Among these were some excellent examples of cultivation. The collections comprised good Onions, Leeks, Carrots, Mushrooms, Turnips, Kidney Beans, Peas, Parsnips, Potatoes, Cauliflower, Savoys, and Artichokes. Mr. Stewart, gardener to the Rev. H. Vernon Harcourt, Nuneham, exhibited a fine sample of a large Onion, shortly to be sent out by Messrs. Cutbush, of Highgate. The variety is stated to be mild-flavoured and very productive, a piece of ground 20 yards by 18 wide having yielded 32 cwt. 4 lbs. Of Henry's Prize Leek, fine examples were shown by Mr. Henry, Dunse, the blanched part in some of them being about 9 inches round, and the leaves as much across at their base.

Awards.—Mushrooms: Prize, Mr. Duncan, Muirhouse, Falkirk. Cucumbers: first, Mr. Johnston, Terregles; second, Mr. Shannon, Redhall. Cauliflowers: first, Mr. Ramsay, Penicik; second, Mr. Duncan. Beet: first, Mr. Watts, Rosefield Cottage, Portobello; second, Mr. Alexander Kerr, Saughton Hall. Leeks: first, Mr. Shannon; second, Mr. Duncan. Onions: first, Mr. Stewart, Nuneham Park, Oxford; second, Mr. Scrymgeour, Holme Park, Reading; third, Mr. Logan, Bowers Hall, Perth. Salads: Prize, Mr. Reid, gardener, New Hailes. Collection of vegetables, twelve sorts: first, Mr. Shannon; second, Mr. Matheson, Tulhullan; extra, Mr. King, Brantsfield House; and Mr. A. Thomson, gardener, Woodburn.

#### PLANTS, &c.

This portion of the exhibition was principally confined to the Music Hall, where a fine collection of Coniferous plants and others remarkable for the beauty of their foliage was arranged in the orchestra, and being lighted up with Gladioli and some other flowering plants an excellent effect was produced. These were contributed by Messrs. Lawson & Son and Dickson & Son, of Edinburgh; Messrs. Downie and Co. likewise contributing Geraniums, Begonias, &c., for the decoration of the entrance hall.

Among stove and greenhouse plants from Mr. Lees, of Tynninghame, were *Renanthera coccinea* with fine spikes of bloom, and from the mode in which they were trained not having that straggling appearance which this showy plant usually exhibits; a fine *Phalenopsis grandiflora*, *Oncidium luridum guttatum*, with five long spikes covered with flowers, several *Statices* in excellent bloom, and *Erica Aitoni Turnbulli* in good bloom. Mr. Lees was awarded the first prize, the second going to Mr. Neil Black, gardener to the Earl of Dalhousie, Dalhousie Castle. Of Cape Heath the only entry was that from Mr. W. Thomson, Dalkeith; it consisted of *retorta major*, *Austiniina*, and *Marnockiana* in fine bloom. In eight fine-foliated plants Mr. Mitchell, gardener to the Duke of Hamilton, Hamilton Palace, was first with a remarkably fine specimen of *Pithecellobium*, *Nepenthes Rafflesiana*, good plants of *Croton variegatum*, *Cordyline indivisa*, *Dasylyron glaucum*, and *Ananassa sativa variegata*, and a noble *Alocasia zebrina*. From Mr. Thomson, Dalkeith, and Mr. Lees, who were equal second, came fine examples of *Pandanus elegantissimus*, *Alocasia metallica*, and a Sugar Cane, together with a splendid pan of *Anectochilus* with *Lycopods* hanging over the edge. Other plants consisted of creditable examples of *Caladiums*, *Alocasia macrorrhiza variegata*, *Begonia Marshalli*, *Cyanophyllum*, *Dracanas*, and *Sansevieria javanica*. In tree Ferns Mr. Thomson was first with a fine *Dicksonia antarctica*, Mr. Lees second with *Alsophila australis*. In eight Ferns Mr. Mitchell, gardener to the Duke of Hamilton, had good specimens of *Cibotium Schiedei*, *Pteris cretica albo-lineata*, *Asplenium nidus*. Good examples of the above, *Pteris tricolor*, *Adiantum formosum*, *Gymnogramma Laucheana*, *Adiantum cuneatum*, and *Trichomanes radicans* came from other exhibitors. Mr. Mitchell was first, Mr. J. Henderson, gardener to John Christie, Esq., Millbank, second, and Mr. Lees had an extra prize.

Of *Fuchsias*, there were well-bloomed plants of *Souvenir de Chiswick*, *Conqueror*, *Rose of Castille*, and *Venus de Medici*; some good *Cockscombs*, *Achimenes*, and *Phloxes* were also shown, and *Asters* were fairly represented both in the tasselled and quilled classes. Several boxes of cut *Roses* were also exhibited, but they were not remarkable for quality. Of *Zonale Geraniums*, however, there were some good specimens of *Madame Vanher*, *François Deshois*, *Rose Rendatler*, *Paul l'Abbé*. Mrs. Pollock, Cloth of Gold, Flower of Spring, and Queen of Queens, were also shown in tolerable perfection.

Awards.—Two *Fuchsias*: first, Mr. John Kennedy, Fordel; second, Mr. Clerk, gardener to Sir John Cox, Kinnellan. *Fuchsias*, in eight-inch pots: first, Mr. John Kemp; second, Mr. John Gilchrist, gardener, Duddingston. *Cockscombs*: first, Mr. R. B. Annandale, Seaton House, Arbroath; second, Mr. W. Watt, Rosefield Cottage, Portobello. *Achimenes*: Mr. Thomson, Dalkeith. *Zonale*, or *Bedding Geraniums*:

first, Mr. James Gordon, gardener, Niddrie; second, Mr. John King, Brunsfield House. Variegated Geraniums: first, Mr. James Henderson, Millbank; second, Mr. T. M'Gwigan, gardener to Mr. Gibson, Woolmet. Twelve cut Roses: first, Mr. George Wemyss, Springwood Park, Kelso; second, Mr. James Henderson, Millbank, Gorebridge. Extra: Mr. A. Boyant, Balcarrais Cottage; and Mr. Robert Starrie, Kinnet, Bo'ness. Twelve quilled Asters: first, Mr. John Taylor, Middlefield Cottage, Inveresk; second, Mr. Duncan Kerr, Glencarse, Roslin; third, Mr. Jones, Bangholm Bower, Trinity. Twelve Chrysanthemum-flowered Asters: first, Mr. M'Cube, Holeyon Hall, Newcastle; second, Mr. William Reid, New Hailes, Musselburgh. Extra: Mr. Duncan Kerr, Glencarse. Six Phloxes: first, William Blackwood, Esq., Minden, Peebles; second, Mr. George Smith, Clermiston, Corstorphine; extra, Mr. John Hamilton, Minto.

Of Gladioli, many beautiful stands were shown, forming one of the most attractive features of the floral display. Those from Messrs. Downie, Laird & Laing, Messrs. Dickson & Son, Newtonards, Ireland, Mr. Harrison, Darlington, and Mr. Marshall, were particularly worthy of remark. Among the finest in the different stands were John Waterer, Napoleon III., Penelope, Lord Raglan, Princess Clothilde, Reino Victoria, Madame Vilmorin, Edm. Linné, Raphael, La Quintinie, Mазeppa, and Mathilde de Landevoisin.

Awards.—For fifty: equal first, Messrs. Downie, Laird, & Laing; and Messrs. A. Dickson & Son, Newtonards; second, Mr. Harrison, Darlington. For twelve: first, Mr. Marshall, Sand House, Northumberland; second, Mr. John Thompson, Preston Tower, Chathill; third, Mr. Henderson, Millbank; extra, Mr. R. Grant, Grange Cemetery.

Hollyhocks, shown in spikes and in cut blooms, were remarkably good. Messrs. Downie & Co., sent eleven very fine spikes, including Earl of Breadalbane, Charles Eyre, Mrs. Downie, Lady Rokeby, Janne d'Or, Orange Perfection, Hon. Mrs. Cheape, Seraph, William Young, and John Cowan. Mr. Thompson, Preston Tower, had the finest spikes in the Amateurs' class. Lord Rokeby, Hon. Mrs. Cheape, Lord Clifden, and Mrs. McKeuzie were particularly good. In other stands, Glory, Lord Loughborough, Countess of Craveu, Mrs. G. Sharpe, and George Keith were fine flowers. A fine rose crimson seedling, named John Downie, from Mr. Allan, Belchester, received a certificate.

Awards.—Eleven spikes of Hollyhocks: first, Messrs. Downie, Laird, and Laing; second, Messrs. Carstairs & Sons. Nine spikes: first, Mr. John Thompson, Preston Tower, Chathill; second, Mr. Daniel Bell, Beechwood; third, Mr. James Vair, Gogar Bank; extra, Mr. James Allan, Belchester, Coldstream. Five spikes: first, Mr. Walter Allan, Ratho House; second, Mr. Thomas Shannon, Redhall, Slateford. Twelve cut blooms: first, Mr. J. Thompson; second, Mr. James Allan, Belchester; Mr. M'Kellar, Kirkland Lodge.

Dahlias were magnificent, finer blooms have not been anywhere seen than those shown in the majority of the stands, and particularly in those of Messrs. Downie, Laird, & Laing, in the class for twenty-four. These were Criterion, Anna Keynes, Harry, Alexandra, Baron Taunton, Willie Austin, Queen of Primroses, Favourite, Miss Henshaw, Lord Derby, Leah, Excelsior, Leopold, Delicata, Ne Plus Ultra, Miss Roberts, Imperial, Garibaldi, Golden Admiration, Charlotte Dorling, Golden Gem, Scarlet Gem, Stella Colas, and Princess Alice. Mr. Harrison, Darlington, had Manve Queen, Criterion, Lord Derby, and several others very fine; and Messrs. Dicksons had also excellent blooms. In the Amateurs' Class for eighteen, Mr. J. Thompson had Criterion of remarkable size, also Alexandra, Norfolk Hero, Lady Lillian Paulet, Umpire, Bob Ridley, Delicata, Goldfinder, Lord Derby, Charlotte Dorling, Stella Colas, Miss Henshaw, Duchess of Northumberland, and Bellona, all of which were fine and some of them very large blooms. Mr. Vair also had very good blooms of several of the above-named kinds; and in the class for twelve blooms some very good stands were set up, in which were included blooms of most of the varieties already enumerated. In Fancies, Messrs. Downie were first, with Prospero, Queen Mab, Sam Bartlett, Norah Crema, Ebor, Mrs. Joy, Mrs. Reid, Startler (Keynes), Startler (Perry), Pauline, Reliance, and Gem. In the Amateurs' classes were also very good examples of most of the above.

Awards.—Twenty-four blooms: first, Messrs. Downie, Laird, and Laing; second, Mr. Harrison, Darlington; third, Messrs. Dickson and Sons, Newtonards. Eighteen blooms: first, Mr. John Thompson, Preston Tower; second, Mr. James Vair, Gogar Bank; third, Mr. Alex. Kerr, Saughton Hall. Twelve blooms: first, Mr. J. Mitchell, Cames Esker, Helensburgh; second, Mr. William Vair, Duloch; third, Mr. Bryant, Balerno Cottage. Twelve Fancy (Nurserymen): first, Messrs. Downie, Laird, & Laing; second, Messrs. A. Dickson and Son, Newtonards, Ireland; third, Mr. Harrison, Darlington. Twelve Fancy (Amateurs): first, Mr. William Vair, Duloch; second, Mr. James Vair, Gogar Bank; third, Mr. A. Kerr, Saughton Hall. Six Fancy: first, Mr. James Gildewan, Crossgates, Fifo; second, Mr. James M'Harden, Orangefield, Belfast; third, Mr. Thomas Weir, Kerse House, Falkirk.

Miscellaneous subjects consisted of an excellent plant of *Vallota purpurea* from Mr. Currie, Salisbury Green, and the rare *Phaleuopsis Portei* from Mr. Lees, Tynninghame. This had about a score of blooms. Mr. Robson, gardener to Viscount Holmesdale, Linton Park, Staplehurst, contributed an interesting collection of cones produced this year at that place. Among them were those of *Cryptomeria japonica*; *Pinus insignis*, *densiflora*, *excelsa*; *Picea nobilis*, and *Web-*

*biaua*; *Abies morinda*; *Cupressus Lawsoniana* and *Lambertiana*; *Thujaopsis borealis*, and *Retinospora pisifera*, and seeds of *Araneaia imbricata*, the cone having unfortunately gone to pieces. From Messrs. Osborn, Fullam, came a collection of ornamental *Pyrus* and *Crataegus* fruit, some of which were very pretty. Beard's system of glazing, which has already been fully noticed in these pages, was also exhibited.

The Judges were—for fruit, Dr. Hogg, Mr. T. Moore, Mr. Webster, Gordon Castle; Mr. Laing, Ardgowan; Mr. Cramb, Tortworth Court; Mr. Laing, and Mr. Carmichael, Sandringham; and for flowers, Messrs. W. Paul, W. Dean, Thompson, Preston Tower; Allan, Belchester, Coldstream; Turnbull, Bothwell Castle; Carmichael, McNab, and Henderson of Millbank.

In the evening a sumptuous and admirably-served dinner took place at the Douglas Hotel. Sir William Gibson-Craig, of Riccarton, occupied the chair, Mr. J. Campbell Swinton and Mr. W. Thomson acting as croupiers. About two hundred sat down, among whom were Messrs. W. Paul, Harry Veitch, T. Moore, J. Standish, C. Turner, R. Parker, J. W. Chapman, R. Fortune, B. S. Williams, Mackenzie (Alexandra Park), R. Glendinning, and numerous leading horticulturists from all parts of the kingdom. The usual loyal toasts having been drunk, the Chairman, in proposing "The health of the Lord Provost and Magistrates of Edinburgh," said that the Council of Edinburgh had now the honour of being presided over by a man who had done more for horticulture and arboriculture, and for the general cultivation of the country, than perhaps any man of his day in Scotland. Of course they were all aware he alluded to Mr. Lawson, the present most excellent Lord Provost. There was no man in Scotland who had done so much for the exhibition of agricultural and horticultural produce in this country, and also at the great shows in London and abroad. In all these things Mr. Lawson had always acted in the most liberal manner, regardless of outlay, and with immense expense of time, trouble, and exertion. He was known not only throughout this country, but all over England, and he might say in every part of the Continent, and he much regretted to think that from an attack of illness he was not able to be present.

Mr. C. GRAHAM LAWSON returned thanks.

The health of the Duke of Buccleuch, having been drunk,

Sir WILLIAM CRAIG said the next toast was one which might be called the toast of the evening—namely, "The Horticultural Society of Edinburgh." He had some difficulty in proposing this toast, because it appeared to him that the best commendation of the Horticultural Society was to be found in such a show as had this day taken place. That show, he was assured by friends who had seen many of the great shows of England and the Continent, was equal in regard to fruit and general excellence to anything they had ever seen in any other country in the world. Now, considering that such a show had taken place in Scotland, where they were supposed to possess a cold and wretched climate and barren soil—although he did not quite admit the description which others had given of it—it must be acknowledged to be a very remarkable one, and in the highest degree creditable to the Scottish gardeners. He did not say it in the least invidiously, and he would be the last to raise a bad feeling between the Scotch gardeners and the English, but it must be admitted in the matter of Grapes, the Grapes of Scotch gardeners had carried off the palm. It might be said that the Scotch gardeners had the advantage, being on their own ground; but on the other hand, they were entitled to say that if the English had had better Grapes and better fruit they ought to have sent them. He thought it a most extraordinary thing that in this cold and barren country, as it was called, they should have produced such fruit. He had no doubt there were English gardeners quite equal to the best they had in Scotland; but this at least he would say, that there was no school for gardeners in the world equal to the Scotch school. He believed the head-gardeners in Scotland, who were generally men of intelligence and education, took the very greatest care in the training of the young men under their charge, instructing them in gardening and botany and the kindred arts, thereby making them fit for any situation whatever in connection with horticulture in any part of the world. It was the tuition of their head-gardeners that made Scotland to be looked to by all parts of the world for men for places of trust, and he knew no other capacity in which he could always more confidently recommend his countrymen than in that of gardening. As they were under a cold climate they were obliged to put forth the more skill and science to counteract it, and they were therefore accustomed to show what could be done in the most adverse circumstances. If he could point to any man pre-eminently distinguished as a Scotch gardener, he would name Mr. Thomson, gardener to the Duke of Buccleuch; and in confirmation of what he had said as to the care in the education and tuition of the under-gardeners shown by head-gardeners in Scotland, he had great pleasure in saying that to-day a testimonial had been given to Mr. Thomson by a body of young gardeners he had trained, along with an expression of their warmest gratitude to him for the care and anxiety he had shown in their training. Of this Society, established by practical gardeners, Mr. Thomson had been one of the originators, and one of the warmest promoters, and he thought his health would fitly be coupled with the toast of prosperity to the Horticultural Society of Edinburgh. This Society was yet a very young society, but he trusted soon to

see it amalgamated with the much older society, the Caledonian Horticultural, and that both might go on together in a career of prosperity.

Mr. THOMSON briefly returned thanks for the kind manner in which his name had been mentioned by the right hon. Chairman. With reference to amalgamation with the Caledonian Horticultural Society, he might be allowed to say that he should be delighted to see that event take place. The only difficulty was the circumstance that the Caledonian was under a charter, and rules and regulations entirely different from the Edinburgh Society, and rightly or wrongly the practical gardeners considered the machinery of the old society too complicated. On the other hand, the Edinburgh Society, though it had existed for only eight years, had had a series of most successful shows, crowned by the great show which they had had to-day. There was no point in the show he regarded with more satisfaction than that they had been able to attract to the Scottish capital so many men eminent in horticulture. The right honourable Chairman had taken a great amount of credit to Scottish gardeners. Now, he had lived a long time in England, and he had had very able English gardeners under him; and there were English gardeners in this room who were second to none he knew in Scotland. There were florists and nurserymen in England who were not surpassed in the world. They had some gentlemen present on this occasion whose names were familiar in their mouths as household words. They had present among them Mr. Turner, Mr. Paul, Mr. Standish, Mr. Moore, and many others, whom they were all delighted to see, and to give them a most cordial reception. He begged to propose "The health of the Strangers present, with the name of Mr. Turner of Slough."

Mr. TURNER returned thanks, and offered, in the name of the horticulturists of England, as cordial a welcome to the Great International Show there, in May next, as they had on this occasion received from their Scottish brethren.

Mr. CAMPBELL SWINTON proposed "The health of the Judges." The very excellent show had, he said, imposed all the more arduous duties on the Judges, whose impartiality, assiduity, and skill would be acknowledged even by those who had not succeeded in obtaining their awards. He regretted the absence of Dr. Hogg, who had done more for the culture and nomenclature of fruit than probably any other living man, but he had the pleasure of coupling with this toast the names of Mr. Moore, well known as a leading authority in horticultural literature, and Mr. Paul, a gentleman who was by universal consent acknowledged to be one of the most distinguished florists in the kingdom, and whose writings had for a considerable period acquired the reputation of standard works.

Mr. MOORE, Chelsea, briefly returned thanks.

Mr. WILLIAM PAUL, of Waltham Cross, in responding to the toast, said that the show of fruits was the finest he had ever seen, and both fruits and flowers were in some instances so near in point of merit that they had taxed the power of the Judges to the utmost. He hoped that the exhibitors were satisfied, and could assure them that the Judges had worked honestly at their task and brought their best powers to the work. Perhaps it was too much to expect that all should be satisfied, as cultivators and exhibitors were from familiar acquaintance so well versed in all the beauties of their own productions while striving to correct their defects, that they were apt to over-estimate the one and not dwell sufficiently on the other. Exhibitors often viewed their plants as parents did their children, and we all know how many wonderful children there are in the world in proportion to the number of wonderful men. The number of good things had not surprised him so much as the thorough absence of all that was bad, and the lowest prize was, in his opinion, a prize to be proud of. He thought the thanks of horticulturists were especially due to the Managers of the Show for the business-like manner in which they had conducted it, and also to those who had aided the movement by their money and influence. Perhaps there was no country in the world where there were so many rich people as in Great Britain, and certainly none where that great wealth was so freely bestowed to promote all that was useful and good, and calculated to improve the taste of the community at large. He could not help contrasting the state of horticulture now and thirty years ago, and congratulating the present generation on the progress that had been made. Thirty years ago Knight and London were the great names in gardening, and Paxton and Lindley were the rising stars. There was then no "Gardeners' Chronicle," no "Journal of Horticulture." Dr. Hogg had not written his "Manual of Fruits," and Mr. Moore had not given us those faithful and minute descriptions of Ferns and other plants which rendered the pencil of the artist almost superfluous. We had then no Hybrid Perpetual Roses; few of the present most beautiful varieties of flowers; no British Queen Strawberries; no Duchess of Buccleuch Grapes; no Castle Kennedy Figs. Yet great as had been the improvement in the past, he looked forward to even a more glorious future. The art of cultivation had been pushed almost to its limits, but there was a wide and almost untrodden field opening before them; he alluded to the improvement of races by hybridisation and cross-breeding. In order to obtain all the results that were derivable from this source, the education of the rising generation of gardeners and nurserymen should be more systematically pursued. In addition to the ordinary routine of education, a special education was demanded. The rising generation should be taught to observe facts correctly, to note all the phenomena

of nature, to collect and classify instances, and to reason accurately upon them. They should be taught to go from the garden to the study, and from the study to the garden, to collect facts in the one and digest them in the other for a crowning act to reduce their conclusions to practice. One word more. He had often regretted that there was not a stronger fellow-feeling between the scientific and practical workers in this great field of nature. The scientific man was too apt to look coldly on the practical man, and the latter to return the compliment sometimes with interest. He could not understand the necessity of this. To his comprehension it was both unchristian and unphilosophical. He looked on the two arms of the service as members of the same body; although each might accomplish—nay, had accomplished—great things alone, he thought that the union of forces would be productive of far greater results. They had accomplished a great deal by their exhibition that day; would they take up this new work? He believed by so doing they would do much good in their own day, and he remembered with gratitude in the future.

The "Horticultural Press" was then proposed by Mr. Thomson, and the "Competitors, successful and unsuccessful," coupled with the name of Mr. Meredith, by Professor MacLagan. Mr. Meredith in replying expressed a hope that many of the Scotch gardeners who had competed so successfully would visit the Great International Show in London, in May next. Mr. Harry Veitch proposed the health of the Chairman, and spoke in highly eulogistic terms of the Exhibition, than which he had never seen a better.

### CONSTRUCTING A SMALL GREENHOUSE.

I THINK of having one about 12 feet by 8 feet. Would a flue work well made about 9 inches square, with a hollow space on each side, carried once round the house below the floor, and then continued above the floor along the back and one end (not the fireplace end) by means of round nine-inch earthenware-pipes? Would it draw sufficiently? And would the back and end get more than their proportion of heat? My object in having it so long is to make the coal do as much work as if used in connection with hot-water apparatus.

Your Manual on "Greenhouses," says, at page 13, "The angle of the roof is best when low—say about 30°, that greenhouse plants always do best when the roof is pitched low. A higher angle is apt to draw the plants too much on one side." At page 29, it says, "An angle of 45° combines more useful properties than any other. For very early things the glass should approach more nearly the perpendicular—say 25° to 35°. For gaining most power in summer, the angle should be larger—say 50° to 65°. In other words, the front would have to be raised, so that the glass would be flatter." In one place 25° to 35° is called "low," or flat, and in the other it is called nearly perpendicular, while 50° to 65° is called low or flat, as though in one place the reckoning is made from the meridian, and in the other from the horizon; and after all a margin of about 20° is left between what is considered the best angle in the different places. Will you please give me a definite figure?

Can you tell me whether Beard's houses let in rain or not? It appears to me that the glass being laid edge to edge, even though ground true at the edges, would let in water, if only by capillary attraction.—WREKIN.

[We have no doubt that the flue will answer the purpose admirably, if the top of the flue forms part of the floor. The hollow space on each side of the flue will also be an advantage. We think you will have quite enough of heat without the continuation of nine-inch earthenware-pipes above the floor; but that you can please yourself about. There will be no difficulty in the flue drawing, provided the bars of your furnace are from 20 to 24 inches below the level of the bottom of the flue, if more, so much the better, and the flue rather rises than sinks to the point where it enters the chimney.]

We have frequently explained how the difficulty is caused about the angles of roofs, according to the side of the quadrant used. The angle of 45° is the same in both modes of reckoning, and the first part of your letter just shows that what is termed the English mode of reckoning, is adopted when it speaks of a house from 25° to 35° getting more nearly to the perpendicular than 45°. In the other place, where an angle of 25° is spoken of as low and flat, it shows that the French mode of reckoning is resorted to, that low roof of 25° being identical with our flat room of 75°, or just a little more steep than a common garden frame. Some time ago figures and explanations were given, illustrative of the whole affair, but there is such confusion, that the context in the meantime must supply the chief information, as to what system the writer adopts. For ourselves, we always reckon from the perpendicular line of the quadrant, and count on the arc beginning at 1°

on to 90°. Thus, if you have a base of 12 feet, and a perpendicular or back-wall line of house also 12 feet, the hypotenuse line will form with the others a right-angled triangle, and the hypotenuse line will give a roof at 45°. When you want a steeper roof, for early and late forcing, you must either greatly raise the back wall, or lessen the width of the base line, so as to have a slope of 35° or so. Now, what is called the French mode just reverses all this. It presupposes calculating from the base line of the quadrant, and hence though 45° would be the same in both cases, 35° in this instead of being steep, would be moderately flat, the same thing, in fact, as 55° with us. By making a quadrant with a piece of pasteboard, or a board, and having a small weight fixed to a string in the corner, and then applying that to the slopes of roofs, you will at once perceive that according to the sides you use, the reading will be thus quite different. It would be well if in this serial, the mode of speaking of the angle of a roof should be made uniform. It is very confusing, because the steep roof of 30° with us is by the other mode the steep roof of 60°, and our 10° would be identical with 80°. Some years ago an editorial decision on the subject was requested.

A roof of 45° is good for general purposes, and especially where there is no front glass. In a greenhouse, where there is front glass, the roof may be as flat, according to our reckoning, as 60°, or even 65°, as a steep roof would necessitate such a height of the back wall above the height of the front glass. A house with a roof of 35° to 40° is chiefly useful for early forcing, and for keeping fruit in winter. From 50° to 60° is a good slope for summer work. As the sun gains altitude its rays do not strike a steep roof with the same force as they do a flatter one. These matters have all been discussed at considerable length. If still there should be any doubt about the angles of roofs we will give, or rather repeat, illustrations.

Mr. Beard's houses do not let in rain, and, what is more remarkable, there is scarcely such a thing as drip from the condensed moisture inside. It had rained the whole day before we saw them. We went without any notice, and we saw not a single mark of drip on the floor. The squares fit closely enough together to prevent rain entering. As far as we recollect, the angle would be from 50° to 55° by our mode of reckoning. Another person has made the inquiry whether such a mode of glazing would do for garden frames. We could not be so sure of that if they were as flat as 80°, but as we saw none we would rather let others speak on that point. The absence from drip from condensed moisture inside we believe to be owing to the plane surface and no interruption of laps. The moisture, both inside and outside, seems to trickle down the glass until it ends in the neat spout, the front square abutting right over it. It did not strike us that the glass was grooved at the edges. It is wonderful how true and uniform large boxes of glass are cut. We may be wrong, but our impression is that no extra care was taken with the glass, but it was very neatly joined.

You will find it difficult to get a cheap work so describing greenhouse plants that you can at once find out and name what you have. Until you are more acquainted with the subject you had better have names with the plants you buy. It would require a first-rate botanist and good references to name a lot of Aloes, Cactus, &c. One of the best that we know as oral instructors would be Mr. Baxter of the Botanic Gardens, Oxford, as he used to have a fine collection of succulents. All works on plants to be particular must be expensive. Perhaps the cheapest work, for its immense mass of information, is "Loudon's Encyclopedia of Plants."]

## THE MODERN PEACH-PRUNER.—No. 15.

### CLOSE PRUNING FOR THE OPEN AIR.

UNDER this term we comprehend both the summer stopping of the shoots and their winter regulation.

Although the work for the winter depends entirely on the condition of the shoots after their summer growth, it is common to see them comparatively neglected during this important period, consequently, the winter pruning is made to assume an undue pre-eminence, which all modern experience tends to show to be an error. By reiterated close pruning of summer wood the trees assume an appearance which has been termed "cordon," from a resemblance to a thick cord or cable. This term applies to trees in any form. Fan-shaped trees may be called *horizontal cordons*. Those planted closely together and trained at an angle of 45°, are styled *oblique* or *diagonal cor-*

*dots*. Trees with any number of upright leaders are *vertical cordons*, while those winding gracefully round wires, or posts, are *spiral cordons*. All these are formed by the same mode of close summer-stopping of the shoots. For trees under glass no better or more simple plan can be imagined, and our object is now to show that there exist no difficulties in the way of a similar treatment of trees in the open air. The advantages of this method are great. In the first place, there is a total suppression of the summer and winter tying-in of the shoots. This alone constitutes an appreciable gain, especially during a period when we have so many claims on our time. Again, the shoots being closer-lying they require less space between the leading branches, and thus there can be more of these.

Systematic summer-stopping of the shoots affects the two-year-old wood more than any other style, and tends to produce and maintain, in the case of the Peach, those valuable fruit-bearing spurs which produce the finest fruit, and last several seasons without much change. In this way we greatly multiply our chances of a good crop, for if one class of shoot is unripe, that is no reason why the shorter and closer-lying class should not be in a riper state. Indeed, close pruners of long practice will not hesitate to consider these short spurs as of first importance in the open air.

In the orchard-house, trees, several seasons old and in good bearing, soon become covered with these short fruit-bearers (classed 5 and 7), no matter what form the tree is trained under. It seems evident that if we can succeed in replacing the old long shoot by a group of several short ones, each fully as capable (to say the least), of production, that we have materially augmented our chances of a good crop. The objection usually made, that on these short spurs no well-developed leaves can be secured, is not sustained by practice. The production of healthy leaves depends far more on the state of the roots, and if these leaves are kept in a clean and healthy condition, there need be no fear of their not elaborating the sap. That the principle of close summer-pruning is sound is evident from the abundant crops produced, not only of Peaches; but also of every other fruit, even including standard Grapes; Vines trained in this way may be seen in the public gardens at Chartres. For Pears, especially in the open air, trained as diagonal cordons, it is admirable. Late sorts are also best ripened in this way. It might be supposed that by repeated summer-stopping of the shoots, and their grouping on short spurs in time some inconvenience might be felt by reason of their protruding too far from the wall. But ten seasons of trial have clearly shown me that this is not the case. In the instances where, by neglect or some other cause, these shoots have really lost the advantage of the wall heat, they have been removed and their loss readily supplied from others better placed.

At the winter season all ill-placed shoots are thinned out, though it is evidently better not to allow them to grow irregularly during the summer. Mistakes or omissions are more easily remedied under close pruning than under long pruning, while, in certain cases, we are not debarred from utilising any applicable part of the older system. Close-pruning, in some shape, has been always known, but it is only within the last few years that it has been reduced to a system. It now includes as its advocates many of the first names in horticulture. "I accepted it with enthusiasm," says one eminent man, whose work, in 1863, received the French Imperial sanction, "because it is normal, and in harmony with the laws of vegetation, and of fructification." It would be an error to suppose that there is but one system of close-pruning. That originated by M. Grin is by far the most severe in its rules. It is, perhaps, on account of this, that it has not been generally adopted, and possibly some change is necessary to meet the exigencies of our different climate. This change is all I have ventured to suggest, for our climate is not understood abroad.

Partly, also, and for similar reasons, no doubt, Professor Gressent in his very recent work, after passing the highest eulogium upon M. Grin's theory, which he acknowledges as the foundation of a totally new school of pruning, recommends a modification of this system, which is very interesting. I, therefore, determined to make a trial of its merits during the present season, on trees in the open air.

The plan adopted may be stated thus:—The eyes (ripe buds) of a bearing branch are disbudded as soon as they are about to develop. In each group one (the strongest) is left on the lower side of the branch, and another (the weakest of each group) on the upper side of the branch. All these are allowed to grow freely, and when they have reached to 6 or 8 inches in length, they are stopped at 5 or 6 inches, according to the sorts

operated on. It is necessary to allow every shoot to make the growth indicated—that is, at least 6 or 8 inches, before arresting its progress. By this means the operation is not done all at one time, which might otherwise produce too abrupt a check in the circulation of the tree, and cause it to lose too much sap, thereby inducing subsequent gumming.

By the time these shoots are thus stopped they will have attained a certain woody firmness, and we may expect that some of the eyes situated at the base of the shoots will become well formed. By suspending the vegetation, and concentrating the action of the summer sap on these eyes, “either the rudiments of flower-buds or May clusters may be constituted, but no premature laterals be thrown out.”

Soon after this stopping, a second growth is made from the extreme bud of the shoot. This new growth is allowed to make 8 inches of growth (this takes us to about the end of June), then, if at this time the eyes at the base are well constituted, the second or new growth is cut back to about half way.

At the winter pruning the shoot is cut down to the second group of triple buds from the base. The next season these groups will bear, and the effect of this winter close-pruning is, that the latent buds at the insertion of the shoot develop themselves, and thus form succession shoots. That which has borne is now cut out, and a fresh short shoot takes its place.

All these operations presuppose, of course, that the buds at the base of the original shoot were sufficiently developed by the effect of the first operations described; but, should they appear neither well formed nor prominent, the shoot should be cut back below the point where it was first pinched several successive times during July, so as to concentrate the sap upon the lowest buds, and form them. This is the part of the method which requires the greatest amount of experience and attention. Possibly one single cutting-back may suffice, but with trees of strong growth, or badly balanced, some portions might need frequent operations. In short, the object being to form and strengthen the eyes at the base of the shoot, all the attention of the pruner should be directed to attain this end.

All these operations were carefully tried this season on my own Peach trees in the open air, and no mention having been made of the necessity of tying-in the shoots (which in England, at least would seem to be necessary), it was found that the two or three extreme buds of the shoots generally sent forth short laterals (owing, in a great measure, to their vertical position, they being untied), but that the eyes of the lower portions of the shoot were well formed. Cutting back beyond the first stopping (which stopping was done at 6 inches as soon as 9 inches of growth were made) is a valuable plan, and very useful in regulating the growth of the whole side of the tree.

This modification of close pruning has been introduced here for the sake of completing our description of the subject, and to show that there exists more than one form of the system. It also proves the interest excited in the matter, and is suggestive in itself of further improvements. Being the very latest continental experience it is also of value.—T. C. BRÉHAUT.

### YORKSHIRE HERO PEA.

THE correspondent who made inquiry in your Journal respecting the merits of the above-named Pea, will not require to grow it if he grows Veitch's Perfection, which is, on the whole, by far the better Pea of the two.

I grew the Yorkshire Hero this season alongside of Veitch's Perfection. The Hero grew considerably dwarfer, shorter in the pod, and its bearing season was much shorter than that of Perfection. The size of the peas was about equal, and as regards flavour there was not much difference.

Veitch's Perfection, Champion of England, and Dickson's Favourite, are three varieties of Pea difficult to beat for general purposes.—JOHN EDLINGTON, *Wrotham Park*.

### LILIUM LANCIFOLIUM AND LILIUM AURATUM AS HARDY BORDER BULBS.

WILL you inform me whether the *Lilium auratum* would be likely to succeed in the open air? I planted three bulbs of *Lilium lancifolium* in an open border in the autumn of 1863, protecting them in the winter with coal ashes. Last year they sent up six shoots, and had more than sixty flowers on them altogether, and this year there are nine shoots, with about seventy flowers. I get about four weeks' bloom, and the flowers

are quite as fine as those usually seen in a greenhouse. I imagine that *Lilium auratum* would succeed with similar treatment. If no one has at present tried it I would let you know the result.—JAMES SNOW WHALL, *Workshop*.

[The *Lilium auratum* we consider as likely to endure the winter under the same treatment as that you bestowed on *L. lancifolium*. They are both natives of Japan. We are not aware that any one has hitherto tried the experiment—EDS.]

### MY PLANTS,

AND HOW AND WHERE I FOUND THEM.—No. 9.

As a sort of counterpoise to the inequality of the growth of the Hart's-tongue in the two counties mentioned in my last I may remark that I rarely met with the Hard Fern in Norfolk, and those few specimens which I did obtain were small and impoverished; whereas in Staffordshire, about Free Hay, Cheadle Common, &c., and also upon the banks of the Dart and other parts of Devonshire it grows most freely, its luxuriant and beautiful male and female fronds forming a contrast to the Ferns around it. A very local Fern is found plentifully in North Staffordshire—I allude to the *Ophioglossum vulgatum*. Its leafy frond and tapering spike is not very easily discerned by the passer-by, particularly as it is often found side by side with the Twayblade, the same loamy soil being necessary to both plants. On a bank at Lower Tean, near Heybridge House, overshadowed by trees, I first saw the Adder's-tongue. On making a second visit to the place a few days afterwards I was some time ere I could again come upon the plants, so much concealed were they by the grass and shrubs with which the bank was covered. In the same spot grew the Herb Paris and the *Equisetum sylvaticum*. In Mr. Moore's invaluable little book of “British Ferns,” Cheadle and Farley are given as localities for the *Botrychium lunaria*. I have vainly at present sought for it in both these places. In meadows near Cheadle and at Oakamoor the Adder's-tongue is quite common; and I am told that some few years since children were sent out by their parents to gather the leaves of it to be made into ointment for a family medicament. Another small harvest for the children is the Coltsfoot gathering. In March and April little ones of all ages are trespassing over ploughed fields in search of the leafless yellow flowers. When collected they are made into beer and wine, the former after the fashion of our ginger-beer. Another plant very common in this county, which was unknown to me before my residence in it, is the *Alchemilla vulgaris*, Lady's Mantle. I have a specimen more than a foot in height; but generally it grows much shorter, and with its green flowers is not very easily distinguished by the uninitiated from the grass by which it is surrounded. I recently saw in a friend's garden a very pretty and useful edging formed of this plant. It made a neat and compact border, and, both flower and foliage being green, it does not distract the eye from the brighter groups within its limits.

I think one of the most glorious days, as far as regarded additions to my fernery, was that on which we drove from Tean, through Oakamoor, and so on to the Wever Hills. Limestone hills they are, rising 1150 feet above the sea. Miles and miles away one sees these three conical eminences covered with fine short grass, and in many places almost perpendicular. Woe to the too eager botanist who unguardedly commences hurrying after some newly discovered plant. Great caution is necessary in botanising upon their sides. From the summit of one of them a splendid view is obtained of Ellastone and other villages in the beautiful valley beneath. The sun was pouring a flood of that purple and golden evening light over the valley as we were quitting the hills, and I never beheld anything which would carry one's thoughts more immediately to the portals of “Jerusalem the golden” than that scene. The mistiness and indistinctness of the surrounding objects, the line of light on the river in the valley, the warmth of colouring, the glorious sun itself which seemed the very door of heaven—altogether the scenery was so magnificent that it did not require a very vivid imagination to feel that these evening scenes are sent to lure our thoughts by such connecting links from earth to heaven. Who has not some child or loved one up there, far, far away beyond the sun, to whom our thoughts fly along this golden sunlight, until they seem to reach the distant spirit-home?

But I am rambling on with my own thoughts instead of commencing our journey from Tean in proper order. After passing along the heathy roadside which leads from Free Hay

to Alton, you can either take the main road to Oakamoor, or perchance a civil word to the keepers of the lodge gates may fortunately obtain you permission to pursue your way along the undulating and romantic drives of Alton Towers, the residence of the Earl of Shrewsbury and Talbot. There is a damp coolness and aristocratic grandeur about the approaches to these places which fills one with a quiet and reverential awe. The noble trees, through whose stalwart branches the sun scarcely ever penetrates; the lichen-covered stones by the side of the drives, with the water oozing over and between them—all bespeak age and years of undisturbed growth and luxuriance, which naturally command respect when we contrast the constant changing of owners and the consequent unthriftness of many small estates and farms which are daily witnessed. The very Mosses and Ferns in these woods and drives look as though they felt their superiority to the Ferns and Mosses of the bank without the gates. I believe there are Dives and Lazaruses amongst flowers as well as human beings. The scent of the turf here is such as one only finds in spots where wealth reigns over all, and where everything is carefully tended and looked after. As I pass under the wall or hedge of a strange garden I rejoice in this undefinable but well-known scent: it portends that better things are to be found within. One expects to see the mowing-machine at work, and gardeners here and there busily employed. It speaks of cool shrubberies of which the walks are green—those dear, old-fashioned, winding walks which one seeks in vain in new gardens; the seats, the stump of some old tree, in the interstices of which the Ivy still makes its way. Here the love-tale was told, and on the trees the initials were carved, which will outlive the carver and the loved one; and here one wandered in loneliness when the carver became estranged and false; and here also one wept in silence for the soul which had just departed from the one who had watched our earliest years, and who had with dying lips blessed us and left us to fight the world alone.

There is no comparison between new and old gardens. The scent of which I have been speaking above, and which clings to old lawns and shrubberies, speaks of grass ever green, which, if the clouds withheld their showers, were never allowed to become parched and dry; and it also surely speaks of moss, almost imperceptible, but still there, inseparable from the grass. How the Ferns revel in the moisture and shade of those Alton woods! and how broad and healthy are the leaves! All up the hills to the right they grow. Then comes at their feet the lichen-covered stone, then the winding drive, then again more Ferns covering the descent to the river, and beyond the river, rising to our left, are Fern-covered hills.

We were long in passing through this place, although I was rather eager to reach Oakamoor, having heard that the Oak Fern was to be found there. I had heard its praises so loudly sounded, that I quite feared lest by any misadventure we should not gain admittance to the wood in which these treasures were obtainable. The descent to Oakamoor is charming, there is no view of the little picturesque village until you are quite upon it. The only thing which rather mars the beauty and simplicity of the scene, is the fact of a horrid silk factory which thrusts itself in view just as you are descending the hill: there it is with its busy workers in the valley beneath. We had hoped that we had left behind us in Tean and Cheadle, with their large tape factories, all the bustle and confusion of machinery and looms; but there it was again, the ringing bell, and its answering stream of hurrying pale-faced workers. We were glad to see them disappear down the valley, and turning our backs on them fancy such things had never been, as we drove over the bridge to put the horse up at the adjacent inn. My husband had some engagement in another part of the village, and I meantime called upon some young ladies who, I had been assured, would show me the locality of the Oak Fern. I fortunately found them at home, and in a kind and ladylike manner they offered to point out the spot, though, they added, so many friends had applied to them for roots of this Fern, that they almost feared my success in securing any, particularly as it was very late in the season. Passing through a farmyard, and over some meadows which were abundantly supplied with plants of the *Ophioglossum vulgatum*, we reached the "promised land." No sportsman's heart could have responded quicker to the "view halloo," than mine to the first assurance of "a find," by my new friends of the plant of which we were in search. As I said before, it was late in the season, and the fronds were brown at the edges, which were also knocked about and broken. Still what a lovely plant it was, so delicate and transparent! No fructification was visible

on the fronds we procured that day. It was stooping under the Nut boughs that we found this Fern. In its secluded habits it reminded me of the Violets. I was so greedy of my new acquisition that I secured a basketful of the tuberous roots, whether they had leaves on them or not, and I planted one of the large baskets which we have in this neighbourhood full of plants, putting broken pieces of brick, &c., at the bottom, and filling it with the earth in which I found the plants. How much I looked forward to my next year in Tean, when these carefully-planted roots should be springing into growth! I had many of these baskets planted with various Ferns, but I believe this would have exceeded them all. We left the village, and gave my baskets in charge of a shopkeeper there, but he took no care of them, and when I applied for them, he said the basket had "rotted away." Having kept them a much longer time myself, I suspect he had emptied out the contents, and made use of the baskets.—ALICE.

#### PRESENTATION TO MR. THOMSON OF DALKEITH.

On the occasion of the International Exhibition at Edinburgh on Wednesday last, nine of those who had been foremen to Mr. Thomson at Dalkeith, but who are now in situations for themselves, took the opportunity of presenting him with a substantial testimonial of their regard for him, and as an acknowledgement of the benefits they had received from him during the period they were in his employment. All of them had become head-gardeners in first-class situations on the recommendation of Mr. Thomson, and the subscription to the testimonial was strictly confined to those only who had acted in the capacity of foremen at Dalkeith during Mr. Thomson's time. The presentation took place in the Douglas Hotel, St. Andrew's Square, in presence of seven of the subscribers, and a number of Mr. Thomson's friends, and it consisted of a very handsome and valuable gold watch, on the back of which was a chaste device, in the centre of which was engraved—"Presented to Mr. William Thomson, by nine of his late foremen," and artistically incorporated with the surrounding decoration, were the initials of the donors, who are—Mr. H. Rose, Floors Castle, N.B.; Mr. Dell, Stoke Rochford, Grantham; Mr. D. Brown, Corehouse, N.B.; Mr. John McIntosh, late of Raby Castle; Mr. W. Prentice, Shugborough Hall, Rugeley; Mr. William Dick, Wynyard Park, Durham; Mr. James Morrison, Anehincruive, N.B.; Mr. Harry Knight, Chateau Pontchartrain, near Paris; Mr. John Simpson, Wortley Hall.

Such a presentation as this is unlike the ordinary testimonials which are too frequently contributed by those who know comparatively little of the recipient. It is an expression of the gratitude of those who had every opportunity of seeing and experiencing the merits or failures of him with whom they served, and it is greatly to the honour of Mr. Thomson, that these nine of his late foremen should unanimously have resolved in paying so high a tribute to his worth. May he live long to receive those expressions of friendship and regard to which he is so justly entitled.

#### THE BOTANIC GARDENS AT ST. PETERSBURG.

THE Botanical Gardens of St. Petersburg are situated on the north side of the Neva, on the Aptekarskoi Ostroff, or Apothecary's Island, at a little more than two English miles from the centre of the town. Although the gardens and houses are very well kept up, there being about seventy men constantly employed in them, they are not much visited. In the first place, it is too far to walk; for in spring, when one naturally feels a desire to see flowers and foliage, the roads are next to impassable—mud and slush having entire sway; and in the heat of summer one does not feel able to move out so far. Then, again, in St. Petersburg every house is profusely—more or less so, according to the means of the owner of course—decorated with green plants and foliage of all kinds. Those who can afford to do so employ a florist, who seizes the opportunity when it offers, and changes all the plants, so that they never look drooping; others, again, take care of their own, having greenhouses in the country, and by that means keep their town houses gay. I ought to say that—now I am speaking merely of the town houses of the nobility and gentry—naturally enough their country seats (or *datschias*) are always beautifully furnished with the finest ornamental plants and shrubs. I

shall have occasion hereafter to speak more fully of these campaigns.

I drove up to the door of the Botanic Garden-house, and although it was a private day, I got in by explaining that I came with the intention of taking notes of what I saw, and presenting them to an English Journal. An intelligent "German-Russian," as the Finlanders are called in St. Petersburg, by name Wihiting, showed me over the place, and proved a very agreeable cicerone. Being a dull cold day, the sun did not light up the various houses as I could have wished, and, perhaps, I thereby lost some flowers; but as on the whole I remained mostly under glass it was not so noticeable.

The first house which we entered was a sort of semi-span, with a circular continuation of the half-roof, making the house wider and more roomy; the height was very great, perhaps 20 feet at the apex. There was a stage in front of the house, covered with fine sand, on which stood the pots with plants. The centre of the house was made into beds, surrounded with a low rockery wall. Here were some graceful *Arancaria excelsa*, fine specimens, and several very large *Rhododendrons*, amongst which a scarlet *R. arboreum* figured prominently. Passing on, we came to a New Zealand *Banksia* (*B. dryandroides*, Baxter, was on the label). This plant was valued at 600 roubles! it being, as the gardener said, the finest specimen of the kind in the world. This must be taken *cum grano salis*, I should fancy.

The paths in this house curved about, and although the trees and shrubs were not all rare, the effect was very good. Passing along I noticed a handsome *Banksia*, *Cunninghamia*, a *Stenocarpus*, a *Dryandra nervosa*, &c., and then found myself in a new and beautiful span-roof. The temperature here was that of a cool stove, although some of the specimens would seem to us to be more fitted for the stove proper. The arrangement of this house was most tasteful. The principal path started from a pool of limpid water, and dividing and joining again, at last met at the other end. The head, so to speak, of the building was a nicely formed rockery, Ferns and Mosses growing most luxuriantly in every crevice, and a few drops of water trickling over the stones into the pool below, whence, alternately disappearing and coming to light again, the water found its way through the entire length of the house.

The path was edged with rockery-work, and the beds planted with Ferns, *Begonias*, *Gesneras*, *Caladiums*, and numerous Orchids, of which there was also a large number suspended on logs, and in pots, many handsome Palms, and I remarked a plant, dignified by a long name—*Lepidozamia Peroffskiana*, a Mexican production, which I do not remember ever having seen before. There also were plants of the *Brassiopsis glomerulata* (Hook.), *Brachyglottis repanda*, *Hedera helix latifolia maculata*, a very pretty variety, and *Lonicera brachypoda* trained in various shapes. Further along were *Agaves* and *Aloes*, a *Rhopala corcovadensis* from Brazil, and one *R. australis*.

From this house we passed on to two warm semi-span-roofed houses, which contained specimens of *Aristolochiaceæ*, *Saurauja macrophylla*, *Carapa guianensis*, *Justicias*, &c. I noticed here a splendid *Coleus*, *C. malabaricus*, the leaves of which were almost black. Is it cultivated in England? I asked myself. Certainly I have not seen anywhere such a black-leaved *Coleus*.

Passing through a small cool house, in which I noticed a *Libocedrus chilensis* of great size, we entered the *Camellia*-house, which was rich in enormous and well-grown specimens of *Alba plena*, *Globosa coccinea*, and others. This brought us to a cool house, filled with *Rhododendrons*, *Azaleas*, *Pæonies*, &c. Conspicuous amongst the first were *R. arboreum purpureum*, *Dalhousianum*, *Thomsoni*, and *Smithii aureum*. All these were really fine, carefully-tended specimens, which did the place credit.

Farther along we passed through houses containing specimens of *Begonias*, *Pandanus utilis*, *Hæmantus*, some of which were in flower; *Clivia miniata*, also flowering; *Caryota urens*, and many *Cordylines*, mostly very good; some were of a very dark hue. It was here I noticed a *Chamædorea* (sometimes called *Numezia*), from Guatemala, glorying in a long name; the plant was noticeable for its fragrance.

Other houses, through which we made our way, details of which would be wearisome, led us at last to the Palm-house. This is worthy a better penman than I, but I must do my best. We all know the Kew Palm-house well; that at St. Petersburg puts ours into the shade. I am now referring merely to the

arrangement of the interior and the dimensions and splendour of the Palm trees. For architectural beauty, there can be but one opinion—the Kew Palm-house is the finer. Further, I believe it is one of the finest, if not the finest in Europe. Its dimensions, shape and construction certainly surpass anything of the sort I have ever seen. Some notes on the respective merits of the great glass houses of the Continent would be very interesting. Perhaps some of your readers are possessed of particulars on this subject, and I am sure all would be glad of descriptions of the noted houses abroad as well as of those at home. Anybody with taste, having seen the two, cannot fail to recognise the artistic talent displayed in the arrangement of the great St. Petersburg Palm-house; and then the specimens there are far finer than ours, larger and denser in foliage.

The paths wind in and out under the trees, so that one is led to think oneself in the tropics. A perfect jungle it is in parts, masses of most luxuriant vegetation all growing healthily, blended harmoniously in a whole, with occasional vistas which must be seen to be appreciated, having a noble Palm towering up into the air at the end. In many places the roof cannot be seen, foliage being the only thing visible overhead. Amongst the Palms may be seen many *Bambusas*, *B. verticillata*, *Livistonia chinensis*, *Attalea princeps*, and a large number of *Yuccas*, *Musas*, &c. There were two very fine *Strelitzias*, *S. Nicholii*, and *S. regine*, a *Phoenix sylvestris*, and many Cinnamon plants, Sugar Palms, and Cacti, some of which latter had attained an altitude of 30 feet.

There were other houses, warm and cool, and stoves, all of which contained plants of much interest to the horticulturist, but to mention more names, or go farther into details, would be needless, and, I fear, tiresome to your readers.

The houses were for the most part heated by hot water, after the approved modern principles; some were heated by stoves (*poêles*), and some few, requiring much heat, by the two combined. The covering was of wood shunters like those of a shop. These are found more to be relied upon than any kind of matting. None of the houses had double glass—a plan of glazing I quite expected to see, as all the dwelling-houses are so provided for the inclement season. The gardener assured me that the cold was kept out entirely by the ample fire-heat.

And now I have done, at least for the time being. Much remains to be said on the arrangement of the houses, gardens, and conservatories of the wealthy class in St. Petersburg; this must form the subject of a future letter.—PATELIN.

## FUNGUSES AS FOOD.

In former Numbers of your Journal, some correspondents recommend the use of most of the Funguses, or Toadstools, as many of the country people call them; and Mr. Fison, page 150, and Mr. Wason, page 88, of the present volume, speak of the prejudice of the people against the use of them as food. I have no doubt that "prejudice" has saved many lives. Science may save the learned, but the ignorant are only safe by their "prejudice," as your correspondents term it. The unlearned are all prejudiced against the bright berries of the Nightshade, and other vegetable products, because they have heard of their fatal consequences from others, and are, therefore, content to avoid those products, rather than prove for themselves.

I have now to state the result of a dish of Funguses that last week came to my table. They were brought in by a man who had for years been a Mushroom-gatherer, and my wife having no suspicion of there being any of a bad quality among them, stewed a few for breakfast, and we all partook of them, I remarking at the time that I did not think they tasted like the last we had.

About an hour afterwards I began to feel unwell, nausea and sickness soon succeeded; suspecting the Mushrooms, I went home, and there found my family in a worse state than myself, they being attacked with violent retching, the worst being my wife. I directly took a good draught of mustard and water, giving some to the others. Mine soon returned, and I was so far all right, but not so my wife. On her the effect was great prostration of strength, her hands and arms becoming cold and benumbed; but I am pleased to say that from the action of kind neighbours externally rubbing, and emetics internally, she soon revived, but it was not till the morning of the third day that anything would remain in her stomach.

After this, I can only advise those that are not "prejudiced," to beware.—G. CLAPHAM, *The Gardens, Eowden Hall.*

### STATICE HOLFORDII MANAGEMENT.

As this is a most beautiful pot plant I think it ought to be more generally cultivated. I have grown it for four years, and find it answer admirably for conservatory decoration.

To propagate it, take off young shoots in April and insert them in thumb pots, filling the pots, after putting in plenty of drainage, with sandy loam, with a little silver sand on the surface. Let the heel of the cuttings be in the sand. Plunge the pots in a bottom heat of 90°, watering very sparingly, and in the course of three weeks they will have filled the pots with fine white roots and be ready for a shift.

They may be now put into a compost formed of rich yellow loam mixed with a small quantity of silver sand and charcoal, and a little leaf mould free from any sticks. Pot them firmly in this compost in six-inch pots, and do not water freely until they are well established in the fresh soil. After this they will require a liberal supply of water, placing them in a heat of 70°, keeping a moist atmosphere. In the course of two months they will be pot-bound, and should have a shift into a ten-inch pot and be placed in a milder heat of 65°; all flower-spikes to be cut off, and twice a-week liquid manure given the plants so as to make them throw out fine healthy foliage. By the end of September they will require a fourteen-inch pot, and by the beginning of January they will have become fine specimens; then allow them to bloom.

Plants treated in this manner will throw up from eight to twelve fine spikes 2½ feet in height, and when tied out well make a brilliant show in the conservatory, the colour being such a very beautiful blue. I have seen them in full bloom for ten months, but that is too long for them to stay in the conservatory, as a change in colour is required.

The only insect which troubles them is the brown scale, and that but very little.—W. B.

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

The weather still continues favourable for the growth of the autumn crops, the whole of which, when necessary, should now be kept well earthed-up. Young weeds will now be making their appearance in abundance where seeds have been allowed to ripen and fall during the summer. The whole of the garden, where it is possible to do so, should be gone over and scuffled with a Dutch hoe, and the young seedlings left to be withered up by the scorching rays of the sun. *Cabbage*, prepare ground for the main spring crop. It should be highly enriched with manure. A quarter on which Onions have been grown is very suitable for this purpose. *Cauliflowers*, prick out the young plants as soon as they are sufficiently large to fix properly in the soil. Some may be pricked into a sheltered border and some into frames. *Cucumbers*, the plants in the forcing-houses must now be carefully attended to, every means must be used to keep them free from insects and in a healthy vigorous state. When the plants are firmly rooted give a little manure water every alternate time with clear water. *Lettuce*, prick out some of the *Cabbage* varieties into a frame to come in for winter use; also, continue to plant out strong plants of the *Brown Cos* for autumn use. *Onions*, pull up those that have done growing, and house them in a dry state. They should be sorted before being laid away in the root-cellar, and the thick-necked ones used first. The *Onions*, *Gherkins*, *Chilies*, and other vegetables used for pickling should be gathered for the purpose as they come in. *Potatoes*, when ripe, should be taken up as opportunity serves. Although attacked with the disease, and indications of an almost total failure were apparent during the very showery weather we had last month, now that we are favoured with fine, bright, sunny weather, it is to be hoped that the crop will be better than was anticipated. *Spinach*, thin the plants to about 9 inches apart; if obliged to step in amongst them, loosen-up the soil after the thinning is completed. *Turnips*, take the opportunity of thinning them as soon as they have made a rough leaf or two. Should slugs attack them, which is not unfrequently the case at this season, sprinkle soot or lime two or three times a-week about nine in the morning.

#### FRUIT GARDEN.

Fruit-gathering should be proceeded with as the different sorts arrive at due maturity. Avoid the error of clearing a tree at once without reference to the ripeness of the crop. Uncover *Currants*, if matted, occasionally during fine days. Trim and dress *Strawberry* plantations, and be careful to injure the leaves of the plants as little as possible, avoid deep digging

between the rows, which injures the roots; besides, the *Strawberry* rather prefers a somewhat firm soil. *Espaliers* and dwarf standards, or, indeed, any kind of fruit trees which exhibit more tendency to produce useless wood than such as is likely to furnish fruit, should be root-pruned as early as convenient in the autumn, cutting out any useless shoots at the same time, in order to expose the wood expected to bear fruit as freely as possible to light and air, so as to have it well ripened.

#### FLOWER GARDEN.

Cut off the flower-stems of herbaceous plants as soon as they become shabby, and endeavour to prolong the beauty of *Phloxes*, &c., by keeping them well supplied with water at the root. *Hollyhocks* and *Dahlias* will still require occasional looking after to secure them against the effects of high winds which may now be expected. Let the borders be cleaned and neatly raked over, filling up any vacant places with *Chrysanthemums*, spring-struck *Pansies*, or spring-flowering bulbs. *Mignonette* for winter and spring flowering may yet be sown.

#### GREENHOUSE AND CONSERVATORY.

When valuable stove plants have to be kept in the conservatory while in bloom, they will require careful management to prevent their being injured by damp; and they must not be over-watered at the roots, as stove plants are soon injured in a low temperature if kept too wet. Give air freely on bright days, but if the house contains many stove plants it will be advisable to shut up rather early in the afternoon to retain a little warmth for the night. Remove *Azaleas* which have set their bloom to the greenhouse, but the later kinds must remain in heat until the growth is matured and the bloom set. Keep *New Holland* plants, which have been placed under glass, cool and airy, and avoid crowding, especially in the case of plants, which are in a growing state; but everything must be allowed sufficient space, so that the foliage may be fairly exposed to light and air. Look sharply after mildew on *Heaths*, as this pest is sometimes very troublesome upon plants that have been growing freely in shady situations in the open air, and are in a rather soft state when taken in-doors, and apply sulphur freely on the first appearance of the enemy. The *Persian* and other *Cyclamens* should be examined and repotted where necessary. Admit air day and night to all descriptions of greenhouse plants. In many species the growth is not yet perfected, and an abundance of air is the only means that remains to bring about that result. This may be assisted on sunny days by early closing for a couple of hours in the afternoon, but open the houses at six again to get the cool night temperature.

#### STOVE.

Stove and greenhouse plants of an herbaceous character, after they have done blooming, should have some care to ripen the roots properly before they are stowed away for the winter. To effect this with *Achimenes*, *Gesneras*, *Gloxinias*, &c., they should be placed in a spare house or pit near the glass, and supplied with water only to keep them from flagging. This will allow the foliage to ripen gradually, and, as a matter of course, the tubers or roots. *Amaryllis* and the different varieties of *Japan Lilies* require the same treatment; the latter, however, being more hardy, may be ripened off at the base of a south wall or in a cold pit. *Brugmansias*, *Clerodendrons*, *Erythrinas*, *Allamandas*, and plants of similar habit, may be gradually induced to enter into a state of rest in any house of medium temperature with an atmosphere drier than a common stove.

#### PITS AND FRAMES.

One of the first matters claiming attention at the present time is that of potting bulbs, as much of the success in securing early flowering depends upon early forcing. Respecting the kinds, the common and cheap single varieties are the best. *Pinks* and *Violets* must also be looked to, the latter, both for potting and blooming, planted out in a frame or pit. It is a good time to set about the construction of store-pits. If proper accommodation is not already possessed, they should be excavated to the depth of 18 inches, and drained so that no water can enter; a few layers of turf and a framework of wood to receive the mats, lights, or whatever may be provided, will complete the necessary preparations. Let *Scarlet* and other *Geraniums* struck in the open ground be taken up and potted immediately they have made roots. They will require a close frame for a week or two, when they should be placed on a dry bottom in a southern exposure, to harden them for the winter. For the same purpose *Verbenas*, *Petunias*, &c., struck in pans and intended to be kept in them through the winter, should be placed in a similar situation, at the same time stopping the points of

the shoots. It should be a point to keep them as hardy as possible by fully exposing them until they are placed in their winter quarters.—W. KEANE.

### DOINGS OF THE LAST WEEK.

A WEEK of glorious summer weather has made some of the rather-behind-hand farmers smile at the impatience of those that carted the valuable grain rather early. What an untold blessing this last week's bright sun has been to the country! The heat, however, and the warm weather early in the season, are bringing in all our fruit at once. Unless in the case of those who shade, &c., there will be few October Peaches this season, and some of the wall-fruit is ripening before it is fully swelled. Several visitors have been complaining of the same, and saying they will have little out of doors, except Apples and Pears, by the end of the month. But then we are never satisfied; there is always an *if*, or a *but*, that prevents us acting out the cheerful philosophy that "sees the bright side of all things." If the fruit is coming in all at once, or rather too quickly, the flower gardens have improved after the rains, as if by magic, and though, perhaps, not so fresh-like, are now more full of bloom than they were in the third week of July.

Less than a fortnight ago the few gardeners we saw were hanging their heads with the most woe-begone aspect, and the wisest went about prophesying that September this year would see nothing but wrecks of flower-beds. If there was even a melancholy pleasure experienced, it was soon exhausted in the half-hearty congratulations that were showered on those whose employers had all betaken themselves to the north, to the moors, deer-stalking and fishing, and who, therefore, would see nothing of the wrecks they had left behind them. This very simple fact is not seldom forgotten. Some care nothing about their summer flowers after the middle of August, but cut and propagate, and lift without compunction. Even as respects labour, the matter is very different, when every bed must show its best until the frost comes.

#### KITCHEN GARDEN.

Trenched up part of the Onion ground, and planted out about half the space we intend for the earliest spring and summer Cabbages. We had a lot of rotting short grass mixed with refuse from the potting-bench, rotting weeds, which had not come to the seeding state, &c., which we dug in at the bottom of the trench. The material would be too rank for anything to grow in, but it will be decayed and sweet enough by the time the roots of the Cabbages reach it in the spring. The soil needed no enriching on the surface, otherwise we would have given a little very rotten manure on the surface, to encourage the young plants. This rough dunging at the bottom tells well on the Cabbage crop, which we generally allow to stand all the summer and the following winter, obtaining, after the first large-sized heads, several successions of young Cabbages until the stumps are pretty well decayed; and then the ground, as a general renovator, is treated for Celery, &c. The rains having battered the ground, ran the fork through borders and quarters of Coleworts, Spinach, young Onions, Lettuces, Cauliflowers, Broccoli, and will follow with a little manure water to all the grosser crops, as it will tell on them very perceptibly in this sunny weather, and when the next rain comes it will be nicely washed in. Turned the Onions preparatory to taking them under cover. We are so far sorry to say that the rains and the heat have so sent the necks next to out of sight, that it will be difficult to string them this season. They are in general best kept in strings, and they occupy less room than when stored on shelves, &c. We have frequently stated that hardly any amount of frost will injure Onions if they are kept dry. We have never known them keep better than when hung in open sheds.

But for the smell they leave behind them, we believe that few vegetables are more conducive to the health of working men, and therefore we always feel pleased to see a good bed of Onions in a working man's garden. We have seen a labourer slice off for his dinner from three to six huge Onions, and that with an evident relish that the rich man rarely enjoys when debating what he shall partake of among his costly dishes. A gentleman lately told us he almost envied the ploughboy discussing his lunch of bread and Onion and next to uncooked bacon as he swung on the field gate. "I am so often shut up, immersed in business, that I cannot take exercise enough to

get an appetite; or I go out for a day's shooting, and come home too fatigued and hungry to enjoy anything." Ah! there is a vast deal more of the equality of enjoyment in the different classes of society than is generally supposed. The law of compensation, which will pervade all classes, is a most beneficial one. The ploughboy on the gate eats with a charming relish, because he eats just when he needs it, and when nature is satisfied he eats not a bit more. There is nothing in the bread and the Onion, or the bread and next-to-raw bacon, to tempt him to indulge, or to excite a false appetite.

Thinned Tomato leaves, exposing the fruit to the sun, and backed up some frames of Cucumbers; gathered the most of the small ones for pickling, Gherkins, &c. Thinned out a few leaves of Vegetable Marrow to give them a little more light. When cooked, about the size of two hen's eggs put end to end, this is one of the most delicious vegetables. For ourselves it is generally too rich to be used above once a-year. We see them growing often in the poor man's garden; but they and the larger Gourds are generally allowed to grow on and ripen, and then they are hung up and used for soups, and for puddings, along with Apples, &c. Allow us to advise him to cook a lot when they are young, and then the plants will ripen quite as many. When of the young size above stated let them be washed clean, and then plunged in boiling water and boiled until, on trying with a fork, the points of the fork go freely into them, and then they will be done. Much of the delicacy will consist in keeping the water outside of the fruit. When boiled soft lift carefully on a plate, pour off any water that may come with them, cut each fruit open in halves, remove the soft centre, and then on the rest of the fruit dust a little pepper and salt, and with a very little fresh butter or dripping, you have a dish fit for a prince.

#### FRUIT GARDEN.

Much the same as in previous weeks. As already stated we suspect that much fine wall-fruit this season will have to be made into jams, jellies, preserves, and tarts, as it has come so soon in. Thinned and shortened the shoots of Apples and Pears as we got at them. Williams' Bon Chrétien Pears have been very fine, and, with a little management, that delicious Pear may be had good for a long time by very frequently picking the most forward first, and that also in a heavy crop, helps the more backward, and causes them to swell better. From a single tree we have frequently had this fine Pear for six weeks, when by one or two gatherings we should not have had it much more than six days. We find birds are beginning to pick many Pears that are yet pretty well as hard as stones, and as for flies we never knew them so numerous. The hot weather early in summer seemed to bring them out in myriads, they are even more troublesome than the earwigs. Bottles with sour beer and sugar will settle a good many of them, but the double hand-glass is as good a trap as any, with a plate of decayed fruit and fermenting liquid in the lower one, and a hole in the top to let them fly up and enter the upper one. Bushels of flies and wasps may thus be trapped. Wasps are now coming, though rather weak on the wing; we saw none during all the rainy time, and we presume many died then. The honey bee this season has attacked fruit, especially the smaller fruit, without mercy; we have seen half a dozen on a single Gooseberry. Plums have been a wonderful crop, but many of them are ripening early. Many trees would have been better of a good thinning. Such loads one year are apt to be followed by a thin crop the following year. Strawberry plants in pots have been well watered and exposed fully to the sun. A little soot was dusted on the surface of the soil in the pots, alike to enrich it, and to keep out worms. Watered Figs and late Vine-border, the latter most likely for the last time.

#### ORNAMENTAL DEPARTMENT.

Here, in addition to potting, regulating climbers to give more light, and preparing plants for being placed under protection, the chief work has been propagating Geraniums for next summer's display in the flower garden. We would have done it a few weeks earlier if we could have found time, but there are cases in which cleanliness, good order, and fine condition of the beds, must for the time obtain the first consideration. The neatness and good keeping, even of a part, required a great deal more time and labour than usual, owing to the warm rains, and the very hot weather succeeding. The grass grew with such rapidity as to be beyond the reach of our single-man mowing machines, for with such machines there is nothing gained by cutting when the grass is long. Under such circumstances we never met with grass worse to mow with

the scythe. Notwithstanding previous rolling the grass was as soft, as yielding, and as difficult to cut as so much pulpy cotton. We shall be glad when we can overtake all with the mowing machines again. When beds are to be dressed, regulated, picked, &c., it is often best to mow round them, as one clearing up does for all, and an extra sweeping in these times ought to be guarded against.

The general work has been so similar to previous weeks, that we shall here advert to two causes that greatly affect the beauty of flower-beds in the flower garden. 1, There is the custom of having numbers of cut flowers stuck all over the rooms of the mansion; it matters not though these from their position and surroundings are anything but ornamental. In some cases the gardener merely sends in a basket of flowers every day. In others, vases, baskets, tables, are sent to him to fill, and then a great amount of time is taken up with the filling of them, which is often little thought about. In either case the flower-beds will be robbed of their beauty, as it will be of no use cutting any except the very best. Cut even twenty trusses out of a good little bed of scarlet Geraniums, and you will not leave the bed as bright as before. Where the flower-beds are to be kept very nice, and yet lots of flowers must be had in-doors, we would advocate a reserve garden or a large mixed border being appropriated to this cutting purpose. We know that much unpleasantness arises from the seeming forgetfulness of the simple fact that the best flowers cannot be in the flower-beds and in the house at one and the same time. With such a border a lady could have the pleasure of helping herself without at all interfering with the pet beds of the gardener, and more satisfaction would be derived from the cut flowers. 2, If taken from the beds, the gardener himself, if possible, should always cut them. He will be very careful in making his selection so that the cut flowers shall be as little missed as possible; he will also go to the beds again and again rather than have too much cut at first. Most likely if he send some one else that has not reason to take a pride in the beds, he will have have made and have more of some things than he wants. Some ladies do this selecting work in fine weather themselves, and in general with great nicety. But if a gardener dare hardly trust some of his own men, what shall we say when house servants are allowed or commissioned to cut and gather such flowers as they please, and when they please? If such work were confined to a definite border it would matter less. True, as the flowers belong to the lady or gentleman employer, they respectively have a right to cut where they please, or to send others to do the same, even to cutting over all the flowers in a bed if it so please them. We have no desire in the least to question the right, but we do question the prudence and fitness of all such proceedings. We go farther, and say, unhesitatingly, that where the practice exists of anybody and everybody doing pretty well what they like in a garden, the gardener must be more than man if his interest and enthusiasm in his work do not gradually decline to zero point. We know that many otherwise kind and considerate employers have lost the services of good gardeners because they failed to recognise the very simple fact that to enable him to serve them efficiently, he must be as independent of all house servants as they are of him; in other words, that no more liberty should be taken by house servants in the garden than the gardener would think of using in the store-room, kitchen, or pantry.—R. F.

TRADE CATALOGUES RECEIVED.

Jean Verschaffel, Rue de la Caverne, 43, Ghent, Belgium.—*Catalogue des Plantes et Prix-courant pour l'Automne, 1865; et Printemps et Eté, 1866.*

Quettier & Son, Ussy (Calvados), France.—*Trade Catalogue of Seedling and Transplanted Forest Trees and Conifera.*

Barr & Sugden's *Compendium of their Illustrated Autumnal Floral Guide.*

F. & A. Dickson & Sons, 106, Eastgate St., Chester.—*Catalogue of Select Dutch Flower Roots.*

Sutton & Sons, Reading.—*Catalogue of Bulbous Flower Roots, Geraniums, Fuchsias, and Fruit Trees, &c.*

R. Parker, Exotie Nursery, Tooting, Surrey.—*Catalogue of New and Rare Stove, Greenhouse, and Hardy Plants.*

Hooper & Co., Covent Garden Market.—*General Autumn Catalogue of Dutch, Cape, and other Flowering Bulbs.*

COVENT GARDEN MARKET.—SEPTEMBER 9.

IMPORTATIONS have decreased generally, with the exception of Grapes which are now coming from Holland and Jersey, as well as from France. The market continues to be heavily supplied, and trade is very dull.

TO CORRESPONDENTS.

FRUIT TREES FOR SOUTH-SOUTH-EAST WALL (*H. J. N.*).—Your wall will do well for Apricots, and the better kinds of Plums; and if the situation be not elevated, but is sheltered, Peaches and Nectarines might be grown tolerably upon it. The grubs feasting on the winter greens, as Savoys, &c., are what gardeners call "leather-coats," they being the larvæ of the daddy longlegs. They are unusually prevalent this season, and eat through the stems a little below the surface. There is no effectual remedy but to search for them and kill them. By all means as they are so numerous have them hand-picked and destroyed.

SCALE ON FRUIT TREES (*Sympathy*).—Spirit of turpentine is fatal alike to both insects and their eggs, and it will not injure the shoots or branches, but destroy every bud it touches, especially when applied after the buds begin to swell. Wash the trees after the leaves fall with Gishurst compound at the rate of 8 ozs. to the gallon of water, applying it with a brush, and brushing it well into every crack, hole, or crevice, and this so effectually as to dislodge the insects, taking care all the time not to injure the buds. Badly infested as your trees must be from the specimen sent, we would advise the trees to be well washed with water at 100° by means of a rather stiff or half-worn painter's brush, which will free the trees of the insects to a great extent, and then wash them with Gishurst early at the rate of 8 ozs. to the gallon of water, or sulphur and soft soap in equal quantities, 8 ozs. of each to a gallon of water in which 2 ozs. of the strongest tobacco has been steeped for twelve hours, and the water poured over it boiling, and 4 ozs. of gum arabic put in to dissolve after it became cool. The trees once or twice washed with water at 160°, as they may be infested, and then dressed with either of the above compositions will be free from the enemy to a great extent, and the process will only need repeating annually for a time to effect a cure. Turpentine, as stated in the "Gardener's Dictionary," is a certain cure for all attacks of the cocoon or scale family; but it should only be applied to the branches, avoiding the buds.

TREES FOR SHELTERING A GARDEN (*M.*).—Of the trees named by you Robinia pseud-acacia is too spare in branches, too spreading, and altogether too large for the purpose. Plane trees are alike too large and spreading, and if it be Platanus occidentalis it needs sheltering rather than is calculated to shelter a small garden. Birch is for the most part the least objectionable, and is mostly of small growth; it is dense in foliage, has numerous small twigs, and does very well in moist soils, but is less ornamental than many others. Ailanthus glandulosa is a tree that requires rather than affords protection. For protecting a small garden from cold winds there is no better shelter than a hedge 6 or 8 feet high of Thorn or Privet, and one of Beech 10 feet high is sufficient protection for any garden of small area. They take up less room and their roots extend less than trees, for the latter should be situated at such a distance that they do not root into, overhang, or shade what they are intended to shelter. Unless the trees can be so planted that their roots do not extend into the garden or their branches overhang it, hedges are the more desirable.

SCHIRAS GRAPE (*T.*).—We know of no synonyms of this Grape except those enumerated in Dr Hogg's "Fruit Manual." You could obtain three varieties of it from M. A. Leroy, Nurseryman, Angers, France. We do not know a fuller address to Mr. Heywood.

GAS TAR FOR GARDEN FRAME (*Della*).—We deprecate from experience using gas tar even outside a plant-house, and to apply it inside is only to enable it to be more speedily and more certainly destructive to the plants. A year must pass before they could be put safely into a gas-tar-painted structure.

**CALIFORNIAN PUMPS.**—The pump described in the last Number of the Journal, by Mr. Freek, of Norwich, has no resemblance to the one I spoke of in the same Number, mine being made of iron and brass, and forcing water to any reasonable height, as well as lifting it like a common pump. I dare say they are cheaper than other pumps. How their durability may be I do not yet know.—W. N. BAXTER, *Thornton-le-Moor*.

**EVERGREENS UNDER LARCH AND FIR TREES.** (*S. P.*)—In addition to the Rhododendrons, which you find do so well under them, *Berberis Darwini*, *B. aquifolium*, or *Mabouia aquifolium*, and *B. repens* would do equally well, also *Laurnstinus*, if not too much shaded and exposed to cutting winds, and *Aucuba japonica* and *Skimmia japonica*. Laurels do fairly, Yew, Box, and Holly moderately well, Butcher's Broom excellently, and, better than anything, *Vineas* or *Periwinkles*. Ivy, to carpet the ground and clothe the trunks of trees, is good, enlivened with *Snowdrops*, *Winter Aconites*, *Primroses*, *Harebells*, and some of the commoner kinds of Ferns.

**VINE FOR GREENHOUSE** (*New Subscriber*).—We suppose the nurseryman meant the "Finger Grape," if so it is the *Cornichon blanc*, and worthless. Have three *Black Hamburgs* and two *Lady Downe's*. An *Apricot* might succeed on a trellis against the glass end of the house. Figs would not prosper under the Vines.

**PROPAGATING-BEDS AND MELON-BEDS IN A HOTHOUSE** (*A. Y. Z.*)—The most economical plan would be to surround your pipes at the bottom of the beds with bricks, clinkers, &c. to the depth of a foot, and then some clean-washed gravel, and then the soil for Melons and Cucumbers, and what you like best for the propagating-bed. A more perfect way would be—have the pipes in a chamber, the chamber covered with slate; but we like the rough mode rather the better. In placing on the soil, leave some upright drain pipes, with the lower end among the rubble, so as to let down water when desirable without soaking the soil. If you keep

your six pipes for bottom heat—that is, have no slides to let the heat out then you will require two pipes all round the house for top heat instead of one. A specimen of Mr. Beard's houses may be seen at the Botanic Gardens, Bury St. Edmunds; also at Mr. Sanders', Victoria Works, Bury St. Edmunds. You have evidently missed the advertisement that appeared on the 15th of August. The volume is out of print, but all the Numbers can be obtained with the exception of five.

**BOILER FOR CUCUMBER AND MELON FRAME** (*E. S. B.*)—If you mean the boiler to do no more than the 21 feet of pit, then a small saddle-back or conical one will answer your purpose. Any bricklayer that can set a copper properly, will also set a boiler to the best advantage. To have Cucumbers and Melons early, you would require two four-inch pipes for top heat, and two for bottom heat. We have two three-inch pipes, but they are not enough for early work. The simplest plan would be to take two pipes along for surface heat, and return them in the chamber for bottom heat. Have the top of your boiler below the level of the lowest pipes in the chamber, and there will be draught to burn anything.

**VINES SHRIVELLING** (*Durham*).—You do not say what the size of your lights is, as, if from 2 to 3 feet in length, the back and front air should have been sufficient, more especially if the back air was given early. There could be no harm in having some square holes in the back wall, if you are at all doubtful as to the quantity of air. Most cases of such shrivelling that have come under our notice have been owing to the leaves being within a few inches of large squares of glass, and neglecting to give air early enough in the morning, so that something like scalding took place. In such hot sunny days as we have lately had, sprinkling the floor with water to neutralise the dryness would also be of benefit.

**NAMES OF PLANTS** (*A. E.*)—1, *Spiraea sorbifolia*; 2, *Viburnum opulus* (*Guelders Rose*); 3, *Alnus glutinosa*. (*W.W.*)—*Tamarix gallica*, or *Tamarisk*. (*June*.)—1, Leaf of an *Orchid*; 2, *Cyanotis vittata*; 3, *Begonia fuchsoides*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending September 9th.

**POULTRY, BEE, and HOUSEHOLD CHRONICLE.**

**THE NATIONAL POULTRY COMPANY.**

BETWEEN the Bromley and Bickley stations on the London, Chatham, and Dover Railway, the traveller perceives the build-

This land is laid out for six similar buildings running from south to north. Between each of the buildings is a market garden 60 feet wide, and about a thousand pyramid fruit trees will form a border to the vegetable garden. On the south, and parallel with the Railway, a range of buildings upwards of 500 feet long will serve as inward and outward offices, stores, manager's residence, and labourers' dwellings. Between this

ing of which the above is a representation. It is 350 feet long and 20 feet wide, of peculiar construction, and erected on a piece of land of about six acres. The site is bordered on the south by the Railway, on the east by the Bromley Gasworks, on the west by extensive hop plantations, and on the north is sheltered by high trees on the estate of Coles Child, Esq., of the Palace.

range of buildings and the poultry-homes the space is divided into several fore courts, in which chickens of a certain age, and classified according to sex, will be left to roam. The inward and outward gates will be formed by two towers surmounted by water-tanks, to obtain high pressure service for the poultry-homes and market garden. The north side of the land is

enclosed by a range of sheds about 500 feet long, and is called the farmyard; the space in front of these sheds will be divided into separate courts, for the proper classification of fowls. Here are also the manure-pits, drained into liquid manure-pits in front of each section of vegetable land, and ponds which are supplied with the rain water drained from the buildings. Behind the sheds are pig-styes, and vermin nurseries. The sheds will be used for preparing the food, as stores, and as killing, plucking, and dressing-rooms for poultry.

In this establishment is about to be tested whether poultry can be raised, partially artificially, on a very extensive scale, and we hope soon to furnish more details.

Those who have advocated the rearing of poultry in large quantities, have frequently referred to the extensive establishment of "M. de Soras," as proving that such a wholesale rearing was not only possible, but profitable. The condemners of such rearing met the evidence by denying its existence, and roundly asserting that "M. de Soras" is a mythical personage. Mr. Geyelin has settled the dispute, by proving that each body of disputants is right, and each party wrong.

There is no "M. de Soras," but there is a vast poultry-rearing establishment. It is at Angy, near Mony, Beauvais, in Picardy, and the proprietor is M. Manoury. Mr. Geyelin has visited the establishment, and says—

"I was received with every courtesy, and informed that he knew of no such name as M. de Soras, nor of any establishment of the kind, but that he devoted his time to rearing some 5000 head of poultry per annum; he neither fed them on horse flesh, nor supplied the markets of Paris, that he sold none but pure breeds, and those to gentlemen and fancy poultry dealers; nevertheless, that his system of hatching, rearing, and feeding was so different to that adopted by others, that it might possibly have given rise to those exaggerated reports; after which he conducted me over his establishment, and explained most minutely the system he has adopted. I have also visited all those places in France so justly famed for their poultry, and from which those celebrated breeds of Houdan, La Flèche, and Crève Cœur are obtained, where also I met with the utmost courtesy in my inquiries, though I had been informed that the farmers never explained or showed their system of poultry-rearing to any one, which possibly may be true as regards their countrymen."

Mr. Geyelin then details what he saw in France, of "natural and artificial incubation," from which details we will make one short extract.

"Amongst some places I visited, in company with two of your shareholders, may be mentioned the farm of Madame La Marquise de la Briffe, Château de Neuville, Gambais, near Houdan, where we observed twelve Turkeys hatching at the same time; here, also, we witnessed the rearing and fattening, which will be alluded to hereafter. In another place, that of Mr. Auché, of Gambais, a hatcher by trade, we observed sixty Turkeys hatching at the same time; and we were informed that

during winter and early spring he had sometimes upwards of one hundred hatching at the same time, and that each Turkey continued hatching for at least three months. At the farm of Mr. Louis Mary, at St. Julien de Fauçon, near Lizieux, in Calvados, I saw a Turkey that was then sitting, and had been so upwards of six months, and, as I considered it rather cruel, the hatcher, to prove the contrary, took her off the nest, and put her in the meadow, and also removed the eggs; the Turkey, however, to my surprise, returned immediately to her nest and called in a most plaintive voice for her eggs; then some eggs were placed in a corner of the box, which she instantly drew under her with her beak, and seemed quite delighted. Moreover, I was informed that it was of great economical advantage to employ Turkeys to hatch, as they eat very little, and get very fat in their state of confinement, and, therefore, fit for the market any day."

We have not space to devote to the very useful and interesting particulars Mr. Geyelin gathered relative to fattening, feeding, killing, and dressing poultry in France, but we must extract what he says on

"UTILISING THE WASTE PRODUCTS.

"Poultry Manure.—In France, as well as in our own country, most eminent chemists have proved by analysis that poultry manure is a most valuable fertiliser, and yet for a want of a proper system in housing poultry, it has as yet not been rendered available to rural economy. The celebrated Vanquelin says that when the value of manures is considered in relation to the amount of azote they contain, the poultry manure is one of the most active stimulants; and when, as a means of comparison, the following manures are taken, in parts of 1000 it will be found that—

Horse Manure contains .....	4.0 parts of azote.
Guano as imported .....	49.7 do.
Guano, when sifted of vegetables and stones .....	53.9 do.
Poultry Manure.....	83.0 do.

"In France, as in England, the poultry manure is left to accumulate in the poultry-homes, to the loss of farmers, and to the detriment of the health of fowls.

"The Feathers are carefully collected and sorted, and when well dried sold to dealers.

"The Intestines are boiled, the fat skimmed off, which is sold separate; the intestines are then minced as food for poultry, and the liquid is used for feeding pigs.

"The Combs and Kidneys are sold to pastrycooks—the first for decorating, and the latter for flavouring pies.

"The Head, Neck, and Feet are sold to hotels, restaurants, &c., for flavouring sauces, or boiled down to make chicken jelly."

The foregoing are extracted from Mr. Geyelin's "Report to the Poultry and Egg Company," whose establishment at Bromley, Kent, is now completed, and of which Mr. Geyelin is the manager. That report is highly interesting, and will gratify any lover of poultry who peruses it.

A GOOD BEE-HOUSE.

I HAVE sent a sketch of my bee-house, which is the best covering for bees that I can find, and very convenient for supering, &c. It is made of half-inch boards, except the floor, which

screwed to the floor, as shown by the sketch of the end. As to flat-square straw-hives I intend making some in readiness for next spring. My plan is, to make a square frame, work the

is 1½ inch thick. It is closed-in all round except the front, 7 inches of which is left open. The ends of the front part of the roof are fixed, but the back board and back part of the roof are moveable. The back board is kept up by two hasps

straw round it, and then screw a board on to the frame for the top. Information as to the size which they ought to be (inside measure), would oblige—A BUCKS BEE-KEEPER.

[Mr. Woodbury's frame-hives are 14½ inches square by

9 inches deep inside, and the bar-hives 13 inches square by 9 inches deep. In either case a space of three-eighths of an inch should be left between the top of the frames, or bars, and the crown-board.]

## THE KEIGHLEY POULTRY EXHIBITION.

SEPTEMBER 1<sup>ST</sup>.

FOR many years past the Keighley show of poultry has proved itself an object of great interest to the exhibitors of poultry and Pigeons, and we are gratified in being able to state that the show just closed has been by far the most successful of any held by this Committee. The entries, as to numbers, proved not only far in advance of those in previous years, but also were attended throughout the classes generally with improvement of quality that evinces the very opposite of decadence as to our poultry exhibitions. This result is most satisfactory; and when we mention the fact that the weather was fortunately most propitious, our readers will readily imagine that the amount received for admission on this occasion was far in advance of that of prior meetings. The fact is, that scarcely an indifferent pen could be pointed out among the many exhibited, and that although mounting-time is now general, there were very few empty pens.

The Keighley show this year was undoubtedly the best we have seen for many years past in all the varieties of *Hamburghs*, so much so, that the excellence displayed in these classes was a theme of general admiration and congratulation among the poultry-breeders assembled. We noticed, also, some particularly good *Spanish* chickens, and the Dark-feathered *Brahmas* were equally good. Some extraordinarily good *Gaucic* chickens were also shown, of which there were several pens, but having been "dubbed" recently, they did not show to the same advantage that they will do a month or two hence. The *Polands* of all kinds were most praiseworthy, and a pen of the now-so-rarely-seen perfectly white ones, were well shown. Not a single Sebright was present, nor was there any new variety exhibited. It was, in fact, a matter of conversation among those assembled, how very rarely we see any new breed of late years, to what were introduced some time back.

The *Aylesbury* and *Rouen Ducks* were most excellent, and so were the *Buenos Ayrean* variety. Some very excellent *Game Bantams* (Black-breasted Reds) were shown, and also some capital *Brown Reds*; the latter, however, were a little too large for competition, though excellent specimens for brood stock.

The *Pigeon* entries were unusually large, and a very close competition ensued, causing a great amount of public interest, far greater than at any previous meeting of the Keighley Society. Under these circumstances, no doubt, this has proved one of the most encouraging meetings held at Keighley.

**GAME.**—Cup, H. Beldon, Bingley. Highly Commended, J. Fletcher, Stoneclough. Commended, E. Aykroyd, Bradford; A. Briggs, Rawden. *Chickens*.—Cup, R. Tate, Leeds. Second, J. Fletcher. Third, R. Payne, Brierfield, Burnley. Highly Commended, T. Hartley, Gomersall.

**COCHIN-CHINA** (Any colour).—First, H. Beldon. Second, C. Sidgwick, Riddlesden Hall. Commended, J. Jackson. *Chickens*.—First and Second, C. Sidgwick. Highly Commended, J. Jackson; J. Duxbury, Keighley.

**SPANISH** (Black).—First and Second, H. Beldon. Commended, E. Brown, Sheffield. *Chickens*.—First, E. Brown. Second, T. Greenwood, Dewsbury. Highly Commended, S. Schofield, Heckmondwike. Commended, Messrs. Birch & Boulter, Sheffield.

**CHITTEPRAT.**—First, J. Dixon, Bradford. Second, A. K. Wood, Kendal. Highly Commended, H. Beldon. *Chickens*.—First, J. Dixon. Second, H. Beldon. Highly Commended, H. Smith, Morton Banks; T. Stell, Keighley. D. Illingworth, Burnley. Commended, R. Longbottom, Bugley; H. Walton, Cowling.

**PHEASANT** (Golden).—First, H. Beldon. Second, R. Tate. Highly Commended, A. K. Wood; W. Driver, Bank House. *Chickens*.—First, H. Beldon. Second, J. Hardwick, Keighley.

**HAMBURGH** (Golden-pencilled).—First, J. Dixon. Second, R. Hemingway. Highly Commended, S. Smith, Northowram. Commended, H. Beldon. *Chickens*.—First, S. Smith. Second, R. Hemingway. Highly Commended, J. Dixon. Commended, J. G. Park, Low Hall, Whitehaven; S. Smith.

**PHEASANT** (Silver).—First, A. K. Wood. Second, J. Newton, Silsden. Highly Commended, H. Beldon. Commended, J. G. Park. *Chickens*.—First, C. Cowburn, Leeds. Second, T. Berry, Sutton. Highly Commended, R. Barret, Sutton; T. Fawcett, Baildon. Commended, R. Barret; T. Parker, Utley; S. Smith.

**PHEASANT** (Black).—First, C. Sidgwick. Second, W. Mand, Bingley. Highly Commended, J. Dixon. *Chickens*.—First and Second, C. Sidgwick. Highly Commended, H. Beldon; J. Hargreaves, Skipton; S. Butterfield, Keighley.

**GOLDEN OR SILVER PHEASANT** (Polands).—First and Second, H. Beldon. *Chickens*.—First, H. Bowker, Keighley. Second, T. E. Kell, Wetherby. Highly Commended, H. Gornal, Farley.

**DORKING.**—First, T. Briden, Earby. Second, H. Beldon. *Chickens*.—First, T. E. Kell. Second, W. Bland, Peak Rydding.

**GAME** (Red).—First, J. Hodgson, Bowling. Second, R. Hemingway. Highly Commended, F. Walker, Silsden; T. Dyson, Halifax. *Chickens*.—First, R. Payne, Burnley. Second, W. Spencer, Haworth. Highly Commended, J. Spencer, Queensbury. Commended, R. Tate; W. Gamon, Thorton-le-Moors.

**GAME** (Any other variety).—First, E. Aykroyd, Bradford. Second, W. Bealey, Scholes. *Chickens*.—First, T. Hartley. Second, G. Noble, Staincliffe, Dewsbury. Commended, T. Dyson, Halifax.

**POLANDS** (White-crested).—First and Second, J. Smith, Keighley. *Chickens*.—First and Second, J. Smith.

**GAME BANTAM** (Black or White).—First, A. Briggs, Rawden. Second,

R. Tate. Highly Commended, G. Noble, Dewsbury; S. Schofield. *Chickens*.—First, G. Noble. Second, R. Tate. Highly Commended, E. Aykroyd. Commended, J. Wade, Silsden.

**ANY OTHER DISTINCT BREED.**—First and Second, H. Beldon (White *Polands* and *Dark Brahmas*. *Chickens*.—First, E. Greenwood, Overtown, Burnley (Dark *Brahma*). Second, W. Spencer, Haworth (Dark *Brahma*) *Ducks* (Rouen).—First, H. Beldon. Second, W. Gamon. Highly Commended, J. Wade.

*Ducks* (Aylesbury).—Prize, H. Beldon.

*Ducks* (Black Indian).—First and Second, J. Hargreaves.

*Ducklings*.—First, J. Newton (Aylesbury). Second, A. Smith, Silsden. (Rouen).

**GEES.**—Prize, R. Tate (Grey).

**GREENS.**—*Cock Pouter* or *Cropper*.—First, C. Cole, Bowling. Second, J. Thackray, York. Commended, C. Cole; E. Brown, Sheffield. *Hen Pouter* or *Cropper*.—First and Second, C. Cole. Commended, J. Thackray.

*Cock Carrier*.—First, H. Beldon. Second, C. Cole. Commended, J. Thackray; J. Firth, Dewsbury; C. Cowburn, Leeds. *Hen Carrier*.—First, J. Thackray. Second, C. Cole. Commended, C. Cowburn.

*Almond Tumblers*.—First, H. Yardley, Birmingham. Second, C. Cole. Commended, E. Brown. *Balds*, *Beards* or *Mottled Tumblers*.—First, C. Cole. Second, J. Dunderdale, Keighley. Commended, J. Lister, Keighley; H. Yardley.

*Oaks*.—First, H. Yardley. Second, C. Cowburn. *Turbits*.—First, J. Thackray. Second, H. Yardley. Commended, J. Thackray. *Jacobins*.—First, C. Cole. Second, J. Thompson, Bingley. Commended, C. Cole.

*Fantails*.—First, H. Yardley. Second, J. Thackray. *Barbs*.—First, C. Cole. Second, H. Yardley. *Dragons*.—Second, J. Thompson. Commended, B. B. Laycock, Keighley; J. Parker, Oakworth Hall. *Trumpeters*.—First, J. Thompson. Second, H. Yardley. *Maggies*.—First, H. Beldon. Second, H. Yardley. *Archangels*.—First, H. Yardley. Second, C. Cole. Commended, H. Yardley. *Any other breed*.—First, H. Yardley. Second, J. Thackray.

Commended, G. Mawson, Carlton; H. Yardley.

Mr. Edward Hewitt, of Sparkbrook, Birmingham, was the Judge of Poultry; and Messrs. H. Smith, of Skipton, and W. Cannan, of Bradford, officiated for the Pigeon classes.

## LONGRIDGE (NEAR PRESTON) DISTRICT AGRICULTURAL SOCIETY.

THE third annual show meeting in connection with this Society was held at Longridge, on Thursday, the 31st nit. Beneath are the awards for poultry:—

**SINGLE GAME COCK.**—First, R. Parkinson. Second, T. Wareing. Third, B. Walmsley.

**DORKING** (White, Speckled or Grey).—First, J. Robinson. Second, J. Pindar.

**SPANISH.**—First, T. Wareing. Second, J. Pindar. **GAME FOWLS** (Any variety).—First, R. Parkinson. Second, J. Robinson. **COCHIN CHINA.**—First, J. Wood. Second, J. Robinson.

**HAMBURGH** (Golden-pencilled).—First, J. Robinson. Second, W. Bee. **HAMBURGH** (Silver-pencilled).—First, J. Robinson. Second, E. Gardner. **HAMBURGH** (Golden-spangled).—First, J. Robinson. Second, T. Wareing. **HAMBURGH** (Silver-spangled).—First, J. Robinson. Second, T. Wareing.

**POLANDS** (Any variety).—First and Second, J. King. **BANTAMS** (Any variety).—First, T. Kenyon. Second, T. Wareing. Commended, M. Turner.

**CHICKENS** (Any variety).—First, J. Wood. Second, J. Pindar. **DUCKS** (Aylesbury).—First, J. Robinson. Second, Executors of the late G. Whittle.

*Ducks* (Rouen).—First, J. Robinson. Second, T. Wareing.

**GEESE.**—First, W. Bee. Second, G. Longworth.

**TURKEYS.**—Prize, J. Wahe.

## THE LOUGHBOROUGH POULTRY EXHIBITION.

THE Poultry Exhibition in connection with the Sparkenhoe Farmers' Club, was this year held at Loughborough. At an early hour on Wednesday last, a most refreshing breeze and brilliant sunshine angured well for a truly enjoyable day at the Poultry Show. Trip-tickets by railway, carriages, both private and public, each tended to increase the numbers, whilst crowds of pedestrians added so greatly to the hosts of visitors, that many thousands must have been present in a very brief period after opening the gates for public admission. The Show took place in the grounds of H. Warner, Esq., of The Elms, Loughborough, nor could a more suitable place for such a meeting be imagined, being park-like in character, and studded abundantly with trees arrived at maturity. Every one seemed pleased with their visit, and numbers who had never previously seen a poultry show, acknowledged that they had not anticipated in the slightest degree the treat that was in store for them. We cannot omit the simple mention, how much the popularity attained by this Show has arisen entirely from the exertions of its Committee from year to year, to provide not only for the comfort of the specimens exhibited, but also for the convenience and pleasure of every visitor. Even had unfavourable weather unhappily been the issue, not a bird nor visitor need have suffered, the most ample provision against rain being provided for all. This is as it should be, and another picturesque arrangement was, four large garden chairs were placed beneath each of the very many well-grown trees, thus affording shade and a rest to numbers of wearied pleasure-seekers as time wore on. What a pleasing contrast to numbers of instances we could adduce, where not a single stool was even available to the fatigued among the fair sex, and Committees would do well to become copyists in these little inexpensive particulars, as tending more than is by many parties supposed to enlist popular sympathies for future meetings.

The Show proved good, though, as any poultry fancier too well knows, old birds have as yet scarcely recovered their plumage. A great feature in the Sparkenhoe Farmers' Club is this, the offer of a five-guinea cup to be awarded to the three best pens of poultry of any variety; in fact, it is alike available for every breed, without restriction or limit of any kind, except the simple one, that the three pens must be different varieties; and a second prize of £2 is given to the second best also. Every one knows the extreme difficulty of selecting three perfect pens from any one yard, more particularly when wanted just at moulting-time; still it is quite as fair for one as another among competitors, and lucky is the man who finds his birds in good condition at the proper time. Five lots were entered, but one set of pens remained empty. We have seen the competition in this class far more severe at former meetings than on the present occasion, not a single competitor showing three perfect pens. To a superficial observer the class would appear at a first glance far superior to what it really proved to be on a close examination. One party showed three splendid pens of *Game* chickens particularly well grown—viz., Black-breasted Reds, Brown Reds, and Duckwings, but the two pullets in the first-named variety were entirely "duck-footed," which at once gave a quietus to their hopes of success. A second competitor exhibited some Grey *Dorkings* with white legs but black feet, the very base of the legs being also of the same objectionable hue. This fatal fault immediately upset their chance of prize-taking. The trial now rested exclusively between two lots only, one composed of Duckwings, Red Piles, and Brown Red *Game* fowls; the other competitor showing Buff *Cochins*, *Spanish*, and White *Cochins*. Among the *Game* fowls just alluded to, was a Duckwing hen, purposely despoiled of her ear-lobes, most probably because they had been previously white. The Red Piles did not match in the colour of the legs, and the Brown Red cock had a twisted spur. The cup-winners were a pen of extraordinarily well-grown Buff *Cochin* chickens, far beyond anything at present exhibited this season; an exceedingly good pen of Black *Spanish*, but out of condition; and a pen of first-rate White *Cochins*, but the cock was evidently quite a martyr to "elephantiasis," a kind of leprosy, that can be cured by strong remedies, patience, and perseverance, but still difficult to eradicate. It will be seen, therefore, that the competition this year for the cup was neither numerous, nor what it should be as to excellence; but, no doubt, the weakness of the class this year will enlist a strong competition on the next occasion, from many who deeply regretted they had not entered. To such we can only apply the old adage, "faint hearts are never successful." Some very good Grey *Dorkings* were exhibited, but we must remind exhibitors, that malformations are always fatal to success in poultry, either for exhibition or breeding, and that black feet in *Dorkings* is quite a novel fault, but one that all other good qualities cannot palliate. The White *Dorkings* were so indifferent as to cause every prize to be withheld. Some splendid Chinese Silver *Pheasants* were shown, but no entry whatever took place for the Chinese Golden *Pheasant* prizes.

The *Geese*, White *Aylesbury*, and *Ronen Ducks* were good, whilst a pen of really good White *Call Ducks* were well shown.

In *Pigeons*, no doubt, the *Powters*, *Carriers*, and *Lahores* were the cream of the varieties shown.

We were pleased to find the poultry and *Pigeons* shown in such good health, the late heavy rains having proved most destructive in many districts within the few weeks last past.

A prize, value £5 5s., for the three best pens of poultry, of any variety, exhibited by and the property of one person.—Silver cup, H. Yardley, Market Hill, Birmingham (Buff *Cochins*, Black *Spanish*, and White *Cochins*). Second, Sir St. G. Gore, Bart., Wirksworth (Black-breasted, Red Pile, and Duckwing *Game*).

*SPANISH*.—First, M. Brown, Melton Mowbray. Second, W. T. Everard, Ashby-de-la-Zouch.

*DORKING* (Coloured).—First, W. T. Everard, Ashby-de-la-Zouch. Second, H. Warner, Loughborough. Commended, W. R. Dick, Derby.

*COCHIN-CHINA*.—First, M. Brown, Melton Mowbray. Second, Mrs. Wolferstan, Tamworth.

*GAME* (White, Piles, and Light Colours).—First, Sir St. G. Gore, Bart., Wirksworth. Second, G. Bott, Atherstone. Highly Commended, W. T. Everard, Ashby-de-la-Zouch; G. Bott, Atherstone.

*GAME* (Red, and other Dark Colours).—First, Sir St. G. Gore, Bart., Wirksworth. Second, J. Tyler, Loughborough. Commended, G. Bott, Atherstone; G. Heafford, Loughborough.

*HAMBURGH* (Gold-spangled).—First, H. E. Emberlin, Leicester. Second, Sir St. G. Gore, Bart., Wirksworth.

*HAMBURGH* (Gold-pencilled).—Prize, Sir St. G. Gore, Bart., Wirksworth.

*HAMBURGH* (Silver-spangled).—Prize, Sir St. G. Gore, Bart.

*HAMBURGH* (Silver-pencilled).—First, Sir St. G. Gore, Bart. Second, J. Meredith, Atherstone.

*ANY OTHER DISTINCT BREED*.—First and Second, J. Meredith, Atherstone (Silks and Andalusians).

*PHASANTS* (Silver).—Prize, J. Buck, Leicester.

*DUCKS* (White *Aylesbury*).—First, Sir St. G. Gore, Bart., Wirksworth.

Second, H. E. Emberlin, Leicester. Highly Commended, W. T. Everard, Ashby-de-la-Zouch; W. & H. Gill, Loughborough.

*DUCKS* (Any other Variety).—First, J. Johnson, Leicester (White Calls). Second, W. & H. Gill, Loughborough (Rouens). Highly Commended, W. Mosely, Loughborough (Buenos Ayrean); W. T. Everard, Ashby-de-la-Zouch (Rouens).

*GEENE*.—First, Mrs. Wolferstan, Tamworth. Second, J. Garton, Loughborough.

*TURKEYS*.—First, J. Johnson, Leicester. Second, Mrs. A. Guy, Grantham. Highly Commended, C. W. Packer, M.P., Loughborough; J. Johnson, Leicester.

*GUINEA FOWLS*.—First and Second, J. Johnson, Leicester. Highly Commended, W. Green, Ashby-de-la-Zouch.

*BANTAMS*.—First, Sir St. G. Gore, Bart., Wirksworth. Second, H. E. Emberlin, Leicester. Highly Commended, W. Draycott, Leicester.

*GAME FOWLS*.—Prize, H. Warner, Loughborough. Highly Commended, W. T. Everard, Ashby-de-la-Zouch.

*DORKINGS*.—Prize, H. Warner, Loughborough.

*HAMBURGHS*.—Prize, W. & H. Gill, Loughborough.

*ANY OTHER BREED*.—Prize, M. Brown, Melton Mowbray (Spanish).

*PIGEONS*.—*Powters* or *Crappers*.—First, H. E. Emberlin, Leicester. Second, H. Yardley, Birmingham. Highly Commended, H. E. Emberlin.

*Carriers*.—First, H. Yardley, Birmingham. Second, W. Draycott, Leicester. *Tumblers*.—First and Second, H. Yardley. *Fantails*.—First, H. Yardley. Second, W. Draycott, Leicester. Commended, H. Yardley.

*Any other distinct variety*.—First and Second, H. Yardley (Lahores and Bruiswicks).

*RABBITS*.—*Heaviest Weight*.—First, A. Houghton, Melton Mowbray. Second, W. Draycott, Leicester. Highly Commended, J. N. Dixon, Commended, G. Jones, Birmingham. *Length of Ear*.—First, G. Jones.

Second, J. N. Dixon. Commended, W. Draycott. *Any other kind*.—First, H. Warner, Loughborough. Second, G. Jones. Highly Commended, H. Warner. Commended, W. Draycott. *Extra*.—Prize, —

Cayless, Loughborough (Angoras).

The Judges were Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, Birmingham; and Mr. Henry Marshall, of Cropwell Butler, Bingham, Notts.

## NOTES ON PIGEONS.

### THE POWTER.

I AM not surprised that the *Powter* has always been a favourite with fanciers, particularly with those whose callings or health keep them much at home; for he is a sociable bird, more so than any other *Pigeon*. Then he is the most important-looking and acting personage of the whole tribe. Others merely walk and fly; but he struts, jumps, and, man-like, disdain looking to the ground, and is as perpendicular in carriage as others are horizontal. Then his long legs are so different to the mere little feet of the others. Hence he stands apart as an individual—he can be classed with none. Like King Richard he may say, "I am myself alone." The *Powter* has great power over other *Pigeons*: whether it is by the exercise of an attractive nature or mere bullying I cannot determine, but so it is. If you keep, say, but one pair among any number of other varieties, the cock will be the recognised head of the fraternity—all will yield to him, and follow his lead as to what parts of the roof to bask upon. If he dies or is sent away it is odd to mark how he is missed; the rest are a mere number of small birds; they scatter to other parts of the roof, seem uneasy—like the French, they delight in an emperor.

Inside the house the *Powter* shows off well. On the landing-board he is in supreme happiness, and struts about to his own entire satisfaction. Along the roof he parades; in all places he seems to say, "Look at me! look at me! What a fine fellow I am!" And even on the wing he is so loud and demonstrative that one is fain to look up at him.

To see *Powters* to perfection you should keep *Tumblers* with them. Each kind sets off the other. The tall *Powter* looks taller beside the short plump *Tumbler*, and the compact and symmetrical *Tumbler* looks doubly compact beside the slim *Powter*. We judge of everything by comparison: it is well, then, to have the means of judging at hand.

Much as I admire *Powters*, I must own that *Powter-love* is an acquired love. Thus ladies, the best judges of appearance, always pronounce them "ugly,"—i. e., provided the said ladies are not fanciers, while they always praise *Jacobins* as "loves, pets, darlings." I would not overpraise any bird, but give each variety its proper place. Thus I would not dethrone the all-graceful *Carrier* in spite of the telling ways of the *Powter*. The *Carrier* is marked by nature as superior to all other *Pigeons*—he is their rightful king; the *Powter*, his self-important lord chamberlain, who is nothing unless he is pompous. Thus, frighten him, down at once goes his wind-bag, and the scared wretch becomes an ill-shaped Runt, so unlike the *Carrier*, who, if you frighten him, looks only the more graceful, and gives an indignant snort. Neither, again, would I forget the minute beauties of the diminutive *Almond Tumbler*, though he does look a little like one of a degenerate and therefore enfeebled race—a sort of modern *Athenian*.

There is, perhaps, another reason besides his sociality, his amusing pomposity, and his remarkable tameness, even impudence, which has made the *Powter* a favourite with English fanciers—viz., the difficulty of breeding good ones, and Englishmen like whatever gives them trouble to get perfect. Who has seen many first-rate *Powters*? I have not seen twenty-five in as many years. This one would be good, but the half-moon is wanting; that is a long bird, but loose-winded; that overblows himself, and loses all self-command. This has too much

white, that too little; this is well-shaped but short, that is ill-shaped though long.

Then as to breeding. Now that it is pretty well understood that they will raise their young if fed on beans there is less trouble than formerly; and I will also add from experience they will equally well rear their young if fed entirely upon Indian corn, but not if peas be mixed with it. Still, after all, good Powters ought to fetch a high price, as so very few come up to the standard.

Next as to colour. In spite of all that has been written in favour of yellow, red, and black pied, I think blue pied is best of all. I believe it to be the original colour, and therefore also the best. Mr. Eaton, who knows Pigeons well, has in his coloured plates of perfect birds figured his Powder as a blue bird. But there are other reasons in favour of blue. The shining green of the crop, so great an ornament, is never seen half so bright in other colours as in blue piers. I have seen blue Powters whose crops looked like balls of glittering metal. Then the lighter blue of the wings and body does not make so harsh an outline as other colours, and the beautiful and most ornamental black bars tell so well; and as it is possible to get a blue tail the white flights lie against it like bright swords. According to my taste and judgment, black for Carriers, white for Fantails, and blue for Powters.

A word about Powder-judging. I think too much stress is laid upon mere length. Judges stretch out the birds, and the longest wins the prize. If I were judge, I should balance all the points, giving so much for carriage, elegance of shape, narrowness of girth, and a coarse long bird should not heat one better shaped though rather shorter. Powters are different to all other Pigeons, and should have a house adapted to their peculiarities. Here is my plan: Suppose you have a high wall, say that of a neighbour's out-house, or the south side of your garden or back yard; build on to it a sort of verandah in shape, 6 feet deep, and as long as you fancy. Arrange at the back large boxes—tea-chests, or any box that would do for a rabbit-hutch; arrange these one above another in rows, the lowest row 3 feet from the ground, the highest 3 feet from the roof. If you like, have rows of wicker the whole width of the front of each box. Well and good, then you can pair or catch the birds readily. If a box is very long the doors need not extend over the whole front, only let them be wide enough, so that the Powters may be able to fly into them at once easily and without hindrance. In front of the boxes there will be a space for you to walk up and down. The door may be in the centre, with a window on each side. The windows should slide back, and have wire netting over them, so that they could be left open for air without fear of intruders. Inside each window I would place a wide board to feed the birds on if shut up at any time, so that what with boards at the window, the tops of the boxes, and inside each wide box, there would be plenty of broad resting-places for these large Pigeons. In the space in front of the boxes you may sit and read your paper, or pet your birds, stroking and talking to them, watch their habits, see if they sit well, and in fact make them by kind attentions as tame as possible. I have had them so tame and playful as to carry on sham battles with my finger, they flipping it with their wings and cooing defiance at me. Let all be cleaned out daily, and nice loose gravel strewed on the floor of the house.

Next the pans for sitting. Have triangular pieces of freestone, so that the birds may alight gently on their nests, as they frequently bruise the shells with their great weight. I say triangular, as the cleaning-hoe can better do its work. Outside, on this verandah-like building I would place several long flat planks, not unlike children's school forms, only made slighter. On these the Powters love to strut. Anywhere else around, on any other building, I would put similar boards. Let the entrance or entrances be above the door or windows, and they must be wide and high. Now I have described just such a fowl-house as I saw recently at Calne, built by Mr. A. Heath, who is a keen fancier, and appreciates thoroughly his stock of good Powters. By the way, before concluding, I think the hen Powder is less noticed and praised than she ought to be, every eye looking at her large mate, but her slender beauties are not to be despised. A good hen pleases me as much as a good cock bird.—WILTSHIRE RECTOR.

### COMBS CONSTRUCTED ACROSS THE BARS.

I HIVED a swarm of bees into a Woodbury straw bar-hive this summer, and I have lately discovered that instead of work-

ing the combs on the bars, the bees have built them crosswise. I thought of either driving or smoking them, and then cutting out the combs and putting them in properly, securing them in the frames by nailing thin strips of wood on each side, to be removed when the bees have fixed the combs. Is this the proper mode of procedure, or can you suggest a better plan for accomplishing the object I have in view? If driving were the best plan to adopt, would it be better to adopt it in the daytime, or in the evening?—INQUIRER.

[Better leave things as they are until spring, as the combs are now too heavy, and too fragile for safe manipulation. Select a fine day in April, and then operate by driving the bees and re-arranging their combs in the manner you propose.]

### APIARIAN EXHIBITION AT STEWARTON.

HAVING received an invitation from Mr. Eaglesham, Secretary to the Stewarton Horticultural, Agricultural, Ornithological, and Apian Society, to be present at the Exhibition of that Society which took place on Saturday the 2nd inst., and being desirous of seeing the honey product of the locality, where the octagonal-hives were invented and are manufactured, I gladly availed myself of the opportunity. I can assure your readers that I was amply repaid for my visit, as I was completely struck with the quality and extensiveness of the exhibition in all its sections, evidencing the spirit and enterprize of the Society, which certainly is deserving of an extended patronage from the manner in which it is conducted. In the honey department, in which I was more particularly interested, the specimen boxes shown by Messrs Ferguson & Brown, Stewarton, and Robertson, Kilmarmock, were paragons for uniformity and straightness of comb and purity of colour. A colony of brightly marked Ligurians exhibited in an eight-bar observatory hive by Mr. Alexander Ferguson, Stewarton, was a centre of attraction, and was the first time, I believe, such has been exhibited north of the Tweed; and from the transparency of the glass and suitability of position in all my apiarian experiences it is gratifying for one to state, I have never seen these insects to better advantage. It was alone worthy of any sacrifice my visit to Stewarton caused. I was also introduced to several of the principal apiaries in the district, and was shown hives of every make and description, including the Woodbury straw hive. Frames were raised, and I was shown matronly Italian queens with hinder parts like laminated gold, which would have been a treat to Dr. Cumming. Wax sheets were also put into my hands to see if I could distinguish any difference of the Stewarton make, from those sold by the Messrs. Neighbour, and the uniform kindness and courtesy I receive that day from the Stewartonians will ever form a very "pleasant memory" to—URBANUS.

### OUR LETTER BOX.

COLOUR AND POINTS OF BRAHMS (A *Subscriber, Ireland*).—We suppose the numbers shown are a good index to the popularity of a breed. Admitting this, the Pencilled Brahms are certainly the favourites. The hens should be grey pencilled all over the bodies, and have silver-striped hackles. The cock should have light hackle and saddle, black tail, black and white spotted breast. Pea combs are much preferred to single combs. The reddish brown and cinnamon are both objectionable colours. It is always well to select your breeding stock free from them. When the light Brahms are well bred as they once were they will be popular. White body, striped hackle, black flight and tail, pea comb, size and shape same as now seen in the Pencilled—these would be beautiful.

GAPES IN CHICKENS (X).—Your chickens are dying of the gapes, and have the roup as well. Give to each chicken a pill of camphor, the size of a pea, and put some lumps of it in every vessel from which they drink.

FOWLS NOT THRIVING.—PIP (E. S.).—You take too much pains by half. Give your fowls good ground oats, mixed with milk, some whole corn for a change, very few boiled potatoes, and seldom. Let them have the good grass run. Discontinue all your condiments except natural ones. If their appetite fail, you may give some cooked meat chopped fine. Your opinion is that strong healthy fowls will not catch this disorder, but weak and sickly ones will. As a measure of precaution as well as cure, put camphor freely in all their water.

CALCULATING NUMBER OF BEES (*Sympathy*).—We are not sure that we perfectly understand your question. Five thousand bees are considered to weigh a pound, if that is what you refer to.

EFFECT OF LIGHT ON HONEY (*Bee-Friend*).—We have heard that honey is injured by exposure to light, but do not know how far the statement may be correct. We have forwarded to you privately the names and addresses of two gentlemen, resident in Ireland, to whom Ligurians have been sent by Mr. Woodbury. We have no doubt that either of them would be happy to show you the little strangers, although they might not like their names published.

PRESERVING QUEEN BEES (*Idem*).—Spare queens may be kept alive a week or two if imprisoned with about a hundred of their subjects in a small wooden box with sufficient ventilation, and provisioned with a bit of sealed honeycomb.

WEEKLY CALENDAR.

Day of Month	Day of Week	SEPTEMBER 19—25, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock after Sun.	Day of Year.

25	M	Grass of Parnassus flowers.	66.8	46.8	56.8	17	53	5	51	5	21	11	28	8	5	8	25	268

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 66.5°, and its night temperature 45.3°. The greatest heat was 82°, on the 25th, 1832; and the lowest cold, 32°, on the 20th, 1840. The greatest fall of rain was 1.21 inch.

LILIUM CULTIVATION.

Purity and beauty Lilies have been esteemed emblematic from time immemorial; and despite the caprices of fashion the old varieties, and especially the lovely white garden

Lily (*Lilium candidum*) are as much, if not more, admired and valued than ever. Most of them are almost, if not quite hardy, but some are esteemed for conservatory decoration. I shall, therefore, treat of them under two heads—viz., 1st, in pots; and 2nd, for flower-garden decoration.

CULTURE OF LILIUMS IN POTS.—Perhaps there are no flowers so beautiful, and so deservedly esteemed as the lovely varieties of the Japanese Lily (*Lilium speciosum*, or *L. lancifolium*, of gardens). The best are—

*Lilium speciosum punctatum*, white flushed with pink; frequently confounded with *L. speciosum roseum*, a much inferior, though fine variety of Japan Lily.

*L. speciosum roseum*, white, spotted rose.

*L. speciosum rubrum*, white with crimson spots; one of the best.

*L. speciosum album*, pure white, and not so strong-growing as others.

*L. speciosum eruentum*, a fine variety of *rubrum*, a strong grower, and more profuse-blooming; white with crimson spots.

*L. speciosum monstrosum*, a fine, bold flower in the way of *rubrum*; white with crimson spots.

In addition to these there are others which I have not grown, but hear well of. Such are *L. grandiflorum*, which is a fine flower, and very large; *L. regale*, highly coloured, said to be very fine; *L. Harrisoni*, of fine form; *L. speciosum corymbiflorum album*, little different from *album*, if I have seen the true variety under that name; and *L. speciosum corymbiflorum roseum*, certainly little different from *L. speciosum roseum*, if not the same.

*Lilium auratum*. Certainly one of the best flowers ever introduced by Messrs. Veitch; white, spotted with crimson, with golden bars parallel with each lobe, and delightfully scented. The best of the Lilies. There are many imported bulbs that are not true. To have it true it is necessary to give a good price.

*Lilium Brownii*. Why change *L. japonicum* to this? Is it that *L. longiflorum* is often substituted for the true *L. japonicum*? It is a somewhat rare species, with large creamy white flowers shaded externally with brownish purple, grows 3 or 4 feet high, and has several blossoms on one stem, in character after those of *L. longiflorum*.

*Lilium cicutium*, a fine form of *L. longiflorum*, taller; flowers larger, and generally more numerous.

*Lilium longiflorum*, dwarf, 1 foot to 18 or 20 inches high; flowers white, trumpet-shaped, fragrant.

*Lilium neilgherrense*, dwarf, a little more than a foot in height; flowers creamy white when opening, but changing to a clear white.

*Lilium giganteum*, leaves large, glossy dark green, heart-shaped; flowers white, borne on terminal racemes, trumpet-shaped, marked with violet crimson streaks, and highly perfumed. It is a stately-growing kind. Its variety, *cordifolium*, blooms two months later, and is not much to my liking.

*L. Thomsonianum* is not so imposing as many, but still a neat, rosy-flowered kind, though hardly worthy of pot culture.

*L. sinicum*.—This is a fine scarlet Lily, and not coarse like *L. giganteum*. About 1 foot to 1 foot 6 inches high.

*L. tigrinum*, orange salmon with black spots; 2 to 3 feet high.

*L. Thunbergianum (crustum)*, orange streaked scarlet, and its variety *grandiflorum*, crimson, grow from 1 foot 6 inches to 2 feet high.

*L. philadelphicum*, orange red with black spots, is fine and dwarf, attaining a height of 1 foot 6 inches to 2 feet.

All the above, except *L. giganteum*, do well in a compost of one-half turfy yellow or light hazely loam from turves a year old, turfy sandy peat one-fourth, and leaf-mould one-fourth, with a free admixture of sharp sand, the whole well incorporated and chopped with a spade, but not sifted, as a free open soil is desirable. Good drainage is very essential; it should occupy at least one-fourth the depth of the pot, and be covered with a layer of sphagnum or cocoa fibre half an inch thick. On this 3 inches of the rougher parts of the compost are to be placed, and then more compost to fill the pot little more than half full. The size of pots will, of course, vary with the size of the bulbs, no better criterion for determining the distance apart can be given than placing them fully their diameter from bulb to bulb, and half their diameter from the sides of the pot, remembering always that the more bulbs that are placed in a pot consistent with their being at a suitable distance apart, the finer will be the specimens; not that smaller specimens are undesirable, for I know they are useful for vases, and other purposes where large pots could not be accommodated, but because few bulbs in large pots are of little use. In selecting roots of the varieties of *Lilium speciosum*, choose those with the greatest number of crowns. Those with three are excellent, and so are those with two, and large single-crowned bulbs are also good, but they will only give one spike of flowers, whereas the double give two, and the treble three. Thus, if you place six roots of each in a 12-inch pot, you have but six spikes with single-crowned bulbs, twelve with double ones, and eighteen with the trebles. Exhibitors frequently gain by employing double and treble crowns, whilst their opponents use single crowns, and as a consequence have only half, or two-thirds the bloom of the winners from a similar number of bulbs and size of pot.

As soon as the leaves turn yellow is a good time to pot the bulbs, whether purchased, or removed from the open

ground, also for repotting those grown in pots. It is desirable, however, to change those that have been grown in pots for years and forced for those grown out of doors; for *Liliums* become weaker after being grown under glass, especially if forced.

The pots being prepared as already described, take the bulbs up carefully, without breaking their fleshy roots, and place the base of the bulb on the compost without pressure, spreading the roots out carefully in all directions as they appear to have grown. The requisite number having been placed in a pot put some compost between each, keeping the crowns erect, and cover to an inch above the crown. This will bring the compost to within one-third the depth of the pot below the rim. *L. longiflorum*, and all the dwarfier kinds should be placed somewhat higher in the pots, so that the pots may be three-quarters full when the bulbs are just covered with compost. Whether the pots be large or small, a space equal to one-third for the strong, and of one-fourth for the smaller kinds, should be left, to allow of a top-dressing of rich compost being given after the shoots have grown sufficiently high, in order to afford a medium for the roots that are emitted from the stem to run through, and so contribute to the support of the stem, flowers, and foliage.

Having potted the bulbs at the time the leaves fall, or immediately afterwards, place them in a cold pit, plunging the pots to the rim in coal ashes, and giving no water if the soil is moist, but if dry a little may be afforded. The lights may remain off day and night when there is no likelihood of frost or rain, drawing them on only in frosty and wet weather. During frosty weather some dry straw, litter, or leaves, should be placed over the pots within the frame, keeping the lights on constantly so long as the frost continues, and until the covering within the frame is thoroughly thawed, when they should be drawn off, the protection removed, and not replaced so long as the mild weather continues. The bulbs require to be protected from frost, though a few degrees will not injure them, if only they are not exposed to light and sun until thawed; protection from cold deluging rains is also necessary, but all the air and exposure at other times consistent with those conditions should be given.

Towards spring the shoots will be appearing, a little water may then be given, but not much, and always on a fine day and early. Air will now be required daily; then open early and close early, protecting during frosty nights by a single or double covering of mats, according to the severity of the weather; and this state of things goes on until the plants grow so as to almost touch the glass, and being kept near it the shoots will become strong, and have the leaves not far apart. It is a main point in the culture of *Liliums*, to keep them cool, well aired, near the light, and healthfully moist at the root, but not wet.

It is a common practice to keep the pots plunged in ashes, tan, or leaves, in a cold pit during the winter. This is good so long as the roots are not kept wet during the winter, and frost excluded; but it very often happens that the shoots have grown through the 6 inches of tan or covering material ere the covering is removed, and the roots are weakened, and so much lanky stem is produced to begin with. If plunged in such materials the pots should be removed before the top growth takes place, for immediately any plant appears above the surface of the soil in the pot, the foliage should be exposed directly to the action of the atmosphere. The potted bulbs should, therefore, be removed by the beginning of March.

A third mode of wintering *Liliums* in pots consists in placing them on the marginal spaces of paths or stages in a cold greenhouse, where preserved from drip. This is a very suitable position, they being kept cool and dry, and the soil, nevertheless, a little moist. Beneath the stages, under other plants requiring watering, the soil is apt to become sodden, and the roots are weakened, and some decay through it.

In whatever position the bulbs are kept they will commence growth in the spring, and must be kept near the glass, have air daily in mild weather, whether in the greenhouse, frame, or pit, and be watered so as to keep the soil moist, always allowing the surface to show a want of water before any be given, then give enough to show itself at the drainage. A moist atmosphere is essential to free growth. When the shoots are from 3 to 3 inches in length, top-dress the pots to within half an inch of the rim with the compost used for potting, with the addition of an equal quantity of cowdung a year old mixed with it thoroughly. Employ the compost in a rough state, for an open surface admits air to the roots. Whether the plants are

in the greenhouse, frame, or pit, it is important to keep them near the glass, and if this cannot be done through there not being the conveniences at hand to change the pots as the plants grow, it may be effected to a certain extent by placing the pot on an inverted flower-pot, and afterwards lowering it as the plants increase in growth.

It is desirable, when there is a sufficiency of any kind to have a succession of bloom, to keep some of the pots in a greenhouse, and such bulbs under ordinary greenhouse temperature will bloom in the beginning of August. Others may be placed in a cold frame, and merely protected from frost, and sheltered from heavy rains, with air at other times. Half of these if placed in a deep pit, and elevated so as to be near the glass at first, but as they grow lowered, so as to be always near it (air being afforded day and night, but the lights kept on except in very mild, close, damp weather), will give the finest specimens, and bloom soon after those grown in the greenhouse. Others grown in a cold frame until the middle or end of May, and then placed out-doors in a light, airy, yet sheltered situation, due attention being given as regards watering, and the pots protected by being plunged, will form fine ornaments for the conservatory or greenhouse in September.

As the plants advance in growth water must be given freely, but a very wet state of the soil is not beneficial to *Lilies* at any stage of their growth. It should, however, be kept moist, and not allowed to become dry upon any consideration. When the flower-buds show weak liquid manure or guano water, made at the rate of 1 oz. of Peruvian guano to a gallon of soft water, may be advantageously applied at every alternate watering until the flowers open. Afterwards pure water is better. During the growth of the plants it is very desirable to turn the pots frequently in order that the shoots may incline equally to all sides, and not in one direction only, as they invariably do when the plant receives the light unequally. If sticks could be dispensed with it would be a step in the right direction; but it being very rarely that this is possible, neat sticks painted green should be placed to each stem, and the shoot tied to it, forming a uniform head with room for each bloom to show itself without hiding its neighbour. The sticks should not be thicker than the stem of the plant, otherwise they will appear out of proportion.

*Liliums* are subject to green fly or green aphid when grown under glass, especially in a close warm house, or in badly ventilated structures of any kind. These pests fasten on the growing points of the shoots, make the leaves curl, and soon disfigure a good specimen. Fumigating with tobacco is the only effectual remedy, and the proper time to do so is when the first aphid is seen, the plants being frequently examined for that purpose.

Whilst blooming *Liliums* should be liberally supplied with water, but when the flowers fall the supply should be gradually diminished, and cut off altogether by the time the leaves fall and the stems turn yellow. This being the case, the stems are cut off to the surface, and the soil taken out of the pots level with and around the roots, but not so as to injure the latter. The stems are then cut off closely above the crowns, and on these underground stems will be found some young offsets or bulbs. These may be potted several in a pot or planted outside, for which directions will be given hereafter. The offsets will bloom in about three years if liberally treated. Make sure that the drainage is perfect, and if not so it must be put right, and fresh compost placed between the roots without disturbing the ball in which the principal roots are situated, covering them with soil the same as when fresh-potting.

If the pots are too full of bulbs these may be potted; but every third year is often enough to do this, the top-dressing in autumn and earthing-up in spring being all that is necessary. Potted every year the main roots are injured more or less. The bulbs should not be potted unless the pots are too full of roots, nor taken out of the soil, much less kept out drying on shelves, except for the purpose of repotting or increase. *L. longiflorum* may have the soil taken out between the bulbs in autumn, and the small offsets removed, fresh compost being filled in. All the *Liliums* which require a cool temperature are best kept from October to March so as to be safe from frost. All the kinds named above may be had in bloom in the end of June by placing them in a vinery in February, and in July if placed there in March, when the Vines are set to work, assigning them the lightest and airiest position.

*Lilium giganteum* and its variety *cordifolium* require rich soil. They do well in turfy loam one-half, one-fourth leaf mould, and one-fourth rotted cowdung, or in place of it peat

may be substituted. Good drainage is necessary, and plenty of pot-room. A fine blooming root will be a giant indeed if put in a No. 1-pot. Suckers or offsets should be placed in pots proportionate to their size, and be grown on under liberal treatment until of a blooming age. All should be potted in autumn, taking off as much of the old soil as can be done without injuring the roots, and deep enough to just cover the crown. They should be kept over the winter in a cold pit, or any similar place from which frost is only just excluded, and in spring as growth commences have moderate supplies of water. When growth becomes active the waterings must become copious; and when the plant is blooming it should stand in a pan of water or be very freely watered. After blooming gradually diminish the supply of moisture, so as to give none by the middle or end of September; and keep near the glass in a pit or frame, by which the ripening of the bulb will be secured and the large leaves will droop. When these are quite gone remove any offsets that are likely to rob the large roots of support, potting the old roots if a shift be necessary, otherwise it is not requisite to pot them every year. Whilst growing manure water at every alternate watering will be serviceable. Plenty of pot-room, liberal treatment when growing, well ripening the bulbs in autumn, and a period of rest are all that is needed to grow this gigantic Lily. It does well in a cool greenhouse or conservatory, and requires one rather lofty, as it frequently sends up stems of 10 feet high.—G. ABBEY.

(To be continued.)

### GREAT INTERNATIONAL HORTICULTURAL EXHIBITION AND CONGRESS OF 1866.

We have much gratification in announcing that Her Majesty has graciously taken this Exhibition under Her patronage, and has liberally contributed the sum of £50 to the subscription list. We are glad to add that the public are responding well to the call which the Committee have made, and with Her Majesty's example before them we hope that contributors will come freely forward and aid in carrying out to a successful issue an undertaking of such national importance.

### PEARS FOR BUSHES AND DWARF PYRAMIDS IN THE NORTH OF ENGLAND.

#### EFFECTS OF DOUBLE-GRAFTING.

You will be conferring a favour on me, and perhaps on many others, if you will give a list of Pears suitable for bushes or dwarf pyramids in the open ground in the north of England. I am induced to ask this for the following reason. *Beurré de Capiaumont* is of extraordinary fertility and good quality on an east wall here, but degenerates into a mere crab when cultivated as a pyramid; whilst *Marie Louise*, although much more tender when in blossom, and later in ripening its fruit on an east wall, retains or perhaps improves its quality by being grown on a bush. It so seldom bears a crop, however, as to offer no inducement here to grow it in that way.

I should also like you to treat on the variations in quality (specifying sorts), which are induced by grafting on the quince and thorn stocks. Here I grow the *Dunmore*; and when I received the grafts I worked several on trees on an east wall which had been grafted on the quince, whilst others were grafted on pear stocks, one of which grows against a south wall. The latter are much larger Pears, but neither from that tree nor from standards on the pear are they at all to be compared with those double-worked on the quince for flavour, or any other good quality. Again, the fruit from the *Beurré de Rance*, double-worked on the quince, were gathered last season on the same day as some grown on pear stocks, both growing against walls having the same aspect; and the fruit, kept in the same fruit-room, became melting and excellent in January, whilst that grown on pear stocks never became melting at all, although kept until May. Again, the fruit of the *Seckle* on a tree double-worked, is with me twice as large and twice as good as that grown on pear stocks.—T. G.

[It is most difficult to give a decided opinion as to the best kinds of Pears for the north. No fruit is so capricious. There are some sheltered warm valleys in the far north in which fine Pears ripen well, while in contiguous sites and soils they refuse to do so. Nothing but experience can determine this, and as trees are cheap it can be bought at a moderate rate. The sorts

of which we give a list form prolific bushes when double-grafted: by this we mean, first to bud a free-growing sort of Pear on the quince, and then graft the sort required on to the budded plant. This is fully treated of in the thirteenth edition of the "Miniature Fruit Garden" by Mr. Rivers. Summer Doyenné, Jargonelle, Victoria (Huyshe), Prince of Wales (Huyshe), Autumn Nelis, Winter Nelis, *Beurré Bose*, British Queen, *Seckle*, Aston Town, *L'Inconnue* (Van Mons), *Joséphine de Malines*, *Beurré de Rance*, Suffolk Thorn, Thompson's.

Sorts that may be grown as bushes on the quince stock without double-grafting.—*Alexandre Lambré*, *Baronne de Mello*, *Beurré Bachelier*, *Beurré d'Amanlis*, *Beurré Goubault*, *Beurré Hardy*, *Beurré Superfin*, *Conseiller de la Cour*, *Doyenné Boussoch*, *Doyenné du Comice*, *Fondante d'Autonne*, *Jersey Gratiosi*, *Louise Bonne*, *Marie Louise D'Uccle*, *Madame Helyne*, *Passe Crassane*, *Vineuse*, *Yat*, *Jalonsie de Fontenay*, *Poire Pêche*.

Systematic double-grafting of fruit trees is likely to lead to most beneficial results, by it we mean the careful selection of stocks to suit different varieties. Thus, for instance, Mr. Rivers points out the *Beurré d'Amanlis* Pear as a fit stock on which to double-graft the *Jargonelle* and *Gansel's Bergamot* Pears, and *Conseiller de la Cour* for other sorts. The truth is, care is required to do the thing well. Useless double-grafting on all sorts of Pears on quince stocks will, to a certainty, lead to failures.

Continental pomologists and nurserymen know little or nothing of this refined method of fruit-tree culture. Much may thus be done in improving the health and fertility of our trees, and the flavour of their fruit. English gardeners seem to have for the most part confined themselves to producing fine Pines, Grapes, Peaches, &c., leaving the study of fruit-tree culture to nurserymen who, we trust, will now see the path open to fame if not to profit.]

### KITCHEN GARDENING.

JULY.

This month, which begins, as it were, another season, might, I think, not inaptly be termed "bedding-out" time in the kitchen garden, as on the first rainy day that we are favoured with winter stuff should be permanently planted out. Presuming that the plants have been pricked out according to previous directions, the next consideration will be where to plant them, as a casual observer would pronounce the garden to be already full; but on the proper use of this month will depend the aspect of affairs in the ensuing winter. I first begin with Brussels Sprouts, as the plants of these from the first sowing will by this time require more room than the nursery-beds will afford them. In planting what I term my first batch this year, I must admit that I have not exactly practised what I have preached, as I planted on the ground previously occupied by spring Cabbage; but I made a very large hole in the manure-heap to atone for my disregard of the laws of rotation.

The next crops of importance will be the Sprouting and autumn Broccoli, though with the latter I never do much, as it is rather a precarious crop with me; but as a row or two of Peas will by this time be done with, I generally occupy their position with two or three rows of autumn Broccoli, finding room for a row of Cabbage by the side of them if possible. Space can be found for four rows of Sprouting Broccoli and two rows of Variegated Kale between and on each side of the first-sown three rows of Scarlet Runners, which will by this time be fit to pick. One of the most important considerations in this double cropping is to exercise great care in gathering the produce of the first crop, so as not to tread upon or otherwise damage the second or winter crop.

The first batch of Savoys having been planted on the ground where the early Peas were grown, space must be found for the main crop. As the Broad Beans will by this time be getting shabby, or at any rate can be dispensed with for giving variety to and keeping up the supply of vegetables, and as the Potatoes between the rows may be taken up, the ground thus set at liberty can be prepared and planted with Savoys. For the first sowing of Turnips I use, or take up, three or four rows of Cabbage of the second lot, and, digging up the Potatoes between the rows of Cabbage, the seed can be sown at once, so that the ground is scarcely idle a day.

As the south border will by this time look anything but neat, with half-used beds of Early Horn Carrots, spring Onions, seed-beds of winter stuff and several other things that are

there, the plan I usually adopt is to give a good coat of manure and dig it down, as the above-mentioned vegetables will not pay for the room they occupy. By so doing a nice piece of ground is set at liberty for the last sowing of Dwarf Kidney Beans, a good bed of Coleworts, and beds of salads, &c., leaving a piece for plunging the Chrysanthemums, and for cuttings of bedding Geraniums if required.

The Scarlet Runners last sown may, towards the end of the month, be staked; and four rows of the second lot of Brussels Sprouts, with two rows of Green Curled Kale, may at once be planted between and on each side of them. Should the ground be dry, which is often the case at this time, the best plan is to draw drills, as if for sowing, where the above are intended to be planted, and to water the drills well the day before planting; after this has been completed by giving the winter stuff and the Beans a good watering of liquid manure, a day or two afterwards going over the ground with the flat hoe, or, rather, draw-hoe, the crop will go on all right.

It often happens at this time that there is such an abundance of vegetables, that the pods of Kidney Beans are allowed to ripen on the plants, which considerably shortens the duration of their productiveness. A very good plan when such is the case is to take the short shears and clip about one-half of them, just as you would clip an evergreen hedge. The plants so cut will break into new growth, and come in as a succession to those left untouched by the shears. Speaking of hedge-clipping reminds me that if there should be any evergreen hedges round the garden they ought now to receive that attention.

The Peas at this time should be kept watered and mulched, as, if the ground is at all of a dry nature, it is almost impossible to have good Peas without such attention; and it should be borne in mind that if they are not well looked after now the results will be felt in September. I have known Dickson's Favourite Peas so treated bear a second time first-rate. Custard and common Vegetable Marrows being now in full bearing, Yorkshire Hero and Veitch's Perfection Peas may be cleared off, and the ground previously occupied by them heavily manured and thrown up roughly, so as to be ready for Cabbage in the autumn, thus giving it two months' exposure to the weather, which will be very beneficial to the crop.

Celery should now receive every attention with regard to putting out successional trenches, watering, &c. The first rows of White and Red may have a little earth drawn to the roots, or, which answers the same purpose, the ground forked deeply on either side of the rows; and as soon as the Dwarf Kidney Beans are well up the last trenches of Red may be put out between the rows, using if possible good stocky plants. The first bed of Endive may be pricked out, and more Lettuce according to the weather and the demand, sowing more of each, but not much at one time. The only way to have good salad-ings at this time of year is to follow out the Rev. W. F. Radclyffe's advice—to have plenty of water in or near the garden, and willing hands to apply it to the crops.—BRUXWOOD, P. D.

(To be continued.)

### IRON FILINGS AS A MANURE FOR ROSES AND STRAWBERRIES.

A SHORT time ago I was informed by a lady that a friend had told her that he had found the application of iron filings, as a manure, highly beneficial to Roses. Since then, in perusing the valuable work of Mr. William Paul on "The Rose Garden," I was struck by the following remarks:—"I have long thought that the iron which abounds in the soil of one of the nurseries here is an ingredient of importance in the culture of Roses. I would not say that it is indispensable, but beneficial; and am almost confident that it heightens the colour of the flowers. When the soil in this nursery is hoed or forked, the rapid increase of growth of vegetation is startling beyond measure. This practice is known to promote growth in all soils; but the extent to which it does so here is, I think, due to the oxygen of the air changing the iron contained in the soil from a substance pernicious to vegetable life, into one favourable to its development."

Turning to the catalogue of fruits published by Mr. Thomas Rivers, I observe that he says that "The British Queen Strawberry flourishes in soils in which iron abounds. Sussex is the paradise of our queen of Strawberries." I know not whether the soil of Messrs. Wood's nursery, at Maresfield, in Sussex, abounds in iron, but probably it does, and hence, perhaps, the fine growth of the Roses.

Assuming that iron is beneficial to Roses and to the British Queen Strawberry, if not to other varieties, it becomes a question whether iron filings may not be advantageously used either by mixing them with animal manure, dug into the soil, or by top-dressing. As the season for manuring Roses is rapidly approaching, it seems to be desirable that more light should, if possible, be thrown upon the matter.

I have scattered iron filings on the surface of two rows of British Queen Strawberry runners, planted in July, twice during rains, and had the soil surface-hoed continually, and I intend to make the same experiment upon a few Roses in the ensuing autumn, incorporating the filings with the soil, instead of strewing them on the surface.—AN AMATEUR.

[We hope that you will report to us the results of your experiments, for if they are unfavourable they will act as warnings, and if favourable as encouragements. The red oxide of iron is likely to be beneficial to the plants, for it is known to retain the ammonia, which would otherwise escape from the soil, and it also has the power of absorbing ammonia from the atmosphere. We know more than one soil abounding in the red oxide of iron, noted for Roses.—EDS.]

### AN AFTERNOON IN SYDNEY GARDENS, BATH.

BATH is the very place for a flower show. Though no longer visited by royalty, though nobility do not, as of yore, make it a residence, yet it has a large, never before so large, population, and one for the most part living in easy circumstances; hence just the people likely to love and cherish flowers, and, of course, understanding them to a degree; also, just the people likely to gather at, and crowd a flower show. It is some years since Mr. Dickens spoke of Bath as "the grass-grown city of the ancients," a description which if then true, is certainly true no longer, for Bath streets are not grass-grown, too many feet are passing along them, and too much attention is paid to them to permit weeds to mar those well-cleaned ways. The taste for flowers, and the demand for them in Bath, may be judged from the great number of nurserymen in and around the city. A refined and leisurely people are sure to love and cultivate flowers, though even in the most adverse circumstances, and most opposing conditions, a great flower-devotion is sure to crop out, as here and there a house in the dingiest alleys in London reveals.

On Wednesday last "the fair city of the west" was to be seen to perfection. The show had been extensively advertised, consequently the trains arriving in the morning and at midday were heavily loaded, so that the streets were full of folks, with the eager happy look of those out for a day's treat, and intending to enjoy themselves to the utmost. From the tower of the old Abbey Church the royal standard was floating, proclaiming a holiday to the eye, and the merry clash of its bells proclaimed a holiday to the ear. By two o'clock streams of carriages were making their way slowly through Pulteney Street—by-the-by, that is about the only street in Bath one can stroll down comfortably, most of the others being paved hills. As I was driving along I could not fail to notice the throng of happy faces on the kerbstone, pleased lookers-on, and I could not but think that a flower show is the cause of pleasure, even to those who never see the flowers, those who are unable to find the half-crown for early admittance, or even the single sixpence for the five o'clock entrance.

But while moralising, I am at the entrance of Sydney Gardens. In that house left of the gate once lodged a gloomy-looking Frenchman, sometimes hard up for cash and credit, now having plenty of both—viz., His Majesty the Emperor of the French. Ah! it is a queer world we live in, full of ups and downs, but some of us get most of the latter; however, there's a good time coming, so don't be downhearted. Soon the gate is passed, and I am lost in a crowd. Lucky Committee! another fine day for your show; and out of twenty shows you have, I learn, only once had thoroughly bad weather.

As to Wednesday last, it was a glorious day, brilliant without being either scorching or oppressive. Near me all was life and clearness, and afar off, to quote Wordsworth—

"The lovely landscape indistinctly glared,  
Through a pale steam."

I am carried on by the force of those behind me, but am brought to a standstill, as all others that had preceded me, in front of the orchestra, where the band of the Royal Marines are entrancing all listeners. How strange it seems that any one can dislike music. Surely Dr. Johnson was very bilious when he

called it "the least disagreeable of noises." But there is something stranger still—that there had ever existed a human being that disliked flowers. Yet Mr. Smiles tells us, that the Duke of Bridgewater, he of the canals and coal pits, "would have neither conservatory, pinery, flower garden, nor shrubbery; and once on his return from London to his country seat, finding some flowers which had been planted in his absence, he whipped their heads off with his cane, and ordered them to be rooted up." No wonder that we also read of this Duke of Bridgewater, that he was a coarse feeder, and smoked more than he talked; that he was rough in speech, and gruff in manner, and that he read little besides "an occasional newspaper."—N.B.—He would not I fear, have read *THE JOURNAL OF HORTICULTURE* even once a-year—also, that he hated woman-kind (earth's animated flowers), and bored everybody to death with his canals and his coal pits. "*Quiescas in pace,*" D. of B., I hope no one living resembles thee.

To return to the Bath Show. Ten thousand people were present, and the tents were so crowded that it was impossible to see everything. I twice tried to enter the fruit tent, and twice retired defeated, for there was a cram or block of people, whose tempers were apt to get a little tart without the aid of the fruit; and others were somewhat crusty with the heat. I luckily met with good "Y. B. A. Z.," who had succeeded in entering the tent earlier in the day, and he declared the Show was magnificent, especially the Black Grapes. One of those good-tempered fellows of the police-force was giving a hint to a man who seemed inclined to touch the said Grapes, saying, "Mind, the Grapes are sour." He got his reply, "Oh! you've been eating of them, then." I wonder whether the latter was an Irishman.

I had a good view of the "Ornamental Plants with curious foliage," and very excellent they were. The most splendid collection was that of Mr. Jesse Gouldsmith, who carried off the first prize for nine varieties, and also the first prize for twelve varieties. I lingered in this tent wondering and admiring, looking at the painted leaves, for painted some of them seemed; then others looked like stained glass as the light shone through them. "What elegance of form in some! what depth of colour in others!"

Next came the Fuchsias. These were arranged down the centre of a long tent, having that centre to themselves. Verily, a look from top to bottom gave one a glorious scene. one seemed to see thousands of miniature chandeliers; but yet I was assured by a good judge that these flowers were not equal to those of former years. Under the same tent, the south aisle of it, to speak ecclesiastically, were the Hollyhocks, which were very good; also the Dahlias, very good, those shown by Mr. Keynes being superb. The Asters, too, called forth much approbation, and many remarks, "Which are the prettier, the French or the German?" I prefer the former, though you must have fresh sent from abroad each year, but, then, the German are so formal-looking. One gentleman near me made a remark concerning the German Asters, which was capital. "What good rosettes they would make for my carriage horses!" A lady said, "What pincushion-looking things!" Verdict, therefore, "French Asters preferred." The Roses which came next drew towards them all eyes. Never was the Rose so popular as now, thanks to those who have brought out the Hybrid Perpetuals. Mr. Keynes was first with twenty-four bunches. Somebody said, "Mr. Keynes was an able man." I would say he beat many able men. Among all the Roses shown, Charles Lefebvre looked best. The vegetable tent was one fearful to encounter. Had I seen it outside my kitchen-door it would have been a welcome sight, but on a fine afternoon, in close proximity to flowers and a fair throng, the huge vegetables, specially the vile herbs, I mean Onions, were terrible. Those frightfully large Cabbages, who could eat them? those dyspeptic Carrots, called Parsnips, away with them, and away from them, and back to music and flowers.

One of the arrangements of the Committee was, I thought, excellent—viz., the best music was reserved for the last; so those who less frequently than their betters hear excellent music, had now the opportunity. A flower show, like everything else, has its extremely amusing side, and I love to watch it; life is full of tragedies, let us catch gladly, then, at the comedies. Thus there was the paterfamilias at the refreshment tent, who had been supplying his youngsters and feeding them at some distance; when he said to the woman who served, "Now then I want to pay—I've had nine buns, two bottles of ginger beer, and an ice," a young man from the country, who stood next, opened eyes and mouth, evidently

marvelling at the gentleman's prodigious appetite. Then there were those who seemed to do nothing but look for other people, whom of course they never found. Then there were the faces that puzzled one, not seen for twenty years, and the thought, "Is it possible that large-waist-coated gentleman was Mr. So-and-so? and oh! tenderer far, that lady with grey hair the lady I used to meet long since?" But I am lapsing into the doleful after having written against it. Teaching and practice should go together. I thought of the past at Bath—its false gaiety, its folly, its gambling, its vice; and the present, that I beheld, was, thank God, free from all these. I applied to what I saw Eliza Cook's words—

"Far more grand a scene is ours  
Than that where jewell'd brows  
In olden days met ball-room flowers,  
And spruce 'Beau Nash's' bows."

—WILTSHIRE RECTOR.

## VISITS TO GARDENS PUBLIC AND PRIVATE.

MADAME LE GRELLE D'HANIS, ANTWERP.

I HOPE those of the readers of *THE JOURNAL OF HORTICULTURE* who take the trouble to look at even the heading of these visits of mine, will not imagine that they are written in chronological order, for they would then assuredly come to the conclusion that I had a season ticket for Belgium, and every now and then went across to see some garden or city. The truth is, that these notes on Belgium were all made in the early part of June, that I had intended to have sent them each successive week to the Journal, but that other matters interfered—correspondents ask for information, flower shows require notice, new plants must be described, and so it is that here in September, I find I have not yet finished these few rambling notes.

If Ghent be the Paradise of nurserymen, it would almost seem as if, like an artesian well, it had drained the neighbouring places of their supply, for I could only hear of one nurseryman in Antwerp, so rich in its works of art, and its associations, and his nursery (M. Van Geert's) one of by no means a first-rate character. To him I was indebted for the information that the wife of M. Le Grelle d'Hanis, who holds an honourable position in Antwerp, was an enthusiastic admirer of flowers, and had been a successful exhibitor at the various Belgian exhibitions, and also at the International Exhibition at Amsterdam this season. So bidding our *cocher* to drive us to the "glacis," the great public promenade and drive of Antwerp, we soon arrived at a handsome villa residence, enclosed on all sides, and within which the best private collection of plants and flowers in Belgium was to be found. In saying this one must bear in mind, that although there is more of the stay-at-home life in Belgium than in France, and the everlasting *café* does not meet you at every turn, and the female portion of the population keep more at home, yet as a rule, amateurs are very scarce in Belgium, and many of those who rank under that name are really growers for sale, from whom a nurseryman, if he wants to execute an order, and is hard pushed amongst his own plants, is sure to obtain what he wants to buy and sell again: consequently an amateur like Madame d'Hanis, who for the mere love of flowers, and honour and glory to be derived from exhibiting, cultivates her tastes, is a *rara avis*, and I felt naturally anxious to see how far she might be compared with some of our leading amateurs in England.

The grounds have nothing very remarkable. There was some good foliage about the place, and the villa and its appurtenances might be fairly compared to such as Mr. Rucker's, of Wundsworth, but immensely inferior to it in the neatness which in English eyes is so very desirable, and which one finds in Belgium more than in France; but the beautiful, soft, velvety turf which marks our villa residences was wanting at Madame d'Hanis's, where it was coarse and rough, "ill-shaven and unkempt;" nor in the houses was there, so far as I could see, so much variety, or that extensive collection of individual genera, as in those at home. There was much to interest, and many plants were in an excellent state of cultivation. In the Orchid-house there were some fine plants of *Oncidium Lancanum*, *Catasetum longifolium*, *Epidendrum longibulbum*, *Zygopetalum rostratum*, *Cattleya Mossie*, *Bifrenaria longicornis*, and other species. In the next house there were some very fine specimens of *Marantas*, especially Van den Heckii, truncata, vittata, very large, zebrina, striata, and majestica, the latter one of Mr. Linden's recent introductions. It is somewhat in the way of *regalis*, but the growth is more

robust, and there is a metallic lustre about it which adds to its interest; but all the Marantas will be eclipsed, even Veitchii, by some new ones (of which more anon), which Mr. Linden has obtained from his collector, Mr. Wallis, in the virgin forests of the high Amazon.

In the fernery there were some fine plants of both tree Ferns and others, but there was nothing very remarkable either in the kinds grown or in the manner of growth. A house was set apart for fine-foliaged plants, and in it were to be found some fine specimens of Caladiums, Colocasias, and other Aroids, such as Anthurium Ghiesbreghtii and magnificum, Alocasia Veitchii, Alocasia macrorrhiza variegata, &c. Here I may notice, that Madame d'Hanis exhibited at Amsterdam seventeen or eighteen species of the beautiful but very miffy Anæctochilus; they had not, however, been bettered by their appearance in public, a complaint which, I believe, many English and foreign exhibitors had to make as well. There was, of course, a fine Camellia-house in which trees planted out were growing luxuriantly; but I do not think they were equal to many collections I have seen in England. There was a remarkably complete collection of Agave, plants very little grown or admired in England, but which here were grown in large numbers. Amongst the most remarkable were filifera, with its curious thread-like appendages, Ghiesbreghtii, Verschaffeltii, xylinaantha, succæfolia, mexicana, and Rumphii. These were placed in the open air and were evidently one of the pet plants of the place. I also noticed in the garden, Iresine Herbstii, grown in a bed with one of the species of Mesembryanthemum, and very pretty it looked, quite confirming my opinion, that it will make a desirable plant for variety; but hedding-out there was none in our sense of the term. Among some remarkable plants which I noticed in the houses (a detailed account of all therein would be useless), were Arca Verschaffeltii, a most beautiful and graceful Palm; and Adelastrum albo-venosum, a beautiful glossy green creeper with white nervures, but which the gardener stated to be a very difficult plant to grow; here, however, it seemed to be succeeding very well. There was a plant of Liliun auratum with thirteen blooms, but the blooms were crowded together and were small. This Lily is as much admired by the Belgians as by ourselves.

After the inspection of the garden we were courteously invited to enter the house and see the large collection of gold and silver medals, the trophies of Madame d'Hanis's success. They were beautifully arranged in a very handsome cabinet, and were upwards of three hundred in number, while the other side of the recess was to be filled up in a similar manner, a large number of medals having already been obtained, nearly sufficient to fill it. With us a more prosaic view of these matters is taken, and "de cash," or a handsome piece of plate is more valued. Does it betoken more desire for "La gloire," than we exhibit?

Such was my horticultural experience at Antwerp. It is not a place where horticulture seems at home, and the traveller who is imbued with such notions will hardly find it worth his while to visit it for this. How rich it is in other respects every one knows. What glorious Rubens those are in the cathedral! and what gems in the Musée! One sight I should not like to have missed at the latter place, and that was M. de Fillenl, a well-known artist, who having been born without arms has succeeded by perseverance and energy in attaining considerable reputation as a painter, and that by his feet. It was certainly very wonderful to see him holding his palette with one foot, and his brush in the other, and painting with the greatest ease. Not only does he do this, but shaves himself, and, in fact, makes his feet perform all the functions that we use our hands for. He can unscrew the little tubes of paints, and when we were leaving gave with his foot to my wife one of his cards, which he had selected from his box. One could not but feel admiration for a man who had thus so signally triumphed over difficulties. He was a gentlemanly man, and his whole appearance and manner very pleasing.—D., Deal.

#### DESTROYING GOOSEBERRY CATERPILLARS.

UNDER this head I read in your Number of September 5th the mode adopted by Mr. McGregor. For the past ten years I have pursued the same course, and scarcely during that time do I recollect of a single infested tree. In November or December I have the earth taken from the stem of each tree for about the space of 18 inches all round, and as deep as the roots will permit. I leave the roots exposed to the weather for three or

four weeks—if the atmosphere be cold and dry I leave them longer—then fill in with manure or fresh earth, and I have a splendid crop of fruit without suffering from caterpillars.—JAMES PRIM, Monkstown, Dublin.

#### GLEANINGS FROM ROCK AND FIELD TOWARDS ROME.—No. 5.

It is not to modern Rome alone, even though it contain St. Peter's, that the traveller turns with longing eye and heart. The grip of the mighty heroes of ancient days is upon him, and he must perforce follow where it leads. There is, perhaps, no place in Rome about which one's fancy lingers so much as about the noble ruins of the Colosseum. Each blade of grass, each simple flower adorning the crumbling masonry, seems baptised in blood. There the gladiators were "butchered to make a Roman holiday"—there, shrinking Christian matrons and timid girlish forms were torn and mangled by wild beasts, while Roman men and women looked on and smiled approvingly—there, St. Ignatius breathed his last in agony, and a whole "noble army" of martyrs were done to death by cruel heathen hands. The mind is well nigh lost in contemplating the exceeding vastness of this stupendous amphitheatre, the colossal size of which earned for it the name of Colosseum, and occasioned the prophecy mentioned in Childe Harold.

"While stands the Colosseum, Rome shall stand;  
When falls the Colosseum, Rome shall fall;  
And when Rome falls, the world."

Several of the flights of stairs leading to the galleries are remaining. I mounted one of these, and wandered round the huge ruins, gathering some of the 420 species of wild flowers, said by Dr. Deakin to find a home there; then I sat down, and dreamed of the terrible days of old. Presently I looked up. Beneath me, by the side of a cross, kneeling in prayer, was a little child, holding his mother's hand—no other figure presented itself in all the vast arena. It was a beautiful picture, that "Triumph of the Cross," seen from the gallery of the Colosseum. Inensibly the mind wandered back near eighteen hundred years, bringing vividly before one the record come down to us of the death in this amphitheatre of that "little child" whom our Lord presented to His disciples as a model of humility, and who grew up to be St. Ignatius, the disciple of St. John, and the bishop of Antioch. Tradition tells us that the Emperor Trajan, in honour of whom was built the column, called by his name, and still existing at Rome, being in Antioch, cited St. Ignatius before him for refusing to worship the gods. The bishop answered the charge by eloquently and fearlessly exposing the follies of paganism: he was condemned to be thrown to the lions, and ordered to be conducted to Rome to suffer with malefactors in the new amphitheatre there. We are told that St. Ignatius heard the sentence with joy, assisted in putting on his own chains, and set out on the long journey as one travelling towards home. Brought into the arena, he knelt, and exclaimed in a loud voice, "Romans present at this spectacle! know that I have not been brought to this place by any crime, but in order that by such means I may merit the fruition of the glory of God, for love of whom I have been made prisoner. I am as grain of His field, and must be ground by the teeth of the lions that I may be converted into bread fit for His table." The lions were then let loose, and devoured him, leaving nothing of his body but the larger bones, which the Christians collected during the night for burial. Hundreds of other Christians suffered within these walls as St. Ignatius suffered, so that each stone has a voice for Christians such as no other building in Rome can have.

No one but a dweller in Rome could understand the exceeding difference of temperature to be found within the six acres which comprise the arena of the Colosseum; it is this circumstance which makes its flora so very interesting to botanists. Within and upon its walls are to be found plants requiring dampness and dryness, warmth and coolness of soil and atmosphere for their development. The Cyclanens hederæfolium, europæum, and neapolitanum are to be found there; but the hederæfolium and europæum would be the most generally known, from their blooming in the spring, when English visitors are most drawn to the Colosseum to witness the processions of the confraternities to the stations erected round the arena by Pio Nono. The Asperula odorata adds its treasure of sweetness to the scentless beauty of the Anemone hortensis, while the Myosotis arvensis claims a familiar nod, together with the Borago officinalis, the latter so pleasantly suggestive of iced claret-cup

to thirsty sight-seers. The *Cerintho aspera* and the *Lithospermum purpurco-ceruleum*, both new plants to me in their wild state, hang out their banners from the walls, and for brilliancy of colouring—the one of yellow and the other of blue—they exceeded all other flowers that I found. I gathered the *Melilotus indica* in full bloom on April 15th, and as I write with the yellow Vetch-like plant before me, its sweet odour is diffused about the room. The *Melilotus indica* is called in Italy *ghirlanda*, or “garland flower;” because it was used by the Italians for making garlands wherewith to crown victors. Gruyere cheese is flavoured by this flower. *Melilotus italica* is also to be found. The *Muscaria racemosum* and *M. comosum* were still in bloom, though their beauty was nearly over. I often saw the former growing in fields where the *comosum* was not visible. There are only three Ferns to be met with—the *Polypodium vulgare*, *Adiantum capillus-Veneris*, and *Asplenium trichomanes*. I brought away a small root of the *Polypodium*, which grew in graceful fashion high on the walls; it is living, and has just put up two young fronds to repay me for my care; and what care did my Fern-basket not give me? At every custom-house the officials pounced on the poor basket with its leather handles, and ruthlessly tumbled out my little mummy-like bundles, and the tin boxes of bulbs, roots, &c. I wondered long why they showed such animosity towards my treasures, but at last I found out—they thought spirits were hidden there! Time would fail me to tell of all the plants and flowers abounding in the Colosseum—of the Sage and Rosemary, the Olive and Arbutus, old friends and new friends, all gathered there to beautify these glorious ruins of a terrible past. To study them all as they deserve would occupy many days, and my time in Rome was limited, but I gathered every specimen that I could, and my wild-flower book is one of the pleasantest memorials of my visit.

From the upper galleries of the Colosseum the eye can take in much of ancient Rome—the Palace of the Cæsars, the Arch of Constantine (forming a link between Pagan and Christian monuments), the Baths of Titus, the Capitol, the Aven-tine, and the Campagna; but the mind fails to keep pace with the eye, so grand, so vast, are these records that rise like ghosts of buried ages on every side. Grand as the Colosseum is, it falls into comparative insignificance before the still vaster dimensions of the Palace of the Cæsars, where excavations on an enormous scale are being carried on under the auspices of the Emperor of the French, who purchased the ruins for £10,000, and by excavating is daily bringing to light more and more of the huge dwelling-place of the Roman Emperors. So great are these ruins, it is nearly impossible to conceive a picture of the whole. One sees, indeed, by ancient monuments daily disinterred, that this was the house of Tiberius—this, the addition made by Caligula—this, the Triclinium or banqueting-hall, with its very walls and floors of inlaid-marble work, and opening out from it the Nymphæum with its baths and trickling fountains, its Orange and Myrtle trees, with lovely statues reflecting themselves in the cool waters; and that this was the vast reception-hall where justice was given, having on one side an altar for the Penates, and on the other the Basilica (with its tribune and stairs still remaining), dedicated to Jupiter. One sees it all, but it is as one sees a dream. I close my eyes in the sweet sunshine, as is my wont, and go dreaming back. I see St. Paul after he had appealed to the Roman Cæsar, on his weary journey Romewards, met by his friends at the Appii forum, and at last brought to this very hall, standing before the tribune with his accusers face to face, as was the custom with the Romans. I hear him and other Christians condemned to death. I look up, and on every side see ruins side by side with Christian temples, and scarce one stone left upon another, to testify to the greatness of the past of that nation, who, from being the persecutors became the chief propagators of Christianity, verifying the saying, that “The blood of martyrs is the seed of the Church.”

How strange it seemed wandering amidst these ruins, now stopping to gather a few Violets from the almost sacred soil, now picking up an Orange fallen from the tree; so strange to be an eye-witness to heathen confirmation of Christian truth, in days when ruthless hands are trying to undermine all faith, and wicked men would fain persuade each other that written testimony is a lie. From the stern poetry of ancient days I turned to the graves of our own Shelley and Keats, who, after life's fitful fever, sleep peacefully in the English burying-ground at Rome. Shelley's grave was gay with flowers, and voices from England and America were speaking his name softly above his resting place. I gathered a few Violets and passed on to the

old Cemetery, overshadowed by the Pyramid of Caius Cestius, the only sepulchral pyramid in Rome, where, apparently forgotten and neglected, was the harp with its broken strings, with the few sad words left by Keats to be written on his tomb. “His name was writ in water.” I remembered the sweet grace of his poem of “Endymion,” and pictured to myself the moonlight stealing through the Cypress-boughs to wander caressingly over his sleeping dust. Not far from the grave of Keats I found some beautiful plants of the *Serapias cordigera*. I had never met with this handsome Orchid-looking plant before, and with my hands I grubbed up some roots, and I call them “Keats' Orchis.”

There is a touching story told (I think in one of Burke's books, showing the vicissitudes of families), of a botanist finding in some country walk a flower unknown to him. He asked its name from the country people about, and they said, “Oh, we call it Aylmer's flower” (I am not sure of the name). He asked, Was there any one of that name in the country round? “Oh! no.” Was it the name of any place in the neighbourhood? Again, no. The flower turned out to be one from the flora of the Holy Land. How had it found a home in that far-off nook? After much searching he discovered, that in the Crusades a knight of the name of Aylmer, after doing fierce battle against the Saracen, returned to his ancestral home in the county where the botanist had found the flower. The home, the family, all had become utterly extinct; all but the tiny flower that returned the grim Crusader's care, by carrying down to posterity the name of his ancient line. From the broken harp of Keats, I turned to the 114-foot-high pyramid, and spelling out the letters, C. Cestius, asked myself, “And who was he?” And the answer came, “Earth has no lasting fame but the influence of righteous deeds, that once done live for ever, passing on through succeeding generations, and found at last written in the hearts of men and angels at the bar of God.” Besides the *Serapias cordigera*, I brought away several bulbs of the *Ophrys aranifera lumbata*, which was growing abundantly and in full bloom on the 14th of April.—*FILIX-FEMINA.*

P.S.—In No. 4 of my “Gleanings,” I inadvertently wrote “*Cyclamen latifolium*,” instead of “*C. hederifolium*,” the latter being the plant I found in the grounds of the Villa Pamfili-Doria, and not *latifolium* as I stated.

#### PLANTING PEAS DEEP.

DEEP planting is not generally resorted to, under the impression that the seed will rot in the ground. This is a mistake. Peas covered 6 or 8 inches deep will produce twice as much as those covered but an inch; they continue to flower longer, and the vines are vigorous, and do not lie down, as is often the case where shallow plantings are made. We have tested this matter, and, therefore, know from experience, that if it is desired to get a large crop, the seed must be buried deep. A suitable piece of ground, enriched the previous year, was deeply ploughed in fall and spring, and put in fine tilth. One-half of the piece was marked out in drills, and the seed covered 2 inches deep. On the other half the plough was sunk beam deep and the seeds scattered at the bottom of the furrow. In this way one-half the piece was gone over and levelled, leaving the seed at least 8 inches from the surface. The Peas that were ploughed-in were a little longer in coming up, but they soon shot a-head of the others, the vines were thrifty and vigorous, and produced treble the quantity of those in two-inch drills by their side. The seed used was the Champion of England; the soil, time of planting and culture, except the manner of putting in, were precisely the same for both. This experiment convinced us that Peas flourish best in deep planting, and we have repeatedly had our attention called to the confirmation of this fact in observing different crops and learning the manner of culture.—(*Utica Herald.*)

[There is a moderation in all things. For main summer crops 8 inches we consider too deep, and 2 inches too shallow. The above example quoted from an American paper merely shows one of those fortunate results on which it would be unsafe to build a principle. The deep ploughing of the land, and the somewhat rough covering of the deep-sown Peas by the plough, so as to allow the air to enter, would be the chief reason why Peas sown at the depth of 8 inches came up at all so vigorously. We know instances, and have recorded them, where Peas sown deeply rotted, and never came up at all. If Peas are only covered 2 inches deep, such kinds as Champion of England,

scarcely have enough of support for their stems; from 3 to 4 inches would be better, in fine, deep-stirred, pulverised land. The chief securities against mildew are deep stirring and rich manuring, the manure being decomposed and sweet, and then sowing some 3 or 4 inches deep in a trench, and the Peas, if in a garden, may be gradually earthed-up a little for support. Our own experience would say, that in general 8 inches would be too deep. But for the deep stirring of the soil previously, we have little doubt it would have been so in the case quoted. The roots must have come up as well as gone down. It is more natural for the Pea to send its roots at once in a downward direction. We have traced them to a depth of 3 feet. If the seeds had been sown in ploughed land, not deeper ploughed than 8 inches, we would have expected the Peas to have made poor headway in the hard fare beneath them.—Eds.]

### THE ACTION OF METALLIC SALTS UPON THE GROWTH OF PLANTS.

SEVERAL years ago, when I was assistant to Professor Horsford, the Professor of Chemistry in Harvard University, he was consulted by one of the parties to an important lawsuit, where chemical principles were largely involved; and where the main question turned upon the action of copper fumes and scorïe on vegetation. We made many hundreds of analyses of soil, grass, bark, and moss from the neighbourhood of the copper-works, and finding copper everywhere, we undertook experiments in watering plants with solutions of copper, arsenic, and other metals injurious to their growth. Having kept no minutes of these experiments for my private use, this summer I made the investigations in poisoning of plants, which are given beneath.

A solution of sulphate of iron, of 8 grammes [123.4584 grains], for the half litre [0.88038748 pint], was taken as a standard, and solutions of acetate of lead, chloride of tin, sulphate of zinc, sulphate of manganese, sulphate of copper, and bichloride of mercury were made, of such strength that equal measures should contain equivalent (not equal) quantities of the respective metallic bases.

Seven *Triomphe de Gand* Strawberry plants, as nearly alike as possible, and seven small Cauliflower plants were transplanted into pots of uniform size, and, beginning on the 1st day of June, each plant was treated with 15 centimetres of the above-named solutions per day, and all the plants were watered with clear water twice a-week. The following are the results:—

1st. Strawberry plants subjected to the action of acetate of lead, no change till June 10th, slight blackness on stems; June 17th, stems a little decayed; June 23rd, two large and one small leaf remaining; July 2nd, two half-healthy leaves left. Cauliflowers with acetate of lead seemed wholly unaffected. July 2nd, strong and growing.

2nd. Strawberry treated with chloride of tin, no change noticeable till June 9th, stems blackened; June 17th, stems decaying; June 21st, stems more decayed; June 30th, entirely dead. Cauliflower plant treated with chloride of tin in perfect health, July 2nd.

3rd. Strawberry plant treated with sulphate of zinc, no change noticeable till June 10th, stems blackened; June 17th, outer leaves gone; June 23rd, one leaf remaining; June 25th, entirely dead. Cauliflower treated with sulphate of zinc, no change noticed till June 23rd, leaves shrivelled; July 2nd, entirely dead, having decayed rapidly.

4th. Strawberry plant treated with sulphate of iron, no change observed until June 10th, stem show slight decay; June 17th, outer leaves going; June 22nd, leaves black and decaying; June 30th, entirely dead. Cauliflower plant treated with sulphate of iron July 2nd, leaves slightly shrivelled, otherwise healthy.

5th. Strawberry plant treated with sulphate of manganese, no change perceptible till June 11th, slight blackness on stems; June 16th, apparently healthy; June 23rd, several leaves dead; June 30th, two healthy leaves left. Cauliflower plant with sulphate of manganese, unchanged till June 23rd, leaves shrivelled; July 2nd, leaves badly shrivelled.

6th. Strawberry plant with sulphate of copper, unchanged till June 10th, stems decaying; June 23rd, three leaves remaining; June 29th, entirely dead. Cauliflower plant with sulphate of copper unchanged till June 23rd, considerable decay; June 30th, rapid decay, almost dead.

7th. Strawberry plant with chloride of mercury, no change

perceptible until June 7th, stems blackened; June 11th, stems rapidly decaying; June 17th, outer leaves dead; June 19th, whole plant entirely dead. Cauliflower plant with chloride of mercury, no change observed until June 17th, somewhat affected; June 25th, badly decayed; June 28th, entirely dead.

These experiments are interesting from one point of view as showing how much better Cauliflower plants can resist poisonous agencies than Strawberries, and what is true of the Cauliflower will probably hold true of all plants of its class.

The action of the corrosive sublimate was most rapid, as may have been foreseen, but how a Cauliflower can grow when daily watered with a strong solution of sugar of lead is mysterious.

The action of the iron and copper salts was about the same, although it might have been supposed that copper would act more energetically than iron.

The first signs of decay were blackening of the stems, then the stems wilted, and last of all the leaves shrivelled. The base of the stem in all cases was affected first. The roots were black and dead. I trust some reader of the "Horticulturist" will continue these experiments on other plants and give us his results. I should suggest the use of weaker solutions, so that the experiments might occupy a longer time, and slighter changes in the health of the plants be noticed.—(J. M. MERRICK, JUN., *Walpole, Mass.*, in *Horticulturist*.)

### GROUND VINERIES.

"J. N." (page 187), by introducing a door at the apex of each span would provide a current, particularly when the sun was fully upon these narrow ridges of glass. I do not think, besides, that a small board attached to the top, with hinges and a hasp to keep it up to any point, would be more expensive than the end ventilation, and it would be more easy to let this down at once than going to each end of the cases. In my notice it reads, "Take them off," but my meaning was to take the air off at midday when the rise of temperature could do no injury. Mr. Heywood's Vines are trained as suggested by "J. N.," but in my opinion a great deal more is to be done by having no direct air whatever, but introducing it by any of the geothermal systems now so well known, and thereby using the air as a heating medium. I hinted that allowing the air to pass through brick rubbish would be an advantage, but the further it travels through this in reason the warmer it will become. I have seen Mr. Rivers's Vines and those of several others since I wrote that notice, and none of them are so successful with their Grapes as Mr. Heywood, who has them by the stone and hundredweight.—J. F.

### PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

*LIPARIS ATRO-PURPUREA* (Dark-purple-flowered Liparis). *Nat. ord.*, Orchidaceæ. *Lim.*, Gynandria Monandria.—Terrestrial Orchid. Not showy. Native of Ceylon.—(*Bot. Mag.*, t. 5529.)

*PHALANOPSIS SCHILLERIANA* (Schiller's Phalanopsis). *Nat. ord.*, Orchidaceæ. *Lim.*, Gynandria Monandria.—On high elevations in the Philippine Islands. White, rayed with pink.—(*Ibid.*, t. 5530.)

*ALSTREMERIA DENSIFLORA* (Dense-flowered Alstroemeria). *Nat. ord.*, Amaryllidaceæ. *Lim.*, Hexandria Monogynia.—Native of Peru, at elevations of from 6000 to 11,000 feet. Flowers scarlet, in an umbel.—(*Ibid.*, t. 5531.)

*HEMANTHUS INCARNATUS* (Flesh-coloured Hemanthus). *Nat. ord.*, Amaryllidaceæ. *Lim.*, Hexandria Monogynia.—Native of South Africa.—(*Ibid.*, t. 5532.)

*LANKESTERIA BARTERI* (Mr. Barter's Lankesteria).—*Nat. ord.*, Acanthaceæ. *Lim.*, Diandria Monogynia.—Native of Western Africa. Flowers yellow, in spikes.—(*Ibid.*, t. 5533.)

*EUPHORBIA MONTEIRI* (Mr. Monteiro's Euphorbia). *Nat. ord.*, Euphorbiaceæ. *Lim.*, Monœcia Monandria.—Native of South-west Africa.—(*Ibid.*, t. 5534.)

*PELARGONIUMS*.—*William Hoyle*.—The darkest Pelargonium ever yet raised. Lower petals deep brownish crimson, white throat; upper petals deep maroon edged with crimson. *Charles Turner*.—Brilliant scarlet, white throat; upper petals dark maroon, with a broad rim of scarlet. Both the above were raised by Mr. Hoyle, of Reading, and are in the hands of Mr. Turner, of Slough.—(*Floral Mag.*, pl. 257.)

