take place without leaving any trace of lesion at the point of entrance, especially during the digestion of fats. After passing through the intestinal wall the tubercle bacilli are carried with the chyle through the lymph vessels and thoracic duct into the blood, subsequently reaching the lungs or other organs.

It is held that tuberculosis is frequently of alimentary origin in children as a result of drinking tuberculous milk or consuming other tuberculous products.

Cutaneous and conjunctival tuberculin reaction in cattle, REINECKE (*Berlin. Tierärzil. Wchnschr., 1908, No. 18, pp. 313–318, fig. 1*).—Of 25 cattle which were subjected to the cutaneous application of tuberculin only one showed a slight reaction. This animal had been inoculated with tubercle bacilli of human origin, but upon slaughter was found to be free from tuberculosis. Of the other 24, 6 reacted to subcutaneous reaction of tuberculin and 2 were found to be tuberculous upon post-mortem examination. Of 5 cattle which were tested with tuberculin upon the conjunctiva, 3 showed a slight reddening of the conjunctival mucosa and 2 of these proved to be tuberculous. The author concludes as a result of his investigations that neither a cutaneous nor conjunctival tuberculin test has a value equal to that of the subcutaneous method.

Report on tuberculosis of domesticated animals (*Bul. Serv. Pol. Sanit. Anim. Dom., 1906, No. 25 B, pp. 297–317*).—Extensive statistical data are given regarding the results of tuberculin tests on cattle for the purpose of showing the frequency and distribution of tuberculosis in Belgium. With regard to the control of tuberculosis, good results have been obtained in all instances from the use of the Bang method. The application of vaccination by von Behring's method showed that a high degree of resistance against tuberculosis may be produced with a duration of about 1 year.

The Dresden method of protective vaccination of cattle against tuberculosis, M. KLIMMER (*Berlin Tierärztl. Wchnschr., 1908, No. 14, pp. 241–243*).—It has been demonstrated that cattle may be immunized against tuberculosis by the use of tubercle bacilli from various sources. The immunity thus produced, however, does not last more than about a year. On this account it is necessary to repeat the inoculation from year to year in order to keep cattle protected against the disease. Such a process is out of the question in the case of dairy cows, for the reason that the milk might contain tubercle bacilli as a result of inoculation with attenuated bacilli. The author, therefore, tested the value of nonvirulent bacilli especially for use in the case of dairy cows. Satisfactory results were obtained and it is recommended that a hypodermic injection of 5 cc. of nonvirulent tubercle bacilli be made hypodermically, that the injection be repeated after 3 months and thereafter at yearly intervals.

Abortion, C. L. BEACH (*Connecticut Storrs Sta. Rpt. 1907, pp. 139–141*).—This disease was introduced into the college herd through the purchase of 6 pregnant animals. During the 3 years following 24 of the 79 calvings were premature. These premature births occurred from 145 to 262 days from time of conception, the average for the 24 cases being 211 days.

The sire was not the sole means of spreading the disease as the 24 conceptions that terminated in premature births were the result of matings with 15 different sires, 8 of which were owned by parties remote from the affected herd.

As it is frequently stated that an aborting cow is usually of little use in the dairy, milk and fat yields following a normal calving were compared with yields between normal calvings, in which the period of abortion was included. The milk yields were found to be 12 per cent less per year during the aborting period. The satisfactory yields are attributed in part to the complete removal of the afterbirth and the thorough disinfection of the animal after abortion, an account of which is given.

Only one of the 24 animals that experienced a premature birth failed to breed after abortion, and this animal at post-mortem examination showed the presence of an ovarian tumor which may originally have been caused by the treatment administered to induce conception.

Twenty-three of these cows produced a normal calf an average of 461 days subsequent to abortion, conception taking place practically 6 months after aborting. Experience indicates that it is useless to attempt to breed a cow for 4 or 5 months subsequent to aborting. To the yeast treatment is attributed in part the success in inducing conception following premature delivery.

The diagnosis of chronic forms of mammitis in cows by means of the method of Trommsdorff. H. MARTEL (*Hyg. Viande et Lait, 2 (1908), No. 4, pp. 161–165*).—A test of the Trommsdorff method for the identification of leucocytes indicated that this method can not be relied on exclusively in the diagnosis of mammitis without a veterinary examination of the suspected cows.

Aphthous pseudostomatitis of cows. LIÉNAUX (*Ann. Méd. Vét., 57 (1908), No. 4, pp. 185–193*).—Various investigators have studied the symptoms and pathology and attempted to determine the etiology of stomatitis in cattle with symptoms resembling foot-and-mouth disease. It is believed that the majority of cases of stomatitis of this form are due to a fungus or bacterial cause which produces an infection more readily after the mucous membrane has become injured or irritated by drugs or from other causes.

Texas fever. L. L. LEWIS (*Oklahoma Sta. Bul. 81, pp. 3–32, figs. 19*).—This bulletin includes a general discussion of Texas fever in which particular attention is paid to the life history, habits, and methods of eradication of the cattle tick. The author considers $750,000 to $1,000,000 to be at the present time a low estimate of the annual loss in Oklahoma due to this tick. In addition to *Margaropus annulatus*, the castor-bean tick, the net tick, the dog or wood tick, the lone-star tick, and the ear tick (*Ornithodoros megnini*) are described as parasites of cattle in Oklahoma.

While cattle may become immune to a certain degree of virulence of Texas fever infection, it is stated to be a common experience in many portions of Oklahoma for them to contract the disease when ticks from cattle shipped from farther south attach to them. In this way a great many cattle are lost every summer on account of the more virulent form of infection brought into the pastures and ranges. The methods of eradicating the cattle tick are described and plans are given for the construction of a dipping vat.

Poisonous symptoms after feeding peanut meal (*Illus. Landw. Ztg., 28 (1908), No. 29, pp. 259, 260*).—A few cases of poisoning have been noted from the effects of feeding peanut meals which have been adulterated or have become contaminated with molds or other injurious materials. The symptoms in one case included diarrhea, loss of appetite, diminution of milk yield, and fever. The peanut meal which caused these effects in cows was found to contain a small quantity of castor-oil beans.

The bacillus of Preisz-Nocard in ovine pathology. H. CARRÉ and L. BIGOTEAU (*Rev. Gén. Méd. Vét., 11 (1908), Nos. 127, pp. 369–380; 128, pp. 433–449*).—The bacillus of Preisz-Nocard has been studied by a number of investigators with particular reference to the details in the pathological lesions which it produces and the criteria for arriving at a differential diagnosis. As a rule, an infection with this organism may be distinguished from anthrax by the fact that in the former case the organism is not found in the blood.

Gangrenous mammitis in sheep. W. PFEILER (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 4 (1908), No. 1–2, pp. 132–136*).—A micrococcus was isolated from the udder of a sheep affected with gangrenous inflammation. This organism was grown on a number of nutrient media and inoculation experiments were tried to determine its pathogenic properties and the modes of infection. The organism readily produced infection when injected directly into the udder or through the milk canal. The mere presence of the bacillus upon the exterior of the udder appears seldom to produce an infection. There is, therefore, little

danger of transmitting the disease in milking sheep where these animals are kept for milk. The disease can not be cured by external treatment, as it is necessary to remove the affected part of the udder.

Certain eye diseases among horses. V. Ohlholm (*Maanedskr. Dyrlæger, 19 (1908), No. 12, pp. 449–466*).—Notes are given on the pathology, distribution, occurrence, and treatment of periodic ophthalmia, simple iritis, and *Filaria papillosa* in the eye.

Immunization against glanders. A. Marxer (*Berlin. Tierärztl. Wchnschr., 1908, No. 13, pp. 229–231*).—Experiments were made in attenuating cultures of glanders bacilli in solutions of glycerin and urea. It was found that the attenuation was directly proportional to the temperature and inversely proportional to the density of the emulsion. No satisfactory results were obtained from the use of attenuated bacilli. By killing the glanders bacilli in a 10 per cent solution of urea a more satisfactory preparation was obtained. For this purpose 0.1 gm. of the bacilli was placed in 4 cc. of the urea solution for 17 hours. A dry extract was obtained from this material and used for immunizing purposes. Similar results were obtained with the use of glycerin in the place of urea.

Experiments were first carried on with laboratory animals and later with horses. It was found possible to produce an immunity in horses for a period of at least 1 year by a single injection with a preparation of dead glanders bacilli.

Loco weed poisoning in horses. A. T. Peters and L. B. Sturdevant (*Nebraska Sta. Rpt. 1907, pp. 74–107, figs. 4*).—As a result of experiments conducted, the authors conclude that "hunger will lead many horses to eat loco weed when the grass is short, especially in the early spring or in the late fall, or even in wet seasons when the grass is not short, probably because the weed is then more succulent. A small grain ration when the grass is short will usually be sufficient to keep the animals from forming the loco-eating habit. After a horse has eaten loco for a time, this habit becomes permanent in most cases."

The loco-eating habit was permanently formed in 1 horse after 118 lbs. of picked *Astragalus mollissimus* had been eaten and probably long before this. "This animal lived 62 days after the picked loco was first fed and consumed a total of 322 lbs. of this besides that eaten in pasture and on the prairie. Six lbs. of picked *Aragallus lamberti* fed in 1 day to a second horse was not sufficient to induce the loco habit, but after 21½ lbs. of picked *A. lamberti* and 10½ lbs. of *A. mollissimus* had been eaten the habit was permanently induced. This animal died 25 days after the first of this weed had been fed. The loco-eating habit was permanently induced in another horse by 5 lbs of *A. mollissimus* fed on each of 2 successive days. The total amount of picked loco eaten by this animal was 221½ lbs., and death occurred 50 days after the first of this was fed. Post-mortem examinations indicated that the greatest change was induced in the nervous system, which showed much congestion throughout.

A protozoan observed in cases of epizootic lymphangitis in mules. E. Ducloux (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 13, pp. 593–595*).—The author had opportunity to examine the pathological lesions in mules affected with epizootic lymphangitis, particularly in the fore legs. The purulent material obtained from swellings contained leucocytes which were infected with a protozoan parasite. In some cases a single polynuclear leucocyte contained as many as 32 of the parasitic protozoa. These parasites were observed in various stages of development undergoing division and changes of form. The author proposes the name *Leucocytozoon piroplasmoides* for the parasite.

Inspection of pork in cases of diamond-skin disease for virulent bacilli of swine erysipelas. A. Schuh (*Deut. Tierärztl. Wchnschr., 16 (1908), Nos. 16, pp. 229–236; 17, pp. 245–248*).—Samples were taken from the musculature and various organs of 23 hogs affected with swine erysipelas. Microscopic examination was made of this material and inoculation tests were carried on to determine the presence and virulence of the bacilli of swine erysipelas.

It was found that in hogs in which a fresh infection of the disease prevailed and in which numerous small diamond-shaped areas had appeared but had not yet become reddened the bacilli of swine erysipelas were present in the organs as shown by the inoculation of minute particles of tissue in white mice. In more advanced cases showing numerous red patches on the skin the bacilli were demonstrated both in cultures and from the inoculation of mice. Similar material taken from cases of the disease in later stages showed that the bacilli are sometimes present and sometimes absent from the organs. By taking a number of samples of tissue, however, it was found that in every case of swine erysipelas to be recognized clinically, virulent bacilli were present, as demonstrated by inoculation of white or gray mice. The bacilli could not be demonstrated in the organs of hogs on which the spots did not appear during life, but only after scalding.

On a spirochete occurring in the blood of chickens in northern India. R. E. Montgomery (*Jour. Trop. Vet. Sci., 3 (1908), No. 1, pp. 1–2, pls. 2, fig. 1*).—The author has observed the unusual prevalence of *Argas persicus* in various parts of India. In an outbreak of the disease among chickens spirochetes were found in the blood in large numbers both before and after death. By experimental tests it was found that the spirochetes could be transferred from one animal to another through the agency of *A. persicus*. The period of incubation varies from 1 to 4 days. The morphology of *Spirochæta gallinarum* is described in detail. In the author's opinion the possibility is not excluded that the human spirochete of India may be inoculable into chickens or vice versa.

Streptococcic diseases of fowls. L. Greve (*Deut. Tierärztl. Wchnschr., 16 (1908), No. 15, pp. 213–215*).—Occasion was had to examine fowls affected with a kind of sleeping sickness due to streptococci. The micro-organisms were found in large numbers in the blood. By means of inoculation experiments it was shown that the disease may be transmitted to pigeons and mice. Apparently the disease is not rapidly transmitted by mere contact with affected fowls.

Infectious leukemia in ducks. C. J. Pound (*Queensland Agr. Jour., 20 (1908), No. 3, pp. 136–138*).—An outbreak of infectious leukemia occurred in ducks causing a mortality of 60 per cent or more. The disease runs a course of 7 to 14 days and the incubation period ranges from 3 to 5 days. The micro-organism found in cases of this disease is described and notes are given on its behavior in various culture media. No remedial treatment seems to be of avail and the author, therefore, recommends the isolation of diseased birds and thorough disinfection.

A plague affecting canary birds. W. Zwick (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 4 (1908), No. 1–2, pp. 33–49, pl. 1, figs. 5*).—According to the available literature on this subject there appear to be five distinct infectious diseases which affect canary birds. The author had occasion to study a serious outbreak of an infectious disease among these birds. The feathers appeared ruffled, the appetite was soon lost, the head was held for the most part under the wing or in the feathers, and in most cases death took place within from 24 to 36 hours. An organism was isolated from affected birds and its behavior was studied on various culture media. The bacillus in question appears not to form a filterable toxin. Pigeons and chickens are not susceptible to the

bacillus but infection may be produced in guinea pigs, sparrows, and other experimental animals.

Local eosinophilia in cases of infections with animal parasites, A. F. Fölger (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 4 (1908), No. 1–2, pp. 102–131, pls. 2*).—Much attention has been given to the variations in the number and relative proportions of leucocytes during the prevalence of infections and parasitic diseases. An increase in the number of eosinophilous leucocytes is generally recognized as an important indication of pathological conditions.

The observations reported by the author were largely made on tissues from animals infested with Sarcosporidia, fluke worms, and cysticerci. Sarcosporidia in the musculature of various animals as a rule caused no general disturbance, the pathological changes being purely local. No alteration in the proportion of eosinophilous cells was observed in such cases. In the liver of cattle and sheep affected with fluke worms, the eosinophilous cells were present in greatly increased numbers. An increase in the number of these cells was also observed in the liver of hogs infested with *Cysticercus tenuicollis*.

Notes on some parasites in Burma, G. H. Evans and T. Rennie (*Jour. Trop. Vet. Sci., 3 (1908), No. 1, pp. 13–27, pls. 10*).—Elaborate anatomical and descriptive notes are given on apparently new species of Gastrodiscus found in cattle and horses, the pancreatic fluke in cattle, and an unknown species of Gastrothylax.

RURAL ENGINEERING.

Installation of an experimental drainage system, W. Robertson and J. T. Stewart (*Minnesota Sta. Bul. 110, pp. 3–99, figs. 62, map 1*).—This bulletin describes the installation of a complete system of open and tile drains on the Northwest Experiment Farm at Crookston, by the University of Minnesota, under the supervision of a drainage engineer connected with this Office, who made the surveys and plans. The investigation made for planning the system included a topographical survey, study of the rainfall conditions, soil examination and analysis, and soil water analysis. The problem was not only to remove the rainfall from the farm but to prevent overflow from higher lands. Underdrainage in the soil found here was considered an experiment and on this account the depth and distance apart of the drains were varied, as well as the kind of tile and the method of laying it.

The construction of open ditches by slip scrapers is illustrated and discussed with the figures of cost. Tile ditches were constructed by hand and by machine, and the cost and methods of each are shown and compared. The operation and construction of the traction ditcher which was used, and the difficulties encountered with it, are described in detail. The soil, a fine clay, was quite wet, and operating delays were frequent, due to slipping wheels, cups clogging, wet earth on the rollers, and grass roots collecting on the knives, as well as breakage. The soil finally had to be broken with a plow before the machine was used, and the work frequently had to be supplemented by hand digging. The machine used was a second-hand one, having been used for demonstration purposes at the factory, and it is believed that many of the difficulties encountered would be overcome by the modern improvements in the more recent machines. The best condition for machine work is deemed to be in dry ground which is in cultivation.

Stress is laid upon the methods of protecting the outlets in tile drains. Outlets were constructed of wood box, sewer pipe, tile inclosed in cement, concrete abutment, and metal pipe, and the total cost of each of these is shown, as well as the method of construction. A tile record contains in tabular form complete

details of the tile system, including the cost of each necessary item for different sizes and depths of tile. The cost of the tile and of hauling and distributing are also noted.

A brief account of house and yard drainage installed is given. There is also a short account of the manufacture of cement tile, both on the farm and in the factory. The experience with that made on the farm indicated that it is not economical to manufacture small-sized pipe.

A portion of the bulletin is devoted to reports on excavating machinery used in the Red River Valley. Two land machines, a ditcher and a walking dredge, are described, the former being reported to be specially suited to land which is stable enough to support its track and which is comparatively free from timber or rock. An elevating grader, used on the farm, is also described.

Irrigation and drainage, C. F. Brown (*Deseret Farmer, 5 (1908), No. 12, pp. 5, 12, 13, fig. 1*).—This is a popular article dealing with the drainage of seeped lands in irrigated regions, and briefly outlines the general principles to be observed in reclaiming this class of land. It describes the procedure necessary to prepare suitable plans for drainage and the practical considerations necessary to maintain the drains in proper order. It is remarked that it is not sufficient merely to intercept the seeped water but that an outlet must also be made on the lower land. The article includes a description of the investigation and plans made for reclaiming a tract of 50 acres of seeped land in the Bear River Valley, Utah.

Geometrical measuring plate (*Illus. Landw. Ztg., 28 (1908), No. 81, p. 704, figs. 5*).—This article describes a simple measuring device suitable for farm surveying and for obtaining differences in elevation. It consists of a plate graduated in degrees like a protractor, and two standards by which a line of sight is established. It is used for surveying by triangulating from a measured base line, and in place of a level by reading horizontal angles. To do this the plate can be set in a vertical plane and a vertical line constructed with the aid of a plumb-bob.

Tests of gasoline-operated farm motors (*Canad. Thresherman and Farmer, 11 (1908), No. 8, pp. 5–6, 70, figs. 20; Nor'-West Farmer, 27 (1908), No. 14, pp. 677, 678, figs. 5*).—There are described here the various machines entered in the agricultural motor contest held in July at Winnipeg, Canada, the first ever held in America, with the conditions prescribed for the competitors and the methods used in judging the winners.

Plowing by the direct system with motor power, V. Thallmayer (*Landw. Masch. u. Geräte, 8 (1908), No. 22, pp. 1, 2, figs. 3*).—A brief discussion of the general principles of motor cultivation, with the following results of tests made in Winnipeg, Canada, at the contest noted above:

Tests of gasoline-operated motors.

Rating of motor.	Weight.	Number of plowshares.	Width of furrow.	Velocity per second.	Results per acre.	
					Time required.	Consumption of gasoline.
H. P.	*Lbs.*		*Ft.*	*Ft.*	*h. m.*	*Gals.*
15	9,880	3	3.51	3.28	1 6	3.91
40	12,900	5	5.81	2.96	0 42	4.25
30	13,500	6	6.98	2.79	0 37	4.41

Beet diggers, G. FISCHER (*Masch. Ztg., 6 (1908), No. 20, pp. 229–232, figs. 6*).—This article deals with the difficulties met with in the construction of satisfactory beet diggers, resulting in their prohibitive cost, and the progress made recently in their manufacture. Several types are illustrated and their mode of operating described, with remarks on their relative efficiency.

Farm implements in Germany, R. R. DENNIS (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3253, pp. 1–4*).—This is an account of the domestic and foreign agricultural machinery on exhibition at the German Agricultural Society show held at Cannstatt-Stuttgart in 1908. The reasons why American, English, and other foreign-made agricultural machinery is so little used in Germany are also discussed, with suggestions to American manufacturers regarding the increase of trade in agricultural implements and machinery.

Strength test of harness leather, G. R. CHATBURN (*Nebraska Sta. Rpt. 1907, p. 73, fig. 1*).—In two breaking tests, made on new 1¾-in. farm harness tugs with attached hame tugs, the leather failed by tearing through the buckle hole. The results gave values of 1,000 and 1,050 lbs., respectively, for the beginning of failure, and 1,400 and 1,570 lbs. for the breaking load, from which it is calculated that on earth roads in fairly good condition the tug is capable of hauling practically 6 tons.

Lighting country homes by private electric plants, T. H. AMRINE (*Illinois Sta. Circ. 121, pp. 35, figs. 11; Univ. Ill. Engin. Expt. Sta. Bul. 25, pp. 35*).—This bulletin discusses the features essential to the success of installing and maintaining at a reasonable cost a satisfactory electric light plant for country homes, and presents the design of such a plant in sufficient detail so that it is believed it will enable anyone to decide on the size and equipment necessary to install a similar plant.

Such plants are now considered practicable by the introduction of the tungsten filament lamp, which, because of its high efficiency, reduces the necessary size of storage battery. Proper attention to the selection of fixtures and planning of the lighting arrangement contributes largely to the economy of the system. Shades should be selected with reference to their ability to diffuse the light or throw it in a given direction as may be required. The placing of fixtures is also important and should be governed by their usefulness rather than appearance in the room. These points are illustrated by an example of a lighting scheme for a medium-sized private residence. A glossary of technical terms is appended.

RURAL ECONOMICS.

The State and the farmer, L. H. BAILEY (*New York and London, 1908, pp. XII+177*).—The author discusses what it is wise and legitimate for governments to do in aid of the farmer and how, in general, it may be accomplished. The present-day needs of rural communities are believed to be greater technical knowledge of agriculture, governmental protection, the development of the cooperative spirit, the establishment of common centers of interest in rural districts, and development of individual initiative. For the improvement of these needs State and Federal governments should cooperate not for the sake of the individual farmer but because of its bearing on National welfare.

Agricultural legislation, H. L. RUDLOFF (*Fühling's Landw. Ztg., 57 (1908), Nos. 14, pp. 497–502; 15, pp. 535–542*).—A summary of the titles of different laws relating to agriculture are presented and discussed in this article. The legislation considered begins with the decree of September 28, 1791, in France and is brought down to 1905. The agricultural legislation of Belgium, Argentina, Hungary, and the two cantons of Aargau and Neuchâtel in Switzerland are likewise summarized and discussed.

Farm leasing system in New York State (*Breeder's Gaz., 54 (1908), No. 7, pp. 255, 256*).—This is a description and discussion of the system of leasing and farm management practiced on the 30,000-acre Wadsworth estate in the Genesee Valley. One of the most unusual features of the lease is that the tenant pays all taxes. This gives the tenant a personal interest in the farm and places upon him the duties of citizenship. The tenant is thus compelled to participate in the activities which the State, county, and district require of citizens.

The system of farm management practiced, which is under the personal direction of the owner, aims to maintain as well as to improve the fertility of the soil. The system has been in operation for a century. It is said to secure permanence of tenantry, to keep the land in good condition, and to work for the economic advantage of both tenant and landlord.

The subdivision of farms in France, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 16 (1908), No. 27, pp. 9, 10*).—This article calls attention to the system of farm holdings which prevails throughout France. It appears that the farms consist of numerous small, noncontiguous parcels of land. As an extreme illustration of French farm-holding conditions, a single proprietorship in the Department of Haute-Saône of 30 hectares (about 74 acres) was composed of 130 separated plats. It is estimated that the farm lands of France consist of more than 125,000,000 plats, "the average of each farm holding being 10 plats. In some eastern provinces a farm sometimes consists of 100 plats."

The author calls attention to the enormous economic waste arising from such conditions, the inability of farmers to use machinery to advantage, the loss of time in passing from one plat to the other, etc., and believes the present farm system is a problem requiring an immediate practical remedy.

The exchange and reassignment of land, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 16 (1908), No. 28, pp. 37, 38*).—The author calls attention to the economic waste arising from the present system of working the 125,000,000 small strips of land into which the farms of France are subdivided, and advocates the reassignment of farm lands directly by the government or the voluntary exchange of separate small parcels by neighboring farmers under government supervision. The latter is regarded as the better plan. The economic advantages of repartition are illustrated from results accomplished in Sweden and Germany. The chief articles of the Saxon law bearing on this subject are included.

The fluctuations in value of agricultural land in France since 1851, R. SAULNIER (*Écon. Franç., 36 (1908), II, No. 32, pp. 202–205*).—The author gives statistics of land values and discusses the causes of the fluctuations in value which the returns show.

From 1851 to 1879 there was with few exceptions a general rise in agricultural land values in all departments of France, averaging for the whole of France 43.8 per cent, and reaching as high as 141.7 per cent increase in value in the Department of Allier. From 1880 to 1905 there was a general decrease in values, reaching 67 per cent in the Department of Aude and averaging 30.5 per cent decrease for the country at large. Since 1905 the decrease in value has continued in 35 departments, while in the rest of France land values have remained stationary or have only slightly increased. The average agricultural land values were as follows: In 1851, 1,275 francs per hectare; in 1879, the highest period, 1,830 francs; and in 1905, the lowest period, 1,264 francs per hectare. Suggestions for the formation of more stable conditions are presented.

The fluctuations in value of agricultural land in France, D. ZOLLA (*Jour. Débats Polit. et Lit., 120 (1908), No. 261, p. 2; Écon. Franç., 36 (1908), II, No. 39, p. 457*).—From statistics derived from the rent-rolls of eleemosynary institutions in several departments of France, the author shows that from 1876

to 1906, land decreased in value from 20 to 43 per cent according to location. The decrease in general is about 31 per cent, which corresponds closely with the figure reached by Saulnier (see above). The author believes, however, that the price of agricultural products is sure to rise and that this tendency will raise the value of agricultural lands again in the near future.

The farm labor problem (*Wallaces' Farmer, 33 (1908), No. 37, p. 1084*).—In this article attention is called to the scarcity of practical farm help and the impossibility of farmers employing men from cities to advantage in modern farm work. The only remedy open to farmers is believed to be in the use of more machinery and less labor.

The white immigrant as a plantation laborer, W. J. Behan (*La. Planter, 41 (1908), No. 8, pp. 125, 126, figs. 4*).—The author relates the experience of southern planters in dealing with Bulgarian immigrants. Instead of paying them by the day and allowing them to board themselves, in which case they would invariably leave the farms after the grinding season, the plan of paying them $15 per month, afterwards increased to $20, with board and lodging was adopted. This method proved eminently successful in keeping these laborers on the land, and in the author's opinion offers a practical solution of the labor problem on sugar plantations in the South.

Rural mutual association, T. Sarazin (*Semaine Agr. [Paris], 27 (1908), No. 1418, pp. 236, 237*).—The author points out the educational and economic benefits to farmers of the principle of mutual help, and sets forth the objects and methods of the different mutual associations in France and other European countries.

The agricultural cooperative congress at Piacenza, E. Ottavi (*Coltivatore, 54 (1908), No. 40, pp. 422–426*).—A brief account is presented of this congress of national and international agricultural cooperative societies, held at Piacenza on September 23–26, 1908. At that date the societies for the purchase of supplies numbered 1,414 and the rural banks 1,650. The "affittanze collettive," or societies of agricultural laborers, numbered 150, a gain of 42 during the year (E. S. R., 19, p. 587).

Agricultural mutual credit banks in 1907 (*Semaine Agr. [Paris], 27 (1908), No. 1420, p. 251*).—The returns for 1907 show that the district banks numbered 88, the local banks affiliated with the district banks 2,168, with 96,192 adherents, and new loans during the year of 45,376,309 francs. These figures show substantial gains over 1906 (E. S. R., 19, p. 692).

Agricultural credit banks (*Economist, 67 (1908), No. 3390, pp. 306, 307*).—This is a discussion of the development and methods of operation of agricultural credit banks in Ireland, Germany, and France, and of their adaptability to England in connection with the working of the Small Holdings Act (E. S. R., 19, p. 1087).

Agricultural credit societies (*Jour. Bd. Agr. [London], 15 (1908), No. 6, pp. 407–414*).—An article similar in scope to the above.

The new development in agricultural cooperation, H. Plunkett (*Irish Homestead, 15 (1908), Nos. 32, pp. 630–632; 33, pp. 650–652; 34, pp. 670, 671*).—This article sets forth the objects and aims of the centralized organization due to the combination of the Irish, English, and Scotch agricultural organization societies. Two boards were constituted, one for extending organization among farmers and the other for extending cooperative trade in farm products. This new machinery will also be used as opportunity offers for advancing and protecting the interests of the agricultural classes in relation to government. The practicability of these lines of activity is fully discussed.

Credit bank for the encouragement of irrigation works and agriculture (*Bol. Soc. Agr. Mexicana, 32 (1908), No. 34, pp. 661–665; Mod. Mex., 28 (1908),*

No. 35, pp. 6, 7).—The articles of incorporation for the establishment of a new bank under authority of a government concession dated September 3, 1908, are reported.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 10 (1908), No. 11, pp. 81–88*).—The usual statistics on the condition, value, and prices of principal crops in the United States, together with the condition and yields of crops in foreign countries, are tabulated and discussed.

AGRICULTURAL EDUCATION.

Preliminary report of the Committee on Industrial Education in Schools for Rural Communities (*Nat. Ed. Assoc. Advance Print, 1908, pp. 64*).—This is the third report of the committee. It includes a brief historical statement concerning the two previous reports, and detailed reports by D. J. Crosby and O. J. Kern on instruction in agriculture in 4 types of schools, viz: (1) High schools in small villages, as represented by the borough and township high school at Waterford, Pa.; (2) rural high schools with a strong agricultural trend to their curricula, as represented by the Cecil County Agricultural School, Calvert, Md.; (3) consolidated schools, as represented by the John Swaney Consolidated School, near McNabb, Ill.; (4) technical agricultural high schools, as represented by the district agricultural schools in Georgia. The report has been previously noted (E. S. R., 19, p. 1197).

Farmers' Institute Report, J. H. Miller (*Industrialist, Farmers' Inst. Ser., 1 (1908), No. D, pp. 80, figs. 20*).—This report covers the biennial period ended June 30, 1908, and includes not only a report covering the work of this period but also suggestions for improving the farmers' institute work, for young people's contests, demonstration work, cooperation with other organizations, agriculture in the rural schools, improving the rural schools and home surroundings, and women's work in farmers' institutes. There is also included an announcement of winter meetings at the Kansas State Agricultural College, a reprint of the Kansas farmers' institute law, a suggestive constitution and by-laws for farmers' institute organizations, and tabular matter concerning the different phases of work carried on by the superintendent of institutes.

Instruction in practical agriculture at the University farm, Davis, California (*California Sta. Circ. 39, pp. 3–18, figs. 19*).—This circular contains the announcements given in Circular 37 previously noted (E. S. R., 20, p. 192), but is illustrated and includes an announcement of the regular two-year course at the school of agriculture, Davis, to be opened in January, 1909.

Manual of agriculture for the common schools of Illinois, D. O. Barto (*New York and Chicago, 1908, pp. 51*).—The author intends this manual for the use of teachers giving instruction in agriculture to pupils of the seventh and eighth grades. It consists mainly of exercises relating to soils and growing crops and includes indoor and outdoor work. A list of books and bulletins which will be useful to teachers and pupils is appended.

A plan for presentation of the science of agriculture for the use of teachers, H. A. Morgan and J. Main (*[Knoxville, Tenn.], 1908, pp. 16*).—A unique diagram has been devised by the authors to illustrate nature's cycle and the relations of the mineral, plant, and animal kingdoms to each other and to man. This diagram and the cycle which it illustrates are made the basis for the order of teaching the subject of agriculture and for illustrating the relation of different branches of agriculture to each other.

Exercises in elementary quantitative analysis for students of agriculture, A. T. Lincoln and J. H. Walton, Jr. (*New York, 1907, pp. XV+218, figs. 32*).—This book contains introductory exercises in gravimetric analysis, acidimetry

and alkalimetry, permanganate and dichromate titrations, iodimetry, stoichiometry, and a section on agricultural analysis covering the examination of milk, butter, cereals and feeding materials, fertilizers and soils. It is designed primarily as an elementary quantitative guide for the use of agricultural students, but may also be used for work in general elementary quantitative analysis.

Dry-land farming: Drought-resistant crops and a system of soil culture, A. M. Ten Eyck (*Industrialist, Farmers' Inst. Scr., 1 (1908), No. A, pp. 25*).—In this article the author discusses (1) drought-resistant crops, dealing with soil and culture, use of water, amount of water required by crops, moisture in soil after cropping, principal dry-land farming crops, dry-land crops in eastern Colorado, crops for western Kansas, breeding drought-resistant crops, and experiment station problems, and (2) a system of soil culture, including systematic tillage, tillage and fertility, implements and methods, deep plowing, soil mulch, disking after harvest, and harrowing wheat.

Demonstration problems for Farmers' Institute members, and others (*Industrialist, Farmers' Inst. Scr., 1 (1908), No. C, pp. 64*).—This pamphlet contains suggestions for cooperative crop demonstrations by A. M. Ten Eyck, cooperative feeding demonstrations by R. J. Kinzer, demonstrations in the orchard and garden by Albert Dickens, demonstrations with poultry by W. A. Lamb, and demonstrations in dairying by J. C. Kendall.

The poultry industry, D. M. Wilson and W. A. Lamb (*Industrialist, Farmers' Inst. Scr., 1 (1908), No. 3, pp. 151, figs. 27*).—This article written from a market standpoint is intended to help beginners and to bring the poultry industry into more prominence. It includes a discussion of (1) the care and management of ducks, geese, and turkeys, and (2) chickens—breeds and history of American and Asiatic varieties, choosing a breed, care and management, feeding for egg production, preparing eggs for market, determining the layers, poultry houses, incubators and brooders, feeding incubator chicks, fattening chickens for market, profit in poultry, the poultry house as a schoolroom, and the study of poultry by town and village youth. A list of "don'ts," a chicken talk, and an official score card are appended.

Nature-study, F. L. Holtz (*New York, 1908, pp. XIV+546, pl. 1 figs. 171*).—This manual "is designed as an aid and guide to the practical teacher, and as a text-book in methods of nature study for normal and training schools." It consists of 3 parts.

Part I is devoted to a discussion of underlying principles and methods—the motive in nature study, its educational, esthetic and ethical values, studying nature in the grades—how and what, illustrative material, and correlation. "Part II contains appropriate subject-matter of a biological nature, and practical hints and suggestions on the collection and care of material, and the presentation of lessons." Part III consists of a course in nature study for the 8 grades, the requirements of both city and rural schools being considered.

A list of primary information books and nature stories and a general reference list are appended.

Our useful birds, J. S. Hine (*Agr. Col. Ext. Bul. [Ohio State Univ.], 3 (1908), No. 10, pp. 16, figs. 12, dgms. 2*).—This is a study of the economic habits of birds, including a diagram showing the relations of birds and insects on an Ohio farm, and comparative statements of the benefits and injuries of 20 different birds.

The story of corn, Mary C. Breen (*Hampton Leaflets, n. scr., 4 (1908), No. 3, pp. 24, figs 10*).—This study of corn, prepared for the use of teachers, includes 10 experiments in seed germination, field observations, and the use of corn products.

MISCELLANEOUS.

Nineteenth Annual Report of Connecticut Storrs Station, 1907 (*Connecticut Storrs Sta. Rpt. 1907, pp. XXV+179*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1907, reports of the director and heads of departments, reprints of Bulletins 43-48 of the station, tests of 6 cows for advanced registry, and special articles noted elsewhere in this issue.

Twenty-first Annual Report of Maryland Station, 1908 (*Maryland Sta. Rpt. 1908, pp. XXXI+298*).—This contains the organization list, a report by the director on the work and expenditures of the station, a financial statement for the fiscal year ended June 30, 1908, and reprints of Bulletins 119–128 previously noted.

Twenty-first Annual Report of Nebraska Station, 1907 (*Nebraska Sta. Rpt. 1907, pp. XXXIII+107*).—This contains the organization list, a review of the work of the station during the year, a financial statement for the fiscal year ended June 30, 1907, and special articles noted elsewhere in this issue.

Twenty-sixth Annual Report of Ohio Station, 1907 (*Ohio Sta. Bul. 185, pp. XXV*).—This contains an announcement concerning the work of the station, the organization list, a report of the board of control, a financial statement for the fiscal year ended June 30, 1907, and a report of the director summarizing the work of the station during the year.

Summary of experiment station work (*Oklahoma Sta. Circ. Inform. 12, pp. 6*).—A brief statement of the lines of work undertaken by the station since its organization in 1891.

How the experiment station can be of service to the farmers of Virginia (*Virginia Sta. Circ. 2, pp. 20, figs. 9*).—A popular summary of the purpose, equipment, lines of work, and publications of the Virginia Station, together with a brief note on the work of the Virginia Truck Station.

Press bulletins (*Ohio Sta. Bul. 185, pp. 311–318*).—Reprints of press bulletins on the following subjects: Spraying potatoes for late blight advisable in 1906; forestry investigations by the Ohio Agricultural Experiment Station; fertilizers for wheat in southeastern Ohio; late blight or rot of potatoes has appeared; fertilizing wheat in the Miami Valley; fertilizing wheat on a run-down farm; forty bushels of wheat to the acre; Hessian fly; what is the condition of your seed corn; and a word of caution regarding alfalfa.

Accessions to the Department Library, January–September, 1908 (*U. S. Dept. Agr., Library Buls. 67, pp. 5–72; 68, pp. 5–52; 69 pp. 5–51.*

NOTES.

Alabama College and Station.—F. E. Lloyd, formerly connected with Teachers' College, Columbia University, has been appointed professor of botany in the college and botanist in the station.

Florida University.—A constitutional amendment proposed by the legislature, authorizing a one mill tax for the benefit of the university, was defeated by a narrow margin in the November election. The correspondence course for teachers in agriculture, carried on by the university, has met with most gratifying success, over 350 teachers of the State registering for this work.

Georgia College.—The agricultural building has been completed at a cost of $100,000. It is about 260 by 80 ft., of cream-colored pressed brick with terra-cotta trimmings, Bedford limestone foundation, and a roof of red tiling. The registration in the 4-year course is now about 60. The cotton school is to be repeated this winter, and a roads school and a farmers' conference at the college are contemplated.

Hawaiian Sugar Planters' Station.—A special feature of the annual meeting of the Hawaiian Sugar Planters' Association, which took place in Honolulu, November 9–12, was the session held at the station at which the directors of the respective divisions gave demonstrations on the work now in progress, to the great interest of the members. At another session short lectures were given by members of the station staff on special lines of work. S. M. Damon was elected president of the association, and subsequently appointed F. M. Swanzy as chairman of the experiment station committee, with G. H. Robertson and T. H. Petrie as the subcommittee for the division of agriculture and chemistry, W. M. Giffard and F. Klamp for that of entomology, and George Davies and J. W. Waldron for that of pathology and physiology.

Idaho Station.—H. P. Fishburn, assistant chemist in the Pennsylvania College and Station, has accepted the position of assistant chemist, entering upon his duties January 1.

Louisiana Stations.—J. B. Garrett, assistant entomologist at the State Station, has been transferred to the Calhoun Station as assistant director in charge, vice J. G. Lee, resigned on account of ill health. W. D. Reid, of the Mississippi College, has been appointed assistant chemist in the State Station, vice W. G. Taggart, who was transferred to the Sugar Station January 1 for research work. A. B. Joffrion, P. H. Doherty, and B. F. Hochenedel are spending the grinding season in Cuba. E. M. Percy has also been added to the station staff at the State Station and is cooperating with the professor of mechanical engineering in the university in tests of the efficiency of the sugar-house machinery in use in the State.

Maryland College and Station.—P. M. Novik, for the last 2 years lecturer in horticulture in the college and assistant horticulturist in the State control work, was killed in a railway accident near Hyattsville, Md., December 9. He was a native of Norway, coming to this country about 8 years ago, and was a graduate of Cornell University.

Minnesota University and Station.—John W. Olsen, State superintendent of public instruction, has been appointed dean of the college and school of agricul-

ture and director of the station, vice E. W. Randall, resigned to accept a commercial position.

Mississippi College and Station.—R. W. Harned, assistant in biology in the college, has been elected entomologist in the station.

Missouri University and Station.—The corner stone of the $100,000 agricultural building was laid October 26 with appropriate ceremonies, the speakers including former Secretary of Agriculture Norman J. Coleman, Dr. B. T. Galloway, of the Bureau of Plant Industry of this Department, President A. Ross Hill and former President R. H. Jesse of the university, B. H. Bonfoeyn, of the board of curators, and Dean H. J. Waters of the college of agriculture. A special feature was the inclusion in the material deposited beneath the corner stone of an ear of corn chosen in a widely advertised competition open to farmers in the State. The building is not expected to be ready for occupancy before the beginning of the next academic year, at which time it is believed the accommodations provided will be taxed to the utmost. The present enrollment in the college of agriculture is 15 per cent in excess of that of any previous year.

A seed-testing laboratory in cooperation with this Department has been established in charge of the station agronomist.

Nebraska University and Station.—Dr. E. Benjamin Andrews retired as chancellor December 31, 1908, on account of failing health, Dr. S. Avery assuming the duties of acting chancellor. E. M. Little, assistant in dairy husbandry, has accepted a position in charge of a stock-breeding farm.

New Mexico Station.—Edward Heringa, assistant in soils and irrigation, has resigned to accept a position with the State Industrial School at Whittier, Cal.

Cornell University.—A farm special train was sent out over the Erie Railroad November 23–25, the staff including a large number of members of the faculty of the college of agriculture, the deans of the State schools of agriculture at Alfred and St. Lawrence universities, and others. The grange, boards of trade, newspapers, schools, clergymen, and others cooperated in making the trip a success. It is estimated that about 8,500 people visited the train.

Ohio Station.—Dr. Adolf Lehmann, for the past 10 years director and chemist of the Department of Agricultural Chemistry at Mysore, India, has accepted the position of assistant in nutrition investigations.

Oregon College and Station.—What is reported as the largest and most complete demonstration train ever sent out in this country traversed the Willamette Valley, November 4–11. The train contained 7 cars, equipped with a large amount of illustrative material, and was manned by a corps of experts from the college and station staff. Demonstrations were given of a milking machine and other dairy appliances, using a pure-bred Ayrshire and a pure-bred Jersey from the college herd; and also of pruning, grafting, and packing apples, together with talks and exhibits on farm crops, insects, and fungus diseases, and other phases of agricultural work. Much interest was aroused among the merchants, commercial organizations, and the general public, as well as among farmers, in many towns the stores being closed in honor of the occasion. It is estimated that over 20,000 people visited the train on its trip.

George Coote, professor of floriculture and gardening from 1887 until compelled by failing health to accept leave of absence in May, 1908, died November 12, at his home in Yaquina. Professor Coote was born in England in 1842. As college landscape gardener he was largely instrumental in laying out and improving the college campus.

Rhode Island College and Station.—In addition to its Adams fund work the station is now carrying on investigations with pigeons and other birds for the purpose of studying the inheritance of some of the more definite characteristics, and is also engaged in the study of the hybridization of distinct species.

An effort is being made to form an agricultural experimental union on essentially the same plan as similar organizations elsewhere. Ground has been broken for the new dormitory and dining hall.

National Association of State Universities.—At the convention held at Washington, D. C., November 16 and 17, the committee reports and papers considered were chiefly concerned with administrative matters in connection with State universities. Of these two dealt with problems having an important bearing on institutions for agricultural education, viz, the report of the committee on standards, and a paper on university extension in State universities. The report of the committee on standards, which was preliminary in nature, defined the standard American university as an institution (1) requiring for admission the completion of a standard American high-school course of four years (not less than 14 units of 5 periods each); (2) offering in the College of Liberal Arts and Sciences two years of general work completing or supplementing the high-school course; (3) offering further two years of university work leading to the bachelor's degree, and "reaching forward to the continuation of this work in the graduate school or the professional school;" (4) offering professional courses in law, or medicine, or engineering, based upon the completion of two years of college work, and (5) offering in the Graduate School an adequate course leading to the degree of Doctor of Philosophy. The committee recommended further that not less than 60 units of college work be required for the bachelor's degree; that the qualifications of teachers in the high school should be not less than the bachelor's degree and ought to be the master's degree; that as a rule professors of all grades of college work should have the degree of Doctor of Philosophy or its equivalent; that professors giving instruction in graduate work should further show their scholastic ability by successful research and publication, and by demonstration of their ability as teachers; that adequate libraries, laboratories, and other equipment should be provided; that three years or 45 units from the beginning of the junior year be required for the degree of Master of Arts, and five years or 75 units for the degree of Doctor of Philosophy and with work in residence; and that to be a standard university an institution shall be equipped to give instruction leading to the degree of Doctor of Philosphy in at least five departments and shall have at least one university professional school requiring two years of college training for admission.

The paper on University Extension in State Universities was presented by L. E. Reber, Director of Extension Work in the University of Wisconsin. This dealt largely with the extension work conducted by that university, which is planned to reach ultimately all classes of people in the State. There will be a central organization reaching out to all parts of the State through lectures, publications, demonstrations, correspondence, various traveling equipments, the services of specialists and traveling teachers, study outlines, and reading and correspondence courses. The State will also be divided into districts, in each of which there will be a university representative with assistants. The plan is a very elaborate one and seems to be well designed to extend greatly the influence of the university. Some of its features as applied to agricultural extension work have been previously noted (E. S. R., 19, p. 798).

Agriculture at the Baltimore Meeting of the American Association for the Advancement of Science.—This meeting of the association, which was held during the week beginning December 28, 1908, was largely attended, the registration reaching nearly 1,100. In addition to section meetings covering practically the entire field of pure science and a large part of the field of applied science, about 35 scientific societies, many of them affiliated with the association, held meetings at the same time.

Several of these societies are primarily interested in science as applied to agriculture, and included in the programmes of nearly all of the sections and societies were papers of direct interest to agricultural science, indicating a rapidly growing realization of the interest and importance of such problems as subjects of scientific research. Of the more than 1,000 papers presented, at least 150 were of this class, many being by workers in this Department and the agricultural colleges and experiment stations.

Especially important and interesting features of this meeting of the association were the celebration of the hundredth anniversary of the birth of Charles Darwin and the fiftieth of the publication of Origin of Species, and a symposium on public health, at both of which addresses of the highest interest were delivered.

In the address of the retiring president, E. L. Nichols, of Cornell University, on Science and the Practical Problems of the Future, attention was called to the approaching end of many of our available resources, and it was pointed out that in obtaining the power necessary for material advancement the inventor and the engineer can but utilize and apply the knowledge which the man of science can supply. The endowment of universities purely for research was advocated as essential to the work of conservation.