*ROSE Princess Mary of Cambridge*.—Raised by M. Granger

from Duchess of Sutherland crossed with Jules Margottin; pale rose with bright centre. Messrs. Paul & Son, who have purchased the stock, state that it is remarkable for its hardy habit and good autumnal properties.—(*Ibid.*, pl. 258.)

**LOBELIA CORONIFOLIA.**—Received by Messrs. Backhouse, of York, from the interior of Caffraria. When grown out of doors in summer it forms a dense tuft, bearing flower-stems from 4 to 6 inches high, each with from three to five or six blossoms, blue, faintly tinged with violet, and remaining in perfection many weeks.—(*Ibid.*, pl. 259.)

**BOUGAINVILLEA LATERTIA.**—Delicate salmon pink bracts, forming a pretty contrast with the mauve-coloured bracts of *B. speciosa*. Obtained by Mr. Daniels, gardener to the Rev. C. E. Ruck Keene, Swyncombe House, Henley-on-Thames, and now in the hands of Mr. Bull.—(*Ibid.*, pl. 260.)

**ANEMONE ANGULOSA.**—“It is a native of Hungary, and is one of the many beautiful hardy spring flowers which the Messrs. James Backhouse & Son, of York, have been fortunate enough during the present year to bring under the notice of the London public. The Floral Committee of the Royal Horticultural Society awarded it a first-class certificate; and a double-first, if it could have been given, would not have shown too high an appreciation of its merits. The habit of this species is exactly that of the allied *A. hepatica*, but the plant itself, as well as its parts, are all at least twice the size of that. Thus, the leaves are fully 3 inches broad, three-lobed, but having the lobes coarsely and rather deeply crenato-dentate. The flowers are upwards of 1½ inch across, of numerous oblong lance-shaped spreading sepals, and of a fine clear greyish blue, set off by the array of numerous black anthers, which surround the tuft of yellowish styles. It is doubtless one of the finest hardy plants of recent introduction.”—(*Florist and Pomologist*, iv., 185.)

## TODMORDEN BOTANICAL SOCIETY.

SEPTEMBER 4TH.

Mr. HOLMES in the chair. W. Manley Eastwood, Esq., of Eastwood, and Mr. Josiah Wade, of Hebdon Bridge, were elected members. Notwithstanding the absence of the President, Vice-president, as well as several others of the Society, on the Silverdale excursion, the attendance at this meeting, considering the season, was quite an average one. Mr. James Hartley, of Heptostall, a young but most enthusiastic and successful collector, contributed specimens of a curiously depauperated form of the common Brake (*Pteris aquilina*); the lower portion of the frond, in the example alluded to, had the pinnules of the usual shape and character, but in the terminal portions the pinnae were either wanting, or so diminished in size, as to amount to little more than a number of small excurrent points; the group of which the frond in question formed a part, was reported to be uniformly of the same character. Mr. A. Dawson, of Knowl-top, Walsden, sent an interesting dish of the Cowberry (*Vaccinium vitis idaea*), and evidently including both the species and the variety *majus*. The berries were accompanied by a note from Mr. Dawson, who stated that the examples sent had been gathered from cultivated plants, and had been yearly loaded with fruit for several seasons back, whereas those in a wild state in the original locality had been almost uniformly barren during the same period. An interesting communication was read from Mr. Rogers (one of the Manchester associate members) on the botany of Ben Lavers and some other parts of Scotland. Of the more rare plants enumerated as being collected by Mr. Rogers, we may name *Pyrola secunda*, *Cornus suecica*, *Cherleria sedoides*, *Cerastium alpinum*, *Betula nana*, *Malaxis paludosa*, *Mnium athamanticum*, *Saxifraga oppositifolia*, *Sedum rhodiola*, *Thalictrum alpinum*, *Trientalis europæa*, *Polystichum lonchitis*, *Lastrea alpina*, *Lastrea Filix-mas var. pumila*, *Polypodium phegopteris var. laciniatum*, *Lycopodium annotinum*, *L. inundatum*, several good Mosses, &c., &c.

## ENTOMOLOGICAL SOCIETY'S MEETING.

THE September Meeting of the Entomological Society was held on the 4th inst.: F. Smith, Esq., Vice-President, in the chair. Donations to the Library were announced from the Smithsonian Institute of the United States, the Royal Academy of Belgium, the Entomological Society of Stettin, Messrs. Saussure, Sichel, Cresson, &c.

Mr. F. Bond exhibited some interesting specimens of the common Heath Moth, *Fidonia atomaria*, a species in which the colours and markings of the wings are different in the opposite sexes; the individuals exhibited being a pair, male and female, in both of which the ordinary colours of the male were seen; and in a second similar pair the female colours and markings were present; likewise a male *Gonapteryx Rhambi*, in which a portion of the left fore-wing was coloured as in the female, and a female in which the colour of the male was present in a portion of one fore-wing; likewise some specimens of the rare Moth, *Ennychia anguinialis*.

Mr. McLachlan exhibited some rare Neuropterous insects from Ramock (Perthshire)—namely, *Æsma borealis*, *Sialis fuliginosa*, (Pictet), *Stenophylax nova species*, and *Rhyacophila*, n. sp.

Professor Westwood mentioned a peculiarity he had observed in the economy of the caterpillars of the *Ailanthus Silkworm*, previous to their changing to the pupa state. He also gave an account of the Exhibition of economic entomology, beneficial and destructive insects, with illustrations of their ravages, Silkworms of various kinds, bee-hives, wax, and other insect-products, which was opened on the 15th of August, at the Palais d'Industrie, in the Champs Elysées, Paris. Among the newest bee-apparatus, was mentioned an octagonal larvive of wood, made in two halves exactly fitting together, so that when the hive is full it can be divided into two parts and empty halves applied to the full portions, thus preventing ordinary swarming.

Mr. Dorville exhibited a common Moth, *Caradrina cubicularis*, attacked by a small red species of *Acarus*, of which a number were arranged symmetrically on the under surface of the wings.

Mr. Stainton also noticed the great numbers of Cheliferidae, which he had observed this summer attached to the limbs of flies. Dr. Hagen had supposed that this was for the purpose of transport, but Mr. Stainton considered them to be real parasites.

Mr. Baly stated, that in the neighbourhood of Aberdeen great numbers of Wasps had appeared this summer; but a letter was read from Mr. S. Stone, of Brighthampton, giving an account of an epidemic which had attacked the Wasp nests in Oxfordshire, and which had entirely destroyed large numbers of them, so that scarcely a single Wasp had arrived at maturity. Earwigs also, which had been extremely numerous, had got into the nests and devoured great numbers of the larvae.

Mr. F. Smith stated that he had not observed a single Wasp whilst collecting Hymenoptera, at Bournemouth, where last year they were extremely numerous; and Professor Westwood read a letter from a correspondent, giving an account of the injury committed in a common bee-hive by vast numbers of Earwigs, what had got under the cover of the hive.

Mr. Stainton exhibited some pods of *Epilobium montanum*, attacked by the larvæ of *Laverna subbistrigella*; and Mr. Kirby a specimen of *Polyommatus Alexis*, measuring only 8½ lines in the expansion of the wings.

Mr. Stevens exhibited portion of a collection of insects recently made in Damarra Land, South Africa, including several rare kinds of Goliath Beetles.

Mr. F. Bond communicated a notice of some swarms of winged Ants, which had appeared round the steeple of the church of St. Morris, at Coburg, and had been mistaken for smoke issuing from it, so as to have caused great alarm among the inhabitants.

Mr. Wormald also stated, that he had noticed a similar instance of flights of Ants in vast numbers.

An account was also communicated of the poisonous attacks of a species of black Gnat on horses, mules, &c., in South America; as well as Sir Gardiner Wilkinson's account of the poisonous attacks of the Fly named Zebub in Upper Egypt.

**PRODUCTIVE OLD PEACH TREE.**—I have an old tree of the Late Admirable under my care; it occupies 240 feet of south wall. I have this year 480 Peaches on it, all fine fruit. The tree is loaded from the bottom to the top. The stock is 22 inches in circumference, and some of the arms are 14 inches round and in a half decayed state.—G. PHILLIPS, *The Gardens, Crowcombe Court, Somersetshire.*

## FORMS OF OUR FRUIT-HOUSES.

THIS subject is one that always attracts attention, and yet there are remarkably few experiments tried with regard to their construction. What causes this it is difficult to tell; and yet I think I am warranted in saying that few experiments are tried, or we should find the result; for fruit-house building cannot be supposed to be the one exception that proves the rule, and obstinately refuses to advance. In writing this letter I am aware that I am not, as the phrase goes, stroking the gardening world the right way. I learned to think before I gave my attention to gardening, and if I do not think like those who learned gardening first, I cannot help it; and pray excuse my accepting the dogma, that what is, is right. Let me, then, as an outsider, throw out a few remarks. I want to advance the gentle craft as much as any one. Is it not true, that if I leave out the application of hot water, our Pine-pits are such as Mr. Le Copr used in 1724? that our Pine-houses are—I was going to say the exact measure—but I will only say substantially the same as Miller gives in his “Gardener's Dictionary,” more than a hundred years ago? and I may say the same of our glassed-in Peach walls and lean-to houses. When our foreign friends visit next year, as is proposed, our great

gardens, and I may include, if the account I read is correct, the royal garden, scarcely, if yet, finished, will they not look in vain for fruit-houses built on any other plan than those I have named? Each time I read an old book on the subject I rise with the feeling, Can it be there is nothing new under the sun? and then I ask myself the question—How is it, with cheap glass and a greatly increased command of heat, that we go on building the same sort of houses? and wonder that we, the most commercial nation, as it is said, have actually retrograded, and by growing our Vines and Peach trees under the glass in lean-to houses, get the least result with the greatest cost? Should not our aim be—the greatest number of square feet of pit or trellis, as the case may be, for the lowest cost, and to suit the cultivation to the shape?

The cheapest shape points, unquestionably, to large, square, tall houses; but when I advocate such, I am always told that nothing can be grown in them but tall orchard-house trees; and as "the Eden-like pleasure of walking about under the shade of my own Vine and Fig tree" does not chime in with my commercial notions, I had no course left, as I concluded the present shape was induced by necessity at some period, but to try and find out that cause, and so be able to judge if it still existed. I have not been able to find this cause, but, on the other hand, a great deal to lead me to believe none ever existed. As I have said, I consider growing Vines and Peach trees under the glass a retrogression. I have two things to prove: that it was not formerly done, and, that it is a mistake. The following is Miller's description of what he calls a "dry forcing stove" for forcing Vines, Peach trees, &c.:—"The area is to be filled with rich earth 2 feet deep, in which the trees are planted to remain, having been first trained in the open ground till they are in a state for bearing; they are planted in straight or oblique lines from the back to the front, the tallest behind, and are trained against the back wall and front to a trellis, and in the area as espaliers." "These stoves begin to be worked in January or early in February." The house here referred to was a lean-to; no dimensions are given, so I conclude we must refer to his greenhouse plan, where he advises from 20 to 24 feet wide. The front is shown as the same height as the doors, and if we assume they were 7 feet high, there was sufficient height for a tree. The last edition of Miller's dictionary was published in 1768.

Let us now turn to Mr. Speechly, in 1790. He advises a lean-to house with a flued wall at the back of from 12 to 14

feet high, and the width of the house to be 10 feet, and says, "In regard to the future management of the Vines at the rafters, it should be observed, that though it will not be absolutely necessary to adhere invariably to the rule laid down of annually cutting every other Vine down to the bottom of the rafters, yet it will be proper to keep these Vines from extending too far over the glass frames, and thereby shading the house, which would tend to injure the Vines on the back wall. It should be considered that the success of the Vines trained against the flued wall is the first and principal object."

I may here say, that a few months since I received a letter from a friend in the south, asking me for some information about pipes and boilers, saying, "My gardener wants me to put pipes into my house, but as I have as many and as good Grapes as my neighbours who have pipes, I do not see the

good of it; can you explain how it is?" I wrote him back in reply, to say, I had very little doubt his neighbours grew their Vines under the glass, and thus as the sun's heat increased the leaves also got larger and formed a green blind, keeping the rays out. I added, "If you intend to grow yours in the same way you will certainly require pipes also." I subsequently heard that it was a lean-to house, but the Vines were planted against the back wall, the front being used for pot-fruit trees.

About four years ago I visited, I may safely say, our most famous garden, that I might see the glass walls; and when there I asked the gardener, who took me round, why they were built so narrow; for the cost of a little more roof the houses might have been twice the size. The answer was, "But how could we train the trees?" The same year I was up in London, and stumbled on a lean-to Peach-house, where the trees were trained to a trellis against the back wall, and, as Miller says, "in

the area, running from the back to the front, on espaliers." When I returned home I put up a house in this manner: back wall and front glass, each 10 feet high; width, 12 feet. Now for the calculation. In the back wall, 52 feet long by 10, = 520 square feet; then I have a trellis 8 feet wide, running at right angles to the glass at each 4 feet;  $8 \times 10 = 80$ ,  $\times 13$ , the number of the trellises, = 1040; add 520 in the back wall, and I have 1560 square feet of trellis in a house 52 feet by 12; granted there is not much room for ladies, but there is sufficient for gardeners.

Let me recommend this plan of front trellisses to Mr. Bréhaud, he complains that his bush trees are unmanageable, and I think it will make his house look more gardener-like.

Mine has a south aspect, and the sun pervades the whole house, and not without result, I can assure you.

Then, of Vines. I have a span-roofed house, 20 feet wide, that does not please me, and to which I intend putting fifteen-foot sides. The Vines are planted 2 feet apart, and I shall back every other, which will result in my having four rows of Vines, each Vine being 4 feet from its neighbour, and the light will be free to enter from the top and all the sides. I should very much like to know how many feet of rod and how many spurs are required for each show bunch. I think my Vines will have at least double the number of spurs per foot of rod that they have now, and we are sure that means capacity for work, and yet the house, as it is, is better than a lean-to.

Have we not, then, been following this one idea—that nothing will succeed well that is not trained under the glass—too long and to our great loss? and is it not time, in this our practical age, to begin to take cubic measure into account? A house with a back wall 15 feet high, and 15 feet wide, treated as a lean-to at an angle of 45°, gives a front of 21 feet; if 50 feet long, it contains 1050 square feet of trellis. On my plan, as shown by the section, the back wall, 15 by 50, would contain 750 square feet, eleven front trellises 5 feet apart and 9 feet wide;  $9 \times 15 = 135$ ,  $\times 11 = 1485$ ; add 750 and it makes 2235 square feet of trellis. Compare this with 1050, and how many will regret that good old plans of gardening were ever departed from?

It is said, those who run may read; and any one who talks about plants being drawn, because they are far from the glass, will not be listened to in these days when we can see for ourselves at Sydenham and Kew.

In closing this letter, I may say I have no interest to serve in recommending a particular form of house; but, as a fruit-grower, who has learned much from the perusal of your valuable paper during the last eight years, I desire, if an anonymous letter can carry weight, that my experience should be at the service of those who are intending to build fruit-houses, and as the most certain way of placing it before them I send it to you.—G. H.

### CUTTING-IN SHRUBS ANNUALLY.

In my garden I have a Sumach, which was as I thought dying, so I cut it down to a stump about 3 or 4 feet high. Next year it shot up and produced some fine foliage; I continued cutting down to the stump each year after the leaves had fallen, and it has in each improved both in appearance and size of foliage and branches. This year is the best year of growth it has had, and it far surpasses all I have ever seen of the sort. The growth from the stump this year is from 5 to 6 feet, and the stems the leaves grow on are about 4½ feet long. I enclose a leaf which is about half a foot long. Several of my neighbours have trees, but have not cut them down; there are also a few at the Botanic Gardens, Liverpool, but not cut; they have but small leaves in comparison to my plant. The soil in my border is the common garden soil, rather stiff. I shall feel obliged if you will give your opinion on this subject.—A SUBSCRIBER, *Liverpool*.

[Many shrubs and plants would be greatly increased in vigour if they were cut-in every year much the same as is done with a Willow stool. No doubt if mere size of foliage is desirable, the young shoots thus formed will yield large leaves, until the stool is exhausted. Are you quite sure, however, that the leaf sent is the leaf of a Sumach? if so, it does not belong to the commoner kinds found in gardens, and more resembles *Rhus venenata* than any we know. If so, the leaves before they drop will become of a purplish red colour. This, and some others which the smooth leaf would seem to point to, are very poisonous, and, therefore, if a Sumach, you must be careful in the cutting, that none of the juice get on your hand.—Eds.]

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

EARTH-UP the Broccoli plants as they advance, this greatly promotes their growth; also earth-up other plants that require it. Keep a watchful eye for the caterpillars; as soon as they are observed have them gathered off by hand, this being the only sure means of extermination. *Cabbages*, the main spring crop may now be planted, the small dwarf sorts at 18 inches row from row and 20 inches in the row. A double quantity

may be planted in the rows, so as to admit of thinning-out every other one in the spring. *Cauliflowers*, prepare the ground for the plants which it is intended to protect with hand-glasses, the soil should be rich, and, if possible, under a south wall; nine plants may be planted under a good-sized hand-glass, and in the spring five or six of them may be taken away, and planted elsewhere. *Carrots*, sow a few Early Horn in a sheltered place to stand the winter. *Celery*, the first earthing of a crop should not take place until it has made considerable progress, by commencing too early it is drawn up weakly; the earth should be closed round the stalks with the hand. *Cucumbers*, the heat of the bed containing bearing plants must not be allowed to decline, or they will not continue productive, whereas by proper attention they will produce fruit till Christmas. Dung should now be procured, and prepared for beds next month. *Dwarf Kidney Beans*, if a supply is required through the winter a sowing should now be made in pots half filled with soil, which allows of the plants being earthed-up. *Endive*, tie-up for blanching when the plants are quite dry, or lay a tile upon each plant; another plantation may also be made. *Globe Artichokes*, cut off the stems as fast as the heads are used. *Mushrooms*, the beds recently made must be spawned immediately the heat has become moderate; when earthed they should be well beaten down, as solidity is one of the principal causes of productiveness. *Salading* should now be raised under a hand-glass, or in boxes placed in a forcing-house; to keep up a constant succession a sowing should be made three times a fortnight.

#### FRUIT GARDEN.

Look over wall trees, and cut off all foreright breastwood, or what are commonly called after-shoots. Strawberry plants in pots must not be allowed to become very dry, nor ought they to be drenched with too much water. Gather carefully and progressively the various Pears and Apples as they arrive at their full growth. Discard at once bruised fruit, its possession entails ultimate trouble.

#### FLOWER GARDEN.

See that the faded blossoms and seeds are regularly removed from beds, other blossoms will be thus encouraged; much of the vital energy of a plant is expended in the perfection of its seeds. Borders deficient of Snowdrops, Crocus, Narcissus, and other such early spring-flowering bulbs should have some introduced. Tender plants which it may be intended to winter for use next season must soon be taken up and placed in safe quarters. Plants, however, which are still in good condition may be left for some weeks longer. Variegated Geraniums will not bear much frost, and when the plants have to be wintered in situations which are not very suitable for them they should be taken up before they are at all injured, as they will be much more liable to damp and die back in winter if the wood is at all touched by frost. Except when there is a sufficient stock of these they should not be cut back as is usually done with the old scarlets, but should be kept over the winter just as they are lifted from the beds, and cut back early in the spring after starting them into growth, when the cuttings will root very freely in heat, and in the case of Flower of the Day or any other free growers, will make useful-sized plants by turning-out time; and even the strongest growers of these do not cover a bed very quickly unless planted thickly, and the plants, therefore, should be wintered in as large a state as the accommodation will permit. The autumn-rooted stock of *Verbenas*, &c., must be well attended to, keeping them perfectly clear of green fly, exposing them freely to the night dews, and keeping them hardy, in which state they will be much less liable to fog off under a week or two's confinement in winter than if they were kept in a growing soft state until overtaken by severe weather. Plants which are not sufficiently established must, however, be treated somewhat more kindly, for there is but little chance of carrying such over a severe winter unless they are at least well rooted, and these might with advantage be placed upon a gentle bottom heat to encourage the roots, but do not keep the atmosphere close and moist, for growth should not be encouraged after this season.

#### GREENHOUSE AND CONSERVATORY.

The principal and most desirable object in the management of greenhouse plants, is to obtain a robust and hardy growth, and at this time to accommodate them to the changing influences of the season by lessening their vital action by free ventilation, and by the gradual and judicious curtailment of water. The great business here will be to house the more tender sorts of plants in good condition, the pots to be rubbed

clean, and search to be made for worms when their casts appear on the surface of the soil. Sometimes the soil is so porous with worm-holes as to render repotting necessary, and this should be done at once. Any moss or weeds on the surface of the soil in the pots to be removed, and the soil fresh surfaced if needed. If any indications of worms appear in large tubs, or large pots, which are more unmanageable, an application or two of lime water will banish them. When housed all the air possible to be given in fine weather, even to the entire withdrawal of the lights, only reducing the ventilation when unfavourable changes in the weather take place. Each plant to be allowed sufficient space for the air to play freely around it.

#### STOVE.

This house to be tastefully arranged, and heat and humidity to be diminished by degrees in accordance with the decline of solar heat. All plants that require it to be top-dressed, and all imperfect drainage to be corrected, more especially the established plants that have been repotted for a considerable time.

#### PITS AND FRAMES.

The sooner the Hyacinths and other bulbs for forcing are potted the better. The principal cause of success is having the pots filled with roots before the top growth commences. The bulbs to be selected for weight or substance in preference to size, to be potted in half leaf mould, or decomposed cowdung, and half loam, with a sprinkling of silver sand. The quality of the soil is not of primary importance, as the flower-stalk will depend in a great measure upon the organised matter stored up in the bulb and brought to perfection under the favourable influences of heat, light, and air. The bulbs when potted should be placed in a fame or pit, and covered with 6 inches of dry sawdust in preference to coal ashes. When the pots are filled with roots and the heads begin to sprout, the potted bulbs should be taken out of the plunging material and treated with a supply of heat according to the time when they may be wanted in bloom. They grow stronger and bloom larger when gently excited by heat and supplied with air. Pot Neapolitan Violets, and let them be plunged in a frame. Lily of the Valley for forcing should now be potted.—W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

A CONTINUATION of the same glorious sunny weather has made us resort to our sewage-tank to give a lift to Peas, Lettuces, and Cauliflowers; and weeds have been again well cleared off, the hoe and the bright sun soon putting all that were to be seen out of view. If this weather continue we shall slightly shade our Celery. At present we are allowing some withered rows of Peas to remain, on account of the shade which they afford. Gave sewage water to Globe Artichokes to keep them longer in producing, as the great heat is apt to stop the formation of nice young heads. Spawnd Mushroom-beds, and earthed-up, and smoked the Mushroom-house with sulphur, and will have all washed and lime-washed before making beds in it.

We are sorry to say that the Potato disease is manifesting itself much in this neighbourhood. We fully expected it to appear among the late kinds after such a course of wet, muggy, sunless weather; but what all along has been most unaccountable to us is, that early kinds, and from magnificent crops that were taken up before the rains came, and harvested in first-rate condition, mostly intended for seed, are now going bad—that is, a considerable number of them, though until lately not a single speck appeared upon or among them. In the gardens and fields it is lamentable to see the best and largest Potatoes left behind unfit for any use. We think that cottagers are wise in demurring to give such diseased samples to the pigs; for in these days of murrains and cattle plagues people cannot be too careful, and the pig-distemper last year was a great loss to many a cottager as well as to the farmers. In some farms not a pig was left, but all died, and within a few days of each other. Many a labourer was put to great straits who depended on his pig as a help to meet the demands of rent-day.

Here we would remark that in many places in the country it would be an act of true charity and kind feeling to take the rents of cottagers much oftener than once a-year. If once a-year cannot be departed from, then shortly after harvest would be the best time, as then working people are generally best supplied with means; and when these means are plentiful there is a great temptation to spend what ought to be rigidly

set apart for rent-day. Demands that might easily be met in September or October can often be very ill met in December. We have met with some sad cases of wretchedness, and illness, and fevers produced by next to starvation in winter, because the year's rent had to be ready at that time, and to get it, or most of it, husband, wife, and children did not have nearly enough even of bread. It is of little use to talk philosophically about saving up to such people; for if such hard knocks will not prove an efficient schoolmaster for the future nothing else can be hoped to be effectual; and we have too much evidence that even these hardships will fail to convince, as again and again the plenty, and even the indulgence of luxuries and fine things in autumn, will be followed by the same scraping, and screwing, and pinching, and next to starvation in winter, to meet the rent-day about Christmas. Did such individuals alone suffer even then it would be lamentable, but it becomes more serious when the diseases and low fevers thus engendered are so apt to sweep over a hamlet or village. Much may be done by landlords ensuring payments at shorter intervals or more suitable times. With a diminished supply of Potatoes and the high price of meat, most labourers will need all possible preparations to lighten the weight of the coming winter.

Gave Celery a good watering previously to earthing it up, tying it up previously, and only earthing-up what will be wanted in three weeks or a month. General work much as in previous weeks.

#### FRUIT GARDEN.

Went over Apples and Pears, gathering the ripest before they fell, and put some kinds of Pears in a warm place to ripen them more quickly when wanted. Our Williams' Bon Chrétien has done us good service for several weeks, and we have still a few gathered quite hard and green, and some others on a tree harder and greener still, that will be prime a fortnight hence. Such Pears should never hang until quite ripe, for then they will be sure to be flat and mealy, instead of crisp and juicy. Birds have pecked our Marie Louise and others a little, but they have left us lately, and the chief annoyance proceeds from clouds of large flies. On a white wall the other night they actually blackened it, and Nectarines they will attack by hook or by crook. Peaches they meddle little with, which is so far good; and we have not noticed they have troubled late Strawberries at all. A few more swallows and other insect-eating birds would be an advantage. We see more and more that there is a law of compensation in these matters, and though it is rather annoying to find the best fruit pecked by birds, we believe that without them we should soon have no fruit at all. If the little fellows would only be moderate we would pepper them no more with shot, as the gun always detracts from the calm interest of a garden, and far less would we trap or poison, as both these systems are more cruel than shooting them at once. Who will invent a trap that for all things called vermin shall insure death instantaneous? Who with a particle of kind feeling could sleep comfortably with the thought that some living thing was writhing for hours, maimed and mutilated by the teeth and claws of a trap?

Gave a good watering to orchard-house, from which all the fruit is gathered, except some Figs in pots. Syringed the house, and shut up early to harden the wood, and also to ripen the Figs. Owing to keeping the house so open the Figs are not so forward as those out of doors, which have come in nicely, and will fill the gap between the succession crop in the Fig-pit. Gave also second orchard-house a good watering, and have sprinkled the surface frequently to keep it cool for the later Peaches. In the first house we planted some Vines, but we hardly know whether we shall be able to keep them without turning out some of the Peaches in pots beneath them. Here we have, so far, met with a disappointment. We made sure we could ripen Buckland Sweetwater in such a house, and therefore planted three Vines of it and some later sorts, which we wanted to hang, if ever we should heat the house. There has been a little bit of fruit on all these Sweetwaters, but to our annoyance they turn out to be Chasselas Musqué, a beautiful Grape, but liable to crack, and not what we wanted. Even now, though not quite amber-coloured, the flavour is delicious, and the flies know it as well as we do. What surprises us, not a berry cracked until the flies cracked them. We are inclined to leave some of the plants for another year, and as the bunches take the last swelling, encase these in very fine muslin to keep the flies, &c., from them. We find, even now, that the skin is so tough that they have considerable difficulty in penetrating it; but then they disfigure the berries left with perambulating over them with their dirty feet. The Vines

are planted rather elevated, and have no great room. If such a Grupo could be secured from cracking, wouid beat it for rich flavour. We have had very good bunches in a vinery, where the roofs were covered with glass, after the second swelling, and plenty of air given. For Strawberries, vineries, &c., see previous week's directions.

ORNAMENTAL DEPARTMENT.

The chief work has been machining part of the lawn near all the flower-beds—the machine making beautiful work, and proceeding with cuttings of Geraniums in a wholesale way. We always decline taking them very early, as it always, less or more, interferes with the beauty of the beds and their regular outline. We were forced to water some Calceolaria-beds. The Geraniums stand the heat well; but even they would be the better of being watered, as, if this weather continue, and should be followed by heavy rains, the most of the bloom will be destroyed. If the rains come after some moisture is thrown into the stems, the trusses will stand the change much better. Such kinds as Trentham Rose needed a good deal of picking. See Mr. Robson's article on plants that stand best. We want more upright and sprial plants, as Pentstemons, &c., to contrast with flat-headed flowers. Of this more presently.—R. F.

COVENT GARDEN MARKET.—SEPTEMBER 16.

The continued hot weather causes heavy supplies of both fruit and vegetables, and of Pears especially. Many of the later sorts are brought to market quite fit for use. Among such are Louise Bonne of Jersey, Duchesse d'Angoulême, and Glou Morceau. This augurs badly for the winter supply. Foreign imports are very limited, with the exception of Grapes, which are coming in in large quantities. Potato market heavy at last quotations. A great quantity turn out badly diseased.

TRADE CATALOGUES RECEIVED.

W. Hooper, St. John's Hill Nursery, Wandsworth.—List of *Hyacinths, Tulips, Crocuses, and other Flower Roots.*  
 Ferdinand Gloede, aux Sablons, near Moiret-sur-Loing (Seine et Marne), France.—List of *New and Beautiful Strawberries.*

TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Books (J. Kerr).—A new and much enlarged edition of Dr. Hogg's "Fruit Manual" is in the press, and will shortly be published.

CALIFORNIAN PUMP.—I have seen the above-named pump in full operation. It is a most ingenious and powerful machine, at a very small cost. It was shown at the Royal Agricultural Meeting at Newcastle last year, and I think the exhibitor has his place in Holborn. "West Croydon" will ascertain this by procuring from some of his farmer friends a Society's catalogue; any gentleman who visited that show will be sure to have kept his catalogue. I have a full description and drawing of it, which I cannot find at present or I should have forwarded it.—JACKSON GILLBANKS.

FRUIT EATEN BY FLIES, WASPS, &c. (*James Pin*).—The only remedy that we know is to have Nottingham net stretched over the openings of the windows and ventilators, and putting the fruit on the walls into very loose bags of the same material.

SEEDLING GERANIUMS (*E. G., An Old Subscriber*).—The petals were all shed. The trusses are bold and abundant-flowered, but not novel in colour. You had better send some specimens to the Floral Committee of the Royal Horticultural Society.

VINES IN POTS IN GROUND VINERY (*W. S. W.*).—You will have no difficulty in doing as you wish, if you sink the pots in the earth, and raise the sides as you suggest. We have so grown Vines and ripened Black Hamburgh Grapes; but we trained the rods along wires, and did not grow the Vines as bushes, which you propose to do. We shall be obliged by the report you offer us.

PLANTING SHRUBS ON A LAWN (*J. H. H.*).—The soil in which all trees and shrubs are to be planted would be better trenched 2 feet deep. The holes in your case, and in all cases of tree planting when practicable, ought to be dug out to a depth of 2 feet, and so wide that no root of the trees or shrubs may be nearer the sides than 2 feet. With your 15 inches of good loam it would be well to take out the soil to that depth, place it on one side, and then dig out the clay, removing any that is very bad and replacing it with soil of a better quality. The soil at the bottom is to be stirred to a depth of 6 inches, and the hole to be three-parts filled with the soil from the bottom and the top, mixed together in the proportion of one-third of the latter to two of the former. This will leave a part of the top soil, which, being incorporated with some fresh compost, as decayed turf, will answer perfectly for planting the shrubs. Plant them so as to be slightly elevated above the surrounding ground level to allow of the soil settling, for if planted on a level with the surrounding soil the trees will, from the subsidence of the soil, appear in a year or two as if in a hole. All the Fir and Pine tribe do much better planted on elevated mounds. Hoies 6 feet in diameter will be sufficiently wide for ordinary-sized trees.

POTTING ACUTAS (*Idem*).—The top spit of a pasture chopped with a spade could not be improved upon for potting these shrubs. If the soils free from stones larger than a walnut sifting it would be more injurious than beneficial. A little rotten dung would be good if the soil is poor, one-fourth well incorporated. Sand, on the other hand, would be desirable if the soil is heavy.

WINTERING DIANTHUS HEDDEWIGH (*E. A. P.*).—Young plants will do admirably pricked out in rows 6 inches apart and 3 inches in the rows, in a sunny sheltered situation, and in a light dry soil. On a wet soil they sometimes suffer from frost and wet, and we have been obliged to winter them in a cool greenhouse. On a dry gravelly soil we have them now as hardy as Sweet Williams; nevertheless we have a few plants in pots, and keep them in a cool greenhouse, where they are found useful for their bloom in autumn, winter, and spring, in fact they bloom successively almost throughout the year.

REMOVING LEAVES FROM VINES (*Idem*).—The leaves should not be removed from the Vines at any stage of their growth, for what is required for the formation and growth of the fruit is also necessary for its perfection, and the perfection of those shoots producing the fruit in a future season. The fruit will not swell, nor will it ripen perfectly if the leaves above and around it are removed.

WINTERING GERANIUMS AND CALCEOLARIAS (*Burt*).—Your pit will answer perfectly for the wintering of Calceolarias, if protected from severe frost by a thick covering of mats or straw, and the sides banked up with litter to prevent frost entering. The pit should not be opened whilst frost continues, but be kept closely covered even if the frost last for weeks. In your brick pit you will have room for a thousand Calceolaria cuttings, which you may put in any time after September, before the plants are frosted, placing 3 inches of river sand on the soil wherein the Cucumbers were grown, dibbling them in about 1½ inch apart, and giving a good watering to settle the sand about them. They cannot have too much air, nor too little heat, all they want being air and protection from frost. Towards the end of March they may be transplanted into trenches prepared as for Celery, kept well watered, and protected by mats from frost until finally planted out. The Geraniums would do best in the spare room, kept without water, or no more given than a little to prevent their drying up. They must be removed to a place secure from frost during its continuance, but so long as there is no frost in the room it will answer very well for the Geraniums. The pit will be too moist for them to be wintered in it safely.

CUCUMBERS FAILING (*F. A. Hill*).—We have not experienced any disease in our Cucumbers this season, except with the ridge ones, which have been for the most part a failure, and then, as in your case, they collapsed all at once without apparent cause. We think your soil was much too rich in the first instance, loam from rotted turves being of itself sufficiently rich without further admixture of manure. One-half of this is alone sufficient to induce disease. As for the bog soil we do not see its utility. There is no better soil for Cucumbers than the top spit of a good pasture laid up in alternate layers with fresh dung for twelve months, and turned over once in summer, and twice in winter during dry frosty weather, adding a bushel of soot to every cartload at the first turning. The best preventive of the disease we have found to be fresh and well-aired soil. The syringing with Gishurst would be sufficient to cause the destruction of the leaves, and fire heat by night, instead of mitigating the evil, would only hasten the death of the plants. The only effectual remedy that we have found available is to use only moderately rich, fresh, sweet, well-aired soil, and to keep the plants frequently changed, instead of depending on one set of plants—that is, to keep on raising plants, sowing every six weeks or so in order to have plants ready to take the place of the diseased, after removing every particle of the old soil. It is an easy matter to throw the plants away should they remain healthy and fruitful throughout the season.

**WATERING VARIEGATED GERANIUM CUTTINGS** (*A Lady Gardener*).—So long as the soil remains moist it is not necessary to water the cuttings inserted in the open ground, but during very dry weather they may be watered so as to keep the soil moist, but by no means wet. Those in pots should be watered as often as necessary to keep the soil moist.

**RAISING DACTYLIS GLOMERATA ELEGANTISSIMA—WINTERING IRESINE HERBSTII** (*Suisse*).—A stock of this very elegant and whitest of dwarf variegated Grasses, is readily obtained by dividing the roots in spring. Last year we had only six plants, and they were divided into 250 plants in March, every stem being slipped off with a little root. They were then pricked of 3 inches apart every way in good loam, with a little leaf mould added and worked in, covered with a frame, and kept moist and shaded for a few days. They were then freely exposed to air and duly supplied with water. They make nice plants by May, when they are planted out with the other bedding plants. With us on dry gravelly soil this *Dactylis* is hardy, but in wet heavy soil it is liable to suffer in winter quite as much from the wet as from the frost. In such soils it is best to take up the plants in autumn, and winter them in a frame or cool greenhouse, dividing the roots in March, potting, and growing on in a frame. We have now tried it two summers, and find it makes an edging-line, or band early, and keeps good until late, elegant and graceful, dwarf and dense, and of easy culture. *Iresine Herbstii* is easily kept over the winter in a dry airy part of the greenhouse with sufficient water to keep the soil just moist. Plants struck in summer and potted off so as to become established before winter are the best, and give a number of cuttings in spring. It requires free drainage and a compost of two-thirds loam and one of leaf mould well reduced, and then it grows as freely as *Verbenas*, and is as easily kept over the winter.

**DRYING AND PREPARING BRITISH-GROWN TOBACCO FOR FUMIGATION** (*Live and Learn*).—When the leaves have attained their full size and become of a yellow hue they are taken from the stalk, tied together in small bunches by the footstalks, hung in a dry airy room to dry, and left there until dry and crisp. The first damp weather after this the leaves will become soft, and they should be watched to ascertain when this occurs; then pack them in a box evenly with the butts or stalk-ends of the leaves all one way. They are then to be pressed moderately, and in a few days a slight fermentation will take place, when the bunches should be taken out and shaken to let the heat escape. When this has been done repack lightly. The leaves will not reheat, but it is best to let them remain for a few days laid lightly in the box; and when all fermentation is over, pack tightly in a barrel, and keep in a dry place ready for use. As the leaves of British-grown Tobacco are not all mature at one time, they must be successively gathered as they ripen. The circumstance of the leaves not being all mature at one time, has led to the adoption of another mode—viz., when the leaves have attained their full size pull the plants up, tie them two or three together, and hang them, root upwards, in a dry warm room, if with a temperature of 90° all the better. When dry sprinkle them with water, and then hang up again to dry. Allow them to become dry again, and then wet them again; dry afterwards, and let this wetting and drying be done thrice. When the leaves become dry, but not so as to break, strip them from the stalks and lay them in boxes evenly, and quite close and tight, pressing for that purpose; then keep in a dry room. This latter process gives the leaves a colour which they will not possess if treated according to the first plan. Leaves prepared in this way will be green, while those treated according to the first mode will be of a pale brown and fit for smoking. Leaves prepared in both ways are alike useful for fumigating for green fly, thrips, &c., and equally as effective as foreign Tobacco. Previous to use, the Tobacco should be chopped like hay and straw, or made into rough shag.

**ORCHARD-HOUSE APRICOTS AND PLUMS CRACKING** (*Nil Desperandum*).—The cracking most likely is owing to the plants having been rather dry, and then being freely watered; and the hot sun at the time, followed by dull weather, and then bright sun again, encouraging the skins of the fruit to swell faster than the energies of the root could supply them with swelling material. In such sudden changes a little shading in the first bright days would have averted the cracking. So our experience would say. But then we do not know what to make of Peaches and Nectarines in the same house swelling perfectly without cracking, unless they were better established in the pots. For ourselves, we noticed some three or four Peaches thus cracked, but no Plums. What say other growers as to the cause?

**WILLOW NEAR A POND** (*H. W.*).—We should say that the Weeping Willow will not be injured by your doing so unless the roots are largely fed by the pond. If many roots are matted round and beneath the pond, it might be advisable to place two or three loads of rotten dung over the bottom of the pond before placing the soil in: that would prevent all injury.

**VINE BORDER** (*E. S.*).—We see no objection to your manuring the border as proposed, provided you do not make the soil too rich. Earth is one of the best deodorisers, therefore unless there be a great excess of manural matter, we do not apprehend any bad smell.

**TRANSPLANTING EVERGREENS** (*Inquirer*).—No such manual has been, nor is likely to be, published. You cannot do better than refer to the instructions from time to time given in these pages.

**INSECTS ON PEAR LEAVES** (*J. M.*).—The insect is the Slimy Grub, the larva of *Scandrius Ethiops* of Fabricius, the eggs of which are deposited in June and July. The insect is of frequent occurrence from July to September, and the remedy which you adopted—namely, dusting with lime, the only effectual one.

**GROWING GRAPES IN AN ORCHARD-HOUSE** (*A. Q.*).—There will be no difficulty in the matter, provided the trees you have in fruit are so low as not to shade the back wall, against which you propose having your Grapes. We would also advise your having the Vines together, but the house would look better if you planted them separately, took them up the back wall, and then brought them over an arch down the roof. The Grapes hanging from the arch would have a fine effect. The only drawback to the Grapes would be the extra air when the Peaches were ripening. When the Peaches were gathered you could give less air, which would ripen the Grapes and harden the wood of the Peaches, &c. For such a cool-house nothing will answer better than the Black Hamburg and the Royal Muscadine (white). We could give you a list of others, as *Esperione* and *Buckland Sweetwater*, but, on the whole, we think the above would be the best.

**VARIOUS** (*Mina*).—Your seedling Pansies will probably bloom early in summer if all go well. If an admirer of *Fuchsias* with golden-blotched leaves, you may add *Aucubafolia* and *Cloth of Gold*, to those which you already possess. Seedling Carnations if not double will not become so (*Statie*).—We do not know what is meant by "cardinals." Removing the seedling Peach tree, if done so as not to injure roots much, will tend to hasten rather than retard fruiting. (*E. M.*)—As the object with seedling *Pelargoniums* is to flower them quickly, instead of growing fine specimens, it is unnecessary to top them. After flowering give the same treatment as to plants from cuttings. *Maréchal Niel Rose* is not likely to be cheap this season, as the demand for it will be great. *Auriculas* cannot be propagated so rapidly as other plants, hence cannot be sold so cheaply.

**PLANTING VINES IN A SHADED GREENHOUSE** (*A Young Beginner*).—The shady position of your house is a very bad one for Vines. They require all the sunlight possible. Besides the *Black Hamburg*, the best Grapes for such a house would be the *Esperione* (black), and for whites, *Royal Muscadine* and *Buckland Sweetwater*. From 2 to 2½ feet will be deep enough for your border. We would take no more soil away than would give room for your rubble, concrete, &c., and the proper depth above. Slaten will be an improvement above the open rubble and the sods. Your soil will be all the better if taken only 2 to 3 inches in depth. We would use only a very little rotten manure, chiefly where you plant the Vines, or leaf mould, but in such a border you may mix a quarter of a ton of boiled broken bones, a few bushels of charcoal, and a load or two of lime rubbish, the light character of the soil renders less of that necessary. With all your other proposed modes of action we agree. The border if 2 feet above the general level at back, may slope down to 6 or 9 inches above the general level in front. The only thing we are sorry for is, that you should go to all this trouble for a house that receives no direct sun, except for a short time at midday. We lately saw a large viney hemmed in with trees on all sides, except a little bit in front, and even that was greatly shut out by a Weeping Willow on the lawn. Things were so unsatisfactory that we advised the house being turned into a fernery and Moss-house, and a new viney to be built where sun could reach the Vines.

**GRAFTING PEARS ON THE QUINCE STOCK** (*W. H. S.*).—It is not necessary to cover the part worked with soil. We have tried them both ways, and prefer those with the union of stock and scion a few inches above the ground level. Our reporter did not recognise it, and we have not seen the specimen.

**STRIKING GOLDEN CHAIN GERANIUM** (*Idem*).—After several years' experience we have given up the propagation of this useful kind in autumn, from our finding that the cuttings strike in half the time, and without failure, in spring. We take up the old plants early in October, and pot them without any reduction of the head or shortening of the shoots, and keep them in a light airy situation, dry at the root, yet moist enough to keep the leaves fresh, and in a temperature from fire heat of 40° or 45°. About the middle of February they are placed in a viney with a temperature of from 50° to 55° by night, and by the middle of March each plant furnishes us with from six to twelve cuttings according to their size. We then fill a sufficient number of three-inch pots with turfy light loam two-thirds, and one-third leaf mould well incorporated, first placing a crock over the hole in the pot, and then half an inch of the rougher parts of the compost. In the centre of each pot we make a hole double the diameter of the cutting, and of a depth corresponding to the length of the cutting, drop a little silver sand into the hole, place the cutting with its base thereon, and fill in round the cutting with silver sand. A gentle watering is then given, and the pots are placed in a frame with a bottom heat of from 75° to 80°, and a top heat of from 65° to 75°. In three weeks we have well-rooted plants, by which time the old plants will have pushed afresh, both they and the cuttings being placed in a cool-house and gradually hardened-off by May. In this we have them equally strong with those struck in August, without the trouble and room lost consequent on wintering them, and they grow as freely, and so do all the variegated class. If our stock were limited and we desired to largely increase it, we would take cuttings in August, and these would afford cuttings in spring, otherwise we would not care about striking any variegated *Geraniums* in autumn, as the younger the plant the more freely it grows.

**COMPOST FOR PRIMULAS, CINERARIAS, AND CALCEOLARIAS** (*Lex*).—Loam from rotted turves a year old two-thirds, leaf mould three parts reduced one-third, with one-sixth of silver sand added for the first, and the same quantity of that or river sand for the last two. Sandy turfy peat is to be preferred to the leaf mould for Primulas.

**PLANTING HYACINTHS** (*Idem*).—The best time to plant Hyacinths in the open ground is in October and early in November. Plant in pots from this time to November, but the earlier the better, and October is the best time to place bulbs in water. All Hyacinths are of the most easy culture, and though we add the names of some really good flowers, to be had at moderate prices, we cannot say that they are more easily cultivated than those at a higher price. Single White: *Grand Vaingneur*, *Elfrida*, and *Rousseau*. Single Red: *Diebitz Sabalkansky*, *Madame Hodgson*, *Norma*, and *Amy*. Single Blue: *Charles Dickens*, *Grand Lilas*, *Nimrod*, and *Prince Albert*. Double White, Blue, or Cream: *Prince of Waterloo*, *La Tour d'Auvergne*, *Anna Maria*, and *La Deesse*. Double Red: *Czar Nicholas*, *Waterloo*, *Princess Royal*, and *Grootvoet*. Double Blue: *Lord Wellington*, *Comte de St. Priest*, *A-la-mode*, and *Blocksberg*.

**FORCING KIDNEY BEANS** (*A. R.*).—We use 11-inch pots, and grow nine Beans in a pot, but sometimes also nine-inch pots, and six Beans in each. Of kinds, after trying all we could procure, *Canterbury*, *Sion House*, and *Fulmer's Early* are the best three, and *Newington Wonder* for using with the pods whole or cut. A compost of light turfy loam suits them well, that from turves a year old is the best, half filling the pots, and then earthing-up when they are sufficiently grown, which is when they show the second leaves or when the first are level with the rim of the pots. We know of no work devoted to forcing, but you will find much on the subject in our pages of the past, and all that is needful is treated in "Thompson's Gardener's Assistant." As to meet special cases is in part the object of our labour, we shall be glad to assist you. Strawberries will do fairly in the same house with an airy and light situation near the glass, but better in a house with a lower temperature, at least until the fruit has set and begins to swell. *Kidney Beans* should not have a less temperature than from 55° to 60° at night, 50° is enough for Strawberries until the fruit is set.

**LILIUMS DONE BLOOMING** (*A Constant Reader*).—The best time to pot Liliams is immediately after the flowerstalks become yellow, and instead of taking the bulbs entirely out of the soil turn the plants out with the ball entire. Remove the surface soil down to the crown of the roots, and cut the stalk or stems off at that point. Next remove the drainage, and mix soil that comes away easily. Clean the pot inside, and replace the drainage with an inch of the rougher parts of the compost over it, then a little compost, then the roots, working the soil carefully around them, and cover the crown with an inch deep. If the work be done well the pot will be about three-parts full; the remaining space should be filled with compost when the shoots are sufficiently high for the purpose. Give a gentle watering after potting. We use a compost of two-thirds turfy loam, a year old, from rotted turves cut 3 inches thick, and one-third leaf-mould or turfy sandy peat, with a free admixture of sand.

**NAMES OF FRUIT** (*G. K., Serenoaks*).—Your Apple is not Golden Pippin but Yellow Ingestrie. The cooking Apple is Springrove Godlin. The Plum is Danmore. (*H. H.*). 2, Bleuheim Pippin; 3, Borovitski; 5, Carlisle Codlin; 6, Kerry Pippin. (*Abandon*).—The Peach is Barrington.

(*C. R.*).—Apple, King of the Pippins; Pear, Doyenné du Comice; Nectarine, Ebruge; Plums quite decayed. (*T. Bugyard & Son*).—1, Bergamotte-Esperen; 4, Bayonne de Mello. The rest are not yet ripe enough. (*G. H.*).—1, Marie Louise; 2, Vicar of Winkfield; 3, Aromatic Russet; 5, a Siberian Crab; 6, Boston Russet; 8, Glou Moreau; 9, Golden Noble; 10, Golden Russet. (*T. C.*).—Marie Louise Pear.

**NAME OF FUNGUS** (*P. S.*).—*Phallus impudicus*, commonly called the Stinkhorn or Stinking Morel. It is not uncommon.

**NAMES OF PLANTS** (*J. L.*).—We cannot tell the name from your description. Send the bloom. (*D. H.*).—We are not surprised at your want of confidence in our determination that your plant is a Violet, as you evidently are unaware that the flowers in most of our Violets are dimorphic—that is, assume different forms or characters. The ordinary Violet flowers with large coloured petals appear in the spring, and later in the season yields smaller flowers destitute of petals, and these produce the finest and plumpest seed-vessels. We can assure you that your plant is no other than *Viola canina*, the stems of which always lengthen out and bear small petalless-flowers late in the summer.

**METEOROLOGICAL OBSERVATIONS** in the Suburbs of London for the Week ending September 16th.

**POULTRY, BEE, and HOUSEHOLD CHRONICLE.**

**THE POULTRY CLUB and THE STANDARD OF EXCELLENCE.**

THE Poultry Club is at last a fact accomplished. It has now *bona fide* members, officers, rules, and a standard of excellence. Phenix-like, it sprang from the ashes of its predecessor. The old Club was a combination of men whose sole object, declared, was the exclusion of dealers from judging, whilst they themselves dealt and judged. The impression abroad was that the desire of the Club was to "crush Bailey of Mount Street," which, if true of him or of any other dealer, would have prevented all good men from joining in the membership. Want of courtesy marked almost all the answers to applications from strangers for information, rules were written about and talked about, which were always nearly ready if they had really any existence, and a standard of excellence was to be had upon application, which no one was fortunate enough to obtain. An angry correspondence in print took place, which ended in consigning the Club to the disgust of the public, and in marking some of the correspondents as wanting proficiency in composition and in courtesy. Finally, at the last Birmingham Show, the Club passed a harmless vote of censure on the Judges, and reached the climax of absurdity.

When things are at the worst they must end or mend. The Poultry Club did not end. We have now before us a printed goodly list of members containing some of the most noted amateurs and dealers in England. We have also a code of clear and intelligible rules. The promised "standard of excellence" has appeared, circulated gratuitously to members of the Club, and at the price of 5s. to non-members. Compiled by the practical ability of Messrs. Teebay, Dixon, and Tegetmeier, it has a guarantee for correctness; yet, as there ever will be divided opinions, I would invite discussion on its merits. There are plenty of your readers quite capable of doing this in the classes which have occupied their attention. I will confine myself to an extract which will give an idea of the simplicity and conciseness of arrangement of a book which should be in the hands of every one who wishes not only to exhibit but to keep perfect specimens of poultry:—

"BIRCHIN YELLOW GAME.

"COLOUR OF COCK.

- "Head.—Dark straw colour.
- "Face and Wattles.—Either red or purple.
- "Neck.—Hackle, deep straw colour, striped with reddish brown.
- "Breast.—Reddish brown; shaft and narrow margin of the feathers cream colour.
- "Back and Shoulder-coverts.—Rich coppery-straw, marked with reddish brown.

- "Saddle.—Deep straw, striped with reddish brown.
  - "Wing-butts.—Dull black.
  - "Wing-bow.—Rich, dark, coppery straw, slightly marked with reddish brown.
  - "Wing-coverts.—Cream colour, mottled with reddish brown, and tipped with chocolate.
  - "Wing-flight.—Reddish brown.
  - "Tail.—Black.
  - "Sickles.—Bronzy black.
  - "Tail-coverts.—Bronzy black, the lesser with a narrow margin of cream colour.
  - "Legs.—Bronzy black, olive, willow, or yellow."
- And so on with the colour of the hen.

"POINTS IN GAME.

Shape of head and neck .....	2
Body and wings .....	2
Tail .....	2
Thighs, legs, and toes .....	2
Colour of plumage .....	3
Symmetry, handling .....	2
Condition and hardness of plumage .....	2
	15

"DISQUALIFICATIONS.

"Colour of legs or plumage in the pen; crooked backs or breasts; adult cocks not dubbed."

The want of some such knowledge as this amongst exhibitors and judges, amongst purchasers and dealers, must cause dissatisfaction and distrust. The spread of such knowledge will do away with that carelessness in judging and in exhibiting complained of recently in your Journal, where prizes are plentiful to encourage exhibitors rather than to mark the merit of their birds.

In racing there is the Jockey Club; in cricket, the Marylebone; in all things some combination and association to promote union and to frame laws. So with the Poultry Club, long may it flourish with such motives and such management as it has recently shown, and speedy be its downfall when it shall become a clique combining against one or against any set of men for its own purposes, or for any purpose save the promotion of honesty and the protection of the public. The public have the matter in their own hands. The larger the number of members the less likelihood of intrigue. The more its doings are made known the more they are likely to be in that spirit of fairness which can only be obtained by general combination and inquiry.—GEORGE MANNING, *Member of the Poultry Club.*

**LEIGH (LANCASHIRE) POULTRY EXHIBITION.**

It gives us great pleasure to record the entire success of the Poultry Show held this year at Leigh, as on the last two annual occasions, the meetings held under the guidance of this Committee were accompanied by weather so wet and unpropitious, that such repeated dis-

comfitures would have entirely damped the ardour of most societies of a like nature; not so, however, at Leigh, bad weather seemed only to redouble the efforts of the managers to secure success, and we rejoice to state that the meeting of last week has fully gratified the most ardent well-wisher among them. Former meetings have been held under a tent, provided expressly for the accommodation of both visitors and poultry, and of course resulted in thronging, more or less severe; but on the present occasion the tent was altogether dispensed with, and an awning of woodwork was thrown over both the public and poultry, giving perfect security from wet. The pens too were spacious and convenient, and the poultry as assiduously attended to as the most anxious owner could desire. The change of ground also now made for holding this Show is obviously a step in the right direction, showing a vast improvement, which will be continued at the future meetings of this Society. Everything augurs well for coming shows, and doubtless the Leigh Poultry Exhibitions will rank highly among those of coming years in Lancashire. In short, the Committee have proved themselves well worthy of public support, and we are glad they have so well succeeded. The Show was open to all England, the competition, however, except in two or three instances, being restricted to birds of the present year.

The classes of young *Game* fowls were really good, and the competition exceeded expectation; still Mr. John Hallsall, of Ince, near Wigan, managed to monopolise quite a heavy sweep of premiums. This gentleman's birds were shown in perfect condition, and of hatches so early as to ensure success among specimens so much younger. The show of *Spanish* fowls was excellent, and Mr. Cook, of Chowbent, exhibited birds very hard to beat at any meeting. With the exception of the prize birds, the *Cochins* were not praiseworthy, though *Brahmans* were both numerous and excellent. We cannot speak so highly of the *Dorking* classes as we anticipated, but as the specimens exhibited were very young no doubt they will yet improve considerably. In *Hamburghs* the Leigh Show was particularly good, and the *Poland* class was equal to any seen for years past. The *Single Game* cocks, the cockerels, and again, the *Single Game* pullet classes were not so fine a feature of the Exhibition as they would have been a month hence, after the birds had done moulting, still some very excellent specimens were shown. The *Ducks*, *Geese*, and *Turkeys* were exceedingly good and well shown, nor were these really useful varieties crushed into a corner, as is too frequently the case, as though worthless, but enjoyed the same advantages as every other variety of poultry shown.

The weather being brilliant and settled, the Show was thronged with visitors from 10 A.M. until nightfall, and consequently proved a decided success.

**GAME CHICKENS (Black-breasted Red).**—First, and Second, J. Hallsall, Ince, near Wigan. Highly Commended, W. Gillibrand, Mill Erow, Boothstown, near Manchester.

**GAME CHICKENS (Brown Red).**—First, R. Cuerden, Stoneclough, near Manchester. Second, J. Wood, Moat House, Haigh. Highly Commended, P. West, Abram, near Wigan.

**DUCKWING (Game).**—First and Second, J. Hallsall, Ince, near Wigan. Highly Commended, J. Eaves, Knowsley, Lancashire; R. Cuerden, Stoneclough.

**SPANISH CHICKENS (White-faced).**—First and Second, N. Cooke, Rose Hill, Chowbent.

**COCHIN CHICKENS (Buff).**—First, C. Sedgwick, Riddlesden Hall, Keighley. Second, A. Bamford, Tonge Lane, near Middleton.

**COCHIN CHICKENS (Any other colour).**—First, R. Wood, Brinsall Hall, Chorley. Second, Withheld.

**BRAHMA POOTRA CHICKENS.**—First, H. Lacey, Lacey House, near Hebden Bridge. Second, E. Leech, Greave House, Rochdale.

**DORKING CHICKENS.**—First, E. Shaw, Plas Wilmot, Oswestry. Second, S. Farrington, Chatmoss, Astley.

**HAMBURGH CHICKENS (Golden-pencilled).**—First and Second, T. Rigley, jun., Tonge, Middleton, near Manchester. Highly Commended, J. Morris, Boat Yard, Dick Mather's Bridge, Leigh.

**HAMBURGH CHICKENS (Silver-pencilled).**—First, J. Platt, Dean, near Bolton. Second, A. Nuttall, Mill End, Newchurch, near Manchester.

**HAMBURGH CHICKENS (Golden-spangled).**—Prize, — Parr, Patricroft.

**HAMBURGH CHICKENS (Silver-spangled).**—First, J. Fielding, Newchurch, near Manchester. Second, E. Collings, Middleton. Highly Commended, J. Turner, Astley near Manchester.

**POLAND CHICKENS (Any variety).**—First, S. Farrington, Chatmoss, Astley. Second, P. Unsworth, Louton, near Warrington. Highly Commended, S. Farrington; T. Woodward, Leigh. Commended, P. Unsworth.

**BANTAM CHICKENS (Game).**—First, R. Tate, Leeds. Second, C. W. Brierley, Middleton. Highly Commended, P. Smith, Westleigh. Commended, R. Cuerden, Stoneclough, near Manchester.

**BANTAM CHICKENS (Any other variety).**—First, Messrs. S. & R. Ashton, Mottram, Cheshire. Second, Withheld.

**ANY OTHER DISTINCT BREED.**—First, C. Sedgwick, Riddlesden, Keighley. Second, H. Ormerod, Bridge foot, Chowbent.

**GAME COCK (Any variety).**—First, J. Wood, Moat House, Haigh. Second, W. Painter, Abram, near Wigan.

**GAME COCKEREL.**—First, J. Eaves, Knowsley, Lancashire. Second, P. West, Abram, near Wigan.

**GAME BANTAM COCK (Any variety).**—First, R. Charlesworth, Brook Bar, Manchester. Second, R. Cuerden.

**GAME PULLET (Any variety).**—First, A. Nuttall, Mill End, Newchurch, near Manchester. Second, J. Wood, Haigh. Highly Commended, J. Eaves, Knowsley, Lancashire; W. Painter, Abram, near Wigan; H. Coupe, Hares and Hounds, Pendleton. Commended, E. Shaw, Plas Wilmot, Oswestry.

**SELLING CLASS.**—First, N. Cooke, Rose Hill, Chowbent (Black Spanish). Second, P. Unsworth, Louton, near Warrington (Polands). Highly Commended, R. Tate; S. Farrington; T. Rigley, jun.

**DUCKLINGS (Aylesbury).**—First, E. Leech. Second, E. Shaw. Commended, — Parr, Patricroft.

**DUCKLINGS (Rouen).**—First, P. Dickinson, Lindley. Second, T. Wakefield, Golborne, near Warrington. Highly Commended, J. Wood, Haigh; C. P. Ackers, Bickershaw, near Wigan; E. Leech.

**ANY OTHER VARIETY.**—First, T. Burns, Abram, near Wigan. Second, R. Tate. Commended, J. R. Jessop.

**GOSLINGS.**—First, J. Southern, Calcheth, near Warrington. Second, R. Tate, Leeds.

**TURKEYS.**—First, Messrs. R. & W. Barton, Westleigh. Second, P. Cleworth, Leigh.

The Judge was Edward Hewett, Esq., of Eden Cottage, Sparkbrook, near Birmingham.

## WAKEFIELD POULTRY SHOW.

SEPTEMBER 9TH.

THE annual Show of poultry of the West Riding Horticultural and Agricultural Society was held at Wakefield on Saturday the 9th inst. The entries were not large, the prizes being insufficient to tempt exhibitors at a distance; but as the Show proved successful we understand that it is intended to increase the amount offered for competition next year.

The classes were entirely for chickens. *Game* were divided into four lots, but did not embrace anything requiring particular notice. The prize Buff *Cochins* were good, and some fine *Brahmans* competed in the class allotted to them; but *Dorkings* were much the best collection. Mr. S. Pickard taking both prizes with particularly good pens. *Hamburghs*, with the exception of the first-prize Golden-pencilled, were a wretched lot. In *Game Bantams* good Black Reds won; and in *Bantams*, any other variety, capital Blacks took both prizes.

**GAME (Black-breasted Red).**—First, T. Vickerman, Chickney, Dewsbury. Second, R. Tate, Leeds. Highly Commended, J. Hodgson, Bowling Old Lane, Bradford; A. Hodgson, Ilkworth, near Halifax.

**GAME (Brown-breasted Red).**—First, J. Hodgson, Second, Messrs. Beauland & Suddick, Bradford. Highly Commended, H. C. Mason, Drighlington, Leeds.

**GAME (Duckwing).**—First, R. Tate. Second, G. Hartley, Gomersal, Leeds. Commended, J. Firth, Halifax; J. Fell, Adwalton, Leeds.

**GAME (Any other variety).**—First, G. Hartley, Second, W. Charter, Driffield. Highly Commended, J. D. Newsome, Batley, Leeds; J. Vickerman.

**SPANISH.**—First and Second, T. Greenwood, Dewsbury.

**COCHIN-CHINA (Cinnamon or Buff).**—First, C. Sidgwick, Riddlesden, Keighley. Second, C. B. Murgatroyd, Rawden, Leeds.

**COCHIN-CHINA (Any other variety).**—First, R. J. Wood, Brinsall Hall, Chorley. Second, W. Dawson, Hopton, Mirfield. Commended, J. Harrison, Dale House, Wakefield.

**BRAHMA POOTRA.**—First and Second, H. Lacey, Lacey House, Hebden Bridge. Commended, F. Powell, Knaresborough.

**DORKING.**—First and Second, S. Pickard, Wakefield. Highly Commended, Hon. H. W. Fitzwilliam, Wentworth Woodhouse, Rotherham. Commended, J. Hirst, Boyne Hill, Wakefield; H. Hemsworth, Lupset Hall, Wakefield; F. Lees, Guisley, Leeds.

**HAMBURGH (Golden-spangled).**—First, E. Hutton, Pudsey, Leeds. Second, H. Hemsworth.

**HAMBURGH (Silver-spangled).**—First, C. Cowburn, Calls, Leeds. Second, E. Hutton.

**HAMBURGH (Golden-pencilled).**—First, S. Smith, Northorram, Halifax. Second, H. Crossley, Bloomfield, Halifax. Highly Commended, E. Hutton; S. Smith.

**HAMBURGH (Silver-pencilled).**—First, D. Ilkworth, Burley, Otley. Second, E. Hutton.

**BANTAMS (Game).**—First, J. D. Newsome, Batley, Leeds. Second, R. Tate. Highly Commended, Hon. T. Fitzwilliam, Wentworth Woodhouse, Rotherham; Hon. W. C. Fitzwilliam; J. Rhodes, Wakefield.

**BANTAMS (Any other variety).**—First and Second, Miss K. Charlton, Manningham, Bradford.

**DUCKS (Aylesbury).**—First, E. Leech, Greaves House, Rochdale. Second, Hon. H. W. Fitzwilliam, Rotherham.

**DUCKS (Rouen).**—First, E. Leech. Second, J. Hirst. Highly Commended, C. Sedgwick, Riddlesden Hall, Keighley. Commended, J. D. Newsome.

**GESE.**—Prize, O. A. Young, Driffield.

**TURKEYS.**—First, E. Leech. Second, C. Sedgwick.

**EXTRA STOCK.**—Highly Commended, H. Hemsworth (Dorking); F. Powell (Brahma Pootra); W. Shaw, George Hotel; W. Crossland, Thornes. Commended, W. Crossland.

The Judges were James Dixon, Esq., Bradford, and Wm. Smith, Esq., Halifax.

## THE MARKET DRAYTON AGRICULTURAL SOCIETY'S POULTRY SHOW.

(From a Correspondent.)

THE fifth annual show of the above Society was held at Market Drayton on the 14th instant, and proved a success. The poultry were exhibited in a large tent, on a piece of ground adjoining the Tower, and well fitted up with excellent pens from the Nantwich Poultry Pen Association.

The *Game* class would have done credit to any of the large poultry shows. The *Dorking chickens* were also very good, and a beautiful pen of Black Red *Game Bantams* were shown by Mr. Haslem. The *Ducks* were a good and extensive class. Mr. R. Corbett, of Adderley

Hall, exhibited two beautiful pens of *Turkeys*. The following are the awards:—

GAME (Single Cock).—First and Second, Mr. Burgess. *Game Cock and two Hens*.—First and Second, Mr. Burgess. *Dorking Cock and two Hens*.—First and Second, Mr. Burgess. *Any variety*.—First, Mr. Haslem (Bantam). Second, Mr. Kemp.

DUCKS.—First, Mr. Kemp. Second, Mr. Burgess. *Geese*.—First, Mr. Mats. Second, Mr. Burgess. *Turkeys*.—Mr. R. Corbett.

Mr. Heath, of Nantwich, was the Judge.

## CROOK AGRICULTURAL SOCIETY'S POULTRY SHOW.

(From a Correspondent.)

The above-named Society held their third annual Exhibition on the 6th inst. The entries were not numerous, but this was owing to the Society not providing pens, which prevented many parties from entering that otherwise would have done so, and many who had entered failed to send their birds, no doubt for this very reason. It is to be hoped that the Committee will provide pens another year, for they were not blind to their mistake, and were willing to do anything in their power to oblige exhibitors. Mr. J. G. Crofton is also one of the most agreeable of Secretaries. The weather was everything that could be desired, consequently a numerous company from the surrounding neighbourhood visited the Show.

The various classes of poultry contained some very good pens of birds, particularly the *Dorkings* and *Hamburghs*; but the strongest class in the Show was the *Bantam* class (all the varieties of Bantams competing together), but Mr. W. Lawrenson surpassed all other competitors with a pen of Duckwing chickens. There was a good entry for both *Geese* and *Ducks*, but many of the latter had faulty bills. Some of the collections of *Pigeons* were very nice indeed. The following is a list of the awards:—

GAME (Black or Brown Red).—First, J. Sutton, Durham. Second, W. Lawrenson, Eaglescliffe.

GAME (Duckwing).—First, withheld. Second, J. Armary, Crook.

GAME (Any colour).—Prize, J. Armary, Crook.

SPANISH.—First, T. Craggs, Crook. Second, J. Fryer, Smelt House.

DORKINGS.—First, J. Bell, Thornton-le-Moors, Northallerton. Second, Mrs. Baxter, Brancepeth.

COCHIN-CHINA.—First, R. Thompson. Second, G. A. Proctor, Market Place, Durham.

HAMBURGHS (Golden-spangled).—First, T. Horn, Tow Law. Second, J. Potts, Sunnyside.

HAMBURGHS (Golden-pencilled).—Prize, W. Lawrenson.

HAMBURGHS (Silver-pencilled).—First and Second, W. Lawrenson, Eaglescliffe.

## RAILWAY DELAYS IN DELIVERING DEAD POULTRY.

WILL you inform me if a railway company is bound to deliver dead fowls at any particular time? I sent seventy-two last week, and they were not delivered in Leadenhall till after the market was over. The salesman said the loss was quite 3*d.* each. Can I make the company pay the loss?—A SUSSEX HIGGLER.

[If the delay in delivering a parcel is unreasonably long, the carrier is liable for any consequent loss. We have not sufficient particulars to give a more definite opinion. When perishable goods are sent, the railway company, or any other carrier, should be informed of the nature of the goods, and be requested to deliver the parcel immediately.—Eds.]

## NEW BOOK.

*Eggs and Poultry as a Source of Wealth.* London: W. OLIVER, 3, Amen Corner.

We opened this book hoping to find it assisting in a movement which is most desirable—promoting the production of poultry and eggs—but the first paragraph we read was this:—

“To commence operations on a small scale, it will be sufficient to buy five hens, and make them set!!” The fifteen or eighteen eggs that each hen may hatch will yield at least from ten to a dozen of chickens. At the end of a month the

chickens must be taken from the hen and placed separately in cages. In the course of three months each of these chickens, if properly fed, will have become a splendid poult, such as sells for at least 2*s.* 6*d.* to 3*s.* !!!”

Our readers will not require to be told that the whole of that statement betrays total ignorance of poultry-keeping. However, we read on, and the conclusion is that we warn our readers that it is one of the most worthless books with a misleading title that we ever had placed before us.

## TAN-HIVES—SUCCESSFUL DRIVING.

I AM now in a position to communicate the result of my experience, during the summer, of the new material for bee-hives—tan; and I am much pleased in being enabled to give a satisfactory report. The inquiry of your correspondent Mr. F. H. West, in a late Number of the Journal, as to whether the hives stand well, and also whether I still think favourably of the material of which they are constructed, induces me to communicate a few more details respecting them. I have now five of these tan hives, all in a prosperous condition; the bees numerous, the hives weighty as to contents, and the material free from the slightest deterioration. The bees appear to have enjoyed their cool summer quarters, there having been less oppression from heat and less clustering out than in any of my boxes or straw hives. For winter I feel assured that hives of this material will far exceed any others in dryness and uniformity of temperature. Of course, owing to their weight, they cannot readily be moved from place to place; this may be somewhat of a drawback, but they can, however, be worked with bars, and are also well adapted for supers. Three of these hives contain swarms of this summer: one, a natural swarm, the others artificial, each of these having worked a considerable quantity of comb and stored honey in supers. I very much doubt whether tan-hives will come into general use, even in the garden of the scientific apiarian, but as an experiment, and a home manufacture, their construction and subsequent management have afforded me much pleasure. I can obtain the material close at hand, and at a cheap rate. The drying of the hives is, however, tedious, requiring some weeks' exposure to the air to effect it perfectly.

My driving operations have been successful this autumn, not one out of the thirty-five hives upon which I have operated having proved a failure. From these “beat-out” bees I have established nine fine stocks, the empty comb and brood from the hives having materially assisted in building them up, and liberal feeding effecting the rest. Most of these stocks contain three united lots, the remainder I have joined to some of my hives, there having been no disagreement in any instance.

A description of my mode of procedure may, perhaps, be acceptable, as it varies in some of its details from that pursued by others, who, nevertheless, may be equally successful operators. It is quite immaterial what portion of the day you select for the manipulations; and I have found, in every instance, that the driven bees, with their queen intact, have settled quietly into their hive, ready for their removal in the early part of the evening.

Having cautioned inquisitive people to get out of my way, foreboding direful consequences should the irritated bees escape, I remove the hive to some little distance, placing another slate on the stand, upon which I spread the cloth in which the driven bees are finally secured, and upon this an empty hive with the straw cap loosely thrown over it. Then, returning to the hive to be operated upon, I arrange the cloth and string for wrapping round, and look out my three sharp metal skewers, with which I secure the hives together in the following manner:—Having inverted the hive, and placed my empty butt upon it, I take one end of the cloth and one skewer, run it through the edges of the hives and one end of the cloth, pass this round; take another skewer, and in the same manner secure the other end; take the string, slip a loop in the end over one skewer, pass it round, and, lastly, the third skewer through the loop in the other end of the string; this saves time and trouble in tying, and secures the hives, so that you might, perhaps, almost roll them about together without their separating. Rap for two or three minutes, then off with string and cloth, and sticking one skewer through the edges of the hives, so as to act as a hinge, raise the butt, and pass the other skewers through the edges one on each side, thus keeping it up at an angle, say of about 45°. Again rap, if needful, and you may watch the stampede; remove the bees to the stand

in place of the decoy-hive; when settled in, tie them up in a cloth, of course not a bee can remain on the stand.

Although in principle the above mode of procedure varies little from that of others, yet I find these little details, more particularly as to the skewers and looped cord, great assistants in effecting a rapid and successful result. The large addition of bees thus obtained and united to my hives may be considered unnecessary, as in almost every instance they were previously well tenanted; but when I find that so large a pro-

portion are, during the autumn, destroyed in our shops, I am exceedingly glad to make up by that means for their greatly diminished numbers; for I can assure your readers that this destruction is something fearful in our little town, and perhaps not to be seen to the same extent in any other. Bees are now, in our neighbourhood, living on the fruit, and conveying large quantities of saccharine matter to their hives, thus causing universal complaint; but not a single wasp have we seen.—  
GEORGE FOX, *Kingsbridge, Devon.*

### THE NATIONAL POULTRY COMPANY.

INSTEAD of saying, as we did in our last, that the Company's establishment at Bromley is completed, we should have said that a sixth part is completed, for it is purposed to have five other buildings similar to that we described and portrayed last week. We then intimated our purpose of giving fuller details, and we now carry our purpose into effect.

The site has been well chosen, for the soil is very light, and the subsoil gravel. This is essential, not only for rearing early chickens, but for the health of adult fowls. It is more especially needful for carrying out the experiment now in course of trial by this Company—namely, to rear all kinds of domestic

fowls in pens, without any runs whatever, avoiding the usual consequent taint and disease-engendering by the deodorising and disinfecting power attributed to dry earth.

The floors of the hutches where rabbits are kept, and of the pens in which the fowls are confined, are covered about 3 inches deep with perfectly dry earth. This earth is turned over thoroughly twice a-week, and had been unchanged when we saw it for nearly a month, and we can testify that though there were about five hundred fowls in the building, and about a dozen rabbits, there was not the slightest offensive effluvia perceptible. The earth in the pens was perfectly dry, and, even

when applied close to the nose, inoerous. Whether after the lapse of three or more months, by which time it is hoped to be rendered a strong fertiliser, it will still be non-offensive, and whether the earth thus treated will be disinfecting as well as deodorising, remains to be proved.

When we visited the establishment the fowls had been little more than three weeks in their pens. They were then apparently in perfect health; but it remains to be proved whether this sanitary state can be preserved. We are inclined to fear that it cannot, and that it would have been a more salutary arrangement to have had grass runs, in which the birds for some hours daily might have had the advantages of free exercise, air, and sun-light.

Each pen is 12 feet long, 3 feet wide, and more than 7 feet high; behind it is another compartment of the same size, with the ground covered with short litter, wetted every day, in which the fowls, six hens and a cock, may scratch whenever so inclined. The dry earth in their front pen supplies them with the dust bath so needful for keeping them free from vermin. In front of each pen, as shown in our engraving, are two boxes, each box containing two circular earthenware nests with hay in them, such as is held by the man shown in the engraving. The yield of eggs, when we were there, was very small; but, then, the fowls were moulting. The feeding-troughs are outside, in front of the pens, which facilitates the supplying of food; but the water-fountains are inside.

Vines are trained in single rods against the woodwork on each side of the path—a vine between each two pens—but we fear, though the roof of the building is glazed, that there will not be sufficient light to enable the vines to be fruitful. They look well, and may promote healthfulness among the fowls by helping to purify the air; but ivy would do the same, would have cost less, and have had the advantage of being evergreen, and, consequently, ornamental and beneficial throughout the year.

The ventilation is particularly good, and the contrivance by which it is effected very simple. The ventilators are at the sides of the ridged-roof, as shown in our engraving last week. They close by their own gravity, aided by a quadrant lever; a rope attached to this lever, and pulled down, raises the ventilator, and another rope from the lever, but passed over a pulley and pulled down, closes the ventilator. It will be better understood, perhaps, from the accompanying drawing.

The food given to the fowls is chiefly ground corn made into a paste, with some offal meat as a compensation for the insects which they pick up when at liberty. For green food they are to have the refuse vegetables and weeds from the garden.

Tiers of fattening-coops are in course of erection in another building. There will be accommodation for about fifteen hundred fowls, six in each coop. The coops are barred in front, and the building is not to be dark.

An incubating-room, fitted up with hot-air flue and regulators, also with hot-water pipes, and gas-heating apparatus, is also in progress. About four thousand eggs can be hatching at the same time. It is proposed that any one may send eggs to have them incubated there. The eggs are to be laid on shelves covered with dry earth.

A house, fitted up with rabbit-hutches, pig-styes, and six tanks for Ducks, is now forming.

In the beds about the buildings are growing cabbages, broccolis, lettuces, and other garden produce, suitable for the London market. One serious drawback is the want of water, but an artesian well and a small steam-engine to raise the water are intended.

Our readers will perceive that the object the Company have in view is to utilise the manure and other refuse obtained from the poultry by applying it to the growth of vegetables and fruits. This can be done only by confining the poultry; whether they can do so and yet maintain the health of the fowls remains to be proved. One fact is established—namely, that the dry earth acts most effectually as a deodoriser.

Mr. Geyelin also told us, that of about 150 chickens just hatched, brought to the building August 24th, only two had died, and that from being crushed accidentally. We saw many of the chickens on the 11th of September, and they were then looking quite healthy, though they had no other nursing than that from artificial mothers of wool.

Mr. Geyelin seems to prefer the French breeds—the Houdan, La Flèche, and Crève Cœur, probably because he observed in France that they bear confinement well. Most of the fowls at the National Poultry Company's establishment are of those varieties, but there are also common Barn-door fowls, Brahma Postras, Cochin-Chinas, Dorkings, and Spanish.

ARE EARWIGS INJURIOUS TO BEES?

WILL you, or any of your experienced bee correspondents, inform me whether earwigs are injurious to bees? I have only just returned home after an absence of three months, and grieve to find that my bees, in the improved cottage hives, have not done at all well. The supers (6 lbs.), have only in two cases been filled, and that only once. As my garden is a large one, and I am surrounded with bean fields and clover, I expected to have found thriving colonies. I can only account for the failure thus: On removing the upper hive or cover, to examine the super, I found thousands of earwigs. The straw plaiting of the hives was full of them, and full, too, of a fine black and white dust, which is, I suppose, in some way connected with the presence of the earwigs. Is it likely that these creatures have got into the hives themselves, and either eaten the honey or injured the bees?

Can you suggest any plan for cleaning the straw of the hives and covers, and, in fact, extirpating the families of these pirates who seem to be breeding in the decay of the straw which they are causing? What is to be done at this time with the supers and adapting-boards? are they to be removed, and the hole in the hive stopped up for the winter, or are they to be left for bees to work up into next spring?—EDW. CADOGAN.

[The vast number of earwigs which have appeared this season in the midland counties were, doubtless, the cause of the injury to your bee-hives, as, for want of fruit or other vegetable matter, they would certainly feed on the bee-grubs. A similar instance of their feeding on wasp grubs was reported at the September Meeting of the Entomological Society. The hives should be carefully plastered round the junction with mortar.

The supers and adapters should be removed, the crown-boards replaced, the orifices stopped up, and all made snug for the winter.]

TRANSFERRING AND FORMING STOCKS FROM DRIVEN BEES.

THE result of my first experiment, as detailed in your Number of the 25th of July, notwithstanding the temporary loss, has been as favourable as could be. Twenty-one days after making the artificial swarm I inspected the parent hive, and found seven sealed royal cells. I did not interfere with them, as I had no hives to carry on with. My next experiment, the transferring of an old stock to a bar and frame hive, was performed on July 4th. I drove the bees (my first attempt) in about twenty minutes, and then cutting the old hive down the middle into halves I had easy access to the comb; six frames I filled fully, two frames partially. I tied the comb into the frames with common quarter-inch tape, passing it round the frames and tying it in a knot on the top of the bar—two tapes to each bar. The next day my neighbours could scarcely believe in the change, so quiet and earnestly at work were the bees. On the third day after, I took out each frame and detached the tape. This hive is doing very well, and has plenty of sealed comb. The great drawback to the frame hives is the price—one guinea—and carriage each hive is no trifle, to a poor man an impossibility. The above transfer was made into a native hive. A simple square frame, with notches fore and aft for the bars and frames, is sewn on to a square straw hive, which is made on a frame of wood; this forms the body of the hive, and when the bars are in their places, their top surface is flush with the top surface of the top frame; the lid is a frame of wood screwing on to the other frame, but, as it is made broader fore and aft than the lower frame, it overlaps the bars when *in situ* and keeps them steady; no travelling or

a. Ventilator—a wooden flap.  
b. Hinge. There are two to each ventilator.  
c. Pulley over which passes the closing rope.  
d. Rope for opening, with ring at the end to hold by a nail or hook.

extraordinary position can upset them. On this frame, let into its upper quarter of thickness, is a plate of glass, leaving ample room beneath for the bees to pass over the frames, and facilitating inspection without disturbance. These hives cost me, complete, under 10s. To my Woodbury straw hive I have adapted a plate of glass as the lid, so that inspection is easy at any time, and I keep this plate quite loose, loosening it almost daily without the notice of a single bee. A six-sided hive, with a rectangular top for six frames only, has been made in the same way. My third experiment was made, as the commencement of what I made inquiries about in your Number of April 18th. On the 5th I brought home the bees driven from a stock in a neighbour's apiary, and on the 6th I brought home a second and joined them to the first swarm. Not a dozen bees were killed, and only the queen was found with one bee attached by its sting to her, early the next morning. On the fourth day I saw pollen being carried in, and on the sixth it was carried in freely, and robbers were vigorously expelled. They took half a pint of thick syrup daily for the first three days, then only half that quantity daily; now they have comb, as they have sealed up with wax much of the perforated support to the feeding bottle. On the 7th I brought home another driven swarm, and joined them to the artificial maiden swarm of my last letter. There were quite two quarts of bees, but the union was not effected without fighting, and I have to lament a good pint of bees. I could not find the vanquished queen, but on the 10th they had settled down quietly, and I see the stock is most certainly the stronger of the addition.

I shall continue the experiment of making stocks from my neighbour's condemned stores, and shall be glad to inform you of the results as they occur, with the accidents, trouble, and failures, &c.—M. D.

#### USING FOUL-BROOD COMBS—BEES NOT HATCHING BROOD.

A SHORT time since I fumigated the bees of a condemned stock, and to my great annoyance discovered, for the first time in my experience, foul brood; the grubs had perished shortly after being sealed over, they were quite brown, and the smell was very offensive. The grubs were placed in the right position. For the satisfaction of those who amuse themselves by making artificial swarms, I may mention that this foul brood was found in a natural swarm of this year, working in a plain deal box in which bees had never been placed before, and they had never been meddled with in any way. The bees, which are common black ones, I placed in an empty hive, where they have built some combs, which I want for guidecombs next season. Now, I want to know if I may venture to use these combs if the queen has not laid any eggs, which I suspect is the case, as I have not seen any pollen go in.

One of my stocks this summer had a failing queen, she had almost ceased laying, and the population was fast diminishing in June. The wise bees raised a young princess, and smothered the old lady; she was imprisoned at least three hours, and there was not the slightest excitement. In August the population was increasing, and there was a great deal of brood in the hive.

Referring to the query in page 203, the want of a sufficient number of bees in the hive over which "F. F." placed the broodcombs, is the reason why they did not hatch out the brood. I have never found them refuse to do so, if they could spare the bees from below. The plan which I adopt is to suspend the broodcombs in loops of wire passed over the bars in a super. Instead of uniting bees, I always give the stocks I intend to keep, the whole of the brood I find in my condemned hives.—J. L.

[We should be afraid to use the combs built by bees from a foul-breeding stock, and would advise their all being consigned to the melting-pot without delay. Both boxes should also be well scraped and purified with chloride of lime, and in order to be on the safe side, we should lay them aside for a couple of seasons.]

#### BEE-HIVE STANDS.

I AM desirous of enlarging my bee-hive stand, and making it applicable for different kinds of hives, and inspecting them with impunity. Can you furnish me with a working plan, and do you recommend weather-boards in front?

The honey harvest with me has not been abundant. The bees have not worked freely in the supers. I have taken two

combs, 10 lbs., one with brood-comb and a queen. My best store of honey was gathered from the pollard elm, where my first swarm settled in the spring. Having failed in securing the bees then, I determined on getting the honey afterwards; so about a month ago, accompanied by a labourer, we sallied out one evening, and having bored a hole in the side of the tree, only partially succeeded in smoking a few up to the hive on the top. We then laid open a hole with a billhook, and exposed some beautiful comb full of honey. My assistant took out sufficient to fill two milk-pans, and on looking into the hole we found thousands of bees. These were left till the third day, as I was unable to look after them the following day, and on going to the tree, I found they had all taken wing. Whither? Perhaps to the domicile of some weak neighbours, who had not strength to keep them out.—B. B.

[We prefer a verandah or lean-to shed closed at the ends, but either entirely open in front or closed only with pheasant wire, with a good-sized opening opposite the entrance of each hive. Possibly the bee-house sketched and described by "A Bucks BEE-KEEPER" last week, may meet your wishes.]

#### IS THE SMELL OF GAS TAR PREJUDICIAL TO BEES?

WILL you inform me if gas tar is prejudicial to bees? I am about to build a small bee-house, and I propose to use "gassing," as it is called here, for a short space in front of the house, as being cleanly, free from weeds, and affording a smooth surface from which to lift up fallen bees. I hesitate, however, until I have learnt whether it is likely to be an annoyance to the bees.—Novice.

[We are not aware how far the smell of gas tar is likely to be prejudicial to bees. Possibly some of our readers may be better informed on this point than we are, and if so we should be much obliged by their communicating the results of their experience.]

#### MANAGEMENT OF A SWARM SUPERED WHEN HIVED.

ABOUT the 20th of June a swarm of bees came to my place in the country, and were hived that evening in a straw hive with a straw super on them. It was the first occasion on which I had anything to do with bees, and did not know at the time that it was wrong to put the super on when I did. I have not looked at the super since, but the hive I have looked at, and it appears about one-third full of comb. What ought I to do—remove the super or not?

Can you tell me what kind of bee is the enclosed?—R. E.

[We should remove the super, strengthen the stock by driving and adding to it the inhabitants of a condemned hive, and then feed liberally, so as to enable them to extend their combs and store them sufficiently before winter.

The insect enclosed in your letter is not a bee but a fly, *Eristalis florens* of Linnaeus.]

#### OUR LETTER BOX.

**PROFITABLE POULTRY-KEEPING** (*One who is Fond of Them*).—The subject has been discussed repeatedly, and the evidence seems to preponderate against their being profitable if all their food has to be bought. Where they have a good run, are carefully attended, and early chickens are successfully reared, we believe they can be kept profitably. The insertion of theoretical conclusions is not desirable.

**LEG WEAKNESS** (*G. R. B.*).—Let the Dorking cockerel have bread soaked in ale once daily, and plenty of green food, besides his ordinary diet. Give him 4 grains of citrate of iron daily, mixed with a little soft food, such as a mash of barley meal. He will probably regain strength in his legs gradually.

**WHITE DORKINGS** (*T. A. W.*).—Apply to Mr. Martin, Linton Park, Staplehurst, Kent.

**FEEDING BEES IN A COMMON STRAW HIVE** (*C. A. M.*).—If there is the usual cork in the top of your common straw hive, draw it out and feed through the aperture. If none exists cut a hole about 2 inches in diameter with a sharp penknife. Administer food by means of a pint bottle, with its mouth tied over with a bit of cap net, inverted, and the neck inserted in the aperture. Commence feeding at once, and replenish the bottle every evening until a sufficient quantity be given.

**FEEDING A UNITED STOCK OF LIGURIAN AND COMMON BEES** (*A Sussex Bee-keeper*).—Having been fortunate in adding black bees to your Ligurian queen you are now doing quite right in feeding liberally. The supply of food should be continued until the box becomes pretty well filled with comb, and its contents weigh from 15 to 20 lbs. nett.—A DEVONSHIRE BEE-KEEPER.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 64.7°, and its night temperature 44.4°. The greatest heat was 79°, on the 27th, 1832; and the lowest cold, 17°, on the 2nd, 1853. The greatest fall of rain was 1.68 inch.

THE RIBBON-BORDERS AND BEDDING-OUT AT OULTON PARK.

THE kitchen gardens here are in extent about four acres, inside the walls, and they are nicely sheltered from the east and west winds by large trees in the park. The

principal approach to them from the hall is through the arboretum and flower garden; they are very pleasantly situated, sloping gently to the south. A main walk passes through them from north to south, and they are divided in the centre by the Peach-wall, famed in years gone by for its fine Peach trees, none of which now remain, for they were killed by the severe frost of 1860-61. This wall runs straight across the centre of the gardens from east to west.

On the north side of the gardens are the forcing-houses, vineries, Peach-houses, &c., and on each side of the walk leading from the flower gardens to the vineries, is a border 10 feet wide; these borders, when I came to Oulton five years ago, were filled with old Apple trees, many of them in the last stage of decay; beneath the Apple trees the borders were in summer filled with annuals, a few Geraniums, &c. I at once asked to be allowed to clear all the old trees away. This was done; then about 30 feet of the old Peach-wall was brought very abruptly into view. There being only a narrow doorway through this wall leading into the upper gardens, I at once suggested the clearing away of this portion of the Peach-wall, so that the line of vision should not be interrupted. This was after a little while agreed upon, the breach in the wall was made to the desired width, and a nice pillar was built on each side to hide the ends of the wall as much as possible. A splendid position for ribbon-borders was thus opened out, with a fine background of trees beyond.

When we had cleared the centre wall away another difficulty presented itself—the portion of the north-boundary wall through which there is a doorway leading into the framing ground became very unsightly; this difficulty was overcome by raising a large mound immediately in front of the walk. This was done by driving a lot of oak stumps into the ground, one tier above another; there in the summer time are planted *Humea elegans* and large Scarlet Geraniums, and evergreens in the winter. This completely hides this portion of the wall; that on the right and left is covered with the lean-to vineries and forcing-houses, and the mound is a beautiful object when seen from the bottom of the walk, which is 140 yards long. The wall is completely hidden, and the graceful *Humeas* waving gently in the breeze, give it a very charming appearance. The effect of this mound is very much improved by two or three

groups of *Humeas*, which are placed in the centre of the ribbon-borders right and left of the walk, as you pass through between the Peach-wall; these are backed up by Dahlias, and in the front close to the edge of the walk are placed some *Fuchsias*. The *Humeas*, Dahlias, and *Fuchsias*, are planted alternately, the ribbon rows covering the ground beneath them. This portion of the borders is planted as follows:—1st row, next the gravel-walk, 9 inches wide, *Cerastium tomentosum*; 2nd row, *Lobelia speciosa*, dotted at intervals with *Geranium Golden Fleece*, then comes a mass of *Verbena Maonetti*, *Princess Victoria*, 4 feet wide, this is backed by a band of *Geranium Bijou*, 18 inches wide. This arrangement forms the centre of the border, it is planted just alike on each side of the walk; the mass of the little *Verbena*, as seen coming from either up or down the garden, has had a charming effect, it has been the admiration of all who have seen it. It is in colour a beautiful violet-shaded magenta. It is a hybrid I obtained last year by crossing the little *Maonetti*, *Impératrice Elizabeth*, with *Velvet Cushion*. This variety has obtained during the past summer the highest award the Floral Committee of the Royal Horticultural Society could give it. I have little doubt but that it will become one of the greatest favourites amongst the novelties for bedding-purposes next year. The flowers are of much larger size than those of the *Maonetti* section. The habit is all that could be wished, and the ground is covered with its beautiful trusses of brilliant flowers from a very early period in the summer till the frost comes in October. It can be kept in cold pits in perfect health all through the winter months. It strikes very freely, and is altogether one of the most chaste and beautiful plants for flower garden decoration I have ever seen. A very large plat of Dahlias, with the ground between them covered with it, has a very charming appearance. Mr. Gibson will, no doubt, turn this to great advantage, by planting it amongst his fine-foliaged plants at Battersea Park, when he becomes aware of its adaptability for that purpose.

Having described what is planted on the mound at the top of the ribbon-borders, also the arrangement of the centre, I will now proceed to describe the principal borders north and south of the Peach-wall, or centre of the gardens. Hitherto, I have each year planted the borders on each side of the walk alike, but this season for the sake of more variety I have planted each border differently.

On entering the kitchen garden from the flower garden or south side, the right-hand border is planted as follows, beginning from the gravel:—1, *Cerastium tomentosum*. 2, *Lobelia speciosa*, dotted at every 4 feet with a plant of *Geranium Golden Fleece*. 3, *Verbena Maonetti* *Princess Victoria*. 4, *Verbena Purple King*, dotted at the same distance in the rows as the *Lobelia* with *Geranium Christine*. Care was taken in planting to have the *Geraniums* planted alternately, so that each plant of *Golden Fleece* should form a triangle with two plants of *Christine*. 5, *Geranium Flower of the Day*. 6, *Calceolaria Gaines's Yellow* (this I find one of the best for standing all weathers). 7, *Geranium Boule de Feu*. 8, *Purple Zelinda Dahlia*. 9, and last, a narrow row of *Calceolaria Amplicaulis*. This

shade of yellow gives a very nice finish to the border, the bloom of the *Calceolaria* just peeping above the purple *Dahlia*.

The plants of *Golden Fleece* dotted in the row of *Lobelia speciosa* gave it a very pretty appearance, as did the *Christine* in the row of *Purple King*. It was a great relief to the eye, and had the effect of toning down the colours to a very pleasant degree.

In this border the arrangement of colours will appear thus:—

- |                           |                                     |
|---------------------------|-------------------------------------|
| 1. White.                 | 6. Yellow.                          |
| 2. Blue and yellow.       | 7. Scarlet.                         |
| 3. Violet-shaded magenta. | 8. Deep purple.                     |
| 4. Purple and pink.       | 9. Light shade of yellow, or straw. |
| 5. White and cerise.      |                                     |

The left-hand or opposite border is planted, commencing from the gravel, with—1, *Cerastium tomentosum*; 2, *Verbena Velvet Cushion*, dotted with *Geranium Golden Fleece*; 3, *Verbena Hebe*; 4, *Stella Geranium*; 5, *Purple King Verbena*, dotted with *Princess Victoria*; 6, *Geranium Bijou*; 7, *Calceolaria Gaines's Yellow*; 8, *Purple Zelinda Dahlia*; 9, *Calceolaria amplexicaulis*. The colours in this border will be—

- |                                    |                                    |
|------------------------------------|------------------------------------|
| 1. White.                          | 5. Purple and magenta.             |
| 2. Deep velvety purple and yellow. | 6. White and scarlet.              |
| 3. Pink.                           | 7. Yellow.                         |
| 4. Crimson scarlet.                | 8. Purple.                         |
|                                    | 9. Light shade of yellow or straw. |

We now pass through the opening made in the *Peach-wall* or centre of the garden, which has already been described above, in a straight line, and come into the upper or north gardens. Two of the most beautiful objects in these borders are *Verbenas General Lee* and *Claret Queen*. These are two of the best of my last year's seedlings of the old section. *General Lee* has a very free habit and style of growth with neat foliage, and flowers very profusely all through the season. Good flowers may be seen of this variety long after all other *Verbenas* have disappeared. The colour is a rich crimson-shaded purple. This with the following varieties will be much sought after for bedding-purposes, as they are quite new in colour, and all possess the desired habit for bedding-purposes. Amongst the many thousands of *Verbenas* that I raise yearly, I only select those of good habit, the type of which is *Purple King*. Those magnificent flowers one sees at the London exhibitions are only fit for pot culture, plant them out in the open ground and they are nothing better than weeds. We do not want form so much in the bedding *Verbena*, but the qualities most desirable are a great and lasting profusion of bloom, distinct colours that are not easily faded by sun or rain, and last, but not least, a good, compact, and erect style of growth. The varieties named above will produce five or seven trusses of bloom to every one produced by the strong-growing large-leaved kinds, such as *Foxhunter*, *Lord Leigh*, &c. The following are the best of my novelties for next year:—*General Lee*, *Claret Queen*, *General Grant*, *Loveliness*, *Laura*, and *Rosignole*.

On the border on the right hand as we go up the garden, we commence with No. 1, *Cerastium tomentosum*; 2, *Lobelia speciosa*; 3, *Golden Fleece Geranium*; 4, *Verbena General Lee*; 5, *Geranium Flower of the Day*; 6, *Verbena Purple King*; 7, *Yellow Calceolaria*; 8, *Purple Zelinda Dahlia*; 9, *Amplicaulis Calceolaria*.

This border for arrangement of colour, the evenness of growth of each row of plants, and for general effect I consider the best of the six borders. From the *Cerastium* in the front row to the *Calceolaria* at the back, the border all through the season has presented a perfectly even surface, and this without much trouble having been bestowed on it. My great object in arranging my ribbon-borders, as well as the beds, is to arrange the plants so that they will each support the others, all the trouble required being merely pulling a stray flower from an adjoining row into its proper place. I also plant them so that the colour shall harmonise without picking out any of the blooms from the plants. This system of picking the blooms out always grieves me beyond measure whenever I see it done. The colours in this border will stand thus—

- |                           |                                  |
|---------------------------|----------------------------------|
| 1. White.                 | 6. Purple.                       |
| 2. Blue.                  | 7. Yellow.                       |
| 3. Yellow.                | 8. Dark purple.                  |
| 4. Crimson-shaded purple. | 9. Light yellow or straw colour. |
| 5. White and cerise.      |                                  |

The opposite or left-hand border commences with—1, *Cerastium* next the gravel; 2, *Lobelia speciosa*; 3, *Golden Fleece*; 4, *Verbena Claret Queen*; 5, *Geranium Bijou*; 6, *Verbena Purple King*; 7, *Yellow Calceolaria*; 8, *Purple Zelinda*; 9, *Am-*

*plexicaulis Calceolaria*. The colours in this border are as follows:—

- |            |                       |                           |
|------------|-----------------------|---------------------------|
| 1. White.  | 4. Claret.            | 7. Yellow.                |
| 2. Blue.   | 5. White and scarlet. | 8. Dark purple.           |
| 3. Yellow. | 6. Purple.            | 9. Light yellow or straw. |

The plants are put out thickly when the borders are first planted, so that the ground is covered almost directly. We do not have to wait till the summer is nearly over before the ground is covered. The number of plants required for the six ribbon-borders every year is upwards of 13,000.—J. WILLS.

(To be continued.)

### FORMS OF OUR FRUIT-HOUSES.

AFTER the lean-to form the orchard-house is, undoubtedly, the next in importance; and though in discussing its merits I run the risk of offending some of its advocates, I do not think I can properly elucidate my opinion of how important it is that the shape of the house and the mode of cultivation should each be adapted to the end in view, without entering upon it; the better, therefore, to guard against a misunderstanding, I will commence by defining what I understand the term "orchard-house" to mean.

My first was 12 feet wide, span-roofed, with five-foot sides; my next 20 feet wide, also with a span roof, and the same height at the sides; my third 36 feet wide, with three ridge-and-furrow roofs, each 12 feet wide, and 7 feet high at the sides, and now, I believe, they are built 30 feet wide, with a single roof. Let me take these as samples of orchard-houses—that is, a span-roofed house of some sort, having glass all round, and with no more pipes than are sufficient to keep the frost out. Lean-to houses are not orchard-houses, even if fruit trees are grown in them. They have been used for forcing dwarf trees, either in pots or planted out, since Miller's day, and I am confining my attention to what may be called the orchard-house system of cultivation, leaving out the question of pruning and the merits or demerits of growing trees in pots.

These houses have succeeded in preserving the blossoms from frost, and, in the south of England, ripening the fruit; but as you come north their success has depended on their size till the midland counties are reached, where their usefulness ends, even with the addition of pipes, and can only be restored by turning them into forcing-houses.

My orchard-houses went the usual way; the first year my new trees had abundance of blossom, but the fruit fell off with the cold winds; the next year I had a wider and larger house ready for them, but less bloom, and the summer's result was the same. Still, reading of the advantages of large houses, I persevered and built a larger; in this I had little bloom and less fruit. How many hundreds of gentlemen and gardeners can say the same was their experience? The large houses keep the spring frosts out, but in the autumn the sun has not power enough to ripen either the fruit or the buds. The small houses I saw described in your *Journal* of September 5th, in the "Doings of the Last Week," by "R. F." under "Fruit Garden." I have already commended this description to one gentleman's attention, who "has a beautiful large orchard-house, supplied with pipes to use in cold weather, and whose Peaches are over out of doors, but in the orchard-house are not ripe yet, though he has had this year a new gardener who knew how to manage them." I said if they would use the pipes they could, I thought, ripen them before November, at which time "R. F." wishes to ripen his Plums.

He is quite right; their proper use is for retarding-houses. Let me give the quotation. "One great advantage of orchard-houses is, that in a forward season like this you may prolong the season, by keeping the house with abundance of ventilation, so as, in fact, to make it cooler than the out-door temperature. If ever we should get the chance we would have a cool glass house for such Plums as *Reine Claude de Baviay*, and *Coe's Golden Drop*, as in many seasons, we believe, they could be thus had beautifully coloured and rich in flavour up to November." This is exactly what I did for four years under the advice of Mr. Rivers. Turn to his book on orchard-houses, and under the head of "ventilation" you will find—"Now let me advise any one who has such a servant, to open all the shutters about the first week in July, and have them nailed so that they cannot be closed; they may remain so till the first of September." Last year, in the third week in August, I had a visit from a French friend of mine, with whom I had often stayed,

and on such occasions had much conversation upon gardening, and particularly fruit-tree cultivation. He arrived after dark, and when he had taken some refreshment our conversation naturally turned upon a subject so interesting to both. "Well," he said, "you will show me great things in your garden to-morrow?" "Yes, I will show you what will interest you, what I think you cannot see in all France—a proof that our climate here, in the north of England, is superior to yours for early fruit." "But, Monsieur, it requires to know you a long time to believe it." "Then I will prove it before we go to bed." "You will prove to me that your summer months—for it is the summer months that ripen the fruit—are superior to ours in France?" "No, excuse me, I have only to prove that they are colder; you speak of the end of a crop. Let us begin at the beginning. First, the trees must have a rest; we will say my trees have made their growth and set their buds, what they want then is cold weather to make them lose their leaves; have you that in France?" "I begin to understand you; then tell me what you can show me." "Peach trees in perfect health without leaves, without leaves and still in August!" "My dear fellow you have proved it, if you can ripen their fruit as early in proportion; but tell me how you in England do this." "I told him I did as Mr. Rivers recommends; when July came in I shut off the heat from the pipes and let the night air in. In July the thermometer at night will range about 55°, in August 45°; of course, I mean, in a house under this treatment.

Any one spending, as I did, three years ago, the months of September and October in south-western France, Switzerland, and northern Italy, could not fail, while admiring the beautiful autumnal tints, to be impressed with the influence cold night temperature has on vegetation. Mr. Rivers says his French friends exclaim on entering his orchard-house, "*Voilà notre climat!*" and so I kept thinking this must be my climate. The following August and September the thermometer marked 95° in the day, and 45° at night, in my Peach-house. I am quite convinced that nothing that has been written by the greatest enemies of orchard-houses has done them a tithe of the harm that this advice so often urged by Mr. Rivers has. Try my practice, those who have orchard-houses; put in pipes, and in proportion as you are north advance the time of starting the house, and your troubles will cease, for you will have as warm weather as there is at Sawbridgeworth, to ripen your fruit and ensure your trees being well set with buds before the summer is over; but do not continue to think you can ripen your fruit with a temperature, and in spite of a treatment that has sent mine to rest two years running.

Orchard-houses have taught us many things, but perhaps the most valuable of all is the knowledge of the sun's power over them. The large firms who supply pot trees have all built immense houses, and though I do not recollect ever seeing any account of the temperatures they thus obtain, I know that these are very high, and the reason why they thus show us this great heating power of the sun is because they are, so to speak, half empty, the pot trees they are built for seldom attaining in such hands more than 6 feet. I have said I know that the temperatures run very high; I compute them at 100° for May and September, and 110° to 120° for June, July, and August. If I am wrong, let some of these firms speak. It is doing no service to horticulture to lead purchasers to think these little trees are set with buds at low temperatures; and let me induce some who are building to accept the experience thus gained, and build large, square, tall houses, to train their Vines and fruit trees that they may take advantage of cubic measure, at the same time giving ample access to prune or syringe the trees, and by growing the foliage so that it will not keep out the sun's rays, save their coals while they are warming their house by a much preferable heat, and be able to enjoy higher temperatures than it would be safe to attain by any other means.—G. H.

SURELY your correspondent "G. H." has taken to gardening blindfolded, or he would not say we "have actually retrograded in building houses." With respect to his strictures on lean-to houses and Pine-pits being the same that Miller and Speechly recommended a century ago, I can see no better mode of building houses for early forcing in our latitude. "Large, square, tall houses" may, perhaps, be adapted to some gardens. As a rule the parallelogram is the fittest shape for fruit-houses, either lean-to or span-roofed; and if houses of the first-named sort are well built and well adapted by their angles for forcing

during early winter, no better form can be invented. There is no retrograding in employing such houses.

With regard to tall span-roofed houses, "G. H." may see scores of them in different parts of the country from 20 to 30 feet wide, and from 50 to 250 feet in length, and but few of them with Vines and Peach trees trained under the glass so as to exclude the sun. It is now tolerably well known that standard and half-standard Peach, Nectarine, Apricot, and other fruit trees planted in the borders of such houses, their heads carefully pruned in summer so as to make them take a lateral growth, soon become most abundantly fertile, and owing to the sun shining through the unshaded roof the most perfect ripening climate is formed. The pruning of the trees is almost a work of pleasure, and there being no trellises to keep in order and to keep the young shoots tied to, the labour is but trifling.

As to the transverse trellises running from front to back for lean-to houses, although when furnished with leaves or shoots they would look much like a Lincolnshire decoy for wild fowl, yet they would give much greater produce to the market gardener than trees trained under the roof. I know of one lean-to forcing-house for Peaches, the back wall is covered with fine trees, the area of the house has espaliers trained to trellises as if they were common garden trees, and the intervals are filled with pyramidal Nectarines in pots. The wall trees bear well, the espaliers and trees in pots ditto, and all is satisfactory, the produce being much larger in my opinion than if a trellis were placed under the glass in the old way, occupying all the space and not allowing any sun, except a scant supply to the upper part of the back wall, to penetrate the leaf-covered trellis.

The training of Vines to upright rods, and in some instances to trellises, in all cases leaving the roof clear, is a nice mode of culture. This is treated of by Mr. Rivers in "The Orchard-House." He states that the produce of a house with Vines trained to upright stakes will be more than 100 per cent. in excess of a house of the same size where the Vines are trained under the glass. I have one house 20 feet by 14—it should be 7½ feet high at the sides and 15 feet high in the centre, at present it is not so high—well, in this house I have a path in the centre, and in each side-border are twenty-four Vines, three rows in each; forty-eight Vines in all. I hope to see them reach 12 feet high on the average, and I can see that their produce, for they have commenced to bear, must be enormously in excess of roof Vines; for I could only have twelve roof Vines in my small house, giving me 180 feet of bearing stems, whereas my forty-eight Vines will give me 576 feet. This calculation is, I am sure, school-boyish, but, I trust, easily understood. From the roof admitting every ray of sunshine the Grapes, even Frontignans, ripen well.

It remains to be calculated which kind of culture would give the larger produce in a given space. We must suppose a tall span-roofed house 24 feet wide, 8 feet high at the sides, and 16 feet high in the centre, the roof kept perfectly clear, and the area of the house planted with espaliers trained to trellises either parallel to the house or transverse; in the former case there would be room for six rows of espaliers trained to trellises averaging 12 feet in height; there is not a doubt but such an arrangement would give an immense quantity of fruit, and consume labour to an equal degree. We must now take a house of the same dimensions, and plant it with low standard trees, their heads pruned so as to give them a lateral tendency. The expense of the trellis, no trifle, would be saved, and also the constant labour all the summer of tying and training. Two rows of such trees could be planted on each side of the central walk, or the centre of the house could be occupied with the trees, and a path made on both sides. The espaliers would require to be planted 20 feet apart, so that a house 60 feet long would in its six rows contain eighteen trees. Standards might be planted 10 feet apart, and twenty-four permanent trees be planted; but for the first five or seven years temporary half-standards might be planted, so that the house might be made to contain forty-eight trees: these would give a large produce.

The whole matter is full of interest; but your correspondent "G. H." must not think that "this one idea, that nothing will succeed well that is not trained under glass" (the roof), is the idea of the present day. There are hundreds of "tall houses" in which the roofs are clear, and fruit trees are grown in them to great perfection. A friend writes me, "My pyramidal Peach trees are marvellously beautiful, they are 12 feet high, and covered with fine fruit from head to foot; the fruit at the lower part of the trees quite as fine as that near the roof."

There is no doubt but that our hothouse builders like the old-fashioned, expensive, heavy-raftered houses, and, of course, when building vineries, never think of recommending any other mode than training Vines and all fruit trees under the roofs in the old way; but they are men that make money, and have but few ideas of what may be done in growing fruit; it is not their province, they are too much engaged to think of such matters. The new ideas must be carried out by intelligent amateur gardeners, and such men as your correspondent are the right men to do the work.—VITIS.

### LARGE PEACHES.

THE largest Peaches I have known of this season were grown at Hallingbury Place, on a tree trained to the back wall of a lean-to orchard-house, in the compartment used for forcing Peaches so as to have them ripe in June. They were fruit of that fine late Peach, Desse Tardive, and measured 12 inches in circumference. It is remarkable that late Peaches when forced grow to an enormous size, they ripen slowly, and seem to keep on increasing in size, when early sorts in the same climate have ripened, and are cleared off. They, in fact, require a warmer climate than walls or common orchard-houses, for it is well known that such sorts as the above, and others of the same race, the Late Admirable, and the Bourdin, are apt to drop off just before the period of ripening, causing much vexation to the cultivator. The largest Peaches grown here were from a tree of the Golden Rathripe in a pot, they measured 10½ inches in circumference.—T. R.

### AUTUMN-BLOOMING ROSES.

ALTHOUGH many persons are ready to pronounce the term "Hybrid Perpetual" a sham, and declare that we ought to abandon it for some other more definite, I think every year convinces us the more of the great value of this class for autumnal purposes. I do not mean for exhibition; for as a rule (there are, of course, exceptions), the attempt, unless from immense collections, to gather together twenty-four or forty-eight good Roses at any one time is a failure. A Rose is a Rose at all times, a "sweet pet," a "darling favourite;" but, as fond mamma cannot see the failure of beauty in their Cecilies and Gwendolines, even after a few seasons of London life, so I fear we are apt to overlook the deterioration of our children, when our trees, after enduring the heat of a summer and blooming vigorously, vouchsafe to give us some blooms in autumn. My own experience on the matter is, that generally speaking the boxes put up at the end of August or beginning of September contain some half-dozen really good Roses, and that the rest are to be classed under various degrees of badness, and this even with those who have whole acres of Roses to cut from. In the same way the forced Roses are generally (I mean boxes of cut blooms), while very fragrant, very charming, &c., devoid of much interest to a genuine Rose-grower; yet who can go round a rosery and see the large flowerless bushes of summer Roses, and then on the Hybrid Perpetuals, and Teas, and Noisettes behold blooms here and there showing themselves, without feeling the immense advantage the latter classes present? I think, indeed, their great beauty is this, that you can cut every day some three or four Roses, which, placed singly in those pretty vases made for the purpose, gladden the eye and refresh the mind of a votary of the queen of flowers. Very, very often these blooms are equal to any produced in the summer—not those which may be gathered at the end of August, when the sun's influence is generally too great, driving them into bloom before they have time to think about it; but from the second week in September, or through October if the weather be favourable, and even into dreary dark November, I have had blooms of Charles Lefebvre, Senateur Vaisse, Triomphe d'Amiens, and others, equal to any one I have gathered in the height of the Rose season, and I think such blooms quite redeem the Hybrid Perpetuals from being a sham.

I hardly think that one can safely give a list of autumnal-blooming Roses. Where a large collection is grown, most probably the greater portion of the varieties will at some time or other give blooms; and where the collection is a small one, it would be perhaps unwise to recommend particular sorts for this object alone. From adopting in some of my beds the principle of pegging-down I have had some wonderful shoots from the centre of the plant; Duc de Cazes, Lord Raglan,

Jules Margottin, John Hopper, and others having made shoots of 6, 7, and 8 feet in length, and the tips in many instances shooting out again and giving bloom-buds; while, again, as far as one can judge, many of the best of the newer kinds, such as Duchesse de Morny, Madame Victor Verdier, Pierre Notting, and Baron Pelletan de Kinkelin are good for this purpose. Amongst those that I have found most useful in this respect (my experience may not be that of others), are Général Jacqueminot and its very near neighbour Triomphe d'Amiens, Charles Lefebvre, Jules Margottin, Duc de Cazes, General Washington (better in autumn than in summer), Senateur Vaisse, Madame C. Crapelet, Baron A. de Rothschild, Madame Caillat, Maréchal Vaillant, Anguste Mié, Madame Knorr, Eugene Appert, Géant des Batailles, John Hopper, Madame Victor Verdier, Pierre Notting, Baron Pelletan de Kinkelin, and Caroline de Sansal. Bourbons are of course always to be depended upon; and such kinds as Souvenir de la Malmaison, Baron Gonella, and Catherine Guillot will always give blooms. They are not so fragrant as the Perpetuals, but nevertheless add much to the number and beauty of autumnal Roses.—D., Deal.

### LILIUM CULTIVATION.

(Continued from page 229.)

OUT-DOOR CULTURE.—Perhaps there is no flower so fine in its season as the White garden Lily (*Lilium candidum*), so well known and esteemed for its snow-white fragrant blossoms, produced in such large heads as to fit it for large central groups in beds or arboretums.

There are many excellent hardy species and varieties of Lilies, and I shall take them in the following order:—

*Lilium candidum* (White garden Lily), flowers white, fragrant, and handsome; 3 to 4 feet.

*L. candidum plenum*, a double form of the preceding, white flowers, fine; 3 to 4 feet.

*L. candidum striatum*, white and purple; 3 to 4 feet.

*L. candidum foliis huteo-variegatis*, a fine variegated form of the species, with golden variegation, and white flowers like those of the species; somewhat variable in character. I fear that it will not retain its variegation permanently, if it do so it will be a favourite. 3 to 4 feet.

*L. candidum foliis argenteo-variegatis*, a white or silvery variegated form of the species, having white flowers; 3 to 4 feet. This is not much as regards variegation, still novel; the flowers, however, are fine.

*L. candidum foliis maculatis*, a blotched-leaved kind, rather more dwarf than the species, with white flowers; height, 2½ to 3 feet.

*Lilium bulbiferum*, orange red, dwarf, and fine; 2 feet.

*L. bulbiferum umbellatum*, orange red, splendid; 2 feet.

*L. bulbiferum umbellatum fulgillum*, a dwarf form of the last with flowers of a richer hue; 18 inches.

*L. bulbiferum umbellatum punctatum*, a spotted variety of umbellatum, and very fine; 2 feet.

The last four have a splendid effect. They vary in height from 1½ to 3 feet, according to soil, &c., and have dark green glossy leaves and magnificent terminal racemes of rich orange-red cup or saucer-like flowers. In herbaceous borders, and early groups in the flower garden, they are gorgeous.

*Lilium aurantiacum*, orange yellow; 3 feet.

*Lilium atrosanguineum*, blotched brown on orange-red ground; height, 18 inches to 2 feet.

*L. atrosanguineum rubens*, orange red, blotched crimson; height from 18 inches to 2 feet.

*L. atrosanguineum Vulcan*, very like the last.

*Lilium venustum*, little different from the well known Orange Lily (*Lilium aurantiacum*), flowers orange; height, 18 inches to 2 feet.

*Lilium kamschatkense*, orange; 18 inches.

The last six have saucer-like flowers like the four preceding them, and might not inaptly be termed the "cup" section.

*Lilium thunbergianum*, and its variety grandiflorum, already described, and not distinguishable from venustum.

*Lilium pomponium*, yellow; 4 feet.

*L. pomponium aurantiacum*, orange; 4 feet.

*Lilium canadense*, shaded orange; 3 to 4 feet.

*Lilium chalcedonicum* (Scarlet Martagon), brilliant scarlet; 3 to 4 feet.

*Lilium colchicum*, rich yellow, finely spotted; 4 feet.

*Lilium Martagon*, purple; 3 to 4 feet. There was a double variety, which I believe is now lost to cultivation.

*L. Martagon sepalis albis*, white; 3 to 4 feet. The double form of this is not now to be had.

*Lilium superbum pyramidale* is the most stately of the North American Lilies, remarkable for the number and elegance of its flowers of rich spotted orange. In rich soil, and especially in that which is moist and peaty, it attains a height of 7 or 8 feet. The flowers are disposed in a graceful manner in the form of a chandelier, and are salmon-coloured and finely spotted.

*Lilium speciosum* (lanceifolium) varieties, and *L. tigrinum*, previously described, with the eight last named, are of the "Turk's-cap" section, of which the Martagon is the type. To these may be added, as desirable for out-door culture, most of those named as suitable for cultivation in pots.

*Lilium Catesbei* is a beautiful dwarf species, with crimson and yellow spotted vase-like flowers; 1 foot to 1 foot 6 inches.

*Lilium pyrenaicum*, yellow; 3 feet.

*Lilium sinicum*, already noted, has smaller, narrow-lobed, vase-like blossoms, of a brilliant scarlet.

*Lilium monadelphum*, yellow, spotted; nothing extraordinary.

*Lilium excelsum* (testaceum), not equal to many, buff; 4 feet.

*Lilium Wallichianum*, large, fine, white; 3 feet.

Ground intended to be planted with the above Lilies should be dug deeply and be in good heart, or be made so by the addition of turfy loam, leaf mould, or rotten manure. Where the soil is very strong or adhesive, after providing efficient drainage, remove it to the depth of 18 inches or 2 feet, and replace it with turfy loam, if possible, or good sound loam, with an equal quantity of leaf mould intermixed. If the soil is good, but heavy, a little light sandy loam and sand will help to open it, and old mortar will answer the same purpose. All Lilliums do not thrive in the same soil, but those of the Martagon, or Turk's-cap section, do best in heavy or strong rich soil, with a clayey subsoil. The cup-shaped, or those after the type of the Orange Lily, are more suitable for sandy soils; but peaty soils will grow all the species perfectly, in fact, no place is so suitable for Lilies as a Rhododendron-bed, for there they exhibit a luxuriance of growth and profusion of bloom not found in those grown in loamy soils. They will also thrive well in certain strong loams, on clay, if free of stagnant water.

Lilliums are very suitable for smoky town gardens, especially the varieties of *L. speciosum*, which are much grown by amateurs near Bradford.

The soil being in good heart, neither too light nor too heavy, and drained so as not to become very wet during the winter, plant the bulbs in clumps of six as early in autumn as the decay of the stems will allow, choosing an open situation, placing them at a distance apart equal to their own diameter, and spreading out the roots, if any, equally on all sides, at about 3 inches below the surface; place each bulb with the crown upwards, and if the soil is wet, put a little river sand around and upon each bulb, finally covering with 3 inches of lightish soil. When planting all kinds of bulbs in the garden borders, it is desirable to drive a stake down in the centre of each clump, leaving it 3 or 4 inches out of the ground in order to indicate the position, so that in cleaning the borders or forking them over the work may be done without injuring the roots. Without such stakes the roots are apt to be dug up in winter, or otherwise injured. The stakes most suitable are those made of what is generally termed "heart of oak," split into pieces 1 or 1½ inch square, and 15 inches long. They should be pointed at the lower end, and that end hid on a wood fire, so as to become charred for two-thirds of its length, and then, whilst hot, dipped in coal tar, taken out immediately, and laid aside to dry. Thus prepared they will last nearly an ordinary lifetime, and their black colour prevents any unsightliness. They should be driven two-thirds of their length into the ground by the side of each clump, or in the centre of clumps composed of large bulbs, such as Lilliums. If the kinds are such as are not known at sight, it is well to cut a notch with a saw at the upper end of each stick, and have a book with the name numbered to correspond with the tally.

After planting it is desirable to cover the surface with an inch or two of partially decomposed leaves before severe weather sets in. This will materially protect the roots, as they are liable to suffer in consequence of the openness of the soil over them. Once planted they will need no further attention beyond staking such stems as appear likely to be broken by the winds; but the fewer the supports the more beautiful will be the group. After the stalks have decayed cut them off at the surface, and cover with a dressing of leaf mould in the autumn of each year, to be forked into the ground in the succeeding spring.

Although autumn is the best time to plant Lilliums, yet this operation may be safely performed from that time until spring, only it must be done before the shoots have commenced growing. The Turk's-cap section, however, cannot be replanted at any period without weakening the bloom for the succeeding season; the Cup section are not so particular in this respect, for they lose most, if not all of their roots annually, and these are not thick and fleshy, as in the Turk's-cap Lilies. Lilliums of all kinds should not be replanted oftener than once in three years, nor then if the roots are not too many to form a nice compact group. *Lilium longiflorum* and *L. japonicum*, or Brownii, do not lose the whole of their roots while in a state of rest. This should be borne in mind by the cultivator, as it will suggest the desirability of not removing the bulbs oftener than is absolutely necessary.

Though Lilliums will for the most part grow almost anywhere, they are worthy of a prominent position in the flower garden, or in groups in arboretums or pleasure grounds. For forming a group of the most unique description in Rhododendron-grounds the magnificent *Lilium superbum* or *L. superbum pyramidale* will hold its own against any of the gorgeous denizens of the flower garden, it is so stately as a plant, commonly attaining a height of 8 feet, and sometimes of 10 to 12 feet, and so remarkable for the number and elegance of its blossoms, and their graceful disposition. It does best in a good peat bed. *L. japonicum* is also very desirable for a bed. *L. longiflorum* is equally so, but of much less growth, and so are the varieties of *L. speciosum*.

In forming beds of *Lilium speciosum* in the open air choose a light, airy, yet sheltered situation. If the soil is of a peaty nature, and free from stagnant water, it will only be necessary to dig the ground to a depth of 2 feet, but if light and sandy mix with it a dressing of 3 inches of leaf mould and well-rotted manure in equal proportions. If it is wet and heavy dig out the soil to a depth of 2 feet; at the bottom place 6 inches of brick rubbish, and then fill to within 3 inches of the surface, raising the bed a little in the centre, with two-thirds turfy peat, such as the common Fern (*Pteris aquilina*), likes to grow in, and one-third turfy loam and leaf mould in equal parts. Thoroughly mix this compost by chopping it with a spade, and place the rougher portion at the bottom and the finer at the top. Arrange the roots in rows, circular or otherwise, according to the shape of the bed, 9 inches asunder, and the roots 6 inches apart for a permanent bed; place the large single-eyed roots in the centre, which may consist of the variety *eruentum*, planting two rows at least for a centre, but the width of the bed must determine the number of rows of one kind. The large roots with single eyes, which invariably grow the strongest, being in the centre, the double-eyed roots should be placed in the next row outwards, and so on through all the species or varieties, the small single-eyed roots being reserved for the out-sides, unless too small to bloom, when they must not be placed in the bed at all. Next to *eruentum* plant one or more rows of *punctatum*, *rubrum* next, then *roseum*, and *album* next; then plant a single row of each of the same varieties in regular order, commencing with *eruentum* and ending with *album*, using in this case the small single-eyed yet flowering roots, which need not be planted more than 3 inches apart, with 6 inches between the rows. Presuming an oval or circle to be planted in this manner, the diameter would be 10 feet; and what could be a finer sight than such a bed during the months of August and September!

Having arranged the bulbs according to the taste of the operator, cover them with three inches of soil, and do not press it down, but if the district is a rainy one, cover with a little sand, and then place the soil thereon. The sand prevents too much moisture from coming in immediate contact with the bulbs, and the latter do not rot so soon as if in immediate contact with the decaying fibry compost. If severe weather set in the surface should be covered with 3 inches of litter, which ought to be removed by the end of March. About the end of April or beginning of May the shoots will be up and growing, and just below or level with the surface will be found numerous roots. Now is the time to apply 2 or 3 inches of top-dressing consisting of old mushroom-bed manure, if at hand, or, what is nearly as good, cocoa refuse, which is much neater in appearance; in default of these, a top-dressing of the same compost as that forming the bed must be given. Unless the weather prove very dry no water will be necessary, but if required, it must be given copiously, so as to penetrate down to the roots. Tie up neatly to small stakes any shoots that may need adjusting. In autumn, after the stalks decay, remove

the top-dressing and take off the stalks level with the crown of the roots, which will bring away all the small offsets, as these are found adhering to the base of the flower-stem beneath the soil. This done, cover with 3 inches of prepared compost, the same as that used in making the bed. All the small offsets being removed, only flowering roots will be left, and the bed will be finer in the second year than in the first.

The most suitable times to plant Lilies is in October and November, and February and March, or whilst they are in a dormant state. A fine bed is formed by placing *L. Brownii* in the centre, *L. eximium* next it, and edging with *L. longiflorum*. *L. Catesbæi* makes a bed of lovely orange scarlet. It succeeds well in peat, but there is not a Lily that will not thrive luxuriantly in the compost named for *L. speciosum*.

*L. giganteum*, *japonicum*, *Wallichianum*, and *auratum* have not as yet proved strictly hardy, but there is reason to believe that they will succeed out of doors with slight protection in winter. *L. japonicum* does well with 3 inches of dry leaves or litter placed over it in November and removed in March. Were the large store roots of *L. giganteum* and others of that section planted out in May, there is every probability that they would bloom finely, and might be taken up and potted in autumn and wintered in a cold pit, replanting them in spring. I am not in a position to pronounce them hardy, but am persuaded that they might be successfully grown in many parts of the country with very slight protection. Any information on this point would be useful to many, and to none more so than myself.—G. ABBEY.

### POTATOES.

I VENTURE to send you a few particulars respecting Potatoes, I shall feel obliged if you can return me some practical advice thereon.

I planted Ash-leaved and Alma Kidneys at the same time, in the same field, the seed of both coming from a distance. The Almas were ripe first, and yielded best; they were scarcely touched with disease. The Ash-leaved were diseased perhaps to the amount of 10 per cent.

I planted a Yorkshire Potato called "Cash-in-Hand" at the same time with Flukes. The Cash-in-Hand were diseased to the extent of probably 50 per cent., the Flukes scarcely at all. The Cash-in-Hand I introduced to this land three years ago. The first year it bore well, with very little disease. The seed put in this year was descended from that of 1863, but came last year from other land. The Flukes I had this year from Lancashire. Where the land was manured with stable manure for this year's crop almost all the Potatoes were diseased.—H. W. B.

[We do not discern on what points you need advice, except not to apply decomposing manures to the soil at the time of planting Potatoes. When the Potato murrain was a subject of much research it was shown that such manuring promoted the disease. The early-ripening varieties only should be cultivated. We reject any variety that is not fit for stering by the end of July or early in August; and we take up the tubers as soon as the leaves begin to turn brown. Storing before the tubers have been subjected to the autumnal rains promotes their keeping. They do not improve by being left in the ground so soon as the leaves begin to decay.]

### TEMPERATURE OF THE SEASON.

We have had some extremely hot weather for September. On the 16th I put out two of our ordinary thermometers at 12.5 P.M. to ascertain the heat. The men were complaining that it was hotter than it had been all the summer. I send my notes and times of taking my observations. I do not know that I ever found so great a change in young nursery stock in three weeks in my practice of twenty-five years.

1.45 P.M., thermometer 12 inches from ground, back to sun, 89°; north wall 4 feet from ground, 79°.

3 P.M., 4 feet from ground, same position, 95°; north wall, 82°.

5.30 P.M., ditto, 78°; north wall, 75°.

—Willow Cottage Nursery, Leicester.

DIRECTOR OF KEW GARDENS.—We have very great satisfaction in announcing that Dr. J. D. HOOKER is appointed to succeed his father in the Directorship of the Royal Botanic Gardens, at

Kew. He is not only worthy of the appointment, but had an additional claim to it from latterly having so much assisted his father.

### FUNGUSES ON PASTURE GRASSES.

CAN you inform me what is the matter with the enclosed grass? Several fields in this neighbourhood have within the last two weeks put on this appearance. The whole surface looks of a yellow colour, and the feet are covered with a fine yellow dust while walking over it. Do you consider it injurious to animals? The disease seems principally to attack Rye Grass.—Hayes, Kent.

[The yellow patches so conspicuous on the grass, leaves, and stems, are a fungus, *Uredo rubigo*, or rust. Being in such vast quantities we fear it will be injurious to cattle pastured upon the grass. We would have it all mown and burnt, and the fields then sown with salt, twenty bushels to the acre. The rain which has now arrived will soon bring forward a healthier herbage.]

### CHANNEL ISLANDS ORCHARD-HOUSES.

THE season, on the whole, has been favourable to the production of the year's crop and the ripening of the wood for the ensuing one. Aphides have been incessant in their attacks; and the spider, *rubra cura*, has remained master of the situation in many instances. Grapes have coloured badly. The Peach crop, which was large, was scarcely an average in size, colour, or flavour. Most houses here are lean-to's, and the fruit on the back walls was decidedly finer than on bush trees in pots, as might be expected. Our powers of ventilation and irrigation were often severely tried, especially the former.

I now send a report on the average periods of ripening of fruits in our houses. Of course it is only approximate on the whole, but this is sufficient for our purpose. It is collected from a certain number of houses within this small radius, and is based on data from one to five years old. Nevertheless, if others would do the same as regards the orchard-houses near them, it is easy to see what valuable information would result. These things have as yet been left undone, while they are of such real value that many mistakes annually occur from this cause alone, and much loss of time and money. Let any one try to give hints to another without having previously himself accurately recorded these periods in his note-book, and he will soon discover that he has done his friend an injury. I speak here of the dates of the various fruits ripening, but there are many other matters equally worthy of being written down and not trusted to memory.

The periods of ripening have been reduced to the compass of a week, which is about the average range.

JULY.—The first Peach that has ripened here during five seasons has, as yet, been Early York. It was ripe in certain quantities by the middle of July. It was closely followed by Early Chevreuse, Desse Hâtive, Early Victoria, Early Silver, Honey, Canary, and Early Grosse Mignonne. These were generally fairly ready during the third week of this month, and gave us an excellent succession. The end of July brought to maturity Doué, Acton Scot, and Golden Purple. These Peaches vary in quality, but are generally good. As mine go to Covent Garden, realising good profits to the dealers, but very little to myself, I am sceptical as to the prices some amateurs say they themselves have netted. However, I can easily say which of the July Peaches are the most to be depended on, and I am building an early-house expressly for this class, which is the most valuable in the London and Paris markets. In the latter case the July Peaches come from Algiers. The Montreuil Peaches come in later.

AUGUST.—We now tread closely on the open wall, and Peaches become comparatively less valuable unless very fine. The first week, however, is still a good test of earliness for orchard-houses anywhere. Early Crawford Peach, Violette Hâtive Nectarine (in abundance), Rivers' Orange, Downton, and Abec Peach, were generally ripe then. During the second week we had Imperial, Du Telliers, Stanwick, Royal Victoria, Bowden, Roman, and Oldenburg Nectarines, and Stump-the-World Peach. Royal George, Red Magdalen, and Grosse Mignonne Peaches from the open wall, making their appearance on table about this period, were formidable rivals. We do not, therefore, place the house in opposition to the wall just now, except for Nectarines, in the Channel Islands. In these it is always unrivalled, no matter the season.

During the third week of August Princess of Wales Peach, De Sables Nectarine, Bergen's Yellow (an American Peach), and Bragton Violet ripened. The end of August brought us the Stanwick on early walls, Alexina Chaupin (new), Chauvière Nectarine, Kensington, and Tardive Belle Fleur, a new American variety, all good, but sustaining severe competition with the open wall at the moment.

An account of the September Peaches will be given hereafter. By the end of the month Peaches on the open wall become rare, and the houses resume a marked superiority. One house, growing late Peaches, easily outnumbers the produce of the islands then. This succession is of great value.

During this warm season the Peaches on the open wall have been very numerous, but small. They ripened simultaneously, and became, at those times, a nuisance rather than a pleasure. No Peach which touches the ground is worth eating, and the supply is too great at one period, and waste ensues.—T. C. BRÉNAUT, *Richmond House, Guernsey.*

### WHERE BANANAS, PINE-APPLES, AND ORANGES COME FROM.

THE vessels engaged in collecting and bringing fruit to this port are mostly British bottoms and are not at all regular traders. Some of these peculiar craft are represented to be wreckers from Nassau, Cuba, Windward Islands, &c., and they are large dealers in old junk. Wrecked goods, vessels, cottons, and iron-work are their customary plunder, the supply of which proving short they betake themselves to the fruit-growing districts, and load their vessels with Bananas, Pine Apples, Cocoa-nuts, Oranges, and Lemons. Loaded with a rich cargo of these edibles, the vessels are put for New York, or whatever port seems most desirable, and forthwith their freight is placed in the hands of commission merchants, who see to the disposing of the cargo. A number of American vessels are, however, yearly chartered by the merchants dealing in such commodities, and these latter trade regularly and in an orthodox manner. Payments for fruit at the plantations are generally made in specie, occasionally varied, however, by bartering of goods, when a captain goes out on a speculating tour of his own. In such cases flour, sugar, tea, and New England rum form the leading articles of merchandise—the rum preponderating. Some cotton and ginghams for the natives form a part also.

These vessels trade along the South American coast, touching at Cuban and West Indian ports, including Kingston, Jamaica. Bananas mostly come from Baracoa, Rustan, and Matanzas; Cocoa-nuts from Brazil; Pine Apples from Cuba, Matanzas, and Nassau.

It is astonishing how much waste ensues from the fruit decaying while in transit for this port, whole cargoes sometimes being lost in this manner, and the crew are always engaged, while on the voyage homeward, in culling out the diseased fruit; still sometimes they do not succeed in checking this great drawback to a cheap supply. Each vessel carries from 3000 to 5000 bunches of Bananas, and from 12,000 to 45,000 dozen Pine Apples or Cocoa-nuts on each trip. They frequently bring a few barrels of rare sea shells, half a dozen or so of turtles or terapins, and, in the case of foreign vessels already alluded to, a considerable quantity of junk and old iron constitutes a portion of their cargo. The voyage of a fruit-drogher generally occupies ten or fifteen days, although from Cuba the trips are naturally much shorter.

Box fruit—consisting of Oranges, Lemons, Limes—come mostly from the Island of Sicily, and the vessels are most laden at the ports of Palermo and Messina, and the fruit is conveyed to this port in sailing vessels of the larger class and steam vessels. The Montown Lemons, usually known in trade as "French Lemons," generally begin to come in about the middle of February, and their season ends in the latter part of June or the first of July, sometimes lasting until August, in unusually prosperous seasons. The Malaga Oranges and Lemons come into the market about August and last until January, thus completing the year.

In Cuban fruits the trade is always lively on account of the regularity of the supplies and the ready sale always found for such fruit. Havana Oranges generally make their first appearance in November, and last through the winter until March. Limes also arrive in large quantities from Cuba, and form no inconsiderable part of the trade.

Baracoa Bananas and Cocoa-nuts have their season from

March to July, when the Carthagena fruit assumes full sway. Matanzas Pine Apples last from May through to July, and the Nassau fruit, the Sugar-loaf kind, come in from May until the end of August.

An instructive lesson might be learned regarding the mystery of the cheap fruit constantly hawked about the streets of the city, by a visit to one of the schooners discharging its fragrant cargo. Pine Apples now range from 10 to 16 dols. per hundred, according to the quality and size. But it is easily seen how the Apple-women manage to make a living, when the spectator observes several of these enterprising dealers buy "specks" at 6 and 8 dols. per hundred. A little lower grade is reached by paying 2 dols. per bushel for Pine Apples almost half rotten. Bananas are culled and sold in the same manner.—(*New York Times*).

### THE ROYAL HORTICULTURAL SOCIETY. SEPTEMBER 19TH.

FLORAL COMMITTEE.—The subjects exhibited at this meeting were not numerous. Mr. Turner, Royal Nursery, Slough, sent several beautiful stands of Dahlias, of which Bullion, golden yellow, received a second-class certificate; and similar awards were made to Mr. Rawlings, Bethnal Green, for Sambo, dark crimson, a large well-formed flower; and to Mr. Legge, Edmonton, for Lilac Perfection, small, bright lilac, shaded with crimson, and Golden Emperor, bright yellow, fine form and substance. Fanny Sturt, a very promising Fancy, was again shown by Mr. Pope, Chelsea; and Mr. Eckford, Coleshill, showed Lady Mary Wilde, and cut Verbenas. Mr. Shortt, Fulham, sent *Litobrochia tripartita*, which was commended, and a charming *Lomaria*, called Bellii, for which a first-class certificate was given. Mr. Earley, gardener to F. Pryor, Esq., Digswell, contributed a handsome variety of *Polystichum angulare* with large graceful fronds. This received a first-class certificate. Mr. Howard, gardener to J. Brande, Esq., Balham, had a special certificate for two plants of *Dendrobium formosum giganteum*, with large white flowers and an orange throat; *Ionopsis paniculata* and *Cattleya bicolor* also came from the same exhibitor. Mr. Wills, gardener to Sir P. G. Egerton, Bart., Oulton Park, Tarporley, contributed a cut spike of a handsome unnamed *Oncidium*, and a *Cattleya* sent home by Mr. Weir. *Cedronella cana*, with numerous spikes of purplish red flowers, was shown by Mr. Thompson, Ipswich; and *Melia japonica*, with handsome foliage, by Messrs. Lee, of Hammersmith.

FRUIT COMMITTEE.—Mr. Osborn in the chair. Prizes were offered at this meeting for the best dish of Peaches from the open wall; the first was taken by Mr. Whiting, of the Deepdene, with Walburton Admirable, and the second by Mr. Turner, of Slough, with the same variety. For the best dish of Nectarines from the open wall, Mr. Turner was first, with Stanwick. For the best dish of Peaches from the orchard-house, Mr. Westcott, gardener to Mrs. Lett, Dulwich House, obtained the first prize, with Late Admirable, and he was the only competitor. For the best dish of Plums, Mr. Whiting was first with Reine Claude de Bavay, Coe's Golden Drop, and Ickworth Imperatrice, the latter quite shrivelled, and a delicious sweetmeat; and Mr. Earley, of Digswell, was second, with Golden Drop, Imperatrice, and Autumn Gage.

Messrs. Rivers, of Sawbridgeworth, sent a seedling Peach, named Lord Palmerston, of such merit as to receive a first-class certificate. It is of large size, and rather pale colour, having only a little red on the side next the sun, and the flesh is remarkably firm, and richly flavoured. It was raised from a variety obtained from the Pavie de Pomponne, and retains in some measure the character of its grand parent, in being very deeply stained with red at the stone, and having the flesh rather adherent. This will prove one of the best, as it is one of the largest late Peaches. Messrs. Rivers also sent the following:—Plums.—Belle de Septembre, a valuable culinary Plum, its usual time of ripening is towards the end of September. Autumn Compôte, a seedling raised by Mr. Rivers from La Délicieuse. Those sent were smaller than usual. This is also a valuable culinary Plum, ripening a week before the above, and much resembling the Victoria in the habit of the tree, and in bearing abundantly. Cherry.—Belle Agathe, a late sort of Bigarreau. Apples.—The old Golden Pippin, from the orchard-house; the tree has been under glass all the summer; and Reimette Van Mons, from the orchard-house. This is generally very rich when grown under glass.

A seedling Apple and a seedling Plum were exhibited by Jonathan Clarke, Esq., but they did not possess any merit to entitle them to an award. Mr. William Paul sent a large collection of Apples, one sort of each, which attracted considerable attention; and Mr. Turner, of Slough, sent a dish of magnificent Cox's Orange Pippin; Messrs. Osborn & Sons, of Fulham, sent fruit of *Psidium Cattleianum*, the flavour of which was very fine; and Mr. Wills, of Oulton Park, Tarporley, a box of dried crystallised Apricots, equal in every respect to those imported from abroad, and with a much fresher Apricot flavour. The Committee considered them worthy of very high commendation. George F. Wilson, Esq., of Gishurst Cottage, Weybridge, exhibited a basket of extraordinary specimens of Marchal de la Cour Pears, grown in an orchard-house.

Mr. George Curd, gardener to M. G. Thoyts, Esq., Sulhampstead, sent two seedling Melons, one of which was named Georgiana and the other Sulhampstead Hero, but the latter only was ripe. It is a white-fleshed variety, and, though of good flavour, is not remarkable for any great merit. The other is a green-fleshed variety, and, when ripe, will probably be superior to the "Hero."

### PLANTING SEEDLING EVERGREENS IN SUMMER.

I TRANSPLANTED ten thousand Norway Spruce seedlings, two years old, early in August last. The loss from moving was almost imperceptible, apparently not exceeding 1 per cent. On examining them early in October, I found they had formed a mass of new roots. I then planted a quantity of different kinds, but found it too late in the season, as they did not root before winter set in. I covered a part of the Norways when winter approached with leaves, and part with slough hay. They wintered finely, and have made twice the growth made by seedlings from the same bed that were transplanted last April. They have all matured this summer's growth, and I think the experiment complete. The loss in either case amounts to a small fraction; but the growth is decidedly in favour of summer planting.

I have continued my experiments this season, by transplanting, June 14th, fifty of last year's Norway Spruce seedlings; June 19th, five hundred same; June 26th, ten thousand same, and several thousand within the last few days (July 1st to 3rd). This morning, on examining the lot planted June 14th, I find new roots already 1 inch in length, and every one living and doing as well as could be desired. The lot of June 24th had not finished their growth when planted, but were just beginning to show the terminal bud; they have hardened up and stand quite erect.

We planted the above in beds 4 feet wide, with two-foot alleys between; if the ground is dry we water it, cover the surface with half-inch of swamp muck, and plant with a dibble 6 inches apart and 2 inches apart in the rows; water well when planted; no shade, but in a hot dry time a little fresh grass thrown lightly over them, as we did on the ten thousand planted last August, would be advisable.

When I commenced the experiment last summer, I would not have dared to plant them with a dibble at that season of the year, fearing it would bruise the delicate roots, had it not been for an article I saw recommending the planting of evergreens at that season, and pounding the ground over the roots with a rammer.

I put on the mulch to keep the moisture in the ground till the roots take a new start, which I am satisfied is within a very few days, at this hot season of the year.

I shall transplant at intervals till the middle of August, but not later in the season.—ROBT. DEUGLASS, *Waukegan, Illinois.*

[We regard this communication of Mr. Douglass's as one of the most important we have ever had the pleasure of laying before our readers. It was at one time supposed that evergreens could not be raised here, and that importation was a necessity. Several of us, among others Mr. Douglass, have learned that they can be as successfully and cheaply raised here as in Europe, and many thousands of dollars will be saved to the country. Now we have the important announcement that we can transplant them at almost any time, which will be a great boon to those who have heretofore supposed that what was to be done had to be finished in a hurry during a few weeks in spring or not at all. With root-grafting in winter, and summer planting, the American nurseryman can find regular employment for his hands all the year round.

Mr. Douglass gives the middle of August as his latest time for planting. In the middle of September we had several thousand *Pinus rigida* and Scotch Pine, raised from seed sown eighteen months previous, and our success was equal to that of Mr. D. Not one of the Scotch Pine failed, and very few of the Pitch Pine, which were very much crowded in the seed-beds. During the coming September we shall risk out thousands of seedlings of last year's raising. Our plan is to put the roots in buckets of water as they are lifted, and they are taken from the water immediately as set in.]—(*American Gardener's Monthly.*)

A LITTLE BOTANY REALLY DANGEROUS.—Sydney Smith was once looking at the plants in the hothouse of a young lady who was proud of her flowers, and used, not very accurately, a

profusion of botanical names. "Madam," said he, "have you the *Acarus scabies*?" "No," said she, "I had it last winter, and I gave it to the Archbishop of Canterbury; it came out beautiful in the spring." *Acarus scabies* is the medical name for the insect causing a cutaneous and not aristocratic eruption.

### WHY DO THE GLANDS OF LEAVES PRESERVE THEM FROM MILDEW?

I HAVE waited to see if any one responded to the request of the Editors in a late Number, to give the reason or reasons of Peaches and Nectarines that have glandless leaves being subject to mildew. As I have seen no attempt to do so, I throw out the following for consideration.

What are glands? They are secretory organs, through which secretions pass. A gland is a duct or channel for conveying away fluid or matter separated. It may be asked, what has this to do with preserving leaves from mildew? Everything. In plants that have glandless leaves, the secretions pass through the leaves themselves, instead of being conveyed away by the glands. In certain weather these secretions become viscous. The fungus pitches on these sticky secretions, and bides its time, till development takes place in suitable weather. In rainy weather the stickiness is washed off, and with it the fungus; and hence in such weather plants have an immunity from fungoid diseases, whether the leaves have glands or not. After a heavy rain aphides and fungi alike disappear.—W. F. RANLYFFE, *Tarrant Rushton, Blandford.*

### OCCUPYING A SMALL MARKET GARDEN.

I AM desirous of living in the country, and wish to have a small house with ground sufficient to grow all my own vegetables, to keep a cow, some pigs, and poultry, the place to be as near the seaside as possible. I will tell you my exact position so that you may be enabled to tell me whether I can live upon my income, where to reside, the utmost rent to be paid, and the quantity of different stock to be purchased for my purpose, together with the quantity of land. I purpose marrying a farmer's daughter. I have an independence of 10s. per week. I have also £60 in cash that I can lay out. I am in a trade that can find work in any place, because every man wears that which I make, but I wish to place that out of the question, as if I obtained work at my trade I should expect to put the money so earned away.—DEVONSHIRE.

[Your letter has been long unanswered from causes that could not be avoided, and now we fear our advice to you must to a certain extent be qualified by the opportunities you have of attaining what is desirable. The most likely way to succeed would be to look out for a plot of land near some small town that is rising into importance, whether as a bathing or fashionable place, or one of trade. If it be without railway accommodation so much the better, as you will suffer less from competition. It is not necessary that the ground be arable, as we would rather prefer a grass field, but let it be good, even if you pay more for it. As your capital is limited we would advise you not to include a cow in the affair, let some one else who can purchase half a dozen go into that business, for the labour where that number is kept is not much more than where there is only one. If you determine to engage in market gardening go into it in earnest, trench and prepare the ground during the coming winter, and plant such crops as come early into use. If you can manage to erect a Cucumber-pit, do so, and it will be of service in many ways, and by all means lay by a good heap of the surface turf for after-use. We would not advise your planting many Apple or Pear trees, or any of the larger fruits which can be carried from a long distance, and are grown elsewhere on a scale with which you have but a poor chance to compete, but plant the smaller fruits which are of most value on the spot where grown, as Strawberries, Raspberries, Gooseberries for the table, and the like. We would also advise you not to plant Potatoes to any great extent, excepting for early use, but all kinds of summer vegetables—as Lettuce, Cauliflower, Kidney Beans, salading of all kinds, and an abundant supply of winter stuff. Such crops are always bringing in money, and you will have some return early in the summer. You will, doubtless, have read in our pages articles bearing on the culture of each vegetable, but you had better buy "How to Farm Two Acres Profitably," as well as other Manuals pub-

lished at our office, which will help you a little. You will do well to unite yourself to a wife likely to aid you by her acquaintance with the household duties of a farm. We urge on you by all means to select really good land, for which if well situated you will likely have to pay £4 or £5 per acre, and about two acres will be sufficient to start with. You may also keep pigs as soon as you have any offal to give them, and if the town be a rising one, make terms as soon as you can with some of the hotel or innkeepers for the manure, and by exercising all the qualifications of industry, perseverance, and carefulness, we doubt not but that your enterprise will, in the end, be crowned with success. The first year, we need hardly say, will be a struggle, and, perhaps, a severe one, but do not be disheartened. "Perseverance must succeed."]'

### MY PLANTS,

#### AND HOW AND WHERE I FOUND THEM.—No. 10.

The choice little Oak Fern, then, was the first piece of good fortune in my Oakmoor discoveries. Leaving my kind guides I strolled about, and at length started walking up the hill which leads from Oakmoor towards the "Wevers." I was prying very closely under the grass whence I saw water trickling down on the right-hand bank, for I had long hoped to come upon the *Hymenophyllum*, and I thought this mossy wet bank a likely place for them. Here, however, I was doomed to disappointment, at least in so far as this genus is concerned; but I came unexpectedly upon a very beautiful Fern, the *Cystopteris fragilis*; one root only I found, and that I took carefully up with plenty of the limestone earth about it, and when we returned planted it in a pot, for it appeared so delicate a plant that I feared to trust it in the rockwork in the garden. It grew most vigorously in our window, and threw up fresh fronds continually. Although I had many *Ferns* in the window, none I cherished so much as this, and as the fates would have it, none was so roughly handled. No less than three times did our clumsy domestic upset this doomed pot when she fastened the shutters in the evening. Three times there lay my pretty *Cystopteris*, under the fragments of the pot, in the garden beneath the window. Each time, of course, it lost some of its native earth, and we were obliged to fill up with what we had. However, grow it would. Mangled as were its delicate fronds by its falls, it soon sent up fresh ones, and when I consigned it to the care of the Plums and tape man over the way with my pet Oak Fern, it was thriving uncommonly well. Alas! it shared their untimely fate and I never saw it again.

"Oh! ever thus from childhood's hour,  
I've seen my fondest hopes decay;  
I never lov'd a tree or flower,  
But 'twas the first to fade away.

"I never lov'd a dear gazelle,  
To glad me with its soft black eye,  
But when it came to know me well,  
And love me, it was sure to die!"

However, as I said long ago, "*Nil desperandum*" is the motto of mottoes for us all, and I am rather inclined to share in the exuberant spirits of "Chispa," than to "cry over spilt milk." In the midst of his versatile fortune he soliloquises in this way: "Thus I wag through the world, half the time on foot and the other half walking; and always as merry as a thunderstorm in the night; and so we plough along, as the fly said to the ox. Who knows what may happen? Patience, and shuffle the cards! I am not yet so bald that you can see my brains; and, perhaps, after all, I shall some day go to Rome and come back St. Peter. *Benedicite!*"

But to return. Whilst I was searching the right-hand bank, my husband, whilst looking over the hedge into a field on the left, spied some roots of the Hart's-tongue; they were of the medium size, but not nearly so fresh-looking or luxuriant as those we had gathered in Norfolk, where the fronds instead of being short and stiff, bent in their length and elegance over the grass and plants beneath them. However, as these were the first specimens we had procured in Staffordshire, I gladly welcomed them, and planted the roots in one of my baskets, where they flourished and formed a pretty contrast to the foliage of the lighter Ferns.

Continuing our journey we passed banks of Wild Thyme; and fine plants of *Briza media*, and several varieties of the Hair Grasses, waved with the slightest breath. We noticed particularly one heathy field which was almost covered with the *Aira flexuosa*. A little further on, from an old wall we extracted roots of *Asplenium trichomanes* and *Polystichum aculea-*

*tum*, variety *lonchitidioides*, neither of them in a thriving condition. As a girl, when visiting in Devonshire, I remember well the exuberant growth of the *A. trichomanes*, how it gladdened the interior of the wells and the sides of those high Devon lazes. And where does the king of Ferns, the *Osmunda regalis*, flourish to the extent or height which it does on the banks of the Dart? About the Hohne Chase, near Ashburton, it revels in the full enjoyment of a congenial soil and climate, and of the constant supply of moisture which it receives from the river—that cruel river! if the countryman's legend is to be believed. Thus it runs—"The Dart every year claims a heart." To corroborate a tale she firmly credited, a true-born Devonshire lass, one living upon the banks of the Dart, related to me the following story:—"How that for seven years no one had been drowned in its waters. For seven years the Dart had not claimed a heart; but," she added, "you will see, Miss, it always has them, for if it misses one year it will have two the next! But what I was going to tell you is this—One day our singers were all asked to play and sing at a wedding feast in a village some miles off; my father was asked too, as he is one of our best players, but somehow or other he seemed as if he didn't like to go, we tried to persuade him, but it was of no use. He said he did not seem to like to go. All the rest went. It was agreed that the singers should return in a boat home; by some means or another, how it was I do not know, but they went too much to one side of the boat and it upset. Seven of them were drowned! We waited for the party to return home, but none came, and the next day they brought home the bodies. Oh! it was such a sight to see them, poor things. But you see the Dart must have its heart, and as father said, we might be sure something would soon happen, because it was so many years since any one had been lost." Whilst relating her little narrative the girl's face assumed a reverential expression, and I recollect when she came to the pith of the tale, that seven were drowned, I really, as a girl, began to feel something akin to a touch of awe with regard to this exacting stream. Certainly, I never afterwards saw it without a sort of dread of its cannibal propensities, and I think I should have felt more satisfied, when upon its waters, if I had previously ascertained that its taste had been gratified; so naturally do a country's legends and tales wind themselves about one's heart, that when once listened to it is most difficult to divest oneself of them. Who that has been in Devonshire as a child does not believe in pixies?—those tiny elves who live in those miniature caves, or holes, in the rocky hills, their homes amid the Ferns and Bluebells, where during the day they silently hide; but after a moonlight night the traces of their revels are left in the fairy-rings in the grass. We felt as sure they had danced there as if we had seen them; and let us seek not to disturb their gambols, or the cow may be dry in the morning, or the butter turned sour, the baby may squint, or a thousand misadventures may have happened. All try to keep in favour with the pixies! I believe these little creatures bear a very good name; but I think I have heard that they have revengeful cousins, although just now I forget their proper appellation. I do not wish to insult the "lords of the creation," but I am very much impressed with the idea that these cantankerous little beings were represented to me as of the male gender, and I have an equally strong conviction that the more benevolent and happier fairies were of the female kind.

"Light and free,  
Through the light blue air,  
Where no mortals dare,  
Career we.  
Moonbeams pale illumine our flight,  
As we float, the balmy night,  
'Mid those islands rare,  
Of the cloudland fair.

"Merrily,  
At the day's bright dawn,  
When the stars are gone,  
When the sun is born,  
Career we.  
Mortal eyes no trace can find,  
Of our gambols on the wind,  
Through those Isles of gold,  
Of our spirit world."

Instead of writing upon human "lords," I should in papers with this heading, be commenting instead upon "Lords and ladies," but this ill-regulated mind of mine is ever given to wandering, and my thoughts run wild and free, and become either solemn or gay according to the chord which is struck. Talking of "lords of the creation," I am reminded of an anecdote, which has amused me, of this recent election, and

with which, though very unbotanical, I conclude this paper. A gentleman having called at a house to solicit a vote, inquired of the good woman therein, whether "the head of the house

was at home?" "No," she said, "the head is not, but the neck is, and" she added roguishly, "The neck can make the head move which ever way it pleases!"—ALICE.

HOLLAND HOUSE, THE SEAT OF LADY HOLLAND.

This magnificent Elizabethan mansion, built in the year 1607, is seen among the trees, seated high in the park, and is approached by an avenue of Elm trees from the Great Western road between Kensington and Hammersmith. The nearest similar mansion is Hatfield House, Hertfordshire.

Before the south front is a large square bowling-green terrace, bounded by balustrades adorned with flowers in Maltese vases, and ten large Orange trees in tubs, and in its centre is a large basin-fountain.

To the west of the house is the flower garden, laid out in the old French style, where the flower-plots are looked down upon from an architectural terrace. On the south side of the north boundary-wall is a chain of double diamond-shaped beds, the middle one is planted with Brilliant Geranium, and then duplicates corresponding on each side of *Gazania splendens*, Lord Raglan Verbena, *Calceolaria angustifolia*, and Commander-in-Chief Geranium. The next are diamond-shaped beds, planted respectively with Purple King Verbena, Heliotrope Miss Nightingale, General Simpson Verbena, *Amaranthus melancholicus ruber*; and the other four beds are duplicates of similar plants. Then follow circular chain borders, one at each side of a broad walk, planted similarly with Madame Vaucher Geranium, edged with the Silver-leaved Ivy, Cloth of Gold Geranium and Iresine Herbstii, Mrs. Holford Verbena, *Amaranthus melancholicus ruber*, Princess of Prussia Geranium, Sweet Alyssum, Purple King Verbena, Lady Middleton Geranium, *Coleus Verschaffeltii* edged with *Cineraria maritima*, Sweet Alyssum, Geranium Rubens, Golden Chain Geranium and Purple King Verbena mixed, *Amaranthus melancholicus ruber*, Mrs. Holford Verbena, Cloth of Gold and Iresine Herbstii. Commander-in-Chief Geranium is planted all along at the back of the chain-border near the wall, and Mrs. Lennox Geranium in patches at the angles of the front border, with an edging of *Lobelia speciosa*.

The wall is furnished with fine healthy Peach, Nectarine, and Apricot trees, which here and against other high walls are bearing fine crops. It is rather rare to see wall trees cultivated with the care and judgment that they receive here.

There are eight large beds of choice Roses, and, pegged down as they are, they display their flowers with an even surface to great advantage, and correspond in height with the other beds; two are edged with *Calceolaria Kayii*, two with *Oenothera macrantha*, two with Lord Raglan Verbena, and two with Purple King Verbena.

In the centre is a large oblong figure, divided by gravel walks into six compartments, and surrounded by narrow borders with a circular bed in each, and the other portions of the compartments are filled up with figures of fret and scrollwork in Box. The outside borders are filled with Tom Thumb Geranium, the cross walks with Flower of the Day Geranium. The circle round the dial, and the borders beside the walk running north and south from the dial, are planted with Christine Geranium. The two circles in the largest triangles are planted with *Stella Geranium*, edged with *Gazania splendens*; these are beautiful beds, more particularly when the sun shines on them; and the four circles in the smaller angles contain *Calceolaria Aurea floribunda*.

To the south of the above is the accompanying design on gravel. The bank on the north of the conservatory is edged with *Gnaphalium lanatum*, then rows (ribbon style) of the following plants:—Heliotrope Miss Nightingale, Baron Hugel Geranium, Bijou Geranium, Springfield Rival Petunia, *Calceolaria Kayii*, *Calceolaria Prince of Orange*, and *Ageratum*, backed by *Zelinda Dahlia*.

The next scene is the Lily-pond garden. The circular pond, filled with Water Lilies, is surrounded by four beds on gravel, planted with Punch Geranium in the centre, then a band of *Calceolaria Kayii*, then Tom Thumb Geranium, edged with Mangles's Variegated Geranium; then two oblong beds to the south with *Zelinda Dahlia* in the centre, Commander-in-Chief next; then *Calceolaria Kayii*, edged with Baron Hugel Geranium. On the west side is an oval in the centre of an oblong grass plot, with four beds like the letter L. The oval has a *Humea elegans* in the centre, Punch Geranium around it, then a band of Flower of the Day, edged with *Lobelia speciosa*. The four beds are planted with two rows of *Stella Nosegay Geranium* in the centre, two rows of *Christine Geranium* at each side, edged with Purple King Verbena on the outside, and *Lobelia Paxtoniana* inside. Two circles near the conservatory contain *Christine Geranium*, and an oblong bed has *Stella Geranium* in the centre, *Calceolaria Kayii* at each side, and an edging of Tom Thumb Geranium.

A small terrace garden, to the west of the flower garden, is composed at each end of a cross, surrounded by triangular beds, and four triangular beds in the centre, two fancy beds and two square beds at each side, with vases innumerable, both on the balustrades and on the gravel, all planted and gay with dwarf-growing flowering plants. Close to it is an alcove, the favourite seat of the poet Rogers, with noble foxes, the family crest, cut out in Box at each side, an octagon marble fountain being in front, with a white lily jet in the centre.

The conservatory is furnished with some fine specimens of Camellias planted in the border, and large hanging-baskets filled with choice plants suspended from the roof, and in the winter with the large Orange trees that now adorn the square to the south front and the bowling-green terrace. Attached to the conservatory, on the north side, is a banqueting-room of handsome proportions, which is finished and furnished in the best style of art and ornamentation. Close to it, on the east side, is a tower, which is approached by a flight of steps, and from the south side of the conservatory is a colonnade, upwards of 100 yards long, running eastward to the mansion. By this means a communication, under cover, is opened from the house to the conservatory, then to the banqueting-room, then to the loggio or smoking-room, then to the tower, and home by the flower garden, by the pleasure grounds, or by the terrace walk on the top of the colonnade.

In the Melon ground are two vineries, a Peach-house, and planthouse, and several useful pits for Melons, Cucumbers, and for storing plants in winter, all heated by hot water. The Peach and Nectarine trees have borne a fine crop of fruit this season, and from their healthy appearance promise to do so for many years. Mr. Dixon applies no wash of any sort to his Vines, but merely peels

1. Gaillardia picta.
2. Tropaeolum, Dixon's Seedling, a brilliant scarlet.
3. Madame Vaucher Geranium.
4. Mrs. Holford Verbena.
5. Verbena, Lord Raglan.
6. A dot of Perilla in the centre of the cross, then *Calceolaria angustifolia* edged with Purple King Verbena.

off the loose bark, and to judge from the healthy state of the Vines and the large bunches of Black Hamburgh Grapes that still remain uncut, a wash of any sort is unnecessary; besides, as Mr. Dixon observed, when the composition is dry the dusty particles are wafted by the air on to the bunches, which are consequently deteriorated in flavour. Ripe Melons were cut in the end of May, and a pit of seven lights was filled with Cucumber plants (Coxe's), still bearing, and from which, on a rough calculation, no less than forty dozen of good fruit had been cut. In walking through the grounds many pleasing views present themselves through the arches of the colonnade and through those of the Lime-tree walk. In the pleasure grounds are large bunches of Mistletoe growing on Apple trees, and in the Lime-tree walk are some young sprigs of Mistletoe growing out of the trees. The seed

in the berries was rubbed into the cracks in the bark, and left to vegetate. The hint was taken from the action of the mistle thrush, which, in removing the glutinous matter from its bill, has recourse to a branch of a tree, and by that means deposits the seed.

Along the north side of the kitchen garden and orchard is an espalier made of posts and strong wires, the latter 18 inches apart, running through the posts the whole length, on which the fruit trees are trained, also a great variety of ornamental and edible Gourds. Upon inquiry to know the distinguishing features of the edible from the non-edible varieties, I was informed by Mr. Dixon that the yellow and orange were edible, and that the green-skinned were not; also that the colour of the flowers was another criterion by which to judge of their properties, as the species with yellow flowers were edible, and those with white flowers to be rejected for the table, but retained as ornaments to train over arbours, &c., and the fruit when dried to adorn the hall.

On the north of the house the ground rises on all sides to the knoll in the park, this knoll is crowned with a group, a most picturesque group, of Cedars of Lebanon. Other trees creep up the slopes, and form groves around the base and along the valley, not thick groves of gloom, but groves in which the forms of the trees are fully developed, and being planted at various distances apart, they produce glades of pleasing landscape scenery. From this fine swelling knoll a pleasant prospect is obtained of Harrow-on-the-Hill, Kensal Green, Ealing, and the church of St. Stephen's at Shepherd's Bush. The green drive, embosomed in a grove, leads to the open grounds in the park where the Scottish and other fêtes have been celebrated. The different scenes that this estate offers are arranged in a manner so obvious and agreeable, that after examining the parts in succession the mind is very clearly impressed with the beautiful effect of the whole. The grounds are now in a high state of embellishment, and in the most perfect order, under the superintendence of Mr. Dixon, the head gardener.—W. KEANE.

## WELTON PLACE,

### THE RESIDENCE OF MAJOR TREVOR CLARKE.

On a former occasion we not only commented upon many things we found worthy of notice at Welton Place, but gave an engraving of its "wilderness" walk; yet, though that is truly beautiful, and though there are other portions of the grounds which a landscape painter would pause long over admiringly, and though we have again visited the grounds, and hope to repeat our visit often—notwithstanding these testimonies of approval, let no one go there with the expectation of seeing first-class horticulture, splendid flower gardens, geometric beds, ribbon-borders, vineries, peacheries, and so forth. There is at Welton Place nothing of the sort. The grounds are varied in surface, have fine specimens of Conifers, and other trees, and are neatly kept. So far is well, but if there were nothing more we should not have coveted as we do covet, repeated visits. What is the great attraction, then? We will reply fully.

The owner of Welton Place is one of those rare amateur gardeners with ample opportunity, who delights in experimental gardening; but though constantly inquiring after some thing new, it is always after novelty leading to utility. The inquiry, too, is always intelligently and perseveringly pursued. Nor is Major Clarke a man of one object; his predominant one just now is, and for some time has been, the cross-breeding of Cotton-plants; but numerous other experiments are in course of trial, every hothouse and greenhouse, every stone trough, and every corner has its object of interest, and wherever we turned our steps, under glass or in the open grounds, we came in contact with an interesting gardening scrap of some kind.

Of Major Clarke's researches and experiments on the Cotton-plant we need not expatiate, for he has lectured fully upon the subject before the Royal Horticultural Society. In the garden at Welton Place you see in every house abundant evidence that his opinions and statements are well sustained by actual research. There are growing specimens of various species, and still more of varieties and cross-breeds. Hitherto he has been unsuccessful in crossing the species of the western with those of the eastern hemispheres; but if there be any species of *Gossypium* a native of both, and we think there is, that might serve as a go-between.

Memory must be allowed to be desultory, and it first brings

for record the Major's experiments on disbudding Conifers. He removed all the lateral buds as often as produced from the stem of a Scotch Fir, and of another species, the name of which we forget. The Scotch Fir is 20 feet high; and the lower 10 or 12 feet, never having been allowed to produce a branch, are consequently without a knot, and the importance of this when the trunk of a Conifer comes to the sawyer, needs no enforcement.

Tender Conifers, such as *Arancaria*, *Cryptomeria*, and *Taxodium*, are usually considered least liable to injury by frost when on dry and elevated soil; but at Welton Place, those in the hollows near the water suffer the least. There the *Taxodium distichum*, or *Deciduous Yew*, thrives well, and leads us to remark that it is usually planted erroneously on dry ground, for it is a native of boggy localities.

Some pods in our pouch remind us that the new scarlet Sweet Pea among other novelties has been here tested, and the verdict is, "It is really a good thing," and the beauty of some successional blossoms justifies us in saying we consider the verdict in accordance with the evidence.

We noticed the geothermal garden when recording our former visit. It is still maintained. During the last winter a flue was employed to impart heat to the soil, but Major Clarke found it less effective than hot-water pipes, and purposes recurring to these. We have heard it objected that many of the plants would be destroyed if the earth were heated sufficiently to prevent the air above being fatally cold. Experience shows this objection to be groundless. Besides, in nature observation has taught that the roots of plants will be uninjured in earth heated nearly to the boiling point of water. Thus, Mr. Forster, the naturalist, who was with Captain Cook in one of his circumnavigations, found the soil near a volcano, in the island of Tanna, raised the mercury in a Fahrenheit's thermometer to 210°, yet the surface of that soil was covered with flowers.

The *Melocacti* and tropical *Aloes* flourish strikingly in the geothermal-bed, but in the winter the *Cacti* are placed for safety in some attic, and the *Aloes* are put under double-glazed frames, which are found to afford them sufficient protection from our winter frosts. A *Cycas* remains in the bed throughout the year. The fronds are cut down by the frosts, but fresh fronds are produced in the spring.

The bees, Ligurian and common, were superlatively active and vigorous. No wonder, for great attention has been paid to testing which flowers yield the most honey, and to having abundance of those flowers in the vicinity of the hives. The prime favourite of the bees is *Nepeta Mussinii*. It has an un-fading succession of blooms from the end of May until the winter arrives. It will grow anywhere. Next held in preference by the bees is *Reseda Phyteuma*. It is not sweet-scented, but is the constant resort of the bees whilst it is in flower. Major Clarke found it wild in Italy. He is sedulously on the look-out for the useful and authentic, even to the being certain as to the nature of the bog-earth of the West Indies; so he had some sent to Welton, and various shrubs have sprung up in it that are not yet identified.

A common complaint is made that the tenants of a marine aquarium will not long survive in its confinement, but by judicious care some of the *Sea Anemones* in that at Welton have been maintained for ten years.

We presume that Major Clarke, agreeing with Addison, that "music can noble hints impart," and that "there's music in all things," has made even his flower-pots musical. They are fixed firmly within each other, but their sides not touching, on a bar of wood passed through the centre drainage-hole of each. They are the common flower-pots, rather thinner than usual, increasing gradually in size to produce the bass notes, and each inscribed with a letter indicating the note it produces. They are played upon by being struck with muffled sticks.

### SALVIA SPLENDENS MANAGEMENT.

This plant makes a brilliant ornament for the conservatory during the winter months if grown well.

To propagate it, take off cuttings in January, and insert

them in sandy soil, plunging the pot or pan in a gentle bottom heat. They will root freely in a fortnight; then pot them off singly in small pots, after which shift them accordingly as they require more room, but never allow them to become pot-bound.

The compost which I find suits them best is formed of three parts rich yellow loam and one part of equal quantities of leaf mould and well-rotted dung; adding a small quantity of charcoal and silver sand.

Keep the plants in a greenhouse, with a moist atmosphere when the weather is very hot. By the first week in June they will have become good plants, and should be in 10 or 12-inch pots. Then turn them out of their pots, and plant them out of doors in a sheltered situation in some good rich loam. When they show bloom stop them, and they will throw out some healthy shoots, and by the end of September they will have made noble specimens; then take them up, and pot them in No. 2-sized pots, giving them the same compost as before. Great care should be taken in lifting them. Water them well two or three days before the operation, then take the plants up with large balls, and carefully reduce each ball until it fits the pot. Pot them firmly, tie them out, and remove them into a cool moist pit, keeping them rather close for a few days. By so doing they will not lose any of their foliage. By the end of October they will have a mass of flowers, and will continue blooming until February.—W. B.

### ESPERIONE AND MUSCADINE GRAPE WINES.

It was not our "chaplain," but another genial Wiltshire rector, well known to him, who called upon us last week. We conned over the productions of the garden, both growing and harvested, and finished off with some samples of my Grape Vines. They were remembered by him of old, and now he has a garden, a Vine, and Grapes of his own. I inquired, "Did he make wine?" "No, he should like to do so, but supposed my practice was a secret." I assured him that I never could keep secrets; my greatest happiness was to impart to others all that I knew which could benefit them. I told him that even before he became curate of Woodstock I had published in THE COTTAGE GARDENER the knowledge I possessed about Vine culture and wine-making; that in consequence of this being a beautiful Grape season I was then engaged in arranging some notes, preliminary to writing a seasonable paper on the subject, giving an account of my progress; and that as he now reads "our Journal" he would there find the desired information. He said, "Give the minute particulars of the operation, for you practical people, who write with a full knowledge of a subject, are apt to leave out the minor details, through a conception that others would arrive at these as a matter of course, whereas it may not be so. It is just those statements which people not versed in a subject want. The result is interesting enough to read; but often, the "how to do it" not being sufficiently specified, there is not sufficient inducement for those who are not grounded in the matter to undertake it." As I am self-educated in every phase of my knowledge, by no one more than by myself could the remark be better appreciated. How much time, right down hard head work, and mental exhaustion have the omissions of small explanations cost me? However, I trust that in what I am now about to write I shall go so far into particulars as to meet the ideas of all persons who may feel interested in the subject.

I have made no alteration in the system of groundwork and in the training of my out-door Vines from that given in the year 1856, further than in lieu of 12 feet in height they are now verging upon 30 feet; and as my chief object now is fruit for the vat, I do not resort to slicing away what I considered superfluous buds, or to thinning out the berries. I reserve such attentions for house culture. As regards my practice in wine-making, although much that I wrote in 1860 must be repeated now, it will, nevertheless, be so blended with what I consider improvements as to render it, I hope, worth perusal by old as well as new readers. In fact, the repetition of old matter cannot be avoided, so necessary is it for the comprehension of the new; and I am sure from experience that this dovetailing of individual practice with progress from time to time tends to keep a subject alive, and to diffuse knowledge, however familiar and common the subject may be.

On account of the quantity of Grapes that the Vines now annually produce I have instituted a screw wine-press, which facilitates my operations greatly; but as nine people out of

ten may not possess so desirable an article, I will point out the homely contrivances that can be made use of. They are to be found in most places, and should undergo a scrupulous cleansing before they are used for wine-making. They are a garden basket, the weight of which is known, in which to place the Grapes when gathered; scales to weigh these; a washing-bench; two large, brown, glazed earthenware pans (I formerly used washing-tubs, but I have discarded these wooden utensils because they absorbed the juice and saccharine matter), holding about fourteen gallons each; casks of capacity according to the requirement, say from five to nine gallons each; two two-gallon stone bottles, and two of one gallon each; a spouted jug measuring two quarts; a two-gallon tin can with a spout to it; a tin pint measure; a galvanised iron lading-bowl; three large, brown, earthenware, glazed milk-pans, borrowed from the bee-hives, which they serve to shelter; one large stone mortar and a mahogany pestle; a tin funnel, a colander, two large wooden spoons, a mallet, gimlet, a pair of pincers, and a pair of cutting-pliers; lugs, vent-pegs, and taps of sizes; a stout piece of canvas; two stout squared stakes each about 5 feet in length; trams and wedges to stand and secure the casks upon, and a saccharometer.

The names of my Grapes in the open air are, the Royal Muscadine (white) and Esperione (black). The former ripens two or three weeks before the latter, and about the last week in October is the time that I usually make my vintage of the Esperione. This year the Grapes will be quite ready to gather by the middle of the month, and, by their present appearance, I shall be operating upon the Muscadines whilst this paper is being put in type. Directly after the Grapes are gathered and weighed they should be picked from their stalks into one of the large pans; and the pestle and mortar being deposited on the washing-bench, having the fruit on one side and an empty pan on the other, bowl after bowl of Grapes should be crushed in the mortar; not by a vertical jam, but by working the pestle with a light circular horizontal motion, using sufficient force only to macerate the skins and pulp without smashing the pips, for in the latter case they would impart an unpleasant roughness to the wine. The pulp is emptied from the mortar with the lading bowl into the pan, and so on until the bruising process is completed. When a pestle and mortar cannot be had, the Grapes can be hand-crushed in the colander, made to rest over the pan upon the two squared stakes. Now strain about a pint of the juice from the must, and prove it by the saccharometer, which is done by nearly filling the tin tube that belongs to it and immersing the glass instrument therein, when the specific gravity of the juice is read on the index plate, and the stated degree should be noted down. On the supposition that ten gallons of wine are to be made, 80 lbs. of Grapes, exclusive of their stalks, will be a good proportion to make use of, and we shall conclude that this is the weight of the now-called "must" in the pan before us. Toss two gallons of clean cold water into it, and stir it about well with a large wooden spoon, or something to answer the purpose. Strain off a pint of the watered juice, and make a note of the specific gravity as before. Place the two squared stakes across the pan, and cover it over with a piece of druggot, or something of the sort, to exclude the air and preserve a temperature of about 60°. The must will now gain daily in sweetness, and should be well stirred, and proved daily with the saccharometer, until it is seen that the sweetness begins to diminish, and then no time must be lost in straining off, as the skins of the Grapes would deteriorate the juice by remaining longer with it. The wine-press now comes into action. To fit into the straining-box I use a bag made of strong cheese-cloth, into which, by raising its open end, is ladled about a gallon of the must to be pressed, and the "cheese" of compressed skins and pips is emptied into a milk-pan, and so on consecutively. Before I used a press I carried out this process as follows:—An empty pan was placed beneath the squared stakes, or a short ladder, and resting upon them or it the colander, into which the must was ladled by degrees; the juice was then well pressed by the hands from the skins and pips into the pan below, and the refuse tossed into a milk-pan, and so on until the muscles of one's arms became rigid. The strained-off juice is now measured with the tin can, and, in every probability, it will be found to have run eight gallons, then one gallon and a half of clean water will be sufficient to pour over the skins and pips in the milk-pan, and if this water can be heated to a temperature of not more than 80° so much the better. Let it be well stirred amongst the skins and pips to express what virtue remains in them; then strain it off and add it with the

juice in the working-pan, and the united quantity should slightly exceed ten gallons.