American Chemical Society.—The presidential address, by M. T. Bogert, touched upon the same ground as that of Professor Nichols, the subject being The Function of Chemistry in the Conservation of Our Natural Resources. H. J. Wheeler, director of the Rhode Island Station, as chairman of the section on agricultural and food chemistry, made a thoughtful and suggestive address on The Future of Agricultural Chemistry, in which he pointed out the need of better provision for the advanced and systematic training of agricultural chemists and urged that such training should be provided in the larger universities, believing that such institutions are at the present time better prepared to give such training than the agricultural colleges. He laid particular stress upon the importance of broad and thorough fundamental scientific training for agricultural research.

A large proportion of the papers presented before the society were related directly to subjects of agricultural importance. In two sections, namely, that of agricultural and food chemistry, which was raised to the grade of a division of the society at this meeting, and that of the recently established section of fertilizer chemistry, the programme was devoted exclusively to such subjects, about 31 papers being presented; and there were also several in the division of industrial chemistry and chemical engineering and the section of physical chemistry.

The character of the proceedings and papers of this meeting give evidence of a marked tendency toward the development of applied chemistry not only with reference to agriculture, but also to other technical industries.

Society of American Bacteriologists.—The opening address was by H. L. Russell, director of the Wisconsin Station, on the ecology of micro-organisms. The speaker advocated a broader treatment in elementary courses in bacteriology, believing that more attention should be paid to the environmental conditions and less to a discussion of species.

A number of the papers dealt with the bacteriology of dairy products. H. A. Harding, of the New York State Station, explained the advantage of using the society's card in classifying and identifying species of bacteria in cheese. W. M. Esten, of the Connecticut College and Station, exhibited charts showing great variation in the acidity of milk from Jersey cows as compared with Holstein milk. Dr. Otto Rahn, of the Michigan College and Station, reported results of investigations on the keeping qualities of butter.

S. E. Prescott, of the Massachusetts Institute of Technology, reported on a study of types of bacteria found in fermented milk products prepared for therapeutic use. E. G. Hastings and B. W. Hammer, of the Wisconsin Station, believed that organisms closely resembling *Bacillus bulgaricus* are constantly found in milk, butter, and cheese, and they ascribed the therapeutic value of the fermented drinks to their chemical composition rather than to the presence of the peculiar organisms. Dr. Carrington, of Turkey, believed the value of yoghourt or matzoon to be due to flushing the intestines, as the beverage is used in that country for all diseases, and patients are urged to drink as much of it as possible.

C. E. Marshall described a cremating furnace for laboratories that had been successfully used at the Michigan College. Dr. Hastings reported the keeping of anthrax spores for 8 years in raw pond water. P. B. Hadley, of the Rhode Island Station, gave the results of studies of white diarrhea in chicks. L. F. Rettger, of Yale University, described a new species of bacterium which is pathogenic in poultry.

Association of Economic Entomologists.—At the twenty-first annual meeting of this association, S. A. Forbes, in his presidential address, on the prospects of progress in Economic Entomology, contrasted the status and conditions existing at the time he was president of the association 15 years ago with those of to-day. A redraft of the constitution was adopted and the name of the association altered to American Association of Economic Entomologists. A large number of common names of insects taken from a list submitted by the committee on nomenclature were accepted. The committee on testing proprietary insecticides reported on the status of the proposed National insecticide law. Resolutions were adopted regarding the deaths of Drs. James Fletcher and W. H. Ashmead, and Profs. F. H. Snow, Alexander Craw, and W. G. Johnson, all of whom were members of the association.

Papers were presented by R. I. Smith, of the North Carolina Station, Edith M. Patch, of the Maine Station, F. L. Washburn and H. J. Franklin, of the Minnesota Station, R. A. Cooley, of the Montana Station, E. D. Sanderson, of the New Hampshire Station, P. J. Parrott, of the New York State Station, H. E. Summers and R. L. Webster, of the Iowa Station, T. B. Symons, of the Maryland Station, E. S. G. Titus, of the Utah Station, W. E. Hinds, of the Alabama Station, E. P. Taylor, of the Missouri Fruit Station, A. L. Quaintance, F. M. Webster, A. D. Hopkins, J. G. Sanders, C. E. Hood, and B. N. Gates, of the Bureau of Entomology of this Department, and by State entomologists E. P. Felt, of New York, Franklin Sherman, Jr., of North Carolina, and E. L. Worsham, of Georgia. In these the results of biological studies were given of *Murgantia histrionica*, *Pemphigus tesscllata*, cranberry pests, and soft scales, and in papers taking up more particularly the economic side were considered house-flies, forest insects, *Empoasca mali*, *Lygus pratensis*, codling moth, tree crickets, San José scale, *Conotrachelus nenuphar*, and an alfalfa leaf weevil. Papers were also presented on methods for securing apicultural statistics, on photomicrography and insect photography, plans for parasite breeding cages, determining the effect of hydrocyanic-acid and carbon-bisulphid gases upon plant and insect life, and on the importance of proper methods of entomological investigations. A discussion of the question Do We Need the Insectary? was entered into by a large number, most of whom considered such equipment a necessity. One of the important developments of the meeting was brought out by E. S. G. Titus, in relation to an imported alfalfa leaf weevil that is becoming a source of great injury to that crop in Utah. This pest is supposed to have been introduced into this country from Europe.

The following officers were elected for the ensuing year: President, W. E. Britton; 1st vice-president, E. D. Ball; 2d vice-president, H. E. Summers; secretary, A. F. Burgess. The meeting was the largest yet held, there being an average attendance of over 100 each day.

Entomological Society of America.—This was the third annual meeting of this society, W. M. Wheeler presiding. Of special interest to the economic entomologists were the accounts and investigations of *Toxoptera graminum* and its parasites, by F. M. Webster, habits of seed infesting Chalcis-flies, by C. R. Crosby, recording and mapping entomological fauna of the State, by Franklin Sherman, Jr., and notes on the host relations of ticks, by W. A. Hooker.

Henry Skinner was elected president, Herbert Osborn and A. D. Hopkins vice-presidents, and J. C. Bradley secretary and treasurer for the coming year.

American Association of Horticultural Inspectors.—The seventh annual meeting was held December 29–30. Among the questions of interest taken up and discussed were those of a National importation inspection law, the desirability of a uniform inspection law for the several States, and methods of certification and of disinfection of nursery stock, and methods for preventing the dissemination of the strawberry root-louse, Argentine ant, peach yellows, and crown gall. F. L. Washburn, of the Minnesota Station, was elected president and T. B. Symons, of the Maryland Station, secretary for the coming year.

Agricultural Economics at the American Economic Association.—The meeting of this association was held at Atlantic City, N. J., December 28–31, 1908. One of the sessions was devoted to agriculture, the following papers being presented: Economic Geography and Agricultural Economics, by E. V. Robinson, University of Minnesota; Cooperative Marketing of Agricultural Products, by Dr. J. L. Coulter, University of Minnesota; The Economic Limitations of Cooperation in the Marketing of Agricultural Products, by J. B. Morman of this Office; and The Relation of Speculation to the Marketing of Agricultural Products, by H. C. Emery, Yale University. A discussion, led by T. N. Carver of Harvard University, followed the papers, which will be published in the proceedings of the association during the year.

American Home Economics Association.—Following a meeting of the Teachers' Section of the Lake Placid Conference for Home Economics, held in Washington on December 31, the American Home Economics Association was organized, with its aim, as expressed by the constitution adopted, the furtherance of the study and consideration of home problems and the uniting for more effective work of all those interested therein. The following officers were elected: President, Mrs. Ellen H. Richards, of the Massachusetts Institute of Technology; vice-presidents, Miss Isabel Bevier, of the University of Illinois, C. F. Langworthy, of this Office, and Miss Mary Uri Watson, of the Ontario Agricultural College; secretary-treasurer, Benj. R. Andrews, of Teachers' College, New York.

The first public meeting of the association was held at George Washington University, on the morning of January 2, at which addresses were made by several speakers. Elmer E. Brown, U. S. Commissioner of Education, pointed out the important work which the association might do by showing home-makers and school children throughout the country how the technical, scientific knowledge for which it stands may be practically applied to increase their physical and moral, as well as their intellectual, welfare. He was followed by A. C. True, of this Office, who spoke of the timeliness of the formation of the association at a period when the interest in home science was increasing so rapidly and when the need was being felt for some regenerative influence in American home life. He suggested as three appropriate lines of

work, research into the problems of home economics, improvement of educational methods, and diffusion of information among the masses of our people. Congressman C. R. Davis, of Minnesota, also urged the importance of making available to the great body of our people the technical information regarding the problems of home-making which now seems largely confined to specialists, and discussed the "Davis Bill," now before Congress, particularly in its relation to the development of secondary instruction in home economics. A resolution was later adopted by the association indorsing the legislation suggested.

John Hamilton, Farmers' Institute Specialist of this Office, vigorously urged upon the meeting the need of bringing before the women in our rural regions definite and practical suggestions for lightening the monotonous and continuous physical labor which housekeeping means to many of them. Following him, Mrs. Mary Hinman Abel, of Baltimore, put in a plea for aid for the city homemakers, suggesting that well-managed laundries, cook shops, and employment bureaus would do much toward solving household problems. It had been expected that Gifford Pinchot, of the Forest Service of this Department, would speak in reference to the Commission on Country Life and its interest in work akin to that of the association, but he was unable to be present.

At the final session a resolution was adopted strongly urging the continuance of the nutrition investigations of this Office.

Conferences were also held on various phases of household economics, and a lecture on Household Arts was given by A. W. Dow. The active and widespread interest manifested in the association is evidenced by the fact that over 125 delegates from outside of Washington were registered at the meetings and that 800 persons have sent in their names for membership.

American Society of Animal Nutrition.—As an outgrowth of a conference of teachers and investigators in animal nutrition at the 1908 Graduate School of Agriculture, a meeting was held at Chicago, November 28, in connection with the International Live Stock Exposition, with about 30 college and station workers in attendance. An organization was effected, its purpose being defined as "to improve the quality of investigation in animal nutrition, to promote more systematic and better correlated study of feeding problems, and to facilitate personal intercourse between investigators in this field." In addition to holding an annual meeting, the society purposes taking up actively the consideration of methods of investigation and later entering upon cooperative study of important problems of stock feeding. Officers of the new society are announced as follows: President, H. P. Armsby; vice-president, C. F. Curtiss; secretary-treasurer, D. H. Otis; registrar, J. T. Willard; committee on experiments, H. J. Waters, H. W. Mumford, T. L. Haecker, E. B. Forbes, and W. H. Jordan.

International Live Stock Exposition.—The ninth exposition of the International Live Stock Association, held in Chicago, November 28–December 10, was again a notable success. In spite of the quarantine of several States on account of the outbreak of foot-and-mouth disease, 20 States, together with Canada, Mexico, England, and Belgium, were represented by entries including over 3,000 animals, and in most of the classes the quality showed continued improvement over previous years.

The influence of the agricultural colleges and experiment stations was quite as strongly in evidence as ever. Their staffs furnished six members of the corps of judges, their students were again a prominent and distinctive feature, and their exhibits were distributed through nearly every class of entry, figuring even more largely than in former years in the prize winnings, easily predominating in the fat stock classes and achieving several grand championships, among them the highly coveted championship of the single steers.

In the fat barrow class the grand championships both for single barrows and pen of 3 were won by Berkshires from the Iowa College, which also furnished the champion Poland China and large Yorkshire single barrows, the champion Duroc Jersey pen of 3, and the champion carload of from 150 to 200 lbs. in weight, besides a large number of class prizes. The champion pen of Chester Whites and the champion Duroc Jersey single barrow were from the Wisconsin University, which also won a long list of class prizes. The Ohio University showed the champion pen of large Yorkshires and won several prizes in other classes as did also Purdue University.

The exhibit of fat wethers from the Wisconsin University was especially noteworthy and won a large number of prizes, among them the championships for pens of Shropshires and Cheviots, for single wethers in Hampshires, and for the champion dressed carcass of the show. Iowa received a second prize for a pen of Southdowns.

For fat cattle the Nebraska University won, in the Shorthorn classes, first on senior yearlings, and Ohio first on junior yearlings, and other prizes went to Missouri, Minnesota, Iowa, and Ohio. On Aberdeen Angus herds, the Kansas College won first with Minnesota second, Nebraska third, and Iowa fifth. On two-year-olds the Kansas College was first, Purdue second, and Nebraska third; on yearlings, Minnesota first, Purdue fourth, and Kansas fifth: and on calves, Kansas first, Nebraska second, Iowa fourth, and Missouri fifth. The breed championship for single steers was again won by the Minnesota University. On Hereford two-year-olds the Nebraska University won third place and Purdue fourth.

The Missouri and Nebraska universities were strongly in evidence in the Galloway classes, the former winning the herd championship, first on yearlings, and second on two-year-olds and calves, and the latter receiving second on herd, first on calves, second on yearlings, and fourth on two-year-olds. Purdue won third and Ohio fourth on yearlings, and Kansas third on calves.

In the grades and cross breds the Iowa College won first on herd, second on two-year-olds, second and fourth on senior yearlings, third and fourth on junior yearlings, third and fifth on senior calves, and second on junior calves. Nebraska received thirds on herd, two-year-olds, and senior yearlings, and Missouri fourth on two-year-olds and second on junior yearlings.

Upon the final assembling of the winners from all breeds, champions were as usual chosen for the groups by ages, and two of the three selected were from the college entries. For the two-year-olds the Angus Fyvie Knight from Purdue was selected, thereby reversing an earlier decision in which first place for Angus two-year-olds had been given to Ideal from the Kansas College. Symboleer, also an Angus from the Kansas College, received the calf championship. The grand championship for all breeds and ages fell to Purdue on Fyvie Knight. The Iowa College won the herd championship with Kansas third.

In the cattle slaughter tests an innovation was the antemortem rating of the animals from the killing standpoint. In this, first place in the two-year-old class went to an entry from the Minnesota University, with Iowa third, and Missouri fourth, and in the yearling class Iowa received second and fourth place. Upon a regrading of the carcasses after slaughter, with the criterion largely the requirements of the general trade, the ratings were very much altered, Nebraska receiving first and Missouri second on two-year-olds, and Iowa fifth on yearlings.

In the carload lot competition a load of "short fed" Angus yearlings fed by the Purdue Station under known conditions attracted much attention and was regarded as a valuable demonstration.

The entries of horses from the colleges were much less numerous than those of fat stock. With Clydesdales Iowa received fifth prize for aged stallions and third for yearlings.

In the special class for college and station stock the competition was, as usual, exceedingly close. With cattle, Purdue won first for two-year-olds and the championship for single steers with Fyvie Knight. Kansas won second place on two-year-olds, with Nebraska third, and Iowa fourth. For cattle one to two years old, the winner was Minnesota, followed by Iowa, Nebraska, and Missouri. For calves, Kansas won first, Minnesota second and fourth, and Iowa third. The herd championship was won by Iowa. Wisconsin took all the prizes for sheep except third on wether lambs which went to Iowa. Purdue received second and Iowa third for barrows under 12 months, and the remaining prizes for hogs went to Iowa.

The usual large attendance of students led to the remark from *The Breeders' Gazette* that "more and more the International is becoming an elective course in the curriculum of agricultural colleges." The judging contests were participated in by teams from eight institutions and several others were represented in the crowd of spectators and at the annual meeting of the American Federation of Agricultural Students, which was held December 1. In the contest for the trophy offered for the highest total scores in judging horses, cattle, sheep, and swine, first place was awarded to the Iowa College, the remaining competitors in order being, Nebraska, Texas, Missouri, Kansas, Ohio, Ontario, and Minnesota.

The Armour scholarships contingent upon these contests and upon the prize winnings of the colleges and stations have been awarded, Iowa receiving 7, Nebraska and Wisconsin 3 each, Purdue 2, and Kansas, Minnesota, Missouri, Ohio, and Texas one each.

National Dairy Show.—The third National Dairy Show was held in Chicago, December 2–10. The cattle exhibits included 6 breeds from 10 States, the entries being appreciably curtailed by the quarantine for foot-and-mouth disease. The milk and cream contest held under the management of the Dairy Division of this Department brought forth 70 entries, representing 20 States scattered from New Hampshire to Utah, the number and quality of the entries showing a marked improvement over those of the previous contest in 1906. There were also extensive exhibits of dairy machinery.

Special programmes were prepared for creamery and cheese-factory managers and secretaries, milk dealers, and dairy farmers, with addresses by Chief E. H. Webster and H. Rabild of the Dairy Division, E. K. Slater of the Minnesota University and Station, several State dairy and food commissioners, and others. A students' dairy stock-judging contest was participated in by teams from the agricultural colleges of Iowa, Kansas, Minnesota, Missouri, Nebraska, New York, Ohio, South Dakota, and Texas. The sweepstakes trophy was won by the Iowa College, with Nebraska second and Minnesota third. Special breed trophies were also competed for, Nebraska winning for Jerseys, Cornell for Holstein-Friesians, and Iowa for Guernseys and Dutch Belted stock.

An informal meeting of the National Association of Dairy Instructors and Investigators was held in connection with the show, with about 35 in attendance.

U. S. Department of Agriculture.

EXPERIMENT STATION RECORD.

VOL. XX. FEBRUARY, 1909. No. 6.

The report of the Secretary of Agriculture for 1908, in addition to reviewing the work of the Department for that year, presents a most interesting and instructive epitome of the progress of agriculture in the United States during the past twelve years, and of the principal causes which have contributed to the phenomenal growth recorded. Among the agencies to whose activities this progress is due the Secretary includes not only this Department "but also the experiment stations, the agricultural schools and colleges, the State boards and commissioners, the agricultural press, and the farmers themselves in their individual and collective efforts."

"Momentous changes," the Secretary states, "have occurred to agriculture in this country during the last dozen years. Features of great import have been introduced. Forces have become operative whose results are already enormous, with the certainty of cumulative and accelerated future consequences for the Nation's good and well-being. The farmer's work and harvest have had the benefit of more varied knowledge and more effective intelligence. His life and living have undergone transformations which increasingly make the farm preferable to the town.

"This period has developed an amazing and unexampled prosperity for the farmer. His improving financial condition has been both an effect and a cause—an effect partly of his own efforts joined to those of public agencies, and also the means of making his life and the lives of his wife and children the better worth living."

The Secretary shows in some detail how the period referred to has been marked by a change from low to profitable prices for farm products and how, "relieved of the weight of debt and of suffering under unprofitable prices, the farmer felt more responsive than before to the help offered by the Department of Agriculture, the experiment stations, and other sources during the period under review. Thousands of learned investigators worked for him. Thousands more talked to him repeatedly. Thousands of demonstrations taught how to do by doing. Many boys were educated in agriculture. Hundreds of millions of copies of publications were sent broadcast."

One of the most important results of these systematic and widespread efforts to apply science to the practice of agriculture has been

the remarkable improvement in practical methods of breeding plants and animals, for "during the past dozen years breeding has passed the unorganized stage and has come under the domain of science." The work in plant breeding has given definite results not only in the production of better yielding varieties of many important crops, but has also produced varieties more resistant to disease and unfavorable climatic conditions, as well as those of higher market quality.

In the field of animal breeding "cooperation of the Department with State stations and farmers has begun to create new strains of farm animals—carriage horses, in Colorado; cattle for beef production under southern conditions, in Alabama; the cross of the horse and the zebra, in Maryland; the reestablishment of the Morgan breed of horses, in Vermont; sheep especially suited to range conditions, in Wyoming; a breed of milking Shorthorn cattle, in Minnesota; draft horses, in Iowa; improved Holstein cattle, in North Dakota; a breed of hens for high egg production, in Maine."

No small part of the improvement of agricultural production during the period named has been due to systematic efforts to discover and introduce promising seeds and plants, and it is stated that "from this one feature of the Department's work many millions of dollars are added yearly to our national production of wealth."

The question of farm management is one of immense importance, and it is stated that through the efforts of the State experiment stations, colleges of agriculture, and the Department of Agriculture this complicated subject is being put on a scientific basis.

"The planning of a new farm or recasting the field plan of the old farm are being reduced to such form that they are profitably taught in agricultural schools. A number of the experiment stations have determined the kinds of crop rotations which yield the largest net returns for given soils and agricultural districts. Numerous long-time experiments on State and branch experiment station farms controlled by the Department are under way to determine those crop rotations and other methods of internal management of the farm which will be most profitable and best adapted to the family and other available labor. . . . Along this line of work important progress has been made in aiding the farmer to put into practice results of scientific discovery."

The improvements in agriculture have not been confined to increasing the productive capacity of the area under cultivation, but have extended to the reclamation and profitable utilization of large areas hitherto considered worthless for agricultural production. This is probably best illustrated in the great progress that has been made during the period under consideration in the introduction of methods of dry farming in the vast region included in the arid part of the Great Plains. Under the guidance of the Department and the

State experiment stations this region is rapidly becoming one of considerable agricultural importance, and dry farming has come to be recognized as an important factor in our future agricultural progress.

In discussing the present and future of irrigation and dry farming, the Secretary makes the following significant statements: "In 1896 the irrigated acres in this country numbered about 8,000,000; in 1908 the number was about 13,000,000, and when projects now in the course of execution by the Reclamation Service and by private individuals under the Carey Act are executed, the total irrigable area will be 18,000,000 acres. It therefore appears that during the period under review steps have been taken and much progress made toward placing under cultivation immense areas of desert land by means of irrigation and of so-called 'dry land' by means of suitable cultural systems. The foundation has already been prepared for the advent of millions of people on previously unproductive land to pursue agriculture in many of its features under conditions which promise prosperity and an enormous addition to the Nation's permanent wealth and to its annual production. In these two lines of agricultural development, in which this Department has already been concerned in the agricultural phases, there is much work for it in the future."

In harmony with the growing sentiment in favor of better conservation and utilization of our natural resources, "instruction in the conservation of the soil and its fertility by all available means has been incessantly carried on by the Department, the experiment stations, agricultural colleges, and by private publications."

A fuller knowledge has been gained of the nature of plant diseases and of the immense losses they cause and their ravages "have been suppressed and avoided during the period under review in a far greater degree than ever before. A true science of plant pathology has been founded and the discovery of the causes and treatment of diseases has led to many improvements in mechanical methods of utilizing fungicides. Still greater advances have been made in the direction of plant sanitation, and improvements in the environment of plants as well as in the plants themselves have increased production, both in quantity and in quality. No part of the work of the Department and the experiment stations yields a more direct cash return than this."

The Secretary's review shows in brief the great progress that has been made in the period considered in the discovery and introduction of effective methods of control of injurious insects by means of natural enemies, insecticides, and improved methods of farm management; in the acquisition and dissemination of more exact knowledge regarding useful and injurious birds and other wild animals; in improving methods of marketing farm products; in control of animal diseases and inspection of meat products; in improving dairy meth-

ods; in road improvement; in developing the efficiency of the Weather Bureau and improving the weather forecasts and extending their distribution; in the application of chemistry to agricultural production and to the detection and prevention of fraud and adulteration in food products and drugs.

"Increased and wider knowledge of the nutritive value of food and of the better utilization of agricultural products as human food has followed the nutrition investigations of this Department, in cooperation with the experiment stations and other State institutions.

"Animal nutrition investigations, begun in cooperation with the Pennsylvania experiment station, are accumulating most accurate and scientific information, developed by use of the respiration calorimeter, an instrument invented by experts of this Department."

The remarkable growth of the Forest Service in recent years and the rapid development of a comprehensive national forest policy is strikingly emphasized in the statement that "for Americans ten years ago forestry had neither a practical basis nor practical interest. On July 1, 1898, there were two professional foresters in the employ of the Government, less than ten in the whole country, no school of forestry on the Western Hemisphere, no scientific knowledge of the first principles of American practice in existence. The very word forestry was usually meaningless except as it was misunderstood."

It is shown, however, that between that date and the present time there has been a complete and rapid change in the attitude of the public toward the forests, and that while in 1897 the number of persons employed by the Department in forestry work was only 14 and not an acre of forest land was then under the management or control of the Department, the number of persons now employed in the Forest Service is 3,753, and the area of the National Forests now aggregates almost 168,000,000 acres, paying annually into the Treasury of the United States over $1,800,000. This enormous growth of the forestry work of the Department has been accompanied by increased activity by State agencies and the development of forestry work by the agricultural colleges and experiment stations.

As concrete evidence of the rapid growth of the Department, it may be stated that while "in 1897 the number of publications issued by the Department was 424, of which 6,541,200 copies were distributed, in 1908 the 1,522 publications of the Department were distributed to the number of 16,875,516. During the eleven years following 1897 this Department has printed 10,449 publications, including reprints, the distribution of which amounted to 129,129,633 copies."

In the same time the Department library has grown from 56,000 to 115,000 books and pamphlets, constituting perhaps the most complete agricultural library in the world.

The growth of the Department is also shown by the fact that while "on July 1, 1897, 2,444 persons were employed, eleven years later, in 1908, the number was 10,420, or over four times as many."

The general educational influence of the work of the Department and of the agricultural colleges and experiment stations has grown rapidly and become far-reaching during the period reviewed. One educational result of great importance has been the training of an efficient corps of workers prepared to guide future advances in agricultural education and research.

The Secretary gives the following striking figures regarding the development of agricultural education:

"The total income of the agricultural colleges was $5,000,000 in 1897, $15,000,000 in 1908; the value of their property was $51,000,000 in the former year and $96,000,000 in 1907. The students in 1897 numbered 4,000; in 1908, 10,000.

"One agricultural high school existed in 1897, and there are now 55. Not one normal school taught agriculture in 1897, but now 115 do so, besides many privately endowed schools. About half of the agricultural colleges now give training courses for teachers in agriculture; 44 States and Territories give some instruction in elementary principles of agriculture in the lower schools. The Graduate School of Agriculture for instruction of investigators and for discussion of advanced problems of research in agriculture was organized in 1902, and is now doing work under the Association of American Agricultural Colleges and Experiment Stations. A strong movement for the systematic organization of all agencies in agricultural extension work has been started within a few years, and the National Education Association has added a department of rural and agricultural education.

"Outside of schools which are for the education of youth and teachers in agriculture, the farmers have received a greatly increased degree of education by means of demonstration work and advice given orally and by letter, by countless official and private publications, by corn and live-stock judging contests, and by farmers' institutes. The number of sessions of the last named held in 1908 was 14,000, with an attendance of about 2,000,000 persons, an enormous increase over the attendance twelve years ago. About 1,200 trained lecturers are now employed in farmers' institute work in all States and Territories."

In concluding this review of the "tangible evidences of the beneficial results of the gigantic movement in agricultural instruction and improvement, of the unprecedented uplift of the farmer, and the betterment of country life," the Secretary calls attention to the interesting and important fact "that this country is passing

through historical phases of agricultural production. First comes the exploitation of virgin land by the soil robber, a proceeding that is justified by the poverty of the settler or his lack of capital; next is the diminished production per acre, which surprises the farmer, and for which he is unable to account; next is the receipt of information from the scientist as to the means of improving the productivity of the land, with slow response; in the course of time, especially when the next or perhaps the third generation takes the farm, important advances are made, at first irregularly and mostly on the farms of the leading farmers, and subsequently with increasing diffusion and accelerated speed.

"In the case of all crops for which production per acre is known, there was an increase during the last ten years and also, in a somewhat less degree, in the case of most of them, during the last twenty years. This is the general fact for the United States in spite of the damaging effect on the general average by reason of decreasing production per acre from land that has not yet entered upon the final historic stage of agriculture.

"The farmers of this country have now made a creditable beginning in this last phase of historic agriculture. It is now a movement of masses as well as of leaders. It is more and more a diffused movement in place of being broken up into localized efforts. This movement has gained most of its headway during the last twelve years. Increased production per acre is clearly indicating the extent and force of this uplifting movement. . . .

"No one need fear that the farmers of this country will ever be unable to provide for its population. They are already demonstrating in the cases of various crops and of various States that they can provide for a population increasing faster than by increase due to excess of births over deaths."

Taking all the facts into consideration, the Secretary draws the broad general conclusion "that agriculture has made wonderful progress and permanent advancement, and that the farmer in results of information, intelligence, and industry has thriven mightily" during the last dozen years. "The progress that has been made is in the direction leading to popular and National welfare, to the sustenance of any future population, as well as to a larger efficiency of the farmer in matters of wealth production and saving, and in establishing himself and his family in more pleasant ways of living."

From the standpoint of the agricultural scientist, the most interesting fact regarding the foregoing review of the recent agricultural progress of the United States is that it is inseparable from the record of the growth and development of our institutions for agricultural education and research. The period of the most effective work of these institutions is the same as that covered by the Secretary's re-

port. During that period these institutions have secured the attention of great numbers of intelligent farmers in every State and Territory. As agricultural prosperity has increased the farmers themselves have taken increased interest in securing larger grants of public funds for agricultural education and research and have cordially supported the managers of colleges, schools, and experiment stations in building up these institutions.

The directions in which agricultural progress has been made have also borne clear evidence of the practical benefits derived from science applied to agriculture. It is therefore impossible to make any accurate account of our agricultural progress in recent years without giving a large place to the results of experimental inquiries and to the relations of science and education in aiding advances in this industry. So far from exhausting the store of material which might have been drawn upon, the Secretary has been compelled by limits of space to confine his résumé to the larger and more striking features of scientific, as well as practical, interest and to treat these in the broadest outline.

An important feature of the development of the Department, as related to its material equipment, to which the Secretary's report calls attention, is the completion of the new Department building. This building, for which Congress appropriated $1,500,000 in 1902, was begun in 1904 and completed in March, 1908. Upon completion of the building steps were "immediately taken toward its occupancy by the various Bureaus of the Department, which were very inadequately housed in scattered buildings rented by the Department." The building consists of two L-shaped wings designed especially for laboratory use which it is planned to connect by a central part to be used for administration purposes.

The wings each have a frontage of 256 feet with an L extending to the rear 100 feet. They are four stories in height above a high basement, and all the floors are made readily accessible by three elevators in each wing. There are twenty-five working rooms on each floor, and the total floor space provided by each building is eighty thousand square feet including the corridors. This leaves about fifty-five thousand square feet in each wing available for office and laboratory rooms. The corridors are wide and well lighted.

The construction is of the most substantial kind and is fireproof throughout. The exterior walls are of marble and of solid masonry, and those on the court side of light brick with marble trimmings.

Each room is so arranged that it can be readily converted into a laboratory, although at present many of the rooms are occupied as offices. Provision is made for supplying each laboratory room with hot and cold water, distilled water, gas, live steam, compressed air

and suction, as well as with electricity for light and power; and there are openings for connecting telephones and call bells. The supply pipes are carried just below the ceiling so that they in no way interfere with office equipment and lead to pipe shafts provided with doors so that the risers are easily accessible. A power house has been erected in the court from which heat is supplied, and where all pumps and machinery for maintaining the service are located. The building is heated by indirect radiation, and a system of room ventilation and of flues for fume chambers is provided throughout.

The new building accommodates only a part of the Department's force, so rapid has been the growth, even in the few years since the building was begun. In the east wing are located the Library, which occupies most of the basement floor, the Bureaus of Animal Industry and of Soils, and the Office of Experiment Stations. The latter has desirable quarters on the second floor, with two rooms in the basement for the respiration calorimeter. The space provided allows the bringing together of the various lines of work in charge of the Office, which in the past have been widely scattered.

The west wing is occupied by the Bureau of Plant Industry. The old main building and the building occupied by the Bureaus of Entomology and Biological Survey will be retained for the present. "Several structures in close proximity to the new building have been or will be removed, in accordance with the provisions of the original plan and appropriation for the building work. In carrying out this plan new quarters for shops, stables, and storage are being erected on the north side of the Department grounds, for which purpose a special sum was appropriated by Congress at its last session."

Not the least advantage of the new building will be the opportunity to bring the forces together which have steadily become more widely separated. This separation has greatly increased the difficulties of administration, and the necessity of adapting the small rooms of dwelling houses and flats to laboratory purposes has placed the work at a constant disadvantage.

In its completed form the new building will compare favorably in its architectural features (see E. S. R., 15, p. 947) with any that has been built for other branches of Government work and is well adapted to the purposes for which it was designed. It is such a building as will worthily typify the national importance of agriculture in this country.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

A wax acid from soils, O. SCHREINER and E. C. SHOREY (*Abs. in Science, n. ser., 28 (1908), No. 710, p. 190*).—This is an abstract of a paper presented at the recent meeting of the American Chemical Society at New Haven.

"In the examination of a black clay loam from North Dakota there was obtained by treatment with boiling 95 per cent alcohol a colored extract from which a microcrystalline precipitate separated on cooling. By washing with cold alcohol and recrystallizing, this can be obtained free of color. On drying this purified precipitate and treating with cold ether it is divided into two portions. The ether soluble portion crystallizes on evaporation of the ether in minute leaflets, melting at 72–73° C. The physical and chemical properties of this body place it among the fatty acids found in waxes. Elementary analyses correspond with the formula $C_{21}H_{42}O_3$, the hypothetical acid of a lactone found in carnauba wax. The name agroceric acid is proposed for this body."

The presence of a cholesterol substance in soils—agrosterol, O. SCHREINER and E. C. SHOREY (*Jour. Amer. Chem. Soc., 31 (1909), No. 1, pp. 116–118; abs. in Science, n. ser., 28 (1908), No. 710, p. 190*).—This is a paper presented at the recent meeting of the American Chemical Society at New Haven. It is stated that "when the alcoholic extract of the soil referred to [above] is separated from the precipitate, which forms on cooling, and is evaporated to small volume, a resinous dark-colored mass is obtained. Cold ether dissolves a portion of this, including the coloring matter. Spontaneous evaporation of the ether leaves again a resinous dark-colored mass. Treatment of this with cold absolute alcohol removes the coloring matter and leaves a white crystalline residue. Purification of this by recrystallization yields a body crystallizing in plates resembling those of phytosterol, melts at 237° and gives the cholesterol reaction with acetic anhydrid and sulphuric acid. Elementary analysis gave figures corresponding to the formula $C_{26}H_{44}O$. The name agrosterol is suggested for this compound."

Critical observations on the Schöne and Appiani methods of physical analysis of soils, G. DE LUCCHI (*Ann. R. Staz. Agr. Forlì, 1907, No. 36, pp. 19–29*).—As a result of comparative tests of these methods the author recommends the Appiani (decantation) method as preferable to the Schöne method on account of its simplicity and rapidity.

Application of the cobalti-nitrate method to the estimation of potassium in soils, W. A. DRUSHEL (*Amer. Jour. Sci., 4. ser., 26 (1908), No. 154, pp. 329–332; Ztschr. Anorgan. Chem., 59 (1908), No. 1, pp. 97–101; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 550, II, p. 735; Chem. Zentbl., 1908, II, No. 13, p. 1126*).—In the application of the method already described (E. S. R., 19, p. 808) to the determination of potash in soils, a weighed quantity of soil is extracted on a water bath with 20 per cent hydrochloric acid, the acid removed by evaporation, and the bases separated by addition of sodium carbonate or ammonia and ammonium oxalate. The ammonium salts and organic matter are removed

by heating to redness, the residue dissolved in water, acidified with acetic acid, and evaporated with excess of sodium cobalti-nitrite. Further procedure is the same as already described.

Detection of ammonia in water, LAMBOTTE (*Jour. Pharm. [Antwerp], 1908, Mar. 31; abs. in Ann. Chim. Analyt., 13 (1908), No. 9, pp. 350, 351*).—The method proposed is based upon the coloration of the precipitate obtained with Nessler reagent in a centrifuge and not of the solution as in the ordinary method.

The estimation of phosphoric acid in food materials, RIETER (*Schweiz. Wchnschr. Chem. u. Pharm., 46 (1908), No. 35, pp. 546, 547*).—A critical discussion of methods.

What is the value of determining the ash content of honey by Ley's method, F. SCHWARZ (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 7, pp. 403–412*).—On the basis of his investigations the author reaches the conclusion that honey should be considered adulterated when it has an ash content of less than 0.1 per cent and also would appear to be artificial honey judged by the Ley test. See also a previous note (E. S. R., 20, p. 11).

The determination of malic acid in food products, H. W. COWLES, Jr. (*Jour. Amer. Chem. Soc., 30 (1908), No. 8, pp. 1285–1288*).—The method described is designed for use with maple sugar products. It is also applicable to fresh and boiled ciders and to cider vinegar. Calcium acetate with 95 per cent alcohol is used as a reagent. The precipitate is ignited, warmed with an excess of decinormal hydrochloric acid, cooled and titrated with decinormal sodium hydroxid.

The estimation of alcohol in fermented liquids, W. ANTONI (*Jour. Amer. Chem. Soc., 30 (1908), No. 8, pp. 1276–1278, figs. 3*).—A pycnometer, rinsing arrangement, and a method of distillation used in determining alcohol in fermented liquids are described.

The determination of cotton-seed hulls in cotton-seed meal, G. S. FRAPS (*Texas Sta. Bul. 109, pp. 3, 4*).—In the method proposed the sample is extracted first with ether and then with boiling water and sodium hydroxid. The residue is dried, ignited, and brought to constant weight, the loss in weight representing the insoluble residue.

Determinations of the insoluble residue found in 17 samples of meal after the hulls had been sifted out ranged from 8.22 to 13.33 per cent, with an average of 10.46. In 16 samples of meal of high purity but containing hulls, it ranged from 9.75 to 14.09, and averaged 11.38 per cent. In 20 samples of hulls it averaged 75.22 per cent. It is believed that a meal free from hulls should not contain over 10 per cent of insoluble residue.

The approximate amount of excess hulls present is estimated by subtracting from the percentage of insoluble residue found to be present 10 per cent and then adding one-third of the remainder.

Mitchell-Walker moisture test, J. W. MITCHELL and W. O. WALKER (*Ontario Dept. Agr. Bul. 167, pp. 12, fig. 1*).—The authors have devised a cheap but durable apparatus for use by the average factory man in moisture determinations in butter, cheese, and curd. This apparatus, which is so constructed that it can be easily taken apart and packed for use for the traveling inspector, is fully described and directions are given for making the test. The underlying principles are the use of a reagent to prevent the foaming of butter, the expulsion of the moisture by heat, and the condensing of the vapor in a receptacle where the amount can be easily read.

Amyl acetate is the reagent used, amyl butyrate, eucalyptol, and various distillation products of crude petroleum having been tried and discarded. The loss of moisture due to the reagent has been found to be approximately a constant

quantity rather than being proportional to the percentage of moisture in the butter. The time required to drive all moisture from a sample of butter or curd varies from 4 to 7 minutes.

Regarding the methods of investigations of butter and other fats, GRIMMER (*Milch Ztg., 37 (1908), Nos. 11, pp. 121–132; 12, pp. 133–144; 13, pp. 145–156; 16, pp. 181–192*).—The methods of determining the various physical and chemical constants of butter commonly used are considered and summarized.

Comparison of different methods of estimating the fat content of cream, M. KERSTEN (*Molk. Ztg., 22 (1908), No. 38, pp. 1083–1085*).—The methods compared are those of Adams, Gerber, Wendler, and Siegfeld, together with that by the use of the revolving balance described below.

A revolving balance, WENDLER (*Molk. Ztg., 21 (1907), No. 45, p. 1278, fig. 1*).—A description of a balance by which 6 flasks may be weighed at once, thereby effecting a saving of time in the volumetric estimation of butter fat.

Determining the energy value of urine, A. ZAITSCHEK (*Arch. Physiol. [Pflüger], 121 (1908), No. 8–10, pp. 550–557*).—As shown by the tests which the author reports, the energy value of urine can be accurately determined with a small bomb calorimeter of 70 cc. capacity.

Report of food commissioner and chemist, E. F. LADD (*North Dakota Sta. Rpt. 1907, pt. 2, pp. 9–164, figs. 9*).—The author reports the results of the examination of a large number of samples of preserves, jams, jellies, canned goods, cereal and breakfast foods, dried fruits, spices and extracts, meats, molasses and sirup, candy, alcoholic beverages, etc., under the provisions of the State law. Special attention is paid to the quantity of goods in cans, etc., as the State law now provides that every package, bottle or container shall display definite information regarding quantity. According to the author very few of the products sold in the State are now seriously adulterated, "but a great many are still misbranded, or, are not branded to show properly the true net weight or measure of the same."

A study of the character of burning oils carried on under the provisions of the State law led to conclusions summarized as follows:

"The flash point and fire test are means of safeguarding against the presence of gasoline and other light explosive products, but afford no complete protection against the sale of oils which are inferior as illuminants.

"The specific gravity, 46° B., now excludes an oil possessed of good illuminating power, while oils with a gravity of 47.3° B. are entirely worthless. Therefore, the gravity does not seem to indicate the true burning quality of an oil for illuminating purposes.

"To exclude the gravity test would work no hardship, but permit of the introduction of other oils, providing the photometric and distilling test be made an essential part of the enforcible features of the oil law.

"Changes in the specific gravity from 46° B. to 42° B., without any other safeguards, might result in the introduction of many inferior, even worthless, oils.

"The photometric test should be made an essential part of the law. . . .

"The distilling test should be emphasized, and at 310° F., not more than 6 per cent of the oil should distill over; and at 570° F., the residuum should not be more than 4 per cent.

"Not more than a trace of sulphur or other tar-like products should be permitted in oil intended for illuminating purposes.

"The Foster cup can not be recommended for the flashing test, but the Elliott closed cup should be made the standard.

"The oils tested, with the exception of [two samples] . . . , were all received from the State oil inspector, and represent the oils shipped into the State;

therefore, in no way tampered with, nor had they been stored by dealers in tanks not properly cleaned.

"The statement generally made that the housewife fails to keep her lamps properly cleaned, in the light of experiments heretofore reported upon, would not seem, in many cases, to be the real cause of failure to burn."

Division of pharmacy [report] by L. A. Brown (pp. 121–150, pls. 5).—Details are given of the examination of a large number of products and proprietary articles under the provisions of the State law.

Report of practical paint tests begun in 1905 by C. D. Holley (pp. 151–162).—The results of experimental tests of paint are summarized, but as the paints have been applied only for a year the author does not believe that final deductions can be drawn.

Annual report of the chemical section of the Hygienic Institute of the University of Halle, M. Klostermann (*Hyg. Rundschau, 18 (1908), No. 10, pp. 572–592*).—A report of the examination of a number of samples of meat and meat goods, milk, culinary fats and oils, water, wine, and other materials.

[Miscellaneous analyses]. E. F. Ladd (*North Dakota Sta. Rpt. 1907, pt. 1, pp. 36–41, 42–44*).—In 102 samples of formalin analyzed the formaldehyde content was found to range from 38 to 41.62 per cent. Analyses are also reported of proprietary stock feeds, linseed meal, bran, middlings, Paris green, sugar beets, and a soft black mineral product that oozes from the earth in the locality of lignite coal veins.

Commercial Sicilian sumac, F. P. Veitch and B. J. Howard (*U. S. Dept. Agr., Bur. Chem. Bul. 117, p. 32, pls. 3*).—Sicilian sumac (*Rhus coriaria*) is the best vegetable tanning material known for pale colors and soft tannage. Sumac-tanned leathers are less likely to be attacked by light and gas fumes, hence are well suited for bookbinding. A good quality of Sicilian sumac is high priced and dealers have complained that stems and other material are added. The culture and preparation of sumac for market are described. Italian laws require that adulterated sumac shall be so labeled.

Samples were submitted to both chemical and microscopical analysis. Contrary to results of English chemists the largest percentage of tannin was obtained by extracting above the temperature of 60° C. The most common adulterant found was *Pistacia lentiscus*. Others less common are *Coriaria myrtifolia, Tamarix africana, Ailanthus gladulosa, Vitis vinifera*, and other species of Rhus.

"Approximately 41 per cent of the invoices from which samples were taken [in 1905] were mixed with lentiscus, this being practically the only adulterant employed, except sumac stems, which were present in excessive quantities in a number of samples. The adulterated samples contained from 19.6 per cent to 33.3 per cent and averaged 26.6 per cent of tannin, or 2.2 per cent less than the average of all the sumac samples. A number of the samples contained an excess of sumac stems, and the average tannin content of these was 29.9 per cent, which indicates that the stems are not added in such large quantities as is the lentiscus. The samples of pure sumac contained from 27.4 to 35.1 per cent and averaged 31.9 per cent of tannin."

Investigations of 1907 showed that 25 per cent of the 53 samples examined were adulterated. The average available tannin of the 53 samples was 29.4 per cent and of the adulterated samples 26.3 per cent. Tables of analyses and details of the methods of the examination are given. One of the most reliable indications of adulteration is the color of the dried sample, lentiscus darkening greatly on heating.

Official and provisional methods of analysis, Association of Official Agricultural Chemists, edited by H. W. Wiley (*U. S. Dept. Agr., Bur. Chem. Bul.*

107, rev. ed., pp. XXI+272, figs. 13).—This is a revision of Bulletin 107 of the Bureau of Chemistry, previously noted (E. S. R., 19, p. 506), embodying further changes suggested by the association and adopted at the 1907 meeting.

Proceedings of the twenty-fourth annual convention of the Association of Official Agricultural Chemists, held at the Jamestown Exposition, Norfolk, Va., October 9–11, 1907, edited by H. W. Wiley (*U. S. Dept. Agr., Bur. Chem. Bul. 116, pp. 143*).—This is the official report of the proceedings of the convention. A summarized account of the meeting has been given (E. S. R., 19, p. 294), and a circular of the Bureau containing extracts from the proceedings noted (E. S. R., 19, p. 1010).

METEOROLOGY—WATER.

The relations between the meteorological elements of the United States and the solar radiation, F. H. Bigelow (*Amer. Jour. Sci., 4. ser., 25 (1908), No. 149, pp. 413–430, dgms. 4; abs. in Sci. Abs., Sect. A—Phys., 11 (1908), No. 10, p. 552*).—It is explained that temperatures in the United States are more largely the product of heat transported in the general circulation than of direct solar radiation, and in order to separate circulation from solar radiation the author analyzes data obtained by the Weather Bureau at 50 stations since 1873 on temperature, vapor pressure, and barometric pressure reduced to strictly homogeneous series. He also takes into account "the annual numbers of the solar prominences and the annual amplitudes of the European magnetic field," and studies their synchronism with temperature and vapor and barometric pressures of the United States in 11-year and 3-year periods.

"The synchronism is better defined in the Pacific States than east of the Rocky Mountains, especially in the short period. The amplitudes of the three elements (curves of temperature, barometer, vapor pressure) increase from south to north. In the long-period curves an increase in the prominence and magnetic-force numbers is always accompanied by a decrease in temperature and vapor pressure, but by an increase in the barometric pressure; in the short period the same rule holds for the east, but the reverse for the Pacific States, whose temperatures generally are the reverse of the central and eastern districts in the sense that the monthly residuals have opposite signs. This is explained by the circulation. The Pacific States may practically be considered as part of the tropical system, characterized by a quiescent state of the atmosphere and freedom from cyclonic circulation; part of the Rocky Mountains cyclones and high-pressure areas advance down the slope eastward."