We are now arrived at the sweetening, and here I will insert a table of the specific gravity of the pure juice of my Grapes used for wine-making during six consecutive years.

	Saccharometer.		Saccharometer

1864,	do..... 20°	do.....	22°

I may mention here that I never add a drop of raw spirits to my wines of any description. I have never had any cause to regret not having used spirits, and I have samples by me of all the wines that I ever made to prove that the addition of spirits is not necessary for their keeping. All the alcohol which they gain artificially is from the sugar, which is always more or less necessary for British wines on account of the smaller amount of sun-heat which the Grapes receive as compared with those produced in foreign countries, and even there, in some parts, a great deal of sugar is added to the Grape-juice. I believe I use more sugar in my practice than what many of our best wine-makers recommend. I have tried less quantities, and I have always found that I was eventually obliged, in order to give body, to add an amount of sugar more than equal to what I should have used in the first instance, for the wines would so attenuate themselves in the cask that if I had not kept adding dissolved loaf-sugar to keep up the gravity they would have been miserably thin, or possibly acetous fermentation would have set in, and then vinegar would have been the result. I find, besides, that it is never satisfactory to have to apply much sugar to keep up a standard of sweetness in wine after the liquor has fermented and been fined off. In short, if the wines have not a sufficiency of sugar added to them in the first instance they cannot be sweetened properly afterwards. If, on the other hand, they have been too much sweetened at first, a cloudy appearance and a mawkish taste, and pricking upon the palate, will be the consequences, and these evils cannot then be remedied. The above causes are those which have tended so much to bring our English wines into bad repute.

I think that I cannot do better now than give a digest of the manner in which I operated last, as being my best practice up to the present time. I must, however, make the preliminary remark that I last year used super-honey from my bee-hives for my Esperione wine, and with very evident improvement, and that for the future I intend to adopt it for all my wines as an assistant sweetening in the proportion of 3 lbs. to every ten gallons of wine. The mode of preparation which I adopt is to place 3 lbs. of honey and 3 lbs. of water in a stew-pan over a bright fire, gently simmer for twenty minutes, skim off the scum as it rises, and allow the liquid to become cool; it is then ready to add along with the sugar to the Grape-juice. I have a fine sample of honey this year for the purpose, and a magnificent crop of Grapes. I have been obliged to securely net over 700 superficial feet of the walls of this house to protect them from the sparrows, blackbirds, and bantams.

1864.—DIGEST.

To make nine gallons of Esperione wine. Take 90 lbs. of Grapes. October 27th gathered Grapes. Weight when picked from the stalks 81 lbs. Roberts's saccharometer floated in pure juice at 20°; added two gallons of clean cold water to the must, saccharometer then indicated 12½°. October 28th, saccharometer 14°; 29th, same as yesterday; 30th, ditto; 31st, saccharometer 12°. Pressed off juice, ran 7½ gallons, saccharometer then floated at 11°; added 1½ gallon of water at 80° by the thermometer, to the skins and pips, well stirred them about in it, and pressed off, saccharometer in the washings indicated 3½°; put it with the premier juice, and the united quantity measured 10½ gallons, saccharometer nearly 11°, allowed 2½ lbs. of loaf sugar per gallon, or 28 lbs. in all, along with the 3 lbs. of prepared honey, stirred every half hour or so till the sugar became dissolved, and the saccharometer then slightly exceeded 44°, covered over; atmosphere 60°. November 1st, saccharometer same as yesterday; 2nd, audibly fermenting, saccharometer 41½°; 3rd, saccharometer 40°; 4th, saccharometer 37°; 5th, saccharometer 34°; 7th, saccharometer 27°. Carried liquor from the working-pan in the kitchen down into the cellar, to a temperature of about 55°, and filled a nine-gallon cask, along with a gallon stone bottle, allowing the surplus to remain in a spouted jug for the purpose of filling up during

the working in the cask, whence the scum is ejected into a pan or large dish beneath the barrel, the latter having been placed on the stand so that the bung-hole might lean a little to one side. When the colander was used to pass the must through by force of hand, a greater quantity than I thought advisable of the pulp of the Grapes passed along with the juice into the working-pan, which is not now the case with the wine-press, so instead of entering the wine at once into the barrel from the working-pan, I used to pass it through cheese-cloth formed into the shape of jelly-bags. Four or six of these were tacked on so as to be suspended between the spokes of a short ladder, which was laid upon the backs of two chairs close to the working-pan, and a couple of milk-pans were placed beneath, in which the liquor filtering from the bags was caught, and the cask was filled with the strained wine as quickly as its running off allowed. November 8th, saccharometer 23° at bung-hole; 11th, saccharometer 17°; 13th, saccharometer 7½°; 14th, saccharometer 5°. Racked off the wine, sulphured the barrel, brought up the specific gravity to 7½° with dissolved loaf-sugar (because I wished the wine to maintain sweetness to please the palates here), and used finings. January 16th, wine attenuated again to 5°. Racked, sulphured, but omitted finings, as the wine had become clear. March 12th, fermentation quite completed, saccharometer 4°. A beautiful rich red wine, with a distinct bouquet, and a port wine flavour. Placed a clean square piece of canvass over the bung-hole, and smote the bung securely down, left the vent open a week, and then firmed the peg there also. I propose to keep this wine in the wood three years.

For a dry wine (claret) I should have allowed the above liquor to remain at 5°, as at its first racking off, and neither sulphured nor used finings until it had been attenuated down to W°—viz., water-float, when the sweetness is exhausted. On the other hand, if my object had been to secure a sweet effervescing champagne, I would have fined off the wine as quickly as possible, after its attenuation to 9° in the working, and bottled it off at a specific gravity of 7°, not later than the first rising of the sap, in the first quarter of March following its manufacture. Thus, when champagne is the aim, and attenuation begins to count under 9°, immediately rack off, sulphur, and apply finings. To do this place one of the large pans (I use a rather large sponge-bath) in front of the barrel, and draw out the tasting-peg, which should be placed not quite 2 inches above the tap-cork-hole, and when the wine begins to run slowly, quietly tilt the cask until thick sediment appears. Lower and run off the latter from the bung-hole into a pan, to allow it to settle down. Never use water to rinse out casks when the wine is to be returned into them. Some of the liquor worked in the gallon bottle can be used for that purpose, and the remainder to take the place of the sediment cast out of the barrel, so here we arrive at the utility of making the extra gallon. Proceed by rinsing the sediment clear from the inside of the cask, cleanse the outside with water and flannel, and replace the peg in front. Now reverse the cask on its stand, or by some means, so as to be able to gain convenient communication with the bung-hole now on the under side. Place about half an ounce of flowers of sulphur on the end of an old iron spoon, set light to the sulphur with the flame of a candle, and allow the fumes to pass through the bung-hole into the barrel. Replace the cask properly on its stand, re-enter the wine immediately, leaving space for rather more than a quart, for the purpose of adding the finings. These should be all ready prepared by having three days previously immersed a quarter of an ounce of isinglass in a pint of clear wine, stirring the liquid occasionally. The isinglass at the end of that time will be found to be quite dissolved; add a pint more wine to it, and mix well, then quietly pour it in at the bung-hole from a spouted jug with one hand, whilst with the other keep gently stirring to half-way down the barrel with a piece of lath. Make sure that the cask is full, put in the bung slightly, but leave out the vent-peg, and in all probability fermentation will now nearly if not quite cease. As soon as it has settled run off what clear liquid remains upon the sediment in the pan, enter it into the gallon stone bottle, or into the cask, if it is required there, and cast the residuum on to the manure-heap.—UPWARDS AND ONWARDS.

(To be continued.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

As the summer crops are removed, manure and dig or trench the ground before the autumnal rains set in; in stiff soils this

is of the greatest importance. Weeds at this season are very troublesome if any have been allowed to drop their seeds during the summer. The autumn-sown crops, such as Carrots, Onions, Spinach, &c., must be kept clear of weeds, otherwise these will soon overrun them. Remove or dig in all decayed leaves and litter. *Cabbage*, continue to plant out the main crops as recommended last week; keep the late seed-beds free from weeds. *Carrots*, slightly thin the autumn sowing, and keep them free from weeds; as soon as the main crops are full grown they should be taken up. *Cucumbers*, plants cultivated in a forcing-house must have every attention paid them; much of their future success will depend on their growth at this time, while the sun has some power and influence on vegetation. Keep the main shoots tied to the trellis, and when they reach the top of the house stop them, but not before; slightly sprinkle the plants every fine day with a fine rose on the syringe. If green fly make its appearance, smoke the house with tobacco. *Lettuce*, plant some of the Cabbage kinds for winter use in frames as these become unoccupied; the soil in which they are planted should be very light. Give but little air till the plants begin to grow. Prick out on a sheltered border some of the Cos kinds previous to planting them where they are to remain through the winter. *Onions*, slightly thin the autumn sowing when they are a few inches high. Immediately the main summer crops have done growing pull them up, and house them when dry. *Parsley*, cut down a portion of the spring sowing so that it may push again before winter. Pot some good roots to put in a forcing-house for furnishing a supply during severe weather.

#### FRUIT GARDEN.

Apples and Pears that have been gathered within the last fortnight should now be looked over very carefully, when it will be found that those that were bruised, or in any way injured, have begun to decay, and unless removed will infect the others. Filberts are now ripe in most situations, and should be gathered. They keep well packed firmly in a moderate-sized hamper. In this way they do not suffer from excess of moisture, and the kernels keep plump and sweet till May or June. It will be of benefit to Peach trees to go over them and cut out those shoots which have borne fruit, but have not a terminal wood shoot; those remaining will be benefited by the clearance, as they cannot be too far apart at this season. It is now time to think of making preparations for filling up vacancies on the walls with young trees, and, perhaps, in some cases, judicious transplanting may be considered advisable. In either case, the sites must be properly prepared with fresh maiden loam; if the borders have been properly constructed with regard to drainage, and without this no good results can be expected, but little preparation beyond removing a considerable portion of the old soil and supplying its place with new, will be required.

#### FLOWER GARDEN.

The principal work in this department will now be confined to mowing and cleaning, and if neatness is to be maintained this will require constant attention; also see to thoroughly clearing off weeds and moss from gravel walks, and roll frequently when wet to keep the surface level and smooth. Cuttings of Laurels, Privet, Box, Aucubas, and various other evergreens, may now be put in, and the layering of others which do not strike readily from cuttings proceeded with.

#### CONSERVATORY AND GREENHOUSE.

The conservatory will still be kept gay by fresh introductions of plants in bloom, and the removal of such as begin to decay. It will, however, not be desirable to overcrowd the house at this season, as the permanent inmates will require to have all the light and air possible, in order to ripen their wood. The climbing plants in these and other houses should likewise have a weekly regulation, shortening back the shoots going out of bloom, and training the remainder in a suitable manner to show a free natural habit. Climbing plants in pots, as *Kennedyas*, *Hardenbergias*, &c., should likewise be neatly tied to thin trellises, and exposed to a good share of light. The borders in the conservatory will require less water, and the supply should be still further reduced as the days shorten, making a difference, however, with strong-rooting plants, which will require larger quantities than others. The buds of *Camellias*, where too thick, should be thinned out according to the strength of the plant; water such as have not been recently potted with clear soft water, which will help them to perfect good-sized flowers. A portion of the stock of *Chrysanthemums* should be placed under glass to forward them; thin out the bloom-buds, and water with liquid manure. In arranging *Pelargoniums* for the

winter allow them the lightest and warmest end of the house, unless there is a separate house for them, when the Fancies should have the best end. Keep them close to the glass, and do not allow them to touch each other; those cut back late may yet be shaken from their old soil and repotted, placing them in a slight bottom-heat afterwards, to facilitate their quick rooting. Let the greatest cleanliness be preserved in every house. The pots should be frequently washed on the outside, and moss prevented from growing. Make it a rule to clean out the conservatory after the morning's watering, that it may become dry early in the afternoon. Specimen plants should be frequently turned round to prevent their becoming one-sided. In cases where there are many stove plants in the conservatory, it will be necessary, in the event of the weather becoming cold and wet, to use a little fire heat, but be as sparing of this as circumstances will allow, particularly if there are any other things in the house likely to be injured by being kept too warm. In this case it will be advisable to dispense with stove plants, even at the expense of rendering the house somewhat bare of flowers, rather than keep them there and run the risk of injuring other plants on their account. Be careful not to overwater plants brought from the stove, and also to use water at a temperature of 70° or 80° for these, as using cold water to plants that have just been brought from a warm house injures the young and tender roots, shortens the duration of the blossoms, and often ruins the plant. Use weak liquid manure for *Salvia splendens*, and *gesneriflora*, so as to preserve the plants in a vigorous state, and keep them blooming as long as possible.

#### FLOWER FORCING.

Those who intend to provide a rich display very early in the spring should now be in the market, and select plants adapted for the purpose, and of a superior character as to amount of flower-buds, and form of the plant. Such are the various *Rhododendrons*, *Azaleas*, of the nudiflora class, with various hybrids; the *Rhodora canadensis*; *Ledum latifolium*, and *thymifolium*; *Kalmia latifolia*, *angustifolia*, and *glauca*; *Andromeda pulverulenta*; the *Daphnes*, especially *cnocorum*, and even the old *Polygala chamæbuxus*. These, with more of the same tribes, although not of very recent introduction, will be found to add greatly to the spring display, and also to the diffusion of a most gratifying fragrance. Such should be obtained forthwith, potted in smallish pots, and plunged in a warm corner in the garden, whence they may be successively introduced to the forcing-house, from the middle of November until February.—  
W. KEANE.

#### DOINGS OF THE LAST WEEK.

AFTER three weeks of scorching weather, we had on Thursday a fine mild rain that will do vast good in this neighbourhood, and will affect nothing injuriously except the brilliant appearance of the flower-beds. The heavy rains in August made these beds very dismal, but they soon regained their former beauty, and would have been brighter than in the end of July and the beginning of August but for the faded blooms that required to be picked off, as a few of these in a bed detract from the interest of the whole. Some *Geraniums* very considerably drop their faded petals, and therefore do not injure the appearance of others in the truss; others bloom first in the centre and decay there first, and these blooms must be nipped out if the others are to appear to the best advantage, and, where there is much ground to go over, the labour of doing this is immense. The high keeping of flower-beds is everything as respects the pleasure to be derived from them, and one bed in the highest order, never showing a faded leaf, a faded flower, nor a plant suffering from drought, will produce more pleasure than a dozen or a hundred of beds whose appearance testifies that the extent and quantity are beyond the labour power at command. The smallest garden, if well kept, will never convey the idea of limited resources; but the largest garden, if rough and untended, will ever conjure up the idea of poverty of means. We write feelingly, for to keep the flower-beds and pleasure-grounds at all up to the mark during the last three weeks involved neglecting other departments to some extent. One of the most troublesome of *Geraniums* has been that fine free bloomer the *Trentham Rose*, but which, unfortunately, blooms and seeds first at the bottom of the truss, and will often show a dozen of staring seed-pods, whilst many blooms remain open and opening in the centre. In such sunny weather in the autumn this is peculiarly the case with this fine old variety. The other plants that baffled us most

were Dahlias, tall and dwarf, which flowered about half their usual size, and began to decay prematurely from want of water at the root, which we could not find time to give them. Borders of a superior kind of Purple Spinach, which looked very nice before the drought, are now becoming weedy and seedy-looking. Borders of old favourites of ours, Love-lies-bleeding and Prince's Feather, began also to show the effects of the heat though very strong healthy plants, and we hope the rains of Thursday will revive them again sufficiently for a month longer. As yet, and with little or no watering, the Verbenas have stood well. With us the best double-flowered Feverfew seldom does much after such dry and scorching weather, and yet we are told it stands all the sun round London uninjured. It should be known, however, what amount of water it receives in such circumstances, as a gardener in the country, with little water except what the clouds give him, can hardly expect to grow it so well as they do in places where a hose can be fitted to a tap and the ground be flooded all round the plants.

#### KITCHEN GARDEN.

Very much a repetition of former weeks. Now that rain has come will turn out some more greens, planting them thickly; they may come in useful in spring, when the forward crops are getting exhausted. The extreme heat will cause Peas to give over bearing sooner than usual. The weather just suited Dwarf Kidney Beans, which bore immensely, and the rains will greatly help Scarlet Runners, the heat being rather too much for the free setting of the blossom. Gathered Tomatoes, and thinned the leaves of the remainder, so as to give the fruit all the air and light possible. Sowed Kidney Beans in pots out of doors, to be moved under protection as the nights become cold. Cleaned Mushroom-beds by sweeping with a hair broom, so as to leave the surface smooth and firm, which prevents the spawn running into anything loose, instead of throwing up Mushrooms. A slight sprinkling of litter or rough hay on the surface keeps beds out of doors, or under open sheds, more uniform in heat and moisture. Examined fresh-planted Cabbages for grubs. Gave manure water before the rain to Cauliflowers coming on, and picked over a lot of stable litter, shaking all the dung out of it, and as it was very dry, built it in a stack, which will be useful for protecting in winter. Had the shortest mixed up with short grass, leaves, weeds, sweepings, &c., which will be a nice heap to go to when we wish to have a little heat thrown into a bed for various purposes. Scattered ashes and lime over young Lettuces, Radishes, &c. The dryness of the ground, and little soft fruit left exposed, have saved us from so many birds, as have invaded some other gardens. Some accounts speak of scarcely an Apple or a Pear being left unpecked, and when once pecked, of course they are only fit for present use. Even hard Peas may do for roasting. Perhaps even in such cases there may be a spice of exaggeration against the poor birds. We recollect of an old man, and a truthful man in other respects, who never spoke of marauders and vermin, except as millions of them, and tens of millions. He evidently had picked up the big word without having the slightest idea as to the numbers involved. For ourselves, though not untouched, the birds have been very considerate on the whole; but whether from gratitude for keeping the gun quiet, time alone will tell.

#### FRUIT GARDEN.

Much the same as last. Gave a little fire to Fig-house after the rain, to help the latest fruit. It was hot enough for anything before without any fire heat, and we always think sun-heat is the cheapest and the best. Gathered the most of the earlier fruit before the rains came. Removed all weeds and runners from Strawberry plants in pots, and gave them a little more room, so that the sun may play on them more fully. The rain that comes will not be likely to injure them this month, but if much come dusting over the surface of the pot with soot or superphosphate of lime will do the plants good, and the strength will be gradually washed among the roots. As much as can be held between the thumb and two fingers will be enough of soot for a six-inch pot, and as much as can be held between the thumb and finger will be enough of superphosphate at one time for a similar-sized pot.

#### ORNAMENTAL DEPARTMENT.

Our work here has chiefly been devoted to the following matters: Picking, cleaning, and regulating flower-beds. The rains and the subsequent heat have changed some of our first arrangements, and it is now too late to make everything square

as it was at first, as some lines and rows will be found to have filled double the space they were intended to do—a very fortunate thing when a more tender row has so far given way that we are rather glad when its neighbour fills up its place. We are always learning by reverses as well as successes. We think we mentioned how very fine a row of Golden Chain was with us in a ribbon border. It was the third line from the grass verge. The border is planted thus:—Cerastium, Lobelia Conspicua, Golden Chain, Purple King Verbena, Centaurea candidissima, Brilliant Geranium, Aurantia multicolora Calceolaria, Stella Geranium, and tall Ageratum for the centre. This border pleased us very much until the rains of August, which encouraged the Verbena to grow very strong, so as slightly to overhang the Golden Chain. We think ourselves that the water thrown by the winds from the flowers of the Lobelia poisoned the Geraniums, as afterwards the fine large beautiful leaves began to drop off, so that now they scarcely form a feature in the border. In other places, where Golden Chain and Cloth of Gold are freely exposed, but still slightly protected by shade, the leaves are all that could be wished. On the opposite border Cloth of Gold was substituted for Golden Chain, and Paxtoniana Lobelia for Conspicua. Part of this border is shaded by a fine tree, and where this shade extends the Lobelia and the Cloth of Gold are all that can be desired; but where fully exposed to the sun, both are showing signs of giving way. Seedlings of Lobelia speciosa have stood the dry weather well without watering, whilst cuttings have suffered considerably. The little dwarf single Marigold alluded to the other week, seems to care little either for moisture or dryness. It has been and is a dense mass of mottled orange, and besides planting, it has received no other attention and no water from the pail in the hottest weather. Has any one noticed the result above alluded to with regard to the Golden Chain and the Purple Verbena? One condition unfavourable to the Golden Chain was its being planted along the north side of a ridged border, that faced the south and the north. Had we suspected the result we certainly would have docked in the Verbena, so that it should not in the least have overhung the Geraniums. We have long noticed, that when the faded petals of some Scarlet Geraniums are deluged by rains, the liquid falling from them will decay not only other petals, but the leaves on which it rests. We have frequently noticed leaves all green to-day all mottled on the second day after drifting rains.

The picking off decayed blooms is, therefore, desirable, independently of the neatness and good keeping it secures. Men not accustomed to this sort of work, however willing, make but small progress. Much of the work is done with the knife, and in some cases it is necessary, and then it passes from one hand to the other before it reaches the basket or pan. Boys brought up to it when young, will do double or triple the work, dispensing mostly with the knife, nipping all out and over between the nails of the thumb and finger, and in many cases using both hands at once. It is quite a treat to see how quickly some boys and young men can thus clear every faded leaf and bloom from a bed.

The dry weather has again enabled us to overtake our short grass, and we mention it chiefly for chronicling a useful fact, as respects the mowing machines. What we chiefly use are small ones for one man, of Messrs. Green's make; but the principle of all the makers is very much alike. The grass after the wet, and then the great heat, became rather silky, and the knives refused to clear all up as they used to do. The knives were in fault as well as the grass, the cutting side from long use having become very smooth. The axil on which the knives are fixed was taken out, and the one end changed to the other end, so as to bring the other edge of the knives in contact with the plate, and everything is again cut up, be the grass stiff, or as fine and silky as the finest wool. This may be generally known, but it is the first time we thought of it, and we forget whether such a matter is alluded to at all by the different makers.

Went on wholesale with cuttings, placing them in frames and pits; exposed struck Verbenas to the open air, and prepared for housing the more tender plants.—R. F.

#### TRADE CATALOGUES RECEIVED.

R. P. Ker, 4, Bassett Street, Church Street, Liverpool.—*The Hyacinth, its History, Culture, and Propagation, with a Descriptive Catalogue of Dutch and other Bulbs.*

Louis Van Houtte, Ghent, Belgium.—*Oignons à fleurs.*

COVENT GARDEN MARKET.—SEPTEMBER 23.

MARKET well supplied, but not to the same extent as two or three weeks ago. Peaches and Nectarines may be considered nearly over. Filberts and Cobs are not likely to prove an average crop; but Walnuts are very plentiful. Vegetables are abundant. Of Potatoes the supply is very heavy, and unfortunately there is ample evidence of the wide spread of the disease.

TO CORRESPONDENTS.

\* \* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

W<sup>o</sup> also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

BOOKS (*A Subscriber*).—Stephens's "Book of the Farm." (M. W.).—"The Garden Manual" and "The Vine Manual." The first can be had free by post from our office for twenty postage stamps, and the second for thirty-two stamps. (T. E.).—There is no book devoted to directions for laying out large pleasure grounds, beds, &c., but the first volume of McIntosh's "Book of the Garden," price £2 10s., contains full directions and many illustrations. The "Fern Manual" contains the entire culture of stove, greenhouse, and hardy Ferns. You can have it free by post from our office for 5s. 4d. in postage stamps. (J. W. M.).—Bentham's "Illustrated Handbook of the British Flora," £3 10s.

LAWN INJURED BY GRUBS (*Hortus*).—The grubs sent are young larvae of the common cockchafers. You should have set children to kill the beetles in the summer. The lawn should be turned up and ducks turned in. Watering with gas tar water repeatedly may be of service, as the grubs are but small at present.—W.

ESSEX RIVAL PEA.—Will Mr. Eley oblige old "NICKERBOR" with the percentage of Essex Rival Pea, for hereby "hangs a tale?" Should this not reach Mr. Eley, "NICKERBOR" will feel obliged by any of his friends forwarding the information.

PLANTING LILUM CANDIDUM (*A. Sim*).—Now is a good time to take this up, planting as soon afterwards as convenient. It should be planted in good loamy soil, though it will do equally well, if not better, in peaty soil, stirred to a good depth, and if light a little well-rotted manure or leaf-mould will be beneficial. The roots should be covered about 3 inches with light rich soil. The situation should be open. Good, sound, flowering roots are worth 3s. or 4s. per dozen.

TREATMENT OF NIGHT-BLOOMING STOCKS (*Idem*).—They may be procured of any London or large provincial nurseryman. They are of the most easy culture if kept near the glass in a dry, cool, airy part of the greenhouse. No more water should be given them during winter than sufficient to keep them just moist, and, as they are liable to damp off at the collar from frequent and injudicious waterings, good drainage should be provided. If kept cool, dry, and airy they grow and bloom through the winter.

DAHLIA—FUCHSIA—ASTER (*N. B.*).—If the seedling Dahlia prove to be very dwarf it will be an acquisition. The Aster is valueless, and the Fuchsia one of a myriad that are unnamed.

THE PINE-APPLE MANUAL (*Horatio Pigott*).—There are not separate drawings supplied of fruit, succession, and nursing-houses; but there are a section and a ground plan of the fruiting-stove, and the others are stated to be of the same width, the dimensions differing only in length. The range, of course, will be the same height throughout, otherwise it would be unsightly, and more expensive to build. The height can be easily ascertained from the section. The glass roof is in one plane, and the plants can be raised so as to be at a proper distance from it whatever may be their stage of growth. It is easier to raise or lower the plants than to move the glass; therefore it is best to have the glass at a uniform height from end to end of the range; and the width being uniform, the heights of the back and front walls must each respectively be so. The proportions you mention for the length of the fruiting, accession, and nursing compartments are nearly enough those recommended by the author. *Fig. 4*, it should have been stated, is a section of the Pine-stove at Enville Hall, which, however, is readily understood from the context. Sheds at the back of ranges of hothouses should run the whole length of the range. They are always understood to do so by practical men. Amateurs will find it not so easy to perfect the fruit of the Pine Apple in April as they would in May, June, and July; and Queens can be the most easily started into fruit; but the plants must first be fairly grown; their growth checked gradually, but not through starvation by cold (see page 24). The directions given for the successful growth of a hundred plants are applicable to that of ten, or to that of one; but, amongst many, some may fail without the loss being much observed compared with the failure of a few where only a few are grown. You may grow a single plant in a single box frame—Mr. Mills found it possible to do so, producing a Providence fruit of the weight of 16 lbs. The compartments into which the range is stated to be divided are each about 15 feet by 104 feet, and seven such can be comprised in the range. If you divide the length, 77 feet, into seven compartments you will find their length run across the range.

STRIKING CUTTINGS OF CERASTIUM TOMENTOSUM (*W. B. M. L.*).—1st. This is not the right season for striking cuttings of *Cerastium tomentosum*, though they will do if inserted 3 inches apart in light sandy soil, and in a dry warm situation, also in a cold frame, and in pans placed on a hotbed. The best time to take cuttings is in March or April, 2nd. The process of taking cuttings is very simple, and merely consists in taking a bundle of the shoots in one hand, and cutting them off with a knife just below the hand as in reaping, the shoots being cut about 6 inches long. 3rd. Without any further trimming they are to be planted with a dibble, 3 inches apart, where the edging or line is required, inserting them 3 or 4 inches, or two-thirds their length, in the soil, and closing the soil firmly around them. A good watering is then given, and they are watered afterwards during dry weather until established. In March, April, and May the roots may be divided; every part will grow, no matter how small. The divisions should be planted 6 inches apart, for a single line or edging from 6 inches to a foot in width, and in a double row for lines or bands of greater width. At the same season the cuttings may be inserted in the same manner, 3 inches apart, in any open situation, where, duly watered, they will be well rooted by heading-out time, and may be taken up with hails and planted where the edging is required. Cuttings from 1½ to 2 inches long inserted the same distance apart in pans of sandy loam, with an inch of silver sand as a surfacing, and, after watering, placed in a frame will be well rooted in a fortnight. They may then be hardened off, and afterwards pricked off 3 inches apart in sandy soil in a light situation, shading for a few days, and in three weeks or a month planted out 6 inches apart where they are to remain. Your 3rd and 4th queries are answered by the reply to the 2nd, and the 5th also, only for so narrow an edging the plants need not be planted nearer than 6 inches, but the nearer they are the more quickly will they cover the ground, or form that which is desired. 6th. It is to be kept in shape by clipping with ordinary garden shears the irregular growths, whether side or upright branches, in the first week in July, when the plants will have grown sufficiently to form the line required, the clipping tending to make the plant produce those tiny sprays which are one of its most attractive features. The first week in every month it should be clipped at the sides to keep it of the right width, and at top to preserve the proper height, and up to October this will be all it requires. If allowed to remain it will in May be a mass of white bloom far surpassing anything of the colour at that season. When the bedding plants are put out the *Cerastium* should be cut off quite close, and the creeping roots removed on both sides so as to form the line of the desired width. In a month it will be all that could be wished after a slight trimming. To have it in good order when the bedding plants are put out it should be trimmed in April. After the second year it will require to be taken up and replanted.

VALLOTA PURPUREA NOT FLOWERING (*A Young Beginner*).—The plants being evergreen require light in winter, and ought not, therefore, to have been kept under the greenhouse stage, for what with the drip from the plants on the stage, which would cause the roots to rot, and the diminution of light, the growth could not be perfected. Instead of placing the plants under the stage in December, and keeping them there until March, we advise their being retained on the stage in the greenhouse, and in the lightest and driest part, from the commencement of September to the end of March, with no more water than sufficient to keep the leaves from flagging. When the flower-scape shows the plant should be well watered, and continue to give water while it remains in bloom. When growth commences water abundantly till the leaves attain their full size, after which gradually reduce the water supply, and expose to light and air. It is an evergreen, and requires more light when ripening or perfecting the growths made than during their formation. Ripen the bulbs well in autumn, keep dry when at rest, and never in the dark, water freely when growing, and do not overpot. With this treatment it is the freest-blooming and one of the handsomest and most useful of the evergreen *Amaryllids*.

POTTING AND PLANTING VIOLETS (*Peppy*).—The Russian and Neapolitan Violets do well either in pots or planted in a bed. They are best in pots when employed for the decoration of the greenhouse or drawing-room, the flowers not being taken from the plants or but sparingly. Plants in pots have the advantage of being readily removed from place to place without injury. Violets are best grown in beds when intended solely for the purpose of furnishing out flowers for bouquets, filling small vases, &c., as the plants give more and a greater continuance of flowers than when grown in pots.

**VINES IN AN ENGINE-ROOM (B. L. T. Steam Engine).**—The dust, we should think, would be great, and the amount of steam excessive; to say nothing of the heat, which would be much too high for Vines; these combined would render successful Grape-growing questionable. But with little dust, steam entirely under command, and the heat controllable, you may grow Vines in your engine-room with a fair amount of success. The heat will be regular, and will require to be reduced by making a greater provision for the admission of air than usual. A border will be required for planting the Vines, and that will have to be outside, and, as the heat will be too great for the Vines to remain in the room all the year round, provision must be made for drawing them out after the leaves fall, and introducing them after a period of rest. Instead of opaque you must use clear glass, and have wires fixed 15 inches from the glass to train the Vines to. Rough plate glass would answer, and it may be procured of the dealers advertising in our columns. The thick glass known as "mill glass" would not suit your purpose. Hartley's rough plate glass is the best. In your room, 20 feet by 13 feet, you might have four Vines—two of Black Hamburg and two of Buckland Sweetwater. It is for you to decide whether there can be sufficient ventilation provided to bring down the heat to 45° at night when the Vines are first introduced, gradually increasing the temperature so that it may be 55° when the Vines are in leaf, and 60° when the fruit is setting and swelling. These temperatures may be increased 5° by 1 p.m. on cloudy, dull days, 10° on cloudy days with clear intervals, and 15° or 20° when the sky is cloudless; increase in temperature being accompanied by an increased amount of ventilation. You must also decide whether the air of the engine-room can be kept moist—partially, completely, and regularly—and whether that moisture can be so reduced as to afford a dry atmosphere. If there is nothing to fear on these heads, and little or no dust (which can be washed off the leaves by a good syringing), then you may grow Grapes with a fair amount of success; but it is doubtful whether the alterations, &c., required to make the room suitable for the growth of Vines would not be as costly as erecting ainery heated by the waste steam of the engine.

**INSECT IN CELERY LEAVES (H. H. C.).**—It is of very common occurrence. The maggots under the outer skin of the leaves are the larvae of the Celery Fly, *Tephritis onopordinis*. The only remedy is to pick off the blistered leaves, and crush them and burn them.

**LANDLORD REMOVING SHRUBS (H. J. G.).**—Your landlord has no right even to come into the garden you rent of him, much less to dig up shrubs and carry them away. You might sue him in the County Court for the damage, and you may order him to quit as a trespasser, and give him into custody if he refuses to leave. You had better consult an attorney.

**PEACHES DROPPING—GRAPES SHANKING (Watchful).**—Your Peaches which drop off sweet and juicy are ripe, and all you want is a net fixed about a foot from the ground so that they may drop into it instead of on the ground. We may have misunderstood you; if so, write again. The cause of the Grapes showing a disposition to shank is probably the drainage being inefficient; and crops ripening during the wet weather we had a month or so ago, with the Vine roots similarly circumstanced, also exhibited signs of shanking. The usual cause of shanking is the roots being in a cold, wet, outside border, and the evil is aggravated when the roots are deep and cold rains set in at the time of ripening. We would recommend the drainage of all Vine-borders to be very effective, and the border to be made inside, or so much of it that the Vines can be planted inside. When the borders are outside they should be protected from cold rains after the Grapes change colour.

**DIANTHUS HEDDEWIGI HARDY (Idem).**—It is hardy in dry well-drained soil, and especially in that of a sandy gravelly nature; but in cold wet clay soil and exposed situations it is quite tender, requiring a dry sheltered situation, or the protection of a dry cold frame or greenhouse.

**KEEPING GRADES (L. P.).**—Grapes allowed to remain on the Vine keep better than by any other mode.

**MELONS SPLITTING BEFORE RIPE (R. C. L. H.).**—They split from the rind not expanding in proportion to the growth. Splitting usually occurs after a continuance of dry weather, when the rind becomes nearly as hard as that of a Pumpkin, and it splits from the pressure of the matter impelled into the fruit. We know of no remedy. As a preventive, keep the atmosphere and soil moist after the fruit begins to swell. A deficiency of moisture in the atmosphere and at the root gives a check to growth, and the consequence is the fruit does not swell, but becomes rind-bound. During very bright weather slight shading is also beneficial, especially when the fruit is not protected from sun by the leaves. It is only when Melons are setting and ripening that they need a dry atmosphere, at other times they require as much moisture as Cucumbers in order to swell to a good size, and that they will do in the first thirty days after setting or never. If they are kept moist when they ought to be dry they crack.

**LADY DOWNE'S GRAPE (Pampinus).**—It is, as you say, "a Grape which has now been some time before the public, and is acknowledged to be one of the best late Grapes." It is a free strong grower, and it never acts badly with us, but, on the contrary, requires much more thinning than the Black Hamburg from setting its berries so thickly. For productiveness it is equal to the Black Hamburg, often showing two and three bunches on a shoot when the wood has been properly matured in the previous year. It is equally productive on long rods as when a closer system of pruning is practised, but it gives larger bunches by the rod than by the spur system of pruning, as is the case with the majority of Vines. It requires a heated vinery to have it in perfection, and is then a productive and excellent late Grape.

**NAMES OF INSECTS (Lieut. Col. Forster).**—It is the grub known to gardeners as the Leather Coat. It is the larva of the daddy long-legs (*Tipula*). No remedy is known but turning up the earth with a knife round the Cabbages, Lettuces, &c., attacked by the grubs. *Miss Stanley's* insects are one of the species of scorpion-mites (*Chelifer cancrroides*). They are often found fixed by their claws to the limbs of flies and other insects, on which they evidently feed. (*J. L. J.*)—The insects sent are *Ptinus hololeucus*, a small beetle imported into this country from Russia in a cargo of leather. It is not known certainly that they are injurious. (*J. Sanders.*)—The small orange-coloured grubs are those of a species of minute gnat, which has been described under the name of *Tipula cerealis*, but which belongs to the genus *Cecidomyia*. This is the first time that we have heard of its existence in England, having been previously noticed in Baden. It has been suggested that the fields of Barley should be mown at the time the gnats are developed, as this would prevent their being reproduced.—*W.*

**NAMES OF FRUIT (D. R.).**—*Apples.*—1 and 4, Hollandbury. *Pears.*—1, Gansel's Bergamot; 2, Gendesboim; 3, Fondante d'Antonne. (*E. Hoare.*)—1, Duchesse d'Angoulême; 2, Louise Bonne of Jersey; 3, Swan's Egg; 4, Gansel's Bergamot; 5, Bonrré Diel; 10, Napoleon; 12, Comte de Lamy; 14, Louise Bonne of Jersey; 15, Swan's Egg; 17, Bel-Hissine d'Hiver. (*G. Brown, Rayners.*)—1, Williams's Bon Chrétien; 3, Beuré Lefevre; 4, Beuré Diel; 5, Vicar of Winkfield; 6, Duchesse d'Angoulême. (*W. G.*)—1, Dumelow's Seedling; 2, Lemon Pippin. (*W. Brown.*)—1, White Doyenne; 2, Beuré Diel; 3, not distinguishable at present, but certainly not Seckle; 4, Flemish Beauty.

**NAMES OF PLANTS (J. F. R.).**—The specimen was too dried up for us to be certain—moist moss should always be put into the box with specimens. We think it is *Anemone japonica*. (*H. W. S.*)—The specimens were smashed, but they both seem to be of the Pistol-plant, *Pilea muscosa*. (*Gregory.*)—1, *Engenia Ugni*; 3, *Eriostemon buxifolium*; 4, *E. myoporoides*. (*G. Brown.*)—*Chloris verticillata*. (*A Subscriber, Hereford.*)—*Xanthum spinosum*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending September 23rd.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

DUCK-FOOTED GAME FOWLS—POULTRY CLUB STANDARDS.

ARE duck-footed Game fowls really disqualified when exhibited? Mr. Hewitt stated that duck-footed fowls are "as useless for fighting as exhibiting;" and at the Loughborough Poultry Exhibition some fowls were disqualified on that account. Referring to the "Standard of Excellence" recently published by the Poultry Club, duck-footedness is regarded as a "defect," but not a "disqualification;" and I can mention instances in which a duck-footed Game Bantam cock has received the first prize from some of our first-class poultry judges. The great

desideratum is a standard by which poultry exhibitors and judges are to be guided; but whether the one authorised by the Poultry Club is to take that position or not, it is not for me to say. Many times the awards at one exhibition are reversed at another in the same week on account of the judges having different standards. Exhibitors begin to be greatly discouraged; some of them cease to exhibit altogether, accusing unjustly the judges of dishonesty.

Again referring to the "Standard," I find that Black Bantams with legs of any colour except black or dark leaden blue, are disqualified; yet at the late Keigley Show, where your correspondent states that "some very excellent Game Bantams (Black-breasted Red) were shown, and also some capital Browns." Black Bantams with light-coloured legs took the first prize. It is very galling and looks suspicious when an exhibi-

bitor sends a pen of poultry to an exhibition and takes a first prize, and again in a few days sends the same birds to another show where a pen that took a very inferior position at the previous show now occupies the "place of honour," and his own does not even get "mentioned." Can this state of things be remedied?—J. H.

[I willingly reply that I maintain my previously expressed opinion—that being "duck-footed" is really a disqualification in a Game fowl for exhibition. As regards the "Standard of Excellence" "J. H." alludes to, as published by the Poultry Club, its dictum on the "duck-foot" in Game fowls may, for aught I know, be binding on those who compiled the work named: but as I myself did not lay down those rules, nor comply with the written request of the Poultry Club to revise such rules before publication, I cannot hold myself responsible as one who is invariably adherent to its standards. That many of the characteristics of the various breeds are therein described with precision I unreservedly admit, and also that in the generality of cases much really useful information may be gleaned for the guidance of an amateur as to the first selection of his poultry. I have also frequently arbitrated, even so late as since the publication of the "Standard of Excellence," for members of the Poultry Club, by appointment at public exhibitions, not in subservience to the printed rules, but, on the contrary, exclusively by my own opinions; so that I think our views are not so widely dissimilar as your correspondent would desire them to appear to be.

Since perusing the letter of "J. H." I have purposely ascertained the private opinions of several of our principal poultry arbitrators, and without any one exception their views are conclusive with my own, as to the "duck-foot" in Game fowls. As in all other similar cases, there ever will be a difference of opinion as to the comparative excellence of living stock. Look, for instance, at the cattle awards at Birmingham and London shows, held only within a few days of each other. Although besides a "standard," such arbitrators have the additional advantage of a measuring-tape to determine girth, &c., how frequently have reversed decisions ensued, though they have been as frankly admitted by the judges themselves as arising altogether from alteration of condition alone, and yet in both cases quite as justifiable!

It is not the formation of rules, but their after-application that brings with it difficulty and dissimilarity, especially when the health, or even the life of the objects of the awards, is quite as precarious and open to sudden alteration as our own. Even only a few weeks since, I gave a first prize to a bird in apparently perfect health, yet which died in less than an hour after, leaving both its companions as well as ever. In only ten minutes after the award was given in, it could not then (under my own arbitration) have gained a prize at all.

As regards the statement of "J. H.," that some amateurs cease to exhibit, simply on account of a contrariety of opinion held by judges, no doubt exists; there always are some few persons who cease to exhibit whenever they are not certain of personal success, and most probably in future days it will always continue so to be. These declensions, however, seem hardly reconcilable to the present general success of poultry exhibitors, for despite the withdrawal of the individuals alluded to, the succession of new exhibitors is largely and continually augmenting. The hopes expressed by your correspondent that never-varying decisions will be ultimately attained, I feel assured are visionary, and quite beyond universal realisation.

I am sorry to entirely differ from the statement of "J. H." as to the colour of the legs of the Black Bantams shown at Keighley. They were dark lead colour, and might have been made much deeper in hue, by simply oiling them previous to exhibition, which is admissible. "Light-coloured legs" in this breed I repudiate as strongly as any one can do. I will not myself venture to determine the motives for withholding the greater portion of the paragraph extracted by "J. H." from your report of the Keighley Show, in THE JOURNAL OF HORTICULTURE. He quotes, "Some very excellent Game Bantams (Black-breasted Reds) were shown, and also some capital Brown Reds;" here "J. H." strategically stops short, though the same sentence goes on to say, "the latter, however, were a little too large for competition, though excellent specimens for brood stock." The best pen of Black-breasted Reds shown in this class was a hen short, consequently they were compulsorily passed over.

If your correspondent really only knew by experience how much more easy a task it is for a disappointed exhibitor to cavil at an award when made, and opposed to his interests,

than to predetermine such premium at the outset, I feel confident I am doing him justice when I say, he would not then have written as he has now done.—EDWARD HEWITT.]

### MIDDLETON (NEAR MANCHESTER) EXHIBITION OF POULTRY, PIGEONS, AND RABBITS.

The seventh annual meeting of this Society was held on the 21st instant, and, as regards both the numbers of specimens competing, and also the quality of the birds themselves, proved a great advance upon those of former exhibitions.

This Show has many advantages—among the most prominent, the place of exhibition is peculiarly pleasant and undulating, whilst the dense population of the closely surrounding large towns ensures, weather permitting, an attendance of visitors that few strangers could believe possible unless themselves eye-witnesses. Great numbers of persons availed themselves of omnibuses, that for the day plied every half hour from Manchester. These, in all instances, were filled until not another individual could be accommodated, whilst the railways put on "special trains every quarter of an hour," bringing such a regular influx of sight-seers, that the parties in care of the admission gates had actually to be changed every hour from sheer fatigue. The receipts must, therefore, have been of a very satisfactory nature indeed, and, as the managing Committee state they intend to eventually make the Middleton Exhibition second to none, a still further increase of the prize schedule may confidently be looked forward to another season. This year the entries of poultry alone were considerably above five hundred pens, irrespective of an entry of more than one hundred pens of Pigeons, and a good competition likewise in Rabbits also.

The night previous to the Show was enough to quite damp the ardour of even the most sanguine of the Managers, a dull, dark, leaden sky, portending an unfavourable change of weather. Go where you might, the fears of bad weather seemed the only theme of conversation. Weather-glasses were examined minutely, and at very brief intervals; long-indulged hopes now gave way altogether, for about eight the rain began to fall in torrents, and without the least apparent prospect of a change. This continued far into the night, or, more truly, the early morning of the Show day. About daybreak, however, the storm (for thunder had prevailed in the distance many hours) suddenly abated, the sun began to gladden the tops of the hills, and it would be difficult to say which rose the quicker, the blighted hopes of all concerned, or the mercury of the now utterly neglected barometers. Had the weather continued as unfavourable as anticipated, not only would it have proved fatal to the best interests of the Society itself, but would, without doubt, have resulted in frightful injury to the poultry exhibited, for they were mostly shown in pens of bee-hive shape, entirely open to every change of weather that might ensue. Nor is the construction of this kind of pen as to want of shelter the only objection; another, and equally grave one, is also inevitable. If fowls are required to be examined in hand by the Arbitrators, prior to giving their awards, the taking out of one bird from a pen gives almost invariably the opportunity of escape to its companion, and the Game pullets were not slow to avail themselves of the chance of so doing, although several men were provided to obviate this difficulty, for each pen had to be fairly lifted before any fowl could be got at without injuring its plumage; and of necessity at the close of the Show when repecking, the same objection retarded operations very considerably. Again, the water-can for fowls being fastened to the pen inside, at every lift the contents were upset, causing a damp pen for some considerable time.

Now, on the subject of exhibition pens, it may be well to name a fact that beyond dispute proved itself at Middleton—viz., that fowls have as great a distaste for hot sunshine as they have to exposure in sudden showers. Among a considerable length of pens that were constructed of wood with wire fronts only, containing more than a hundred lots, without even a solitary exception, each trio were closely grouped upon one another in the shady corner, a relief impossible to those fowls whose misfortune from open pens all round entailed continuous panting and discomfort. We are informed an improvement in this direction will not be neglected.

The Game fowl classes were particularly good, and were evidently the leading attraction of the Show. The Brown Reds were beyond question the most successful as prize-winners, and the competition in the class for pairs of pullets (the principal prize for which was a silver cup) was undoubtedly as keen as could be referred to at any of our most noted poultry meetings. The *Brahmas* were also remarkably good, and none of the prizes to this variety were won without a hard struggle. The general improvement in this breed during the last two years is remarkable. Of *Hamburghs* the best class was the Silver-spangled, in fact it is hopeless to wish for better. A very noted old exhibitor, however, sent a peculiarly good pair of pullets with a hen-feathered cock of this breed, now-a-days a novelty, and a fatal fault we thought years back exploded. The *Game Bantams* were of exceedingly good quality, with a numerical entry that proves how quickly they become favourites among poultry fanciers. Almost all breeders expressed themselves disappointed in the *Cochin-China* classes, and it was a positive fact one of the best, if not decidedly the very best, pens shown of this breed was entered in the "selling class," where every pen was claimable, as by rule, at an outside price of 30s. the pen.

The Cochins alluded to, Partridge-coloured ones, some very good Spanish, and several other pens were immediately disposed of, for buyers of good birds proved very plentiful at Middleton.

That renowned breeder of *Geese and Ducks*, Mrs. Seamons, of Aylesbury, left behind her a very scanty board of prizes for division among her rivals. The lady's birds were shown in wonderful condition, nor could a more conclusive acknowledgement of their merits be suggested than the statement of many competitors—"it was no use trying to win when she exhibited."

The Middleton Show of *Pigeons* was stated to be exceedingly fine, but the continuous throngs of people, by which they were surrounded, prevented many from seeing this portion of the Exhibition.

The *Rabbits* were excellent, and evidently possessed much local interest.

So close was the competition among the poultry exhibitors, that although the Arbitrators commenced their arduous duties at so early an hour as 6 A.M., it was nearly mid-day before their labours were concluded.

**GAME (Black-breasted and other Reds).**—*Chickens*.—First, J. Wood, Haigh, near Wigan. Second, Sir St. G. Gore, Bart., Hopton Hall, Wirksworth. Third, W. Bourne, Monsall Lane, Newton Heath. Highly Commended, R. Payne, Brierfield, near Burnley; J. Halsall, Lowgreen Farm, near Wigan. *Cockerel*.—First, J. Halsall, Ince, near Wigan. Second, J. Jackson, Bank Top, near Bury.

**GAME (Any other variety).**—*Chickens*.—First, Sir St. G. Gore, Bart., Wirksworth (Duckwings). Second, W. Bourne (Duckwings). Third, R. Whittun, Brierfield, Lancaster (Red Piles). *Cockerel*.—First, Withheld. Second, W. Bourne (Duckwing). *Pullets*.—First and Cup, T. Statter, Whitefield (Brown Reds). Second, J. Wood (Brown Reds). Third, J. Schofield, Castleton Moor, Castleton (Black Reds). Fourth, R. Payne, Brierfield, near Burnley (Brown Reds). Highly Commended, J. Fletcher, Stoneclogh, near Manchester; A. Nuttall, Newchurch, Manchester; F. Sale, Crewe; W. Bourne.

**SPANISH.**—*Chickens*.—First, E. Brown, Sheffield. Second, N. Coop, Chowbent. Third, J. Marchant, Halifax. Highly Commended, T. Greenwood, Dewsbury. *Cockerel*.—First, N. Coop. Second, E. Brown. Third, M. Brookbank, Manchester. *Pullets*.—First, T. Greenwood. Second, H. Beldon, Bingley, Yorkshire.

**DORKINGS.**—*Chickens*.—First, Sir St. G. Gore. Second, T. Statter. Third, J. White, Warlaby, Northallerton. Highly Commended, H. W. Fitzwilliam, Wentworth Woodhouse, Rotherham; D. Parsons, Cueden, near Preston; A. Fenton, Crimble, near Rochdale. *Cockerel*.—First, J. Stott, Healey, near Rochdale. Second, Mrs. Dale, Scarborough. *Pullets*.—First, D. Parsons. Second, Mrs. Dale.

**BRAMA POOTRA.**—*Chickens*.—First, R. W. Boyle, Bray, Co. Wicklow. Second, T. Statter. Third, H. Lacy, Hedden Bridge. Highly Commended, E. Greenwood, Overton. *Cockerel*.—First, R. W. Boyle. Second, H. Lacy. Highly Commended, T. Statter. *Pullets*.—First, R. W. Boyle. Second, T. Statter. Highly Commended, E. Leech, Rochdale.

**COCHIN-CHINA (Buff and Cinnamon).**—*Chickens*.—First, W. A. Taylor, Manchester. Second, C. Jennison, Belle Vue, Manchester. Third, W. A. Taylor, Manchester. *Cockerel*.—First, Withheld. Second, W. A. Taylor. *Pullets*.—First, C. Jennison. Second, A. Bamford, Tonge Lane, near Middleton. Highly Commended, C. Jennison; C. E. Risdale, Skircot, near Halifax. Commended, J. Stott, Post Office, Healey, near Rochdale.

**COCHIN-CHINA (Partridge and Grouse).**—*Chickens*.—First, J. Hindson, Tonge Lane, Middleton. Second and Third, Withheld. *Cockerel*.—First, R. J. Wood, Brinscall Hall, Chorley. Second, Withheld. *Pullets*.—First and Second, R. J. Wood, Brinscall Hall, Chorley.

**COCHIN-CHINA (Any other variety).**—*Chickens*.—First and Third, Withheld. Second, W. Gamon, The Green, Thornton-le-Moors, Chester. *Cockerel*.—Prize, J. B. Wilkinson, Marsden Hall, near Burnley. *Pullets*.—First, Withheld. Second, P. F. Taylor.

**HAMBURGH (Any colour).**—*Chickens*.—Silver Cup, J. Fielding, Newchurch, near Manchester.

**HAMBURGH (Golden-pencilled).**—*Chickens*.—First, S. Smith, Northowram, Halifax. Second and Third, T. Wrigley, jun., Tonge Lane, Middleton. *Cockerel*.—First, S. Smith. Second, T. Wrigley. Highly Commended J. Wrigley, Middleton. *Pullets*.—First and Second, T. Wrigley, jun.

**HAMBURGH (Silver-pencilled).**—*Chickens*.—First, Sir St. G. Gore, Bart. Second, H. Beldon. Third, J. Preston, Allerton, near Bradford, Yorkshire. *Cockerel*.—First, J. Preston. Second, H. Charnock, Church, near Acerrington. *Pullets*.—Prize, C. Illingworth, Burley, near Otley.

**HAMBURGH (Golden-spangled).**—*Chickens*.—First, J. Buckley, Tainton, near Ashton-under-Lyne. Second, J. Ogden, Chadderton. Third, Sir St. G. Gore, Bart. Commended, R. Simpson, Chadderton. *Cockerel*.—First, J. Buekley. Second, M. H. Broadhead, Stabbin, Holmfirth. Commended, J. Moody, Edge End, Holmfirth.

**HAMBURGH (Silver-spangled).**—*Chickens*.—First and Cup, J. Fielding, Newchurch, near Manchester. Second, Sir St. G. Gore. Third, J. Lancashire, Chadderton. Highly Commended, T. Collinge, Boarshaw Clough, Middleton. Commended, J. Partington, Middleton. *Cockerel*.—First, J. Hope, Werneth, Oldham. Second, H. Beldon, Bingley, Yorkshire. Highly Commended, S. Lancashire, Chadderton. *Pullets*.—First, J. Fielding. Second, E. Collinge, Boarshaw Clough, Middleton. Highly Commended, J. Lees, Hollinwood; T. M. and J. Ashton, Broadbottom, near Mottram, Cheshire; J. Collinge; T. Rhodes.

**HAMBURGH (Black).**—*Chickens*.—First, J. Lord, Little Green, Middleton. Second, R. Battersby, Heywood. Third, J. Hope. *Cockerel*.—First, R. Battersby. Second, W. Holt, Middleton. Commended, E. Worsley, Middleton. *Pullets*.—First, J. Marshall, Middleton. Second, J. Holt.

**ANY VARIETY OF POULTRY NOT INCLUDED IN THE CLASSES.**—*Chickens*.—First, S. Farrington, Astley, near Manchester (Black Polands). Second, J. M. Procter, Hull (Silver-spangled Polands). Third, P. Unsworth, Lowton, near Warrington (Black Polands). Highly Commended, H. Beldon (Silver-spangled Polands). *Cockerel*.—First, S. Farrington (Black Poland). Second, Withheld. *Pullets*.—First, H. Beldon (Silver-spangled Polands). Second, S. Farrington (Black Polands).

**GAME BANTAMS (Any colour).**—First, J. W. Morris, Rochdale (Black Red). Second, J. D. Newsome, Batley, near Leeds (Black Red). Third, D. Parsons, Cueden, near Preston (Brown Red). Highly Commended,

C. W. Brierley, Middleton. *Cockerel*.—Cup, First, and Third, J. W. Morris (Black Red). Second, D. Parsons (Black Red). Commended, R. Tate, Leeds.

**BANTAMS (Any other variety or colour).**—First, C. W. Brierley (Gold-laced). Second, E. Hutton, Pudsey, near Leeds (Blacks). Third, J. Cope, Barnsley (Cochin Bantams). Highly Commended, Sir St. G. Gore, Bart., Hopton Hall, Wirksworth, Derbyshire; Messrs. S. & R. Ashton, Mottram, Cheshire; C. W. Brierley.

**SELLING CLASS.**—First, E. Smith, Middleton (Spanish). Second, J. Horrocks, Tonge (Partridge Cochins). Third, A. Bamford, Middleton (Buff Cochins). Highly Commended, T. Wrigley, sen., Chadderton; J. Hargreaves, Skipton in Craven; H. Shuttleworth, Middleton. Commended, T. Dym, Halifax; J. Jackson, Bank Top, near Bury. *Cock*.—First, H. Beldon (Brahma). Second, C. Broadbent, Saddleworth (Golden-spangled Hamburg). Highly Commended, T. Wrigley.

**DUCKINGS.**—First and Second, Mrs. M. Seamons, Hartwell, Aylesbury. Third, E. Leech, Rochdale.

**DUCKINGS (Rouen).**—First, E. Leech. Second, W. Gamon, Chester. Third, J. D. Newsome, Batley, near Leeds. Highly Commended, T. Wakefield, Golbourn, near Warrington; E. Leech; Sir St. G. Gore, Bart.

**DUCKINGS (Any other variety).**—First, D. Parsons (Grey Calls). Second, H. Nield, Worsley (Buenos Ayren). Third, E. Hutton (Grey Calls).

**EXTRA STOCK.**—Prize, C. W. Brierley (Carolina or American Summer Ducks).

**GOSLINGS.**—First, Mrs. M. Seamons, Hartwell, Aylesbury (Empden). Second, T. Houllker, Revidge, Blackburn (Toulouse). Highly Commended, J. Radcliffe, Balderstone Hall, near Rochdale. Commended, F. J. Bright, Green Bank, Rochdale.

**TRKEYS.**—Prize, E. Leech, Rochdale.

PIGEONS.

**ALMOND TUMBLERS.**—First, H. Yardley, Market Hall, Birmingham. Second, J. Fielding, jun., Rochdale.

**CARRIERS.**—First, C. J. Samuels, Ashville, Longsight, near Manchester. Second, W. Massey, Fulford, York.

**POWTERS.**—First, Messrs. C. & E. Roys, Greenhill, Rochdale. Second, H. Yardley. Commended, C. J. Samuels.

**BARBS.**—First, J. Thackray, York. Second, W. Massey. Highly Commended, L. Glassey, Rochdale.

**JACOBINS.**—First, J. Thackray. Second, C. J. Samuels. Highly Commended, J. B. Pinder Harpurley; Messrs. C. & E. Roys. Commended, C. J. Samuels.

**FANTAILS.**—First, J. Thackray. Second, H. Yardley. Highly Commended, S. Farrington, Chatmoss, Astley, near Manchester.

**OWLS.**—First and Second, J. Fielding, jun. Highly Commended, The Right Hon. the Countess of Derby, Knowsley Hall, Prescot. Commended, J. Thackray.

**NUNS.**—First, J. Thackray. Second, Messrs. C. & E. Roys.

**DRAGONS.**—First, H. Yardley. Second, J. Thackray. Very Highly Commended, J. Smith, Openshaw Bridge, Manchester. Highly Commended, Messrs. C. & E. Roys; S. Heap, Tainton, near Ashton-under-Lyne. Commended, A. Hilton, Butler Green, Chadderton.

**ANY OTHER VARIETY.**—First, The Right Hon. the Countess of Derby. Second, H. Yardley, Birmingham. Highly Commended, J. Thackray, York (Magpies).

**SELLING CLASS.**—First, J. Hawley, Burnley. Second, J. Thackray (Turbits).

RABBITS.

**SPANISH.**—First, Messrs. C. & E. Roys, Green Hill, Rochdale. Second, A. Firth, Hyde, Cheshire. Highly Commended, J. Lucas, Rochdale. Commended, G. Barlow, Chadderton.

**ANY OTHER VARIETY.**—First, T. Jackson, The Mount, Alkington. Second, T. Leech, Middleton. Highly Commended, R. F. Smith, Chester (Himalaya Rabbit).

The Judges for *Poultry* were Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, near Birmingham, and Joseph Hindson, Esq., of Barton House, Everton, Liverpool. The prizes for *Pigeons* and *Rabbits* were awarded by Mr. Morgan, of the Waterworks, Manchester, and Mr. Pearson, of Cheetham Hill, Manchester.

THE WORCESTER POULTRY EXHIBITION.

SEPTEMBER 19TH AND 20TH.

Few shows of poultry have met with more uninterrupted success for many years past, than that now so well established at Worcester. It is certain, however, that this success is mainly to be attributed to the never-failing care of the Honorary Secretary, Mr. Holland; for early and late his best energies seemed to be thoroughly devoted to its welfare and permanence. That the Worcester Coin Exchange is most especially suited to the purposes of a poultry show few will deny, and as the weather was fortunately most propitious throughout, we have the pleasure to record one of the most successful results yet attained by any poultry show held in the neighbourhood of Worcester. It is evident that this Show will now prove annually progressive; but even should such be the case, it is certain by a little careful arrangement, that the Worcester Coin Exchange might yet comfortably accommodate even double the number of entries of the present year.

The prize schedule is a very liberal one, and independently of premiums to the classes of £2 and £1, five silver cups are given, respectively for the best pen of Game fowls of any breed, the best pen of Grey Dorkings, the best pen of any breed of Cochins, the best pen of the four varieties of Hamburgs, and for the best pen also of Bantams, irrespective of breeds. This, of course adds materially to the competition, as any winner of a silver cup can receive either the silver plate proposed, or its money-value at his own option.

Nothing can be more fair, nor can any appointment be more duly appreciated by exhibitors.

The *Game* classes were excellent throughout, and formed a very prominent feature of the Show. Mr. James Fletcher, of Stoneclogh, near Manchester, however, managed to secure the first premiums in every class, consequently, the silver cup fell, as a matter of course, to his share, though the Judge expended a good deal of time unnecessarily in its appropriation, the birds being very even in quality, and the Arbitrator naturally conceiving, until the decision was recorded, that they belonged to different parties. The cup birds were Black-breasted Reds. In *Spanish*, the Show was, undoubtedly, not so good as some others of former years, and it certainly struck that the hens in the first-prize pen, like some other bipeds of the same sex, had taken a liberal discount from their actual age as pullets of 1865. The Coloured *Dorkings* were one of the best classes in the Show. We noticed with regret, however, a malformation that discomfited not a few pens—viz., the spurs being placed on the outside instead of the inside of the legs, a serious drawback to success. In *Cochin-China* fowls, no doubt the Partridge and Grouse-coloured were the best varieties as classes, the White ones next, and the Buffs taking the rear. A first-rate pen in the latter class (of Buffs) exhibited by Mr. Tomlinson, of Birmingham, were quite a feature of the Exhibition; and took precedence for the cup. Mr. Tudman, of Welshpool, showed some magnificent Grouse-coloured ones, that when moulted out completely will be difficult to beat. Mr. Chase's White Cochins also fully supported that gentleman's reputation in this pretty variety. The *Brahmas* were one of the best classes in the Show, and the competition was most severe. In *Hamburgs*, the Worcester Show as usual stood well, Silver-pencilled winning the cup for the best of any variety; but all the prize birds in each of the four classes were unusually good. In the *Poland* class some exceedingly perfect specimens of Silver-spangled ones, the property of Mr. Atkins, of Birmingham, took the lead. In the "Any distinct variety" class, a pen of the now-so-rare Ptarmigan, exhibited by Mr. Zurhorst, of Dublin, were universally admired, and were shown in truly unexceptionable condition. In *Bantams* the show was good, but many pens were moulting heavily.

The *Geese*, *Ducks*, and "Selling classes" were all filled abundantly and with capital specimens, and, consequently, not a few of these entries changed hands. Nothing could possibly exceed the cleanliness and good order of the Exhibition, and all the birds shown, with a single exception, were in perfect health.

**GAME** (Black or Brown-breasted Reds).—First and Cup, J. Fletcher, Stoneclogh, near Manchester. Second, T. Burgess, Whitchurch, Salep. Highly Commended, T. Statter. Commended, J. Fletcher.

**GAME** (Duckwings and other Greys and Blues).—First, J. Fletcher. Second, Sir St. G. Gore, Bart., Hopton Hall, Derbyshire.

**GAME** (Any other variety).—First, J. Fletcher. Second, E. Winwood. Commended, Sir St. G. Gore, Bart.

**SPANISH**.—First, W. Rouse. Second, G. Lamb. Highly Commended, G. Lamb. Commended, Rev. R. Young.

**DORKINGS** (Coloured).—First and Cup, Sir St. G. Gore, Bart. Second, O. E. Cresswell, Hanworth Rectory, Hounslow, Middlesex. Highly Commended, Rev. M. Amplett; Mrs. Young; J. Hill, Bladon Castle, near Burton-on-Trent. Commended, J. Norman; J. Holme, Knowsley, near Prescot.

**COCHIN-CHINA** (Cinnamon and Buff).—First and Cup, H. Tomlinson. Second, F. W. Zurhorst. Highly Commended, T. Stretch. Commended, T. Tatham.

**COCHIN-CHINA** (Partridge and Grouse).—First, E. Tudman. Second, J. Peale. Highly Commended, T. Stretch; E. Tudman; J. R. Redbard; J. Stephens.

**COCHIN-CHINA** (White).—First and Second, R. Chase, Balsall Heath, Birmingham.

**BRAHMA POOTRA**.—First, T. Statter. Second, R. W. Boyle, Galtrim House, Bray, Co. Wicklow. Highly Commended, R. W. Boyle; H. Lacy, Lacy House, Hebdon Bridge.

**HAMBURGH** (Golden-pencilled).—First, W. Lawton. Second, Sir St. G. Gore, Bart.

**HAMBURGH** (Silver-pencilled).—First and Cup, T. W. Walsh. Second, Sir St. G. Gore, Bart. Highly Commended, Mrs. Alsopp, Hindlip Hall near Worcester.

**HAMBURGH** (Golden-spangled).—First, J. Roe. Second, T. May. Highly Commended, Sir St. G. Gore, Bart.

**HAMBURGH** (Silver-spangled).—First, Sir St. G. Gore, Bart. Second, A. K. Wood, Burneside, Kendal. Commended, W. Stephens.

**POLANDS** (Any variety).—First and Second, G. C. Atkins, The Lightwoods, near Birmingham.

**ANY DISTINCT VARIETY**.—First, F. W. Zurhorst (Sultans). Second, Sir St. G. Gore, Bart. Commended, J. K. Fowler, Prebendal Farm, Aylesbury (Crève Cœurs).

**BANTAMS** (Any variety).—First and Cup, H. Shumack. Second, R. B. Postans. Highly Commended, W. Bradley, Severn Navigation, Worcester; R. B. Postans; D. Parsons; T. Davies, Stow Hill, Newport, Monmouth; J. Cook, Severn Bank Tannery, Worcester. Commended, G. Manning; Sir St. G. Gore, Bart.

**BANTAMS** (Gold and Silver-laced).—First, M. Leno, jun. Second, H. S. Salsbury. Highly Commended, M. Leno, jun. Commended, G. Manning.

**BANTAMS** (Black or White).—First, Rev. P. W. Story. Second, Sir St. G. Gore, Bart. Highly Commended, E. Cambridge, St. Phillip's Iron Works, Bristol; T. Davies.

**GEESE**.—First and Second, J. K. Fowler. Highly Commended, Mrs. Welferstan.

**DUCKS** (Aylesbury).—First, H. Jones, The Pheasantry, Dintan, Aylesbury. Second, J. K. Fowler. Highly Commended, Sir St. G. Gore, Bart; F. W. Zurhorst; H. Jones. Commended, T. L. Mayes; J. K. Fowler.

**DUCKS** (Rouen).—First, Sir St. G. Gore, Bart. Second, R. W. Boyle. Commended, J. Helme.

**DUCKS** (Any other variety).—First, Sir St. G. Gore, Bart (Carolina Ducks). Second, T. H. D. Bayley, Ickwell House, near Biggleswade, Beds (Grey Call). Highly Commended, T. L. Mayes (Buenos Ayrean). J. K. Fowler (Buenos Ayrean); F. W. Earle, Edenhurst, Hayton, Liverpool (Buenos Ayrean). Commended, A. J. Lamb (Wild Ducks).

**SELLING CLASS**.—First, Rev. A. K. Cornwall (Dorkings). Second, R. H. Nicholas (Chinese Silkies). Highly Commended, Rev. A. K. Cornwall (Game Bantams). Commended, R. B. Postans (Dorkings); T. C. Mayes (Golden-pencilled Hamburgs); J. Lycett (Geese); Rev. M. Amplett (Guinea Fowls); D. Young (Cochin-China); W. Hodges (Game).

Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, near Birmingham, officiated as Judge.

## WOODSTOCK POULTRY SHOW.

(From a Correspondent.)

THIS was held at Blenheim Park, the seat of His Grace the Duke of Marlborough. The following were good classes:—Dorking chickens, White Aylesburys, White Geese, Grey Geese, Black Turkeys, and Grey Turkeys. The two champion prizes, given by C. E. Thornhill, Esq., for old and young poultry of any kind in the Show, were easily obtained by the Duchess of Marlborough with a first-class pen of Aylesbury Ducks, and a splendid pen of Silver-Grey Dorking chickens. The following are the prizes awarded:—

**SPANISH**.—Prize, Rev. — Dodd. *Chickens*.—Prize, — Cactus. **DORKINGS**.—Prize, Lieut.-Col. Thomas. *Chickens*.—Prize, the Duchess of Marlborough.

**BRAHMAS**.—Prize, the Duchess of Marlborough. *Chickens*.—Prize, the Duchess of Marlborough.

**COCHINS**.—Prize, Rev. — Dodd. *Chickens*.—Prize, J. James. **HAMBURGS** (Spangled).—Prize, — Hillersden. *Chickens*.—Prize, — Hillersden.

**HAMBURGS** (Pencilled).—Prize, J. James. *Chickens*.—Prize, J. James. **GAME**.—Prize, W. Rowles.

**DUCKS** (Aylesbury).—Prize, the Duchess of Marlborough. *Ducklings*.—Prize, the Duchess of Marlborough.

**DUCKS** (Any colour).—Prize, W. Rowles. *Ducklings*.—Prize, J. Hutt. **GEESE** (White).—Prize, Viscount Dillon. *Goslings*.—Prize, Viscount Dillon.

**GEESE** (Grey).—Prize, the Duchess of Marlborough. *Goslings*.—Prize, the Duchess of Marlborough.

**TURKEYS** (Black).—Prize, H. L. Gaskell. *Poulters*.—Prize, Viscount Dillon.

**TURKEYS** (Grey).—Prize, — Barnett. *Poulters*.—Prize, the Duchess of Marlborough.

**CHAMPION PRIZE FOR THE BEST PEN OF ANY AGE**.—The Duchess of Marlborough.

**CHAMPION PRIZE FOR THE BEST PEN OF CHICKENS**.—The Duchess of Marlborough.

Mr. H. Yardley, Market Hall, Birmingham, acted as Judge.

## TARPORLEY AGRICULTURAL SOCIETY'S POULTRY SHOW.

(From a Correspondent.)

THE annual Show of the above Society, held at Tarporely on the 21st inst. under the very able management of Mr. Vernon, the Society's Secretary, together with a working Committee, proved a good one. Lord Binning, the President of the Society, who occupied the chair at dinner, expressed himself much pleased with the manner in which the Show was carried out. It took place in a spacious tent, fitted up with pens from Nantwich, in a field belonging to Richard Aston, Esq.

The following is the list of awards:—

**DORKINGS** (Grey or White).—First, W. Vernon. Second, Sir P. Egerton, Bart., M.P. Commended, W. Vernon.

**SPANISH** (Black).—First, J. Sheen. Second withheld.

**GAME** (Any colour).—First, — Grocett. Second, — Woolley.

**HAMBURGS** (Spangled).—First and Second, J. L. Sellon.

**HAMBURGH** (Pencilled).—First and Second, — Bates.

**ANY OTHER BREED**.—First, — Woolley. Second, J. Shaw. Highly Commended, — Shaw.

**GUINEA FOWL**.—First, — Newport. Second, — Dain.

**DUCKS** (Aylesbury).—First and Second, J. Groucott.

**DUCKS** (Rouen).—First and Second, — Prescot.

**TURKEYS**.—First, Sir P. Egerton, Bart., M.P. Second, — Goulbourn.

**GEESE**.—First, — Barber. Second, Mrs. Wade. Highly Commended, — Prescot.

Mr. Heath, Nantwich, was the Judge.

## PATENT HATCHING MACHINE.

A company (limited) is in process of formation for the sale of the Patent Hatching Machine. Our opinion of the invention remains the same—that it is certainly the best thing of the sort we have ever seen, and one calculated to be eminently useful to all interested in Game and poultry. We do not, however, expect that at any time there will be an artificial mother as good as the natural one. This one consists of a box about 5 inches high, from the top of which are suspended strips of woollen fabric or flock, reaching to the bottom, but fastened only at the top. They consequently readily yield to every motion of

the body of the smallest chicken, and form around it not only protection from draught, but they provide the heat that is essential to growth.

The machine will shortly be advertised, and will be seen at work in all its details. It is eminently calculated to interest the amateur and man of science. We believe it will be found very profitable to those who look to poultry as part of the means which provides a livelihood.—B.

### MORPHOLOGY IN FOWLS.

I AM not myself at all fond of malformations and monstrosities, but two so peculiar have just accidentally dropped into my hands, that I send them to your office, as there are individuals who feel an interest in such things.

Both the birds were killed on the same day by one of our principal poulterers, nor were the parties who plucked them aware of the eccentricity of either till pointed out to them.

The first singular freak of Dame Nature was a full-grown Duck with two wings on one side and one on the other. The "double wing" I forward dried, but when just killed, and consequently pliant, you could open or shut them at pleasure, as they would fold over each other, showing but little singularity when closed beyond a common wing, though the flight feathers of each were alike fully formed.

The same day a well-grown chicken was killed, and proved to be the owner of the two feet sent. They are web-footed entirely between the two external toes, and also much more webbed than usual between the middle and inner toes. When I first saw it the body was entirely plucked, consequently, thus nude, I can only say no malformation of body existed. The head was evidently that of a well-bred Brahma pullet, pea-combed, and dark-feathered. The two legs, also now forwarded, were at the first densely covered with feathers on the outside, quite 2 inches long; but unfortunately these were stripped off before I saw it again, and it had occurred to me to send this odd lot to the Journal. Some of the nails of the feet are worthy of attention on account of their close similarity to those of a Duck, the remainder being precisely like those of a common fowl.—E. HEWITT, *Eden Cottage, Sparkbrook, near Birmingham.*

[The malformations are as Mr. Hewitt describes. The double wing is such a duplication as occasionally occurs in all domesticated animals; but the web-footed Brahma Pootra seems something more, and we should have considered it an evidence of an intermixture with the Duck tribe if Mr. Hewitt had not written "No malformation of the body existed."]

### POINTS OF BRAHMA POOTRAS.

I HAVE at various times placed a protest in your pages against making colour a prominent point in Brahmas. It appears, however, inevitable, and the important part would seem to be to obtain the best.

I am led to these remarks by your reply to "A SUBSCRIBER, Ireland." You there state, "the reddish brown and cinnamon are both objectionable colours." I should agree to this, if this colour were the prevalent tint; still, I believe I am correct in writing that some breeders prefer an orange tint over the pencilling of the breast in the hen.

I know one of our most successful exhibitors is of this opinion, and I understood him to say that he had kept Brahmas largely in America before they came into fashion here, and that he considered this the correct colour. I notice in "The Standard of Excellence," that there is no mention made of this orange colour. My experience of dark Brahmas leads me to say that the cocks may be found of two colours—silvery white, and straw-coloured white hackle, back, and saddle, &c. The former for the most part have the breast black, the latter spotted with white. The former have rarely any bronzing on the wing, the latter, perhaps, always have a touch of this, sometimes very objectionably so; still, my experience of the shape and substance of the straw-coloured birds, with the addition of the spotted breast, leads me to prefer these. Dark Brahma hens may be seen, as I believe, of three different colours. I cannot see that one of these is any better than another, whilst I have headed the prize list in tolerably stiff competitions with birds of each variety.

The three varieties I have noticed are dark brown pencilling, light grey pencilling, and dark (almost black) grey pencilling. The first are those that usually have the breast more or less of

an orange tint, and the ground colour is a very light brown. The light grey are exceedingly beautiful birds, the ground colour I take to be nearly white, the pencilling is more distinct, possibly because of the lighter colour of the ground. The breasts are often beautifully pencilled, but are frequently quite white—a great defect, as I take it.

Lastly, let me notice the dark grey. Here the pencilling is almost black, and the ground colour is darker. The breast is often very light, almost white, each feather beautifully laced with black or dark grey, making a very pleasing contrast. The head and hackle feathers are black, though some traces of silver are to be found as the hackle approaches the shoulders. I am disposed to think that some of the best-shaped birds I have ever seen have been of this colour, whilst some of my cottage friends tell me they lay better than the other colours.—Y. B. A. Z.

### REGICIDE AMONG BEES.

HAVING had some further experience this season of regicidal attacks by bees I propose relating it, and at the same time fulfilling the promise which I made so long ago to consider what has been advanced on the subject by Mr. Lowe in a series of able and well-written articles which appeared in "our Journal," and extended throughout the whole of January to the commencement of February in the present year.

On the 14th of June I discovered the queen of a nucleus closely imprisoned in a dense cluster of her own workers, and being satisfied by former experience that her life was really in imminent danger, I at once proceeded to release her from her tormentors. As my mode of effecting her deliverance differed from that adopted by Mr. Lowe, who states that he forced the reluctant bees to quit their hold by means of a small twig, I may as well describe it, believing that it is attended with less risk to the valuable life of the hapless prisoner than almost any other. Placing the dense knot of bees gently in the palm of my left hand, I carefully detach the workers one by one with my right hand, and throw them into the air, quietly strolling round the garden in the meantime, so as to baffle them in their attempt to return, and this process is continued until the cluster is reduced to very small proportions, and the queen herself becomes distinctly visible. I then convey the remainder in-doors, where I complete the release of the royal captive in front of a closed window, so that if she chance to take wing I may be sure of experiencing no difficulty in recapturing her. I should add that this operation is always performed by me without gloves, and that it very rarely entails a sting, the chance of which I am, however, perfectly willing to encounter rather than risk entire failure by clumsily manipulating with covered hands. I then subjected the distressed monarch to a milder form of imprisonment in a small cage, and returned her to her hive. I should add that she was a remarkably fine Ligurian queen, only six days old, having been hatched on the 8th of June.

On the same day I made a similar discovery in the case of another Italian queen, also at the head of a nucleus, and seven days old, having been hatched on the 7th of June. I had at once recourse to the same mode of proceeding, and shut her also up in her own hive out of the reach of her relentless persecutors.

Both these queens were set at liberty the next morning, when, the regicidal frenzy having passed off, they were well received by their worker sisters.

It is not a little singular that three days afterwards I again found both these queens imprisoned at the same time, when a similar course of treatment on my part was attended with a like fortunate result, and no attack has since been made upon either of them. The larger of the two queens escaped entirely unscathed, and having commenced egg-laying on the 22nd of June is now one of the finest and most fertile I possess; whilst the other, although with one wing permanently distorted and constantly projecting from her body at right angles, began to lay eggs on the 20th of June, and has since proved herself by no means deficient in fecundity.

The third instance did not come under my direct observation, but occurred during my absence at the seaside to a young queen of such a diminutive character that she only obtained a reprieve through my excursion. On my return I found she bore the marks of severe imprisonment in the mutilation of two of her legs on the left side, and believing her, in the absence of eggs, to be unimpregnated, I soon destroyed her as being altogether useless. A *post-mortem* examination, although

it proved me to have been mistaken on this point, gave me no reason to regret the loss of so diminutive and mutilated a queen.

The fourth and last case has caused me much vexation, having cost me the loss of a young queen bred late in the season, and which I was especially anxious to preserve. On the evening of the 4th inst. I noticed a violent commotion among the inhabitants of a nucleus box containing a queen thirteen days old, having been hatched on the 22nd of August. On opening the hive and lifting out the combs I presently discerned the horrible little regicidal cluster, with whose appearance I have, unfortunately, become too familiar not to recognise it immediately; and having manipulated it in the manner before described, I had the mortification of finding its nucleus to consist only of the lifeless and disfigured remains of my once beautiful queen—a mortification which was by no means diminished on a minute examination leading me to believe that she had been murdered on her return from a successful wedding trip, and in this, as in a former instance related last year, my hopes had indeed been blasted in the very moment of their fruition.

So much for my more recent experience of regicide and regicidal attacks among bees. I will now turn to the consideration of Mr. Lowe's articles on the subject, to which, however, he has preferred giving a different name.

In "our Journal" of the 3rd of January, page 19, Mr. Lowe expresses an opinion that the queen, in a case previously related by me, was "evidently wounded" before being returned to her own hive, where she was incarcerated and killed. This is, however, quite a mistake, since I can assure Mr. Lowe that, on the contrary, she was perfectly unhurt by the strangers by whom she had been so briefly imprisoned.

As all the instances I have now related refer to queens artificially reared they would unquestionably appear to bear out Mr. Lowe's idea, that such queens are peculiarly liable to maltreatment by their workers. Such, however, is not my own opinion. These miscarriages bear but a small proportion to the number of queens successfully reared, and none of them escape discovery. My observation of apiaries in which natural swarming alone takes place, convinces me that at least as great a proportion of mishaps of some kind happen to young queens, but the construction of the hives, and lack of observation on the part of the bee-keepers themselves, preclude the production of evidence which would in all probability establish the fact, that queens reared in the ordinary manner are quite as liable to become victims to regicidal attacks as their so-called "artificial" sisters.

I am unable to indorse the opinion of "A LANARKSHIRE BEE-KEEPER," that regicidal attacks on young queens may always be referred to the presence of stranger bees; nor can I, on the other hand, agree with Mr. Lowe, that they are owing either to defects in the procreative powers of the queen or to the want of timeous fecundation. In the first two cases which I have related, both the queens which I succeeded in rescuing commenced egg-laying within the average time, and have since proved themselves fully competent to fulfil all the duties of their position; whilst the one that perished so miserably was barely thirteen days old, and had I been so fortunate as to have been warned in time to save her, would probably have turned out by no means inferior to her rescued sisters.

Whilst thus doubting the theories advanced by others, I must honestly confess to being unprepared to propound any of my own. So far as my observations extend, regicide and regicidal attacks still appear to me to be a mysterious and very unsatisfactory chapter in the natural history of the honey bee.—A DEVONSHIRE BEE-KEEPER.

### GAS TAR INJURIOUS TO BEES.

ONE of your correspondents asks if gas tar is prejudicial to bees. If my experience is worth anything, he ought on no account to use it. Some years since I covered the walks of my kitchen garden, where I kept my bees, with a mixture of gas tar and ashes from the furnace of a steam boiler, and in a day or two all the walk in front of the hives was strewed over with thousands of bees in all stages of decrepitude. It seemed to act on them like chloroform, only they never got up again.

Whilst I am on the subject of bees, let me ask how the bees get rid of the drones. You see them generally in August driving them out of the hive by hundreds, but I have very rarely seen one stung to death. If observed carefully, ninety-nine out of every hundred are held by the working bees at the

base of one of the wings, which the bee seems to be biting as ferociously as possible; and my belief is, although I have never seen the remark made nor a similar question asked, that the wing is weakened by this, and breaks down during the flight of the drone after escaping from its persecutors.—T. G.

### LIGURIANS IN STAFFORDSHIRE.

I SEND the sole surviving queen raised from the brood of my first Italian queen. I believe she is rather more than three years old, and shall be obliged by Mr. Woodbury informing me if she exhibits any symptoms of an exhausted spermatheca. She has been very prolific during the whole of this season. I have not seen this queen since last summer, and could not swear to her identity with the one raised in July, 1862; but the hive has never changed queens to my knowledge, and the colour of her progeny this year agrees with that of the two preceding years. She is either three years old, or not more than one.

The hive which I reserved for late drones still contains a great number of those gentlemen. They have a young queen which is, I have no doubt, impregnated, but she had not commenced to lay a few days ago when I examined the hive. She is almost certain to prove pure. A second queen was either lost on her wedding trip, or killed by her subjects, as she has disappeared. The bees in the drone hive are persecuting the drones.—J. E. B.

[The spermatheca of the queen which accompanied your letter proved, on examination, to be fully charged with spermatozoa, nor did it exhibit the slightest sign of exhaustion.—A DEVONSHIRE BEE-KEEPER.]

GAME BANTAM CUP AT BIRMINGHAM.—I have received the following promises of subscriptions:—Geo. Manning, Esq., £1 1s.; Mr. J. Crossland, jun., £1 1s. I hope other exhibitors will allow me to add their names.—R. B. POSTANS, *Brentwood, Essex.*

### OUR LETTER BOX.

WHITE SPANISH FOWLS (*A. P. B.*).—We have not seen any White Spanish fowls for a long time. They were always looked upon more as pets and eccentricities than anything else, and were not largely bred. They lacked the contrast that forms the chief beauty of the Spanish—black plumage, white face, and red comb.

CALNE POULTRY SHOW.—We are glad to observe the Committee show their appreciation of the value of Brahmas by making separate classes for light and dark. We trust the error in the schedule of their being styled light and dark *penitiled* will not cause confusion, as it was not observed until too late for alteration. The classes are well divided, and the prizes though not large, as liberal as the funds will admit of.

EARTH FLOOR OF POULTRY-HOUSE—NESTS (*A. S. B.*).—After seeing the floors of the pens at the Poultry Company's establishment, and their entire freedom from offensive smell, we would, if we had need of manure, turn over the dry earth of the poultry-house floor three times weekly, and remove it entirely, and replace it with fresh dry earth at the end of every two months. We think that a nest having for its flooring nothing but perfectly dry sandy earth would be excellent, and free from vermin than if lined with hay or straw.

POINTS IN SILVER-SPANGLED HAMBURGERS (*J. B. B.*).—Well-formed combs; piked behind, and the pike turning slightly upwards, firmly placed on the head and perfectly straight. The hackle feathers of the hen should be black and white-striped. A white hackle is a defect. The tail should be white, but tipped or mooned with black at the end of each feather. The body should be mooned all over, and the wing laced and barred. Legs blue.

PROFITABLE POULTRY (*Pussy*).—Brahmas, Cochins, or Spanish will be the birds that will suit you best. They will agree with the common barn-door fowls; but we do not see why these latter should be kept if you adopt our suggestion of one of the breeds we have named.

PEACOCK'S FEATHERS BRITTLE (*J. P.*).—We are at a loss to know to what to attribute the breaking of the Peacock's feathers, but he will recover his plumage.

POULTRY DISEASED (*C. T. T.*).—We believe the rain, which is beginning to fall as we write, will remedy many of the diseases which have tormented you, and us, and many more. Everything is too dry and husky. Give every fowl affected a table-spoonful of castor-oil, continue the bread and beer, and give to each a pill of camphor as large as an ordinary pea.

VELVURE-HOKED BRAHMA POOTRAS (*W.*).—The vulture hawk is as objectionable in these as to the Cochins.—The legs should be well feathered. We hardly know what to advise in the case you mention. We have never had a similar case. We should advise that it be treated with stimulants.

CANARY WITH SORE FEET (*S. D. H. H.*).—Sore feet may arise from two causes. If the perches cross each other so that they catch the dirt, the feet become dirty and sore. Wash the feet clean and anoint them with salve. Scrape the perches clean, and alter them so as not to catch the dirt. Sore feet may also proceed from wool or the fibres of silk or cotton becoming entangled around the toes, cutting to the bone and becoming embedded in the flesh, causing the toes to mortify and drop off. Wash the feet clean, pick out the fibres—a magnifying glass may be necessary to enable you to see them—then anoint the feet, and if you get out the thread they will soon heal. This is not infrequently when ladies allow their birds wool or floss silk to build with.—B. P. BRENT.

WEEKLY CALENDAR.

Day of Month	Day of Week.	OCTOBER 3—9, 1865.	Average Temperature near London.			Rain in last 38 Days.	Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock alter Sun.	Day of Year.	
			Day.	Night.	Mean.		m.	h.	m.	h.	m.	h.	m.	h.				
3	TU	Walnut leaves fall.	63.8	44.6	54.2	16	6	af	6	32	af	5	45	4	35	af	9	276
4	W	Virginian Creeper turns red.	64.7	43.4	53.8	19	7	6	30	5	16	5	16	5	0	20	11	277
5	TH	Sloes ripe.	63.2	41.1	52.2	19	9	6	28	5	40	5	18	6	16	37	11	278
6	F	Common Reed Grass ripe.	62.0	44.0	53.0	21	11	6	26	5	25	6	1	8	17	55	11	279
7	S	Maple and Beech leaves fall.	62.6	44.6	53.6	19	12	6	23	5	6	7	20	9	18	12	12	280
8	SUN	17 SUNDAY AFTER TRINITY.	61.5	42.3	51.9	20	14	6	21	5	52	7	33	10	19	29	12	281
9	M	Poplar and Cherry leaves fall.	60.6	42.5	51.6	21	16	6	19	5	45	8	37	11	20	45	12	282

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 62.5°, and its night temperature 43.2°. The greatest heat was 80°, on the 4th, 1859; and the lowest cold, 25°, on the 5th, 1850; 8th, 1852; and 9th, 1849. The greatest fall of rain was 1.05 inch.

GROUND VINERIES.

VERY lately your correspondent "J. N." suggested an idea which was recommended in the first description I gave of the ground vinery—I mean an aperture at each end under the gable. I found, however, that although calculated to allow the egress of heated air, it was of no perceptible use if the bricks for ventilation were properly arranged. Till this season I have never had a scorched leaf, never any red spider; but foreseeing the importance of free ventilation in confined gardens, my ground vineries are in a most exposed place. I have recommended two rows of bricks, placed so as either to make two rows of pigeon-holes, or so as to make the interstices double the size—i. e., double the depth of a single row of bricks. Treated thus, Vines grow healthily, and the fruit ripens well. No better, no other, mode of ventilation is required, if my seven years' experience is of any value. I grow but few Vines in ground vineries, merely because I have more Grapes than my family and friends can consume in lean-to vineries; but I am aware of the extent Grapes can be grown in these simple structures, as I know that a clergyman in Berkshire sold his ground-vinery Grapes for £20, which he distributed among the poor of his parish.

My favourite Vine is a Trencham Black, which I have suffered this season to bear fifty bunches merely for the experiment; but the berries did not set well, owing to the Vine being taxed too heavily. This Vine has now run through seven five-foot lengths, and is of course 35 feet long. I intend to place some small heaps of compost at intervals of 20 feet, so that fresh roots may be produced, and I hope to live to see it 100 feet long. I see no reason why it should not reach to 200 feet. Its fruit was fully ripe the first week in September, and was of the most delicious flavour.

I can see a great future for these interesting structures. Some variation in the training of Vines may be exercised. Instead of the Vine lying on the slates it may be trained to a wire in the centre, about a foot from the ground. For this purpose the vineries should be more roomy than I at first recommended. Three feet in width at base will give ample room for one Vine trained to a wire in the centre, and for two rows of double lateral cordons of Cherry, Peach, Apricot, Pear, and Plum trees, which by summer pinching may be made most prolific trees under glass, and are most easily protected from our spring frosts. My ground vineries used for this purpose have no bars, and are well and cheaply made by Mr. James Rivett, builder, Stratford, Essex.

With regard to geothermal ventilation mentioned by

"J. F.," it would in my opinion be perfectly impossible to keep Vines in health without considerable volumes of external air passing into the vineries. In the south of England there is always heat enough to ripen Hamburg Grapes. If geothermal heat could be applied under the vineries, and I believe it can be, Grapes would ripen early in summer, but they must have abundance of air.

As to the paraphernalia of hinges and apertures at end or at top, I believe them to be of no consequence. In all new methods of cultivation simplicity should be the rule, or people get bothered. As far as my experience has gone, the simple method of low ventilation by the apertures formed in the rows of bricks is quite sufficient; still I am not bigoted enough to despise the hinged vineries of Mr. Wells—they are luxuries, and, like all such things, they must be paid for liberally.

Feeling interested in the question whether Grapes would ripen better suspended from a wire in the centre, and as close as possible under the ridge, so as to be in the hottest part of the vinery, I have this moment (Sept. 21), walked up through the rain to my little batch of ground vineries on a sand hill 600 yards from my house, with my man Friday. I find that the bunches hanging from the upright spurs are just under the ridge, and a trifle over a foot from the ground—in short, just where they would hang if suspended from a wire in the centre. The Grapes in these bunches are nearly or quite ripe; the bunches lying on the slates are not quite so ripe; but the ripest of all are bunches hanging so that their tips touch the slates. This, I hope, has settled the question; so we may now have our Vines trained to wires in ground vineries, and calculate that if the bunches are suspended so as to touch or partially to lie on the slates, so as to receive their radiation, Grapes will ripen well.

On examining the Vine I have alluded to—a Black Hamburg, I discovered that enough bunches had not been cut off in spring; and to my dismay, my man found, on counting them, sixty-three bunches, averaging half a pound each, on this Vine of five years' growth, occupying a ground vinery 14 feet long, 30 inches wide at base, slope of roof 20 inches, depth in centre 16 inches, placed on a single row of bricks end to end, with spaces of 4 inches between each for ventilation. There are no apertures at the ends, but the structure is almost exactly after that given in the seventh or eighth edition of the "Miniature Fruit Garden." A very interesting fact is shown connected with the above vinery—One or two bunches on the same Vine are outside at the end, and within 3 inches of their brothers under the glass; the unsheltered bunches are full of small berries as hard as green sloes.

Although I have thus mentioned and given a favourable account of these rather narrow 30-inch-wide vineries with bars, I much prefer those without bars, and 3 feet, or even a little more, wide. The extra width adds but little to their first cost, and room under glass is always so convenient and valuable.

The one great trouble of these structures is thinning the berries, at all times and in all vineries a tiresome operation, yet most necessary, for without it such Grapes as the

Black Hamburg and most others become very inferior, and will not ripen kindly. It is just probable that we may originate sorts from seed that will not require this thinning. I only know of one variety at present likely to allow of it—viz., the Fintindo, a round-berried, deep purple Grape of excellent flavour. I have reason also to think that the Sultana, a white Grape from Smyrna, may be placed in the same category, as my Smyrna friends tell me it is highly esteemed there, owing to its berries never being crowded, but hanging loosely and detached on the bunches.

It is some years since I prognosticated that Grapes would be grown by the acre: the time is coming. 1 lb. per square foot could be grown in ground vineries properly cultivated, on a light good soil = 43,500 lbs. Take off half for spaces between vineries = 21,750 lbs. Deduct one-third for more space between and casualties: say 14,000 lbs. per acre—a low calculation.—THOMAS RIVERS.

## THE DUBLIN BOTANIC GARDENS.—No. 1.

### GLASNEVIN.

GLASNEVIN has been so often described, and is so well known to botanists who have visited Dublin, that a new notice of it may seem superfluous; but every one who inspects these celebrated gardens must look at them with different eyes. Experience and taste differ so widely, and the season of the year when they are visited is so likely to vary, every week making a change in the aspect of the place, that the impressions produced a fortnight since on one who had never before crossed the Irish Sea, may possibly possess a little novelty.

From the useful little handbook prepared by Dr. Moore, it appears that the gardens were founded about seventy years ago, when the Royal Dublin Society possessed themselves for this purpose of the pretty and very suitable grounds, rendered classic by the former residence in the midst of them of the poet Tickell. The house which he inhabited still exists, and many of the fine trees that cast their shadows upon the sward were, no doubt, of his planting. The names of other literary celebrities are associated almost as intimately with Glasnevin, as those of Steele and Parnell, and, pre-eminently, that of Addison. An undulating walk between two rows of tall Yews, which at the time of my visit were strewing the ground with their scarlet berries, is said to have been a favourite resort of the famous essayist, and is known to this day as "Addison's."

The general surface of the ground is very agreeably diversified. There is sufficient of slope to produce picturesque effects; the rise and fall are renewed in every part, and the side furthest from the entrance is bordered by the little river Tolka, advantage of which has been taken to secure a capital Salicetum, and also to introduce many moisture-loving herbaceous plants. These flourish charmingly on the reedy margins, and give a completeness to the collection far more natural than is possible where the preparation for such plants has to be wholly made by hand.

The hothouses and greenhouses are capacious and well-placed. Objection may be taken to the external lines of the Palm-house, but it is not fair to talk of the ill-binding of a book when the contents are as rich as the heart can wish. A marvellous place is this Palm-house. Perhaps the grandest thing it contains is a plant of that most exquisite of tree Ferns, the *Cyathea serra*, a vast vegetable parasol, the stem gracefully bending, fawn-coloured, and glossy at the upper part, with silvery-grey scales, while the great green pellucid fronds, silvery upon the under surface, form arches upon every side. Another very striking plant in this house is a great *Urania speciosa*, the vast leaves so intensely equitant at the base as to form a solid flat mass, and the general aspect reminding one of the vegetation in a pantomime scene. The crowd of rare and noble plants that share in the shelter of this grand department is beyond description. The simple list of species, with deserved commendations of their healthy and hearty condition, would make an article.

The adjacent houses are equally rich, especially in plants noted for their economic value, and many of great rarity; yet, pleasant as it is to take in almost at a glance the Clove and the Camphor tree, the Sugar-cane and Guava, it is even more delightful to be harpooned at every turn by such things as Cockscombs with pink flowers; the pyramidal variety of the same plant with queer little wattles on the very summits of the tall spikes; *Martynia proboscidea*, with large and handsome lilac corollas, internally speckled, and with a yellow stripe down the centre; *Drosera dichotoma*, with clusters of white

flowers, each  $1\frac{1}{2}$  inch across, and on a scape 2 feet high, and so on till we cry out *El Dorado!* Such strange *Begonias* too. How slight an idea is given of this singular genus by the common "elephants' ears" of our conservatories! Instead of the large grey leaf spanned by a silvery arch, or dotted with white, here we have the most elaborately digitate, and in the tomentosa a leaf as fleshy as that of a *Sedum*, and completely covered with pale pubescence. Not far from it was an odd *Convolvulus*, raised from seeds lately received from India, and flowering for the first time. The corolla, instead of being campanulate with an even rim, has the five petals united for so short a distance upwards that they hang together like those of the *Azalea* when half withered. In other respects it resembles the common *Convolvulus major* of every garden. It is the sight of such plants as these that renders a visit to Glasnevin so valuable. The notions we pick up in ordinary gardens must necessarily be imperfect, because derived from a single expression of what is often a multiferm type or idea, and we discover at the same time how false are all definitions; for directly we have laid down what seems to be the rule, something comes in to upset it. No fence is so ingeniously constructed, but some queer exceptional thing is found walking through it.

In the *Victoria regia*-house, *liee* is freely grown in several distinct varieties. There, also, is the pretty *Pontederia cordata*, abounding in spikes of gay blue flowers. This plant does well during summer in a tank out of doors, where the water is slightly warmed from within. It is also being tried, and apparently with success, in the swampy ground where earlier in the summer we may see the lovely bloom of the *Menyanthes*. Among the very special oddities was shown a *Maregravia*, clinging like Ivy to the wall, only that the leaves instead of being Ivy-like, are oblong, an inch or two in length, and light green. In Brazil this plant is seen clinging to every old tree-stump, both in the forests and when washed-up on the river-banks—a sort of vegetable barnacle. It would have been missed but for the kindness of Mr. Orr, the Superintendent of the plant-houses, whose courtesy and attention to visitors are on a par with his extensive and most accurate knowledge of plants. It would be invidious to mention his name without saying at the same time, that everything a botanical visitor to these famous gardens can desire in connection with the hardy and out-door plants, whether names or location, is afforded by Mr. Macardle, who positively seems a piece of the garden, so bound up is he, heart and soul, with its life and contents. The ancients had a pretty fable in their mythology about hamadryads—nymphs who lived and died with the trees they belonged to. The living for thirty years in a garden like this seems to show that poetry may have more truth in it than we are sometimes disposed to admit, though put in a fanciful way.

Innumerable are the small evergreen shrubs and suffruticose plants found in the greenhouses and the little receptacles supplementary to them. Every type of Cape and Australian botany is represented; and not inferior to this class of plants is the collection of succulents. I was much struck while revelling in this opulent in-door garden with the number of butterflies that were at play among the plants. Probably there may be as many in other places, but it has not been my good fortune to observe them—good, since their painted wings and delicate movements seem to harmonise best of all with these rich and rare plants of foreign climes. Minutely examining the little flowers of *Hypericum agyptiacum*, the stamens were found to be united, not simply at the base, as in all the British species of this genus, but into three little arborescent bunches, after the manner of those of certain Myrtaceous plants—*Beaufortias* to wit. *Disandra prostrata* was trailing from the tub of a tree Fern, and had leaves  $2\frac{1}{2}$  inches across; and *Oxalis sensitiva* was almost a weed, producing its yellow flowers in plenty, and shrinking when touched.

The gardens, strictly so-called—such portion of the ground, that is to say, as is not conservatory, present features if possible more surprising. The first plant noticed was *Reaumuria hypericoides*, a neat little grey-green undershrub in the greenhouse border, with axillary pink flowers the size of a sixpence. The student of vegetable anatomy should not fail to examine the ovary and ovules of this plant whenever the opportunity may offer. Alongside was the singular and showy *Amicia zygomeris*, a purplish-green leguminous undershrub, with hollow and pubescent stems, and leaves formed of four large, curiously truncated leaves, that differ from those of most other Leguminosae in possessing abundance of transparent dots. The stipules are conspicuous and remarkable; the flowers (not seen at Glasnevin), are yellow. *Phygelius capensis* makes a very

handsome border-plant here, resembling *Gesnera zebrina* in inflorescence, but more like a *Pentstemon* in foliage. As for *Tritoma uvaria*, its grand scarlet and yellow sceptres were lifted in clusters of sixty or more, literally in sheaves. *Solanum jasminoides* instead of being, as in Lancashire, a greenhouse plant, was here flowering abundantly against a wall, like a *Clematis*; while *Clerodendron fatidum* made great bushes, crowded with dull purple flowers growing in bunches like those of an *Ixora*.

Perhaps the first observation made by a visitor accustomed to the immediately modern style of flower gardening, would be the total absence from Glasnevin of bedding-out plants. There is nothing to be seen here of the Turkey-carpet mode of arranging flowers; no patches of red, white, and yellow; no long lines and ribbons, where these would be seen in other Botanic Gardens, as at Kew, Birmingham, Sheffield, Manchester, Liverpool, &c.; the ground is considered too precious for anything but science; and, in truth, after a minute or two's consideration the mind is far more gratified, for instead of two or three ideas, we have two or three hundred, as genuine a "feast of reason," as in the other case we have blaze for the eye. The lawns in front of the houses are covered with flower-beds; but these, instead of *Calceolarias* and *Pelargoniums*, endlessly recapitulated, are devoted to as many different races or families of plants, and as some species or others are pretty nearly always to be found in bloom, the contrasts are as remarkable as the wealth. Just then the Composite were in their zenith, and magnificent was the unfolding of golden stars and bouquets. Every conceivable modification of the aureolus may be studied here, and happy may be the Dublin art-student who, like a truly wise man, will visit such a garden when he wants ideas and inspirations, enjoying not merely the privilege of the flowers, but of the absolute freedom of access to them, for this admirable place is thrown open to the public every day with some slight reservations, and like the Phoenix Park, and the delicious sea-margins of Bray and Killiney, are the unbought property of every Dublin man, woman, and child. Immense is the privilege thus liberally accorded, the greater, perhaps, that it extends to the Sunday afternoon, when if a man be disposed to obey the Divine behest, to "Consider the Lilies," after the scythe of the mower shall have swept them from the field, here may he learn "how they grow," and gather from their simple loveliness a serene and elevating wisdom. Though a man may be indifferent to written truth, he cannot shut himself up from the access of the humanising lessons that enter his mind from flowers and trees, in a place where he is required to be calm, as here on the Sabbath afternoon. If possible, the visitor to Dublin should try to get into Glasnevin early in the morning. The birds are then in full song; the short-lived flowers of the *Cistus* and the *Convolvulus* are at their best, and saving a gardener or two in the distance, we are "monarch of all we survey."

Closely adjoining the borders devoted to the natural orders of herbaceous plants, is the best portion of the arboretum. There are many fine trees and many very interesting species. Rubbing the leaves of various species of *Juglandaceæ*, with a view to compare their odours, I noticed that the leaves of *Juglans nigra* are totally destitute of odour, while those of *Juglans fraxinifolia* and of *Carya tomentosa* yield a pleasant though rather faint perfume, and this only after considerable bruising of the tissue. Old *Juglans regia*, "the kingly Walnut," evidently stands first, alike in marbled timber, in kernel, and in scented foliage. Among other interesting trees are here to be seen *Tilia lutea*, with yellow flowers, and leaves resembling those of *parvifolia*, the true *Acer saccharinum*, for which the *A. platanoides* is often mistaken; *Acer rubrum*, but like the former, never flowering; and several of those grand Mexican Conifers, the tufted leaves of which resemble locks of straight green hair, such as *Pinus apulcensis* and *Montezumæ*, for they do not thrive here, the soil being unfavourable. A fine tree of *Corylus colurna* stands close at hand, now covered with the rudimentary catkins, that in March, 1865, will be in the full pride of their beauty. It is very pleasing to note in this tree, as in the common Hazel, the Filbert, the Alder, the Birch, and to a considerable extent in the Willows, how spring is prepared for months before its consummation; Spring, as we witness it, some three months after New Year's-day, being simply the last scene of a long drama, the greater part played, it is true, behind the curtain, but with enough of the incidents set forth to view, as here in the *Corylus*, to assure us that it is a succession of phenomena, covering, perhaps, six months. Hazel catkins in preparation for the following year may often be found as early as July.

The lower portion of the arboretum contains many unusual shrubs, such as *Shepherdias*, and two or three kinds of *Symphoricarpos*, there are also an *Aristotelia Macqui*, various *Pavias*, &c., all very interesting. A walk alongside leads to a portion of the garden set apart for small quantities of the plants specially useful in connection with manufactures, and the food of man and cattle, partly with a view to experimentalising upon them, partly to give completeness to the idea of the garden, which is thus rendered highly educational. Here we see such out-of-the-way plants as Woad, Madder, Pennycreek, *Chenopodium Quinoa*, and *Bohmeria nivea*. Artichokes lift their great mauve-coloured heads, and even the common Cabbage is allowed a place. Further on is a little sanctum, with the door locked, in which there are all sorts of new and odd things, Laplanders, Indian Buddleas that have not yet been named, and many another stranger from the far east, for at Glasnevin we have not alone the stereotype and duplicate style of plant, but new faces from all parts. From this garden Kew was furnished with its Balsam of Tolu trees, and from this garden were dispersed the first plants of that queen of ornamental Grasses, the *Gynerium argenteum*. The two sexes of this magnificent Grass are here planted near each other, in order that the contrast between them may be the more readily observed. The staminate plant sends up its panicles to the height of only about 6 feet, those of the female or pistillate rise to the height of 18 feet, but are destitute, of course, of the beautiful anthers that hang upon every branchlet of the former. By artificial fecundation seed is obtained easily and in plenty.

Two more references and I have done. One of the most striking objects in the garden is a green plant of *Aristolochia siphon*, trained upon a wire cage in such a way as to give the exact semblance of a lady's dress, from the waist downwards, and trailing behind, upon the ground—rather amazonian in the proportions certainly, being 11 feet high, but the breadth and imbrication of the great cordate leaves give at once the idea of continuous substance and of folds and plaits. The other remarkable specimen is not in the garden, but in the trim enclosure adjoining Mr. Macardle's residence. It is a tree compounded of some twelve or fifteen different species! The stock is a Quince, rising with a clear stem to the height of about 5 feet, and hereabouts have been grafted Apple, Pear, Mountain Ash, Thorns of various kinds, and other *Rosaceæ*, to the number above stated—a most curious and complete illustration of what "a happy family" may be made to consist of in plants. The work is entirely that of Mr. Macardle, and has been in progress about four years. Another stock has, in addition to various *Rosaceous* plants, a vigorous young *Mistletoe*!

It is not too late in the season for any lover of plants who has not seen Glasnevin to go over and enjoy it at once. The Dublin Exhibition, and cheap trips in connection therewith, offer additional inducements, and I can promise that there shall be no disappointment. While in Dublin, however, on no account must a visit be missed to the gardens belonging to Trinity College. These are almost another Glasnevin, as I shall endeavour to show in detail in a week or two.—LEO.

#### SEEDLING FRUITS—EATABLE FUNGUSES.

WHAT you throw out in page 205 as a mere probability—namely, that the Pitmaston Orange Nectarine sprang from a white-fleshed parent, is, I believe, a fact. Mr. Williams, its raiser, so asserted, but until the experiments of Mr. Rivers showed that this was no impossibility, few were disposed to believe it; and, indeed, Mr. Rivers has, within fifteen years, brought out more facts bearing upon the subject of seedling Peaches and Nectarines than were ever discovered during centuries before. Bushels of stones must be sown annually in the United States, France, Australia, &c., where Peaches grow like weeds, and require no expense of glass; but the well-directed and limited observations of one man have produced greater results than those of all others put together.

I have often raised plants from Pitmaston Orange and its descendants uncrossed; once, and only once, I had a seedling without glands. Last year I crossed four flowers of Pine-apple Nectarine with Early Newington, and of the four seedlings, three are, like the male parent, without glands. No great gain I am aware.

I regret to see (page 218), that friend "CLAPHAM" has been unfortunate in his experiments on Funguses. I can only say

that I have partaken, with much pleasure and no detriment, of *Agaricus procerus*, *cephastipes*, *deliciosus*, and *nebularis*. The last is excellent. The appearance of *deliciosus* is, no doubt, suspicious. He is a large orange-coloured fellow, turning green when bruised. All Fungi should be eaten sparingly, well cooked, and well masticated. I dislike *oreades*, *prunulus*, and *personatus*. The latter is sold at Covent Garden under the name of Blewitts.—G. S.

### THE MODERN PEACH-PRUNER.—No. 16.

#### CLOSE PRUNING FOR THE OPEN AIR.

I HAVE now to state the original theory as broached about thirty years ago, and carried out up to the present date at Chartres. The system has been applied exclusively to trees in the open air.

In the earlier stages of growth it is a recognised principle that the summer stopping of the shoots and their winter regulation should be but small, consisting mainly in merely pinching-off the point of the growing shoot, and especially in checking the advance of any shoot which has a tendency to become gross. In this way the tree is kept in fair balance. It is thus prepared for the work in hand, to be done only when the tree is about to bear a little.

M. Grin says that he commences then by untying all the leading branches in November. (In our climate good judges prefer October.) A selection of bearing shoots is then made. Those situated at the back of the branch are rigorously suppressed by being cut clean out. Forerights, on the other hand, are preserved. These, under this close system, never get too far from the wall's heat, and form an essential part of the bearing wood. In England they are too often cut out, which is an erroneous notion altogether. Of the other classes of shoots, those which show the best-formed eyes (ripe buds), and which have the best promise of wood-buds for succession at their base, are carefully chosen to bear the next year's crop. These shoots are then, generally, cut back to two eyes, and if the upper eye be the more developed and the stronger, it is bisected before it attains any length, and is thus arrested for a time. Meanwhile the lower and the more feebly-constituted eye receives all the spring sap, and is prevented from languishing. The wood-shoots which spring from each spur—and here it is important to mark the distinction made on the continent between a spur and a shoot, and also to state that the term "spur" refers mainly to the product of manipulation—are kept as a reserve to be transformed, by close summer pinching to two leaves, into fruit-bearers, as required. On the spurs situated on the upper sides of each leading branch one shoot will suffice to bear the next season's crop, but on the spurs situated on the lower sides of the leading branches it is better to leave two shoots. All these shoots are now cut back to two good eyes. This constitutes the general winter pruning.

The first summer operations commence in the middle of April, in ordinary seasons; or, in the beginning of May, in backward years. At this time the number of shoots to be left is finally settled. As they develop themselves their true character is best seen, and our author has taken care to have an abundant reserve, which is one excellent result of all close pruning—plenty to choose from, but no useless growth. Some of the shoots vary much in character. "Here, for instance," said our author to me, "we have a shoot with only a *bouquet de mai* (cluster spur, Class 5), at its base, while all the shoot above this cluster is bare for perhaps 2 inches." We, therefore, prefer to cut down the shoot to this single cluster, and we know how to make it either bear a wood-shoot or fruit. If the former is decided on, we shall have to bisect all the flower-buds, and then the central wood-bud will extend freely, which it otherwise would not do. (Here we find bisecting recommended instead of the too common plan of disbudding. This is a useful hint to orchard-house pruners who desire beauty of arrangement.) Should a shoot have two of these clusters at its base, then it may be cut down to them very closely. It then presents an excellent basis for the summer work, for one of these clusters may have its flower-buds bisected to allow the central wood-bud to extend, and the other cluster may be permitted to bear fruit. (Besides, it generally occurs, that by this close keeping-in of these groups the latent-buds at the point of insertion on the parent branch develop during the summer heat, and thus form an excellent reserve. Let us also remark the dependance placed on shoots of Classes 5 and 7 for fruit-bearing. This ought, at least, to teach us, that in the orchard-house with our

climate comparatively at command, these two classes can be safely relied on to bear the general crop. Such, at least, is my own experience, and on my old trees, hardly anything but these classes appear. This is the end and the result of close pruning.) If at the base of a spur the buds seem unusually latent, and it is difficult to develop them after one season, some even asserting it never to happen, then the shoot of the year which springs from that spur is shortened-in to one good group of triple buds, and at the first May stopping whatever appearance of fruit there may then be is carefully suppressed, and the central wood-bud of this group is allowed to extend. Thus a new shoot is obtained, not so well placed as the others, but still near enough to produce.

The general run of shoots may be said to be pinched-in to two well-developed leaves. The two or three small leaves which are seen lower down on the shoot, having no buds in their axils, do not count. This first pinching-in to two leaves generally takes place in May, the time being regulated, however, by the season and the locality, and is done as soon as the shoots have made about 4 inches of growth. The second pinching takes place as soon as the second growth, which springs from the axils of the two leaves first operated on, is about 2 inches in length, and is described by writers treating of M. Grin's system, as leaving untouched the first leaf, or even the first pair of leaves when they spring together, of the second growth—that is to say, that the second pinching is to one more leaf. M. Grin, however, repudiates this plan, and expressly states that he has made many trials, and that if even one leaf be left at the second pinching, the second growth being vertical, and made at the moment of the strongest summer sap, its strength is such that a strong shoot is the result, which prejudices the development and maturity of next year's crop.

"These severe operations have for object to suspend, for a time at least, the vegetation of the latent eyes, and to hinder their becoming wood-shoots. Thus, during a certain time, the whole action of the sap is directed to the nourishment of the eyes at the base of the spur, so as to strengthen them, and to produce cluster spurs in the following season." It is also clear that this very close second pinching leaves little scope for the production of a third growth, also described by the writers in question as requiring a fresh pinching-back to one leaf more.

Be this as it may, my present object is rather to show how essentially different this, the original theory, was, and has ever continued to be, from the old-established forms of long pruning. It is a little revolution of itself, has attracted much attention, and is gaining ground daily. Not only in the case of Peach trees, but to other fruits and vegetables is it applicable. For orchard-houses there can be no system equal to it. Carried out with a due regard to locality and other circumstances, it must prevail eventually, and supersede all others.

What has been stated in this article comprehends the latest development of this system, now a generation old, and always advancing without having much to retract. As was said before, the author desired it to be known at present in this form, and some ten years of personal trial have convinced me that it is sound and practical. All that I should, therefore, venture to suggest would be a modified form suited to the wants of our climate, which will be the subject of my next communication. —T. C. BÉHAUT, *Richmond House, Guernsey.*

### PEARS WHICH SUCCEED IN THE NORTH OF ENGLAND.

If the experience which I have gained in Pear culture on a very limited scale in the north be of any utility to your correspondent it is at his service. My small garden is on the south-west of the town (Darlington), and very dry. I rarely sustain injury from frost, but am exposed to and suffer from winds ranging from N.W. to N.E., though I have a wall to the north. My garden is about a mile north of the Tees, and the district, I should say, possesses a good climate for its latitude; indeed, the vale of Tees is both warm and fertile. In 1857 or 1858 I saw a bunch of Grapes (Black Hamburgh), weighing 2½ lbs., cut from a Vine on a flued wall, with no glass or any protection except thin canvass.

I find some Pears, which with me require a wall, do well otherwise at a very short distance from me. For instance: to-day I saw on a wire trellis a fine crop of *Beauré d'Areberg*, of which I never could obtain good fruit from a trellis; it is

the same with Beurré Diel, though in the lower part of the town it does well as a standard.

I grow the following, all on quince stocks, as standards:—Williams's Bon Chrétien, Louise Bonne, Beurré d'Amanlis, Doyenné d'Été, Seckle, the latter I have only just obtained, but the others yield fine fruit; on a wire trellis Joséphine de Malines, Comte de Lamy, Williams's Bon Chrétien, Beurré de Capiaumont, and Marie Louise. These usually do well; the bloom of the latter was destroyed by a wet cold week in May this year, and I think of putting it against a wall.

I have not been able to fruit as standards or on trellises Beurré d'Aremberg, Beurré Diel, Winter Nelis, Glon Moreau, and have put them against the wall. Doyenné Defais and Doyenné Robin are also useless as standards, and I shall discard them. On the wall, besides those mentioned, I have Jargonelle, Marie Louise, and Chaumontel grafted or budded on a Summer Portugal; they usually do well, as also Louise Bonne of Jersey: I have gathered some fine fruit off it to-day. I am told Doyenné Gris and Beurré Superfin do well as standards, I have not seen them. Uvedale's St. Germain is very fine this year on a trellis. Easter Beurré does well as a standard or on a trellis.

Of course, all the commoner Pears, such as Hessel, &c., are plentiful. Many other fine ones do well, but I only speak of those which I have proved, or know to be successful from those on whom I can depend.—A. Z.

## KITCHEN GARDENING.

AUGUST.

THE chief work of the kitchen gardener during this month should consist in removing every crop that is done with, or that can possibly be spared, in preparing the ground for crops for winter use, and planting or sowing these. In the first place, the Onions may be pulled up; and after they are properly dried and stored the ground which they occupied should have a heavy dressing of well-rotted manure, and be prepared for the winter Spinach by digging it one spit and a crumb deep—that is, shovelling each trench out, and laying the soil on the top of the last-turned spit, so that the ground lies light and dry, and is some 2 or 3 inches deeper than it would be by ordinary digging. I think that the after-well-doing of the Spinach will repay a little extra trouble before sowing, which should be done some time this month when the ground is in good working order.

The first lot of Turnips will no doubt be up by this time, and should receive attention as to cleaning, thinning-out, &c.; and as it will be time to sow a bed for winter use, the rows of Bedman's Imperial Peas may be taken up, as the Champion of England will be in by this time, and the Potatoes which were planted between the rows should be taken up, if this has not been already done. After preparing the ground previously occupied by the above crops by manuring and digging, it should at once be sown with White Stone Turnip. The first lot of Scarlet Runners being removed, the ground between the rows of winter stuff should be forked, laying the earth to the stems of the plants. The Brussels Sprouts, Broccoli, and Savoys should likewise receive the same attention, but previous to so doing the plants should be thoroughly cleared of the fly, which at this season often attacks them in this locality. It has been very troublesome this season. The only effectual remedy that I find for it is to set a sharp-eyed lad, with an ordinary painter's brush, to remove the greater part of the insects from the plants, and then to water overhead with soot water. This operation, and the moving the ground between the rows, will give the crops such a start that they will need no farther attention till they are fit for use.

The first row of Celery should receive its final watering of liquid manure, and be earthed-up about halfway. With regard to the successional trenches, a good soaking of liquid manure about twice a-week will keep them all right. What I term a good soaking is allowing fifty gallons of water to thirty yards of trench. If the weather is at all dry, it is a very good plan, after watering, to draw a little earth to the plants to retain the moisture. A bed of Leeks should be planted at once, if not done before, as they are a first-rate vegetable when properly grown, and often come in very useful in the ensuing spring. The last sowing of Dwarf Kidney Beans, as soon as fairly up, should receive attention as to watering and earthing-up, for to be of any use they must be grown quickly at this time of year; in fact, if they are not well managed at this time they had

better not be sown at all. The crop of these now in bearing between the rows of late Celery, if the weather be at all dry, will scarcely be worth gathering, as the pods will be tough and stringy. Whether such be the case or not, they will have to be removed towards the end of this month or the beginning of next; so that the better plan is to look well after the last sowings of Dwarf Kidney Beans, Scarlet Runners, and late Peas; also attend well to the beds of Vegetable Marrows and Mushrooms where the latter are grown.

About the middle of the month sowings should be made of Cauliflower, Cabbages, and a small bed of winter Onions. The early Coleworts should have the earth drawn to them with a flat hoe, not forgetting to keep the latter very busy among the weeds. For salading there will be Lettuce and Cucumbers, and the Batavian Endive will by this time be ready for blanching, by inverting pots over it, or tying it in the same way as Lettuce when small; and as the ground on which the second crop of Dwarf Kidney Beans was grown will be at liberty, it should be heavily manured and deeply dug, remembering that the same piece of ground has produced a crop of Coleworts or Savoys, succeeded by spring Spinach, and lastly Kidney Beans, in one season. For the fourth crop I think it deserves to be well prepared; and when this has been done it should on the first showery day be planted with the main crop of Curled and Smooth-leaved Endive, and a row or two of Hardy Hammersmith Lettuce. The Winter White Lettuce should be sown some time during the month, also a final sowing of Endive as a reserve in case of accident. Herbs should be cut and dried if required.—BURNWOOD, P. D.

(To be continued.)

## HAMILTON PALACE.

THAT there is something in a name is all but universally admitted, and it sometimes happens that a high-sounding name is all the merit of the object to which it is attached, and yet that name is maintained simply because the public do not care to look into the matter; but where it happens that a name calls up associations from which something more than usual is expected, honest John Bull is displeased when his nomenclature is unfairly used. It is, therefore, with no ordinary feeling of respect that we approach a residence to which the word "castle" is attached. Our ideas of a bygone age are called up, and we wonder, while approaching its portals, how many generations of retainers of the occupiers of the venerable pile have traversed that road before us, and possibly now and then hostile bands as well, leaving enduring traces of ruin and desolation behind them. Feelings of this and a kindred nature are entertained when we approach a residence erected on or near the sites of one of those ancient fortresses; but such feelings we do not entertain when the building we are approaching assumes the more peaceful character of hall, grange, lodge, or villa in addition to the local appellation. The word "abbey" calls up feelings of another kind, carrying us back to an equally distant age with the more warlike castle. These terms, indicative as they are of being the homes of the highest gentry of the land, are nevertheless in themselves a grade lower than one affixed to the house of the highest Scottish peer whose residence, Hamilton Palace, I shall here attempt to describe. The appellation "palace" certainly carries with it the idea of its having been the residence of royalty; expectation accordingly is raised on approaching it, and something noble or grand is expected, and in the present case the traveller will find his anticipations fully justified by the grandeur of the place he visits.

Hamilton Palace, the residence of the Premier Duke of Scotland, is pleasantly situated on gentle rising ground in the midst of a park of vast dimensions, stretching in all directions to a great distance, and varied by all those happy features which alike give dignity and beauty to the landscape. Finely undulated, well timbered, and having a river of considerable importance running through it, it has in itself some claim to the royal dignity which the name of the mansion implies. Rich pasture land, with grass knee deep, occupies the slopes and levels, while steep declivities fringing the sides of streams and rivers are clothed with trees and bushes appropriate to such inaccessible places, and now and then high precipitous rocks frown with all their natural majesty over some chasm or waterfall. These features, be it understood, are not the general ones of the park; for it is not placed in the midst of Highland scenery, but occupies some of the richest land in the

valley of the Avon; but that stream at places presents precipitous banks 150 or more feet in depth, while at other places it meanders forth slowly amongst lovely meadows, its clear stream spreading out into all the dimensions of the Thames at Kew, or even wider, while its tributaries intersect the park in other directions, leaving, nevertheless, a large breadth of table land stretching away to the northward of the mansion, on the more distant part of which is planted a fine avenue. First of all let us approach the mansion, and if we do so on this side there is no need to trespass on the grass edging for want of room on the gravel walk, for I believe it to be 48 feet wide, and not a foot too much to correspond with the other noble features of the place. I fear that I cannot give an adequate description of the mansion, which, like many others of its class, strikes the looker-on more by its vastness, and the richness of its architectural decorations, than by any particular feature in its structure. It is a noble pile of the best style of architecture prevailing in the end of the seventeenth century, and suggestive of internal magnificence and comfort rather than of feudal tyranny, as in the oldest class of baronial residences. The immensity of its proportions, the character of the site, and the extent of its appendages, all combine to produce that grandeur which would justify the mansion being styled a palace, even had it not a claim of ancient date to that title.

Leaving historical associations for the present, I will confine myself to stating that this noble residence is a building of decorated Grecian architecture, and of great extent, the central front receding behind the wings, and the whole occupying a sufficiently elevated position in the park to command an extensive range of country, without at the same time being unduly exposed. The Vale of the Clyde, terminating in that busy hive of industry Glasgow, may be traced throughout most of its length, and far beyond the brown peaks of some of the Highland mountains come into view, while the softened and undulating character of the country in the opposite direction, conveys an idea of rural comfort and progress which is not in any way marred by the presence of factory chimneys. The pleasant village, or rather town, of Hamilton, adjoining the upper part of the park, improves rather than intrudes on the general effect. The mansion, as I have before observed, occupying a sort of central position in a park of some 4000 acres or more, is, of course, sufficiently removed from everything likely to obtrude on its privacy, at the same time the presence of trees in sites judiciously chosen gives it a clothed appearance without being encumbered with wood. Looking from the mansion in a northerly direction, a handsome terrace and steps lead to a gentle slope at some considerable distance, and passing along a gravel walk, 48 feet wide, we reach another walk or road crossing this at right angles. From their point of intersection a vista or avenue follows the line of the broad walk; this avenue, which appeared to be at least 1000 yards long, was level throughout, and of more ample width than avenues usually are, I should say about 250 or 300 feet, and there were two or three lines of trees on each side. I forgot the object to which this avenue leads, but its length and ample breadth give it importance irrespective of external objects, and when seen from the mansion as a continuation of the broad gravel walk it has a noble effect.

The cross walk, which terminates the broad one alluded to, points to the mausoleum, a wonderful pile, erected by the late Duke at great cost, and which in its way has perhaps no equal in the kingdom. Its external appearance reminds one of those magnificent temples erected by some eastern potentate to the memory of a deceased relative, and I believe the design is from some such source. It is solid, massive, and grand, rather than enriched with architectural devices externally, and the mind is still further impressed with the sublimity of the interior by the echoes rising in successive reverberations to the apex of the cupola by which it is surmounted. The floor of the main building is of various coloured marbles worked into suitable designs, while underneath is the vault, approached in a contrary direction, wherein are deposited the remains of many of the noble house of Hamilton, who had figured in the many changes which have occurred during the last four or five centuries, including one or two members of the house who met with violent deaths for their loyalty or patriotism. Returning from such a scene, and passing some good examples of sculpture fronting the portals of the departed, we take a stroll to another part of the park, anxious to see all its features before we settle down to the garden department.—J. ROBSON.

(To be continued.)

## GLEANINGS FROM ROCK AND FIELD TOWARDS ROME.—No. 6.

It is a very pleasant task to connect with a flowery link ancient and modern Rome—to remember that the "Lilies of the field," about which I write, have suffered no change since they came fresh and fair from the hands of the Creator—that kings, consuls, emperors, and popes have alike felt their gentle ministrations; learning from them, if they were so minded, the selfsame lessons of humility and purity—to know that when this generation shall have passed away the same tiny wayside flowers will lift up their heads in storm and sunshine preaching the same lessons still.

From the state of the few gardens I saw at Rome I should say that horticulture, as a science, was little practised there. Wishing for some local information about the plants I met with, I asked if there was any professor of botany in Rome? I was answered, and I believe with truth, that there was not one! that I must wait till I arrived in Florence for any help of that kind; so I could do little more than gather anything strange-looking to my English eyes, put it in my blotting-book, and wait. My patience was rewarded at Florence, for, through the kindness of a friend, I had my specimens named for me by Professor Parlatore on De Candolle's system; for those plants which Professor Parlatore did not see I have availed myself of other help as able as his own, but I needed no professor to name for me the treasures that I most love amongst my little Roman collection. I have about a dozen healthy plants of *Adiantum capillus-Veneris* daily increasing in size and beauty, and each time my eye falls upon them it sees an old crumbling wall within the inner court of the church of St. Pudenziana, and I am standing before it in a helpless manner, gazing on the fair tresses of a Fern on which, it may be, eighteen hundred years ago the eyes of St. Peter and St. Paul rested lovingly as mine do. My gaze was a troubled one, for I was out hunt ng for churches not flowers, and my trowel was left at home; at last I bethought me of a certain knife given me just before leaving home as "the best knife in England," and in a few minutes two blades had been sacrificed, but not in vain, for I secured a tolerable plunder, and the little Ferns grace my fernery in forgiving beauty. While I was thus engaged, the rest of my party had been peering into a well, covered with a grating and full of bones, said to be the bones of Christian martyrs, gathered together by the love of the Saint whose name the church bears.

There is no church in Rome that exceeds in interest that of St. Pudenziana—tradition, history, and recent excavations lend their aid to give it a charm in the eyes of Englishmen as well as Romans, history coming to the aid of tradition with dates and circumstantial evidence, and the excavations stamping both with the seal of truth. Tradition points out this church as having been built A.D. 145 by Pope Pius I. on the site of the house occupied by the Senator Pudens, who entertained St. Peter from A.D. 41 to 50. History speaks of Noctus and Timotheus, sons of Pudens, building baths on the site of their father's house. St. Paul, writing from Rome A.D. 66 (2 Tim. iv. 21), says, "Eubulus greeteth thee, and Pudens, and Linus, and Claudia, and all the brethren." Claudia was the wife of Pudens, and tradition speaks of her as being the daughter of the British chief Caractacus. History again tells us that about the year A.D. 51 the wife and daughter of Caractacus were taken captive by the Romans, to whom the prince himself was delivered up by the queen of the Brigantes; we read also that the unbroken spirit and noble demeanour of Caractacus when taken to Rome commanded the admiration of the Emperor Claudius, who pardoned him. Modern excavations are going on beneath the present church, and every turn of the pick and spade brings something of interest to light.

1st, The remains of a much earlier church than the upper one, the peculiar structure of the masonry of the walls proving the date pretty accurately.

2nd, Below this ancient church the house of the Senator Pudens—that is, a house of considerable pretensions, with inlaid marble floors, such as would be suitable to the rank of Pudens in those grand days of old.

3rd, Added to this house are to be seen the remains of noble *bas*s.

The excavations have only been undertaken very lately, and it was no easy matter to search out these things for ourselves; no earth had been allowed to be removed, and we had to stumble over heaps of soil, with here and there a ghastly-looking skull, and only the feeble light of our candle to prevent

our falling into deep holes, or knocking our heads against the very roof that had sheltered St. Peter and St. Paul.

How interesting these excavations are I could never tell; how full of hallowed interest, to tread where the peaceful foot-prints of Apostles were once heard, as they passed to and fro in the sunshine of the dear human love that ever fell on them in this house; did they, I wonder, cast a pleased eye on my little Fern, remembering the Voice they loved so well, which had hidden them "consider the Lilies of the field," a Voice that spoke to the one on earth and to the other from heaven?

Vying in its exceeding interest with the church of St. Pudenziana is that of St. Maria in Via Latè. Tradition points to the subterranean chapel beneath St. Maria as having been an oratory formed by St. Martial (one of the immediate disciples of our Lord) in the "hired house" in which St. Paul dwelt two years, which at different times sheltered both St. Peter and St. Luke, and from whence St. Peter and St. Paul were led to the Mamertine prison. This sacred tradition is supported in part by history. The walls of the oratory are of large blocks of quadrate travertine, which a well-supported theory refers to the structure of the Septa Julia *b.c.* 26. In part of this extensive edifice St. Martial is said to have lived—it is a matter of history that he was sent by St. Peter to preach the gospel at Ravenna, when he is supposed to have left the Apostles residing in his house. The oratory with the huge stone blocks is there; within its sacred precincts there is an altar of very ancient inlaid coloured stonework, while upon the walls are faded frescoes of early art referring to these events, and cold indeed must be the heart that does not thrill with emotion when standing on the spot where the blessed Apostles of the Lord lived, and thought, and prayed.

It is a happy thing when history and tradition go hand in hand, for when they are at variance it is very perplexing. For instance, when visiting the Mamertine prison you see in the horrible gloom of the frightful abode (the only entrance to which was by a hole in the centre of the roof, through which prisoners were let down, seldom to return to the light of day) a well, which you are informed sprung up miraculously at the command of St. Peter to enable him to baptise his jailors—you long to believe in this beautiful tradition, it may be you touch the cool water of the spring and with it make a sign upon your brow, but history comes with its disenchanting wand, and tells you that 101 years before Christ this spring was spoken of by Jugurtha, who perished in the cell.

On our way from these gloomy subterranean places to revel once more amidst Nature's loveliness in the Villa Wolkonski, we stopped for a few minutes to watch the kneeling penitents ascending the Scala Santa—those stairs, said to have been brought from Pilate's house at Jerusalem and to have been trodden by the feet of the Saviour, were filled by a motley assembly making their weary pilgrimage to the top; some of these were dressed as for a bridal, all of them had a gala look which visibly altered before they were half way up the stairs; the penitents have to stop three times to kiss the *rotas* or sacred stones, and the effect was peculiar in the extreme, particularly when the penitents happened to be stout, or to be in a hurry.

There could scarcely be a pleasanter garden for a lounge than that of the Villa Wolkonski, where Violets of the bluest were to be had by the basketful for the gathering, and where many a wild-flower specimen may be gathered while scrambling up and down one of those grand old aqueducts that stride like giants over the vast campagna; and where, sitting in the sunshine, I could look far away on the snow-capped Alban hills, with the villages of Frascati and Tivoli lying at their glittering feet; or I could rest my eyes on the nearer beauty of the three lines of aqueducts, visible from the Villa; and, as I sat, I could stretch out my hand and gather specimens of *Erodium romanum* (contrasting it with the *Erodium cicutarium* of our own banks, to which it bears much resemblance, save that the flower-stem rises from the root instead of from the stalk), of *Reseda odorata*, *Muscari comosum* and *racemosum*, with many others passed away from my memory, for I gave my bouquet to a friend.

The flower garden was, to my English eyes, very untidy and badly cultivated; the flowers small, and the plants allowed to grow after their own wild fashion, with many a weed trailing amongst them; yet how lovely it was! with the ruined aqueduct passing through the garden, with dripping fountains reflecting Maiden-hair in their clear waters, with boughs laden with Oranges resting their weight against the broken stone;

while rolling in the distance was the sound of many carriages conveying the "beauty and fashion," of not only Rome but of England and America, to witness the English races held on the almost sacred ground of the Campagna.—*FILIX-FERMINA.*

## ESPERIONE AND MUSCADINE GRAPE WINES.

(Continued from page 259.)

My Esperione wine of 1863 I allowed to become a claret. I neither sulphured nor used finings, but allowed the fermentation to take its natural course down to W°; it was then racked off, and brought up to a gravity of 2° by the addition of about 4 lbs. of dissolved sugarcandy. The saccharometer will now float in it at W°; and it has been pronounced to be, by an M.D., "an excellent dry wine." This wine is intended to be used next year.

1864.

### MUSCADINE WINE.

To make nine gallons of Muscadine champagne. Weight of fruit and quantities the same as given in the Esperione wine digest. October 6th, gathered Royal Muscadine Grapes, saccharometer in pure juice 22°; after adding the two gallons of water to the must, saccharometer 14°; 8th, saccharometer 15°; 9th, saccharometer 15½°; 10th, saccharometer 15°. Pressed off juice; added water of the temperature of 80° to the skins and pips, well stirred, and pressed off; saccharometer in this washing 4°. Put it with the premier quantity, and the saccharometer floated at 12½°. Allowed 3½ lbs. of loaf sugar per gallon (no honey), saccharometer 46°. October 13th, saccharometer 37°; 14th, saccharometer 35°; 15th, saccharometer 30°; 16th, saccharometer 28°; 17th, saccharometer 25°; 18th, saccharometer 23°. Took the wine from the working-pan in the kitchen into the cellar, and filled cask and gallon stone bottle. October 27th, saccharometer at bung-hole 15°; 30th, saccharometer 12°. November 4th, saccharometer 10°; racked, sulphured, and used finings. January 7th, saccharometer 6°. Racked again simply, and brought saccharometer up to 7°, with 2 or 3 lbs. of loaf sugar dissolved in some of the wine from the gallon bottle. March 9th, saccharometer 6½°. Bottled the wine, wired down the corks, and laid the bottles in a recumbent position. June, 1865, an effervescing wine; sparkling; of a fine, bright, straw colour—a wine, as all wines should be, pleasing to the eye. My Muscadine of 1863 I allowed to become attenuated down to 4° by bottling-time, at the beginning of the following month of March; it is, however, an effervescing dryish wine, with a fine sparkle and colour, and it drinks "nearly as soft as cream." The Muscadine of 1861 I allowed to attenuate itself as much as it would. It has become quite a hock.

While the above was going on I was on the outlook to purchase champagne-bottles of both sizes in the cheapest market. I have usually bought them for less than 1s. per dozen, and they ought always to be obtained second-hand for that price when they require washing. This should be done by warming water, and casting in some soda when the bottles are laid to soak. Two or three ounces of shot successively passed into each bottle through a funnel will greatly facilitate cleaning. Rinse the bottles in clean water, and turn them upside down to drain dry. It takes a gallon of wine to fill six large champagne-bottles. The best champagne-corks should be procured, and a bundle of galvanised bottling-wire, with a cork-presser, will be found necessary adjuncts. A fortnight or so previous to bottling prove the clearness of the wine either with a syphon from the bung-hole, or by drawing a pint or so off from the tasting-peg-hole. If the wine prove fine all well, otherwise use finings after the manner already explained; or, if greater expedition be necessary, cover over the mouth of the jug containing the isinglass and pint of wine with a cloth, and place it in a basin of hottish water on a warm hob; this will hasten the dissolving process. I draw off the wine from the cask after the mode I adopt for racking, and the bottles are simply filled by jug and funnel to within 3 inches of the mouth. Dip each cork in a little of the wine, press it if too large, and drive it in firmly and carefully with the mallet to two-thirds of its length. Examine a wired cork in a soda-water bottle before corking, as it is quite necessary that our corks should become so secured. When corked the bottles should be placed in the cellar, in an equable temperature of 50°, recumbent, and having the date of the wine ticketed legibly over them. If I may judge by my own, this champagne may be kept for an indefinite period.

A few days more of such hot weather as we have lately ex-

perienced, and my Grapes will fall into the pannier, ripe and gushing, to become speedily transformed into bruised unsightly must, and undergo those subtle changes so anxiously watched, in order to become an exhilarating beverage. There is an adage which says, "They are clothed who live in sunshine, rich enough if the Grapes but grow." Perhaps that is the aim of the English company we read of in the "Daily Telegraph," August 12th, which has "just purchased for ten years the produce of the famous vineyard near Bordeaux called Château Margaux. National prejudice accuses the proprietors of a want of patriotism, since, it is said, the French will now be obliged to purchase their wine in England. There will, however, be no need of that. The wine-makers in the south are clever enough to find out some means of giving the real 'bouquet' of claret to ordinary wines. In fact, that is already done. According to the Customs returns of the Zollverein, no less than 4,500,000 bottles of Bordeaux of first-rate quality have been imported into the treaty States. Now, I should like to know how much claret is drunk in France if that be true, since all the slopes of the Gironde, good, bad, and indifferent, would never produce nearly that quantity." Like to know! Yes, and so should I, whether many of the wines sent to us do not more or less partake of the nature of those American wines which were exposed by Dr. Hiram Cox, of Cincinnati, in 1856. The Doctor wrote, "I analysed a lot of liquors for some conscientious gentlemen of our city, who would not permit me to take samples to my office, but insisted on my bringing my chemicals and apparatus to their store that they might see the operation. I accordingly repaired to their store, and analysed samples of sixteen different lots. Among them were port wine, sherry wine, and Madeira wine. The distilled liquors were some pure, and some vile pernicious imitations; but the wines had not one drop of the juice of the Grape! (the italics are my own). The basis of the port wine was diluted sulphuric acid coloured with elder-berry juice, with alum, sugar, and neutral spirits. The base of the sherry wine was a sort of pale malt, sulphuric acid, and bitter almond oil, with a per-centage of alcoholic spirits from brandy. The basis of the Madeira was a decoction of hops, with sulphuric acid, honey, spirit from Jamaica rum, &c. The same week, after analysing the above, and exhibiting the quality and character of the liquor to the proprietor, a sexton of one of our churches informed me that he had purchased a gallon of the above port wine to be used in the church, and that for this mixture of sulphuric acid, alum, and elder-berry juice he paid 2 dols. 75 cents a-gallon."

In the daily paper already quoted of August 24th there is a capital leader and an *exposé*, under the heading of "Champagne for the Million." "A chemist within the postal district has recently been purchasing low French white wine or sherry, with which the market is at present glutted. The operator places it in bottles of the orthodox shape, and submits it to the action of the soda-water machine, by which it is copiously charged with carbonic acid, giving it the required degree of effervescence, which of course disappears soon after the bottle is opened. A tinfoil capsule and an attractive label are then added, which render this exhilarating beverage fit for the market, where to our knowledge it has been sold and is now on offer." So return we to our home-made wine, the constituents of which we know, and which must have been largely produced by our forefathers, if we take the widely dispersed names of vineyard here, wine-clove there, &c. When the introduction of foreign wines, and the commerce and agriculture of the country improved, it was probably found that the ground could be more profitably employed for other purposes; but how many thousand acres of the surface of bare walls could now be made useful and ornamental by means of excellent wine-making Grapes? Think of the loss to the nation through so much unproductive surface! If I can produce in a cold ungenial situation, from 700 square feet of house frontage, enough Grapes to make twenty gallons of pure wine annually, given the genial house frontage of half England only for an answer. It is a calculation truly worth working out—in casks. It would prove at any rate a grateful beverage to many who cannot afford to use foreign wines in their families; and I know many of those who visit here always prefer my Grape wines to sherry or port at table. I am not writing for rich people, to whom these home growths may scarcely appear worth a consideration, upon the principle or prejudice that no wines can be good which are not foreign and do not cost a great deal of money; but how many of us are there who are not overburdened with riches, and yet have satisfaction in knowing

and partaking of what our own country is capable of producing? I myself am one of the latter class, and accordingly I intend to follow up this manufacture of Grape wines as being both needful and convenient, and likely to contribute to the comforts of those about me.—UPWARDS AND ONWARDS.

## A PEEP AT THE WOODS IN ODD PLACES.

### No. 1.

#### THE LIVE OAK, DWARF OAK, AND PITCH PINE.

IN the month of September, 1864, I found myself one afternoon in the United States Navy Yard, at Pensacola, Florida, and just about starting for a walk, or rather wade through the sand of that curious district. I may at once state that all the land in the immediate neighbourhood of this navy yard, and I believe, though I cannot speak from experience of the interior of this portion of Florida, and, indeed, to my own knowledge of the sea coast generally of the Mexican Gulf, is composed of sand produced by the breaking down of coral, and thus this minute insect has laboured in the formation of a coast extending upwards of one thousand miles. Thus we see how wonderfully the minutest and most insignificant creature is raised to an important position by the omniscience of the Creator, teaching us that however lofty our own position may be, we must not look down upon, or despise as of no importance the very smallest particle in creation.

But let us turn from the sand and try to gain some idea of the various and exquisite forms springing from it, I refer to the plants and trees; and we will as we walk from the hospital in the Navy Yard to the nigger camp on the Lagoon, take a passing glance at some of the most prominent beauties. Having descended the steps and come out into the boiling sun from under the piazza surrounding the building, my eye is attracted by the instantaneous transition of some small object from the upper rail of the fence running along the walk, on to the leaves of a large Aloe growing near it. I approach as gently and noiselessly as possible, and much to my surprise and delight fall upon a complete small menagerie. Picture to yourself an unlimited number of small eyes, the extraordinary brilliancy of which, with their opalescent changes, no words can depict, each pair of these belonging to a lovely little brown and bright green lizard, a small obese, phlegmatic, pale green, striped with darker green, tree toad, or an insect gentleman who bears the inelegant local soubriquet of the "Devil's riding horse." Truly his systematic and cold-blooded massacre of mosquitoes (for which God bless him and give him long life and health), house flies, even bees and wasps, and all other winged insect game, together with his evident enjoyment in their sudden destruction and sanguinary end, to be devoured by him, give the gentleman with this abominable name an unenviable claim on his master, without even taking into consideration his extraordinary form. He is entirely green, with six legs on his body, and two large folding gauze-like wings, a very large anterior thorax, to which are attached two enormously powerful long arms, covered with hairs in such a manner as to enable them to seize and hold with certainty his winged prey. On the top of the thorax is the extremely moveable head which is a perfect triangle, two of the angles of this are occupied by eyes, the third by a powerful pair of mandibles with which he quickly terminates the existence of his prey, and satisfies the cravings of his satanic maw. Master tree toad is also worthy of attention and careful watching, for he is an active and energetic little fellow, although spending his days—*i. e.*, the hot hours of the day in indolence, motionless, and apparently lifeless, sitting in the shade upon some green leaf which on account of his colour forms an excellent hiding-place; yet when the long shadows of returning eve bespeak the close of the hot day, and the advent of the short moments of the semi-tropical twilight, he is seen issuing from his leafy covert to spring upon and devour at a gulp any luckless fly or other insect which may be suitable to his dainty palate. But although an active and quick little fellow, he must by no means be confounded with his elegant, sprightly, and beautiful little cousin, the Italian tree frog. Our friend is emphatically the tree toad, and to mistake the one for the other would be as difficult as to mistake the common frog with its enormous bounds on land, and elegance in the water, for the common toad with its repulsive slowness and crawling awkwardness of movement. My little lively friend the lizard, needs no further description, for his elegant form and lightning-like movements are familiar to every one acquainted

with our own pretty country lanes, and warm grassy woodland banks.

Leaving my little friends to enjoy life in the shade, I looked around for a little of the same comfort for my own person, and forthwith turned into a most delightful unbragous walk paved with brick, and arched over by an avenue of Evergreen Oak, called here Live Oak. This is a beautiful tree, varying in size from a large shrub to a forest tree 80 and even more feet high. The bark is a dark ash colour, but slightly fissured when compared with that of the Oaks generally. The head of such trees as grow by themselves is nearly globular, and the leaves, which are small, present a dark, shining, holly-like appearance; the fruit is also small, and not so prettily-shaped as the acorns of our own Oak; indeed, the whole tree lacks the nobility and grandeur of the British Oak. The timber, which is of two kinds or rather colours, called the white and red, is of great value for ship-building, and other purposes, where strength and durability are required, being a heavy, dense, tough, and durable wood, breaking with a stringy, fibrous fracture, and capable of bearing a great strain; but it has the serious disadvantage of being subject to dry rot, which greatly lessens its value.

Having proceeded some distance down this avenue I turned aside again into the sun to pluck a flower growing very nearly upon the sand, it was of a sweet bluish pink colour, and I quickly stooped to seize my prize, but to my sorrow at once discovered that if there be "no Rose without its thorn," the saying holds equally good in the case of the Caeti, and having learnt wisdom by experience, and paid for my momentary forgetfulness of their nature by half a dozen pretty deep and acutely painful punctures from the sharp spines of this individual plant, I carefully gathered the flower, and, like the bear with the honey, growlingly bore off my prize, and not much of a one either, for ere I had walked half an hour in the blazing sun the poor beauty had perished and withered away, and was then cast aside as useless, being like many another beauty possessed of that evanescent charm alone, with no sweet scent or inward virtue to recommend it after its one single merit of external loveliness had passed away.

Having passed from the Navy Yard through the straggling town, or rather village, adjoining it, I came to a road through a quantity of scrub and timber of various sizes, kinds, and dimensions—came to a road, no, not quite, 'tis a slight *lapsus calami*, for even I, acquainted as I am with the roads of all parts of the world, could hardly feel justified in calling a space between the bushes cut up in every conceivable manner by wheels, horses, pigs, and cattle, in some places knee deep in sand, in others the same in a mixture of sand, leaf mould, and water, by the lofty title of a road. Still, why find fault with that track? no doubt it answered Uncle Sam's soldiers just as well for their traffic between the village and camp as the very best road in all Europe could have done; but I feel satisfied that few lovers of the picturesque would not have been as unreasonable as myself, in loudly denouncing Uncle Sam and his nephews, for tolerating such a nuisance, though nothing could possibly exceed in picturesque beauty the road and its frequenters. One of the scenes upon it would have particularly struck the eye of a painter, had any such been present to see it. By the side of a pure crystal stream, which crossed the track, and is in turn spanned by a rustic wooden bridge, stood a pretty well-house formed of strong rough timber with an over-hanging roof built something after the Swiss fashion, and shaded by noble trees of various kinds, one in particular being noticeable on account of its waxy-looking foliage, in striking contrast with the Pitch Pine's needle-like leaves, and the Cotton-wood's soft-looking boughs; it is the Bay tree, and grows to the height of 80 or 100 feet, being of singular beauty and grandeur. Around on all sides are flowers of the most brilliant hues, from snow white to bright gamboge and brilliant scarlet, intermingled with lovely blues and delicate greens; in fact, all the varied and exquisite colours in which Flora delights to bedeck her children. Amidst all this lavish display of Nature's beauties, within and around the well-house, sat or stood groups of United States' soldiers in uniforms war-worn and stained, and scarcely recognisable as such, they and their horses looking alike lean and dirty, and reminding one far more of a set of bandits than soldiers fighting for their country's existence; still they looked very picturesque, and no one on viewing them if previously unacquainted with the neighbourhood would have imagined that the men who sat there laughing, joking, and smoking, whilst they gossiped and watered their horses, were constantly on the *qui vive* for an active and energetic enemy, who might momentarily make an attack, and whose advanced

posts were, as the crow flies, within a mile and a half of that very spot, and within five hundred yards of their own pickets, and seldom an hour passing without the compliment of a rifle shot being exchanged.

Let us push on, however, and leave our picturesque but unpleasant neighbours, for we shall find something by going a little further, which I think will interest us more. Having walked through the camp of a white infantry regiment, we come to the edge of a small chapparal or flat plain, grown over with Dwarf Oak. In the middle of this rises an old Portuguese fort once considered of great consequence, being reckoned impregnable. It now belongs to the Americans, having as they assert been bought by them between forty and fifty years ago, it is called Fort Barramas, and is one of the defences of Pensacola Harbour. The Dwarf Oak of these chapparals seldom grows taller than 12 or 14 feet high, sometimes as little well-formed trees, but far more often as shapeless bushes, being frequently so closely crowded together as to render it utterly impossible to follow the trail, either of man or beast, and many even of the most experienced hunters and Indians will sooner skirt an Oak chapparal (which in some parts of America, as in Texas, Sonora, and Mexico, is of such a size as to require hours, and sometimes days to cross), than attempt to cross it, as where this Oak is found it is principally loose, sandy soil, destitute of water or game. The best idea I can give of this Oak itself, is to recommend those who wish for its likeness to go and look at the stump of some Oak which has been felled about two years, and from which the young shoots have been allowed to spring, these with their large leaves will at the end of the summer give some notion of the Dwarf Oak.

Going on a little further and passing by a bit of swamp caused by the overflowing of the Lagoon, where grows in great abundance a very curious and beautiful Pitcher-plant, we will bend our steps towards that elevated ground on which we see growing those fine straight trees. Ah! here we have something to interest us, for the tree before us is the valuable, I had almost said invaluable, Pitch Pine, which forms so large a portion of the wealth of some of the Southern States, and which has been so wantonly, recklessly, and absurdly cut down and destroyed, both prior to, and during this late American war. The Pitch Pine is a noble tree, straight and boughless save at, and near the crown, varying in height from 60 to 130 or 140 feet, and seems to grow like other Pines in belts, a few hundred yards on either side of which it will be almost impossible to find a specimen. The timber of this tree is the hardest and most durable of the Pine tribe, and like the tree itself, goes by the name of Pitch Pine. It is very heavy but tough, elastic, and extraordinarily durable, pieces of it containing much resin being more lasting than even Elm, Oak, or Teak. When planed and clear of knots its appearance is very beautiful, looking like a collection of orange and pale yellow ribbons. It is used extensively for the spars and masts of ships, though on account of its great weight and straight grain it is not equal for this purpose to the Cowrie Pine of New Zealand, which stands alone as spar timber. It is also most valuable for decks and ship-building purposes generally; but its value does not cease here. Before being cut down for timber the tree is made to yield articles of still greater cost than the timber—viz., turpentine and resin, the market value of both of which is now so enormously high; for the sources from which England, and, in fact, the world was to a great extent supplied, have during the last four years been checked and almost extinguished by the lamentable civil war of America, and it will require years for this branch of commerce to recover itself, if, indeed, it ever does, about which many competent judges seem doubtful. Most trees will bear several tappings for the purpose of obtaining the juice, and the process is roughly as follows:—A hole is bored into the stem of each tree, from this the rough turpentine flows and is caught in vessels placed to receive it. This juice is then carried away to a kind of still and boiled, the part evaporated being preserved, and after being further purified sold under the name of turps, oil of turpentine, or spirits of turpentine, the residue after being allowed to cool and concreted, being the valuable substance known as resin. Tar and pitch are likewise obtained from the roots of this tree. Some idea may be formed of the importance of the tree in some of the Southern States, when I inform the reader, that I was told by an American officer that he was present at the destruction of, in one place alone, over a million and a half barrels of resin which had been placed at a station ready for transmission by railway, and I have every reason to credit the statement.—A SURGEON.

CULTIVATION OF THE FIG.

THE dimensions of a Fig-house need not be large ; 30 feet by 18 feet will mostly be ample provision for the growth of Figs for a large family. In form it may be either a lean-to, span, or half-span.

Beneath are end sections of these forms of Fig-houses. Fig. 1 is an ordinary lean-to Fig-house, with a narrow border in front for dwarf plants ; a centre pit or bed affording room

grown under glass. Not only the sides, back, front, and centre should be made use of, but the ends also ; but if the house is covered with Vines, and trees are in the central pit, then it would be better if the ends were not occupied with Fig trees, for the light transmitted through the ends is of vast importance to the trees beneath the Vines. Our house, whatever form it may be of, is for the growth of Figs, and would be best kept

Fig. 1.

for bush trees, and a border at back for trees trained to a trellis against the back wall.

Fig. 2 is a span-roofed Fig-house with two narrow borders along each side, and a central one, occupied with a row of standards on three-foot stems, and a row of dwarfs on foot stems on each side of the standards. The outside borders are for bushes.

Fig. 3 is a half-span-roofed Fig-house, little differing from those represented in figs. 1 and 2, there being a border in front for dwarfs either in pots or planted out, a bed in the centre for a line of dwarf and standard trees, and a narrow border at back for trees to be trained to a trellis against the back wall.

In all the houses the borders are narrow, and well drained. The front and back borders are 2 feet wide, and about 3 feet deep, and the central ones 6 feet in width, and of similar depth to the side borders. Beyond confining the roots, the arrangements of ordinary houses will answer for the growth of Figs. Probably no place answers so well as the ends of these houses, the trees being planted in shallow borders, and the shoots trained to a trellis 6 inches from the glass. The Figs on these trellises are the best of those

to that purpose only ; the Figs will then be more plentiful, and finer, to say nothing of their flavour, which is the reverse of high when they are grown under a roof covered with Vines. If Vines are tolerated they should be not less than 4 feet apart, and better at 6 feet.

In cultivating the Fig in houses exclusively devoted to this fruit, it is desirable to have the borders narrow, for when these are wide and shallow, the roots from being near the surface are very subject to external influences, such as vicissitudes of heat, or of dryness, and moisture, any of which act prejudicially ; and the trees grow so luxuriantly in wide borders as to fruit very little, producing long-jointed wood and very large leaves. When the borders are wide, and formed of rich

Fig. 2.

compost, it would be advisable to have the trees in pots, standing the pots on the beds or borders, and allowing the trees to root through, for were they planted out in the wide borders they would probably grow amazingly for a year or two before they fruited to any extent, and would require much pruning in after-years to keep them within bounds.

Borders 2 feet, and not exceeding 3 feet in width, are sufficient for trees as bushes, and standards with heads not ex-

ceeding 4 feet in diameter; wider borders must be provided if more than one row of trees be planted, and narrower if the trees be of less size. Two feet of soil is deep enough, and below that there should be 1 foot of drainage; for the great quantity of water which the Fig requires renders efficient drainage necessary. Below the drainage materials, which may consist of half-bricks, stones, &c., a drain should be provided to carry off the water. The drainage may be covered with a layer of turf 3 inches thick, with the grass side downwards, and then with 2 feet of the same a year old, and roughly chopped up with a spade. The turves are best from a field of yellow or hazel loam. It is scarcely possible to improve this soil in any way for the growth of Figs.

The best time to plant the trees is when the second growth is made, and the foliage is becoming yellow. If growing in pots, as in all probability they will be, the roots are to be slightly disentangled, but not to any great extent; it will be sufficient to loosen the outside of the ball. They are to be planted in the front border of *figs.* 1 and 3, and the side borders of *fig.* 2, at 3 feet apart, and in the centre beds of *fig.* 1 and 3, at 4 feet from tree to tree, and those in the centre bed of *fig.* 2, at 6 feet apart. Those in the back borders of *figs.* 1 and 3, should be 12 feet from each other, and one may be planted in each of the end borders of these houses, and two at each end of *fig.* 2, the doorways being in the centre of the houses. After plant-

ing the trees should have a good watering to settle the earth about the roots. From planting early in autumn we may expect a certain amount of root-action to take place before the fall of the leaf, and unless we obtain this we need not expect the fruit, then in embryo and about the size of peas, to remain on longer in spring than to half swell. With autumn planting there is a chance of a first crop, but little hope, if any, when the trees are planted in spring.

After the leaves have fallen the house should be kept cool, and the borders dry, merely excluding frost, though even a

few degrees of that will not matter, if the soil and atmosphere be dry. Early in February the trees are to be washed with a composition of 1 lb. of sulphur vivum, lime, and soft soap, made of the consistence of paint, by the addition of tobacco water, prepared by pouring half a gallon of boiling water on an ounce of the darkest or strongest shag tobacco. This composition should be applied with a brush and rubbed into every hole and crevice. The woodwork and glass must likewise be well washed and cleaned, and the former painted if necessary. The walls and sides of the pits ought to be washed with 2 lbs. of flowers of sulphur, and half a pound of soft seap, in a gallon of water, with as much quick lime added as will bring the whole to the consistence of whitewash. The washing and cleaning of the house will save trouble afterwards from the attacks of insects.

The first year it would be well if the trees were not much excited by fire heat at an early season. The first week in March will be sufficiently early for the first season. The house should then be what is generally termed "closed;" nevertheless it is necessary to keep a little air on continually, for of all fruits the Fig is the last to do without a pure atmosphere. The temperature is to be kept at 40° by night for the first fortnight, and the trees and every part of the house should be sprinkled with water before 9 A.M., and before 6 P.M., the best time for the latter sprinkling is at the time of, or shortly after reducing the air, or shutting the lights. The soil is to be kept moist, and yet not wet, until growth has fairly commenced, when liberal supplies of water are to be given, never allow-

ing the trees to be in want of it at any stage of their growth.

The temperature of the house from fire heat after the first fortnight may be increased to 45°, and then progressively every fortnight, gaining a couple of degrees or so in a week, until a night temperature of 55° be attained. Care should be taken not to exceed this degree at the present stage, for the fruit is then undergoing a process similar to stoning, when fruit if unduly excited by a high night temperature will turn yellow and drop. The fruit will remain as it were stationary for a time, and if sufficient air be not given, and the tree suffered to become dry either at the root or in the atmosphere, the same result will follow. Keeping the soil well watered, the atmosphere moist by sprinkling the paths and every available surface twice daily, giving air freely, and early, and a little all night, and closing the house early to catch and retain the sun's rays, will do more towards retaining the first crop on the trees than anything I know. Unless the roots have firm hold of the soil at this critical stage, none of these precautions will prevent a large per-centage of the fruit dropping.

After the fruit again commences to swell a temperature of from 60° to 65° at night may be allowed, and instead of syringing the trees the atmosphere should be kept moist by sprinkling twice daily the floors, paths, walls, &c., with water; but when the first signs of ripening present themselves, this should

be discontinued, and as red spider is sure to make its appearance, the pipes are to be washed with sulphur mixed with water in which a little soft seap has been placed to cause the mixture to adhere the better. It is an old practice to dust the leaves with sulphur, to prevent red spider, whilst the fruit is ripening; but I find that the insect cares no more for dry sulphur than for a dry atmosphere. The only preventive quality exercised by sulphur applied in this manner, arises from its fuming when acted upon by the sun. Unless its fumes are emitted, sulphur is perfectly harmless,

Fig. 3.

but if wet it is like its fumes destructive, though not in so marked a degree. The leaves are so unsightly when dusted with sulphur, and its property of preventing the attacks of red spider so uncertain, as to make its use objectionable; but whatever we do we must keep red spider under, and this will be best secured by having the hot-water pipes or flues, and the walls on which the sun strikes powerfully, coated with sulphur, a little soft soap being mixed with it, as already recommended, to make it adhere the longer and better. Softsoap, I may remark, is a better antidote for the attacks of red spider than sulphur, and this from the ammonia which it contains. Syringing with a solution of this just before the fruit begins to ripen will mostly keep the trees clear until the crop is ripe, when the syringe can be again brought into requisition. A solution of 2 ozs. to the gallon is sufficiently strong; if much stronger it will bring the leaves down, and the fruit will wither, and not ripen fully.

The atmosphere should be kept dry when the fruit begins to ripen, otherwise it will not swell kindly, but crack, or become insipid. Abundance of air, and a dry atmosphere are the requisites when Figs are ripening, but the soil should be kept moist, otherwise the fruit will not swell, and the second crop will be injured. If the trees are not forced until March they will ripen their first crop in July.

After the first crop is gathered the trees should have a good syringing, and an occasional syringing afterwards will do good. A moist atmosphere should be maintained as before

by sprinkling the paths, &c., up to the time of the second crop's ripening, which will be towards the end of September, and during October; the soil ought likewise to receive a good supply of water, but less than in the case of the first crop, partly from the trees having a tendency to ripen instead of grow, and also from the evaporation being less, in consequence of the advanced period of the season. They will ripen off perfectly in a temperature of 55° from fire heat.

By the time the second crop has been all gathered the leaves will have begun to assume their autumn tints; then keep dry, and give all the air practicable, with no more fire heat than sufficient to prevent any great amount of frost in the house.

During the first year the border will sustain the trees without manure waterings, or top-dressings; but in the second the roots will probably have extended to the limits of the border. This will be best ascertained by the growth. If the shoots come strong, and the leaves or joints are wide apart, either the border is too rich, or the roots have too much room. In that case avoid liquid manure and rich top-dressings. If, on the other hand, the roots are cramped, and there is no lack of nutriment in the soil, the wood will be strong, and the joints short. In that case a dressing of rich compost will be beneficial. Fresh cowdung is the best; next comes a compost formed by mixing equal quantities of good loam and sheep-droppings together, and letting them lie for six months; then night soil mixed with four times its bulk of soil, and used a year old; and, lastly, 2 or 3 inches of the short manure from an old Mushroom-bed. The cowdung should be spread over the old soil of the borders to the depth of an inch, and the others are laid on 2 or 3 inches deep, previously removing the loose surface soil. These dressings should not be applied until the shoots are so far advanced as to require stopping. If the borders are not top-dressed they should be watered with liquid manure at every alternate watering up to the crop's ripening, and then again for the second crop. In subsequent seasons the old top-dressing is to be removed as far as practicable in autumn, when the leaves turn yellow and begin to fall, and replaced with fresh, which being supplemented with a good watering will induce a certain amount of root-action in autumn. If top-dressed late, or in spring, the fruit will fall prematurely, from diminished root action just when it is needed, and then a glut of nourishment will cause over-luxuriant growths, which are to be avoided in the case of all fruit trees, and particularly in that of the Fig.

In the second year the trees may be started in February, and the crops will then ripen in June, and in August and September, respectively. The earliest period at which it is possible to start Figs is in January, in which case the first crop will ripen in May or early in June, and the second in August, a third being had by forcing the trees hard in October and November. In a previous article I asked if three crops had ever been obtained in one season, but met with no response, and I have now to state that such has been done, but it is not desirable, for it takes nine months of growth to perfect two crops, the third being obtained at the expense of the next season's fruiting. Fig trees require rest, and three months are not too much; therefore, if Figs are wanted late, it is better to grow trees for the purpose, allowing them to come on naturally so as to ripen one crop in autumn, and a second in October, November, or even December. For this purpose it is best to have the trees in pots, and to keep them out of doors until the middle of September, when they will be studded with the second crop on the midsummer shoots, and if then introduced into a house with a temperature of 55° at night the fruit will ripen in November, and thus green, though ripe, Figs may be had at Christmas and on New Year's-day. In writing of temperature, that of the night is only here given, and that is understood to take place once during the twenty-four hours or at 6 A.M. Whatever temperature may then be proper, the reading should be 5° higher by 8 A.M. and 10° at noon on dull days, 15° on cloudy days with clear intervals, and 20° or more with a cloudless sky, a corresponding amount of air being given in each case. 20° of sun heat will do no harm, but, on the contrary, will prove of the greatest benefit, whilst 5° extra fire heat may be attended by the most serious consequences.

The best sorts for forcing are the White Ischia, a small but delicious Fig, the White Marseilles, Brown Turkey, and Pregnassata, a large Fig much resembling the Brown Turkey, and possessing all its good qualities, except that it ripens its fruit at once, whilst the Brown Turkey ripens almost continuously, or during a lengthened period. The Genoa

for size may have a place, whilst the Castle Kennedy will, I am persuaded, supersede all white Figs for every purpose.—G. ABBEY.

### THE CACTUS PLANTS OF CALIFORNIA.

THE Cactus—the celebrated family of the floral kingdom, the glory of the hothouses of Europe, and the wonder of travellers, whose flowers and fruits are seen on every league of surface in South Carolina, Arizona, and the Peninsula—has never sufficiently attracted the attention of our florists or farmers. Fifty-five species of Cactus are known in the botany of these sections, and they include some with magnificent flowers and of extraordinary appearance, forming beautiful ornaments when in the vicinity of other vegetation. If the different species, all covered with thorns, could be brought together in a Californian garden, they would form one of the most singular and unique displays it is possible to conceive in gardening, and it is to be remembered that the fruits are as valuable for human food as the flowers are for feasting the eye.

The Cactaceæ have an immense range in the altitudes of central North America, or in what we may term the California *stimulacra* of climates and soils, as they are found from the parallel of Cariboo to Cape St. Lucas, and from the eastern slopes of the Rocky Mountains in North Dakota to the Gila river. They are met with in all latitudes between Gila and Panama, from the line of perpetual snow to that of the sea-shore. Some two hundred different species of this singular family of American plants are enumerated in the botany of Mexico, ranging from the shape of a Cabbage to that of a Grape Vine, and looming high as a tree and umbrageous as a small Oak. Their flowering is of extraordinary splendour and loveliness, and is from the purest white to vermilion, including every mixture of the prismatic colours. But it is the fruit, the standby of the poor and the Indians in the seasons of drought and famine, that unfolds this providential blessing of the desert in all its value.

Engleman, of St. Louis, an eminent writer on this family, enumerates as indigenous to Arizona and South California four genera of the Cactus—that is, thirty-seven species of the *Cereus* or perpendicular stems, six *Mammillarias* or *Mamaes*, and six *Echinocacti* or Cabbage-Heads. Almost every one of these is found in the mountain ranges and deserts of Los Angeles, San Bernardino and San Diego counties. In Lower California many specimens are met with which are foreign to our parallels of latitude, one of which, a climbing variety, is found in the driest months to be full of the purest water. One of the *Opuntias* has a small fruit, specific in scurvy and blood impurities, while others have fruits with the flavour of Pine Apples, of Strawberries, Peaches, Plums, and Cherries, of the luscious *Cherimoyer* and *Mangosteen*, of the Fig and Grape, and of the Lemon, Apple, and Pear.

The Cactus *opuntia*, or Indian Fig of Mexico—white and red—was introduced into the mission gardens of our state from Santa Clara to San Diego in the early settlement of the country, some seventy years ago; but they are also found indigenous to the mountains of Colorado, in San Bernardino and San Diego counties. Near all the southern missions below Point Concepcion they grow luxuriantly, particularly at Santa Barbara, San Fernando, and San Gabriel. At the two last-named places they are extremely abundant and luscious. These varieties of the Prickly Pear are valuable additions to the food of our state, as the food is not only very plentiful in the summer and fall, but is highly nutritive and agreeable, and can be gathered at will, and the plant requires no care. When stripped of the prickles they can be boiled down to an excellent conserve or syrup, or dried in the sun for preservation, as they contain a large quantity of sugar and gum. The plant is easily propagated by slips or seeds, and has a wonderful endurance, vitality, and hardness. It comes to perfection in three years. Its seeds, which are very abundant in the fruit, are toasted by the Indians as a substitute for corn. The mucilage of the leaves or fronds is thrown into water and used in making cements and whitewashes, and gives great strength to those house-building materials in the arid districts of Mexico. It is in common use around Los Angeles.

Being such plentiful and excellent producers of sugary fruit, so necessary to the labouring man in our dry and attenuated atmosphere, this matter should be attended to by our people, as well as the arts of making molasses from Mangoes, Pumpkins, Melons, Water Melons, Grapes, Pears, Beet, Cornstalks and the wild Sugar-cane, or *Panoche-carisso*, of the Tulares. All these fruits are well known to the Indians and Mestizoes of Sonora

and New Mexico, and those of Chihuahua and Coahuila, as producing sugar; and particularly the Cactaceæ and Agave, among the Pimos and Papagos of Arizona, who consider the Cactus and Mango as gifts from the gods, for from them they receive food, clothing, shelter, and fencing. The reduction of these articles to conserves and molasses is often facilitated among these simple people by a concentrating process of roasting and baking, and boiling down slowly afterwards, with a little water, to a viscid syrup which never ferments in their keeping, though several of them are also used in the fabrication of mescal or spirits. Of such an exhilarating quality is this fire-water that they often give for such alcohols weight for weight in silver, and bless the vendor for his trade.—(*San Francisco Bulletin.*)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

FRESH plantations of Cabbages and Lettuce should be frequently examined, any that droop without an apparent cause should be examined at the roots, where probably a grub will be found, which, if not destroyed, will continue its ravages. *Earth-up* the plantations of Broccoli, as they will now be growing rapidly. *Cauliflower*, continue to prick out the young plants under hand-glasses and in frames, a few may be potted in small pots and placed in a frame, where they can have abundance of air and light, and be protected from excessive wet. *Celery*, a few rows of that which is required for immediate use may be earthed up to the full extent of the leaves; the successional crop should only be earthed up at long intervals until it is required for use, or on the approach of winter. It should at all times be thoroughly dry before earthing, or it will soon rot. *Cucumbers*, where there is any forcing-house, those in frames are scarcely worth the trouble and expense of keeping in a bearing state after this time. Plants in frames produce the finest fruit for show, but as they are only grown through the winter for use, they are cultivated at much less expense and with greater care in a forcing-house. A little manure water should occasionally be given to those in pots or boxes. Stop the laterals immediately the fruit shows itself, at the same joint, or one above it. Some prefer the latter mode, but if the leaf at the fruit-joint be not injured, we have not been able to discover any difference between the one and the other in the swelling of the fruit. *Mushrooms*, keep the outdoor beds protected from heavy rains, by a good covering of litter. Maintain a regular degree of heat in houses containing beds, and guard against aridity. *Potatoes*, continue to take up the crops as they reach maturity; sort them before they are housed. *Radish*, slightly thin the late sowings of the Spanish sorts; if a succession of the common sorts is required a sowing should be made in a frame. *Spinach*, thin the winter crop, leaving the plants about 9 inches from each other. Keep it free from weeds. *Tomatoes*, should there be any apprehension of frost, the unripe fruit may be cut and laid in any of the forcing-houses.

### FRUIT GARDEN.

Pay every attention to getting the wood of Peaches and Apricots well ripened by exposure, shortening, &c. Most kinds of Apples may be gathered during the present month. Late Pears should be left on the trees while the weather continues favourable to their ripening. Prepare for planting all kinds of fruit trees, by getting the ground in good order for the different kinds. On cold, stiff soils it is advisable to plant on hillocks 1 foot or 18 inches higher than the surrounding surface. The trees will not grow so fast in consequence, and will require more attention in summer in the way of mulching, but they will form short-jointed, well-ripened, fruitful wood, which is the best preventive of canker, gum, &c., and will save the labour of resorting much to root-pruning.

### FLOWER GARDEN.

The scarcer varieties of variegated Geraniums should not be risked in beds too long, they had better be taken up and potted immediately the weather becomes at all threatening. After potting it will be a good plan to place them on a gentle bottom heat in a pit or house, where the atmosphere can be kept sufficiently dry to prevent the foliage being injured. So circumstanced they will soon become established, when they may be stored away for the winter in a cool, dry house, where they will be out of the reach of frost. Any beds which may have become shabby, and which are to be planted with bulbs or anything else for spring decoration, should be cleared at once, and

replanted. Keep grass short and frequently rolled, so as in some measure to prevent the growth of moss, and keep the surface firm and smooth. Also, roll gravel walks frequently in damp weather so as to render them smooth and comfortable to walk on.

### GREENHOUSE AND CONSERVATORY.

Hyacinths and other Dutch bulbs, if not already potted, should be procured and potted without delay. Orange trees meant for forcing in the winter for the decoration of the conservatory, should also now be attended to. These and Daphnes are invaluable for winter blooming, and should be largely grown for that purpose; also see to having plenty of *Salvia splendens*, which is useful for mixing among *Chrysanthemums*. It is a good practice to place the largest plants of *Salvias* in a shady situation out of doors for a few weeks in the autumn. Plants so treated will be found to bloom more strongly and last longer in beauty than others run up in a warm house. Look carefully after the watering of large specimen hardwooded plants in pots, especially Heaths, which are soon injured by being either over or under-watered. Examine the specimens often and carefully, and where they are found to be dry, water thoroughly, so as to moisten the whole of the ball; also look sharply after mildew on softwooded Heaths, and dust the plants with sulphur directly the enemy is perceived. Let *Azaleas* be tied into form as soon as can be done, in order to give them a neat appearance; also attend to the staking and training of other things as leisure time can be found. Look carefully after red spider on *Bossias*, *Chorozemas*, and anything else found to be liable to that pest, and see that it is eradicated before the plants are disfigured. Red spider is easily cleared off by laying the affected plant on its side and well washing the under sides of the leaves with the engine, applying the water with as much force as the foliage will bear. Repot strong-growing *Pelargoniums*; plants that are fairly established after repotting can hardly be kept too cool; also keep *Cinerarias* as cool and moist as is consistent with safety, and attend to repotting such as require it. *Primulas* must also be carefully attended to in order to encourage them to make rapid growth, particularly double varieties. Keep tree *Violets* clear of their great enemy, red spider, by a liberal use of the syringe, and give them plenty of manure water, which will assist in keeping them in vigorous health. *Van Thol Tulips* for forcing may be potted. Early *Chrysanthemums* will now be in a forward state, and such as show their buds prominently should be taken under glass; if it is desirable to have them in bloom as soon as possible, they may now be placed where a little artificial heat can be afforded them. Take care, however, that they are placed near the glass, well supplied with manure water, and air given them freely, as anything in the shape of close confinement would soon ruin them. Indeed the whole stock of them should now be placed where it can be covered at night, in case of frost; for although they will bear more of that than most plants, it is not good policy to leave them to the mercy of the weather much after this season, unless in favoured localities. It is better, however, to place them in skeleton frames, or in a sheltered situation, where they can be covered in case of need, than to huddle them too thickly together under glass, or to put them, as is sometimes done, under the shade of Vines. See that *Epaerises* and other winter-blooming plants are placed in a light part of the house where they will be fully exposed to the sun, so as to have the wood well ripened, and to ensure their blooming freely. In the case of *Ageratums*, *Heliotropes*, and dwarf *Labelias*, it is useless wintering young stock, as these grow so freely in heat, and are so easily propagated from soft cuttings, that a few good-sized old plants, which require but little room or attention in winter, will furnish a very large quantity of plants by bedding-out time. Attend to the potting of cuttings sufficiently rooted, and give every after-attention to these in order to have them well established.—W. KEANE.

## DOINGS OF THE LAST WEEK.

THE rain of Thursday week helped many things in the kitchen garden, gave a little aid even to late Apples and Pears, and tended to keep such flowers as *Calceolarias* good and passable for some time longer. *Verbenas* looked washy for a day or two afterwards, but have again been brilliant under an Italian sky, as for several days not a cloud or a semblance of a cloud was to be seen. The bright sky after the day's rain seems to have greatly improved the colour and appearance of out-door fruit, rendering Apples rosy and bright, and also

making the buds appear full and prominent, and therefore promising for another year.

#### KITCHEN GARDEN.

Sowed Cauliflowers for a second spring crop. Watered Lettuces, Endive, &c. Planted more Lettuces—some to be raised again. Watered Cauliflowers with manure water, the heads swelling for use. Watered also Coleworts, Celery, and young Cabbages; dug ground for more Cabbages. Wheeled lots of Onions into orchard-house, where they can lie dry on the floor until we find more time to string, bunch, and house them. Cleaned winter Onions, Spinach, Radishes, &c. Went over a bank of Dwarf Kidney Beans, pulling all the pods off that were at all advanced; forked the ground, and gave it a good soaking of manure water, so that if the weather continue fine we may have another month's gathering. Placed some old lights over another piece where the pods are just setting, and sowed more to go under cover and into a little heat as soon as the cold nights come. Exposed late Tomatoes to the sun. Examined a heap of spawned bricks for Mushrooms, and find all as it should be. Extra heat must be guarded against. See a few hints lately in answer to a correspondent.

Thoroughly smoked our Mushroom-house with burning sulphur, keeping all shut up for two or three days. This smoking, we believe, helps to keep us clear of woodlice in the winter months; but that is no doubt partly owing to the manure being well prepared in the autumn, whilst for spring-beds we must use pretty well what we can get, and as heat is dear to the woodlice, no doubt we take them into the house with the droppings, &c. At any rate, by March and April we are always sure to have them in-doors, less or more, and all we can do is to keep them down by trapping and scalding. At one time we were so pestered that we could not keep a Cucumber plant safe from them in spring, unless the plant was supported from the ground, and the supports of the trellis and the stems of the plants were surrounded with a circular vessel filled with water. Though found in damp places, woodlice always prefer a dry one. A mere rill of water in a circular vessel will not stop them. The width for the water should be at least from 1 to 1½ inch. We have seen them sitting on the edge of such vessels, and trying with their feelers or antennæ, if there was any chance of bridging the water. We have never noticed anything among them like the sagacity said to be displayed by some kinds of monkeys and ants, who, hanging together by their tails and hinder ends, make a living bridge over a stream, by means of which their compatriots may pass over without wetting their feet. A little soap, or salt, or quassia in this circular trough, but open in the middle to let stems, &c., through, renders the water still more distasteful. Once, however, we recollect daubing part of the outside of a pot with soft soap, but it was all cleared off in the morning, with what sanitary effects on the grey-coloured gentry we never knew. Water alone is a great annoyance to them. Hence, on watering a Mushroom-bed, they are sure to escape from the bed into any crannies at back and front, and there afterwards they may be scalded with hot water, or if a little dry hay be strewed along they will nestle into it, and next morning myriads may be destroyed by pouring hot water on them. Small flower-pots with a little dry hay in them, with or without a piece of boiled potato, or carrot, make capital traps, but the finer, the looser, and the drier the hay, the better will they like it. The quickest way to end them, is to tumble the contents of the pots into water near the boiling point. In all old gardens it is next to impossible to eradicate them entirely. We hardly know if they are useful to us for anything, but we do think that at times they are condemned without reason. That they meddle with our young Mushrooms at times is no doubt true; but they are often blamed for what snails and grubs manage to effect. We have seen them boring holes into young Mushrooms, and yet at other times we have seen numbers on a bed, and not a Mushroom touched for months. What could tempt them in the one case, and lead to abstinence in the other, we know not. Many birds are their natural enemies, and in confined places, as pits and frames, toads, and even frogs, are helps to the gardener. The toad in putting a woodlouse out of sight, affords one of the very best instances of physical dexterity. The great Wizard of the North could scarcely exceed it. At any rate, the man who can see the toad transfix one woodlouse after another, will have no reason to complain of weakness of eyesight. So long, however, as our prejudices against the toad continue, it would not do to have him in our Mushroom-beds. We may add that all who keep toads in frames, &c., should keep a little saucer always supplied with water, that they may bathe or drink

at will. We can well enter into the feelings of revolt and aversion, which a correspondent says she cannot help experiencing as regards the toad, notwithstanding his beautiful eyes, and, therefore, she must lessen the myriads of woodlice that annoy her, without his aid, and of all things must not give them the chance of wandering among her Mushrooms. We mention the little matter of the saucer of water for the sake of those who feel no such aversion to employing the toad as their servant, and who would be as unwilling, knowingly, to abridge his necessary comforts, as they would be to lessen the due remuneration of any servant that was well worthy of his hire.

#### FRUIT GARDEN.

Went on collecting hardy fruit. We hope after such ripening weather the late fruit of Apples and Pears will keep well, as most of the early kinds have shown a disposition to decay prematurely. This is the case especially with all that have dropped. We wished a lot to be cleared off by the men when they would have been useful. Something prevented them taking them, and in three days the scent told how matters were going. All wall fruit, as Peaches, &c., came in prematurely this season. Late kinds, as Walburton Admirable, &c., were gathered a fortnight ago, and quite ripe enough, though they kept good for several days. The same kinds have been good, and will be so for a little longer in the late orchard-house, as with a fair command of air fruit may be kept much later there than on the open wall. As stated the other week, we have no doubt that our latest Peaches, and such Plums as Coe's Golden Drop, and Reine Claude de Bavay, could be kept very late in such houses. The Plums especially would be grand in November, if there were the means of keeping out any sudden frost.

#### ORCHARD-HOUSES.

This week we have had a number of notes about these, speaking of failures, partial failures, and inquiries about heating, &c. A few words here will meet the most of these cases. First, then, we would wish it to be laid down that all heated houses, properly speaking, cease to be orchard-houses, and become heated fruit-houses or forcing-houses. Mind, that is no reason why such houses as are called orchard-houses should not be heated. We believe that all or most would be the better of being heated, or at least of the heating material being at hand, ready to be used when wanted, if not regularly, at least on an emergency. Merely for distinction's sake, however, it would be well if the title orchard-house were confined to an unheated house, except, perhaps, one with a portable or brick stove in severe weather. Then, supposing that an orchard-house is made with large squares of glass, instead of so many little pieces, we are inclined to say that in all places where it is worth while to build a wall for tender fruit, it would suit the builder's purpose to front it with glass, either as a lean-to or otherwise, and if that is done in the economic orchard-house style, it will soon save the expense in certainty of result, and saving of all protection. Far north, and in very cold exposed districts, we would not say exactly the same of a span-roofed house, without any means of heating, as it would contain no storehouse of heat, as the back wall of a lean-to always is. Even such a span house will give great facilities to the gardener, for the still air it secures in winter, and the high temperature it will also afford in summer, if that temperature is desirable. Such a house, to a certain extent, though not quite to the same extent as a lean-to, can be used as a protecting, accelerating, or retarding-house, even without any artificial heat being used. One principal cause of failure in some eight or ten cases presented to us, in these unheated houses, is owing simply to the fact of having the buds too forward, and the blossoms opening too early in the spring. This is partly owing to not being satisfied with keeping the orchard-house for fruit trees, but filling it in the winter with Lettuce, Cauliflower, &c., which a little frost will injure. Even then, if shut up at night, much might be done with plenty of air during the day when the thermometer rose above freezing point, and leaving the house open at night when frost was not apprehended. When the frost outside did not exceed some 7° or 10°, it would be as well for trees with well-ripened wood to have the ventilators open all the winter. When much besides the trees has to be attended to, a compromise must be made. The chief danger arises from keeping the house too much shut as the spring advances. If there are tender things on the floor, then they had better be covered over to permit of more air being given.

Some of our friends who have failed, wrote to us in rather a boasting spirit, that their trees were in full bloom in February. Now, we would have been better satisfied if the trees were in

such a state in the end of March, or even later. For all such unheated houses, as well as for open walls, the later the blooming, comparatively speaking, the better and more secure will be the crop in general seasons. Blossoms will stand a number of degrees of frost in the still dry air under glass, but coming into bloom in February there is more likelihood of the bloom suffering from frost. They are also apt to suffer from coldness at the roots, and hence the want of reciprocal action between roots and branches. If the bloom came a month later, the ground would be getting warmer as well as the atmosphere. In a cold unheated house, therefore, early blooming is to be avoided. Plenty of air is, therefore, to be given, provided the frost is not severe enough to hurt the buds. If to guard against this last evil the house must be shut at night, it should be opened as soon as the sun tells upon it. In very cold nights in January and February, with very bright days for a week or a fortnight, in addition to plenty of air, it may often be advisable to dull or shade the glass for a time, to lessen the force and power of the rays, just as it would be advisable in similar circumstances to shade a wall of Apricots or Peaches, to prevent the blossom coming too early, so as to be a prey to future frosts. Let it be set down as a general rule, that very early blooming in unheated houses is more likely to be an evil than an advantage.

When the trees have bloomed and set in a comparatively low temperature they become very obedient to our wishes afterwards, if we use them at all fairly, and do not subject them to too great changes suddenly. By shutting up the house with sun heat, without any other heat whatever, the fruit may be gathered ripe some four or six weeks before it can be in the open air; or by keeping on air night and day in good quantity the fruit may be obtained later than that on the open wall. We can thus gain results according to our treatment of an unheated house. The three or four accounts of failures from scalding, burning, and dropping in shut houses arose, we believe, not as our correspondents think, from an insufficiency of air-giving power, but from not giving that air, or a little of it, early enough. The top ventilators should be at least partially opened as soon as the sun begins to tell on the house. An hour or two of neglect may sacrifice the whole crop. Amateurs who are doubtful about getting out in the morning should give air, at least at the top of a lean-to, however little, the last thing at night. It is not the high temperature of even 100° during the day that does the harm, if that temperature rises gradually, and with air on to prevent heated moisture having any place; it is the raising of the temperature suddenly in a close house that does the mischief. In such a house to be accelerated the air may be reduced by 3 p.m., and removed by 4.30 p.m., thus shutting in a good amount of sun heat. If there is a doubt, a little air may be given again on warm nights about 8 p.m. The trees may be syringed when thus shut up in a sunny afternoon; when dull and cloudy the syringe may be dispensed with. There will be a great difference in the temperature of such a house, after a sunny day, at 5 p.m., and at the same time after a dull cloudy day; but the same thing takes places with fruit trees out of doors, and with no bad results following. As the sun, however, tells more powerfully under large squares of glass than in the open air, it may be advisable at times, when very bright sun comes after very dull weather, just to dull the glass with whitened water, so that the change should not be too sudden. The early use of the ventilators will greatly neutralise all such sudden extremes, and for such cold houses that are to be accelerated, the right use of the ventilators is the great point of safety and success.

To ripen fruit as late as possible, the ventilators may be open night and day, except in emergencies, after June, when all danger from frost may be considered past. A good succession of fruit may thus be had even from these unheated houses, and the practice may be varied to meet the requirement. They would, of course, be more under control, if they were heated, but some people have such a dread of pipes, and bricks and mortar, who really enjoy walking and working among trees, merely under glass, and when once they reap the full enjoyment of such a house, they are very likely to end in having more substantial heated houses. We believe that these simple orchard-houses have already led to pretty well doubling the number of more substantial houses in the country.

We have been giving less air to our first orchard-house, for the purpose of hardening the wood, and ripening Figs in pots. We have taken the sashes off a Peach-house, to have the rafters, &c., repaired, and the glass had not been off ten days before we noticed a tree or two affected with scale, which gave

no signs of it before. We have syringed with soap and quassia water, as the scale insects greatly injure the wood when they get on it.—R. F.

COVENT GARDEN MARKET.—SEPTEMBER 30.

We have nothing fresh to report, supplies are well kept up, rough descriptions of goods meeting a very heavy sale at former quotations. The best Pears now are Marie Louise, Duchesse d'Angoulême, and Brown Beurré the best Apples, Cox's Orange Pippin, Ribston, and King of the Pippins.

TRADE CATALOGUES RECEIVED.

Eugène Verdier fils aîné, 3, Rue Dunois, Gare d'Ivry, Paris.—*Trade Catalogue of Gladiolus.—Rosiers Nouveaux, pour 1865—1866.*

E. G. Henderson & Son, Wellington Road, St. John's Wood.—*Catalogue of Bulbs and other Flower Roots, &c.*

Paul & Son, Old Nurseries, Cheshunt, Herts.—*Rose Catalogue, 1865-6.*

D. Dauvesse, Rue Dauphine, Orléans, France.—*General Catalogue for 1865-6.*

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BOOKS (B. C. D. E.).—"The Poultry-Book" contains what you need. It can be had from our office post free for seven stamps. "The Garden Manual" may be had similarly for twenty stamps. To ask for "two of the best Dahlias" is far too wide a question. Lord Palmerston, deep scarlet, and Canary, light yellow, might suit you. Any florist who advertises in our columns could supply them.

RUSTED GRASS (Henry Clark).—The "red brick dust" which came from the grass upon your shoes are the spores, or seeds, of the *Uredo rubigo*, or Rust, a parasitical fungus.

SEEDLING DAHLIA (N. B.).—The colour is not good—the white and crimson run together. As it is so high a plant and the flowers small it cannot be valuable.

**ORANGE TREES UNHEALTHY (T. C. W.).**—From what you state we should think that they are old, and have been grown in the tubs for a number of years without shifting, until retubbed last year in May, and that pieces of the old tubs, into which the roots frequently penetrate, were buried in the new tubs. We do not affirm that this was the case, but it is very likely, and we know that such pieces of wood aid in the production of fungus, and its mycelium spreading takes possession of any decayed roots, and eventually of live roots also. The roots perishing, the shoots die back, and the leaves fall, until at last the tree dies, and this we have ourselves experienced from the same cause. In any case the condition of your trees shows an unhealthy root-action. Examine the drainage at once, and, this being perfect, the trees will become no worse until February. In the end of that month, or early in March, take the trees out of the tubs, and with a wedge-like and pointed piece of wood pick out the old soil from amongst the roots, taking great care of the fibres, and cutting out all dead roots with a sharp knife. If the roots are very much diseased and decayed the soil should be washed entirely from them, and the dead and decayed roots thoroughly cut out. The tubs being pierced with holes at the bottom (half a dozen  $\frac{1}{2}$  inch in diameter will be ample), put in crocks for drainage, previously washed clean, to one-fourth the depth of the tubs, placing the largest at the bottom and some smaller ones upon them. As regards soil, though we have tried many kinds, we have found none so good as turfy loam from turves cut  $\frac{1}{2}$  inch thick from a pasture of good hazel or yellow loam, and if rather strong all the better. Lay this up for twelve months and turn it over twice, mixing with it every turning a bushel of soot to every cartload of turves, to render it distasteful to wireworms, and it will be eminently suitable for Orange trees, and, in fact to all fruit trees in general cultivation. This compost should be kept under cover for a short time so as to be neither dry nor wet, and may then be chopped up with a spade into pieces 1 or 2 inches square. Some of this is to be riddled with a sieve having inch meshes, and what remains in the sieve is to be placed at the bottom of the tubs upon the drainage to the depth of 3 inches. Then introduce the trees, using the compost chopped but unsifted, and work it well but carefully in amongst the roots. Place the neck or collar of the trees a little higher than, rather than a little below, the edge of the tubs. Spread out the roots, and place soil between the layers as they rise. Do not cover the uppermost roots with more than  $\frac{1}{2}$  or 2 inches of soil. Make the soil pretty firm, but neither very firm nor loose. Leave space for watering, give water as soon as the trees are retubbed, and at once place in a temperature of  $55^{\circ}$  by night, sprinkling the trees morning and evening with water of the same temperature as the house, and maintaining a moist atmosphere. If the tubs could be plunged in a bed of tan, or other fermenting materials, at a temperature of  $75^{\circ}$  or  $80^{\circ}$  for a fortnight or three weeks, quick root-action would be ensured, and they should be gradually withdrawn when top-growth commences. The temperature by day should not exceed  $65^{\circ}$  with sun at this season, and with all but leafless trees, little water will be needed; none to be given so long as the soil remains moist. If the heads are full of wood they may be thinned out before growth takes place. After growth has recommenced if the soil become dry water copiously and at once, but never until really necessary. Give abundance of air after growth takes place. To keep the roots cool the tubs may be surfaced with an inch of cocoa-nut refuse. The trees will not need anything in the way of manure or manure water during the first season after retubbing, but in future top-dress the trees in February with an inch of cow-dung, kept dry for six months and then broken fine, and on this place a little loam for the sake of appearance. After the trees have been a number of years in tubs the old soil around the sides of the tubs should be removed annually in February along with the loose surface soil, and any that can be picked out with a stick from between the roots without injuring them; then replace with turfy loam mixed with an equal quantity of cow-dung not more than a year old nor less than six months. Weak liquid manure may also be given during summer. The rich compost and liquid manure are only for plants in good health, though they may be weak. From some cause or other your trees are in a very bad condition; bad drainage, sour and too rich soil, will produce the effects which you mention, and so will treating the Orange as a bog plant. When the roots are in a suitable medium the trees will thrive, but once these are in a bad way they are slow of recovery.

**HERBACEOUS PLANTS—AZALEA LEAVES BROWNED (W. D. B.).**—"Flower Gardening for the Many" contains a full and descriptive list of herbaceous and other border plants, which you can have by post from our office for five stamps. The Azalea leaves are browned from allowing water to stand upon them during very bright sun, and from the plants being grown without a sufficiency of air. Spraying with a solution of soft soap will also produce the same result. What Cyclamen is if you wish to know how to cultivate? Write us, we shall be glad to furnish the information necessary.

**SCREEN FOR A GARDEN (S. S. S.).**—There is no question about a Beech hedge best serving your purpose. It is of rather slow growth for the first two or three years, but after it becomes established it makes shoots from 1 to 2 feet long in a season. You may perhaps be able to get trees 6 feet or more in height, but of whatever height they must be feathered to the ground, or have side shoots not more than 1 foot from the surface. The common Beech (*Fagus sylvatica*) is the most suitable, and it stands smoke pretty well. The larger the trees for your purpose the better, as they will form a hedge almost at once if planted 2 feet apart. If smaller trees are planted, say 3 or 4 feet high, a foot or 18 inches is the proper distance. The ground where the trees are to be planted should be dug deeply, 2 feet if possible, and a liberal dressing of manure given if the soil is poor. Trees 3 or 4 feet high will not make a hedge 12 feet high in less than seven or eight years; trees 6 feet or more high in half that time. If a thick hedge be wanted the trees should be planted in double lines, 18 inches apart in the lines, and 1 foot from line to line, planting quin-cunx fashion. The first year the trees will need no clipping, only any long side shoots may be cut in after the growth is made and the leaves have fallen, or, if they remain on dead, cut during the winter. In future years clip the sides after the fall of the leaf and before fresh leaves are produced. Allow the heads to grow, cutting at the sides only until the hedge attains the desired height, but if any much overtop the others they should be reduced to an equality with these. Immediately after the leaves fall is a good time to plant, and from that time (November) to March. When once established the hedge will grow fast, watering in dry weather during the first year will enable it to become more speedily established, and rich soil will do the rest. Poplars would grow more rapidly, but soon go off where there is much smoke.

**POTTING VALLOTA PURPUREA—LILIAM BULBS DRIED (P. P. P.).**—The best time to pot *Valloia purpurea* is when the plants are growing freely, but any time will do except when the flower-scape appears, and during flowering. From March to May is as good a time as any. So long as the drainage is good and the soil not sour the plant will bloom all the better of the roots touching the sides of the pot; repot, therefore, only when the soil becomes sour or the plants too large. The best of the white *Liliums* for pot culture is *Lilium speciosum* (Lancifolium) album, but all the varieties of that species have white flowers spotted with red in its various shades. Bulbs purchased would bloom well another year if large enough. Nurserymen keep such bulbs in the soil until ordered, so that they are not long enough in their seed-shops to be injured to any great extent. The sooner they are potted after being taken up the better.

**LILIES OF THE VALLEY NOT BLOOMING (A. V.).**—They ought to bloom next spring if taken up from the bed and potted at this season. We never pot any except those with large plump buds, feeling them with the finger and thumb, and if they are large and firm you will, on opening one or two, find the flowers within them. Such roots are the right ones to take up and pot, nine out of every ten of them will bloom if not forced so hard as to go blind. To your having potted the roots last year with small thin crowns is to be attributed the coming up of the leaves without flowers, unless, as before stated, the plants were too rapidly forced into growth.

**WINTERING ROSE CUTTINGS (S.).**—The cuttings recently potted off, and which are well rooted, will be best plunged quite up to the rim of the pots in coal ashes in your cold frame. If placed on the stage the frost will injure the roots. Give them abundance of air in mild weather, with a covering of mats, or something dry over the glass, in severe nights, and during the day so long as the plants remain frozen.

**EVERGREEN PLANTS FOR COVERING A TRELLIS (Rosery).**—You confine us to evergreens for your shaded east and open south-east aspect, and yet you say you do not wish for Ivy on the east shaded aspect. Ivy is the very plant for a corner. However, though we do not know any suitable evergreen climber, the following plants may answer, if not too much shaded—*Crataegus pyracantha*, *Cotoneaster microphylla*, *Berberis Darwinii*, and *Photinia serrulata*. South-east aspect:—*Viburnum suspensum*, *Raphiolepis ovata*, *Eucallonia glandulosa* and *oreganensis*, *Garrya elliptica*, *Cotoneaster Simonsonii* and *buxifolia*, *Ceanothus azureus pallidus* and *floribundus*, *Buddleia globosa* and *Lindleyana*, *Arbutus Menziesii* and *procera*, *Olea europaea* and *ilicifolia*, *Ligustrum japonicum*, and the Exmouth variety of *Magnolia grandiflora*.

**DACTYLIS GLOMERATA VARIEGATA CULTURE (S. Edwards).**—This is a somewhat tall and rather coarse Grass, besides not being permanent in its variegation. It is quite hardy, simply requiring to have the roots divided in April and planted 6 inches apart where it is to remain, watering after planting, and during dry weather until established. If it be *Dactylis variegata elegantissima* that you mean, which is of closer and more dwarf growth, and the whitest and most permanent of variegated Grasses, it is only hardy in dry well-drained soil. It is best taken up in autumn, potted in sandy loam, and wintered in a cold greenhouse or frame. In spring if the plants are divided every shoot will come away with a little root or one partially formed at the base of the divisions. Pot these in sandy loam in pots  $2\frac{1}{2}$  or 3 inches in diameter, and set the pots on coal ashes or plunge them therein in a cold frame. If watered and kept rather close and moist for a few days roots will soon be emitted, then harden off, and plant out in May, at 1 foot apart in lines, or from 6 to 9 inches apart when planted in curves. This grass will grow in any soil, but best in light loams, with a little leaf mould added. In rich soil it grows more strongly, and attains a height of 1 foot or 15 inches. We mean to try planting it as a permanent edging, and clipping it with the shears until it becomes thick, and then mowing it with the machine like a grass verge, as we think it will become less strong in stem by cutting.

**OXALIS TROPICOLORS CULTURE (Idem).**—This is synonymous with *Oxalis corniculata rubra* and *O. corniculata foliis atropurpureis*. It is a hardy perennial, forming dense tufts of deep purplish-brown leaves, and does well in loam or gravel. It strikes as freely from cuttings as the Verbena, and at any season; but to have good plants they should be struck in July or August in a close cold frame, and when well rooted pricked off 3 inches apart every way, and planted out in spring where they are to remain. Cuttings struck in March make nice plants for planting out in May. It is easily raised from seed. Good plants may also be secured by sowing in pans in a frame late in summer, and when large enough to handle pricking off 3 inches apart in sandy or well-drained ground, or potting off in small pots in sandy loam with a little leaf mould and sand, and wintering in a cold frame. If sown in February and March like *Lobelia speciosa* and treated like it, nice plants are obtained for planting out in May. It is an edging plant of dwarf compact habit and withstands rain well; it is of the colour of Ectrot leaf, not so dark as Perilla, but deeper than *Amaranthus inchanolicus ruber*, and better than either for small beds and narrow borders. So common a plant deserves more extensive cultivation. It is a charming plant for the lower fissures of rockwork. The flowers are bright yellow.

**SOILING NEMOPHILA INSIGNIS (T. S.).**—To have it in bloom in September and October, it should be sown during the third week in June, in warm situations, and on dry sandy or stony ground, and during the first or second week in that month, if the soil is heavy and cold.

**LEAKING TANK (A. K.).**—The tank being of bricks laid in Roman cement and leaking after frost, there is no question as to the leakage being caused by the expansion of the water converted into ice. We have a tank of this kind sunk so as to be covered with 1 foot of soil, and having a moveable lid to get at the water, and the latter was never known to be frozen, nor the tank to leak. It is used to hold soft water for watering the garden. We only wish we had more tanks of a similar description. The only suggestion we can make is to have yours covered with soil upon the tiles to the depth of a foot, and thus render it proof against frost, or to ram clay firmly round it, so that if the bricks and cement gave way from frost, the clay would prevent leakage.

**DESSERT APPLES AND PEARS (S.).**—The six best dessert Apples and the six best dessert Pears for a small garden in the south, the trees to be grown as espaliers, and the fruit to come into use from November to April or May, are—Apples: Cox's Orange Pippin, Reinette Van Mons, Sturmer Pippin, Scarlet Nonpareil, Dutch Mignonne, Wyken Pippin. Pears: Consciller de la Cour, Winter Nelis, Beurré Diel, Zephirin Grégoire, Beurré de Rance, Josephine de Malines.

**APRICOT TREE UNFRUITFUL.—EASTER BEURRÉ PEAR CRACKING AND DECAYING (G. Pitt).—**We should think that the Apricot runs much to wood, caused from the soil being rich, and the pruning excessive. When Apricots have covered their allotted space the growths are very often abundant and vigorous, and to keep them close to the wall much summer pruning has to be resorted to, which is seldom done until the shoots are a foot or more in length. This keeps the tree constantly producing wood, so that no bloom-buds are formed. Try stopping the shoots (except those wanted for filling-in and extension, which should not be stopped at all), at the fourth leaf, and when they push again at the first joint, and after this keep them close-stopped to one joint throughout the season. If the roots are not deep you will then have bloom-buds for fruiting another season. If the roots are deep and the soil rich, the tree will always make a great deal of wood, no amount of pruning and stopping keeping the shoots short and stubby, and as for spurs they will be few and far between. To take up the trees immediately the leaves turn yellow, and replant, would most likely give short-jointed wood, and many short spurs another year set with buds, from which you may calculate on having fruit in the ensuing season. If the tree is old and large it would be as well to try root-pruning, taking out a trench at a distance of half the height of the tree, and to a depth of 2 feet, and cutting off all roots there if any, and if none be found work towards the stem of the tree, cutting off all roots that go perpendicularly down, leaving all those less than the little finger as little disturbed as can be. Fill in the trench after you have worked the soil between the trench and the stem to within a yard or so, and leave the surface roots undisturbed; but if no roots that go down be found in that space, then follow up the trench to the stem, so that any roots striking down there can be cut off. This will be almost equivalent to lifting the tree, which if it is excessively vigorous, is what we advise to be done, and in the following manner:—Dig out a trench 2 feet wide and 18 inches deep, at half the distance from the stem that the tree is in height, and at an equal distance all round from the stem. With a fork remove the soil from amongst the roots for a distance of 3 feet, or half that between the trench and the stem of the tree. Then remove the surface soil down to the roots, and work under them with a spade so that the roots may be moved with some earth to them. This done quite up to the wall, lift the tree clean out, having first unnailed the branches and tied them together so as to prevent breakage. Ascertain whether there were many roots that had gone down by the wall, and if there were place a thin flag stone, a yard square, close to the wall just where the tree is to be planted, and at exactly 1 foot below the surface. The soil being removed from the opening to a depth of 1 foot 3 inches, lay at the bottom 6 inches of fresh and rather light loam, and if the top spit 6 inches, of a pasture, chopped with a spade roughly, nothing could be better. Lay about 3 inches of rather finer soil on this, and then place the tree in its proper position, and if the roots next the stem be just on a level with the surface all is well. Cover them with 3 or 4 inches of fresh soil, so that the stem may appear slightly elevated. Spread out the other roots not in the ball regularly, cover with a little fine soil, and finally cover up with 6 inches of good turfy loam. If the border is not cropped, then the roots should be 3 inches nearer the surface. The best time to do this is immediately the leaves turn yellow. The Pear tree root-pruned last year could not have been so effectually. That kind of root-pruning at a distance from the stem, and which only takes away the thick roots there going deep is worse than useless. The roots that go down are in nine cases out of ten tight under the bole, and for root-pruning to be effectual these must be cut. The roots have penetrated into bad soil, and must be brought nearer the surface to effect a cure.

**PRESERVING KIDNEY BEANS AND SCARLET RUNNERS (Idem).—**We have known them kept quite fresh until March, and, in one or two instances, until these Beans came in again. The process was simply gathering the pods, when of a size fit for use, on a dry day, and during dry weather if possible. A thin layer was then placed at the bottom of a stone jar, then a thin layer of fine salt so as to cover them, and on this a layer of Beans, then salt, and so on until the jar was full. We cannot say how much salt was used, but we think that it was equal to one-fourth of the bulk of the Beans.

**LOMATIAS—CLARY WINE (W. Harlow).—**Lomatia ferruginea is a native of China. *L. silaifolia* is from New South Wales. We never remember a recipe for effervescing Clary wine.

**A SMALL MARKET GARDEN (Devoniansis).—**To answer your query would require us to be acquainted with the rent paid for houses along the whole south coast. You must go and see for yourself. Select a lightish soil, and begin at some village on the shore of the Southampton water, such as Weston; but you will be puzzled to find a £5 house anywhere, we think.

**VINES OUT OF DOORS (Obliged Reader).—**You may try on your S.W. and W. wooden fences Black July, Early Saunier Frontignan, and Early White Malvasia. We have a series of very narrow glazed frames, like the lights of a Melon frame, but much narrower, to cover our Vines. At the bottom they rest on a course of bricks, at the top they go under a coping. They join closely to each other, and each can be easily lifted off to admit air or for any other purpose.

**GROWING PLANTS FOR PLEASURE AND PROFIT (Nemo).—**You may grow plants profitably and add a little to your income; but you must not think to do it and not let others know you grow plants for sale, as if it were something of which you feel ashamed. Your most likely way of disposing of your plants will be to those requiring them in the immediate locality, though we do not say you might not sell them at a cheap rate wholesale in dozens and hundreds to some dealer. You will find those plants suitable for windows and decoration of rooms most remunerative, especially those grown by the little-imitated in horticultural matters, as, for instance, Pelargoniums, Fuchsias, &c., for summer; Chrysanthemums for autumn; and Primulas and winter-blooming plants in winter. You will soon learn what is most in demand, and then go to work so as to meet the demand. Your seven hundred plants are, we presume, chiefly bedding plants, worth wholesale to a nurseryman 15s. per hundred, as he will probably have to send them out at 20s. or 30s., with the trouble of repacking and giving six or twelve months credit to the purchaser. Now, were they plants of which everybody liked a few, but which they have not convenience of raising, they would bring 6d. or 1s. a-piece. To grow plants for profit, the better kinds of common plants must be grown in quantity, and to effect sales the grower must not only openly announce himself a grower for sale, but solicit orders. Almost anything can be made to pay, the main points being principle, and supplying a good article at a fair price. Considering the time and uncertainty in the sale of plants, we are inclined to think fruit would pay better. Fruit always commands a ready sale; plants do not, being often kept in stock more for the accommodation of customers by nurserymen, than for the profit which they afford. Vines would pay well. A viney 18 feet wide would cost about £1 per foot run, and with the Vines 3 feet apart, an outlay of £3 per Vine would be necessary. The first year there would be nothing, and until the third year the produce would be no more than would pay for fuel and wear and tear. After the second year, up to the sixth year, 12 lbs. of Grapes per Vine would be what you might reasonably calculate upon having, worth 5s. per lb. in May, 3s. 6d. in June, and 2s. 6d. in July, and never lower than 1s. 6d. per lb. In full bearing they would give 20 lbs. per Vine without at all taxing them too much, worth at least £2. In the growth of Grapes successfully the profits are, reckoning wear and tear and first cost, equal to 25 per cent., and very often 50 per cent. may be made of them. Besides, you can make arrangements with a fruiterer to take all your Grapes at a stated sum, and not have one-tenth the trouble necessary in disposing of plants.

**DESTROYING LABURNUM TREES (Laburnum).—**Make about four incisions in the bark down to the wood, and in these place arsenic. If done a little below the surface it will not be necessary to put a bandage round to keep out the air, covering with earth being sufficient. As you wish to grow Ivy upon the trunks of the trees, though the arsenic will destroy the Laburnum it would prove equally fatal to any climbers, from the roots absorbing the arsenic from the soil. We should advise the heading-down of the trees now; and then, opening out the soil around the stems, cut the bark through level with the soil, and strip the trunk and roots of bark quite down to the wood. If you do this completely, with the trunk and the roots for a length or depth of a foot or two, the trees will die. Had you applied the salt, as you mention, in sufficient quantity it would assuredly have destroyed the trees. We should plant the Ivy without attempting to kill the trees. The foliage of the two, and the blossom of the Laburnum, would look well combined, as long as the Ivy allowed the Laburnums to live.

**WHITE GRAPE (F. H. R. A.).—**To ripen in a viney with your Black Hamburgs and Lady Downe's Grapes, if you wish for a muscat-flavoured Grape have the Muscat St. Laurent. If you do not wish for a muscat flavour have Royal Muscadine.

**NAMES OF FRUITS (A Young Gardener).—**1, Cornish Aromatic; 2, Shepherd's Seedling; 3, Catshead; 4, Alfriston; 5, Rymer; 6, Keswick Codlin; 7, Dutch Mignonne; 8, 9, Dumelow's Seedling; 10, Downton; 12, Kentish Codlin. (E. M.).—3, Beurré de Rance; 4, Louise Bonne of Jersey; 5, Knight's Monarch. (O. N. S.).—1, Flemish Beauty; 2, Winter Nebis; 4, Figue de Naples; 5, Boa Chretien Fondante; 6, Passe Colmar; 7, Thompson's; 10, Duchesse d'Angoulême; 11, Beurré d'Aremberg; 12, Glou Morcan. Never stick pins in fruit; it is a dangerous practice, and numbers so affixed are apt to become detached. (C. S.).—1, Beurré Diel; 2, not recognised. (A Subscriber, Alorton).—1, Cornish Aromatic; 3, London Pippin; 4, Marie Louise; 5, Hollandbury. (W. D.).—Your Pear appears to be Williams's Bon Chretien, but its flesh was completely rotten when it reached us. It is impossible, however, to tell the name with certainty from such an abnormal specimen. The fruit has been punctured by an insect when in a young state.

**NAMES OF PLANTS (T. Edwards).—**1, Doodia caudata; 2, Selaginella Martensii; 3, insufficient. (Aethica).—Polystichum angulare proliferum. Was it really found wild in Wales? It is a cultivated variety, and has never been recorded as a native of Wales. (Subscriber).—Yes, it is the water weed you suppose; the name is Anacharis alsinistrum. (Cistic).—Gentiana campestris.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending September 30th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### A FATAL DISEASE AMONG POULTRY PREVAILS IN PARIS.

SUCH is the whole of a paragraph which appeared in a local paper a short time since. Possibly more has been said elsewhere; but if so, it has escaped my notice. If this newspaper account be true it is very necessary to be informed on two points—firstly, what the disease is like, and, secondly, how the Parisians treat it. Then follow the questions—Are we likely to have it amongst our birds? and if so, What are the best means to adopt for prevention? What are the symptoms? Have we got it already?

This last question brings to my memory a paragraph in the "Field," of the 9th of last month, headed "Cholera in Poultry." It is there stated that several young chickens were almost all seized at once with excessive purging, and that they died at from two to four days after the beginning of the attack. A brood of nine chickens came in contact with these, and all died in one night. I have noticed amongst my own birds a tendency to diarrhoea; but by constant watchfulness I have had neither illness nor death from this cause. With disease around us in animal and vegetable life, it is necessary that at every sound of alarm public notice should be aroused.

I have been too short a time a poultry fancier, and too fortunate in the health of my birds to be learned in their diseases. Perhaps I am about to discover a mare's nest, or to inquire into that which is very well known to every one else; but I think your readers will agree with me that to ventilate the subject of diseases, particularly at this time, is a matter to be desired.

During last winter I had some birds sent to me, which were out of health and with a slight roupish cold. They came from a yard where roup was said to have been. By great care these birds recovered. A bird of my own stock was soon seized with a swelling on the right side of the face under the eye. This increased very much, and a discharge from the eye and nostril, apparently the result of much inflammation, set in. I showed the bird to a surgeon, who had once operated on a fowl for a tumour. He said that the swelling, except to the touch, had all the appearance of being one, but that it was not so, and that it felt more like an enlargement of the bone. He said further that it would be useless to operate. I applied warm lotions, and gave soft, nourishing, but not heating food; yet, in spite of all, the bird died. Another bird was seized in the same way, and being a valuable one, I took the nursing into my own hands. I gave castor oil, a pill of calomel and antimony on alternate nights, washed the part affected night and morning with warm water, and then bathed it with vinegar, fed every night on oatmeal, and gave after a time cod-liver oil daily. In about a month, during snow and very trying weather, the bird began to recover, but remained weakly until summer weather began. She then laid, hatched, brought up chickens, moulted, showed signs again of the disease, and whilst I was away from home this summer she died.

About the end of July last a cock bird was seized with the same attack, but before the second attack of the hen took place. In this case, as soon as the tumorous swelling was of considerable size, and we noticed an affection of the roof of the mouth, my man suggested that an incision should be made. This was done, and with a loop formed by a twisted hairpin, he extracted a filthy offensive core, and effected much discharge from the eye and nostril. I gave castor oil, but no other medicine, and afterwards Douglas's restorative. The bird is almost well again. In this and one or two other cases, where the birds being of little value were either killed or died, the affection came on the right side of the face. With these exceptions I have been singularly fortunate in the health of my birds.

I hear, however, frequent complaints from others of the loss of birds and illness of one kind or another. A neighbour has some Golden Pheasants all suffering from the same kind of attack as that which my poultry suffered from. We are too far apart, and have no communication with one another by which disease could be carried. He has lost several. I opened the swelling in the roof of the mouth of one of his birds, with the same results as in my own case. The bird is now recovering; the others have not been touched with the knife. The last that died I believe he sent to you, that you might examine it.

I hope this French disease may prove to be a fable, the cholera an exceptional case, and, at the risk of boring your readers, that I have told them nothing new in the disease I have mentioned. Still there is enough to justify inquiry, and I shall be indebted to any one who can furnish a speedy remedy or a simple preventive for the cases that I have named, and who will help to make known any coming disease with which we may be threatened.—EGOMET.

### BROUGHTON, BARTON, AND GOOSNAIGH DISTRICT POULTRY SHOW.

SEPTEMBER 21.

THIS Poultry Show was held at Broughton, near Preston; there was a numerous entry in some classes, and the competition was very severe. In *Dorkings* there were some good specimens shown; whilst in *Spanish*, although prizes had been offered, there was no competition. There were some capital *Game* birds exhibited, especially the chickens. *Cochin-Chinas* figured conspicuously, there being some remarkably good specimens exhibited. In the Golden-pencilled *Hamburgs* some beautiful old birds as well as chickens were shown. The same remark would almost apply to the Silver-pencilled birds. Golden-spangled *Hamburgs* were moderately represented. Silver-spangled on the whole were a good show, especially one pen of chickens. In *Game Bantams* the Show was excellent. *Geese*, though very noisy, were a good show. The *Aylesbury Ducks* were only moderate. In *Rouen Ducks* only one pen was exhibited. In *goslings*, and *Aylesbury* and *Rouen ducklings*, some very promising specimens were exhibited. Of *Pigeons* there were few entries. The awards were—

**DORKINGS** (Any colour).—Prize, J. Robinson, Vale House. *Chickens*.—Prize, J. Robinson. Highly Commended, W. Miller, jun., Cottam.  
**GAME**.—Prize, J. Harrison. *Chickens*.—Prize, J. Robinson, Commended, J. Harrison, J. Bamber, J. Turner.  
**COCHIN-CHINA**.—Prize, J. Robinson. *Chickens*.—Prize, J. Robinson.  
**HAMBURGH** (Golden-pencilled).—Prize, J. Robinson. *Chickens*.—Prize, B. Bee, Goosnaigh. Highly Commended, J. Robinson.  
**HAMBURGH** (Silver-pencilled).—Prize, J. Robinson. *Chickens*.—Prize, T. Pomfret.  
**HAMBURGH** (Golden and Silver-spangled).—Prize, J. Robinson. *Chickens*.—Prize, J. Robinson.  
**BANTAMS**.—Prize, J. Butcher, Lee. *Chickens*.—Prize, W. Blackhurst, jun., Highly Commended, J. Butcher.  
**GEESE**.—Prize, B. Bee. *Goslings*.—Prize, B. Bee. Commended, T. Rawcliffe, Broughton.  
**DUCKS** (Aylesbury and Rouen).—Prize, J. Robinson. *Ducklings*.—Prize, J. Robinson.  
**PIGEONS**.—Prize, J. Roberts, Penworthan.  
**JUDGE**.—Mr. H. P. Watson, Preston.—(*Preston Guardian*.)

### LANCASTER AGRICULTURAL SOCIETY'S POULTRY SHOW.

At this show which was held at Lancaster on the 19th September, the show of poultry was very large.

The awards were as follows:—

**GAME**.—First, G. Hodgson, Whittington. Second, J. Robinson, Vale House, Garstang.  
**GAME COCK** (Any colour).—Prize, J. Robinson.  
**HAMBURGH** (Golden-pencilled).—First, J. Parkinson, Elswick. Second, J. Robinson.  
**HAMBURGH** (Silver-pencilled).—First and Second, J. Robinson.  
**HAMBURGH** (Golden-spangled).—First and Second, J. Robinson.  
**HAMBURGH** (Silver-spangled).—First and Second, J. Robinson.  
**DORKINGS** (Any colour).—First, J. Robinson. Second, J. Parkinson.  
**COCHIN-CHINA** (Any colour).—First and Second, J. Wood, Chorley. Highly Commended J. Robinson; J. Hodgson.  
**SPANISH** (Black).—First, J. Hodgson. Second, M. Slater, Tatnam.  
**BANTAMS** (Game).—First, T. Kenyon, Blackburn. Second, J. Parkinson.  
**BANTAMS** (Any variety).—First, C. J. Clarke, Torrisholme. Second, W. Jackson, Lancaster.  
**TURKEYS**.—First, J. P. C. Starkie, Ashton Hall. Second, J. Armistead, Quernmoor.  
**DUCKS** (Aylesbury).—First and Second, J. Robinson.  
**DUCKS** (Rouen).—First, J. Parkinson. Second, J. Robinson.  
**GEESE**.—Prize, Mrs. Gardner, Quernmoor.  
**JUDGES**.—Mr. R. Teebay, Fulwood, near Preston; Mr. Peel, Lancaster.

**MANCHESTER POULTRY SHOW**.—The Messrs. Jennison, of the Zoological Gardens, Belle Vue, near Manchester, have just issued the prize schedule for their fifth Meeting, to be held in the Music Hall connected with their extensive establishment, for the exhibition of Poultry, Pigeons, and Rabbits. The days fixed for the show are the 28th, 29th, and 30th of December next. The prize list embraces the unusual number of sixty-nine classes for poultry alone; for Pigeons there are twenty-four classes; and for Rabbits ten classes. To *Dorkings*, £57 in money, besides two silver cups, value five guineas each,

will be awarded; to Spanish, £29 in cash, with one five-guinea cup; and to the Cochiti classes, £64 in money, and a five-pounds silver cup, will be given. Brahmas receive £17, and Polish, £6 as premiums; to the Game classes, the very liberal sum of £106, besides two five-guinea silver cups, is appointed. Geese and Ducks receive £18; Turkeys, £13; and £6 will be given to Extra Stock. Premiums to the amount of £7 are given to Black Hamburgs, whilst £53 in prizes will still further reward the successful exhibitors of Hamburgs generally; £22, besides two five-guinea silver cups, will enlist a warm competition in the Game Bantams; and £6 will be given to Bantams of any other breed. With like liberality £90 10s. will be awarded to Pigeons, and £20 to Rabbits. It will be thus evident that to Pigeons, Rabbits, and Poultry alone an aggregate sum of nearly £500 will await the decision of the Judges; and when it is remembered how perfectly adapted to the purposes of a show the Belle Vue Music Hall has always proved itself to be, we with confidence anticipate not only a very extensive entry, but also the presence of most of the principal pens of prize birds to be met with in the kingdom.

### MIND THE PAINT OR DYE.

CAUTION TO ALL BUYERS OF POULTRY.

WHEREAS, last week I wrote to an advertiser in that knowing county Yorkshire, for a few Duckwing Game Bantams to be sent on approval, and, whereas, the said advertiser forwarded the said Bantams the next day; and, whereas, on taking them out of the hamper I could not help admiring their legs inasmuch as that they were splendid in that colour known as willow: Now, this is to give notice, that on close examination the said legs were found to be painted or dyed, and their natural colour was blue.—GENUINE.

### POULTRY CLUB STANDARDS.

My object in writing my last was not to "cavil at an award when made," but simply to gain information. I am extremely sorry that Mr. Hewitt has put a construction on it which was never intended by the writer. I entertain the highest opinion of Mr. Hewitt as a poultry arbitrator; but, as it appeared to me that very serious differences of opinion exist amongst the principal arbitrators, it would be better if these matters were freely discussed, and, if possible, the differences reconciled, so that the feeling of distrust and dissatisfaction amongst exhibitors might be greatly allayed. I began by asking a question, and then gave my reasons for so doing, hoping by this means that some of your correspondents would give the *pros* and *cons*, on the subject, from which I could draw my own conclusions. Mr. Hewitt replies that he still maintains his previously expressed opinions, strengthened by the evidence of several of our principal poultry arbitrators.

The next point in my letter is the desirability of a standard by which poultry judges and exhibitors shall be guided. This is practicable in other things, why not in exhibiting poultry? Where standards vary exhibitors are perplexed and dissatisfied, for their chance of success depends partly on the appointment of judges; but let there be one general standard, then all may know what to expect. Mr. Hewitt says, "The hopes expressed by your correspondent that never-varying decisions will be ultimately attained, I feel assured are visionary, and quite beyond universal realisation." Will Mr. Hewitt be kind enough to point out where I express such a hope? The case of the reversed decision of the cattle awards at Birmingham and London is not to the point, because the reversed decision arises altogether from alteration of *condition alone*, and not from one judge disqualifying for a point which is merely considered a defect by the other.

I now come to the Black Bantams at the Keighley Show, which appeared to illustrate the same thing. I am sorry that my eyes and ears have so deceived me, for not only were their legs, in my opinion, light-coloured, but it was a subject of remark by many exhibitors present. My only motive in giving only a part of the paragraph from the report of the Keighley Show in the Journal was to show that the class was not unopposed, but that some very excellent and capital birds were shown against them.

In conclusion, let me assure Mr. Hewitt that although I am often an unsuccessful exhibitor, I am not a dissatisfied one; I acknowledge that I am often beaten, but not discouraged. I

only want a standard of excellence to aim at, and even then, should I be disappointed, I hope you will hear no cavilling from J.H.

[We agree with our correspondent in thinking that it would be very advantageous to have what are "disqualifications" recognised unanimously by poultry judges; but we retain our opinion that to attempt to assign any number of points to any characteristic of a variety is a delusion, and must often be an unjust trammel upon judges, and a cause of dissatisfaction to exhibitors. Take two Game cocks, as an example, and suppose one was rather superior to the other in all points except symmetry and condition, would any competent judge, unless bound by encumbering rules, award the prize to the first-named?]

### DRONE-BREEDING HIVES.

As the problem—whether the eggs found in a drone-breeding hive are laid by fertile workers or very small queens, has not yet been satisfactorily solved, every case bearing on the subject must promise a certain amount of interest. I do not profess to determine the point, and shall therefore simply relate what came under my observation during the spring and summer in a hive containing a swarm, which was led off by a pure fertile Ligurian queen on the 30th of July, 1864.

The hive was in a very prosperous state at the beginning of winter, and at the arrival of spring had a vigorous and very numerous population. On the 7th of April, however, drones made their appearance, at once awakening suspicions that all was not right; but as the bees appeared to continue their labours, I delayed inspecting it till the 22nd of May. I could wait no longer, drones now forming the major part of the colony. Forthwith the frames were elevated, but not a single comb contained worker brood, every one was studded with disgusting drones. What perplexed me most was finding in the hive no queen. I made a most minute search for her, and if she had been there I would have found her; but queen of greater dimensions or different in appearance from that of an ordinary worker there was none. Drone-breeding went on, and every after-inspection was attended with the same result.

To enable the hive to raise an artificial queen, I supplied it with a comb containing eggs and larvæ. The eggs and larvæ were duly hatched; but no attempt was made to rear a queen—only a queen cell was formed in an adjoining comb. Matters were then allowed to take their course till June 26th, when I furnished the hive with a queen and a few bees, which were taken from one about to throw a second cast.

From the sound subsequently heard, the queen was no doubt imprisoned; but she afterwards regained her liberty and soon restored the hive to a flourishing condition. After this experience I may be excused for expressing my belief in the existence of fertile workers.

Before concluding I may mention that the weather has been exceedingly warm and beautiful for a fortnight. The earth, however, so far as flowers are concerned, is a sterile waste, and, as a consequence, the bees will not suffer a single egg laid by their queens to be developed.

By feeding a little, I stimulated the queen in my observatory hive to lay hundreds of eggs; but the day after I ceased to feed the eggs began to disappear, and in a few days there was none.

One hive, tolerably well supplied with food, and in process of raising an artificial queen, foolishly banished its drones, just as the young lady was about to make her appearance. So much for the perfection and imperfection of instinct.—R. S.

### GAS TAR NOT INJURIOUS TO BEES.

In answer to the inquiry of "Novice," I may say that gas tar has no ill effect upon bees.

Several years ago I covered a bee-house, in which were twenty-four hives, with gas tar, in the month of July, when the bees were in full work, without any injurious effect upon the bees.—GEORGE RAYNOR, *Keledon Hatch Rectory, Brentwood.*

DEATH OF MR. PEPLOE CARTWRIGHT.—The poultry fancy will hear with regret of the death of Peploe Cartwright, Esq., of Oswestry, on the 29th of August last. He has been known for some years past as the successful breeder of Partridge Cochins.

His numerous triumphs testify as to the goodness of his stock. Exhibitors lose a formidable opponent, and the medical profession a distinguished ornament.—E. T.

**A BEE-KEEPER'S MISHAP.**

I SHOULD much like to have the advice of "A DEVONSHIRE BEE-KEEPER" on the following points in your next impression. On Monday last a friend came to inspect my apiary, and I lifted off the cover of one of Nutt's collateral hives to show him the working of the interior; unfortunately, at this moment, I was called away on important business, and, in my hurry, forgot to replace the cover on the boxes. When I returned about four o'clock in the evening, to my dismay I found the bees in a state of the greatest commotion, the main body of them in immense clusters on the outside and bottom of the centre box, hundreds of them on the wing about the entrance, and the ground, alas! strewn with dead bodies. I immediately detected the honey dripping down from the table on all sides, and saw at once that the intense power of the sun (it was the hottest day we have had this year) had detached the combs from the top bars.

Early next morning I made an investigation, and found matters even worse than I anticipated. On lifting the centre box several of the combs were in a complete mash, and hundreds of dead bees were on the floor-board. I immediately cleared away all the debris, and restored matters as well as I could, but I fear one of my best stocks is destroyed. What ought I now to do? the centre box is not more than quarter filled with honey, quite insufficient for the support of the bees that remain for the winter. I thought of driving them and uniting them to another hive, but all the hives (I have now five) appear to me to be overstocked with bees and honey. I examined them all the other day, and was surprised at their weight and the extraordinary number of bees in each. Your assistance in this dilemma will be invaluable to me. I may add that the bees that remain, and they are still a strong body, are working away in their now half-empty home. Would I by feeding them be able to carry them over the winter?—SQUIB.

[If your hives are fitted with either bars or frames a contribution of a comb from each of the other stocks would at once supply the deficiency without injuring them. If not (as I imagine is really the case), prompt and liberal feeding may meet the emergency. By adding the driven bees of a condemned stock success would be rendered more probable. If the bees turn out, as they are very likely to do, too few to grapple with the difficulty themselves, and you cannot add to the population, you need not fear uniting them to another colony whenever the weather becomes cooler.—A DEVONSHIRE BEE-KEEPER.]

**BEE-HIVES.**—Your correspondent "M. D." gives a description of what he call "a native hive." Would he have any objection to state where it can be purchased?—M. S.

**TEA.**—A French chemist asserts that if tea be ground like coffee, before hot water is put upon it, it will yield double the amount of exhilarating qualities. Another writer says, "If a piece of lump snigar, the size of a walnut, is put into the teapot, you will make the tea infuse in one-half the time."

**OUR LETTER BOX.**

**COCKERELS' EYES BURSTING** (*Cog Héron*).—We cannot tell the cause of the mortality of your cockerels from their eyes bursting. We know the disease only in Spanish fowls. They suffer much from it. Your acreage allows you ample space. We advise you to rail off a small enclosure, and to put the Hamburgs in it. It would be very vexatious if it were to spread.

**INQUIRY.**—Can any of your readers give me any information respecting a person giving his address as H. C. Lewis, 218, St. Paul's Road, Islington, N.? I advertised in your Journal of the 29th of August last for poultry, when the above-named person replied, stating he could supply me with what I required, and would forward them on receipt of a post-office order for the amount, which I sent; but, instead of the poultry, I received a letter from my correspondent making an excuse for the delay in sending them. If any of your readers can throw any light upon this I shall be greatly obliged.—C. A. G. [We are quite at a loss to account for any one sending money to a total stranger before they receive the goods.—EDS.]

**Book (Beta).**—The work on poultry, with coloured plates, is now printing.

**HOUDAN AND LA FLÛCHE FOWLS** (*W. Hendry*).—There are drawings and full descriptions of these breeds in Nos. 62 and 65 of this Journal. We think they are likely to succeed in small runs. Our correspondent says that he finds sifted coal ashes act as a deodoriser if put fresh on the floor every second or third morning, but we are quite sure that such ashes do not deodorise so effectually as dry earth, and turning this over frequently.

**WORCESTER POULTRY SHOW.**—By a slip of the pen Mr. E. Tudman is named in our report of this Show as being of Welshpool instead of Whitchurch, Salop.

**MIDDLETON POULTRY SHOW.**—Mr. Massey, Fulford, York, we are informed, took the first prize for Carrier Pigeons, and Messrs. C. & E. Roids, of Greenhill, Rochdale, the second, instead of Mr. Samuels being first and Mr. Massey second, as stated in the list of awards at page 265, which, however, agrees with the list which we received.

**TREATMENT OF DUCKS** (*Sussex*).—Ducks of all kinds should be kept in a house separate from other poultry, and with a brick floor, to admit of frequent washing. Give them plenty of room. Boiled roots, mixed with a little barleymeal, is good food for them. Add a little milk when fattening them. Eleven eggs for a large Duck, and nine for a small Duck, are enough for them to sit upon. The eggs do not keep so well as those of the common hen, so sit them on the freshest. Make the nest on the ground, and in a damp place. The Duck requires to be fed every morning and evening whilst sitting. Let her have food and water near to the nest. Boiled but cold oatmeal porridge is the best food for ducklings until they are ten days old; afterwards barleymeal, oats, and pollard, with plenty of green food. They are ready for table in eight or ten weeks if well fed. Never give them hard spring water, but water from a pond. They may be taken away from the Duck when three days old if they have a confined yard to be kept in, well supplied with water, and a dry, warm house to retire to, and if never allowed to come out of that house before nine o'clock in the morning. The tails of young ducklings need not be clipped off.

**WARMING AN AVIARY** (*J. W. A.*).—You do not say what aspect your conservatory has. If north then a stove, as you mention, will be good to keep out the severe cold in winter, but if it faces the south, and is sheltered from the north and east, I do not think it will require heating. Canaries can stand our climate very well if sheltered. Your greatest trouble will be to guard against the sudden changes of temperature. The small conservatory becomes very hot when the sun shines on it, and at night quickly becomes cool, especially when the windows are left open to cool the rooms adjoining. This sudden fall of temperature gives the birds colds, coughs, asthma, and inflammation, and causes many deaths. It is the sudden change that injures the birds. They do not mind cold if sheltered from the wind and rain.—E. P. BRENT.

**COLLARED TURTLE Doves** (*Columba risoria*).—Your feeding them on light wheat and a little hempseed occasionally is good, but instead of hempseed I would recommend a little buckwheat or Canary seed as a change. The price of Collared Turtle Doves in the London shops varies from 8s. to 7s. 6d. per pair according to circumstances.—B. P. BRENT.

**STRENGTHENING WEAK STOCKS—DARK-COLOURED HONEY** (*A. B. C.*).—Our experience of superposing has not been very favourable. We should prefer driving and uniting in the manner recommended in page 59 of the fifth edition of "Bee-keeping for the Many." Clarifying your honey by standing the jar in a saucepan of water and boiling it, skimming off all impurities as they arise, would render it more fluid, and might probably improve its appearance.

**DRIVING BEES** (*A. T. S.*).—The following are Mr. Payne's directions:—"I very much prefer the middle of a bright day to any other time. The process is very simple, and may be effected in a few minutes. I very much wish that I could persuade all my cottage friends to adopt it, instead of the cruel and wasteful method of 'burning;' for in weak stocks the bees themselves are frequently of as much value as their little store of honey and wax; and by joining them to other stocks, very considerable advantages arise. My method of driving is this:—On a bright day, between eleven and one o'clock, turn the hive from which the bees are to be driven bottom upwards, in a shaded corner of the garden, and place upon it a hive of the same size; see that they fit closely, and, to make the junction more complete, tie a cloth round the hives where they meet. Then, with two sticks, keep up a gentle but continuous tapping upon the sides of the inverted hive for about ten minutes, the bees will by that time have left it and gone into the upper one. Having ascertained that fact, take it immediately to the place where the driven hive was taken from, and place it upon the same floor-board; carry the driven hive 50 or 60 yards away, and place it upon a fresh floor-board; the few bees that remain in it, as well as those that are out at work, will return to the driven bees. All is now finished until an hour after sunset, except emptying the driven hive of its store, when two sticks may be laid upon the ground about 8 inches apart, opposite the stock to which the driven bees are to be joined; then, with a smart stroke, dash out the bees between the sticks, and instantly, but very gently, place the stock they are intended to enter upon the sticks; leave them for the night, having first defended them from rain, should any fall; and in the morning, an hour before sunrise, replace the stock in its original position, and all will be peace and harmony."

**LONDON MARKETS.—OCTOBER 2.**

**POULTRY.**

ANOTHER Michaelmas has passed, only to convince us we were right when we said years ago that the goose-eating part of it was fast falling into disuse. The number this year were so small, that had there been any demand they would have sold very dear.

14	S	Swallow last seen.	60.2	41.3	50.3	18	24	6	8	5	57	0	53	2	25	15	287
15	SUN	18 SUNDAY AFTER TRINITY.	61.5	41.1	51.3	19	26	6	6	2	0	2	20	3	26	14	288
16	M	Hazel leaves fall.	58.8	40.2	49.5	17	28	6	4	5	3	3	45	3	27	11	289

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 60.5°, and its night temperature 43.1°. The greatest heat was 74°, on the 15th, 1812; and the lowest cold, 24°, on the 15th, 1860. The greatest fall of rain was 1.64 inch.

CYCLAMENS AND THEIR CULTURE.

CYCLAMENS being handsome both in their foliage and flowers, deservedly rank high as ornaments for the greenhouse and drawing-room; indeed, few plants

rival them in the gracefulness and beauty of all their parts, besides which their growth is confined to a small compass. The nomenclature of Cyclamens is the most difficult part of the subject; for they are grown under many different names. I hope, however, to avoid adding any confusion to that which already exists, but if in error, I shall be happy to be corrected.

**CYCLAMEN COUM.**—Leaves orbicular, green above, without any marbling, red on the under side; flowers bright red, produced for the most part external to the leaves, to which they form a margin. It blooms from January to March, and occasionally as early as November. There is a variety, *carneum*, in which the flowers are of a pale flesh colour, but variable in hue. Besides the above there are numerous varieties, called *C. coum* in the trade, that have slight markings of *C. persicum* on the leaves, but which are not worth having. *Cyclamen coum* is a frame perennial. It is not fragrant.

**C. NEAPOLITANUM** (*hederæfolium* of some), is hardy and blooms in autumn before the leaves are produced. The flowers are red or a fine rosy pink, rise directly from the root, and are succeeded by the foliage, rendering the plants fine objects throughout the winter. It usually blooms from the latter part of September to near Christmas. It goes to rest in April or May.

*C. neapolitanum album* only differs from the preceding in having white flowers. Both are inodorous.

**C. EUROPEUM.**—Leaves heart-shaped, inclined to be orbicular in some instances, but not nearly so round as those of *C. coum*. Sometimes they are entire or but very slightly crenated, having the marbling on the upper surface almost equal to that of *C. persicum*, and being much smaller than the rest, and finer in texture; in other cases the leaves are decidedly toothed, and but slightly marbled on the upper surface, and never orbicular in shape; whilst in others again they are double the size that they are in the two preceding forms, and the plant is all but an evergreen and continuous-blooming. This form of *C. europæum* is not generally met with, but is by no means scarce. The bulbs, or, more strictly, corms, of *C. europæum* vary much; in some cases they are round, smooth, and flat, but generally they are very irregular, being covered with knotty excrescences; they also throw up stems, in some cases of considerable length, on which the leaves and flowers appear. These stems are sometimes very numerous

and appear on the crown, rising erect, and also from the sides of the corms beneath the soil. These also vary in colour; some are brown, others a pale yellow, and occasionally but rarely white. *C. europæum* blooms in August, occasionally, but very rarely, in July, and is decidedly a summer bloomer, the flowering being prolonged into early autumn. The flowers vary in colour, in some forms they are red or rose, but not so bright as in *C. coum*, and the shades become paler in others till pure white is reached. The fragrance of the blooms of this species and all its forms is most delicious. It is the *C. Clusii*, *fragrans*, *anemoides* (of the Dutch), and *autumnale* of some.

**C. REPANDUM** (*hederæfolium*, *neapolitanum*, and *astivum*).—I take this to be the true *C. hederæfolium* of Britain, for it is the only one like *C. neapolitanum* that blooms in the spring; but all the forms of the Ivy-leaved Sowbread of Suffolk origin with which I am acquainted, invariably bloom in autumn, and are not distinguishable from *C. neapolitanum*. How is this? They are said to bloom in spring; but after a couple of years' growth they bloom in autumn. I fear the Suffolk Ivy-leaf is not now to be obtained, but others are palmed off for it. *C. repandum* differs little from *C. neapolitanum*, except in blooming in the spring, usually about the end of April. The flowers are bright rose. This species, which is quite hardy, is much confounded with *C. neapolitanum*, the autumn bloomer, and is much more scarce. It may easily be distinguished from *C. neapolitanum* by its blooming in spring, it being the last to bloom of all the Cyclamens, commencing with *C. europæum*.

**C. VERNUM.**—This should have been named *autumnale*, or *hyemale*, as it is an autumn or early-winter-blooming kind. The leaves are orbicular and entire, the lobes overlapping at the base, and they are marked on the upper surface with an irregular band of white, and are bright red on the under side, more so than those of *C. coum*. They are larger than the leaves of *C. coum*, and double the size of many of the smaller-leaved kinds of that species and of *C. europæum*, but only a trifle larger than good-sized leaves of these species. The flowers are a shade lighter than those of *C. coum*, and are of a decided reddish purple, especially at the tips of the segments, otherwise they differ little from those of *C. coum*, except in being a little larger. This Cyclamen blooms in November, and continues in flower for three months, or until February, and often March. It is exactly like *C. coum* except in three particulars—viz., it is larger every way, the flowers have a decided purple shade, and the leaves a white marking. After all it is a very questionable species. Did any one ever cross *neapolitanum* with *coum*? Surely the result would be *vernum*. I may state that it comes very true from seed, quite as true as *C. coum* generally does; but the seedlings are exactly like *Cyclamen coum* for two or three years, yet when they arrive at a blooming state their foliage acquires an irregular band of white marbling distinctive of *vernum*. Take this marbling away and it is not distinguishable from *C. coum*. I have seedlings of *vernum* one, two, and three years old, as well as blooming plants; the one-year-old are all like *coum*, so are the two-year-old, but of those

three years old there are some that have the marking of vernum, and others of the same age without it, and if they produce the flowers of eoum, how can vernum be considered a very distinct species? I believe it to be a hybrid; and if it be possible to bloom *C. eoum* early enough, or retard *C. neapolitanum* so that a union of these could be effected, I believe that there would be more than one vernum among the offspring. *Cyclamen vernum* is a frame perennial.

*C. ATKINSI* is a hybrid between *C. eoum* and *C. persicum* for which we are indebted to the late Mr. J. Atkins. The leaves are large, often from 2½ to 3 inches by 2 to 2½ inches, ovate obtuse, cordate at the base, the lobes overlapping and having a deep sinus, deep glossy green, with an irregular band or pale zone within the margin; the under side is of a dull reddish purple. The flowers are white with a crimson centre or eye, and very beautiful. It blooms from January to April according to treatment. In *C. Atkinsi roseum* the flowers are blush or pale rose with a dark centre. The varieties of *C. Atkinsi* are endless, exhibiting many different shades of colour. All of them are scentless. They are very ornamental for greenhouses, and specimens can be grown so as to have nearly one hundred blooms expanded at one time. *C. Atkinsi* and its varieties are frame perennials.

*C. AFRICANUM* is certainly nothing more than *C. neapolitanum* with more robust foliage. The flowers are the same, though some are blush with rose markings. There are, too, to my knowledge, nearly a dozen forms of *C. neapolitanum* differing as regards the foliage. What are called *C. africanum*, *macrophyllum*, *latifolium*, and *robustum* are only differently marked forms of *C. neapolitanum*, and different shades of the red and white Ivy-leaved Sowbread. The foliage, however, is large and handsome. They bloom in autumn, and continue in bloom a long time. They are half-hardy perennials.

*C. MERCURII*, leaves flat and heart-shaped, open at the base, or having an open sinus, and entire or very slightly crenated, deep green on the upper surface, with an irregular band of grey about one-fourth the width of the leaf from the margin, dull reddish purple on the under side; the veins sunken on the upper side, prominent and green beneath. The flowers are of a pale rose colour with a tinge of purple, and have a deep crimson (also tinted with purple), spot or bar at the base of the segments and extending to the mouth. It blooms in November and throughout the winter, but more generally in February and onwards, the temperature to which it is subjected making all the difference. This is a very questionable species and much confounded with *C. Atkinsi*. The original species is, I believe, very scarce, and the one that I had with flowers as described, has much smaller leaves, and the whole plant is dwarfer than those now sent out for it. The flowers vary much; in some plants they are white with the same ovate blotch at the base of each segment as in *C. Atkinsi*; in others the blooms have rosy or pale flesh-coloured segments with a purple base; and in others, again, they are light or deep rose with crimson or crimson-purple ovate blotches at the base of the segments. Surely no true species is so sportive as this, nor gives different-coloured seedlings from the same pod without crossing, not one in ten being exactly like the parent. The original species, if it is one, is very scarce if not lost.

*C. PERSICUM* has handsome foliage and fine flowers, some of which are delightfully fragrant. Leaves variously heart-shaped, toothed at the edge, deep green with white or grey marbling on the upper surface, pale flesh on the under side. Flowers variable in colour, borne on erect slender stems, from 6 to 9 inches in height, terminating individually with elegantly recurved coronets of white, oblong, lanceolate petals, blotched with violet crimson at the base; they are for the most part erect and close, but in other varieties assume a singular curved outline. It flowers in autumn, winter, and spring according to the treatment. The varieties are—

- C. persicum rubrum*, purplish crimson.
- C. persicum purpureum*, purplish red.
- C. persicum stellatum*, white with star-like spots in each petal.
- C. persicum delicatum*, white with pink centre.
- C. persicum album*, pure white.
- C. persicum roseum*, rosy red.
- C. persicum roseum coccineum*, rose with scarlet centre.
- C. persicum odoratum*, white with rose eye. Delightfully scented.
- C. persicum odoratum rubrum*, rosy red. Finely scented.
- C. persicum striatum*, striped and spotted rose on a white ground.
- C. persicum marginatum*, shaded rose.

There are many varieties of *C. persicum* besides those named; but the above will be found the most desirable and distinct.

In addition to the *Cyclamens* already enumerated, there is one, *C. nobile*, which is said to be fine, but not having seen it I must content myself with naming it. *C. odoratum*, if it is the same that I had under that name, is only *C. europæum album*. They are half-hardy perennials.—G. ABBEY.

(To be continued.)

## VISITS TO GARDENS PUBLIC AND PRIVATE.

MESSRS. IVERY & SON'S, DORKING.

If a cool and shady bank, a deep and gloomy wood, or a moist and dripping cavern, be associated with the idea of Ferns, the delusion was dispelled on the day when I, at the latter end of August, paid a visit to Messrs. Ivery's well-known establishment, one of the special homes of our beautiful and elegant native varieties. The day was insufferably hot, the sky laden with heavy thundery-looking clouds, and suggestive of storms yet to break; and as we stood at the various pits where the treasures were placed, it required no small amount of zeal to stand the broiling influences of the sun that streamed down upon us. However, I was bent on seeing all the beauties and novelties, and under the skilful guidance of Mr. Ivery and Mr. Appleby I managed to have a most interesting morning amongst them.

It may give some idea of the rapid increase of varieties amongst our native Ferns to say, that when Messrs. Ivery's last catalogue was published it contained 158 species and varieties of British Ferns; their present catalogue contains 345, and this number is exceeded by the catalogues of other growers. Of some species the variations seem never-ending. Thus, of *Athyrium Filix-femina* (the Lady Fern), there are 69 varieties; of *Lastrea Filix-mas* (Male Fern), 21 varieties; of *Polystichum angulare* (Short Prickly Shield Fern), 58 varieties; of *Scelopendrium vulgare* (common Hart's-tongue), 70 varieties; and even of the common Hard Fern, *Blechnum spicatum*, which would seem to afford little scope for variation, there are 20. Some of these many varieties were remarkable for their great beauty, not exceeded, I think, by our choicest foreign Ferns; and some, like a Skye terrier, remarkable for their ugliness and monstrosity. What strange differences in the same species! Here is the grand and stately *Lastrea Filix-mas cristata*, one of the very finest of our British Ferns; and here is his next neighbour, *eriopa*, a dwarfed and compact little thing, never exceeding a foot in height; then, again, look at the *Athyrium Filix-femina plumosum*, with its beautiful, light, feathery appearance, and compare with that the curiously fan-shaped *pinna* of *Frizellia*, and they seem too diverse even to belong to the same household.

Instead, however, of rambling at will over the different classes, let me take them in order, and enumerate what I saw very noticeable in each. Amongst the *Aspleniums*, *trichomanes cristatum* and *t. Harrovii*, the latter obtained by Mr. Holland, of Isleworth, were the prettiest that I chanced to notice. The *Athyrium Filix-femina* presents a wide field. Of the more common and better-known varieties I would enumerate *apuaforme*, *conioides*, *corymbiferum*, *crispum*, *dareoides*, *diffusum*, *Fieldia*, very beautiful; *Frizellia*, *grandiceps*, *plumosum depauperatum*, and *thyssanotum* as well worthy of a place in all collections. There were some exceedingly beautiful and curious newer varieties, such as *Applebyanum*, very like *Frizellia*, the most remarkable difference being the manner in which the fronds branch at the apex into a flat head of several divisions. Then there were *frizellia-excurrens*, more odd than pretty; *glomeratum*, which somewhat resembles *multiiceps*, but the fronds terminate in an almost globular head; and *micronatum*, which bears some analogy to *Fieldia*, but has more of a fringed appearance. All these may be safely added to a collection; and so may *A. Filix-femina Verneuxii* and *Victoria*, the former having a great likeness to *conioides*, only more beautifully cut; and the latter having the *pinna* forked at the base and divergent, so that they cross one another up the whole length of the frond. Of the Male Ferns, *Lastrea Filix-mas cristata*, *cristata angustata*, *Blandie*, *fureans*, and *paleacea* were the handsomest; while the curious little *eripa*, already noticed, and *pumila*, are worthy of a place for their odd character. The *Polystichums* include some of the very finest and most beautiful varieties we have, especially the

varieties of proliferum. Proliferum itself is remarkably beautiful, but it is eclipsed by the finer varieties of *Holeanum*, *Footii*, and *Wollastonii*. The latter is certainly one of the handsomest of our native varieties of Ferns. Nothing can be more graceful than its wide and wavy fronds. Besides these varieties of proliferum, there are several forms of *Polystichum angulare* which are certainly acquisitions—viz., *Elworthyi*, with its tapering dark green fronds; grandiceps, beautifully crested, with a large corymbose head; *Kitsonicæ*, and *Wakeleyanum*, a curious and somewhat elegant variety; and so are *pterophorum*, nearly erect, with deep green fronds, and discovered, I believe, by the Rev. H. A. Walker, of Henfield; and *plumosum*, the most beautiful, perhaps, of all the *Polystichums*, with charming wavy fronds. *P. aculeatum* *aeroladon* is more striking than the ordinary crested form, and its habit being evergreen it is most desirable. Among the *Blechnums*, spicant *inbricatum*, a short stumpy-looking variety, which, as a friend said, almost made him laugh to look at it, *crisatum*, and *concinnum*, were all noticeable. The Hart's-tongues were innumerable. What could be more pretty than a pitful of *Scelopendrium vulgare crispum* raised from seed?—a fact which was almost doubted by one of our most successful hybridisers and raises a few days afterwards, who said he had never seen a fertile frond of *crispum*. Then how grand is *crispum latum*! and how curious *marginatum*, and *muricatum*, and *endiviefelium*!

No one who has not seen such an establishment can have any idea of the extent to which Fern culture is carried—the thousands and tens of thousands of seedlings raised here from time to time, and the curious forms that come up amongst these seedlings; and if Mr. Berkeley be right we are only on the threshold of these things, for he believes a wide field to be opened for the hybridising of Ferns; and as one of our greatest living botanists, his words are not likely to be spoken at random. That the cultivators of our British Ferns are very numerous there can be no doubt; but I think they ought to be increased a hundredfold. With a pit in some shady place, or rockwork in some corner where nothing else will grow, they afford a source of unceasing pleasure, and that with comparatively little care and attention; and, as I have already said, their forms are so beautiful and various, that one need not envy those who can grow their collections of exotic Ferns. It were needless, I think, to give a list of the sorts suitable for this purpose. Those I have named may be, I think, relied on; but a beginner could not do better than place himself or herself (for our columns bear witness to the zeal with which ladies cultivate them), in the hands of any of our great Fern-growers, for they may rest assured that they would receive sound advice as to the sorts.

Messrs. Ivery are also well known for their fine collections of Azaleas, and for the many excellent seedlings which have been sent out from their establishment. Of these there are now several fine sorts, the two most remarkable being *Forget-me-not* and *Fascination*. The former is of a brilliant glossy purple, deeply spotted in the upper petals, dwarf habit, and very enduring in its bloom. The latter is one of the most lovely flowers we have. It is a seedling, not a sport, and quite eclipses *Etoile de Gand*, *Due d'Arenberg*, and other flowers of the same class. It is a beautiful rosy pink, with deep crimson spots on the upper petals, broadly edged with white, perfect in form, and very smooth. *Beauty of Dorking*, a large-foliaged form of *Beauty of Reigate*; *Flower of the Day*, an improvement on *Iveryana*, and *Variegata Superba*, are also good kinds of Mr. Ivery's raising; while the flowers of other growers, both home and foreign, are to be found here in large numbers. I believe *Fascination*, although advertised, will not be sent out this year, as Messrs. Ivery wish the plants to be larger before they distribute it.

In walking round the nursery I was attracted by a most delicate perfume, which seemed as if some bulbs of Lilies were at hand, but found that this was occasioned by a plantation of the Chinese Yam, *Dioscorea batatas*, the bine of which was trained so as to form a long arch, and the blossoms of which loaded the air with their fragrance. This is worth knowing, for the root may be used for this purpose. Mr. Ivery grows it very successfully in good deep soil. There was a nice collection of the French varieties of that favourite autumn flower, the *Gladiolus*, in bloom. Amongst them I noticed *Egérie*, *Oracle*, *Mathilde de Landevoisin*, *Ninon de l'Enclos*, *Le Pous-sin*, *Penelope*, and *Janire* as very good. These are amongst the cheaper varieties. Messrs. Ivery have a nice collection of *Ivies*, some of them very pretty both in their variegation and

the character of their foliage. There were some rows of Pater-son's seedling Potatoes, which have made so much noise, but which, if these were a fair sample, were fit for field use, but certainly not for the garden. There were four kinds—*Victoria*, *Blue*, *Blue Kidney*, and *Seedling Rook*. The latter was the largest cropper; but they were all coarse, very deeply eyed, good, as I have said, for cattle, &c., but not to be named with some of those long-established favourites which we have grown for many years. By-the-by, have any of our Potato-growing friends noticed the entirely different character of the disease this year? Here, with us, it does not assume that brown dry appearance, but the Potatoes become a mass of corruption, almost as if they had mortified—very unlike any form of the disease I have before seen, and I have watched it now since 1846. What a proof, too, of our feebleness and ignorance it is! We knew as little about it, and can provide as little against it, as when nearly twenty years ago it came upon us.

There were many other things to be noticed in Messrs. Ivery's establishment, but my time was limited, and I wanted to see *Deepdene*, so I had to leave; but I have, I hope, indicated enough to show how well worth visiting it is. As it is only an hour's ride from London by rail, it is accessible not merely to residents in or near the great metropolis, but to that large and increasing class who find that their circulation gets sluggish unless from time to time they come into contact with the great heart of England, where everything of every kind, good or bad, is to be found.—D., Deal.

#### THE RIPENING OF PEACHES IN ORCHARD-HOUSES.

IN your Number of the 26th ultimo, your correspondent "G. H.," in his scientific dialogue with his French friend, has made some unfavourable comments on my system of free ventilation of orchard-houses, it therefore behoves me to say a few words. I have one great comfort when I read such matter. I have for some fifteen years practised with the greatest success the mode of cultivation I recommend, I still practise it; in short, all that I say should be done, I do, and never fail in my culture.

We fruit-cultivators all have our little climatic worlds; that of "G. H." must be miserably cold. Mine is in an eastern corner of Hertfordshire, the climate dry and cold in winter, and dry and moderately warm in summer, the temperature in hot weather being always 5° below the maximum at Chiswick; and out-of-door fruits ripen about ten days later than they do at Twickenham, and Teddington, to the north of the Thames. Now, my climatic world has rather a wide extent, for all through the eastern counties, through the south, through the west, through the midland counties, as far north as the Trent, and I may add in places much farther north, for at Liverpool, in the Highlands near Perth, and at Stornoway, Isle of Lewis, do Peaches ripen in houses not heated by hot-water pipes, but simply orchard-houses, with free lateral ventilation; so that, as it will be seen, my climatic world is not a small one, and I feel perfectly satisfied that the system I have recommended is the safe one. It will, however, be seen, that I have been cautious, for at page 15 of the later editions of the "Orchard-House," I have recommended a four-inch hot-water pipe to be carried round span-roofed houses "in the cool, moist climates of many places in the north." Again, I read in the twelfth edition, page 16, "In the cold stormy climates of the north of either Scotland or Ireland, it will, perhaps, be quite necessary to introduce hot-water pipes into houses in which Peaches, &c., are cultivated, not exactly to force them, but to insure their ripening properly. The shoots of such trees also require a dry and warm atmosphere in the autumn, or they will not ripen." This passage also occurs as far back as the eighth edition, so that "G. H.," if he lives in a cold, unfavourable climate, ought not to have committed himself as he seems to have done.

It may, perhaps, interest some of your readers if I give a register of the ripening of orchard-house fruit here this season in a span-roofed house 100 feet long, 5½ feet high at the sides, and about 12½ feet to the ridge. I must first premise that the side shutters, 20 inches wide, were open night and day from the 10th of July, closed by day during the stormy weather in August, open night and day at the end of that month, and they continue so to the present time. My Apricots, a most magnificent crop, ripened as follows (including Peaches, &c.):—June 26th, Sardinian Apricot, ripe; July 2nd, Oulin's Early Peach Apri-

cot, ripe; July 16th, Moorpark and Peach Apricots, ripe; July 14th, some early Peaches from seed, ripe; July 24th, Black Mulberries, ripe, very rich; August 7th, Early York and Victoria Peaches, ripe; August 10th, Early Silver Peach, ripe; August 14th, Early Grosse Mignonne, Belle de la Croix, Early Savoy, and Belle de Doué Peaches, ripe; August 22nd, Grosse Mignonne, and many other kinds of Peaches, ripe; August 30th, Noblesse, Royal George, and many other kinds of Peaches, ripe; September 10th, Barrington, and Princess of Wales Peaches, ripe; September 18th, Late Admirable and Walburton Peaches, ripe; September 24th, Desse Tardive and Montagne Tardive Peaches, ripe; and this day (September 28th) I have Poole's Late Yellow, Salway, and the Comet Peaches approaching to ripeness; and so ends my register for this season. I think it will be seen from this that the system of free ventilation I recommend I practise, and I know well that it may safely be applied to the orchard-houses in England, in the districts I have named. If any cultivator happens to have pitched his tent in a cold, cloudy, windy climate, he should do as I did in August last, husband the heat by closing the ventilators early in the day. I will now in a few words give the temperature of my free-ventilated houses.

Yesterday (September 27th), was one of those bright, warm days such as we have in June and July, the great difference in temperature occurring at night, as usual at this season. Well, at 2 P.M., my thermometer out of doors in the shade, 5 feet from the ground, gave 69°; in the house, with doors and ventilators all open, and the instrument under dense shade, it stood at 80°. With submission to "G. H.," and Mr. Fish, who, by the way, has, I fear, but little experience with large houses, this is not a retarding climate. During the night of the 27th, the thermometer outside fell to 35°; in the orchard-house to 45°. I have become so accustomed to complete success in my culture, that I have not observed daily the thermometer in my house; it is always there, but sometimes not in a sufficiently shaded position to be accurate; but as far as I have noticed during the past summer, I have found the house, with its wide doors at each end and all the ventilators open, generally in sunny weather from 10° to 15° above the open air; thus, if we have had it in the shade out-doors at 80° (this has happened frequently this summer), in the house it has been 92° to 95°, at night going down within 10° of the open air. This, as far as my experience has gone, is the most perfect of ripening climates, as the coolness at night gives a racy flavour to fruit far superior to that from houses kept close and hot.

The practice and the logic of "G. H." are most amusing, "lean-to houses are not orchard-houses, even if fruit trees are grown in them," see page 248, September 26th. Why? Because "they have been used for forcing dwarf trees, either in pots, or planted out, ever since Miller's day." Heavy reasoning this, "hard pounding," as the Duke once said.

As to his practice of putting his trees to rest by opening all the ventilators of his forcing-house night and day, I can only say it was delightfully original. "G. H." has not made use of his eyes; the "immense houses half empty," with the temperature in June and July, from 110° to 120°, are fictions of fancy. Spanish air-castles. No such houses, and no such treatment exist.

Here, where there are as many thousands of orchard-house trees grown as there are hundreds in most places, twenty houses are but 14 feet wide, and 9 feet high, and the largest houses are but 24 feet wide, and from 12 to 13 feet high. In all, as soon as summer heat sets in towards the end of June, all the ventilators are open night and day, and in July half the trees—this applies only to young trees for sale—are placed in the open air in full sunshine. "G. H." should come and see. Now, this treatment is, as a matter of business, the most economical, for without the free air night and day, red spider would be a perfect pest, and not a shoot would ripen. I am inclined to think that the experience gained by "G. H." is not of high value, and will not be thought so by your readers.

The style of "G. H." is sharp and decisive, I must imitate it. His trees were put to their unhealthy rest in August by management so base as to be almost incredible. Fancy a man getting out of his warm bed, going to his dressing-room, opening the window in a cold morning, and standing before it naked, he would most likely die. The wonder is that the wretched trees of "G. H." did not. His trees did not drop their blossoms from the effects of cold winds. In March and April, when Peach trees bloom, the cold dry winds in a sunny day, if properly admitted, dry and disperse the pollen, and do infinite good. It was stagnant air that made them drop.

Muggy, warm, showery weather, will do it effectually, if a house is not well ventilated.

To conclude, I beg through your columns to give "G. H." a hearty invitation; if he merely lives at a short distance from here—say, Stony Middleton, in Derbyshire, where they harvest their Oats in December, or on the "Backbone" between Yorkshire and Lancashire, where they never harvest them, he can easily come; but if he lives in the Orkneys, the Shetlands, or the Loffodens—from his non-ripening climate, it seems probable—I cannot expect him. I can only say that I will give him a hearty welcome, feed him, drink him, I mean give him drink, show him all, tell him all, and "put him in the way he should go." I only stipulate that he should send in his card to me, with "G. H." on it.—THOS. RIVERS, *Sawbridgeworth*.

#### DOUBLE-FLOWERED PEACH FRUITFUL.

SOME months ago a correspondent inquired whether the *Amygdalus persica flore pleno* produced fruit, and if so, was it edible? The fact of its producing double flowers would have negated the question if the flowers were always double, but exceptions sometimes occur.

A small tree was planted here about seven or eight years ago, and has uniformly thriven well ever since; it has also in most seasons flowered profusely, and in the spring of the present year excessively so. Upon examining the bloom it was found that many of the flowers were single, and the spring frosts being slight, fruit was the consequence. The continuous warm weather has ripened it; and on the tree, which is now about 12 feet high, before the fruit began to fall, there were three dozen Peaches, most of them quite equal in size to ordinary wall Peaches, but differing from them slightly in having a deeper cleft. To the taste they are by no means disagreeable, but rather harsh, and if not perfectly ripe too tart. The *Amygdalus persica* is one of the most beautiful of our flowering trees, and deserves a place in every garden. Cultivation for the sake of the fruit must not be taken into consideration; for although edible it is greatly inferior to that of the cultivated Peaches, and the bearing is uncertain.

It is worthy of remark that the present year has been highly favourable to the production of fruit upon exotic trees and shrubs that have either never before, or very rarely, borne fruit in this country. Some notable instances of *Coniferae* have been given by Mr. Robson. Some useful facts would be gleaned if correspondents would make known cases that come under their notice.—ADOLPHUS H. KENT, *Blechnigley, Surrey*.

#### HIGH LEIGH, HODDESDON, HERTS.

ON one of those prettily-wooded knolls, with which the county of Hertfordshire abounds, about two miles from the Broxbourne station of the Great Eastern Railway, is High Leigh, the seat of Duncan J. Kaye, Esq. At the entrance is an elegant lodge, in the construction of which convenience as well as beauty seems to have been kept in view; draped in the verdure of numerous trailing plants, and surrounded with gay and odorous flowers, it attracts many a passer-by to pause and admire. This is on the right-hand on entering, and on the left is a belt of mixed evergreens and deciduous shrubs, including a choice and well-varied collection of Hollies, and good and vigorous examples of *Thuja Lobbii*, *Thuja gigantea*, *Cupressus Lawsoniana*, *Juniperus chinensis*, *Wellingtonia gigantea*, the Cockspur Thorn laden with clusters of red berries, and the elegant but little used *Symphoricarpos vulgaris variegatus*. It is worthy of remark here that these and other valuable trees and shrubs were planted two years ago on a bed of gravel, and are the best evidence we remember to have seen in overcoming this disadvantage of soil by deep trenching, and the addition of a little good loam, and occasional watering in dry weather; Laurels, Mahonias, and even Roses grow there with an extraordinary vigour.

As we proceed up the carriage-drive we observe to the right, at some distance, the farm and farm buildings, all in beautiful keeping, and we wish momentarily that we might diverge to take a closer view of them, but our business is with the garden. We enter the court-yard, and a fine Elizabethan mansion with square tower, built some thirteen years since by Mr. Lucas, of London, and recently redecorated by Mr. Rayment, of Hertford, immediately confronts us; the servants' compartments and laundry on the north side are covered with neatly-trimmed Ivy.

Leading eastward from the house is a sunk walk winding through the shrubbery, the agreeable coolness of which at once obtained recognition; near one end is a rustic arbour, circular in form, and embowered in trees, the panels in the interior decorated with branches of trees laid on moss in such a manner as to show the character and direction of the spray. A pretty idea this, and not only pleasing but instructive also. Returning through the croquet ground we see to the right large masses of Holly, in front of which on a gentle incline is a ribbon-border filled with the customary gay and effective bedding plants. Here is a terrace wall, against which is trained the *Gnaphalium lanatum*, its silvery foliage contrasting well with the red bricks; while grand spiral columns of the *Humea elegans* rise at given distances above the wall. Ascending four steps we are in the Italian flower garden, which surrounds the house on the east and south sides. The small paths are of white spar and gravel, and designs in dwarf Box abound. There is a fountain in the centre, and single specimens of *Thuja aurea*, 4 feet high and as much through, and perfect in colour and form, Irish Yews, and Irish Junipers are judiciously introduced. There are also beds of the beautiful *Juniperus tamariscifolia* forming a complete carpet of silvery-green foliage; these are occasionally watered with manure water. The majority of the beds are filled with the usual bedding plants, gay enough in their season, but winter is also deprived of its gloom by margins of Ivy, the Box, and other evergreens above mentioned, which retain for the garden a furnished appearance when the flowers of summer are departed. Figures and ornamental vases sparingly and judiciously introduced aid also in the attainment of this end.

From the terrace fronting the house is a wide and extensive view commanding the valley of the Lea, with the Essex hills beyond; Nether Hall, Nazing church, Epping Forest, and Monkham's Hill are prominent objects. In the park fronting the house are good specimens of timber trees, the tops only of some visible, owing to the ground falling rapidly at a short distance from the house; the *Cedrus deodara*, Scotch Pine, and the narrow-leaved English Elm were also conspicuous; while to the west were groups of various trees, between which the open country beyond, nicely undulated, was distinctly visible. We approach the conservatory, which adjoins the mansion, and is built on the ridge-and-furrow principle, the dimensions 50 by 60 feet. The pillars in the interior are covered with various creepers, of which the *Jasminum grandiflorum*, *Passiflora*, *Fuchsias*, *Habrothamnus*, and *Geranium Unique* are in full bloom. In the centre, planted out, are magnificent specimens of *Camellias*, some 12 feet high, others 12 feet in diameter, perfect in shape, with leaves black as ink, and plentifully adorned with flower-buds. As the leading prizes for *Camellias* at the London spring shows were won by flowers taken from these specimens, it may be interesting to know the mode of culture adopted. So soon as the flowering is over the house is kept warm for about two months, and the trees syringed freely. During this period the growth is made and flower-buds set; the plants are also watered freely during the season of growth with water in which sheep-manure is steeped; they are watered twice only in winter. The flower-buds are thinned out early in autumn, and not more than one bud is ever allowed to a leading shoot. The variety known as *Elegans* has produced flowers 8½ inches across, and other sorts are proportionally fine. Sundry *Azaleas*, and greenhouse plants, and hanging-baskets—at this season mostly filled with Ferns—are also in the conservatory. There is a vestibule between the drawing-room and conservatory, and this is furnished with various articles, rare and beautiful. The beds of the conservatory are margined with a pretty green moss, and the paths are of white spar. There are, in addition, several plant-houses well contrived and well built. In the stove we observed very fine specimens of *Croton variegata*, *Cissus discolor*, *Ixora coccinea* well set with bloom, *Franciscas*, *Cyanophyllums*, and a plant of *Cypripedium insigne* in full flower. In the roseroy many of the autumnal *Roses* were still beautifully in bloom. Terrace walls, which abound, were covered principally with *Roses*, *Pyracantha*, *Cydonia*, *Forsythia*, *Ampelopsis*, *Magnolias*, *Jasminums*, and *Weigelas*.

We are now on our way to the pinetum, and passing some beautiful specimens of Gold Hollies on the lawn west of the house, we are confronted by a plant of *Picea nobilis glauca*, till recently out of health, but restored by digging round it, and filling the trench made with fresh loam and cowdung. Here, also, are fine trees of *Juniperus chinensis*, *Pinus pyrenaica*, *P. excelsa*, *P. strobus nivea*; *Abies Nordmanniana*, *A. pinsapo*

(20 feet high, a perfect specimen), *A. Douglasii* 50 feet, *A. cephalonica* 20 feet; a huge bush of *Taxus adpressa* bearing fruit, and smaller plants of *Pinus Hartwegii*; the variegated Red Cedar (*Juniperus virginiana foliis aureis*), and many of the choicest kinds. Passing under a rocky archway we encounter a sunk cave or grotto, built by Mr. Pulham, and which realises the end sought in being deliciously cool. We also sight screens of Ivy, which answer perfectly, and an arcade of climbing *Roses*.

Although trees and flowers form the greatest attraction of this place, fruit is by no means overlooked. The Cucumber-house, in which the *Telegraph Improved* is the favourite, is full of fruit, many from 20 to 24 inches long. In the late vintage only was there any fruit, but the early vintage showed signs of having done well. Capital Black Hamburgs, both as regards size and colour, and Muscats, and *Lady Downe's*, the two latter sorts in pots, were still in fine condition. One Muscat Vine in a pot had borne fourteen bunches averaging a pound weight each, and the berries on *Lady Downe's*, were like Damsons, both in size and colour. There is also a walled kitchen garden well stocked with the best and most useful fruits, while the sides of the walks are planted with pyramidal Pears and Apples. The following Pears were very fine—*Beurré Superfin*, *Triomphe de Jodoigne*, *Seigneur d'Esperen*, *Grand Soliel*, *Beurré Diel*, *Beurré d'Artemberg*, *Beurré d'Amanlis*, *Passe Colmar*, *Louise Bonne de Jersey*, *Chamantel*, and many others.

Many objects which we have missed in this somewhat hasty survey, might form matter of comment, but this article is already exceeding the bounds anticipated. Mr. Trusler, who manages the garden, has recently invented a van with glass roof and heating apparatus for conveying plants to the spring shows, which your readers will, doubtless, hear more of in the future. That such a contrivance was necessary more than one exhibitor will, we believe, be ready to testify, for at the spring shows this year many of the plants sent arrived at the shows frozen stiff, and were not only unfit for competition, but returned only to be consigned to the rubbish-heap.—W. P.

## POLEMONIUM CERULEUM VARIEGATUM

(VARIEGATED JACOB'S LADDER.)

FEW if any of the native plants of Britain are to be met with in the flower gardens of the present day. Perhaps they do not deserve a place among the gay and select few that are considered effective enough to play their part in the summer flower gardening now so fashionable. The rage in certain quarters is all the other way, and the natives of more sunny climes are being pressed into out-door service; but these latter will never become common in the gardens of this country. Two considerations will, of necessity, tell against anything like a popular attempt at turning our stove plants into the open air, even in our finest summers. First, the expense of rearing and wintering them, and above all the very few localities where the climate will allow of them being planted out with any reasonable hope of their remaining respectable, to say nothing of making progress. For this reason the examples being so ably set to us of planting tropical plants out-doors is not at all likely to benefit the millions, especially of Scotland. If we are to have any new blood introduced into the present parterre system of planting in the shape of new materials, they must be hardy enough to at least look respectable during summer and autumn, to do without stove heat in winter, and if hardy enough, to cope with our frosts unprotected all the better.

The subject named above cannot be charged with tenderness. In this respect it is a thorough Briton; and in point of appearance all summer and autumn it has a grace and beauty all its own. Almost every gardener must be acquainted with the common form of *Jacob's Ladder*, and this is a variegated variety of it with much more white or cream colour in its composition than green. I have had it here for several years, and it has grown in favour very much, and has this year been used as single plants in blue groundwork and as an edging to beds; and few bedding plants have pleased so much. Some amateurs have exclaimed, on first seeing it, "Oh! what a pretty Fern!" and it has all the appearance and much of the grace of some of the Fern tribe about it, its leaves being pinnate. It lasts in full beauty the whole summer and autumn, and shows no disposition to flower.

Some years ago I directed attention to the *Centaurea ragnina* as a bedding plant, and the patronage it has met with has

proved the correctness of the opinion expressed so confidently about it. This is a much more easily-managed plant, and I can recommend it very confidently as a decorative plant, and venture to predict for it great popularity. As a dinner-table plant in pots it is very useful, and planted in lines it has just the air and grace of a compact Fern, while there is but little green in its colouring.—D. THOMSON, *Archerfield, N. B., in Scottish Gardener.*

## THE ROYAL HORTICULTURAL SOCIETY.

OCTOBER 3RD.

**FLORAL COMMITTEE.**—Very few specimens were sent to this meeting. The collections of cut Roses from Messrs. Paul & Son and Mr. Turner of Slough were extraordinary for the time of the year, and more especially for this dry season. Mr. Turner's collection of Pom-pone or miniature Dahlias was very attractive and much admired. Both of the collections of Roses and miniature Dahlias were awarded special certificates. Mr. Rawlings sent two seedling Dahlias:—Silver Swan, no use, and Little Beauty, of dwarf habit, small flowers, orange ground, heavily tipped and shaded with red, useful as a bedding variety—first-class certificate. From Mr. Turner, Slough, came four seedling Dahlias:—Le Domino Noir, a white and maroon Fancy—second-class certificate; Arrah-na-Pogue, Artemus Ward, and Arthur. Mr. Turner also exhibited a single cut specimen of a seedling Rose, Prince of Wales, a bright cherry red, of excellent form, promising to be a first-class flower. Mr. Pocock, gardener to Mr. Barber, Wincanton, exhibited a box of seedling Verbenas of no particular merit, not equal to the best varieties now in cultivation; and Mr. Melville, gardener to the Earl of Rosberry, Dalmeny Park, four seedling Tropaeolums, by no means novelties; the flowers were out of condition. Mr. E. Davies sent two seedling Fuchsias—one, Lady Sherborne, with a double white corolla; the other, Lord Sherborne, with a double purple corolla, but both were worthless. Mr. G. Smith, Hornsey, again exhibited his seedling Nougay Pelargonium La Grande, which gained a first-class certificate in June; it still maintained its good character both for its dwarf habit and splendid large truss of brilliant flowers. Christabel, having a white ground with deep salmon centre, a good form and petal, but not equal to Beauty and others of the same class, came from the same exhibitor. Messrs. Downie, Laird, & Laing, exhibited an Alternanthera with dark variegated foliage, the colour of Iresine Herbstii, of very dwarf habit, but not likely to be useful. From Mr. F. Priest, gardener to E. Wood, Esq., Hanger Hill, Acton, came Asplenium dimorphum, a Norfolk Island Fern, the plant producing broad and narrow sections in the same frond. It is a useful greenhouse plant. Mr. Earley sent cut specimens of Ipomoea Bona Nox (*I. noctiluca*?), also of a variety of Ipomoea Quamoclit, with larger and bright deep crimson flowers. Mr. Bragg, Slough, sent seedling Dahlias Commander, Fair Lady, Lady Geraldine Wellesley, and Model; and Messrs. Paul & Son a basket of Nerine Fothergilli, a very handsome plant, with bright scarlet heads of flowers. This plant should be more extensively grown, for it is one of the most useful and ornamental flowers for greenhouse decoration at this time of the year, and very distinct from the Guernsey Lily. Messrs. Paul & Son also exhibited in their stand of Roses seedling Princess Mary of Cambridge. From Mr. Southby, Clapham, came Cineraria maritima nana, a very dwarf-growing plant. If it maintain its dwarf habit it will be very useful, but some doubts were expressed on this point. Rev. C. Rose exhibited two stands of seedling Dahlias, none of which were thought worthy of distinction; and Mr. Mackintosh, Hammersmith, sent a basket of his seedling hybrid Solanum capsicastrum covered with scarlet fruits, also hybrid Veronica Madame Jacotot. These plants came too late to be entered for examination.

**FRUIT COMMITTEE.**—G. F. Wilson, Esq., F.R.S., in the chair. Prizes were offered on this occasion for the best collection of Grapes, except Muscats, also for the best collection of white Muscats, but in neither class did any exhibitors come forward. Prizes were likewise offered for Muscat Hamburg. Here the only exhibitor was Mr. Osborne, Kay's Nursery, Finchley, to whom a second prize was awarded, the berries being deficient in colour and flavour. In the class for three dishes of dessert Apples some very good fruit was shown. Mr. Earley, gardener to F. Pryor, Esq., Digsweil, was first with Cox's Orange and Ribston Pippins, and Sam Young; and a second collection from the same exhibitor consisted of the last-named, King of the Pippins, and Fern's Pippin. Mr. Cox, Redleaf, was second with splendidly coloured Ribston Pippin, Cox's Orange Pippin, fine, and Pimston Nougayil. For Pears, three dishes, Mr. Whiting, gardener to Mrs. Hope, The Deceptene, Dorking, was first with Thompson's, Marie Louise, and Comte de Lamy; and Mr. Earley second with Brown Beurre, large and very good, Gansel's Bergamot, and Marie Louise. A second set of three dishes came from Mr. Whiting, and Messrs. Ivory of Dorking and Mr. McLaren likewise exhibited. Of Pearmain Apples only one collection was staged. This was sent by Mr. Whiting, and was awarded a first prize. It consisted of Adams' Pearmain, beautifully coloured, Parry's, Claygate, Traveller's, Lamb Abbey, Winter, Mickleham, and Mannington's.

Among miscellaneous subjects was a handsome Providence Pine of, 9 lbs. 6 ozs., for which a special certificate was awarded to Mr. Ruffett,

gardener to Lord Palmerston, Brockett Hall; and Mr. A. Stewart sent Slindon Park Peach, a freestone, as large as the Late Admirable, and of excellent flavour for a late kind. A first-class certificate was given for this; also to Messrs. Paul & Son for Raspberries Belle de Fontenay, and October Red and October Yellow, known also as Merveille de Quatre Saisons Rouge and Jaune. Brinckle's Orange, Cushing, both of which are summer kinds, Large Monthly, and Autumn Black, came from the Society's garden at Chiswick. The last-named variety is one of Mr. Rivers's raising, and produces fruit of the colour of the Blackberry, from which parentage it has sprung. Fine specimens of Black Prince Grapes, and of good flavour, from an open wall, as well as a collection of Plums, also came from the Society's garden. Mr. Baxter, gardener to — Kaiser, Esq., sent an amber-coloured somewhat oval Grape, but it was not considered equal to existing varieties. F. J. Graham, Esq., of Cranford, exhibited his Autumn Nelis Pear and Cranford Muscat Grape; and Mr. Ingram, gardener to Her Majesty, Frogmore, a white Grape called Napoleon, apparently a better variety of the Royal Muscadine, and stated to be useful for growing on open walls. Samples of Hands's Freedom Potato, a variety raised by Mr. Hands, of Newcastle-under-Lyne, were also submitted to the Committee, who deferred, however, passing an opinion upon its merits till it had been seen and tasted later in the season.

## STRAWBERRY ROOTS DECAYED.

In July I planted strong runners of Strawberries British Queen, La Constante, Frogmore Pine, Sir J. Paxton, President, John Powell, and Royal Hautbois in beds, well trenched and manured, and with a quantity of old turfy loam worked in with the natural soil, which is light. All grew strong and healthy until about the 5th of August when some sorts, especially the British Queen, La Constante, and Frogmore Pine threw up leaves curled and moulty at the tips, and the growth has since been checked. Can this be attributed to the manure being fresh? I could get none that was decayed, and used two-thirds horse and one-third cowdung, strong and fresh. On taking up some of the plants I found that some of the roots, 6 or 8 inches deep, were rotten. Can anything be done to improve their health?—A SUBSCRIBER.

[We sent your note to an authority on Strawberry culture, and the following is his reply:—

"I should not break up the plantations; they will make new roots in spring. It has been here quite a red spider and fungus season. The mould on the tips of the leaves may possibly be fungus, or the effect of the preceding cause. Water the plants freely while this hot weather lasts. The plants here of all kinds are most beautiful and healthy.—W. F. RADCLIFFE, *Tarrant Rushton.*" ]

## HAMILTON PALACE.

(Continued from page 274.)

I HAVE mentioned that on one of the fronts of the mansion a broad walk, continued by a still broader avenue of fine healthy trees, carries the eye a great distance; I may now state that on the opposite side is another vista, not exactly an avenue in the sense in which that term is often used, but a clear opening about two miles in length, affording a view of what appears to be another mansion almost equally spacious with the one near which we stand. This second building, I understood, is a model of one of the Duke's seats in France, for it must be borne in mind the Duke of Hamilton holds a similar title amongst the Peers of that country, as well as sundry English ones besides. This representation of his Grace's chateau in France, occupies a gentle rising ground on the opposite side of the river Avon, which, however, is not seen from either position, though it crosses the line, the whole distance appearing, as it in fact is, a continued park. The building in question is ornamented with grass terraces, flower-beds, and the usual accompaniments of an ornamental kind met with as surrounding a country gentleman's mansion, although it is devoted to other purposes; nevertheless, the keeping is good.

As I was told of the great antiquity of some of the remains in that part of the park, I was induced to visit it, and through the kindness of Mr. Mitchell, the very able and intelligent gardener, who accompanied me the whole way, and pointed out the various objects of interest, we made our way across some of the best park land in the kingdom, until we approached the river Avon—not the classic Avon of the English midland counties, but a clear pure stream as large as its southern namesake, but exhibiting more diversified features, even in the bounds of the park, than many rivers do in their whole course.

It is sometimes hemmed in by precipitous banks, clothed to the edge with rich woodland foliage, while rocks 100 feet in perpendicular height, and upwards, cast their long dark shade on its troubled waters, which struggle on over a rocky bed; at other times the stream widens into a broad expanse, shining like limpid silver, and seemingly proud to show itself to the admiring gaze of the visitor, whose eye wanders over the softer portion of the park, the banks being low, and the ground level on both sides. We had to cross it at one of those precipitous spots, and in doing so my conductor led me into one of those old-fashioned gardens which must certainly have ranked high among the works of art of that time. A steep declivity had been cut into terraces, and planted with a great variety of shrubs, which had been cut into the many fanciful forms our ancestors no doubt thought indicated the highest amount of ingenuity. Many of these figures had, no doubt, outgrown their original shapes, or had fallen into the hands of a less skilful generation, but enough remained to show the long-continued attention of its managers or originators; for although I failed to make out dogs and horses, cups, vases, pyramids, cylinders, and many fanciful figures difficult to describe met the eye at every corner.

We must now leave the scene, and crossing the river by a substantial bridge of considerable elevation, we find ourselves in another part of the park, more interesting from the objects it contains than any we have yet been in. Here we are introduced to members of both the vegetable and animal kingdoms, which carry us back to an age differing widely from that in which we live; and were it not for the living witnesses before our eyes, we might be almost tempted to doubt the accuracy of the legend which at least belongs to the vegetable department—the other admits, or hardly so, of any doubt whatever. We are, in fact, in Cadzow Park, and in company with, though at a respectful distance from, the occupants of that same park, whose ancestors had lived there probably before the human race invaded and battled for the same spot. On the part which Cadzow Castle played in the early history of Scotland I have no intention to enter, but it was, doubtless, a place of much importance when its proprietor received instructions from his sovereign to plant the Oaks which form so remarkable a feature in it. We are told this was done in the fourteenth century, or in the early part of the fifteenth, thereby indicating 450 or 500 years as the age of these relics, and, I believe, that there is some authentic record as well as tradition, that these fine old trees were then planted; and the somewhat regular manner in which they are scattered over the ground implies that if not planted by hand, the latter had something to do in thinning them out. They occupy a somewhat elevated position in the park. The soil, I should think, is rather inclined to be gravelly, not wet, and yet not too dry. The trees exhibit every feature common to old Oak trees. A few, but only a very few, may be called healthy, but I doubt much if any of the timber is sound throughout, and the greater portion of the trees exhibit traces of old age and decay in a greater or less degree. Several of them are dead, but still with perfect good taste they are allowed to remain where they are; many have large limbs quite dead, with a little life showing itself on a portion of one side perhaps. This struggle to prolong an existence is seen in its various stages, some seeming as if the last effort had been made, others promising to continue it for at least another generation of the human race, or longer. Antiquity rather than size is their peculiar feature, for much larger Oaks are met with in England; but nowhere that I know of are so many aged trees found together. The table land of a large portion of the park was dotted over with these venerable trees, while some dells and extensive boundaries were planted with trees of modern growth, or which had been cut and grown again. I regret omitting to notice any acorns, as it would be worth while ascertaining whether these belonged to the long or short-stalked species, the respective merits of which caused no little discussion some years ago.

These Oaks presented the usual outline of the monarch of the forest, generally short-boled, more or less enlarged by the swellings or protuberances, which form the beautifully-grained panels so prized in furniture-making, while now and then large portions of the outer part of the tree, or what is called the sap, had fallen into decay, leaving the heart smooth, and bleached white by the sun and rain. I did not see any trees that had been blown down; generally speaking, they seemed to die piecemeal from the top downwards, as some showed little else but a short trunk. One circumstance, however, more than any other struck me as remarkable—the absence of middle-aged and young trees which we meet with in natural forests, and

other places where timber has been the principal growth for centuries; so that if these trees were not planted by hand in the first instance, as is generally asserted, they must have received due attention at least a couple of centuries ago, as well as since, and younger trees must have been kept down so as to keep these favourites by themselves. However, they are a remarkable assemblage of old trees, and may in some degree be compared with the patriarchs of Mount Lebanon, which, though reduced in number so as to be very easily counted, are, nevertheless, not mixed up with younger members of the same family. Whether the same natural causes may have operated in both these cases or not, it is difficult to say. If we allow them to have been influenced by the same causes, we weaken the argument of those who assert the Oaks to have been planted, as the Cedars assuredly have not, and yet it would seem almost superfluous to plant Oak trees at a time when the country was, in a great measure, covered with them, and when there were so many evidences that Nature performed that office herself; therefore, the subject must still remain in doubt.

We now turn to another and still more important feature which renders Cadzow Park remarkable above all other parks in Scotland, and, with the exception of Chillingham in Northumberland, it may be said of England also; and here, again, we have to carry our inquiry centuries further back than in the case of the Oak trees mentioned above. I allude to the breed of cattle, which there is every reason to believe roamed over this island long before the Christian era, and which is still maintained in this park and that of Chillingham.—J. ROBSON.

## BEDDING-OUT AT OULTON PARK.

(Concluded from page 248.)

On entering the flower garden from the arboretum we come upon a large round bed filled with Mrs. Pollock Geranium; the plants were all spring-struck. The bed previous to planting-out time was filled with a mixture of new loam, peat, leaf soil, and well-decomposed manure in equal proportions. The plants all grew very vigorously, and soon covered the ground. This appears to be one of the principal secrets required to be known by cultivators of Mrs. Pollock generally—namely, the soil cannot be too rich for it when it is planted out in the open ground, provided the beds are well drained, so that no stagnant water can remain near the roots. I found, on taking the plants up the other day, that they had made roots 18 inches and 2 feet long. The foliage the plants made during the summer was truly magnificent, all the colours on the leaf being brought out very distinctly and beautifully. I have found in every instance that spring-struck plants grow much more freely than old ones; they also produce better foliage. Therefore I should strongly advise spring propagation for this section of bedding Geraniums, and, instead of growing them in pots, planting them out in frames where they can have the benefit of a very slight bottom heat. Another point should also be strictly observed: in taking cuttings a due amount of patience should be exercised. Never take any cutting off unless it has four or five fully developed leaves; if taken off at an earlier period there is great difficulty in making it secure in the ground, and very many probabilities of its damping off, because its wood is not sufficiently matured. A cutting taken off in the state described above will emit roots much more rapidly and grow more freely after it is struck than a small weak one; and soon after it becomes established in the frame the top may be taken off, leaving about three eyes above the ground. Three cuttings may again be taken from the plant before bedding-out time, and one from the first top taken off. If proper care has been taken according to instructions given in previous articles on the propagation and after-management of bedding plants, five good plants may be propagated from one cutting between the months of February and June, so that from a few good stock plants a large quantity may be obtained.

I have entered into this explanation on here, because I think it may guide many who are as yet unacquainted with the proper management of the Mrs. Pollock section of Pelargoniums. I do not think the appearance of Mrs. Pollock as a bedding plant can be improved by an edging of any other plant, especially if the bed in which it is grown is surrounded by grass. The bed should, however, be nicely filled, putting the tallest plants in the centre, and reserving the very smallest for the edge of the bed next the grass.

The next bed to Mrs. Pollock is filled with *Iresine Herbstii*

with a good band of *Cerastium Biebersteinii* between it and the grass. Although I have in a previous article condemned the *Iresine*, I am now compelled to retract my words, and to assign the cause of its being condemned to the want of knowing how to manage it properly. Many valuable plants are lost by a too hasty judgment being pronounced upon them before they have been subjected to various kinds of treatment. For the last six weeks this has been by far the most beautiful bed in the flower garden; it presents such a beautiful outline to the eye. There is not that flat appearance which the *Amaranthus* presents, and the colour is magnificent—far surpassing the *Amaranthus* either for distant effect or close inspection. What the plant appears to want is more moisture than it has received from natural sources this season. The soil it likes is also very rich, and it requires a more shady position than I have seen accorded to it at many places this season. If grown under these conditions I have little doubt but that it will yet become a favourite in our gardens. Then, again, the nature of the plant was almost worked out of it by frequent decapitation in the spring. I have proved in many other instances that very few new plants are so good the first year they are sent out as they are the second; it takes them a long time to regain their proper strength and character after being subjected to the high-pressure system of propagation. From what I can see of the *Iresine* now, I think that in a more wet and humid season it will far surpass the *Coleus*, so that it will be worth while to keep a sufficient stock of it to give it a fair trial next year.

To the right of this is a bed of one of my new seedling *Verbenas* edged with *Viola cornuta*. The *Verbena* is a bright cerise or cherry in colour, and the *Viola* is a rich slate blue, or mauve. This bed has been surpassingly beautiful ever since the first week in July. The *Viola* still keeps its place in my estimation as one of the most chaste and beautiful plants for flower-garden decoration I have ever seen. It will be equally valuable for spring bedding as it is for the summer. It commences blooming, if the weather is not too severe, in March, and continues without any intermission till it is completely cut down to the ground by the frost in autumn. No doubt some valuable hybrids will be obtained by crossing this with some of the garden varieties. I shall turn my attention to this in the spring, if I am spared, and have little doubt that I shall be able to produce other colours in this *Viola*, with the same habit and constitution; and if this can be done it will be a great addition to our plants suitable for bedding-purposes. I hear that Mr. Tyerman, of the Liverpool Botanic Gardens, has a beautiful blue *Viola* called *montana*. This I think cannot be the same as mine, as his is described as blue. I shall, however, send him a bloom of mine to see if they are identical: if they are not, then we have two great acquisitions in the way of bedding plants suitable for spring, summer, and autumn decoration.

The next bed a little to the left of the *Verbena* and *Viola*, has its centre filled with *Verbena Velvet Cushion*, and a margin of *Mangles's Variegated Geranium*. This bed has been very much admired; it is now (October 7th), a blaze of floral beauty. Another large bed a little to the right of this has a centre of *Beaton's Stella Geranium*, with a wide row on each side of it of *Lobelia speciosa*; around this is a row of *Lady Plymouth Geranium*; and between this and the grass, *Claret Queen Verbena*. This has had a very fine effect. The opposite bed to this is filled with *Amaranthus melancholicus ruber*, with an edging of *Viola cornuta*. This bed has been, and is still, remarkably fine. The rich colour of the *Amaranthus* is so much toned down by the soft and pleasing colour of the *Viola*, that it has attracted all eyes to it immediately on entering the garden. The effect when seen at a distance is grand in the extreme. A large circle near the two last-mentioned beds has a centre of *Geranium Christine*, then 2 feet of *Verbena Purple King* around this, and a margin of *Geranium Golden Fleece*, 1 foot wide, next the grass. This bed has also been very good.

Behind the bed last described is a large circular bed raised on blocks of wood similar to that at the top of the ribbon-borders. A fine specimen plant of *Humea elegans* forms the centre. On the lower tier of blocks are six large *Humeas*, then the whole of the space between the *Humeas* is filled with *Geranium Boule de Feu*. There is also a thick row of *Boule de Feu* planted all round the outside of the wooden blocks next the grass, so that no wood is seen. This forms a perfect pyramid of scarlet, which is much relieved by the *Humeas*, and it has altogether a very imposing effect. It is placed just opposite the mouth of the tunnel leading to the pleasure grounds and

pinetum. As you come up from the pleasure grounds it stands just in front, and prevents the eye from catching the whole of the flower garden at once; and when seen from the opposite side of the garden it forms a nice centre or enlivening-point to the whole arrangement of beds in the garden, which is laid out after no particular form, the beds being all irregular. This being the case, it is a very difficult matter to arrange the colours in the beds so that they may harmonise well as a whole.

Right and left of this pyramid are two large beds filled with *Gladioli*. Amongst these are planted *Canna discolor*, *C. Warszewiczii*, some of the *Caladiums*, and *Cyperus alternifolius*. This is the first time I have tried the *Cyperus* bedded out. It grows remarkably well. I have no doubt that the variegated form of this would grow equally well if planted in a warm and partially shaded place. This, by-the-by, is one of the most beautiful things for effect in a bouquet that I have ever used, if one spike is put in the centre and about three smaller ones around it; they should be so arranged in the bouquet that they may appear a little above the flowers, this gives the whole a very graceful appearance, and relieves the monotony of the colours very much. It also does away with that flat appearance too often seen in bouquets.

The ground between the *Gladioli*, *Cannas*, &c., is covered with mixed colours of *Verbenas*, and near the edge plants of *Amaranthus melancholicus ruber*, *Lobelia Paxtoniana*, &c. Behind these beds are several more large plants of *Humea elegans*, which, as seen in the distance, give a very nice finish to the *Gladioli*, *Cannas*, &c. Beyond this are raised banks planted with *Hollyhocks*, *Dahlias*, *Phloxes*, and miscellaneous bedding plants.

Another bed of one of my best *Verbenas* of last year, *Lady Binning*, edged with *Lobelia Paxtoniana*, has been very fine. This is one of the very best scarlet *Verbenas* in cultivation, the colour is very brilliant, and the habit all that could be wished. This bed has been so dazzling that it has been almost impossible to look on it for any length of time, especially when the sun is shining on it. This *Verbena* stands the weather well, and is altogether a very desirable variety. Besides the beds described above there are many others filled with *Stocks* and *Mignonette*, and various other bedding plants. I have only selected the above as being the most striking and containing many novelties which are not yet generally known.

There is a long terrace walk leading from the Hall to the flower and kitchen gardens. On each side of this are a number of beds, 2 feet square, cut out on the grass. These are filled with standard *Roses*, large specimen *Fuchsias*, *Pelargoniums*, and at intervals of about 30 feet a pair of large plants of *Humea elegans*; around these are placed plants of *Iresine Herbstii* and *Geranium Golden Fleece*, the ground about the *Roses* being covered with various coloured *Verbenas*, and the best varieties of *Tropaeolums*. This arrangement has been very much admired. Amongst the *Fuchsias* *Carter's Meteor* has been very conspicuous, appearing in the distance a perfect pillar of gold.

Time will not permit me to describe my own trial garden. This, with the novelties it contained, must be left for another occasion. I must leave the description of the general character of this fine old place to more able hands, and must soon resign its management, and bid farewell to all its associations, with the proud feeling that I have done all in my power to raise it from utter ruin to its present improved state.—J. WILLS.

#### CLOTH OF GOLD GERANIUM.

THERE must be something materially wrong with the soil in which Mr. Flitton's Cloth of Gold *Geraniums* are growing, as he says his plants have all the requisite shelter, &c. I may state, for his information as well as "R. F.'s," that I have four beds of Cloth of Gold and *Amaranthus melancholicus ruber* planted plant for plant, and edged with *Lobelia speciosa*, and I can assure Mr. Flitton and others that no beds up to September have succeeded better than these. When they were being planted many shook their heads, and I confess my own hopes were not very sanguine on the matter, knowing that they would have to withstand the bitter east winds off the sea, from which they are separated about 200 yards. These beds are so beautiful and the contrast so fine that I intend planting them on a large scale next season. I shall also prepare the soil by improving its texture, something in the way that Mr. Pearson describes.

By the way, it is not every gardener that can do as Mr

Pearson describes; fine loam is not found everywhere, nor is dung *ad libitum* at every gardener's command, even though his garden may be acres in extent, and his bedding plants may be counted by thousands. A very good plan is to graft the weak-growing fine-foliaged Geraniums on Tom Thumb.—W. McLELLAN, *Wemyss Castle Gardens, Fifeshire, N.B.*

### RAIDS AFTER FERNS.—No. I. DARTMOOR.

Up the valley of the Teign, by the side of the prettily wooded river, cricking one's neck in turning to catch a view of the frail-looking suspension bridge spanning the river from Teignmouth to Shaldon, with the blue waters of the sea beyond, bearing many a vessel to the secure little harbour round the ruddy headland of the Ness; then turning for the upward view, where the soft undulating hilly distance gives to the river the sweet characteristics of a lake; then through King's Teignton, taking a turn to the right and presently coming to the old straggling Teignbridge, on each side of which *Asplenium ruta-muraria* abounds, not in small half-starved morsels, but in full rich bunches. By applying a little judicious leverage the old stones can be moved and the plants extricated, with some of the mortarised earth clinging to them. Another turn to the right and you are at the pretty church of Teigngrace. Near this place *Polystichum angulare imbricatum* has lately been found, and after a while you are very near some of the finest specimens of *Osmunda regalis* that I have met with. Still on, and you come to the Bovey potteries where the huge mounds of earth, the railway trams, and the toil-stained faces of the men, are but pleasant shadows of comfortable cottages, well-paid workmen, and wives and families clothed and fed. A little beyond the potteries and a road to the left is the high road to Manaton. The hedges on either side contain *Asplenium adiantum nigrum* in every varied form of growth, the fronds measuring, together with the rachis, from 2 feet in length to 1 inch; one curious specimen beginning with two fine-spreading pinnae, as if determined upon doing great things, but, suddenly changing its mind, ending by sending up a tiny frond, having the appearance of a child's head on a man's shoulders. In this same hedge there were more than one plant having the same stunted appearance, which, though very curious, is, of course, only a freak of Nature; but I rooted them up, for one never knows in ferndom what may come of what. Still on the Manaton road, just before entering on the moor, there were some plants of *Lastrea oreopteris* by the roadside, stunted in growth, but very welcome to me as being the first I had seen in this part of Devonshire. And then—the moor! the fresh bracing wind coming cheerily to welcome you, making you inhale long whiffs of the elastic Heather-scented air, that seems to bring new life and vigour on its wings.

Such a moor! Heather of three kinds—the *Erica cinerea*, *Erica tetralix*, and the common Ling, mixed in vast masses with the golden Gorse, and here and there and everywhere tufts of bright green *Blechnum spicatum*, now peeping up from a large moss-covered boulder of rock, caressing it with its tender arms; now contending with *Polypodium vulgare* for the prettiest nook of an old weather-beaten tree; and now rioting in luxurious ease with *Lastrea dilatata*, *Filix-mas*, *oreopteris*, and *Athyrium Filix-femina*, on banks of richest turf, till in the neighbourhood of Becky Fall, the wayside was literally carpeted with the tender green of multitudes of fresh young fronds; some of the *L. dilatata* assuming so nearly the appearance of *Polypodium phegopteris* that I jumped out of the carriage with a joyful cry to gather it, but returned with only the slow step and whine of disappointment.

Some light carriage had passed us up the steep ascent to moorland, and when we reached the pretty village green of Manaton we found that our approach had been heralded, and the rosy face of a Devonshire "lass" was standing out from a cottage porch of Roses and Honeysuckles to welcome us, while a huge flock of geese stretched their wings and cackled vociferously at the unwonted appearance of a stranger. Round the village green a few picturesque cottages are collected. There is Ivy Cottage, where we took up our abode, the "Half-moon" tavern, an innocent-looking cottage with whitewash and Ivy, and adjoining, another cottage known far and near as "The Shop." On the side opposite Ivy Cottage is the new trim little school, where a wise-looking lady in spectacles strikes terror into the very marrow of a group of stolid-faced urchins by her big-sounding words of wisdom. Nearly opposite the school is

a lych gate, through which the inhabitants of the peaceful moorland are carried to their last earthly dwelling place beneath the shadow of the grey old church, whose tall white tower is a beacon to the shepherd for many a mile around.

No place could well be prettier than Ivy Cottage, with its thatched roof, its casement windows, and its glorious surroundings of rock-strewn moor and grey dream-like distances. We had not been long installed before we had visitors—a long, thin, sedate shepherd's dog, demurely shaking his tail as his eye wandered round, drawing its own conclusions as to the likelihood of a dinner. The dog was followed by a fine black pig and a brood of chirruping chickens; the latter gave my thoughts a practical turn. I called (Ivy Cottage ignores the idea of bells) to the pretty daughter of our hostess, and said, "You will be able to roast us a chicken?" "Oh, no," she replied, "but you may roast one at our fire." "Bless me," I said; but I thought "Oh that I had taken WILTSIRE RECTON'S advice, and made visits to the kitchen before I came;" but after a while I found out it was only humility on the part of the maiden, and on the assurance that I was "not much of a cook," I was promised not only a chicken but rashers of ham and eggs, and—"A goose," suggested I, "there are plenty outside." Then the pretty maiden laughed derisively, and said Christmas would be time enough to talk of "they geese, they was so lean," and, "none of our feeding." So I left the geese to cackle in peace, and sallied forth to the shop to buy some calico for Fern wrappers. What a shop it was—groceries, draperies, stationery, bread and meat, and all from one counter, with an intermittent fever of gossip going on during the protracted process of selling. "You'll be the strangers up at Master Lee's. I seen you come; you drove in your own carriage. You come Newton way I seen. Well, there's two more Newton gentlemen a drinking next door. I seen 'em go in, so I know sure enough. There's more strangers up at Wescott's. I know it, you see, because they always uses dips theyselves, and they come here for composites; so if they ain't come they are coming, sure enough. I always regglate my prices after market day up at Exeter. Master Lee he goes to market sometimes, and sometimes the butcher he comes, so it's all quite correct." And quite correctly dear everything was; but they please theyselves, and the calico he did very well, when her had folded he up and given he I without any expense of paper for folding or string for tying up.

Directly above Manaton, looking down on the church and village, are a number of rocks heaped together in wild and grand confusion, and called the "Town Rocks," while lying all around in pasture land and amidst the waving corn are thousands and thousands again of huge boulders, and these peculiar forms of shattered rock make the chief features of the scenery. What geologists say about them I do not know; but there must have been a grand commotion going on beneath the water-floods when "Heytor" first raised her magnificent head erect and dry, and the rattling rocks settled themselves here and there in confused masses of wondrous beauty, little thinking of the curious names by which they would be distinguished in far off ages. One of these tors is formed of five masses of rock, and is more than 30 feet high; it is called "Bowerman's Nose," and seen in some lights it bears a marvellous likeness to a human figure with a very prominent nose. No family of the name of Bowerman exists at Manaton; but there is a record stating that in the time of the Conqueror a person of that name lived at Houndtor in the neighbourhood.

I cannot find words adequately to tell how beautiful these various tors can be when seen in the soft evening light. Rising heavenwards from a rich valley, with its nesting homesteads, its lowing kine, and waving corn, they crown the hill of Gorse and Heather, and seem to melt away into the very heavens, their rugged outline growing soft and intangible-looking, while other tors and other valleys stretch far away in the distance. And then the Fern-hunting, amidst scenes like this! the suddenly lighting on a moorland, by the banks of which you may wander, gathering Ferns at pleasure. On such a bank I found a very curious form of *Athyrium Filix-femina*, var. *odontomanes*. At first I thought I had a very great treasure. The narrow tapering fronds of dark green, with their spinulose serratures, looking as unlike *A. Filix-femina* as possible; but the eyes of a wisdom far greater than my own, looking upon it, have declared the graceful Fern to be only a curious form of *odontomanes*. About the bog close at hand I found the *Campanula hederacea*, which, strange to say, I had never noticed before. Its pale blue bell-flowers spring up about the treacherous green close to the *Drosera rotundifolia* and the Golden *Asphodel*, while a little

higher on the heath the banks of Gorse were covered with *Cuscuta epithymum* in full bloom, the crimson tendrils spreading far and near in matted confusion.

*Polypodium phegopteris* has been given to Becky Fall; but I searched there for it in vain, nor did I think the locality gave a good promise of it; I cannot help thinking that the very small *L. dilatata*, var. *collina*, I have mentioned before, has been mistaken for *phegopteris*. From the dripping rocks about the waterfall I procured specimens of both *Hymenophyllum tunbridgensis* and *unilaterale*. I have oftentimes been puzzled about distinguishing these delicate little Ferns when apart; but when you bring the two together all difficulty vanishes. *Tunbridgensis* is erect, and the fronds flat; *unilaterale* is drooping, with convex fronds; there are several other botanical distinctions, but I think these simple ones would always be sufficient. It is in dissecting the minute parts of these small Ferns that a Coddington or other lens becomes so invaluable and indeed so necessary.

Do not be content with only searching about the waterfall, but follow the higher path to the right and you will presently emerge on a sunny upland slope, not far from Lustleigh Cleave; here, within reach of the music of the waterfall, you will find a bank covered with *Asplenium trichomanes* and small *A. adiantum nigrum*, shaded by the drooping branches of the trees through which the sunlight winks and gleams.

In a hedge-bank close to Manaton I found several very curious forms of *Lastrea Filix-mas*, one of which I hope may turn out to be *cristata*; nearly every pinnæ is divided, and the apex of the frond is slightly crested. I should have thought this Fern a simple sport had there not been a little fructification. I found many varieties of *Lastrea dilatata*, and three plants of *L. spinulosa*. *Polypodium dryopteris* is said to grow near Chagford, but I have yet to find it. I hope shortly to have many more successes to relate, for the entire district abounds in Ferns and wild flowers.—FERN-HUNTRESS.

### THIRD CROP OF FIGS.

MR. ABBEY (page 280), says that he had asked your readers about a third crop of Figs, but met with no response. In an orchard-house, warmed during the colder days of spring, but not till the beginning of March, the first crop of Early Violet ripened this year on the 4th of July, the second on the 8th of August, the third in September.

The rationale of a third crop is very simple. When four or five leaves are made the point is pinched out, and the second crop is formed in the lower axils, but a wood shoot proceeds from the terminal one. If this is stopped again, the same results ensue, and a so-called third crop is formed. The ripening of this third crop depends—1st, on the earliness of the variety operated upon; 2ndly, on the shoots being stopped before they have made many leaves; 3rdly, on the variety being prolific, so as to insure fruit being formed on shoots however short; and 4thly, on there being sufficient heat to carry out the ripening. I have never found any variety so ready to produce a third crop as the Early Violet, which is, I believe, synonymous with the Malta; but I doubt not the White Marseilles would do the same. This last-named variety, side by side with the Early Violet, ripened its first crop this year on the 23rd of June, and the second on the 12th of August.—G. S.

### PAULOWNIA IMPERIALIS.

TEN years ago I wrote to ask you about the Paulownia. You did not give me much hopes of success; however, I planted one. It is now a large tree, measuring (nearly 3 feet from the ground, before any branches begin) 3 feet 6 inches in circumference. I enclose a piece with flower-buds. The tree is thickly covered with them; but I fear they will not open so late in the season. It is the first year it has had any flower-buds. I should be glad to know if there is any hope of the flowers opening, or of its flowering another year. The tree is at Mrs. Egerton's, in the Vale of Gresford, near Wrexham, very much sheltered, near the river Alyn, which runs at one side of the garden. It is a very handsome tree; the leaves are beautiful.—M. E. G.

[Your experience hitherto is in accordance with our warning. The flower-buds will not open this year. In 1852 this tree flowered freely in the Bishop of Exeter's almost tropical grounds at Bishopstowe, near Torquay; but it was in April, and before

the leaves were fully expanded. In Japan, the tree's native country, it acquires a height of 40 feet; but even in that country it only flourishes in the valleys and southern hill slopes of the southern districts. The flowers are very pale bluish purple, with a slight violet-like odour.]

### LEVELLING A SLOPING BANK.

WE have been asked by a correspondent "D. V.," for directions how to level a sloping bank, and as it is an operation not generally conducted on sound principles, we will reply to the inquiry rather fully.

Our correspondent does not say whether the slope is to be made into a level piece of ground, or still kept on the slope with the surface made even or regularly sloping. If the ground is to be made level (as, for instance, that represented between the points A and B, *fig. 1*), fix a stake, *a*, at one corner

Fig. 1.

of the ground, and at the lowest point of the base of the slope, *B*. In line, at a right angle with *B*, along the base of the slope, drive in another stake, and then place a spirit level by *a*, first driving in a peg at right angles with the first stake *a*, up the slope at half its height, *b*. Now, the spirit level being held against the stake *a*, at the bottom of the slope, at such a height that in looking along the level (quite level), you see the peg half way up the slope, *b*, moving up or down until the peg is seen over the spirit level, cut off the stake at that height; then make the other stake, at the other end of the base line, level with the first (*a*), not by looking over the stake first sawn off but with the spirit level, its upper side being placed level with the top of the stake, and not upon it, having some one to mark the level on the other stake which is to be sawn off at that. The spirit level being brought to this stake you looking along it up the slope will show where a peg is to be driven in, which, of course, will be equal to that at the other end of the slope, and how far, so that its head may be level with the other or stake at which you stand. Turning your eye along the base and looking over the stakes, have one driven in at the middle equal in height to the two end stakes. Repeat the same with those pegs half way up the slope, and you are ready for removing the turf.

Take the turf off evenly, roll it up, grass side inwards, lay it on one side, and clear of the ground to be levelled. If the ground is not deep in soil, then from 9 inches to 1 foot of the whole surface should be taken off and placed on one side to surface the levelled ground afresh. If soil can be had for this purpose, or the soil is all good, then this is not necessary, but you must not expect to bring bad soil to the surface, and, turning upon it, expect the turf to do well when relaid. You will bring the soil above the pegs down, and raise the ground around the stakes even with the tops, and by looking over the top of the bottom stake *a*, and peg *b*, up the slope, find the ground above level with them; if not so it must be brought level, driving in pegs, as at *c*, to show it at both ends and in the middle likewise. You will now have nine pegs, and looking from every corner the tops are of an equal height. If so, the ground inside them can be made level by a line stretched over the tops of the pegs, from peg to peg all round, and from corner to corner crosswise, putting in more pegs if the line (as it will) be not tight, to preserve the level between the stakes or pegs. You will now have a terrace, as shown by the dotted lines between

the peg *c*, and the stake *a*, and two slopes instead of one—one at the bottom, and another above the levelled piece of ground, as shown by the dotted line from *c* to *a*; and whatever their perpendicular height be, their base should be equal thereto (the levelled ground being less in width by half the width of the slopes), or to both if the lower slope be on the same ground. In that case the stakes must be taken the width of the slopes inwards. These slopes will look well grassed, or better still if planted with Roses pegged down, the slope at back, or upper one, being planted with Laurels pegged down, and the ends for half their width, for there will be slopes there also. The terrace and the slopes must be covered with good soil not less than 6 inches deep, and it need not exceed 9 inches in depth, and this made level and firm may be turfed at once, allowing 3 inches in every yard of depth for the soil settling—that is, where the fresh soil is placed; where it is solid no allowance need be made.

In case you wish to render the sloping piece of ground even in surface, still keeping it on the slope, provide a number of stakes and pegs, the stakes 4 feet, and the pegs 1 foot in length. Beginning, as in the former case, by driving a stake, *a*, in at the base *b* (*fig. 2*), and at one corner, 1 foot into the ground and

Fig. 2.

3 feet out, less the thickness of the level, and with the spirit level placed upon it level, apply your eye to the upper surface of the level, and you will see where the level strikes the slope. Put in a peg *b*, 3 feet from the first stake *a*, measuring from the top of the stake *a*, horizontally towards the slope, and drive it so far into the ground that its top is level with the upper surface of the first stake *a*, looking over the level. A straight stake a yard long, less the thickness of the level, placed on the top of the peg *b*, and the spirit level set upon it will show where to put in the next peg *c*, and so on to the top as shown by the dotted lines of the stakes and pegs up the line between *b* and *a*. Level the base lengthwise, and the upper line also, and up hill, in the middle, and at the other end. Reduce the first stake a yard, less the thickness of the level, or cut it off level with the ground line *d*, and you have the pegs all of a sloping height throughout, as shown by the dotted line drawn from *a* to *b*. Form the ground level with the pegs, and your ground will be evenly sloping towards the base.

A DEFECT IN MOWING MACHINES.

Now that the above machines are so generally used, information respecting their management would doubtless be acceptable to many of the readers of your Journal, myself included. Having had one in use for the last three years, by noted makers, I have experienced considerable inconvenience owing to the knives not being of uniform hardness, the softer ones wearing so that they were prevented from being set at cutting-distance to the plate by those harder, which were so very hard that a file would make no impression on them. No maker living near, I was obliged to have them taken off and ground down upon a stone; but after replacing them they were found to be round in the middle, which caused the grass to be only crushed instead of cut. I then tried to bring them to an even face by grinding them the reverse way with emery and oil against the plate, but without any beneficial effect. I at last had them softened enough to admit of their being filed, which proved satisfactory. Perhaps some of your readers may be able to

tell the proper method of reducing the knives when they happen to become uneven as mine did. Occurrences of this kind tend to prevent the use of mowing machines, especially when persons are obliged to send the knives long distances to have them rectified, which might be obviated were the manufacturers to furnish more comprehensive instructions with each machine.—VERAX.

HARDINESS OF LILIUM SPECIOSUM (LANCIFOLIUM).

It may be interesting to your correspondent and others to know that *Lilium lancifolium* can be grown to great perfection in the open border. In the autumn of 1859 I planted a single bulb in an open spot about the centre of my garden, and this, without any protection whatever, stood the intense frost of the following winter. I have now eleven vigorous stems, which, when the topmost buds shall have all opened, will have borne this season at least 120 flowers, with colours more rich and clear than could be produced under glass. Some of the stems measure about 4 feet in height, and they are as thick as an ordinary walking-stick. Album is not so vigorous, and it is the latest in blooming. Except in fine seasons it does not do so well. It is, however, in full bloom here at present, and I am sure it never was seen in finer condition. *Lilium auratum* being of a similar constitution will, I doubt not, prove as hardy, and the situation which is adapted to the one will be sure to suit the other.—H. C. R., Troon, N.B.

WORK FOR THE WEEK.

KITCHEN GARDEN.

EVERY piece of ground that now becomes vacant should have the requisite quantity of dung laid on, and trenching should be carried on at every favourable opportunity. It is not good management to leave pieces of ground in a rough untidy state until spring, when, from pressure of other work, the trenching is frequently imperfectly performed, or the ground not trenched at all, thereby neglecting one of the fundamental principles of good gardening. To be beforehand with time is a maxim which every one should endeavour to keep before his eyes, and those who look forward to having good crops next year must now begin to make the requisite preparations. *Asparagus*, when the tops are decayed cut them off close to the ground, the beds to be then made clean, and afterwards covered 3 or 4 inches deep with rotten dung or decayed leaves, the alleys to remain as they are and not be dug out, as by so doing many of the roots are injured. *Cabbage*, the main spring crops to be planted out as early as possible. Those which were planted in August for Coleworts should be earthed-up. *Cauliflowers*, prick them out in places convenient for covering with a frame, the soil to be light but not too rich. *Cauliflowers* may also now be taken up for storing away. There are various methods of doing this, one of the best is to choose the most solid heads, take them up with the roots, denude them of the greater portion of the leaves, and bury the roots and stems in leaf mould or old tan in an airy shed. *Cucumbers*, this month may be said to be the commencement of the professed Cucumber-grower's year; the seed-bed should now be made with well-worked dung over a layer of faggots, the frame to be then put on, and when the heat is up the dung inside the frame should be forked up every other morning for a week or ten days, at the end of which time it will be ready to receive the seed, if the dung was properly worked previously to making it into a bed. *Dwarf Kidney Beans*, the first sowing in pots should now be earthed-up as they require it. If they are placed over a flue or hot-water pipes in a forcing-house, the pots should stand in saucers when the fires are kept going, otherwise the soil at the bottom of the pots will get very dry. *Endive*, continue to blanch it. An expeditious and very good way is to invert flower-pots over it when it is in a very dry state. *Lettuce*, continue to plant the Cabbage varieties in frames for winter use. The *Cos* varieties for spring use should also be planted on a sheltered border as soon as they are of sufficient size. *Sea-kale*, gather seed when ripe, and as soon as the leaves begin to decay clear them away. It is necessary to do this as early as possible, when it is required for early forcing. *Turnips*, thin the late sowing, but it is not necessary to leave them at so great a distance apart as the spring and early autumn-sowings. Take every opportunity of clearing the ground from weeds. In

the best-kept gardens they are troublesome at this season, more especially as the present one has been exceedingly favourable for ripening seed.

#### FRUIT GARDEN.

Look over fruit remaining out of doors frequently, and gather it as it becomes ripe. Also examine that stored in the fruit-room, as there will occasionally be found a few decaying for a few weeks after housing, and these should be removed as soon as perceived. Keep the fruit-room cool and airy in order to allow of the escape of moisture given off by the fruit, which is considerable for a few weeks at first. Where it is intended to make fresh plantations of fruit trees this season, the ground should be prepared at the earliest convenience, and any fresh soil to be used for planting should be thoroughly exposed to the action of the weather, so as to have it in a mellow state when wanted for use. Trim and dress Strawberry plantations, and be careful to injure the leaves of the plants as little as possible, and avoid deep digging between the rows, by which the roots would be injured.

#### FLOWER GARDEN.

The principal work in this department for the present will be mowing and cleaning-up, and if anything like neatness is to be maintained, sweeping-up leaves will soon require daily attention. Let the early-flowering spring bulbs be all planted and the Carnation layers potted or planted out. Lose no time in planting offset Tulips, and any of the main roots which do not appear in a healthy state.

#### GREENHOUSE AND CONSERVATORY.

The plants in these structures will, as yet, require a rather liberal watering, and this should be performed early every morning with regard to those which require it. Winter-flowering plants which have thoroughly ripened their wood may have occasional applications of weak and clear manure water. A free ventilation must be permitted, leaving a little at night. Let Cyclamens, Lachenalias, Oxalis, Centradenia, tree Violets, and such little winter favourites be kept on a warm front or end shelf totally unshaded. Roses in pots intended for flowering through the next two months should be allowed a very light situation, where there is a constant circulation of air. Summer-flowering twiners, which usually become unsightly by this season, should be cut back rather freely, as also any others that will bear this treatment. Shade can now well be dispensed with, therefore not a spray that can be spared should be left to obstruct the light. Acacias and other winter-flowering plants, having been subjected to a period of comparatively dry treatment to ensure their blooming profusely, should now be pretty liberally supplied with water at the roots in order to get them into flower at the dull season, when they will be much more esteemed than in the spring when flowers become more plentiful. Manure water, if it can be used, should be given frequently to Chrysanthemums. Avoid cold draughts against plants that have been brought from a warm house, and guard against damp by using gentle fires, with a little top air, on wet days. Let pot specimens in bloom be frequently re-arranged, so as to make the most of them, for the finest specimens become too familiar to be interesting when allowed to remain too long in one place. Bark or other beds of fermenting materials for plunging plants should be renewed, if necessary, as soon as the proper materials can be collected. A surface of either sawdust or sand, old tan, or decayed leaves, will be found useful for plunging. For early forcing a bed of this kind, capable of supplying a lasting heat of from 65° to 70°, will be found of the utmost value. Introduce Roses for forcing; no fire heat will be required at present; by shutting up early on bright days sufficient heat will be enclosed to induce an early root-action.

#### STOVE.

A temperature of from 65° to 70° by day, and of 60° by night, will suffice, still using a somewhat moist atmosphere in the afternoon and during the night, with a free circulation of air, keeping also a quiet ventilation all night. As some of the Orchids become ripe, such as the *Catasetum* family, the *Cycnoches*, *Lycastes*, &c., they may be removed to a drier and somewhat cooler atmosphere. Pursue a kindly course of treatment with the *Euphorbias*, *Gesneras*, and such things for winter flowering; these will soon be of great service. The *Phajus grandifolius*, with the *Stenorhynchus speciosus* will soon begin to blossom; also *Cypripedium insigne* and *venustum*. Let them have plenty of heat and moisture.

#### PITS AND FRAMES.

Regulate the general bedding stock, and get the majority

established in small pots. Give as much air as possible, and restrict the supplies of water to mature the growth as far as possible. All temporary pits for their accommodation should be completed by this time, and glazing and other repairs forthwith finished. Common mats afford scarcely sufficient protection to the half-hardy plants in store-pits. For such purposes a stock of straw or reed mats should be made in wet weather. See to securing as many cuttings as possible of any scarce plants which it may be desirable to increase while there is a fair chance of rooting them.—W. KEANE.

#### DOINGS OF THE LAST WEEK.

THURSDAY gave us the first frost to speak of, since the beginning of the summer, but not enough to do more than crust the grass early, all higher plants being scarcely touched. Nothing, therefore, has suffered much as yet, and notwithstanding the continual dryness, the flower garden, and even *Calceolarias*, still look well. What has suffered most from dryness and want of watering are Dahlias and Zinnias, the former yielding flowers below the usual size, and the latter wanting strength to open properly the succession-buds. Were we sure of a few weeks' mild weather, we would contrive to water at least these two flowers. *Calceolarias* have gone so much to bloom that there will be a difficulty in procuring nice stubby side shoots for cuttings. We hear from some of our friends, that they will be forced to prune in and take up lots of old plants, which is so far good, at least, for securing cuttings in spring; but we would rather have cuttings about the middle of this month, if possible, as at from 1 to 1½ inch apart a good many will stand in the room that would be necessary for a single plant, and, on the whole, we prefer autumn cuttings of *Calceolarias*, to spring made ones, just as we prefer spring-cut *Verbenas* to autumn-struck ones, only some must be saved in autumn to take the cuttings from. What are fine masses of *Verbenas* now, notwithstanding the dry weather and scarcely any watering, were struck in a wholesale way in April, by being dibbled in 1½ inch apart, in soil under a frame, and taken up and planted when nice plants in May. Autumn-struck ones may bloom so as to fill the bed earlier, but they do not generally last out the autumn so well. This holds good, however, in the case of all early flower gardening on the bedding system. Beds of Scarlet *Geraniums* full to overflowing in the end of June, and beginning of July, will hardly keep on equally good in October, unless attended to as regards pruning, disleafing, and watering, too, if necessary. Considerable trouble and labour are required to have every bed first-rate in June and July, and first-rate also in September; but this is not sufficiently considered by those who require high keeping at all times.

We have received several letters on what was advanced a few weeks ago, on limiting the size of flower gardens, rather than having large pleasure grounds which cannot be well kept. Let it never be forgotten, that two or three flower-beds tastefully arranged, full of bloom, and without gaps, dead flowers, or dead leaves, will ever be more satisfactory than a hundred beds thinly and irregularly planted, and with dead flowers and dead leaves staring at you everywhere. A few poles of lawn, level as level can be, without weed or daisy, smooth and soft to the feet as a Turkey carpet, will yield an amount of satisfaction that no number of acres of pleasure ground will give, which the labour power cannot overtake and keep nice, either by scythe or mowing machine. In no direction have gardeners more erred than in using their influence to extend flower gardens and kept lawns. This we know has been done in some cases against the judgment of the proprietors, who have candidly stated, "Well, you may have the ground, and I will not grudge trees and shrubs that may be necessary, but I can afford no more labour." In many such cases part of such grounds eventually have been left pretty much to themselves, and in many places where a considerable number of the Pine tribe, and other ornamental trees have been planted, it would be to the benefit of all concerned if such parts were left rough, or mingled with masses of Broom, and Gorse, and Heath, and then more attention could be given to the principal parts of the lawn. From the end of March to the middle of November, that lawn to be kept well will require going over at least once a-week, often once in four days, and then when fresh done it will be no better than it ought to be. To keep even a moderate space as it ought to be, many other things often have to be neglected during the summer. The evil would be lessened if

we kept in mind that a large lawn even with the help of mowing machines, becomes the most expensive thing in the garden.

#### KITCHEN GARDEN.

Very much a repetition of the work of the previous week. Having a bit of spare ground, planted it with Coleworts, Brussels Sprouts, and Savoys, trenching the ground first, and then digging out trenches 2 feet apart, and laying the plants up to their necks in the trenches, watering, and then fastening well. These will do well for spring cutting. *Scarlet Runners* showing a disposition to stop bearing, we forked along the sides of the rows, gave a good soaking with sewage water, and pulled off the pods too large for use, saving some for seed. These plants have grown so strong, that though the sticks were high and mixed with young Larch trees with the tops on, the vines have met in the middle; and as numerous little incipient pods hang farther down, these will be protected from frost by the canopy above them, if they swell nicely, as we expect from the watering given to them. We have frequently kept these runners well into November by placing some poles along the rows and running a very rough straw rope along the rows from pole to pole. The rope was left rough by leaving out the ends of the straw for a foot or so in twisting the rope. When the Runners are grown on the ground without stakes they are still more easily protected; however, even with this protection they will do little good unless the old pods are cleared off. We noticed the other week clearing off all the pods from a bank of Dwarf Kidney Beans and giving them a good watering, and they have since yielded some gatherings; and if they go on well we shall take means, by the help of a few spars of wood, for throwing a piece of frigi domo over them on a clear cold night. The ground is so warm as yet, that it will require a rather severe frost to injure them if a little protected.

Here we may notice that a correspondent tells us that she has succeeded very well with *Scarlet Runners*, and in some cases with Dwarf Kidney Beans, by taking up the roots before frost, packing them in dry earth and sand, and planting them out in the end of April, and asks what we think of continuing the practice. Well, we have a great opinion of every one following that plan or system that answers best with him. It is well to know that the roots of *Scarlet Runners*, especially, may be saved over the winter, and grown next season like the roots of a Dahlia or a Marvel of Peru, and the system might be very useful after cold seasons, in which the seeds ripen imperfectly; but after several times trying the plan, our own impression is that it causes more trouble than sowing seed, and we failed to perceive any advantage either in earlier or more continuous cropping.

#### FRUIT GARDEN.

Cleared the runners from a piece of Strawberries. We fear the plants have been allowed to become too dry, as much of the foliage is greatly browned. Moved Strawberry plants in pots, so as to give them more room than the sun and air may reach them thoroughly. If, after this time, the sun also beats on the pots, so much more likely is it that the plants will be well ripened. Weeded all such plants in pots, and removed all runners, nipping them off close to the plant. Gave manure water in these sunny days, as the pots are now full of roots; will water only as required. The plants must not have flagged leaves, but if, with the heavy dews of late, the tops stand without showing distress, then they should have no water given to them.

In the open air have had good gatherings from forced plants turned out, and would have had them better and more plentifully if we had watered them more. Gathered most of the Peaches from orchard-house; they have done us good service after late ones on the open wall had ripened. The only objection to great quantities of Peaches is that you cannot keep them, but as soon as ripe they must be eaten, or preserved in some mode or other. This is also one reason why, when they are plentiful, we should thin more than we generally do, as very heavy crops one year, and especially on young trees, injure their bearing in the following year. We left more than we ought to have done, in order to moderate the strength of the wood on some young trees.

Cut off laterals and shortened long shoots, that the sun might have freer access to the buds and wood. Figs have ripened well out of doors this season, and come in between the succession crops in our pit-house. The fruit in the latter are still ripening plentifully, but they are less in size, and, if we continue taking fruit many weeks longer, the first spring crop is almost sure to suffer. Watered with manure water Fig trees in Fig-house and in pots in orchard-house. But for the

Plums in the late-house, we would keep it closer in sunshine now, and use the syringe freely in the afternoon, to help to keep the trees clean and have the wood well ripened. Removed netting from Gooseberries, and for the most part from Currants, these fruits refusing to hang so long as usual this season. Many of the best Pears, and even *Mario Louise* yet quite hard, are rotting on the trees before they approach maturity. It is singular what a difference there is within short distances. We have as yet used but few *Mario Louise*, and in some places, not far distant, there is not one left. In some places *Williams's Bon Chrétien* decayed from over-ripeness before we had one fit for use. The decaying of fruit, alluded to above, is in some few instances owing to their being pecked by birds, but some fine specimens half rotten have no appearance of having been touched by birds. We have scarcely noticed an Apple thus attacked, except, perhaps, a few of the earliest. Later ones look, too, as if they would keep pretty well. This rotting of the Pear before ripening seems to be owing to some peculiarity in the atmosphere in this scorching weather, which, we have no doubt, affects fruit and vegetable as well as animal life.

There are three things we have noticed lately out of the common way. First, the immense number of flies of all sorts and sizes, so as actually to blacken white-coloured buildings; secondly, the dense clouds of gnats and other small insects during bright sunshine; and, thirdly, the immense quantity of gossamer, not only in the shape of spiders' webs on grass and shrubs, but the long strings of the same material, almost as rough-looking as loose cotton, floating in the air, sometimes free, and at other times fastened by one end to a house or a tree. One of these threads, suspended between two trees, and moving backwards and forwards with the slight breeze, was fully 30 yards long, and numbers of detached and flossy pieces fixed by one end were from 20 to 60 feet in length. What a spinner the little spider must be! A gentleman who noticed these flossy streamers said that they generally denoted a close, unhealthy state of the atmosphere, and added, that under such circumstances, or even when the grass seemed to be more than usually studded with cobwebs, it was of very little use to attempt fox-hunting, as the scent would not lie. Although, then, we are well aware that a good downpouring of rain would settle the beauty of the flower garden for this season, and might somewhat injure the flavour of our late fruits, we are at the same time fully convinced that such rains would be the most effectual agent for purifying the atmosphere, and thus be of benefit to field and garden, to beast and man. Taken altogether, the oldest inhabitant never recollects of such a season as the present. Even after the slight frost on the morning of the 5th inst., the day had the heat and the unclouded bright blue of an Italian sky. With a repetition of frosty mornings we may make preparations for rains ere long. The condensation of moisture will be too copious to be deposited even in heavy dews.

#### ORNAMENTAL DEPARTMENT.

The dry weather enabled us to keep the principal parts of the lawn short by means of the hand-mowing machine, and a roller so flattened any worm earth-heaps as to make the grass smooth for the feet. Did a little to the beds just to keep them tidy, and have as yet taken nothing up. In one group we have the centre bed chiefly filled with *Cassia corymbosa*, and it has been very massive and fine, with its huge branches of orange-coloured flowers, since the beginning of July. We have merely gone over the beds a little to keep them passable, hardly deeming it worth while to be very particular now until we see what the end of the week will do.

We have accidentally alluded to *Zinnias*. Than these and the *Heddewigii* and *laciniata* sections of Indian Pink few flowers are better, or remain longer fresh in small flower-glasses. We have nothing to say against the double flowers amongst such Pinks if the colours are bright; but among *Zinnias* we prefer single flowers to the double ones. This, of course, is merely a matter of taste.

Hollyhocks have been pretty well removed now; will plant a lot of young ones as soon as possible. Striking in any position, Hollyhocks always appear to us most beautiful when they are backed by evergreens, as Laurels or Hollies. Some rows of a good kind of Purple Spinach have also been cut down, as the dry weather brought it into seed prematurely and the tops began to wither. Regulated, tied, and slightly pruned Honey-suckles and Roses over arches. Fresh-budded Roses that have started will need protection. If no rains come we must water *Calecolarias*, in order to insure cuttings about the middle of the month. The sooner the ground is prepared for fresh Roses

the better. Bulbs for forcing should be potted without delay. Those intended for beds, which will not be at liberty for a month or more hence, may either be potted or set on three inches of rough leaf mould, and covered with the same; they may then be leaved to the ground in rooted patches. It will be necessary to have all the kinds named, so that they may be arranged according to blooming and heights.

Chrysanthemums showing bloom were afforded rich waterings, and it would be as well to place them so as to be able to give them a little protection from frost if necessary. Cinerarias in largish pots, keep as cool as possible under glass; Primulas as airy as possible under glass, preventing them being soaked with cold rains now. Geraniums of the florists' kinds should also be placed under glass, giving all the air possible, and no more water than is necessary.

All hardwooded greenhouse plants if not housed should be placed where they can be protected from frost and heavy rains. Many Camellias and Epacrises do badly in winter, because, without showing it on the surface or readily on the foliage, the roots next the sides of the pot have been frosted before the plants were housed. Thinned climbers in greenhouse and stove, preparatory to a final thinning and cleaning ere long. All plants should be examined for insects, the drainage made efficient, and worms extirpated out of the pots before winter. All cuttings of Verbenas, Geraniums, &c., which are struck, should be kept as hardy as possible. Where glass is at command they will be better under it now, but with the sashes off in these fine days, and air on back and front at night, except when cold and frosty. The less of artificial heat all such plants have the better will they thrive, and the more free will they be from insects during the winter. In fact, the very best means for keeping insects away is a low temperature with plenty of air, for all such plants, yet high enough to be free from frost—say, ranging from 35° to 40°. In such a temperature, and the atmosphere pretty dry, the Verbenas will be free from mildew, while in a moister atmosphere and a temperature from 45°, and onwards, they will often be smothered with it. Coolness, a certain degree of moisture, and plenty of air, except when frosty, will keep Calceolarias all right, when a very little fire heat will bring the spot, the gangrene, and other diseases and evils. Coddling such plants with heat is their ruin.

Have begun to curtail water from the Amaryllis tribe, that have had a rather close pit to grow in during the summer. Cyclamens should now be set to work and watered. Syringe Violets with sulphur and quassia water wherever there are signs of the red spider, or even of mildew. For the latter the plants when rather damp on the leaves may be dusted with flowers of sulphur from a pepper-box, but one of a good size, if there is much to do. A dredger of any kind will do. Remove all runners from Neapolitan Violets. Only the crowns yield flowers for the first year. The runners if struck will make good plants for a second year. These, and double blue, and Russian do very well in pots, as well as in beds; but like Strawberries, they should, for winter-flowering, be well established in the pots in autumn.

Although many such matters have come under our attention during the week, the chief work has been collecting a few desirable seeds whilst the dry weather lasted, and putting in great numbers of cuttings of Geraniums and other bedding plants. We are thus late partly because we could not get at them earlier, and partly from choice, as we did not wish to break in on the regularity of the beds, and as yet we have no reserve ground to which we could go for cuttings. These reserve grounds are very useful for such a purpose, and also for supplying cut flowers. No heds will long stand cutting from without showing it. At this time we insert the cuttings thickly in pots or boxes, giving them about 1 or 1½ inch between cutting and cutting, and keeping them close under frames during the day, and giving air at night to prevent damping. They will generally be struck by the end of the month, and as the stiffest side pieces are used they take up but little room during the winter. As soon as roots are formed, of course plenty of air is given, unless in frosty weather. About the middle of the month, if no frost that would be dangerous threaten before that time, we shall commence with Calceolaria cuttings, slipping off the side shoots from 1½ to 2½ inches in length. We like them best when about 2 inches in length and with a firmish heel close to the older stem. Those plants that did best with us last year, were inserted as cuttings from the middle to the end of November after there had been a rather sharp frost. We have already mentioned that some of our rooted Calceolarias began to go off in the spring, and we attribute it to dibbling them in a mixture

of old and fresh soil. Fresh sandy loam suits them best. We believe a fungous matter was about the roots. They recovered after being turned out into earth-pits, and have done well during the season. Of course, those that looked very sickly were never turned out into the earth-pits at all, but were at once thrown away. Some kinds, rather new, that do well in certain places, seem too tender for us. We have seen Watson's Bijou, a neat dark one, do well in some places, but it seems too delicate with us, and for that colour we must use Victory, Crimson King, Victor Emmanuel, and others of that dark colour.—R. F.

COVENT GARDEN MARKET.—OCTOBER 7.

The market remains much the same as last week, quotations being stationary. Dutch Hamburgh Grapes are unusually good this year, and equal to those now imported from Jersey. Melting Peaches may now be said to be over. Great complaints are made among farmers and growers as to the diseased state of the Potato crop.

TRADE CATALOGUES RECEIVED.

- Louis Van Houtte, Ghent, Belgium.—*Catalogue de Plantes de Serres.*
- William Paul, Waltham Cross, London, N.—*Rose Catalogue, 1865-6.*
- Ambroise Verschaffelt, Rue du Chaume, 50, Ghent, Belgium.—*Plantes Nouvelles.*

TO CORRESPONDENTS.

- \*.\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*
- We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.
- N.B.—Many questions must remain unanswered until next week.

BOOKS (Q. D.).—The "Fruit Gardening for the Many" can be had free by post from our office for five postage stamps.  
 ACORN VEGETATING OVER WATER (Sam Weller).—No doubt it would do if in a bottle so that the air about it was kept moist.  
 GARDEN PLANS (Mrs. Fairfar).—You had better write to Mr. Chapman Garden Designer &c., Richmond Surrey.

**CLEMATIS LANUGINOSA (Leighton R.).**—There is a large lavender-coloured flowering Clematis, blooming in summer, under that name, and it is one of the very best. There is a variety with paler flowers, and even larger in size, which may be the same as your kind with grey flowers. The name of the species is Clematis lanuginosa, and its variety is Clematis lanuginosa pallida. Both are of the most easy culture, requiring a rich well drained soil, and a trellis against a wall; or, in warm situations, the trunks of trees may be covered with them. They are also fine plants for the roof of a cool greenhouse or conservatory.

**SOWING VIOLET SEEDS (Idem).**—The seeds of Violets are best sown in the open ground, and immediately they are ripe, in light sandy soil, covering them lightly, and watering if dry weather ensue. When sufficiently large to handle prick the seedlings off 3 inches apart in good light soil, with which a liberal dressing of leaf-soil has been worked in. Water after planting, and subsequently during dry weather. They may be sown next March in pans of light soil, or in April in the open ground; in the former case place the pans in a cold frame, and, when the seedlings are large enough, prick them off and finally plant out in autumn.

**PAMPAS GRASS NOT FLOWERING—PROTECTING IN WINTER (A Subscriber).**—It is remarkable that the plant which you have had for ten years has never flowered. Surely the soil is very poor, and very light and dry in summer, and the situation bleak and exposed, so much exposed indeed as to cause the foliage to be cut off to the ground every winter. We should advise transplanting next April, taking up the plant with a good ball, which is easily done, for it is difficult to remove the soil from the closely matted roots; then take the ball and plant clean out. The opening should be 1 foot wider than the ball all round, and if there is a piece of naturally strong ground, wet, but not stagnant, that is the situation for it. Fill in around the ball with the richest compost that can be made, say equal quantities of loam from rotted turves and manure well-reduced, and give a good soaking of water. It will drink up thirty gallons per week of liquid manure during dry weather throughout the summer. From the miserable specimens of this Grass we have met with it seems as if the aim was to starve them into flower. There is not a plant in the country above four years old that would not be better taken up next April and served in the above manner. You may protect the plant in winter by tying the long grass up straight, and covering with straw as in thatching, and then fasten with hay bands to keep the straw from being displaced and blown about.

**YOUNG CUCUMBERS TURNING YELLOW (A Young Gardener).**—This arises from a deficiency of bottom heat and a moist stagnant atmosphere, with a deficiency of heat by day and too much by night. These are conditions inimical to free growth. An unhealthy state of the roots is indicated by the leaves turning yellow, and the blotching is produced by an excess of moisture and the sun shining on the leaves whilst wet from the deposition of moisture on them during the night, air not being given sufficiently early to dry it up. A brisk heat of 70 by day without sun, and of from 55 to 60 at night, with a little air, may be given, and with more sun more heat by day, a greater amount of air being afforded. Soil sufficiently moist for healthy growth, but not wet, and a moderately moist atmosphere, are the essentials at this season. For want of details we cannot do more than conjecture the treatment from similar cases.

**STRIKING BEGONIA LEAVES (Idem).**—This may be done at any time. If the leaves chosen are not too old, if the atmosphere is moist, and the heat brisk, they root freely. Spring, however, is the best time.

**TRICHOMANES RENIFORME CULTURE (F. E. H.).**—If the plant is healthy, and seems to have been potted some time, though against all rules for Trichomanes, it would be well to leave it alone. You will, by this time, be able to see whether it promises to do well, if not report it. It is a very distinct creeping species, with nearly round, undivided, deep green, beautifully veined fronds, heart-shaped at the base, and 4 or 5 inches broad, on tall wiry stalks. It is a native of New Zealand. It requires to be kept very humid, but rather airy. A temperature of from 40° to 50° in winter, and of 70° in summer, suits it well.

**BROMELIA LEAVES DISCOLOURED (Idem).**—The leaf appears healthy, and the discoloration so slight indeed as to quite puzzle us to observe any on the part of leaf sent. One side of the leaf is quite gone, and that appears to have been scorched by the sun shining on it whilst wet. A little air all night and early in the morning will, to a great extent, obviate this. The white specks are caused by the punctures of some insect; but not by thrips nor red spider.

**CONSTRUCTING GROUND VINERY (Clericus).**—You will find the directions and a drawing in "The Vine Manual." You can have it free by post from our office for thirty-two postage stamps.

**ICE-HOUSE (A Man of Kent).**—Enclose four postage stamps with your address, and order No. 173 (New Series) of our Journal to be sent. It contains a drawing and full directions for constructing an ice-house.

**POINCIANA REGIA (H. G. Bangalore).**—A coloured plate is in the "Botanical Magazine" t. 2881. This gorgeous tree has hitherto been found only in Madagascar. It belongs to Nat. Ord. Leguminosae. Linn. Dodecandria Monogynia. Unarmed; leaves abruptly bipinnate; eleven to eighteen pairs of pinnae, which are 4 inches long; horizontally patent; petals crimson, orbicular, crenate at the margin, involute at base. It is called Tanahon in Madagascar.

**ROYAL HORTICULTURAL SOCIETY'S KENSINGTON GARDEN (G. Elliott).**—A plan of this was given in No. 607 (Old Series), which you can have post free by sending your direction and four postage stamps. No doubt some of the London seedsmen could procure seeds of the variety you name.

**PACKING GRAPES FOR EXHIBITION (An Exhibitor).**—Yours is a somewhat difficult question to answer, for various modes are adopted with varying success according to the distance which the Grapes have to travel, the mode of conveyance, and the usage which they receive on the way. The plan which, judging from what we have seen, seems to be attended with most success is attaching the bunches firmly to the stand on which they are exhibited, and so that they cannot shake about, and then to pack the stand immovably in a box in which they are to be conveyed to their destination. This box must be kept in a horizontal position throughout the journey, otherwise the Grapes will be more or less damaged. If you have been in the habit of attending shows you will doubtless have heard from your brother exhibitors of the anxieties which they have experienced on this point, even when accompanying their fruit, and few of them trust to the mercies of railway porters. You will learn much by observing the modes which other exhibitors adopt.

**PLANTS FOR A PASSAGE (L. P.).**—The greatest drawbacks to your growing plants in the passage will be the deficiency of light and the probability of draughts, combined with extreme dryness. If the air is never violently agitated by a thorough draught, the passage would be tolerably good place for such Cyclamens as comi, Atkinsi, and persicum whilst in flower, also for Primulas and Camellias; and some of the hardier kinds of greenhouse Ferns, as well as hardy ones, may remain there permanently, or for a lengthened period, introducing among them flowering plants of the above, and forced Dentizas, Dielytras, Hyacinths, Tulips, Crocuses, &c., to be afterwards replaced by Cinerarias, Calceolarias, and Pelargoniums. It is one of those situations in which plants may be placed whilst in flower, but which are of very little use for their growth, for the air will always be too dry. You will, therefore, see that what you can spare from your greenhouse will do in your glazed passage until the flowering is past, when they must be placed in an atmosphere more favourable to their growth. In the same way the Ferns should be placed in the greenhouse to make a good growth, and when the fronds are fully developed if they are removed to the passage they will retain their beauty for a long time.

**TROPEOLUM SPECIOSUM CULTURE (J. L.).**—It is best grown in a compost of one-half turfy light loam, and one-half peat and well reduced leaf-mould in equal parts, with a free admixture of sand. The plant's not growing more than a few inches may be attributed to dryness of situation, or to an unsuitable soil, and cold exposed situation. Planted in light soil, or gravel enriched by a liberal application of leaf-mould, it grows freely, and if trained on a trellis against a wall with a south or south-west aspect it will attain from 5 to 8 feet in height in a season, but the plants must be established for a year or two before this growth can be expected. Treat it as a perennial, covering the surface of the soil over the roots with 3 inches of leaves or short dry litter. In order to make it succeed well outside it is necessary to plant out strong plants, giving them a rich well-drained soil, copious supplies of water, and a warm sheltered situation. It does best in a porous soil on a dry subsoil.

**ALTERING AND IMPROVING A GARDEN (E. S., Mitcham).**—Your proposed alterations seem to be good, and your objection to a high or steep bank for Roses is also well founded, for your soil being dry such a bank would only make it still drier. Laurustinus not being the hardiest of shrubs will be much battered and injured by cutting winds, and will suffer during severe weather. Laurels would be more suitable, and any objection which you may have to their growing higher than is required to screen the kitchen, or so spreading as to interfere with the Roses, may be obviated by cutting them in to the desired height and width every year in August, after the year's growth is made, or in April before this commences. The Roses would do well on their own roots on such a dry soil, or if on a stock at all, it must be the Manetti, as the Dog Rose would give numerous suckers on your soil. No evergreen will succeed well under Yew trees, and, as these have no pretensions to ornament and render the grass very shabby, we would cut off the branches that overhang the grass, and if the trees are not wanted higher than the wall, to screen the view of the house from windows on the opposite side of the road, cut them off equally all round, taking off the tops, and thus convert them into cones and pyramids of deep green foliage. You need not fear that the trees will not push afresh from the branches left, for they will do so as freely from the trunks as from the shoots of the previous year. This cutting-in may probably expose the wall, which you no doubt would wish to hide. The wall in that case might have strong Ivy planted against it, and the Ivy, if liberally treated to fresh rich soil, good-sized openings being made for the reception of the plants, would cover it in a few years. The Yews being cut-in, grass might be laid to within a short distance of them, and the lawn so gained would be available for flower-beds, especially as it is in front of the drawing-room windows. Unless you cut down the Yew trees, or reduce them considerably, it would be of no use to plant anything in the border under them, unless the branches are at some distance from the ground, when the latter might be surfaced with Periwinkle and Ivy. Were they cut-in you might plant Aucubas, Berberis aquifolium and Darviani, and Laurustinus with a fair prospect of success.

**TWELVE EXHIBITION STOVE PLANTS TO BLOOM IN AUGUST AND SEPTEMBER (W. H. W.).**—Plants for exhibition purposes are not always shown at their proper period of blooming, but are retarded or forwarded should they not be likely to flower by a certain date. For these and other reasons, which you will learn by a little experience, you will find that blooming a collection of twelve plants in a stove at a given time is difficult to accomplish by growing that number only. More than this, schedules are seldom if ever framed for the exhibition of twelve stove plants, but for twelve stove and greenhouse plants. However, twelve stove plants: *Rondeletia speciosa* major, *Schubertia graveolens*, *Xora javanica aurantia*, *I. alba*, *Echites splendens*, *E. crassinoda*, *E. magnifica*, *Cyrtoceras reflexum*, *Clerodendron Thomsonae*, *Eschymanthus splendens*, *Allamanda Schottii*, and *A. grandiflora*. Those you have seen—viz. *Aphelandra cristata*, *Stephanotis floribunda*, *Xora coccinea superba*, *Clerodendron fallax*, and *C. Kenapferi* are also good. All may be cultivated by an amateur; but though of easy culture fine specimens are not to be had without extra pains being taken, neither are they so easily grown as many in the list of stove plants.

**ARTIFICIAL MANURES (H. B. B.).**—You neither mention the nature of the soil of your garden nor whether you require the manure for flowers or kitchen vegetables. You can have free by post the manual entitled "Manures, or Muck for the Many," if you send four postage stamps to our office with your direction. Read that, and then write again to us if you need further information.

**COMMON SALT AS A MANURE (T. L. M.).**—The best reply we can give you is the following extract from the little manual "Manure, or Muck for the Many"—you can have it free by post from our office for four postage stamps—"Common salt, applied in the spring at the rate of twenty bushels per acre, has been found very beneficial to Asparagus, Broad Beans, Lettuces, Onions, Carrots, Parsnips, Potatoes, and Beets. Indeed, its properties are so generally useful, not only as promoting fertility, but as destroying slugs, &c., that it is a good plan to sow the whole garden every March with this manure, at the rate above specified. The flower garden is included in this recommendation; for some of the best practical gardeners recommend it for the Stock, Hyacinth, Amaryllis, Ixia, Anemone, Colchicum, Narcissus, Ranunculus, &c.; and in the fruit garden it has been found beneficial to almost every one of its tenants, especially the Cherry and Apple. On lawns and walks it helps to drive away worms, and to destroy moss."

**CAMELIAS MAKING SECOND GROWTHS** (*Prinus*).—This is by no means uncommon, and is mainly due to maintaining the plants in a moist growing heat after the first growth is made, and to the soil being kept moist, and the roots having abundant pot room. Camellias very often make second growths in consequence of having been checked whilst making their first growth, either from a deficiency of moisture in the atmosphere or at the root, and when a return is made to an atmosphere conducive to growth, fresh shoots are made instead of the buds already formed swelling. The new growths indicate a vigorous root-action. To prevent the buds falling keep the soil neither wet nor dry, but moist, and let the plants have the advantage of a well ventilated light structure and a temperature of from 40° to 45°.