The extension of this system of observation is urged since in the author's opinion "this subject will in the future assume large proportions, because it is the only way at all promising in which to lay the foundations for a system of seasonal forecasting. The Weather Bureau has now adjusted its records to the required standard of observation and computation for about 100 stations, and the future records will continue automatically to unroll the hidden story of the sun's influence upon the earth's weather and climatic conditions."

The moon and the weather, Jochimsen (*Fühling's Landw. Ztg., 57 (1908), No. 14, pp. 502–510*).—Data and arguments are presented to show that the moon does not control the weather to an appreciable extent.

Further notes on the difference of temperature between Mount Royal and the McGill College Observatory.—Local temperature forecasting, C. H. McLeod and H. T. Barnes (*Proc. and Trans. Roy. Soc. Canada, 3. ser., 1 (1907), Sec. III, pp. 3–7, dgms. 2*).—This is a third communication on the subject (E. S. R., 17, p. 224; 18, p. 813), and summarizes further records which confirm the conclusion that the differences in temperature at the mountain top and at the observatory, though small, are of value for local temperature forecasting. Ob-

servations by Church at Reno and on Mount Rose (E. S. R., 18, p. 529) are also referred to as confirming this conclusion.

Indications of approaching frost, R. Strachan (*Quart. Jour. Roy. Met. Soc. [London], 34 (1908), No. 145, pp. 47–50*).—Data are adduced to show that "in the majority of cases the evening dewpoint is no indication of frost unless the sky during the night becomes clear, or a radiation fog is on the ground with a clear sky above it. . . . For the purpose of making forecasts the psychrometer should be noted at or after sunset, or at 9 p. m., and the amount of cloud at the time, and during the fore part of the night if convenient. The dew-point can then be found by Glaisher's Hygrometrical Tables, or roughly by taking the difference between the two thermometers from the reading of the wet-bulb. When the dew-point is at or below 32°, frost is in evidence, but may be evanescent, due to a rise of temperature, with change of wind, rain, or overcast sky. Even when it is above 32°, if the sky is clear it is probable that the temperature on the ground will go low enough for frost to form."

A two years' study of spring frosts at Williamstown, Mass., W. I. Milham (*Mo. Weather Rev., 36 (1908), No. 8, pp. 250–254, fig. 1*).—This article gives reference to recent articles on frost prediction and protection, and summarizes the results of observations at 10 frost stations located in different parts of Williamstown. The following conclusions, which apply not only to Williamstown but probably to the whole of New England, are drawn from the results:

"The so-called spring frosts may be expected from the last of April until the first of June and occur on still, clear nights, with the wind almost invariably from the northwest. They are likely to come on the first or second night following the passage of a low and the transition of the weather control to an area of high pressure. This facilitates both the importation of colder air and radiation, the two processes which cause the low temperatures required. The air is so dry and the dew-point lies so low that it plays no part whatever in determining the amount of the drop from the maximum to the following minimum. The drop is, however, far from a constant, and must be estimated for each individual case, taking into account the probable characteristics of the afternoon and night.

"If, after the probable minimum temperature in the thermometer shelter has been estimated, it is desired to determine what the probable temperature of low-growing vegetation in the coldest part of the limited area will be, three things must be taken into account. First, that plant temperatures go below the real air temperatures, because the plants are in the open without such a hindrance to radiation as is the shelter about a thermometer; second, that vegetation is located near the ground and not at the height of the instruments in the shelter; third, that the variation in temperature over a limited area may amount to several degrees. Were this computation carried out with the average values for Williamstown, about 2° would be allowed for exposure in the open, 3° for height, and 6° for variation between the shelter and the coldest part of the area. Thus the temperature of vegetation in the open, near the ground, in the coldest part of the village may be expected to average 11° lower than the estimated minimum in the shelter as it is now located."

Monthly Weather Review (*Mo. Weather Rev., 36 (1908), Nos. 7, pp. 197–230, figs. 10, charts 6; 8, pp. 231–274, figs. 4, charts 9*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of July and August, 1908, recent papers bearing on meteorology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 7.—Rain-making in New Zealand; Report upon the Dry Period and Rain-making Experiments at Oamaru, New Zealand (illus.), by D. C. Bates; Inter-

national Exchange Service; Waterspout at Beaufort, N. C., by B. McGlone; and Australian Weather (illus.), by D. J. Mares.

No. 8.—Annual Rise of the Columbia River in 1908 (illus.), by E. A. Beals; The 1907 Annual Rise in the Columbia River; Storms and Ice on the Great Lakes, by N. B. Conger; Studies on the Vortices of the Atmosphere of the Earth (illus.), by F. H. Bigelow; A Two Years' Study of Spring Frosts at Williamstown, Mass. (illus.), by W. I. Milham (see p. 514); Government Meteorological Work in Brazil, by R. DeC. Ward; Further Observations of Halos and Coronas, by M. E. T. Gheury; The Observatory on Mount Etna; The Heaviest Rainfall in One Hour, by A. G. McAdie; and Studies in the Formation of Frost (illus.), by D. A. Seeley.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander and R. C. Lindblad (*Massachusetts Sta. Met. Buls. 237, 238, pp. 4 each*).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during September and October, 1908. The data are briefly discussed in general notes on the weather of each month.

[Meteorological observations at North Dakota Station], E. F. Ladd (*North Dakota Sta. Rpt. 1907, pt. 1, pp. 24–33*).—This includes, as in previous years, summaries of temperature and rainfall, monthly record of sunshine, and record of wind velocity. The mean annual temperature of 1907 was 37.26° F., the rainfall 15.34 in.

Annual report of the director of the [Philippine] Weather Bureau for the year 1905, J. Algué (*Ann. Rpt. [Philippine] Weather Bur., 1905, pt. 2, pp. 386*).—A record of meteorological observations at the secondary stations in 1905.

Evaporation from water surface, E. F. Ladd (*North Dakota Sta. Rpt. 1907, pt. 1, pp. 33–36*).—This is a record of a continuation of observations on evaporation from the surface of water contained in a galvanized iron tank, the evaporation during 1907 being compared with that of 5 previous years and with the rainfall during the same period.

Rain and run-off near San Francisco, California, C. E. Grunsky et al. (*Proc. Amer. Soc. Civ. Engin., 34 (1908), Nos. 4, pp. 339–358, pl. 1, figs. 2; 6, pp. 640–660, pl. 1, fig. 1*).—This article discusses the results of a study of the rainfall and run-off of the basins tributary to three storage reservoirs supplying water to San Francisco.

Fluctuations in the level of the ground water and in the flow of springs, C. Mezger (*Gsndhts. Ingen., 31 (1908), No. 32, pp. 501–511, figs. 10*).—The influence of precipitation, atmospheric pressure, temperature, direction of the wind, and other factors upon fluctuations in ground water and flow of springs is quite fully dealt with in this paper.

The removal of iron from potable waters in Germany and the Netherlands, H. Schwers (*Rev. Hyg. et Pol. Sanit., 30 (1908), Nos. 8, pp. 643–673, dgms. 9, map 1; 9, pp. 756–786; 10, pp. 846–878*).—The methods used and their efficiency are discussed at considerable length.

Sterilization of drinking water by chemical agents, H. Labbé (*Rev. Sci. [Paris], 5. ser., 10 (1908), No. 11, p. 343*).—Various processes, particularly those making use of iron and manganese salts, are briefly described.

Sewage and waste waters of industries, P. Razous (*Eaux d'Égout et Eaux Résiduaires Industrielles. Paris, 1908, pp. 192, illus.; rev. in Rev. Sci. [Paris], 5. ser., 10 (1908), No. 7, p. 222*).—This book discusses irrigation and biological processes of purifying sewage, and describes various methods of handling waste water from industrial establishments, such as starch factories, cheese factories, breweries, wine-making establishments, tanneries, dye houses, and abattoirs.

The rôle of the septic tank in the biological purification of sewage water, A. Calmette and E. Rolants (*Rev. Hyg. et Pol. Sanit., 30 (1908), No. 8, pp. 633–643*).—The authors take issue with those investigators who assert that the action of septic tanks is purely mechanical, and report investigations which show that a large amount of decomposition of putrescible substances occurs in the tanks, only the difficultly decomposable materials remaining behind and being precipitated.

Comparison of broad irrigation and intensive biological purification of sewage, Bezault (*Abs. in Rev. Sci. [Paris], 5. ser., 10 (1908), No. 6, pp. 181, 182; Engrais, 23 (1908), No. 39, pp. 926, 927*).—Some objections to the use of irrigation as the sole means of disposal are pointed out.

The agricultural utilization of sewage, Bechmann et al. (*Ann. Sci. Agron., 3. ser., 3 (1908), I. pp. 180–193*).—This is a summary of reports on this subject made to the Eighth International Congress of Agriculture at Vienna in May, 1907. The present status of sewage irrigation in different countries is briefly presented and the advantages and disadvantages of this method of disposal are pointed out. It is shown that under certain conditions sewage irrigation has been successfully used as a means of disposal, but that in many cases it is impracticable on account of the large area of land required. For this reason it has been found in many cases desirable to combine sewage irrigation with other methods of purification.

[Sewage irrigation at Pasadena], W. J. Wright (*Mich. Farmer, 131 (1908), No. 3, p. 43, figs. 2*).—This is a brief account of the use of sewage by the city of Pasadena in the growing of hay, grain, pumpkins, walnuts, and fruit.

The importance of the agricultural utilization of town sewage on the Posen sewage farm to the drain tile and agricultural machinery industry, A. Wulsch (*Gsndhts. Ingen., 31 (1908), No. 35, pp. 549–552, fig. 1*).—Data regarding the cost of installation of the drainage system and of the machinery required on the sewage farm are given.

SOILS—FERTILIZERS.

Soils: Their nature and management, P. McConnell (*London, 1908, pp. XII+104, pl. 1, figs. 10; rev. in Nature [London], 78 (1908), No. 2016, p. 150*).—This is a short practical treatise for the use of the British farmer and gardener. It discusses from the practical man's standpoint the origin, composition, classification, distribution, physical properties, improvement, tillage, and management of the soils of Great Britain. The book also discusses the physical geography of the farm and gives suggestions regarding the selection of farms.

On transported soils with especial reference to the Roman Campagna, G. de Angelis d'Ossat (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 17 (1908); I, No. 7, pp. 439–448, figs. 5*).—The author shows by means of diagrams how transported soils increase in complexity from the head of a valley downward according to the various strata cut through and formulates the following law: The agricultural value of a transported soil is equal to the algebraic sum of the elements of each generating rock, taking account, however, of the transformations undergone.

Results of tests of soil samples taken in the valley of the Teverone River are given which show a high percentage of carbonate of lime. This accounts in part for the fact that the chief characteristic of the transported soil of the Tiber Valley is carbonate of lime.

Study of Belgian soils (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), No. 5, pp. 543, 544*).—The results of analyses of 47 typical soils and subsoils of Belgium are briefly discussed in this article, attention being called especially to the deficiencies and fertilizer requirements of the different soils.

Nature of the soils of Morocco (*Bul. Mens. Off. Renseig. Agr.* [*Paris*], 7 (*1908*), *No. 5, pp. 564–566*).—The soils of Fez are briefly considered in this article. They are grouped as cultivated soils and pasture soils, there being several subdivisions of each group. Chemical analyses of typical samples of red and black clay and sandy soils are reported.

Report of Adzhibay Experiment Field for 1904 to 1906, D. P. Shushak (*Adzhibaĭskoe Opuitnoe Pole. Otchet za 1904, 1905, i 1906. Simpheropol, Russia, 1907, pp. 91; rev. in Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *8* (*1907*), *No. 6, pp. 709–711*).—Observations on the influence of fallow, fertilizers, and cultivation on the physical, chemical, and biological properties and processes of the soil are recorded in this report.

On the rate of some phenomena of weathering, P. Zemyatchenskiĭ (*Trav. Soc. Imp. Nat. St. Petersb., Sect. Géol. et Min., 34* (*1906*), *No. 5, pp. 181–190; abs. in Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *8* (*1907*), *No. 6, p. 707*).—The author observed that in certain ruins in Austria there has formed from limestone during 500 to 600 years a soil layer 10 cm. thick with 4.4 per cent of humus, while on the adjoining natural deposits of limestone the soil layer has a thickness of 38 to 40 cm. with 7.7 per cent of humus. On the basis of the rate of the formation of the soil on the ruins, 2,400 years should have been required for the formation of the 38 to 40 cm. soil layer. On a fortress wall of limestone in the Crimea, which has been exposed to weathering during 600 years, a soil layer 10 cm. thick has formed. The adjoining lands have a soil layer 65 cm. in thickness which should have accordingly required 3,600 years for its formation.

Some laboratory experiments on the capillarity of soils, N. Tulaykov (*Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *8* (*1907*), *No. 6, pp. 629–666, figs. 3*).—The experiments were made with soils from the Muganj steppe, with the object of clearing up some details of the process by which the soils of that region are turned into alkali lands. See also a previous note (E. S. R., 18, p. 818).

The capillary rise of water was studied in sandy soil from 7 different depths and a clay loam from 5 different depths, the samples of soil after passing a sieve with 2 mm. mesh being carefully packed in glass tubes 3 cm. in diameter and 150 cm. long. In the case of a coarse-grained sandy soil the capillary rise was rapid at first—55 cm. during the first 24 hours. The water had reached a height of 135 cm. in 513 days and was still slowly rising. In a fine-grained clay soil the water rose 52 cm. in the first 126 days and apparently became stationary at 65 cm. after 1½ years. In other soils of this kind, however, the rise was considerably higher and did not become stationary after 1½ years.

In different layers of a sample of clay soil the height of rise of water during the first 30 days was inversely proportional to the content of particles less than 0.005 mm. in diameter. The velocity of rise in the early stages was greater the larger the soil particles, but it decreased in the course of time more rapidly in coarse-grained than in fine-grained soils. Where the layers of soil were arranged in the tubes in the order in which they occurred in nature the rise of water seemed to depend entirely upon the capillary capacity of the lowest layer immediately in contact with the water supply.

An experiment was begun on February 15, 1906, to study the relation of capillary rise of water to movement of alkali salts. On November 28 the water had risen to a height of 150 cm. and on January 4, 1907, needle-shaped white crystals of salts were observed on the surface of the soil. On March 4 the tube was cut into sections of 10 cm. in length and the salt content of each section determined. The data thus obtained showed a gradual and more or less complete transport of the salts from the lower to the upper layers. Thus the first upper section

contained before the experiment 0.59 per cent of salts, and after the experiment 6.61 per cent, while the lowest three sections, the salt content of which was originally 1.95 per cent, retained at the end of the experiment, respectively, 0.09, 0.06, and 0.33 per cent. The surface of the soil in the tube presented the typical appearance of alkali land.

An examination of the water content in the different sections of the soil after the water had risen to the surface showed that only near the source of the water supply was the soil completely saturated, while the upper layers contained only about one-half of their full capacity.

On comparing the rate of the movement of the water in a vertical and in a horizontal tube it was found that the same distance was covered in a horizontal tube in an hour as would take a month in a vertical tube.

Effect of carbon bisulphid on soils and plants, M. A. Egorov (*Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *9 (1908), No. 1, pp. 34–95; abs. in Jour. Chem. Soc.* [*London*], *94 (1908), No. 547, II, p. 421*).—The author's experiments show that the capacity of the soil for moisture is reduced by treatment with carbon bisulphid and that the particles of the treated soil are less easily moistened than those of untreated soil. In vegetation experiments, however, treatment with carbon bisulphid increased the yield of oats. On examining the soil after removing the crops it was found that carbon bisulphid still remained in all pots to which it had been applied, proving that the entire growth of the plants had been made in the presence of carbon bisulphid.

The favorable influence of the bisulphid is usually accounted for by its action on the nitrogen of the soil, but the author could not discover an increase of the nitrogen content of either the soil or the crop produced. An increase of the nitrogen content of the soil took place only after the removal of the carbon bisulphid. In the opinion of the author the effect of carbon bisulphid consists in stimulating the growth of the plants, and he reports experiments which showed that etiolated germs of Jerusalem artichoke and pumpkin grew better in solutions of 0.03 to 0.06 cc. of carbon bisulphid or ether per liter of water than in pure water.

Investigations on nitrification, L. C. Coleman (*Centbl. Bakt.* [*etc.*], *2. Abt., 20 (1908), Nos. 12–14, pp. 401–420; 15–17, pp. 484–513; abs. in Jour. Chem. Soc.* [*London*], *94 (1908), No. 546, II, p. 315; Chem. Ztg., 32 (1908), No. 31, Repert., p. 206; Chem. Zentbl., 1908, I, No. 14, p. 1415*).—Investigations are reported on the influence of dextrose and other substances on nitrification in the soil; the influence of moisture on nitrification and denitrification and on the action of dextrose in the soil; on pure cultures of nitrate organisms and the influence of dextrose on the activity of such organisms; experiments with nitrite organisms; the carbonaceous food of nitrate organisms and the assimilation of carbon by such organisms; and the influence of carbon bisulphid on nitrification in soils.

It was found in these investigations that nitrification was considerably increased in nonsterilized soils by the addition of small amounts (0.5 per cent) of dextrose, the greatest increase being observed in the second and third weeks. Subsequently the effect decreased and denitrification due to organic matter increased.

Cane sugar, glycerin, and lactose in small amounts seemed to have a favorable effect on nitrification. Calcium butyrate seemed to have no effect, while calcium acetate apparently retarded nitrification. Peptone and urea (0.5 and 0.75 per cent, respectively) greatly retarded nitrification.

Nitrification was most active in loam soil with a moisture content of 16 per cent. It was greatly retarded when the water content was reduced to 10 per cent or increased to 26 per cent. With the higher percentage of water the addition of dextrose was injurious rather than beneficial.

The activity of nearly pure cultures of nitrate and nitrite organisms in sterilized sand or soil was increased by the addition of 0.02 and 0.05 per cent of dextrose. Under similar conditions the activity of pure cultures of the nitrate organism was increased by the addition of 0.05 per cent of dextrose. A supply of carbon dioxid is necessary for both the nitrate and the nitrite organisms whether dextrose is added or not. Carbon bisulphid retarded nitrification at first, but afterwards increased it, probably as a result of stimulating action.

Course of nitrification under the conditions of field experiments, S. Frankfurt and A. Duschechkin (*Vyestnik Sakh. Promuish., 1907; abs. in Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *8* (*1907*), *No. 6, pp. 707, 708*).—Determinations of nitric acid and ammonia in the soils of fields of the Russian Society of Sugar Manufacturers, which have been under experiment during a number of years, are reported, the object being to ascertain the influence of barnyard and green manures on the course of nitrification. During the years 1903 to 1906 determinations were also made of nitrate and ammonia nitrogen in soil planted to beets and in unplanted soil.

Some of the main results were as follows: An increased nitrification was observed only on those fields on which the manure raised the yield. Large quantities of straw manure did not lower the content of nitrate nitrogen in the soil. Green manures lowered the content of nitrate and ammonia nitrogen in the soil, and in this respect there seemed to be no difference between leguminous and nonleguminous plants. The effect of the green manure is attributed to changed moisture conditions resulting from the cultivation of green-manuring plants.

Periodic observations on the content of nitrate and ammonia nitrogen in the soil showed these to be very variable, but no close connection between the variations of the nitrate and ammonia nitrogen in the soil was observed. The soil not occupied by beets always showed a higher nitrate content than soil planted to beets. This difference is accounted for not only by the consumption by the plants of the nitrates of the soil but chiefly by the greater humidity of the soil not occupied by the plants.

The effect of carbonates upon nitrification, W. L. Owen (*Georgia Sta. Bul. 81, pp. 42, pls. 4, figs. 4*).—This bulletin discusses the importance and advantages of nitrification in relation to plant growth. In view of the importance of nitrification (1) in supplying the plant with highly available nitrogen, and (2) in preventing the loss of nitrogen from decomposing organic matter, the author undertook investigations having as their object the discovery of the best means of stimulating the activity of the nitrifying organisms.

The investigations here reported dealt with "the extent to which nitrification depends on the supply of carbonates present, and what forms of carbonates are most conducive to nitrification." In order to determine these points series of experiments were undertaken on (1) the effect of increasing amounts of carbonates on the nitrification of a given amount of ammonia; (2) the relative values of potassium, magnesium, and calcium carbonate in their effect on nitrification; and (3) the nitrification of an equal amount of ammonia in (a) ordinary culture flasks, (b) special flasks so constructed as to admit of air deprived of its carbon dioxid content, and (c) flasks to which carbon dioxid is supplied in excess.

"Pure cultures of the Nitrosomonas and Nitrobacter were obtained by inoculating with 3 gm. of garden soil a medium of the following composition: Ammonium sulphate 1 gm., potassium phosphate 1 gm., magnesium carbonate 5 gm., distilled water 1,000 cc. This medium was sterilized by the intermittent method for 15 minutes on each of three consecutive days. The flask containing the inoculated medium was placed in an incubator and kept for several days at a

temperature of 37.5° C., at the end of which time microscopical examinations were made in order to determine whether the nitrifiers were present. In most cases there was little difficulty in obtaining pure cultures by this method, for the media used being entirely inorganic there was but little danger of contamination. But in order to be assured of the purity of the stock cultures used in the experiments, an inorganic solid medium was prepared by thoroughly washing agar-agar until the impurities and organic matter were dissolved, and then adding the inorganic salts used in the liquid stock cultures. The medium was prepared by adding 15 gm. of agar-agar to a liter of distilled water, dissolving it by heating over a radial stove, and then distributing equally among 4 large flasks. To each of these flasks was added distilled water in sufficient quantities to fill them, and this supply was renewed daily for 2 weeks. At the end of that time the agar had been thoroughly washed, and its organic matter largely lost in the process. The 4 flasks were then placed in an Arnold steam sterilizer and the agar having been thoroughly dissolved, the inorganic salts were added in the proportions used in the preparation of the liquid media for stock cultures.

"The medium thus made was then sterilized in an Arnold sterilizer in the usual manner, after which it was inoculated from the liquid culture and plated out in petri dishes. The colonies that developed on this medium were soon identified by means of microscopical examinations, as being Nitrosomonas and Nitrobacter, and transfers were then made to a flask containing liquid media of the same composition as that from which the agar was inoculated.

"The stock cultures thus prepared proved very satisfactory, and this method of isolating the organisms was used almost entirely in the investigation. The use of washed agar gave much better results than that of Winogradski's silicic acid medium, since the colonies developed more rapidly upon the former, and the agar having a smoother surface, the bacterial development was more clearly defined, and therefore more easily detected."

Culture media in which the supply of carbon in inorganic form (magnesium carbonate, calcium carbonate, potassium carbonate, and free carbon dioxid) varied were inoculated with these organisms and the rate of formation of nitrites and nitrates noted.

A special flask designed by the author for the investigations which required the elimination of the carbon dioxid of the air is described.

The author concludes from the results obtained that nitrification is affected by carbonates and that magnesium carbonate is more efficient than the other carbonates tested in promoting the growth of nitrifying organisms. He also concludes that "the nitrifying organisms of the soil do not depend to any appreciable extent on the carbon dioxid of the air for their carbon supply."