**LILIU ACRATUM** (*Idem*).—It is just likely that the plant in the cool position was ready for free growth and came into flower sooner than the plant in the warmer position, which might be a bulb less ripened, or so dry as to remain at a stand-still, and so cause the later flowering. It is also certain that the falling of the leaves after the flowering of the second root was induced by the plant being kept much drier than the other either at the root or in the air, which caused the growth to be perfected sooner, hence the falling of the leaves at once. Under the same treatment the same species of plant will flower at different times, some individuals sooner and some later than others. This is constitutional, occurring in the case of the progeny as well as in that of the parent, but what causes this earliness of flowering and ripening of the growth remains a mystery, though it might be explained by those cultivating the plants so affected from their noting the treatment. The one may have had rich soil, the other poor soil, and this alone would cause a difference in the time of flowering, and of the ripening of the roots, and consequently of the fall of the leaves.

**MARANTA VITTATA IN WINTER**—**STEPHANOTIS FLORIBUNDA NOT FLOWERING** (*Idem*).—The Maranta should be kept dry at the root in winter, but the soil must be sufficiently moist to keep the plant from drying up. It will require in winter about one-sixth the quantity of water that is necessary in summer when the plant is growing freely. The Stephanotis, if trained near the glass and kept dry at the root after the growth is made, should flower freely. We fear the plant is induced to make new growths in a close atmosphere, that the pot-room is too limited, and the supply of water copious after growth is made. We pot ours immediately after blooming—that is, in May, plunge the pot in a mild bed of tan at one corner of a Pine-pit, and keep moderately moist until the roots have taken hold of the fresh soil, and new growths are being made. The supply of water is then copious, and the shoots as they grow are trained neatly over a wire trellis. The plant has the benefit of a moist heat until September, when the atmosphere is kept drier, diminishing the supply of water at the root until in November none is given. It receives as little water as the Pines during winter, but should the leaves become rather soft a little is given; after March more water is afforded so as to keep the soil just moist, and when in flower it is plentifully supplied. Similar treatment, we think, would cause your plant to bloom. The drainage should be perfect, two-thirds turfy peat, and one-third turfy loam, with a free admixture of sharp sand form a suitable compost. Too much vegetable matter, as leaf-mould, in the soil causes the production of strong and very long shoots, and such are not likely to flower.

**PRESERVING MOUNTAIN ASH BERRIES** (*P. Prior's Marston*).—The method we should adopt for preserving the bunches of Mountain Ash berries for the Christmas decoration of a church, would be to cut off the bunches and hang them across strings in a cold cellar.

**MEALY BUG ON VINES** (*T. B.*).—Vines attacked by it should have every branch and stem brushed over sedulously with a hard brush, and then with a painter's brush as thoroughly painted over with this mixture:—Soft soap, 2 lbs.; flower of sulphur, 2 lbs.; tobacco, 1 lb.; and a wine-glass of spirit of turpentine. Mix the sulphur, turpentine, and soap into a paste with warm water; boil the tobacco for an hour in a covered saucepan in some more water, strain it, mix it with the soapy mixture, and then add enough water to make five gallons. More tender plants can only have their stems and leaves sponged with water at a temperature of 115°, frequently, and so long as a single insect can be detected.

**PLEROMA BENTHAMIANA AFTER BLOOMING** (*A Subscriber*).—The plant may now be cut-in, or after it has done blooming; and when it has made new shoots a few inches long it may be repotted, without, however, disturbing the roots much at this dull season.

**FERNS IN SPHAGNUM AGAINST A WALL** (*E. G. H.*).—We have no recollection of the communication you refer to. There is no difficulty about fastening moss against a fernery wall. Nail up wide-meshed galvanised iron wire, and pack in the moss as the nailing-up proceeds. There is a good direction for forming fernery rockwork in our No. 437, in vol. xvii., page 324.

**GROUND VINERIES** (*L. T.*).—They are not sold ready made. Any country carpenter and glazier could make them.

**NAMES OF FRUIT** (*C. S.*)—6, Glou Moreau; 7, not determinable; 8, Chaumontel. No others came into our hands. (*G. B.*)—Your numbers commenced with 8, which is Cornish Aromatic; 9, Adams' Pearmain; 10, Beurré Bosc; 11, Urbaniste; 12, Beurré Clairveau; 13, Cox's Orange Pippin; 15, Beurré Diel; 16, Duchesse d'Angoulême. (*M. P.*)—1, like Bellissime d'Hyver; 2, Hacou's Incomparable; 3, acid and worthless; 4, Blenheim Orange. Plants are not determinable with certainty without flowers. (*C. W. H.*)—A basket of Pears, with the leaves, from Lancashire, without any indication from whom it came, we presume to be yours, the handwriting being apparently the same; 1, Beurré Bosc; 2 and 7, Winter Nelis; 3 and 12, Urbaniste; 4, Eyewood; 6, Passe Colmar; 8, Easter Beurré; 9, like Althorp Crassane, seems not suited for your climate; 10 and 13, Glou Moreau; 11, Beurré Diel; 14, Beurré Rance; 16, Napoleon; 17, apparently Broom Park. (*Pyrus Malus*).—Apples: 7, Court-pendu-Plat; 5, Relette Blanche d'Espagne; 7, Pearson's Plate; 8, Dumelow's Seedling; 9, Blenheim Orange; 10, Hollandbury; 11, Golden Russet; 12, Boston Russet; 14, Adams' Pearmain; 20, Court of Wick; 23, Alexander; 24, Waltham Abbey Seedling; 25, Gloria Mundi. Pears: 1, Van Mons Léon le Clerc; 2, Passe Colmar; 4, Beurré Diel; 5 appears to be Figue de Naples; 7, Althorp Crassane; 8, Eyewood; 9, Knight's Monarch. Of the rest some had their numbers detached from being fixed on with pins; others were not determinable.

**NAMES OF PLANTS** (*J. W. O.*)—1, Pteris tremula; 2, a young silver Gymnogramma—perhaps pulchella. (*F. E. H.*).—A Lygodium, probably japonicum. (*X. D.*)—Lilium tigrinum—tiger-spotted Chinese Lily. (*A Young Gardener*).—1, Pteris scaberula; 2, Niphobolus rupestris; 3, Blechnum, young; 4, Asplenium fontanum; 5, Pleopeltis venulosa; 6, Pteris hastata macrophylla; 7 and 8, Platyloma rotundifolium; 9, Adiantum capillus-Veneris; 10, 11, and 12, Selaginellas, unnameable; 13, Asplenium trichomanes; 14, Blechnum spicant. (*F. S. P.*)—Lactrea renula. (*D. S.*)—Clematis tubulosa. The Grape is Esperione. (*Holmwood*).—Schomburgkia tibicinis, var. (*Elizabeth*).—Miraldisjalapa. (*Sam*).—6, Polygala cordifolia; 7, Erica multiflora; 8, Cassia floribunda; 9, Paliurus aculeatus. (*Eskdale*).—Verbascum blattaria. (*T. S.*)—1, Eupatorium cannabinum; 2, Erythraea centaurium; 3, Scabiosa succisa; 4, Plantago coronopus. (*J. L.*)—Dimorphanthus elatus.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending October 7th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE MURRAIN—A WARNING TO POULTRY-KEEPERS.

"I CANNOT endure a man with only one idea," said a friend to us. We winced a little, for we are apt to gauge all things as they bear on poultry. We are in days of alarm, and it is the fashion to talk of plagues, pests, and epidemics. Cattle, sheep, and pigs are suffering. "Suppose," said Sydney Smith, speaking of locking-in on railways, after enumerating the notabilities who might suffer in the event of a carriage catching fire, "Suppose," said he, "one of the bench of bishops should be burnt! why, Sodor and Man would be better than nothing." So we say: Suppose poultry really should be attacked, what should we do?

We have the murrain in our district, and have taken great interest in the treatment. In the first case, we saw an angular pre-Raphaelite-looking cow standing in "most melancholy mood" under a tree, surrounded by five or six men, each holding a bottle. One said, "Brandy;" another, "Glauber salts;" another, "Strong beer, with burnt tobacco in it;" then, "A painful of gruel, with a pint of castor oil in it;" the last produced a piece of newspaper he had carefully kept, because it contained a certain cure; but on opening it found to his dismay nothing but advertisements. He had inadvertently lighted his pipe with the remedy the night before. "No great odds," he said, "for the cow was dying." All the remedies were tried, and the animal was yet alive, when some one saw an old copy of the "Times," wherein it was stated that water in which lots of rusty iron were put was a cure. All the remedies were tried, yet the cow lived!

The most successful treatment has been homœopathic. While we were considering these things, and while we were asking our-

selves what we should do if poultry were attacked, we saw the *Times*, and were after dinner dosing over the foreign correspondence, when we were suddenly aroused by reading that much alarm had been caused by the appearance of a poultry plague in some parts of France, which had already caused heavy losses among the farmers. Then we read of the same thing in Ireland. Our first impression was "They manage these things better in France." Fancy English farmers in a state of consternation because there was a murrain among the fowls. Eggs might be missed at the breakfast table; Ducks and chickens might be *desiderata* at times; but in an English farm, so far as profit and business are concerned, poultry is viewed more in the light of a tolerated nuisance than as an income. In the teeth of this, professional men, with but scant leisure, and having everything to buy, keep poultry (and many thanks to them)—good accounts, whereby they prove they make a profit of their hobby. Why does the idea of a poultry plague cause consternation in France? Because millions of eggs come to this country every week; because the Pigeons, the Geese and Turkeys are with them what they should be—"farming stock." And here we would observe, let it not be thought that all poultry-breeders abroad are small men. We have visited places where poultry was "to the fore," and the acreage of the farm considerably over five hundred. The eggs, the birds, all enter into the weekly computation, and all go to market. It is not necessary that the mistress or her daughter should take them.

We are not partisans of the opinion that because a man is an agriculturist, farming five hundred acres, and employing a capital of five thousand pounds, his wife ought at daylight to be milking, his daughters cramming poultry, or that the farmer himself should address every young lady as "Miss," and pull a fore-lock. Things are changed from the day when the farmer's wife rode on a pillion behind her husband to market, and took her seat in the market to vend her butter, eggs, and poultry. It is no longer the fashion of the times. Trade is trade. We are not going into the question of classes, which has split up society. We hold that every man who works for his livelihood, and honestly fulfils his vocation, is entitled to respect, and to those indulgences for himself and his family which he can pay for.

We make these remarks because we want a larger breed of poultry, greater production of eggs, and altogether more active production of food. The question is on the eve of becoming a serious one. Men are asking themselves what they can fall back upon if the cattle murrain become a more serious question than it is now. Already, beef at many tables causes every one, like Nelly Cook, to "look askew." Alarmists run about the country, and tell those who are "gaping" for something fresh that the "clever men" have discovered there are certain parasites in pork that are not killed by heat, and are taken into the system with pork. What a pity! A nobleman said to his cook one day, "Give me something new for an entrée." The "artiste" put himself through his vocabulary. "Suprême de Volaille," "Cotelettes aux pois," "Poulet à la Marengo" "Eis de veaux sauce tomate," "Cotelettes aux concombres," "Grenadins de veau aux olives," "Filets de Chevreuil sauce piquante." Nothing would do. The "chef" scratched his head, and vowed his vows to ——. Who was the god or goddess of cookery under the "ancien régime?" We cannot recollect, or we do not know. But his prayers were heard. "I have it, my Lord." "What is it?" "Two necks of very young pork cut carefully into outlets, correctly braised, dressed on a mould of stiff apple sauce, a border of mashed potatoes round the dish, and a "Soubise," with a smart dash of sage for sauce." "Capital!" *L'entrée fit fureur.* Pork, sage and onion, and apple sauce! We would at any time face the parasites for such a dish.

Our anecdote would be out of place were we not treating of the present probable scarcity of food, and the straits to which we may be reduced. If quadrupeds fail in supplying the wants of our increasing population, we must see what our resources are. We believe poultry, and above all eggs, will be found valuable adjuncts. Our capabilities in the way of meat seem to be at the end of the tether. We are obliged to draw largely on Holland and Spain, and get both meat and murrain. We cannot go into the question of fish; but poultry and cookery will stop many a gap, and will induce habits that will last. We wish to increase the supply of both. Eggs are Protean; they have a hundred different forms, and never lose their nutritive properties. They are things that every one likes, and there is many a worse dinner than three new-laid eggs and bread and butter to match.

But if disease gets among the fowls we shall be short of eggs. Forewarned is forearmed. Do not keep unnecessary birds; by such we mean cripples, and worn-out fowls. Let their places be scrupulously clean. As the weather becomes colder feed the fowls better, but without overfeeding. Watch narrowly, and remove sickly birds at once.

#### LABELS FOR POULTRY TO BE EXHIBITED.

The time is approaching for holding the great Birmingham Poultry Show, and I would suggest to the Committee that improved hamper-labels to those hitherto used by them would be desirable. The exhibitors who have sent poultry there know well the trouble and time required to fasten on a number of hampers the Birmingham old-fashioned labels with four holes, and there is now in use by many other Committees an improved one, with a single hole at each end. These labels also require no cutting of strings, but can be easily turned over when the hampers have to be repacked and sent to their destination.

I append a sketch of one.

—SELINI.

#### DUCK-FOOTED GAME FOWLS.

IN some of your recent impressions a correspondence has been carried on between Mr. Hewitt and a correspondent writing under the signature of "J. H.," on the question of how far a fowl's being duck-footed should disqualify it for receiving a prize. If I may be permitted to offer a suggestion, I should submit that the real point at issue lies between the two extremes. It is quite possible that there may be a tendency in a bird towards being duck-footed without his absolutely being so; or it may have the defect in one foot and not in the other; besides which, if I correctly understand Mr. Hewitt, where a bird has in all other respects the advantage over its competitors, he would not disqualify it from the circumstance of its being somewhat inclined to be duck-footed.

One fact relative to Mr. Hewitt, which should not be forgotten, is, that every exhibitor of poultry feels a degree of satisfaction on learning that he is to be the sole judge, from the feeling that he will make an honest award of the prizes, although, like all other fallible beings, he may occasionally err in his judgment.

I fear the same cannot be said of all; certainly the same degree of confidence is not felt in some, to which may be attributed the circumstance of so many having discontinued to exhibit; and it will be patent to every one who reflects—that a breeder and exhibitor of any length of standing, must possess as correct a knowledge of the points of merit in a bird as a professional judge; and when he sees his fowls unfairly dealt with, naturally retires from the contest in disgust. In proof of this, I need only mention the last two Birmingham Shows, and the great dissatisfaction manifested—a circumstance which cannot have escaped the memory of many of your readers; and the fact of the principal prizes finding the same destination where a certain party is connected with the judging, and the fact of the principal prizes finding the same destination where a certain party is connected with the judging, to say the least, wears an air of suspicion. Understanding that the Birmingham Committee do not contemplate making any change in their Judges of Game Fowl, and as Mr. Jennison, of Manchester, has brought out a very liberal prize list—the exhibitors having, moreover, had general confidence in the Judges he has appointed—I think, unless the Birmingham Committee pursue a new and improved course, exhibitors could not better mark their sense of such conduct than by passing the Birmingham Exhibition by and patronising Mr. Jennison.—EXHIBITOR.

#### SICKNESS AMONG POULTRY.

I AM sorry to say the disease among poultry is no fancy; there is a good deal in this neighbourhood. My yard is considered by my farmer friends to be absurdly well taken care of. There are a good house, kept scrupulously clean, all the adjuncts of dust bath, water pans, dry runs, and three fields of

three acres each, in which the fowls have full liberty, good food, and plenty of it; but all in vain. I have just lost a Brahma cock for which I gave £1 1s. a short time since—the third, which has died in the same way. He seemed moping, and I found him very thin. The only noticeable ailment was a difficulty of breathing after eating, and an inflamed mouth and tongue, with little ulcers on it. In spite of careful nursing and feeding he died; the comb and eyes were bright to the last. The hens seem to escape better; I have only lost one; but the young chickens are dying rapidly; seemingly well one hour, and the next evidently dying.

One peculiarity in the cocks was a constant shaking the head, but no gaping, nor indeed any symptom to guide me as to their malady. I shall be glad if any one can suggest the nature of the complaint or a cure.

I have a complaint among the Ducks also. They are fat and well one day, and the next the crop looks greatly distended, but no food in it. The voice becomes a harsh croak; they refuse to eat, but drink incessantly; diarrhoea follows, and in two or three days they die. Up to the present time they have been remarkably fine Ducks, in capital condition. As I have lost several I shall be much obliged for any light thrown on their disease and its treatment.—M., *Sunny Vicarage*.

[We believe that if the livers and intestines of your fowls and Ducks had been examined that one or other, or both of those viscera, would have been found ulcerated. It is a disease usual in autumn, and might be expected to be more than usually prevalent this year, for we believe it is occasioned by the extreme variation between the day temperature and the temperatures of the night and early morning.]

#### POULTRY SWINDLING.

THE inquiry of "C. A. G.," in your last, and your reply to it, opens up a subject which has, I feel sure, been much needing discussion for some time past. Every amateur who buys or sells valuable poultry must have met with similar cases to that of "C. A. G." I have lost several choice birds through sending them to unknown correspondents on the faith of their promise to send payment; and yet you say, "We are at a loss to account for any one sending money to a total stranger before they receive the goods." The fact is, there are some difficulties on both sides, and it is well known that there are numbers of poultry sharpers who profess to buy and sell, and who look out for advertisements likely to afford them opportunities of swindling. Cannot some plan be adopted by which references can be given to you as security for the position and respectability of amateur poultry dealers?

Some time ago a person wrote to me under the name of Firebrace, for a valuable pen of Buff Cochins. The letter appeared to be that of a lady, and I forwarded the birds. No payment has ever been made, but I received a request for more (which I did not send), and from that day to this I have not been able to discover the rogue. Could not some arrangement be made by which, on your keeping books of reference, such as the "Clergy List," Medical and Law Lists, and Post Office Directories, inquiries might be made through you of all doubtful cases. A very small sum contributed by all your subscribers would furnish sufficient to defray the cost of these, and either buyers or sellers, if they have any position at all, would easily be recognised. I merely, through your columns, wish to throw out a suggestion which possibly may be put in a more practical form by some one else who has been like myself—A SUFFERER.

[We would readily aid in protecting our subscribers in the mode suggested, if we did not foresee that it would involve an amount of anxiety, consumption of time, and responsibility, for which no payment could compensate. We the less reluctantly announce this conclusion, because every vendor and every purchaser may most easily be his own protector. If a purchaser unknown to us applies for poultry, we invariably write to some one in his vicinity, or, with a stamped and directed envelope enclosed, to the head of the police in the district. If we wish to buy we never do so without first seeing the birds, and if we thought we were unknown to the seller, we should send a reference when we made an application for an inspection of the birds, and give a promise to prepay the carriage if we declined purchasing. But if there were any difficulty about obtaining a reference, all such difficulty can be avoided where prepayment is required, by the purchaser availing himself of this postal rule relative to money orders:—

"Rule 50. In order to enable the remitter to obtain an acknowledgment of the receipt of a money order before the money is paid, it is arranged that he may make his order payable ten days after date, provided that, in the presence of the Postmaster, when he obtains the order, he affixes thereto, in the space after the request C., a penny receipt stamp, and write his signature across the stamp."]

#### OSWESTRY POULTRY EXHIBITION.

OCTOBER 5TH.

To many of our readers, no doubt, it will be well known that the supply of live poultry for table purposes has, for a long series of years, been a principal feature of the Oswestry market. Indeed, long prior to the institution of railways, dealers from towns so distant as Manchester, Liverpool, Wolverhampton, Chester, and Birmingham constantly attended this weekly market, and as from year to year the demand increased so has the supply also augmented, until Oswestry holds position among the principal markets of the kingdom for live poultry generally. At length a few local breeders of the surrounding district thought an exhibition of poultry, to be held annually, would arouse a spirit of useful competition, and tend still further to improve the quality of the poultry that was customarily at that time brought to market. Although some of its first promoters are now dead, still the acting Committee of the present hour are evidently men who do not intend to let the matter sleep, but to push onwards until Oswestry Show shall hold its own among even the most noted of local poultry meetings.

At its first institution the birds were all exhibited in pens erected in an open field, and, as it then happened that heavy and continuous rainfall ensued, ample provision was this year made to provide against such an exigency, should it unfortunately arise. We are glad to say that the weather was, on the contrary, as fine as could be desired, accompanied by bright sunshine. The tent provided, however, still proved quite a luxury, not only as giving the most welcome shade to the numerous visitors, with which it was constantly well filled, but also an equally appreciable amount of comfort and ease to the really excellent collection of fowls, for which it was especially engaged. The tent itself was 120 feet long by about one-third that width, whilst the height was most ample, and the expense of hire only £8. It would easily have accommodated three or four hundred pens. A tent even ten yards longer can be engaged for £10, which includes all expenses; consequently few Committees can longer plead the item of expense, as forbidding this call upon their exchequer, nor need we hear the complaints, so frequently urged by owners, of birds being ruined by exposure.

It is pleasing to record the fact that only one pen of poultry showed any symptom whatever of disease; they were from Whitehaven, and were very properly not permitted entrance to the tent. Though excellent in quality, the condition of this one pen was absolutely "filthy," and it was most undoubtedly very reprehensible of the owner to send them out in such plight, as it was evidently a disease of long standing, strongly confirmed, and of a highly contagious character. The prompt vigilance of the Oswestry Committee is, therefore, the more worthy of approval in at once excluding them and returning them unpened.

The Game classes were of very high character, and, as no limits was placed on the competition, many specimens from distant localities were entered, thus well-filled classes resulted. Mr. George Owen, of Plas Issa, Oswestry, however, managed to make a clear sweep of the prize list, with specimens of both Black-breasted Reds and also Duck-wings, that would greatly add to the credit of even the largest of our shows. Mr. Burgess, of Whitechurch, also exhibited some Brown Red Game fowls, such as leave little room for improvement when a couple of months older. In Grey *Dorkings* the Show proved very strong; Mr. Zurhorst, of Dublin, however, took first prize with a most lovely pen, and shown in such condition that few persons would have credited that they had travelled so far; indeed, their condition was faultless against a capital competitor. Mr. Edward Shaw, of Plas Wilmot, Oswestry, gained the second premium. In Partridge-coloured *Cochins* the Oswestry class was a show in itself; it is long since we saw so many and so good ones at any one meeting. Mr. Tadman, of Whitechurch, carried off both premiums, with birds as excellent in colour as they were perfect in feather. This gentleman's yard, strengthened as it has been, we are told, by the purchase of the whole of the Partridge *Cochins* belonging to the late Mr. Peplow Cartwright, of Oswestry, will now doubtless be very successful during the season without much difficulty. In Buff *Cochins* we confess disappointment, only two pens were entered; the principal prize birds of Mr. Tomlinson, of Birmingham, consisting of a first-rate cockered, but the pullets were by no means A1. Mr. Zurhorst, of Dublin, was winner of the second prize in this class. The class for *Spanish* fowls (all of this year) were the best collection yet shown in 1865. The most barefaced case of "trimming," till not a single feather remained between the eye and comb, in a really good pen of Spanish, here met with its deserts, being passed over; they would probably otherwise have been successful. The *Hamburghs* were all good, in fact unusually so, taken on the aggregate of shows, though at previous meetings at Oswestry, *Hamburghs* were failures. No *Polands* were exhibited. Black-breasted

Red Game Bantams secured all the Bantam prizes. In *Geese, Turkeys, and Ducks*, the show was excellent.

The "cottagers' prizes" were a complete failure, only a fourth prize being given, the first, second, and third being withheld. It appears, that at present, little is known by the district cottagers as to exhibition poultry. Brown Red Game cocks exhibited with Black Red hens, Hamburgs single-combed, and Golden-pencilled Hamburgs without any approach to marking, being among their short-comings; though the careful inspection of the Exhibition generally by cottagers, will, no doubt, enlighten such inquirers for future years, if then competing.

The attendance was very good indeed; in fact, the influx of visitors filled all the inns of Oswestry to repletion.

**GAME** (Black-breasted and other Reds).—First and Second, G. Owen, Plas Issa, Oswestry. Highly Commended, T. Burgess, Burleydam, Whitechurch. Commended, A. Shone, Sodyllt; W. Gamon, Thornton-le-Moor, Chester.

**GAME** (Any other variety).—First and Second, G. Owen, Plas Issa. Commended, W. Gamon, Thornton-le-Moor.

**DORKING**.—First, F. W. Zarhorst, Donnybrook, Dublin. Second, O. E. Cresswell, Hanworth Rectory, Hounslow. Highly Commended, Miss Davies, Wrexham Road, Chester. Commended, Lady F. Lloyd, Felton Grange; E. Shaw, Plas Wilnot.

**COCHIN-CHINA** (Brown or Partridge).—First and Second, E. Tudman, Ashgrove, Whitechurch. Highly Commended, R. J. Wood, Brynscall Hall, Chorley.

**COCHIN-CHINA** (Any other variety).—First, H. Tomlinson, Birmingham. Second, F. W. Zarhorst, Dublin.

**SPANISH**.—First, Miss Davies, Wrexham Road, Chester. Second, G. Lamb, Compton, Wolverhampton. Highly Commended, Miss Davies, Chester; W. Nicklin, Atherton Street, Walsall; G. Lamb, Wolverhampton. Commended, E. Shaw, Plas Wilnot.

**HAMBURG** (Silver or Gold-pencilled).—First, J. Robinson, Vale House, Garstang. Second, A. K. Wood, Burnside, Kendal. Highly Commended, T. J. Saltmarsh, Chelmsford, Essex; J. Platt, Dean Street, Bolton, Lancashire.

**HAMBURG** (Silver or Gold-spangled).—First, T. Blakeman, Upper Green, Tattenhall. Second, J. Robinson, Vale House, Garstang. Highly Commended, T. May, Bloomsbury, Wolverhampton. Commended, A. K. Wood, Burnside, Kendal.

**BANTAM**.—First, G. Raynor, Kelyeden Hatch, Brentwood. Second, T. Davies, Stowhill, Newport, Monmouthshire (Black-breasted Game Bantams). Highly Commended, G. Raynor, Kelyeden Hatch, Brentwood (Red Pikes, Game Bantams); A. Briggs, Slack Beck Farm, Rawden, near Leeds; E. Shaw, Plas Wilnot, Oswestry (Gold-laced Bantams). Commended, G. Smith, Belvoir place, Stavely, near Chesterfield (Silver-laced Bantams).

**TURKEYS**.—First, Miss Davies, Wrexham road, near Chester. Second, E. Shaw, Plas Wilnot, Oswestry.

**GEESE**.—First, Mrs. Scamons, Hartwell, Aylesbury. Second, E. Shaw, Plas Wilnot, Oswestry. Commended, Mrs. Scamons, Hartwell, Aylesbury.

**DUCKS** (Rouen).—First, J. Holmes, Knowsley, Prescott. Second, W. Lumley, Heaton Mersey, Manchester. Highly Commended, T. Burgess, Burleydam, Whitechurch; W. Gamon, Thornton-le-Moor, Chester.

**DUCKS** (Aylesbury).—First and Second, Mrs. Scamons, Hartwell, Aylesbury. Highly Commended and Commended, E. Shaw, Plas Wilnot, Oswestry.

**EXTRA**.—Highly Commended, Miss Gill, Trewerne.

Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, officiated as Arbitrator.

CALNE POULTRY SHOW.

This was held on Wednesday and Thursday, the 4th and 5th inst., when the following prizes were awarded:—

**DORKING, SPANISH, COCHIN-CHINA, or GAME**.—Prize, A. Heath, Calne (Spanish). Highly Commended, H. Waller, Beversbrook, Calne (Black-breasted Red Game). Commended, W. Beaven, Lickhill Farm, (Black-breasted Red Game).

**DUCKS** (Rouen or Aylesbury).—Prize, W. Bleaden, White Hart, (Aylesbury). Highly Commended, H. Waller (Rouen); H. Woodward, Rookery (Rouen). (The prizes in the above classes were given by Mr. & Mrs. Poynder, of Hartham Park, and competed for by persons residing in the Calne Union).

**SPANISH**.—*Chickens*.—First and Second, A. Heath, Calne.

**BRABMA POOTRA** (Dark).—Prize, J. Hinton, Hinton, near Bath. *Chickens*.—First, Rev. W. H. Fell, Stalmine, near Fleetwood, Lancashire. Second, J. K. Fowler, Prebendal Farm, Aylesbury. Highly Commended, J. Hinton.

**BRABMA POOTRA** (Light).—First and Second, J. Pares, Childown Hall, Chertsey. *Chickens*.—First, H. Lacy, Lacy House, Hebden Bridge, Yorkshire. Second, E. Sheerman, Chelmsford.

**HAMBURGS** (Any variety).—First, J. Orledge, Chippenham. Second, and Third, J. W. W. Hutbert, Causeway, Chippenham (Golden and Silver-pencilled Hamburgs).

**BANTAMS** (Game).—First, E. Cambridge, St. Phillip's, Bristol (Black-breasted Red). Second, W. F. Entwistle, Otley, Yorkshire (Black-breasted Red). Highly Commended, Rev. G. Raynor, Kelyeden Hatch, Rectory, near Brentwood, Essex.

**BANTAMS** (Any other variety).—First, E. Cambridge (Black). Second, T. Davies, Belmont Cottage, Stow Hill, Newport, Monmouthshire (Silver-laced). Highly Commended, G. Manning, Chapel House, Springfield, Essex (Golden-laced Sebright).

**ANY OTHER VARIETY**.—First, J. J. Fox, Devizes (Malays). Second, J. Pares.

**DORKING CHICKENS**.—First, G. C. Murton, Bishopstow, Warmminster. Second, Rev. A. K. Cornwall, Bencombe, Dursley (Grey).

**COCHIN-CHINA CHICKENS**.—First, Miss J. Milward, Newton St. Lee, Bristol. Second, J. Gardner, Bristol (White Cochin). Highly Commended, J. K. Fowler (Partridge).

**GAME CHICKENS** (Any variety).—First, A. Elling, Saiton Parva, near

Warmminster (Black-breasted Red). Second, G. M. Hulbert, Perret's Brook, Cirencester (Black-breasted Red).

**CHICKENS** (Any variety).—First, J. Hinton (Malays). Second, J. K. Fowler (Crève Coars). Third, W. Miller, Sherbourne, Dorset (Silver-spangled). Highly Commended, G. Manning (Black-breasted Red Bantams); Mrs. J. Pares, Childown Hall, Chertsey (Japanese Silkie). Commended, J. Hinton (Silver Poland).

**TURKEYS**.—First, Miss J. Milward, Newton St. Lee, near Bristol (Cambridge). Second, E. Mandrell, Quemerford, Calne.

**GEESE**.—First, J. K. Fowler. Second, H. Woodward, Rookery. Highly Commended, H. Waller, Beversbrook; H. Brown, Blacklands Park.

**DUCKS** (Aylesbury).—First and Second, J. K. Fowler, Aylesbury.

**DUCKS** (Rouen).—First, J. K. Fowler. Second, G. M. Hulbert, Perret's Brook, Cirencester.

**DUCKS** (Any other variety).—First, Miss J. Milward (East Indian). Second, H. Adney, Benbleton, Collumpton, Devon (Wild Ducks).

**SWEETSTAKES** (Spanish).—Prize, A. Heath, Calne.

**BRABMA POOTRA**.—Prize, H. Lacy, Yorkshire (Light).

**GAME**.—Prize, H. Adney, Benbleton, Collumpton, Devon.

**ANY OTHER VARIETY**.—Prize, Rev. A. K. Cornwall, Bencombe, Dursley (Black-breasted Red Game Bantam).

PIGEONS.

**CARRIERS** (Black).—*Cock*.—First, F. Else, Bayswater. Second, H. Wade, Laurel Cottage, Birmingham. Highly Commended, W. Massey, Fulford, York.

**CARRIERS** (Black).—*Hen*.—First and Second, F. Else, Bayswater. Highly Commended, E. M. Roys, Greenhill, Rochdale.

**CARRIERS** (Dun).—*Cock*.—First, H. Yardley, Market Hall, Birmingham. Second, F. Else, Bayswater. Highly Commended, F. Else.

**CARRIERS** (Dun).—*Hen*.—First and Second, F. Else, Bayswater.

**CARRIERS** (Any other colour).—*Cock*.—First, J. C. Ord, Pinlock. Second, W. Massey, Fulford, York (Blue).

**CARRIERS** (Any other colour).—*Hen*.—First, W. Massey (Silver). Second, J. C. Ord. Highly Commended, J. C. Ord.

**POWTERS** (Black, Blue, or Yellow Pied).—*Cock*.—First, J. Thackray, York (Blue). Second, A. Heath, Calne (Black). Commended, E. E. M. Roys, Greenhill, Rochdale; A. Heath (Yellow).

**POWTERS** (Black, Blue, or Yellow Pied).—*Hen*.—First and Second, A. Heath (Yellow and Blue). Highly Commended, A. Heath (Black).

**POWTERS** (Any other colour).—*Cock*.—First, J. J. Fox, Devizes (White). Second, E. E. M. Roys. Highly Commended, A. Heath. Commended, H. Yardley, Market Hall Birmingham; F. Else (White).

**POWTERS** (Any other colour).—*Hen*.—First, H. Yardley. Second, E. E. M. Roys. Highly Commended, A. Heath (White).

**TURBETS** (Almond).—First, F. Else, Bayswater. Second, J. Percival, Cleat Villa, Harborne, Manchester. Highly Commended, H. Bunce, Walworth.

**TURBETS** (Any other variety).—First, F. Else. Second and Third, H. Yardley.

**TURBETS AND OWLS** (Any colour).—First, H. Yardley (Owls). Second, J. Percival (Owls). Commended, H. Yardley (Turbits); J. Thackray, York (Owls); F. Else (Owls); C. Bulpin, Riverside, Bridgewater; E. E. M. Roys.

**JACOBS AND TRUMPETERS** (Any colour).—First, J. Percival (Jacobs). Second, F. Else (Trumpeters).

**BARBS AND NUNS** (Any colour).—First, J. Thackray (Barbs). Second, F. Else (Nuns).

**PANTALS** (Any Colour).—First, F. Else. Second J. Thackray.

**ANY OTHER VARIETY**.—First and Second, H. Yardley (Spots and Brunsicks). Third, J. Percival (Swallows). Highly Commended, A. Heath (Isabels). Commended, J. Percival (Dragons); J. Thackray (Swallows); E. E. M. Roys (Swallows).

**JUDGES**.—Mr. Sainsbury and Mr. Tegetmeier.

ABERGAVENNY AGRICULTURAL SOCIETY'S POULTRY SHOW.—OCTOBER 6th.

We are informed that the birds were more numerous and better than in previous years. The Judge was T. Davies, Esq., Newport, and the following were his awards:—

**SPANISH**.—First, W. Lewis, Coldbrook. Second, R. H. Nicholas, Newport.

**DORKING** (coloured).—First, R. Rees, Coldbrook. Second, J. Skinner, Newport.

**COCHIN-CHINA** (Any variety).—First and Second, R. H. Nicholas.

**HAMBURGS** (Golden or Silver-spangled).—First, J. Skinner, Newport. Second, R. H. Nicholas.

**HAMBURGS** (Golden or Silver-pencilled).—First, R. H. Nicholas. Second, Hon J. F. C. Butler. Commended, J. Williams, Goltre; J. Skinner; Hon J. F. C. Butler.

**POLANDS**.—First and Second, J. Skinner.

**GAME**.—First, G. Pritchard, White House, Lanvihangel. Second, R. Rees, Coldbrook.

**ANY OTHER VARIETY**.—First and Second, R. H. Nicholas.

**BANTAMS**.—First, W. Lewis, Coldbrook. Second, G. Aldridge, Monmouth.

**TURKEYS**.—First, Mrs. G. Holford, Buckland. Second, J. Williams.

**GOYTE FARM**.

**GEESE**.—First and Second, R. Rees, Coldbrook.

**DUCKS** (Aylesbury).—First, J. Skinner, Newport. Second, J. Pye, Spitty Farm.

**DUCKS** (Rouen).—First, J. Williams. Second, J. Skinner.

**EXTRA**.—Prize, R. H. Nicholas (Black East Indians). Prize, W. Lewis (Cottager's Dorkings). Prize, W. Lewis (Cottager's Prizes).

LONG SUTTON POULTRY SHOW.

In the schedule of entries for this Show, there is a notice that the catalogue will be ready on the 1st of October. When I made my entries I also sent the price of the catalogue, with a

note requesting that it might be forwarded to me as soon as published. I have not received it, nor has any notice been taken of my application. The publication of a catalogue ten days before a show is an unusual course, and is open to many objections, even if circulated alike to all. Where the circulation is only partial this plan is obviously unfair. Under any circumstances it is likely to create dissatisfaction, and to make exhibitors watch narrowly the awards in the prize list.—AN EXHIBITOR.

### DECLINE AND FALL OF A QUEENLESS HIVE.

EARLY this year there issued out of a common straw hive of mine a very heavy swarm, and the hive itself became naturally very much weakened, and I was not surprised to see at first a great alteration in the numbers and activity of the workers.

As the summer advanced I expected that the fruitfulness of the young queen would supply the deficiency in the number of her subjects, but I was unable to observe any difference in this respect; and as the bees came out and returned in the ordinary way I did not suspect that which I have only lately ascertained, that there was no queen. The drones came out in very great force, much exceeding in number the male bees in some adjoining colonies, and this circumstance tended in some degree to impart an appearance of activity to the hive, and to hide the paucity in number of their more industrious companions.

In due time the workers killed off all the drones, so that by the beginning of the month of September not a drone was left alive; and this circumstance, although it rendered the fact more apparent of how weak a stock it was, merely induced the belief on my part that some extra care might be required to preserve the colony through the winter.

After all the drones had disappeared the bees kept more constantly at home than before, and never failed to present themselves in force whenever a robber bee appeared; and although they were frequently seen in mortal combat with the robbers, they never failed to hold their own, although numbers of them must have died in the encounter. As similar combats were daily taking place outside a Ligurian hive close by, I thought nothing of the attacks upon the weak hive, except, of course, to regret that, few in number as they were, the bees should still further diminish from a cause I was utterly unable to prevent; for although I narrowed the entrance to the smallest possible aperture I could not prevent them coming out on the landing-board, which the bees persisted in doing, and I feared the weakening process of shutting up the entrance altogether.

On the 25th ult., about 4 P.M., a more determined attack by far than had been ever previously seen was made upon my hive, and the robbers in many instances succeeded in effecting an entrance; this went on until sunset put an end to the strife, which proved but the prelude to a scene that an experienced apiarian, who witnessed it, pronounced of an unprecedented character. The next morning, before the heavy dew of autumn had disappeared, robber bees in greater numbers still again attacked my unfortunate hive, and were opposed with a resoluteness and tenacity that could scarcely be imagined, and this continued unceasingly the whole day through, until the ground for a long distance round was literally strewed with the dead bodies of the combatants—a result that can be easily imagined when it is remembered that the fighting lasted about ten hours.

When the evening once more set in it was agreed by all who saw the battle that the attacked had held their own—an opinion confirmed by the great preponderance apparent between the number of the dead robbers over that of their opponents.

I next proceeded to repair the disorder arising from the disturbance in question, sweeping away from outside the hive great quantities of small pieces of wax that had been forced outside by the spoilers within, and I also resolved to change the floor-board, judging from the appearance of things, that much litter of a similar kind must have accumulated inside.

On lifting the hive for this purpose I was surprised at the diminution in weight, having had occasion to lift it not long before, and this induced me to turn the hive upside down, when I discovered that not a single bee remained within it, so that the inmates had literally fought to the last.

I examined the comb, which completely filled the hive, and found no trace of mildew, or of an insect of any kind, and although the robbers had torn open many of the cells there still

remained some 4 lbs. of honey a good deal intermixed with bee-bread, and here and there a pupa scaled over, and very little advanced, but there were no signs whatever of a queen, or of a royal habitation, and I can only presume that her majesty must have met with some accident which prevented her returning from her first matrimonial excursion.

I have detailed the circumstances of my queenless hive, because they seem somewhat at variance with what one reads of the consternation of bees that have lost their queen, as most certainly nothing of the kind was ever witnessed in the present instance, all that we ever noticed being that fewer bees came out and returned during any given time than in the case of the other hives, nor did the bees raise a queen in the manner peculiar to them, when deprived of their lawful monarch.—C. H. HODGSON.

[You have given a graphic and very truthful description of the dwindling and ultimate violent extinction of the inhabitants of a queenless colony. The stock may possibly have failed to raise a queen, or the juvenile sovereign may have met with some accident during her wedding flights, may have mistaken her hive on her return from one of them, or may have been murdered by her own workers. Mr. Woodbury considers that more young queens perish through regicidal attacks, than in any other manner.]

### DEPRIVING BEES OF THEIR HONEY.

I HAVE been asked by cottagers if I knew of any way to take the honey from their bee-hives without using sulphur, which is generally used, and they complain that the honeycomb is turned black by it. Can you tell me any other means of taking the contents of the hives?—A. H. D.

[The best mode of appropriating the contents of common hives is by driving, and uniting their inhabitants to those stocks that are intended to stand the winter. Full instructions for performing this operation are given in "Bee-keeping for the Many," and were quoted by us in page 288; whilst articles on driving and uniting bees, from the pen of Mr. Woodbury, appeared in Nos. 139 and 144 of this Journal.]

### THE HONEY HARVEST IN SCOTLAND.

WE copy the following from the *Scottish Farmer*:—

Since the labours of the bees for the year 1865 may now be said to be at a close, it may not be amiss to note the kind of season they have had, and the results.

It is well known to most bee-keepers that the winter of 1864 and spring of 1865 were very unpropitious. The long periods in which the bees were unable to get out during the winter, from the cold and snow, were very injurious to many, and a number died in consequence; others were attacked with dysentery, which, if they did not succumb to, were much injured thereby, so that in the early spring most hives were weak; but as the spring advanced the fine weather enabled the bees to get out, and they began to breed fast, which enabled many to get early swarms. What with the amount of turnip seed grown in this quarter, and also the extraordinarily fine crop of white clover in the fields, they increased in strength and weight very fast, and a number of tops of fine flower honey were obtained by many who never got them before, and were sent to market as soon as possible, until the merchants were fully stocked. When the price fell, all were anticipating an abundant harvest of heather honey; but how woefully we have all been disappointed.

For my own part, out of seventeen hives which I have at the heather, I shall not have any; but I have had a good share of flower honey. I began the season with nine hives, and from them have now twenty-three, and have taken from them 290 lbs. of flower honey. I had three tops of as fine honey as ever was seen, weighing respectively 40, 36, and 32 lbs. nett. The 40 lbs. was gathered by a top swarm within five weeks, the others about the same time. They are the heaviest which have ever been seen in this locality. I attribute my success to the liberal feeding which I gave the bees early in spring when the queen was breeding. By so doing, I had strong hives, which were ready to take advantage of the white clover; and as my bees are now all Ligurians, or hybrids between them and the black ones, I cannot help giving them the preference, as I never could obtain such results before with the common bee.

Those hives which are meant to be kept for next year will require to be weighed, and if found less than 30 lbs.—that is, the common straw-hive and board—then they must be fed at once. They would be better at 35 lbs.; still I find it a good plan to feed in the autumn, as it sets the queen breeding in about six days, and, consequently, a fine lot of young bees are in the hive all the winter, ready to commence operations with vigour in the spring. All the bees which have been working this summer will be dead before spring; it is only bees which are hatched in September and October which remain during the winter. At times a few old superannuated bees may be found in the spring, but if they do not move off by their own accord, they are soon expelled by their younger brethren. The bees have no idea of a poor-law; when they are unable to work they are expelled without remorse from their home.

In removing tops at this season, especially when the weather is cold, it will be found that the bees are in a dormant state, and do not leave the combs. In that case it is a good plan, after removing the top and turning it upside down, to place an empty one of the same size on the top of it, wrapping a cloth round where they join, and carrying them into a warm room. The heat will soon cause the bees to revive; and after filling themselves with honey, which they always do as seen as disturbed, by striking gently the lower top, the one with the honey and bees in it, they run up into the empty hive, and it can be carried out and put on the hive to which the bees belong, when they will at once join their comrades; the empty top should then be taken away, and the hole in the top closed carefully up for the winter.

In taking off tops at this season great care should be had that no honey is spilt or left about the hives; all should be taken away at once, as the bees in the other hives soon smell it, and they then begin to rob their neighbours, if they are allowed, and severe fights occur on these occasions.

If it is observed that they have begun to rob one, by the great commotion of the bees at the entrance, the door of the attacked hive should be shut, and the hive moved away into a cool room or cellar for the day, and taken back to its place at night; or it may be kept for a day in the cellar if the weather is warm, and put out the following night. If once bees begin to rob a hive in an apiary they do not generally rest satisfied with that one, but will begin on others if the weather allow them; so that they should be watched after they come from the heather: and when feeding them, it should be done at night, by placing the food in troughs within the hive, and removing the empty ones in the morning.

#### TREATMENT OF A DRONE-PRODUCING HIVE.

In your Journal of March 7th of the present year you inserted a communication from me asking advice in the case of a hive producing drones in large numbers in the early part of February. Your advice was to destroy the queen, to appropriate the honey, and to unite the bees to the nearest stock.

Being unwilling to destroy a stock apparently one of the strongest in my apiary, I allowed matters to remain *in statu quo*, carefully watching proceedings. About the end of March the drones gradually disappeared, and the working bees as gradually increased in numbers until, on the 25th of May, it threw off a fine swarm, which I placed in a Stewarton hive; but feeling little confidence in the leader of this swarm, two days afterwards I added to it another, placing underneath a third box. On the 3rd of June, eight days after the hiving of the first swarm, I placed a fourth box, as super, on the united stocks, and which was taken off on the 22nd of June with a nett weight of 18 lbs. of the finest honeycomb I ever saw. The remaining three boxes are well filled, and the population numerous. After the issuing of the swarm I placed a super upon the old stock, which super has been well filled to the weight of 12 lbs., and the stock with its new queen continues in a most flourishing condition. This is a simple statement of facts, on which I make no comment. Perhaps you or some of your learned apianian correspondents may be able to solve the mystery.—G. RAYNOR, *Kelvedon Hatch Rectory, Brentwood.*

[Our advice would be correct under the circumstances in probably ninety-nine cases out of a hundred. Yours just happened to be the hundredth case, and, therefore, we were wrong. The key to the mystery lies in the fact, which, however, is but little known, and has indeed been very seldom ob-

served, that young impregnated queens will in certain rare instances commence by laying either a batch of drone eggs, or those of drones and workers intermingled in a most singular manner. This phenomenon appears to arise from some little stiffness or want of power in the delicate and as yet muscled voluntary muscles of the spermatheca. After the lapse of some time these seem generally to become capable of fulfilling their functions, and worker eggs are deposited in the usual way. A case in point was related by Mr. Woodbury in page 350 of the first volume of our New Series.]

#### AUTUMNAL UNIONS—MOVING HIVES.

I OWE you my thanks for your prompt and valuable reply to my inquiry as to autumnal unions, which appeared in your Journal of August 8th. I lost not a day in putting to the test of experience the advice you gave on the subject, and on the same evening I united two stocks, taking the contents of one hive for myself, and the result was entirely satisfactory. In the morning all was, as stated in the "Bee-keeping for the Many," peace and harmony. I fancy the use of a little peppermint water with the syrup, as recommended by you, is of great use in causing the combined stocks to unite without fighting.

I have since operated unsuccessfully on several other stocks, and am quite satisfied that this mode of uniting stocks is deserving of general adoption. I have always chosen the dusk of the evening, as soon as the bees are all quietly settled, for the operation; but I have not found that it could be effected quite so rapidly as some of your contributors appear to have done. A quarter of an hour's steady drumming I find none too much to drive all up; and it saves a great deal of trouble afterwards to leave as few as possible to be got rid of separately. I have found, also, that it is better to use something pretty heavy to beat with (though, of course, not with too much force), rather than a light stick or the hands, how smartly soever you may rap. A croquet mallet answers admirably, the shock goes more completely through the body of the hive, and sends the bees up much more effectually than anything lighter.

On the subject of moving stocks short distances, I find it advisable in the first place to commence by turning the hive with the entrance in the opposite direction to that in which it is desired to remove it, and when the bees have become accustomed to it, then day by day withdraw the hive a foot or so at a time towards its intended resting place—making it, to use a Hibernicism, advance backwards. The bees more rapidly follow their home for a short distance in the line of their flight to it, than they turn either to right or left in quest of it.—G. S. C.

#### QUEENS AND QUEEN CELLS BY WHOLESALE.

I AM tempted to relate an occurrence of to-day, thinking it may interest your bee-keeping readers. On the 4th inst., we removed an Italian queen from a full colony and shipped her to a customer, giving the stock a young fertile queen on the 7th inst. Being very much hurried we neglected to make a final examination, but supposed the young queen was accepted. This morning the colony threw a large swarm. On opening the hive the peculiar "piping" of an imprisoned queen was plainly heard, and an investigation resulted in the capture of ten beautiful young Italians, all of whom had their full colour and were able to fly; but after cutting the cap of their cells had been resealed by the bees, and fed through an opening in the lid, as so correctly described by Huber. The colony having started queen cells as soon as their queen was removed, had refused the young queen given them on the 7th, and an enumeration of the cells showed that they had finished twenty-five, one of which contained an immature drone swimming in "royal jelly." (This attempting to convert drone eggs into queens is by the way, a common occurrence). Several had been opened and their inmates murdered; others had hatched, and two we cut out and placed in a box, leaving one in the hive. Our next onslaught was on the swarm which had clustered on a small tree. We hived it, getting five more young queens which had accompanied it, and on returning to the queen cells which we had cut out, found one hatched and the other just hatching, thus securing seventeen young queens and a queen cell for the old hive! I think this a pretty good haul from "a buckwheat

swarm." Although I know of no buckwheat nearer than a mile and a half from our apiary, we are having swarms from our Italians almost daily, and they are rolling in the honey famously.

The amateurs who have examined the Italian bees closely, have noticed in every hive many workers, whose yellow bands were of the most brilliant hue, while their abdomens were of a jet black—rivalling Day and Martin's blacking. We have had numerous inquiries in regard to this, some thinking that these fellows were the *pure* bees, and that the presence of others was a mark of impurity in the queen producing them. This is what may be called *a posteriori* reasoning. The fact is that there are old bees whose bodies have been worn smooth by hard labour, and any one doubting has only to catch a worker, and with a wet finger rub its back gently for a few moments to polish him up to the African type.—JAMES T. LANGSTROTH, in *American Country Gentleman*.

### GAS TAR INJURIOUS TO BEES.

A correspondent in your Journal the other day states that gas tar is not injurious to bees; but there can be no doubt that it is. He states that he merely covers his bee-house with gas tar, and this makes all the difference, for the vapour from it flies off above the bees. The vapour was under them in the former case. As you had some accounts in your Journal of freeing supers from the bees, I send you an extract from a lady's letter, describing a very ingenious plan, that may be of use:—"If you have not used the little talc traps for freeing your supers or boxes of bees, I think they would save you much trouble. I made one the other day, and every bee passed through it from my large supers, and as not a bee can return, no watching is needed. I merely take a slip of perforated zinc or earboard, cut four square pieces out about a quarter of an inch wide, and suspend, either with thread, or by sticking the upper edge on a small piece of ribbon, and fixing to the zinc or earboard over each hole a small piece of talc. This is so light that if you tack it on the entrance the bees run through, and it falls and prevents their return. I found it most useful."—A. W.

### BEE INVASION AT OBAN.

THE proprietor of a fruiterer's shop at Oban thus writes to the "*Glasgow Morning Journal*:"—"Since the notice of the invasion of my shop by bees the annoyance has continued, though I have smoked the premises every day. Yesterday, the young woman who keeps the shop had to shut up and take herself off, as the bees were unusually cross, and prone to use their stings. Indeed, I was myself afraid during the afternoon to enter the passage leading to the back shop, and the public outside had difficulty in moving along, owing to the swarms of bees which, round the door and windows, were literally in clouds. In spite of the free use of brimstone they tried to force themselves through the keyhole and shutter-holt holes. After I had done with the smoking process the shop was opened, but in two hours the enemy had full possession of the premises. I closed and smoked again, which finished the work for that day. This morning at half-past seven I opened as usual, but before nine o'clock I had to run with all the skeps, mugs, and plates of honey out of the shop into a back store, and to plug up every hole through which air could penetrate. While so engaged I was attacked by the bees, who stung me through my eap and veil. To-day I again smoked the shop, which, since the removal of the honey, has not been so much run upon."

[The only wonder is that such occurrences are not more common in shops where honey is exposed for sale. The invasion might readily have been checked at the outset by removing everything likely to attract the bees to a safe place, and then throwing open doors and windows to permit them free egress. When satisfied that no booty was to be obtained they would speedily have taken their departure, and, beyond a few stragglers during the next two or three days, probably nothing more would have been seen of them.]

### SANITARY PRECAUTIONS.

At a meeting of the Sanitary Committee of Dublin, held recently, it was decided to circulate the following suggestions

for improving the sanitary condition of dwellings, drawn up by Professor Cameron, public analyst.

The reported appearance of cholera in Southampton should incite the inhabitants of Dublin to increased attention to the sanitary condition of their dwellings. All the efforts of the sanitary department of the Corporation cannot keep the public health in a satisfactory state if, as is too often the case, the most simple and obvious principles of hygiene are violated by private individuals. The operations of the Corporation can only be extended to the interior of the dwellings of a certain portion of the poorer classes of the community; but they have frequently published suggestions for the improvement of the public health, which all ranks of society might with great advantage to themselves act upon. As the present time should be one of preparation against epidemic disease, attention to the following points ought to be given by those whose houses are to a great extent exempted from Corporation inspection.

Fresh air should be abundantly introduced into every part of the house. The windows should not be closed during the day; where air stagnates disease seldom fails to appear. Bed curtains should not be used. Direct sunlight is a potent agent in the preservation of health. Cholera, fever, and other endemic diseases make greater ravages in houses situated on the shady side of the street than in those where the sun's rays penetrate. It is far better to allow our carpets and curtains to fade than to exclude from our rooms the health-giving beams of the sun. Effete matters of every kind should be as speedily as possible removed from the house. Ashpits and other receptacles for offal and rubbish should be frequently cleaned out. Water-closets are often the source of disease, produced from noxious gaseous matters which force their way up through the pipes. To guard against this source of danger a saucerful of chloride of lime (bleaching powder) might with great advantage be placed in the water-closet. It would cost only a few pence, and would be a most efficient disinfectant for at least a month, after which it could be renewed. No untrapped sewer should be permitted to exist; and large oblong stone sinks, especially when untrapped, should be looked upon as sources of malignant effluvia. Every wall that admits of it should be frequently whitewashed; and at present it would be most desirable to add a quarter pound of chloride of lime to every bucket of whitewash. In the case of stables this addition would be productive of great benefit to the health of the animals kept in them. At all times, even the careful dusting and rubbing of furniture is a matter of sanitary importance, as minute purulent organic particles, by which disease is often generated, adhere to the surface of even tables and chairs. And here it may not be out of place to remark that personal cleanliness, embracing complete ablation of the body, is the first principle of hygiene.

[Whitewashing poultry-houses with chloride of lime is much to be commended also.]

### OUR LETTER BOX.

ILLUSTRATED POULTRY BOOK (*B. G. H.*)—It is printing, and will be published about the end of this month.

ADDRESS (*T. N. S.*)—Mr. Brierley's address is Rhodes House, Middleton near Manchester.

TEA MAKING.—A correspondent (*J. Noon*) says—Put the boiling water into the teapot and the tea in *over* the water. The tea being put in on the water causes the leaf to expand before sinking to the bottom of the teapot.

GEESE AT WORCESTER POULTRY SHOW.—Our reporter made a mistake in assigning the first prize to Mr. Fowler; it was awarded, we are informed, to Mrs. E. S. Wolferstan, Shalford Hall, Tamworth.

QUILLBOUND (*Q. B.*)—The cure for a quillbound fowl is to oil the affected parts thoroughly, and then to break the skin where a slight protrusion points out the locality of the stub, by passing a needle through and breaking it upwards.

CHICKEN MORTALITY (*S. G. A.*)—You cannot do better than administer castor oil to your fowls, now drooping their wings, breast puffed, and wasting away, following it with stimulants, such as bread and ale. It is a dangerous taste to introduce, but there is nothing so beneficial to wasting fowls as raw yolks of eggs. Put camphor in all the water used in your runs.

SUNFLOWER SEED (*Evelyn*)—We have heard sunflower seed much praised as poultry food, but have never tried it. Perhaps bruising the seed might induce the fowls to eat it, as you say that they now refuse to touch it.

BUYERS OF CHRYSALISES (*A Subscriber*)—We know of no one who purchases these for resale.

ANATOMY OF THE BEE (*M. D.*)—You will find what you require in the volume on bees of the "Naturalist's Library" written by the late Dr. Dunbar. The spermatheca either of the virgin or impregnated queen is, however, always fully distended, the only difference being in the character of its contents.

WEEKLY CALENDAR.

Day of Month	Day of Week.	OCTOBER 17—23, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.

23	M	Wild Duck arrives.	55.5	49.1	47.8	20	40 6	49 4	12 10	8 7	4	15 36	296

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 58.3°, and its night temperature 40.8°. The greatest heat was 73°, on the 21st, 1831; and the lowest cold, 17°, on the 23rd, 1859. The greatest fall of rain was 0.96 inch.

THE DUBLIN BOTANIC GARDENS.—No. 2.  
TRINITY COLLEGE.

VEN were the newly-arrived visitor to Dublin, *en route* for Glasnevin, to be blind-folded and taken to the gardens of Trinity College, judging from the vast num-

ber and the rarity of the plants there collected he might reasonably suppose himself upon the banks of the Tolka. The Trinity College garden is Glasnevin over again, but uttered in another language, the plants, despite the excellence of the Glasnevin collection, being to a very considerable degree another set entirely. Many hundreds of species of course are to be found in either garden, but each at the same time has its specialities. This may be accounted for, perhaps, in the case of Trinity College, by the requirement that a living specimen of every natural order of plants, in blossom if possible, shall be ready for the students at any and every season of the year—a requirement sufficient, in truth, to try the skill and patience of even such a curator as Mr. Bain. When Napoleon was upon a campaign, it is said that he required his cook to have a hot roast chicken for ever in readiness, so that at any and every hour of the day and night, and in whatever circumstances he might be placed, still his favourite dish should be ready for serving up. Something like this, but to satisfy an intellectual instead of a physical appetite, seems to be the care of the Superintendent of the Trinity College garden, and it is but simple justice to say that he acts, as nearly as can be, to the demand. The quantity of plants here crowded together is incredible. There seems scarcely room to squeeze in another, having proper care to leave access to the sun and air. Old things and new stand side by side, almost as closely as pictures in a first-class gallery, and every now and then a poor relation gets, as might be expected, jostled out, and is compelled to take up its lodging on the footpath. The oddest instance of this was a plant of Samphire, *Critillum maritimum*, old, tough, and woolly, among the gravel, yet covered with flowers and fruit! So extraordinary a change of location is seldom found possible with a maritime plant. From sea-washed rocks, wetted by the spray of every tide, to an arid path, is about as remote an extreme as could be thought of.

Much of the charm of Trinity College garden is no doubt referable to the bland conditions under which the plants exist, just as at Glasnevin, at Beaumaris, in South Devon, &c. A delicious climate, though no doubt with its drawbacks, enables many plants to thrive in a way seldom seen in the corresponding latitude in England. Here, for instance, against the boundary-wall are *Berberis fascicularis* 12 feet high, with a stem 3 inches thick, and superb

masses of foliage that roll out like Ivy; *Bignonia radicans* in full flower; and also in blossom *Paliurus Spina-Christi*, the plant used, in all likelihood, for the crown of thorns. It is intensely absurd to depict the crown, as painters often do, as if made of the *Crategus crus-galli*, representing it with some ten or twelve spines as long as the finger. In the *Paliurus* we have slim and flexible branchlets admirably adapted for twisting into a chaplet, and at the axil of every leaf is a little brown spine, resembling the lower half of the finest and sharpest needle, a spine pointing every way, so that the punctures would be at once acute, and incessant, and certain upon every side. The flowers are small, pale but decided yellow, in form like little stars, and are produced in leafy racemes at the ends of branchlets that are mostly without spines. The whole of the upper portion of the plant, from 10 to 12 feet above the ground, was, at the end of September, gay with them in abundance.

The lawn, like the wall, is occupied by shrubs and trees of the highest interest. Nearly the first one seen is *Arbutus andrachne*, superb in foliage, and with plenty of young berries, the cinnamon-coloured bark peeling off the trunk edgeways, and giving the latter a very odd appearance. Above a mass of magnificent compound leaves, each large enough to cover a moderate-sized dinner-table, we see, not far off, the grand creamy inflorescence of the *Aralia japonica*; on the other side is *Garrya elliptica*, 12 feet high, and giving ample sign in its grey catkins of the flowery triumph it will have in readiness for New Year's-day. The great pendulous racemes of the *Garrya* form one of the handsomest possible ornaments for an *épergne* in the depth of winter, and gardeners who have to supply such ornaments would do well to look after its culture. Of course it is only the male plant that should be grown for this purpose. The female, though in its native country decorated with purple berries, is of no use in England except as a source of seed.

Interspersed among the trees are some grand suffruticose plants, such as *Bupleurum fruticosum*, which here makes a circular bush 5 feet high in the middle, and bearing, probably, five hundred yellow umbels! A speciality worth remark is *Lobadium aromaticum*, a shrub related to the *Sunnachs*, and, as would be expected, possessed of a powerfully acrid juice. If a branch or twig be gathered incautiously, and there be any little scratch or wound upon the hand by which the sap can enter the skin, a very disagreeable and painful sore is soon occasioned. Near it, and of very pretty aspect, is that great rarity *Atraphaxis spinosa* loaded with white flowers, and looking, at the first glance, like a *Leptospermum* or the *Babingtonia*. Accustomed as we are in England to regard the *Polygonaceæ* as weedy herbaceous plants, it is once again very delightful to see how Nature can diversify her simplest types. A hard, dry, almost wiry shrub, with innumerable little branchlets striking out nearly at right angles, and loaded with delicate little white flowers, is not exactly what we should anticipate from studying a Dock or a Knot-Grass. Here, however, we may study it—an unmistakable "variorum reading," as classical scholars express it, of the idea played forth in those rude and worthless ancient

Britons. The order Polygonaceæ is one of those that present the widest possible contrasts, and hence is most valuable to the student. A shrub like the *Atraphaxis* is not so remote as not to be readily associated with the English weeds; it is when we look at those odd *Coccolobas* in the greenhouse that faith is for a moment shaken, yet only to be made the stronger by proper scrutiny. On the one hand, for example, is *Coccoloba platyclada*, made up, apparently, of innumerable bits of narrow green ribbon, sewn end to end, and bearing no distant resemblance to many a green seaweed; on the other is *Coccoloba pubescens*, a noble, single-stemmed, and erect tree, clothed all the way up with great leathery leaves more than a yard across, and terminating in an erect raceme 2 feet long or more, of innumerable flowers of the richest scarlet! Think of that, ye whose notion of the Polygonaceæ has been formed from the Sorrel of the meadows, or of the Black Bindweed of the corn-fields. The fruit of this plant, like that of some other tropical representatives of the order, as *Triplaris* and *Podopterus*, is berry-like, and produced in bunches, whence in their native countries the plants are known as "sensitive Grapes." For quickening the habit of observation, and teaching how to discern distinctions and resemblances, where without it all would be confused, and more than half overlooked, there is no science like botany. It is the best of eye-salves and the most successful of opticians; in a word, no learned treatise upon logic or the "laws of the mind" ever taught a man better how to use his wits than does the practical working-out of a proposition in regard to plant-structure. To take half-a-dozen species of as many different genera of a natural order, carefully dissect their flowers and other parts, and then satisfy the mind as to the nature of their resemblances and distinctions, is every bit as useful as learning how to demonstrate a theorem in Euclid. A man who will accustom himself to such examinations, not jumping at conclusions, but considering as he goes on, and not looking to books until he has exhausted all his own resources, not only becomes a good botanist, and therefore a better gardener, but he acquires sharpness and accuracy in other things, and proves in his own experience that for mental discipline nothing yet surpasses living nature.

In-doors the typical character of the garden is quite as well sustained as in the open air. Superb Orchids, though not many, expand their odoriferous flowers by the side of leafy Spice trees; and lovely Bromeliads and Scitamineous plants stand alongside of the *Upas* tree. This, though an unpretending, is, from the associations that fable and poetry have connected with it, one of the most interesting plants in British collections. The leaves are ovate, about 3 inches long, pointed, and hairy, and exude so venomous a juice from the end of the petiole when gathered, that if incautiously placed in the hat for safe conveyance home, should the skin of the head be touched by the juice, the roots of the hair are destroyed, and a bald place is left! It is scarcely necessary to say to any intelligent reader of books now-a-days, much less to a botanist or to a gardener, that the qualities assigned to the *Upas* tree are in a considerable degree not possessed by it. Though the sap and products are deadly, the tree gives out no exhalation of a poisonous character, nor does it blight or affect anything in its vicinity. Death, when occasioned in the neighbourhood of the *Upas*, came not of the tree, but of certain effluvia that arose from the ground, probably carbonic acid gas. The two things have no more connection as to cause and effect than the Goodwin Sands and Tenterden Steeple. Such tales do capitally, however, to horrify an audience fonder of platform harangues than of facts; and the *Upas* tree will no doubt remain for ever a stock image with soul-harrowing declaimers. Speaking of it brings to recollection a deliciously comic bit I once heard at a meeting held for a serious purpose, where one of the speakers, not quite up in his botanical geography, dragged in once again the story of the bulb found in the hand of the Egyptian mummy; and finished the recital by telling his audience that the said bulb, on being placed in the earth, "kissed by the solar beams, suckled by the dews of heaven," &c., eventually "bloomed and blossomed into a beauteous Bahlia!!!"

But let us return to Mr. Bain and his rich garden. Never certainly was the Killarney Fern, *Trichomanes speciosum*, grown so magnificently as it is here. There are two or three varieties in as many different boxes, with sloping lids of glass that can be lifted up at pleasure. Nothing can exceed the transparent delicacy of the fronds, or the richness given by their abundant fructification. Many appear to be upwards of 15 inches long, with the base broad in proportion. In one of the houses I noticed another plant of the Fern alliance, the *Adder's-tongue*,

*Ophioglossum vulgatum*. It was not that the plant was a rarity—it is one of the "common things" of Cheshire—but it was the place, and more particularly the special companionship, for who would expect to see the little green tongues of this pretty plant shooting up under the shade of an Indian *Dracæna*, and deriving their nourishment from the same pot of soil! Such, however, was the case, reminding us of the accounts given by travellers of the vegetation upon some parts of the Himalayas, and other sub-tropical mountain ranges, where at certain elevations the flowers of Europe and of the equinoctial zone come nearly in contact. The fronds were in full fructification, showing along both margins of the spike that curious row of apertures by which the spores make their escape. One of his *Dracænas* being too large and tall for convenient accommodation, Mr. Bain, a few years ago, in the style of old Procrustes, but with more amiable intent than the famous Attic robber, tried the experiment of shortening it by a partial cutting through of the stem, waiting awhile till roots were protruded from the under surface, and then completing the work of the saw. The top thus severed made a capital and healthy plant, which is now one of the ornaments of the greenhouse. A similar experiment is being tried with a Palm, *Sabal Blackburniana*. It has been in progress for nearly six years, and seems likely to prove successful. Should it do so, the experiment will certainly be a triumph for Mr. Bain, since, so far as we are aware, although roots are readily produced by the cut stems of such plants as *Dracænas* and *Fouquierias*, and by those of the genus *Ficus*, it is rather contrary to the nature of Palms. One of the prettiest plants in the greenhouse here is *Chamæbatia foliolosa*. It does not often occur in collections, but is well worth growing for the extreme delicacy of its foliage. The leaves are about 3 inches long, and something like *Cheilanthes tomentosa*, combined, if it were possible, with those of *Tansy*. The flowers, which though not here, I have seen elsewhere, resemble those of the common Blackberry, and soon fall to pieces; in habit the plant is an undershrub.

The general collection comprises examples of every great class and section of plants, and includes abundance of Ferns and of succulents. No one who has access to it need sigh for Kew or any other garden, for like *Glassevin*, it is botanical nature brought to a focus. In conclusion should be mentioned two or three things belonging to the prodigious mass of herbaceous and suffruticose plants in the open borders. *Ephedra monostachya* is a quaint little grey bush, looking as if it had existed since the time of the Bauhins, and with its tough old stem crusted with Lichens. *Lobelia tupa* forms a superb mass, the score of spikes of flowers, of the richest crimson, rising 6 feet high. *Androsace lanuginosa*, instead of a lean and tender pot plant as I have been accustomed to see it in Lancashire, forms a great patch upon the flower-border, glossy in its beautiful silver-grey, and with plenty of umbels of fairy lilac flowers that seem the *Primula farinosa* of the Westmoreland mountains repeated half-size—a most lovely plant for a rocky in general localities. *Phytolacca decandra*, though coarse and ungainly in habit and foliage, is worth growing for the very curious and noble spikes of fruit that follow its insignificant green flowers. The fruit-spikes are 12 or 15 inches in length, and seem as if formed of ripe Blackberries. Let no one who visits Dublin for the sake of seeing *Glassevin* fail to reserve a day for the gardens of Trinity College.—LEO.

#### FORM OF FRUIT-HOUSES.

THE thanks of the amateur gardening public are justly due to "G. H." for so kindly coming forward to explain the system of growing fruits in houses, which he considers most profitable; for though "VIRIS" may fancy that he "has taken to gardening blindfold," yet, probably, few of your readers have known much, if anything, about the houses "G. H." has taken the trouble to describe, until he endeavoured to open their eyes. Probably there are some, myself among the number, who would be glad of any further information which can be given on the subject—as, for instance, the expense of building such a house; the system of ventilation used; whether the fruit trees trained from back to front, and consequently facing east and west, the house being south, do as well as if they were with their fronts towards the south; whether the sun would not strike more powerfully on the back wall if it were higher, and the roof a lean-to, instead of a span as shown in the drawing? How many bunches of Grapes would the Vines 10 feet high carry? Eleven or twelve only appear in the drawing; and on a fourteen-

fect rather I grow twenty with ease, taking off twenty more as too much for the Vine. Whether there is any means of forcing, or whether such can be easily applied; whether the roots of the trees are entirely inside the house, and if so, whether the space would be enough after a time for the growth of the Vines and trees; and what kind of border is used? I have heard, though I never saw it, that there was a house of this kind in Kew Gardens, but that it did not answer. I might also ask where one of these houses may be seen?—LIVE AND LEARN.

## CYCLAMENS AND THEIR CULTURE.

(Continued from page 290.)

CYCLAMENS are easily cultivated, thriving well in soil that is free of stagnant water, and which contains a quantity of vegetable fibre. Soil from turves, 2 inches thick, cut from places where the ground is naturally dry and of a light yet good loamy nature, laid up for twelve months in an open situation, and turned over twice, may constitute one half of the compost, and the other half may be sandy peat, such as is used for Heaths, not the mossy, spongy, brown peat used for Ferns and Orchids, and well reduced leaf mould in equal parts, adding one-sixth of silver sand, or in its absence clean river sand, the whole being well mixed and chopped pretty fine with a spade, but not sifted. This will grow all the Cyclamens well; but whether from usage or fancy, I invariably grow *C. eorum* and *C. europæum* in equal parts of turfy loam, peat, and leaf mould, adding sand if the soil appear deficient in it.

The most suitable time for potting Cyclamens is when they are on the point of commencing growth. The dates of this work I find noted down as follows, taking 1859 as being about midway between the extreme earliest and latest dates for the past ten years:—*C. repandum*, February 6th; *C. europæum*, July 26th; *C. neapolitanum*, August 23rd; *C. vernum*, August 28th; *C. Atkinsi*, September 4th; *C. eorum*, September 12th; *C. ibericum*, September 1st; *C. persicum*, September 15th; and *C. macrophyllum*, *africanum*, *robustum*, *latifolium*, or whatever else they may be called, at the same time as *C. persicum*. These dates refer to the time when it was considered most suitable to pot, and any one acting up to them will not err, though they are earlier by a fortnight than they were in the following year. I think, however, that it is better to pot early than not until the foliage or visible growth is made, for then there is danger of pulling away lumps of soil full of fibres, and this exerts an injurious effect, as the succeeding bloom will show.

The soil being in good order for potting—that is, neither wet nor dry, or when it may be handled nicely without forming a soapy mass when squeezed, the pots to be used should be clean washed both inside and outside. Let the pots of plants be taken up and the plants turned out of them. Removing the crocks, take away the loose soil carefully, and so as to remove all that is not occupied with roots. Select a pot three times the diameter of the bulb—this the eye will determine without actual measurement—crock it to one-third its depth, and put in an inch or so of the rougher parts of the compost. At one time I used to place only one crock over the hole, and then half-inch bones on it to one-third of the depth of the pot, mixing also a quart of bones with every six quarts of compost, and the same of charcoal. This, I thought, improved the foliage, the size of the flowers, and their fragrance; but whether such was the case or not I cannot positively assert, but I mention the practice that others may try it. Having prepared the pot in either of the ways named, fill it with compost so far that when the bulb or eorum is placed thereon its crown may be level with the rim of the pot, and precisely in the centre. The bulb being properly placed, fill round it with soil and press gently down at the sides of the pot, so as to fix it tolerably firm, but not very tightly in the soil, and leave a space of about half an inch for watering. Water lightly, and stand the pot in coal ashes in a cold frame with the lights facing the north, for though we want light the scorching rays of the sun are not required just now. If the pots be plunged three parts down in coal ashes, and their rims be from 6 to 9 inches from the glass, they could not be better placed.

From the 1st of June to the 1st of October, the lights are only to be put on when heavy rains occur, and then air must be given by tilting back and front. Coddling plants under glass for any length of time will not answer, and Cyclamens are the last to be treated in that way. They will not require much water, but it should be given copiously and seldom,

rather than in dribbles and often, and this so as to keep the soil healthfully moist for the roots to run in; for if the soil is dry growth ceases, and if it is saturated with moisture the flowers are poor and few, as they damp off at the surface. From October 1st to June 1st the lights may be kept over the plants when the air is frosty, wet, and foggy; but when it is dry and mild, and the external temperature above 40°, they should be drawn down; yet cold cutting winds must be guarded against by leaving the lights on, tilting them at the opposite point from which the wind blows. When the air is cold, but not frosty, a little air will be of service; but when frost prevails the frame should be shut close, and protection of some kind, as mats, straw, or litter, placed over the glass to keep out frost, the sides of the frame being lanked up with ashes, or what is better, dry litter. When the weather becomes mild remove the covering, but do not expose the plants to light until quite sure that they are completely thawed; it will, however, be better if they are not frozen. During the winter the frame should face the south.

"But I have a greenhouse," some one says, "and I can do without all the bother of covering up, &c." That is all very good; but many have not the means to run up a greenhouse, and yet are fond of flowers in winter. Cyclamens, however, can be bloomed in a sunny window, the plants being grown in a cold frame as described, and when they commence flowering it is easy to remove any plant to the sitting-room, where they will bloom finely for weeks, care being taken to keep the soil moist, and the plants in the lightest situation. Those who have greenhouses will find it an easy matter to remove the plants as they come into bloom from the frame to the shelves, or any other light airy position in such structures. One great advantage of growing these plants in pots is their portability, and another of some importance is that one-half of the plants can be taken into the greenhouse a fortnight before the others, and this gives an earlier bloom and a longer continuance of it. The plants should not be removed from the frame to the greenhouse until the flower-buds show themselves. In the greenhouse they ought to be placed as near the glass and points at which air is admitted as possible, so as to have the advantage of both light and air. Water is to be given copiously when the soil shows that it is required, and slightly sprinkling the leaves with water at the same temperature as the house will be of benefit in freeing them of dust; but it must be done only on bright mornings, air being given immediately afterwards, or the leaves and flower-buds will damp off. A free circulation of air, all the light practicable, with a temperature of from 40° to 45° from fire heat, are the essentials of Cyclamen culture in heated structures; close, warm, dark situations are their destruction.

When the plants show signs of the foliage decaying water should be gradually withheld, discontinuing it altogether in about a fortnight; the pots may then be plunged to the rim in an open but not sunny part of the garden. It is, however, a much better plan to plunge them to the rim in coal ashes in a cold frame, where they can be protected from heavy rains, but at other times enjoy gentle showers and pure air. Keeping the roots dry for a period of three months or more is injurious, and brings on that sickly condition which is never prolific of bloom.

*Cyclamen persicum* is decidedly a half-hardy plant, but is best grown in a frame in autumn, until November, when the plants may be removed to a greenhouse, and kept there until the foliage decays. They may then be placed outside, for the extreme drying process is very pernicious to their well-doing.

Although it may be desirable to grow a number of specimen plants in pots for the decoration of greenhouses, conservatories, drawing-rooms, &c., on account of their being so handy, yet in this way they are not half so effective as when grown in masses. They are, indeed, magnificent when grown in pans, from 1 foot to 1 foot 6 inches in diameter, and 6 inches deep. These should be drained perfectly, and filled with soil to within an inch or so of the rim, rounding it slightly in the centre, but not more than an inch or two. Place the strongest bulbs in the centre at double their diameters apart, and preserve the same distance from the sides of the pan. Put soil round the bulbs so as to cover them about half their depth, and then bring to a level with the crown with cocoa refuse, and let it be old or nearly reduced to mould. In default of this its place may be supplied with some of the compost passed through a half-inch riddle. Grown in this way the smaller kinds, as *C. Atkinsi*, *vernum*, *ibericum*, and *eorum*, so very interesting when in pots, form truly splendid masses; such usually produce from

three hundred to five hundred blooms in a season; and I have the authority of an enthusiastic cultivator for a pan of *C. Atkinsi*, 18 inches across, giving 987 blooms during the first three months of the year 1856. Growing *Cyclamens* in pans is the next best plan to growing them in frames; but in the latter they are not so handy for decorative purposes. We may grow them in pots singly, in pans by the dozen, and what is to hinder our having them in frames by the square yard, so that handfuls of flowers may be gathered every morning all through the winter? Nothing, if only there be the convenience and requisite number of bulbs at command. Some twenty years ago, when gardeners knew how to grow such plants as these in addition to minding bedding stuff, and knew how to keep up a succession of bloom in their gardens all the year round, I remember seeing them grown in frames in the same way as Neapolitan Violets. Since then I have grown them planted out in frames, and I do not hesitate to state that they never do so well as when grown in frames or low pits; then why not have them not only in pots and pans for decorative purposes, but also in frames for gathering from for bouquets?

Suppose we have a two-light frame of red and white neapolitanum, another of ibericum and vernum, another of coum and Atkinsi, and one more of persicum, with a hot-water pipe along the front just to keep out frost, and to enable us to gather them earlier or later as desired, we may have red and white neapolitanum in September and October, or even in November; ibericum and vernum will keep up a succession until January and February, by which time coum and Atkinsi will come in, closely followed by persicum, and thus we have *Cyclamen* blooms from the 1st of October (and a month earlier if desired, by adding a one or two-light frame of europæum, which is sure to be a favourite on account of its fragrance), up to the last week in April. The mode of proceeding which I would recommend would be to choose a sunny, sheltered, and naturally dry situation, to lay without mortar just two courses of bricks, on which the wooden-frame is to rest, and along the front put a four-inch hot-water pipe within the frame, and then two courses of bricks. Fill the bottom of the frame or pit level with the top of these two courses with rubble, and then lay two more courses of bricks on these to keep the compost from the pipes. On the rubble place a few inches of the very rough compost, and then sufficient compost to raise the bed 9 inches deep all over, sloping it from the back to the front, and if the frame is of a proper depth the surface will be exactly 9 inches from the glass. If there are no frames it would be better to do without them, and build the walls of brick, making that in front 1 foot high, and the back wall 2 feet in height, with wall plates on them, and the usual woodwork of pits. Beneath the bed a four-inch hot-water pipe might be placed, with the rubble over it, not that *Cyclamens* need bottom heat, but to be ready for Melons, or other plants requiring it. All that would be necessary in this case would be a two-inch return-pipe, with stop-cocks to turn the water into the pipe beneath the bed or not as required.

Such pits may be planted with Cucumbers or Melons in March, and these will have yielded a sufficient return by the beginning of September; at all events, No. 1 frame or pit must be prepared and planted with *Cyclamen europæum* by the last week in July, planting them 6 inches apart every way, and in quincunx order, with the crown just level with the surface. After planting give a gentle watering, and in a day or two mulch the surface with half an inch of cocoa refuse, or the sifted compost. Water will not be much needed in August, but it must be given when required. The lights should remain off day and night, except when heavy rains occur, when they must be drawn on, admitting air, however.

No. 2 pit should be made ready and planted with *Cyclamen neapolitanum*, red and white, by the third week in August; No. 3, with *C. vernum* and ibericum, in the last week in that month, or in the beginning of September; No. 4, with *C. coum* and Atkinsi, in the second week in September; and a week later, No. 5, with *C. persicum*. All should be planted at the same distance apart, except in the case of large bulbs, which must be allowed more space, and the reverse as regards those which are below the ordinary size. If the soil is moderately moist it will not be necessary to give more than a gentle watering to settle the earth about the plants, and if it is dry bring it into a moist state by gentle rains or gentle waterings, drenching showers and soaking waterings being injurious to *Cyclamens*. Afterwards give gentle waterings in the absence of showers, and a gentle sprinkling overhead on dewless nights, but little of this will be needed after the middle of September.

As to air, they cannot have too much, provided frost and cold rains be excluded, and even then a little air will be of service, for a little heat in the hot-water pipe will prevent injury from frost, and allow of air being given during damp weather; the flowers, too, may then be gathered at all times, which is not the case when they are grown in cold frames. The heat being the same in all the frames may be considered an objection. Such, however, is not the case, for the temperature may be kept down by giving more air to plants which have done blooming, and the foliage will be matured all the better if not frozen. It should be borne in mind that the hot-water pipe is not intended to stew the plants, but merely to obviate the necessity of covering up with mats, &c., in order to keep out frost, to dry up damp, and to allow of the flowers being gathered at all desirable times without hindrance. It should also be remembered, that when any kind ceases growing it should be kept drier than when vegetation is active, and should have more air, though *Cyclamens* can scarcely have too much of this. All of them, however, will not require to be ripened off at one time; *C. europæum* will be the first to ripen, as it dies down in winter; *C. neapolitanum* will follow in March; *C. vernum* and ibericum in April; *C. coum* and Atkinsi in May; and *C. persicum* in the beginning of June. If the pits be wanted for Melons, the different kinds may be taken up when ripe, and planted in an open situation, yet shaded from the midday sun, and in this position they may remain until the time arrives for replanting them in the pits. On the other hand, if the pits are not required for other purposes, the plants may remain in them, protected from heavy rains.

Grown in the above way the *Cyclamens* would do much better in the second year than in the first, and better still in the third; at least, that is my experience. It may then be necessary to take them up, renew the soil, and replant. They produce seed so freely in this way, that if allowed to sow itself, the frame will soon be a complete mass of plants. The largest number I ever had from a plant in a single year was one hundred. This would be the best plan of raising plants in quantity to bloom at three years old.—G. ABNEY.

(To be continued.)

#### CUTTING THE RUNNERS OFF STRAWBERRY PLANTS INTENDED FOR FORCING.

AM I right or am I wrong in cutting the runners off my Strawberry plants, which I intend forcing? I visited a friend recently, and his gardener had not cut off one of the runners, and did not intend doing so until he put them into the forcing-house. He also told me that my gardener had quite spoilt my plants by cutting the runners off so closely, as it greatly injures the plants.

[This is one of those cases which show how careful a gardener should be in giving his opinion, and more especially in pronouncing on the practice of others. Many seemingly divergent plans, if carefully carried out, will come to the same result in the end, just as you may often go by various roads to one place, and with no great difference as to time and labour. It would be a very different affair if, instead of keeping right on by one road, you made it a practice to go a bit upon one, cross from that to another, and having proceeded a little way to cross back again, and so proceed until you had patronised a portion of every way that led to the place. Something equally unsatisfactory will be apt to take place in gardening if you attempt to combine into one the different parts of discordant systems. In the present case we do not see why, if it be desirable that Strawberry plants in pots should have all the runners encouraged until they are put in for forcing, they should not also be allowed to remain on them. We can well understand how the encouragement of a few runners at first will add to the strength and luxuriance of a plant, though we can also understand how by their increase these runners will act ultimately as exhausters rather than as feeders. But again, though luxuriance and strength are desirable, these must not be obtained at the expense of the maturity of the buds. It is also of importance that the matured strength of the plants should be concentrated in the crown of the plant. This can only be done by giving the crowns all the light and air possible, and for this purpose the plants should be set far enough apart, so that the crowns may have every help to mature themselves, and have fruitful juices stored up in them. We adopt your gardener's practice, and cut off all the runners as they appear,

phenomenon of all is, that some of these Willows, still crowned by a verdant capital of branches, have their hollow boles filled by tap roots sent down by these branches themselves, and by the splitting of the rotten stump this inner system of pipes and roots comes to light.—MARGARET PLUES.

#### ACHYRANTHES VERSCHAFFELTI—COLEUS VERSCHAFFETI—STELLA GERANIUM.

VARIOUS opinions have been given during the past few months respecting the qualifications of *Achyranthes Verschaffeltii* (commonly called *Iresine Herbstii*) as a bedding plant, and after hearing so much of this "new red leaf plant," I was anxious to give it a trial. A few plants were purchased, and after being placed in heat for a short time soon produced a good crop of cuttings, sufficient to make plants for one bed in the first week in June. The plants had been tolerably well hardened off, but did not make much progress for several weeks. Being in London on the 1st of July, my employer gave me a ticket for the Rose Show at the Royal Horticultural Gardens, at which place I saw a large bed of this new plant, and to tell the truth, I was somewhat disappointed after hearing so much of it. The *Amaranthus* in the same garden was, in my opinion, much superior, both in habit and colour. On my return home I was anxious to see how the *Achyranthes* was getting on, and found that it had made but little progress. Still I thought we might as well be out of the world as be out of the fashion, and the plants were allowed to remain, thinking that after a little experience they might do better. We have not been disappointed, the plants have been regularly pinched in, and have made quite a thick bed, and likewise become more of a red colour, which is what was wanted. We have secured a good crop of cuttings, and shall place some in stove, greenhouse, and cold pit. A stove or warm greenhouse will, I expect, be the best place for them.

The *Coleus Verschaffeltii* disappointed many as a bedding plant, and I believe there are but few who use it extensively at the present time. The best beds of it that I ever saw were at Slrubland Park, last year, under the management of Mr. Blair, and "taking a leaf out of his book," we planted a bed very thickly; this has done well all the season, and is one of the best beds in these gardens.

Mr. Fish has lately said that *Geranium Stella* is "A1" with him. We call it our A1, for it is undoubtedly one of the best *Geraniums*, if not the very best, that ever was introduced. The only drawback it has, is that its flower-stalks are rather too long. We have been fortunate in raising a variegated *Stella*, and if it should bloom as well as its parent, it will be "a *Stella* indeed."  
—JOHN PERKINS, *Thornham Gardens, Suffolk.*

#### PEAR BLOSSOM IN OCTOBER.

THE long-continued summer is now at an end, and here in Lancashire, at least, the rain which has for many weeks past been so trying a necessity, is falling in abundance. The bedded-out plants, as a matter of course, are rapidly losing their brightness, and even the cheerful *Michaelmas Daisies*, which in the south you call by the pretty name of "Farewell Summer," have been so drenched and battered that it is questionable if they will recover the condition they were in on Saturday. The bloom is by this morning (October 11th), entirely beaten away; but it may be worth while to place upon record, that on October 7th, 1865, two *Jargonelle* Pear trees standing in a garden at Coleyhurst, not more than a quarter of an hour's quick walk from the Manchester post-office, were perfectly white with bloom, just as in April. To see a few flowers, or even a branch or two at the close of a fine season like the one we have just enjoyed, is, perhaps, not very unusual; but for a whole tree to be covered with bloom, is, I think, quite exceptional. The first exclamation on seeing it was naturally, "No Pears next year;" but on examining several twigs, it appeared that only a portion of the flowering-buds had thus prematurely expanded, and that plenty remained to give promise, at all events, of a crop of fruit in 1866—whether to be fulfilled or not, will be known in twelve months.

The trees are situated in the immediate neighbourhood of some dye works, the warmth of the atmosphere caused by which, and possibly some of the chemical matters cast into the air may probably have had something to do in inducing this remarkable precociousness. Independently of the existence of

unexpanded flower-buds, it is quite likely that the splendid autumn we are now passing out of, will have so ripened the wood of these, and of other trees that may have similarly bloomed elsewhere, as to give them strength and impetus to develop new ones. The organic bases of which leaves and flowers are composed are primarily alike, and it is quite conceivable that on the same principle that plants "run to leaf," when over-saturated with moisture, here there may be a sufficient tendency in the contrary direction, owing to the fine season and its effects, to compensate the loss caused by the production of flowers in October.

I have noticed in many places, Strawberries in full bloom. In one garden, I think near Bristol, the bed was covered with flowers, and the same is the condition of things rather extensively with the wild Strawberry of the hedge-banks. Very pretty was it the other day, during a long walk in the lanes of Derbyshire, to note the white circlets of this little favourite, and how sweet and unaccustomed a contrast they formed with the azure bells of the round-leaved *Campanula*. What an amazing quantity, too, this season of red berries in the hedges! The Hawthorns bend their branches with the load, and the great clusters of the wild Rose hedges stand so erect and proud, and shine so brightly in their vivid vermilion, that in its decline the plant seems to eclipse even its own summer. How glorious, too, this year, the Acorns and the Chestnuts. Surely that beautiful passage in the seventh *Elogue* must have been penned after such a season at that of 1865.—LEO.

THERE is now (October 7th) in the garden of Mr. Hall, linen-draper, High Street, Stoke Newington, a *Jargonelle* Pear tree in full bloom. It ripened its fruit in July, and is now bare of leaves, but the blossoms are as abundant as if it were spring, and apparently as well developed.—A SUBSCRIBER FOR MANY YEARS.

#### PREPARING STRAWBERRY PLANTS FOR FORCING.

I HAVE a number of good Strawberry plants which I am preparing for forcing, but have no better forcing-house than ainery heated by a flue, and which cannot be started very early; I therefore propose making up a slight hotbed about the end of January, but fear the roots would be injured by much bottom heat. I presume I may place boards for the pots to stand on, and remove the plants into the greenhouse vinery just before they come into bloom.—A GARDENER.

[You cannot do better, but decidedly use the boards, and give plenty of air at first. After the first fortnight you might place a few leaves between the pots, to give these a little more heat, but it is safest not to let the pots be more than 2° or 3° higher than the atmosphere in January. Farther on in spring plunging the pots in a mild heat would do no harm. If this is done early, rooting and foliage are more apt to be encouraged than flower-trusses. We generally start our succession crops in frames. Even a cold frame is better than no other assistance.]

#### KNIVES OF MOWING MACHINES.

IN reply to your correspondent "VERAX," as to the best method of grinding the knives or cylinders of his mowing machine, I find that a piece of grindstone laid flat below the machine instead of the ledger plate, answers the purpose very well. Care must be taken to turn the crank of the driving wheel so that the cutter revolves in a contrary direction to the way it does when cutting. Also, it is of the greatest importance to have the knives a little higher, or convex in the middle, so that the point of contact with the plate may be easy, without causing a grating noise. When using emery, the emery ought to be shaken well on to each end instead of the middle, as is done in most cases, and which often causes the machine to get quite out of order, as the middle of the cylinder becomes concave, and only the ends touch the ledger plate, causing the machine to make a noise without cutting at all.—GEORGE ROTINIE.

HAVING noticed a letter signed "VERAX," in your last week's Journal, we take the first opportunity to state, that all the cutters of our machines are properly tested before being sent out, and that we guarantee them to give entire satisfaction; if not, they can be at once returned unconditionally. 2ndly. The

cutters fitted to our machines never require to be taken out to be either ground on a stone or with emery. They are made with steel on each side, and when they become blunt by running one way round, all that is necessary to be done is to reverse the cylinder end for end, which brings the opposite edge of the cutter on to the bottom blade, and the machine will then cut as well as when sent out from the manufactory. This can continually be repeated when necessary, and can be done in a very few minutes by any person using the machine.

—THOMAS GREEN & SON, Leeds, London, Liverpool, and Dublin.

## DUBLIN INTERNATIONAL SHOW OF FRUITS AND VEGETABLES.

THE Executive Committee of the Dublin Exhibition having made arrangements to hold an International Show of fruits, gourds, vegetables, cereals, and other agricultural produce, it was opened to the public on Tuesday the 3rd inst., and, as a first effort, was attended with considerable success.

The fruit was displayed on a nearly continuous line of tables, about 4½ feet in breadth, and extending nearly the entire length of the great southern transept; the roots, cereals, and other agricultural produce being displayed under the colonnade in the garden.

With regard to the Show, it could scarcely be called international, inasmuch as in the department we are about to notice there was only one foreign exhibitor, M. Cappenick, of Ghent, and three from England, the principal being Mr. Charles Turner, of the Royal Nurseries, Slough, near Windsor; T. W. Swannell, Esq., of Bedford, and another whose name we did not ascertain. The display, therefore, was almost entirely confined to Irish growers, who came out very creditably indeed, more especially in what may be strictly called the pomological section. Even the Irish exhibitors appeared, we regret to say, to be almost altogether confined to parties resident in the metropolitan county; outside it the credit of Leinster was only maintained by the counties of Wicklow and King's County. The northern and western provinces were entirely unrepresented, as far as we could see, and the southern province by one only, Mr. Unthank, of Limerick, and by him very creditably indeed.

It is to be regretted that the provinces and the sister islands were not more largely represented; but, as previously observed in this journal, we fear the inducements offered were not sufficiently liberal to bring exhibitors from the other side, or even from any considerable distance at home.

Having said so much, we will now proceed to details, following the arrangement of the schedule, beginning with collections, premising that for the prizes offered for collections from horticultural societies, public gardens, and the colonies there was no entry. For collection exhibited by a fruiterer, the only competitor was Mr. Lamb, of Grafton Street. His collection was fine, varied, and extensive. Among its more noticeable features were very excellent Queen Pines and fruit of the Cactus, the latter very large and fine, in this country a rather unfrequent addition to the dessert. He had also specimens of Salway Peach.

Of collections from private growers there were two—one from the gardens of the Duke of Leinster, the other from those of Thos. Hutton, Esq. The former deservedly obtained first honours; Mr. Hutton second. The collection from Carton comprised White Muscat, Black Hamburg, and Lady Downe's Grapes, the latter very fine, Peaches (Chancellor and Guldade), Brown Ischia Figs, Pears (Beurré Bosc, Marie Louise, Flemish Beauty, and Louise Bonne of Jersey), Plums (Reine Claude and Coe's Golden Drop), Medlars, Citrons, very fine Quinces, and Princess Alice Melon.

In the class of twelve Dessert Pears there were five entries, the first prize going to M. Cappenick, of Ghent, for a very fine lot, made up of the following sorts:—Colmar d'Areberg, Benrre Diel, Poire M. le Curé, Nouvelle Fulvie, Culebasse Bosc, fine, Benrre de Rance, very large and fine, Benrre Clairgean, a very handsome fruit, and Duchesse d'Angoulême, extremely large and fine; the names of one or two we could not come at. The second prize was awarded to a very excellent collection from the gardens of the Chief Secretary, Phoenix Park. In this fine lot Benrre Bosc was particularly fine, also a very handsome light-coloured Pear, named Pius IX., said to be of great merit. The manner in which the collections from M. Cappenick and Mr. McNeill were named was particularly neat and satisfactory, as was also that from the gardens of the Hon. Major Bury, whose collection was next in merit. In his lot Culebasse Tougard was very pretty; it was much paler, but still it looked very like Bon Chrétien Fondante. He had also Williams's Bon Chrétien, very fine, and Benrre Goubault remarkable for its singularly mottled surface.

In the class of six dishes there were three competitors, the Chief Secretary taking the lead with very fine specimens of Beurré Bosc, Marie Louise, Louise Bonne, Duchesse d'Angoulême, and Gansel's Bergamot.

In the class of three dishes there were six or seven entries, the first honours being deservedly won by Mr. Charles Turner, of the Royal Nurseries, Slough, near Windsor, with admirable specimens of Benrre Diel, Benrre Clairgean, and his famous British Queen, seen for the first time here on this occasion.

In the class of Dessert Pears, single dish, there were eight competitors, and here all of them and their varieties had again to give place to Mr. Turner and his British Queen. The second prize was won by, we think, Captain Stuvely, of Croydon Park, with a fine dish of Marie Louise.

In Kitchen Pears, single dish of any kind, the first prize was awarded to T. W. Swannell, Esq., of Bedford, for Uvedale's St. Germain, weighing 9½ lbs.; the second prize going to Mr. Unthank, of Limerick, for the same variety, weight 8½ lbs.

In the class of the heaviest five Dessert Pears, Charles Cobbe, Esq., showed a splendid and very handsome variety, Culebasse Grosse, the five fruits weighing just so many pounds. None of the weights mentioned above nearly approached that of the Uvedale's St. Germain Pears we saw exhibited at the Rotunda some years since by Sir G. Hodson.

In the class of Dessert Apples, twelve dishes, there were four entries, the first prize going to the Chief Secretary, M. Cappenick being obliged to content himself with second. The first prize lot was made up of Gravenstein, King of the Pippins, Cox's Orange Pippin, Ribston Pippin, Red Astrachan, Reinette du Canada, Pitmaston Nonpareil, Braddick's Nonpareil, Hughes's Golden Pippin, Margil, and Ross Nonpareil. M. Cappenick's collection was made up of Court-Pendu-Plat, Reinette Blanche, Reinette Grise, Calville Rouge, Calville Blanche d'Hiver, Pomme du Vin, Belle du Bois, and Gravenstein. It would trench too much on our space to go into details of the minor classes of dessert Apples, so we proceed to the classes of baking Apples, merely mentioning that the first prize for the best dish, any variety, was won by Mr. Turner, with Cox's Orange Pippin.

Baking Apples, twelve dishes, two or three competitors; the Chief Secretary was again first, with fine specimens of Echlinalve, Lord Sufield, Red Streak, Tower of Glammis, Reinette du Canada, Striped Beefing, Carlisle Codlin, Yorkshire Greening, Waltham Abbey Seedling, Winter Collin, and Bedfordshire Foundling. In the class of six dishes the Chief Secretary was in the front again, with six of the varieties mentioned above. In the class of three dishes, Hon. Major Bury was first, with Catshead, Sanyeur, and a variety whose name we could not catch.

The prize for the heaviest baking Apples was won by Mr. Barlow, with Alfriston. Baking Apples, best single dish, the first prize in this class was won by Charles Cobbe, Esq., D.L., with Catshead; the second prize going to Mr. Gough, the gardener at the Convent of St. Clare, Harold's Cross, for the same variety.

Messrs. Bridgford & Son, Lower Sackville Street, and Spaffield Nurseries, Ball's Bridge, exhibited, not for competition, an exceedingly large, well-arranged, and varied collection of Pears and Apples, numbering over 160 sorts, in itself a goodly show, which, no doubt, was regarded, as it deserved to be, with great interest.

Messrs. Edmondson & Co., of 10, Dame Street, also had a most extensive collection, including the singular Bird's Nest and other Gourds, the whole very interesting, and, we may add, very neatly set up.

In the classes of Grapes, the Hon. Major Bury had it nearly all to himself, the only other exhibitors being Mr. Cobbe and Mr. Hutton. The first of these had a dish of Muscat, and the latter a White Grape, not Muscat. The Muscats, both in the class of six bunches and of three, shown by the Hon. Major Bury, it is almost superfluous to say, were very fine indeed, as the fame of his excellent gardener, Mr. Roberts, as a Grape-grower, is now so well known. He took, as a matter of course, first prize in both classes. In the class of Muscats, three bunches, Mr. Cobbe was second, with bunches that were well handled, and did credit to his gardener, Mr. Helman, but they were scarcely ripe. In the classes of Black Hamburg there was no competition, and Major Bury took first prize with very fair bunches, but nothing like those he exhibited on other occasions this year. In the class of Black Grapes, any other variety, he was again first, with very fine bunches, named Muscat Hamburg, but certainly not in shape of berry and other external points, what we know as the Muscat Hamburg. We understand, however, they were from Vines not on their own roots, but grafted on the Black Hamburg. It is interesting if this has such a marked effect in changing the normal character of a variety, and we should like to know if the flavour, as well as the appearance, is more or less affected by it. Of Plums, there were six or seven dishes, the variety exhibited by all, with one exception, being Coe's Golden Drop. Much the finest in appearance came from the Chief Secretary's garden.

In the class for miscellaneous matters, in which fruits elsewhere provided for in the schedule, were not admissible, there were five or six Melons, none of them looking of much merit, except a large and handsome-looking Scarlet-flesh, exhibited by Mr. Turner, called the Hedsor Prize. Beyond appearance it did not seem to possess merit as regards flavour. Specimens of Red-fleshed Abyssinian Melons were exhibited in this section by Major Speedy, of the Royal Hibernian School, Phoenix Park, which were highly commended by the Judges. Peaches were shown by Mr. McNeill, of the Chief Secretary's garden; and Mr. C. Turner, of Slough. The former had a very fine dish of Wallbrton Admirable, and the latter a splendid dish of his famous Salway Peach. This last is a magnificent fruit, and beautiful even to look at, with its rich Apricot tint, of which the flesh, too, partakes; no garden should be without it. The Judges, to mark their approbation in an especial way, accorded it the International Medal. A dish of very superior Morello Cherries, and another of Red Currants, were

also exhibited in this class, we are not sure by whom, as, except in some cases, there were no names attached to the ears. It is most desirable that at exhibitions this should not be the case, as mostly it is only those who may get the first or second prize that are known, and though, perhaps, nearly quite as meritorious, nobody knows who the owners of the other lots are. Wax models of some varieties of Apples and Pears, as grown in the colony, were exhibited by the Superintendent of the Victoria Department of the International Exhibition, showing in many instances what an extraordinary degree of development many of our well-known kinds are capable of when grown in that distant country.

The Gourd show was almost a failure, there being only three specimens of home, and none of foreign growth, exhibited. The heaviest, and to our mind the best, came from Miss Hemenstall, of Sandymount; the next in merit from Glenart Castle gardens. In the way of Ornamental Gourds, the only specimen shown was one by the truly active and energetic Secretary of the International Exhibition, Henry Parkinson, Esq.

In the class for Table Decorations, there were only two entries, neither, we thought, up to the conditions as laid down in the schedule. That, however, exhibited, we believe, by Herbert Manders, Esq., was much the better of the two. He had a handsome centre of plate, with branches and pendant baskets, supported on either side by Higginbotham's crystal stands, and which he has named the Alexandra Flower Vase. The centre stand of the second was also of plate, with glass vases, of March's pattern, on either side. The flowers at the base of both were rather prettily arranged, but above there was an appearance of hurry and want of finish. Messrs. Higginbotham had a great variety of stands, some with flowers and many without, which we thought, though pretty enough for their purpose, gave the table a confused look, and detracted somewhat from the effect of the stands put up for competition.

The Vegetable section did not present any features that would call for special notice, if we except the enormous Cabbages from Sybil Hill, and some other places; these were infinitely superior to what was exhibited in the agricultural section. Parsnips were also a feature; the best came from Holywoodrath (Thos. Thompson, Esq.). Carrots, too, were excellent, those exhibited by Mr. Thompson being wonderfully fine, as were also the Cardoons exhibited by Mr. James, head gardener to the Duke of Leinster. Capt. Stavelly, of Croydon Park, exhibited a miscellaneous collection of garden vegetables. We must, for the successful competitors, and other particulars regarding this section, therefore, refer to the official prize list, which follows:—

Collections of Fruit (Fruiterers).—Prize, Mr. Lamb, Grafton Street. Collection of Fruit Grown by Exhibitor.—First, Duke of Leinster. Second, T. Hutton, Esq., of Drumcondra. Collection exhibited by any person not a fruiterer, and without restriction as to grower.—First, Duke of Leinster. Second, T. Hutton, Esq.

Grapes, White Muscat, six bunches.—Prize, Hon. A. Bury, of Tullamore. Three bunches.—First, Hon. A. Bury. Second, C. Cobbe, Esq., Newbridge. Any other White kind, three bunches.—Prize, T. Hutton, Esq. Black Hamburgs, six bunches.—Prize, Hon. A. Bury, of Tullamore. Three bunches.—Prize, Hon. A. Bury. Any other Black kind, three bunches.—Prize, Hon. A. Bury, for Muscat Hamburg.

Pears, dessert, twelve dishes, distinct kinds.—First, T. Cappenick, of Ghent, Belgium. Second, the Chief Secretary. Six dishes.—First, Chief Secretary. Second, Lord Justice of Appeal. Three dishes.—First, Mr. C. Turner, Royal Nurseries, Slough. Second, J. Lane, Esq. Single dish, any kind.—First, Mr. C. Turner. Second, Capt. Stavelly, Croydon Park. Kitchen, single dish, any kind.—First, T. W. Swannell, Esq. Second, G. F. Unthank, Esq. Limerick. Heaviest five fruits, dessert.—First, G. F. Unthank, Esq. Second, Lord Justice of Appeal.

Apples, dessert, twelve dishes, distinct kinds.—First, Chief Secretary. Second, T. Cappenick, Ghent. Six dishes.—First, Chief Secretary. Second, Lord Justice of Appeal. Three dishes.—First, Chief Secretary. Second, Earl Fitzwilliam. Single dish, any kind.—First, Mr. C. Turner, Slough. Second, Earl Fitzwilliam. Kitchen, twelve dishes, distinct kinds.—First, Chief Secretary. Second, C. Cobbe, Esq. Six dishes, distinct kinds.—First, Chief Secretary. Second, Lord Justice of Appeal. Three dishes, distinct kinds.—First, Hon. A. Bury. Second, C. Cobbe, Esq. Single dish.—First, C. Cobbe, Esq. Second, J. Gough, Esq. Harold's Cross. Heaviest five.—First, J. Barlow, Esq., Raheny. Second, Hon. W. Proby, Glenart Castle, Arklow.

Melons, single fruit, any kind.—First, Earl Fitzwilliam. Second, H. Manders, Esq.

Plums, single dish, any kind.—First, Chief Secretary. Second, T. Hutton, Esq.

Miscellaneous.—Bronze Medal (special), to Mr. C. Turner, of Slough, for Salway Peach, being very superior. A prize to the Chief Secretary for Wallburton Admirable; a prize to Earl Fitzwilliam for a dish of Morello Cherries; a first prize to the Chief Secretary for a dish of Tomatoes.

Table Decorations.—First, H. Manders, Esq. Second, T. Hutton, Esq. Highly Commended, Messrs. Higginbotham & Cullinan, for stand of vases of flowers.

#### GOURDS.

Single specimens, heaviest home growth.—First, Miss Hemenstall. Second, Hon. Mr. Proby (gardener, Mr. Geddes).

#### GARDEN ROOTS AND VEGETABLES.

Twelve Onions.—First, North Dublin Union, Dublin. Second, T. Thompson, Esq., Holywoodrath, Co. Wicklow. Highly Commended, Marquis of Headfort, Kells. Commended, J. B. Stavelly, Esq., Croydon Park, Co. Dublin.

Carrots, twelve.—First, T. Thompson, Esq. Second, Earl Fitzwilliam, Coollatin, Co. Wicklow. Highly Commended, T. Barlow, Esq., Raheny. Commended, T. Hutton, Esq., Drumcondra.

Twelve Parsnips.—First, Mr. T. Thompson. Second, T. Barlow, Esq.,

Highly Commended, T. Hutton, Esq. Commended, the Marquis of Headfort.

Twelve Globe Artichokes.—First, C. Cobbe, Esq., Newbridge House, Co. Dublin. Second, T. Thompson, Esq.

Six Roots of Beet.—First, J. B. Stavelly, Esq. Second, T. Barlow, Esq., Highly Commended, T. Hutton, Esq. Commended, H. Manders, Esq., Richview.

Three kinds of Turnips, six of each.—First, Earl Fitzwilliam. Second, T. Thompson, Esq.

Turnips, six of one kind.—First, T. Barlow, Esq. Second, H. Manders, Esq.

Scorzoneria, twelve roots.—First, C. Cobbe, Esq. Second, Earl Fitzwilliam.

Peas, one dish.—First, T. Barlow, Esq. Second, Duke of Leinster. Highly Commended, T. Thompson, Esq. Commended, Marquis of Headfort. Commended, Beans of T. Hutton, Esq.

Brussels Sprouts, three stalks.—First, H. Manders, Esq. Second, T. Hutton, Esq.

Borcolles, three kinds, two of each.—First, T. Thompson, Esq. Second, J. Gough, Esq.

Broccoli, six heads.—First, J. B. Stavelly, Esq. Second, Earl Fitzwilliam.

Savoys, six heads.—First, North Dublin Union. Second, T. Barlow, Esq. Highly Commended, T. Thompson, Esq. Cabbage, any other kind, six heads.—First, T. Barlow, Esq. Second, H. Manders, Esq. Highly Commended, J. B. Stavelly, Esq. Commended, T. Thompson, Esq.

Celery, Red, six heads.—First, Duke of Leinster. Second, T. Barlow, Esq. Commended, T. Hutton, Esq. White, six heads.—First, T. Thompson, Esq. Second, J. B. Stavelly, Esq.

Endive, six heads.—Commended, Mr. Pyra.

Cardoons, four heads.—Prize, Duke of Leinster.

Miscellaneous.—Commended in this class T. Hutton, Esq., for Mangels of the growth of 1864; and a special prize to a general collection shown by J. B. Stavelly, Esq.

—(*Irish Farmers' Gazette*.)

## PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

CALATHEA VEITCHIANA (Mr. Veitch's Calathea). *Nat. ord.*, Marantaceæ. *Lim.*, Monandria Monogynia.—Sent from western tropical South America by Mr. Veitch's collector, Mr. Pearce. An ornamental-foliaged plant, having leaves dark green, with paler crescent-shaped markings.—(*Bot. Mag.*, t. 5535.)

DIANTHUS CHINENSIS, var. LACINIATUS (Laciniated Indian Pink). *Nat. ord.*, Caryophyllaceæ. *Lim.*, Decandria Digynia.—Portrayed to show the change produced in "the modest little Indian Pink" by continued cultivation in rich soil and selection.—(*Ibid.*, t. 5536.)

DENDROBIUM TATTONIANUM (Lord Egerton of Tatton's Dendrobe). *Nat. ord.*, Orchidaceæ. *Lim.*, Gynandria Monandria.—Native of North Australia. Flowers white, petals tipped with yellow, lip blotched with mauve. They are insignificant, but sweet-scented.—(*Ibid.*, t. 5537.)

STACHYDARPHETA BICOLOR (Two-coloured Bastard Vervain). *Nat. ord.*, Verbenaceæ. *Lim.*, Diandria Monogynia.—Native of Bahia. Flower-buds deep purple, but changing to a greenish blue.—(*Ibid.*, t. 5538.)

MESEMBRYANTHEMUM ACINACIFORME (Scimitar-leaved Fig-Marigold). *Nat. ord.*, Ficoideæ. *Lim.*, Icosandria Polygynia.—Native of the Cape of Good Hope, "the head-quarters of the Fig-Marigold." Flowers 4 inches in diameter, purplish lilac.—(*Ibid.*, t. 5539.)

DENDROBIUM JOHANNIS (Mr. John G. Veitch's Dendrobe). *Nat. ord.*, Orchidaceæ. *Lim.*, Gynandria Monandria.—Native of the northern coast of Australia. Flowers purplish brown, exhaling a honey smell. Insignificant.—(*Ibid.*, t. 5540.)

EPIDENDRUM VITELLINUM MAJUS.—A large and brighter-coloured flower than the parent species, E. vitellinum. It is in the possession of Mr. Veitch.—(*Floral Mag.*, pl. 261.)

CYCLAMEN EUROPEUM PEAKEANUM.—Collected by R. W. Peake, Esq., during 1859 in the south of Europe. Its remarkable features are being evergreen, constantly blooming, and its flowers fragrant. Colour deep lilac. Leaves heart-shaped, and with an irregular band of very pale green on their upper surface.—(*Ibid.*, pl. 262.)

ALLAMANDA HENDERSONII.—Imported from Guiana by Messrs. A. Henderson & Co., Pine Apple Place, from whom it was purchased, and will be exhibited by Mr. W. Bull, of Chelsea. "The largest-flowered orange-yellow Allamanda known."—(*Ibid.*, pl. 263.)

PICOTEES.—Milton, white, broad-edged with purplish lilac. Raised by the Rev. C. Fellowes, Shottesham Rectory, near Norwich. Mrs. Fisher, white, with very slight rose edge. Raised by Mr. Taylor, Oxford. They are for sale at Mr. C. Turner's Nursery, Slough.—(*Ibid.*, pl. 264.)

ANTHURIUM SCHEZZERIANUM.—"The genus Anthurium, one of the Orontiaceæ, is remarkable rather for the beauty of its foliage than for the showiness of its inflorescence. Some spe-

cies of recent introduction, as, for example, *Anthurium cordifolium*, *alias* *magnificum*, and *grande*, furnish, indeed, leaves which vie with those of almost any other plants we cultivate—so graceful is their outline, so soft the blendings of their velvety colours, and so pleasing the contrast afforded by the flowing lines of ivory white, marking the course of their nerves and nervures; but these, and indeed the majority of the species, can claim no importance from an ornamental point of view, in regard to their inflorescence, which comprises a spathe of dull green, and a spadix of an equally dull tone of colour.

"In the subject of our present plate we have floral beauty combined with brilliancy of hue in no common degree, winning for its subject one of the foremost places amongst stove plants recently introduced to our gardens. Its improvement since first brought into notice, too, has been wonderful. Shown first in 1862 in company with the glorious *Lilium auratum*, it was, indeed, admired, but elicited little warmth of admiration; and the figure, which about that time appeared in the "Botanical Magazine," shows the plant in a state ludicrously inferior to that in which it has been shown the present year, as represented in our plate. In the older figure just mentioned the spathe measures 1½ inch in length, and three-quarters of an inch in breadth, while as now grown, it measures about 3 inches in length and 1½ in breadth. In this improved state it ranks, indeed, amongst the finest of decorative plants.

"*Anthurium Scherzerianum* is a native of Guatemala and Costa Rica. It was introduced in 1862 by M. Wendland to the Royal Gardens of Hanover, and from this source, we believe, was received by Mr. Veitch, of Chelsea, by whom it was first exhibited in this country, and by whom the wonderfully improved plants just adverted to were also produced. It is a dwarf-habited herbaceous plant, having a short erect stem, on which the petiolate, elongate-oblong, acuminate, leathery leaves are closely packed, and from which roots are protruded between the leafstalks. From between the leaves spring up the flower-stalks, which are coloured red, and terminated by an oblong, ovate, rich scarlet spathe, which forms the most attractive part of the inflorescence, and is always bent back against the stalk. The spadix, which is orange-coloured, is quite exposed, and vermiform. The plant is easily cultivated in the stove."—(*Florist and Pomologist*, No. xlvi., p. 209.)

#### PAULOWNIA IMPERIALIS BLOSSOM-BUDS.

I SEE an inquiry in your Journal from "M. E. G.," regarding *Paulownia imperialis*. Its blossom-buds will stand through any moderate winter, and will open before the leaves appear in the spring. It has been so with me in Somersetshire. —

#### GLEANINGS FROM ROCK AND FIELD TOWARDS ROME.—No. 7.

AMONGST the ruins of Rome, most affecting in their stupendous magnitude and majestic loneliness of decay, are the vast remains of the *Thermæ*, or Baths, of Antoninus Caracalla, where the *Arbutus unedo* and *Viburnum tinus* clothe with their dark verdure the summit of stupendous walls, each leaf and cluster of blossoms standing out clear against the soft blue sky. We read, and we do not wonder to read, that Shelley loved these ruins. The aerial height of the tremendous arches, the touching sight of so much beauty in decay, which Nature's kindly hand seeks to bide with new and wondrous forms of loveliness, are calculated to turn the dullest prose to poetry, and give a poet's spirit inspiration half divine. Built to accommodate 1600 bathers at a time, they occupy nearly a mile in circuit; and you can pass many an hour wandering about the deserted halls, climbing up crumbling walls, or examining the remains of mosaics which lie scattered about in huge fragments of ceiling or floor. Many portions of the ancient mosaic pavement remain still in the same position they occupied perchance some 1400 years ago. Some of these mosaics are entirely broken up; and I plead guilty to having gathered up a handful of tiny morsels, some of green or red porphyry, some of white marble, which I brought away to adorn my English fernery.

The water for the Baths of Caracalla was brought in part by the Claudian Aqueduct from a distance of forty-six miles, ten miles being carried over arches!—six of which still exist striding over the Campagna, and forming one of the most picturesque remains of ancient Rome.

The walls and the grass-grown chambers of the Baths abound

in interesting plants. Besides the wild *Laurustinus* and *Arbutus*, the ruins are in many parts quite hidden by trees and flowering shrubs. The Evergreen Rose (*Rosa sempervirens*), mixes its long trailing branches of bright shining green with large quantities of *Coronilla*, with its profusion of yellow blossoms scenting the air. I believe I gathered the *Coronilla glauca*, called in olden times the Day-smelling *Coronilla*; but I managed to lose my specimen, retaining only branches of a plant very like *C. glauca*, which Professor Parlatore pronounced to be only a *Medicago* (*tribuloides* ?), of which seven varieties are to be found about the ruins of Rome; and a tolerable specimen of the *Coronilla stipularis*, the *Coronilla valentina* of some botanists.

In "Curtis's Botanical Magazine" for 1788, t. 185, I find the *Coronilla valentina* figured, and described as a native only of Spain; and this information is also added—that the large stipule, the distinguishing feature of *C. valentina*, drop off when the plant comes into bloom. Another handsome plant I saw for the first time at Caracalla, as the enormous *Thermæ* are familiarly called, was the *Asphodelus microcarpus* or *ramosus*. This *Asphodel* is abundant in some parts of the Campagna, and its large raceme of blossoms rising from amidst the broad grass-like leaves makes it a very striking object, while its fleshy roots are sought after and eaten by the foxes. There is a much smaller *Asphodel*—the *A. fistulosus*, which only grows on the Colosseum, but I did not find it there myself.

Vying in size with *Asphodelus microcarpus* was the *Reseda alba*, its long close spikes of blossoms varying from 3 to 5 feet in height. This *Reseda* is not so beautiful as it is remarkable in its appearance, being almost like an ornamental shrub. It has whitish-looking petals, buff-coloured stamens, and large pinnated leaves. It gives you rather the idea of *Mignonette* striving to make itself suitable in size to the vast building which it has to adorn. But the botanist will not find large flowers alone strewn over the green carpet. He will find the *Anemone hortensis*, so faithful to Italian soil, the *Muscari*, the *Hyacinthus*; there also I believe he may find the tiny *Ornithopus compressus*, with its soft grey leaves and little yellow flowers, for it was there I think I first found it peeping up amidst the gayer bloom around.

It gave one a strange feeling, gathering those simple blossoms from amongst the shattered ruins of such glorious works of art. Strangely, too, came the thought that though the sun in the blue heavens shone never so brightly above, lighting up the noble expanse of building so unspeakably touching in its utter decay, and glancing so merrily from bough to bough and from leaf to leaf—yet in this spot, where Nature seemed so at unity with herself, the fatal malaria reigns supreme, preventing the custodian of the *Thermæ* from remaining in the ruins at night. How I hated the mysterious malaria I could never tell. It is worse than the brigands, for when once it seizes you, no ransom will effect your escape. It is worse than assassins—more stealthily in approach, more difficult to elude. Taking innocent country drives, you return with a headache, you tremble—it is the malaria. Unwittingly you have invaded its territory and you are caught. Sometimes it comes stealing up from its invisible lurking-place quite early in spring, and monks and nuns have to flee before it, away from their country monasteries to the town, into which it follows them, house by house, and street by street, into the very Corso itself. Sometimes it waits for summer; but sooner or later it comes, bringing fever and death in its train. The contadini have to shut up their cottages and find homes elsewhere for the unhealthy season, so that one misses in their dwellings the home-like look of the English labourer's cottage garden.

Leaving the Baths of Caracalla, a very slight detour brings you into the Via Appia, or ancient Appian Way, the very road along which St. Paul travelled when, met at Appii Forum by the "brethren," he accompanied them to Rome. St. Paul was on his way to prison and to death; we, in a luxurious carriage, were taking our easy way to the Catacombs of St. Sebastiano. We passed by the tombs of the Scipios, by the little church of "Domine quò vadis?" said to be built on the spot where our Lord met St. Peter trying to escape from martyrdom. The legend states that St. Peter, startled at seeing our Lord, exclaimed, "Whither goest thou, Lord?" and that Jesus replied in a voice of tenderest pity, "To Rome, to be crucified for my servant Peter." Then St. Peter turned and retraced his steps to sufferings and death, counting it joy to suffer for his Lord; and then the legend adds that our Lord left the print of His feet in the stone where He stood; and they show you a copy of the stone, and sell you medals com-

memorating the miracle. Still passing onwards by ruined tombs—by the Catacombs of St. Calixtus, we come in sight of the tomb of Cæcilia Metella, which St. Paul must have seen even as we see it, only with the marble whiter and purer. He, too, must have seen the wondrous beauty of the Claudian Aqueduct on its mission of mercy, bringing, as he brought, waters of consolation to thousands of thirsty souls.

I can fancy nothing more weird-like than the Catacombs, or ancient dwelling-places of the dead. Far down below the light of day, each visitor proceeds to examine them with a long lighted taper in his hand, the procession being led by a monk. As the party winds along the subterranean passages in single file, every here and there you meet other weird-like processions—some of priests, some of pilgrims, some of gaily dressed ladies, whose bright voices, telling of earth and earth's gay hopes, seem out of place in these gloomy regions. I shut my eyes, and the fading footfalls seemed to my imagination as those of the early Christians, stealing along in silence and fear to worship the God and Saviour they loved amidst the bones of a thousand heathen. Every now and then we came on a small square chamber, in which the little persecuted band met to celebrate the Last Supper of their Lord. How fresh in their memory was the blessed thought, that not very long before St. Paul had trodden the sacred way by which they approached the Catacombs, leaving them an example of courage and constancy to follow in his steps. The highest interest of the Catacombs is now wanting, as nearly all the monuments have been removed to the Gallery of Inscriptions in the Vatican; and it was with an intense feeling of relief that I passed from the ghastly subterranean passages up to the clear light and free air of heaven.

Better than wandering in the Catacombs did I like to wander up and down that noble Gallery of Inscriptions in the Vatican, reading many a useful lesson of pride brought low and humility raised even to the heavens. Amongst the ancient Pagan inscriptions are many curious ones—curious in grammar, curious in the proud disregard they paid to all the laws of metre in their verses, and curious in the diversity of the trades recorded. There is one to a "medicus jumentarius," or cattle doctor: did he know a cure for the rinderpest, I wonder? Another is to the "topiarius," or ornamental gardener: and from this I thought that the ancients must have paid more attention to their gardens than the modern Romans seem to do. But the monuments on the left hand of the gallery are the most interesting, for they are those of the ancient Christians: and their affecting expressions of peace and hope shine out in bright contrast with the Pagans' hopeless grief. How wonderful they were in their rude and hurried workmanship! Probably they were executed in fear and haste, with but little light to guide the trembling hand. Many of them had been over the dust of martyrs, yet there was no grief expressed—they all speak of joy, and peace, and life. I read no high-sounding praises of the poor form whose mortal agony was over. On one there was the rude sculpture of a dove, and by its side these simple words, "Aurelia vivas." I seemed to see the inhuman Roman crowd watching the expiring breath of the young maiden, thinking that she was dead; but it was not so—"Aurelia lives." Some of the slabs had a rudely chased chalice, some a vine, some the dove with the Olive branch; but one and all had the breath of Immortality about them, testifying of faith in Him who is the Resurrection and the Life.

I cannot leave the Vatican without telling of its picture gallery up the weary flight of stairs, to which I was carried by two men in a chair of state. Arrived at the top, I sunned myself for a few minutes, while looking from the windows at the view of Rome. Below lay the Piazza of St. Peter with its playing fountains, and beyond was the city, and beyond the city were the snow-clad glittering mountains, and above, a sky of soft grey blue, with banks of fleecy snow white clouds.

From the world of Nature you pass to that of Art, each perfect in itself. The gallery contains not more than fifty pictures, but nearly all are good; and yet to me there seems but one—one which by its radiance dims all others. As the interior of St. Peter's satisfied me, so did Raphael's "Transfiguration" satisfy me, stamping itself on my mind in colours never to be effaced. Each figure speaks, telling the sacred story in language unutterably forcible. On the mountain top the Lord is transfigured. Raised from the earth, His body floats in the air in a flood of glory. St. John longs, yet hardly dares to meet the sight. St. Peter, more bold, looks on. St. James hides his face. Moses and Elias are on each side below

the Lord. At the foot of the mount are the nine Apostles, the poor demoniac just brought before them. The faces of the father, mother, and friends express an agony of faith just broken—not gone, but startled. They seem to say, "We believed that ye could cast the devil out: we have brought our son, obedient to our faith. What! have ye no power? To whom, then, can we turn for help?" One of the Apostles is pointing to the mount with outstretched hand; he seems to say, "Alas! we are powerless, but the Healer is there." This picture must stand alone for ever, it has the very life of painting in every part.—FELIX-FEMINA.

### THE FUCHSIA SPORTING SEASON.

If your columns are open to the recording of sports, freaks, and monstrosities in the vegetable kingdom, perhaps you will allow me, a subscriber of some years, a little space to state what has come to my Fuchsias.

In my garden at the present time (October 11th) may be seen one flower with only two sepals, and another with five, whilst a third bears eight perfect sepals, equidistant, and reminding any one of an eight-sailed mill.

These eccentricities appear on three separate plants of distinct varieties, and may not be an unusual occurrence after all, though they struck me as being somewhat remarkable. May the dry season be the cause, the pots having been plunged in the open ground?—CHAS. OLDHAM, *Rhosddu, Wrexham.*

### SUPPOSED NEW EDIBLE-FRUITED PASSIFLORA.

I HAVE sent you a few seeds of an entirely new and unnamed *Passiflora*, which I raised from seeds brought by a friend of mine from outside Rio Negro, on the Amazon River, South America. The leaf is very large, about 8 inches across, the blossom white, spotted with pink, very original; and the fruit, for which I shall hereafter grow it, is by far the best of any of the tribe. It is about the size of a Peach, covered with bloom, and the inside is most delightful, most like a very fine Pear, and as good, I think, as any fruit we have. Two judges of such things, who tasted with me, express the same opinion. I consider it the best hothouse fruit I ever tasted. It is a free setter, I should think, as the only three flowers I have yet had produce fruit which I eat about a week ago. I may add, it requires a high stove heat, very great damp, and little air. My seeds from America were sown this time last year. It is, however, rather rambling. Can you suggest anything likely to make it keep more within bounds? I intend devoting a span-roofed house entirely to this one, with *Passiflora edulis*, and *P. quadrangularis*. A few hints would very much oblige.—J. H.

[We have sent the seeds to the Royal Horticultural Society. The best way to lessen the luxuriance of all such *Passifloras*, is to plant them in boxes made of terra cotta, brick, or slate—say 2 feet square, and as much in depth. These mulched on the top, or supplied with manure water, will make the plants luxuriant enough. Ringing the stems, and root-pruning, will also prevent extra luxuriance.]

### VINES WITH ROOTS CONFINED WITHIN THE VINERY.

CAN you give the result of planting Vines inside a house, and keeping their roots there, having no outside border? Opinions vary on the advantage of this system, but experience is a more certain guide. If any person can speak as to the success or otherwise of this treatment from, say a ten-years trial of its merits, he would by doing so confer an advantage on those who contemplate erecting vineries.

I have recently put up two houses 26 feet by 15 feet, with arches in the front walls, to allow the roots of the Vines to pass under, if they should ever be required to do so. These arches are closed with brick, and the Vines are planted on a thoroughly well-made inside border. I hope the border will support the Vines for several years as it is, and for many years afterwards by means of top-dressing, that there may be no necessity for making an outside border.—ALFQUIS.

[We have seen fine Grapes from inside borders, and have known trees bear heavily for many years planted in the middle

and back of the house. There can be no doubt that your plants will do well planted inside. We have a strong opinion that when Vines are planted inside, there should be openings between the Vines to let the sun reach the ground inside. When the whole roof inside is covered, the ground inside does not receive enough sun. With Vines trained up the rafters, or down the rafters, there can be no objection whatever to the roots being all inside the house, and any amount of strength can be given by top-dressings and rich waterings.]

#### CLIANTHUS DAMPIERI MARGINATA ELEGANS. AUBRIETIA CAMPBELLI.

We have received from Messrs. E. G. Henderson & Son, of the Wellington Road Nursery, drawings of these acquisitions to our garden plants. The *Clianthus* is white, with a uniform scarlet edge round the wings, keel, and standard, whilst the two-lobed projection at the base of the disk is purplish velvety black as in the old species. It is a most beautiful and unique flower.

The *Aubrietia* has white-eyed purple flowers, which it produces in great profusion. It has had awarded to it a first-class certificate at one of the Regent's Park shows, where it was exhibited by mistake under the name of *A. Hendersoni*. It was raised by Mr. N. Campbell, Queen's Nurseries, Brighton. It must become a popular bedder.

#### BARCELONA NUTS GROWN IN ENGLAND.

More than thirty years ago I sowed some Barcelona Nuts in consequence of a conversation at table, when some denied they would grow, as they were supposed to be kiln-dried. I send you herewith a sample in a bottle of the produce of these same nuts lately gathered. They appear to me to have come true to their parent, although I think larger, and we find them richer in flavour and finer in texture than any English nut, not excepting Kentish Filberts. They are tender, and the shells are very thin. All the trees are not of equal quality in size and handsomeness of fruit, but the latter are all thin-shelled, and first-rate in flavour in all seasons.—CHARLES ELLIS, *Upper East Sheen*.

[We could discern no difference between the nuts sent to us and those imported, except that the shells were rather more tender, and the kernels more moist—characteristics attributable to their being more fresh than those brought from abroad.]

#### A BORDER OF BULBS.

For a border several hundred feet long, close on 4 feet wide, in front of a wall covered with Roses, as needed by our correspondent "A. K.," the great difficulty is to have it in full bloom with spring hardy bulbs at one time—that is, if you vary greatly the kind of bulbs. For instance, that border would be very beautiful in February and part of March if planted with *Crocus* alone, say beginning at front with 1, purple; 2, white; 3, blue; 4, large yellow; 5, dark blue; 6, Cloth of Gold or Cloth of Silver; or three serpentine lines might be run along the border, filled with purple, large yellow, and blue, and the semicircular spaces in front filled with *Crocus versicolor*, and those at top with white or Cloth of Silver. To produce a grand effect the good bulbs should not be more than 2 inches apart in the row. To succeed these there might be four rows of *Hyacinthus*, of distinct colours, as rose, blue, white, crimson. The small *Duc Van Thol* Tulips alone would give five rows of distinct colours in the single section, and would only be from 4 to 6 inches in height; they should be planted about 3½ inches apart, as 1, red and yellow; 2, rose; 3, white; 4, scarlet; 5, yellow. These would be over early in May, to make way for bedding plants. Of double Tulips there might be four rows, beginning with 1, *Duc Van Thol*, scarlet and yellow; 2, *La Candeur*, white; 3, *Rex Rubrorum*, crimson; 4, *Tourneol*, shaded dark yellow. These would need no protection, and *Hyacinths* would need some in wet and frosty seasons. We have only mentioned the common hardy sorts, of which there would be no difficulty in securing plenty for a row several hundred feet in length.

A nice border would be thus made:—A row of yellow *Crocus* within 6 inches of the front; a row of *Duc Van Thol* Tulip, within 9 inches, choosing the scarlet single; then a row of *La*

*Candeur*, white; then *Rex Rubrorum*, crimson; and then for the back a row of *Soleil d'Or*, or *States General* Narcissus.

The straight-row system might be used this season, but our impression is that such a border would be better if, by the mode of planting it, it were either waved or broken up into a regular *parterre*, and the whole would look better if the surface of the ground were thinly covered with the Swiss *Forget-me-not* in blue, and *Virginian Stock* for blush, or with some other early flowering low plant, as *Nemophila*, sown in autumn and planted out early in spring. These little plants would be a sort of carpet for the bulbs. We hope some of our friends will help this correspondent better.

#### "IS THE ROSE A FLORIST'S FLOWER?"

Is the salmon a fisherman's fish? A florist's flower, as I understand it, is a flower which those men who love it most are carefully endeavouring, by selection, inoculation, and cultivation, to improve in form, colour, and habit; and what flower in all the world is so worthy of their service as the lovely Rose? I believe "*Rosa Canina*," in his letter to your contemporary of October 7th, to be entirely mistaken in supposing that the florist deprecates those flowers which do not reach his ideal of perfection. It is because he sees so much beauty in a *Général Jacqueminot*, that he strives for a *Senateur Vaisse*, and it is because his admiration of all Roses is so earnest, that at last he throws up his hat in ecstasies, and gloats upon *Charles Lefebvre*. I, of course, agree with "*Rosa Canina*," that he, of all men else, is to be shunned, who goes about a garden like an excise-man with his gauge, and admires by line and rule; and I am grateful, as he is, that the Rose defies those wily manipulations which are practised upon certain flowers; but I hold that the true florist has no sympathy with the ignorance of the one, or the impositions of the other, and that the Rose is, *par excellence*, that florist's flower.—MARÉCHAL NIEL.

#### BOTANICAL COLLECTIONS.

We recommend the following to the attention of our readers:

"J. Smith, late Curator of the Royal Botanic Garden, Kew, having through failure of his sight resigned that office, is now desirous of disposing of his herbarium, either as a whole or in separate collections.

"It consists of a very complete collection of Ferns, and also a general one of flowering plants:—

"I.—The Fern collection represents more or less fully the Fern Flora of the islands of the West Indies, North America, Mexico, Central America, Peru, New Granada, Venezuela, Guiana, Brazil, Tropical Western Africa, South Africa, Mauritius, Ceylon, India throughout, Malayan Peninsula and Islands, the Philippine Islands, Hong-Kong, Formosa, China and Japan, Australia, Tasmania, New Hebrides, Sandwich and other islands of the Pacific.

"Each species, with few exceptions, is on a separate sheet of stout white paper, 21 inches by 13, with name, synonyms, and references written on the sheet, as also the native country, and from whom received. Each sheet contains one, two, or more often many specimens of a species; the various peculiarities and geographical range of individual species is thus well illustrated, and has been particularly attended to in the formation of this collection; the number of species being about 2000, more or less, including all the rare and interesting species. The total number of sheets, 6460. If the collection were broken up it could be formed into at least three good sets. The whole collection is scientifically arranged, and contained in a cabinet 6½ by 6½ feet, divided into fifty-five compartments. This collection was considered by Sir William Hooker to be second only to his own.

"II.—The flowering collection of plants consists of about 5000 species, representing nearly the whole of the natural orders; of these 1600 are native specimens, and above 3300 garden, chiefly collected between the years 1824 and 1844, the early-collected ones being on paper less than the usual herbarium size; the larger number, including *Proteaceæ*, *Myrtaceæ*, New Holland *Acacias*, and other *Leguminosæ*, *Euparietideæ*, &c., are all on full-sized herbarium paper, and arranged in their respective orders. The garden specimens are records of plants introduced by our early collectors, as Masson, Cunningham, Bowie, and others, many of which are singular and remarkable, and not now in the gardens of this country. The

1600 native specimens are chiefly selections from the Indian collections of Wallich, the herbaria of Lambert, Gardner, Cunningham, and Bowie. Besides the above there is a collection of Gramineæ, Cyperaceæ, Juncaceæ, &c., amounting to about 450 species; they consist chiefly of garden specimens, collected between the years 1826 and 1836, when these orders were particularly studied, and they are believed to be all correctly named. The general collection contains a small set of Australian terrestrial curious Orchids, introduced by Cunningham, during the years 1824, 5, and 6, and which flowered at Kew. There is also a special collection of garden Ferns, consisting of 460 species, all fixed on the usual herbarium-sized paper; likewise several small special collections.

"Further information and particulars respecting the above collections will be given on application, by letter or otherwise, to Mr. J. SMITH, Park House, Kew, near London."

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

Now is a good time for thoroughly draining any part of the garden that wants it, to replant Box and other edgings, or to mend the gaps where it is not necessary to remove the whole, to prepare gravel, &c., for new walks, and for repairing the old ones, to make any necessary alterations, and to thoroughly trench and drain ground newly taken in, and every spare piece in the garden, choosing suitable weather for these operations. Care should always be taken not to operate on close, retentive, badly-drained soils when full of water, which they will continue to be while heavy rains prevail. *Broccoli*, such as is now becoming too luxuriant may be checked by laying. *Cabbage*, those who have spare ground should still continue to put out Coleworts and Cabbage plants, or if any strong plants of Savoys or the varieties of Kale should be left in the seed-beds, by all means put them out thickly—say at Colewort distances; and those that are fond of Turnip Greens at an early season, if they have any overgrown Turnips left in the beds, should at once collect and plant them 1 foot apart on warm borders, quarters, or sloping banks. *Carboons*, tie-up for blanching when the leaves are quite dry. Twist haybands round so that the soil may not come in contact with the leaves when earthed-up. *Cauliflowers*, continue to prick out under hand-glasses and in frames. Any that are now fit for use should be preserved in a cool place. *Celery*, advantage should be taken of fine weather to earth it up. Keep the whole of the leaves together. *Cucumbers*, those in boxes or pots should have a top-dressing of rich soil occasionally. When giving water at the roots let it be heated to 80°. *Herb-beds*, fill up and dress them for the winter. *Horseradish*, dig up a portion for winter use, clear away the leaves as soon as decayed. Hoe and stir amongst all growing crops in suitable weather, and collect all dead and decaying leaves.

### FRUIT GARDEN.

When the wood is well ripened and root-pruning is intended, either with wall trees or those in open quarters, a commencement should be made with the earliest-ripened trees first. See that the potted Strawberries are secure from the wet. Run a soft broom over the Peach and Nectarine trees with great care to take off just the very ripest of the leaves. Pruning may now be commenced amongst Pears and Apples. Cut the dead wood out of Raspberry stools, and tie the young wood to the stakes to prevent injury from high winds. The preparation of quarters for the reception of Gooseberry and Currant bushes should be completed, as planting may shortly commence. The storing of fruits as well as their after-management, must this season receive particular attention. The Apples and Pears should be carefully wiped and regulated after sweating. The Medlars and Quinces should be collected in good condition. To select perfect Walnuts for storing, the best plan is to immerse them in water after the husks are taken off, and all that are quite perfect sink at once to the bottom, while the imperfect Walnuts will float, even those that have the least possible deficiency in the kernel will do so. Those that have been sweated should be well cleansed by being placed in a dry sack and shaken by two persons from end to end, the friction will clean them perfectly. Shreds should be prepared in wet days, as well as labels for naming fruit trees. See that the old wall nails are cleaned and in readiness for use.

### FLOWER GARDEN.

Steps should now be taken to fill up the beds as they are cleared, for the purpose of contributing to the enjoyment of

spring. A miscellaneous mixture of dwarf early-blooming shrubs, perennial plants, and bulbs is most commonly planted; but, as has often been stated, in regularly laid out beds, or in geometrical flower gardens, the arrangement of colours should be carefully considered, as there is an abundance of spring-flowering plants and bulbs to form a rich and varied display, if properly arranged. A very pleasing effect can also be produced by sowing all the spare beds with Californian and other hardy annuals. These stand the severity of our winters, and by their gaudy colours make quite a gay appearance in the months of May and June. The following are the species which will answer the purpose well:—*Nemophila insignis* major and minor, blue; *Nemophila atomaria*; *Clarkia pulchella* alba, and *Iberis coronaria*, white; *Silene pendula*, *Leptosiphon densiflorus*, *L. androsaceus*, *Collinsia bicolor*, and *Gilia tricolor*; *Clarkia pulchella* and *Iberis umbellata*, rose; *Erysimum Peroffskianum*, and *Eschscholtzia crocea*, orange; *Godetia Lindleyana* and *Collinsia grandiflora*, purple. *Sphenogyne speciosa* sown now, and protected during winter, will make a brilliant orange-yellow bed. *Lupinus nanus*, and *Convolvulus minor*, treated in the same manner will form splendid blue beds. A good stock of new sawdust should be laid by in a dry shed to put round the stems of tender Roses or half-hardy plants; this should always be obtained as new and fresh as possible. It should not, however, be applied to the plants for some time, and when this is done a dry period should, if possible, be chosen, as a casing of such material after heavy rains would probably prove very prejudicial, for confined damp is even a greater enemy than frost in many cases.

### GREENHOUSE AND CONSERVATORY.

All plants belonging to these structures should now be under glass. Cleanliness and free ventilation, whenever the weather will admit of it, should receive constant attention. If unfavourable weather should occur, do not hesitate to use a little fire heat at times, especially if the houses contain a good many plants in bloom. The Chinese Primroses to be now removed to a shelf in the greenhouse as near the glass as possible; give plenty of air at all favourable opportunities. Herbaceous Calceolarias to be treated in the same manner, and duly attended to with water. Cinerarias to be protected from the ravages of green fly by fumigations of tobacco or by syringing with tobacco water. If any of the beautiful tribe of Tropæolums, particularly *T. tricolorum* and *brachyceras*, that have flowered early in the season, begin to grow they should not be checked, but allowed to grow slowly through the winter; but if there is no appearance of growth, which is best for their future success, the roots should be kept inactive in a cool place with the soil about them quite dry, and protected from mice. Camellias to be carefully supplied with water, to prevent the dropping of the buds, leaving not more than two flower-buds on each shoot, and retaining the largest and the smallest in order to have a succession of flowers. The leaves, if necessary, to be washed clean.

### PITS AND FRAMES.

As the Right Hon. W. F. Cowper has kindly placed at the disposal of the clergy, and the managers of ragged schools, refuges, hospitals, and workhouses the plants in the public parks, a few instructions on the subject of their preservation may be acceptable. When the plants are obtained and potted, they will require a little bottom heat or a close place to start and establish the roots in the fresh soil. For the want of bottom heat to start the plants we have seen persons put to much unnecessary trouble in their fruitless endeavours to preserve them through the winter. As the frost has not touched them there is a greater probability of preserving them. The plants that have been headed down for cuttings, and are now breaking, are the best for keeping through the winter. The cuttings of Calceolarias may be now put in in a close pit or frame, where they will be easily kept during the winter, with air in mild weather, as they are very liable to damp off in heat. We would advise those who can spare time to wash all their pit and frame glass before the dark weather sets in, the great disproportion of the light to the heat is the great drawback to forcing in Great Britain and Ireland during November and December.—W. KEANE.

## DOINGS OF THE LAST WEEK.

THE rains that we expected as the result of clear hot days and frosty mornings, came in due course in the beginning of

the week, and have done much not only to moisten the dried soil and invigorate all growing vegetables, but also to produce, for our benefit, a purer and healthier atmosphere. A regular downpouring, as we had on Tuesday and Wednesday night, combined with a nice bracing breeze, will, we hope, tell on the health of our cattle, as well as promote the comforts of the inhabitants in our towns and villages.

The rains which we have already had, and those we may yet hope for, will render the ground very suitable for all alterations in lawns, turf-laying, walk-making, and planting and removing all kinds of evergreens. Even if the ground were still dry enough, it would be of importance to hasten on all such work, though watering should have to be resorted to, as the milder and somewhat cloudy condition of the atmosphere will arrest evaporation from the foliage, whilst the heat in the soil will excite the roots to push out fresh fibres at once, and thus establish themselves before the severity of winter. The great advantage of early autumn planting is thus securing fresh roots to the plant, and hence enabling it to meet the bright sun and the dry air of the next spring without shrinking and shrivelling. Moderate watering, so that all the roots are moist and firmly packed, will be a better plan at this season than soaking and puddling them with water, which places the roots in an unnatural position as respects moisture, and, unless the surface is kept dry, will also make the soil cold by the increased evaporation. Such plants, even in the spring, if they need watering, should have it given in moderation. Often we have seen hogsheads bashed on the soil, when a few gallons thrown over the stems and branches, or a little shade, would have been more acceptable to the plant.

*Turfing*, and other alterations on lawns, can now be done with more ease and comfort than at almost any other season. Furnished with leather knee caps, or a thick pad, the workman, so long as the ground is warm, is not likely to suffer from colds and the attendant rheumatism, and there will be no difficulty about making sure of the grass growing well with the smallest modicum of beating and rolling. To do much of such work in winter is often very unsatisfactory to all concerned. When performed late in spring the sun often renders considerable labour necessary to keep the turf from gaping, or even drying up; and, besides, in most gardens now, the spring brings such an amount and variety of extra work, that it is wise and sound policy to have as much as possible of all new work, changes, and improvements completed in the autumn.

#### KITCHEN GARDEN.

Before the rains came we managed to run the hoe through all growing cress, and, in the case of Artichokes and Asparagus, to remove a few of the weeds. A lot of Chickweed was beginning to thrive among the Asparagus, which it was not easy to get at, and made the cutting down of the Asparagus very desirable, as the seed was ripe enough, but the branches were not so free from green as we would wish to see them. At a late horticultural show Asparagus was shown in a collection. We presume it was obtained by cutting the beds down too early. A correspondent informs us this week that his beds becoming very weedy, he mowed them over in September, so as to clear them thoroughly, and now, he says, the fresh shoots are 18 inches long. He fears, as we do, that the beds, which were in good order, will show the effects of this second growth next spring. No doubt the extraordinary, almost tropical, heat of the season had something to do with it, but it would have been better if the clearing of the beds had been delayed.

Moved away all the withering and a few of the greenish leaves from Sea-kale in order to arrest growth and prepare for forcing. Where this is used largely during the winter a considerable space will be required for it. This, Rhubarb, Asparagus, Artichokes, Globe and Jerusalem, Horseradish, herbs, and small fruit demand a good space in a small garden; and yet, though all these are grown, and for forcing too, in an acre of ground, some people think that that acre should never be without the other vegetables that are wanted every day for a large consumption.

Gave plenty of air to young Cauliflowers intended for the main crop next spring, the plants being still small. Watered with manure water that forming nice heads. Planted out more Lettuces to stand the winter, tied-up others for use; covered Endive with tiles and boards for blanching, and earthed-up a piece of Celery. Will take up Carrots as soon as the weather is drier, the ground is not yet wet at all, though more comfortable on account of the rain. In rainy days washed pots, made tallies, &c., and collected into a heap a lot of rubbishy brushwood and weeds to be ready for charring and burning. Such

things accumulate during the season, and we generally set fire to the heap when there is no one particular about the place, or when the wind is in the right direction for taking the smoke away. Bad weeds, as the Bindweed or white Convolvulus, &c., are generally taken to such a place during the summer, for when charred, or burned, there is no chance of their growing. Such weeds, grass, odgings of walks, &c., generally cover the heap before any refuse or worthless soil is added, and when all that is possible is charred, the rest is burnt up with such earth and forms a good addition to heavy soils. Before making up the heap the best of the rubbish, prunings, &c., is selected for small handfuls of wood for lighting fires, which are generally kept under cover. These bad-rooted weeds, and a few that may be showing seed, are, as a general rule, all we care about moving out of the garden. Others, cut up when young, will generally find the sun too much for them. We have proved over and over again, that the troublesome though beautiful white Bindweed, which if left to itself will soon cover a garden with its long white roots, every bit of which will grow, may be thoroughly destroyed if every shoot is cut with the hoe by the time it is 2 or 3 inches long, but the shoots must not be missed or ever allowed to grow. We believe that lots of it sprung up in the garden from some pieces of roots being long ago taken to the general rubbish heap (of which we are careful as manure), and being from thence wheeled back to the garden and dug in for different purposes; the smallest bit of the white stringy roots is almost sure to grow and increase as rapidly below ground as the top does above it. There is scarcely anything that runs so quickly either above or below the soil.

Many bad-rooted weeds, such as the Nettle, may also be eradicated by constantly cutting the tops when young. Cutting once or twice a-year will not do, though that will weaken the roots. Digging the ground to pull out the roots will be of little use if they are not taken out very clean. The Nettle generally attends the footsteps of man. By the sides of roads, amid the ruins of old buildings, and in neglected worn-out gardens the Nettle has its appropriate home. Whatever there may be of the cheering about it, as thus associated with man and his doings, is, however, more than counterbalanced by the tale it tells of carelessness and neglect. Some of our vegetarians have much to say in its favour in a sanitary and a nutritive point of view, and there are worse vegetables than very young Nettles nicely hoiled, but, unfortunately, the lovers of the Nettle may find plenty of it without as yet having any necessity for growing it in gardens. Where even the spade and the fork have failed to destroy the intruder, the scythe and the hoe frequently during the summer settled the matter. Many of the worst spreading perennial weeds will in time be destroyed below ground if they are allowed no rest or leave to expand above it. In most gardens some of these will escape our notice until the growth above, by reproduction, has increased the strength of the roots and stems below. Many of our keen villa and amateur gardeners could easily amuse themselves with a spud or a small sharp Dutch hoe where they could not well be expected to labour with a spade or a fork, and these little tools persistently used will do wonders in eradicating our worst weeds. The best place for Nettle roots, if dug up, is the charring and burning heap.

#### FRUIT GARDEN.

Took the last of the clearings from a piece of Strawberries, to be thrown over the charring rubbish-heap. A good many leaves had become brown from the heat, and if any thrips or red spider should be on them the heated heap will be the best place for them. This season we have noticed lots of the red spider on pastures, and on the trees of young plantations. Moisture and coolness at night we look upon as the great enemies of this little pest under glass. The coolness at night, so refreshing to many plants, is very detrimental to insect life that rejoices in a high temperature and a dry atmosphere during the day. Other preventives and deterrents, as sulphur fumes, must also generally be resorted to.

Went over again all Strawberry plants in pots, removing all runners close home; but they had been so picked off that there were only comparatively few to remove. The great object now should be to concentrate the strength of the plant into the crowns, and to mature them as much as possible. The weather, until this week, was so hot that a good deal of watering was necessary; but now if much rain fall the plants would be better to be protected from it, and if other means cannot be resorted to, the pots may be laid on their sides: we shall shortly do so with the earliest that we shall use first.

Will gather almost all but the very latest Apples and Pears

as soon as the weather shall be thoroughly dry. Examined what had already been gathered, and removed all rotting and specked fruit. Soft early Apples should rarely go to the fruit-room, but be kept in a place by themselves until used up. If the fruit-room is kept airy at present, so as to thoroughly dry the fruit and take off the exhalations of moisture, the place may be kept pretty close in winter, and thus prevent the chance of shrivelling. Some of the best late fruit of Apples and Pears keep longer plump and sound if each is wrapped in paper, and packed in dry sand in little barrels or earthenware vessels. They often come out in spring as plump as on the day in which they were gathered.

Could we find time we would prune the trees that were pinched-in in summer, as it would concentrate the juices of the trees more, and the work is much more pleasantly done now than in cold days in winter; but there are always plenty of jobs jostling each other.

Preparations should also be made for planting fruit trees, by removing old soil and giving fresh, or at least as much as will furnish an elevated station, and securing drainage where needful. Some stiff soils need little drainage owing to marl with the clay in the subsoil, which opens a passage for the water. Putting a lot of rough stones below a station for a fruit tree in a close subsoil, through which the water does not easily pass without draining, is nothing less than securing a reservoir of water beneath the roots, and encouraging them to strike down every dry season. It would be well did we oftener recollect that great luxuriance and great fruitfulness will ever be in an inverse ratio to each other. If we want an Oak to tower up nobly we must let it root deeply, and the better and deeper the soil the freer and quicker the growth. Were we to treat a Pear tree in the same way, we might expect the fruit to gladden the next generation. By shallow planting and keeping the roots near the surface, at times giving rich surface-dressings, and pruning roots when necessary, fruit may be obtained two or three years from the time the tree was grafted.

Our last Peaches from the lean-to orchard-house will be used before this is printed. It is quite true, as Mr. Rivers suggests, that we have had no such large houses as his to manage, but what little has come under our observation confirms us in the proposition that such unheated houses, according to the kinds used and the treatment given, may be employed either for accelerating or retarding to a certain extent. Of course we cheerfully look up to Mr. Rivers as our best master in such matters, and we are well aware that the management of lean-to's must be something different from those huge wide span-roofed houses. To Mr. Rivers belongs the honour of demonstrating that in such large span houses side ventilation was so far sufficient that little or no roof-top ventilation was necessary, greatly simplifying the whole affair as respects fruit-growing. We much wished to have paid our second visit this summer, as no one should be content to sit still if he can by any means get on the line of progression. Our observations lead us to conclude that many failures in the smaller lean-to houses have been the consequence of not having enough of top ventilation, or not giving it early enough. If left on night and day there could scarcely be a mistake. The suitability of side ventilation almost alone for span-roofed houses has led some to be careless of top ventilation in lean-to houses, though these top-openings were there the chief means of safety.

ORNAMENTAL DEPARTMENT.

Very much the same as last week—cleaning, potting, making cuttings, &c., giving more room to Cinerarias, Primulas, &c., and collecting some fresh soil from the sides of the highway for planting Calceolaria cuttings next week. Some of the Calceolarias had made so little wood that had not flowered, that we gave them a watering a few days before the rain came. By-and-by we shall begin to take up some of the most tender bedding plants, as the beds will scarcely be so fine again after the rains and winds. Room! room! will soon be the outcry with us, and with every gardener whom we know. Few, indeed, can have a place for everything, and many compromises must be made before the middle of May comes round again.—E. F.

TRADE CATALOGUES RECEIVED.

John Scott, Merriott Nurseries, Crewkerne, Somerset.—*Descriptive Catalogue of Nursery Stock. Descriptive Catalogue of Fruit Trees.*

COVENT GARDEN MARKET.—OCTOBER 14.

SUPPLIES continue ample for all requirements. Some very good second-crop Strawberries have made their appearance, also green Figs, for which, however, there is not much demand. Some good specimens of Salway Peach are still to be had. Grapes are still very plentiful. Vegetables the same as in previous reports.

TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

HOGG'S FRUIT MANUAL (*A Fruit-Grower*).—The third edition is now passing through the press.

BUILDING VINERY (*Amateur*).—If you send seven postage stamps with your direction you can have "Greenhouses for the Maury" free by post. It contains drawings and directions for erecting such a structure as you require, and others still more cheap.

OAK TREE BLEEDING (*A Constant Subscriber*).—The constant oozing from the wound in your ornamental Oak probably arises from an ulcerated wound of the albumen. We should remove the bark over the wound down to the albumen, and if that appeared bruised or decayed, cut it away until we came to sound wood. A very sharp chisel or gouge should be used, so that the edges of the wound might be smooth. The edges of the bark should be also pared very smooth, and then the whole wound filled and covered with a plaster of equal parts clay and cow-dung. If the internal wound is very extensive it will be useless to cut away any of the wood, and we should merely apply the plaster to exclude the rain and air.

CATERPILLAR OF DEATH'S-HEAD MOTH (*A Young Entomologist*).—Your description is not sufficient for us to identify it. If the sides and under the head were green, seven oblique, lateral, violet stripes on it, the spiracles black, edged with white, horn yellowish, rough, turned backwards and recurved, it was the caterpillar of that moth. The chrysalis will not give birth to a moth before next July. Kept in the earth under a hand-light, or in a box of earth in-doors under a bell-glass will do. The caterpillars feed on the leaves of the Potato, Jasmnia, and "Tea tree" (*Lyceum afrum*).

LYCUM CUTTINGS OF GERANIUMS (*W. B. W.*).—Placing them on a mild hotbed would much encourage their rooting, if the atmosphere be kept dry or not so close as to cause them to damp off. Though by this means a greater number would root, yet they may be placed in a cold greenhouse, from which frost is excluded, fully exposing them to light, and keeping the soil dry rather than wet; they will there strike in about six weeks. The greatest obstacle in the way of striking Geraniums at this season is damp. In whatever position the cuttings are placed they cannot have too much light and air.

**WINTERING OLD BEDDING GERANIUMS (W. B. W.).**—We practise three plans or methods with ours. 1st. Any kinds of which we are short of stock we take up before frost, reduce the roots a little to make them go into the pots, pick off the old, yellow, and a few of the largest, leaves, and put the plants in pots proportionate to their size. This we do with all kinds of variegated Geraniums, and never shorten the shoots at all, being content with removing any straggling growth. The plants are potted in maiden loam, the top spit of a pasture without any admixture of leaf-mould or other ingredient, unless the soil be strong, when we add sand to make it a sandy loam. They receive a good watering after potting, and during the winter no more water than is sufficient to prevent their drying up. Placed in a dry airy house with no more fire than to keep frost out, they only need the dead leaves to be picked off. In March each plant gives a number of cuttings, which are made then as they usually are in autumn. The cuttings being inserted and placed in a mild hotbed make plants equal to autumn-struck cuttings of those kinds employed for their foliage, and of the flowering kinds for blooming in August and September. The old plants soon shoot afresh, when they are potted in a compost of turfy loam two-thirds and one-third leaf-soil, giving a pot proportionate to their size, the largest being placed in No. 1 pots. These plants are fine for cool conservatory decoration all the summer, and we employ them for circles in pannelled borders, as we find it easier to have a symmetrical circle a yard wide from one plant than were three or more employed. They also produce an effect at once by simply plunging the pots. The smallest are excellent for vases and similar purposes; those not growing then in this manner can form no idea of the fine specimens they make. 2nd. All those Geraniums which we wish to preserve, except those wanted for specimens and all the variegated class, we take up after the first frost and cut down, taking out all the old wood possible, but leaving the young shoots unshortened unless very long, when they are cut-in. These we pot, after shortening the roots, until our stock of pots is run out. We then resort to boxes, and pack the plants closely together in the same soil just moistened. The variegated class are treated in the same manner with this difference, that as we begin with them they are always potted, and the shoots are not shortened, all knife work being confined to removing straggling growths. In this way they are kept, with very little water in winter, in a light airy house secure from frost. 3rd. Those that cannot be accommodated under glass are placed close together in boxes of very sandy and half dry soil, taking off every leaf of any pretensions to the name, and then we put them in a dry place just warm enough to be free from frost, and yet so cool as not to excite growth. There they remain until the end of March, when they are placed in a frame, cool greenhouse, orinery, and they soon become green and shoot afresh. The plan recommended by Mr. Fish so far back as 1855 is an excellent mode of keeping old plants over the winter.

**SHOOTS FOR CUTTINGS, AND COMPOST FOR GERANIUMS, &c. (A. B. C.).**—We like the moderately strong shoots—strong certainly, but not very gross, and from 4 to 6 inches in length, and always with the growing point attached. In fact it is the growing points or shoots that are available for cuttings. The extremely weak and very gross shoots are not desirable, inasmuch as the former, though they root freely, are a long time before they make strong plants, and the very strong shoots are very liable to damp off, and take up too much room in the cutting-state. For potting Geraniums, and all soft-wooded plants, we use two-thirds turfy loam and one-third well reduced leaf-mould, with a free admixture of river sand if the loam does not contain enough sand. Your gardener's using turfy loam is good, but we do not see the value of the bog soil, for Geraniums naturally do not grow in bogs. Though a little of it is no great evil, yet we think it quite unnecessary. It would be better used for Rhododendrons and other bog plants. Leaves a year old will so far from retarding growth promote it more than were they more reduced, but we prefer leaf-soil well reduced for Geraniums, as we do not care so much for a strong coarse growth as for a strong close growth likely to give abundance of bloom. The leaf-mould would certainly be better if freed of the mast of Beech and the cups of acorns; and sticks of all kinds should be rigorously excluded, for they cause funguses in the soil.

**FRUIT TREES FOR BUSH OR PYRAMID FORM (Young Amateur).**—Apples—Dessert: Melou Apple, Ribston Pippin. Kitchen: Bedfordshire Foundling, Cox's Pomona. Pears—Bourre Clairgean, Bourre Baehelger, Bourre Diel, Duchesse d'Angoulême. Plums—Kitchen: Victoria, Prince Euglebert or Pond's Seedling. Dessert: Jefferson, Belgian Purple. Cherries—Monstrous Heart, Black Tartarian, Nouvelle Royale. The Apples should be worked on the paradise stock, the Pears on the quince stock. Fruit of equal size may be obtained from either bushes or pyramids.

**PROPAGATING STEPHANOTIS FLORIBUNDA (A Subscriber).**—It is propagated by cuttings of the half-ripened wood cut off immediately below a joint, short stubby shoots that grow but a few inches long being the best. These, taken off close to the blue or branch from which they spring, will have a kind of heel, which should be made quite smooth. Insert the cuttings singly in small pots to one-half their length, previously removing the leaves for that distance. For soil use very sandy peat or one-third peat and two-thirds silver sand. Let the base of the cuttings rest on the silver sand. The soil being moist only a little water will be needed to settle it about the cuttings. Place in a bottom heat of 80° or 85°, and, if the atmosphere be dry, cover with a bell-glass; if moist, and a little shaded, this is not necessary. Keep the soil just moist, and in about six weeks the cuttings will be well rooted. Gradually harden off or draw from the bottom, and, when hardened off, shift into larger pots and grow on in the stove. Cuttings are best taken off in the early part of the year if they can be had, as such strike much more freely than later in the season.

**SHRUBS FOR POTS IN FLOWER-BEDS (Chadlington).**—*Andromeda floribunda*, from its dwarf compact habit, and evergreen foliage, with its flowers of delightful fragrance, is of all plants the finest for the purpose. *Berberis Darwinii*, with handsome deep green Holly-like foliage, and golden flowers in early spring, is the second best flowering plant for beds. Then there are Box, both green and variegated; *Hollies*, green-leaved, and gold and silver variegated; common Yews as dwarf bushes, pyramids, and standards; the upright Irish, Weeping, Davostan, and the very distinct *Taxus adpressa*; *Laurustians*; *Portugal Laurels* as dwarf pyramids and standards; *Common Laurels*; *Peroettya mucronata*; *Acubas* in variety; and dwarf early-blooming *Rhododendrons*. Among the Conifers, also, there are numerous subjects of the most graceful habit, and having foliage of different hues, which may be made available for the purpose.

**TAKING UP GOLDEN CHAIN GERANIUM (Agnes).**—Take the plant up without breaking and disturbing the roots more than can well be avoided, and remove from the roots any soil at all loose, but that closely matted with roots should not be disturbed. Any very long straggling roots may be shortened, the better to enable you to get them into pots sufficiently large to contain them properly. A six-inch pot will be large enough for a good-sized plant. It is not necessary to take the plants up with balls of earth to the roots, but they are better of a little soil adhering to these.

**PRUNING VINES (An Old Subscriber).**—You may prune the Vines immediately after the leaves fall. You should have stopped the late laterals to one joint from whence they rise, and we would do so at once. They shade the house and prevent the wood hardening. There is no necessity for keeping the house at 45° on account of the large Lemon tree at one end, unless you wish to ruin the Vines for the sake of it. It will do well if the temperature is not allowed to fall below 33°, providing it is kept moderately dry at the root, yet healthfully moist. For forcing in January the Vines should now be at rest, and be pruned next month. Your border may now be covered with a foot of dry litter, higher over the collar of the Vines, unless the border slope, so as to have the surface sloping to the front and the boards upon it. A fortnight before commencing to force, the border should be covered with hot dung, leaves, or other fermenting materials, to stimulate root-action before leaf-development takes place, and this covering should be renewed to maintain a slight heat until the sun has sufficient power to heat the border.

**DICKSONIA ANTARCTICA CULTURE (Squib).**—Your plant will lose its old fronds more or less throughout the winter, as it, from your statement, is now doing, the lower fronds withering and going off. They ought not, however, to wither but to die off yellow. Your syringing will only tend to aggravate the discoloration of the fronds. Syringing is not necessary at any time if a moist atmosphere is maintained. At this season dryness, rather than moisture, is essential to preserve the fronds in good condition and healthy in appearance. The air suitable for ordinary greenhouse plants will suit the *Dicksonia*. Discontinue syringing, though you may resort to it occasionally to free the fronds of dust. Do not water so copiously at this season as when the plant is growing more. From the present appearance of the plant we do not think you have anything to apprehend, and therefore would advise your keeping it in the tub moderately moist. If you could have it planted out in a prepared border of turfy brown peat two-thirds, and yellow loam one-third, with large pieces of sandstone in it, providing good drainage, it would in a year or two quite astonish you. A circular pit of 6 feet in diameter is not too large for this plant, and, being edged with rock stones and smaller Ferns and Mosses growing on and amongst them, it would be a pleasing feature. Six inches of cocoa refuse placed on the surface might be covered with Mosses. *Hymenophyllum* and *Trichomanes* might also be grown, they being furnished with a suitable soil, and sprinkled with water twice daily, or oftener if needed. The *Dicksonia* would afford them an agreeable shade without that close stagnant air found under a bell-glass. For so large a specimen the box is very much too small, it should have a larger one, or, better still, be planted out in the centre of a not very narrow house, otherwise the fronds will come in contact with the sides. We have had a plant with a head 15 feet in diameter on a stem much shorter than yours and less in diameter.

**HOT WATER PIPING REQUIRED FOR GREENHOUSE—JOINING GLAZED TILE PIPES (J. S.).**—Your proposed greenhouse, 12 feet by 9 feet—a lean-to, 2½ feet in front and 10 feet at back, will be satisfactorily heated by flow-and-return three-inch pipes along the front and both ends, omitting the doorway at one end. For joining the pipes first run a piece of tarred rope into the opening between the pipes pretty tightly, and then another unstranded piece of rope, but slightly twisted and untarred, drawn through some thick red lead paint, and ram this quite tight with a thick-pointed yet thin chisel, finally filling up the joints with Roman cement.

**BUILDING A CUCUMBER-HOUSE, VINERY, &c. (J. S.).**—You do not give us sufficient data to enable us to answer your questions satisfactorily. We would say 1st, that this is a very good time for putting up new houses, and if bad weather set in the painting could be deferred until spring. 2nd, If the same boiler is to heat the new houses as well as the old, would it not be well to be guided by the width of the old houses in forming the new? Your greenhouse seems to be 18 feet, which would be a great width for a Cucumber-house, but the length might be all the less. A nice Cucumber-house might be span-roofed, 12 or 14 feet wide, 5 feet high at sides, 9 feet in centre, with a bed on each side, and a pathway in the middle. These beds would hold plants in winter, and a spar shelf could be suspended over the pathway. A good lean-to Cucumber-house might be made 8 or more feet wide, 3 feet high in front, and 10 or 12 feet high behind, with bed in front, and plants trained within 15 inches of the glass. Such a house could have a stage in winter. The same remarks apply to vineries. If you tell us the plans you propose we will say which will answer best. Then, 3rd, as to the expense. If there is no wall against which to place the houses, then a span-roof will cost less at first than a lean-to, just because wood and glass are cheaper than brick and stone. If you wish, however, to keep up a high temperature, the span-roof will cost more for fuel than a lean-to enclosing the same space. 4th, In either case the cheapness of such houses will depend on having all the glass and wood fixed, except what is used for ventilators, and using largish squares of glass between the rafter sash-bars, much in the same way as Mr. Kivers employs for his orchard-houses. The size of these rafter sash-bars must depend on the length of the rafters and the width between them. If the width is 20 inches between rafter and rafter, and the length 14 feet, then the rafter should be 1½ inch thick and 4½ inches deep. If only 12 or 15 inches between the sash-bars, then 3½ to 4 inches would do in depth. If the width between were from 12 to 14 inches and the length of rafter 9 feet, then 3 inches in depth would do. And lastly, if economy is your object, when the plan is decided on it will be the cheapest mode to have all the wood cut to size and planed by machinery; but whether it would be best to have a builder do all the work of building, or have it done under your own supervision by village carpenters, will depend on the circumstances of the case and the aptitude of the carpenters for such work. Generally speaking, a man knows his own business best, and much is gained by the division of labour. We do not like to specify builders; but some of our best do not care much for these fixed roofs, but prefer rafters and sashes in the usual way, and of course they must cost more. The patent metallic houses lately alluded to will be economical in the end, though costing more at first.

**VINE LEAVES TURNED YELLOW (W. E.).**—The cause is evident. Your border is rich—probably too rich—for the leaves are very large and robust; growth, consequently, was continued longer than usual, and now that the colder season prevents so abundant a supply of sap, ulceration (shanking) of the fruit-stalks and yellow blotches (not natural autumnal fading) are the consequence. If you give more air next year, and have the surface of the border covered at night during the early autumn, and in summer during cold weather and heavy rains, the evil will be avoided.

**AUCUBA BEARING BERRIES (An Old Subscriber).**—Write to Mr. Standish, Royal Nurseries, Ascot, and tell him what you require.

**FORMING A HOUSE OF OLD GLAZED LIGHTS (E. L. W.).**—The plan you propose will answer very well, and the houses will be very useful whatever the height of the side walls. The economy of your three houses thus placed side to side will be that four walls, four wall plates, and four water-spouts will do for the three houses. The two middle wall plates may be hollowed out and pitched, to receive and take off the water. If economy is the chief object, these walls may be from 34 feet in height, and if there were a double ridge-board, with space for ventilating between, the sashes could be fixed, and little or nothing in the way of rafters would be required for 10-foot-wide houses.

**GLASS FOR VINERY, &c. (J. Roberts).**—We have no doubt the specimen of glass enclosed would do very well, and especially for plant-houses, but for fruit-houses we would prefer clear glass, equally thick.

**GLAZING A VINERY (N. F. H.).**—For Vines we like clear glass best. Supposing the pipes to be close to the windows, we would prefer planting the Vines more within the house. The Vine stems should be a foot or 18 inches from the pipes if possible.

**EARLY FORCING OF STRAWBERRIES (J. B.).**—To have Strawberries ripe on the 1st of March, you would require to have nice plants in pots, the pots full of roots, and buds well swelled and ripened. Take these about the middle of the month and place on a north aspect, and keep from rains to rest the plants a little. If wet enough, and no protection be handy, turn the pots on their sides with the plants facing the north. Protect them from more than 2 or 3 of frost. About the end of November clean the plants by removing withered leaves, stir the surface soil, remove a little, and add a surfacing of rich compost, and place the plants about 1 foot from the glass where you intend to force them. Be careful that the plants have no stagnant water, and especially before they are in bloom and the fruit set. The place may be a frame, a pit, or a house, but much bottom heat should be avoided, and until the plants show bloom, the soil should be dryish rather than very damp, but not so dry as to hurt the plant. For the first fortnight do not let the artificial heat exceed 45° in the second fortnight raise the temperature gradually to from 50° to 55°, and not above 60° until the fruit be set, when you may raise it gradually, from 5° to 10° more if you wish to hurry the fruit. With sun heat and air given early the temperature during the day may be from 10° to 15° more, and in cloudy weather from 3° to 5° above the artificial temperature.

**GRAPES SHRIVELLING (R. D. J., Jersey).**—Not knowing where the Vines are not how cultivated, how can we form any opinion of the cause of the Grapes shrivelling?

**NICKER NUTS (J. C.).**—They are produced by the Nicker tree, Guilandina Boudac, and are powerfully tonic. We believe they may be obtained of the principal London druggists. Of the Plantain Bougies we know nothing.

**HONEYSUCKLE FOR A RUSTIC PILLAR (An Amateur).**—You could not have anything better in the way of Honeysuckle for the purpose wanted than the common one, or Woodbine. If well manured and watered, it will bloom not only in summer but through the autumn. To be sure of blooming in autumn as well as summer, and growing freely, we would prefer *Lonicera frut.*, or Evergreen Honeysuckle, the leaves remaining for a part of the winter. It blooms also freely. It has not so much yellow as the common Woodbine. You give us no idea of where you live. Except in Devonshire, &c., we should hardly expect the *Chionanthus* and *Passiflora* to stand out of doors with a few ashes over the roots; but considerably north of London the *Bignonia*s named, and the *Passiflora* certules, will do with little or no protection. From the midland counties northward the plants, in addition to ashes over the roots, would be better of a mat or evergreen boughs over the branches. We do not know of such a French work as you require.

**FRUIT SENT TO THE ROYAL HORTICULTURAL SOCIETY (E. S.).**—Whether your box was received, and, if so, why the fruit was not exhibited we cannot tell. You must write to the Assistant Secretary for the information.

**PEAR FOR EAST WALL (H. F., Ely).**—A large dessert Pear to be ripe by December on that aspect would be Duchesse d'Angoulême.

**BOOKS (R. C. P.).**—The work, so far as we are aware, has only reached a third edition.

**POTTED GERANIUMS ON A VINE BORDER (H. E.).**—The roots coming through the holes in the pots would certainly impoverish the border. Unless the pots were very close and small, and the plants large, the roots would do no great harm, but if the contrary they would prove injurious by impoverishing and shading the border.

**ROSES IN POTS (Idem).**—Place in a sheltered yet open situation, plunging the pots to the rim in coal ashes. If not yet potted this should be done at once if needful. Prune the Roses in November after the greater portion of the leaves have fallen, and place in a cold frame or pit, plunging the pots to the rim in ashes. Protect from heavy rains and severe frost; from the former by drawing on the lights, and from the latter by a covering of mats. Here they may remain until wanted for forcing. Introduce them into a cool house at first, with abundance of air and all the light practicable. Begin with a temperature of 40°, gradually increasing until 50° be attained when they are in leaf, and give a temperature 5° higher to bring them into bloom. Unless they are strong, and have well-ripened wood, the bloom will not be fine.

**POTATO DISEASE (C. Innes).**—It is due to the Fortyfolds being an earlier Potato than Regents that the disease has shown itself sooner in the former. We found our Ash-leaved Kidneys much diseased when taken up, whilst Myatt's Prolific, Jackson's Seedling, and Lapstone, taken up at the same time, were free from the disease, but we now find all equally bad.

**ICE-HOUSE (J. McL.).**—There is no book upon the subject, but if you enclose four postage stamps with your direction, and order No. 173 of our Journal, you will find in it a drawing and directions for forming an ice-house.

**THRIPS ON FERNS (Mr. T. L. Taylor).**—Choose a still or calm evening, and with the atmosphere of the fernery dry, and the fronds dry also, shut the house up closely, and fill it quite full of tobacco smoke, so that a plant cannot be seen from the outside. Syringe the plants in the morning; and, not on the same night but on the following one, fill the house again with tobacco smoke. Let the plants stand a day and then syringe. This will kill all thrips at present existing, but it will not destroy their eggs. Watch for the reappearance of the insect, and smoke again with shag tobacco, or good tobacco paper will do. Be sure that the fronds are dry, and do not fumigate too hard, or they will become brown, and be destroyed by the smoke. Your Ferns being greenhouse kinds it is not necessary to use fire heat, except to keep the temperature at 40°, and to cause a circulation of air in damp weather. For stove Ferns the temperature should be from 50° to 55° at night. (L. L.).—The frond of *Platyloma adiantoides* or *Pteris hastata* is infested with thrips. The insect is encouraged by a dry atmosphere, and it is most troublesome in an atmosphere too warm and too dry for the species. The first step to root out the enemy is to cut away all the worst infested fronds and burn them, and then to fumigate as above directed. Keep the house moist by sprinkling the floors, &c., twice daily, morning and evening, and fumigate whenever you find a very thin black insect beneath the white places on the fronds. You will sometimes find it on the upper side also. Do not overdo the fumigation; just fill the house with smoke, and repeat the operation on alternate nights rather than smoke too hard one night in the hope of killing the pest at once, for by doing so you may kill many of the fronds, especially of the *Adiantum* family.

**WINTERING CINCERARIA MARITIMA (Ler.).**—You may keep them over the winter in a cool dry airy part of the greenhouse, giving no more water than is sufficient to prevent their flagging. They do well under the same treatment as *Geraniums*. The tubs being well drained, and the soil light and porous, we do not think that you have anything to apprehend, only keep them in a dry, cool atmosphere, and no more than just moist at the root.

**REMOVING GREEN FIGS (C.).**—We should think your climate warm to ripen Figs on a west aspect. The reason the crop on the west was small, and that on the tree on the south aspect abundant, is that the greater warmth of the latter ripened the wood more fully. You may pick off all the fruit about half swelled, but those of less size should be carefully retained. Were you to leave all it is probable that a few might ripen a month to six weeks earlier than usual; but it oftener happens that they fall in spring just after the appearance of the leaves.

**BED INSIDE A GREENHOUSE (Idem).**—Your bed would look best planted with Tulips, Hyacinths, and other bulbs. You might have for instance at back a row of different kinds of early Tulips, as Pottebakker, white; Belle Alliance, Sunbeam, both scarlet; and double Duc Van Thal, and Tournesol; and then two rows of Hyacinths, red, blue, and white, edged with Crocus, yellow, blue, and white, with a few Snowdrops, and Scillas to give variety. Now is the time to plant them, the earlier the better.

**POTTING WEAK YOUNG VINES (C. Innes).**—Pot them in February, shaking most of the soil from the roots, and disentangle these if possible without breaking them. Use pots 9 inches in diameter, drain them well, and employ a compost of turfy loam, that from rotted turves is the best, and if cut 3 inches thick, and about half rotten or decayed, it could not be improved upon, except by mixing with it when laid up to rot one-third of manure. Pot an inch or two lower in the pot than they were the year before, and spread out the roots towards the sides of the pots. Cut the Vines down to three eyes, and when they have grown a few inches make choice of the strongest, rubbing off the others. Train this upwards to a stake, and when the laterals show stop them at the first leaf. Syringe morning and evening, and keep well supplied with water, but let the soil show signs of dryness before giving any. Upon no consideration must they be allowed to suffer from the want of it, neither will they root well if the soil be kept in a saturated condition. In June, or early in July, the roots will be matted round the sides of the pots; shift the Vines forthwith into thirteen or fifteen-inch pots, draining well, and using the soil as before. If a quart of half-inch bones were added to the soil required for each pot and mixed with it, half being placed at the bottom of the pot over the drainage, the effects on the growth would be apparent in that and the following year. If you could train the canes 15 inches from the glass all the better. Stop the laterals as before at the first joint, and at every joint after the first until the canes are 10 feet long, then take off their ends. The laterals will grow rapidly, but never head them until the middle of September, when their length should be gradually reduced, and finally cut them away quite close early in October. Whilst growing, water at every alternate watering with weak liquid manure. After the middle of September lessen the supply of water, and discontinue it when the leaves turn yellow. Keep the Vines clear of red spider and they will bear fruit in the year after.

**NAMES OF FRUIT (J. F. R.).**—The Apple has never appeared, or if so there was no indication whence it came. (Q. S.).—Plum—Coe's Lato Red. Apples—1 and 4, Hollandbury; 3, Keswick Codlin; 5, Shepherd's Seedling; 7, Ord's Apple. (J. Hall).—1, Louise Bonne of Jersey; 2 and 3, Beurr' Die; 5, Althorp Crassane; 6, Beurr' de Capiaumont. (W. N.).—1 and 6, Beurr' Bosc; 2, 8, and 5, Dumelow's Seedling; 4, Blenheim Pippin. Glon Morecau, Knight's Monarch, Easter Beurr', Beurr' de Rance, Ne plus Meuris, and Josephine de Malines grown as pyramids, and Passe Colmar on a wall if the situation is much exposed. (J. J. B.).—2, Beurr' Gris d'Hiver; 4, Calchasse; 5, Brown Beurr'; 7, Gansel's Bergamot; 8, like Beurr' Bennett; 9, Easter Beurr'; 10, Van Moos Léon le Clerc; 11, Comte de Lamy; 13, Louise Bonne of Jersey. (Mr. Watson).—Flemish Beauty. (G. H.).—Holland Pippin.

**NAMES OF PLANTS (W. G. B.).**—We cannot undertake to name plants from leaves only. (Aethea).—It is *Asplenium bulbiferum*, an Australian and New Zealand Fern. (A Keatish Man).—1, *Pteris serrulata*; 2, *Cyrtomium falcatum*; 3, *Scalaginella pubescens*; 4, *Doodia caudata*; 5, *Adiantum pubescens*; 6, *Pteris hastata*; 7, *P. longifolia*; 8, *Asplenium ebennum*. (A Constant Subscriber).—*Athyrium Filix-ferma*, *Blechnum occidentale* var. This will not survive the winter out of doors. (W. F.).—*Onychium lucidum*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending October 14th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.				
			Max.	Min.	1 ft. dp.	2 ft. dp.			
Sun. . . 8	29.509	29.377	70	43	56	56	S.E.	.14	Heavy rain at 6 A.M.; hazy; overcast at night.
Mon. . . 9	29.384	29.283	72	43	57½	57	S.E.	.79	Showery throughout the day; heavy rain at night.
Tues. . 10	29.298	29.253	66	51	57	56	S.W.	.58	Foggy; cloudy; frequent heavy showers; warm at night.
Wed. . 11	29.283	29.190	64	48	57	59	S.W.	.10	Partially overcast; heavy clouds; sunshiny and showers alternately.
Thurs. 12	29.520	29.437	64	27	54	57	S.W.	.00	Fine; rather windy; fine; frosty at night.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BETTER SUPPLIES FROM THE POULTRY-YARD.

We left off before with advice to poultry-keepers to be followed in the event of the appearance of a poultry pest. Let us hope the change in the weather will avert all such visitations. We must not, however, forget to use every possible means to increase our stock, and to make it as profitable in every way as may be. Day after day the newspapers seem to be casting about for something to add to the stock of food. It seems to be almost an accepted fact with many, that the day is not far distant when it will not be a question of price about the supply of meat, but when there will not be enough for all. Is the problem of the clever French writer and statistician being realised? He affirms that every human being during his life takes from the earth more than he returns to it; that Europe has arrived at the acme of production, and must perforce remain stationary, while population hourly increases. He points to the sea as a resource. So much the better for all but the fishes. We wish to point to poultry, to increase the present supply, and to make that which we have more valuable as food. The first step towards getting fowls is to have eggs, and the greatest increase in poultry will be to have chickens and eggs all the year round, instead of having them only in the natural season. The next will be by means of cookery to make that which we have capable of feeding more people. A hen is a benefactress, because she is continually providing food in a most delicate and delicious form, without losing any of her own valuable properties except youth. A pullet lays her first egg when she attains a certain age, let that happen when it may; but after the first laying she falls into the beaten track and lays only at the natural time. In order, then, to have chickens all the year round, we must have a succession of pullets to lay the eggs that are to produce them, and as sitting-hens are often vainly wished for in winter, we must adopt the best substitute we can in the way of hatching-machines, which are now coming before the public in "such a questionable shape," that we expect to find them in general use and duly appreciated. But if our supply is to be derived from pullets only, and they are to be discarded when they have reared their first brood, we shall have kept them till they have passed from chickens to hens, and are supposed to be too hard for the table. They are so, if we confine ourselves to the old heresy that there are only two ways of dressing food, roasting and boiling; but it is here that cookery is valuable. The fowl that has done laying, or that from any cause is apparently useless, may be made to provide a savoury dish. The old cock or hen put down to the fire, or into the pot for the proper time, only becomes harder; but there are other ways of making them valuable and wholesome food. Take, for instance, the French *pot-au-feu*, that national comfort known to every woman from the top to the bottom of the social ladder. The old hen is here the chief ingredient, she contributes strength and flavour. Instead of being thrown in whole, and boiled as if for dear life, she is cut up into small joints and allowed to simmer for many hours, till her flesh has become soft and tender, and, leaving the bones, passes into pulpy food. For delicacy of flavour, and for much of its strength, the *pot-au-feu* is indebted to poultry; not only that which forms a fowl when it comes on the table, but every other eatable part—the neck, head, gizzard, liver, heart, and the feet. These in France are bought by the "easy" classes who live on their incomes. In large towns and in the metropolis of England, they are bought by the lower classes

only, who for a few pence get enough for a copious and savoury family meal.

That terrible roast and boil, and the dislike to what some persist in calling "messes," have a great deal to answer for. They contrive to make the largest quantity of meat do the least possible service in feeding. That "pot on the fire," always there, is the receptacle for all that is eatable—the broken bones of all sorts; the scanty cheap piece of coarse beef cut up in small square morsels; the carrots, turnips, leeks, and potatoes; where meat is scarce, a little piece of dripping; in the spring when peas are first in pod, a dozen pods put in for flavour, run through with a needle and thread, that they may be easily removed. We are speaking now of a cottager's cookery. The fire consists merely of the embers of wood, or the ashes of peat and turf, so that the pot may remain without fear of boiling; a slight steam escapes from the partially open lid, but as the hour of dinner arrives, and the husband is expected, the lid is at times removed and the fragrant smell of the contents diffuses itself about the kitchen. This must be, and it is a better meal for the family than the little piece of coarse beef, affording scarcely a mouthful to each. It is the difference between England and France in cottage cookery. But some may not like soups, and will ask [us what is to be done with the old hen or the cock. We have told them before, and we will repeat it. Cut the fowl up in joints, dividing at the joints that there be no splinters of bone. Gather together all the scraps of meat you have, those that adhere to the bones, odd pieces of ham or bacon, knuckle, or leg, or shoulder of mutton; cut a few slices of fat bacon and bread; get an earthen vessel with an earthen cover, of course having a small hole in it; at the bottom of the vessel lay a layer of bread, then one of bacon, and then begin to fill in with all the scraps and joints you have—nothing is too common that is sweet and clean. Go on in this way till the vessel is full. Fill up the hollow places with water, put on the lid, and tie it down. Let it be put at night in a slack oven, and remain there till the morning. Stand it in a cold place, and when thoroughly cooled eat it for dinner, breakfast, luncheon, or supper. You will find it tender, succulent, and savoury. The water that was poured in is become jelly, and the whole will cut out like brawn or red-coloured marble. In any other way the old fowl would have done little; but this is not working man's cookery.

POULTRY SHOWS IN THE OPEN AIR—MR. HEWITT FOR BIRMINGHAM.

I HAVE only just now noticed a letter in your Journal of August 29th from our eminent poultry Judge, Edward Hewitt, Esq.; and as it contains, like the majority of his valuable letters, so many important matters in reference to poultry shows, I cannot let it pass without giving my endorsement to the truth of his remarks.

For some weeks past I have been so thoroughly engaged with other matters than poultry that your valuable Journals have been reluctantly neglected; but now the pressure of business is over, the shortness of the days rapidly encroaching, and the length of the evenings daily extending, it affords me, like many others, greater scope for reading, and the past Numbers of your Journal were with me, as with any other man who feels the interest in poultry which I do, the first periodical to be read.

I must say whenever I see a letter in your Journal from Mr. Edward Hewitt, it acts with me as the tip from the training-stables does on a racing or betting man—he has his eyes opened to what is going on at head-quarters, and similarly Mr. Hewitt's

letters open my eyes to poultry matters, and what is going on at a distance. Mr. Hewitt's remarks are found by long experience to be truthful, and full of sound good advice. I, with many other poultry amateurs, feel that we are much indebted to him. Again, referring to Mr. Hewitt's letter, I have had so many valuable birds that suffered from such exposure at the shows he refers to, that I have quite made up my mind never to send to any show that does not provide covering to shelter the birds from rain and sun. At one show recently held, my birds, which had gained the first honours at a show only the previous week, were unnoticed, and the cock bird, a very valuable one, has since died. I well recollect the Cochin cock of the late Mr. Geldard, and the facts referred to by Mr. Hewitt, and I think those who would have their shows successful must act upon the useful hints given by him, otherwise such shows will fall to the ground. If we carefully examine the list of poultry shows that take place during the year, we find that there are a great many that have been established for many years, and which are regularly held every year. These shows are known to be well managed, are held in large rooms, or spacious marquees, and every possible attention is bestowed upon the birds, and they pay well, from the simple fact that exhibitors know that their stock will be taken care of. Let others follow their example, and doubtless their success will be equal.

Before concluding, there is one important matter I wish to refer to—the most important I think of all that concerns poultry exhibitors just now—Are we to have the assistance of Mr. Hewitt as one of the Judges at our next Birmingham Show? Exhibitors should not let this matter rest, for in a very few weeks it will be “yes” or “no;” and I do trust every exhibitor, who feels an interest in this important question, will do as I have done—address a letter to the Council, praying of them to add Mr. Hewitt's name to the list of Judges. It is something lamentable to think of that one of our very best and most honourable Judges should be excluded from the list. I trust it may not be so, or I feel sure it will prevent many from exhibiting.—AN OLD EXHIBITOR.

#### CALNE POULTRY AND PIGEON SHOW.

WHEN an essayist of a past generation once wished to describe a man living in a very out-of-the-way part of England, he said of him that he lived “at Calne in Wiltshire.” If this were true then, which I much doubt, it is true no longer, for straight up to the town runs the railway. But was it ever true? Calne nestled in the last century, as in this, under the shadow of Bowood; and happily in England, every great noble's residence is a centre of light and intelligence to a surrounding district, and more particularly to that nobleman's borough. This was especially true of the late and great Lord Lansdowne, who drew around him at Bowood prose writers, poets, artists, and men of eminence in the literary and scientific world; and as to Calne, through him it had for its representative in Parliament at one time Lord Macaulay, and now has one who stands in the front rank of statesmen, the eloquent and sagacious Robert Lowe. Last week, while journeying thither in company with many a lover of flowers and birds, I noticed in the same carriage a clergyman intently reading “our Journal.” I inwardly blessed that good man. I felt towards him a degree of kindness I can scarcely express. Once arrived, I walked into the town; and although Calne cannot be said to be a remarkably pretty place, as the streets are very narrow, and some long as well, yet as I descended the hill from the station, with the whole town lying beneath me, and the fine tower of its old church, recently restored, standing out against the blue sky, I could not allow the truth of an old couplet I once heard which spoke of Calne as “ugly.”

I had no need to inquire where the Show was held, for tents, and flags, and music on a hill to the left plainly indicated its whereabouts. Meanwhile, to amuse and instruct myself, I take out of my pocket the announcement and schedule of the Show, which had been kindly sent to me. I scan the list of patronesses and patrons. Well, little Calne, thou art indeed honoured! Here are supporters for a show indeed!—a Marquis and a Marchioness, the High Sheriff of Wilts, a Right Honourable, admirals, “colonels, and captains, and men at arms,” and half a dozen squires and squires. Calne, thou owest much to thy proximity to Bowood.

The Show was held in the grounds of Col. Ward, the popular Commander of the Wilts Volunteers, and very suitable grounds they are for such a purpose. First came a tent with fruits

and vegetables, but I will not say a word about them—I cut the first part of “our Journal” this week; then a long tent of flowers and floral devices, but I pass them by without remark for the same reason, and hasten on to the poultry and Pigeons. It should have been called a Pigeon and poultry show, for the Pigeons were far better than the cocks and hens. Many and liberal prizes had been offered, an earnest Pigeon fancier lives in the town, and so, in truth, the show of Pigeons was most excellent. It has seldom been my lot to see such first-rate birds brought together—indeed, I had a thorough treat. There were nearly a hundred pens. I will take them in order. First, Carriers (Black, best cock).—First prize, Mr. Else, a truly beautiful bird of the old substantial sort. Next, Carriers (Black, best hen).—Mr. Else first and second. Then Carriers (Dun, best cock).—First, Mr. Yardley and Mr. Else. Carriers (Dun, best hen).—Again Mr. Else first and second, the first a most excellent bird. I exclaim, What *Else*? Why, nothing but *Else*? Carriers (Any other colour, best cock).—Massey and Ord prize-takers. Carriers (Any other colour, best hen).—Again Massey and Ord. Among all the Carriers shown I noticed only one inferior bird. Next came Powters; and among the exhibitors the two neighbouring fanciers, Mr. A. Heath, of Calne, and Mr. Fox, of Devizes, bore off a good share of the prizes. I do not give all the names, as the complete prize list appeared last week.

I now came to the pretty little Tumblers. The Almonds were extraordinarily numerous, considering we have not, alas! any Almond fanciers in this district. Again Mr. Else was triumphant with beaks and heads that filled a fancier with delight. Among the “Any other variety of Tumblers” was a pen, the first prize—*Else*, nought but *Else*—of Black Mottles, which I considered the gems of the whole Show. I repeated my visit to that pair again and again. There was also one pair of Short-faced Blue Beards, a bird not often seen. Beards! “Little cut-throats,” as I heard somebody call them.

Turbits and Owls came next, and wonderfully soft-feathered and beautiful they were. Then followed Jacobins and Trunnpeters, then Barbs and Nuns. I regretted not to see more than one pair of Barbs, and those not black, which is surely the best colour. The first-prize Fantails drew forth warm commendations from Fan-lovers; indeed, their tails were over their heads. The poor birds looked exceedingly uncomfortable, but quite prepared for a shower of rain with their feathered umbrellas.

But I must linger a little over the last class, entitled, “Any other variety, the best pair.” There were fourteen pens of them, and almost all first-rate. Mr. Yardley's Spots were the best I have ever seen, and well worthy of being painted. Singular to say, there were three pairs of Swallows, and all good; one took third prize—Mr. Percival's. Nor must I omit to notice the same gentleman's pair of Blue Dragons, which were excellent. While looking at the Pigeons an incident befell me of scarce an alarming, but certainly of a startling, character. The same clergyman, the worthy reader of “our Journal,” entered into conversation with me, and suddenly said—perhaps he had noticed I was marking the catalogue—“I wonder whether you are ‘WILTSHIRE RECTOR.’ I think you are.” I looked straight at the pens, trying, like the First Napoleon, to divest my face of all expression, as if I had never even heard of “WILTSHIRE RECTOR.” That clergyman being unable to make anything of my (I flatter myself) Sphynx-like inscrutable gaze, being a man of this world as well as the next, then looked at Mrs. “WILTSHIRE RECTOR;” and by a smile in that quarter I was undone, revealed, and all hope of secrecy was at an end. However, there is no need of regretting, for I made a most agreeable acquaintance, to be ripened by a visit proposed and accepted.

Leaving the Pigeons, I turn back and cross the grounds to the poultry tent. In Spanish Mr. Heath was triumphant, getting the £5 prize for persons residing in the Calne union, and first and second for Spanish chickens. The Brahmas mastered strongly, including chickens. A promising pen of the latter belonging to Mr. Hinton took a prize; and Mr. Pares was first and second with Light Brahmas, heavy into the bargain. N.B.—These large fowls were all placed high up, so one saw little more than their legs and breasts. This is a mistake. All large birds should be at the bottom, then smaller and smaller according to height.—The number of Game Bantams, all Black-breasted Reds, formed quite a feature, and lovely some of the tiny pets were, particularly the first-prize pen belonging to Mr. Cambridge, and the prize cock (sweepstakes) owned by the Rev. A. K. Cornwall. The Hamburgs were

only fair, Black Bantams and Sebrights few and not over-good. The chickens of 1865 were promising; among them Miss Milward's Buff Cochins and Mr. Gardener's White both took prizes. Mr. Hinton's Malay chickens were declared A1 among the Any variety.

In conclusion I will make a remark or two which must not be misunderstood. I write to cause improvement, not from love of fault-finding. On the first day there was a sad want of celerity—not until nearly four o'clock were the prize cards nailed on the pens; and when I entered the Show at past one o'clock, one tent was then only in the act of being reared. I understand there was a paid Secretary, hence less excuse. These and other delays were vexatious and confusing—vexatious to exhibitors and confusing to the public. The size of the pens was also not the thing: the poor Turkeys were crushed and the Geese crowded, and the larger Ducks had scarcely room. Let me indulge the hope that next time nothing so unfortunate will occur. May I see next year as pretty but a better arranged Show at Calne. I cannot bear to find fault, and I hope what I have said will be taken kindly.—WILTSHIRE RECTOR.

### THE LONG SUTTON (LINCOLNSHIRE) POULTRY SHOW.

This show of poultry, numbering nearly three hundred pens, took place in a very large and commodious tent, erected for the purpose on the grounds of H. Anderson, Esq., and being closely adjacent to the principal hotels of Long Sutton, it was easily accessible to every one. The arrangements of the Committee were, undoubtedly, good, and when another line of railway (now being made) is completed, no doubt a great accession of entries will immediately ensue, as the greatest drawback is the difficulty of speedy railway transit to and from Long Sutton on the present line. The early morning of October 11th did not augur favourably for fine weather. It rained, however, only at intervals, and as most persons hope for the best, it was thought by many that it would all clear off, and the result would be a fine day. With occasional rainfall, and a watery sun, the morning passed by, but about 2 P.M., a very severe, though happily brief, thunderstorm took place, the rain being excessively heavy, and the peals of thunder directly in the zenith. All things exposed to its fury, of course, were quickly drenched through, though happily for the poultry and Pigeons, no less than the visitors themselves, the tent proved a perfect protection to everything, affording an additional proof that all poultry penned for exhibition should be provided with shelter against sudden stress of weather. Had efficient protection not been in this instance provided, no doubt numbers of pens of the most valuable exhibition poultry in the kingdom would have been ruined beyond recovery, though as it was, not a moment's suffering occurred to a single bird.

Though several pens of good Grey *Dorkings* were exhibited, the collection, both old and chickens, was not equal to our expectations. Most of the *Spanish* shown were excellent, but the small number of *Game* fowls entered was the subject of general remark. It is said "the surrounding district is not favourable to them." Why this should be so, it appears impossible to say, as *Game* fowls are famous for their extreme hardiness. The *Cochins* were very good, but most of those shown were still heavily moulting; the present season seems especially unfavourable for speedy moulting; in fact, many exhibitors complain that their adult birds will even yet be a month or more before they be in perfect exhibition trim. In Buff Cochins, the Long Sutton Show proved excellent, the first-prize birds in this class taking the silver cup, also, as given for the best pen of poultry of any kind exhibited, without restriction as to breed. A marvellous pen of Cambridge *Turkeys* were in close competition for this much-coveted premium. With the exception of one pen of Partridge-coloured Cochins, and a very excellent White adult cock, the latter, unfortunately, shown without hens, to his "disqualification," no other really good varieties of Cochins competed. The Spangled *Hamburghs* far surpassed the Pencilled ones, but the entries of *Hamburghs* were limited to but a few pens. The *Polands* shown were very superior. The *Game Bantam* class was good, but many of the birds were still scarcely recovered from moulting. A pen of excellent Gold-laced Sebrights were the winners in the variety Bantam class. The *Turkeys* shown by Mr. Smith, of Breeder Hills, Grantham, fully maintained that gentleman's high reputation as to Turkeys, and when we hint to Turkey breeders, that a single pen weighed nearly 50 lbs., it proves beyond question, that at our later shows such weighty antagonists will require much beating. The class for "Any other variety" of poultry contained nothing of great note, though a pen of "hybrids" (as stated by the exhibitor, "a cross between a Pheasant and Game Bantam") proved actually simply Bantams, without the slightest pretension to a cross of any kind.

In *Geese*, some very good ones were shown, the so-called "Lincoln breed" proved not very truly-bred Emblends. A pen of *Ducks* also, entered as "Spanish Ducks," turned out to be simply Muscovies. Few breeders, we fancy, will, therefore, adopt the new nomenclature attempted by some owners at Long Sutton. Some very first-class Aylesburys, and also Rouen Ducks were shown.

The show of *Pigeons* was remarkably good, their excellence being very far beyond that of even many of our largest exhibitions. Many good pens of birds were, however, almost a mass of pen feather, and the remark was general, that the reproduction of feather on fancy Pigeons has this season proved unusually difficult, arising, most probably, from the long succession of dry weather. The silver cup for the best pen of Pigeons shown, was allotted to a splendid pair of black Carriers. The class of Barbs was an unusually good one, though not a few pens were shown in fearfully dirty feather, whilst tolerable cleanliness is indispensably required. A pen in this class were labouring under severe and highly contagious disease, but we are glad to say they proved the only diseased birds in the whole show. The classes for Jacobins, and the variety classes, proved especially good.

The efforts of the Long Sutton Committee to insure success, have thus met with a hearty response from amateurs generally, a result fully deserved, and obtained by much personal self-denial. The silver cups offered at future meetings, it is said, will be more numerous than at present, and it is but just to record, that the cups given this year very fully represented their money value, a feature of which we could not by any means speak so favourably at many shows of much higher pretensions. The poultry were very carefully managed, and not a single mishap occurred to any of them.

**DORKINGS** (Any colour).—First, T. Tatham, Kingsthorpe, Northampton (Grey). Second, H. Lingwood, Needham Market, Suffolk. *Chickens*.—First, J. Smith, Breeder Hills, Grantham. Second, J. A. Clarke, Sutton Marsh (Coloured). Highly Commended, W. H. Robson, North Reston, Louth (Coloured); T. Tatham; H. Lingwood; J. White, Warlaby, Northallerton, Yorkshire. Commended, J. H. Ivimy, Small Bridge, Rochdale.

**SPANISH**.—First, H. Beldon, Gilstead, Bingley, Yorkshire. Second, E. Brown, Albert House, Sheffield. Highly Commended, J. G. Hobson, Curlew Lodge, Sutton Marsh.

**GAME** (Black-breasted and other Reds).—First, J. Smith. Second, Messrs. McConnell & Bagshaw, Uttoxeter (Black Red).

**GAME** (Any other variety).—First, J. Frith, Lily Lane Mills, Halifax. Second, Miss H. G. Kemp, Fleet, Lincolnshire (Black).

**COCHIN-CHINA** (Buff).—First and Cup, H. Tomlinson, Birmingham. Second, T. Tatham. Commended, H. Lingwood; H. Beldon.

**COCHIN-CHINA** (Any other variety).—First, R. J. Wood, Brinsell Hall, Chorley, Lancashire (Partridge). Second, Withheld.

**HAMBURGH** (Golden-spangled).—First, P. Hutchinson, Spalding. Second, A. K. Wood, Burnside near Keadal. Highly Commended, I. F. Loversidge, Newark, Notts.

**HAMBURGH** (Any other variety).—First, A. K. Wood. Second, T. J. Saltmarsh, Chelmsford, Essex (Silver-pencilled). Commended, A. K. Wood.

**POLANDS**.—First and Second, H. Beldon.

**BANTAMS** (Game).—First, J. Smith. Second, T. C. Harrison, Hull. Commended, O. E. Cresswell, Hanworth Rectory, Hounslow, Middlesex (Black Red).

**BANTAMS** (Any other variety).—First, G. Manning, Springfield, Essex (Golden Sebright). Second, H. Beldon. Highly Commended, H. Draycot, Humbersstone, Leicester (White). Commended, H. E. Emberlin, Humbersstone, Leicester (White).

**ANY OTHER VARIETY**.—First, E. Sheerman, Chelmsford (Brahma Pouter). Second, Messrs. McConnell & Bagshaw, Uttoxeter (Brahma Pouter).

**TURKEYS**.—First, J. Smith. Second, Mrs. Harris, Sutton St. James (Cambridge). Highly Commended, Mrs. Harris (Cambridge).

**DUCKS** (Any variety).—First, Mrs. J. M. Dring, Long Sutton. Second, H. Beldon. Highly Commended, J. G. Hobson; R. Tate, Green Road, Leeds. Commended, J. A. Clarke, Sutton Marsh (Rouen); Mrs. J. Clarke, Old Bank House, Long Sutton (Aylesbury); Miss L. Folley, Long Sutton (Spanish); E. Gee, Wisbeach Fen (Black); H. Snushall, Gedney (Black East Indian).

**GEESE** (Any variety).—First, J. B. Bailey, Kingsthorpe, St. Edmunds, Second, S. Vincent, Clenchwarton. Highly Commended, Mrs. Harris, Sutton St. James (Lincoln).

**SELLING CLASS**.—First, J. G. Hobson (Dorkings). Second, W. Massey, Fulford, York (Cochin-China). Highly Commended, E. Sheerman, (Brahma Pouter); H. E. Emberlin (Golden-spangled Hamburghs). Commended, G. Manning (Black Red Game Bantams); H. Beldon; R. Tate, Leeds (Bantams); J. A. Clarke.

### PIGEONS.

**CARRIERS** (Any colour).—First, Second and Cup, T. Colley, Sheffield Highly Commended, H. Yardley, Birmingham; J. Beaver, Cross Lane Salford, Manchester. Commended, H. Beldon.

**POWTERS** (Any colour).—First, J. Beaver. Second, H. Wade, Laurel Cottage, Birmingham. Highly Commended, H. E. Emberlin; C. Cole, Hartley's Buildings, Bowling near Bradford; J. Beaver. Commended, H. Yardley.

**TUMBLERS** (Short-faced).—First, H. Yardley. Second, E. Brown. Highly Commended, H. Yardley; J. Beaver. Commended, J. Percival, Cleut Villa, Harborne, Birmingham (Almond).

**BANDS** (Any colour).—First, J. Thackray, York. Second, W. Massey, York (Black). Highly Commended, E. Brown; J. Beaver. Commended, H. Yardley; H. Beldon.

**JACOBS** (Any colour).—First, H. Yardley. Second, I. I. H. Stockall, Broad Green, near Liverpool. Highly Commended, T. Young, Eyre Arms Hotel, St. John's Wood London; J. Percival, Commended, T. Thackray; T. Rule, Durham (Red); G. Woodley.

**ANY OTHER VARIETY**.—First, H. Yardley. Second, J. Thackray (Swallows). Extra Second, J. Beaver. Highly Commended, P. Hutchinson (Silver Routs); H. E. Emberlin (Maggies); T. Rule (Mottled and Black Trumpeters); J. Percival (Dragons); W. Massey (Blue Dragons); H. Yardley; J. Percival, Peckham (Archangels). Commended, T. Young (Fantails); H. Snushall, Gedney (Black-headed Nuns); I. I. H. Stockall.

**SELLING CLASS** (Any variety).—First, W. Massey (Black Barbs). Second, H. E. Emberlin (Powters). Highly Commended, J. Percival (Swallows); H. Snushall, Gedney (Red Pied Powters). Commended J. Thackray (Turbits); E. Massey (Blue Dragons).

**RABBITS**.—First, Miss J. Fletcher, Long Sutton. Second, G. Needham Lutton Garngate. Highly Commended, W. Jeffrey, Long Sutton; Z.

Woodward, Kirton. Commended, Master W. Dring, Sutton Marsh; Mrs. Grainger, Sutton Marsh; R. Bush (Spanish).

The Arbitrator appointed was Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, near Birmingham.

### SUNFLOWER SEED FOR PHEASANTS AND POULTRY.

SEEING in your Letter Box an answer to a correspondent about sunflower seed for poultry, I send you a short account of how it succeeds with me.

I have this year grown a large quantity, as an experiment, for food for Pheasants, and I find they are most greedy after it. It is quite impossible to keep them away from the place in the garden where I have laid the sunflower heads to dry; as many as thirty are sometimes among them in the morning.

When I give the seed to Pheasants I only lay the heads along different paths in the woods, and leave the Pheasants to pick out the seeds, which they find great amusement in doing. If your correspondent were to give them in the same way to his poultry doubtless they would eat the seeds.—A MAN OF KENT.

### THE HUMBLE PETITION OF EXHIBITED TURKEYS

TO ALL POULTRY SHOW COMMITTEES.

We hope that you will pardon us for intruding upon you; but on the eve of the poultry-show season we earnestly implore your attention to one complaint. We feel emboldened by the success attendant upon former suggestions, when the Bath and West of England Society enlarged their Turkey pens. Well would it have been for us had the Committee of the late Poultry Show at Calne followed so good an example. But alas! our miserable enclosures there, in a full sun, were a "cruelty to animals;" and bitter were the laments of our owners that our beautiful plumage, just moulted out, would be effectually ruined for any future exhibition. We envied the useless heights of the Pigeon pens at that Show, to which none of the officials were tall enough to affix the commendatory cards! and we would humbly suggest that committees should consign the construction of their pens to some one versed in the rules of proportion. Then may we hope that our majestic forms will not only have room for comfort but for display.—THE TURKEY PRISONERS AT CALNE.

### BEE-KEEPING IN YORKSHIRE.

HAVING lately returned from a tour through the East Riding of Yorkshire, including the Pickering Valley, which is a noted bee-country, perhaps some readers of "our Journal" may like to know how they manage matters in that quarter. The season of 1865 has not been very satisfactory, the complaint being that no good has been done since the early part of July. As regards the heather, the season could hardly have been worse, many hives returning as light as they went. I lifted hives which had just come back from the moors, and others on the same stand that had remained at home, and there was but little to choose between them. The bean-blossom is the chief dependence of the bee-keepers in the summer time, there being very little white clover grown in the district, while beans are a very extensive crop. A swarm which came off just as the flower was at its prime, had filled the skep with comb, and was accordingly eked in ten days after swarming. This, and some other examples of the kind, would seem to indicate a very favorable country; but the universal statement was that the heather furnished the principal harvest. I did not meet with a single exception to this remark, or I should have been disposed to question its correctness. The land is good; a fair proportion of it is under grass; there is abundance of fruit, and a still greater abundance of wood, in fact, every apparent indication of a good honey country; nevertheless, hives are scarcely ever fit to "take" unless sent to the heather. Things are managed in the old-fashioned style—bell-shaped hives on stone slabs. The only novelty I could discover, and the fame of which was spread far and wide, was an ornamental hive, standing in a garden in solitary state. It is an accurate model of the neighbouring hall, every stone in the walls, and each slate on the roof being distinctly marked, the patterns of the chimney-pots likewise. The front door is panelled, and neatly painted in imitation of mahogany. It has a brass handle, and

wants nothing but a brass knocker (at which the pollen-bearers might knock, and which the nurses might open). The door is about 4 inches wide, and is left rather short to form an entrance for the bees, the opening looking like a splashboard to keep off the rain. This miniature hall ought to have stood in a miniature garden, instead of which it is placed on the summit of a rockery, the rockwork consisting of glittering white spar. By way of heightening the incongruity, it is covered like a chair of state by a royal canopy of crimson and gold, sustained on pillars of blue and gold, a Prince of Wales's feather surmounting the whole. The only sensible thing about it is that when unlocked the whole front of the house comes away, and shows a glass window behind it the full size of the hive. The hives stand rather thickly on the ground, and some of the better class of cottagers will have as many as twenty or thirty, in a few cases even more, though the average is from six to ten. The general practice is to let a stock hive stand as it is until the drones are killed off, and then eke and send to the moors. Swarms are eked as they fill up, and so remain through the winter. You may frequently see hives of the second year with three and even four ekes, and standing half a yard high or more. They reckon that unless a hive weighs three stone it is not worth taking, while four and even five stone are not uncommon weights; but the honey is coarse, and very different from what is obtained in this neighbourhood. Nearly the whole of it is run before being sent to market; but here and there is a travelling workman who has added honey-dealing to his other callings, and who buys a score of hives, and after sulphuring the bees takes the hives with him just as they are, and disposes of the honey in the comb. Doubtless, with better management, much better results might be obtained. It is impossible to look at the country and not be satisfied of this; but although the bee-keepers generally are a fine set of fellows, good-natured, frank, and hearty, they have no liking for new-fangled ways, and they prefer in these matters primitive simplicity. The only innovation on the traditions of their fathers respecting bees was "to mesmerise 'em a bit," fungus being the mesmeric agent; but this was only another way to destroy them without injuring the honey, as the bees thus stupified are never added to another stock. Nobody was willing to be convinced that wood was better than stone, or that bees should be furnished with water in the spring. Super honey was a grand thing, and a man once got some in a straw cap; but if they began meddling with new fashions they would, may be, do very badly. Such seemed to be the prevailing idea; but I shall always have pleasant recollections of the men themselves, and the picturesque, often romantic nooks, in which some of them have their homes.—F. H. WEST, *Potternewton, near Leeds.*

### REMOVING BEES TO A SHORT DISTANCE.

HAVING taken a house, situated about 600 yards from the one I at present occupy, the removal of my bees demanded a little consideration. An intermediate trip with nine frame hives with covers, stands, &c., would have involved a good deal of trouble, independently of the difficulty of finding suitable quarters for their temporary accommodation. After some deliberation I resolved to try the following plan with one hive:—The entrance was closed in the evening with a slip of perforated zinc, and the bung having been removed from the crown-board, a piece of perforated zinc was fastened over the aperture to confine the bees, but ensure sufficient ventilation. On the following morning the hive was carried to its new site, and a circular feeding-trough with a float, containing about a pint of syrup, was placed upon the perforated zinc, closing the aperture in the crown-board; the zinc was then withdrawn, and the bees were permitted to enter the feeder. The entrance of the hive was kept closed until a good deal of excitement prevailed; but when the trough was well filled with bees, and the excitement of feeding had pervaded the whole community, the slide closing the entrance was removed. The bees at once rushed out most tumultuously, but under the combined influence of feeding and confinement, carefully noted the change which had been made in their locality, and very few returned to their old quarters. I subsequently removed the remainder of my stocks (one or two at a time) in the same way, with most complete success, in some cases scarcely a bee returning to the old garden.—J. E. B.

P.S.—On Sunday I discovered that a cottager's hive, which had sent out two swarms in the summer, was queenless. The young queen had, no doubt, either been killed by her subjects, or been lost on her wedding trip.

## FOUL BROOD.

AFTER what has been written on foul brood, it will be deemed quite unnecessary by those who have never experienced the evil, to return to the subject; but I am convinced that its existence in our apiaries, either in a mild or virulent form, has much more to do with unsuccessful bee-keeping than most apiarians are aware of. It is beyond doubt the greatest enemy with which bee-keepers have to contend, and from the difficulty of wholly eradicating it, or preventing its spreading from affected to healthy hives, the utmost vigilance ought to be maintained in case of a visitation. The present time, when egg-laying on the part of the queen has altogether ceased, is very suitable for making a thorough inspection of the state of our hives, and if in any of the brood-combs we find cells still sealed with dark brown covers, or a hardened crust black as ink lying along the bottom of any that are open, we might be quite certain that the disease is present. In some of the unopened cells there will also, probably, be found a dark, slimy, tough, putrid mass.

This year I am in a position to affirm, without the slightest doubt or hesitation, that neither "chilled brood" nor dysentery amongst the adult population, is the cause of the disease called foul brood, as developed in my apiary. I have now watched its progress during two summers, and I believe that the deaths which take place in the larva state, irrespective of the far greater evils arising from death in the chrysalis state, are quite sufficient to reduce any hive to an unprosperous condition.

In the beginning of August, 1864, I introduced a large swarm to a Huber-hive which had undergone the purifying process recommended by Mr. Woodbury for foul brood, and placed it within reach of heather, where it made such progress, as at the end of a fortnight to have combs brought nearly half down. Subsequently I fed it with sugar, and breeding went on extensively till the close of the season, not a single foul cell being visible. The winter proved severe, but it did not sensibly affect the population, and with the return of spring they vigorously resumed their labours.

The 9th of April was somewhat cold, and on that day I was surprised to see them more than ordinarily busy, when most of my other hives were idle. The mystery was soon explained; for on inquiry I learned that a neighbour at a little distance, whose bees were never prosperous and which had been defunct for a year or two, had thrown into his garden some old comb containing honey from a hive that had long ago perished. Could this be the source whence the disease with which my hive had been affected in 1863 was derived? If so, I concluded, I shall not have seen the last of it, my bees having found out and partaken so liberally of the spoil.

I had not long to wait, for with the arrival of June, fine weather also arrived, and the half combs of the Huber-hive were completed and filled with brood. Larvæ disappeared, several cells presented a most suspicious appearance, but notwithstanding these drawbacks great numbers of young bees reached maturity, and on the 1st of July the queen led off a swarm; but from that moment the hive might be said to dwindle, foul cells increased, and the queen had only one successor, all the other embryo queens having succumbed at an early stage. Besides, there were not sufficient bees for a second swarm. How different the result from that of another hive which was more backward in spring than the one in question, but being in a healthy condition was able to swarm earlier, and throw off three swarms without being too much diminished in numbers.

I next wished to see the effect of numbers in a foul-breeding hive, and for this purpose joined three swarms together and put all into the diseased hive, filling it to overflowing. No attempt was made to clear out the foul cells. The coverings were merely perforated when the enclosed matter became viscous, and apparently the contents of every foul cell are left undisturbed to become a dark crustation, and so hard as to return an audible sound when scratched with the point of a knife. From the bees in the hive having diminished to less than half the numbers added, and that, too, at a time when the queen was prolific, I strongly suspect that foul brood exercises a deleterious influence on the adult population.

Having cut out the brood-combs containing foul cells, and subjected the stored honey to the fumes of sulphur for twenty minutes, I shall be glad to have Mr. Woodbury's opinion whether it is probable that the disease will re-appear when the breeding season returns.—R. S.

[We all owe a debt of gratitude to "R. S.," for his persever-

ing investigations into the cause and effects of, as well as the possible remedies for, foul brood. In my own case I must honestly confess, that as soon as I had identified the malady all my efforts were at once directed to banishing it from my apiary as speedily and as entirely as possible, and so well have I succeeded in this endeavour, that "my last glimpse of foul brood," which occurred fully twelve months ago, appears also to have been a final one, for I have, I am happy to say, seen nothing whatever of it since. Far different has been the course of "R. S.," who (and all honour to him for it), during the past two years has been observing and experimenting upon what he most justly terms "the greatest enemy with which bee-keepers have to contend," having even gone the length of purposely inoculating previously healthy colonies by feeding them with honey taken from foul-breeding stocks. That he may ultimately succeed in obtaining a satisfactory insight into the causes of, and the best remedies for, this mysterious malady must be the earnest wish of every apiarian, and I for one shall have great pleasure in affording him my best advice and assistance.

Judging, then, from my own experience of the virulent character of the disease, I should say that there were little or no chance of its being eradicated by partial excision even when combined with sulphurous fumigation; but in advancing this opinion I must be understood to do so with extreme diffidence, since in some cases foul brood, even when fully developed, appears to have become modified and even subdued altogether without any apparently sufficient cause, as the following instances will show.

It may be remembered that in "our Journal" of the 17th of November, 1863, I published a lamentable appeal from a German bee-keeper for advice and assistance in the cure of foul brood, which was then devastating all the apiaries in the neighbourhood of Guben, in Prussian Saxony. The following letter, dated February last, describes the remedies adopted, and an apparent cessation of the disease:—

"In 1863, I asked bee-keepers far and near, whether there was not a means of curing foul-breeding stocks. In consequence of this request, I received several replies with various excellent propositions, for which I now return my best thanks, wishing that those gentlemen who sent these replies, and all bee-keepers, may be protected from the worst of all evils in bee-keeping—foul brood. Of the remedies prescribed for foul brood, I have employed two, and, as I firmly believe, with the best success.

"1. For ten stocks take a peeled nutmeg, make it into fine powder, mix it with the honey for feeding, and feed three times with it every other evening.

"2. Take three loth (1½ oz.) of powdered Indian anise, and pour a quart of boiling water on it. After cooling dilute with it two quarts of old honey and mix one auntechen (one-eighth of an ounce), of laudanum with it. With this mixture feed twelve stocks morning and evening.

"These two remedies have been employed by myself and some other bee-keepers in this district. I say purposely some other bee-keepers, as many bee-keepers detest the name of foul brood like that of pestilence. However weak their stocks, however idle the bees may be, yet their stocks are not foul-breeding, although one after another may leave the hive during the best time for gathering, and although they may count the heads of their darlings every month, and find each time a few dear heads wanting, and a few others tying on their death-bed.

"'When the child is drowned the well is covered.' + So have I almost every day examined my bees, and with trembling hands searched for new traces of the evil on all the brood-combs; but I am glad to be able to state, that not even a suspicious cell was found, either in my apiary or in the apiaries of some neighbours, where the stocks had been fed with this medicine, while in apiaries where everything is left to dear 'mother Nature,' I have seen that the evil had become much worse. I should say with certainty we had cured our stocks of foul brood by the above-mentioned medicine, if there were not some few stocks in the neighbourhood which were foul-breeding in 1863, but which, nevertheless, worked well in 1864, and even swarmed; yet these are mostly such hives only as are examined closely but once a year—namely, at the time of the honey-harvest. Whether these stocks that have not been fed are, in spite of their busy flight, really healthy is not yet proved; but that

\* Vide JOURNAL OF HORTICULTURE, Vol. VIII., page 141.

+ German proverb.

the stocks which were very foul-breeding in 1863, and well fed with medicine in 1864, were quite healthy in the summer and autumn of that year, I have seen with my own eyes. The year 1865 will, I hope, be probation time.—N."

I shall, probably, be excused for doubting the efficacy of the so-called remedies above described, which, indeed, appear to me very unlikely to have produced any effect whatever, especially as the following extract from a letter recently received from my valued friend and correspondent, "A RENFREWSHIRE BEE-KEEPER," into whose apiary the disease had been imported in 1863, by a Ligurian stock sent to him in ignorance by me, and where it had manifested itself in the most virulent form, proves that it is, at any rate, in some instances quite as capricious in its duration, as it is mysterious in its origin:—

"While I have my pen in my hand, I may tell you, that this season I have fortunately escaped my accustomed August desolating visitation of foul brood, although I had two singular glimpses of it, a narration of which may interest you, showing a singular variation in its effects on very strong colonies compared with those more thinly peopled. In removing my first full-sized octagon super from the strong Italian stock, the only one that escaped the foul-brood visitation last season, or, I should rather say, whose *noli me tangere* strength saved it from examination, the severing thread had missed a portion of comb attached to the upper breeding-box, and the super on being raised lifted along with it one of the frames, and afforded a momentary glimpse of its contents ere it dropped back into its place, and I was quite horrified to observe several bad cells—sharp reversed pupae of the abominable brown colour—clearly seen through the widely-perforated cell-covers. I replaced the super instantly with the upper one to confine the bees, and, of course, concluded the colony of which I was so proud had its doom sealed. I, notwithstanding, had the good fortune to take from it in succession, four more such supers, and on preparing it for the winter, at the end of last week, saw the four boxes in which it now stands crammed with bees, and, I fear, rather overloaded with body honey, as on attempting to guess at the present weight, on tugging away at the pile, I could only get for reply the unmistakable cracking of the giving way of the handles of the lowest box by which I held.

"The other case was a square straw frame-hive. After I saw the queen had begun egg-laying, the hive having been left undisturbed with a full supply of pure empty comb, and the summer was well advanced, when one Saturday afternoon I bethought me to have a look how matters were going on. On drawing the slides I was amazed at the teeming population that poured up from every opening, and although not quite pure, they were the best-marked Ligurians I have yet had the good fortune to raise. The hive was so crammed with bees that they massed up thickly on the top of one another on the hive-top, and on raising the frames I was still more astonished to find every frame loaded; indeed, overloaded, as there were projecting portions added, and these as well as the frames themselves, were one mass of the finest sealed healthy brood with not one defective cell from end to end. This sight impressed me more than anything I ever witnessed, with the conviction of the superior productiveness of the Italian bee. Some fortnight or three weeks thereafter, my attention was attracted by little pellets of stuff on the landing-board of this hive, scarcely the size of peas, dirty-white in colour, and of the consistency of soft sticky putty. This led to an examination of the hive, when I found still an overflowing population but the fine healthy brood picture reversed—nothing but decaying embryos. I shut it up in disgust, till eight or ten days afterwards, prepared with a spare box and queen cage, I again opened the hive, preparatory to putting the bees through the purgatorial process, when judge of my surprise to find every brood cell empty, and so clear of every appearance of foul brood, that I could conceive its passing muster as a healthy hive, even with you. A most minute examination alone showed a rather darker tinge on the very white cells than ought to be. Finding such a state of things caused me to pause in my purgatorial proceedings, and I have almost determined to allow it to stand over to see if foul brood break out afresh in spring, which I much fear it will. A singular thing which I noticed on my last examination, was a barricade of propolis built along the entrance of the hive, closing it up with the exception of a little space at each end. Could the transformation of the brood be caused by some sudden fall in the temperature, and this be built by the bees as a safeguard against a repetition of such an occurrence? I have read of such barricades, but never before had one under my own observation.—A RENFREWSHIRE BEE-KEEPER."

My Renfrewshire friend's suggestion that the strength of his two infected colonies enabled them to cope with and even to vanquish the disease, appears to be negatived by the experiment of "R. S.," who united three swarms to his foul-breeding hive, thereby "filling it to overflowing," but all without effect. I must confess myself wholly unable to offer any solution of the mystery, the clue to which can, probably, only be discovered by long and patient investigation and experiment. I hope both our Dumfriesshire and Renfrewshire friends will not fail to communicate the result; but in the meantime I may venture to hint that apparent are not always permanent cures, and that it seems to me that for the present they cannot do better than "wait and watch."—A DEVONSHIRE BEE-KEEPER.

## NATURE AND TREATMENT OF THE CATTLE PLAGUE.

This is the title of a pamphlet just published by Messrs. Churchill & Sons, from the pen of Dr. R. H. Allnatt, and is the most rational that we have seen. At the same time we record as our conviction, that the deaths of cattle by the disease are much fewer than would be suspected when we read of such exceptional instances as the herds of Earl Granville and Miss Burdett Coutts.

As soon as the first symptoms appear—discharges from the eyes and nostrils, languor, and groaning, the animals should have a mixture of salts. We will quote Dr. Allnatt.

"The specific formula for an ox or a cow labouring under the disease, will be as follows, which may be administered in any stage of the attack:—

Chloride of Sodium .....	3 oz.
Nitrate of Potassa .....	2 oz.
Carbonate of Potassa .....	3 oz.
Sulphate of Potassa .....	2 oz.
Sulphate of Magnesia .....	4 oz.

Mix, and dissolve in two quarts of boiling water, and give luke-warm.

"The quantities must of course, be modified according to the age and strength of the animal, and after the primary effects of the full dose, administered in subdivided proportions.

"All wild animals have a strong natural craving for salt, and are instinctively led to immense distances in pursuit of it. It is the natural stimulant to the digestive organs. It was once the custom, on almost every farm throughout England, to use what were denominated "Salt Lickies." Large boulders of crude crystallised rock-salt were deposited in mangers and other feeding-places to which all the domesticated cattle had easy access.

"It is astonishing with what avidity they resorted to these lickies, and how sleek and healthy they became under the continued use of the saline.

"The good old custom has, I fear, become obsolete; if so let it be at once revived, for it was founded on wise and salutary physiological principles."

**NORTHERN COUNTIES POULTRY SHOW.**—This Show, better known as the "Darlington," is to be on the 6th, 7th and 8th of December. The prizes as usual are liberal, and no less than twelve silver cups are offered as extra prizes.

**LONG SUTTON POULTRY SHOW.**—We are sorry that any exhibitor met with neglect at our hands, mistakes will arise sometimes. We have now made the *amende* by posting a copy of our catalogue and prize list to each of our eighty-nine exhibitors.—CLARKE & SNUSHALL, Hon. Secs.

P. S.—For the future catalogues will not be the printed until day of show.

## OUR LETTER BOX.

**POULTRY FOR CONFINED SPACE (J. S.).**—For cottagers any of the varieties of Cochin-China, but especially the dark coloured, and Brahma Pootra. Six pullets and a Dorking cock would produce a good supply of eggs, and chickens excellent for table.

**BOOK (Malvern).**—A volume with very numerous coloured plates and woodcuts will be published at our office at the end of this month.

**SILK SKAINS (B. P. C. E.).**—Our correspondent wishes to know where she can find a market for skains of silk wound from English cocoons, as she has a considerable quantity.

From observations taken near London during the last thirty-eight years, the average day temperature in the week is 55.6°, and its night temperature 37.3°. The greatest heat was 67°, on the 28th, 1860; and 29th and 30th, 1833; and the lowest cold, 23°, on the 26th, 1859; and 29th, 1843. The greatest fall of rain was 1.06 inch.

A SURGEON'S NOTES ON GRAPES.

DO not mind confessing that growing Vines is my especial hobby in gardening. The every-day work of my laborious profession does not leave much time

for any solar amusement, but I can find enough to look after my Vines. And then they are so grateful; they thankfully acknowledge the slightest attention—climbing, pushing, and clasping; even late in the summer developing miniature lateral bunches in some neglected corner while the main crop is colouring! I have no fault to find with stone fruit under glass, except their tenacity of attention; they insist on so much syringing, so much watering, are so fond of red spider, and flies of all colours, and throw their fruit upon the least offence, that I determined to bid them a friendly farewell, and fill up their place with Vines.

The very growth of the Vine is joyous and bold, meeting you every morning with a fresh burst, and almost rushing up the wires to greet you after a longer absence; and a professional man's pet ought to bear a short absence without materially suffering. This is eminently the case with the Vine, and is a most powerful argument for its adoption as his hobby. These remarks sufficiently premise that I do not force. Why should I? As I shall presently show, I can get Grapes quite as early as I can find time and place to eat them; for we are equally fond of bush fruit. Even now the October Red Raspberries are nearly in as much request on my breakfast-table as Black Hamburgs. Grapes, however, have never been more relished than in this past September; it gave us a slight idea of the necessity they become in Southern Europe. With us they are usually eaten in the cool half of the year as dessert after a good dinner, when their finer qualities are with difficulty appreciated; but this summer they have been consumed in large quantities as a cooling article of diet, escaping their usual fate of being transformed into "wine," which, if its qualities are somewhat doubtful, has pretty tolerably certain effects. What the extremely carefully-written directions of "UPWARDS AND ONWARDS" may effect in the improvement of these national beverages remains to be proved. At present British wines are very little better than sweetened small beer, with the special flavour of the name of the wine attempted to be added. For the poor, who buy largely of these drinks in illness, the introduction of good and cheap Marsala is an excellent boon. But if I do not force Grapes I can keep them, and so enjoy them late, about seven months out of the twelve. This is longer than we get game, and it is, perhaps, better to be without such high-flavoured luxuries for a time, that the zest may be more ardent when their season returns.

I grow my Vines in three ways—on walls, in ground vinerias, and in cool vinerias, and I hardly know which method has this year given me the most pleasure. With out-door Grapes this has been the finest season since 1857, though 1856, 1857, 1858, and 1859 were all good. The next four years—1860, 1861, 1862, 1863—were nearly equally bad from the well-remembered winter-summer of 1860, and the partial failure of the succeeding summers. 1864 was too dry, though, perhaps, the fine crop of this year owes its existence to that dryness.

Although in Huntingdonshire, just on the verge of the parallel where Grapes refuse to ripen (52° 20'), I grow and succeed in ripening ten varieties out of doors. They are given in their order of ripening—Early Malingre, Sweetwater, Miller's Burgundy, Grove-End Sweetwater, Royal Muscadine, Hyland's Hardy Black, Muscat St. Laurent, Black Hamburg, Esperione, and Muscat de Sarbelle. Eight of these are pitted against each other, in the fairest possible manner, on the Thomery system, planted 2 feet apart, each with two aris, 4 feet long, spurred in closely to one eye at every 7 inches along the rod. This system gives perfectly fair results, and if faithfully chronicled for a term of years would give valuable data as to the growth and ripening of the different varieties.

To the first-named, the Early Malingre, I am glad to attach my testimony of its good qualities. For three years it has ripened on the 20th of August on an open wall, when other varieties with exactly the same exposure and treatment were still stoning. It is a very elegant oval Grape, with the crimson calyx still adhering to the berry. The bunch is also prettily shaped. I was sorry to see Dr. Hogg's low estimate of it in the "Fruit Manual;" but Jove is reported to have occasionally nodded. The Grove-End Sweetwater, in spite of its synonyme, is hardly so early or so fine as the old Sweetwater. To my taste the Royal Muscadine is superior to both, more gelatinous, *croquant*, and has not the rank taste that the Sweetwater acquires when grown on walls. Miller's Burgundy will always ripen, and if opportunity be allowed for eating, will always please with its Black-Currant flavour. Hyland's is a very good Grape, reared by the late gardener at Hinchinbrooke. It is a most lovely Vine in the spring, from the beautiful pure light green of the young shoots, and the number of bunches it shows. It is not a good setter if the weather is cold and wet at the flowering; but this year it has been most successful. It has closely-set bunches: berries black, oblate, roundish; slight Muscat flavour, more fully developed under glass. I cannot say I care for the Esperione, though a most prolific bearer, with fine bunches. Except in such favourable seasons as the present, it is sadly deficient in sweetness and flavour; and I can well believe "UPWARDS AND ONWARDS" when he says that honey is an excellent addition to the wine made from it, even in excess of the sugar. Muscat St. Laurent is a watery Grape, decidedly Muscat; rather shy bearer out of doors, though prolific under glass. The leaf in dying shows the Sweetwater parentage. Sarbelle shows freely, growing well, but is difficult to ripen, and is hardly so good as Hyland's.

The out-door Vines are trained on three systems—the old spur, the Thomery above mentioned, and the Hoare system of long rod; and I like the Thomery best, for its compactness and its preventing waste of walling. In the two latter nailing is dispensed with by straining galvanised wire through eyelet nails half an inch from the walls, about 9 inches from the bearing rods, and tucking the young shoots under them as they grow. No further trouble but that of stopping is required with the horizontal arms of the Thomery system. Hoare's plan requires vertical rods and wires, and shoots with heavy bunches will probably require tying; but the comfort and saving to my fingers and walls are enormous. The yield is, perhaps, much the same with all. Young wood gives larger bunches; old wood, I am inclined to think, higher flavour, and it seems to have more ripening power.

The ground vinery is one of the many good things we owe to Mr. Rivers. I grow four varieties in this manner—Black Hamburg, Black Prince, Chasselas Musqué, and Grizzly Frontignan, the last a mistake on the part of the nurseryman. They all grow well, are very strong and healthy, and have ripened their fruit easily. My ground vineries run east and west, and are roofed on the north with either slate or boards. They are wide enough for two rods, and the northern Vine ripens its wood, though not enjoying quite so much sun as its fellow; but I train the rods pretty near the edge of the frame, and throw the shoots of both into the centre. They are ventilated with perforated bricks, made in this locality, each brick having twelve rectangular narrow holes, so that birds and mice are prevented from entering. These are set up edgewise, close together, on another line of bricks bedded level in the ground. The south front of the lights is hinged, so that, as in this hot summer, the light can be raised an inch or two, so as to avoid burning, which some of your correspondents complain of. Slates inside I use very sparingly for the same reason, they often proving fatal to a young shoot or bunch on a hot May day. Flat tiles keep the bunches nice and clean, and are quite sufficient; the ground is quite hot enough for the ripening of the shoots. Red spider, as Mr. Rivers has told us, cannot exist in these structures if a little sulphur is strewn on pieces of slate. There is no necessity for overdoing it. Begin when you see the first leaf with the yellow spots.

I have always found it necessary to protect these ground vineries from spring frosts, from which I suffer in the most disheartening manner. A single mat, sack, or canvass bag thrown over the glass is quite sufficient to save the shoots. Vines are evidently quite at home in these structures, and if it were not for the stooping required in tying the shoots and thinning the bunches, I should increase my surface considerably. My plan cost rather more than Mr. Rivers's, though the hinged light is most comfortable, but is not nearly so expensive as the "patent," so industriously advertised. I ran them east and west on the border of a cool vinery to drive off the incursions of my groom gardener, who always attempted to make it his seed-bed, and they must also assist considerably in warming and drying the border, and the ground is thoroughly economised.

In two cool vineries I grow eleven varieties, spurred in closely to one eye. If I had more faith, I think no eye would be better still. I continually find myself cutting off the spur entirely, choosing a shoot which has sprung from the rod itself. This, of course, is in the spring. The names are Black Hamburg (half the surface of glass), Black Prince, Lady Downe's, Trentham Black, Muscat Hamburg, Black Frontignan, White and Grizzly ditto, Buckland Sweetwater, common ditto, and Chaptal. All ripen well, the old Sweetwater leading the van about the 13th of August, followed rapidly by Chaptal, the Frontignans, and Black Hamburg; the latter and Lady Downe's keep easily till February if frost will let me. The Muscat Hamburg is best eaten when first ripe. This I have grafted on Sweetwater and Black Hamburg stocks; to the former it is like a young cuckoo to its step-mother hedge-sparrow; but the old Vine does its best to nourish the big bunches. The flavour is the highest and most composite in my experience among Grapes. The piquancy of Black Prince, gelatinous muskiness of the Chasselas Musqué, sugary richness of Black Hamburg, and even the high aroma of the Muscat of Alexandria, are all represented in this wonderful Grape. The Frontignans are very fruitful, ripen well, but are so capricious in shanking, that they will never, I fear, be grown to profit under glass. White Frontignan, in my experience, is the most healthy, and, perhaps, nearly as nice as the Red. Chaptal has large handsome bunches, exquisitely sweet berries, but must give place

to Buckland Sweetwater, which merits all the encomiums it has received. Our Nestor of fruit-gardening has called this variety a true "White Hamburg," and its handsome well-shouldered bunches with large elegant berries, gelatinous, and full-flavoured, form the most beautiful contrast on the dessert dish. Neither the wood nor the general habit is quite so robust as in the Hamburg, and there is, perhaps, a slight hereditary delicacy in these points. Not much need be said of the Black Hamburg. Its besetting defect, imperfect colouring, may be traced in almost every instance to over-cropping, or its analogue, deficient supply of proper nutriment to its roots. In this brilliant year complaints of want of colour are numerous, and deficiency of heat cannot be alleged. Mere ammoniacal manures are powerless in averting this defect. The border must contain sufficient bone earth, and the bunches must be unsparingly thinned in number and individual bulk. Much experience on this head may be gained from fruiting Vines in pots. Want of colour is a fatal defect, and the flavour is always more or less spoiled. Though showing a handsome cylindrical bunch, colouring under almost any treatment, and most prolific in bearing, I am yet at a loss to know why Black Prince should still be considered a first-rate Grape. It is certainly brisk, piquant, not deficient in sweetness, but it is thick-skinned, and can with difficulty escape the charge of coarseness.

Mine are shallow borders of light friable materials, bones, and ashes, refreshed two or three times a-year with the emptyings of a manure tank. The largest leaves and thickest shoots do not always show the best Grapes the next season; but I feel that in this and many other points I should be only repeating what is so often given in THE JOURNAL OF HORTICULTURE, and as it is, must apologise for the length of this communication, which will hardly escape the Editorial scissors.—J. H. H.

[No fear of the pruning scissors being applied to such communications, and the more we are favoured with, the more shall we be obliged.—Ens.]

## CYCLAMENS AND THEIR CULTURE.

(Concluded from page 314.)

WITH respect to the cultivation of Cyclamens as hardy plants, the red and white neapolitanum are, perhaps, the most beautiful of all during the late autumn and winter months. What would be finer than the white neapolitanum in a row 1 foot from a Box-edging, and another of the red 1 foot behind it in a ribbon-border? Why not plant them thus with good balls in October, and at 6 inches apart? They are, indeed, beautiful objects from the beginning of November till spring.

In some localities these plants will not succeed, but except in cold clay soils and bleak situations, there are few places in which they cannot be grown. The only season in which I knew them injured was 1860, when the foliage was cut off to the ground; but as a proof of their hardiness, although many other plants were killed in that extremely severe winter, the roots of these were uninjured. On the other hand, I have grown them in strong rich soil, and they have been killed by 10° of frost, whilst in light well-drained soils they stood our ordinary winters uninjured.

*C. europæum* I have not found hardy until recently, and this, I think, was in consequence of growing it in too rich and wet soil. It is, I am quite sure, not to be grown as a hardy plant in cold wet soils; it does best in an elevated, dry, stony situation. It was with me a most sickly plant, and would not bear so much frost as a *Calceolaria*; though no frost had any effect on the root, yet it became weaker, as we might expect, from losing its foliage early every year. To grow it it should be planted on an elevated site, such as rockwork not too dry, and if it be shielded from the midday sun in summer, I find it succeeds better than when fully exposed, though it likes an open situation. In such a position, with a soil composed of leaf mould, peat, and light loam in equal parts, free drainage, and plenty of fresh air, though in a sheltered nook, it is one of the prettiest and sweetest flowers in any garden.

*C. repandum*, like *C. europæum*, likes fresh air, and it is not so tenacious of life as the last, but will perish if kept in a wet soil whilst in a dormant state. It is quite hardy, however, and requires nothing but a free, open, well drained soil, and then it blooms in spring, but generally not before May, though it will sometimes do so in April. It is a good plant for flower-garden decoration in April or May in favourable localities, but

is as yet not generally cultivated, the red neapolitanum being confounded with it, but the latter flowers in autumn.

C. eorum I have not found hardy, though I find it set down as a hardy plant by various writers. In some favoured localities it may do fairly, but I have had to afford it the protection of a frame, and even there unprotected it perished.

I cannot conclude this communication without adverting to the subject of raising Cyclamens from seed, that being the only digible method of obtaining plants, though occasionally they may be increased by taking off the spurs that rise from beneath the soil, yet this is apt to cause the parent root to rot where the wound is made, and brings on disease, and ultimately death. It seems to me very strange, that if we take a spur, such as is frequently noticeable in Cyclamen europæum, or stem with a crown, and remove it close to the corm, the wound on the stem will heal over, that on the corm not doing so; and though the spur or stem will grow, and annually produce leaves and flowers, it will not form a corm, though it may elongate, yet that is chiefly at the point from which the foliage appears.

The seed should be sown when fully ripe (and when this is the case the seed-pods open at their apex, and let the seeds fall), using well-drained pans, and a compost of sandy peat and loam in equal parts. Just cover the seeds with soil, and after giving a good watering place the pans in a cold frame, giving the preference to one in a shady situation, as insuring a uniform degree of moisture in the soil, and, consequently, speedy germination. Sometimes an inverted pan is placed over the other to secure this; the pan being plunged in the open ground, but a better plan is to cover the surface of the pot or pan lightly with moss, and to keep the moss moist by gentle sprinklings of water, removing it when the first seedlings make their appearance. Both these modes have a tendency to draw the plants, but without some such contrivance they do not come up so soon as desired. Care must be taken to remove the inverted pot in time, and to take off the moss gradually, otherwise the seedlings will receive a check, and be a year later in blooming. Keep them moderately supplied with moisture, never allowing the soil to become dry, and never saturated, admit abundance of fresh air, protect from heavy rains, and as winter approaches lessen the supply of water, yet keep the soil moist, giving air on all favourable occasions, and protecting from frost. In spring water more liberally, sprinkling slightly overhead, and do not "coddle" them, but use the lights more by day than night, for nothing is so good for plants wanted to grow fast as the evening air, the cold of night, and the dew of the morning. Keep lights on during the day, and at other times to keep out frost and rain; a mat can be thrown over them from 10 A.M. to 3 P.M. in hot weather. Persist in this until August, then cease to shade, reduce the watering, and expose to the sun and air continually, except when heavy rains occur. Towards the end of September pot the young plants singly, using small pots, but if they are still in the seed-pan it would be quite as well to prick them off, about an inch or so apart, into other pans. I sow the seed at such distances apart that there is no necessity to remove them until they are potted out of the seed-pan; but when the seeds are sown thickly the seedlings are best pricked off when a year old; for the best seedlings, which are invariably the weakest, will be smothered if not either potted or pricked off. I do not like to handle Cyclamens when very small, otherwise I believe they would be better pricked out when sufficiently large to handle. After they are potted they require the same treatment as established or old plants, and they will bloom at two and three years old.

In conclusion, I would enter a protest against drying the bulbs of Cyclamens, by taking them out of the pots, or keeping them in them throughout the summer on shelves in the greenhouse, and without a drop of water. Well may such plants as these not be successfully cultivated in England, when they are roasted in summer, and drowned in winter. When at rest they should be plunged out of doors, or in a cold frame, in a situation shaded from the midday sun.—G. ABBEY.

TODMORDEN BOTANICAL SOCIETY, October 2nd.—On the table were various examples of flowering plants and Ferns. Among the latter was a very curious and quite novel form of the Male Fern (*Lastrea Filix-mas*), gathered last year in Westmorland, and named *excurrens*, all the pinnae being permanently abrupt, and furnished at the apex with a sharp excurrent point; also a form of the same Fern, regularly interrupted in the pinnae, and tasselled at the ends, very pretty indeed, but whose permanency remains to be tested. G. C. Churchill, Esq., of London, sent specimens of the two rare *Aspleniums* *Selovii* and

*fissum*, the former from Lienz (gathered on the dolomite), the latter from a mountain in the Wochein, Carinthia. Mr. J. Hurlley brought *Blechnum spicant heterophyllum*, a fine example, found in the Hebben valley, a valley than which few in the north of England are more rich in cryptogamic plants. Mr. Nowell also submitted a very singular form of the last-named Fern, combining at once the characteristics of *concinnum*, *projectum*, and *strictum*. This oddity in the way of a Hard Fern Mr. Nowell had likewise gathered in the valley of the Hebben.

### WHAT'S IN A NAME?

It is unparliamentary in either House of Parliament to speak of what transpires in the other, except by the vague term "another place;" and so, I suppose, we must observe the same rule in journalism, and merely in speaking of our contemporaries say, "It has been said elsewhere." And thus I must now say that there have lately appeared elsewhere one or two articles on the Rose, on which I think, as one of the "enthusiastic and good-natured correspondents of the gardening papers" there alluded to, I ought to say a few words. The statements there made seem to require an answer, and I hope to do this without the least feeling of annoyance. When I for one give those lists of new Roses which "*ROSA ANGLICA*" (not, if I mistake not, the usual signature of the writer), alludes to, the readers of THE JOURNAL OF HORTICULTURE will bear me witness that it is not for the purpose of praising them. No one has more thoroughly reprehended the plethora of new things with which we are every year threatened than I have, and I have thereby drawn down on me from more than one French grower letters which do not breathe that vast amount of politeness for which our neighbours are celebrated; but when their lists are published I have generally dissected such, and from either the knowledge I have had of the growers, or of the character of the flowers previously sent out by them, or from having seen the flowers, I have given my opinion or conjecture of what were likely to turn out good. Sometimes one is right, and sometimes wrong; but in my opinions and conjectures in the past season, I am glad to say I have been in many instances right. However, I anticipate, and will take the matter in order.

The writer names thirteen crimson Roses, and says that the years 1864 and 1865 have not produced anything to equal them; and I there join issue. Two of these Roses I grew and discarded long ago—*Souvenir de Lady Eardley* and *Turenne*. They are both, though fine in colour, far too thin to be ever of any use, except in the bud, when others are equally beautiful. I am quite ready to admit that it is almost impossible to beat *Charles Lefebvre*, but even it is faulty; it wants a few more petals in the centre, although without doubt it is the grandest Rose we have. Amongst the others, *Due de Rohan*, *Alphonse Damaisin*, and *Maurice Bernardin* are all fine, but all very much alike; and I contend that *Pierre Netting* of the 1864 season is worthy of a place amongst the very choicest ones, superior to many of those named, and equal in character to *Senateur Vaisse*, though of a different shade of crimson. The same may also be said very nearly of *Rushton Radelyffe* (1865); while *Madame Victor Verdier* (1864), is not one whit behind any of them, and I believe will stand in our lists when *Alphonse Damaisin* and others he has named are forgotten. Then as to rose-coloured Roses—by which, I suppose, he would include deep pinks—I am very much mistaken, from what I saw of *Duchesse de Caylus*, if it is not fully equal to *Jules Margottin* or *John Hopper*; it is so beautifully formed, and such an exquisite shade of rose. Then, again, *Duchesse de Morny* cannot be overlooked as a splendid addition to rose-coloured flowers. With regard to white or flesh-coloured Roses the past two years have certainly given us no addition worth naming. *Louise Darzens*, *Madame Macker*, and others are rather Hybrid *Noisettes* than *Perpetuals*.

In giving the list of new Roses of last year, "*ROSA ANGLICA*," curiously enough, omits from his list of raisers, and thus puts amongst the small growers, my old friend *Margottin*, the raiser of *Jules Margottin*, *Louise Odier*, *Souvenir de Comte Cavour*, &c. Some of the raisers he has there named do indeed give us a vast deal of rubbish, and the only way for our ever hoping to have a more select list is by Rose-growers resolutely refusing to purchase.

I think the test that "*ROSA ANGLICA*" gives of the goodness of old Roses and the badness of new ones—that whenever he detects a fine Rose in a garden or box he is sure to find it to be one of his old favourites—arises from this, that where he has one plant of a new Rose he has twenty of an older one. And the same in stands; very few of the new Roses appear until

after the second year, except in one or two stands; and I perfectly remember that Charles Lefebvre himself did not take his position until he had been over here two years.

But it is as to the naming of the new Roses that "*Rosa ANGLICA*" waxes strong; and not contented with the attempt "*spargere ambiguas voces.*" comes out at once with the charge, direct and clear, that the reverends whose names have been appended to French Roses have received a douceur of new Roses, and in consequence thereof have given a lift to them—that is, praised what they have never seen. Now, Mr. Radclyffe and myself are the only two Protestant clergymen whose names are to be found appended to French Roses by French raisers, Mr. Hole's having been given by Mr. Standish. Whether we are capable of doing such a thing, or whether we have done it, the readers of *THE JOURNAL OF HORTICULTURE* can determine. I have never, and I do not think Mr. Radclyffe has ever, praised a Rose that we have not seen, and I do not think we need be ashamed of those which bear our names. I know that amongst Bourbons, to which class the Rose named after me belongs, there is not one to equal it in colour; and, as I have said, Rushton Radclyffe is a fine Rose of the light crimson class. Of the Roses I saw last year I named this and Maréchal Niel as the only two of Eugène Verdier's I had seen that promised to be good, and the latter I pronounced magnificent. Has it not proved so? I also conjectured that Duchesse de Caylus, Duke of Wellington, and Duchesse de Medina Celi would prove good, and I am pretty sure that they will do so. So amongst the Roses of this year which I have seen, I am fain to stake my reputation as knowing something about Roses on the two fine flowers Margaret Dombain and Alfred Colomb; and let this be observed, that if we do not say anything about a new Rose the first year, the French growers care very little what we say afterwards. The first year is their harvest; after that our English raisers can equal if not exceed them.

As to nurseries, "*ROSA ANGLICA*" says plainly, "Any English florist giving an order to a French Rose-raiser to the amount of five hundred francs may have a Rose dedicated to him—that is, named after him: it is thus we have so many French Roses with English names attached to them." Imagine this—the silly vanity of which he supposes our English florists guilty! I find the names of James Veitch, John Cranston, John Keynes, William Bull, William Paul, George Paul, and others attached to French Roses. Which of you, gentlemen, ever gave five hundred or five francs to have a Rose named after you? Not one, I venture to say. Is this silly charge a new one? Is it only of late years that the practice has become reproachable? Yet after all, what's in a name? "That which we call a Rose would smell as sweet by any other name;" and whatever names French raisers choose to give to the productions of their gardens, be good-natured, and do not quarrel as to the nomenclature.

Had "*ROSA ANGLICA*" put forward his views without these insinuations, I should have more agreed with him, and do in fact agree on the main point—viz., that we are flooded with new Roses, and must protest against them. Already I see M. Eugène Verdier announces twelve. It is impossible that they can be all good. One of them I know is; two others I saw, but cannot say that I considered them first-rate, and probably none of them, save the one I have mentioned, will prove so. We shall have probably a hundred Roses: if six of them prove valuable we shall do well. Rose-growers must judge by past experience, and be chary of ordering the Roses of those growers whose productions have proved to them a loss.—*D., Deal.*

#### CLOTH OF GOLD GERANIUM—SOIL FOR GERANIUMS.

I AM pleased to hear of the success of Mr. McLellan with Cloth of Gold Geranium. I only regret that he did not send his communication earlier, for I would then, if agreeable, have sent some of my plants to him, with a portion of the soil in which they were growing, as he thinks there must be something materially wrong therewith. The soil which I prefer for the whole class is fine, soft, mellow loam, cut 4 inches deep with the turf, packed away turf inwards for twelve months or more; peat of a kind that contains a considerable quantity of fine white sand; and some leaf mould and good manure used rather sparingly than otherwise. If Mr. McLellan, or any of your numerous correspondents, can recommend something better I shall feel obliged for the information.

In my former communication I did not refer solely to my own plants, for I had seen the variety under different circumstances and in various situations doing very differently indeed. I should here like to tender my thanks to "R. F." for informing us of his failure. For my own part I have done with Cloth of Gold as a bedder, since we have varieties that do better and answer the same purpose. From what I have at present seen of Miss Walton I am unable to discover any improvement on Mrs. Pollock. "R. F." has referred to the variety; perhaps he has had a better opportunity of judging of its qualities, and may therefore be able to give us a little information on the subject.—*F. FLITTON.*

#### THE RIPENING OF PEACHES IN ORCHARD-HOUSES.

BEFORE answering the remarks Mr. Rivers has made on my paper on "The Forms of our Fruit-houses," I will say a few words upon my intention in writing it.

I have now for some years given my leisure hours to the study of horticulture, and during this time I have continually been impressed with the little change the introduction of hot water has made in the construction of our fruit-houses, and more and more convinced that the time is fast coming when a garden will no longer be looked upon as a luxury and an expense, but treated from the same point of view as a model farm. I had, therefore, two desires—to learn the opinion of the gardening world on the possibility of getting what I called cubic measure out of a house, and also to query if the present mode of training Vines and Peach trees is not wasteful of light, heat, and space.

The only answer I have seen is from "VITIS," and he wrote under a false impression, which he would see by the second half of my paper. I hope he will next year tell us how his Vines have succeeded. I do not think we differ on the question of pruning, I did not enter upon it; but as he does, I may say, that if he studies Mr. Bréhaut's book he will find an espalier will require no more attention than a bush tree. When I saw my paper in your Journal, I thought it read too much as if I was laying down the law, I only wanted it to read as if it came from one who believed what he wrote. Mr. Rivers does not charge me with ambiguity, and if he can prove that I am wrong, I will freely acknowledge that my letter was not written in vain, but that I at least have gained in knowledge; and let me ask as a matter of courtesy, that he will treat me as one who can comprehend small things, and that after he has called my figures "fictions of fancy, Spanish air-castles," and said "no such houses and no such treatment exist," he will take as much pains to prove his statement as I have done.

He begins with what he calls my "scientific dialogue." I have often heard of the science of gardening, and though I did not use the term, I think if Mr. Rivers had given us the reasons why orchard-houses answer in the places he mentions in the north, his letter would have merited the term semi-scientific, for he would have had to give us the geology and meteorology of each place; but then he would have proved them the exception, not the rule. Mr. Rivers must not think I am an enemy to orchard-houses, if I lived in his climate I would build one at once. But what is an orchard-house? Mine would not have a bush tree in it, and I should call it one, and yet the lean-to houses at Hallingbury Place are claimed by Mr. Rivers as orchard-houses, though the description as given in his book reads to me like that of a Peach-house. Then I come to the question of temperatures, and what is shade? If I enter a house and ask the gardener what temperature he has, will he think I mean in the shadiest corner? I think not, for if a thermometer is to be of any use it is fairly to represent the temperature of the house for the information of those who have charge of it, and that is the sort of indication I gave; and I am ready again to state that the Peach-house and viney in my garden, and of which I sent you sections, were during the hot weather at the end of last month, with the ventilation on, at 100° in the day, and from 40° to 45° at night. I may also say that I am at a loss to understand how Mr. Rivers could get a reading of only 80° in one of his large houses, and out of doors 69° at 2 P.M., "on one of the bright warm days we had last month," when I read in the *Times*, that the thermometer in the open air was as high as 81.3° in the shade in Cumberland.

I will now refer to the high temperatures Mr. Rivers considers so absurd, and I regret very much he does not give us the highest he has observed in his houses. I think I have a

right to ask this after the positive manner in which he denies the truth of the temperature I gave—110° to 120°. The house I referred to had been on the day of my visit at 126°, so I was told by the foreman, who said the thermometer often rose to 120°; the time was the second week in August.

I do not think I am authorised without asking leave, to give the name and place; but it is not important, as my Pine stove will go as high as I said.

Mr. Rivers writes in so amusing a strain, that it is difficult to tell when he is joking, and to understand his comparison of "a man at a window" with a Peach tree going to rest. He says mine "were put to their unhealthy rest in August, by management so bad as to be almost incredible." Covent Garden can testify that the Peaches were ripe in May. Is August then untimely? and will it hurt their feelings more to be put to rest by means of a soft August wind, than by the same process in October and November? Cold nights will alone send trees to rest, and as long as they continue vegetation is kept in check.

In his last preface Mr. Rivers says, "he feels that he is now a central authority in matters appertaining to orchard-houses," so even in this my practice is, I am pleased to find in as perfect accord (as is possible under the circumstances of one set of trees being fixed, and the other moveable) with what the Fenians would call the "head circle." Mr. Rivers, speaking of the trees he raises for sale, says, that he grows them in his houses till July; by this means he gains for them several weeks at the start, when June comes he lets in the night air; in July more impatient than I am, or, perhaps, I should say, having a better knowledge of the importance of stopping their growth that they may have the longer period wherein to mature their buds, he turns them out of doors. Why? Because he tells us he secures for them by this means a ten-degrees-colder night temperature. The trees he sent me I am ready to testify were beautifully set with buds, and this must confirm us both, I am sure, in the opinion that we cannot do better than continue to follow this treatment, and I am only sorry that he should have thought "it was delightfully original on my part."

This subject, the effect of night temperatures on vegetation, is one that merits more attention from gardeners than it has received, and I should like to send you long quotations from Dr. Bennet's interesting book on Mentone bearing upon it, but as I have already written a good deal, I must limit myself. The night temperatures of the four winter months he gives at from 40° to 48°. In January, 1861, he sat out of doors reading two hours each afternoon, "I was, however, always obliged to screen myself by the lined parasol, without this precaution the position would have been quite untenable. A thermometer in the shade near me marked 50° to 62°." "The deciduous trees lost their leaves in December, as soon as the nights became cold, and did not regain them until April, when they were becoming warmer." "On the other hand, in the sheltered situations exposed to the south, the heat of the sun so warmed the soil, that it had not time to cool at night, and such situations became regular forcing-beds, producing, as I have stated, Violets in December, Anemones in January, and all our spring flowers early in February. Where the sun did not penetrate, on the other hand, the ground vegetation remained torpid, like the deciduous trees, till March."

Am I not, then, simply working by Nature's own laws, and using those faculties of observation which I received from her for this purpose?

In conclusion, I beg to thank Mr. Rivers for his most cordial invitation. I have already partaken several times of his hospitality, and I shall hope to visit him again when I come up to the Great International next year.—G. H.

P.S.—In reply to "LIVE AND LEARN," if you will undertake to forward it to him, I shall be very glad to send a working plan from which he can get an estimate of the cost. I think you will agree with me, it would be improper that I should give one. This will answer most of his questions. On the angles of houses, as affects sunlight, I can add nothing to what he will find in your Journal for May 16th, 1865. All practice in gardening tends one way in planting rows of trees, that the lines should run north and south. Orchard-houses are built this way, and market gardens and orchards follow the same rule.

SUMMER FRUIT IN OCTOBER.—As a remarkable instance of the effects of this year's prolonged summer may be mentioned,

that I have in my garden (Weston-super-Mare), a second crop of Raspberries, and also a few Strawberries. They are quite ripe and sweet, and equal in flavour to the first crop.—F. W. B.

### ORCHARD-HOUSE TREES.

ALLOW me to call the attention of cultivators to the great benefit derived from chalk or lime rubbish, when finely powdered and mixed with the compost for re-rotting or the autumnal top-dressing of all stone-fruit trees. For Apricots I believe it to be quite indispensable, judging from the unvarying success of their culture here, the soil used being full of comminuted chalk. As far as I can judge, one-tenth of the potting-compost should be of the above materials. This mode of making an artificial calcareous compost is perfectly safe, and may probably lead to perfect success in Apricot culture.

May I be permitted to correct two slight misprints in the article at page 291? It should be "closed at night," instead of "closed by day;" and in page 292 "base" should be "bad."—T. R.

### KITCHEN GARDENING.

#### SEPTEMBER.

DURING this month there will be a few more summer crops to be removed that their places may be taken up by winter ones. In the first place, there will be the Champion Peas now over, which may be at once removed, and the ground which they occupied should be prepared, and sown with Corn Salad; or, if so much Corn Salad is not required, the spare part of the ground may be planted with Coleworts, as I am an advocate for the last-named vegetable, though I am aware there are many parts of England where it is scarcely known, or, if so, not appreciated as it deserves to be. The variety we grow here is called Rosette-leaved Hardy Green, and I always make it a rule, to continue planting this on every spare foot of ground till I have a thousand plants in successions.

Early in the month I plant my first lot of Cabbage for spring use in the ground that was prepared for the purpose six weeks or two months previously, and which by this time will be in first-rate order. I plant for this batch seven rows at 2 feet apart and 1½ foot asunder in the rows, drawing drills, and watering these the day before planting. Towards the end of the month the last lot of Peas (Knight's Dwarf Green Marrow) will be useless and should be cleared off, and the Beet and Carrots being adjacent these may be taken up and stored away, thus setting a good piece of ground at liberty. This I have well manured, deeply dug, and then planted with what I term my second lot of Cabbage, and four or five rows of Coleworts. This second lot of Cabbage does well for standing for sprouts a year or so if wanted. One great advantage that we London gardeners have is the facility of obtaining plants of Cabbages, Coleworts, &c., of any size and in any quantity from the market gardeners, but of course where this privilege does not exist plants must be prepared at home.

The Cauliflower plants will by this time require pricking out under the hand-lights, but by no means put the tops on till frost renders it necessary to do so, as the more they wither and flag to get a good root-hold the better will they stand the winter, and, for that reason, I generally put mine in a row across the open part of the garden, about nine to each hand-light. Previous to protecting them I find it a good plan to cover the earth about their roots with about half an inch of cinder ashes, which keeps out the frost and also keeps them dry.

The established crops of winter stuff should have the ground between the rows kept continually stirred when practicable, as this month with such crops is almost of as much importance as the time a crop of Grapes is swelling is to that crop. The Turnips and Spinach should be hoed occasionally to keep the ground open and the weeds in check. The first row of white Celery should, in the beginning of the month, have its final earthing-up so that it may be ready for use at any time, and it is as well to use it while it is good, for if kept too long it is sure to pipe or rot. The red Celery for second and late crops should receive every attention, and I think this year they have given more trouble than anything on account of the Celery fly, which has been here very troublesome. The only plan to master it which I find effective is to pick off the affected leaves about twice a week. Two rows of Late Red that I had were literally stripped to the bare stalks, and I had

decided on taking them up and making some better use of the ground they occupied, but wishing to see whether the grub or myself was to be the conqueror I let them stand with not a particle of foliage on them, and they are now (October) looking exceedingly well. Some of the Endive will be ready for blanching; and if a scarcity of salading should be felt, as it often is at this time, the thinnings of the Lettuce and Endive seed-beds will form an excellent substitute till better salading come in, or at all events till the Celery is in full play, and the blanched Endive is ready. A bed of Lettuce should be pricked out on a dry border. The supply during this month will be rather limited, on account of the summer crops being removed before the winter ones afford much variety, but we may depend upon having Scarlet Runners, Dwarf Kidney Beans, Coleworts, Cabbage, Brussels Sprouts, and Vegetable Marrows.—BURSTWOOD, P. D.

(To be continued.)

### MY PLANTS,

AND HOW AND WHERE I FOUND THEM.—No. 11.

It was on ascending the hill from the village of Oakamoor on our return home, that we gathered specimens of several species of Buckler Ferns; the *Lastrea dilatata*, *L. Filix-mas*, and *L. thelypteris*, all growing under the friendly shade of the trees above them, and being freely supplied with moisture from the continual trickling of tiny springs above and around them. I am not quite sure whether it was from this spot, or the Alton woods, that I obtained my present fronds of the *Lastrea montana*, Mountain Buckler Fern, but it was during this expedition. Moore says of it, that it "is a very elegant species, the fronds growing shuttlecock fashion around the central crown, which terminates the stem, to the height of from 2 to 3 feet. The plant is so fragrant, that when drawn through the hand it may be recognised from its kindred by this circumstance alone." On Chaddle Common I one day gathered some very pretty and elegant fronds, which were fringed or tasselled. I believe it was the variety *cristata* of *Lastrea Filix-mas*, the foliage when mixed in a bouquet of garden flowers had an uncommon and lovely effect. Growing in a ditch near this place, and beneath the shelter of a Pine wood, I came upon a plant of the same species of most luxuriant growth, but of a very unusual shade of colour, and which contrasted beautifully with the *Athyrium Filix-femina*, and the two *Lastreas*, *thelypteris* and *Filix-mas*, of a light green hue, which were in close proximity to it. I believe that a rich maroon would describe the colour of the fronds. As the summer was then passing into autumn, I suggested that this change of foliage might be attributable to this cause, but from the fact of the surrounding Ferns retaining the full green shade of their summer dress, and that every frond of this particular plant was of the same dark hue, we came to the conclusion that Dame Nature was alone to blame, if blame her we could, for so pretty a relief and contrast to the mass of green around us.

The want of water in our Staffordshire landscapes has often struck me as a curious circumstance, whilst the Ferns and flowers seem to rejoice in a continual supply of moisture from tiny and almost hidden sources; springs seem to be arising on all sides, but there seems to be no general gathering together of these little forces to form any important amount of water. Where, however, we occasionally meet with a stream in the valley, forming a bright and refreshing feature amongst the mass of vegetation with which the sides of the hills are clothed, then, indeed, I think that the scenery of this county can rarely be excelled. In Norfolk, besides the rivers, we frequently meet with broad expanses of water, which come under the denomination of small lakes, and in these broad expanses revel the white and yellow Water Lilies. There upon the bosom of the lake or stream they pass their short-lived day, their roots firmly fixed in the bed of the river or lake, and their beautiful blossoms reposing upon the dark green leaves, basking in the noontide rays of the sun above them. It has been said that at the moment when the sun sinks below the horizon the Lilies close their petals and retire beneath the water. This, however, is not strictly correct, for many flowers may be seen upon the surface during an evening's stroll by the margin of the water, although with contracted petals when the golden light of the sun has departed. Fit emblems of purity and faithfulness are these favourites of the stream. In America, Africa, and other parts of our globe, are Water Lilies of various colours, as red and blue, which float upon those far-off waters;

China, also, possesses a beautiful Water Lily called *Leenhwa*, it is very odoriferous. The Lotus is equally fragrant, a writer says of it, "Its flower is much valued by the Hindoos, and consecrated by them to one of their deities. Its leaves serve them for many domestic purposes, as they cover their tables with them, and eat their food from the smaller ones, while flowers and fruit are presented to the stranger in a simple basket made of the Lotus leaf." Moore evidently believed the tradition with regard to Water Lilies, for he thus writes of the Lotus—

"Those virgin Lilies all the night,  
Bathing their beauties in the lake,  
That they may rise more fresh and bright,  
When their beloved sun's awake."

The estimation in which these beautiful flowers are held, is fully corroborated by the fact, that no ornamental water is considered perfect without them. I remember in childhood's days the splendour of these *Nymphææ* at a gentleman's seat in Suffolk, and there also what magnificent Thorns graced the grounds, under which we girls and boys with several companions of our own ages, children of the neighbouring rector, came to spend a merry afternoon, our chief object being to gather bunches of Mistletoe, with which these Thorns were plentifully decorated. Having secured, with the help of our youthful gallants, as much as we could conveniently carry, we started off homewards. There a kind-hearted aunt awaited us with the genial cup of tea, her bright and happy face always portended good, and in her hospitable house was the kindly welcome for all who entered it. She, too, was a botanist. A love of Nature, and of her wonders and beauties, certainly softens our natures, and rubs off the rust and hard business-like tone which we should otherwise get in dealing with this working world.

But now, as we are sure to have a merry tea-party with "aunt," let us after our meal reach down from amongst her numerous books some which will enlighten us upon the plant which we have left under the verandah, for it must always interest us in connection with the ancient religion of this, our own loved country, and of the

"Druids, who whilst arms are heard no more,  
Old mysteries and barbarous rites restore:  
A tribe who singular religion love,  
And haunt the lonely coverts of the grove."

With a peculiar reverence the ancient Britons looked upon these, in those times, learned men, who combined the four important functions of "priest, magistrate, scholar, and physician." Their principal reliance, however, seems to have been placed on Nature's great prophylactics—temperance, cheerfulness, and exercise. These they earnestly prescribed to their patients as the surest means of preserving or restoring health. It is also to be mentioned, that they taught the people that no medicine could be efficacious without the Divine blessing. The practice of the Druids was simple and rational, and if it was of little efficacy, it was at least harmless. Their sovereign remedy, however, was our friend the Mistletoe, its name in their own language signified *heal-all*. It was on the sixth day of the moon that they sought the Mistletoe, which grew on their favourite Oaks, to which as well as the former plant, they ascribed a peculiar virtue and sacredness. The discovery of the Mistletoe was an occasion of rejoicing and solemn worship. "Preparations for feasting and sacrifice are made under the tree," says old Pliny, "they drive thither two milk-white bulls, whose horns are then for the first time bound. The priest then ascends the tree, robed in white, and cuts it with a golden sickle. It is caught in a white mantle, after which they proceed to slay the victims, at the same time praying that God will render His gift prosperous to those to whom He has given it. They believe, also, that it is a remedy against all poisons." Thus far do we learn to hold the old priests of our country in some reverence, as lights, though somewhat dim ones, in those dark ages.

The old custom of "hallowing largess" at the termination of the harvest, which is in use in the counties of Norfolk, Essex, and Suffolk, appears to me to bear reference to some of the old Druidical rites. I have seen no account of its origin in any book at present, and should be glad of some information upon this subject. The junior members of a family in the country generally look anxiously forward to the last night of the in-gathering of the treasures of Ceres, when the last load returns crowned with Oak boughs, and the weary workmen are rewarded by a hospitable table, groaning beneath the weight of beef, Potatoes, and other vegetables, pork, pies, and plum pudding; also, an unlimited quantity of beer, which is handed round during the feast and late into the night. Smoking and songs

succeeded the harvest supper, the opening and evidently legitimate one of the evening being—

"Here's a malster's good health, boys,  
And drink o' yer be-e-e-e-er,  
Here's a missus' good health, boys,  
She perwides us good cho-e-e-e-er, &c."

You will perceive that the words beer and cheer are continued almost *ad infinitum*—in fact, as long as each singer has any breath left. Other songs follow, either in the sentimental or comic strain as may suit the tastes of the company assembled, or of the singer for the time being. The master, mistress, children, and dependants are generally present at these gatherings to offer their good wishes, and also contribute some substantial proof of their good will, in the shape of half-crowns, shillings, or smaller coin. The moon being fully risen a scene commences which always awakes in my mind a longing to fathom its antiquity and origin, certainly it is very impressive. On the lawn, or some convenient grass space in front of the house, are assembled our half-inebriated sons of toil, and from the hall-door or windows all the inmates of the house are gathered together to witness this curious spectacle. The men stand in a semicircle around the bailiff, or head man, who faces them, waiting reverently until he has thrown up his face towards the sky, shouting in his loudest tones, and pausing upon each word, as if invoking some unseen Deity, "Holla lar," "holla lar," "holla lar." Immediately he and the men around bow down their heads until they almost touch the ground, and all together utter the almost un-writable words, "Jah bah." This scene is enacted three times, and it is scarcely credible the distance which the sound of these largess gatherings can be heard. In the holy stillness of a summer night I heard the voices of two sets of men in different directions, one of them proceeding from a farm at a village four miles off across the valley.—ALICE.

#### REMINISCENCES OF AN OLD FLORIST.

I WELL remember Mr. Keynes telling us, at a florist's dinner, how he pawned his watch, unknown to his father, to buy his first collection of Pinks; but I managed it without that; and it is remarkable how, after more than fifty-two years, I could go to the garden where I grew them and point out the spot to a few inches. The leading varieties at that time (1813) were *Midshipman*, I believe, a red variety, and *Davy's Eclipse*, black and white. The Pinks of those days would now scarcely be grown as border-flowers. Mr. Bow, of Broughton, near Manchester, above forty years ago, became a Pink-grower, and, being a man who, by his own energies, had pushed himself into a position, turned those energies to flowers; and his gardener, under his directions, raised many Pinks, which for a time eclipsed those in cultivation, and led the way to greater improvement. Falkner's Duke of St. Albans became, as it was termed, a clipper, and eclipsed all the purple-laced ones for many years, until now it is consigned to oblivion, and I question if it could be obtained, although its only fault was serrated edges. At that period there were but few florists in the south, excepting Maddock, succeeded by Groom and Davy of Chelsea—all were principally supplied from the north, it being almost like a bee hive swarming with florists; and one Thomas was the collector or buyer for the southern growers, by which he made an independency, and retired. Pinks have now arrived at perfection, and they are nearly as large as Carnations. John Ball, were it not for the centre, which is called by the northern florists the "mooning" (that is, round as possible) being stary, which is a drawback, it would be perfection itself, as that is the only drawback it has. In 1822 there were forty-five varieties of purple-laced amongst the winners; and Turner's Prince Regent took 19 first and premium prizes, and Ardwick Beauty took 15, all of which are non-extant. The red-laced numbered 35 varieties, and Field's Fair Phyllis took the lead. The same may be said of them as of the purple-laced. The black and whites numbered 30, *Davy's Eclipse* taking the lead. Auriculas began to take my attention, and I purchased from Daniel Bradshaw, of Prestwick, near Manchester, a small quantity, and remember well that we had a large flag outside the summer-house, which served for various purposes, not quite a yard square. Under this flag, which stood on four pieces of wood, I wintered them for many years, and then they got at last a frame with glass for their winter quarters, but I did not observe that they grew any better.

It may probably be interesting to present growers to have

some particulars of this flower. Joseph Partington,\* seventy-three years ago, took the first prize, which at that time was twenty-one shillings, with Taylor's Victory—a green-edged variety, rather bare in the dust or farina, and not a dark green edge. At that period they were all of a pale green. Red-mayne's Metropolitan, a self, was introduced about 1780 by a florist named Tottle. It is generally supposed that it was stolen from some one in the south. One Heys, of Castleton Moor, near Rochdale, got it and sold it under the name of Apollo, by which name it is more generally known than its true one. He sent it to some distant place, supposed to be in the south of England, when it was sent again to this neighbourhood by some one else, under its proper name; but where the raiser lived is not known. It is a singular fact that many years ago it was so plentiful that it became a border flower (which many now living can remember), and sold at twopenny per plant. The Auricula was grown by Mr. Wrigley, of Langley Hall, near Middleton, in 1767.

In 1776 the principal varieties were Taylor's Victory (this variety in 1822 took three prizes—two fourths and one fifth); Siberon's Fame, light green edged; Foden's May Duke, green edged; Pott's Delegate, green edged; Clough's Defiance, green edged; Clough's Jingling Johnny, green edged; Riding's Junius, grey edged; Ashworth's Man-of-War, grey edged; Hortaine, white edged; Hughes's Pillar of Beauty, white edged; Berry's Lord Lee, self; and Pope's Gardener, self. These were then considered very fine, but only three out of these are now in cultivation—Jingling Johnny, Lord Lee, and Pillar of Beauty. In 1822 of the leading varieties in green edges, Pollit's Highland Boy took 30 prizes; Stretch and Barton's King, 29; Buckley's Jolly Tar, 22; Rider's Waterloo, 16; Stretch's Alexander, 15; Lee's Colonel Taylor, 12; and Booth's Freedom, 9; and the prize list contains 55 winning sorts, but only nine besides those enumerated are now in existence.

The grey-edged class consisted of 52 varieties—the leading ones, Grimes's Privateer took 16 prizes; Kenyon's Ringleader, 44; Rider's Waterloo, 25; Taylor's Plough Boy, 13; Hey's Lovely Ann, 11; and Popplewell's Conqueror, 9; and about eight others that were grown a few years ago.

The white edge consisted of 31 varieties, Hughes's Pillar of Beauty, 38 prizes; Taylor's Glory, 33; Leigh's Bright Venus, 33; Taylor's Incomparable, 28; Pott's Regulator, 25; Popplewell's Conqueror, 16; Ashworth's Rule All, 14; and four others which were grown a few years ago.

The selfs consisted of 45 varieties—the leading ones, Red-mayne's Metropolitan took 39 prizes; Berry's Lord Pimate, 34; Flora's Flag, 27; Schole's Ned Lud, 28; Whittaker's True Blue, 17; Grand Turk, 18; Lord Lee, 14. These are all that are now grown.

At Middleton, near Manchester, the Auricula was cultivated as early as 1725. The oldest varieties known are Rule Arbitrar, green edged; Hortaine, white edged; and Pott's Eclipse, green edged. The first and second can be traced as far back as 1757—one hundred and eight years ago, and the third to 1767, ninety-eight years ago. About the year 1785 the following varieties were introduced:—Grimes's Privateer, green edged, shown then in the green edged class; Popplewell's Conqueror, white edged; Grimes's Hyder Ali; Wrigley's Northern Hero, green edged; Walker's Goldfinch, yellow self, now known as Gorton's Goldfinch; Gorton's Champion, green edged; and Gorton's Stadtholder, yellow self.—JOHN SLATER, *Northenden, near Manchester.*—(*West of Scotland Horticultural Magazine*).

#### MANAGEMENT OF MOWING MACHINES.

VERY seldom have I found the knives uneven, but when so I think it was through a stone being caught between the cutters and the plate, and pressing one or more of these deeper into the cylinder, as I find every cutter is not set at the bottom of the groove out for it in the cylinder. It is an easy matter for any smith to raise or lower any of the cutters as required. Should it be necessary to grind the cutters, the quickest way I have tried is oil and silver sand, screwing the cutters as near the plate as can be, and turning them the reverse way. This is quicker than using emery, but, of course, grinds the plate away very much, which hastens the end of the machine.

In the machines now made, there is no need of grinding.

\* This information I procured some years ago from the oldest and earliest growers living, some of whom were 88 years old, and became growers at the age of 14 years. The father of one died some years ago, aged 86 years, and his son John was 83 when he gave me the particulars, and was hale and hearty then.

As soon as the cutters are liunt turn them end for end, which is easily done in a few minutes. I have had one in use three years, and by reversing the cutters when desirable, it cuts as well now as when it first came.

I would just say, Never let the edge of the cutters or plate rust, always oil them when done working. We all know how much easier tools are to use, and how much better work we can make with them, when kept bright and clean. If the machines are expected to work easily, and do the work well, keep them clean and dry when not in use.

I have often heard said, "How hard the machine works! I had much rather used the scythe," when at the same time I have seen the machine after working run into the shrubbery, and there left without any protection. If a machine must be left out, have a board a yard square, elevated a little, to set the machine on, and with a square yard of oilcloth cover the working parts.

Use the best oil, and keep the machine thoroughly clean, by so doing it will work easier, better, and last longer.—W. C.

### DUCHESS OF BUCCLEUCH GRAPE.

MANY are the conflicting opinions in circulation regarding the qualities of this Grape, but the majority of these opinions have no foundation in fact. On the contrary, they have been picked up upon mere hearsay, and transmitted till that which is false has come to be regarded as true. I write not as the defender of the Grape Mr. Thomson has produced, but under the dictation of truth, which leads me to say that in more than one case its character has been assailed most unjustly, whether to serve interested purposes does not clearly appear; but whatever the motive, such procedure is unmanly, ungenerous, and unjust. Whatever may be the opinion of some, those who have made the acquaintance of this Grape will willingly admit that the flavour acknowledges no superior; and where this is held to be a desideratum it will always hold a prominent position. The Judges placed it equal to the Muscat of Alexandria at the Edinburgh International Show. A few days afterwards I had an opportunity of making the same comparison at Dalkeith, and can fully confirm the accuracy of that decision. I grow the Grape myself, and therefore speak with more confidence.

This is by no means an attractive-looking Grape, the berries being somewhat small, but this defect is covered to a great extent by the large size of the bunches, the vigorous constitution of the plant, and its productive habit; added to this, it submits to early forcing as freely as the Black Hamburg. The fruit does not crack like the Chasselas Musqué, nor shrivel at the stalk, which is frequently the case with the White Frontignan.—EXCULTURATOR.

### THE CULTIVATION OF THE MANGO FOR THE DESERT.

As I have never seen any mention of this fruit in your columns, and as I have for some years past been most successful in its cultivation for the desert, I trust that a few practical hints on the subject may not be unacceptable.

There is a common belief that this tree is most difficult to grow, and to this, in a great measure, may be attributed the neglect it has always experienced. I can affirm, however, from my own experience, that there is little more trouble in fruiting the Mango than in growing a Pine Apple, and I strongly recommend those who wish for an agreeable addition to their dessert to try their hand at growing it.

The Mango (*Mangifera indica*), grows most abundantly in India and South America, and is generally esteemed one of the most delicious of tropical fruits. The tree there grows to a large size, although here it seldom exceeds 20 feet in height. The leaf is not unlike a Walnut in size and appearance; the flowers are small and in bunches, of a pinky-white colour, and the fruit is about the size of a large Plum. At first it is green, but it afterwards becomes, if well ripened, of a deep orange, and the perfume is then most delightful. Outside, the fruit has a thick skin, and underneath a pulp which melts in the mouth almost like jelly; the flavour is exquisite, indeed, it must be tasted to be fully appreciated.

In growing the Mango it is important to remember in the

\* We once saw in India a variety, called the Malwa, which remained green when ripe, and was esteemed the most.—Ems.

first place, that success depends in a great measure upon having a very high temperature, the ordinary Pine stove hardly suiting it, as in winter it requires to be kept dry as well as hot. Indeed, the temperature of the house in which mine are grown is never allowed to sink below 80° in the daytime, summer or winter. When growing the trees require an abundant supply of water, which must be withheld when they are at rest. My mode of culture is this:—Early in February the tubs in which the trees are planted are thoroughly well soaked through with water, the flues of the house being sprinkled night and morning, and the temperature kept up to 85° by day and 75° by night, with a good bottom heat of about 85°. As soon as the trees show signs of growth the temperature is slightly increased, particularly when the sun shines, and the house is kept well moistened. Air is given sparingly until the blossoms show, when a little more is afforded in the day. A check, however, from cold air or wind is most carefully avoided, as it would be quite fatal to the future crop. As the days become longer so the temperature is increased to 100°, or never less than 90°. If, however, the blossoms should droop—a very common complaint—the house is kept rather cooler for a day or two, and less moisture given. In a week or ten days after the flowers open the fruit begins to swell off, and the greatest care is then necessary to insure a proper flavour. Air is admitted day and night in small quantities, and the trees are never shaded, no amount of sun doing them harm. As the fruit ripens less air must be given, and the house kept closer.

When all the fruit is cut no more water is given until the next spring, excepting a little now and then to prevent flagging. Unless this is attended to no fruit will be produced the next year, however well ripened the wood may have been. It is also of importance that the fruit should ripen when the sun's power is at its height, for although Mangoes may be had at almost any time, unless they are ripened between July and September they will have but little flavour.

If properly managed the Mango is a free setter and bears well. It is little liable to the attacks of insects, and is in general very healthy. It is very impatient of removal, and should be disturbed as little as possible. My plants are grown in tubs 2 feet deep and 30 inches wide, the soil I use is a strong loamy one by no means rich, but the trees are watered twice a week during growth with weak liquid manure, and the tubs are plunged during the spring and summer up to their rims in a bark-bed where they can have plenty of bottom heat. Young plants for the first three years should not be pruned-in, but allowed to have pretty much their own way.

If these few directions are carefully followed I feel sure the Mango will grow and fruit freely. From a tree only four years old I have this summer cut upwards of seventeen dozen fruit all perfectly ripened. Any one who has ever tasted this splendid fruit will, I am sure, agree with me that too much pains cannot be taken to obtain it in England.—J. H.

P.S.—I shall be happy to give one cutting next spring or summer to any person who requires it.

### ROSES OF 1864 AND 1865.

As the catalogues of Roses will soon be out, it may be a guide if I state the final result of my experience this trying season.

*Roses of 1864.*—Madame Victor Verdier, Pierre Notting, Lord Macaulay, Baronne Pelletan de Kinkelin, and Lord Herbert—these have been the cream of 1864. The next best have been George Prince, Eugène Verdier, and Leopold Premier; they are good Roses. The next best have been Madame Derreux Douville, La Duchesse de Morny, and Lord Clyde. The first eight are sure to please you. Select them as they stand. Buy as many as you can of the first two.

*Roses of 1865.*—Madame Moreau, Rushton Radelyffe, Duchesse de Caylus, Duc de Wellington, Mdlle. Amélie Halphen, Elizabeth Vigneron, and Général d'Hautpout; these are seven superior Roses. The next is very dark, handsome, and free-flowering—namely, Souvenir de William Wood. If you buy these eight they are sure to please you. Buy them, if you select, as I have placed them. Three of these Roses I have not yet referred to in previous recommendations—namely, Madame Moreau, Elizabeth Vigneron, and Général d'Hautpout. Madame Moreau is full-sized, full, and a splendid, large, crimson, show Rose. Elizabeth Vigneron is very handsome; the colour tender silvery rose, in the way of Laëlia, but of better habit. It is full-sized. Général d'Hautpout is rich,

velvety, dark shaded crimson. It is globular, handsome, and a free bloomer.

There are other Roses of 1865 that I think well of; but till they do well no man is justified in recommending them. It may amount to a national fraud. Roses may do badly the first year, and do altogether well the next season. Some require to be on strong stocks before they can come out in their true form. I fancy that King's Acre, Medina Cœli, and Charles Margottin will eventually deserve a *testatur*. Considering that the Roses of 1865, with the exception of Rushton Radclyffe, came here this spring on very weak stocks, and were weak in themselves, I am surprised that they should have done so well. The Roses of 1864 were stronger plants, and wintered out of doors well. Things must be equal before you can draw a just comparison. —W. F. RADCLYFFE, *Tarrant Rushton*.

### FENNIAN SYSTEM OF SYRINGING WITH HOT SEWAGE.

WHEN I received "A BEGINNER'S" letter I had not sufficiently satisfied myself on a subject that was then under my observation, in connection with syringing orchard-house trees. To use the foliage thick waters charged with anything but sweet odours, when the fruit is arriving at maturity, would be repugnant to our ideas. As regards red spider or any other evil affecting the foliage of my trees after the fruit was gathered, there was none, so healthy, clean, and green did the leaves appear; but just as I was about to rest upon my oars and banish all care in that direction, on the 16th of October a cloud appeared to envelope us, and a minute winged black aphid covered us, entering both ears, eyes, and nostrils most offensively, and I prognosticated disease for something under my charge. After the lapse of a few days, and although the air continued to be charged with the flies, I began to console myself for false judgment in this respect till a quantity of yellowish leaves caused me to look suspiciously on what I call the lungs of a Royal George Peach tree — viz., some shoots which I train outside on the end of the wall which forms the back of my lean-to orchard-house, merely for the sake of the leaves, because this tree, strong of growth naturally, is rather circumscribed for space inside. On a close inspection of the back of the leaves I found there were thousands of a winged black aphid, with their wingless progeny apparently of all colours, established and sucking away at the leaves so effectually, that at the slightest touch these fell off. To appearance the foliage of the trees inside the house was unaffected; but upon examination underneath I saw the plague increasing there also, so that prompt proceedings had to be taken.

About two gallons of sewage were heated in the evening to 160°, and with this I operated upon the "lungs" of the Royal George by directing the sewage from the syringe well beneath the foliage, and to prevent scalding my hand from the continuance of the heat, I counteracted it by only half charging the syringe at each dip. The force used in applying the liquid struck off the leaves most affected; but upon those retaining their hold and greenness I found, on examination next morning, that the above degree of heat had sealed to death nearly all the aphides and their progeny without, to my great surprise, having at all injured the foliage. That day was Sunday, so of course further operations were suspended till Monday, when at evening, and the foliage of the shoots outside showing no signs of being scalded, after two days' hot sunshine, several gallons of sewage were heated to 160°. I then closed all ventilation, excepting 3 inches at the apex at the back of the house, which is a permanent opening and is never closed; and the Peach trees against the wall, Nectarines, a Peach Apricot, and some young Vines in pots, along with a Prince of Orange Geranium in full bloom, and which was affected with the green aphid, were thoroughly syringed with the scalding stuff both over and under the foliage, and every cranny of the house besides, till the stone-coloured paint of the woodwork became stained of a dark oak colour. Well, it could not be helped, I was intent on an experiment, and during the operation I was several times obliged to burst into the open air to gain breath, in consequence of the dense hot steam being so powerfully charged with acid gas. I have ventilators opening from the back wall of the orchard-house into the vinery; these I closed, still the smell insinuated itself in there to such an extent as to cause me to remove some ripe Melons which I had cut and intended to remain there for a day or two, for there is no fruit more likely to acquire and retain a foreign odour than

ripe Melons. Everything looked particularly well in the house next morning, excepting the paint. There was not a vestige of stain upon the dark stone-coloured wall, and all the female aphides were dead, as well as the majority of their progeny. The Prince of Orange Geranium stood it out without even a petal being injured by the heat, and most of the green fly upon it were dead or dying. I fancied, also, that the paint did not look quite so dark. I opened the front ventilators and allowed the sun to beat strongly upon the glass and foliage without any shading, and not a leaf was injured. The smell during the hot sunshine would have been disagreeable to ladies, and, indeed, it would have been so for twenty-four hours to a man; but on the following day, it had in a great measure disappeared whilst the paint was certainly recovering its proper colour.

Feeling satisfied with what I had done so far, I concentrated my thoughts upon a young Ribston Pippin against the garden wall, and which, from the sowing of a Blenheim Pippin seed to raise its stem, then grafting the scion upon it, up to gathering its delicious fruit this autumn, has claimed part of my attention for eight years. It has been a consolation to me not to perceive a scab or speck upon it till this autumn, when it became affected with the American blight; and where these white fluffy insects are congregated, there they are laying the foundation for the dreaded canker on the best of Apples to a certainty. I had been thinking of painting all over the wood with train oil, but the success with which I had encountered the enemy before with hot sewage determined me to try it in this case also. The tree is horizontally trained, and I unfastened the shreds, excepting those at the extreme ends of the shoots, and kept the branches about 2 inches from the wall with some stumpy forked sticks so as to allow the hot sewage to reach the back of the wood as well as the front. I then syringed the tree well with the hot sewage at a temperature of 160° on the evening of the 20th of September, repeated the operation two days afterwards, and I am gratified to find that the American blight is more effectually killed in that way than its black compeer on the Peach tree. Although some of the leaves of the Apple tree suffer a little from so severe a scalding, being scorched and becoming brown at the edges, we may well be able to put up with that when we consider the good effected by getting rid of one of the worst of all blights. Whether the black visitor we have been pestered with this autumn is new to us I cannot say, I do not remember it before, and it has not injured any trees with me excepting those above mentioned. A neighbour called upon me, during my operations against it, complaining that almost all the leaves had suddenly fallen off his Peach and Nectarine trees, a circumstance which he could not account for, and to inquire if I had experienced anything of the sort with mine, and I explained to him the cause and the remedy which I adopted.

On the 21st of September I received from you the letter of "A BEGINNER" asking further advice on the subject of hot syringing. I could have answered him at a guess at once, but as a great many of my operations run out of what I may term the gardening groove, I am never in a hurry to recommend my practice to others till I am well satisfied that it has proved beneficial to myself, or so as to form a conclusion. I again inspected my orchard-house trees, and found that new colonies of the aphid were beginning to settle on the under sides of many of the leaves, so the whole of them underwent a thorough syringing as in the first instance. On the 23rd I saw that the female insects would persist in coming, and again I syringed the foliage with the hot sewage to the certain destruction of all the winged ones, but the cry was still "They come!" The foliage in the adjoining vinery seemed invigorated, and I fancied that the Grapes became more rapidly black. Visitors being expected, to make sure that no disagreeable odour should exist, I well syringed the orchard-house and trees on the 25th with clean water heated to 160°, and scattered a surfacing of fine dry soil over the soil of the house next morning, ventilated early, and set open the ventilators to the vinery; and, when the party visited us in the afternoon, the houses smelt fresher and better than if I had never applied any of the sewage water, but the foliage looked more grey and did not exhibit the rich glazed appearance which it invariably has after the syringings with sewage. At the third syringing the Prince of Orange Geranium leaves having exhibited signs of suffering, I moved it into the open air, and it is now insectless and flourishing.

The only flower with me that has been affected with this persevering aphid is a *Convolvulus major* against the wall of the house near the front-door, and having for its neighbour a *Gloire de Dijon* Rose. The leaves of the Rose, in consequence

of my disinclination to use the hot strong-smelling sewage there, were being riddled by the roseleaf caterpillar, and, knowing that I had kept my Roses in the open free from that insatiable pest through the agency of sewage, I applied it to them at 160° well under the leaves, for both insects skulk beneath, and never appear upon the upper side. To two syringings the grub succumbed; but the aphides on the Convolvulus would come to be killed, and how the plant and its delicate flowers braved out the hot applications is a mystery.

After I had cut my Turner's Scarlet Gem Melons from the frame the plants and leaves remained perfectly healthy and green, as I ever wish to see them at those times. The leaves had never had a drop of moisture upon them, and as they were now done with I gave them a syringing with soapsuds heated to 150°. It had no effect. Two days afterwards I operated upon them in the evening with the sewage at 160°, and next day allowed the hot sun to strike the foliage through the glass unimpeded, as is my wont. The plants and leaves stood this severe test exceedingly well, and would even now prove capable of producing a second crop did not the lateness of the season preclude the idea.

At intervals of a few days I gave the orchard-house two more syringings; and now that the winged interlopers are on the eve of decrepitude from the cold I have desisted, and caused the woodwork of the house to be thoroughly scrubbed with soap and water, and the glass to be cleaned. The paint looks as bright as ever. I am now as proud of the healthy, gradually ripening foliage of the trees as I was of the fruit upon them. I will here give the periods of ripening in answer to the

general request made by the Rev. T. Bréchant. I gathered the Peach Aprieot from a pot in this locality (Woodstock, Oxfordshire), on July 29th; Royal George Peach from the back wall of the house, August 5th; and also from the wall a Peach which I will call, till I am better advised, the Alexandra Noblesse, because it is a seedling from the Noblesse which Mr. Rivers sent in lieu of the latter, and which at the time he strongly recommended. It is a lump of delight; as large, richer, and more conical in shape than the Royal George. It is a elingstone, pale, and partaking of a gentle blush. It began ripening on the 20th of August, at which date Rivers's Orange and Duchess of Oldeuburgh Nectarines in pots gave us some ripe fruit.

To return to the letter of "A BEGINNER," I may state that the hot-sewage syringings applied directly the fruit is gathered, and at a temperature of 160°, are certain death to the red spider should the leaves be affected with it, and that is too often unfortunately the case; and we may conclude that they are so to most other insects as well, for with what will destroy the red spider when established anything else would stand a poor chance. From 120° to 125° is hot enough when the foliage is young and tender in the spring; from 130° to 140° from thence up to the swelling of the fruit; and from 180° to 190° after the leaves have fallen till the buds are on the move again. "A BEGINNER" says he has a considerable quantity of house slops, and he inquires "how" these should be diluted for the purpose of using them in the troughs, or "on" the hot pipes in a greenhouse or vinery, or for the syringing of orchard-house trees. I answer: The contents of a tank which receives

a. Greenhouse.  
 b. Back shed.  
 c. Hot-air oven.  
 d. Furnace.  
 e. Ashpit and door.  
 f. Cold-air flues leading up to oven from shed. They are on each side of the furnace, 3 inches wide by 5 inches high, and their sides next the ashpit are 7 inches from the centre of the door.  
 g. Cast-iron elbow from furnace, in conjunction with the chimney flue bent under the hot-air oven.  
 h. Liquid-mannre sancepan and steam pipe. The recess to admit the sancepan is never closed, although, perhaps, a sliding door might be

placed there with advantage. It is 1 foot square. When the pot is not there, a foot-square firebrick is constantly placed over the six-inch top opening of the furnace, where the fire is fed, and removed and replaced by a small spade each time the fire is replenished with coke or cinders I always use the latter. Coal should never be burned on account of the smallness of the chimney flue. Of course, on a larger scale coal incl might be used.  
 i. Opening for tin steam-pipe and hot air.  
 j. Brick to take out for the purpose of cleaning flue.  
 k. Stone wall, 2 feet thick, dividing greenhouse from shed.  
 l. Damper to be closed when steam is not wanted.  
 m. Large stone slab forming roof of oven, 4 feet 6 inches from the floor.

all the flowings from the closets and water used for household purposes may be safely employed either hot or cold to the roots, leaves, fruit, and even the flowers of plants; and that six parts of water to one of pure manurial matter is what I conclude to be the natural proportions of house sewage, provided no undue overflow of clean water from rain, or otherwise, has been allowed to flush into the reservoir. The "pure urine" in question is one of the strongest of manures, but by being diluted with six times its bulk of water it becomes safe and beneficial when applied to the foliage of trees and plants after the manner I have described, using a syringe with a rose-nozzle. To the query whether it may be used "in the troughs" or "on" the hot pipes in a greenhouse or vinery,

I answer, Yes, in the troughs; they may be filled with it in the evening, and emptied again the next morning. On the pipes I would not use it, for fear of their maintaining the smell. In preference, if the house is paved I would enter the liquid near the boiling point into buckets, and syringe from one bucket into another, which would soon raise in the house a cloud of pungent steam disagreeable to insect life, and quite sufficient for any foliage during the night. If the floor is of earth, like my own, I would simply syringe the hot liquid over it, and doing so would prove beneficial to the roots; at the same time clouds of steam would be raised for the foliage, and this mode of proceeding might be persevered in up to the ripening period. For a greenhouse the sewage would be best used

at periods when no ladies were likely to visit the structure for a few days.

I have a plan for steaming my "*mulum in parvo*" here after this fashion. A portion was cut out of the back wall, an ash-pit formed on the floor, and some bars laid to form the bottom of the furnace, which is broader at the bottom than the top. It is formed of firebricks well set in fireclay, and a six-inch-square opening is allowed at the top for the purpose of lighting and feeding the fire. A flue is cut out and carried up and along inside the wall, and made flush with the inside of the greenhouse. An opening or recess is formed sufficiently large to admit of a two-gallon saucepan over the furnace; above that is a square oven; and from thence, opening into the greenhouse, a six-inch orifice is allowed. At the bottom of the oven an opening 1 inches by 6 inches is made so as to be just over the lid of the saucepan, which opening is made to be closed or kept open by means of a damper. A loose square firebrick is made to act as the lid of the furnace. Two flues are made on each side, opening from the floor at the ash-pit-door, and they are continued up on each side of the furnace into the oven, in order that whatever burnt air finds its way there from the furnace may be instantly mingled with the pure air rushing up by the side flues to meet it, so that it cannot at any time enter the house in such a state as to be prejudicial to the plants. When the cinders in the furnace have become of a bright heat; and the saucepan, which has been filled with sewage or plain water, as may be required, and boiled already on the kitchen fire, is brought to hand, the loose firebrick is removed, the pot slipped into its place, and the damper which closes the opening into the oven above is withdrawn. Then I step into the greenhouse, and slip down a tin tube made to fit into a hole in the lid of the saucepan; and by this tube the steam arising from the boiling liquid is conveyed into the house, filling it with vapour for a greater or less length of time, and varying in density as may be required. That is all the heating apparatus my greenhouse is fitted with. The furnace will burn anything. I never use any fuel now but sifted cinders, and I have with them kept all my plants perfectly well, and with little trouble or anxiety, through three winters, at a very small cost. The fire frequently continues to burn for twenty-four hours without being replenished. I can command moist and dry air in a very short space of time; and in consequence of the hot and cool air meeting and mixing in the oven, a powerful and healthy current is ever being created to pour itself into the greenhouse through the permanent opening. It is impossible for stagnation of air to take place. The hotter the furnace, of course the more violent is the rush into the house, for the ascending heat sucks up and compels the cool air of the flues to quicken its motion also. I do not know what the little apparatus would prove itself capable of as a healthy heating medium. I have pleasure in sending you a section of the plan.—UPWARDS AND ONWARDS.

[N.B.—We can assure our readers that the system now described and named has no relationship or allusion to the Fenianism of Ireland; and we only hesitated to publish the name, fearing it might cast upon it an air of ridicule, for "As absurd as Irish Fenianism" will hereafter be proverbial. The originator of the hot-sewage syringing is a Mr. Fenn.]

### GRAFTING GERANIUMS.

ALTHOUGH these directions are in reply to the inquiry of "A SUBSCRIBER, *Marford*," we insert them thus prominently because they are of general interest.

The most sure mode of grafting Geraniums is by approach or inarching. We have had upwards of twenty kinds upon one stock by this method. It is simply placing the stock near the plant furnishing the scion, and bringing the branch or shoot desired to the stock. Unite them at a smooth part of the stock by side or tongue-grafting. Bind them together with matting, and upon this place a little moss, and bind lightly with matting. They will be well united in six weeks; then cut away the part of the stock above the graft, and take away the plant furnishing the scion, having first cut the latter off just below the point of union. Inarching is adopted more for the sake of novelty than utility.

A wholesale plan of grafting Geraniums is to pot the stocks early in March from 60's into 32-sized pots, and plunge them in a bottom heat of 75°. In a fortnight they will have made fresh growth. Take off the scions as for cuttings, and as they have not been placed in heat the wood will be firm, which is

all the better, as it is to be united to the firm wood of the stock. Cut off the head of the stock, leaving a few leaves upon a side branch a little above where the scion is to be inserted, which cannot be too low. Prepare the scion or graft by making a slanting cut downwards an inch in length, bringing it out a little below an eye or bud. Make a corresponding cut in the stock, removing the wood nearly half way through it, and then both cuts must correspond. Make a tongue or slit upwards in the scion, and downwards in the stock, so that the one may fit into the other, as shown in the annexed engraving. Bind tightly but not very closely with a shred of best mat, taking care that the outer edges of the stock and scion coincide at least on one side. A little moss placed upon that, and bound with matting, will keep the part moist and exclude as much air as is needed. In ten days loosen the matting, still keeping the scion bound to the stock, and close with the moss as before to keep it moist. When the graft begins to grow keep the matting loose, and cut away the upper part of the stock down to the graft, as shown by the bar in the engraving. It is hardly necessary to observe that the stocks should be retained in the bottom heat, and should have a moist and shaded atmosphere until the operation is known to be successful. Gradually harden off, and the plants will be fit to plant out at the end of May. Crown or cleft-grafting may also be practised, and when the stock and scion are of equal size is an equally successful and more expeditious method.

### CHRYSLIS OF DEATH'S-HEAD MOTIL.

In your last Number, page 324, in answer to your correspondent, "A YOUNG ENTOMOLOGIST," you state that the chrysalis of the Death's-Head Moth "will not give birth to a moth before next July." Now, in the "Naturalist's Library," vol. iv., page 135, it is said that "The caterpillars are usually full-grown about the middle of August, when they bury themselves in the earth and form an oval cell, in which they undergo their destined changes. The moth seldom appears before the end of September," &c.—[We have had a moth at the end of July.—Eps.]

I have this year had three remarkably fine caterpillars of this Sphinx Atropos, which buried themselves in a large pot of earth in the month of August, and according to the terms of the above quotation I have been looking for the appearance of the moth; but from your reply it would seem that I have still some months to wait for the birth of this magnificent moth. I believe it is very difficult to carry it through its transformations. I keep the pot in my greenhouse under a bell-shaped cover of perforated zinc. May I ask you to have the kindness to say which is the correct period, that which you have given, or that which I have quoted from the "Naturalist's Library" above?—C. P.

### GRAPE VINE OF SANTA BARBARA.

ONE of the celebrities of Spanish California is the immense and beautiful Grape Vine now growing at the Montecito, two or three miles below Santa Barbara. The planter of the Vine was Donna Marcellina Feliz de Dominguez, of the earliest expedition to Sonora, before 1780. It was planted by her over sixty-five years ago, from a slip which she cut from the young vineyard at San Antonio Mission, in Monterey Co., for a horse-whip. Her husband had got permission to make a small garden near the warm springs of Montecito, a favourite place for the washerwomen of the new settlement of Santa Barbara, and here she planted it on the edge of a knoll. It immediately took root, and began to bud and leaf, and from careful attention, before she died, it was made to produce more than any known Grape Vine in all America, North or South. Between 1850 and 1860 it had trailed over some 80 feet in circumference, with a trunk of 1 foot in diameter, rising quite 15 feet from the ground. Some years it has borne over 6000 bunches of ripe and sound Grapes, or close on 8000 lbs., and become

the wonder of every resident or sojourner in that part of California; and what is more, for the last thirty years it has principally maintained the old woman and her numerous family.

Professor Silliman, when he visited it last year, said he had never heard of such an immense Grape Vine in any other country, which is saying a great deal, as he has travelled much in the south of Europe.—(*San Francisco Bulletin*.)

### ONE OF SHAKESPERE'S PLANTS.

In Act iv., Scene iv., of "Lear," Cordelia describes her insane father as

"Crowned with rank fumiter and furrow weeds,  
With hardock, Hemlock, Nettles, Cnckoo-Flowers,  
Darnel, and all the idle weeds that grow  
In our sustaining corn."

Some editors of this tragedy have accepted "harlock" for "hordock," and then concluded that Shakespere meant what is now known as Charlock (*Sinapis arvensis*), but we believe that there is no need for a departure from the authority of those old quarto editions of the play which have the name "hardock." It seems to be the same plant alluded to by Lyly in his "Woman in the Moon," where Pandora, whilst deranged, says to a shepherd—

"Thy head is full of *hediokes*, Iphicles,  
So shake them off."

In the east of England the Corn Poppy is still called *head-aches*; and it is certainly one of the weeds most usual "in our sustaining corn," and most likely by its gay flowers to attract a madman's notice.

The same name "headaches" is applied to the Corn Poppy in the Irish counties Carlow, Wexford, Waterford, and Wicklow, where its flowers "are particularly obnoxious to females, the more so to unmarried young women, who have a horror of touching, or of being touched by them."—(*Notes and Queries*.)

In Scotland it is called *head-wark*. In "The Complaynt of Scotland," published in 1548, it is spelt "hedeverk," signifying head-ache, as does the Northumberland and Lancashire "head-wark." The East Anglian pronunciation of the words would be "head-erk," for the w is slurred over; wood being pronounced ood, and this is a very near approach to Lyly's "hedioke." There seems but little difficulty in perceiving that this name, "headaches," was applied with reference to its soothing quality, and consequent power to remove disorders of the head. Many other names of plants are similarly derived, such as Feverfew, Scurvy-grass, Flix-weed, &c.; and from the shape of its seed-capsule it would be the more readily accepted as a remedy for head complaints in those days of symbolic pharmacy, when a plant, or part of a plant, was considered as marked out as applicable to the diseases of the part of the human frame which it resembled in form. Gerard, among other qualities, enumerates that "greater force is in the knobs or heads which do specially prevail to move sleep, and to stay and remove distillations and rheums." The leaves boiled in water, and "the head, feet, and temples bathed therewith, it doth effect the same." Yet others of the old herbalists warn against the continued use of preparations of the Poppy, because of its then causing derangement and insensibility—whence Pandora's warning to the shepherd.—J.

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

MAKE it a rule never to allow the haulm, leaves, &c., of plants to remain on the ground when the crops gathered; a convenient place outside the garden should be appropriated for the garden refuse; and as the leaves, &c. are wheeled to the heap, let a sprinkling of ashes or charred refuse be placed over each layer, by which means a heap of valuable manure will be formed. When the ground is dry proceed with digging up vacant spaces, throwing it into ridges that the land may the more effectually be exposed to the influence of frost. It should also be a rule to double-spit or trench land each alternate year at least; but when two crops are taken off the same piece yearly, trenching should alternate with digging each time the ground is cropped. *Artichokes*, cut down any remaining flower-stalks, remove a few of the large outer leaves, and cover the roots with dry litter or old tan; it is a common but erroneous plan to earth them up with the soil between the plants. *Beet*, take up the roots carefully, and having divested them of leaves preserve them in sand in the same manner as Carrots. *Broccoli*,

this is an excellent period for laying spring Broccoli. It is best performed by two persons, one on each side of the drill or row. Keep a good trench and sink all the heads to the north, burying the stems in soil up to and even amongst some of the lower leaves. *Cucumbers*, keep them securely tied to the trellis, and the shoots stopped as recommended, slightly syringe them every fine day, and give air at all favourable opportunities. *Dwarf Kidney Beans*, another sowing should now be made. Keep the first crop duly supplied with water. This must be particularly attended to when they are in flower, for if allowed to become dry at that time, the whole of the blossom will fall off without setting. *Lettuce*, give air at every favourable opportunity, more particularly to the young plants. The Cabbage varieties intended for winter use will not need it so freely. *Mushrooms*, take advantage of wet days for making fresh Mushroom-beds and clearing out those that are spent; also, collect and prepare droppings for forming fresh beds, by spreading them in a shed and turning them over every day until they are sufficiently dried to prevent excessive fermentation after putting up. *Parsnips*, it is generally more convenient to have them taken up and stored in the root-cellar than to dig them up as wanted. Taking them up should, therefore, be immediately attended to. *Potatoes*, in mild and favourable situations a few may be planted to come in for early use, but there are few places where this can be practised with safety. *Rhubarb*, the forcing of this and Sea-kale must soon be attended to, and where there is a good stock of strong roots, a supply will be easily kept up. The Mushroom-house when there is room, forms a very suitable and convenient place for forcing them. The roots should be placed in a slight hotbed of warm dung, filling up the intervals between them with old tan, or the soil and manure mixed, from an old Mushroom-bed, giving a good watering to wash it in amongst the roots. The bottom heat should not exceed 70°, as too much heat is not favourable to securing strong growth; but except for the first crop it may be dispensed with altogether. *Scorzonera* and *Salsafy* may now be taken up and preserved like other culinary roots.

#### FRUIT GARDEN.

Now that the summer's business is fairly at an end, it is time to take steps to provide against an inordinate pressure of business in the forthcoming spring, for any arrears of autumn or winter business at that busy period will prove a great hindrance to the carrying out a properly-devised system through the ensuing season, and can only be justified on the ground of necessity. Planting, pruning, training, trenching, &c., are matters that belong peculiarly to the dormant period. The habits of fruit trees vary, more especially as to the manner of forming and exhibiting their buds. Thus there is no difficulty in distinguishing the bearing portions of the Apple or of bush fruit in general, whilst the Apricot and the Filbert are at this period somewhat obscure in regard to these points. Even in the Pear, more especially in some of the newer kinds, and such as the Passe Colmar, the Seckle, the Marie Louise, and some others, it is difficult to prune with safety in the early part of winter. For these reasons, therefore, prune bush fruit the moment you can find time. Follow closely with Cherries, Plums, and Apples, and towards Christmas lay aside the knife until the early part of February, when the Filberts will be blossoming, then after a slight thinning of the crowded and inside spray, male catkins may be brought if requisite, and suspended among the bushes. By this time the true blossom-buds of the Apricot may be distinguished with certainty, and the trees may, therefore, be immediately pruned. The Peach and Nectarine will succeed the Apricot, and these may be followed by the Pear, and lastly by the Fig. In pruning bush fruit, thin liberally. Let no two branches in the Black Currant and Gooseberry touch when finally thinned; these seldom require shortening, an equal and judicious thinning is everything here. In pruning Apples the thinning of the branches or old wood should be the first step. This, however, requires caution. The late Mr. Knight, of Downton Castle, was much opposed to cutting out large limbs, unless a strong necessity existed. In thinning the young wood of espaliers, the first point is to secure a free admission of light to all parts of the tree.

#### FLOWER GARDEN.

Chrysanthemums will soon be in flower here, let them be tied out so as to display their blossoms to the best advantage. Fuchsias and such things, if not already protected for winter, must soon receive attention. Dry fern is an excellent material for covering the stems, &c., of plants that require a slight protection in winter. The Dahlias must be marked and numbered

forthwith. Let all bulb-planting be completed immediately. Planting evergreen and deciduous shrubs may now be performed with every chance of success. Be very careful to secure transplanted shrubs against wind, especially if large; these should never be left until they are properly staked, or otherwise made fast, for when this is put off it frequently happens that the roots are injured in consequence of the tops being rocked about by the wind. The weather has assumed an aspect so decidedly wintry, that further hope for the lingering beauty of the flower-beds can scarcely be indulged in. Roses may now be transplanted, preparations should be made to receive such subjects. Fresh loam, rotten dung, and burnt earth, form an excellent compost. Hardy creepers should be examined at this season, and all unnecessary spray removed, and their security from the blasts of winter ensured. Examine stakes and ties generally. As soon as the greater part of the leaves are off the trees, let the pleasure ground be thoroughly cleaned and swept; the leaves if in sufficient quantity should be stacked up for forcing-purposes, covering the borders, and the like. Such parts of the lawn as are near the house should be swept daily to remove leaves and wormcasts, and the gravel-walks should be frequently rolled to preserve a smooth surface. The present is a good time for re-arranging the herbaceous ground, a work which is rendered necessary every two or three years by many of the free-growing plants becoming too large.

#### GREENHOUSE AND CONSERVATORY.

As the beauty of out-door scenery yields before the storms of autumn, the conservatory should be made as attractive as possible, as it will now become in some respects the only place where flowering plants can be inspected with comfort in unfavourable weather. Let the requisite arrangements both as regards watering and changing the plants take place early in the day, that the effects of watering, syringing, &c., may be removed, and an agreeable dryness pervade the house, before it is visited by the family. No pains must be spared to keep the house gay, by introducing plants in succession as they come into bloom, including a portion of the stove plants which have been grown expressly for this purpose. A little gentle forcing will bring the different varieties of *Epiphyllum truncatum* in bloom, and with the addition of *Chrysanthemms*, late *Fuchsias*, and *Pelargoniums*, *Panacratiums*, *Amaryllis*, *Mignonette*, *Neapolitan Violets*, &c., a tolerably gay appearance may be maintained until the time when forced plants shall be more generally available.

#### PITS AND FRAMES.

Have straw shutters, or whatever else it may be intended to use for coverings for these, put in readiness for use without delay. Straw shutters if well made are expensive in the first instance, but are considered by many to be the most efficient of any kind of covering in use, and taking into account the time they last, they are, perhaps, as cheap as any. Expose the stock freely to air on every favourable opportunity, so as to check growth, and get the wood firm.—W. KEANE.

#### DOINGS OF THE LAST WEEK.

RAINS have now come in earnest, filling the pools, water-courses, tanks, &c., and with the winds, tending, we hope, to purify the atmosphere and render it more healthy for man and beast. Our tanks are now full, which they have not been for the last three years, and with more means of saving it, there would be a large quantity of water that might now be stored up. Such another season as 1864 would render gardening next to an impossibility, where nothing but rain water could be depended on. It has set people husbanding water by various means, who never thought of doing so before. For several days work out of doors has been pretty well at a standstill, which gave a needful opportunity for overtaking much in-doors work, as roping Onions, cleaning sashes, washing pots, making sticks and tallies, clearing and greatly reducing climbers in greenhouse and stove, that light may be admitted in winter; washing shelves, stages, inside of glass, &c., preparatory for the arrangement of plants for the winter. A few of the most tender *Geraniums* have been taken up and placed in a shed until we find time to pot them, and place them in a suitable position. Such pruning and thorough washing now, and when the glass is dry a good smoking with tobacco or laurel leaves before the plants are set in, will tend to keep all clear of insects for the winter.

#### KITCHEN GARDEN.

Here very little has been done, except roping Onions in wet

weather, and tying-up and earthing-up a little more Celery on a dry afternoon. Notwithstanding the heavy falls of rain the ground is still dry at no great depth, and we have observed in consequence few drains at all deep that have yet begun to run; the excessive heat dried the ground to an extent that we scarcely ever noticed before, and yet most vegetables thrived very well, no doubt by pumping up moisture from great depths.

Did we anticipate frost soon we would lay the tenderest *Broccoli*, as the leaves appear more than usually juicy and robust, the very circumstances in which frost would do them the most injury. In performing this work it is best to lay the tops to the north, and the next best is the east, so that the sun during winter may strike very little on the centre of the plant. Supposing that the rows run north and south, the following is the simple mode of operation, choosing a dry day for performing it:—Begin at the north end of the row, take out a spadeful or two of earth on the north side of the plant, without coming too near the roots; bend the plant to the ground and partly in the opening, then move earth from the second plant and place it over the stem; do the same with the second and all the rest until the row and piece is finished. We generally take a number of rows across at a time. The above mode and a sprinkling of litter over the heads will save the crop in most seasons. When the *Broccoli* plants are wide apart, say a yard, or one to 4 square feet (as some of our best growers do, but which is seldom done in a gentleman's garden, because, in addition to scarcity of room, the huge heads would not generally be liked on the table, except in the servants' hall), then in addition to a slight laying to arrest free growth, more earthing-up could easily be given so as to thoroughly protect the stems. The putting the heads in a slanting position to the north not only protects the centre better and keeps it more free from moisture, but even if frosted, it thaws more gradually, because the sun cannot act directly upon it. On this last account alone we have noticed one row thus laid down pass scathless through the winter, whilst a row of the same sort standing upright had almost every centre rotted out and destroyed.

Cauliflower being more tender must be protected, and the easiest way is to take the plants up as the heads approach perfection, and keep them in sheds and frames. Without this taking up they may often be had pretty well up to Christmas, in mild seasons, by breaking a few leaves from the cut heads over those coming on, and using a little litter over these on the first frosty nights.

*Mushrooms*.—We have just spawned a small bed in the Mushroom-house, and would have had more preparing but for scarcity of material. The beds in the shed are still doing good service. The spawn used was chiefly what was made lately, and which has given us little trouble, as it was mainly set on a shallow bed of litter, and covered over with the same, for the heat of the atmosphere was pretty well enough to make it run. The litter had been so beaten down with the first rain that little water seemed to penetrate, or we should have required means to have kept the spawn dry; it will be better to remain a week or two longer, though what we used was very good. When a good large heap is made it is rare that all the pieces will come in at the same time—at least, we generally select the best spawned once or twice before we house the whole. Wherever housed it should be kept dry and cool before using it. If the place is very open over-dryness may be prevented by covering with a mat or two or a little loose litter. A shed which is made at all warm and dry from a fire or stovehole is not a suitable place, as there it would become too dry; but such a place would do very well if the shed were large, and kept rather open. If the spawn is kept rather moist and hot it will waste itself in producing little *Mushrooms* all over. When once the piece is permeated by the small, very small, hair-like white threads, these should be prevented growing more by being kept in a state of rest until they are wanted to plant the bed from which the *Mushrooms* are to be gathered. Even then a slight excess of heat and moisture will destroy the spawn, and too much dryness in the bed will be almost sure to give you small dried-up *Mushrooms*.

Only a few can obtain the most suitable material, and that in the most suitable condition for a Mushroom-bed, but provided the temperature be all right, from 70° to 80°, at the time of spawning, we can greatly modify other matters to suit our purpose. For instance, if the bed is rather damp, we wrap each piece of spawn in a good handful of dry, short litter, containing a very little dried horse-dung, and insert it firmly in the bed, the litter just appearing above the surface. If the bed is warm enough, but rather dry, we know the spawn

will run in it, but to give the Mushrooms substance we cover the bed with an inch of fresher damp material before putting the earth on. In making beds in winter, the material is generally apt to be too wet. We would rather have the bulk of our beds made before winter; but all the year through we want all the horsedung we can obtain. In winter, when our materials altogether are wetter than we like, we cut some dry litter or a truss or two of dry straw into lengths of from 1 to 2 inches, or more, straw in proportion to the size of our heap, and when well mixed and blended we thus have the heap when it heats a little in that desirable condition, when it is neither too wet nor too dry.

We question if we should have mentioned these little matters so much in detail, but for the fact that we have had several letters of thanks respecting the dry-litter-and-cut-straw plan, and because in our young days we had, under the direction of others, a little to do with Mushroom failures arising from totally different causes. In the one case the Mushrooms were attempted to be grown in a close, roof-ceiled shed, without any dry heat. There the beds were chiefly made of a good size, from fermenting material prepared as for a Cucumber-bed. In every case in which we saw the beds made, we are now sure the material was too wet, and this was increased by placing a heap of such fermenting material in the house in winter to keep up the heat. Very few Mushrooms ever came out of that house. Prizes were taken for Mushrooms, but in all cases that we were aware of, these came from borders inside the forcing-houses, unbidden, and, therefore, with no credit to the cultivators. With materials drier, spawned in the usual way, and the beds covered with a little litter or hay, such a shed would have produced Mushrooms as plentifully as some of our friends now have them in a spare stall in their stable.

In the other case, the failure was just from the opposite cause. The Mushroom-house was a lean-to, to the north, with a flue against the north wall, and three or four tier of shelf-beds against the south wall, a glass house being in front on the other side. Droppings of horses and soil were chiefly used. These droppings were carefully dried in open sheds, turned, dried, and turned, and dried until their virtue was pretty well dried out of them. Such very dry material was put in the shallow beds, in very shallow layers, and every layer was beaten so hard, that if there had been enough of operators the moisture that dropped from their faces would have done something to moisten the beds. There was little difficulty as to the spawning, as the extreme of dryness, and the extreme of firmness generally prevented the beds heating overmuch. The dryness of the beds, and the dry atmosphere from the flue, rendered the gatherings of the little buttons few and far between. Large, bonnet-headed, juicy fellows for frying were never seen at all. With the material a little more moist, not quite so firmly beaten, and moisture thrown along the floor in winter, or evaporating-pans in the flue, the beds should have produced freely, and with a tithe of the labour and preparation.

Here we ought to mention one thing more as one of the minor causes of disappointment. Most of these shelf-beds were made during summer and autumn, and were spawned shortly after they were made, but were earthed-up at the certain number of weeks before they were expected to produce the crop. No Mushrooms were attempted to be grown in summer, the most difficult time for cultivating them. Now, we have often thought, that even if the spawn run in the beds it might almost waste its strength there, and from the dryness, &c., be unable to make a fresh start through the soil. Be this as it may, we have made it a general rule not to spawn a bed so very long before we earth it up, so that the spawn shall have a chance to run both ways. We should like very much if we had the material for several beds, instead of one piece, now in our Mushroom-house; but if we had it we would let it lie so loosely as not to heat much; or if that would not do, we would firm it to keep out air—the great cause of fermentation, of heating, and wasting away; and then we would turn it a little, and add a little fresh, just to increase the temperature before spawning and earthing-up. We have done a good deal with large beds out of doors, covered up to keep them at the right temperature, and have gathered long and plentifully; but to keep up something like a moderate constant supply, we do not know if anything beats small shallow beds, say from 12 to 18 inches deep; and where the material is scarce, as with us, a little bit can be made when a large bed could not be thought about. Over-heat, over-dryness, and over-wetness of material we consider the chief causes of failure; and in shallow beds, as a minor cause, we would name the spawning a bed months before it was

earthed-up. We should be glad to have the opinions of others, based on their practice and observation, as to the spawning of beds, say from one to three months before earthing them up. By such a plan many beds might often be finished, except the earthing-up, early in the autumn, when the material is so much more easily dried. Our own experience would lead us to the conclusion that beds on the whole do best that are earthed over only a few days after being spawned. This earthing may take place after spawning as soon as there is the least sign of the temperature of the bed falling, say, below 75°, as the soil itself, from being rather cool, will help to cool the bed, and the firming of the soil, from keeping out the air, will cool it still more. If there is no mode of heating the place, a good plan is to cover the bed to keep the heat in. As soon as the spawn is working the heat of the bed will again increase.

#### FRUIT GARDEN.

Had we the material we would have protected the Vine-borders from the continuous wet, but as they were rather dry it will do them less harm, more especially as it is still warm. A little litter over the borders now will prevent the heat of the earth escaping so freely, a matter of importance in early houses. Figs are still bearing well, and as the sun has been propitious they are pretty good in flavour, but ere long we must cut off the most forward fruit in the house, as, when the plants bear early, and also very late, the first crop in the succeeding season is apt to be much injured. Fig trees out of doors may have all the green fruit cleanly and neatly cut off that are larger than the largest Peas. Those smaller may be kept safely through the winter with a little protection, and will come in earlier than the smaller ones just showing. Strawberry plants in pots should, for want of better protection, be laid on their sides in such weather. Forced plants of last spring have yielded some fine dishes this autumn. They should be fastened up with small twigs, as otherwise in damp weather slugs and snails will have some of the best of them. We wish now that more of our Apples and Pears had been safely housed. However, we shall soon have a dry day or two; we would then, also, rough-prune many fruit trees, Raspberries, &c., before the winter. In the orchard-house we have now little left except Plums, which are still very good. Nipped a few decaying berries from Grapes in later houses, and put a brisk fire on during the day, with a fair amount of air at the top of the house, allowing the fire to go out at night. Will take the first chance to have all furnaces properly cleaned before the winter sets in. Fruit trees in pots now receive but little water, as, in such dull dripping weather, if they have but little water at the root the leaves and stems absorb nearly as much as they perspire.

#### ORNAMENTAL DEPARTMENT.

*Lawns—Mowing Machines.*—The answer about sharpening knives of machines, at page 316, is just the same as the plan we alluded to a month or two ago. We are glad that Messrs. Green have alluded to the simple plan in their machines of merely changing or reversing the ends of the cylinders. We found out this simple but grand secret as much by chance as anything else, and had we known or thought of such a simple process would have resorted to it earlier. It answers admirably, and renders all modes of sharpening the cutters unnecessary. On a part of the lawn not much in sight, and where the grass had not been cut for six weeks, we mowed in the mornings when suitable, as we want this long grass and a few fallen leaves to mix with long litter from the stables to make a fermenting-heap, giving us a little heat to help on with many things now. We have no hesitation in using such grass as a component in all sorts of fermenting-heaps for giving heat, except for Mushroom-beds, and if we used it at all for them it would merely be for the bottom of such beds. Such a heap as the above will be useful now for many purposes, and especially for giving a start to large Geraniums, &c., taken up from the flower garden.

From the beds we have as yet taken nothing but a few tender plants. For cuttings, &c., under glass in cold frames, we have run over all the old glasses, filling up holes, &c., and will finish washing all the glasses as soon as the weather is suitable. We have commenced inserting *Caleolaria* cuttings in a cold pit, in the manner described in previous years, only we made sure this year that above a couple of inches of rough leaf mould and riddlings of loam there should be 2½ inches of fresh sandy loam from the roadsides, and a quarter of an inch of road drift sand over all. In this the cuttings are dibbled at about 1½ inch apart, and being watered they will need little more but air every night when mild, and a dewing from the syringe on a

very sunny day. We shall give them pretty well to Christmas to strike, and if not hurried, and the cuttings are sound, scarcely one in a thousand will fail. Owing to the heat, and very free blooming, the cuttings of many kinds are scarce. What we like for cuttings, are short, stubby, side-shoots, not showing bloom, taken off close to the older stem, when they are from 2 to 3 inches long. We generally take off the lower leaves, shorten the top ones, cut the bottom with a sharp knife, and pull every leaf through soap, Gishurst, tobacco, or quassia water. After such a season the eggs of red spider or green fly are apt to be on the cutting though not seen, and the swinging through the water will help to remove the eggs, as well as settle any little insects that may be alive. If kept all the winter in such cool quarters, insects will not be likely to meddle with them, unless they have gone into the pit with the cuttings. Coolness alone will destroy many insects. From some experiments we once made we are inclined to believe that that is the best mode for eradicating that pest of our hothouses.

**Mealy Bug.**—We agree, therefore, in the advice once given to the possessor of a valuable collection of tropical plants, of which the destruction was threatened by their mealy-coated enemies. The advice was to take all the plants out of the house, to wash all the stems and heads in tobacco and soap water; to keep the plants in another house, as cool as to be within the point of safety, washing and rewashing them; to expose the old house to a sharp frost; to wash the whole, walls, stages, &c., and every crevice with turpentine water, and when dry to paint or whitewash the whole. Whilst that was being done the plants were to be turned out of their pots, shaking away every bit of earth, and washing the roots, and repotted in fresh soil in smaller pots. The heat in their old quarters would soon cause them to make fresh growth, and it is hoped that the insects would not trouble them for some time. All the labour would be next to in vain, unless the house was well frosted, as, protected though the insect is by its woolly covering, it is very sensitive to cold.

But for the weather would have planted out Pinks struck during the summer. If not done soon they had better be potted and receive a little protection during the winter, giving them plenty of air, but protecting a little from heavy rains and severe frosts. If planted in time to make fresh roots, hardly anything will injure them, except slugs, and rabbits and hares, which will soon clear a bed off. Carnations and Picotees are almost as hardy if planted out early, but now they will keep better in pots. Auriculas, Polyantuses, and the finer Primroses in pots, should have the pots cleaned, fresh surfaced, and receive all the air possible in such mild weather, but be protected from such heavy rains. The best mode is to prop up the sash at the four angles, so that there shall be a clear sweep of air all over the plants. Chrysanthemums in pots, even to bloom late, had better be taken in-doors, or under such protection as, though open, will keep the drenching rains from them, otherwise when the plants expand their bloom the leaves will be likely to be troubled with mildew, and thus be made unsightly. As soon as the flower-beds are cleared preparations should be made for bulb-planting, and if that cannot be done early enough, the bulbs may be set in boxes in leaf mould, so that they may be planted with roots, or may even be placed in small pots to bring them on a little.

Ixias, Sparaxis, Oxalis, Cyclamens, &c., now showing growth should be potted, and allowed to grow on slowly. The fine, small-flowered Tropæolums that have been resting in dry earth and sand, should also be potted as soon as they begin to start into growth. A good plan is to pot first in a small pot—say one of 6 inches in diameter, using loam and peat, with a little sand, and grow in that until the shoots are a foot or more in length, and then turn out into a large pot of 12 or 15 inches. Apply the trellis, and train at once, using similar soil, with a fair amount of dried, sweet cowdung in small pieces, and water very carefully until the roots begin to fill the pot and get round the sides.

It will be advisable to take all Camellias, Azaleas, and hard-wooded greenhouse plants under glass. For Primulas, Cinerarias, &c., see previous weeks.—R. F.

TRADE CATALOGUES RECEIVED.

Thomas Rivers & Son, The Nurseries, Sawbridgeworth, Herts.—*A Descriptive Catalogue of Fruit Trees, by Thomas Rivers. Catalogue of Roses (Thirty-second edition).*

COVENT GARDEN MARKET.—OCTOBER 21.

We may now say that some diminution has taken place in the supplies. Apples and Peas have very much fallen off, and vegetables are only sufficient for the demand. Potatoes are brought in much better condition, and the supply is still heavy.

TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

**GERANIUM FLOWER AND LEAF (F. H. N.).**—We do not see anything uncommon in them. They may be from a plant that would be a good bedder, but that would entirely depend upon its habit.

**PROPAGATING VARIEGATED HOLLIES AND IRISH YEW (F. G.).**—Graft the variegated on stocks of the green-leaved Holly, removing a little of the soil around the stock, so that the graft can be inserted a little below the surface. Put in the scion by whip grafting, and when the stock is just commencing to grow, which usually is towards the end of April. The scion being fixed in its place by a mixture of matting, and the usual covering of clay (full directions for grafting are given in the "Science and Practice of Gardening," page 24), cover the grafted part with soil, drawing this towards and placing it against the stem so as to cover the union completely, but leaving the scion with a few inches of its length exposed. By midsummer the scion will have taken; remove the soil, untie the bast matting, and cover with soil as before. Sow the berries of the Irish Yew next March in beds of light earth, and cover with half an inch of fine soil. They will come up in due season, but it will be a very long time before they become useful plants. Such plants are cheaper bought, instead of being reared in private gardens.

**PRIVET CUTTINGS TO FORM A SCREEN (A Subscriber).**—Privet is the suitable shrub; Lantana is too tender for such a purpose as screening a garden, for if anything it requires protection or at least a sheltered situation. Privet is the fastest growing of hedge plants, and is second to none for appearance if kept neatly trimmed. Now is the time to put in the cuttings in two rows 6 inches apart, and 3 inches asunder in the rows, in quincunx order. Rooted plants would be more sure to grow, and they can be had by the hundred or thousand of any nurseryman for very little.

**FRUIT TREES FOR NORTH AND SOUTH WALLS (An Eight-years Subscriber).**—Cob Nuts and Filberts would do on a north aspect, and yet they will not do if you train them to it. Not trained to the wall they grow from it and obtain sufficient light; besides they are unmanageable trees to train to a wall. Of Raspberries we have no experience, and yet we should think them very untractable wall trees. Morello Cherries would do well, and so would Currants and Gooseberries. A north wall is the very place to obtain fruit late, and keep it a long time after it is ripe. For the south aspect Peaches and Nectarines would do very well. They fruit equally well on a low as on a high wall, only the trees must be planted farther apart. It is too low for Apricots.

**IMANTOPHYLLUM MINIATUM CULTURE (A Subscriber).**—Your plant growing freely will certainly flower in due time. It is not strong enough to bloom, we should think, as the *Imantophyllum* is a free bloomer. Pot it, when growth recommences in spring, in a free border, or in a tub, two-thirds, and leaf-mould, one-third, with a free admixture of silver sand—river sand will do. Give a moderate shift, and drain the pot well. Water freely whilst growing, and place in a vinery or warm greenhouse

When the growth is made less the supply of water, and place in the full sun. Keep moderately dry during the winter, and it will assuredly flower next year.

**PLAGUE OF ANTS (*Idem*).**—You cannot pour ammoniacal liquor into, or spread gas tar about their haunts in-doors without damage to the plants. As you are able to entice them with treacle, mix arsenic with it, and this, if they come and eat it, will kill them. Be sure to keep it out of the reach of fowls and domestic animals.

**LAUREL LEAVES FOR DESTROYING INSECTS (*S. R.*).**—The common Laurel leaves in winter and young shoots in summer are destructive to various insects, such as green and brown aphids, thrips, red spider, and mealy bug. A good barrowload of the shoots and leaves bruised between a mallet and stone and put into a small house, will often make short work of every insect in it, and leave a pleasant perfume behind, like a manufactory of custards. We often find that burning such bruised materials, provided the smoke that issues from them is cool, will kill green fly when the tobacco smoke has failed to do so; but just like tobacco and pastils, it will not always do so. As a wash from the syringe and garden engine, we consider laurel water next to good tobacco water for efficacy, and most of the stone-fruit trees like it as much as the insects dislike it. A good barrowload of shoots bruised like it as much as the insects dislike it. A good barrowload of shoots bruised like it as much as the insects dislike it. A good barrowload of shoots bruised like it as much as the insects dislike it. Gallons, covered over with four gallons or six gallons of boiling water, left covered up all night, the barrel filled up with common water in the morning, the liquor poured through a sieve into the engine and used directly, will generally do good.

**YELLOW PERSIAN ROSE CUTTINGS FAILING (*John Wallace*).**—The reason of their not taking root was the want of a little bottom heat, and the shoots being too mature when they were made into cuttings. They take root more tardily than Hybrid Perpetuals, but not more so than Moss Roses, and the reason of these rooting so tardily, is that the shoots or cuttings are not put in immediately after flowering, which is the proper time.

**STRIKING VERBENAS AND CALCEOLARIAS (*Idem*).**—We cannot undertake to write articles on subjects that have been repeatedly treated of so recently. Verbenas are best struck in pans with a little rough soil at the bottom, about an inch of loam and leaf mould upon it, and then 2 inches of silver sand; or fill the pans one-third of their depth with loam and leaf mould in equal parts, and then fill up to the rim with silver sand. Take short-jointed growing, not flowering, shoots about 8 inches long, and if they have a couple of joints to be inserted in the soil and a growing point they are the right kind. Cut them transversely below the lowest joint, take off the lowest two pairs of leaves, and dibble them in the pan 1½ inch apart every way. Water to settle the sand about the cuttings, and stand the pans on ashes in a cold frame. Keep close and shaded for a few days, and after the fourth day give about an inch of air to prevent their damping off. In ten days or a fortnight they will have struck; gradually harden off, and place the pans on boards in an open situation until the end of September. Then take out the points of the cuttings with the finger and thumb, and remove the pans to a sheltered but open situation. In November remove to a cool house only just frost-proof, place them near the glass, give air daily, and enough water to keep them from flagging, but not a drop more. The cuttings are to be put in about the third week in August for store plants. They may be put in after that time, but must have bottom heat. In March the store pans, if 12 inches in diameter, will each afford about 150 cuttings, which may be inserted like the others, but must be placed in a little heat until struck. A mild hotbed of 75° with a corresponding top heat will cause them to strike in a week; harden, and then pot off, or prick them out in a frame. Another lot of cuttings may be taken from the store pans, and those recently struck will need stepping; the points taken out will make excellent cuttings. If these are not sufficient another batch of cuttings may be obtained from the store pans, but two from these and one from the spring-struck cuttings are all we care about, preference being given to putting in more store cuttings than depending too much upon those struck late in spring. Just now is the time for putting in Calceolaria cuttings. We insert ours in a cold frame on the system recommended by Mr. Fish, and which has never failed during a trial of several years. The frame is placed facing the north, on a row of bricks level with the surface, and if Calceolaria cuttings have been inserted in the same place, the old soil is taken out 6 inches deep and replaced with 3 inches of good, rather strong, turfy loam, well mixed with leaf mould in the proportion of two-thirds loam to one of leaf mould. On this is laid 3 inches of pit sand, and, after heating this a little with a spade to make it firm, the cuttings are inserted 1½ inch apart every way. They are slipped off from the old plants and are slips instead of cuttings, being side shoots about 3 inches in length slipped off with a kind of heel. All the leaves below the upper pair and growing point are removed, and any raggedness at the lower end of the slip removed with a knife, and but very little of that is needed. They are inserted up to the leaves, well watered, and all the air possible is given, lights being only used to protect them from heavy rains and frost. We do not care about their rooting before Christmas, by which time we mostly expect frost. From this they are protected by covering of straw over the lights, and they never receive light all the time the ground remains frozen hard. In mild weather they have all the air possible. About the end of March, or early in April, they are planted out in beds prepared as for Celery, and protected from frost by mats spread over hoops. The points of the shoots are taken out soon afterwards, and the plants are finally planted out with balls in their blooming quarters.

**VINE SHOOTS DISEASED (*W. J. S.*).**—Your very unripe and weak Vine shoots sent us have these appearances usual after a very severe attack of thrips, and there seems to have been a little mildew also. If it were mildew the shoots and branches would be covered with a fine mealy white powder. To kill it dust the parts affected with flowers of sulphur. To destroy the thrips fill the house with tobacco smoke two nights consecutively, and every other night for a week, then keep a sharp look out, and whenever a thrips is seen smoke again on two consecutive evenings. The leaves, judging by the appearance of the wood, must almost all be destroyed by the pest, and that with the wood little more than half ripe. It is the worst case we have seen. We could have been more positive as to the cause had you sent us a leaf.

**CUT FLOWERS OF ZONALE GERANIUM (*W. W. E.*).**—We know of no objection to their being employed in the formation of bouquets for exhibition, but no Committee, we think, would offer prizes for them to be exhibited alone as cut flowers.

**FORCING STRAWBERRIES AND VEGETABLES (*A. R. Reader*).**—Your plants having sound well-ripened crowns may be placed in your house for force in December, but far better not until January. If you wish to force them early they must not now be potted, and for early forcing the pots are not too small. They ought to have been potted in July, but it is now too late to make up for lost time. They will fruit all the better in consequence of the pots being full of roots. Beneath the shelves or stages you may force Rhubarb and Seakale, as they do not need light, and the Seakale must be covered with pots to exclude the light in order to have it white. Of Rhubarb—Mitchell's Albert, Crimson Perfection, and Linnaeus are good sorts, and so are Victoria and Giant for bulk of produce. There are no better forcing Potatoes than the Ash-leaf Kidney and Myatt's Prolific Ash-leaf Kidney. Peas will not pay for their room under glass, and the only kind for growing in pots or boxes is Tom Thumb or Beck's Gem. Sangster's No 1 yields a far better crop, but will not do where the forcing is great, for it needs room, and air day and night. Dwarf Kidney Beans would do better, and pay at least ten times better than Peas, for they will barely pay for the expense of seed. The temperature will not be high enough for Kidney Beans until the Strawberries have set their bloom, after which it will be sufficient.

**SHOWING IRESINE HERBERTI FOR BEDDING NEXT YEAR (*F. D. T. Jersey*).**—Instead of sowing the seed now sow it in a gentle hotbed in the first week of next March, and when the seedlings come up and the rough or first leaves appear, prick the plants off an inch apart, still continuing them in the frame. When they become strong gradually harden off and place them in the greenhouse. Pot off singly into small pots and grow on in the greenhouse, planting out in May, by which time they will be nice plants. Without a hotbed plants to be out next year cannot be had. Plants from cuttings would suit your purpose better, and they may be struck as freely as Verbenas; besides we do not know where seed is to be procured.

**MRS. POLLOCK GERANIUM CUTTINGS FAILING (*Idem*).**—Without heat Mrs. Pollock and others of the same family do not take root freely in autumn. They strike last enough in a little heat in spring, and make fine plants for planting out, if strong cuttings be taken. They may be struck freely during the summer without heat if not put in too late in the season.

**SOWING CERASTIUM BIBERSTEINI (*Idem*).**—The seeds should be sown in March, but it is better raised from cuttings and divisions of the roots at that time. Obtain a plant, grow it a year, and you can have thousands of plants by that time twelve months. It is not so good as *C. tomentosum*, for it is stronger, grows less freely, is whiter and more woolly in the leaves, which are double the size of those of *C. tomentosum*, and we like the latter better from the multiplicity of its silvery spray; it is more tractable, and can be cut into any shape or size. *C. Biebersteini* is, however, a very good silvery or white edging and ribbon plant, and we grow it largely for edgings, bands, and lines, and for whiteness, distinctness, and having a less tendency to flower it is superior to *C. tomentosum*. Both are good and may safely be grown and employed in one flower garden, for they both have charms peculiarly their own.

**HOUSING CHRYSANTHEMUMS (*Idem*).**—Take them up before frost; they will produce a fine effect in the greenhouse. Water with liquid manure twice a week until the flowers expand fully, then use water only. The liquid from a stable will do well, diluted with water so as to make it the colour of strong tea or beer.

**MUSK FOR THE MILLION (*A Subscriber, Manchester*).**—Having the roots, nothing is easier than to have Musk in quantity by the first week in March. Pot them now in good turfy loam, light rather than heavy, with one-third of leaf-mould. Fill the pots three parts of their depth with this compost, then put in the roots and cover with soil of the same kind. Plunge the pots in coal ashes to the rim. In the second week in January place them in a heated house (40° to 45°), and if a little bottom heat could be given all the better. Increase the temperature to 50° by the 1st of February, and 5° more in a week, keeping the house moist by sprinkling every surface morning and evening, and give abundance of air. By March Musk will be plentiful, and by introducing plants at intervals of a fortnight a succession may be kept up until it grows in the open ground. In March the seeds may be sown, say half a dozen in a 4 or 6-inch pot; or a few scattered over the soil in the pot and just covered with soil will soon come up in gentle heat, producing fine plants by July. Seed may also be sown thickly in pans, and the young plants pricked off into pots when large enough to handle. A large supply of plants may be produced from a few ounces of seed sown in spring, the plants when large enough to handle being pricked off into pots, and these plunged to the rim in coal ashes in the open ground after May. Due attention being paid to watering, these plants will fill the pots with roots before autumn, and be fit for forcing another year. Seed may likewise be sown in four-foot beds in the open ground in the first week in May, just covering with light soil, and shading so as to keep the soil uniformly moist until the plants appear. If kept watered during dry weather the beds will in autumn be full of roots, and these taken up and potted will be good for forcing in the ensuing season.

**BOOKS (*A. T.*).**—The third edition of Dr. Hogg's "Fruit Manual" is in the press. The other work which you name can only be picked up at the old-book stalls.

**EVERGREENS FOR NORTH WALL OF HOUSE (*Firm, Devon*).**—In your wild locality *Crataegus pyracantha* or Evergreen Thorn, and *C. crenulata* will serve your purpose.

**COVERING A VINE BORDER IN WINTER (*A Lady Gardener*).**—Six inches of cowdung placed upon the border would, from its keeping the border very wet, tend very materially to destroy the roots of the Vines, at the same time it would enrich the soil by the rain washing the nutriment out of it. Shinters of wood would be the best covering, but as you object to these, and do not require the Grapes before July or August, you may cover the border with a feet of dry leaves, placing on them about 3 inches of rather long litter to prevent the leaves blowing about, and removing the whole in April or early in May. If the leaves are not procurable dry litter will be preferable to cowdung.

**FARMING A SMALL PLOT (*Alphe*).**—You may very easily keep two cows on your plot, but as you say you know nothing of farming we recommend you to read "How to Farm Two Acres Profitably." If you send thirteen postage stamps with your address, you can have it free by post from our office. It will teach you how to manage your cows, crop your land, &c.

**GLEICHENIA SEMIVESTITA—TODEA PELLUCIDA—LEPTOPTERIS SUPERBA**  
**CULTURE (Anxious).**—The whole are greenhouse Ferns, *Todea pellucida* being all but hardly, indeed it will endure its fronds being frosted. *Gleichenia semivestita* is best grown in a pan rather than a deep pot. Draining it well, three parts fill it with very fibry brown peat, and then place on this the delicate wiry rhizomes, filling in around them with very fibrous peat and one-fourth silver sand, to which a little loam may be added; just cover the roots and no more, keep moist, but avoid syringing on the foliage, and let the atmosphere be moist but not stagnant. The soil should be neither very moist nor yet dry. A temperature of from 40 to 45 in winter is sufficient. *Leptopteris superba* will do under the same conditions, but in a pot, and when either of them becomes established it is of free growth, but both are difficult to establish, requiring great patience and coaxing. *Todea pellucida*, or hymenophyllodes of some, may not do well from the atmosphere not being sufficiently moist. It requires a moist and rather close atmosphere, plenty of moisture at the root, a spongy soil, and a cool temperature, and then it grows freely. When the atmosphere is no more than moist enough for the majority of Ferns it is well to cover the plant with a bell-glass, tilted a little.

**POSITION AND HEATING OF SPAN-ROOFED HOTHOUSES — REMOVING SASHES IN AUTUMN TO RIPEN THE WOOD (Idem).**—When it can be conveniently done, we prefer span-roofed houses to have their ends north and south, as then both sides of the house receive a nearly equal amount of the sun's rays, and the power of the sun is least at noon, when in lean-to houses, facing the south, it is the most powerful. We have seen span-roofed houses, however, with their ends east and west, and their sides facing south and north, do very well for most things, and especially if the roof on the south side was not too thickly covered with vegetation. For low-growing plants such a position answers very well. Between these the position may be varied to suit circumstances, but, all things considered, we prefer the ends of the house to stand north and south. We think that the idea of taking glass sashes from the roofs of houses at this season for the purpose of ripening the wood is quite a mistake. Something might be said in its favour as respects early houses if the trees were exposed to a bright sun in September, but then if it happened to be showery the whole purpose would be neutralised, and growth would be encouraged instead of ripening and resting. The plan of uncovering such houses, if good for anything, is good for starving and destroying insects, especially if a little frost comes after wet. To ripen the wood thoroughly we would prefer the glass to remain on, so that with all the sun possible there might be a rather dry atmosphere, and as high a temperature as could be given without starting the buds, and there will be little danger of that whilst there is any green in the leaves of the plants. With the top and bottom ventilation you propose you may safely depend for success on a fixed roof, and if stout bars are used instead of sashes there will, as you state, be a great difference in the expense. As to heating, when much is to be done, there is no mode equal to hot water, and especially in forcing. Where great economy in fuel is an object, a flue from the furnace might be taken wholly or partly through one of the houses. For a single small house a flue will answer very well. For early work one flue should not be expected to do more than from 30 to 40 feet long. Whatever mode is adopted, you can only obtain a certain amount of heat out of a certain amount of fuel. To have a hot-water apparatus for a single small house is so far wasteful, that do what you will in the way of regulating by damper, &c., much heat will escape

from the chimney, which would have been absorbed and given out by a flue. For a large house, or several houses to be heated from one furnace, hot water is the best mode of heating.

**DWARF APPLE TREES (J. A.).**—You do not say whether they are required for dessert or kitchen use, so we can only name for dessert—Cox's Orange Pippin, Red Jugestrie, Golden Harvey, Putnam's Nonpareil, Sturmer Pippin, Cocker Pippin, Golden Rainette, Marfil. For Kitchen—Blanks Collin, Hawthorned, Cellin, Nonsuch. The "largest" Apples do not succeed as dwarf trees.

**VARIOS (W. S.).**—We think your Geranium leaf a temporary defect, and that the leaves of the shoots next year will be green. The old dents of the weaving machine make good pegs for Verbenas, and so does the thickest of flexible wire sold for training purposes. Mareschal Niel Rose is hardy for a Tea Rose, but would require a slight protection in winter in your district.

**SPAWNING MUSHROOM-BEDS (T. Read).**—Inquirers should be particular in their references. There is not a word on Mushrooms in the Number for the 3rd of September, nor could there be, for there is no Number of that date. There is information as to making Mushroom spawn in the Number for the 12th, but nothing is said there as to the management of the beds. Such spawn is generally broken into pieces of the size of a walnut and larger, and plated over the bed at from 7 to 9 inches apart. When the heat has declined to about 70°, watch, and if all is right—that is, if there is no tendency to rise higher, earth over with from 1½ to 1¼ inch of good stiff soil, well and hard beaten. If the bed is all right, Mushrooms may be expected in from six to seven weeks, according to the state of the bed and the heat round it. If above 60 the Mushrooms will come earlier, and if from 50 to 55 they will be longer in coming. We have made a shallow bed, put in good lumps of spawn, and much thicker than the above, covered with three quarters of an inch of soil, and gathered in three weeks. We have had good beds that we expected to produce in six weeks that did not produce under ten weeks, so that circumstances will greatly modify the time. As a rule, quick returns give short returns.

**POTATOES (—).**—Sutton's King of Potatoes is an excellent, very productive, second early variety, sometimes kidney-shaped, sometimes round and has a clear yellow skin. It has taken several first prizes at different shows. Daintree's Seedling is one of the earliest, and most productive Potatoes known, keeps well, and is of excellent flavour.

**NAMES OF FRUIT (E. H.).**—Franklin's Golden Pippin; Croft Castle Pear. (W. H.).—Gloria Mundi. (B.).—Golden Russet. (C. W. H.).—19 appears to be Beurré Diel. The other Pear, of which the tree only bore one fruit, is Easter Beurre; 5 and 15 in the previous lot were not determinable. (Mr. Porter).—1, Glou Moreceau; 2, Hollandbury; 4, Beurré de Rance; 5, Golden Reinette; 6, Wyken Pippin; 7, Court of Wick; 8, Nonpareil; 10, Franklin's Golden Pippin. (L. T. W., Hornsey).—Your Pear is the Old Colmar. (Rev. Mr. M'Calmont).—Your Apple is the Hampshire Yellow.

**NAMES OF PLANTS (C. J., Thame Park).**—Your tree is *Salisbriaria adiantifolia*. (Iago).—*Verbascum blattaria*. (J. Pearson).—*Cupressus macrocarpus*. (A Subscriber, Marford).—1, *Salvia hornimium*; 2, *Gypsophila serotina*; 3, *Ethionema grandiflora*, var. *mirantha*. (A Young Gardener).—1, Fern frond without fructification; 2, *Candollea cuneiformis*; 3, *Crasula*, but without leaves we cannot determine the species.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending October 21st.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

DUCK-FOOTED GAME FOWLS.

MR. HEWITT, one of the leading poultry arbitrators, says the duck foot in Game fowls is a disqualification. The "Standard of Excellence," compiled by parties considered equally able to judge in the matter, says it is a defect. Now, as there is a great difference between that and a disqualification, I think it is desirable that a proper understanding should be arrived at.