On the present state of knowledge of micro-organisms which fix free nitrogen, L. Palmans (*Ann. Gembloux, 18 (1908), No. 5, pp. 289–309*).—This is a review with a bibliography of 60 references to literature of investigations on the subject.

Utilization of the nitrogen of the air by plants, T. Jamieson (*Ann. Sci. Agron., 3. ser., 2 (1907), I, pp. 1–46*).—This is a reprint in French of a revision of the original paper on this subject (E. S. R., 19, p. 127).

Nitrogen fixation for nonleguminous plants, W. B. Bottomley (*Country Life [London], 23 (1908), No. 598, pp. 899, 900, figs. 5*).—This article briefly discusses the possibility of aiding the growth of nonleguminous plants by inoculation of the soil with nitrogen assimilating organisms, and refers to recent experiments by the author with oats, barley, cabbage, turnips, radishes, beets, strawberries, etc., which it is claimed have given promising results.

Do roots assimilate nitrates? P. Slezkin (*Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 9 (1908), No. 1, pp. 27–33, figs. 4*).—The author conducted vegetation experiments in vessels divided into 4 sections, each containing a different nutritive solution, thus making it possible to transfer the roots of a plant at different stages of growth from one solution to another. In one case a long root from a nitrate solution was so bent that it was partly immersed in the nitrate solution and partly in a solution containing calcium phosphate. In the latter solution new shoots soon appeared, while the part of the root in the nitrate solution remained smooth as before. On the other hand, a root from a solution containing calcium phosphate partly bent over into a nitrate solution continued to strongly develop in the former, new shoots appearing and old secondary roots growing considerably, while the part in the nitrate solution did not increase in length and formed only rudimentary shoots. The conclusion is drawn from these experiments that if the growth of the roots is an indication of independent assimilation, roots assimilate only phosphoric acid and do not assimilate nitrates.

Note on a toxic substance excreted by the roots of plants, F. Fletcher (*Mem. Dept. Agr. India, Bot. Ser., 2 (1908), No. 3, pp. 16, pl. 1; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 549, II, p. 617*).—From observations on cotton, sorghum, cajanus, and sesame grown side by side in field plats and on the same crops, and wheat and gram, grown in water cultures, the conclusion is reached that plant roots excrete a substance which is injurious to other crops. This seems to be especially pronounced in case of sorghum. The results both in the field and in water cultures indicate that the substances excreted by various plants are identical. Chemical tests of the substances obtained in water cultures indicate that they are alkaloidal in character.

"The amount of substance given out by the roots is not inconsiderable. For instance, the precipitate obtained by adding potassium sulphate to a solution containing the excrement of 10 cotton plants growing until their combined air-dry weight was 0.4 gm. weighed, when dry, 0.21 gm.

"Sesamum in its early stages of growth appears actually to excrete a greater amount of material than it builds up in its own substance." See also a previous note (E. S. R., 19, p. 822).

An alleged excretion of toxic substances by plant roots (*Nature [London], 78 (1908), No. 2026, pp. 402, 403*).—Reviewing recent investigations on this subject, including especially those of the Bureau of Soils of this Department and of F. Fletcher, the conclusion is reached that "we can not consider that the question of root excretion has been materially advanced in any of these publications."

The productiveness of the soil: Biological factors, J. Massart (*Ann. Gembloux, 18 (1908), No. 6, pp. 347–353, pls. 6*).—This is a review of work of the Bureau of Soils of this Department on the relation of toxicity to fertility of soils. For another article of this series see a previous note (E. S. R., 19, p. 1015).

Further soil tests in paraffined wire baskets, B. L. Hartwell and F. R. Pember (*Rhode Island Sta. Bul. 131, pp. 15–31*).—This bulletin contains an account of a continuation of work previously reported in Bulletins 120 and 121 of the station (E. S. R., 19, p. 317), "and concludes the comparison of the results of soil tests in the field with those secured by the 'wire-basket method for determining the manurial requirements of soils,'" which were made in cooperation with the Bureau of Soils of this Department.

"Results by the basket method, with soils from eight different localities in the State during two seasons, are presented. In certain cases, first and second trials have been made with the same soil during the same season.

"The frequent failure of the method to secure at different times similar indications regarding the deficiencies of a given soil, even when carried out in the same manner, is the most discouraging feature concerning the usefulness of the method.

"The many instances of disagreement between the results by the basket method and those secured in actual field practice render unreliable the indications which the method in its present form affords regarding the manurial requirements, at least of certain soils.

"The addition of muriate of potash resulted in a retardation of the transpiration as compared with its effect on the green weight of the tops. The average difference in the percentage change according to the two criteria of growth was equal to 10 per cent, an amount of sufficient importance to make it seem desirable in work of this kind to adopt the weight of the green crop rather than the transpiration as a measure of the manurial effect of such salts, owing to their tendency to retard transpiration."

Notes on humus and the best means of supplying it, F. B. Guthrie (*Agr. Gaz. N. S. Wales, 19 (1908), No. 3, pp. 200–205*).—This article discusses briefly the functions of humus and the methods of supplying it through barnyard manure, compost, and green manures. It also includes the results of some experiments in which the amount of material and proportion of nitrogen supplied to the soil in green-manuring crops of vetches (roots and tops) were determined.

Technique of fertilizers, J. Dumont (*La Technique des Engrais. Paris, 1908, pp. 432; rev. in Chron. Agr. Vaud, 21 (1908), No. 12, pp. 297, 298*).—This is an extension and revision of the author's treatise on the Rational Use of Fertilizers, published several years ago (E. S. R., 5, p. 1098), and deals especially with specific conditions under which fertilizers may be used with advantage, although the general theories of fertilization are also discussed.

Analyses of commercial fertilizers, B. L. Hartwell et al. (*Rhode Island Sta. Bul. 130, pp. 11*).—"This bulletin contains the analyses of such potato and vegetable fertilizers as were found on sale in Rhode Island during the spring of 1908, as well as certain other brands carrying guaranties similar to those usually accompanying potato fertilizers. The analyses of the samples of ground bones which were collected in 1908 are likewise included."

Fertilizer experiments (*Dept. Landb., Nijv. en Handel, Verslag. en Meded. Dir. Landb. [Netherlands], 1908, No. 1, pp. 1–26*).—Experiments with barnyard manure, lime, nitrate of soda, sulphate of ammonia, lime nitrogen, guano, superphosphate, potash salts, and other materials are reported.

On the nitrification of certain nitrogenous fertilizers, S. de Grazia (*Rend. Soc. Chim. Roma, 6 (1908), No. 2, pp. 40, 41*).—In a series of experiments on the rate of nitrification of sulphate of ammonia, calcium cyanamid, and dicyandiamid on sandy, clay, humus, and calcareous soils it was observed that on all soils nitrification was very slow or did not occur at all except in the case of sulphate of ammonia. Denitrification occurred at first and nitrification had hardly begun at the end of 4 months. In case of the dicyandiamid almost no nitrification occurred.

The physiological action and the fertilizing value of salts of dicyandiamid, R. Perotti (*Rend. Soc. Chim. Roma, 6 (1908), No. 7, pp. 124, 125*).—Soil organisms grew normally and seeds of wheat, corn, clover, and mustard developed normally in nutritive solutions containing 0.25 per cent of the sulphate or chlorid of dicyandiamid. Injurious effects were observed when the proportion was increased to 1 per cent. In pot experiments with normal soil sprinkling with 1 per cent solutions at the rate of 4 to 5 quintals per hectare (about 350 to 450 lbs. per acre) was not injurious, and there was no evidence of nitrogen hunger. There was no evidence that the dicyandiamid was very

corrosive as asserted by Frank. The author believes that such corrosive action as is observed should be ascribed to the cyanamid, for in normal soils of alkaline reaction dicyandiamid or even its sulphate can have but a brief existence in the soil, being rapidly changed to ammonia.

The properties of calcium cyanamid in relation to water, air, and bacteria, L. Grandeau (*Jour. Agr. Prat., n. ser., 15 (1908), No. 21, pp. 645, 646*).—This is a brief summary of the main conclusions from investigations by Wagner (E. S. R., 19, p. 627) on this subject.

Recent work on calcium cyanamid and its fertilizing value, L. Grandeau (*Jour. Agr. Prat., n. ser., 15 (1908), No. 20, pp. 613, 614*).—This is a brief summary of the main conclusions drawn from recent work by Immendorff and Wagner (E. S. R., 19, pp. 424, 627), relating especially to the chemical and biological changes which occur in calcium cyanamid in the soil.

Transformation of the nitrogen of calcium cyanamid in cultivated soils, L. Grandeau (*Jour. Agr. Prat., n. ser., 15 (1908), No. 23, pp. 709–711*).—This is a brief review, mainly of work by Wagner (E. S. R., 19, p. 627) on the rate of transformation in the soil of the nitrogen of cyanamid into ammonia and nitric acid, showing that the rate of such transformation is to a large extent dependent upon the character of the soil.

Investigations on the gaseous products of decomposition of lime nitrogen and their effect on plant growth, E. Haselhoff (*Landw. Vers. Stat., 68 (1908), No. 3–4, pp. 189–228; abs. in Chem. Ztg., 32 (1908), No. 48, Repert., p. 311; Chem. Zentbl., 1908, I, No. 26, p. 2199; Jour. Chem. Soc. [London], 94 (1908), No. 550, II, p. 728*).—It is shown that in the decomposition of lime nitrogen in water, ammonia, acetylene, hydrogen phosphid, and hydrogen sulphid are formed. It was found that these gases exert an injurious effect on germination, and this effect is to be attributed primarily to free ammonia and hydrogen phosphid. The results of pot experiments and water cultures showed the injurious effect of these gases on growing plants, and in the water cultures hydrogen sulphid was also found to be decidedly injurious. Injurious effects of acetylene were not observed.

Fertilizer experiments with lime nitrogen on winter grain and sugar beets, A. von Liebenberg (*Ztschr. Landw. Versuchsw. Österr., 11 (1908), No. 3, pp. 153–180*).—The lime nitrogen was less effective than nitrate of soda and sulphate of ammonia on the grain, apparently being slower in action. With sugar beets the results reported are inconclusive.

Experiments in 1907 with nitrate of lime in comparison with nitrate of soda, R. de Limay (*Bul. Soc. Agr. France, n. ser., 40 (1908), May 1, Sup., pp. 286–289*).—Experiments with oats and barley are briefly noted, in which the effect of the two nitrates was practically the same.

Cold, the checking of growth, and the use of nitrates, L. Grandeau (*Jour. Agr. Prat., n. ser., 15 (1908), No. 18, pp. 549, 550*).—Attention is called to the beneficial effect of applications of nitrate of soda in overcoming injury by cold in case of cereals, potatoes, beets, asparagus, and other vegetables.

The manufacture of nitrates, E. Bazin (*Bul. Soc. Agr. France, n. ser., 40 (1908), May 1, Sup., pp. 323–328, figs. 2*).—The construction of a peat niter bed on the principle described by Müntz and Lainé (E. S. R., 18, p. 430) is described.

Atmospheric nitrogen as a future commercial source of plant food, L. L. Van Slyke (*West. N. Y. Hort. Soc. Proc., 53 (1908), pp. 100–108*).—This is a summary of information regarding the commercial sources of inorganic nitrogen compounds used in agriculture; different methods of utilizing atmospheric nitrogen, including methods of preparing and using nitrogen compounds derived

from this source; and a discussion of future possibilities in commercial production of nitrogenous plant food.

Experiments with feldspathic rock as a source of potassium, B. L. Hartwell and F. R. Pember (*Rhode Island Sta. Bul. 129, pp. 197–206, pl. 1*).—This bulletin refers to experiments by this Department on finely ground feldspathic rocks as a source of potash for plants and reports water cultures with wheat seedlings in which varying amounts of fine ground feldspar were used alone or in combination with potassium chlorid and ground quartz, together with pot experiments with wheat in which fine ground feldspar and sulphate of potash were compared in varying amounts.

It was found in the water cultures that the addition of feldspar and of quartz to 32 parts per million of potassium in form of potassium chlorid increased the green weight of plants, the quartz being practically as efficient in this respect as feldspar. There was no evidence that this increase was due to the potash of the feldspar.

In the pot experiments feldspar was apparently unable to supply the deficiency of potash in a soil very poor in this element. "The maximum increase with the feldspar was only 18 per cent, whereas the maximum application of sulphate of potash increased the yield about one and one-half times, or 148 per cent.

"An average of the results from the three different applications reveals the fact that, even though 5.5 times as much ground feldspar as sulphate of potash was used, in order to supply an equal amount of potassium, the yield was increased ten times as much with the sulphate of potash as with the feldspar. From the standpoint of crop production, then, the sulphate of potash was in this case 55 times more valuable than an equal amount of ground feldspar."

Investigations on the formation of oceanic salt deposits, J. H. Van't Hoff (*Sitzber. K. Preuss. Akad. Wiss., 1908, No. 22, pp. 436–439*).—This is the conclusion of this series of contributions, and explains a cooperative plan for scientific study of the German potash deposits.

Contribution to the knowledge of the natural factors involved in the solution of tricalcium phosphate in the soil, R. Perotti (*Atti R. Accad. Lincei. Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 17 (1908), I, No. 7, pp. 448–451, fig. 1; Rend. Soc. Chim. Roma, 6 (1908), No. 4, pp. 64, 65; abs. in Chem. Zentbl., 1908, I, No. 22, p. 1945; Jour. Chem. Soc. [London], 94 (1908), No. 548, II, p. 527; Jour. Soc. Chem. Indus., 27 (1908), No. 13, p. 696*).—From experiments with different soil organisms in culture media using various sources of nitrogen—ammonium tartrate and sulphate, potassium nitrate, urea, and asparagin—the author concludes that in media containing physiologically acid salts, as, for example, ammonium sulphate, there is a uniformly important solution of tricalcium phosphate, while this action is insignificant in media containing physiologically alkaline salts, such as sodium nitrate.

Tests of the use of gypsum as a fertilizer, C. Dusserre (*Ann. Agr. Suisse, 9 (1908), No. 1, pp. 7–9*).—Tests of the effect of gypsum on the yield of potatoes, beets, oats, and wheat are reported, showing that in case of potatoes and beets the application of gypsum greatly increased the yield. In case of potatoes the mineral matter and starch were also considerably increased by the use of gypsum. In case of sugar beets the proportion of lime and potash in the ash was slightly increased on the gypsum plats.

In laboratory experiments it was found that the mixture of gypsum with soil resulted in a considerable increase in the amount of potash extracted by pure water. If the amount of potash extracted by pure water from untreated soil be taken as 100, that extracted from soil containing gypsum was 127, from

soil containing Thomas slag 104, and from soil containing calcium superphosphate 492.

Mineral resources of the United States, calendar year 1906, D. T. Day et. al. (*U. S. Geol. Survey, 1907, pp. 1307, figs. 2*).—This is the usual detailed report on this subject. The chapter of greatest agricultural interest is that relating to phosphates, a preliminary summary of which has already been noted (E. S. R., 19, p. 422).

Regarding the future of the guano industry and the guano-producing birds of Peru, R. E. Coker (*Bol. Min. Fomento [Peru], Dir. Fomento, 6 (1908), No. 4, pp. 25–34; Science, n. ser., 28 (1908), No. 706, pp. 58–64; Amer. Fert., 29 (1908), Nos. 4, pp. 10–12; 5, pp. 20–22, fig. 1*).—This paper is substantially a reprint of a report recently submitted to the Peruvian Government. It describes briefly the past exploitation and present status of this industry and suggests methods by which it may be saved from entire destruction. It is explained that the present system of exploitation results in the continual disturbance and gradual extermination of the birds which produce the guano. It is believed that this may be corrected to some extent by placing the extraction of guano in the hands of a single company, and providing for a rotation in the working of the deposits and a closed season with increased protection for the birds.

Production and extraction of guano, R. E. Coker (*Mem. Dir. Fomento [Peru], 1907–8, vols. 1, pp. XCIII, XCIV, pl. 1; 2, pp. 5–30, pls. 6*).—This is the full text of the report referred to in the above abstract.

Utilization of wrack, A. Swalm (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3171, pp. 6, 7*).—A brief note regarding the use of seaweed as a fertilizer and for the manufacture of iodin on the Island of Jersey and the south coast of England.

City household garbage, L. Danger (*Illus. Landw. Ztg., 28 (1908), No. 37, pp. 327, 328*).—The composition, fertilizing value, and methods of using this material are discussed. Raw garbage is considered of little value or even may be positively injurious as a fertilizer. When treated, as is done in the garbage works of Altona, near Hamburg, by careful sorting, the fine garbage has considerable fertilizing value, comparing favorably with barnyard manure.

Utilization of household wastes, Bocher (*Bul. Soc. Nat. Agr. France, 68 (1908), No. 3, pp. 147–163*).—Incineration, grinding, and other methods of handling garbage are discussed and methods employed by various municipalities are briefly described. Incineration is condemned. Grinding as practiced at the Vitry factory is recommended because of the value of the products obtained, viz, from 100 tons of raw garbage 80 to 85 tons of inodorous fertilizer equal in value to farmyard manure and 15 to 20 tons of waste valuable as fuel.

Apparatus and transportation appliances for utilizing and handling dead animals and slaughterhouse refuse, Fränkel et al. (*Arb. Deut. Landw. Gesell., 1908, No. 139, pp. 159, figs. 35*).—This article deals in detail with the mechanical construction and operation of the apparatus and appliances, the handling of the liquid wastes, value of the products, and adaptability and selection of the apparatus. An appendix gives the police regulations adopted in connection with the Dieburg establishment.

AGRICULTURAL BOTANY.

The physiology of stomata, F. E. Lloyd (*Carnegie Inst. Washington Pub. 82, pp. 142, pls. 14, figs. 40*).—A study was made of 2 types of desert plants (*Fouquieria splendens* and *Verbena ciliata*) to determine some facts relating to the physiology of stomata. Neither of these plants has any special stomatal

modifications to regulate transpiration. The investigations were carried on to determine the alleged regulation of water loss by the stomata and the physiological causes of stomatal movement.

On the theory of stomatal regulation of water loss, a close correlation would be expected between the daily periodicities of transpiration and of stomatal movement. The rate of transpiration, however, was found to increase for a considerable period after the maximum stomatal opening had been reached. The diminution in the rate of transpiration during the latter part of the day may be interrupted by intervals of increase without any interruption in the diminution of stomatal dimensions. Such conclusions throw doubt on the accuracy of the view of stomatal regulation as suggested above.

It was found that the rate of transpiration may undergo sudden and wide changes without the accompaniment of a sufficient change in the dimensions of the stomata to account for them on this theory. It appears that stomatal regulation of transpiration does not occur, although conservation of the contained water follows the complete closure of the stomata.

Observations on the changes in the rate of transpiration during constant conditions of temperature and relative humidity, and in total darkness, brought out the fact that there exists in Fouquieria an induced rhythm in transpiration, the cause for which is quite obscure.

During the process of wilting there was found to ensue a gradual closure of the stomata without any preliminary opening such as is claimed to occur by Francis Darwin. The beginning of closure occurs somewhat later than initial wilting and seems to be a result of water loss by the leaf as a whole.

In studying the physiology of guard cells, the author found in the Verbena a fluctuation of the amount of starch within the plastids of the guard cells, accompanied by a complementary fluctuation of the oil content. The presence of the oil and the conditions of its formation indicate that it is of secondary importance. The starch content was found to be at its minimum during the later hours of the morning. During the earlier hours of the morning the starch is dissolved and disappears from the plastids of the guard cells, to reappear and increase to the maximum toward the afternoon and earlier part of the night. The movements and periods of stasis of the stomata are closely correlated with this appearance and disappearance of starch. The author states that it would appear that the plastids of the stoma, which present certain morphological differences needing further investigation, normally accumulate starch when exposed to the blue end of the spectrum, to darkness, and to air devoid of carbon dioxid. This is contrary to the conditions under which starch is ordinarily formed in the chlorenchyma. Beginning with an initial condition of the entire absence of starch, this substance was found to be formed and to materially increase when photosynthesis was impossible. It seems that the guard-cell plastids are not only able to accumulate starch in the dark without a supply of carbon dioxid, but normally do so by drawing upon the general supply of the leaf. The disappearance of starch from the guard cells in the early morning, and its persistence in darkness, especially in plants in which a supply of food materials is available, compels the assumption of a mechanism of digestion of a different kind from the ordinary diastase of the leaf, and while such an agent has not been demonstrated, its probable occurrence has been reported. It is believed that a clear understanding of this assumed ferment will account for the movements of stomata which have remained unexplained by the generally prevalent photosynthetic theory.

The relation of stomatal activity to normal, though high, temperatures and to the very low humidities of the desert appears to be the same as to these conditions anywhere, and there seems to be no adaptive behavior particularly

suited to the supposedly trying climate to which the plants studied by the author are subject. As long as a water supply is available and the plant is kept cool by transpiration, it suffers no more in the Tropics than in temperate regions. There does not seem to be any evidence that the behavior of the stomata tends to mollify the rigor of the environment.

A bibliography of the subject is given.

The influence of a mixture of soluble salts, principally sodium chlorid, upon the leaf structure and transpiration of wheat, oats, and barley, L. L. HARTER (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 134, pp. 22*).—The investigation reported was undertaken with a view of ascertaining whether the presence of a mixture of soluble salts, consisting chiefly of sodium chlorid, such as occurs in excessive quantities in many alkali soils, will affect the structure of plants not especially adapted to such soils, and if modifications of structure take place whether they resemble those which characterize plants growing naturally in saline soils.

It was possible to demonstrate that culture in a soil containing considerable quantities of sodium chlorid together with other salts produces measurable changes in the leaf structure of wheat, oats, and barley. The most notable modification produced was the conspicuous bloom or waxy deposit that formed on the surface of the leaves. This development of bloom was accompanied by an easily measured increase in the thickness of the cuticle and outer walls of the epidermal cells and by a marked decrease in their size.

In regard to transpiration of the plants, it was found that when the alkali salts are present in sufficient concentration to cause the modifications of structure noted, transpiration is considerably reduced. On the other hand, the same salts when present in amounts too small to produce any measurable influence upon structure have a decidedly stimulating effect upon transpiration.

The value of sodium to plants by reason of its protective action, W. J. V. OSTERHOUT (*Univ. Cal. Pubs., Bot., 3 (1908), No. 3, pp. 331–337*).—According to the author, the idea that sodium is valueless to plants is based on the nutritive function of mineral salts and does not take into consideration their protective function. In previous publications (E. S. R., 19, pp. 727, 933), the author has confirmed Loeb's conception regarding balanced solutions when applied to plants.

Experiments with sodium *v.* potassium, ammonium, magnesium, and calcium in water cultures and in sand showed with a large number of plants a protective influence against the injury resulting from growing plants in cultures to which a single salt solution was added.

It seems clear that sodium has no nutritive function in plants, but only a protective action, and this seems to be also the case for animals. It appears probable that sodium may render the plant a useful service as a protective agent, and in the case of certain plants it appears to be indispensable.

The protective effect of sodium on plants, W. J. V. OSTERHOUT (*Jahrb. Wiss. Bot. [Pringsheim], 46 (1908), No. 2, pp. 121–136, figs. 3*).—This is a detailed account of the experiments noted above.

Notes on hydrocyanic acid in some plants, A. W. K. DE JONG (*Ann. Jard. Bot. Buitenzorg, 2. ser., 7 (1908), pt. 1, pp. 1–17, fig. 1*).—The author has made an investigation of the hydrocyanic acid contained in *Pangium edule*, and finds that the glucosid occurring in the leaves of that plant is identical with gynocardine, a glucosid occurring on the seeds of *Gynocardia odorata*.