It appears to me that the first thing to consider is, What is the cause of the duck foot "or heel?" Is it a flaw in the breed of the fowls, something hereditary? In fact, will duck-footed fowls be likely to produce duck-footed chickens, or is it only a defect produced by the fowls not having a proper place to roost? If it can be substantiated that the former is the case, then I think it ought to be considered a disqualification, so that exhibitors would make it their duty to keep their breeds of fowls free from the defect, in the same way as the hanging comb in Spanish, the want of the fifth toe in Dorkings, single

comb in Hamburgs, are guarded against. If, on the other hand, it is only the effects of carelessness in rearing (as I have always heard it attributed to allowing chickens to roost on a flat surface, instead of a proper perch), then I think it ought to be considered only a defect, and where fowls are much superior in other respects to those competing against them, it ought not to disqualify them from taking the prize. I hope that Mr. Hewitt, and the compilers of the "Standard of Excellence," will give their reasons for arriving at different conclusions, in order that an amicable arrangement may be brought about. —SCOTCHMAN.

In "The Poultry Book" we find the Birchin Yellow cock's plumage described as follows:—"The Birchin Yellow cock has a yellow and black-streaked breast, blackish-grey thighs, tail and belly nearly black, with the remainder of the plumage yellow." This description does not exactly coincide with the Poultry Club's notion of colour. And, again, in the disqualifications, I do not find so great and natural a defect as duck-footed birds mentioned. I think a duck foot ought to be as much ignored as either a crooked breast or back. I have not

seen the "Standard of Excellence," but should wish its merits to be freely discussed in your Journal.—SKETCHLY.

[We sent the two preceding communications to Mr. Hewitt, and the following are his notes in reply:—

The deformity in the hind toe of Game fowls, commonly known as "duck-footed," appears now to be quite a leading subject of discussion among amateurs, so much so, that I think every fact that can be adduced in proof of its hereditary tendency, or otherwise, will be a matter of interest to most of your readers, and prove far more conclusive than the most ably supported theory could possibly be. I will be as brief as possible. Some eighteen or twenty months ago a gentleman, at that time a stranger, requested my opinion as to the desirability of purchasing a first-prize pen of Game chickens at a show at which I had just arbitrated. As to the question of price I always decline to intermeddle, as I consider it entirely a matter of personal determination between buyer and seller; but of the quality of the birds as they then stood I gave a most favourable opinion, and, in short, they were "claimed" at the catalogue price, though a liberal one for chickens so young as they then were. I am quite clear on one point: at that time there was not observable even a tendency to "duck-foot" in either of the three birds. Two extra pullets were afterwards bought from the same yard, and placed with the pen previously exhibited, for breeding-purposes; the five birds thus ran all together, and the not-very-modest demand of the same sum was paid for the two pullets as for the three birds previously claimed. I am told a noted "cocker," two months or more afterwards, examined very carefully the whole lot, and spoke favourably of them.

To my astonishment, as time wore on, I was informed by the owner that all his Game fowls were "duck-heeled," and I accepted an invitation "to examine them for myself." The fact was, the cock and three out of the four hens were, at that inspection, undoubtedly "duck-footed," in fact, confirmedly so. We next examined minutely sixteen or seventeen chickens (two hatches clutched together with one foster hen) from the same Game parents. They were only about a week old, and to make assurance doubly sure, they were placed one at a time, at the proprietor's suggestion, to stand on a tea-tray, and we could not find a single instance of "duck-foot" in the whole brood. The next inquiry was naturally as to the roosts, and finding them to be about 1½-inch-square scutlings, with the sharp edges planed carefully off, we both arrived at the same conclusion—that the perches being flat and too wide for the foot to grasp with comfort, had tended to produce the ailment. On the simple face of the just-narrated facts this impression appeared to admit of no doubt, although my previous convictions rested on hereditary malformation. The young chickens were kept from any roost whatever, large or small, till about seven weeks old, for they were compelled by their owner to roost (if it can be so called) on loose straw scattered on the floor; the feet were still, I am told, perfect when allowed the privilege of first taking their chance among the elder trees growing around the house, for every artificial perch had been removed beforehand. Of course they could now make their own selection, and roosted variously: yet from information received that "they were all gone duck-footed," I again called, and with only three exceptions they really had become so. Their owner, it seems, felt so grievously annoyed as to give all these chickens at once into the hands of the cook, and the parent birds were also similarly treated. It so happened that not long afterwards I was travelling in the immediate neighbourhood from which the original birds "claimed" by my friend first came, and without giving any reasons to the breeder I called, and saw the parent cock of the five Game fowls first purchased, he was grossly duck-footed, his hens, so far as I examined them, not being so; and walking a mile or more still further on placed me also with that cock's father in my hands, he of course being the grandparent of my friend's original stock of five, and this bird was "duck-footed" equally with his descendants. My somewhat extensive connection with poultry exhibitions also convinces me that this failing is by no means entirely confined to Game fowls. I know a yard of Cochins in which the same imperfection exists; also a strain of Pencilled Hamburgs alike defective, and acknowledge in their case, also, that it acts as a drawback to success; but as such fowls are not required for fighting, I would myself consider it of far less importance than in Game fowls, even for exhibition, as in the latter breed unrestricted motion, when fighting, is one of the very first elements of success.

There are many differences of opinion as to the first causes

producing duck-footedness, some persons confidently argue that it proceeds from constitutional weakness of the parent birds; others say, with equal positiveness, it is not hereditary, but entirely arising from a nervous affection of the bird itself. I leave others to the full enjoyment of their own opinions; of this only I am myself sure—some chickens are actually hatched duck-footed, others become so only when matured.—EDWARD HEWITT, *Sparkbrook, Birmingham.*]

## NOTES ON PIGEONS.

FORMER WRITERS ON THE SUBJECT—JOHN MOORE, A.D. 1735.

At the suggestion and by the wish of the Editors of this Journal I have agreed to write a few papers, readable ones I hope they will prove, on the subject of Fancy Pigeons. After sundry prefatory remarks I hope to speak of those varieties known to me, and of my experience as a fancier. A few notes on the *Powter*, published September 12th, must be considered the first of the series, first, however, only in point of time. I do not expect to be able to say much that is new, if, indeed, anything; but I shall be satisfied, and even gratified, if I can succeed in bringing the claims to regard and affection of these beautiful birds prominently before those who have a yearning for pets, but who, as yet, have adopted none; or, if increasing the love of those who already love them; or, if that be impossible, of pleasing fanciers by praising what they praise. Indeed, the thought had come across my mind that Pigeons, birds of so many varieties, with such broad and marked differences, have of recent years scarcely taken so prominent a position in this periodical as they were entitled to take. Thousands in England love these charming birds, from the just-breeched—no, just nickerbockered—boy, with his first pair of common ones, to the graceful girl who feeds with her own hand her snowy-necked Fantails, her pets and almost rivals in beauty.

Many persons who have not, and cannot have, a poultry yard, for whom no garden can bloom a flower, yet could manage in some little loft to place a few choice Pigeons, and snatch half an hour from business to enjoy their pets. And, mark me, it is not only the old bachelor, or the man retired from business, or the lady who lives

"In maiden meditation fancy free,"

who needs the solace that pets can give; but it is the man full of business, who has many cares, who wants a little recreation, and yet must not run away from home—this is the man who requires a little nook to retire to, a very arbour of rest for his mind; and such a nook, such an arbour, is his loft to a Pigeon-fancier. In crowded cities we most of all find this yearning for pets, hence it is that smoky London, sooty Birmingham, and grimy Bristol are full of ardent Pigeon-fanciers. Then there are my brethren the clergy. A witty bishop said to us,

"Hunt not, shoot not,  
Fiddle not, flute not;"

but in spite of this couplet I should, had he been my bishop, have boldly taken him not only to see my roses, but my poultry and Pigeons as well. My bishop was here the other night, and I showed him my dear in-door pets; had it been day I should have showed him my out-door ones as well.

One word, too, upon a piece of scandal against Pigeon-fanciers. Blackguards may keep Pigeons, and fly them for bets; however, I never knew such, but I have known very many ladies and gentlemen, and a very great many respectable tradesmen and artisans, both in England and Scotland, who were excellent, worthy men, and whom, when I meet, it gives me unfeigned pleasure to give and receive a hearty shake of the hand; no scandle, then, please; the best class have had ones among them, but no class is all bad.

A word next upon the various books which have been written about fancy Pigeons. For aught we know to the contrary, until the year 1735 the Pigeon fancy was guided by an unwritten code of laws. It may be that we have altogether lost sight of some older work; but clearly we only know as the first work on the subject "The Columbarium, by John Moore, printed for J. Wilford, behind the Chapter-house in St. Paul's Churchyard, 1735." And a good old book this is, and a thorough master of his art was Moore, for he produced a work which for a century was the standard work on the subject, and which other writers copied line by line and page by page; but, alas! without acknowledgment, adding indeed some little, but the bulk was ever Moore and Moore only. First in time, as far as we know, and certainly in fame and worth, is old Moore. I

imagine that he was a timid author, and caused but one edition, and that a very small one, to be printed. Perhaps, too, he was not over-blessed with cash; however that might be, we now scarcely know of the existence of more than one copy. Poor Moore, he dedicated his book to Sir William Stapleton, Bart., as he says, "seeking a proper refuge against any ill-attended censures." Of course he thought the learned naturalists would pooh-pooh the pages of the mere fancier, and for the humble fancier the book would be too dear; so perhaps Moore lost by his work, and his wife in her pets—pet though she herself might be—threw his book (I hope only figuratively) at the poor man's head, and his authorship was tabooed; he regretted it as a weakness, gave the servant-maid (no Mrs. Moore would do this) the unsold copies, the greater number, to light the fire with, or the maid took them, saying "Only Columbariums, Mum, they don't matter;" and, as a conclusion, Moore went to his grave lamenting he had ever been an author.

Moore describes himself thus:—"Mr. John Moore, Apothecary, at the Pestle and Mortar, in Laurence Pountneys Lane, the first great gates on the left hand from Cannon Street, who formerly lived at the Pestle and Mortar in Abchurch Lane, London." An apothecary, then, was Moore, a member, I fancy, of the old Apothecaries' Company, for he was an educated man. He was not a surgeon, not a grand bewigged doctor, who walked about with a hollow-topped gold-headed cane, in which top was some strong perfume, aromatic vinegar most likely, which the doctor of the day—I fear a solemn humbug frequently—kept smelling when in a sick room, till the habit grew, and in the street, when in conversation, the gold nob was ever at the nose, and the ignorant looked with awe upon that gold-headed cane, and a very poor chance would a clever fellow who abhorred humbug have had if he had started in doctoring without a gold-headed cane. John Moore was none of these, he was a compounder and seller of drugs; others prescribed them, he made up the prescriptions merely, so was guiltless if the patient was killed, unless he made a mistake, and if so, he was the man to take prescriptions to ever afterwards, as he would be extremely careful in future.

The little man at the "Pestle and Mortar," left the pestle quiet in the mortar at times, and was in his Pigeon-loft, or in the loft of his brother fanciers, taking country walks to "cull simples," and see Pigeons. Then came the thought of writing a book on his favourites, and while beating his mortar he combined the ingredients of his pills, and framed his sentences at the same time. "Pestle and mortar"—the old apothecaries had two mortars—one a large, heavy, three-legged thing, which stood on the floor, which uttered when in use solemn sounds; the other, a little brass thing, which stood on the counter, and which had a spiteful, sharp, ringing sound. A wag remarked the big mortar says, "Linger him long, linger him long;" the little one, "Kill him quick, kill him quick." Now, whatever skill John Moore possessed as an apothecary has long since faded from all recollection, but his fame as an author lives, and will live as long as a Pigeon fancier exists in the world. He writes like a man of good taste (remembering the age he lived in), and of good education. He writes modestly and correctly, orderly and methodically. His profession crops out now and then, as in his chapters on the "Distempers of Pigeons" and "Their Usefulness." He had read books of travels, and knew better Latin than the dog Latin of his prescriptions. He was something of a wit too, quaintly saying when he did not believe a tale, "Let who will swallow this gudgeon." I, also, would note, that although an enthusiast, I find no one ill-natured remark save this, "Mr. Hickman, a distiller, in Bishopsgate Street (not one of the lying Hickmans)." Perhaps that family pestered the poor apothecary, always getting physic out of him, and always promising payment, but forgetting their promise. This made him write sharply, or, I rather incline to think, it was mere fun on his part, and no lying Hickmans existed, he said it to please his friend the distiller.

Moore describes birds admirably, pointedly, clearly—you see the bird as you read his description. This combined with its truthfulness on fancy points, and its thoroughly practical character, are the reasons his book became a standard work on the subject. A man who writes what lives its century is entitled to praise; nay, more, a man who struck into a new path and did his work so well that others for a hundred years after did little more than copy him, is entitled to great praise.

I said "Moore's Columbarium" is a scarce book. Mr. J. M. Eaton has happily reprinted it with notes of his own and of other authors. I have never seen an old copy of Moore. I will relate Mr. Eaton's account of his finding a genuine copy. At

page 191 of his work he says—"Although it cost me many pounds one way and the other to obtain this book [John Moore's work, 1735], besides great loss of time, for I searched every bookseller, north, east, south and west, besides advertising it several times through the different channels, had I not seen and read the work I should not have believed there was such a book. The fancier to whom the work belonged, used to say it was the only copy in the world. He promised me he would lend it to me (if he had I had made up my mind to have employed some one to have written it out before I returned it), but he had lent it to a fancier and could not get it back. I still, therefore, hunted for the book, and the more I hunted the further I was off the scent. However, one day seeing two boys, apprentices I suppose, in deep conversation at an extensive second-hand book shop—I believe if I had asked one of them if he had 'Moore on Pigeons,' he would have said 'No.' (I had my wits about me for the first and last time)—I arrested their attention by saying, I would give them a shilling's worth of brandy and water if they got the book I wanted. I told the boys to consider before they said 'No.' They looked at each other as if surprised. I think they smelled the brandy and water. After a little consideration one of them went down the long shop to his employer, who went and laid his hand on a book. I saw the boy coming with the book in his hand, I thought it was something about Pigeons, but never thought it was Moore's work. To my astonishment and delight it was the very identical work I was in search of. Having it in my hands, I thought my eyes would have darted out of their sockets. I thought 'this book shall never leave my hands whatever the price.' I bought it, gave the boy a shilling and left, all pleased with the transaction." I do not doubt Mr. Eaton's delight.

Now, farewell old Moore, the first that gathered up the floating ideas about Fancy Pigeons. I wish he could have known how his name and work would have lived. When next in London I will pay a visit, at any rate, to the street he lived in.—WILTSHIRE RECTOR.

#### CALNE POULTRY AND PIGEON SHOW.

IN "WILTSHIRE RECTOR'S" account of the Calne Poultry Show in last week's Number, there is an expression which is calculated to mislead your readers, which I am sure he never intended, and which, if not explained, would be most prejudicial to the success of any future Show of the kind at Calne. He says "When I entered the Show (I presume he means the grounds of Castle House, where the Show was held) at one o'clock, one tent was then only in the act of being reared." I fear this will be understood as either the Pigeon or poultry tent, both of which were erected the day before, the one referred to being a supernumerary tent for the Committee, or some other purpose, for which, however, it was never used, nor was its erection ever completed. With regard to the smallness of the pens for Turkeys and Geese (and here I would also reply to the complaint of "THE TURKEY PRISONERS AT CALNE," in the same Number), it should be remembered that poultry shows of any extent, in this part of the country, however much they are desired and desirable, are few and far between; that in a rural district like this, where the majority of the farmers consider poultry-keeping a very minor consideration, and look upon a poultry-fancier as a weak-minded individual, who is to be pitied if not contemned, it is most difficult to excite in the public mind sufficient interest in such matters so as to raise the funds necessary for the effectual carrying out of such an exhibition, and that, consequently, with the exception of Devizes, there is no place where pens can be hired except from a great distance. On the occasion of the last Show, in 1862, we did go to a distance in order, as we thought, to get the right thing, and had to pay £8 for carriage; but unless I am greatly mistaken, the Turkey pens were as small then, or very nearly so, as in the present instance. To Devizes, therefore, on this occasion we went, not feeling justified in spending such a large item for carriage, and obtained the largest pens we could, and put the Turkeys in the most suitable; more we could not do.

As regards the remarks of the "TURKEY PRISONERS"—"We envied the useless height of the Pigeons pens," I may state that as there had never been a Pigeon Show at Devizes we were obliged to use poultry pens, and there surely could be no objection to the Pigeons having plenty of room, while the statement that none of the officials were tall enough to affix the commendatory cards, and that the Turkeys were exposed to a

full sun and effectually ruined for any future exhibition, is simply untrue. I do not complain of "WILTSHIRE RECTOR'S" strictures, feeling sure, as he himself says, that he wrote "for improvement, and not from love of fault-finding;" but I trust, the above explanation having been given, whatever shortcomings there may have been, will appear the less reprehensible. As an instance of how ready some people are to find fault, one successful exhibitor has already complained at not having received his prize money; but surely a fortnight after the Show is not an unreasonably long time to wait, and I fully believe that all the prizes will be paid by the time this is in print.—ALFRED HEATH, *One of the Committee.*

### THE LONG SUTTON POULTRY SHOW.

IN No. 237, I raised an objection to the announcement in the schedule of this Show that a catalogue would be published ten days before the award of the prizes. I still maintain that objection; but I think I am bound to state that I have seen nothing in the management of the Show, or in the award of the prizes, with which I can find fault, and I will add, that had I been aware Mr. Hewitt was to be the judge I certainly should not have made any allusion to the prize list. I do not by any means think Mr. Hewitt's judgment is infallible, but I cannot put my prizes in a case when I do not think the judgment honest.—AN EXHIBITOR.

### MIDDLEWICH AGRICULTURAL SOCIETY'S POULTRY SHOW.

(From a Correspondent.)

THE annual Show took place in a field adjoining the town, on the 17th inst., and proved successful. The poultry were shown under a large tent well adapted for the occasion; and the classes were well filled, the number of entries being more than in any previous year. Great credit is due to the Secretary, Mr. Taylor, together with a working Committee, for the manner in which the Show was carried out. The *Game* class was very good, and such was the merit of the birds that it was a difficult matter for the Judges to decide which was the best pen. The *Dorkings* showed up well, also the *Hamburghs*. The *Poland* class was small, but the birds were good. The *Bantams* mstered well. Some beautiful White ones taking away the first and second prizes. The *Ducks*, Any variety class, were excellent, the first and second prizes being awarded to very fine Aylesburys, such as would not disgrace the great Birmingham Show. *Turkeys* and *Geese* were few, and not very excellent. The following is a list of the prizes:—

SPANISH.—First and Second, J. Siddons.  
DORKING (Any colour).—First, T. Pickering. Second, D. Harding. Highly Commended, D. Harding. Commended, P. Marron.  
GAME (Any variety).—First, J. Grimes. Second, J. Heath. Highly Commended, J. Platt. Commended, E. Wigger.  
HAMBURGHS (Pencilled).—First, D. Harding. Second, J. Greaves. Highly Commended, D. Harding.  
HAMBURGHS (Spangled).—First, J. Greaves. Second and Commended, T. Dale.  
POLANDS.—First and Second, J. Heath.  
BANTAMS (Any variety).—First, Mrs. A. Butler. Second, C. Hollinshead. Highly Commended, T. Butler.  
TURKEYS.—First and Second, P. Marron.  
GEES.—First, C. B. Lea. Second, P. Marron.  
DUCKS.—First, Mrs. Hornby. Second, J. Platt.

The Judges were Mr. Fell, Warrington, and Mr. Bebbington, Missan Vernon.

### DARK BRAHMA POOTRAS.

HAS it not been considered by some connoisseurs of Brahmas that the light Brahma is the original, and the dark Brahma a later production?

From a Dorking cock (grey) and a light Brahma hen I have produced a cockerel marvellously like a dark Brahma, and I cannot help thinking but the dark Brahmas have sprung from some such cross. Perhaps some of your Brahma-loving correspondents would enlighten me on this point.—D. P. P.

WEST CUMBERLAND AND NORTH OF ENGLAND POULTRY SOCIETY.—It will be seen by an advertisement that the above Society have fixed their next Exhibition for the 10th and 11th of January, 1866. The prize list includes eighteen silver cups. Six of them are confined to West Cumberland—for single cocks of Game, Dorking, Spanish, Cochin, Hamburg, and Game Bantam. The whole of the other classes in the Shows are open.

For Game cocks, the first prize is a silver cup, value £8 8s.; second ditto, £3; third ditto, £2; fourth ditto, £1; and fifth ditto, 10s. To go through the whole of the classes would take up too much of our space, but we will add that there is a cup for the best pen in the Exhibition, and cups each of the value of £3 3s., for the best pens of Game, Dorking, Spanish, Cochins and Brahmas combined, Hamburgs, Bantams, and Ducks. For Pigeons there are twelve classes, each of £1 for the first, and 10s. for the second, with a cup added for the most successful exhibitor. This Society has tripled the amount of money given in prizes in less than three years; for, in 1863, £55 was given; in February, 1864, £68; and in December, 1864, £116; and at the next Show over £180 will be given.

### GAME FOWL JUDGING.

THE controversy in your columns on the subject of Duck-footed Game fowls now embraces several other points in consequence of the contribution of "EXHIBITOR" in page 305. In this communication various assumptions as to Game judging are indulged in, and as "an honest award of the prizes" is the sole object of his letter, a further ventilation of the subject will perhaps conduce to so desirable an end.

"EXHIBITOR" says "that a breeder and exhibitor of any length of standing must possess as correct a knowledge of the points of merit in a bird as a professional judge." Such, undoubtedly, is the case in some instances, although it does not necessarily follow that such knowledge can be either bought or rented, as many prize birds are. "EXHIBITOR" then seeks to illustrate his point by alleging the retirement of an exhibitor consequent on non-success, and mentions the two last Birmingham Shows as instances of such retirement. A reference to the Birmingham catalogue of 1863 and 4, certainly shows the names of some exhibitors, "conspicuous by their absence," as prize-takers, but your readers will scarcely be able to credit the avowal of "EXHIBITOR" as to "the great dissatisfaction manifested." It is quite true an attempt was made to throw discredit on some of the decisions; but it is well known that the alleged dissatisfaction merely existed with one or two disappointed exhibitors, and perhaps the best answer to such insinuations is the re-appointment by the Birmingham Committee of the Game Arbitrators.

It is a matter of current rumour that an attempt has been made this year, as heretofore, by a certain large Game exhibitor to influence the appointment of the Game Judges at Birmingham for the forthcoming Show, by the threat of non-exhibition in case of non-compliance, and as your correspondent states "that the Birmingham Committee do not contemplate making any change in their Judges of Game fowl," it will, perhaps, not be far wide of the mark to assume that such person is identical with "EXHIBITOR."

"EXHIBITOR" then notices the very liberal prize list issued by Mr. Jennison, of Manchester, and after stating that exhibitors had general confidence in the judges he has appointed, proceeds to deduce that Birmingham should be passed in favour of Manchester. At Manchester, two years ago, the name of a certain Game exhibitor does not appear in the catalogue, although the fowls usually shown by such person were supplied to, and figured in the prize list in other names, which, quoting from your correspondent, "wears an air of suspicion."

It would be satisfactory to know if the well-known dictation as to the Game Judges at Birmingham in 1862, attempted again this year, prevailed successfully at Manchester in 1863. Mr. Jennison is reputed to be a shrewd man of business, and, wishing his enterprise every success, it is to be hoped that he will not accept any nominee, but select judges of known ability and integrity, and at all events not recur to the memorable Birmingham régime of 1862, which resulted in the retirement of such exhibitors as Mr. Archer, by whom Game fowls were more improved than by any other breeder of his time.—JUSTITIA.

### PIGEONS WITH WEBBED FEET.

IN a recent Number Mr. Hewitt described a Brahma's foot that had the web largely developed. I fancy such cases are not uncommon among birds with feathered feet. I have a first-rate tumbling breed of Birmingham Rollers that is heavily feathered on the feet. Several of these birds have the middle and outer toes united by a web, in some half way, in a few quite to the end; but the web is narrower than that of a Duck's

foot. I have one young one in which the toes are closely united by a narrow web, the centre toe being bent aside, and the nail of the outer and middle toes united in one. One of these Rollers has the extraordinary number of eleven flight feathers in each wing.—B. P. BRENT.

### BEWARE OF SWINDLERS.

I ENCLOSE you the following letters that I received in answer to an advertisement in your Journal, in the early part of last month, for a few Brahma and Cochin chickens. Being rather doubtful about the party, on receipt of the first letter I looked over both the "Post-office Directory," and "Medical Register," the writer signing himself a surgeon, for the name, but could not find it; but at the address he gave I find is a post office. Knowing that I should be in London in the course of a few days, and not wishing to be duped, I wrote the party that I would call upon him on the following Wednesday. He wrote by return that he had been called away in great haste, and would not be at home for several days, but if I would "run down" to some address at Croydon (this letter was written in pencil), I could see the birds there; the party was keeping them for him till he found a customer. Well, I happened to have a little business at Croydon, went and took the letter with me, showed it to several old residents, the postmaster, &c., but no one could decipher the address, and that is the end of the affair. It was a good attempt, but did not succeed. Had I sent any post-office order I should have adopted the suggestion made by you—ten days' order, and if the birds had not come in the meantime, I should have had time to have acted. I am willing to co-operate with one or two gentlemen to bring this party to justice, if they will favour me with their names through you; or you can furnish my address.—CAXTUS.

### EXPERIMENTS WITH FOUL BROOD.

IT may well be said that 1865 has been one of the finest seasons that many of us have ever experienced, and one which will not readily be forgotten. It was enough to rouse the most lethargic to a state of activity and admiration. The fields were so thickly clad with flowers that their fragrance filled the air, inviting, as it were, the whole insect creation to the feast. Not less delightful was it at dusk to observe the great variety of moths; many of the most beautiful were quite new to us, and we may, perhaps, never see the same species again. In the morning was to be seen and heard that interesting one the humming-bird moth, so agile in flitting from flower to flower, while its sound was no less pleasing. The only insect we have lost sight of these five years is the leaf-cutter, not one having been seen during the whole of that time. Our bees, then, have had a most favourable season in the dales, but the heather proved almost a failure, the highest I have heard of only reached 30 lbs., whilst the lowest was but 17 lbs.

I will now relate some of my observations and experiments during the season as nearly as my memory will allow. First, then, in April I sent a piece of foul brood to the Editors for an explanation, but not with any desire for information, but rather to censure them, as I knew too well what foul brood was, although my notion as to the cause might be wrong, as I by subsequent experiments found it to be, and now bid fair to renounce my former opinions on the subject. The hive from which the piece of brood was taken was one that the bees partially deserted in April, and in which it appeared evident that chill was the cause of the mischief, as there was nothing wrong previously. Although in this case I asked the Editors' advice, I did not intend to take it, as I had already made a partial excision leaving nothing but what appeared fresh, being two combs of brood and two combs of sealed honey in the upper box, the under one being also full of new-made comb. Having filled the upper box from the under one, keeping the brood in the centre, I added a number of black bees, thinking this would set all right; but no, matters only became worse, and on the 1st of June I transferred them to a straw hive, full of comb and bees, that had a drone-breeding queen whose brood was also foul. Things now went well with this hive, for in six weeks afterwards I had two swarms from it, and all the three are now doing well. I almost forgot to say that when I transferred the bees to the straw hive, I took particular care of the combs that were free from brood. For experiment, about the middle of June I put a swarm amongst these combs, and in twenty days (about fourteen honey-making days), the weight of the hive rose 60 lbs., the gross

weight being 80 lbs.; since then I have seen young bees emerging from these combs, and at present it is the best hive in my apiary.

The old stock from which the swarm originated was divided into three, but only one queen hatched out, the rest appeared to be all abortive from foul brood; but by giving them a piece of brood-comb from another hive they soon had queens hatched again. Out of these three, one remained healthy, but two became quite offensive with foul brood. From one of these I cut out all the brood, and the top box being well filled with honey, I removed the under one, after the brood was cut out, to a distance of 300 yards, putting it in the place of a hive which was removed to my garden. The queen being put into it, I allowed the returning bees to enter in order to see whether or no foul brood would appear. At the end of three weeks I examined it and found twelve cells affected out of about two hundred, but I fear this experiment will have to go for nothing, as it appears that the hive from which the queen was taken had also been affected.

I must now return to the top box from which I removed the queen, she being a hybridised one, and substituted a royal cell, placing it in a small cap on the top of the hive, and in this case all appeared well. The other hive I allowed to stand undisturbed for more than a month after I detected the offensive smell. When I opened it there were five combs completely and compactly filled with rotten brood, but it appeared that a change had taken place, for there was a patch of about 3 inches square perfectly free, the brood being in all stages, so that it appears the disease had left it. One thing, however, I must not pass over. The eggs in this hive were very irregular, there being from one to thirty in a cell; in fact, the cells appeared to be quarter filled, and in many two worms were hatched together. I may here observe, that in all foul-breeding stocks in which the queens are young and very prolific, and irregular in depositing their eggs, it will be well to notice if they continue their fertility, and whether they are attacked a second time. It appears that a strong inclination to lay comes on whenever they are attacked. It also appears that foul brood arises from the queen, as I have proved by experiment by inserting a piece of healthy brood-comb in the heart of a foul-breeding stock, and it all hatched out;\* but, perhaps, this experiment would be better to be renewed before it could be relied on.

I will now give a brief account of a few other things which have come under my observation. 1st, then, it appears that excision in the early stages does not effect a cure, but after a time it does. 2nd. That the bees in the first stages carry an unusual amount of pollen, and that the queens begin to lay early and are extra prolific, the eggs being deposited in a careless manner; there are also a smell of fermentation in the honey, with a multitude of animalculæ, and a slight phosphoric appearance after it has stood some days, hundreds of inverted pupæ, but by no means all foul brood, although all abortive, as in many cases I could pull them out quite whole. Twelve days after excising the combs I examined what I had cut out, when I found some of the worms had grown much and many others were still living, which proves conclusively foul brood is not chilled brood, although it often occurs under circumstances which might lead us to believe it to be so.

A hive that had lost its queen commenced cutting away all the raised parts of the cells, leaving nothing but the centre partition; but as I then gave it a queen I did not see whether it would change them into drone cells. I also found in a hive that had lost its young queen (supposed by regicidal attack), eggs of a fertile worker two days afterwards. I would also ask, if any one can explain the reason why, when bees barricade their doors, they leave a hole at each side; is it for ventilation, or is it for their better protection? I may also state, that hives that had been heated in transit fell victims to the disease. I hope, however, that I shall not again have it in my power to experiment to such an extent, but as I have watched and marked down every symptom, I hope that others may derive some benefit from it.

I have at present two hives with combs taken from foul-breeding stocks, but which appear healthy; four with comb excised, and as yet no symptoms of the disease have re-appeared, and these shall be kept for further experiment. One thing is, that in Ligurian stocks the brood is kept more compactly together than in black hives, which gives the malady a more deadly appearance. I was somewhat sanguine that the Ligurians would have a great advantage over the blacks by being able to work on the red clover, but to my astonishment I found that the blacks as well as the Ligurians wrought both on the first and

\* This experiment scarcely seems to warrant the conclusion drawn from it, which is, moreover, contradicted by the fact that if the queen only of a foul-breeding colony be placed at the head of a healthy stock, she does not carry the disease with her.—A DEVONSHIRE BEE-KEEPER.

second crops of red clover, not sucking the sweets from the tube, but at the base of the flower; and so late as the 22nd of September some hives rose a little in weight. That the Ligurians are a superior kind of bees is beyond doubt. In their superior fecundity and earlier breeding, the great desideratum in bee-keeping, has been attained. I may remark in corroboration of the above statement, that in a nine-frame hive with super and nadir, I saw the queen repeatedly dropping her eggs in twelve days after hiving, having no empty cells in which to deposit them; there would, therefore, be no less than 30,000 eggs deposited in that time—a very much greater number than many suppose. I had a conversation the other day with an old critic, and he remarked on seeing about two hundred bees lying dead near a hive, that they would soon make it up, as he had no doubt but that they laid as many as one hundred or even two hundred eggs a-day, when I asked if he did not think that they would reach as many thousand in the same time, and inquired how a hive could swarm at all if bees did not breed more rapidly than that? but he only remarked that the eggs laid would then be of larger bulk than the queen herself.

Before closing, I may mention that this year will have taught many to adopt the plan of artificial swarming, as this season I can count in my own neighbourhood no less than thirty stray swarms. Four of these I took out of chimneys, with entrances at top, and one was in the roof of a house. They had been in three weeks when I was sent for to see if I could take them out, which produced rather an amusing scene. A ladder was placed against the eaves of the house, and then one was suspended to the roof, when in a twinkling the gardener was mounted on the top, the young gentlemen scrambling up the house and relating wonderful stories about these wonderful bees, how they would not sting their master, how obedient they were to the commands of their king, how grateful they were to those who were good to them and did them a good turn, by meeting them when they saw them approach their hives, and buzzing around them with joy, and how a friend of theirs kept bees, and once when he saw them struggling with a sickly bee, he approached and killed it, and ever after when they saw him come near they carried out those that were sick to be killed. Such-like stories showed at once that bees were strangers to them. Notwithstanding the courage of the gardener at first, no sooner had I commenced operations to get at the honey, which I managed by driving, tapping gently on the sarking, than the bees instead of running up ran all downwards. In this case there was an example of the bees' choice of an entrance, where they had an opportunity of entering anywhere. They cemented up the whole seam between the wood and stone and entered below, having a space of 3 feet by 7 inches by 6, completely filled with honey. But about the gardener; the bees at first seemed a little irritated; by this time he appeared to lose his courage, and in vain did he beseech me to let him pass by the ladder, as I required his assistance; but rather than suffer a slight sting he scampered over the roof, and dropped on the lawn beneath, fortunately escaping unhurt.

Throughout the year I have invariably found young bees emerging from their cells twenty-eight days after the exit of the old queen. Can any one explain why the eggs of a fertile queen, from the beginning of February till the beginning of April, although regularly deposited to the amount of six thousand, were never brought forward, the hive being both strong in bees and with plenty of food? Some of these eggs were given to a stock of Ligurians, and not one of them was brought forward. Some of these observations will probably be passed over by many as worthless; but I am disposed to hope and believe that they may be of service to others as well as to—A LANARKSHIRE BEE-KEEPER.

### NATIVE HIVES.

In answer to "M. S.," I would state, that the makers of my "native hive" are the village carpenter, and a day labourer, whom I have instructed how to make straw hives square. As yet, I have only had four made, and have not kept them through a winter. I could, however, have any number made for the price mentioned, 10s., or if "M. S." would like to know how my straw hives are made, I would send him a sketch of the frame, on which, or rather round which, they are made. The "native" would consist of a floor-board, and a square straw hive made and sewn with cane to a wooden frame, having as in the Woodbury hive, notches for ten frames; these when *in situ* are flush with the top of frame, and are overlapped and kept tightly in their places by the top, which is screwed down with four brass screws. This top is in a frame with a rabbit,

in which fits a board with central hole (or a glass, which is not provided, may be used in the summer months), leaving space under for bees to move over the top of the frames.—M. D.

### PRESERVING BROOD—TRANSFERRING BEES— APPARENT QUEENS.

1. How long will brood from condemned hives keep? and is there any way of preserving it?

2. Will it be a good plan to place a common hive of combs, &c., after having driven out the black bees, over a Woodbury straw frame-hive containing a weak stock of Ligurians, for them to carry down the honey, and hatch out the brood?

3. Is it probable that there would be more than one queen in a hive of Ligurians? as I find, in looking through a hive lately purchased, several bees that are longer and more acute in the abdomen, and with shorter wings.—A. R.

[1. Sealed brood would probably keep many days, and might even hatch out if kept in a uniform temperature of about 85°. Unsealed brood, on the other hand, protrudes, and dies when the larvæ attain a certain stage if there are no bees to seal it over. In practice, therefore, it is very desirable to keep brood as short a time as possible out of the hive.

2. It would be much better to cut out the combs, fit those containing brood into frames, and insert them in the Woodbury hive.

3. It is certain that there is but one queen in the stock. Those bees that appear larger than the others are gorged with honey, whilst the taper-pointed abdomen is a general characteristic of the Ligurians.]

### FEEDING BEES IN AN OLD STRAW HIVE.

I wish to know how to feed bees in an old-fashioned straw hive. I have been feeding them in a little trough outside the hive. I think I am doing wrong, as several bees are lying dead on the ground. This morning I picked up sixty bees all apparently dead. Some of them looked numbed as if cold; and I put these between my hands and breathed on them, which recovered them, so that they could fly. I put three or four of them into the hive's entrance, but they were instantly beaten and turned out again, and appeared as bad as ever.—J. R. P.

[If there be, as there frequently is, a cork or stick inserted through a hole in the centre of the crown of your hive, draw it out and feed through the aperture. If there is no such opening make one, say 2 inches in diameter, with a sharp penknife. The best means of feeding is by means of an inverted bottle with a short neck, which must be tied over with a bit of cap net, or such like material, and inserted through the orifice thus formed. Feeding bees outside the hive is at all times bad practice. Those bees which were refused admission into the hive were most probably strangers to it.]

### OUR LETTER BOX.

DISEASED PIGEONS (A. W.).—I suspect your Pigeons are in a bad state of health from over-feeding or want of salt, and their blood being impure, they break out in sores when pecked in fighting. You can try dough pills containing one grain of calomel, repeat one pill each day for two or three days, then a dessert spoonful of castor oil, and bathe the eyes with goulard water.—B. P. BRENT.

BEANS FOR PIGEONS.—Evesham will be obliged by the address of any party who has old small beans to dispose of, suitable for Pigeons. He wishes for some little larger than peas.

GERMAN PIGEONS (Flora).—The white Pigeons with black heads and tails which you noticed at Wiesbaden were probably Florentiner, oder Hinkel Tauben; a breed similar to what we call Leghorn Runts. Your Ducks, I suppose, are the Bebe or Black East Indian variety, the shells and skins of the yolks of whose eggs are often dark-coloured. I have heard that feeding on acorns will darken the yolks.—B. P. BRENT.

GREYPATED GOLDFINCHES (F. E. R.).—I suspect they die from eating rapeseed. The change from green food, chickweed, groundsel, and thistleseed, which they get in a wild state, to hard dry seeds, especially hot pungent seed like rape, is too great for them, and they die of fever caused by the unnatural food. You can have "The Canary and Other Finches" from the office of this Journal, free by post, by enclosing nineteen stamps with your direction.—B. P. BRENT.

SUBSTITUTE FOR INSECT FOOD (F. W. B.).—Mealworms may generally be procured at most mills or bakeries, though it is not all bakers that care to acknowledge they have them, or will take the trouble to look for them. If you procure some of the parent beetles and put them in a tub with some meal you can breed them and so have a constant supply. Emmets' eggs, or the cocoons of the ant, may be collected and dried in the oven and so preserved for winter use. Lean beef scrap and mixed with hoiled yolk of egg, German paste, and chopped suet are sometimes used as a substitute.—B. P. BRENT.

WEEKLY CALENDAR.

Day of Month	Day of Week.	OCT. 31—NOV. 6, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock after Sun.	Day of Year.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 53.4°, and its night temperature 37.7°. The greatest heat was 67°, on the 31st, 1854; and the lowest cold, 19°, on the 3rd, 1861. The greatest fall of rain was 0.88 inch.

ALPINE PLANTS.

CONSTANT succession of interesting and beautiful flowers is provided by Nature, from the first appearance of the Snowdrop and Aconite, to the blooming of the Christmas

Rose; unfolding their beauties in the open air, they are within the reach of numbers who cannot cultivate the more costly denizens of the greenhouse and stove, and they possess the additional advantage that they may be seen and enjoyed in a purer atmosphere than that which prevails in these structures. Such plants, however, are not now in fashion, and in their stead are cultivated those which produce great masses of colour for a brief season, leaving the beds tenantless, flowerless, and bare for half the year. Whilst this continues to be the case, we deprive ourselves of that pleasure which we might otherwise enjoy in the possession of a long succession of beautiful flowers; but though the present system is one requiring a change, I by no means wish unjustly to deery it; I grant its merits in certain respects, but I object to the general exclusion from the flower garden of certain plants for the sake of bedding plants alone. Our gardens have some of the loveliest flowers that expand even before the snow melts; these give place to others more brilliant, which are in turn succeeded by many more, until the monarch of trees throws off his summer garb, and even then, notwithstanding chilling winds and darkening days, many interesting plants continue to display their charms until sealed under the snow. These are destined to contribute to the interest and beauty of our gardens at times when the plants cultivated for summer display are not in bloom, and to accompany, not replace, the latter when they are confined within proper limits.

For a number of years the prevailing fashion has been colour; recently foliage has been called in to aid in toning down the vastly-too-bright display. Great the strides taken to enrich our gardens during the summer, short and slow those towards a gathering of those plants that bloom early and late. It is the fashion to have flowers in gardens during summer, and these for a brief period only, and, if wanted in winter, spring, and early summer, they must be sought for under glass. Everybody knows that there used to be plants that blossomed at such seasons, but they are not now the fashion. They had their day. It is said that fashions endure for a while, and that the old ones come round. Let us, then, have flowers that can be seen in the pure fresh air, that are objects of interest and beauty not only when the butterfly flits from flower to flower, but at all seasons, in sunshine and in gloom, in frost and snow, in wind and rain, and let us thus create a garden "wherein

things of beauty are severally had in season." Among the plants best calculated to produce such a result, are herbaceous and alpine plants, and of the latter class I now propose to treat. In previous articles the mode of constructing rockwork has been described, and such will be found suitable for the successful cultivation of a large proportion of the most showy species; indeed, many of these will succeed in an ordinary border. Rockwork, however, best imitates the natural conditions in which they grow. The general hints as to filling the crevices, and covering ledges with soil, given in a former communication, will be found to answer well for the majority of the plants about to be enumerated. There are others, however, that require rapid and perfect drainage, and an equally rapid and continuous supply of water, which is best secured by making that part of the rockwork destined for their reception very perfect in drainage, and having a pipe laid so that water may escape from it in a small stream, or in a rapid succession of drops, which will keep a large area below moist and cool; and others, again, require to be placed under an overhanging rock. Where, however, the treatment of any species differs materially from that of the ordinary kinds, brief notes will be appended to them.

As to soil, large masses of it are not essential to success. Many of them grow better on the bare rock than with much soil under them. Coarse sandstone broken of all sizes and forms, from sand to the size of a hen's egg, with a small addition of loam or peat, and kept constantly moist, will grow many kinds with a vigour quite surprising.

ALYSSUM SAXATILE, flowers yellow. Its variety compactum is more dwarf, with dense and very showy spikes.

ADONIS VERNALIS, Anemone-like yellow flowers, larger than a crown-piece, produced before those of the Alyssum, in spring. It requires a compost of loam and limestone.

ACHILLEA CLAVENNE, silvery foliage, flowers yellow. It does best in dry, sunny fissures; in wet soils it goes off in winter.

ACHILLEA AUREA, as its name implies, has golden heads of bloom.

ACENA NOVE-ZEALANDLE, forms a close carpeting on rockwork, with crimson spikes of bloom. Very sandy peat and loam, and little of it.

AJUGA ALPINA, compact habit, erect spikes of deep blue bloom. It and its variety rosea, with smaller flowers of purplish rose, require sandy or gritty loam. A reptans variegata is oftener green than variegated-leaved.

AGROSTEMMA CORONARIA, with bright rosy crimson flowers; A. coronaria bicolor, white, with rose centre; and A. coronaria splendens, of a brighter crimson than the species, do well on the lower parts of the rockwork in loam and gravel. In soil of the same kind they do uncommonly well in borders, and though this plant has fine silvery leaves it is not cared about, being old, and in nearly every cottage garden of any standing. There is, I believe, a double crimson variety

ALCHEMILLA ALPINA, and its variety conjuncta with A. pentaphylla, are all we need care about under this head, pretty-leaved, and curious-flowered though they be.

ANTENNARIA HYPERBOREA, is a silvery-leaved plant, that

may some day be employed as an edging to beds, as well as for the upper parts of rockwork. Sandy loam.

*ACERETIA DELTOIDEA*, and its variety *grandiflora*, cover rockwork, both in sun and in shade, and bloom nearly all the year round.

*ARENARIA CÆSPITOSA*, *CERASTIFOLIA*, and *BALEARICA*, the last being a tiny creeper upon rocks, and having multitudes of little white flowers, need very gritty soil, with just water enough to keep it moist.

*ANEMONES* are numerous. One of the best is *A. apennina*, sky blue, grows anywhere if it has plenty of loam and leaf soil. *A. ranunculoides* is a Wood Anemone, with yellow flowers. The double white (*A. nemorosa plena*), and double red (*A. nemorosa rubra plena*), are indispensable for shady fissures filled with rich loam and leaf mould. *A. sylvestris* has white flowers early in summer, but *A. alpina* is the most stately of the white-flowering kinds, and succeeds well in deep sunny fissures. *A. coronaria*, or the garden Anemone, affords a great variety of brilliant colours. Among others of the same family, I must name *A. stellata* or *hortensis*, with rosy purple flowers; *A. palmata*, with Cyclamen-like leaves, and golden yellow flowers; and *A. sulphurea*, with lemon-coloured flowers, and which requires grit and stone along with the loam, and sunny, sloping banks.

*ARNICA MONTANA*, flowers orange yellow; solitary.

*AZALEA PROCUMBENS*, delights in sun, and moist gritty peat soil.

*ARABIS LUCIDA VARIEGATA*, is neat for sunny fissures, and *A. caucasica variegata*, is nearly as free as *A. alba* and *alpina*. Flowers white.

*ASTER ALPINUS*, flowers large and solitary, lilac purple. There is a white variety.

*AQUILEGIA ALPINA*, a charming Columbine for shady fissures containing turfy loam, moist, but well drained. The flowers are purplish blue with a white centre.

*ARETIA VITALIANA*, forms a carpet of yellow bloom, and like *Androsace*, requires moist grit in sunny fissures.

*ANDROSACE*.—This genus gives us *A. carnea* with Saxifrage-like foliage, and rose-coloured flowers, with a yellow eye; *A. lanuginosa*, silvery trailing foliage, flowers lilac and white, in umbels; *A. ciliata*, rose colour; *A. coronopifolia*, white; and *A. chamæjasme*, white, with yellow eye. All succeed in sunny fissures under overhanging rocks. Moist grit with a little peat. They should be kept moist by filtration from above without wetting the foliage, especially in winter.

*BRYANTHUS ERECTUS*, a little evergreen shrub with pink flowers, by some said to be a natural hybrid between *Rhododendron chamæcistus* and *Kalmia glauca*. Moist peat and grit, and a sunny exposure.

*BELLIS PERENNIS ACCURIFOLIA*, the finest of the Daisies for the lower parts of rock; moist loam.

*CAMPANULAS*.—No plant is more effective on rock than *C. garganica*, from its pendant habit and sheets of lilac flowers. *C. mrralis*, *C. pulla*, difficult to obtain true, *C. hederacea*, and *C. alpina*, succeed in sunny fissures in sandy loam.

*CERASTIUM TOMENTOSUM* and *C. BIEBERSTEINI* are well known as edging plants, and never look so well as on rockwork.

*C. ALPINUM* is by no means so easy to grow as the two preceding. It forms dense, prostrate, silvery tufts, and is impatient of wet on the foliage. Peat, loam, and grit, kept moist.

*CAREX NIGRA* is suitable for the base of rockwork, where the roots can reach water, being best on the margin of such.

*COCHLEARIA GRÆNLANDICA* needs peat and loam, with grit, kept wet.

*CHEIRANTHUS ALPINUS*, a lovely bright, dwarf, yellow Wall-flower, doing best in sunny fissures filled with loam and sandstone. *C. Marshalli* is well known for its dwarf habit and orange flowers.

*COLCHICUM ALPINUM*, rosy-purple flowers in autumn and winter; of dwarf habit; slopes of deep loam. It is somewhat rare. From the Alps.

*CISTUS*.—I may enumerate the following species—viz., *C. formosus*, yellow, with dark spot in the centre of each petal; *C. algarvensis*, yellow, with dark ring in the centre; *C. lusitanicus*, yellow; *C. albidus*, whitish leaves and pale purplish flowers; *C. salviifolius*; *C. Ledon*, and *C. ladaniferus* with white flowers; *C. purpureus*, *C. creticus*, purple; *C. roseus*, rose-coloured. They are somewhat tender, requiring sunny slopes, and loam upon limestone, or the last mixed with the soil.

*DAPHNE CNEORUM*, trailing over rockwork when planted in fissures in peat and loam, well drained. It does better on limestone rock than on sandstone. Flowers pink, produced abundantly, and very sweet.

*D. mezereum autumnale* is a fine autumn *Mezereum*. Both for sunny exposures only.

*CYCLAMEN REPANDUM*, bright rose, blooming in spring. On warm ledges or fissures only, well drained, nearly dry in winter, and having a rather shady exposure; peat and loam with an equal proportion of grit. The following require similar treatment, and are beautiful for rockwork:—

*C. COUM*, red, blooming out of doors in February and March unless prevented by frost. It need not be so dry in winter as *repandum*. *C. coum vernalis* has irregular blotches of silver on the leaves, and blooms later.

*C. EUROPEUM* blooms in summer and autumn, red, fragrant.

*C. ODORATUM*.—I am inclined to question whether this is more than a variety of the preceding. It has pale and almost white flowers, having a delicate scent.

*C. NEAPOLITANUM*, or *C. hederæfolium*, rose or pink, and its white variety are beautiful, both in flowers and foliage; the flowers appear before the leaves.

*CROCUS NUDIFLORUS* is an autumn purple-flowering species, for deep fissures of rich loam. *C. nivalis* or *Sieberi* is a light violet-flowering autumn and winter species.

*CORONILLA GLAUCA*, yellow, in warm situations in sun, and in fissures of loam well drained. *C. varia* and *C. coronata* will be found useful yellow-flowering under-shrubs or shrub-like plants.

*CORNUS CANADENSIS*, a Dogwood for moist well-drained peat and grit.

*CONVOLVULUS SEPIMUM ROSEUS*, rose-coloured variety of the white wild *Convolvulus*. Planted in loam in sunny exposures it runs over rocks, and is quite a novel and charming feature. The white *Convolvulus*, so common and troublesome a weed, is indeed charming for a like purpose.

*DIANTHUS ALPINUS*, very dwarf, rose-coloured flowers produced in great profusion; peat, loam, and grit in deep sunny fissures, kept wet, but well drained. *D. deltoides*, *D. floribundus*, fringed pink flowers; *D. fragrans*, like the last, fringed, but with white flowers, and very sweet. The varieties of *D. Heddewigii* do well in sunny situations.

*DRABA ALZOIDES*, dwarf, yellow; flowers in a sunny part of the rockwork in spring; loam and grit. *D. boeotica* is very like *D. aizoides*, but paler in colour.

*DRYAS DRUMMONDI*, a trailer with sulphur flowers. *D. octopetala*, fine pendant evergreen foliage, and creamy-white flowers; moist peat and limestone fissures.

*ERIANTHUS RAVENNÆ*, a very ornamental and stately Grass; sand and loam kept wet.

*ERINUS ALPINUS*, a beautiful plant for old walls; flowers rosy purple; its variety, *roseus*, is dwarfer and has larger flowers of a rosy pink.

*ERGEON SPECIOSUS*, flowers purple with a yellow disc, of long continuance. *E. grandiflorus* has lilac flowers with a yellow centre; sandy loam.

*ERICAS vulgaris*, *Hammondi*, *rigida variabilis*, *variegata*, *decumbens*, and *Alporti*; *carnea*; *E. tetralix alba* and *rubra*; *E. scoparia* and *mana*; *E. cinerea alba*, and varieties *rosea*, *rubra*, and *atropurpurea*; *E. stricta ciliaris*; *E. mediterranea*; *E. herbacea* and its variety *carnea*; *E. vagans alba*, *carnea*, and *rubra*, are what I have had in fissures and slopes of rock in peat and grit, and they are alike ornamental in foliage and bloom, which varies in colour from white to deep rosy scarlet. In summer they should not be allowed to dry up for want of moisture; they rarely do so after they become established, but are apt to suffer for a year or two.

*ERYNGIUM MARITIMUM*, a dwarf Holly-like plant, with silvery leaves; plenty of moisture and deep light loam and stones are essential. *E. alpinum* had large and showy bluish involucres; sand and loam.

*ERIOPHORUM ALPINUM*, or Alpine Cotton Grass, has small cottony heads, and forms a dense dwarf turf; wet peat and grit on ledges.

*EUPHORIA PORTLANDICA*, for hot sunny fissures only, where the leaves and stems become scarlet; sand without any addition.

*GENISTA PROCUMBENS*, prostrate, triquetra, and *sagittalis*, excellent yellow-flowering under-shrubs; sandy loam and peat.

*GERANIUM ARGENTEUM*, a silvery-leaved hardy Geranium. I have notions in respect to it as a bedding plant; rare or little known; habit dwarf and prostrate; flowers white or blush, veined with purple. *G. sanguineum* and *lancastræ* are well-known British plants.

*GLECHOMA HEDRÆACEA FOLII VARIEGATIS*, handsome, creeping over rocks and running in fissures kept moist; loam.

*GNAPHALUM HYPERBOREUM*, or *Antennaria hyperborea*, is a fine edging plant; everybody should have it, being dwarf and both sides of the leaf silvery. *G. leontopodium*, dwarf, and good, is a mass of white cotton; grit, with a sparing mixture of peat and loam.

*GEUM MONTANUM*, flowers yellow, large and solitary; grit, peat, and loam.

*GENTIANAS*.—Of these *G. acaulis* and *alpina* are nearly related, but the flowers of the latter are less than those of the former, but both are fine. Besides these there is such a host of beautiful species that it is no easy task to enumerate them. *G. verna* has charming bright blue flowers, more than an inch across. Loam and stones, and I imagine it flourishes best when pieces of limestone are mixed with the soil; it requires good drainage and a good supply of water. I may name in addition *G. Fortuni*, *G. lutea*, *G. ciliata*, and *G. bavarica*, which are all beautiful and but little known. All the family succeed well in fibrous loam, with gravel or limestone forming the understratum, and if moist in summer and dry in winter all the better. They like sun and open exposures. Some few, as *G. Fortunei* and *G. pneumonanthe*, require peat, and grit, and that moist.

*HEDYSARUM OBSCURUM*, has ornamental spikes of purplish crimson flowers. Loam and grit or sand, kept moist.

*HYPERICUM CALYGINUM* (St. John's Wort), flowers yellow and solitary. Loam, sandy peat, and gravel or limestone.

*IBERIS SAXATALIS*, *I. Tenoreana*, and *I. sempervirens*. White flowers in dense masses. Loam and a sunny aspect.

*LEPIONGON RUBESTRE*, requires sand in deep sunny fissures, and a sheltered situation. Like all plants enjoying the sea breezes, it is tender.

*LINARIA CYMRALARIA VARIEGATA*, leaves creamy white, sometimes rose and green. *L. alpina* is a pretty plant for sunny crevices among rockwork. Loam and grit kept moist.

*LITHOSPERMUM FRUTICOSUM*, evergreen and hardy. Ledges of rockwork, with a warm aspect. Peat, loam, and grit.

*LINUM MONOGYNUM*, dwarf; flowers white. A moist sandy loam, well drained. *L. alpinum* has pretty little blue flowers, and *L. flavum* with yellow flowers is well known.

*MECONOPSIS CAMBRICA*, flowers yellow, and a weed with me in light loam or gravel. Prefers a shady position.

*MIMULUS CUPREUS*, dwarf and creeping. A very ornamental plant for rockwork, though of little value for bedding-out. Flowers yellowish orange. Moist loam, peat and sand, in slight shade.

*MENZIESIA POLIFOLIA*, and its white variety *globosa*, are effective rock plants. *M. empetrifolia*, with rosy purple blooms, is very pretty. Moist peat and grit, and a sunny position.

*MYOSOTIS AZORICUS*, flowers purple changing to blue. Requires moist loam and grit. *M. montana* blooms in early spring, and *M. alpicola*, deep lilac, with sometimes a yellow eye, in May. Both require shady fissures, or ledges, and continuous moisture, with perfect drainage. Of *M. palustris*, bright blue with pink eye, I have an edging 50 yards long, and a foot broad, and it is never out of bloom, more or less, from April to December. It likes moisture, and slight shade, but sun if the moisture be constant; *M. sylvatica*, loam or gravel.

*OMPHALODES VERNA*.—Blue flowers in loose spikes, produced early in spring. Very sandy loam and leaf mould, on warm ledges of rockwork which are shaded in summer.

*OXYTROPIS URALENSIS*, a dwarf, procumbent plant, with silvery leaves, and purple flowers. Grit and fibry peat, kept moist, and a sunny exposure.—G. ABBEY.

(To be continued.)

## THE CULTURE OF THE MANGOSTEEN FOR THE DESSERT.

IN the last Number of your Journal I briefly gave the result of my experience in growing the Mango. I now purpose saying a few words about the Mangosteen (*Garcinia mangostana*), another tropical fruit, almost unknown in England, which I have successfully cultivated. This tree, although more difficult to grow than the Mango, is well worthy of a place in every fruit stove, as not only is the foliage graceful and the flowers large and ornamental, but the fruit is one of the most delicious known, being preferred by many persons to the Mango.

The Mangosteen is a native of Borneo and one or two of the adjacent islands, where it grows to a moderate-sized tree. The leaves are about 9 inches long, in shape somewhat like a Laurel, of a fine green on the upper side, and dark underneath.

The flower, which resembles a Camellia, but is larger, is of a deep crimson colour, and very fragrant. The fruit is about the size of an ordinary Apple, and when ripe turns to a dark brown, curiously spotted with green. Internally it is divided into cells like an Orange, each division being filled with a pulp of the most delicious taste, combining the flavour of the Pine Apple, Grape, and Apricot, with one peculiarly its own.

In order to grow the Mangosteen successfully, it should be planted in a deep tub or box, well drained, and either trained against a back wall of a hothouse or grown as a standard. The soil should consist of equal parts of good turfy loam, well cut up, but not sifted, and leaf mould mixed with a little sand. The following is the best method of cultivation.

Towards the middle of January the boxes containing the plants should have a good top-dressing of fresh loam, mixed with a little rotten cowdung, first removing as much of the old soil as can be got out without touching the roots, the plants may then have a good watering with very weak liquid manure, and the temperature, which during the two previous months should have been 75° by day and 60° by night, may be raised to 80° by day and 70° by night; the trees should be frequently syringed, and the house kept moist and close, little or no air being required for the first fortnight.

As soon as the new leaf-buds begin to open the temperature must again be raised 5°, and may range between 85° and 95° in the day, and 70° to 75° by night. Air will now be needed in order to strengthen the young wood, and it may be given in small quantities during the middle of the day; but it should be borne in mind that the Mangosteen loves a close atmosphere, and requires less air than any other stove fruit.

When the young wood is about 2 inches long, the flower-buds will begin to show themselves, and as soon as they are the size of large Peas the shoots may be stopped, allowing only two or three buds on each shoot; unless this is done the tree is apt to run too much to wood, and the fruit is not nearly so fine. The trees should now be kept very warm and moist, frequently syringing them overhead until the flowers open, but taking care not to overwater the roots. In a week from showing colour the flowers will begin to open, and the rich hue of the blossom, together with its large and striking appearance, renders the trees at this time most beautiful objects, sometimes from thirty to forty blossoms, each as large as a full-grown Rose, being open at a time.

As the flowers open they must be set by hand, as, unless this is done, in England the fruit will not swell. Strange as it appears, hardly a fruit is produced without taking this precaution. As, however, the flowers are large, and the pollen most abundant, the operation is an easy one, and it should be performed early in the day.

The flowers continue to open for some weeks in succession, and it will be necessary, if the sun is hot, to give a little shade in the middle of the day for about two hours when the trees are in bloom. As long as there are any blossoms open the syringe must not be used, but the house may be kept moist by sprinkling the pipes or flues. Air must be given but sparingly, and the house should be shut up closely by two or three o'clock in the afternoon.

When all bloom is over, and the fruit begins to swell, the trees can again be well syringed every night until the fruit is ripe. When this takes place—which may be known by the fruit turning brown, and emitting a faint but very pleasant scent—no more water must be given over the foliage, and the house itself should be kept drier, the temperature being about 90° or 95° by day, and 10° lower at night.

The fruit when ripe will hang for seven or eight weeks if the house is kept dry and close. In gathering be careful to cut, not pick the fruit, and to take those which are ripest first, leaving the largest, which always hang the best. In serving for dessert the fruit should be garnished with its own leaves and flowers, a few blossoms always appearing about the time the main crop is ripe.

As soon as the fruit is all off, which will not be before November, the temperature of the house should be lowered to 80°, and air admitted in the mornings of fine days. All the new shoots must be cut back to within a foot or 18 inches of the old wood, thinning out straggling and weak branches, and picking off the decayed leaves. The plants must be kept dry, giving only sufficient water to keep them from flagging.

The Mangosteen is easily raised from both cuttings and seeds, the latter should be sown as soon as possible, as they will not keep.

Like the Mango, the Mangosteen delights in a high tempera-

ture, no amount of atmospheric heat seeming to injure it. It is rather liable to the attacks of insects, particularly the green fly, which attacks the young shoots, and the tree must be constantly searched to discover these pests; they are generally found under the young leaves or on the flower-buds. Tobacco water is, I think, the only remedy.

As an ornamental tree the Mangosteen is unrivalled: the blossoms, too, are invaluable for dressing ladies' hair, or for bouquets, as they last for many hours without fading, and give a beautiful and refreshing scent, somewhat resembling the Stephanotis. There is a variety grown in Borneo with white flowers remarkably fragrant, but I believe it has not been introduced as yet into England.

I had intended saying a few words about the Durion and Anona, both of which I have fruited, but will postpone what I have to say until next week.—J. H.

### ROSES IN GROUPS.

An excellent practical article with the above heading appeared in the Journal of May 23rd. of the present year, from the pen of Mr. Abbey. Although the distinguished rosarians appealed to for the information sought have not replied, the subject is sufficiently important not to be allowed to drop, especially as the copious rains that have fallen since the heat and drought of September, have rendered the soil highly favourable for the formation of such groups. The few suggestions now offered are not presumed to satisfy the inquiry, for the conditions attached to it are too stringent to be literally fulfilled, yet the time is not far distant, judging from the improvements that are gradually being effected, when a sufficient variety of Roses will be in cultivation to answer the requirements Mr. Abbey has specified. Already we have kinds of the highest merit, which, as Mr. Radclyffe truly says—"It will take half a century to beat." The possession of these has created the desire for more of the same excellence. In time we hope they will appear.

The directions for preparing the beds, given in the article above alluded to, are simple, but at the same time indispensable to secure good growth and free blooming. "The ground should be well drained, deeply dug, and liberally supplied with manure." And in after-times, if the manuring is continued with occasional mulching to admit free action of sun and air, and watering in very dry weather, now and then with manure water if obtainable, the beds will last for years. A plant or two may die if too much neglected, but this is a contingency not likely to happen if well-established strong plants are put in at first.

The best form of the plants intended for grouping, especially on light soils, is undoubtedly those budded on the Manetti stock. Mr. Abbey says truly—"The Manetti after two or three seasons does not cause trouble on account of suckers, and is never half so bad in this respect as the Dog Rose." The soil of my garden is of the lightest, and I experience this truth constantly. In the present year I have not had twenty suckers from 150 Manetti Roses, while the briar Roses have been a source of continual trouble on that account. My first Manetti Roses, planted five years ago, have not sent up half a dozen suckers in the whole time; they are still in a most satisfactory state of health and vigour. Even on heavier soils the Manetti is not unfavourable for grouping. In the early part of the summer of the present year, my good friend Mr. Goddard, gardener to H. Bannerman, Esq., of Hunton Court, near Maidstone, pointed out two groups which he had formed, and which were on the Manetti; they were then just coming into bloom, and for brilliancy of colour, freshness of foliage, and other good qualities that we like to see, they were very evidently superior to any in the garden on the briar, of which there are a considerable number. They were also quite equal in bloom, and superior in vigour to those on their own roots, although Mr. Goddard has for some time past successfully propagated and grown Roses on their own roots, and gives that form the preference. It should be remembered that in putting in Manetti plants in light and deep soil, from 4 to 6 inches below the point of union is not too much.

The conditions which Mr. Abbey insists upon as being requisite in Roses for grouping, may be thus summed up:—1, They must have good flowers. 2, They must be profuse bloomers. 3, They must have free and healthy foliage, and be of strong and vigorous habit, but not rampant. All rosarians are agreed that the above qualities are always desirable, and

when any appear possessing them in a greater or less degree they are pronounced A1. A supplementary negative condition is added to the above. "Those that are inconstant, or those that only open occasionally and produce few blooms, or more imperfect than perfect ones, are useless." Such are General Washington, Sœur des Anges, and in some seasons La Reine, Souvenir de la Reine d'Angleterre, and others of that class, which, beautiful as they are when they do come, cannot yet be dispensed with as exhibition flowers. They must be omitted in grouping on lawns. "A combination of hardiness, dwarf habit, profuse foliage and bloom is most wanted;" therefore, only such as possess these qualities should be planted; for a group on a lawn must be necessarily conspicuous at all times, more especially when in flower, and this must be more or less for five months of the year. Most people would prefer variety, but it is not yet possible to furnish even a limited variety possessing the requirements to the letter; but it is quite possible to form a group that shall be good and pleasing. The best I ever saw was formed and planted by Mr. Radclyffe, at Critchill, the seat of H. C. Sturt, Esq., in Dorsetshire. This group consists of more than one hundred plants all on the Manetti stock, and comprises the *élite* of the Hybrid Perpetuals. It is highly admired and gives a very attractive feature to the beautiful grounds at Critchill. The plants are arranged with the most vigorous in the centre, and the dwarfier kinds round the outside.

In forming a group of Roses on a lawn, the situation, size, and shape of the bed must influence the arrangement of the kinds planted. If the bed is a small circle, oval, or rectangle—for simple figures are always the best—the varieties selected should be of uniform habit, and if situated apart, dwarf and compact-growing kinds are preferable. If the bed is large and not required to be viewed at a glance, it will be well to plant strong-growing kinds in the centre with dwarfier ones towards the outside, as is done at Critchill. If the bed is only to be looked at from one side, it will evidently be the best plan to plant the strongest kinds at the back and the less vigorous towards the front.

As regards the kinds suitable for this style of planting, my own idea of a small bed would give a decided preference to one kind to each bed, if several small beds are to be formed, because we possess Roses that fully come up to the standard recognised by Mr. Abbey, and I think correctly. Such is Charles Lefebvre, which has eminently every desirable point of excellence, and not inferior to it is Senateur Vaisse; Cecile de Chabillant must also claim a place, after the other two only in not being quite so free-blooming in the autumn months. More vigorous and sturdy in habit, but, nevertheless, more prolific is Jules Margottin, our old favourite. Caroline de Sansal is also well adapted for the same purpose. A bed of either of these is sure to be attractive, and in the case of the two first-named grand. Effective groups of a single variety may also be planted with Général Jacqueminot, Duchesse d'Orleans, Maréchal Vaillant, Prince Camille de Rohan, and Madame Boutin. The last two, however, do not bloom quite so freely here as on heavier soils.

I subjoin two lists. The first contains kinds that are either naturally dwarf or may be kept so by a judicious use of the pruning-knife. Their height should not be allowed to exceed 2 or 2½ feet. The second list consists of more vigorous varieties, which should be allowed to grow to the height of 3 or 4 feet as may be required. They will do better supported by a neat stake of wood, or still better by a slender iron rod painted, or covered with pitch. Green paint seems the most appropriate. Both lists contain some varieties that would not be considered good enough for exhibition flowers, but they compensate for this defect, if defect it is, by blooming freely. There are none inserted but what have been proved here, hence it may seem that there are omissions; to supply these must be left to the judgment of those who may avail themselves of these suggestions. The kinds are arranged according to colour, the lightest being first.

No. 1. Mademoiselle Bonnaire, Caroline de Sansal, Duchesse d'Orleans, Cecile de Chabillant, John Eopper, Baron Gonella, Louise Odier, Colonel de Rougemont, Catherine Guillot, Alpaide de Rotalier, Gloire de Vitry, Triomphe de Paris, François Lacharme, Senateur Vaisse, Charles Lefebvre, Eugène Appert, Géant des Batailles, Duchess of Norfolk, Cardinal Patrizzi, and Empéreur de Maroc.

No. 2. Louise Darzens, Acidalie, Anna Alexieff, Duchess of Sutherland, La Ville de St. Denis, Jules Margottin, Madame Clemence Joigneaux, Madame Charles Wood, Madame Charles

Crapelet, Madame Boutin, Madame de Stella, Madame Julie Daran, Maurice Bernardin, Maréchal Vaillant, Général Jacqueminot, Duc de Cazes, and Prince Camille de Rohan.

The following newer kinds would probably equal many and surpass some of the foregoing. To list 1: Princess Lichtenstein, as a white variety, seems promising so far as yet proved; Duchesse de Caylus, Rushton Radclyffe, Madame Victor Verdier, and Eugène Verdier. Lord Macaulay is one of the very best crimson scarlet Roses, and rather dwarf and compact in habit. To list 2 Elizabeth Vigneron would be an acquisition, it grows very freely and far surpasses Lælia or Louise Peyronny. A bloom of it sent to me by Mr. W. Paul, in September, was really grand in form and colour. Pierre Notting, as a darker crimson than Charles Lefebvre, is also a valuable addition. Beauty of Westerham is very free blooming in autumn and very fragrant, but hardly full enough for exhibition. Recent information on the newer sorts will also readily suggest other additions.—ADOLPHUS H. KENT, *Blechingley, Surrey.*

## ON AND ABOUT THE ROCKS AND SANDS OF TENBY.—No. 4.

LET me gather together, in conclusion, the fragments remaining scattered through my note-book.

Is it not Burkhardt who tells of leaning over an autograph on the wall of the Pyramid, and of the memories and thoughts which that autograph summoned forth?—for it was the handwriting of an old and far-off friend. Such memories and such thoughts—some more sad, probably, than Burkhardt's—were mine when I came to a memorial cross beneath the giant rocks of Giltar Point; it is on the verge of the sand in Lydstep Bay, and bears this inscription:—

“To the memory of JOHN COCKBURN THOMSON, who near this spot was accidentally drowned whilst bathing, May 26th, 1860. This stone is raised by his affectionate sister H. God touched him, and he fell asleep.”

He was no commonly-gifted man. Great were the hopes justly fostered that he would take a high rank in the sacred profession to which he was dedicated, and it is no mere smooth monumental sentence which records of him elsewhere that he was noble, gentle, charitable, and devout. Yet I would not have jotted down this note had he not been the son of one still better known—Dr. Anthony Todd Thomson, one of the earliest lecturers in London on botany. In 1822 he published the first, and it is to be regretted that it was also the last, volume of his “Lectures on Botany.” They first enunciated much before unrecorded relative to the physiology of plants, and deserve especially to be noted as evidence of microscopical research, when the use of the microscope for such a purpose had fallen into neglect. All the engravings and woodcuts are from Dr. Thomson's own drawings, and comprise illustrations of the vessels, glands, pores, forms of leaves, and other parts of plants far exceeding those in any other work known to me.

I passed on, revisited the wondrous Lydstep caverns, mounted to the summit of the cliffs above them, and pursued my way to Manorbeer. What a quaint old church is there! arches without shafts, its ribbed vaulting, and the tomb of a De Barri. Who was thus memorialized by this mailed, cross-legged, recumbent figure?—the armour partly ring and partly plate, the shield emblazoned with the De Barri arms, the foot resting upon a couchant lion; but the natives maintain it is a bear, and that the warrior when he attacked the beast shouted, as to the issue of the encounter, “Man or bear,” and that the place of conflict has retained that as a commemorative name! How etymologists agree to differ; some maintain that this locality was named from old British words meaning the Mansion of Pyrrhus (Maenor Pyrr), whilst others maintain that it is merely a corruption of the words Manor of Bere, as Barry was often spelt!

No matter—the district is replete with interest, and foremost among the *notabilia* is the castle. Its ample ruins show that it was of irregular form, surrounded by a high, embattled wall, having no windows outwardly, nor any other openings but such narrow apertures as served for observation or the discharge of missiles. Into the inner court all the windows opened; and with the same aspect is the not unusual dovecote made by omitting bricks in a chequered arrangement from one of the walls. It would not harmonise with your purposes to describe the ruins more in detail, but I may add that the park wall, of some extent, is still traceable, and between it and the main road a narrow wooded valley marks where the garden,

orchard, and vineyard, and Hazels were when Giraldus wrote some six centuries since, and the little stream trickles on which he mentions, and which sustained the fish-ponds of his boyhood.

That Giraldus de Barri—better known as Giraldus Cambrensis—was a memorable man; he was our first topographical writer, and he was born in this Castle of Manorbeer in or about 1146. He travelled through Wales with Baldwin Archbishop of Canterbury in 1188, and with a feeling with which I fully sympathise, he thus speaks of the place of his birth and boyhood which he then revisited:—

“The castle called Maenor Pyrr, or mansion of Pyrrus, is excellently well defended by turrets and bulwarks, and is situated on the summit of a hill extending on the western side towards the seaport, having on the northern and southern sides a fine fish-pond under its walls, as conspicuous for its grand appearance as for the depth of its waters, and a beautiful orchard on the same side, enclosed on one part by a vineyard, and on the other by a wood remarkable for the projection of its rocks and the height of its Hazel trees. . . . Maenor Pyrr is the pleasantest spot in Wales, and the author may be pardoned for having extolled his native soil, his genial territory, with a profusion of praise and admiration.”

I could jot down much about this birthplace of old Giraldus, and show of its management and mismanagement, until finally the King, our fourth Henry, declared it forfeited, and wrenched that and the manor of Penally, with some others, from the De Barry's, and handed them over to a courtier, one John Windsor; but enough, and now for Stackpool Court.

He who has not passed along the approach to Stackpool Court has yet to be gratified by the sight of one of the finest approaches in the British islands.

Stackpool Court is a comparatively recent acquisition of the Cawdor family. Its earliest recorded possessor was Sir Elidur, or Leonard de Stackpool, a crusader, whose cross-legged effigy, in chain armour, reclines in the neighbour church of Chenton. In the sixteenth century Stackpool had the Vernons as its possessors, from whom it passed to the Lorts, whose heiress at length brought it to the Cawdor family by marriage with Sir Alexander Campbell. But again I must whip off from archaeology, and pursue more congenial game.

What magnificent Beech trees are at Stackpool, not old picturesque wrecks like those at Burnham, but giants, and giants in the fullest vigour of Beech-hood. But even these are second to the Evergreen Oaks, than which I never saw such magnificent specimens, with stems 3 feet in diameter and 70 feet in height; and when I mention these and the Beeches as specimens, let it not be concluded that they are few and choice, they are to be counted by hundreds. The climate is all in their favour, for the grounds have a southern aspect, and slope down to the sea, and the trees descend the slope and dip into the water of one of its estuaries. Rarely is such a combination of mountain, water, and foliage seen; it is like a section of the Wye taken bodily and deposited here. The abundance of shade is opposed to the display of flower gardening. Mr. Slater, the head gardener, has managed to find space for a small geometric garden, but its beauty cannot be appreciated from being on such a level that there is no good point to look upon it from. It would appear to more advantage if sunk. Everything looked vigorous and healthy, and all around the estate I noted that air of comfort in the cottages, and that love of window plants, which is to my mind the best evidence that happiness prevails within. Who cares to adorn an unhappy home?

Since the foregoing was written I find that full forty years since the then Earl of Cawdor made especial efforts to promote an attention to gardening among the cottagers. His head gardener, Mr. Buchan, thus writes upon the subject:—

“His lordship, ever anxious to promote the comforts of his dependants, gave directions for additional chambers, and a better system of ventilation in his cottages; to repair the exterior in the cottage style, and build new ones where wanted. I was then instructed to put the gardens in a proper form behind each cottage, and to make a court in front, for the cultivation of flowers. I furnished them with such fruit trees as were best adapted for that climate, and stocked their courts with herbaceous plants, shrubs, and creepers of the common kinds; informing the cottagers at the same time that they would have to keep the whole in good order for the future; and I must here observe, that the information was not received with a good grace by some of them, prejudiced as they were against the introduction of anything new.

"Five premiums or rewards, of different value, were then offered to those who had the best cultivated gardens, and most flowers in their courts, and about the 10th of August I inspected their gardens, and awarded the premiums. As the garden labourers, from the nature of their employment, had some advantage over the others, they were not allowed to compete with them, but were competitors among themselves; and the premiums were not confined to those who had had their gardens put in form for them, but extended to the cottagers of the three parishes.

"The successful candidates were so elated with the idea of having gained a prize, and the others flattered with the hope of doing the same the following season, that the spirit of gardening soon became general, and cuttings of fruit trees, plants, and flower seeds were in great request with those very individuals who were most prejudiced against them at the formation of their little gardens.

"The village of Stackpole was new frequented in the summer season by the ladies and gentlemen of the neighbourhood to see the flowers and improvements of the cottages; and many of the labourers, who had worked about the gardens for years, and never asked the name of a plant, began to ask the names of flowers that a certain lady or gentleman had admired the preceding day.

"Two years before I left Stackpole Court the premiums were discontinued, being considered unnecessary; and it was gratifying to see that the cottagers paid the same attention to their gardens, in the evenings and mornings, as usual; they had experienced the comfort and advantage arising from so doing; for their fruit trees were now in a bearing state, and their market for common fruits and early vegetables was tolerably good."

It is most gratifying to find that the influence of such encouragement is enduring, and not only enduring, but is contagious; for I noticed that excellent window plants, and good kitchen gardening prevail over the adjoining districts, and contrast most favourably with the neglect of gardening so characteristic of North Wales.—G.

### NEW ROSES.

WHAT good is there in clairvoyance, electro-biology, or second sight? Where are those wretched beings called mediums, but whom the United States tax-gatherers properly call jugglers? Why don't they come to our rescue? Will Mr. Home, or Alexis, or Madame Card, or even Sandy McAllister with his second sight, tell us something about the new Roses? Of all the arrant "hums" of the day this spiritualism is the greatest, for why does it not do something useful for us? I don't see the good of setting one's sofas and round tables dancing a polka, or of twitching one's legs with an invisible hand, or sending tambourines and fiddles flying through the air; and as to the calling-up of spirits, about the most sensible thing I have heard of Pius IX. doing was his giving Mr. Home notice to quit. If, indeed, they would tell us what Roses to buy—which of the ninety or hundred, as the case may be, are worth having—which do the growers themselves know to be bad, or on what do they lay the greatest stress—if any of our spiritualists would do something of this kind for us, we should then be perhaps inclined to say there was something in it. However, here are the lists; and in spite of "ROSA ANGLICA," or "ROSA CANINA," (which I should think means dog in the manger), I must now do as I have done before.

As when in early days (although I used not to walk the hospitals, yet many a day found me in the lecture-room, where some "don" was holding forth on one of the various branches of medical science), I used often to be courteously invited to come to the dissecting-room, they had got such a "capital" subject (I have no doubt they say now-a-days such a "jolly" subject, but the word was not known then), and the eye of my friend would glisten at the thought of what cutting and hacking there would be; so now I, as the inviter, must ask the kind readers of THE JOURNAL OF HORTICULTURE to come with me, with penknife and spade, and cut away, or dig up, or east upon the dunghap, many a limb of that very interesting and exciting production, the catalogue of new Roses.

Before I do so a word or two on those of last year may not be unacceptable, that the correctness of one's surmises may be tested. I find that those of the Hybrid Perpetuals which I conjectured or thought, from having seen them, would be good were \*Duchesse de Caylus, \*Rushton Radclyffe, \*General

d'Haultpoult, \*Duchesse de Medina Coeli, Madame C. Verdier, Xavier Olibo, \*Souvenir de William Wood, Charles Margottin, Marguerite de St. Arnaud, Jean Rosencrantz, Triomphe de la Terre, \*M. Moreau, Charles Wood, Souvenir de Bernardin de St. Pierre, and \*King's Acre. Those marked with an asterisk were praised in last week's JOURNAL OF HORTICULTURE by Mr. Radclyffe from his knowledge of them; while of those not included in it the only one was Duc de Wellington, of which I hoped good things, and Mlle. Amélie Halphen; for Elizabeth Vigneron I had not seen advertised at the time I wrote the notes. Madame C. Verdier, I am inclined to think, will be an excellent Rose; but Xavier Olibo I have not seen or heard of, still I believe we shall hear of him again.

Adopting the plan I did last year of keeping the Roses under the names of the raisers, I shall begin with the heaviest contributor to our lists, M. Eugène Verdier. That he should send out so many is, I think, detrimental both to himself and to us. I feel sure that it would be far better to send out some four or five than this round dozen, which frightens growers.

#### M. EUGÈNE VERDIER, FILS AÎNÉ.

1. *Alba Mutabilis*.—Vigorous. A seedling from Jules Margottin. Flowers large, 9 centimètres in diameter (about 3½ inches), full, white tinted with rose, and becoming completely shaded with rose in proportion to its opening.

2. *Charles Rouillard*.—Plant vigorous, about 10 centimètres (4 inches), in diameter; form perfect, full. Beautiful tender rose, more lively in the centre.

3. *Fisher Holmes*.—Very vigorous and free-flowering. Flowers large, fine, imbricated like a Camellia, magnificent brilliant scarlet red.

4. *John Grier*.—Very vigorous. Flowers large, flowering in clusters of six to twelve, full, fine shape, globular, sweet-scented, clear red or shaded rose; reverse of petals silvery.

5. *Jean Lambert*.—Vigorous. Flowers very large, 12 centimètres (4½ inches), in diameter, full, shaded fiery red. The buds are extraordinary, and resemble a pigeon's egg.

6. *Mademoiselle Marguerite Dombain*.—Vigorous. A seedling from La Reine. Flowers very large, 12 to 14 centimètres in diameter (4½ to 4¾ inches), full, globular, and well-formed, very sweet-scented, beautiful virgin rose, very tender and very fresh.

7. *Prince de Porcia*.—Vigorous. Flowers full, well-formed; colour beautiful vermilion, richly shaded.

8. *Professeur Ducharte*.—Vigorous. Flowers large, flowering in clusters of four to six, full, globular, well-formed, clear red; reverse of petals satiny.

9. *Souvenir d'Abraham Lincoln*.—Vigorous. A seedling from Cardinal Patrizzi. Flowers medium, full, well-formed, crimson shaded with red, purple, and rose.

10. *William Rollisson*.—Very vigorous. Flowers large full, globular, magnificent lively cherry red.

M. E. Verdier brought to me, as I have before mentioned, a few of the above when I was at Paris in June, and of two of these in his list I can speak favourably. No. 1 was an exceedingly delicate and pretty flower, but not very large; I should have called it a pale rose. No. 6 is unquestionably, as I saw it, a noble-looking flower. Its parentage might suggest difficulty in opening; but I do not think that this need be feared, for the buds are of quite a different shape, long, and not globular, and when this is the case I do not think there is much doubt as to its opening. No. 5 is a large flower, coarse to my mind, and somewhat difficult, I imagine, to open in our climate. Of the others I know nothing. Evidently 9 is too small for our requirements. I have not translated those parts which have reference to foliage, for our neighbours are more curious in such matters than we are. Whether thorns are red or brown, straight or recurved, foliage pale green or apple green, are not matters about which we take much concern, and I have therefore not burdened my paper with these matters.

#### M. LACHARNE,

The raiser of Charles Lefebvre, and the possessor of an indubitable yellow Perpetual, deserves an honourable place; and one, at any rate, of his Roses for this year is likely to add to his reputation as one of our first raisers.

11. *Alfred Colomb*.—Plant vigorous, having some analogy to Charles Lefebvre. Flowers large, full, form of Centifolia, very lively fiery red. Superb.

12. *Prudence Besson*.—Plant very vigorous, having some analogy with Souvenir de la Reine d'Angleterre. Flowers very large, nearly full, well formed, carmine red. Very effective.

13. *Souvenir de Docteur Jamain*.—Plant very vigorous. Flowers large, full, well-formed, bluish violet, new colour.

Laclarme was kind enough to send me up to Paris a box of blooms of No. 11, and I have no hesitation in pronouncing it to be a grand Rose; to me it seemed a combination of the good qualities of Charles Lefebvre and Senateur Vaisse, evidently of vigorous habit, and very free-flowering. One can never be sure in these matters, but I shall be very much surprised if this Rose does not hold its own in the foremost rank for many a year. No. 12 sounds well, for a well-formed *Souvenir de la Reine d'Angleterre*, in lieu of the coarse and flaunting flower that that is, would indeed be a great boon. I do not fancy that 13 is of a shade of colour, however novel, that will be very much appreciated on this side of the Channel.

#### GULLOT FILS.

14. *Joséphine de Beauharnais*.—Plant very vigorous. Flowers very large, very full, well-formed. A seedling of Louise Peyronny. Magnificent tender rose, the edge of the petals silvery. Superb.

15. *Pline*.—Plant very vigorous. Seedling of Mère de St. Louis. Flowers very large, full, varying from a beautiful red velvety vermilion to violet red. Very striking.

16. *President Mas*.—Plant very vigorous. Seedling of Triomphe de l'Exposition. Flowers very large, full, well-formed, a beautiful velvety shining red, sometimes shaded with violet. Superb.

Of these 14 and 16 are, I know, considered by the raiser fine Roses. There are several announced which seem to be seedlings of, or have a strong likeness to, Louise Peyronny or Lælia. If they are improvements on that fine flower they will be very valuable.

And now I must close for the present, not without, however, drawing the attention of our Rose-loving readers to a notice which appears in another column relative to a testimonial to the Rev. S. Reynolds Hole—a project which has been most warmly received, and has already a certainty of success. There are many rosarians who have not the pleasure of personal acquaintance with as genial and hearty an English gentleman as one meets with; but there is not one who can be ignorant of the benefits conferred on the culture of their favourite flower by the founder of the National Rose Show, and from one and all we look for countenance and support.—D., *Deal*.

### ON THE PROPAGATION OF CYCLAMEN PERSICUM.

CYCLAMEN cultivators have had a treat in the very valuable papers which have appeared during the last three weeks, and much useful information is now at their disposal, which was previously unattainable. Allow me, however, to inform amateur cultivators, that there is no need to wait three years for seedlings to bloom, and to detail my limited experience, in the hope that it may prove useful to amateurs like myself.

I sowed forty-four seeds of *Cyclamen persicum* on the 9th of February in the present year, in a box containing a mixture of leaf mould, rotted turves, and silver sand. The seeds were about 2 inches apart, and covered about half an inch. The box was then placed on a Randle's tank, which occupies the front of my little stove, and a bottom heat of about 70° was maintained for two months, after this the heat was increased to about 80°. Only thirty-five seeds germinated, they were about six weeks in appearing, and came up very irregularly, some of the latest being eight and nine weeks before they did so. This heat was kept up until the middle of June, when I had a severe illness which prevented my attending to my plants for about six weeks, during which time the fire was rarely lighted, and they were left pretty much to themselves. I fully expected that they were doomed for this season's blooming. However, they progressed very well under the influence of sun heat and frequent waterings. About the middle of August I potted them in a similar mixture to the above, with the addition of a little peat. When engaged in this operation I fancied I observed some incipient bloom-buds on the largest and most forward of the bulbs. In two or three weeks this suspicion became a certainty, and as the roots got hold of the fresh soil, they quickly pushed on, both in foliage and bloom-buds; and at the present time (October 25th), no less than twenty-eight out of the thirty-five are showing for bloom, the largest bulbs having from twelve to eighteen bloom-buds, part of which I hope to

see expanded in a week or ten days. Had I been able to continue bottom heat for a longer period, no doubt I should have had several in bloom at this time.—G. H.

### RAIDS AFTER FERNS.—No. 2.

#### DARTMOOR.

Still on the moor!—the fresh invigorating breezes playing around me as I go peering about bank and brae in search of something new and strange. Sometimes the bank is my best friend; sometimes the ditch; sometimes the moor. My choice would lead me to a sunny tract of moorland rather abruptly descending to the banks of a river, whose waters come tumbling headlong over huge blocks of rock; but this half-cleared moorland will only give you a certain number of Ferns—the *Lastrea dilatata*'s that do not care for much moisture, so that their roots may find shade under big stones; the smaller varieties of *Athyrium Filix-foemina*, and a sprinkling of other Ferns; but down by the river the larger varieties may be found, and the water's music is always, to my hearing, so very, very sweet.

On the banks about Manaton I found some splendid specimens of *Asplenium adiantum-nigrum*; one verging towards *acutum*, and called "intermedium"; another "scarcely obtusum" but very like it—so like it, that had I not a friend with a very high title amongst the aristocracy of Fern-land, who kindly names some of my specimens, I should boldly have stated that I had found both *acutum* and *obtusum*; so strongly marked in their difference of form were these two beautiful Ferns—each with free-waving pinnæ—the pinnules of *obtusum* being like little bells.

Beneath the friendly shade of banks, bright with Ferns, and trailing along which the wild Raspberry (*Rubus idæus*) may occasionally be found, we passed on our uphill-way to Heytor.

Heytor, though not the highest of the Dartmoor tors, commands more general attention from its majestic form, its ease of access, and the glorious views which greet the eye on every side of its castle-like keep. It is formed of immense rocks, piled into two grand masses, that crown the mountain top, and, in their calm and solemn grandeur, bid defiance alike to time and tempest. On the top of one of the great rocks there is hewn out a "rock-basin"—one of those ancient remains about which so much has been conjectured and so little known. We ascended the height and looked around. Beneath our feet was, as it were, the ruined city of the tors—thousands of shattered rocks lay on the green sward, caressed by tender grass and Ferns, by moss and heather—on every side nothing but heath, and rock, and moor; there was not even a bird to break the solitude by its cry and give one's heart a memory! I think I must have felt as the Sir Eger of the old romance of Graysteil felt when

"He saw neither rich nor poor,  
But Moss and Ling and bare wild moor."

I know, whatever it was, that I liked it!—and it was many minutes before I raised my eyes from the scene beneath to the scene beyond. How different it was—wavy outlines of sweeping distances, of soft grey hills, crowned here and there by tors rising in silent solitude majestically towards heaven.

These tors have each their name, their separate individuality—you get to know them as you know the face of a friend. This one, with a sort of jelly irregularity of outline, as if the rocks were hob-nobbing with each other, is Houndtor; beneath its huge fragments may be found—with dark fronds seeking the light of day—a curious form of *L. dilatata*, the fructification of which is coal-black, and through a lens has the appearance of rich ripe Blackberries. To the left is Honeybaggot—a name derived in some way probably from the fact that wild honey in ancient times when found near royal forest-lands was claimed by the king, and it was not till Henry the Third's time that a freeman was allowed to retain the honey which he found in his own woods. Still further to the left is Rippextor; turning still to the left, your back upon Houndtor, you see far off old Ocean's bright blue arms circling round the Ness at Shaldon, and stretching far away into the dim distance. Then your eye travels inland, where here and there are bright-looking villages nestling in peaceful valleys. There are several, but I see but one—Chudleigh—for had I not a little time before found on rocks near that pretty village a beautiful form of *Asplenium adiantum-nigrum*, with branched and tufted fronds; not only rare, but new to learned eyes?—there, also, had I found a lovely *Athyrium*, which also promises good things,

but is at present too young and tender to be decided upon. Wherever the eye rested, it rested on beauty; and I thought the fair world had seldom seemed more fair than when looked upon from the rock-basin of Heytor.

Descending from the huge rock, we passed on our way to another moorland home, and as we went we stopped at Widecombe hill to examine one of the "hut circles" or remains of the stone dwellings of the ancient Britons. These remains are very scanty in their rude proportions, but they occur constantly on Dartmoor; and from the imaginary buildings which we are able to erect from these ruined basements, they seem to agree with the description that Cæsar gives of the houses of the Britons, and with the representations of the British cabins as depicted on the Antonine column. All that in most cases is now left is a single course of large stones, rudely put together in a circle varying from about 12 to 30 feet in diameter. The door-jambs may be traced; they also are of stone, and placed nearly at right angles to the outline of the circle.

Given these premises, a wide field is left for the imaginary architect. Some see the tree-clothed hills, on which not a shrub is left, dotted about with circular buildings, in form like a soldier's tent, with the cheerful smoke curling up from a hole in the centre of the roof, while peaceful flocks and herds adorn the smiling landscape around! Others see the dwelling-places of our forefathers hidden beneath a thatch of the boughs of living trees, planted round the hut and bent to their purpose—a sort of "wood of Dunsinane"—beneath which a pastoral rather than a warlike people are hidden.—For me, I wonder where the people came from to live in the huts, where they are gone to, and how they managed to exist at all in such bleak and desolate regions, where in 1865 there is no post office, no butcher nearer than seven miles! Mayhap they did as a moor-lad told me they were now sometimes reduced to do: "When us," he said "hasn't got no mate to ate, us shoots the hathefells (heath fowl or black-cock) and ates they, and in summer us seeks the Hurts (Whortleberries) across the riding bogs; they Hurts make good dumplings."

Not far from Widecombe we took up our residence in a cottage beneath the frowning shadow of Hamildon hill. Dark, gloomy, and portentous looks this hill in a storm, and even in sunshine it only condescends to break into a grim smile; yet it is rich in flowers and Ferns. Down its rough sides streams trickle through narrow gullies, and it is these gullies that form the best hunting ground. In one, just above Wooder House, I found what seems to be a new variety of *Athyrium Filix-femina*; it is very finely serrated, in irregular pinnæ and pinnules, and both frond and pinnæ are forked. I also found a dwarf *Blechnum* spicant, a neat compact little plant, with tiny fertile fronds of not more than 2½ inches in length. I had never met with this variety before, and I only found a few plants, but they grew in the locality of large *Blechnums* and gave every promise of being true. By the side of the mountain stream, interspersed with lichen-covered rock, were small bogs where I found two plants of *Pinguicula vulgaris*; directly the tiny plant was gathered its pale green leaves curved backwards lengthways; the leaves of one of the specimens were veined a deep reddish purple. The flower was of a pale lilac, with the lower part of the cup orange veined with brown. At first sight I mistook the plant for *Pinguicula lusitânica*, but I believe I have rightly named it *P. vulgaris*. Trailing over the moss, and over the stones on all sides, I found *Campanula* or *Wahlenbergia hederacea*. I had been told that I might find the *Silthoropia europæa*, but I hunted for it in vain; in Cornwall it was as common as the little Ivy-leaved Bell-flower is on Dartmoor. On the drier rocks I found several beautiful Mosses and Lichens; amongst the latter was the Coral Sphærophoron (*Sphærophoron coralloides*); seen under a lens the coral appears like a brilliant scarlet fungus growing in cup-like form on a pale green rock; on the same stone was the Elk's-horn Cup-lichen (*Seyphophorus alaicornis*), and, scattered about several others equally curious.

The hedges about Widecombe were still—though my visit was in September and October—bright with many a flower. The *Viola palustris* was full of blossoms, the dark purple lines showing clear against the pale lilac of the flowers. The little yellow star of *Hypericum humifusum* still lingered near the white-starred *Sedum album* or the more rare *Sedum dasyphyllum*. I fancied that the tender purple stem of the *S. album* sought for shade more than the better protected *dasyphyllum*, but it may only have been fancy.

On the moor I only found the *Ericas cinerea* and *tetralix*, with quantities of *Calluna vulgaris* intermixed. We bought

some heather-scented moorland honey, having often heard its praises sung; but though it had certainly a strong scent and taste, I found neither very pleasant. We bought it at the Widecombe shop!—for Widecombe is not behind Manaton in civilisation so far; nay, I think it is a little in advance, for while we were bartering for honey, a tea-pot, oil, and flour, a poor girl came in, with a face sorely swelled, asking to see the master. "Is it particular business?" said the lady of the incongruous wares. "Perhaps you wish a tooth extracted?—Mr. — will attend to you presently." I made my escape—but was immediately attracted by a beautifully divided *Asplenium adiantum-nigrum*, much like the Chudleigh one, in the opposite wall; I went back to borrow an old knife to root it out, and was followed by the "master" with a bricklayer's trowel (for he was mason as well as dentist, &c.), who offered his assistance in a most gallant manner, "but," said I, "the poor girl?" "It should have been seen to a month ago," returned my friend, with an air as though he should say "She has hid her time, she must now wait mine." Alas, poor jaw!—but the dentist and I extracted two promising roots of *A. adiantum-nigrum*, and I only hope that he managed the tooth as dexterously.

Returning to our cottage by the fields and river, I came on an upland bog covered by huge *Osmundas*, and near at hand were some monstrous plants of *Athyrium Filix-femina*—some purple-stemmed, some white; they were nearly, if not quite, 4 feet high; I believe the variety to be that of *davallioides*. A little further on I found purple-stemmed *A. Filix-femina rhaeticum*, and, still further, a large *Pteris aquilina* very much forked. One of the great characteristics of the Dartmoor Ferns is this tendency to fork. I have found nearly all of the Ferns of the moor forked; *Filix-mas*, *Filix-femina*, *Blechnum spicant*, *Asplenium trichomanes*, *Asplenium adiantum-nigrum*; the *Lastrea dilatata* and *L. oreopteris* are exceptions. During a fortnight's hunt, I only found two plants of *Polystichum angulare*, and not one of *Polystichum aculeatum*. One of the two plants is the usual form, the other is, I believe, the variety *alatum*, the very small pinnules being joined to the rachis by a decided wing; but the plant is yet very small, so that I fear to speak with decision.—FERN-HUNTRUSS.

P.S.—Since the above was written, there has been found in a sequestered part of Becky Fall, or rather in its neighbourhood, a clump of *Polypodium phegopteris*.

## NOTES ON GRAPES.

I SEE in the *Gardeners' Chronicle*, of October 7th, a person is advised to plant the *Barbarossa* in a house where *Black Hamburg* and *West's St. Peter's Grapes* are grown, as it does not require so much heat as a *Muscate*. I think it is impossible to give worse advice than this, for if any Grape requires strong heat it is the *Barbarossa*. However good-looking and well-coloured it may be, it is seldom high-flavoured, because it hardly ever receives enough heat. At Sir Edward Walker's, of Mansfield, where it is grown with more heat than is generally given to *Muscates*, I found it the best flavoured *black Grape* in the house, and it was compared with *Black Hamburg*, *Lady Downe's*, and *Black Alicante*; and, let me add, this is the only place at which I have found it of first-rate excellence. Nothing is more disappointing than a badly-selected lot of Vines, and I would caution any one against planting *Barbarossa*, *Black Alicante*, or even *Lady Downe's*, if he is not prepared to give sufficient heat to ripen *Muscates* in the same house. If I were planting a late viney, these three and *Muscate* of *Alexandria* are all I should select, as *West's St. Peter's* is generally inferior in flavour.

I am more than ever pleased with *Muscate Hamburg*, when grafted on the *Black Hamburg*, as an early Grape. With me it fruits as freely, and colours as well as the *Black Hamburg*. To try if it would ripen in a cold house, one was planted in the large orchard-house, which is 90 feet by 30 feet, and has no artificial heat. Though planted late in spring it has reached the top, and a bunch only 4 feet from the ground ripened perfectly, though a good deal shaded by the Peach trees. I have now no doubt that it will require no more heat than a *Black Hamburg*, and I know that it will sell for one-half more money in the market. *Trentham Black* has again proved better and earlier than *Black Hamburg* in the same cold house, so we have three first-rate *black Grapes*, which will ripen with little or no artificial heat.

*Duchess of Buccleuch Grape* has proved with me in every respect superior to *Chasselas Musqué*, richer in flavour; and

with both larger bunches and better berries, it ought to supersede the latter variety, for it has less tendency to crack and shank, though not free from these faults. It is not large enough for a market Grape, but will be valued by those who estimate flavour rather than appearance. Napoleon is in every respect inferior to Royal Muscadine, of which it is a variety. Foster's White, which also resembles Royal Muscadine, is superior to its parent in size and appearance, but is hardly its equal in flavour. Of Royal Vineyard, I have formed a very unfavourable opinion, a white Muscat in appearance, without any Muscat flavour, it appears a very bad setter; if it has any good qualities time will develop them.—J. R. PEARSON, *Chilwell*.

ROSES FOR EXHIBITION.

"J. C.," of Atherstone, asks, "Which are the best twelve Roses to grow for Exhibition; also, the best twenty-four for that purpose?" As "J. C." does not say anything about the families of Roses, or whether he objects to summer and Tea Roses, I shall confine my recommendations to autumnal Roses, of the families of Hybrid Perpetuals, Bourbons, and Tea-Noisettes. I may say, however, that if summer Roses are not objected to, the very best show Roses among them are Paul Ricant and Charles Lawson. If Tea Roses are not objected to, Devoniensis, Madame Willermoz, Souvenir d'Elise, and Souvenir d'un Ami are the very best; and Sombreuil as a white Rose, is hardy, most excellent, and never suffers from fungus.

It is an invidious task to select twelve or twenty-four Roses, and say these are the best. There are admirable Roses which I cannot generally recommend, and I must leave them out. I am bound to suppose that "J. C." wishes garden Roses and show Roses combined in one; and, above all, that he wishes Roses of good constitution and good general attributes. Moreover, I presume that he wishes Roses, whether twelve or twenty-four, to be varied in colour. This being so, I will endeavour to help him; and, as far as I can, I will put them alternately, light and dark, or by a fair contrast.

- |  |   |
|--|---|
| 1. Charles Lefebvre, darkish crimson.                  | 7. Pierre Notting, clarety crimson.                         |
| 2. Souvenir de la Malmaison, flesh bluish.             | 8. La Ville de St. Denis, pure rose.                        |
| 3. Senateur Veisse, vivid crimson.                     | 9. Madame Victor Verdier, vermillion rose.                  |
| 4. Gloire de Dijon, orange yellow.                     | 10. Cecile Chabillant, pink, and silvery reverse of petals. |
| 5. Prince Camille de Rohan, velvety black crimson.     | 11. Mariee Bernardin, vermillion.                           |
| 6. Sœur des Anges, white, with a delicate peach tinge. | 12. Triomphe de Rennes, yellow.                             |

If "J. C." can grow these well, and they are very easy to grow, the sooner his fellow competitors take up their bed and walk, the sooner they will be in a position to respect themselves.

I have now to add twelve more, alternately light and dark. As I ended with light, I will begin with dark.

- |  |   |
|--|---|
| 13. Duc de Cazes, dark purple crimson.             | 19. Celiue Forestier, yellow.   |
| 14. Duchesse d'Orleans, lavender bluish, roseated. | 20. Madame Bontin, rich crimson.  |
| 15. Jules Margottin, bright light cerise.          | 21. Caroline de Sansal, flesh bluish.   |
| 16. Duc de Rohan, light vermillion red.            | 22. Madame Moreau, lustrous red; a splendid novelty of 1855.                        |
| 17. Aedalie, white.                                | 23. Madame Boll, pure rose; or John Hopper. The latter has the better constitution. |
| 18. Maréchal Vaillant, bright crimson.             | 24. Baron Gonella, dove-pink, distinct.   |

I add these as surplusage, they are excellent and good—William Griffiths, salmon rose; Alfred de Rougement, deep purple or violet crimson; Madame Julie Daran, vermillion; Baronne Prevost, rose; Solfaterre, yellow; Souvenir de la Reine d'Angleterre, rose; Monsieur de Montigny, reddish rose; Madame Knorr, bright rosy bluish; Victor Verdier, rosy flesh; Madame C. Crapelet, rosy crimson; and Lord Macaulay, rich dark crimson.

The whole of the above Roses are admirable here all the season round. Mr. John Keynes cannot select for "J. C." another such lot, either with or without alternations of colour (that have constitutions), out of the existing proven Roses. The descriptions given in the catalogues are truthful. I have only put in three new Roses—viz., Pierre Notting, Madame Victor Verdier, and Madame Moreau, they will be found to be admirable.—W. F. RADCLIFFE, *Tarrant Rushton*.

RESULTS OF THE SEASON.—As letters from correspondents have appeared in the Journal commenting on the fact of Pear trees being now in bloom for the second time this year, it may not be deemed out of place to mention that a Pear tree in the garden of a house in the Camberwell New Road blooms a

second time every year, the period of the second bloom being in June. Raspberry canes of this year's growth are blooming, and fruit-forming, in my garden.—M. S., *Brixton*.

GROUND VINERIES,

The following extract from a note recently received from a friend at Southampton may be of interest to some of your readers:—"Two years ago I saw your ground or curate's vineries at Sawbridgeworth, and immediately on returning home I established a Vine on this principle of culture. I find I can grow better Grapes in this ground vinery than in a hothouse adjoining; and the success of it has been so great that I intend giving up a considerable portion of garden ground to such vineries."

Allow me also to correct that part of my communication in page 269 respecting these structures, in which I said that the sixty-three bunches of Black Hamburgh Grapes in a vinery 14 feet long would average half a pound each. I find, on gathering them, that many bunches weighed 1 lb. each, and that they would average three quarters of a pound each; thus in round numbers, say sixty bunches, I have had from a vinery occupying but a very small space 45 lbs. of Grapes quite ripe, but not of a good colour. I must, however, add that the crop was far too heavy for the Vine, and the result of oversight, as half the quantity would have been enough for the future well-doing of the Vine.—T. R.

TWO CROPS OF PEARS GROWING AT ONCE ON THE SAME TREE.

In your Journal of October 17th, I observe some curious instances of Pear trees flowering at this late season of the year. It may, perhaps, be interesting to some of your readers to learn, that there is a Pear tree in the gardens here, which flowered at the usual time, and set a beautiful crop of fruit, and it again flowered about the end of June, most of the blossoms setting; it had thus, as it were, two crops at one time in different stages of growth.

The variety being the Autumn Bergamot, the first crop was ripe in the last week in September, and proved excellent. The produce of the second flowering was gathered a day or two ago, and were quite hard when gathered, and in size and appearance very unlike the fruit of the first gathering.—THOS. PROSSER, *The Gardens, Longford House, Gloucester*.

POTTING CHEILANTHES ODORA—EFFECTS OF HOT SUMMERS.

Will you inform me when I ought to repot Cheilanthès odora? I brought it from Italy with me last spring, and potted it at the end of April. It now seems at rest, but has made very little, if any, growth during the summer.

It may interest your readers, perhaps, to be told that I have had this month some fine, well-ripened bunches of the Black Hamburgh Grape, from a Vine planted against the east wall of my house, without any artificial protection or heat whatever. The great warmth of the autumn has produced several most unusual growths. I have picked Lilacs, Laburnums, flowers of Dogwood, wild Roses, Apple and Pear blossoms, and many other shrubs and plants, which have put forth a second bloom.—HENRY BURNEY, *Waverdon Rectory, Woburn*.

[The soil being sweet, and the drainage of the pot good, the plant need not be potted until March; but if the soil be at all saturated or sour the sooner it is potted the better. Be very careful not to injure the roots. It will not grow to any extent during the winter unless the house be warm, and warmth at that season is one of the greatest drawbacks to its cultivation. During the winter keep cool, just free from frost, airy, and just moist at the root.]

INTERNATIONAL HORTICULTURAL EXHIBITION AND CONGRESS.—We hear that this will commence on the 22nd of next May, and conclude on the 25th.

THE NEILL PRIZE.—The late Dr. Neill, of Edinburgh, at his death left the sum of £500 in trust of the Council of the Caledonian Horticultural Society, the interest of which was to be given once in three years to some one in Scotland who had

advanced any branch of natural science, including botany, vegetable physiology, horticulture, &c. The first was presented to Mr. McNab, of the Botanic Garden at Edinburgh, and we are happy to announce that this year the prize has been most properly conferred on Mr. Win. Thomson, gardener to his Grace the Duke of Buccleuch at Dalkeith.

#### PLANTS FOR TABLE DECORATION IN WINTER.

Would you let me know the names of about two dozen hardwooded flowering plants, greenhouse or stove, to come in flower from September to Christmas? I have no accommodation for forcing, so they must bloom naturally.—G. C.

[It is no easy matter to give a list of highly ornamental plants flowering in November and December, in an ordinary greenhouse, but by preparation during the summer much may be done. Early plants of *Cineraria* may be brought into flower then, as also may *Primula sinensis*; and *Coronilla glauca* will assist in its particular colour; while all the winter-flowering Heaths, as *Erica hyemalis*, *Wilmoreana*, *rubra-calyx*, and others may be brought into use. *Chrysanthemums*, we expect,

you will already have. *Salvia splendens* makes, perhaps, the finest autumn-flowering plant we have; *S. fulgens* is also good, while, perhaps, some late-flowered *Calceolarias* may be taken up from the open ground. *Plumbago capensis* often blooms late; and *Tricyrtis hirta* should not be forgotten, its beautifully pencilled flowers give it a pleasing appearance. *Cyclamens* likewise come in at this season, and if a little heat could be given, *Epiphyllum truncatum* and its varieties form useful additions to the display at this season. Much also may be done by introducing fine-foliaged plants or those ornamental by their fruit. *Skimmia japonica* is a useful plant, and so is *Solanum capsicastrum* and other species. In plants with ornamental foliage, there are several Ferns and Lycopods, *Isolepis gracilis*, *Sedum californicum*, *Centaureas*, and New Zealand *Veronicas* alike useful as flowering plants and for foliage. The variegated forms of Japanese *Euonymus* are useful plants, as well as *Eurybia*. Many of the above will do for dinner-table decoration as well; but we expect an article on this subject shortly, which will comprise various stove plants, and others not enumerated in your list, which, as will be seen, is confined to greenhouse plants.]

#### THE MODERN PEACH-PRUNER.—No. 17.

CLOSE PRUNING BY ALTERNATE SHOOTS.

It is probable that the severity of the original form of close pruning the Peach in the open air, has presented some obstacle to its general adoption—at least, in this country; and it must be allowed that what is suitable for trees luxuriating in the brilliant sunshine of France, and comparatively uninjured by the adverse influences of damp and fog, cannot, without the necessary modifications suggested by personal experience, be expected at once to secure popularity here. To obtain public

confidence it is necessary that any new system practised abroad under such different conditions, should also successfully pass through the test of a fair trial at home. Its merits can then be proved, and reported on, and the general public, having neither time nor inclination to examine for itself, can securely receive this report on the good faith of those who are able and willing to attempt it. It is not always, it is true, that the time, the labour, and the money spent in such trials are repaid,

Fig. 18.

but in any case the public is the gainer. In examining, then, the merits of the original system of close pruning, it may not be out of place again to repeat, that at least ten seasons were devoted to giving it a fair trial, and to modifying it. During this period it was taught by me to others, who largely adopted it, and whose gardens and orchard-houses (in some cases of no small importance) sufficiently attest to the completeness and success of the method.

In considering the original system, we notice, at the outset, that the first growth of the year is stopped, in the ordinary run of shoots, at two full-sized leaves. The result always is, that the buds in the axils of these two leaves burst into a rapid second growth, which is as suddenly closely suppressed, and it follows that all the fruit-buds, and also the few intermingled wood-buds, are formed at the point of junction of these two growths.

Though valuable groups are thus produced, which, in the

dry, sunny, and manageable climate of the orchard-house are just what we require, still it may fairly be questioned whether the general vigour and necessary progress of the entire tree may not be prejudiced by this restraint placed on them. In a semi-tropical sunshine, with a dry and ripening autumn, and planted in a rich soil, Peach trees would certainly thrive under this very close treatment; but in our uncertain, damp, and comparatively sunless atmosphere, the balance between the roots and leaves might become unequal. It must not, also, be forgotten, that one chief aim of M. Grin's system is to produce those two-year-old clusters (class 5), which are known to bear the finest fruit. When, therefore, several of these valuable groups are formed at the base of the spur, the upper growths become of secondary importance. This is essentially orchard-house pruning, but it does not admit of that scope and largeness of treatment which is required for open-air work, especially in England.

For similar reasons, after many experiments, I think that pruning to three leaves as soon as six are formed (which style I advocated in "Cordon Training," published five years ago), although an admirable system for trees under glass, is not, on the whole, sufficiently long to meet all the accidents and risks that the Peach has to undergo.

Pruning to six or eight leaves, provided care was taken to insure the early formation of the fruit-buds on the lowest portions of the shoot, by cutting back below the point of the first stopping in time, as described in No. 15, is a valuable system for some localities; forerights to be closely pinched in, and short spurs preserved. This is a mixed system; but I have now no doubt that the safest, the most profitable, and the simplest way is to make the first summer-stopping of the shoots at four leaves, as soon as at least six full-sized leaves are developed. These four good leaves will each have a bud or buds in their axils, and there is now length enough in this shoot to satisfy any pruner; for if these four buds are not to bear, where does the long-pruner expect his fruit to be? And if they are to bear, what need is there of more growth beyond them than is sufficient, as in the Vine, to nourish the fruit?

The first stopping of the shoots, then, is at four full-sized leaves. The smaller leaves at the base, having no buds now in their axils, do not count. Of the four leaves left, some of the upper buds will burst into second growths, and the lower ones will be constituted. These shoots not being tied in, we may suppose that one or two of the upper-buds will thus burst. If the shoot be on the under side of the branch, or on the upper side and tied in, only the point-bud will burst. As soon as the second growth has made four leaves, it should be reduced to two. If, by the time this second stopping to two leaves takes place, the lowest buds on the shoot, having had most of the sap, appear full, prominent, and formed (which one or two seasons' experience will enable any one to be a judge of), then let the third growth be reduced to one leaf as soon as two appear, and any

further autumnal growth may be allowed to make several more inches, according as it is desired to strengthen the tree, after any casualty. If, on the other hand, at the time of regulating the second growth the pruner's experience shall have taught him that the lower buds are not progressing well, then let him cut below the point of junction of the first and of the second growths. The object is to concentrate anew the summer sap at the lower buds, so as to develop them, without causing them absolutely to burst. This is almost sure to succeed. Should, however, the buds not become formed, then the pruner would be justified in cutting right down to the lower two buds, because the shoot is of little value, and the worst that could then happen would be to cause the bud to break, and the shoot would then have to be cut in very closely at the winter pruning.

We suppose that the two upper buds burst. In this case the buds at the junction, and those on the second growth, are very valuable. In the orchard-house these are certain fruit-bearers, and out of doors they may also be generally relied on, being formed so early in the season. If only the extreme or point-bud burst, then the lower three will give ample chances of fruit. In any case we have both the junction-buds and the ordinary triple groups of long pruning to depend on, thus uniting every chance.

There should always be at least two shoots on each spur. The object is to prune them alternately, as fruit and wood bearers. One of these, the most promising, is left long to bear. It is cut above the junction-buds, because, as a rule, we must not cut too near to the group which is to bear, and at the junction are several wood-buds. The other shoot on the spur is cut rather closely in, but not so as to sacrifice some well-placed groups. It is cut, however, quite near to the point whence the new succession shoots are to appear.

In time a certain number of shoots will spring from each spur. Of these we leave the best long to bear, and the others are cut in closely for succession wood. Of the bearing shoots

Fig. 19.

—say two, one is left longer than the other, and, if desired, tied in. This is to economise the wall. One shoot having two or three good buds is really enough in practice to secure succession shoots. In the orchard-house we preserve all we can. In the open air forerights are preferably removed at the winter pruning, but there need be few, because such shoots as show this disposition could be very closely stopped to two leaves, and so become short spurs.

Young trees under this system, should only have their first year's shoots equalised at 6 or 8 inches. At the first winter's pruning these shoots should be cut in to two good eyes, thus forming a short shoot, which eventually becomes the spur. The next summer each of these two buds puts forth a shoot, which is then ready to be manipulated to four leaves, to two, and to one leaf.

Beyond equalising the branches, and directing them into the proposed shape, no further shortening of the branches takes place. Blank spaces are filled in by grafting by herbaceous approach, or by budding.

Under long pruning the leading branches were excessively shortened, thus throwing the shoots out into corresponding length. The modern style, on the contrary, allows the branches

to remain at full length, merely suppressing any rampant growth, and equalising all the parts, while the shoots are closely pruned to concentrate the sap instead of dispersing it. To closely prune the shoots, and, at the same time, reduce the length of the leading branches, would be to dwarf the tree; but to allow the growth to take place only where it is required, is evidently the natural way. Any form of tree flourishes when thus treated for it is a return to first principles.

Fig. 18 represents the system I have been describing. This is the autumn appearance of the two shoots springing from the central spur. In this figure it is easy to distinguish how the four leaves of the first summer stopping have fared. In either shoot only the point-bud has made a second growth, which has been stopped to two leaves, and a third growth, which has been stopped at one more leaf. The junction-buds (where the point-bud burst) appear full and healthy. One of them, in the right shoot, even shows a disposition to become a cluster-spur. This reveals to us the secret of the original theory. The small leaves at the base of either shoot are not counted in the four. This beautiful specimen was carefully drawn from nature, and is a perfect illustration of the theory advanced.

Fig. 19 represents the winter pruning of these shoots. A is

the original spur. B is the right shoot, which has been selected to bear (both shoots are, however, perfect) mainly on account of the presence of the good buds at the junction F. The second growth, E, has been left (this is optional here). The left shoot, C, is cut to the lowest group of triple buds; for the central bud of this group, being a good wood-bud, will give us a strong new shoot, which will be stopped at four leaves, and be kept to bear in its turn. At its base are reserve buds which may become cluster spurs, or put forth other succession shoots. Any of the three good groups left on the shoot, B, may bear the fruit. If the highest be selected, its central wood-bud should be stopped when it has made two leaves, there being abundance of leaves at the junction above it. The remaining groups, and, perhaps, the latent buds at the base will now extend, and afford the pruner ample scope for his skill. C is to bear the fruit now; therefore, B has to provide the succession wood. Besides this, however, it is proper to develop one shoot more on B, at least, so as to multiply the chance of fruit, and so that by the winter, the spur, A, shall have three or four shoots of various kinds found on it to select from.—T. C. BRÉHAUT, *Richmond House, Guernsey.*

### GOURD—JERUSALEM ARTICHOKE—CASTOR OIL PLANT.

Will you allow me to call your attention to the Portmanteau de Naples as a Vegetable Marrow? I fancy I can with propriety use that term. It has been in bearing for months. My gardener cut one weighing 28 lbs. this morning. I hang these Gourds in the kitchen, and have slices cut off as wanted. It forms a useful side dish in winter, and is excellent with roast meat.

I have a large patch of Jerusalem Artichokes in full bloom, many with eight flowers fully expanded. I cannot call to mind seeing them in bloom but once before, although I have been a gardener upwards of forty years. My Castor Oil plants this year are as tall as Chung.—F. DAVIES, *Captain 10th W. R. V., Pershore.*

### A PEEP AT THE WOODS IN ODD PLACES.

No. 2.

#### ACER SACCHARINUM (SUGAR MAPLE).

PICTURE to yourself a beautifully wooded hill, with a silvery rivulet trickling around its base. It is a glorious day, the sun is shining brightly overhead, with its warm rays bringing miraculously into activity the slumbering powers of the vegetable creation. The sap is beginning to rise, buds to shoot, corn to spring up, and trees to foliate; all bespeaking the wonderful power which the sun possesses in Canada West, and forcibly reminding us that to the unchristianised mind of the Aztecs and ancient Mexicans both prior to and during the reign of Moctezuma, their religion is not the unreasoning belief that some would have us think, but a beautiful conception in the weak mind of man of the eternity and omnipresence of a Supreme Being, whom the poor human understanding can in no wise comprehend. I refer to the worship of the sun. And now I will turn to the scenery in which the elegant and most valuable Sugar Maple (*Acer saccharinum*), rears its softly rounded, and delicately green foliage. The tree grows to the height of from 20 to 60 feet; the leaves are shaped somewhat like those of the common Maple, of a most delicate pale green in the spring and summer, becoming converted, as autumn draws on and stern winter heralds his advent, into yellows, varying in tone from pure gamboge to deep chrome, and reds, and scarlets, from the bright scarlet Verbena to the dull heavy Indian red shown in the wing of the caged and pining Virginian nightingale. The bark is of a whitish brown colour, rather deeply fissured in the sap-bearing trees, something after the manner of the common Ash (*Fraxinus excelsior*), of our own country. It is brittle, and from between the bark and the young wood, or outer woody rings of the trunk, called by carpenters and mechanics the sap-wood, in contradistinction to the darker inner rings denominated the heart, flows, on piercing the bark, a clear sweet liquid, containing the sugar from which the tree acquires its name.

Having thus briefly described the tree and the position in which it is most commonly found—viz., upon hilly ground in the neighbourhood of water, I shall next proceed to give an

account of a sugar-boiling "bee." Lest any of my readers should not know the meaning of the word "bee," it is as well to state that when in any part of the northern states of America, or Canada, a large amount of work is required to be performed in a limited time, as the preparing of Apples for drying, busking corn, quilting, or raising a house, the person requiring aid notifies to all neighbours, near and far, that on a certain day he wishes their company, not to meet together in the evening as we do in this country, too often to talk over and scandalise our neighbours, but to go the whole day from early morning and devote their best energies to forward the welfare of the undertaking; and they well know that when evening shall have put an end to their labours, the cheerful glass and song, varied with dancing, will fully reward them for a day spent in hard work and helping a friend.

Perchance some of my fair readers may wish to have an insight into the *arcana* of my western hall and supper-room. I must beg of you to imagine the day's hard work completed, and the actors in the scene instead of being, to use our own phrase, quite tired out, only just primed for any amount of fun or dancing that can possibly come in their way. The building in which we are met is a stately one for that part of the country; the gentleman, if I may so apply the term, for whose good the "bee" was held, was in a superior position to the generality of those around him, and, therefore, the building—namely, the barn in which our gathering took place, was more roomy and better adapted to such an occasion than often happens. It was constructed of sawn timber regularly put together like the frame of an English boarded house, and planked outside so as to be a perfect shelter against inclemencies of weather. Of course, in Canada we consider a current of air which would extinguish a gas light as a mere zephyr, and not worthy of being noticed. But let us haste to the dance, where we can hardly say—

"We foot it fleetly as we go,  
On the light fantastic toe."

but what was missed in airiness and elegance was most fully compensated for in activity and perseverance, for we all followed in the steps of Goldsmith's village swains, who

"Simply sought renown,  
By holding out to tire each other down."

and I may boldly add, that the city belle who could dance down some of the company then present, would have been a lady possessed of no small amount of thews and muscles, and would require no surgeon's certificate to testify as to the soundness of her heart and lungs. But "tell it not in Gath;" here, even here, in the heart of a country in which it would be difficult, nay almost impossible, to find a hundred acres cleared from its virgin forest, the almost entire surface of which was twenty-five years ago bush land, that had hardly been trodden by the feet of white men, where the bear and the Indian, the moose and the deer, were the lords paramount, and held undisputed sway over the country—even here Venus and Bacchus hold court, and wield their sceptre over a numerous train of subjects; and it can hardly be expected but that at a meeting of young folks brought together for the purpose of fun and frolic, many worshippers of both goddess and god, would not be found: consequently love-making on the broadest basis was plentifully intermingled with libations to Bacchus, in the shape of whiskey, and the wreathing fumes of the calumet of peace of the red lords of the soil, or according to our host, who was of Irish extraction, a "shangh of the dudeau," *Anglice* a whiff of the pipe. This combination of dancing, love-making, whiskey, and tobacco, taken in rapid succession, soon brought matters to a conclusion; for, as in hunting the pace kills, Morpheus came to the aid of the previous god and goddess, and notified to the guests that it was time for retiring to their various homesteads; and between three and four in the morning the "bee" had ended, and none remained save a few single young men who stopped to complete the work commenced on the previous day.

Having previously mentioned the object of the "bee," I will now proceed to a description of the process of sugar-obtaining. A small tree, varying from 9 to 18 inches in diameter, of some hard wood, perhaps even a worn-out Maple, is cut down, and chopped into lengths of between 2 and 3 feet; these small logs are then split in two, and each half is rudely hollowed out by the axe into a small trough. One of these troughs is placed immediately below an incision made obliquely through the bark to where the sap flows; the object of this direction being chosen is that the liquid may run from the wound along a chip thrust into the cut, and thus drop into the trough. It is as well to mention,

that the sap flows most freely on warm, damp days; cold, even when accompanied with rain, checking at times almost entirely the ascent, and consequent flow of the juices. As each trough is filled it is emptied into a bucket, the well-known light American pail being that principally in use in Canada West.

These buckets, again, when full are carried by the collector to the boiling kettle, which is a large three-legged iron pot, suspended by a chain hanging from a cross-beam or gallows, which chain is attached to the handle, thus enabling it to be kept at sufficient height above a fire kept constantly burning under it. The whole of this process is carried on out of doors, and in the immediate neighbourhood of the trees whence the saccharine liquid is drawn. All the time the pot must be kept boiling and well stirred, that the evaporation of the aqueous portion may take place regularly, and to enable the sugar left behind to granulate, without which it would become a mere sweet lump, not presenting the appearance of sugar at all. After being boiled into thin molasses, it is strained, eggs are beaten up with the shells, and mixed with the cold syrup, which is again boiled to the necessary consistence, and then allowed to cool in vessels which form a kind of mould for it. These masses when set are pierced to allow any of the uncrystallised molasses to drain off, and when sufficiently drained are broken up, and put away for keeping. According to the cleanliness used in the different processes, and the art of the boiler, the sugar will vary in appearance from the very light and pleasant-looking crystalline substance known as fine West Indian coffee sugar, to the coarse, luscious, dark-coloured sugar exported in cases from the Brazils. The flavour of the finer kind, although unmistakably showing its source, is to many more agreeable than even the best specimens of West Indian sugar, and incomparably superior both in appearance and flavour to the high-dried, tasteless, and sandy-looking compound known as East Indian and Mauritius sugar. The finer qualities also have the advantage of keeping better, but the sugar made by the whites, especially by some of the neat housewives of Canada West, is so superior to that made by the Indians, as scarcely to be recognisable as an article bearing the same name. This sugar, on account of the labour required in making, is dearer than that imported to such places as lie within the reach of easy carriage, and is, therefore, seldom made except for household use, and in districts remote, and imperfectly provided with roads.

The Sugar Maple might with advantage be planted more plentifully in this country, being of quick growth for a hard wood, of great beauty, either singly or in clumps, and invaluable in ornamental grounds and small parks, both on account of the beauty of its shape, and the delicacy of its foliage. The changeableness of its hues according to the season, makes it a most pleasing object in the landscape. Neither heat, cold, nor moisture seems to affect this sturdy tree. Its timber is of great worth to the upholsterer and turner, being a clean, hard, and close-grained wood, easily worked, and not given to warping, capable of bearing a high polish, and, in fact, useful for all the purposes of neat, durable furniture.—A SURGEON.

#### CALCEOLARIA SANG'S AMBASSADOR.

Not having seen mention made in the pages of THE JOURNAL OF HORTICULTURE of this really excellent Calceolaria, I beg to draw attention to it, as a most decided acquisition to the list of bedding Calceolarias. It was sent out last spring by the Messrs. Sang, of Kirkealdy, Fifeshire, and is known by the name of Sang's Ambassador. Another bearing the same name, but much inferior to it, is, I believe, in the trade.

In colour it is a rich crimson, with a strong glow of scarlet in it. In fact, at a short distance it has all the appearance of being a scarlet, a colour quite new in the Calceolaria, and the want of which has long been felt.

A circular bed of it here (Whittingham Gardens, Haddingtonshire) edged with a dwarf-growing yellow Calceolaria (canariensis) has, throughout the season, obtained general admiration, being when viewed at a short distance, and with the sun shining on it, quite dazzling, so much so, that it was with difficulty that the eye could rest upon it.

Another powerful recommendation is, that it seems to defy all sorts of weather, having stood the heavy and continuous rains of August better than any of the many Calceolarias used here. This, however, may be partly attributed to its being thinly planted, being from 15 to 18 inches apart. Thin planting is almost indispensable, in order to insure success. It is

of compact growth, throwing up immense trusses of flowers, which are all the better of being slightly staked, or supported in some other way. Flowering so profusely, it cannot be expected to produce many cuttings. A good plan, therefore, is to plant out a few plants in some shady situation, and then by pinching out the flower-stems as they appear, and thus encouraging growth, an abundant supply of healthy, tender cuttings may be obtained in autumn. Such plants, being lifted and potted in a light soil, and placed in a cool airy house during winter, will produce a large number of cuttings for spring propagation.—J. ADAMSON.

#### NEW BOOK.

*The Orchard-House.* By T. RIVERS. London: Longmans & Co.

THE twelfth edition of this useful and excellent little volume has just been published. The following is one of the additions it contains:—

"I have, however, gathered an idea with regard to compost, which may be useful to amateurs, and which the experience of the present season (1865) seems to confirm. In other words, I have for some time suspected that which I now know—viz., the necessity of calcareous matter in all composts used in the cultivation of stone-fruits. Many orchard-house amateurs have for several seasons felt surprise at the robust healthy appearance of the Apricot trees cultivated here in pots, and their extreme fertility. I had been so accustomed to perfect success in their culture that I felt no surprise, thinking it a matter of course, and scarcely crediting accounts I heard of their failure with some cultivators.

"At last my attention was aroused, and I was induced to look into my soils, more particularly the loam used in potting fruit trees. This I found to be, like all the soils in this district, full of finely comminuted chalk; and to this large preponderance in our sands and loams, amounting in the former to 25 per cent., I fully believe I owe a portion of the great success which attends the cultivation of orchard-house fruits here.

"The question is, can this calcareous nature be given to composts used in the cultivation of fruit trees in pots, or in prepared borders? I believe it may, and with but little difficulty. It is merely procuring chalk from the districts where it exists. It is very cheap, a truck-load being easily dug and placed on the rail. This will, of course, be sent in lumps: all the preparation it requires is being reduced to powder, and half a peck of it mixed with a bushel of compost thought to require it. Or if we say, mix two bushels of powdered chalk to a one-horse load (twenty bushels) of compost, it will be near enough.

"I believe this addition of chalk to composts not calcareous, and to loams of an iron nature, to be quite necessary in the culture of stone fruits; and if not necessary, still most beneficial to all kinds of fruit trees.

"The fine Cherries on pyramids, in pots, grafted on the *Cerasus Mahaleb*, now cultivated here, and the great success of Plum culture, are owing to the calcareous soil; so that I earnestly recommend chalk to be used in cases where it is at all comestable."

#### ENTOMOLOGICAL SOCIETY'S MEETING.

THE October Meeting of this Society was presided over by F. Paeose, Esq., the President, and afforded much interesting matter for study. Amongst the donations to the library received since the last meeting were the publications of the Royal and Royal Agricultural Societies, and a new part of the "Transactions" of the Entomological Society of New South Wales, in which the death of the eminent naturalist, W. S. Macleay, Esq., President of the Society, was announced. The death of Dr. Scham, of Berlin, one of the honorary members of the Entomological Society of London, was announced by Mr. MacLachlan.

Mr. Kirby exhibited a specimen of the rare Moth, *Sterrhia sacaria*, taken near Brighton, in July; and Mr. Stevens a fine series of Butterflies, collected at Labuan, in Borneo, by Lieut. De Crespigny.

Mr. Jenner Weir exhibited specimens of the rare Moth, *Xylina petrificata*, one of which resembled *X. semibrunnea* in colour. He also stated that he had observed that the lesser Earwig employed the pair of forceps at the extremity of the body in closing its wings after flight.

Mr. MacLachlan exhibited several species of Phryganeidæ taken in ice caverns of the Swiss Alps, by the Rev. J. F. Brown. He also read descriptions of a new British species, and of various species of the same family taken in the Malayan Archipelago, by Mr. Wallace.

Mr. Evans exhibited two deformed specimens of the *Vanessa Atalanta*; and Mr. W. W. Saunders the pseudo-bulb of an Orchid, from New Granada, entirely destroyed by vast numbers of specimens of two distinct species of limpet-scale insects (*Coccidæ*). He observed that there appeared no fixed period of the year for the development of these insects, and he had never yet been able to discover a single male of either of the species in question.

Dr. Wallace exhibited a specimen of *Argynnis Lathonia*, captured at Colchester, by Mr. Harwood, at the end of the preceding month; also, an extensive series of living specimens, in all their different stages, of

the Ailanthus Silk-worm and its moth (*Bombyx Cynthia*), which he had succeeded in cultivating at Colchester in the open air, showing satisfactorily that this species might, with a moderate amount of care, become a new article of commerce in this country. He had obtained a grant of a portion of a railway embankment for a plantation of the Ailanthus trees, which will grow in the poorest soil. It was of importance that the eggs should be hatched upon the leaves of growing trees, as the young larvae did not thrive well on gathered leaves, a circumstance completely contrary to the habits of the common Silk-worm. The moths hatch from the cocoons at a temperature of 70°, and he had procured two broods during the present season.

Mr. W. W. Saunders made some observations on the comparative value of the Ailanthus, contrary to the statements of M. Guérin Ménéville in its favour.

Mr. S. Scudder, Secretary of the Natural History Society of Boston, U.S.A., also made some observations on the cultivation of silk from the *Bombyx Polyphemus*, in North America, the cocoons of which very nearly resemble those of the Ailanthus Moth. He also exhibited a remarkable fossil insect, allied to the genus *Ephemera*, and which must have measured as much as 5 inches across the expanded wings, which had been found by Mr. Hart in the Devonian Rocks of New Brunswick.

Mr. Sydney Saunders exhibited a fine series of specimens of the Bee parasite, *Hylelethrus Rubi*, in different stages of growth, found by him at Corfu; and Mr. T. Boud several very beautifully preserved specimens of the caterpillars of British Moths.

A paper by Mr. F. Walker, containing the description of a new exotic genus of Chalcididae, was read; also, the continuation of a memoir by Mr. C. Wilson, of Adelaide (South Australia), on the Buprestidae of Australia, of which beautiful family he believed there were not fewer than 800 native species, 350 of which inhabited southern Australia, a fine work by M. Henri Deyrolle, upon the species of the same family, collected in the Malayau Archipelago, by Mr. Wallace, was also exhibited.

An interesting conversation took place on the various peculiarities which had been observed in the development of insect life during the two last unprecedentedly dry and hot seasons.

## RECENTLY-DISCOVERED PHOSPHATIC DEPOSITS IN NORTH WALES.

BY DR. VOELCKER.

(Read at the Meeting of the British Association at Birmingham.)

The discovery of new supplies of phosphatic materials, it is scarcely necessary for me to say, is of the highest importance to the English agriculturist, who, in the shape of superphosphate and similar artificial manures, consumes annually many thousands of tons of phosphatic fertilisers, the demand for which is yearly increasing, not only in this country, but on the continent and in the colonies. Under these circumstances it is fortunate that from time to time fresh mineral deposits are discovered, and others are made available for manufacturing purposes, which previously were known only as objects of interest to the geologist or mineralogist.

Those engaged in the manufacture of artificial manures, or of phosphorus, are well acquainted with the fact that bones, South American bone-ash, Cambridgeshire and Suffolk coprolites, apatite from Canada, phosphorite from Spain, Sombbrero rock-guano, phosphatic guanos from the South Pacific Ocean, and other varieties of mineral phosphates, find a ready sale, and are largely consumed by manufacturers of manures in this country.

Apprehension has, indeed, been expressed that with the yearly increasing demand for phosphatic manures the supply for the raw materials could not keep pace. Such apprehensions, however, appear to me to have no foundation, for new sources of mineral phosphates are rendered practically available at the present time, and a very extensive mine has recently been discovered in North Wales. This mine contains, besides copper and iron pyrites, two phosphatic minerals, both of which are of considerable importance to the English agriculturist. One of them is a phosphatic limestone, the other a black shale, largely impregnated with phosphate of lime.

These minerals were discovered recently by Mr. Hope Jones, of Hooton, Cheshire, whilst he was searching for other minerals in the neighbourhood of a place called Cwmgynen, about twenty miles west of Oswestry. The phosphate deposits occur not far from the clay slate and lead-bearing districts of Llangynog. The rocks are Silurian, of the Llandilo series, and a large fault south of the vein and parallel to it brings in the Denbighshire grits. Cross faults north and south also occur, which are highly metalliferous, containing ores of copper, lead, manganese, &c. The strata (slaty shale) contains several beds of contemporaneous felspathic ash and scoria; and the

usual fossils of the Llandilo series are found, but not in great numbers.

Mr. Hope Jones has traced the phosphatic beds a long distance, and informs me that they are continuous for about two miles. I have myself visited the phosphatic mine at Cwmgynen, and on that occasion collected various specimens of limestone and black phosphatic shales, to the composition of which I shall presently refer.

The black phosphatic slate or band is fully 18 inches thick, and the limestone bed from 8 feet 6 inches to 9 feet. The vein which separates the two deposits from each other is 14 to 16 inches wide, and filled partially with white pipeclay, calcareous spar, and copper and iron pyrites. The deposits are readily approached by a horizontal passage which has been driven into the vertical beds of phosphatic minerals. The high level is only 76 feet long, and close to the summit of the hill. The average depth from the summit level to the drainage level is about 500 feet, and the distance here to the phosphatic deposits about 100 yards.

At present the mine is approached only by the summit level; but experience having shown that the black band widens as the depth gets lower, operations have been begun at Cwmgynen to drive a horizontal passage into the hill at a depth of about 200 feet below the upper level, which passage is now being driven with as much rapidity as is possible, and will probably be completed in about three months, when a large supply of the phosphatic deposit will be obtainable.

The bed of black shale is 18 inches in thickness. This shale contains variable quantities of phosphoric acid. Towards the summit of the hill it is not nearly so rich in phosphate of lime as at a lower depth. Thus, in specimen No. 3, taken from a higher level, I find only 24.07 of phosphoric acid, equivalent to 48½ per cent. of tribasic phosphate of lime; while in another sample, taken at a lower level, I find as much as 29.67 of phosphoric acid, which is equivalent to 64.16 per cent. of phosphate of lime.

The mine of Cwmgynen, as worked at present, produces specimens containing from 54 to 66 per cent. of phosphate of lime. Blocks weighing above 1 cwt., I am informed, are now worked out, which resemble intimately the specimen in which I find 64 per cent. of phosphate of lime.

The black band contains no carbonate of lime, little magnesia, some fluoride of calcium, alumina, and oxide of iron, soluble in dilute acids, and, more or less, iron pyrites. In some specimens I find much less sulphur than in others. The highest per-centage of sulphur amounts to 7.02, equivalent to about 13½ per cent. of iron pyrites. The more compact masses, found at a greater depth from the surface, contain less iron pyrites than the deposit nearer to the surface. The occurrence of graphite in this phosphatic shale is also peculiar.

Lastly, we have to take a glance at the composition of the black limestone beds. The darker-coloured varieties contain more graphite, and are richer in phosphate of lime than the lighter-coloured specimens. In the latter I find only from 10 to 20 per cent. of phosphate of lime; in the darker varieties from 30 to 35 per cent. The beds contain a good deal of carbonate of magnesia (5 to 8 per cent.). On burning, they furnish a lime which is very valuable for agricultural purposes; for the farmer who applies this lime to his land not only supplies it with lime—a constituent required by every description of agricultural produce—but also with the still more important mineral constituent of plants—phosphoric acid. It is scarcely necessary to observe that it is chiefly the phosphoric acid in bones which renders the latter so valuable as a fertiliser; nor need I specially dwell on the fact that the application of this newly-discovered phosphate of lime is, in point of fact, almost equivalent to liming and boning in one operation.

## WORK FOR THE WEEK.

KITCHEN GARDEN.

THE recent heavy rains have somewhat impeded spade-operations. The necessity of an examination of all drains and water-courses will be readily suggested by the now frequent recurrence of wet weather. In the course of time weeds and rubbish accumulate in quantities sufficient to impair the efficiency of the common water-conduits, and every facility should be given at this season for the passage of the water from the garden. *Beans*, in soils favourable to vegetation during winter a few *Mazagans* may be planted, either where they are to remain or on a sheltered border, for planting out early in the

ensuing year. *Cabbages*, vacancies in the main plantation should be filled up immediately. Employ lime or soot about young Cabbage and Lettuce plants. *Cauliflowers*, those in the frame and under hand-glasses should be divested of their dead leaves, and if any vacancies occur they should be filled up; give air freely every fine day. *Celery*, continue to earth up; if severe frost should set in, some long litter to be laid over the most forward crops. *Cucumbers*, a little discretion is necessary to be observed as to the quantity of fruit a plant is capable of swelling off at one time, winter-fruited plants are frequently injured by overbearing, one fruit is sufficient for a plant to swell off at this season, but there may be several fruit in different stages of growth. *Endive*, when quite dry a good quantity should be tied up for blanching, a quantity of it could then be laid in, in pits or frames, before severe weather set in. *Jerusalem Artichokes* may now be taken up, or this may be done as they are wanted for use, but then the ground should be covered with litter during severe frost, to lessen the trouble of digging them up. *Onions*, the autumn-sown to be hand-weeded, and the ground slightly hoed between them. *Peas*, in very favourable soils and situations the first sowing may now be made, but we cannot recommend it where there is the convenience of pits and frames. *Shallots* and *Garlic* may now be planted in light and dry soils, otherwise they had better not be planted until February. The work of storing away esculent roots should now be carefully attended to, as on this being properly performed depends the whole success of their keeping.

#### FRUIT GARDEN.

The planting of fruit trees, either in the open quarters or against walls, may be commenced at once, supposing the borders to have been sufficiently prepared for their reception. In planting trees between old-established ones against walls, a hole of considerable size should be made for the young trees, and filled with fresh compost. In preparing new soil for planting fruit trees endeavour to keep it as dry as possible, and choose a dry day for planting, that the soil may be favourable to the growth of fresh roots. The present time is also the most favourable for lifting and root-pruning such trees as are too luxuriant, and require checking to induce a fruitful habit. We prefer lifting the trees entirely, unless they are very large, to cutting off the roots as they stand. After shortening the roots proportionably to the strength of the tree, spread them out near the surface and fill in with compost, on which a mulching of half-rotten dung should be spread, to prevent frost from entering the ground. But while the above is often necessary with existing trees planted in too rich or too deep borders, it should be borne in mind that it is only a palliative measure, and, in the course of a few years, will require repeating, unless measures are at the same time taken to make the borders shallower or poorer as the case may be. We are of opinion that most wall trees would be more fruitful were their roots confined to borders of very limited extent compared to what is generally the case, and by which the balance between the roots and branches could be adjusted without the trouble and expense of lifting and root-pruning. Clear off the remaining leaves from wall trees, to give the wood the advantage of sun and air to assist its ripening.

#### FLOWER GARDEN.

The frost has in many localities been sufficiently severe to destroy all remains of beauty in the flower garden. When this is the case the beds should be immediately cleared of Geraniums, and such other plants as are killed. Dahlias should be taken up the first dry day after the tops are cut off, as they will not in the slightest degree be benefited by remaining in the ground any longer. It is no unusual thing that in the hurry and bustle of autumn operations many things are forgotten that are really essential. Such being the case, we shall just mention a few matters which should not be forgotten. Do not be niggardly in planting out a good stock of spring flowers, especially if a gay spring garden is required. Abundance of early Tulips and Crocuses in variety should be planted now. Do not forget hardy Cyclamens, these planted near the edges of borders will have a fine effect. Hepaticas, too, should be remembered; the colours red, white, and blue, form a pleasing variety, and when they are well established they flower most abundantly. Snowdrops, Winter Aconites, and Dog's-tooth Violets play an important part in early spring, the bloom of these come almost through the snow, reminding us that spring is returning. Standard Roses should be gone over, and all the long shoots shortened considerably. Ornamental climbers on trellises, arcades, &c., in blossom should have protection. Half-hardy plants and shrubs will likewise require some protection on

frosty nights. Continuous and heavy rain during the week has prevented much work being done in the flower garden. Especial care must be taken of the Auricula-frame to prevent drip. If the glazing is not perfect it must be made so. The plants should be exposed to a south-eastern aspect, and have very little water; once a-week will be ample. Every precaution must be taken against damp, a free circulation of air at this season being absolutely indispensable. Tulip-beds must be made up at the first opportunity, and as soon as the soil is dry, plant.

#### GREENHOUSE AND CONSERVATORY.

The period has now arrived when the increasing scarcity of flowers outside should be compensated for by those conservatory plants peculiar to winter, and by retarded summer flowers. These together, will lead us imperceptibly up to the products of the forcing-pit, which form a distinct section, and, of course, require a separate course of treatment. The Camellias will form a most prominent object for the next five or six months. A very considerable amount of atmospheric moisture should be afforded them, drip, however, must by all means be avoided, and the syringe is out of all question. The Chrysanthemums must be treated with manure water constantly, and all suckers and waste shoots trimmed away. Plants of intermediate character require a little more warmth, with a permanency of atmospheric moisture. Such are *Euphorbia jaquiniaeflora*, *Gesnera zebrina*, *Achimenes picta*, *Gesnera oblongata*, *Linum trigynum*, *Plumbago rosea*, *Begonias*, &c., all of which should have a temperature of 60° secured by day, rising to 80° in sunshine, and sinking to 55° by night. The above are all most useful and interesting flowers for the dead of winter. Keep a sharp look-out for insects in every department, especially for thrips and fly on *Acceclarias* and *Cinerarias*, and mildew on Heaths, and other greenhouse plants. Do not use fires in the greenhouse until you are obliged to do so, as it is of importance to keep the plants as hardy as possible.

#### PITS AND FRAMES.

Everything should be finally arranged here as soon as possible. See that Mignonette has a very light situation, and is plunged or placed near the glass, free from drip. Store *Verbenas* growing rapidly should have the tops pinched, as also *Petunias*, or other ordinary mass flowers. Give all the air possible, and give water sparingly. Leave air on all night, be it ever so little. If not already done, let straw shutters or whatever else it may be intended to use for covering for them, be put in readiness for use without delay. Straw shutters if well made are expensive in the first instance, but are considered by many to be the most efficient of any kind of covering in use, and taking into account the time they last, they are, perhaps, as cheap as any.—W. KEANE.

#### DOINGS OF THE LAST WEEK.

"NEVER allow the haulm, leaves, &c., of plants to remain on the ground when the crop is gathered." So says our coadjutor Mr. Keane (page 344), and we give it our hearty concurrence, though we are often unable to make in this matter practice accord with precept. It is but sad uphill work when we have occasion to resort to the well-known subterfuge "Don't do as I do, but do as I tell you." How often do we feel as if we wished we could do a dozen things at once, and thus bring up our leeway. It would be well for all would-be instructors to recollect, that a pound of good example will be more influential than a hundredweight of precept unbacked by that example. It is true there is scarcely a rule without an exception, as, for instance, in the late burning weather we were glad to leave rows of Peas, with nothing but their haulm on them, between beds of Celery, on account of the agreeable shade which the haulm afforded to the Celery; but in this wet weather we never see two or three rows of spent haulm of Peas, which we cannot well get at owing to the wet, and serving no purpose whatever, without the above words, "Never allow the haulm, &c., to remain," coming before our mental vision to anything but our personal satisfaction. The worst of it is we do not believe that we are alone in the matter. Slovenliness, untidiness, carelessness, endurance of filth, and the decay of organic matter are tolerated at this season of the year in thousands of gardens, from those of the peer to that of the peasant, but would not be endured for a moment in the cheering days of spring and early summer. We can well recollect that when the late Mr. Loudon was giving his descriptive outlines of his gardening tours, something like real alarm was felt

by some of the leading Scotch gardeners lest he should visit them in September and October. Notwithstanding the general attention to neatness, they dreaded the account that might be given of compartments of the remains of used-up vegetables, quarters of wet decaying haulm of Peas, with somewhat slimy, green, or rough walks in the autumn months. The difference in many gardens in spring and autumn might well lend force to the, we believe, unsound dictum that man is, or ought to be, the creature of circumstances. This is, perhaps, if anything, more observable in the gardens of the amateur and the cottager than among us professed gardeners, though too many of us have our omissions to remember, but for the present we say nothing of the causes of these omissions.

Look at the cottage garden in April, May, and June, every plant attended to, and secured; the alleys neat and straight, not a weed on the walks, not a dead leaf to be seen—everything in unison, with the balmy breezes, and the glorious cheering march of the sun as he progresses towards his highest point in the heavens. Contrast all this cheerful inspiring neatness with what now so often meets the eye—Honeysuckles and Roses that were over the porch subjected, unfastened, to the sport of every gale; stalks of cut Cauliflower with their flabby decaying leaves, and those of cut Turnips scenting the breeze; tops of Carrots, and Parsnips covering the ground in which the roots had grown, and pieces of Pea and Bean haulm in their wet slimy rottenness conjuring up in such a day as this all that is melancholic, intensified, if that be possible, by the walks being covered over up to the doorway with fat strong weeds, as if intended not to be walked upon cleanly and comfortably, but for sheep to nibble at and pasture on. Why should the shortening day, the lessening light, and the falling leaves, saddening enough in themselves, be increased in their sadness by the woe-begone aspect of such gardens? Talk and reason as we may, no man or woman can come out of a cheerful room without being unpleasantly affected by such slovenliness in the garden. Did we study our own happiness the garden should have extra pains bestowed upon it, to secure neatness and cleanliness in autumn and winter. When rain, and wind, and frost, and snow render it uncomfortable on the open wold, is that any reason why we should abridge our comforts around a blazing fire and a clean hearthstone? When Nature outside is disrobing herself of her summer attractiveness, is that any reason why the pet and profitable garden should be left to look after itself in the autumn months, and to speak chiefly of carelessness and untidiness, aye, and wastefulness too? For what is offensive to the eye and the nostrils would be valuable in the rot and the rubbish-heap, covered with soil to keep the enriching virtues from polluting the air we breathe. In many districts it is fashionable to give prizes for the best-kept and best-managed gardens, and the results have generally been very beneficial. Before such prizes were awarded, we think the gardens should be visited more than once, and one of the times we would specify to be from the middle to the end of October.

#### KITCHEN GARDEN.

*Storing Carrots and Parsnips.*—Here we have done very little, except tying-up and earthing-up Celery on a dry day, and taking up all our Carrots and part of the Parsnips on a dry day, and spreading out the roots under cover that they may be better dried before building them in heaps or bins. We lately met with a recommendation to use dry sawdust for packing among the roots; but scarcely anything could be worse. If the sawdust is from wood at all fresh, whether Pine or hard wood, it will less or more flavour the roots, and if at all freely used it will cause the heap of roots to heat and decay to a certainty. Dust-dry sand, earth equally dry, or dry burnt clay and earth, are the most suitable for this purpose. Where these cannot be had, and the roots are so juicy as to be inclined to heat in a heap, a good plan is to place layers of branches of trees between each two layers of Carrots. Air thus circulates freely among them. Covered over with old sashes our last piece of Dwarf Kidney Beans, still hearing nicely, and added another covering over the glass at night. Brought pots, sown under protection, under glass where they can now have a little heat.

#### FRUIT GARDEN.

Selected the only dry breezy day we have had, and gathered all, or nearly all, of our Apples and Pears left. This was so far fortunate, as there was a stormy gale during the night that would have dislodged most of them. A number had been pecked within a few days, and among others the rats had their nibble, and also began to carry to their burrows some of the best Plums from the orchard-house. Having found some holes

we set some ferrets to work, and killed several, and the smell of the ferret will keep them away for some time. It is amazing the instinctive ingenuity the rat, and the mouse too, will exhibit in securing a free outlet and inlet. It matters not how large the house, or how large the garden, they will never be satisfied until they have free access to every part of both, and a free outlet to the ground beyond. This instinctive habit must be kept in view, or whilst we watch at one hole the rats will escape at another. We have known a single mouse keep the residents of a house from sleeping by his constant gnawing, because, though he had every other room and closet open, two bedrooms had their doors shut, and he wanted free quarters there as well as elsewhere. The poor little mouse, however, has on the whole but a little of the great sagacity of the rat.

#### ORNAMENTAL DEPARTMENT.

Owing to the wet a little clearing, moving, and rolling was all that could be done. In addition to tallies, stakes, pot-washing, &c., potting and cleaning and top-dressing pot plants, tying Azaleas, regulating climbers, &c., our chief work has been getting on with Calceolaria cuttings, as detailed last week, and taking up and repotting Fuchsias, Cassias, *Scarlet Geraniums*, &c., from the centre of flower-beds. After these drenching rains we cannot expect the beds to do much now. All these plants above will be potted separately, in as small pots as the roots can be made to go into, and we retain the Geraniums for centres at their full length, merely taking away the larger leaves. Few of these take up with balls, but they soon make roots. We shall endeavour to stand them under glass, and in a few weeks most of the leaves will wither and decay. We never care for this if we can keep the stems sound, and a leaf or two fresh at the end of the stems. Thus kept, merely, in winter in a cool dryish place, these plants come in useful where beds are planted in the pyramidal style. Where flat beds are wanted, or nearly so, there is no necessity for keeping more than from 4 to 6 inches of the strong summer shoots.

We have several times mentioned how, after removing every leaf from such cut-in plants, we have packed them firmly and thickly in shallow wooden boxes and in cold pits. The only objection to cold pits is, that some of the plants will be apt to rot in very damp, frosty, foggy winters. Two or three correspondents tell us they become confused about pits, boxes, and pots, and would wish to have the simplest plan by which they can save the greatest number stowed away in fair-sized pots, say from 8 to 12 inches in diameter. Well then, we will tell them what we think is the very best method after a good deal of practice with different plans, and by which the *Scarlet Geraniums*, in the beds of their lawns or parterres may fill the same beds next year, and with little care or attention during winter. The chief essential is a dryish place to keep them, and we will mention a few places, the best being named first. The best place, then, would be a cool greenhouse, where frost and extra damp could be kept out, with a little dry heat; the second best underneath the stage or by the sides of the path, in a cool greenhouse, anywhere so that there shall not be much drip from the plants above; a third place would be a small spare room, in which a fire could be placed in very severe frosty weather; near the windows would do equally well in sitting-rooms, kitchens, &c., only in the latter case the plants must not be kept too hot nor too dry; a fourth place would be an unheated room, but where in severe weather you could throw a cloth and a little dry hay or litter over the plants and pots; a fifth place would be a dry garret, hay-loft, corn-loft, dry light stall of a stable, dry cellar with a little light, or any place naturally dry, where light could be given in mild weather, and frost kept out by covering in cold weather. In all these latter cases the plants would give less trouble than in cold pits or frames out of doors, and all could be done in the dry. If leaves the size of a sixpence come by the beginning of March the plants will be early enough.

Now for the minutiae. To please you we shall take 12-inch pots, merely premising that for pots larger or smaller we would just cram them with more or fewer plants. We drain these pots in the usual way, and fill them one-third full with any rough sweet material, as turfy loam and rough leaf mould, that we can obtain. What we mean to pack among the roots will be sandy loam, and leaf mould that has passed through an one-inch sieve. Both of these are to be in a nice friable condition, neither wet nor dry. We now go to the flower-bed, and with fork or spade dig up the plants. It does not greatly matter which tool is used, as, provided the roots near the collar of the plant are secured, we are less concerned about those that run

down deep into the soil. Holding the plant in your hand you will notice that it has one main stem 6 or more inches in length, and from that proceed from three to five secondary stems, and from these a number of summer shoots. Very weak ones of these we remove, and the others we cut down to within a joint or bud of the secondary stems. If particular we smear these cuts in dry soil, or better still, in dry lime. Whilst holding the plant in one hand, we dock off most of the roots that are beyond from 5 to 6 inches in length. We then pack these roots firmly and thickly in the pots, leaving the stems chiefly above the rim, and fixing the soil well about them. In such a pot may be packed from a score to two dozen or more of these docked-in plants. If any very dry soil is handy we fill up to within an inch of the top, give the pots a fair watering before taking them to their winter quarters, and when well settled we cover with about half an inch of the dry soil. This so far prevents evaporation that little or no water will be needed in winter, except where dry heat in some way is applied artificially. Bear in mind that the plants are more apt to suffer from damp than from dryness, only the roots must not be dust-dry. If you find the soil beneath is becoming too dry, it is often better to pour the water through a hole made with a stick, instead of watering all over the surface of the pot, until the stumpy plants, with not a leaf left on them, begin to make small fresh leaves. Comparative dryness, airiness, and freedom from frost are all that they require. We have forgotten to say, that when no dry soil is handy the potting soil may come up to within half an inch of the rim, and then be watered; but as soon as the surface becomes dryish it should be broken with a pin or stick, and left loose, to prevent evaporation and keep moisture about the roots without more watering.

As the leaves come from the size of a threepenny silver coin to the size of a shilling they must have more light, a little more attention as to water, and be merely kept from frost. By the end of March or the beginning of April the plants will be hurting each other, the young shoots coming thickly and the roots a wig of fresh fibres all near home, and then you may either plant separately under protection, or pot the plants separately, and keep them under calico protection, or in a greenhouse, or window, or spare room where they will have light, hardening off until they will stand out of doors by the 18th of May. These old plants will not give so much trouble, or require so much care by a great deal, as plants propagated during the summer and autumn. The latter are more sensitive to cold, and also must have full light all the winter, whilst the old plants do with very little before the fresh foliage begins to come.

**Cloth of Gold and Golden Chain Geraniums.**—On the principle, we presume, that it is pleasant to have comrades even in misfortune, several correspondents have noticed what we said about being disappointed with both of these when exposed to the full sun in this very hot summer; but they have not noticed what we also stated, that in more shady places they did very well. In a long border, two-thirds of which was exposed to the morning and mid-day sun, and a good portion of the afternoon sun, the Cloth of Gold disappointed us, as though the plants were very good when turned out, they actually became much less during the summer. In the other part of the border, treated every day alike, but considerably shaded, the plants were strong and beautiful, with large handsome leaves. In two beds in a sunk panel garden, fully exposed, the plants were neither so good as the last-named, nor so bad as the first—were middling. In a series of beds where the sun would act on them pretty freely from between 7 and 8 a.m., to noon, but which were shaded from the sun after that time, the Cloth of Gold and Golden Chain both did very well, though with the exception of the shade the plants were treated as much as possible in the same way. Have any of our correspondents found these facts corroborated in their experience?—R. F.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Roses, Fruit Trees, Coniferae, Hardy Trees, Shrubs, &c. Select List of New Pelargoniums. General Collection of Auriculas, Carnations, Picotees, Pinks, Cinerarias, &c.*

Dreghorn & Aitken, 79, King Street, Kilmarnock.—*Catalogue of Gladioli.*

John Morse, The Nurseries, Dunsley, Gloucestershire.—*Catalogue of Cuttings, including Chrysanthemums, Verbenas, Pelargoniums, &c.*

COVENT GARDEN MARKET.—OCTOBER 28.

SUPPLIES about the same as last week, and we have nothing fresh to report. There are still some good Salway Peaches coming, and a few dishes of Strawberries about the market.

TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London. E.C.*

N.B.—Many questions must remain unanswered until next week.

**STORING CARROTS (Waverley).**—Until the shed is empty in which you purpose storing them in sand, we recommend you to make a long heap of them on the surface of the ground, and cover it a foot thick with earth, smoothening the outside so that the rain may run off.

**SIX GOOD KEEPING PEARS (A Constant Reader).**—Winter Nelis, Joséphine de Malines, Bergamotte Espéren, Beurré de Rance, Jean de Witte, and Forelle.

**SPARE TIME (M. H. B.).**—If you devote your spare time to raising Geraniums, &c., as you propose, the only market you must depend upon is Wycombe and other places in your neighbourhood. The wholesale nurserymen and florists raise such plants in their own gardens quite as cheaply as you could.

**GLADIOLUS (Stewart & Mein, Kelso).**—Your seedling Gladiolus appears to be of first-rate character, but it is too late in the season to form a fair judgment of it. The broad, bright rosy featherings are very conspicuous on the white ground, the individual flowers well formed, and the spike everything that could be desired. There can be no doubt but that in the proper season it will prove a very useful and valuable variety.

**WIGANDIA CARACASANA (H. G. M.).**—It would survive the winter in a cold greenhouse; it would do better under the shelves in a stove, but it must have as much exposure to the light as possible. The plant is *Nicotiana Langsdorfii*. We cannot undertake to say what the insect on your Pear trees is from your description.

**WORM CASTS (Ignoramus).**—Water your lawn with lime-water twice a-week, and it will banish the intruders upon your croquet ground.

**VINES LIFTED NOT GROWING (John Bowthby).**—The Vines lifted last winter would be better taken out at once, for though they might shoot next year they will never be otherwise than weak, and more time will be lost upon them than were new Vines planted. We should not only plant young Vines in the place of old Vines, which have not grown this year, but plant a young Vine by the other old Vines that were lifted at the same time, that have made weak wood this year, and that require a little fire to ripen the wood. By this means you will have a house full of young Vines that will give good and improving crops quite as soon as the old weak Vines. When Vines are very old they are only worth lifting to make room for new ones, though they may remain for a year or two to afford fruit until the young Vines demand all the space.

**SEEDLING VERBENA (J. N. Barnstaple).**—A pretty flower, but not superior to many others already well known.

**CUCUMBER (J. H. P. M.).**—It is impossible for us to give an opinion of a Cucumber we have never seen. If it possesses the merits you state, and when you have a stock of seed you had better advertise it, and state where the seed is to be obtained.

**VARIOUS (W. J.).**—The following are good baking Apples, and come into use in succession as named: Keswick Codlin, Hawthornden, Besmy of Kent, Yorkshire Greening, and Royal Russet. Plums for your south wall: July Green Gage, Green Gage, Coe's Golden Drop, Ickworth Impatrice.

**SUPPLY-HOUSE—PEACHES AND NECTARINES IN POTS (Rustic).**—If you have to use your small pit in the stove-house for supplying the conservatory, we should advise you to think twice before you planted any sort of Palm in it. We should think it better to keep everything in pots, with the exception of a few climbers. The Peaches most suitable for pot-culture in the late vinery, are Early York, Early Grosse Mignonne, Acton Seat, Grosse Mignonne, Royal George, Barrington, Walburton Admirable, and Salway to come in very late after the Walburton Admirable. For Nectarines the best are Pitmaston Orange, Violette Hâtive Peaches or Bellegarde, and two Violette Hâtive Nectarines; and for the trellis Noblesse, Royal George, Téton de Venus, and Walburton Admirable.

**WARDIAN CASE (Sophia).**—The best materials for making it are common red deal and sheet glass, 21 ozs. to the foot, as the size and proportions must entirely depend upon your own requirements and taste. The bottom part for holding the earth should be lined with zinc, and the top may be made to take off altogether, or one side may be made to slide. The following are ornamental forms, but they may be made quite plain.

**PROPAGATING POLEMONIUM CERULEUM VARIEGATUM (Sunset).**—This very pretty edging, line, or ribbon-plant is increased by division of the root, which may be performed when the plant commences growth in spring, and in autumn after it has done growing. In either case the offsets are taken from the roots with at least a crown, and a root if possible, and planted in a border of good light soil or potted into small pots, and placed in a cold frame with the pots plunged in coal ashes. The only difficulty is to obtain strong plants, and that is but small, as the plant is perfectly hardy, and its propagation by division only a work of time.

**RAISING STOCK OF VIOLA CORNUTA (Idem).**—This, like the above, is increased by division, and the best time to operate is in spring, pricking off the divisions in beds of moist earth about 3 inches apart every way, or so far apart that they may not interfere with each other; or they may be planted at once where they are to remain during the summer, visting copiously until established. On wet soils it grows freely, but on dry soils it requires abundant supplies of water in order to bloom continuously during the summer. It comes true from seed, which should be sown in the spring in moist soil. For directions as to how to get up a stock of *Oxalis corniculata rubra*, see answer to *S. Edwards* page 284.

**THRIPS ON FERNS IN PLANT-CASE (C. P.).**—The fronds of *Asplenium adiantum-nigrum* which you sent were suffering from thrips, which are the small insects which you see on the fronds. Your best plan would be to have the case removed to an outhouse, and there filled with tobacco smoke until not a frond were visible, taking care to have the Ferns dry. If you do not object to the smell of tobacco the plant may be fumigated in the room, and afterwards whenever you find any insects on the fronds. This would be the most effective mode of killing them, but if you object to the smell of tobacco you may remove the insects with a wet sponge, afterwards keeping the case more moist to prevent a recurrence of the attack.

**KEEPING THE APPLE-PIE MELON (A Subscriber).**—Keep it in a dry cool room free from frost. It will remain good throughout the winter, and be ready any time for making into pies in the same manner as Apples, for which it is said to be a good substitute. It cannot be eaten as a fruit like the Melon.

**ARE DECAYED LAUREL LEAVES INJURIOUS TO PLANTS? (A Gardener).**—Your question is fully answered in your own words "I gave my flower-beds an extra dressing of leaf mould made from Laurel leaves and my bedding plants thrived exceedingly well." In this we fully concur; and we think it was not the cause of the Calceolarias falling, unless the leaves were not fully decomposed, when they would render the soil too open and dry. We do not know what will keep Calceolarias from dying off soon after planting out.

**LATANIA COMMERSONII (Quæstor)** is identical with what is generally sold as *Latanis rubra*, and requires the same treatment as other tropical Palms.

**STELLA GERANIUM CUTTINGS NOT ROOTING—WINTERING IN A SPARE ROOM (An Amateur).**—You do not state under what conditions *Stella* refused to root. We suppose the pots have been out of doors, and have been kept very wet in a shaded situation, in addition to which we should think that the cuttings were put in very close together and the soil very rich, or of a heavy instead of a sandy nature. We put in ours about the same time—the first week in September—and placed the boxes containing them on boards about a foot from a south wall, and in the full sun. We put 150 in a box 4 feet long and 4 inches wide, and counted them the day we received your letter, and 143 were struck and fine rooted plants. The most frequent cause of the cuttings damping is rich soil. The best soil is poor, light, sandy loam. You may keep the old plants in your spare room, covering them with hay in severe weather to protect them from frost. When the weather is mild remove the hay, and give them air and light. Keep the soil dry, giving no more water than sufficient to prevent the shoots shrivelling, and only during mild weather.

**CUCUMBER-HOUSE (J. S.).**—We can only repeat again what was stated at page 325. As you have reasons to object to a high wall for lean-to houses, then we would decidedly recommend a span roof for both vinery and Cucumber-house. Keeping in view that economy in building is your chief object, then for the Cucumber-house we would recommend a house 20 feet in length, 12 feet in width, 10 feet in height to the ridge-board, and the side walls 3½ feet high. We would divide the base line into 4½-foot beds at each side, including the inside walls, and 3 feet of a path in the middle. At the bottom of each of these side beds we would place two four-inch pipes, and 4 inches above them a slate to receive the earth, or for economy from 5 to 6 inches of rubble covered with fine clean-washed gravel, and, above that, from 15 to 18 inches of soil. Two pipes would also be required on each side for top heat. If Cucumbers were wanted all the winter, a third pipe would be desirable on the north side. The highest of these pipes should be close to, and fully a foot from, the tops of the side walls. Five openings should be left in each side wall opposite these pipes for ventilators, say each 15 inches long and 8 inches wide. For top ventilation we should propose a double ridge-board, the boards being braced together by cross-pieces keeping them about 9 inches apart. That space would be filled with a wooden ventilator hung on pivots, and protected by two boards forming a cowl ridge-board, with an opening on each side to let the air in. These ridge-boards, and the two wall-plates, would be almost all the large work necessary. These modes of ventilation would permit of all the roof being fixed. As the length of glass roof on each side would be only a little more than 8 feet, sash bars 1½ inch wide and 3 inches deep would be sufficient, if placed not further than from 15 to 16 inches apart. Glass of that size and of good quality, commonly called thirds, can be bought at 2d. per foot if 16 ozs. to the foot, and at 2½d. to 3d. per foot having an average weight of 21 ozs. to the foot. Of course fourths would range considerably cheaper, but we would not advise its being used. Taken in the lump and leaving out the wall-plates, the wood cut to size, planed, &c., by machinery, would cost pretty much the same as the glass. If economy is the sole object, the orchard-house style of Mr. Rivers must be adopted. Such a house as the above would be very neat, lasting, and also economical. It would be cheaper to have a number of squares made to open at the ridge instead of the double ridge-board, but it would not be so satisfactory. By the double ridge-board and cowl air can be given in all weathers. We would recommend a similar house for the vinery, whether the border were made outside or inside, say 20 feet wide, 3½ feet high at the sides, from 12 to 14 feet at the apex. For such a house deeper rafter sash-bars will be required, and an iron rod should go longitudinally along the middle, screwed to each, and there should be a neat iron column for support at every 10 or 15 feet. Such a house may be modified to any shape, and be from 30 to 50 feet long, and 14 to 16 feet wide, and 11 to 14 feet at the apex; or even the same size as the proposed Cucumber-house would grow a good many Grapes, and, if of narrow width, the Vines could be planted on the south side, trained up the rafters there, taken to the top and down the other side. This is how the Vines are trained in the large vinery at Messrs. Lane's at Berkhamstead. For such a large house as we have first proposed, of 20 feet in width, &c., two pipes would be required on each side to have Grapes in the beginning of July. To have them early would require three pipes on each side. Muscats will do well enough either for the early or late house. It will be easy to turn either of these houses into a hip-roofed one, by having the north wall from 5 to 7 or more feet in height, and then taking the hip to the apex, making the south front all the longer. By the mode proposed all the ash-bars would be fixed at once to the ridge-board and the wall-plate at such a distance from each other as to suit the width of the squares of glass. Gardeners are quite right in what you say as to the expansion and contraction of iron roofs and the breakage of glass in consequence, but that is altogether neutralised in Mr. Beard's patent by placing non-conducting material between the glass and iron. If found successful, puttying and painting will be altogether dispensed with.

**HOUSE FOR BEDDING PLANTS (G. Smith).**—We do not consider it advisable to have a lean-to facing the north for growing bedding plants. No doubt, as you say, they would do very well in summer, but in winter we would use such a house chiefly for keeping plants and not growing them much, as the absence of sun will cause them to draw, unless abundance of air is given with the artificial heat needed. We do not quite see whether the ten-inch pipe attached to the end of the furnace, with a six-inch pipe added in the propagating-house, acts as a flue or merely as a means of conducting heat from the furnace, but as surrounded with clinkers and covered with coakle shells it gives much heat, or we presume too much heat. In the first case, pots may be plunged or set on the shells with or without a hand-light over them. If the heat is too strong, it would be advisable to form either an open chamber over the brick-bats, or make a rough chamber with more brick-bats, before adding the shingle or shells, with openings to let the heated air into the house whenever it was too hot for the cuttings. The old kitchen boiler placed over the furnace, and holding twelve gallons of water, with a pipe inserted near the top and carried far enough, say 6 or 10 feet into the propagating-house, and the end of the pipe open, would enable you, by plugging, or opening the end of that pipe, to have moist vapour thrown into the propagating-house at will. You can also carry a two or three-inch pipe from that boiler through the pit near it, but, unless the top of the boiler is close to prevent all outlet of steam, and the water is kept at or near the boiling point, you would not get so much heat from the vapour as you might expect. If the boiler and pit were suitable, you had better

take a couple of three-inch pipes from it, and fill with water in the usual way. You will find much to suit you as respects propagating in "Window Gardening for the Many."

**ATHYRIUM FILIX-FEMINA PTEROPHORUM.**—By a slip of the pen in my paper on Mosses, Ivory's Nursery at Dorking, this is referred to Polystichum. It is a fine and very distinct variety of the Lady Fern, found in Scotland by the Rev. H. A. Walker, of Enfield, and is a great addition to the already fine and numerous varieties of this favourite Fern.—D., Deal.

**NAMES OF FRUIT (P. B.).**—1, Autumn Colmar; 2, Beurré Diel; 3, Winter Nelis; 4, Beurré Bosc. (J. Bryan).—1, Henry Moring; 2, Bedfordshire Pounding; 3, Hanwell Soring. (H. L.).—1, Easter Beurré; 2, Beurré de Capiaumont; 3, Brown Beurré. (A Subscriber).—1, Golden Noble; 4, Autumn Pearmain; 5, Bell's Searlet; 7, Golden Russet; 8 and 12, Northern Greening; 11, White Nonpareil. (J. Button).—Apples: 1, Pear-

son's Plate; 2, Ord's; 3, Autumn Pearmain; 4, Court-Pendu-Plat; 5, Ribston Pippin; 6, Beauty of Kent; 7, London Pippin; 8, Dutch Mignonne; 15, Nonpareil; 16, Scarlet Nonpareil. Pears: 3, Fondante d'Automne; 6, Brown Beurré; 7, Urbaniste; 20, Glou Morceau. (A Subscriber).—1, Duchesse d'Angoulême; 2, Red Doyenné; 3, Glou Moreau; 9, Passe Colmar. (Mr. Watson).—2, Delices d'Hardenpont; 4, Beurré d'Arenberg; 5, Knight's Monarch; 6, Beachauwell; 7, Court of Wick; 8, New Rock Pippin; 9, Golden Winter Pearman; 10, Syke House Russet; 11, Northern Greening.

**NAMES OF PLANTS (M. F. M.).**—1, too young to name; 2, Scopolodrinum vulgare marginatum; 3, Cytominum falcatum; 4, Nephrolepis tuberosa; 5, Didymocarpus Rexii. (G. N.).—1, Hypolepis tenuifolia; 2, Adiantum assimile; 3, Scopolodrinum, uncertain, probably digitatum; 4, Athyrium Filix-femina crispum; 5, Doodia caudata; 6, Lastrea decurrona. (John Hutton).—4, Aeganthus umbellatus minor variegatus; 5, Candellica cneata; 7, Rochea falcata.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY PLAGUE.

THE gravity of the case must plead our apology for returning to the subject of the disease among poultry. We plead now for quoting from the Times. "The disease among poultry, which caused so much destruction some time since, and which it was hoped had disappeared, has again broken out with great violence in the department of the Eure and the adjoining districts. One farmer in the commune of Jamericourt has lost 850 hens. No explanation can be given of this new malady. While waiting, until a remedy can be discovered for it, precautionary measures are adopted. The first precaution is great cleanliness, and the frequent washing of the hen-houses with lime water to destroy the insects which torment the fowl. It is very beneficial to fumigate the hen-roosts from time to time by burning near them a handful of brushwood. The Journal de la Ferme, noticing the disease, observes that in a well-kept poultry-yard fowls are not only less subject to disease, but they become fatter, better flavoured when brought to table, and less tormented with insects. The poultry-yards of France, however, are in process of improvement. They are not only better cleansed, but the breed is being improved by being crossed, according to the system of the celebrated English physiologist, Dr. Darwin."

If our memory serves us aright, one of the best writers on poultry, Mr. Jacque, advocates, on the testimony of those who do nothing for a livelihood but fatten poultry in France, that the birds undergoing the process shall never be cleaned out, affirming that the filth in which they live contributes to their well-doing. No fallacy can be greater.

Without in any way detracting from the merits of French table poultry, it may be safely said that in this country we succeed in fattening fowls at a much earlier age than they do in France, and that we attain as great weight as they do with birds twice as old. Our system, then, is worth something, and in it the greatest cleanliness is practised. To ensure it to the fullest possible extent, and to prevent the possibility of any dirt, the bottoms of the fattening-coops are made of bars only. The birds sit thereon in a roosting position, while everything objectionable in its nature falls through to the ground. The size, fatness, and quality can only be attained by taking advantage of every favourable circumstance, and cleanliness is one of them. That which is good for table poultry is good for stock birds. They cannot be kept too clean.