A study was made of the presence of free hydrocyanic acid in the leaves of Pangium, and the author found that it is formed in greater or less quantity.

Sugar is also present in considerable amount, but aldehyde or ketone, while present, exists in relatively small amounts.

The author investigated the occurrence of phaseolunatin in the leaves of *Phaseolus lunatus* and found that this substance, which has been reported by Dunstan et al. (E. S. R., 19, p. 129) in the seed of the Java bean, also occurs in considerable quantity in the leaves of that plant.

A study of yeasts from California grapes, H. C. HOLM (*California Sta. Bul. 197, pp. 169–175*).—A study was made of 8 varieties of yeasts obtained originally from California grapes which were either sent to the experiment station or purchased in the local market. The experiments were carried on with the intention of determining the amount of alcohol which the various yeasts were able to form in sugar solutions, and whether the yeasts occurring on California grapes consisted of types which might be depended upon in wine making.

The yeasts were all used in pure cultures. The results show that most of the yeasts found on California grapes grown in regions remote from wine-making operations are inactive as regards the formation of alcohol, and many of them are detrimental to the wines. Most of the varieties impart an unpleasant flavor and taste, and the general characteristics do not favor the production of a sound wine of good quality. The author recommends the repression of the growth of these organisms and the introduction and application of pure yeast in California wineries.

[Report of the] department of botany, H. L. BOLLEY (*North Dakota Sta. Rpt. 1907, pt. 1, pp. 45–76*).—An outline report is given of the work carried on by the department of botany of the station during 1907 and of the different lines of investigation. Notes on the North Dakota fungi, by F. J. Seaver, and a list of plants observed in the Williston area, by W. B. Bell, are included in the report.

The author gives an account of his work on seed breeding in reference to crop disease and states that the studies on the resistance of immune flax have progressed to a point where it is desirable to test different varieties under field conditions. For this purpose small amounts of seed were distributed in the spring of 1908 for cooperative trial by farmers in different parts of the State.

Seeds and plants imported during the period from July, 1906, to December 31, 1907. Inventory No. 13 (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 132, pp. 192*).—This inventory represents the acquisitions of the Office of Seed and Plant Introduction between July 1, 1906, and December 31, 1907. It contains 2,672 items, the seeds and plants being introduced for experimental purposes. Among the more important collections mentioned are those of F. N. Meyer, in northern China, and N. E. Hansen, in northern Europe and Siberia. More attention than formerly is now being paid to the introduction of small collections which are imported for the specific purpose of being used in connection with plant breeding experiments, and a considerable number of varieties of seeds and plants from different parts of the world have been secured for this purpose. In addition to the names of the plants, brief accounts are given as to their habits of growth, uses, etc.

A catalogue of the poisonous plants of Iowa, L. H. PAMMEL and ESTELLE D. FOGEL (*Proc. Iowa Acad. Sci., 14 (1907), pp. 147–176, charts 4*).—A list is given of 275 species of plants reputed to be poisonous that have been found in Iowa or suspected to occur in that State. In connection with most of them, notes are given regarding the distribution of the plants, the active principle, where it is definitely known, and the effects produced upon animals which have eaten the plants in injurious quantities.

FIELD CROPS.

Field experiments, 1907 (*Dept. Agr. and Tech. Instr. Ireland Jour., 8 (1908), No. 2, pp. 279–326*).—In barley experiments it was found that Danish Archer grown in Ireland 1 year and Danish Archer freshly imported were equal in value and both better than Irish Archer. This work with seed of the same variety from different sources has been in progress only 2 years. The results further show that Irish Archer grown for four successive seasons in Ireland has improved its position, and Danish Archer grown one season in Ireland has maintained it, as compared with seed freshly imported.

Of different manures applied on meadow hay the application consisting of 1 cwt. of nitrate of soda, 2 cwt. of superphosphate, and 2 cwt. of kainit per acre gave the best results.

Apparently the most suitable application for potatoes consisted of 15 tons of barnyard manure, 1 cwt. of sulphate of ammonia, 4 cwt. of superphosphate, and 1 cwt. of muriate of potash. Factor, Up-to-Date, and Duchess of Cornwall were the best-yielding varieties this season. Sprouting seed potatoes before planting increased the average yield during the 5 years by from 1 ton 13 cwt. to 2 tons 13 cwt. per acre, as compared with unsprouted seed.

The greatest profit in growing fodder beets was secured with the use per acre of 20 tons of barnyard manure, 4 cwt. of superphosphate, 2 cwt. of sulphate of ammonia, and 4 cwt. of salt. The average yield with this treatment was 34 tons 5 cwt. per acre. On the average salt produced a yield of 1 ton 10 cwt. per acre more than kainit, at a cost of about half as much. Among the best-yielding varieties may be mentioned Yellow Globe, Prize Winner, Windsor Prize Taker, and New Triumph.

The best yield of oats was secured where 1 cwt. of sulphate of ammonia, 3 cwt. of phosphate, and 3 cwt. of kainit were applied per acre, and the next best yield was obtained with a similar application but with the kainit omitted. These two applications have given satisfactory returns in each of the 5 years during which the experiment has been in progress. The best yields of grain were given by Banner and Waverly, but Potato and Black Tartarian gave heavier yields of straw.

From the experiments with turnips it was found that where 4 cwt. of superphosphate was used with 10 tons of barnyard manure a slightly heavier crop was secured than where the manure was applied alone at the rate of 20 tons per acre. Centenary was one of the best-yielding varieties, as shown by the average returns for a number of years.

Fertilizers for Jerusalem artichokes. D. Doxon (*Jour. Agr. Prat., n. ser., 15 (1908), No. 13, pp. 391–393, fig. 1*).—Experiments with different applications of barnyard manure and commercial fertilizers on Jerusalem artichokes were conducted for several years. The results indicate the importance of potash fertilizers in bringing about a high yield of tubers regular in form, smooth, easily harvested, and rich in nutritive matter.

An application per hectare of 15,000 kg. of good barnyard manure, 400 kg. of phosphatic manure either as superphosphate or slag, 200 kg. of sulphate of potash, and from 100 to 150 kg. of nitrate of soda is recommended.

Tests with different strains of root crops. H. Helweg (*Tidsskr. Landbr. Plantecavl, 14 (1907), pp. 240–275*).—First-class seed of Barre, Elvetham, and Eckendorf fodder beets was compared. The average yields per tondeland (0.734 acre) were as follows: Barre 83.7 cwt., Elvetham 80 cwt., and Eckendorf 76.4 cwt. of dry matter. Little Taarŏje, a strain of the Barre fodder beet, proved more valuable than first-class strains of Eckendorf.

Variety tests and storage experiments with fodder beets, B. Sjollema and C. K. Van Daalen (*Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat [Netherlands], 1907, No. 2, pp. 31–51*).—The largest yields of dry matter and sugar were produced by Mammoth, followed by "Jaapjes." These two varieties have repeatedly given the best yields in experiments conducted in different provinces of Holland. The yield of beets, as well as the average sugar content and sugar yield, were greater when the beets were planted 40 by 50 cm. than when planted 50 by 50 cm. apart.

The siloed beets lost about 2 per cent in weight from October to January and less than 1 per cent from January to April. Inversion of the cane sugar in the beets rich in sugar progressed very slowly during the first 2 months, while in the individuals low in sugar about 1½ per cent of invert sugar was formed. In the varieties lowest in sugar the invert sugar content in April had reached from 2 to 3 per cent, while in some of the richer varieties it was lower than 1 per cent. The "Jaapjes" beets showed the best keeping qualities.

Storage experiments with fodder beets, 1904–1907 (*Tidsskr. Landbr. Plantcarl, 14 (1907), pp. 571–584*).—The loss in weight and in dry matter of fodder beets kept through winter under different storage conditions was determined. The largest loss occurred in root cellars during March and April, the loss in dry matter being 1.77 per cent as compared with 0.65 per cent during November and December. Large roots lost less than small roots, the average loss in the large roots being 0.57 lb. dry matter per 100 lbs. of beets. The dry matter content of large roots decreased from 11.2 in the fall to 9.7 per cent in the spring, while the dry matter in the small roots was reduced from 13.6 per cent to 11.2 per cent during the same time.

Is it advisable to remove the leaves of mother beets when placing them in the silo? H. Briem (*Centbl. Zuckerindus., 16 (1908), No. 30, p. 840*).—The results presented in this article lead the author to recommend that mother beets be siloed with all their leaves. It is suggested that such beets be as dry as possible and be siloed above ground, the silo remaining open as long as advisable. It is stated that such silos should not be over 50 cm. (about 20 in.) high and a width of 1 meter is considered best. The author also recommends that the entire beet be left to wilt for several days before being put in storage.

Dry matter and sugar content of the beet and their importance in breeding, H. Plahn (*Centbl. Zuckerindus., 16 (1908), Nos. 23, pp. 640, 641; 24, pp. 670–672*).—The results of the investigations here reported showed that the dry matter and sugar content of fodder beets were not in exact correlation with each other. A comparison of these two factors without knowing this fact would lead to overlooking the amount of invert sugar formed during the time of storage. The dry matter content for this reason is not considered one of the principal factors in mother beet selection, and it is suggested that the basis of seed beet selection should be the results of polarization because the nutritive value of the fodder beet is mainly determined by its sugar content. It is recommended that the examination of individual beets be made in the spring, as at that season the keeping qualities of the beet are also shown.

Studies on seed formation in clover and alfalfa, H. L. Bolley (*North Dakota Sta. Rpt. 1907, pt. 1, pp. 80, 81*).—White clover, alfalfa, and red clover plants were grown under screens to determine whether bumblebees were needed in the fertilization of clover for the production of seed. It was observed with regard to white and red clover that when grown under screens with 12 or 6 meshes to the inch practically no seeds were formed. Screens with $\frac{1}{3}$ in. and $\frac{1}{2}$ in. meshes, so far as known, proved sufficient to exclude bumblebees, but while there were a great number of unfertilized heads under these screens there were also heads which were well filled. "The work with the larger

sized meshes would seem to indicate that in some cases red clover is self-fertilized or else fertilized by small insects, while the work with the finer meshes would seem to indicate that it is seldom, if ever, self-fertilized. It is possible that wind rustling is a necessary element in this work and that the screens with the finer meshes largely prevented this." A later and more complete report on this work will be made.

Distance between hills for corn in the Illinois corn belt, A. N. HUME, O. D. CENTER, and L. HEGNAUER (*Illinois Sta. Bul. 126, pp. 357–374*).—Distance experiments with corn were conducted by the Illinois Experiment Station in different sections and on different soils in Illinois from 1903 to 1907, for the purpose of determining the distance at which check rows of corn returned the highest and most profitable yields and whether planting 2 kernels per hill at closer distances is better than 3 kernels at greater distances. The thickness of planting was varied by increasing or decreasing the distance between rows in both directions. The hills were checked on different plats at distances ranging from 33 to 44 in., the intermediate distances being 39.6 and 36 in. The different series were repeated as many times as practicable according to the size of the fields, and variations in stand were eliminated to make results comparable.

In northern Illinois on the 2-kernel plats the average yield for the 4 years ranged from 44.1 bu. per acre for the 44 by 44 in., or widest planting, to 54.3 bu. for the second thickest, or 33 by 36 in. planting. Where 3 kernels were planted per hill the widest planting produced on an average 54.1 bu., which increased as the distance was narrowed down to 61 bu. per acre for the closest, or 33 by 33 in., planting.

In central Illinois the plats planted with 2 kernels per hill increased in average yield from the widest planting to the second thickest, the yields ranging from 47.7 to 55 bu. per acre. The plats with 3 kernels in the hill ranged in average yield per acre from 46.8 bu. for the closest planting to 52.3 bu. for the 39.6 by 39.6 and the 36 by 44 in. distances. The plats planted 36 by 36 in. with 2 kernels per hill yieled 2.2 bu. per acre more than the plats planted 39.6 by 39.6 in. with 3 kernels per hill. In the northern part of the State the best yields were taken from the plats with 3 kernels per hill and also from those in which the hills were not more than 36 in. apart each way, and in the central part of the State the highest average yield from land producing over 50 bu. per acre was secured by planting 2 kernels at a distance of 33 by 36 in., but almost the same yield was obtained when the hills were planted 39.6 in. apart each way with 3 kernels per hill. On land yielding less than 50 bu. per acre practically the higest average yield was secured where 2 kernels were planted per hill in rows 36 in. apart in each direction.

It is advised that on all ordinary corn belt land in northern Illinois the hills be planted not more than 36 in. apart with at least 3 kernels per hill, and that in central Illinois on the common brown silt loam prairie lands usually producing over 50 bu. per acre corn be checked 39.6 in. apart and 3 kernels planted per hill, while on the common prairie land not generally producing 50 bu. per acre the hills should be 36 in. apart and only 2 kernels planted per hill.

Ten generations of corn breeding, L. H. SMITH (*Illinois Sta. Bul. 128, pp. 457–575, figs. 2*).—This bulletin discusses the importance of corn improvement, outlines the fundamental principles upon which this work at the station is based, reviews some of the earlier results, describes the general plan of the experiments, and summarizes the results secured during 10 years of investigation. Much of this subject matter is condensed from Bulletins 55, 82, 87, and 100 of the station previously noted (E. S. R., 11, p. 633; 14, p. 855; 15, p. 352; 17, p. 26).

The effect of breeding on the protein and oil content is shown in the following table, compiled from the general averages of each generation:

Ten generations of breeding corn for increase and decrease of protein and oil.

Year.	High protein.		Low protein.		Difference.	High oil.		Low oil.		Difference.
	Seed.	Crop.	Seed.	Crop.		Seed.	Crop.	Seed.	Crop.	
	Per ct.	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*
1896	.....	10.92	.....	10.92	.....	.....	4.70	.....	4.70	.....
1897	12.54	11.10	8.96	10.55	0.55	5.39	4.73	4.03	4.06	0.67
1898	12.49	11.05	9.06	10.55	.50	5.20	5.15	3.65	3.99	1.16
1899	13.06	11.46	8.45	9.86	1.60	6.15	5.64	3.47	3.82	1.82
1900	13.74	12.32	8.08	9.34	2.98	6.30	6.12	3.33	3.57	2.55
1901	14.78	14.12	7.58	10.04	4.08	6.77	6.09	2.93	3.43	2.66
1902	15.39	12.34	8.15	8.22	4.12	6.95	6.41	3.00	3.02	3.39
1903	14.30	13.04	6.93	8.62	4.42	6.73	6.50	2.62	2.97	3.53
1904	15.39	15.03	7.00	9.27	5.76	7.16	6.97	2.80	2.89	4.08
1905	16.77	14.72	7.09	8.57	6.15	7.88	7.29	2.67	2.58	4.71
1906	16.30	14.26	7.21	8.64	5.62	7.86	7.37	2.20	2.66	4.71

With reference to protein these results show that starting with a single variety it has been possible in 10 generations of this work to increase the protein content from 10.92 per cent to 14.26 per cent, a gain of 3.34 per cent, while by breeding in the opposite direction it has been possible to reduce the protein content from 10.92 to 8.64 per cent, or a reduction of 2.28 per cent, making a total difference between the two strains of 5.62 per cent. It is further shown that the high-oil corn has increased from 4.70 per cent to 7.30 per cent of oil, while a low-oil corn has decreased from 4.70 to 2.66 per cent, the difference between the two strains in 1906 being 4.71 per cent.

High protein and low protein seed were planted together on one plat and high oil and low oil seed on another. These plats were continued for 3 years, and the results secured did not indicate that the soil influences the protein or the oil content.

A study of the secondary effects produced by selection to change the composition of the grain indicated that the change in the composition of the grain has produced no very marked effect upon the composition of other parts of the corn plant. Continued selection has apparently induced a certain correlation between protein and oil content and has resulted in characteristic types of kernel and perceptible modifications in the type of ear. Selection for high protein is considered as evidently accompanied by a reduction in yield. It was also found that climatic conditions exert in certain years a marked effect upon the composition of the corn crop as regards its protein, oil, and starch content.

The detailed plat records of the four strains and the analytical results of nearly 5,000 individual ears analyzed during the 10 years are given in tables so arranged that the maternal pedigree record of every ear is shown. The work on the four breeding plats is still being continued.

Corn: Selection, storing, curing, and testing for seed, J. A. JEFFERY (*Michigan Sta. Circ. 3, pp. 19–30, figs. 17*).—In pointing out the importance of testing corn for seed it is stated that of a large number of ears tested for vitality those selected from the shock invariably produced an exceedingly low number of germinations. More than 50 per cent of the ears produced no germination whatever, and of those that did show vitality it was rare that 100 per cent of the kernels germinated. Directions are given in detail for the selection of seed corn, its care, grading, and testing.

Testing the germination of seed corn, M. P. JONES (*New York Cornell Sta. Circ. 1, pp. 8, figs. 3*).—The selection of good seed ears, the method of making

the germination tests, and the care of seed corn are discussed in a popular manner.

The culture of cotton without irrigation, G. Prétrel (*Bul. Soc. Hort. et Aviculf. Tunisie, 7 (1908), No. 31, pp. 91–95*).—Experiments in growing cotton without irrigation were made in 1907 in the vicinity of Tunis. The results show that a good fiber, although not quite as valuable as Egyptian and American cotton grown with irrigation, can be produced in that locality under those conditions. In one of the fields in which this work was conducted, and where weather conditions did not interfere with the experiment, a yield of 7.81 kg. (about 17 lbs.) of fiber was harvested from 322 plants. It was also observed that the tap root of the plants was in most cases quite straight and long, having gone down deep into the soil for the purpose of finding the necessary moisture.

The flax stem, T. Tammes (*Natuurk. Verhandel. Holland. Maatsch. Wetensch. Haarlem, 3. ser., 6 (1907), No. 4, pp. VII+285, pls. 6*).—This publication is a monograph on statistics and the anatomy of flax. The following subjects are treated: The origin and history of cultivated flax, the variation and correlation of macroscopic characters, the influence of soil and space on flax plants, the development and structure of the stem, and the fiber. An extensive bibliography on flax and its culture is included.

Trials of hemp, H. L. Bolley (*North Dakota Sta. Rpt. 1907, pt. 1, pp. 81, 82*).—Comparative tests were made with hemp seed secured from Russia, Manchuria, and Kentucky. The Russian hemp did not prove very satisfactory. The Kentucky seed produced hemp straw 8 or 12 ft. high, of good quality and mature, but the seed did not ripen before frost. It is believed, however, that by planting the crop earlier mature seed can be grown in that region. The Manchurian hemp when planted for seed purposes matured thoroughly, but in quality of fiber it ranked behind the Kentucky type.

Hop culture and handling, C. Fruwirth (*Hopfenbau und Hopfenbehandlung. Berlin, 1908, pp. VIII+185, figs. 59*).—This book treats of the structure and the life of the hop plant, the culture of the crop, hops as a commercial article, and the methods of promoting hop culture and commerce.

A study of the factors influencing the improvement of the potato, E. M. East (*Illinois Sta. Bul. 127, pp. 375–456, figs. 10*).—This bulletin discusses the use of species of Solanum other than the potato, cites descriptions of the original plant from the earlier writers on the subject, describes the modern plant, outlines methods of breeding, considers at some length the inheritance of characters in tuber selection, and more briefly the hypothesis of degeneration, discontinuous variations, and graft-hybrids, and reports results secured in experiments on the improvement of the tuber in quality. In the treatment of the different subjects the work of a large number of investigators is reviewed, and the bulletin concludes with a bibliography of 114 references.

The author found a great difference in varieties regarding the value of luxuriant vegetation as a guide in selecting high-yielding plants. Large vines as compared with medium vines gave fair results in most cases, but in some varieties, as Manistee, large vines rather indicated that excessive vegetative growth was opposed to maximum yields of tubers. No constant difference was found due to selection of plants with a single stem and those branching just below or just above the ground, providing other conditions were equal. There is apparently an optimum shade of color in vines constant with the variety and correlative with or a result of vigor in the plant. Light-colored vines gave fewer potatoes although of good size, while darker-colored vines either gave no set of tubers or a large set of very small ones.

A study was also made of the four physical divisions of the tuber, these being designated from outside to inside as skin, cortical layer, outer medullary layer, and inner medullary layer. The varieties used in this connection were Rural New Yorker No. 2 and Carman No. 3. It was found that the dry matter is quite variable and regularly decreases from the outside to the inside of the three inner zones. The total nitrogen content is only slightly variable, although showing a regular increase to the inner medullary layer on the dry basis. Ash determinations varied little from 0.90 per cent on the fresh basis, indicating a higher carbohydrate content in the cortical layer and a low one in the inner medullary layer. This is considered as showing that there is a difference in the time of cooking in the different zones. A number of methods of sampling were tried, and the most satisfactory results were secured by cutting a cylinder with a 12 mm. cork borer parallel to the long diameter but a little to the side. Variation in nitrogen content did not show a noticeable effect on quality, although it appears that extremely high nitrogen might make the flavor more pronounced. On the other hand, it was found that there is a lower limit in the amount of dry matter or more probably of carbohydrates, below which tubers can not be of good quality. In Rural New Yorker No. 2 it was found to be about 18 per cent, or probably about 15 per cent of starch.

In observations to determine a correlation between physical structure and quality it was found that anatomical difference is a varietal character, the difference between varieties being very great. The difference in quality within the variety, however, was found to be almost as great as the difference between varieties. This method of determining the quality of the tuber through its anatomical structure can not be used for selecting potatoes for the table because it is necessary to cut the tubers. In enumerating and discussing other factors influencing quality, it is pointed out that the number of eyes has a marked effect, due to the fact that the internal medullary extends a branch to each eye. This fact makes the quality vary inversely with the number of eyes. In a count of 219 tubers of Rural New Yorker No. 2 the number of eyes varied from 7 to 28. In connection with this work 189 tubers of this variety were analyzed and a large number found to be of very good cooking quality, although the average 200, and 400 lbs. per acre.

Investigations on the influence of fertilizers on quality showed that the quality grew markedly better where potassium chlorid was applied at the rate of 300 lbs. per acre, but apparently little difference resulted from doubling the applications of phosphorus in the form of bone meal given at the rate of 100, 200, and 400 lbs. per acre.

A microscopical examination in connection with a study of the influence of maturity on the quality showed that the starch grains in the cells of the immature tubers are small in size and few in number. In the cortical and outer medullary layers of mature tubers the starch grains averaged about 75μ and were found as large as 105μ, while in immature tubers under an ounce in weight the starch grains averaged only 25μ. The composition of tubers of different degrees of maturity was determined and from the results it is concluded that quality depends upon homogeneous anatomical structure, dry matter content, and degree of maturity. In general the quality increases with the thickness of the cortical layer and decreases as the number of eyes increases. The dry matter content must be such that the cooked starch fills the cells to the bursting point. The degree of maturity is affected by all factors of soil physics, soil fertility, cultivation, and climate during the growing period.