The article we have quoted speaks of insects, and we know these pests are productive of much disease; but there is a remedy for them. They appear mostly in wet weather, and as we are likely to have much of that now, it will be well to be prepared for it. Fowls in confinement require the same help

against them that Partridges and Pheasants do in a state of nature. Those who study the habits of these birds know what it is to find them, what is technically termed, dusting themselves, and the traces of the operation are found in all dry spots where these birds abound. It is not the luxury that is imagined; it is a positive necessity. It is the means they employ to rid themselves of vermin. For this reason, in a wet time, it is common to see under a beetling bank, among the roots of a tree where the rain has not reached, that Partridges have been dusting. We must provide our fowls with the same opportunity. Let the floors of their roosting-houses and their haunts be covered some inches deep with dust, or, if that is not convenient, let them have in one corner of some other dry place a good heap of dust or wood ashes. Mix therewith some black sulphur, and you will see how the fowls appreciate it. You will always have them constantly in health. If it can be done, divide them; do not let too many roost in one house, and choose the places as lofty and airy as you can. Lime-white the houses frequently, and put camphor in their water-vessels.

We do not wish to be alarmists. We do not think the disease will visit us, but we think it wise to adopt all precautionary measures. Poultry is not kept in England on so large a scale as in France and some parts of Germany. Few farmers in England can lose 850 hens. It may be that in some instances the number kept has produced the disease. It is very difficult to keep a large number on a limited space. But it would be very annoying, just when public attention is more than ever called to poultry, and when owing to the disease in cattle there is greater demand for poultry and eggs, to have our stocks decimated or destroyed, when a little painstaking might have saved them.

THE APPOINTMENT OF JUDGES AT THE BIRMINGHAM POULTRY SHOW.

ON perusal I feel assured that the two exhibitors of Game fowls, signing themselves "JUSTITIA" and "EXHIBITOR," have quite overshot their original subject, in giving vent to statements so very closely approaching to personalities, instead of exclusively adhering to the mode of appointment, as a body, of the Birmingham Judges. The great ground of complaint by exhibitors at Birmingham is this, that the appointment of arbitrators rests exclusively with a single individual instead of being the selection of the whole of the Committee. The Committee very curiously shelve every remonstrance, as was the case a few years back with the memorial which then obtained the signatures of so many poultry amateurs, and was at the time fruitlessly presented. This will as certainly be the fate of any future application. Exhibitors undoubtedly have a right to a voice and a proper consideration of their appeals for even-handed

justice; but if these are still refused them by the Managers of the Bingley-Hall Show, it is an absolute waste of time to persist in the endeavour to turn them from their error.

In case of another refusal this year, a remedy is now close at hand, that once applied will tend much to the popularity of the Show, and also its extension more than heretofore, and put an end to all such unseemly agitations. My suggestion is this. Let an entirely new Committee be chosen from parties only, whose desire is rather to see a good show of poultry and Pigeons for Birmingham, than a mere exhibition of agricultural implements, to which purpose of late years the shows at Bingley Hall have been so sadly perverted. A far more eligible building is now fast drawing to completion, Curzon Hall, situated still nearer to the railways, infinitely better lighted and warmed, and containing a gallery all round sufficiently large to hold considerably more entries than have been as yet ever made for a Birmingham Show.

Every one who has seen the Birmingham poultry pens at Bingley Hall, well knows how very short of present requirements such pens are. In fact, they appear modelled from bygone plans, and totally defeat the principal object—that of allowing a correct sight of the specimens; for most of the bottom rows are so dark as to render inspection a downright impossibility. If the poultry and the Pigeons were conjoined to the Dog Show—that is, so far as being held at the same time and place, on the ground floor and gallery respectively, the attendance of visitors to amply repay all expenses, independently of a substantial balance accruing from year to year, might be with certainty realised; and then, if Bingley Hall can support itself under the restrictions of a show of fat cattle, sheep, pigs, and implements only so much the better; if not, the conservatism of present abuses has alone the merit of its downfall, for the new poultry exhibition will still have annual increase and prosperity.

It is not my intention to touch exclusively on the appointment of particular gentlemen as Judges, or the individual classes which their knowledge as breeders makes each of them most competent to arbitrate, though I am sorry to find a great portion of your communications tend in that direction. It is surely rather the principle of selection than the personality of the Judges that is the matter in question, and most good would ensue by confining it to this subject altogether. "JUSTITIA," however, no doubt unconsciously, makes one remark that needs correction, or it may obtain credence from those readers who happen to be as little conversant with facts as this statement of "JUSTITIA" evinces. He says, "It is quite true an attempt was made to throw discredit on some of the decisions, but it is well known that the alleged dissatisfaction merely existed with one or two disappointed exhibitors, and, perhaps, the best answer to such insinuations is the re-appointment by the Birmingham Committee of the Game arbitrators." This is, on the contrary, a mistake *in toto*, and cannot be reconciled with the circumstance, that at a meeting held at the Bingley Hall Tavern during the continuance of the Show named, and close to its very doors, nearly a hundred exhibitors of all breeds of poultry passed an unanimous vote of their high disapproval of the mode of electing the Birmingham Judges, and ventilated their grievances publicly in language perhaps far more pungent than courteous. Surely, then, such a meeting could scarcely be said to be the impersonation of the "one or two" malcontent exhibitors that "JUSTITIA" describes.—OLD COCHIN.

#### ATTEMPTED SWINDLING.

I ADVERTISED a week or two ago for some Goldfinch mules for exhibition, which I am always ready to buy if they are first-rate, and my letter was answered by a man calling himself a surgeon, whose name began with a C and ended with an s, saying he had some to dispose of, and giving me an address in Caledonian Road, Islington. Of course I sent to see about him, and found the address was a post office. He would not send the birds without the money, which he did not get, although I gave him several references in London. Now, I have no doubt that this is the same man who tried to do your correspondent "CAXTUS" with the poultry, and if so, and your correspondent can punish him, I will subscribe £1 1s. towards the expenses.—H. A.

CHELMSFORD AND ESSEX POULTRY SHOW.—It is proposed to hold a poultry show in the Corn Exchange, Chelmsford, at the same time as that of the Chelmsford and Essex Chrysanthe-

mum Society, on Wednesday 15th November next. (See advertisement.) Proper exhibition pens, with food, water, and attendants, will be provided in the large and well ventilated Hall of the Corn Exchange. The entrance fee will be 1s. per pen for subscribers, and 2s. to non-subscribers; and prizes will be given ranging from 10s. to 5s. It is proposed to exhibit also photographs of all the celebrated exhibitors, and copies of all the modern works on poultry and Pigeons. It is hoped that exhibitors and others will help the attempt, as the facilities of communication by railway are great. The promoters of this Show trust eventually to establish an annual show in Chelmsford, with a more liberal prize list and a more comprehensive schedule.

#### SHABBY.

OTHER correspondents have told you how they have been "fairly diddled," as Lord Byron sings in *Don Juan*, by some unfair Mrs. Firebrace or some angel at Islington; but I have a tale to tell of a transaction for which, in spite of Dr. Johnson's condemnation, there is no word but "shabby."

Nearly a year ago I was written to by an individual holding a most respectable position in society. He wanted some birds which I had, and he proposed an exchange for others which I did not want. I declined the proposal, but I offered to sell what he wished to have. All sorts of offers and proposals came in letter after letter, which I answered courteously, until, wearied of the correspondence, I sharply closed it after an expenditure of much patience and postage.

In the beginning of August last my voluminous correspondent wrote again, asking me this time to sell him a pen of birds that would be sure to take a first prize at Chippenham. I offered him at £4 a pen of chickens which had been highly commended at Plymouth, the only time when they had been exhibited, and when I was afraid they would be too young to gain a notice. I offered him also at £3 an adult pen which had taken two first prizes, besides gaining a highly commended notice at Plymouth this year during the moult. He accepted the latter offer, and the birds were sent to his uncle's. Then began again the arrival of two or three letters a-week with inquiries and objections, all of which for a time I answered patiently. Three objections only did he profess to raise—not many for a pen at £3 which had taken two first prizes. It was evident he wanted such a pen as I should not object to give £7 or £8 for, with a warranty of taking a first prize, which no honest man would give, and that he wished to obtain this either by an exchange or at some paltry price. I saw I was in for another bout of letter-writing, so I offered the alternative of returning the birds or sending the money. The money was sent. More letters followed, which I answered briefly by saying that I would give £3 for the pen after the Show if they did not take a prize at Chippenham.

I hoped for a little repose, at all events until after the Show. My voluminous objector, however, suddenly broke out again about the time of the Calne Show. He was going to carry off the first prize there, but one of the hens had died; and he wrote in post haste, asking me to send a bird that would match and renew the pen. This I could not do; but I sent instantly a matched pair of pullets, saying that I would take the odd hen again in part payment if he would send it carriage paid, and that he must forward to me £1 in money. He expressed himself pleased, and, what was better, ceased writing, although he owed me 20s., and returned the pen without paying the carriage.

I heard no more until after the Show, where he had entered a pen of adult birds and a pen of chickens. He did not get a notice. He then wrote for a pair of pullets of a different kind, which I could "warrant as first-prizetakers," and claimed by virtue of a promise—which, he it remembered, was made with reference to Chippenham and not to Calne, and concerning a tried pen of adult birds, and not an adult cock with two untried chickens—that I should take the birds back again at their full price, or rather at a price which he put upon them, and which was a shilling more than what I had charged for them.

Disgusted beyond measure, I replied that his conduct was shabbily evasive, and that to get rid of such a nuisance, although my prize pen was destroyed and he had had the use of my birds for three months, I would send him a cheque for the amount he claimed, deducting only the 20s. which he still owed me for the pullets. The birds were returned to me, the cheque has been paid, and I have a receipt contained in a

letter sealed with a crest, where something is said about a reconciliation which reduplicates the letter *l*.

So much for my postage and peace of mind. The one is reduced and the other restored. I have now ended my philippic, and have told the tale of my shabby voluminous correspondent, who twice received birds of mine at his uncle's as purchased, and returned them unpaid after he had enjoyed the use of them for some time.—COCK-A-DOODLE-DOO.

### MIDDLETON POULTRY SHOW.

It may appear late to make complaint of the above Show, but by giving publicity to the following facts relative to my case as an exhibitor, it may induce the Middleton Secretary and Committee to be more careful and attentive at a future exhibition.

On entering the Show field at one o'clock I first went to the Pigeons, which I found at that hour exposed to the full sun, and neither supplied with food nor water. I requested one of the attendants to feed them, which he promised to do. An hour after, the birds were still unsupplied, and suffering from exposure to the weather, and it was not until I placed a piece of silver (in the shape of a shilling) into the man's hand that I could prevail on him to procure food and water.

Now as to elaiming birds at the Middleton Show (it was done, I believe, but how I do not know). I went repeatedly to the sale office for this purpose, but no Secretary was to be found, and no purchases to be made. Several intending purchasers with myself were wasting our time waiting for the return of the Secretary; but as this seemed of no avail, one of the clerks informed us we should be sure to find Mr. Mills in the Show field; but as we did not happen to know Mr. Mills we did not find him, and it was only very late in the afternoon that I did see the Secretary in the sale office, though I paid many and frequent visits.

I have now a word or two to say as to the payment of the prizes. I had a first and second prize for Pigeons, and a third for Buff Cochins, which were claimed, and am receiving payment by instalments. My first remittance was the amount of Pigeon prizes (less one shilling and sixpence, for what I know not, and am not informed) in stamps, charged at the post office for being over weight. Since then I wrote to the Secretary requesting him to forward the balance due, and have lately received the amount of the poultry sale, with another deduction, besides the usual commission. I have applied again for the prize awarded to the fowls, but my letter is not acknowledged.

Again, I exhibited a mastiff dog, and as it did not return from the Show I telegraphed to Mr. Mills as to its safety, paying at the York office for a return message, and received no answer. I did, however, the third day, after telegraphing, receive a letter, and on the fourth day the dog arrived.

I have no wish to complain unnecessarily of the management of the Middleton Show, but I do say exhibitors have a right to courteous treatment, and their specimens to have proper attention.—WILLIAM MASSEY, *Fulford, York*.

**BIRMINGHAM AND MIDLAND COUNTIES EXHIBITION.**—We have received the prize lists and programmes of the seventeenth Annual Show of this deservedly popular Society, and observe that considerable additions and alterations have been made in the number and value of premiums offered, the whole being now upon a most liberal scale, and the total amount reaching the sum of £2080, upwards of one-third of which is appropriated to poultry and Pigeons. The arrangements for excursion trains are progressing satisfactorily, and the principal railway companies have also kindly consented to convey stock and implements back from the Show free, if unsold. We remind our readers that the entries in every department will close on Wednesday next, November 1st; intending Exhibitors should therefore, at once communicate with the Secretary, whose address will be found in our advertising columns.

### MANAGEMENT OF DRIVEN AND UNITED BEES.

I HAVE been induced by reading the articles on bees in your Journal to try driving and uniting the bees from old stocks, instead of the old plan of killing them. My first attempt was

on a strong old stock early in September, and I succeeded in getting the bees into a new hive, in which I had put a side window, and fastened three pieces of comb which I hoped would give them a start, and which I was sorry afterwards to find fallen down. In about three weeks I gave them another lot of driven bees, and they have now about half filled their hive, an ordinary-sized one, with comb and honey, and for the last week I have fed them with honey. I am very anxious to preserve them and try to obtain a few glasses of honey next summer, as I have hitherto had none but the old straw hives without supers or any method of experimenting. I should be glad to visit an apiary and learn to distinguish the different kinds of bees, if I could do so without intruding. I should also be glad to know how and where to purchase one or two new kinds of hives to put my swarms in next summer?—S. BRIERLEY.

[If you feed your driven bees up to a nett weight of from 15 to 20 lbs., there is every probability of their surviving the winter and doing well next summer. Any of our bee-keeping correspondents would, we are sure, be most happy to show you their apiaries, whilst Messrs. Neighbour & Sons, 149, Regent Street, and 127, Holborn, will readily supply as many hives of modern construction as you may require.]

### A BEGINNER'S DIFFICULTIES.

I COMMENCED bee-keeping this year, but was at first very unfortunate in losing swarms from my only stock (a set of Nutt's collateral boxes), and smothering one of those I did get (which, to make matters worse, was the first one), in endeavouring to hive it in a large bell-glass. My stock now consists of a set of Nutt's boxes and two stocks in Woodbury bar-frame hives. No. 1 Woodbury was formed by uniting three condemned stocks in August to a stray swarm, hived July 10th, one of which driven swarms, I believe, left and joined Nutt's hive the first day they stirred out, which was five or six days after being driven, the intervening days being very wet. No. 2 Woodbury was formed by uniting two condemned stocks to two very weak swarms from Nutt's box. This stock is not so strong as I supposed it would have been, but what cause to assign for it I cannot say, as in all the swarms joined I could not find more than about twenty bees killed by fighting. Some certainly went back to their old place of residence, a neighbour's hard by, but very few. I fed the stocks liberally at the time of junction, as they had but little honey gathered, and the weather continued very unfavourable for some time.

Some of my greatest difficulties now lie in not knowing how properly to manage Nutt's boxes. They have been in use for the last ten or twelve years, and, I believe, were kept more for ornament than anything else, as they seldom gave more than one of the side boxes of honey in any one year, and the bees often died in the following winter from want of food. The centre box or pavilion not containing enough honey to support the bees, I have now put a box on the top of the pavilion (having removed the crown-board), containing 450 cubic inches, and which I intend to leave there permanently, which makes the stock box contain altogether 1450 cubic inches, and stand 18 inches from floor-board to apex. Is that height too great for the stock box? or say how I could have managed better. I feared leaving them any honey in one of the side boxes, as when cold weather sets in they would in all probability retire to the pavilion. I may say that since I took from them the side box and gave them the top one, they have worked far better than before; but then the unprecedented fine season we have had since then may have been the only cause of that.

This set of boxes wants a new floor-board; will it be a good plan to make three entrances sunk in the new one—of course one left constantly open for the centre box, and the others leading to side ones, to be used when bees are working in them, so that they may go in and out by either way as they please? I saw in a late Number of your Journal that you advised a correspondent to make holes so as to save the lives of bees which could not find their way out of side doors. Did you intend them to be permanent as I mean these?

There has been but very slight mention made in your Journal of Nutt's boxes, owing, I suppose, to their not being in favour with scientific apiarians; still I, for one, will feel much obliged for any information which any of your correspondents may give concerning them, more particularly as I fancy if Woodbury hives could be worked profitably on the collateral system, it would save a great amount of trouble, such as lifting on and off supers when manipulating them. Also say, Does it answer to

have supers on Woodbury hives as large as a standard stock box: as it occurs to me that by so doing, and using frames as in stock box, they would be found invaluable in strengthening weak stocks, &c. My No. 2 Woodbury hive is a framed glass one. Is it sufficient to replace the glass crown-board by a wooden one for the winter, or should I change the bees altogether to a wooden one? They are working in a dwelling-house through a four-inch brick wall. Will it be too late to do so after the 1st of November? How can I tell the difference between drone and worker brood?—W. W., Ireland.

[Your No. 2 Woodbury hive may possibly be queenless, which would account for its lack of strength. This doubt should be set at rest by lifting out and examining the combs the first fine day. Should there be no queen, and if you are unable to supply the deficiency, the bees must be united to another stock. The "pavilion" of your Nutt's hive seems to be a cube of 10 inches inside. This is much too small, and we doubt whether the addition you have made on the top may turn out an efficient remedy. Whilst making a new floor-board we may hint that we have found it very convenient to divide it into three, in fact, a separate floor-board to each box, and we should at the same time take the opportunity of substituting a new pavilion, which, if wished to take frames, might be 14½ inches from front to back, by 13 inches wide, and 9 inches deep inside. This would accommodate nine Woodbury frames, and would afford the opportunity for trying a frame hive worked collaterally. We advise a small entrance being made to each of the side boxes, but should use them only in case of necessity. Woodbury hives, properly so called, are fitted with what their inventor calls "compound frames," in which the bars and frames are separate and distinct, as delineated in page 15 of the fifth edition of "Bee-keeping for the Many," published at this Office, price 4d. Although hive-makers frequently omit this contrivance, it is in reality essential to the carrying out of the Woodbury system of bee-keeping, in which, by its means, frames are used only in stock hives and bars in supers, without forfeiting the advantages arising from unlimited interchangeability of every comb in every hive and super in the apiary. If you get the new "pavilion" ready by the month of April there will then be no difficulty in transferring to it both bees and combs, and if you cannot refer to former Numbers in which directions are given for performing this operation, we will repeat them if you make the inquiry, describing at the same time your new box, early in March.

It will be well to shift the bees from the glass box to a wooden one before winter sets in; but whether this operation can be prudently attempted so late as November depends entirely on the season.

Drone brood is easily distinguished from that which will produce workers by the greater size of the cells in which it is deposited, as well as by their being elongated above the general surface of the comb, and the great convexity of their covers.]

### EFFERVESCING CLARY WINE.

To every gallon of water add 2½ lbs. of loaf sugar; and one quart (exactly) of Clary flowers (blue) gathered dry, *not pressed down*. Boil the sugar in the water and let it cool; then add the Clary flowers and half an ounce of yeast to each gallon, and stir a-day for a fortnight. At the end of that time add to each twice gallon half a drachm of isinglass, melted in water. Bung up very closely for three or four months. Bottle in champagne bottles, using good corks, and keep the bottles upright on a cold stone floor. Let the wine clear for a few hours in a vessel after it comes from the barrel before bottling, and be careful that the barrel has no taste, or it will spoil the flavour, which is very delicate, and much better than that of ordinary champagne. A little white brandy may be added if wanted to keep more than one year.

### OUR LETTER BOX.

**POULTRY SHOW IN LONDON.**—"Are we likely to have a Show in London this year, either at the Crystal Palace, or at the Agricultural Hall, Islington, or at Alexandra Park?—I see none as yet advertised.—D. P. P." [Can any of our readers send us any information in reply to the above query?]

**FEEDING GAME FOWLS (F. K.).**—Game fowls for exhibition should be fed on meat, good barley, bread and ale, and white peas. Nothing improves the condition of a Game cock like raw yolk of egg. Black Game are not sufficiently numerous to take the same standing as other colours; but in open competition, if they had more merit than others, their colour would be no bar to success.

**GROUND OATS FOR POULTRY (Perey Cross).**—The ground oats you want can be had of Mr. Agate, Slougham Mills, near Crawley, Sussex. He will send them if you write to him.

**GAME BANTAM COCK (A Young Shower).**—A Game Bantam cock should be a Game cock in miniature in every particular. The head should be very fine, and give the idea of a snake. Such an one will always be preferred to a thicker-headed one. The smaller he is the better. Under no circumstances should he exceed 20 ozs. The lighter pullets are preferable, if they are equally good in other points. A most important part of a Game cock is that he should carry his wings up and close to his sides. Many carry them too much like a Sebright.

**WARNING A POULTRY-HOUSE (Bromley).**—A Joyce's stove may be placed in a hen-house as an experiment, but it will not be found desirable. Fowls do not need artificial warmth, and the result of it is to give them a chill whenever they leave the house in sharp weather. Nature wants very little help if we observe her conditions, and merely supply the food birds would obtain in a natural state. The cold weather comes when the plumage is new, and thick, and close; able to repel all wintry attacks. Artificial warmth only induces them to open their feathers. Let your house be free from draughts, your perches low, and your food generous. The colder the weather the better the food.

**SUNFLOWER SEEDS—WOOD PIGEONS ROBBING (Wimblim).**—Since we last wrote we have made inquiry about sunflower seeds as food for poultry. Many tell us they are very fond of them. A very good correspondent of ours, and an old sportsman, tells us, "My fowls like the seeds much, but my Pheasants are greedy after them. There is, however, this difference—they infinitely prefer them in the flower. They seem to like to knock them out, and eat them with greater relish than when they are thrown down. They prefer them to any other food." The sunflower requires a good soil. The only way to prevent the Wood Pigeons from eating the Pheasants' food is to feed them from hoppers. If these are made of zinc they do not warp or injure by exposure to any weather. The food can only be got at by the bird jumping on a treadle there is in front. The weight of the bird opens it and shows the food. Being weighted for a Pheasant, a Pigeon will not open it. They can be had at Baily's in Mount Street.

**HENS HOW LONG PROFITABLE? (D. P. P.).**—Hens may be kept profitably till they are four or five years old, and sometimes older. They have been known to live twelve years. The origin of Dark Brahmans is involved in mystery. We are, however, in a position to say that the first were imported from the United States.—B.

**BASKET FOR POULTRY (G. R. B.).**—The first requirement of a poultry basket is, that it be round, high enough for the birds to stand upright in it, and that the top be strong canvas, so that if the birds fly or jump up they will not injure their heads. It should be close all round. The basket should be 30 inches high, 28 inches in diameter for four fowls, 22 inches for three, made of ordinary wickerwork, and as close as possible. There is no necessity for any contrivance for food. For Pigeons a similar basket, 15 inches high and 12 inches in diameter, would be sufficient. We cannot name any price. A basket-maker in your neighbourhood could make them.

**PROFIT FROM POULTRY (N.).**—If you want eggs, keep Spanish, La Flèche, or Crève Cœur. If you want hardy useful fowls, keep Brahmans or Cochins. If you want choice table poultry, keep Dorkings. Begin operations at once. Start with fifty hens and six cocks.

**COCKATON WITH BROKEN WING (A Ten-years Subscriber).**—We advise you to let the bird remain as quiet as possible. It is useless to try to bandage the wing, as it would soon pull the bandage off. The feathers ought to have been cut off short at the time of the accident to lighten the wing; but as the injury has been done some days we would not advise disturbing it unless it is seen to be quite loose at the broken part, and as it were dangling at the bird's side; then you may resolve upon cutting away the feathers.

**MAGPIE PIGEONS (J. R. J.).**—Magpies are usually bred in this country are only Toys, and would not be eligible as Tumblers, unless they really did tumble; then, of course, they would be entered as Magpie Tumblers.—B. P. BRENT.

**TO MAKE TUMBLERS FLY (Highflyer).**—Put your Pigeons in a basket and send them out by some one, at first a quarter of a mile daily, increasing the distance till they will come home three or four miles. Continue this for a month, when you will find them in flying condition; but there will be some difficulty to keep them off their favourite resting-place. Send them out hungry, so that they may go in directly they come home, and keep them in for the rest of the day. They will then, in a measure, forget the places they used to settle on. When you begin to fly them at home it would be as well, if you could do so, to hoist a flag on that place, or put a boy there to drive them away till they entirely forget it, but unless they are of a good flying sort it will only be lost trouble. Better kill them and buy some trained high-flyers, and do not let these acquire bad habits.—B. P. BRENT.

**CHRYSLIS OF DEATH'S-HEAD MOTH.**—It may help to the solution of "C. P.'s" query in your last Number, page 343, if I inform him that a chrysalis of the Sphinx Atropos was brought to me from a potato field on the 29th of September last, and that the moth emerged on the 10th of October.—W., Forest Hill, Ozon.

**NATIVE HIVES.**—Mr. M. Smith, 8 Pelham Place, Holland Road, Brixton, wishes to write to "M. D." about these hives.

**SUPERING A COMMON STRAW-HIVE (A Young Subscriber, C.).**—There is no difficulty whatever in cutting a three or four-inch hole in the crown of a common hive with a sharp penknife, but it will be better to leave doing it until spring, unless it be required at once for feeding.

**CARRIING BEES TO A DISTANCE (J. Alexander).**—Confine the bees by tying the hives up in pieces of cheescloth, and then passing a cord tightly round each about 2 inches from the bottom. Steadily invert the hives, and secure them in that position by carefully packing them round with either hay or straw. Employ a light vehicle, hung on good springs, and drive slowly. Select a sheltered position, and let the stocks face any point from south-east to south-west that may be most convenient.

**PHOTOGRAPHS—VENTILATING (A South Lancashire Bee-keeper).**—The cartes of the principal contributors to our various departments, and among them that of the "DEVONSHIRE BEE-KEEPER," are published at this office, price 1s., or free by post for thirteen postage stamps. We do not ourselves ventilate our hives, but it is practised and recommended by many good bee-keepers, and the present is about the time for carrying it out.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 50.7°, and its night temperature 35.1. The greatest heat was 63°, on the 12th, 1841; and the lowest cold, 18°, on the 9th, 1854. The greatest fall of rain was 1.16 inch.

FOUR HOURS AT CHATSWORTH.

HERE is always something to see at Chatsworth; and as no two observers look at things in the same way, a few notes I made a week or two ago may not be without interest. Fortunately, the

day that I selected for my visit was most brilliant; and as if on purpose to give an extra gratification, the great fountains were set playing. This was in compliment to a large party of the Social Science Congress, which had come over from Sheffield to examine the innumerable and admirable treasures contained in the Hall, as well as to enjoy the beauty of the gardens and pleasure grounds. The fountains are wonderfully fine. The great jet called the "Emperor," in compliment to the Czar Nicholas, who once visited Chatsworth, throws the water to the immense height of 240 feet! On a fine sunshiny day the rainbows play about in its mimic rain, three or four at a time, sometimes forming perfect arches, then fragments of arches, and changing their angles in the most beautiful manner, according to the direction given to the spray by the wind. Viewed, as this lovely spectacle is, from the foot of tall trees, the effect is magical.

Going in the first instance through the kitchen garden, the visitor to this grand place cannot fail to be struck by the Pines, which are grown in large quantities, and are in the finest possible condition. Some of the plants almost deserve to be called gigantic. When the pits for them were dug, it would appear that the earth was thrown into one great heap, for alongside of them there is literally a "Strawberry hill," the mound of earth being shaped into circular terraces, the edges of which are supported by miniature palings, and the plants disposed so as to let the fruit be sustained high and dry, almost as if grown against a wall. Whether such were the origin of the mound or not, it has been taken advantage of in the most ingenious manner, and is a capital model for those who would grow Strawberries to perfection. Under glass was the Cape Gooseberry, *Physalis edulis* (?), in flower and fruit; also a pretty variety of the Love Apple, named Tomato de Lave. The fruit was perfectly globular, the size of a large marble, and grew in racemes of six or eight. A White Mulberry, *Morus alba*, grows against one of the walls—a most extraordinary place for it if planted there in expectation of fruit.

The stoves and greenhouses belonging to this part of the establishment are crowded with curious plants. On entering the first, we have a perfect veil of Pitcher-plant stems and foliage, with scores of the strange little receptacles alluded to in the name. The luxuriance of these plants

appears to be in a large measure referable to their being grown in living sphagnum, the surface of which looks as green and fresh as if it were only just transplanted from its native swamp. Close by is the famous plant of *Amherstia nobilis*, to hold which this house was specially built. It is the largest example in Europe, though even here only a couple of yards or so in height from where the branches spring, and with the exception of the plant at the late Mrs. Lawrence's, is believed to be the only one that has yet bloomed in England. Nothing, said Mr. Taplin, could exceed the gorgeousness of its appearance early in the spring of the present year, when thirty-two great racemes, a yard in length, of red and yellow flowers, were suspended among the enormous pinnate leaves. The young leaves have a peculiar brown tinge, and hang down as if half dead, reminding us in the former character of the young leaves of the Brownias, which, unlike these, however, stand erect.

In the next house is a capital collection of such rarities as the Arnotto Tree (*Bixa orellana*), and the Ebony Tree, *Diospyros ebenum*. The plants are not large, but serve their purpose perfectly well. *Ficus elastica*, on the other hand, is almost rampant: a noble plant truly is this, growing 5 or 6 feet in a single season. There is a fine young specimen, also, of the Upas tree, *Antiaris toxicaria*, and one of that very elegant-leaved ally of the Nettles, though without their stings—the Artanthe. The blade of the leaf of this plant resembles that of the Elm, in coming down further upon one side of the petiole than it does upon the other. Many plants show the same thing in some degree, but there is none, perhaps, in which it is so noticeable as in these two. Elms, however, are by no means constant in the obliquity of their leaves, examples being often met with in which the base is quite symmetrical, while others, on the contrary, have a bare stem of half an inch or more. The herbaceous plants in this house include several of those pretty little curiosities the Peperomias, with minute green flowers, disposed in long and slender spikes that exactly resemble the tails of mice or other diminutive quadrupeds. The Artanthe produces its blackish green flowers in a spike of similar figure. Quite as interesting is the Nardoo-plant, now becoming common, and so quaintly like an Oxalis with quaternate leaves.

Next into that glorious flower-palace, the Victoria-house. The first time we entered it was by the light of the full moon, which, shining upon the water, and the great oval leaves, and the one huge white blossom in the midst, made a fairy scene of it not soon to be forgotten. This year the Victoria has done remarkably well at Chatsworth. At the end of September there were no less than seventeen full-grown leaves afloat, and in one part of the tank they were becoming so crowded as to require no thinning. The flower of the Victoria opens in the evening, and is fragrant for some time after expansion. The next day the fragrance is less powerful, but the loss of odour is compensated by the increasing beauty, which attains its maximum on the second evening and then declines. Only one blossom is seen in perfection at once, but there is a long-continued succession of them. The contrast this noble plant presents with its regal relative the *Nelumbium speciosum* is most

imposing; the one, horizontal and floating on the water; the other, lifting its magnificent shields to the height of many feet—great flat green disks poised, as it were, upon reeds. The strange and foreign air of the latter is greatly intensified by the capsules, which are like broad cones with the bottom upwards, and are excavated all over the flattened surface. Seeds have several times been ripened at Clatsworth, but as a rule they are prone to fail. Around a plant of such history as the *Nelumbium* there clings quite a fascination. Figured in one kind of art or another upon the ancient monuments of Egypt and India, the sight of the living individual carries the mind to the days of the building of the Pyramids. Looking at it, we seem transferred from modern to primeval times, and it wants but a mental step or two, and we stand in imagination among *Sigillarias* and *Lepidodendra*.

Around the tank that holds the *Victoria*, which, by the way, first flowered as regards Europe in this garden, there are many capital plants—not that they are uncommon ones, but the condition is so fine. The *Papyrus*, for instance, owing to the abundant supply of moisture and the freedom with which it can grow, has grand rhizomes resembling those of the English *Acoris calamus*; while barely at arm's length is *Coix lachryma* hanging out plenty of those strange grey fruits, which in due time are to seem beads made of lilac enamel. In one corner is a great mass of that rare and striking plant, the *Thalia dealbata*. Petioles 5 feet long support great oval leaves, and higher still above the surface of the soil are the racemes of rather inconspicuous purple flowers, made, however, eminently remarkable by the whole of the exterior portion of the inflorescence being covered with white meal, that rubs off with the slightest touch. The student of flower-structure, who thinks he has obtained all he needs to learn from the dissection of a *Primrose* or a *Violet*, should obtain, when he has a chance, a blossom of a *Thalia* or some such plant. *Orchids*, with all their quaintness, are plain English compared with the *Thalia*, and the educational value is, of course, great in proportion. A *Testudinaria*, with a huge irregularly conical rhizome nearly 4 feet high in the middle, and surmounted by a bush of green shoots, must not be forgotten; nor yet some pretty plants of *Russelia juncea*, resembling juvenile *Casuarinas*, excepting that some of the younger branches are crowded with little ovate leaves that are mostly disposed in whorls of three. The *Mango*, the *Guava*, the *Cherimoyer*, *Ilex paraguensis*, *Jambosa vulgaris*, &c., are here as a matter of course, and mostly exuberant in foliage.

A delightful walk of twenty minutes through the park brings the visitor to the entrance-gates of the Hall. For beauty this park cannot be excelled, the ground being everywhere agreeably undulated, and the extensive area enclosed in the most picturesque manner by gently rising hills. Every portion is well studded with trees, a large number of them fit subjects for the artist; and the herds of dappled deer give that exciting sense of life which is so agreeable an adjunct to, if not an essential element in, the sense of the beautiful. Before proceeding to the grand conservatory, the visitor is led through the *Camellia-house*, and under and along the glazed trellises that form a sort of botanical and floricultural cloisters. In the latter all is good. *Indigofera tinctoria*, with large pinnate leaves, and dense racemes of pretty pale pink flowers; *Schinus Muli* (not melle, as often improperly written), again with neat pinnate leaves; *Mimosa prostrata*, the bean-ideal of an airy climber; and *Camellia reticulata*, 20 feet high, are but a few of the gratifying ornaments here associated. This *Camellia* is a species seen very seldom, yet the very plant for those who like a large flower, the scarlet blossom, which is not very double, being often a foot across! Shaddock trees, loaded with green fruit, are seen every here and there, being grown for the purpose of making marmalade of the produce. What a strange extension of meaning that word "marmalade" has acquired with us! Properly and originally, a preserve made from the Quince marmelos, the Bitter Apple, first it was passed on to the bitter conserve made of the peel of Seville Oranges; and now in many a shop it is the appellation of a sweet yellow pulp, called facetiously "Orange marmalade," but in reality manufactured out of Carrots! One of the prettiest plants in this department just now is *Solanum capsicastrum*, trained against the walls, and absolutely loaded with its scarlet fruit, no doubt through the influence of the kindly atmosphere provided for the *Camellias*. It is a plant difficult to keep free from green fly and red spider; here, as managed by Mr. Taplin, it is perfectly clean.

On the way hence towards the conservatory through the

grounds, the eye is caught by many things—a tree of *Hippophae rhamnoides*, for instance, willow-like, and 25 feet high. After the manner of the *White Poplar* and many other trees, it sends out long underground suckers, which emerge from the soil at a distance of 30 or 40 feet. The individual here referred to is a male, therefore not embellished in autumn with those crowded masses of orange-coloured berries that render the female so conspicuous. Conifers are plentiful, and in many cases very striking. How oddly the cones of *Pinus Banksiana* cling to the branches! After enduring the rigours of two or three winters they seem to become a part of the branch, standing upon it like woody excrescences, or half consolidated with the stem, like the fruits of some of those outlandish Australian shrubs—*Melaleucas* to wit, that seem indisposed ever to quit their birthplace. On the grass are innumerable shrubs and small trees. Once, it is said, the arboretum was one of the most complete in the country; circumstances, however, and an inhospitable climate—for in winter it is often very trying—have considerably interfered with the maintenance of its ancient character. Casually examining a *Caragana*, I noticed that the spines are the extremities of the central stalks of pinnate leaves, the thorns holding the same position that tendrils do in *Vetches*. This is very curious, and I think it must be nearly peculiar.

The conservatory is known too well to need a description. The *Palms*, though not many, are grand ones of their kind; while the *Cycadaceous* plants, the *Musas*, and the *Furcraas*, hold our gaze as if by enchantment. Then there is the grand rockery for the *Ferns*, 20 feet high, with a tasteful intermixture of *Begonias* and "cool-culture" *Orchids*. *Araucaria brasiliensis* touches the roof with its head, and hangs down branches that we may handle, so near do they come to the ground. *Linum flavum* forms great bushes 4 feet high, and in its season bears thousands of flowers; and to stop somewhere, for stop I must, lastly there are noble plants of *Dichorizandra* with purple-violet spikes. Dr. Lindley, in the "Vegetable Kingdom," says of the *Commelinaceae*, to which order this plant belongs, "Sepals herbaceous," and "some of the stamens deformed," giving us plainly to understand that these are absolute and universal characters. In *Dichorizandra*, however, the sepals are petaloid, violet externally, and white on the inside, and the six stamens are all perfect; and in *Tradescantia*, the commonest species of the order, the stamens are again all perfect. It would not be worth pointing out only that with many similar statements (that, for instance, of *Saracenia*s having a hinged lip to the pitcher), for some reason that does not appear, the error is made a standard one by being continued in one edition after another. So much for "authority." One other plant I must mention, and I have done—*Cadia*, or, as it was formerly called, *Spandonea*, *tamarindifolia*. The foliage is strikingly like that of the true *Tamarind*. The solitary and axillary blossoms are not unlike a small *Fritillary*, an inch in length, pendulous, and dull pink.—LEO.

#### THE CYCLAMEN WHEN AT HOME.

HAVING cultivated *Cyclamens* for many years with varied success, I have read with great interest the remarks of Mr. Abbey, the more so because I have always felt that there was some peculiarity in the natural habit of the plant, which required attention to insure a more certain success in flowering the plants than usually falls to the lot of amateurs, myself amongst the rest; and because one season I might have a fair show of bloom, and the following one, with the same care and treatment, I could not obtain a flower, I felt that my *Cyclamens* wanted something that they did not get. As a tour in the spring of the present year through Sicily, and afterwards through Palestine, Syria, and Turkey, gave me a fair opportunity of seeing the *Cyclamen* "at home," I made a few notes which I venture to send for the perusal of Mr. Abbey and your readers.

1st. Although I searched diligently, I never could find a *Cyclamen* growing with the bulb or corm exposed or uncovered.

2nd. I never could find the plant growing on a level surface, or in an open plain, away from the shade of a bank, rocks, or trees.

3rd. The places where it grew in the greatest profusion and perfection were dry elevated banks, partially shaded by bushes and trees, amongst rocks and stones, and invariably with the bulbs buried 4 or 6 inches deep in loose friable soil and decayed leaves.

I was not able during the whole of my tour to find one un-

covered or exposed eorm, and I returned home with the conviction that I might as well expect to find a bank of wild Bluebells or Snowdrops with their roots or bulbs exposed flowering luxuriantly. There is, indeed, great similarity in the most favourite locality of the Cyclamen's home in Sicily to the coppice banks in which our Bluebell delights to live. I recollect, however, finding a large Cyclamen eorm growing in the cleft of a rock at Solomon's Pools near Jerusalem, but even it had its sheltering bush, and was covered with decayed leaf mould. I therefore venture to suggest that the proper place to grow Cyclamens according to their natural habit must be on a sloping bank, or something resembling a miniature rockery, with clefts in the drainage, into which the eorms will grow and adapt their shape to the crevices, and with 5 inches deep of loose friable mould above them, through which they can send their leaves and flower-stems.

The smallest cultivator may make an appropriate place for ten or twelve Cyclamens in a large seed-pan. Let him build up a cone of drainage in the centre, and upon it a hard bed of soil for the eorms, putting in a few pieces of stones to support the loose open soil of the little mound above the eorms, imitating as closely as possible their natural localities.—W. X. W.

### CHANNEL ISLANDS ORCHARD-HOUSES.

I RESUME my notice on the periods of the ripening of Peaches and Nectarines, by stating my experience in the case of those which ripened during September and October.

Early in September Stanwick Nectarine was abundant; I have some large trees of it, and none of the fruit cracked this year, but neither in size nor in flavour were they up to the mark. There were also Téton de Venus Peach, like Chancellor and Boudin, all ugly in name, and not good enough now; also, Walburton Admirable, over-praised, and too shy a bearer for small houses. Then seedling Peaches came in, which will one day be famous.

The second week ripened Desse Tardive, an old kind, ripening in France early in October in warm localities. It has had its day, but is useful to raise new sorts from. Shanghai, one cannot well decide on, but it is not prolific enough for small houses. Kensington is a Peach which seems to require the open air, but when there it was too tender, and was always mildewed, so it is practically useless. A few Nectarines still remain, also a fine new American Peach given to me by Mr. Rivers. It is called Heath's Northern Free, and much like Noblesse. It will be a gain for our house. What my good friend will report on it I do not know yet, but he is so very particular, that the public may best learn from him.

September, then, on the whole is not here a favourable month for the houses—that is, their first glory is over, and Grapes are so abundant now that we hardly miss Peaches.

The first week of October brought in a small but very useful class of Peaches. The first and choicest is Pavie (clingstone) de Tonneux. This noble Peach eats as hard as an Apple, but when placed in the best situation becomes sugary, and has a rich flavour. These clingstone Peaches are more valued abroad than here; they are, nevertheless, very delicious to true Peach fanciers. Another, which ripened here later, was Mitchell's Mammoth, which was also good, paler in colour, and looking more like a freestone; but whatever is fairly ripe by the middle of October should be accepted without severe criticism.

Thomas's Late, an American, and first fruited here three years ago, is a good Peach. It is very prolific, above the middle size, and has a juicy flesh, with a brisk flavour.

Tecumseh, a new Georgian, sent me from Sawbridgeworth this year, will be a gain. It is above the middle size, of a pale straw, mottled feebly on the sunny side with crimson dots, round, with a distinct suture, flesh juicy; a freestone. The leaves have kidney-shaped glands. Ripe about the middle of the month. What pleasure to the amateur to fruit a Peach, and to describe it.

Tardive d'Espagne, one of my oldest trees is always good for the season. It is said to be only eatable at Angers, when the season is very warm. We thus see that orchard-houses augment our ripening power, far from diminishing it, as some pretend. This Spanish Peach is a perfect yellow variety, very pointed, and highly coloured like an Aprieot, juicy, large, and a freestone. Showy for dessert, and makes an acceptable present to a friend at this season.

Baldwin's Late, first fruited here in 1863, is our last. Very prolific, but difficult to swell and soften. In fact, had we fire

heat at command we should now urge it on, and so incur the censure of those critics who argue that lean-to's are not orchard-houses, and that artificial heat of the most supplementary character vitiates the claim of a span-roof to be ranked as an orchard-house also. What about half-spans?

We have had an abundant supply of Peaches since the middle of July, without fire heat. On one day we gathered four hundred, one-half of which went to Covent Garden, one-quarter was disposed of as presents, and the rest gave much labour to get rid of.

It might interest some of your readers who thought it worth while to come to see me this year, to state that our new lean-to will shortly be finished; and I mention this chiefly for the sake of saying, that I do not agree with those who in any way encumber the glass of their houses. The whole roof should be left perfectly clear. Those who think that I find potted trees unmanageable, must have misunderstood me, for there is really no difficulty about it. I have a tree eight or nine years potted, which bears regularly about fifty Nectarines, and it is not 6 feet high, and the stem is not at all large.

I have long had seventeen transverse espaliers, and have had less fruit on them in proportion than on bush trees in pots. Not, however, that these espaliers are not good in their proper place, and well-known means to an end, but good as they are I shall not choose them for the new house. Visitors here, almost as a rule, prefer the spiral cordon, and it is certainly most beautiful and profitable. Two trees are twisted round three wires, and wind upwards to the glass. The wires may be at any distance apart; of course, the farther from each other the longer is the twist of the cordon trees. I place two trees together, or even three, because otherwise the angle of the ascent would be too great. Now, I propose having immense trees ten years trained as cordons, to coil them round wires, leaving the centre open for, say 3 feet. Sun and air freely play round these cordons, and I know, from many years' experience, that they bear immensely. During the blossoming period nothing can surpass them in regular beauty. I should, therefore, imagine that fifty or sixty of these in a double row, would look rather nice in the spring; so with deference to others of greater experience, I shall choose this way for the new lean-to. As to encumbering the glass in any way, it is not to be thought of; and as to any other way of treating the shoots except by very close pruning, it is a mere waste of time in orchard-houses. The comparison of the produce of espaliers under the old system, and of spiral cordons on the new, would speedily dissipate any doubts. Our back wall is to be covered with diagonal cordons, now fine trees, which are to be removed from the old house to the new one. The wall of this last being much higher, these cordons will be single, at 16 inches interval. These diagonal cordons were first applied to orchard-houses in my own, and I think that this new wall will not be easily surpassed, if equalled, by any other style.—T. C. BRÉHAUT, *Richmond House, Guernsey.*

### GRAPES IN AN ORCHARD-HOUSE.

THE Muscat Hamburg has succeeded here (Tiehurst, Sussex) admirably this year in a cold vinery; it is not grafted. The bunches are large, very compact, and of good shape; the berries are also large, very black, with perfect bloom, thoroughly ripe, and the flavour high and excellent. The crop is large. This is the second year of bearing; the first year the berries were small, and some never ripened, and the bunches were long and loose. I had not a good opinion of the Grape excepting as to flavour. This Vine is in an orchard-house, where all the Vines were turned out for the winter; the chief care being bestowed on the orchard-house trees. About the end of April the Vines were taken in, the Peaches and Nectarines being sufficiently advanced not to be injured by the shade of the Vines. The whole roof, 72 feet long by 36 span, the house being 30 feet wide, is now covered with Grapes of the finest description.

The orchard-house trees are also in the best condition for next season. The Golden Hamburg also did very well this season, the berries being very large and the bunches compact; but it is not a favourite with me, the flavour is very sweet, but rain, if the roots are outside, causes the Grapes to decay in a few days.—CONSTANT READER.

MR. FLEMING'S NEW BEDDING GERANIUMS.—The seedling Geraniums exhibited by Mr. Fleming, of Cliveden, before the Floral Committee of the Royal Horticultural Society during

the past summer, and that received first-class certificates, have we are glad to hear, passed into the hands of Mr. Turner, of Slough, who will, no doubt, soon increase their number sufficiently to be able to supply them to the public. The D. wagneri Duchess of Sutherland is the best N.osegay strain of Donald Beaton, but different in colour from any other of that class, having also trusses larger than Stella. Cliveden Rose is also of a most brilliant tint. All of them are more or less different in colour from any other varieties in this class, and will prove great acquisitions for the decoration of the flower garden.

### A PLEA FOR ATHYRIUMS.

Few countries have a higher appreciation of ancient lineage than the English; mere mushroom rank, apart from ancient birth, is simply a higher form of vulgarity, and meets with but small consideration excepting from the lower varieties of its own species. But wisdom has been ever accorded to length of days, and the accumulated wisdom of many generations is supposed to dwell with certain inhabitants of particular places. For myself, being an inhabitant of the British Isles, I am disposed to agree with this idiosyncrasy, when carried out to a fair construction. I am ready to defer to ancient lineage, and quite willing to give up the claims to a patient hearing I am about to advance, should one of older family than myself speak.

It will be, perhaps, difficult for me to adapt the language of my race to the modern human tongue, which I consider in itself poor and barely sufficient for the wants of the scattered genus; still it is all they are acquainted with, so I must reduce my faculties to the human level. I am, as I said, an inhabitant of the British Isles, but my people exist over the entire known and (humanly speaking) unknown world. A few thousand years more or less are nothing to me. When the first human creature stepped on British land I was here to welcome him. One of my family saw Romulus in Rome, another greeted Nimrod on the plains of Assyria. But why speak of so recent a period, when I have lived through Tertiary, Cretaceous, Oolitic, Triassic, Permian, and Carboniferous, some of my ancestors claiming acquaintance even with the Old Red Sandstone and Silurian,—but I myself consider this going a little too far. Should, however, our claims to antiquity be disputed, we have only to point to our burial grounds (millions of our race having been embalmed in such fashion as would sorely puzzle man to imitate), and they sufficiently testify to the truth of my assertion.

During all these years we have been allowed to manage our families in our own way; and I think I may fairly say we have earned general respect from our arrangements. I cannot help laughing at the poor attempts I see human creatures make at imitating us. Alas! they know but little about it; and had I not a personal grievance, becoming too great for acrogenical, not to say foliacea-kish endurance, I should content myself with smiling and waiting.

I wish to stand well with the whole world—I own it is a weakness, but I do think it a trying circumstance that these human creatures will assign to me a family so overgrown and so constantly increasing that I fairly give up all attempt at managing them. Moreover, they really do not belong to me; they are many of them only neighbours' children, who, their tastes and habits of life assimilating with mine, have taken up their residence near me. I am not ashamed of them, they are near relations, and do me much credit; but, for all that, they are far too numerous for me to look after them as I could wish. Besides, I have heard rumours of a grand International Exhibition, when I expect a great many foreigners of distinction nearly connected with my family, and I shall be grieved for them to be able to throw out skits at England, as I greatly fear they will, and all through a misunderstanding which has arisen between ourselves and the biped animals of the Recent period. Why should I have such an overgrown family, when so many of my relations have none? Why should England have not more, if so many as, forty-four species of Ferns, when there are two thousand in the world?

Of course if there were only nineteen in Britain that would be sufficient answer, but I ask, Are there no more? Who decides the point? Who decided that my cousin *Asplenium trichomanes* should be one species and *viride* another? I see no difference to speak of, saving that one is green and the other black in the rachis. Our friend Mr. Moore says, describing *A. trichomanes*, "rachis not winged, black throughout; frond

normal; pinnules entire or crenate;" and of *A. viride* Mr. Moore only says "rachis not winged, green above."

I have no jealousy in my composition, but I do think if my aunt *Asplenium* is to settle *viride* in a house of her own, that my child *odontomanes* deserves one quite as much. I do not find fault with my aunt, but I do not forget that we had the same grandmother; and my mother *Athyrium* and aunt *Asplenium* were considered to have so strong a family likeness that they were often taken for each other. One may say, indeed, it was more the shape of their dress than any graver distinction that separated them, my mother's petticoat being fringed instead of plain; and I do think it a little hard that while my cousins *Asplenium fontanum*, *lanecolatum*, *adiantum-nigrum*, *marinum*, *trichomanes*, *viride*, *ruta-muraria*, *germanicum*, and *septentrionale* should have little or nothing of family cares, I should have nearly a hundred unruly children apportioned to me. They are none of mine. I disclaim them. Let *odontomanes* set up housekeeping for herself—she and her already large family are sufficient for one house; let her be *Athyrium* No. 2. No one will mistake her for me, when once she is settled. I found one of her children in a ditch the other day, and very pretty she was. Her frond was about 15 inches from apex to root, of an elongated lanceolate shape, the pinnae curving crescent-wise to the apex of the frond, the pinnules connected to the secondary rachis by a very visible leafy margin, each pinnule so deeply notched or toothed as to render them almost pinnatifid. Does this answer to the description of my normal state? Then again in the *species* of *odontomanes*, in fronds both young and old, the indusium is singularly absent or out of sight, and, when visible, it is more kidney-shaped than oblong. *Odontomanes* has already many varieties, some stumpy with ovate fronds, some much forked, some 2 feet and upwards. Then there is *rhaeticum* with her red-legged variety, quite as worthy of distinction, for all I can see, as black-legged *trichomanes*. And *davallioides*?—why, one of her pinnae is as fine as many a frond, and as minutely divided. Yes, *davallioides* must be a *species* too.

Something must be done for me before the International, but who will do it? I appeal to our friends Dr. Hooker, Mr. Moore, and Mr. Newman. Cannot they, in consideration of my ancient lineage and high birth, provide more suitable accommodation for the numerous family of—*FILIX-FEMINA*?

### CULTURE OF THE MANGO, MANGOSTEEN, AND OTHER TROPICAL FRUITS.

It has often surprised me that persons, whose means enable them to maintain continued fires in bothouses, should waste their energies in producing at Christmas tasteless Asparagus or miserable Kidney Beans, while they might, with no more trouble, and not much more expense, enjoy the luxury of tropical fruit. Surely it is more reasonable to employ heat for the purpose of producing things which cannot be grown without it, than to waste it upon articles which may be had of better quality, though somewhat later, in every cottage garden. Holding these views, I was much pleased at seeing the letter of "J. H." in page 340 of your Journal, and hope that its perusal may stimulate those who are able to cultivate the Mango.

There are, however, in that letter two points on which I would make an observation. First, "J. H." most liberally offers a cutting; but do Mangoes grow from cuttings? I have never heard of their being raised except from seed, and grafted when needful. However, there would not be much difficulty in getting from the West Indies Mango stones packed in damp earth. These would serve as stocks upon which "J. H.'s" cuttings could be grafted. Secondly, the high winter temperature which "J. H." has so successfully employed cannot, I think, be necessary. I remember reading in some travels in the north-west of India that the party encamped near a Mango tree, and that in the morning water froze. Again: I understand that Mangos grow at Saláranpur, which, in addition to considerable elevation above the sea, is in latitude 30°; they grow also in Madeira.

Bombay is considered the head-quarters of the Mango. Possibly grafted trees of the Alfonso and other choice varieties might be procurable from thence. At the Crystal Palace two healthy Mango trees may be seen; they flower freely, but do not set their fruit.

If I mistake not, "J. H." is conversant with many other tropical fruits besides the Mango; if so, I should feel obliged

by his stating his experience as to Cattley's Guava. Is it equal in quality to the ordinary Guava?—G. S.

FEELING much interested in tropical fruit culture, I am glad to see an article on the subject. From what your correspondent "J. H." states last week we might imagine that fruiting the Mangosteen was an annual circumstance. I was not aware that it had been fruited more than once in this country, and that once at Sion House, and from the appearance of the plants and general report I considered it rather a difficult subject to manage. I should be obliged by being informed where plants can be obtained; also, if your correspondent found it necessary to employ bottom heat, and to what amount.—T. N.

[I can assure "T. N.," in answer to his letter, that it is quite a mistaken idea to suppose the Mangosteen cannot be reared in England without great difficulty. I have seen it growing at one or two places, and many years ago I saw a tree at Allestree, near Derby, covered with blossom, and which afterwards, I believe, bore some fruit. The chief point seems to be procuring a good variety, as many sorts, almost the same in appearance, will neither flower nor fruit in England. I procured my trees direct from Madras (by far the best way), and although I have not now one of my own, I believe I can obtain a plant for "T. N." if he requires it.

The tree at Sion House, to which "T. N." alludes, I only saw once, and then it was not in flower, but it appeared to me remarkably like *Garcinia Mangostana celebica*, a sort which will not fruit in England.

I obtained fruit for three successive years (1859-60-61) from one small tree, and I am certain that with good management the tree would bear annually.

I forgot to mention in my article on the subject, that while growing, the Mangosteen should have a brisk bottom heat of from 90° to 100°.—J. H.]

#### DEATH OF DR. LINDLEY.

IN rapid succession to that of Sir William Jackson Hooker, we have now to announce the death of Dr. Lindley, which occurred at his house, Acton Green, on the morning of Wednesday last, the 1st of November. For a considerable time past Dr. Lindley has been wholly incapacitated from following his ordinary pursuits, or of engaging in any occupation that required mental application. For some years he had been afflicted with a gradual softening of the brain, and this disease had made so much progress that at the time of his death, which resulted in apoplexy, he had become, so to speak, dead to the world. And thus expired an intellect much above the common order, a sacrifice to its own untiring and unceasing toil.

JOHN LINDLEY was born February 5th, 1793, at Catton, near Norwich, which may now be styled the City of Botanists, for there were born three of England's greatest botanists—Sir James Edward Smith, Sir William Jackson Hooker, and Dr. John Lindley. His father was a nurseryman, but being unsuccessful in business, he subsequently undertook the direction of the Bristol Nurseries of Miller & Sweet, at that time one of the most extensive and prosperous establishments in the kingdom. He was the author of a very useful work, which was edited by his son, entitled "A Guide to the Orchard and Kitchen Garden," but it appeared at a time when the present taste for garden literature was as yet undeveloped, and when what is now called gardening was confined more to the establishments of the higher classes, who were themselves not gardeners, and consequently that excellent work never met with the encouragement it merited, and never reached a second edition. Trained as young Lindley necessarily was among plants and flowers, and being surrounded by so many botanical associations and associates, it is not to be wondered at that an intellect like his should soar above and beyond the ordinary ideas of a nurseryman, and see something in the objects with which he was surrounded of greater interest than that which was connected with their commercial value. We find, therefore, that instead of being a nurseryman he was bent on becoming a botanist, for so early as 1819 he published a translation of Richard's "Analyse des Fruits;" and in his twenty-first year he produced his "Rosarum Monographia," the preparation of which must have occupied him a long time previously, for the excellent plates are all from his own drawings, and the study of the subject must necessarily have engaged his

attention at a period when he was yet a mere youth. In the following year Mr. Lindley published "Digitalium Monographia," and about this time he became garden clerk at the Chiswick Garden of the Horticultural Society, which had then been newly formed; and in this capacity he remained till the retirement of Mr. Sabine in 1830, when Mr. Bentham was chosen Secretary and Mr. Lindley was appointed the Assistant Secretary. In this capacity he remained till his retirement in 1858; and, as a recognition of his long services to the Society he was chosen secretary—an honorary appointment he retained till 1863. About the time he became connected with the Horticultural Society, he was engaged by the late Mr. Loudon in the compilation of the "Encyclopedia of Plants," which occupied him for a period of seven years, and which was completed in 1829.

During the time he acted as Assistant Secretary to the Horticultural Society he held several other appointments. In 1826 he succeeded Mr. Bellenker as Editor of the "Botanical Register," established by Sydenham Edwards in 1815; and the botanical attainments he exhibited in the management of this and the execution of his other works recommended him to the botanical chair of University College, London, where, in the end of April, 1829, he delivered his introductory lecture as Professor of Botany in that institution. This appointment he held for twenty-nine years; and it has been remarked by one of his old pupils, "I can truly say, as a lecturer he was one of the best teachers I ever heard. Free and conversational in his manner, his matter was excellent and methodically arranged. I entered his class with little knowledge of, and less liking for, botany, and left it, having taken his gold medal at University College, having amongst my competitors Dr. W. B. Carpenter, Dr. Lankester, Dr. Jenner, &c.," and I maintained the superiority of his teaching by taking the silver botanical medal of the Apothecaries' Company open to the competition of all the students in England.

In his introductory lecture he announced his intention of teaching the natural system of botany, at that time unpopular among those who had been educated in the Linnæan school: to this he rigidly adhered. We question, however, whether so much of the credit usually attributed to Dr. Lindley as the fosterer of the natural system in this country is not unduly rendered. He encouraged the study of it in preference to that of the Linnæan, and in all his works on the subject he adhered to that system. Still it cannot be forgotten that, not content with the natural systems which Jussieu and De Candolle originated, he was always propounding some theory of his own, which was never fixed, but which at uncertain intervals was doomed to be supplanted by another idea that seemed to find greater favour in the mind of the author. Students who were willing to adopt the natural system were thus, by Dr. Lindley's teaching, kept in a state of constant uncertainty. In his "Synopsis of the British Flora," published in 1829, he there adopts the arrangement of De Candolle, a system which has received universal acceptance from every botanist in this country and America; but in 1830 appeared his first elementary work on the natural system, entitled "An Introduction to the Natural System of Botany." Instead of following the systems of Jussieu or De Candolle, he adopted that of the latter, ignoring the apetalous classes of both, and throwing them in with the polypetalous class. This, as a consequence, destroyed any ideas of sequence, or even of arrangement, that may have been formed by the student who had just mastered either of the other systems, and confused those of others who were but on the threshold of the science.

In 1833 Dr. Lindley published his "Nixus Plantarum," in which he restored the apetalous group, which three years previously he abolished, and ignored altogether the hypogynous and perigynous structures, which form such distinct characters in the other systems; retaining only the epigynous, which he made to represent a subordinate section, and adopting the character of the albumen for the primary divisions. In this case the affinities and sequence of the orders were again entirely disturbed. Three years later appeared the second edition of "A Natural System of Botany," in which the arrangement set forth in the "Nixus" was generally adhered to, but differed in some of the details, and this form he introduced in the subject "Botany," published by the Society for the Diffusion of Useful Knowledge in 1838, and which was intended as a book of instruction for the masses; but there is not even a reference in it to the system of De Candolle, which at the time was being taught by Hooker in Glasgow, Graham in Edinburgh, and Henslow in Cambridge, and which is that now generally accepted and taught in every institution of the country.

In 1845 appeared "The Vegetable Kingdom," with a wholly new arrangement, differing entirely from all the others he had previously been labouring to introduce. In this he restores the great hypogynous, perigynous, epigynous, and declinous divisions of Jussieu, and suppresses the apetalous, which he distributes among the other divisions. This is, undoubtedly, by far the best scheme he has ever proposed, and had he introduced such a system in 1833, instead of that set forth in the "Nixus," he might have lived to see it adopted in botanical education as a formidable rival to that of De Candolle. But this last and certainly his best effort, was the result of a gradual building up of material prepared by others. It was first of all a recurrence to the Jussieuan and Candollean systems, with the adoption of such views as had previously been enunciated by Bartling, Endlicher, Martins, Brongniart, and others, aided by the labours of our own countrymen, the Hookers, Beetham, Griffith, Gardner, Miessner, Wight, and many more, but it came too late for adoption.

It is not, however, with the view of drawing attention to what may be supposed Dr. Lindley's uncertain ideas with regard to classification that we have directed attention to these matters, but rather to show that an opinion we have often heard expressed, to the effect that it is to him we are indebted in this country for the adoption of the natural system as it is now taught, is not a correct one; and that if students in botany had relied for guidance on the works of Dr. Lindley alone, they must have experienced that feeling of insecurity that one has when in a strange country he places himself under a guide who hesitates at every deviation of the beaten track.

In 1832, Mr. Lindley received from the University of Munich the honorary degree of "Doctor of Philosophy," and henceforth he has been known as Dr. Lindley. In 1834 he published "Ladies' Botany," a work in two volumes, and written in a familiar and popular style in the form of letters; but whether the style of the letters did not suit their taste, or the subject their capacity, or whether it was that what is suitable for gentlemen is equally so for ladies, the work proved a failure, and has long since fallen into obscurity. He was a voluminous writer, and besides those of his works to which we have already referred, and numerous others of smaller character, he was the author of an "Introduction to Botany," which passed through four editions; "The Genera and Species of Orchidaceous Plants;" "Sertum Orchidaceum;" "School Botany;" "Elements of Botany," &c.; and, in conjunction with Mr. Hutton, "The Fossil Flora of Great Britain." His greatest and best works are "The Vegetable Kingdom," already referred to, and "The Theory of Horticulture," the first edition of which appeared in 1849, and the second under the title of "The Theory and Practice of Horticulture," in 1855. In 1841 he united in establishing the *Gardeners' Chronicle*, of which he remained the Editor till little more than a month ago, when he was succeeded in that office by Dr. M. T. Masters.

Dr. Lindley was a Fellow of the Royal and Linnean Societies, and a member of most of the learned societies of Europe. He was awarded the gold medal of the Royal Society, and two years ago his friends presented him with a piece of plate in the form of a candelabrum as a testimony of their regard.

Dr. Lindley was not what might be termed a great botanist. He raised himself to a degree of eminence, not so much as a botanist as a journalist, and by his connection with the Horticultural Society. With the exception of his works on the Orchidaceae, and the "Vegetable Kingdom," he has not contributed much to the store of botanical knowledge; and when we compare what he has done for the extension and encouragement of the science with the labours of Sir William Hooker, or his contributions to it with those of Mr. Bentham and Dr. Hooker, the latter of whom is a very much younger man, we are not inclined to concede to him so high a position in the rank of botanists. What he might have attained if he had devoted that time to botany which he gave to journalism, can, of course, only be left to conjecture. He was a man of an extraordinary energy and activity of mind frequently amounting to impetuosity; yet he was no genius—he had no inventive power, no originality of thought. He never made a great discovery, or propounded principles that caused men to think out of the ordinary train of thought, or out of which great results came. He had not the philosophic mind of Darwin, or Mohl, or De Candolle, and many others. His name will not rank with those of Ray or Robert Brown. But although he came short of all those qualities he had great powers of generalization and adaptation, and he could so combine and apply the views of others as to render them practical and popular, as has been so well exemplified in "The Theory and Practice of Horticulture" and "The Vegetable Kingdom." As

a teacher, therefore, he was not only well adapted, but successful. His classes at one time were well attended; and it spoke much in his favour that his students frequently numbered as many as two hundred, the greater number of whom were purely voluntary, and not compelled by any college curriculum to attend on the course. Still, as a teacher he never attained the position of Sir William Hooker, Professor Henslow, or Edward Forbes.

In his manner there was a certain brusqueness and a want of courtesy that was frequently offensive, and a disregard of the feelings of others, while freely indulging his own; but these are traits which may now be referred to the nature of his malady, which, it would appear, had been steadily yet silently gathering over him.

He was buried yesterday in the new cemetery at Acton.

#### TIME FOR PLANTING VINES IN COLD VINERY.

We have just completed a cold glass house, in which I purpose growing Vines. I have purchased some good strong plants in pots; but though the border is quite ready to receive the plants, my gardener advises their not being planted till next spring, say May. He insists that if then transferred from the pot to the border and cut back, they will make better growth than if planted now.

I cannot persuade myself that this can be, and shall be very much obliged by your opinion.—L.

[The gardener will succeed best with his own mode of operation. There would be but little difference resulting from the time of planting the Vines. In a cold wet border the roots will do little in winter, but we should prefer planting before May. With a good fresh border, and in good order, we would prefer planting now, spreading out the roots regularly, and covering the ground over the roots with warm litter, so as to keep the roots moving slowly all the winter. Then we would cut back the plants to the necessary height in spring, rubbing out all the buds except one or two intended to take the growth.]

If this care is not taken after planting we would keep the pots with the roots mulched up all the winter, and plant early in the spring before the buds began to move. We think this better in a cold house than planting after the Vine has started.]

#### PROLIFIC POTATOES.

EARLY in last March I planted a plot of ground with Lapstone and Dalmahoy Potatoes; the piece of land is 7 yards across, and was formed into drills 3 feet apart. The sets were put in in the usual way about 1 foot apart in the row. The land, a stiff loam, had been well limed in the previous autumn; it also received a good dressing of stableyard manure at the time of planting. The Lapstones when taken up in September were a little diseased, and yielded on an average 62 lbs. of useable tubers per row; the Dalmahoy tubers were taken up at the same time, were entirely free from the disease, and yielded fully 10 lbs. per row more. One row of this kind planted with large whole sets yielded 89 lbs., and one large tuber cut into eleven sets produced 51 lbs. of large Potatoes. I have no doubt that the produce of all would have been considerably larger had not the growing season been so very dry. The Dalmahoy, though not a handsome Potato to look at, yet is an excellent sort when cooked, and the quality of a Potato ought to be in the eating of it, and not in its appearance when uncooked. From my own experience with this variety I think too much cannot be said in its praise. Where and by whom was this raised?—W. L.

SECOND CROP OF OUT-DOOR FIGS.—I picked on the 20th ult. a dozen and a half ripe Figs of the second crop in my garden here. This is the first time that I ever knew the second crop of Figs to ripen in this country, and I believe it to be a very rare occurrence, even in the most southern parts of England. I have, therefore, taken the liberty of mentioning it to you now. The Fig is of the Large White Genoa kind.—WILLIAM BERESFORD, Hampton Court.

#### HEATING BY GAS.

FOR two winters I have found an oil lamp attached to one of the Waltonian cases has been sufficient to keep out the frost from a small greenhouse in the mild climate of the south of Devon. This, however, is a dirty and uncertain mode of heating it, the lamp burning low and going out early in the morn-

ing, and a stove being out of the question, from having no one to attend to it. Gas would be a never-failing source of warmth and would give no trouble; and, as there is round the water tank a chamber through which the hot air would pass before it entered the greenhouse, I should be glad to know if there would be any danger of its being hurtful to plants.—EMILY.

[A single jet of gas sufficient to heat a Waltonian case would not produce a quantity of fumes sufficient to injure the plants in the greenhouse, but the jets sufficient to heat the greenhouse would. For many years we heated a smallinery by a gas-stove, which is merely a small ornamental iron case, with a door, inclosing a ring of gas jets. From the top of the case proceeded an iron pipe which conveyed all the fumes into the open air. In another instance this pipe passed through the brickwork into a chimney.]

### CATTLEYA EXONIENSIS.

This magnificent Orchid has been in flower with me for the last three weeks, and is, I think, one of the finest of all Cattleyas, a free grower, and free-flowering. Its flowers are as large as a small bloom of its parent, *Laelia purpurata*, but better in form and colour than any of that species which I have seen, and the sepals and petals do not curl as in the parent. The plant which I have flowered differs a little from others that I have seen in flower—viz., the terminal half of the lip is of the deepest crimson purple, beautifully frilled with a white border; the lateral part of the lip is not frilled, but has a large purple margin, and a blotch of yellow in the centre, and behind that, in the throat, is cinnamon brown. The sepals and petals are of a delicate pink. I think the above ought to be in every collection. It is a seedling raised by Mr. Dominy, to whom we are indebted for many fine hybrid Orchids, but I think the above is the gem of them all.—C. KEMMERY.

### MY PLANTS,

#### AND HOW AND WHERE I FOUND THEM.—No. 12.

"Falling on my weary brain  
Like a fast-falling shower,  
The dreams of youth came back again,  
Low lisping of the summer rain,  
Dropping on the ripened grain,  
As once upon the flower.

"Visions of childhood! stay, oh stay!  
Ye were so sweet and wild!  
And distant voices seemed to say,  
It cannot be! They pass away!  
Other themes demand thy lay!  
Thou art no more a child!"

BETWEEN the counties of Essex and Suffolk runs a river, the very mention of whose name brings back to my mind slumbering visions of bygone times, childhood's days, those happy hours of pure enjoyment which come chiefly in the earlier part of our short lives, brief seasons of cloudless felicity, but which are so vividly remembered unto life's closing day. How tenaciously the memory clings to each well-remembered spot! how it conjures up the face of each merry companion of our sports and pastimes, the fishing excursions, rides on horseback, drives, walks, the haymaking-party, the visits to the gleaners in the corn fields, which, now cleared of their golden harvest, yet yield enough scattered ears to gladden the hearts of the poor. How hot the sun was! and how it poured its fervid rays upon that animated and eager party; as one of the workman said, "It didn't half shine." At such times I remember, one of our chief delights was to make our appearance amongst the gleaners, occasionally assisting to add to the scanty store of some poor decrepid old creature, who, already bowing down under the weight of eighty years' toil in this world of ours, yet persisted she could compete with her younger sisters in their laborious employment. Again, what a charm there was in distributing from a capacious basket those luscious Apples to the overheated little ones, receiving in return a full recompence from the bright and glistening eyes of the recipients. Then memory brings back days of sickness, when these same bonnie bairns, now grown into lads and lasses, sent their much-prized offerings to the chamber of sickness, in the shape of bouquets of wild flowers, or, perchance, such as their humble gardens afforded. Honeysuckle there was, all bathed in the early dew of the summer's morning, gathered as the lads went to their work in the hay fields, and left silently at the kitchen-door. No costly gift in after-years awoke keener pleasure in my breast than these thank-offerings from my village choir. Health

returned in time, and again my eyes were gladdened with a stroll in the garden, and to my astonishment, in my own particular border were springing into flower numerous plants of the Lily of the Valley (*Convallaria majalis*); in all stages of growth rose its beautiful pale-green leaves, protecting the snowy bells upon their elegant stalk—another proof of my children's love, for the roots were planted clandestinely in the early mornings some months before.

These simple and kindly thoughts made me, as a girl, a staunch defender of the poor. I regret that in advancing years these feelings were somewhat and necessarily modified, and one sighed for the unenlightened and simple belief which girlhood has in the goodness of the motives and actions of all around; yet is this belief still best kept in our relations with mankind in spite of occasional disappointments. To believe a motive pure and honourable may make a friend, whereas to doubt an intention certainly creates an enemy. Across my mind now comes a vision of our busy Sunday—certainly to us no day of rest. There was teaching in the village school, playing the organ, and teaching again, after the evening's service. Tired out we were, not from *ennui*, but from the incessant strain upon the mind, and the unavoidable talking. A quiet stroll, however, down to the river Stour refreshed us after our work. How cool were the breezes that blew across it on those hot and dusty evenings! On its banks in profusion grew the purple Loosestrife with its spike of reddish flowers, and close by its side the fragrant Meadow-Sweet (*Spiraea ulmaria*), with its white blossoms. There the Arrow-head, Bar Reeds, and Iris pseud-acorus put forth their varied beauties to the passer-by, and most beautiful of all the Flowering-Rush, whose umbels of rose-coloured flowers, we, as girls, all eagerly sought after at the peril of a ducking in the stream below. The pretty melancholy Forget-me-not, with its blue eyes, which speak to each heart more or less of love, and often of sadness and parting, grew on our river's banks in great luxuriance. The legend connected with the name of this flower awakens in our hearts a sympathetic feeling for the fate of the young lover who, sinking in the water, threw a handful of these flowers to his distracted mistress, uttering with his dying lips "Forget-me-not." In Germany this flower is used to deck the resting-place of the loved and lost. Ragged Robin, and the brown flowers of the Water Figwort, increased the beauties of our river bouquet; and now, perceiving the fog arising around us, we slowly wend our way along the wood side, taking a last look at the setting sun which is casting a glorious coronet of crimson light above the hills behind us. A light supper and to our chamber to seek that healthy sleep, which is so rich a gift, wafted on the bonnie country air. Priceless boon! how oft thou art the companion of the poor man's couch, and flyest the draped chamber of the rich! No need have we, however, to woo thee, care has not yet stamped our young brows, and

"There is in the air  
A fragrance, like that of the beautiful garden  
Of Paradise, in the days that were!  
An odour of innocence and of prayer,  
And of love, and faith that never fails,  
Such as the fresh young heart exhales  
Before it begins to wither and harden!"

Such was our case: "Sleep, balmy sleep!" and fairy dreams blessed us all the night, and we were up early, busily preparing for a day on the river. Quickly we get over our breakfasts and pack our baskets of necessaries, look well to our fishing gear, and with proud and bounding hearts take down with us a sail, which we have made for our boat, the effects of which we are to try for the first time on our winding stream, the numerous bends in whose banks, and the consequent changing of the sail from side to side, make it rather a hazardous affair. So much the better for young adventurers! Chattering and singing alternately, and making our boy carry the weightier part of our luggage, we arrive at a back-ditch in which our little craft is safely stowed away from the prying eyes of predatory bargemen. My brother piloting her into the river, we are soon seated; he and I take possession of the oars, and we are gently moving down stream. Oh, happy days of sunny memory! when, moored beneath the dark green Alders, we dropped our lines into the sparkling waters, and silently, and breathlessly watched for the bobbing of our floats, precursor of the triumphant landing of some unfortunate pike, perch, or roach, to be hereafter produced in a more enticing form upon the dinner table at the Hall. Every now and then the beautiful little kingfisher would dart from beneath the Alders, and securing his prey with the most perfect *nonchalance*, would make his meal upon a branch close by us; most likely he is discussing

the merits of one of those little gudgeons which swim in shoals and disport themselves in that bright gravelly spot under the water near our right. Tench and carp will add to our day's sport, for these fish also are found in the Stour. Earth, which from time to time had accumulated in one spot, formed green islands in the water, being covered by Reeds and Sedges, the favourite resort of the reed-bunting and water-hen, with its tiny brood; and there we occasionally took our lunch, and, sheltered for a while from the overpowering heat of the mid-day sun, ballads and glees we sang, as only such light hearts could sing, making the occupants of a passing barge stare as they heard sounds proceeding from a place usually unawakened, save by the incessant chattering of the bunting. Amongst the Reeds grew abundantly our favourite Forget-me-not; wreaths we gathered of it for the evening's social gatherings, when our morning costume should be discarded for one more befitting the votaries of Terpsichore.

"In all places, then, and all seasons,  
Flowers expand their light and soul-like wings,  
Teaching us by most persuasive reasons,  
How akin they are to human things!"

—ALICE.

### A VINEYARD UNDER GLASS.

ANOTHER doctor ventures to give you a description of his Grape culture without fire heat, and he does so the more willingly in gratitude to Mr. Rivers for his suggestion of a "vineyard under glass."

As yet, I have not seen an account in any journal how this mode of treating the Vine has answered. But as my friends and patients (many a grateful smile have I had for a fine bunch of Hamburgs), declare my house is a great success, I will give a short description of it, in the hope that many of my brethren, worn in body and mind, will follow my example, and find in it the same solace and relaxation that I have.

My vineery is a span-roofed orchard-house, 30 feet by 14. It was erected in the spring of 1860, and is made entirely of wood, iron, and glass, at a cost of £35. At one end I planted about six Vines in the border, 30 inches apart (3 feet is a better distance), and trained them as bushes to iron rods, 6 and 7 feet in length. At the other end I attempted to grow Peaches, Nectarines, and all the other stone fruits in pots; but year by year the Vines have encroached on their neighbours, and the house is now entirely filled by them. This is due to the Vine bearing a little neglect, and not being so liable to the attacks of insects. My failure in the cultivation of other orchard-house fruits is, I freely confess, due to myself. I have seen such superb fruit in the houses at Sawbridgeworth, and in those of Mr. Bréchant, in Guernsey, that I now know what can be done by the assiduous care and attention of a man who can command his own time.

In this one house I grow thirty-nine Vines (twenty-six varieties), all bushes but two, a Golden Hamburg and a West's St. Peter's, which run along above the path, and 2 feet below the ridge-board. The path is central, and the bushes are planted in two rows in the borders. In the autumn I prune each shoot to two eyes, not leaving more than two stumps to each joint. I can assure "J. H. H." that cutting to no eye does not answer. I have tried it; wood only is formed. In the West Indies, to secure two crops in one year, I am informed that all the spurs that have borne the first crop are cut off directly the Grapes are gathered, and that the dormant eyes of the naked stem break and bear well. The climate of England does not ripen the wood sufficiently to allow our Vines to bear such treatment.

The Vines that have reached maturity and have borne well this year are the Sweetwater, Muscat St. Laurent, Mill Hill Hamburg, Black Hamburg, Golden Hamburg, Grizzly Frontignan, West's St. Peter's, and Muscat of Alexandria. The Black Hamburgs have been superb in size of herry, colour, and bloom, even to within 20 inches of the ground, and the largest bunch weighed 22 ounces. West Somerset must be a more favourable locality for the Grape than Huntingdonshire, for I cannot join your able correspondent, "J. H. H.," in his complaint, and condemn my Hamburgs for deficiency of colour.

My borders are made of light friable soil from the garden, and they get in the autumn a liberal top-dressing of fowl manure. The subsoil is gravel.

It is rather with a troubled conscience that I write this paper. I may be riding my hobby too hard. Will you, therefore, be so kind as to append your opinion of the samples that I send you,

which are not to be taken as specimens of best bunches, they having been gathered some time since?—M. B., *West Somerset*.

P.S.—A word more to those of my medical brethren who have but a few feet of garden wall. Try Mr. Bréchant's system of diagonal cordon training of fruit trees. I have seen that it is good.

[The *Black Hamburg* was well grown, and as highly coloured and richly flavoured as could be desired. *Golden Hamburg* was dead ripe, and had hung rather too long, the point of union between the berries and the stalks having begun to decay; but the flavour was excellent. *Mill Hill Hamburg* required to hang longer. It is not so early as the old *Black Hamburg*; the specimen, however, is very good both in the size of the berries and the colour; the flavour will be unexceptionable. *West's St. Peter's* is not nearly ripe, and we doubt if it will ever acquire such a pitch of excellence in flavour as the others. It requires more heat than you can give it in an orchard-house. The same remark applies to *Muscat of Alexandria*, which, although good and highly musky, is not nearly ripe. *Grizzly Frontignan*, we think, cannot be true. We cannot detect any *Frontignan* flavour in it, and we are rather inclined to think that this is *Chasselas Rouge de Falloux*, or one other of the *Red Muscadines*. It is perfectly ripened, and very good as well as handsome. Altogether the collection is very interesting. You are labouring under the same mistake that many make in calling the *Royal Muscadine* the *Sweetwater*. What you have under the latter name is the *Royal Muscadine*, and a very good bunch it is.]

### MANAGEMENT OF MOWING-MACHINES.

SINCE writing my former letter about mowing-machines, I have again tried the effect of emery on the cutters of mine, and found it answer perfectly. The reason of its failure before, I find, was attributable to the smith I employed not applying it in a proper way, and screwing the cutters too tightly against the ledger-plate. I will, therefore, relate the modes of proceeding for the benefit of those who may require it.

I took off the small rollers, freed the iron ones from the pinion, set the knives so as just to touch the plate, placed the machine upon a table, and allowed it to recline on its handles. I then fixed a handle to the end of the axle, poured a quantity of fine emery into the hollow of the concave-plate at the back of the cutters, and turned them the reverse way. They carried the emery with them as they rotated, and it was continually swept up and again poured regularly along the before-mentioned hollow. In a short time I found they would cut a hair through if placed against any part of the plate. I beg to thank your correspondents for their several replies, and think with "W. C.," that finely-sifted sand would be a good substitute for emery.—*VERAX.*

### RAINFALL IN OCTOBER.

THE past month having been as extraordinary for the amount of its rainfall as the previous months were for drought, I expect that we shall hear of floods more or less disastrous. In Kent September was remarkably dry, the average heat of the first twenty days and nights together exceeding that of any similar period of consecutive days since July, 1857. The latter part of the month was also warm, and the dry hot weather continued up to the 9th of October, having commenced on the 25th of August. During that time only eight-hundredths of an inch of rain fell, and that was apparently what remained of a thunder-shower, which had spent itself elsewhere. Previous to the 25th of August we had some very heavy rain, which prevented vegetation suffering so much as it would otherwise have done; but in the first week of October the pastures and lawns were brown, and burnt up with the heat. A copious rain on the 9th, 10th, 11th, and 12th, amounting to 1.39 inch, was of great service; the next four days were fine and dry, but on the 17th rain fell in more than ordinary abundance. From then to the 31st 6.75 inches of rain fell; almost half an inch a-day. This is a greater rainfall than I have any record of for the last twelve years. The total rainfall in the month was 8.14 inches; that in the wettest month during the above period of twelve years (November, 1861), was 6.10 inches. The ground being dry at the commencement will no doubt account for so little of the rain making its way into our rivers; nevertheless I hear of some districts under water, and as 1.23 inch of rain fell on the 31st, when the ground had been tolerably well soaked beforehand, I expect to hear of much

of the level land bordering on the Medway being flooded. One of the tributaries of that river has spread itself over the adjacent flats for a mile or more wide in places.

These heavy falls of rain following a period of unusually dry hot weather have given the season a somewhat tropical character, especially as the dry period was preceded by a similar wet one, and that again by the hot dry month of June. It would be idle, I fear, to deduce anything from this unusual state of things, as it may be completely reversed another year; but it would be well to ask some of your many readers, who keep a register of the rainfall of their respective districts, if they ever before experienced so much rain in so short a time? Of course it is needless to ask the question of those residing amongst the Cumberland and Westmoreland hills, nor, in fact, of any of those bordering on the west coast, where the rainfall is so heavy; but I believe so very wet a period is without precedent for many years in this part of England, the most of the rain falling in what appeared to be thunder-showers. I hear of some whose registers show even greater rainfall than at Linton Park; would some of your readers be kind enough to report their experience, that a comparison may be made?—J. ROBSON.

### VINES ON A GLASS-FRONTED WALL.

In an obtuse angle where two open walls join we have a White Frontignan Grape Vine facing south-east, and a Black Hamburgh facing east. This year the Grapes are ripe, and very fine, but in ordinary seasons they do not ripen. We have been thinking of putting glass over the Vines, as they are established there, having been planted about thirty years. Would glass over them ripen the Grapes in ordinary seasons? and if so, what sort of a house would you recommend, having regard to economy as well as efficiency? The walls are 10 feet high. Would glass the same height in front, with a short span roof, be advisable? We have some old spare lights that are 9 feet long, would they be of any use in the construction? and what ventilation would you advise? If we use the old lights in an upright position, what width from the wall would you advise? Would it be better to use the old lights for a roof, and make a lean-to house with them? and in that case, would it be a good plan to have a small light between every light to open for ventilation, something after the same plan as in the Paxton houses?—INQUIRER.

[We have no doubt of the Grapes ripening in general seasons, where there is a fair amount of sunshine, if you attend to ventilation early enough, and take it away soon enough to shut up a certain amount of the sun's rays. This season is not a criterion to go by. We have seen Grapes in Bedfordshire, on the open wall, that would have passed for hothouse Grapes, but we cannot expect many such seasons, and, therefore, the glass would be an advantage. We think that the different plans you propose have each their own advantages, and that their superior fitness is more dependant on your own taste than on anything superior in the plan of making the most of your nine-foot spare lights. Thus you might have a nice upright fruit-house on the Trentham plan, from 4½ to 5 feet in width, by having a short double span for the roof, the apex some 15 inches above the top of the wall, and half of the span to open for a ventilator. Your nine-foot sashes could then stand on a stout rail or plate, supported on posts 1 foot above the surface of the ground, and a board could be hinged there for bottom ventilation.

If you adopted the Paxtonian system, and your sashes are strong, you could dispense with rafters. Have merely a receiving-board beneath the coping for one end of the sash, and a strong rail on posts, 2 feet from the ground, and 5 feet from the wall, to support the other end, fixed in its place by screws. Small sashes 4 or 6 inches wide, or even a board if the sashes consisted of large squares, could go between sash and sash. The front could be boarded up or covered with asphalt, water-proofed calico, &c. Of course, you could build a wall if you liked. By this plan, however, your glass will join the roof at a very acute angle, and for a foot or two there you will not easily get at it. To neutralise that we would have a small lean-to hip there, especially if you decided on rafters—say larch poles cut down the middle; and if that hip, whether of wood or glass, were some 15 inches wide, you could have the house all that wider, and you would have more room. If that lean-to hip were 15 inches wide, or even 18 inches, the top underneath the coping, and the lower part just over the top of the front sashes, these could be placed so as to give you a

house of from 6 to 7 feet in width. The front wall might be of boards, bricks, or whatever you pleased, and should be about 2 feet high from the ground. With such a lean-to hip of wood, but better if partly of glass, we would have 9 inches of it to open for ventilation, and a similar space in the front wall opening—say by means of a hinged board, and then we would fix all the sashes at once.

You cannot have all the advantages by any one mode. Presuming that you would not like to make ventilators in the back of your wall, your simplest plan would be to fix one end of your sashes below the coping, the other end on a rail or plate from 4½ to 5 feet from the wall, and from 18 to 24 inches from the ground, closing that space with anything the most handy. Fix the sashes, with from 3½ to 4-inch openings between them, and fill that opening at first with a thin board hinged on, cut into two lengths, so that you can give air to the top part first. This would cost very little, and you could alter it afterwards by merely unfastening the sashes.]

### WEST HOUSE, CONGLETON.

THE RESIDENCE OF JAMES PEARSON, ESQ.

WEST HOUSE, originally the property of Mr. Patterson, late Governor of the Bank of England, is one of those pretty suburban villas of moderate extent and in good keeping, that are occasionally to be met with in the environs of large manufacturing towns. I had the privilege of calling at this place a few days ago while on a ramble through the neighbourhood, and the extreme kindness which I received from the worthy proprietor, and the affability and attention of Mr. Chaddock, the head-gardener, rendered the visit most agreeable.

It struck me forcibly that in this age of travelling, many have an impression on their minds that in order to see what is grand and beautiful we must take tedious journeys from home. I remember about twelve months ago being much pleased with an interesting article by Mr. Robson, in the pages of this Journal, in which he strongly recommended gardeners to visit places far from home. I then agreed in the main with all that he said, and being acquainted with most of the places mentioned, I can vouch for the rich treat there is in store for any gardener wishing to explore those districts. The wealthier of our neighbours not specially interested in the progress of horticulture, and yet requiring a little relaxation from the common avocations of life, seek out spots famous either for health or pleasure; they resort to some noted watering place on the British coast, or they seek out some inland spot remarkable for its scenes of attraction and beauty. They must either go to the Vale of Clwyd, the Lakes of Windermere, or Walton-on-the-Nase; but it is a certain fact that, great as are the means of travelling, and the cheap excursions offered by the different railway companies, it is not always convenient for gardeners to leave their places for many days together, nor have they all the means to do so. My residence being the charming village of Biddulph, about four miles south-east of Congleton, I determined to call upon some of my neighbours; so after an early dinner I sallied forth, resolved to seek out near home some of those places where gardening is cherished, and having jotted down a few notes by the way, I here present them to the readers of THE JOURNAL OF HORTICULTURE.

The first part of my journey being performed on foot, I was anxious to make the best of it, so I chose the way past Biddulph Hall, an old-fashioned mansion situate on the summit of a high hill, but lying partly in ruins. As I stand by the old dilapidated place a glorious scene of unrivalled beauty appears. To my left, and only about a quarter of a mile distant, lies Biddulph Grange, surrounded by the far-famed gardens of James Bateman, Esq.; a little further on stands the venerable village church, surrounded by its old Yew trees, and beneath the shade of which and the shadow of the old spire, many of "the rude forefathers of the hamlet sleep." In the churchyard there are some ancient tombs, bearing crosses, pickaxes, swords, &c. A little beyond stand Knyppersley church and schools, built by the late respected owner of Knyppersley Hall, Mr. Bateman, sen.; and a little distance from the church are the gardens renowned for Mr. J. Bateman's large collection of Orchidaceous plants, and where the visitor finds himself at once transported from the bleak district around into the wild luxuriance of a tropical world. In addition to the Orchids is the span-roofed vinery nearly 200 feet long and 20 wide, and there are many houses of smaller dimensions. Near this place rises the famous river Trent, as also a branch of the Dane. Before me at the other

side of the valley is the celebrated mountain called Mow Cop, noted in history; and on its summit, which is nearly 1100 feet above the sea level, is the old tower around which has gathered many a jovial pic-nic party. Behind me is a range of hills

that take their rise at the Cloud, a fine dome-shaped hill about two miles east of Congleton, and from which south-eastward rise the rocky ridges about Biddulph, Knypersley, Brownedge, &c. By my side stands the ancient Hall of Biddulph, built by

*Pinus excelsa.*

*Wellingtonia gigantea.*

*Pinus excelsa.*

- 1. *Calceolaria Aurea floribunda.*
- 2. *Verbena Purple King.*
- 3. *Geranium Stella.*
- 4. *Geranium Alma.*
- 5. *Calceolaria Aurea floribunda.*
- 6. *Calceolaria Victor Emmanuel.*
- 7. *Lobelia Paxtonii.*

- 8. *Tropaeolum Lobbianum elegans.*
- 9. The outer row next to the Box edging. *Cerastium tomentosum*; next this *Lobelia speciosa*; and the centre filled with yellow and white-edged *Geraniums* alternately.

Francis Biddulph in the fifteenth century, and now in the possession of Mr. James Bateman. As I stand and gaze on the scenery for a few moments, I cannot help thinking of the bloody struggle which here took place, according to the stray relics of history and tradition, more than two hundred years ago, when the Hall was defended by the royalists. The Protector placed his large guns on the hill adjacent, but being

unable to accomplish his work of destruction at such a distance, he was compelled to cross the valley with his staff and take up his position on a more favourable spot on Troughstones, a high eminence, one of the ridge of hills just named. From this point he demolished the Hall, and the Royalists finding they had no chance of success, surrendered to Cromwell's army. I now pursue my course onward into the valley, and cross

the warbling brook on an old rickety plank, a peer substitute for a bridge.

Apologising for this digression from the heading of my subject, I pass on to West House, the object of my travels. The mansion and grounds are situate at the western extremity of Congleton; and though the grounds are so closely adjacent to a thickly populated portion of the town, yet the visitor, when walking over the green velvety sward, or pausing for a moment beneath the shade of the tall trees to admire some object of interest, has no idea but that he is visiting some country seat far away from the bustle and clamour of town life.

As the grounds are entered the house lies to the right. It is a square-built mansion not of palatial pretensions, nor yet of architectural beauty, yet presenting a very pleasing exterior, and fitted up internally with considerable elegance. Its internal arrangements are admirable, and offer a vast amount of domestic comfort and convenience. The kitchen garden lies to the left surrounded by turreted walls, but not discernible from the house. The stables, carriage-houses, yard, &c., are on the west side of the mansion, and judiciously screened from view by large Hollies and other evergreen trees of extraordinary size. In the kitchen garden there is a large vinery 100 feet long and 20 wide, the roof being covered with good Grapes of such varieties as Golden Hamburgh, Muscat of Alexandria, White Nice, Black Hamburgh, Black Prince, &c., the black varieties possessing that jet-black hue which is so desirable in Grape culture, instead of that dingy red colour which is too frequently met with in these wonderful days of Grape cultivation. Beneath the Vines, I noticed large Orange trees and Camellias, and in addition a miscellaneous collection of flowering and fine-foliated plants, including in the former Achimenes, such as Mauve Queen, and Sir Treherne Thomas; Gloxinias, &c.; while in the latter were Caladiums of every tinge and hue, Begonias, Ferns, &c. Passing out of the vinery we enter a Peach-house; here is a trellis a short distance from the wall to which the trees are trained, the path running in front of the trees. This system is in advance of what we occasionally see, where the trees are trained to a trellis below the glass, where only an occasional glimpse of the fruit can be obtained through the foliage. The trees were in a vigorous state of health, and the best mode of praise I can confer on the fruit is, that it was such as Mr. Chaddock usually grows. On the walls outside I noticed some very fine Plums—such as Goliath, Nectarine, Green Gage, &c., which took a first position at the Cheshire Agricultural and Horticultural Exhibition, held at Congleton about three weeks ago.

Leaving the kitchen garden and wending my way towards the front of the mansion, I noticed a magnificent specimen of the Purple Beech (*Fagus sylvatica purpurea*), its branches extending 150 feet in circumference. In front of the house is a neat and well-kept flower garden. The beds are all edged with Box, and the walks covered with white gravel. The plants in the various beds were all in full bloom when I visited it, and the colours were nicely balanced and produced a good effect. The accompanying is a plan of the flower garden, one well adapted for places of limited dimensions. At the farther end from the house, opposite the central walk, was a Wellingtonia, and on each side a Pinus excelsa. Near the flower garden I noticed a small piece of water, in which were luxuriating beautiful Nymphæas. A bed of superb Gladiolus produced an imposing effect. The dressed grounds are separated from the land below by a raised bank of Rhododendrons, and in front of these was a winding ribbon-border, of which the first row was a broad belt of *Cerastium tomentosum*; 2nd, *Lobelia speciosa*; 3rd, *Tropæolum Lobbianum elegans*; 4th, *Calceolaria Aurea floribunda*; 5th, *Stella Nesegay* Geranium, the background being the Rhododendrons.

The view of the adjacent portion of the town is entirely excluded by a large mound of earth and rockwork, which it took the proprietor years to raise at a great cost. It extends the whole length of the pleasure ground, and is diversified by evergreen shrubs. From the northern side of the mansion views of a charming landscape are obtained; in the distance may be seen the village church of Hulmewallfield, and in the valley the river Dane flows in a winding stream.

Before taking leave of the subject before me, allow me to suggest to my brother gardeners, that they might profitably employ the few hours at their command by visiting occasionally some of our delightful suburban villas. There is frequently something to be picked up even where no pretensions to display are attempted. Things that appear trifling in themselves sometimes may be of great importance in their results,

and for that reason not to be despised, even when found in places where we least expect to meet with them.—QUINTIN READ, *Biddulph*.

## NOTES FROM OUR VILLAGE.

PERHAPS you will be kind enough to allow me space in your Journal—perhaps I should be going too far to say in "Our Journal," but really it sounds so familiar that I cannot help so speaking of it, for it is a great favourite of mine. I am always glad when my master hands it over to me, which is generally not later than Wednesday evening, and it is my pocket friend until I have well read and digested every article, and then I anxiously wait for the next.

Now, I should like to jot down a few notes from "our village," beginning by saying a little about the Celery fly and maggot, as it has been very troublesome here this season. The first thing I should like to know is, What fly it really is, I hear so many different opinions about the fly! I have always seen a small light green-coloured fly about one-quarter of an inch long on the Celery on summer evenings, and as we have walked between the rows it has taken wing from the Celery in front of us, and our head-gardener used to say that that was the fly that did the mischief, and he is a man of thirty-years experience in his present situation. Now, as a preventive, I find nothing is better than to sprinkle the foliage over with water, and then to dust it with a mixture of lime and soot, and if you add a little sulphur all the better. Always pick off an affected leaf and burn it.

Now, I always thought that the maggot as soon as hatched in the leaf kept continually feeding until it had finished that leaf, then fell to the ground, and there was an end to it for the season; but from watching carefully this season I find several in the morning outside, on the upper surface of the leaf, and I think that they enter again in a fresh place, if so, the sooner they are picked off the better.

Another fact I must mention; I have often seen the robin picking them off the upper side of the leaf early in the morning.

Potatoes have been very much diseased in this district; I have had some of the finest I ever saw, and a good crop as regards quantity, but the diseased were three to one that was good.

Carrots and Parsnips are very good; in fact, this is a Carrot year with us about Bickley. We are making Bickley quite a large horticultural locality, and, above all, we are about to establish a working man's reading institution for lectures and readings. It is supported by very influential gentlemen. We have Sir John Lubbock, Bart., as President, other gentlemen are patrons, and one gentleman, Coles Child, Esq., has given the ground, which is freehold.—J. R. P.

[In our very earliest volume we published a drawing and description of the Celery Fly, which we will now repeat for information to the present generation:—

"In the autumn it is very common to observe part of the leaves of Celery plants blistered and turned yellow; and this

occurs occasionally to such an extent that their growth is checked and their size proportionally diminished. If the withered parts are examined, and the cuticle, or skin, of the blisters, is raised, there will be found beneath it some small green grubs, which have eaten away all the green pulp (parenchyma) of the parts so withered. These grubs are the larva of the Celery Fly (*Tephritis/Onopordinis*). The grubs may be found in the leaves of the Celery in June, July, September, October, and November; for there are two or more broods of them in the course of the year. The grubs, though less frequently, are found doing similar damage to the leaves of Alexanders and Parsnips. When full-grown, the grubs descend into the earth and remain in the chrysalis state until the spring following, when they give birth to the fly. This, the Celery Fly, may usually be found upon

the leaves of the Laurel, hovering over flowers and resting upon palings in the sunshine, from the middle of May to the end of July. It is one of the most beautiful of the English two-winged flies, and has been thus described by Mr. Westwood. The general colour of the body, which is five-jointed, varies from rusty-brown to shining black; head buff, with black hairs; legs yellow; thorax (throat) sprinkled with long black hairs; wings black, with various pale spots; eyes green. The whole length of the insect is not more than one-sixth of an inch, and its wings, when outspread, barely half an inch across. The cross-lines in our woodcut shows these proportions, as well as the insect magnified. The motions of this fly are very peculiar, seated upon a leaf in the sunshine, the wings are partially extended, yet partially elevated, and it has a sideling kind of motion. The withered leaves of the Celery should be picked off, and the grubs within them crushed as soon as seen. Mr. Wedgwood suggests that a string, smeared with birdlime and stretched over the Celery-plants, might catch many of the parents." ]

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

If any esculent roots remain in the ground they should be taken up immediately. *Asparagus*, the haulm may now be cleared off, cleaning the ground and giving a good dressing of rotten manure, and in the case of young plants, which are only very lightly covered, the manure might be mixed with a quantity of leaf mould, applying a good solid coat 2 or 3 inches thick if the manure and leaf soil can be spared. *Cauliflowers*, the plants in head, if not wanted for use, may be pulled up and hung in a cool shed, where they will keep for weeks, and be out of the way of injury from frost, unless this should be very severe. *Celery*, the late crops should now be earthed-up rather closely, making the ridges as narrow as the top as conveniently be done, and nicely finishing the sides with the back of the spade, so as to prevent, as far as possible, the soil about the plants becoming saturated with wet. The soil about the early crops, or that fit for use, should also be made to throw off the wet as much as possible, pressing it firmly about the tops of the plants, and making the top of the ridge narrow and smooth. Of course Celery will not be earthed-up after this season, when the plants are wet, neither should it be done when the soil is wet, if this can be avoided. Mixing plenty of quicklime with the soil about the plants will be found of considerable use in preventing their rotting in winter, and it will also save them from being disfigured by slugs. *Endive*, continue to blanch it by tying up or by wrapping the leaves together and laying two flat tiles on each plant, so as to form a slight ridge, one tile overlapping the other. *Cabbages*, earth-up those planted for Coleworts for winter and early spring use; look over the principal plantations frequently to see if slugs attack the plants, if they are numerous lay a quantity of Cabbage leaves on the ground and examine them daily, a pail of hot water or some lime may be taken round at the same time and the slugs shaken into it. Thus many thousands may be destroyed at this time of year. *Lettuce*, pay the same attention to the autumn plantations that was recommended for the Cabbages. Give air to the young plants in frames daily; Cabbage Lettuce in frames for winter use will not require much air. *Peas and Beans*, a few may be sown on a dry and warm border. They are sometimes covered with cinder ashes, which is a bad practice, and they are liable to go off in the spring from that cause.

### FRUIT GARDEN.

If fresh trees are to be planted in old borders let it be done with as much care as possible, a harrow-load or two of fresh soil may be put into each hole and mixed with the soil of the border. Let the holes be made sufficiently large for the roots when laid out straight; it is by inattention to this that snickers arise, which is in a great measure caused by cramping and twisting the roots. Strawberries for early forcing should be placed where they can be protected from drenching rains—a cold frame or pit, when either can be spared, would be the best situation for them, but the lights should not be put on save in case of rain or frost, and, indeed, the whole stock in pots for forcing would be benefited by being placed where it could be guarded from heavy rains. Let there be no lack of attention in the fruit-room at present, for fruit requires more care during the first few weeks after gathering than all the season afterwards. Give just sufficient air to carry off damp, but nothing more, as allowing dry winds to blow over the fruit would only cause shrivelling.

### FLOWER GARDEN.

Those who purpose making additions to their collection of Roses should do so at once, as there will be a better chance of obtaining good plants now than after the nursery stock has been repeatedly picked. The present season is also very favourable for planting all but tender sorts, which had better be kept under glass until next May; but these should be procured at once, and if they can be placed in a gentle heat through the winter they will grow freely, and furnish cuttings which will root just as freely as Verbenas. In preparing ground for Roses, let it be trenched at least 2 feet deep, and well incorporate a heavy dressing of manure with the soil to the full depth. It is hardly possible to make the soil too rich for any kind of Rose, particularly the autumn-blooming kinds, and 4 or 5 inches of good rotten farmyard dung will not be too much where the soil is naturally rather light and poor. Large-headed standards that have done blooming for the season should be cut back pretty freely to lessen the chance of their being injured by heavy gales of wind. Continue to clear the beds of their summer occupants, as these become unsightly, and after trenching or doing whatever can be done to save time next planting-out season, furnish them for the spring. The principles of protection are few and simple, and may be said to be within the reach of every one, at least as far as such can be carried out without the aid of houses and artificial heat. A comparative degree of dryness is the first great essential, whether in the atmosphere or the soil. In a frame or pit this amount of dryness cannot be guaranteed without motion in the air, and this, of course, in the absence of fire heat, must be accomplished by a very free ventilation at every fitting opportunity, remembering that a small amount of frost is, in general, less prejudicial than an accumulation of damp, which will rapidly tend to a kind of mortification in the system of the plant. The same atmospheric conditions are to be obtained out of doors as far as attention can secure them: thus half-hardy plants, against trellises or detached, if covered with a mat stuffed closely with hay inside, will be in danger of perishing of what we may for the present term suffocation; the same specimen will always pass through a long winter better with the mat alone, more especially if the collar is well protected by some dry and porous material, and above all, the roots well top-dressed with sawdust or ashes.

### GREENHOUSE AND CONSERVATORY.

Take advantage of unfavourable weather for out-door work to thoroughly clean the foliage of Camellias, Orange trees, &c., for it is hardly less essential to the health of such plants that their foliage be kept clean and in a fit state to perform its functions than that their roots be kept healthy and active. Look over the plants in the greenhouse frequently, and examine plants very closely that are liable to suffer from mildew and damp, such as *Leschenaultias*, *Boronias*, &c., for a short neglect will sometimes result in the disfigurement of a promising plant. The *Boronias*, *Leschenaultias*, *Gompholobiums*, &c., are very impatient of exposure to cold drying winds, but air must be admitted by the top sashes freely on fine days. Young specimens of *Azaleas*, which have been growing in heat, had better be removed to a cool house for a few months, which will cause them to start away more freely in spring. Keep *Cinerarias* and other soft-wooded stock clear of green fly, and endeavour to secure stocky plants by affording them sufficient pot room. The bulbs of *Japan Lilies* to be shaken out of their pots, and to be re-potted in half good fibrous loam and half peat soil, or decomposed leaf mould as a substitute for peat, with a small portion of silver sand. As the bulbs, when making their spring growth, emit roots for 2 or 3 inches up the stem, they will now require to be planted that depth from the surface of the pot, and to be earthed up with the compost in the spring.

### PITS AND FRAMES.

Roses for early forcing should be pruned by this time, and placed where they will at least be safe from heavy rains. Where American and other shrubs are used for forcing these should be taken up and potted without delay, placing them in a cold pit until they are wanted for forcing, or in a turf-pit where they can be protected from severe weather, by straw mats, shutters, or other covering.—W. KEANE.

## DOINGS OF THE LAST WEEK.

*Tidiness*.—As well attempt to wash an Ethiopian white as to keep all trim and neat in gardens now. Ere long we shall be glad of a sharp frost that will finally settle all the summer

flowers in the flower garden, and so bring down the leaves of deciduous trees that a rake and a brush will be somewhat telling. Now, all work of this description requires to be begun again before it is well finished. It is do, do, and never done. Unless where there is abundance of labour, and in cases where the lawn would be injured by a thick deposit of leaves, it generally becomes a matter of necessity to keep all tidy in the principal places, and allow the rest of the domain to be somewhat rough until a more general cleaning up would be more effectual. It must be remembered that we have nothing to say against the extreme of tidiness where it can be attained, and it should if possible be attained in places that come prominently and regularly before the eye of a resident proprietor; but in most places where work, needful work, has to be done, there is something unsatisfactory and next to tantalising in using a broom on a lawn all day, and then from the falling leaves being unable to perceive in an hour or two any visible proofs of your workmanship. Than this want of visible result there is nothing in the whole field of labour more depressing to the workman. We do not say that the lawn would not be better if swept and rolled every day, even amid the falling leaves; we only say that, carried on continuously, the doing, doing, and never done exercises in time a depressing influence, and one that often will not be removed when the occasion has passed away.

This constant cleaning and never clean also tends to keep back other work, as mowing, planting and transplanting, turfing, &c. If the full benefit is to be derived from the fallen leaves, they will be more serviceable every way, keep their heat much longer, and be more easily brought home if collected somewhat dry instead of wet. Besides, at this season most trees in their changing and fading foliage have a beauty peculiarly their own, and many are more attractive than when appalled in the luxuriance of summer. As we lately admired some beautiful Thorns, the foliage of various colours, but adding a richness to the large yellow, and scarlet, and crimson fruit with which the trees were loaded, we could not help thinking that the leaves and fruit that studded the grass added to, rather than diminished, the attractions of the scene. Call such thoughts poetical instead of practical if you will; but many will be glad if such poetry would pass current, instead of their being forced to neglect necessary work for the never-ending use of the broom on the lawn, though far removed from the mansion. We have met with several instances where the most important work was always necessarily behind, because a large lawn had to be kept rigidly neat at all times. Part of the lawn at a distance from the house was devoted to Pinuses and the finer deciduous trees, and in these circumstances it would have been much preferable to have allowed the ground there to go roughish, or even to be covered with low plants of Furze, Broom, and other shrubs. We feel sure that with plenty of room to spread, the Pines, &c., would even look better in such circumstances, more natural even, than when the ground was brushed about them several times a-week just now. The saving of unseemly and therefore often unappreciated labour would be immense.

#### KITCHEN GARDEN.

*Blanching Celery.*—Here, on Thursday, being our only dry day, we brushed our Celery with a light broom after breakfast, to cause it to dry sooner, and then set to tying each head up with a strand of matting, after seeing that no suckers were left, and earthing it up, placing dry siftings from coal ashes round the stems, which will keep slugs and worms from them, and help to keep moisture and frost from injuring them. But for the frosty mornings we would not have hastened this operation, as large Celery is easily injured by frost, and especially after it has received a little earthing-up. Smaller heads that are planted shallow and without earthing-up, will often stand uninjured in frosty weather. Just in proportion to the care and coddling given to them, will be their liability to be injured by frost. Instead of earthing-up too high, we prefer now, if we had the material, to place a layer on the top, packed in close to the plants, of tree leaves, stubble, or litter of any kind; and this is more necessary when the Celery is grown in beds, as if this covering material is raised a little in the centre, as soon as it becomes smooth and firmish there, it will send off the rains as well as keep out the frost, as the whole of the loose light stuff beneath the eaked surface will be a porous non-conducting material. Six inches will be enough of this porous material, especially at first. In severe frost a little may be placed over the tops of the heads and removed when the frost is gone. Mr. McDonald, of Woodstock, Ireland, uses moss for

blanching with very good effect. Some use tubes of earthenware. Half-circular or half-moon tubes are good for placing round the plants, if you use ashes next the stems, but good workmen manage all that nicely with a few boards, drawing them out and pressing the earth to the ashes. We generally manage to have a heap of unsifted ashes at this season for the purpose—a matter of importance on our heavy soil. We use a sieve with quarter-of-an-inch openings, or rather less. What goes through is used for this purpose, and what remains goes to the furnaces. Cauliflower coming in, we protected by placing several leaves over the head. We have not yet moved that or Endive under protection, but the sooner it is done the better and the safer the Endive will be.

#### FRUIT GARDEN.

Much the same as in the previous week. Had protection ready for Strawberry-pots if necessary. A lot showing bloom, especially of Black Prince, have been put under glass, so that they may not be injured. No time should be lost in preparing for planting fruit trees in the modes recently alluded to. If not done presently, there will be little gained in doing it until March. Threw a little stubble on the Vine-border; pruned and cleaned part of the first Peach-house; drew a light broom over Peach and Apricot trees; took off the leaves and fruit from plants in the small Fig-house, and, but that the fruit was asked after, would have done this by the middle of October, as that is long enough for Figs to bear, if they are expected to bear early next season.

#### ORNAMENTAL DEPARTMENT.

The continued wet has prevented us doing much on the lawn. The sooner all the summer flowers are removed the better now, for all the beauty that is left. The small dwarf *Tagetes tenuifolia* is still as fine as ever, seeming to rejoice in dry weather and wet weather alike. We would rather let the beds seem out of order for a few days than have feet and barrow-wheels on the lawn after so much wet. A dry day or two will make all right, and in a dry day the double of the removing work can be done, and with but little cleaning afterwards. We recollect being one in doing a day's work on a wet day, and it took just two days to remedy the injuries made on the walk and lawn. The two days' labour would have been saved, had the men done something in the sheds, and colds and rheumatisms, the results of the soaking in the end of November, would have been avoided.

The whole week has been chiefly employed in potting, putting in *Caecolaria* cuttings, and pruning and striking old *Geraniums* in pots, as stated last week. *Chrysanthemums* under glass needed some picking, and to be watered with manure water. *Cinerarias* needed placing under protection; also all Chinese *Primulas* not in the greenhouse. In the mild days gave hardwooded plants plenty of air. Abundance of light is now given in plant-houses by reducing and pruning back climbers, which bloom on young shoots chiefly in summer. Bulbs potted or planted must be guarded from mice, and all florists' flowers—as *Auriculas*, *Polyanthus*, *Carnations*, &c., must have plenty of air, and be protected from the heavy rains. As good a plan as any, if the plants are in pits or frames, is to elevate the sash by a half brick or other means at the four corners, so that the air shall pass through unobstructed, and yet the rains be all thrown off. In a fine dry day, as Thursday, after the frost in the morning was gone, and the sun shone so brightly, the sashes should be taken off entirely, and replaced in the afternoon. We did so in the case of thousands of young striking cuttings of *Geraniums*. The drying of such a day is the best preventive against damping. In their case, however, as the young plants were neither so hardy, nor yet so injured to the open air, the lights were all replaced between one and two o'clock. In dull muggy weather we would merely give a little air at back, and less in front, but the sun was so favourable that we were glad to give them all we could unobstructed. Of course, if the air had been cold with the sun, so much exposure would have been injudicious.

*Centaurea candidissima.*—We think we have touched upon most of the bedding plants except this, and there are several inquiries as to its propagation, &c. It may be struck at any time, summer, winter, or spring, by being inserted firmly in sandy soil, over good drainage, and close to the sides of the pot, a little hole or cavity being left in the middle of the pot for giving a little water when necessary, instead of watering all over and on the cuttings. In winter, especially, it does not like much moisture. The best time to strike it quickly is in spring. Cut down or nip out the points of the larger plants, and ere long lots of shoots will come from the stems and as

suckers. When these are about 3 inches in length they are not so woolly, and slipped off they strike quickly in a little heat where there is not very much moisture. The plant is comparatively hardy, and will never grow in a house with the same luxuriance that it will do out of doors after June. These little bits may be inserted round the sides of pots in the way spoken of; but if quick work is wanted, they must be repotted singly as soon as they are rooted, as the roots are excessively brittle and tender, and snap easily when we attempt to separate those of one plant from another. The best of all plans, therefore, would be to place a single cutting at the side of a small, say thumb pot, and repot with a ball whenever it was struck. This would require more trouble and room at first, but there would be no check from broken roots.

As to hardiness, we believe it is nearly as hardy as the *Cineraria maritima*, and that generally stands the winter with us, but not always, as it has been frequently next to lost in wet winters, and in such a severe one as those of 1860 and 1861. We have, therefore, taken a good portion of our *Centaurea* up, and divided the most of the plants by splitting down the stems above the roots, saving a portion of the roots and potting each divided piece (each of these, again, having two or three stems), into single pots of some 3 or 4 inches in diameter. These, if we like, we can top in spring. At present all leaves but some small ones at the point are removed, and as the lower leaves were rotting, we sprinkled the stems with charcoal and lime. Others we cut over a few inches above the ground, and packed them firmly in larger pots, fastening the roots round the sides firmly, and making the pot as full as in the case of *Scarlet Geraniums*. They did well treated both ways last year. The small young plants struck early in spring will make the neatest edgings in summer. To have plants with good foliage in winter, they should be kept in pots the previous summer, and not be potted after September. When planted out they seldom lift well with anything like a ball, and, therefore, the old plants which we take up and keep we deprive at once of most of their leaves. If after this roughish treatment they can be kept in a temperature of from 45° to 55° and 60°, and the heat given be dry rather than moist, they will begin to fresh root and grow sooner, and after that a cooler dry place will suit them very well. All through the winter they will be more apt to suffer from damp than from dryness, or cold, if frost is excluded. To "ELSTER," who wishes very much to know, if we prefer the candidissima to ragusina, or either to *Cineraria maritima*, we can give no other answer than that if there is a shade of preference in our mind, it would be in favour of the *Cineraria*, but all are good and useful.—R. F.

COVENT GARDEN MARKET.—NOVEMBER 4.

SUPPLIES moderate, and a fair amount of business doing. Dessert Pears chiefly consist of Marie Louise, Beurre Diel, Crassane, and Duchesse d'Angoulême. Apples comprise Ribston Pippin, King of the Pippins, Nutmeg Pippin, and some others of less note. Potato trade heavy.

TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

POTATO MURRAIN (T. R.).—It was first publicly noticed in this country in August, 1845, and was, we believe, equally prevalent in England, Scotland, and Ireland.

GLASS AGAINST SOUTH WALL (H. C.).—Nothing to prevent your having Vines, Peaches, &c., against your wall, and with a glazed lead-toe covering as you propose. It will be an orchard-house. If you send seven postage stamps to our office and order "Greenhouses for the Many" to be sent to you, you will have it free by post, and at page 57 there is just such a structure described.

WATERPROOFING CALICO (N. C.).—Pale linseed oil, 3 pints; sugar of lead (acetate of lead), 1 oz.; white rosin, 4 ozs. Grind the acetate with a little of the oil, then add the rest and the rosin; incorporate in a large iron pot over a gentle fire; tack the calico loosely on the frame, and apply the compound with a large brush while hot.

THE MODERN PEACH-PRUNER (A Constant Reader).—M. Grin advocates one universal system of pruning to the leaves. The modern Peach-pruner (as will be seen in No. 17) does not, however, consider this suitable to our climate without the modifications suggested. The pruning of Plums is simple enough; provided you attend to the general growth, and do not shorten the branches; the rest is easy.

FRUIT DROPPING IN ORCHARD-HOUSE (A. J. P.).—Its dropping as soon as formed seems to intimate that the root-action of the trees is defective. This may arise from the soil being too dry; or the wood on which the fruit is produced was not ripened last year. It is difficult to assign a cause of failure without knowing how the trees are managed, nor even the sorts.

BLEACHING SKELETONISED FERNS (Mrs. B.).—Dissolve 2 ozs. of chloride of lime in 3 pints of water. Let the skeleton remain in some of the solution in a flat dish for an hour, then take it out and wash it thoroughly with two or three changes of water.

REMOVING THE BANDAGE FROM BUDDED ROSES (E. C.).—The wool with which the buds were bound should be loosened to allow of their swelling, and, as it has not been removed before, it may remain bound lightly round them until spring, when it should be removed altogether. The buds that are looking very green and plump will shoot strongly in the spring.

SOILING PINK-FLOWERED CHESTNUTS—SIFTED COAL ASHES FOR DRAINAGE (Caleolaria).—You may sow the Horse-Chestnuts (*Pavia*) now in lines a foot apart, or keep them in a cool place in sand until March and then sow them in an open situation, covering with about an inch of light sandy loam. The majority, if not all, of the seedlings will have pink flowers like the parent; but to be certain of this it is best to graft the pink-flowering Chestnut upon stocks of the Horse-Chestnut when the sap is flowing, whip grafting being the most eligible. Sifted coal ashes will, to a certain extent, act as drainage, but not more so than friable loose soil.

PLANTING AND PRUNING PILLAR ROSES (Country Curate).—Your very strong last-year's-budded Roses you may plant in November, or, if the soil be heavy or wet, defer doing so until the first open weather in February or March. The best time to plant hardy Roses is from October to April, when the weather is mild and the ground in good working order. If you plant in November, which is what we recommend, you need not shorten the shoots of those budded this year, for the few leaves and green shoots will tend to a speedy formation of roots, or cause them to callus where cut. In March prune them to five good sound eyes, and if they shoot strongly allow all to grow, but if weakly disbud to three, or to one if very weak. Make choice of the strongest shoot and train it to the pillar, allowing the others to grow loose. In the pruning, after another year's growth, prune the side shoots to five eyes each, and the other or upright shoot to two-thirds its length, or take off one-third if strong and two-thirds if weak. In future years prune all the side shoots to three eyes, and the leading shoot to one-third its length. When the old shoots become weak train a strong shoot from the bottom, making room for it by cutting away an old worn-out one when it has done blooming. We do not perceive what you seek to gain by taking up the Roses budded this year, unless they are tender kinds, as Tea-scented. They will certainly be more secure from frost taken up, potted, and placed in a cold frame; but unless the weather prove unusually severe, it is quite unnecessary, as they are as safe the first as the second year. If you take them up for potting or planting where they are to remain, you may cut the stock down to within 6 inches of the bud, and when the Roses have grown a little next spring cut the stock away entirely above the bud. We do not recommend you to take them up and pot them.

HARDINESS OF CYCLAMENS REPANUM AND ODORATUM.—*Practical Inquirer* wishes to be informed if any reader of this Journal has ever known either of these to withstand a severe frost, and to really grow out of doors in this country with any appearance of success?

EMIGRATING TO WISCONSIN (An Emigrant).—We advise you to take neither plants nor seeds with you, but to adopt those which you find succeeding there. It will be more easy and less expensive to have sent out to you the few things you find defective.

**SEEDLING GERANIUM (W. S.A.)**—If constant—the leaf half green with a black zone, and the other half primrose with a pink zone—it will be unique, and be in much request.

**POTATO (Idem).**—The varieties of Potato are far too numerous for us to venture on assigning a name from seeing a single tuber. It must be of very peculiar form to enable us to do so. The foliage and flowers usually require to be seen.

**MAKING A FERNERY OF A SUMMER-HOUSE (P. B.)**—We do not see anything objectionable in your proposed alterations, so far as the growth of the Ferns is concerned; but we should prefer the continuance of the span roof on account of convenience and appearance. Your sloping roof will look odd with the wall so much higher than the bottom of the roof. It will also waste room, and make the ternery gloomy in winter. If you were to have a span roof, as at present, in the summer-house you could have Ferns in baskets suspended from the apex, and in building you could, in addition, have the corners built so that plants of pendant habit could be placed there in pots as you propose; but, instead of this, we would have a ledge of stone  $3\frac{1}{2}$  feet from the glass, extending 1 foot into the house, and on this we would place soil with a few rough stones as an edging, and plant with Ferns having creeping rhizomes, and which would run up the wall and down also, as *Davallia discolor*, *Nipholobus rufopretis*, &c., with a Stag's-horn Fern planted in each of the corners, or a pendant Fern if you like such better; 2 feet 6 inches above this, and 1 foot from the glass, we would have another ledge of stone projecting 6 inches from the wall, cover it with soil, and plant it with *Selaginella denticulata*, and other Lycopods. All round, excepting where the doorway is, we would have rockwork carried to the height of the first ledge, leaving a pathway 3 feet wide in the centre, and Ferns being suspended in baskets from the roof over the pathway, your house would have a charming appearance. Rough plate glass would be best for the roof, and the roof should fall 2 feet in 8 feet 6 inches, or the half if a span.

**PLANTING A LOW PIECE OF GROUND (A Subscriber).**—Rhododendrons do not succeed well on a limestone subsoil, so far as our experience enables us to form an opinion; but this has been more from a want of a suitable soil, and dryness, than anything there is in limestone to render it obnoxious. We had Rhododendrons do fairly planted in the interstices of limestone rockwork filled with peat, and kept moist by the drainage from the upper part. You may, therefore, plant Rhododendrons in your rich vegetable party ground, though there is limestone underneath, providing that it is not of a nature to burn in summer; and, though we cannot guarantee success, we think it likely. Of Ferns you may plant *Osmunda regalis*, *O. cinnamomea*, *O. interrupta*, *Oncoclea sensibilis*, *Scelopendrum* in variety, *Lastrea Filix-mas* and many of its varieties, *L. dilatata*, *L. thelypteris*, *Athyrium Filix-femina*, and *Pteris aquilina* for the drier parts. The above Ferns would do well if the soil is wet and slight shade afforded. A few plants of the Pampas Grass and of the common Sedges may be introduced with good effect.

**LAWN BURNING IN SUMMER (G. R.)**—Yarrow, or *Achillea millefolium*, which you have been recommended to sow, does well on dry gravelly soils, but we should not sow it alone, nor indeed at all, until we had tried something better, for, though it grows fast and is green enough, it is a tuffy plant, and we are glad to get rid of it on our soil which is a light loam on a bed of gravel. At its best it gives a lawn a patchy appearance. We recommend you to sow during showery weather next April, after giving a dressing of rich compost, *Festuca duriuscula* (Hard Fescue Grass), 6 lbs.; *Festuca ovina* (Sheep's Fescue Grass), 2 lbs.; *Festuca tenuifolia* (Fine-leaved Fescue Grass), 4 lbs.; *Festuca rubra* (Creeping Fescue Grass), 1 lb.; *Cynosurus cristatus* (Crested Dog's-tail Grass), 4 lbs.; *Lotus corniculatus* (Bird's-foot Trefoil), 1 lb.; *Trifolium repens* (White Clover), 3 lbs.; and *Trifolium minor* (Suckling Clover), 3 lbs. per acre; avoiding the Yarrow altogether. Roll well after sowing, and obnoxious weeds being grubbed up, we think your lawn would please in a year or two.

**HELYCIUM NOT FLOWERING—PRUNING IPOEMEA HORSFALLII (J. Bayly)**—We had a plant of *Helycium Gardnerianum* that we could not induce to bloom, though it, like yours, grew amazingly every year. We grew it in the stove, but finding it not worth its room it was doomed to be thrown out and the room occupied by something better. This was in July, and the plant had then made shoots 5 or 6 feet long. In the hurry it was placed in front of a south wall, and we were surprised to find the shoots thicken rapidly. This induced us to take it in September into the stove, where it bloomed finely during the winter. Since then we have grown it in ainery till it made a good growth, and then exposed it to sun so as to ripen the wood fully, and it has always bloomed well; we keep it in a cool stove in winter. You may cut away the growths of last year when they turn yellow, leaving only those of the current year, for it is those that bloom. The weak shoots of this year may be removed, as they only tend to weaken the others. Strong well-ripened growth is necessary to ensure blooming. *Ipomea Horsfallii* may be pruned with a long stem the height of the house, depending on the shoots that come from the spurs for bloom. Under this treatment the plant breaks strongly from the upper part, whilst the lower part, though naked, is covered by shoots trained downwards, and is thus equally in bloom with the upper part. By cutting down to the bottom of the latter the shoots come strong from the bottom and grow upwards, flowering more at the top than near the bottom, unless shoots are brought down. For our part we like the latter mode of pruning, but both are good.

**VARIOUS (A Lady Subscriber).**—Inarch your Wood Muscat on the Frankenthall, though it would probably do as well on the Black Hamburg. The Duclech of Binelech Vine is quite as easy to grow as a Muscat Hamburg. Cox's Golden Drop Plum will do even better on a southern than on an eastern aspect. Green Overall is a good dessert Gooseberry, combining flavour with size. If you carefully plant a good-sized transplanted bush now, it ought to bear fruit next year.

**KEW BOTANIC GARDENS (U. Thoughtful).**—You had better write to Mr. Smith, Curator, Royal Botanic Garden, stating your wishes and the testimonials you can have.

**FIGS IN ORCHARD-HOUSE (M. Smith).**—Every Fig above the size of a small Pea should be cut away now, and even those left will not stand, if subjected to severe frost without some protection. The Figs just now showing like pins' heads will do best next summer.

**BOTTOM HEAT IN CUCUMBER-PIT (W. Parnell).**—As your Cucumber-pit acts satisfactorily we say, decidedly let well alone. The brickbats over the pipes act as conductors of heat. The tan, recommended to be substituted for them, if thick enough and fresh enough, would yield heat of itself by fermentation, but, fresh or old, it would prevent heat rising from the pipes when it becomes dry, as then it acts as a nonconductor of heat. Be content with what answers so well. The "Vine Mammal" can be had free by post from our office, if you enclose thirty-two postage stamps with your address.

**CHRYSANTHEMUM LEAVES DYING OFF (W. Sanbergne).**—Chrysanthemums lose their lower leaves in autumn—1st, from an insufficient supply of water at an earlier period of the season, which causes them to mature; 2nd, from the shoots being trained too close together, thereby preventing a due amount of light and air reaching the lower leaves; and, 3rd, from being removed to a closer and warmer situation for blooming. We know of no remedy except keeping the plants well supplied with water through the summer, keeping the shoots thin, and regulated early and repeatedly during the growing season; and to house them in a cool, light, and very airy structure before very wet cold weather sets in.

**LIME TREES BARE AT THE BOTTOM (W. K. H.).**—You cannot adopt any means to make the trees break lower down without taking off their tops, and, though this would cause them to break lower down, it would be ineffectual, as they will not quickly grow up, unless suckers come from the root, which will not be the case to any extent until the trees are old. You might plant some Ivy against the building, and so diminish its unsightliness; and by planting some shrubs in front of the Limes, as Yews, Laurels, Hollies, and Aucubas, the part not hidden by the Lime trees may be screened from view.

**HERBACEOUS CALCEOLARIAS FAILING—SOWING ANTIRRHINUM AND AQUILEGIA TO BLOOM NEXT YEAR (M. N.).**—We have experienced a similar dying off of herbaceous Calceolarias, which we attributed to a want of moisture in the atmosphere during the whole of September. We had others on a north aspect, along with some Runners, and none of them have gone off. We think the hot dry weather in September was the cause. You had better wait until spring, and sow the seed then in a mild hot-bed, and grow the plants on in a cold frame. They will bloom finely late in summer and in autumn. The *Aquilegia* and *Antirrhinum* seed should be sown in March in the same way as that of half hardy annuals, pricking off the seedlings into small pots when sufficiently large to handle, and when established they should be hardened off. The *Antirrhinum* will bloom finely, but we question if the bloom of the *Aquilegia* will be good. It would be better to sow the latter in May in the open ground, and take up the plants and pot them in September. The *Antirrhinums* sown in August, potted off before winter, and kept in a sheltered situation would make much finer plants.

**WHITE SCALE ON PHELIENA BUXIFOLIA (A. C. B.).**—It will be a difficult matter to dislodge the scale. Your safest plan will be to pick it off with the point of a knife. Having gone over the plant in this way, cover the surface of the pot with moss to prevent the roots being injured by the coming ordeal. Lay the plant on its side, and syringe it with water at a temperature of 140°. Turn the plant over and over again so as to let the hot water reach all the insects. Continue to remove the insects still remaining in the crevices with the point of a knife or brush, and in ten days repeat the application of hot water if requisite. This in time will clear the plant. Be careful not to deluge the pot with hot water, otherwise the roots will all perish; and if the leaves have been long infested with scale they will drop. Knowing the plant was suffering from white scale we would not have had it at a gift, much less bought it. It is discreditable to sell such things.

**DESTROYING WOODLICE (E. M. H.).**—We have experienced great annoyance from woodlice in Fern culture. Our plan was to cut a raw Potato in two parts, scoop a little out of the middle with a knife, and, placing the cut part downwards on the pots or elsewhere at night, going in the morning we found them swarmed in the hollow beneath the Potato, and feeding on it, and thus killed great numbers. These baits last a long time, but are better when fresh. Another and more wholesale mode of catching them is to place a boiled Potato, wrapped loosely in a little hay, at the bottom of a small flower-pot, and laying the pot on its side near their haunts. This is done at night, and in the morning the Potato is taken out and the hay dropped into a bucket of boiling water, holding it over the bucket whilst the Potato is being taken out. The woodlice when plentiful will eat the greater part of a boiled Potato in a night. Continue this for a time and their numbers will be considerably diminished. You cannot have the pots half dipped in anything poisonous without injuring the plants, but you may provide large saucers or feeders, fill them with water, invert a smaller saucer in the centre so as to have its bottom above the water, and then place the pot containing the plant upon the inverted saucer. Woodlice cannot bridge the water and attack the plant.

**LILICUM TIGRINUM—MUSCARI ROTYROIDES—TRITOMA CVARIA IN FLOWER-BED (A. C. C. H.).**—*Lilium tigrinum*, grows to a height of 3 or 4 feet in rich soil, and ordinarily to 3 feet. It is of the turbinate or Turk's-cap section, of good erect habit, and branching; the flowers are orange or orange-salmon with dark brown or black spots, hence its name Tiger Lily. *Muscari* (*Hyacinthus*) *botryoides* or Grape *Hyacinth* grows to a height of 6 inches, has long narrow *Hyacinth*-like leaves, and the flowers are blue and closely set on an erect spike. *Tritoma avaria* will live unprotected in beds and borders, but is better with a few inches of half-decayed leaves laid around the crown, which act as a sort of protection and assist the succeeding growth.

**NAMES OF FRUIT (Hortus).**—1, Gansel's Late Bergamot; 2, Reurre Débonnaire; 3, Knight's Monarch; 4, marked Passe Colmar? (Winter Nelis?). (*J. F. Lombard, Dublin*).—1, Gloria Mundi; 2, Lemon Pippin; 3, Golden Winter Pearmain; 4, Summer Pearmain.

**NAMES OF PLANTS (R. W. Collingham).**—1, *Asplenium adiantum-nigrum*; 2, *A. trichomanes*; 3, *Pteris hastata*; 4, *Doodia longifolia*; 5, *Cyrtomium filicatum*; 6 and 8, *Campyleris bidentata*; 7, *Pteris longifolia*; 9, imperfect. (*J. B.*)—1 and 4, *Adiantum hispidulum*; 2, *A. pedatum*; 3, *A. formosum*; 5, *Lastrea dilatata*; 6, *L. spinulosus*. (*J. W. D.*)—*Nephrolepis tuberosa*. It has many habitats in the East Indies. (*Sophia*).—*Lastrea dilatata*. (*A. M. R.*)—*Escabonia macrantha*. (*A. B.*)—*Sonerila margaritacea*, or pearl-spotted.

## METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending November 4th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
			Air.		Earth.				
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.			
Sun... 29	29.991	29.116	58	44	51	50	S.W.	.12	Rain; boisterous with heavy rain; fine at night.
Mon... 30	29.297	29.146	53	38	51	51	S.W.	.53	Rain; heavy showers and sunshine alternately; heavy rain.
Tues... 31	29.278	29.278	50	27	51	51	N.E.	.13	Heavy rains and boisterous; slight frost at night.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

## REARING CHICKENS ARTIFICIALLY.

As I consider that I was successful in rearing a stock of eight dozen chickens with very little trouble or expense, and as I owe the attempt to do so to having read the discussions on the subject in your Journal last winter, I think that I ought to say a few words in acknowledgment my success.

Being only a half-believer I did not incur much expense in the matter, merely procuring a stout box made with the lid on hinges, and close-fitting, cut on a slope like a melon-frame, one half of the lid only being glazed, and there was a hole in the side, with a sliding door. In this box I put two low stools with a thick fleecy top, for artificial mothers, and I placed the box close beside a spare large garden frame, which stood on dry ground. I had the chickens close to my flower-frames, and looked after them chiefly myself. This frame, to which I admitted them at pleasure by drawing the slide, answered for their covered run or "day room," till they were a few weeks old, when I used to allow my pets to take a run in the garden several times a day. It was quite curious to see how fond they became of the frame, and how they used to flock to me from all sides to be let in, and to bask on the warm gravel under the glass. I took each chick from the hen the day it was hatched. I had not one sickly or drooping chicken the whole summer.

The advantages I found in this system, even trying it in a small way, were these: First, they did not cost in feeding nearly so much as when carelessly fed in the fowl-yard, where stronger fowls, dogs, &c., robbed them of their milk and food. Secondly, they thrive quicker and feathered better a great deal, from getting the full share of that food appointed for them, as well as from the genial and uniform warmth of the frame, instead of being often weary and wet when enticed by the hen to walk about all day through grass and elsewhere. Thirdly, I found the hens lose so little in condition by merely twenty-one days sitting (being well fed once every day), that they laid and hatched a second time early in summer. These advantages ought to make the system worth a trial, even by those who might not count it, as I did, an amusement.—A SUBSCRIBER.

## DUCK-FOOT IN GAME—WHITE FACE OF SPANISH FOWLS.

WHATEVER may be the opinion of your readers with regard to the Poultry Club, and its management, there can be no doubt that the publication of a "Standard of Excellence," by a body composed chiefly of extensive breeders of almost all the varieties of fowls, must be of very great use to exhibitors. When any one takes to fowls as a hobby, and in order to make his hobby more attractive breeds for exhibition, he is probably at first entirely ignorant of the points most necessary to insure success. To such a tyro a "standard of excellence" is of great value, and has long been a desideratum.

There is another advantage. The difference of opinion with regard to the most valuable points in fowls must produce discussion, when the assertion of a standard calls it forth. As an example, let us instance the valuable paper which the discussion on the "duck-foot" in Game fowls has drawn from Mr. Hewitt, I never saw a more lucid or truly useful essay. In that paper, the question whether this deformity is hereditary or not is fairly discussed, and Mr. Hewitt supplies facts which seem conclusively to prove that it is so. Should other ob-

servers be able to produce similar facts, there can be no doubt about the propriety of making the possession of such a deformity a cause of disqualification.

In the "Standard of Excellence" it is clearly laid down that the face of a Spanish fowl should be free from folds and wrinkles, and that any corrugation of the face which prevents a bird from seeing is a disqualification; yet, how often do we see prizes awarded to cocks which are blind, or must be so in time; to hens with such coarse faces that it is impossible that they can produce cocks free from this troublesome defect. Every breeder of Spanish fowls knows how useless such cocks become, and that nothing but a cruel mutilation can make them able even to feed themselves. Such birds are generally useless as breeding stock after their first year. Surely such a deformity, which is decidedly hereditary, should invariably disqualify its possessor.

It would be a great boon to Spanish breeders if Mr. Hewitt would give another of his valuable papers on this subject, which is evidently not sufficiently thought of by some judges, and is a source of difficulty and doubt to those who breed Spanish fowls for exhibition.—QUALITY.

[I am obliged by the favourable opinion expressed by your correspondent, who signs himself "QUALITY," of my communication respecting the deformity of "duck-foot" in Game fowls. I also embrace the present opportunity to return my best thanks for the many courteous letters of like approval which I have received from other sources. I can only say, that if I have aided in any degree to ventilate the subject, I am satisfied that my trouble will not have been thrown away; at least, so far as it elicits the expression of opinions that might not otherwise have been made public.

Your correspondent asks me to give my own views as to the coarse corrugated faces which we frequently meet with in Spanish fowls. My ideas assimilate so very closely to those expressed by "QUALITY" himself, that to enter on the greater portion of that gentleman's details would amount to a useless recapitulation. I have, however, known a very heavy-faced Spanish cock well shown for several successive years, but he was in very careful hands. His face was kept scrupulously clean, being frequently washed with cold milk-and-water, and afterwards tenderly dusted, under the folds, with violet powder. This bird never became excoeriated at all, and could see well to the end of his days, but in his late years proved an almost useless stock bird. This is, however, rather the exception from the general rule. Most of such Spanish cocks at three or four years old become hopelessly blind, and cannot feed at all, except from corn in a vessel, eating rather by the guidance of the touch than by eyesight. All specimens in this state fail entirely for procreation. Neglected faces in Spanish cocks very frequently become absolutely offensive from ulceration; certainly not a very great point for encouragement or admiration to even the fondest of Spanish amateurs, and a failing that has often caused me to pass birds unnoticed.

But if we will but look for it, we can always find a sunny as well as a dark side to everything in this world. "Cauliflower-faced" Spanish fowls, as they are commonly called, are a most useful auxiliary to keep up the size of the faces in Spanish fowls, by occasional judicious crossing, and not less so, to keep up, or rather increase, the size of their progeny; for the beautiful white kid-like faces of most specimens, if bred closely for a few years, entail a degeneracy of size in their chickens to such an extent as amounts to imperfection. The smooth delicately white face in Spanish fowls, without folds or corrugations, is quite an exhibition favourite; but I cannot go so far against the larger-sized strain as "QUALITY" suggests—viz., to at once

disqualify, simply for a development that is with them absolutely inseparable from age alone.

The chickens of the large-sized corrugated-faced Spanish fowls are invariably the most attractive at the first chicken shows of the year, and it must be ever remembered, exhibition poultry should always be judged, at *what they then are*, rather than at what they *have been*, or ultimately *may prove*. These latter also, if assiduously attended to, frequently carry out a very long course of success, but if neglected they soon fall to decay. The very fine exquisitely white-faced Spanish fowls, shown, as they sometimes are, without possessing a single fold or imperfection, require occasional "crossing," or degeneracy of both bodily size, and also of face, inevitably creeps in. The middle course between this Scylla and Charybdis in the breeding of Spanish fowls, is the one I would myself pursue were I, like your correspondent "QUALITY," and many others, to adopt as my hobby the exhibition of Spanish fowls.—EDWD. HEWITT, *Sparkbrook, Birmingham.*]

I do not pretend to lay down standard rules and regulations by the aid of which Game fowls are awarded prizes at our poultry exhibitions. It is evident that very often a smart dandy-looking bird is preferred to the good, old, honest fellow, who would make short work of such a puny antagonist, if pitted on the sod. This brings out the question, Whether Game fowls, when exhibited, are now to rank merely as "fancy" fowls, or to be considered the worthy descendants of forefathers whose character was "free, able, and willing," and to whom the rough work of the cock-pit seemed almost a delight?

The greatest fault of a real fighting-cock is being "cow-footed," *alias* "duck-footed." If unsuccessful at the first two or three blows, he reels just like a cock pricked by the steel in the spine, though not mortally; he cannot direct his motions, and, thus powerless, he soon bites the dust. A twisted breast, though bad enough, is often no objection to fighting; but the cow-footed cock, to use the cant phrase of collegians, may "have a large heart, but he has no understanding."—COCK-FIT.

#### GAME-FOWL JUDGING.

AFTER a careful perusal of the communication of "JUSTITIA" on this subject in No. 239, I must confess myself at a loss to understand the object of the writer in penning it. If it is intended as a reply to my previous communication, a more signal failure cannot well be conceived. It is, however, satisfactory to find that your correspondent admits the importance of the points raised in my letter, and the advantage of a further ventilation of the subject of an honest award of prizes at poultry shows, to which it refers; and I can only say that it will give me pleasure to assist him in the process, if after the present communication he desire it; although it would involve little beyond traversing the ground gone over in the controversy on the same subject in your columns in 1863.

In noticing the more salient points in your correspondent's production I am struck with the soreness manifested by the writer. Whether he is personally interested in the matter, and feels my remarks as a personal rebuke, I will not hazard an opinion, but were such the case he could not have displayed more sensitiveness.

"JUSTITIA" designates my remarks on judging Game fowls assumptions; but as he has not ventured to controvert my positions I can only regard it as a tacit admission of his inability to disprove their correctness: the attempt to stigmatise as assumptions what he cannot answer is too transparent to mislead any one who is capable of reflection. The statement, for instance, that "a breeder and exhibitor of any length of standing must possess as correct a knowledge of the points of merit in a bird as a professional judge," he admits to be true; "such," he says, "is undoubtedly the case in some instances, although," he adds, "it does not necessarily follow that such knowledge can be either bought or rented as many prize birds are." What this last clause has to do with the one which precedes it would sorely tax the powers of "JUSTITIA" to explain. Is it intended to illustrate the exceptions which qualify his admission of the capabilities of experienced exhibitors to judge the points of merit in fowls? or is it to be taken as an example of his mode of "ventilating" the subject? Most of your readers, I apprehend, will be of opinion that so palpable a *non sequitur* speaks little for your correspondent's logical acumen, and promises less in the way of elucidating the

matter he has undertaken to write upon. As, however, he "assumes" to know the present writer, his reference to "renting prize birds" may be designed to convey a personal insinuation, particularly as he reiterates the insinuation in a subsequent part of his letter; if so, I reply that the assumption is as unfounded as it is gratuitous; and for the rest, if he knew of any exhibitor being guilty of infringing the rules by exhibiting birds which were not his own, it would have been more consistent with the character of one who writes under the signature of your correspondent to have made an open protest at the time, instead of insinuating the charge in an anonymous communication. But it not unfrequently happens that persons most ready at insinuating charges against others are guilty of the alleged practices themselves.

Then he makes allusions to a "certain Game exhibitor," whose name "does not appear in the catalogue" of the Manchester Show two years ago. Whoever the exhibitor may be to whom this refers, I apprehend he was at liberty to exhibit his birds where and when he pleased. The insinuation of birds that were his property taking prizes in other names at this Show has already been disposed of. One of the most extraordinary portions of "JUSTITIA's" communication is that where he so positively asserts that the alleged dissatisfaction with the judging of Game fowls at the Birmingham Exhibition was confined to one or two discontented exhibitors. How your correspondent could make the assertion in the face of the fact, that a vote of censure was passed by the Poultry Club on the Birmingham judging last year, in consequence of the defective decisions referred to in my previous communication, it is not easy to explain. The most charitable conclusion is that he either must not have known of or have forgotten the circumstance, which does not say much for his authority on these points; besides, were further proof required, it is supplied in the advertising columns of your Number of October 24th, from which your readers may see that a memorial on this very subject is now receiving the signatures of exhibitors.

The only other point I need notice is that relating to the retirement of Mr. Archer. At the Exhibition in question he was a more successful exhibitor than usual; whilst, on the other hand, I understood from Mr. Martin, who had charge of his birds, that his discontinuing to be an exhibitor arose from circumstances unconnected with that or any other Show. Your readers, I apprehend, will now be at no loss to judge of the weight to be attached to the statements of "JUSTITIA."—EXHIBITOR.

#### WHITE SPANISH FOWLS.

IN the Journal of September 26th are some remarks on White Spanish Fowls, which, I think, ought not to pass unchallenged. The statement is—"They were always looked upon more as pets and eccentricities than anything else, and were not largely bred. They lacked the contrast that forms the chief beauty of the Spanish, black plumage, white face, and red comb." Now, as to their being bred as pets and eccentricities; if as pets, they are deservedly so, for who can look upon them with their glossy pure white plumage, bright red faces, and pendant combs, and deny that they are beautiful? They are very delicate, and have the same proper respect for a fence and disinclination to trespass as Cochins. That next word "eccentricities," I do not half like, nor do I think White Spanish deserve it so much as Black Spanish, for is not the chief beauty of Black Spanish, the white face, as great an eccentricity as any point in any other breed? I trust that brother fanciers will pardon me for calling the white face of the Black Spanish an eccentricity. I think that any distinct point in any breed should be called "a distinctive characteristic," not "an eccentricity."

For instance, no fancier would call the top-knot and beard of the Polish "an eccentricity;" but I recollect showing my Polands to a non-fancying friend, when he exclaimed, "What eccentric fellows! If they were mine I'd have them shaved!"

I will now endeavour to show that White Spanish fowls have other and greater claims to be more largely bred and patronised. One writer describes them as being "very precocious;" and my experience for the last three years proves that they are so; for having bred Dorkings, Game, Polands, Hamburgs, and Black Minorcas, the White Spanish pullets have all commenced laying at from four to six weeks younger than either of the other breeds. Many persons near Torquay keep the White Spanish, and all agree that they are very early and very good layers.

They were first brought here by Mr. Tordiffe, who purchase

a splendid prize pen, and I do not think any new blood has been introduced for the last five years; but I have now secured a cockerel and pullet from Mr. H. Leworthy, who purchased Miss Northote's celebrated stud, and in another year I hope to hear my White Spanish crowing victory in the "any other variety" class at some of our best shows.—CHAS. DRAKE.

#### REJOINDER FROM THE TURKEYS AT CALNE.

MR. HEATH'S virtual acknowledgment of the justice of our complaint of the discomfort we experienced at Calne inspires us with the hope of redress in future; but we cannot accept his plea for leniency on behalf of small shows when their entrance-fees are the same as at large ones; and surely we should do more credit to any show that invites us to exhibit if every advantage were afforded us for that purpose. We also feel aggrieved at Mr. Heath's doubt of our veracity. We remember with gratitude the kindly act of a visitor at Calne, who drew some empty baskets over our pens to shade us from the fierce rays of the sun; whilst we fear the equally kind act of another visitor, who, *being able* to reach the top row of Pigeons affixed the commendatory cards to them, has been forgotten by at least "one of the Committee."—THE TURKEY PRISONERS AT CALNE.

#### BRAHMA POOTRAS.

Your correspondent "D. P. P." has raised the question as to the original colour of the Brahma Pootra fowl, and asks which variety is the genuine one. In reply, I beg to call his attention to the following quotations which have reference to the earliest-known specimens of the breed:—"The colour of the body is white, with the slightest possible tinge of gold, the hackle being dark grey, and the primary wing feathers and tail glossy black, with resplendent tints of green. The hen matches in colour, the hackle, wings, and tail being dark grey."—(Quotation from "Profitable Poultry" given in Martin Doyle's "Domestic Poultry," page 44.)

"I have a pair of Brahma Pootra fowls of the same breed as those sold by Dr. J. C. Bennett, and I consider them decidedly the most splendid and beautiful fowls ever imported. Their colour is white, inclining on the back to a rich cream colour; the hackles on the neck slightly streaked with black; the legs are yellow, heavily feathered with white," &c.—(Quotation from a letter of the Rev. R. W. Fuller, given in Miss E. Watt's "Poultry-Yard," page 62.)

My third extract, from the same work, shall be Dr. Bennett's own description of the Brahma Pootra fowl:—"The cock is mostly white, with neck-hackles pencilled with black, and rump-hackles of the palest possible shade of straw colour; the tail is black, with glossy green plume feathers; the wings pencilled with black. The pullets are white, with black tails; the wings and neck slightly pencilled with black," &c.

I will leave it for the advocates of the Dark Brahma to account to "D. P. P." for the suspicious resemblance between the cock of that variety and one crossed between the Grey Dorking and a Light Brahma hen; and, without condemning the Dark birds, I can only assure "D. P. P." that if he possesses Light Brahmas, such as those described above, he will find them to have all the characteristics of a pure and genuine breed, and if he keeps them for years

"The warm blood in blushing streams will run,  
Ceaseless and stainless down from sire to son."

—BRAHMA POOTRA.

#### LIGHT BRAHMA POOTRAS AT CALNE.

AM I to understand by "WILTSHIRE RECTOR'S" article on the Calne Poultry Show, that Mr. Pares took first and second prizes in the chicken class for light Brahmas? I quote the Rector's own words. "The Brahmas mustered strongly, including chickens. A promising pen of the latter, belonging to Mr. Hinton, took a prize; and Mr. Pares was first and second with light Brahmas, heavy into the bargain."

On reference to the prize list, in the light Brahma class for chickens, Mr. Lacy took first, and Mr. [Sheerman second. Mr. Pares also exhibited two pens, neither of which was noticed.—AN EXHIBITOR.

["AN EXHIBITOR" is not to understand that Mr. Pares took

first and second prizes in the *chicken* class for light Brahmas at the Calne Show. By the term "latter," I referred to Brahmas as distinguished from Spanish, for neither Mr. Hinton's chickens nor those of Mr. Pares took a prize, while in adult birds those gentlemen, as I have stated, took first, and first and second, in the order I have written. I did not think any of the Brahma chickens of sufficient merit to demand a special notice in a second paper on the same Show. I had the official catalogue before me when I wrote. I have been away from home the last fortnight, and although "AN EXHIBITOR'S" letter was forwarded to me, yet as I had not the copy either of "The Journal," of my country paper, or the catalogue of the Show with me, I could not reply until my return. I may add, that I never send catalogues, they go to "The Journal" from other sources. My papers on shows are meant to supplement the usual reports, and to keep up and spread the love of poultry among ladies and gentlemen, and I am gratified to learn that sometimes they do this. My rule is only to name those birds that I deem extra meritorious.

I was very glad to see that Mr. A. Heath made clearer an expression of mine about the tents. The exhibition tents were excellent, both were reared all in good time, and both Pigeons and poultry were well housed, even had the weather become cold or wet. I hope Calne will have an annual Show. The dilatoriness, which I know the Committee lamented as much as myself, need never occur again. What is done every year is sure by practice to be done well. We must not lose a single show from this neighbourhood. May prosperity rest upon that of Calne!—WILTSHIRE RECTOR.]

#### BEE-KEEPING IN DEVON.—No. XXVI.

ABNORMAL DRONE-PRODUCTION—LATE-BRED QUEENS—MARAUDERS  
ATTACK QUEENS—VALUE OF SMALL DRONES.

SOME singular phenomena in connection with drone-breeding have recently occurred in my apiary, a description of which may prove acceptable to the readers of "our Journal."

Before entering into particulars, it may not be amiss to state what has already been discovered with regard to the phenomenon of drone-breeding queens.

Huber appears to have been the original observer of this extraordinary fact, and having first remarked in the case of queens confined to their lives (in which state there seems no reason to doubt they are perfectly incapable of obtaining intercourse with the males, however numerous these may happen to be within the hive at the time), he instituted a series of careful experiments, the results of which warranted him in ascribing to retarded impregnation the remarkable circumstance of the occasional existence of queens, which, during the whole of their lives, remained incapable of laying any eggs other than those which would produce male bees or drones; and he ultimately laid it down as an axiom, that queen bees whose fecundation has been delayed until after the twentieth day of their existence must perforce turn out drone-breeders.

This conclusion was very generally accepted until Dzierzon, the great German apiarian, promulgated the theory that all drone-breeding queens were in reality virgins, and that even in the case of impregnated queens all eggs that would produce drones are in point of fact unfecundated eggs, whilst those only that would produce workers or queens are fecundated by the voluntary action of the queen herself prior to their being deposited in the cells. This theory was investigated and confirmed by Von Siebold, the distinguished German naturalist, who demonstrated beyond the possibility of a doubt the fact of parthenogenesis in the honey-bee. Having myself repeated and verified most of the experiments and investigations of Von Siebold, I can bear witness to the soundness of his conclusions; but as the subject has already been more than sufficiently discussed in these pages, I would refer those who are interested in it to Von Siebold's "True Parthenogenesis in Moths and Bees," a translation of which by Mr. Dallas has been published by Van Voorst, and to Nos. 25 and 30 of THE JOURNAL OF HORTICULTURE.

With regard to the fecundity of one of his drone-breeding queens, Huber remarks that it was "astonishing." My own experience in this respect is, however, directly at variance with that of my illustrious predecessor, no drone-breeder that I have ever met with having displayed anything approaching the breeding powers possessed by an ordinary impregnated queen.

Mr. Langstroth, the eminent American apiarian, relates an instance in which a young queen inhabiting a hive with a

contracted and obscure entrance, commenced laying drone eggs only, but after being removed to a hive of a different construction she gradually left off drone-breeding, and deposited the eggs of workers in the usual manner. Reasoning on these facts, he asks, "Is there any reason to doubt that these drone eggs were laid by the queen before, and the worker eggs after, her impregnation?" To this question I should, only a few weeks ago, have replied that there is the greatest reason for doubting it, and that as far as my observations extend, when once egg-laying commences either in the virgin or impregnated queen bee, all disposition to seek intercourse with the male is for ever at an end. It is, however, but justice to Mr. Langstroth to state that circumstances have recently come under my observation which tend to throw doubts on the conclusion at which I had arrived on this point, and, at the same time, confirm the views of my trans-Atlantic contemporary. What these circumstances were will be related in due course.

I once witnessed an instance in which a young queen began by laying a large patch of drone brood in worker cells, and another in which worker and drone brood was most singularly intermixed. In both these cases, which were related in "our Journal" at the time, this abnormal drone production soon came to an end, and workers only were bred in the ordinary manner. My own theory is, that in both these queens there was some slight temporary defect in the action of the delicate voluntary muscles which regulate the fecundation, and consequent sex, of the eggs before they are deposited, which defect disappeared as they advanced in age.

To come then to more recent experience. A fine Ligurian queen, artificially reared and hatched on the 8th of June, laid eggs on the tenth day, which turned out to be, for the most part, those of drones, interspersed with a few workers. This phenomenon continued throughout the summer until the population of her hive having become very much diminished, I added to it the inhabitants of a condemned stock, ultimately destroying its quasi-mother and substituting for her a fertile Ligurian queen. Although this drone-breeder was never very prolific, and laid all her eggs in worker cells, the small drones produced by her have turned out extremely valuable, as we shall see.

Peculiar circumstances, which I need not at present make public, but which, being of absorbing interest to myself, will, I doubt not, when related at no very distant period, excite some attention in the apian world, have induced me to raise a few young queens rather late in the season, and to watch them with more than ordinary vigilance. As their history has been attended by some curious facts, a succinct narrative may not be without interest.

The first, hatched on the 22nd of August, the fifteenth day after the formation of the artificial swarm, laid eggs on the 9th of September, being then eighteen days old, and is now at the head of a strong colony, built up by the gradual and careful addition of broodcombs.

The second, hatched the same day and from the same brood-comb as the preceding, fell a victim to a regicidal attack, as related in page 268, on her return from an apparently successful wedding flight, being at the time but thirteen days old.

The third, hatched on the 24th of August (the eleventh day), did not lay eggs until the 25th of September, having then attained the mature age of thirty-two days! As two days is the general time which elapses between fecundation and actual egg-laying, it follows that she must have exceeded by about ten days the before-mentioned limit prescribed by the immortal Huber. Notwithstanding this delay she has turned out perfectly fertile, and has recruited the waning population of her hive by the welcome addition of a goodly multitude of late-bred workers.

The fourth, hatched 5th of September (the eleventh day), laid eggs on the 24th of September, being nineteen days old. The season being so far advanced, it was of course necessary to increase the scanty population of these late-formed stocks as rapidly as possible by the addition of broodcombs from other colonies. No sooner, therefore, was the welcome fact ascertained that egg-laying had fairly commenced, than I set to work to shift this small colony into a full-sized hive with the view of affording sufficient room for the accommodation of additional broodcombs. The day happened to be very warm, and, in defiance of Dr. Cumming, marauding bees were provokingly numerous. I therefore expedited proceedings as much as possible, consistently with keeping a bright look-out for the juvenile matron, for whose safety I was necessarily most anxious. Comb after comb was lifted out, carefully scanned,

and transferred to the new domicile, but all in vain, no queen could I see, and, dreading a repetition of the operation in the face of so many foes and equally fearing to leave her fate in uncertainty, I anxiously examined the few stragglers remaining in the now unfurnished habitation. Amongst them, to my great joy, appeared the missing queen, which I at once carefully took up in my hand with the view of transferring her to her new habitation. Whilst in the very act of doing this, she was pounced upon by a marauding bee, locked in whose dire embrace she rolled to the bottom of the new hive, the bees in which were now in a state of the utmost agitation from the removal and the incessant attacks of a fast-increasing cloud of marauders! What was now to be done? Nothing, but again to lift out the combs and rescue the queen, if haply she had not already received some fatal injury. This was effected as rapidly as possible, and the poor queen appeared still locked in the deadly embrace of her foe. Taking both in my hand, I quickly crushed the life out of the aggressor, and most apianians will, I think, sympathise with the feeling of relief I experienced at finding that the royal and unoffending object of this fierce attack had escaped uninjured. Her troubles were, however, not yet entirely over, for scarcely had I freed her from the mandibles of her first antagonist, which still kept their hold with bull-dog-like tenacity even when the body to which they had belonged was crushed into a shapeless mass, than, whilst still in my hand, she was laid hold of by another marauder. To this would-be regicide I speedily administered the *coup de grace*, popped the queen between a couple of the exposed combs, and covered the hive with its crown-board as speedily as possible. Its entrance having also been contracted, a vigorous resistance was now offered to the marauders, who, finding their efforts unavailing, speedily desisted from the attack. This occurrence, whilst it proves that marauding bees will readily assail the queens of such hives as they are desirous of plundering, scarcely seems to me to bear out the theory that such assaults by isolated stragglers are the cause to which we must attribute regicidal attacks on queens by their own workers, since it cannot fail to be observed that whilst this distressed monarch was struggling with her would-be assassin in her own hive and amidst her own subjects, although not one attempted to aid her, there was at the same time not the slightest symptom of any tendency among them to what has been not inaptly termed "the regicidal frenzy."

The fifth queen, hatched on the same day as the fourth, has developed some extraordinary phenomena, which have caused me, as before intimated, to modify the views I had previously entertained with regard to the indisposition of virgin queens to seek intercourse with the males when egg-laying has once been fairly commenced. When she was about ten days old I noticed a single egg in a worker cell, which appeared to be the signal for the destruction of a few full-sized drones which existed in the hive at the time. More eggs were gradually deposited in the adjoining cells, and all receiving the raised convex coverings appropriate to drones, whilst the abdomen of the queen (a very small one) remained undistended. I doubted not that she would turn out a confirmed drone-breeder. When rather over twenty days old, I noticed, much to my astonishment, a remarkable change in her appearance, which suddenly assumed the graceful degree of *embonpoint* proper to an impregnated queen. This was accompanied by an equally notable change in the manner of her oviposition, which, from being sparse and unequal, became copious and regular. Soon afterwards it also became evident that her progeny would not be entirely of the male sex, a few cells of worker brood appearing here and there amidst the protruding cradles of the drones; and this proportion has gradually and steadily increased until, I have every reason to believe, she has assumed the status of a fully-developed queen, breeding workers only, as is proper at this season. I need hardly say that I have watched the phenomena exhibited by this queen with the most lively interest—an interest which has not been diminished by the fact that they have upset an opinion long held by me, and heretofore promulgated in these pages. I might, of course, preserve my theory intact by ascribing the production of drone eggs to the presence of fertile workers, but all the probabilities appear to be so much the other way, that I am impelled to the conviction that this queen commenced laying male eggs whilst yet a virgin, and that after impregnation drone-production diminished and ultimately ceased entirely.

The sixth succeeded her hapless sister before referred to as having fallen a victim to a regicidal attack by her own workers. She was hatched on the 6th September (the twelfth day), and

escaping the sad fate of her predecessor, laid eggs, I believe, when twenty-one days old. I am, however, unable to fix the date with absolute certainty, having added a brood-comb about the same time containing eggs recently laid by another queen.

The seventh, hatched the same day as the sixth, laid eggs on the 28th of September, being then twenty-two days old.

The eighth, hatched 7th September (thirteenth day), laid eggs on the 29th of September, being twenty-two days old.

It will be perceived, therefore, that I have been successful with seven out of my eight late-bred queens, all of which are now at the head of good stocks, and, what is not a little curious, all have been fecundated by small drones bred in worker cells. It is true that during the first half of the month of September I possessed a very few full-sized drones, but these being in the hive presided over by the fifth queen, were turned out and destroyed by the workers, as before stated, immediately on her first laying drone eggs. I have the strongest reasons for believing that the drones in every hive in my neighbourhood had been destroyed long ago, and have, therefore, no doubt whatever that, at any rate, all except the first (and most probably this one also) of these late-bred queens owe their impregnation to the abnormal drone offspring of the Ligurian queen above referred to. This fact confirms the conclusion to which the *post-mortem* examination of small drones had already impelled me—viz., that notwithstanding their diminutive size, they are perfectly competent to the performance of every male function.—A DEVONSHIRE BEE-KEEPER.

**NUTT'S COLLATERAL HIVES.**

In answer to "W. W." respecting any information on the management of Nutt's collateral hives, and that being the only kind in my apiary, it is with great pleasure that I offer him my experience for the last five years with them. First, then, we will suppose him to begin with a stock in the pavilion in spring; and as soon as he perceives that they begin to increase in numbers—say early in May, take one of the side boxes and fix a nice piece of clean comb to the roof or frame, or dress it with a little syrup. Having replaced the box in its position, and made all secure, withdraw the dividing-tin, and if it is a mild spring the bees will commence building combs in a short time. When you perceive that they have three-parts filled the box with comb, treat the other box in a similar manner; but be sure to keep the ventilators closed in the side boxes till the bees have begun working in them for a few days, when they may be opened gradually as the warm weather advances, the object of the inventor being to prevent swarming, and to obtain pure honey by means of the ventilation in the side boxes. The only instance that I know of a Nutt's hive swarming was in the summer of the present year, when a friend of mine, on leaving home for a few days, neglected to draw up the tin of the second box, when it threw a small swarm, but this returned to the hive again in the evening.

I would advise "W. W." to adopt the suggestions which our valuable Editor gave me two years ago, and which I have adopted with success—that is, to fit his collateral boxes with bars or frames; by so doing he can make artificial swarms, take a comb of honey, or strengthen a weak stock, as circumstances require. I may add, in conclusion, that my hives and boxes are rather smaller than the size stated by "W. W.," and I make them all myself of a winter's evening. There is but one entrance, and that in the floorboard under the middle box, which latter I never move only to clean the floorboard in spring and again in autumn, when I take off the side boxes, and if "W. W." or Mr. S. Brierley, chance to be in my neighbourhood, I shall feel much pleasure in showing them my apiary and all connected with it.—T. SEDGLEY.

**OUR LETTER BOX.**

**DUCK-FOOTED GAME (Novice).**—If you refer to our No. 225, published on the 18th of July, you will find at page 53 not only a description but a drawing of the deformity.

**COCHIN CHINAS WITH CROOKED TAILS (Eboracum).**—No ailment in poultry is more hereditary than this deformity, which arises from spinal curvature. On no account breed from any bird with this malformation. We advise you to add fresh blood to your stock. The deformity is probably derived from the cock you mention who carries his tail on one side when walking. As you have no other, and as he does not so carry his tail when at rest, you may be successful with him in the exhibition pen.

**BRARMA POOTRA HEN (A. H. D.).**—This hen with a hanging abdomen we fear will never recover, she is ruptured, and has also disease of the egg organs. If she do not die, she will never lay, and is, therefore, valueless.

**FEEDING TURKEYS FOR EXHIBITION (Retriever).**—Keep your Turkeys in a small place, and feed them generously on ground oats and a little meal slaked in water. Where a number are kept, a pig trough is a good thing to feed them out of, and a pig sty is not a bad place, if the sheltered part is high enough for them to roost comfortably. They must have plenty of clean straw that they may not injure their plumage. A cock and two hens to exhibit with good hope of success should weigh, if old birds, from 54 lbs. to 60 lbs., if birds of the year, 40 lbs. to 45 lbs.

**POINTS IN ROUEN DUCKS (Idem).**—Rouen Ducks should be exactly like Wild Ducks but larger. The bill of the drake should be yellow, washed over with light sea green, so lightly as to allow the yellow to be seen through it. That of the Duck should be yellow with a dark mark on it, like that on a horse bean. They should weigh from 7 lbs. to 7½ lbs. each. The Ducks must have no white whatever in their plumage; the Drake only the ring round his neck, no white feathers in the wings. Feed them on oats, gravel, and you may give some raw flesh if you will.

**GOLDEN-FENCILLED AND SILVER-FENCILLED HAMBURGH COCKS (W. B.).**—The comb is one of the principal points of a Pencilled Hamburgh cock. It must be full of points, well piked behind, and turning upwards, quite firm on the skull. The colour of his plumage should be rich; the tail ample, and with black ground; the principal feathers edged with gold or silver as the breed may be; bright blue legs, and cheerful carriage.

**PIGEONS UNWELL (J. T. Cooke).**—As your Pigeons do not moult freely, it may be as well to alter their diet. Leave off the beans and barley for a time, and give wheat and buckwheat for a change. A little hempseed may assist them. I suppose your Pigeons are sheltered from the cold winds, and have access to water for bathing. As to canker in the mouth I think it arises from an impure state of the blood, and is, I think, also infectious. See that the mice do not taint the food, that their water is clean, and let them have salt to peck. If they have not been accustomed to salt you must be careful first, otherwise they may be so greedy after it, as to eat more than is good for them. Cleanliness will assist their recovery. You can dissolve some chlorate of potash in hot water and mix with their drink, let them have only that to drink for two or three days, then wait a day or two and try it again. As to a local application to the diseased parts, after removing the pus, rub in salt or touch with caustic.—B. P. BRENT.

**PIGEON-COTE ON A POLE (Pi! John!).**—Mr. Rogers, of the City Road, makes this sort of Pigeon-cote, but such are only fitted for the hardier sorts, and those that do not breed in cold weather. They may be made square, octagonal, or circular, and two, three, or four stores high, with some finish to the top. The square form is, perhaps, the best, as the nest places can then also be made square, and they should be 9 or 10 inches inside. The other shapes are not so commodious on account of the nests all going off to a point towards the centre of the cote. We would recommend in preference a loft over the stable, and the entrance to the southward may be made as ornamental as you please.—B. P. BRENT.

**TURBIT PIGEONS WITH MOUSTACHE (J. R. Robinson).**—There is a breed of Pigeons in Germany resembling Turbits having the moustache like the Trumpeter, and I have no doubt that breed originated in the mixture of those two varieties. The continental Pigeon fanciers are very fond of making varieties by crossing and combining the different properties of various sorts in the same individuals. Thus they breed Jacobins with the addition of the moustache, Barbs with the ruffe of the Turbit, Fan-tails with silky plumage, &c. No doubt Mr. Robinson's Turbits have some German blood in their veins, and that some ancestor many generations back had the moustache which has just now reappeared. Should he continue to breed from the same old ones he will most likely have some more young ones with the moustache, and should he be successful in rearing a pair he may then be able to establish a new variety of Turbit. I have a pair of feather-footed Black Mottled Rollers. They are paired, mother and son, and first-rate Rollers, yet last year they threw a Red Mottled cock with turned crown, and this year they have again a turned-crown nearly black young one. If any one has a desire to breed a variety of Rollers with turned crowns, these two are at their service. Their parents tumble so much that they cannot fly well.—B. P. BRENT.

**FLYING PIGEONS (S. A. C.).**—Not having seen your Pigeons, and as you give no description of them, I cannot tell what sort they are. You had better obtain the "Pigeon Book," published at this office, and sent free by post for nineteen postage stamps. That will enable you to find out what sort they are, and gives more information than space can be found for here. The only Pigeon I know of by the name of Ruff, is a coarse Jacobin, and these are the worst of flyers. You must not attempt to fly them with the Tumblers. If what you call sandy are Short-faced Almonds, as you have been told, they are too delicate for long or high flying; but you can train your Blue Tumblers as directed in answer to "HIGH-FLYER," last week. If you persevere with them for a few months after they have their new feathers and full wings without success, you had better put them in a pie and buy a better sort. Some of the common Tumblers have no dash in them, and are so lazy that it is only waste of time to try and train them. Obtain a few well-trained birds of a good flying breed, so much depends on pedigree.—B. P. BRENT.

**PULLETS LAYING—PROFITABLE BREEDS (Ibid).**—Pullets commence laying at from five to nine months old, according to the time of year at which they are hatched. As to the sort to keep, so much depends on fancy that you had better have the "Poultry Book," which will shortly be published, and choose for yourself. All are good under favourable circumstances, none will succeed in adverse ones. If your space is confined, and you only require eggs, Spanish or Polish will suit you; but if you want chickens then Shanghaes, either Cochins or Brahmas. If you have an extensive run, then the rose-combed everlasting layers, commonly called Hamburgs, will produce the most eggs. For general purposes I prefer White Dorkings.—B. P. BRENT.

**WOOD FOR HIVES (Israel Todd).**—Red deal, well seasoned, and fully three-fourths of an inch thick, is suitable for making wooden hives.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 48.3°, and its night temperature 33.9°. The greatest heat was 62½°, on the 16th, 1840; and the lowest cold, 18°, on the 15th, 1849. The greatest fall of rain was 1.24 inch.

THE DURION.

**DURIO ZEBETHINUS**, the Durion, is the tropical fruit to which I now wish to draw attention as one likely to become, hereafter, very useful for the dessert. This tree,

of which there are many varieties, is a native of the warmest parts of southern Asia, where it grows very rapidly, and attains the height of 30 feet. The leaves are about 4 inches long, very smooth at the edges, and shaped somewhat like those of an Apple. The flowers, large and fragrant, are produced in small bunches, and are of a yellow colour. The fruit, which is covered with a hard knotty rind, is about the size of a child's head, and is not unlike a Chestnut in appearance; when ripe it becomes of a dark yellow, and cracks at the top. Inside, the fruit contains five or six large cells filled with the pulp mixed with seeds. This pulp or cream is of a pure white colour, very thick, and highly nutritious; the taste is peculiar, but very agreeable, and although of the very richest nature never palls upon the appetite, or injures the most delicate digestion. For an invalid the fruit is invaluable, its only drawback being the disagreeable odour when ripe.

When growing the Durion for fruit, it should be planted out in a border within the stove, and is best trained up the roof like a Vine; indeed, where the room can be spared, an entire house should be devoted to its culture, as few plants will thrive under the shade it causes. When in full bearing such a house presents a striking appearance, the large fruit hanging down in all stages of growth from amongst the leaves and flowers.

Unlike the Mango and Mangosteen, this tree requires a season of complete rest, and directly the fruit is all off, which will be by the end of November, the temperature should be at once reduced, lowering it to from 60° to 65° by day, and from 55° to 60° by night. No water must be given unless the border becomes very dry. Never mind a few leaves falling, the trees will be all right, and the better for it in the next spring, as it is vain to expect fruit on the Durion unless the tree has previously had at least two months' rest.

Towards the middle of February the trees will start again, and the temperature must then be raised to from 75° to 80° by day, and from 65° to 70° by night, at the same time keeping the house close and moist, and watering the plants frequently. When the flowers open the temperature may again rise to from 85° to 90° by day, and from 80° to 85° by night, giving air freely in fine weather, and occasionally syringing the trees overhead.

The flowers will set freely, and little attention will be needed until the fruit is half grown, or about the size of an

Apple. This is a critical time with the Durion, as much fruit will then fall off, sometimes nearly the whole crop. The only way to prevent this is by maintaining a high temperature, and, at the same time, admitting plenty of fresh air, care being taken that the air is well warmed by passing over the hot-water pipes or flue before it reaches the trees, as the least chill stops the new growth, and materially injures the fruit.

As the fruit ripens the heat may range between 90° and 95° by day, or even higher, and 80° and 85° by night. It is of the greatest importance that the trees at this time should be frequently syringed—twice a-day will be by no means too often; unless this is done the smell of the ripe fruit will be very strong and revolting. The crop will continue ripening for some weeks, all stages of the fruit being seen on the trees at the same time. When ripe the fruit must be cut, or it will soon putrefy, and affect the rest; by not attending to this many fine fruit may be lost. It should also be eaten fresh from the tree, as it very rapidly deteriorates, and will not keep more than twenty-four hours. If it is wished to send some of the fruit to a distance it should be cut before it is quite ripe, and it will then keep two or three days.

On account of the great size and weight of the fruit it is advisable to give it some support just before it ripens; this may easily be managed by tying it up to the tree with two pieces of matting, about an inch wide, placed crosswise under the fruit, and tied over the branch.

The border in which the Durion is planted should be the entire length of the house, about 3 feet wide, 18 inches deep, and well drained. As this fruit delights in rich food, the soil should consist of one half good leaf mould, one quarter sandy loam, and one quarter rotten manure taken from a spent hotbed. These ingredients, thoroughly mixed together, should be sifted through a sieve, adding now and then a little charcoal, broken into pieces the size of a hazel nut, and a few whole bones. In planting be careful to spread out the roots, pressing the soil firmly around the trees. When once fairly established the trees will require very little attention beyond renewing the top soil occasionally, and keeping the roots well watered. For a house 20 feet long two trees will be quite sufficient.

The Durion, though by no means so handsome a tree as the Mangosteen, is, when loaded with fruit, a very beautiful object; the flowers, too, are very fragrant, emitting a peculiarly grateful scent. The fruit is particularly valuable for invalids, uniting, as it does, in itself the flavour of a delicious fruit with that of a delicate animal food; it is also very useful for the dessert; and as it bears freely with proper treatment, and grows rapidly after the first year or two, it is, I think, well worthy of cultivation.

One thing which baffles me is the pruning, and I have little doubt that from not doing this properly I have lost a good deal of fruit. The Durion is a puzzling tree, sometimes bearing from the young wood, and sometimes from the older branches. One tree will also occasionally bear entirely from new wood, while its neighbour bears from the old, or, more frequently, from both. The mode I have hitherto adopted is to train a stem up each rafter (the

rafters are 3 feet apart), and allow the new wood to grow out on either side from the main branches, cutting back every alternate shoot to the rafter branch each year. By this means I have obtained a fair amount of fruit; but I feel certain that did I fully understand the nature and habits of the tree I should have more. Perhaps some correspondent would kindly throw a little light on the subject, as there seems to me no fixed law in the matter.

The Durion is difficult to propagate, as it is a long time in coming to a fruiting state from seed, and cuttings are very shy of striking. The best way seems to be to peg down a branch to the soil, first cracking, but not breaking, the bough where it touches the earth, and covering it over with a little mould. When rooted plant it in a pot, and plunge into a brisk bottom heat; it will, when once established, grow freely. A tree raised from seed will not bear under five or six years.

I had almost forgotten to mention that the fruit must never be cut with a steel knife, and should be eaten at dessert with bone or ivory spoons, in preference to silver ones.—J. H.

## CULTIVATION OF THE VINE.

(