In studying the variation of the potato in chemical composition as a basis for its improvement it was found that the nitrogen content does not vary directly with the number of eyes, that it is not correlated with particular shapes, that

smaller and younger tubers are richer in nitrogen than larger and older ones, and that the error in determining starch from specific gravity tables is much greater than is generally supposed. Selections were made to determine whether the fluctuations in a chemical constituent are transmitted by tuber propagation. One plat in 1902 was planted with tubers containing an average of 2.95 per cent of nitrogenous matter in the fresh substance. A second plat was planted with low protein selections, the average nitrogenous matter in the fresh substance being 1.78 per cent. The composition of the tubers harvested did not indicate a definite response to selection for high or low protein, although the average of nitrogenous matter when calculated to a water-free basis was 2.11 per cent higher in the high nitrogen selections than in the crop from the low nitrogen selections. In 1903 similar selections were again made, but from other potatoes than those grown on these two plats, and it is not considered that very definite conclusions can be drawn from the results secured. It is pointed out, however, that there is a difference of 0.81 per cent in dry matter in favor of the high protein plat. Attention is also called to the fact that the low protein potatoes were larger, and it is pointed out that the higher dry matter should have ordinarily been expected from the low protein potatoes on account of their greater size. A difference of total nitrogenous matter in favor of the high protein plat of 0.33 per cent on the fresh basis and 1.61 per cent on the dry basis is recorded.

In general statements on the improvement of the potato the author presents three possible methods of improvement: (1) The crossing of desirable plants and raising of many seedlings under controlled conditions; (2) selections of the most desirable fluctuations among the plants and tubers of a variety; and (3) selection of discontinuous variations, and a study of ways of causing them, a possible example being the so-called graft-hybrid.

Irish seed potatoes in England, 1907 (*Dept. Agr. and Tech. Instr. Ireland Jour., 8 (1908), No. 2, pp. 254–259*).—The results shown in tables and discussed indicate that Irish seed produces much heavier crops in England than English seed, even when the English seed is changed from one district to another. It is recommended that for the purpose of supplying the English market with seed from Ireland varieties popular in England should be grown, only seed pure and true to name of well-selected tubers should be put on the market, and the seed crop should be slightly immature to favor early ripening, the production of vigorous plants and of heavy yields.

Solanum commersonii violet and the Blue Giant, G. H. Pethybridge (*Dept. Agr. and Tech. Instr. Ireland Jour., 8 (1908), No. 2, pp. 247–253*).—The results of this comparison led to the conclusion that the claims for *S. commersonii* violet regarding special cropping power, suitability to wet soils, disease and frost resistance, and excellence of flavor have not yet been established for Ireland, and that the variety if not absolutely identical with the Blue Giant so far resembles it that the enhanced price of seed for *S. commersonii* is not justified. It is stated that far better varieties are already in cultivation in Ireland than *S. commersonii* violet.

Dwarf Essex rape for winter forage, J. M. Scott (*Florida Sta. Bul. 95, pp. 21–25, figs. 2*).—Brief directions for the culture of rape and its use for feed are given, and the results of culture and fertilizer tests are reported. Rape at this station has given yields ranging from 27,200 to 33,296 lbs. of green forage per acre. On September 25, 1907, plats 1 and 2 were sown in drills 30 in. apart on a very light sandy loam soil. December 21 plat 3 was sown. On September 25 plat 1 received 389 lbs. per acre of a complete fertilizer, plat 2, 778 lbs., and plat 3 on December 21, 615 lbs. Plat 2 received a second application of 389 lbs. on February 10, 1908. The best yield, which was secured from two cuttings,

amounted to 16.59 tons per acre on plat 2. Plat 3 showed no increase over plat 1.

Ten years' trials with different varieties of rye, M. L. MORTENSEN and K. HANSEN (*Tidsskr. Landbr. Plantcavl, 14 (1907), pp. 45–150*).—This report covers trials conducted at 4 different stations in Denmark during 1894 to 1905. The highest yields of grain were obtained from Brattingsborg, Petkus, Heine Improved Zeeland, Heinrich, and Probstei in the order given. Walkenhaus and Brattingsborg ranked first in straw production, while Schlanstedt, Petkus, and Heinrich in the order mentioned produced the stiffest straw. The average content of nitrogen in the water-free kernels ranged from 1.51 per cent in Petkus to 1.66 per cent in Hoffmansgave, and the content of crude fat from 1.72 per cent in Probstei to 1.86 per cent in Hoffmansgave. A discussion of the history and characteristics of the various varieties is given.

The fertilizing value of hairy vetch for Connecticut tobacco fields, T. R. ROBINSON (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 15, pp. 5*).—In connection with a discussion of this subject the importance of inoculating hairy vetch is pointed out. Results of field and pot experiments secured along this line are reported.

Sample cuttings of hairy vetch in 1907 at Hockanum, Conn., indicated yields of 7 tons 400 lbs. per acre of green material for the inoculated vetch and 2 tons 240 lbs. for uninoculated vetch. Rye on this land made a vigorous growth, yielding at the rate of 7 tons 720 lbs. per acre. Determinations of total nitrogen in samples of this soil, made by the Bureau of Chemistry of this Department, showed that the soil where vetch was grown without inoculation contained 0.19 per cent of total nitrogen, while the soil from the rye plats contained only 0.17 per cent and that from the uninoculated vetch plats 0.14 per cent.

Results of greenhouse tests with 20 plants each showed that uninoculated hairy vetch produced 25 gm. of dry weight with 0.82 gm. of nitrogen, inoculated plants 44 gm. of dry weight with 1.33 gm. of total nitrogen, and rye 16 gm. of dry weight with 0.27 gm. of total nitrogen. Assuming that one-fifth of the green weight represents the dry weight of vetch, the author calculates that on the cover-crop plats at Hockanum inoculated vetch furnished a crop of 2,880 lbs. dry weight per acre with 100.51 lbs. of nitrogen, uninoculated vetch 848 lbs. of crop with 28.91 lbs. of nitrogen, and rye a crop of 2,944 lbs. dry weight with 49.75 lbs. of nitrogen per acre.

In pot experiments with tobacco, sodium nitrate was applied at the rate of 200 and 500 lbs. per acre. This was applied in pots in which hairy vetch and rye had been grown and turned under or removed. It appeared that the turning under of inoculated hairy vetch was slightly superior to the application of 200 lbs. of sodium nitrate per acre, while the turning under of rye was inferior to the application of the fertilizer. When cover crops were turned under and fertilizer added the hairy vetch showed greater fertilizing power than rye. In pots that had borne no cover crop the application of nitrate of soda at the rate of 500 lbs. per acre was no more effective than the use of 200 lbs.

[Comparative and chemical studies of wheat varieties], W. H. SCHERFFIUS and H. WOOSLEY (*Kentucky Sta. Bul. 135, pp. 327–340, pls. 11*).—The 12 best yielding varieties for the years 1905, 1906, and 1907 ranged in yield from 27.41 to 31.16 bu. per acre. The leading sorts given in decreasing order of their yields were Jersey Fultz, Kansas Mortgage Lifter, Fulcaster, B 377, and Beechwood Hybrid, all producing 29.23 bu. per acre or over.

In determining the number of pounds of straw required for each variety to produce 1 bu. of grain it was found that no regular relation between the yield of straw and grain was apparent. The high yields of straw, however, were

generally associated with low yields of grain. Blue Stem produced 95 lbs. of straw per bushel of grain, while No. 9129 produced 218 lbs., these two varieties standing lowest and highest in straw production, respectively. The average yields of straw for the 3 years and for all of the varieties under test ranged from 2,637 to 3,547 lbs. In average weight per bushel for 1905 and 1906, Turkish Red stood first with 62¼ lbs. for the first season and 61½ lbs. for the second.

Tables are given showing the protein content of wheat of the different varieties on an air-dry and water-free basis. It was found that weevil-infested wheat contained relatively more nitrogen and protein than wheat not infested, showing that the weevil had fed on the starch-bearing portion of the grain. The tables also show that some of the high-yielding wheats, such as Kansas Mortgage Lifter and Fulcaster, may also be rich in protein and that the protein content of a given variety varies with the season.

Some new hybrid wheats, E. E. Elliott and C. W. Lawrence (*Washington Sta. Popular Bul. 9, pp. 8*).—The methods of improving wheat are outlined and the hybridization work at the station is described. A table is given showing the yields at Pullman for 3 years of 20 new hybrid wheats. Eight hybrid varieties derived from Winter Fife and Little Club gave an average yield of 46.25 bu., 5 varieties, crosses between Turkey and Little Club, 42.80 bu., 4 hybrid sorts from White Track and Little Club 43.75 bu., and 3 crosses between McPherson and Red Chaff 36 bu. per acre. Two standard Red Russian varieties grown for comparison gave an average yield of 42.25 bu. per acre for the same period. Ten hybrid varieties of true winter wheats with club heads are described.

HORTICULTURE.

A further study of soil treatment in greenhouse culture, H. J. Wheeler and G. E. Adams (*Rhode Island Sta. Bul. 128, pp. 183–194*).—In a previous bulletin of the station (E. S. R., 17, p. 464), the results are given of a study of the initial and residual effects of stable manure and different combinations of chemical manures used with greenhouse radishes, tomatoes, and cucumbers and of a test of finely cut hay as a soil improver. In similar experiments reported in this bulletin finely cut rye straw was substituted for the hay which often contains weed and grass seed.

The first crop grown was radishes planted shortly before December 1, followed by lettuce planted on February 14 and again by lettuce planted on May 7. The same 4 plats and the same fertilizers were used as in the previous work except that before planting the second crop of lettuce the stable manure plat was remanured and the other plats received a complete fertilizer containing a large amount of basic slag meal, but no sulphates or chlorids.

With radishes it was found that partially composted horse manure applied at the rate of 75 tons per acre gave better results than any of the chemical manures used either with or without cut rye straw. The crop where the cut straw was used matured much more quickly than with chemicals alone. The manure and straw appeared to exert a beneficial effect upon the physical condition of the soil "and thus possibly indirectly upon the character of the fungi and bacteria capable of existing therein." This beneficial effect was not so marked with the first crop of lettuce, although the stable manure plat gave slightly earlier maturity and the crop matured somewhat earlier where cut straw was used than where the chemicals were used alone. Although the stable manure plat was remanured previous to the second crop of lettuce, better results were secured with the chemicals and the cut straw than with the horse manure. With the same chemicals the weight of the heads where the cut straw

had been used was considerably greater than where it was omitted. With both the radishes and lettuce nitrate of potash and nitrate of soda appear to be much superior to muriate of potash and sulphate of ammonia as sources of potash and nitrogen.

Carnations were grown in the same kind of subsoil as that used with radishes and lettuce. The bench was divided into two equal beds. One bed received a complete fertilizer while the other received no nitrogen, the object of the experiment being to ascertain what influence, if any, would be exerted by the nitrogen upon the tendency of the calyx to split open. The results appear to show that when the house is maintained at the same temperature generous manuring with nitrogen may increase the total number of perfect blooms of one variety of carnations and lessen the number of another variety.

The French garden, C. D. McKay (*London, 1908, pp. 62, pls. 9*).—A brief practical treatise on the intensive cultural methods employed by French market gardeners including data relative to crop rotations and working instructions for each month in the year. The work is issued with a view of introducing French methods among English gardeners.

Orchard cover crops, W. S. Thornber (*Washington Sta. Popular Bul. 8, pp. 4*).—A popular discussion of the value of orchard cover crops with suggestions for planting and plants to use.

Fruit marketing investigations in 1907, J. E. Higgins (*Hawaii Sta. Press Bul. 21, pp. 27, fig. 1*).—The practical results for 1907 of fruit marketing investigations which have been conducted by the station for the past 4 years (E. S. R., 19, p. 338) are given and subjects relating to transportation, markets, and organization for market purposes are discussed.

On August 14 a carload of pineapples and avocados was shipped from Hawaii to Chicago. The pineapples were sorted and repacked in San Francisco, but the avocados were not repacked. The fruits were placed in a refrigerated car, arriving in Chicago, August 31, and were marketed September 3. The pineapples were in good condition, the loss being less than 1 per cent. The avocados were in good condition for immediate consumption, but hardly firm enough for the market. It is believed that if avocados are perfectly hard when taken from the steamer, they will arrive in Chicago in the same condition. It appears thus far that papaias will not endure a long journey by rail, after reaching the mainland.

Hay and excelsior were again compared for packing pineapples in crates. The fruit was preserved equally well in both materials, but the excelsior makes a better appearance. The keeping quality of pineapples from different fields continues to show a wide variation and emphasizes the importance of soil studies and fertilizer experiments in relation to the keeping qualities of the fruit.

The results from shipping long and short stem fruits confirm those previously reported. On fruits showing a great tendency to decay in transit the part saved by cutting long stems averaged 17 per cent of the whole. The difference in favor of long stems as compared with stems broken off at the natural joint was over 46 per cent.

The value of wrapping each fruit in paper was again brought out, the average difference in favor of the wrapped fruit being about 6.6 per cent. Fruits that were cut with long stems and also wrapped in paper showed an average saving of 22.37 per cent of the whole as compared with short stem fruits packed without paper.

There appears to be no constant advantage in favor of carrying pineapples on either the orlop deck or the after deck of the ship. The need of furnishing transportation facilities equipped to handle fruit in all weather is pointed out.

A portion of the pineapples was placed in the ship in a compartment held at a temperature of 50° F. The fruit was not pre-cooled and the compartment did not attain the above temperature until 2½ days from the time of sailing. Under these circumstances the loss was practically the same in refrigeration as on the after deck.

Shipments were made to San Francisco of Chinese bananas, some bunches of which were wrapped in dried banana leaves and others were entirely unprotected. Neither method was satisfactory. The results previously secured relative to methods of picking, packing, and shipment of avocados were confirmed in 1907. It is especially emphasized that the spaces between the avocados should not be filled with paper as is often done.

Cape fresh fruit export trade, season 1908. C. Du P. Chiappini (*Cape Good Hope, Spec. Rpt. Trades Comr. London, 1908, pp. 16*).—A report on the export fruit shipments of the Cape of Good Hope relative to the size of the shipments, condition of the fruit, prices received, varieties, grading, and packing, with suggestions and recommendations to growers for improving conditions and for the further extension of the fruit business.

Peach, apricot, and prune kernels as by-products of the fruit industry of the United States. F. Rabak (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 133, pp. 7–34*).—The present commercial supply of almond oils is derived from European countries and is manufactured, not alone from almonds, but to a great extent from apricot, and in some cases, peach kernels. This bulletin contains the results of an investigation conducted to obtain information as to peach, apricot, and prune kernels, with special reference to their similarity to sweet and bitter almonds and to compare chemically the fixed and volatile oils obtainable from them. The methods of extracting these oils are discussed in detail and consideration is given to their commercial uses.

The investigation shows that the fixed and volatile oils which can be derived from peach, apricot, and prune kernels compare very favorably as to their physical and chemical properties and in some cases are almost identical with the commercial oils obtained from sweet and bitter almonds. The oils from these kernels are at the present time substituted for the rarer almond oils and can be used for the same purposes. Peach, apricot, and prune kernels are cheaper and furnish a more available raw material than bitter almonds. Hence their increased use might sufficiently reduce the price of these oils and create a greater demand for them. Owing to the ready saponification of these oils they should find a demand in the toilet-soap industry, and their production in the United States is suggested on account of the large amount of raw material available. The processes of extracting and distilling fruit-kernel oils are not particularly complex and could be carried on in establishments such as canneries already equipped with steam or other power at comparatively small expense. It is suggested that the press cake, owing to its high content of nitrogenous matter, might be employed either as a stock food or as a fertilizer.

Commercial fertilizer experiments with coffee. G. Helmrich (*Tropenpflanzer, Beihefte, 9 (1908), No. 4, pp. 185–220, pls. 12*).—An extensive series of fertilizer experiments conducted by the author on his plantations in Guatemala are reported. Potash, phosphoric acid, nitrogen, and lime were used both alone and in combination and were compared with stable manure. The results are presented in tabular form and are fully discussed. The author concludes that although the application of the organic manures is indispensable in coffee culture, the best plants and largest returns are secured by the additional use of a complete fertilizer.

The future of cacao planting, H. H. Smith (*London, 1908, pp. XIII+95, pls. 2*).—A paper read at the Colonial Fruit Show of the Royal Horticultural Society, June, 1908, followed by an extensive discussion and supplementary notes on grafting, pruning, and the question of shade in Trinidad. The paper deals with the various branches of the cacao planting industry, including certain phases which have not been generally discussed, such as suggestions relative to the use of vacuum chambers for drying beans, the practice of planting belts of rubber and other economic plants in conjunction with cacao, and restriction of affected areas in case of disease. Among other points discussed are grafting, improved pruning methods, and green manuring.

Street trees, their care and preservation, A. D. Taylor (*New York Cornell Sta. Bul. 256, pp. 451–491, figs. 37*).—In this bulletin the writer points out and shows by means of illustrations and discussion the harm to which trees are subjected through ignorance and neglect, with a view of interesting public spirited citizens in the protection of shade trees. Part I deals with the sources of injury to shade trees including public utilities, unintelligent pruning, construction work, wind and ice storms, freezing, bites of horses, grazing of wagon wheels, starving of root systems, overcrowding and improper placing, and injury from wire labels. Part II deals with methods of protection and the pruning of shade trees, and Part III contains a discussion of some of the main points in the municipal control of shade trees with notes on protective measures adopted in various States.

The small country place, S. T. Maynard (*Philadelphia and London, 1908, pp. 320, figs. 100*).—A popular work intended for persons seeking country homes and for those already owning small country places who wish to improve them and make them more profitable. In the introductory chapter consideration is given to various economic and social phases of country life. Succeeding chapters deal with the remodeling and improving of old buildings, building new houses, the decoration of home grounds, the lawn and flower garden, the family garden, practical suggestions for the growing and handling of the common orchard and small fruits and vegetables, poultry keeping, dairying, the family horse, and bees. The book concludes with a monthly working calendar.

The preservation of cut flowers, V. Ducomet and L. Fourton (*Rev. Hort. [Paris], 80 (1908), No. 14, pp. 333–336*).—The results are given of experiments conducted in 1906 and 1907 in continuation of the authors' previous investigation (E. S. R., 18, p. 44), in preserving cut flowers in solutions made by using various mineral and organic acids, bases, salts, antiseptics, and other materials.

Fully ten thousand experiments were conducted in which flowers of over one hundred species were used. The important fact brought out by the work is that the flowers differ so much in their requirements as to render it impossible to use similar treatment or a uniform liquid for preserving all plants. In many cases which are noted, however, it is found that by the use of sugar as well as several other substances of which the principal are sodium chlorid, bi-potassium phosphate, chloral and sulphate of maganese, the life of the flowers can be prolonged sufficiently to warrant the extra expense.

Exploitation of medicinal plants (*Le Brésil: Ses Richesses Naturelles; ses Industries. Rio de Janeiro: Centro Indus. Brasil, 1908, French ed., vol. 1, pp. 228–238*).—Brief notes on the more important medicinal plants of Brazil, including local and botanical names and economic uses, together with statistical data relative to the exports and value of various leaves, roots, and medicinal extracts.

FORESTRY.

Neudamm forestry manual, A. SCHWAPPACH ET AL. (*Neudammer Förster-Lehrbuch. Neudamm, 1908, 3. ed., XIX+818, pls. 6, figs. 203; Repetitorium, pp. 228*).—The first edition of this work, which is offered as a guide for instruction and practice as well as a handbook for the private forest owner, appeared in 1899. The present edition has been considerably enlarged and revised. The work is diveded into 9 parts, treating in detail the following phases of forestry: Botany, zoology, locality factors, forest mathematics and mensuration, sylviculture, utilization, protection, valuation, and hunting, fishing, bee culture, and fish and game protection. An appendix deals with the measures and laws relative to the insurance of workmen and forest officials. In addition to the text figures there are colored illustrations of 117 different forest insects.

The work is accompanied by a supplement containing 1,431 questions and answers, with cross-references to the related paragraphs in the manual.

Forest survey methods, A. H. D. ROSS (*Canad. Forestry Jour., 4 (1908), No. 1, pp. 39–52*).—A discussion of methods employed in making a complete forest survey which the author states includes a more or less accurate plane and topographic survey of the tract under examination, a careful estimate of the amount of timber upon it, a determination of the rate at which the timber is growing, and a study of the conditions of light, moisture, soil, and other factors influencing both the present and future condition of the forest crop.

Handbook on forest mensuration of the white pine in Massachusetts, H. O. COOK (*Boston, 1908, pp. 5–50, figs. 8, dgms. 5*).—A handbook prepared by the author under the direction of the State Forester, F. W. Rane, with a view to furnishing the people of Massachusetts with a practical working knowledge of commercial forest values. The data given include log scales, volume tables, yield tables, financial rotations, thinnings and growth tables, together with miscellaneous notes of interest chiefly to lumbermen and mill owners. Descriptions and illustrations of instruments for measuring heights as found in Bulletin 36 of the Forest Service of this Department (E. S. R., 14, 576) are also given.

Fertilizer experiments with pine on high moorland, C. VON TUBEUF (*Naturw. Ztschr. Forst u. Landw., 6 (1908), No. 8, pp. 395–407, figs. 3*).—Potash, phosphoric acid, nitrogen, and lime were tested both alone and in various combinations as a fertilizer for pine seedlings in new moorland soils. The investigations were started in 1897 and concluded during the present year.

Good results were secured whenever phosphoric acid was used alone or in combination with one or more of the remaining elements, but the largest, most luxuriant, and greenest plants with long needles and well-developed buds were produced by the use of a complete fertilizer. Phosphoric acid in basic slag was much less available than that in bi-sodium phosphate. Superphosphate influenced the plants unfavorably, hence it is advised that a quick-acting phosphate be used on the high moorland. The lack of phosphoric acid, a dwarfed condition of the seedlings, and the presence of anthocyanin, indicated by a red coloration of the pines, appear to coincide, although a red coloration was noted to some extent with large and luxuriant-growing seedlings.

The author is of the opinion that the formation of anthocyanin occurs under too varying conditions to be given any definite biological explanation. It is suggested that the lack of phosphoric acid necessary for albumin and cell building may prevent the utilization or conversion of sugar, which thus becomes stored up and leads to the development of anthocyanin.

A test was also made of pine seed secured from different sources. The seedlings showed an important variation in size and color in the first and second years. The seed obtained from Galicia and Eberswald produced large quick-growing plants, while seed from Finland and Norway produced small slow-growing plants. During the present year, when the experimental plat became severely attacked by the needle blight, the seedlings from the northern-grown seed remained almost free from attack, while the Eberswald seedlings were badly affected in the lower part of the plant. The Galicia seedlings were still more severely attacked, notwithstanding that they were sprayed with Bordeaux mixture and later on with copper carbonate solution.

The author points out that newly planted conifers must be considered as sick or weakened plants particularly liable to attack by weevils and bark beetles. The relation between the bark turgidity and insect attack is briefly discussed.

Eucalyptus in California, N. D. Ingham (*California Sta. Bul. 196, pp. 29–112, figs. 69*).—This bulletin contains the results of an extensive study of eucalyptus culture in California, the work being based on careful observation over all the cultivated portions of the State south of Shasta County. Consideration is given to the importance of eucalyptus for timber, fuel, and oil, the soil requirements and methods of growing these trees, the commercial qualities of the different species, their adaptation to conditions in the various parts of the State, and the quality and amount of the product which can be reasonably expected from them.

Over 65 different species and varieties of Eucalypts are growing on the University of California Forestry Station grounds at Santa Monica. Of this number 18 species held to be the most promising for commercial planting in California are specially considered relative to their botanical characteristics, present range, adaptability and use, illustrations being given of the trunk, foliage, and fruiting organs of each. Lists are also given of those species the wood of which is the most durable in the soil, the lumber and fuel species, and the frost and drought-resistant species.
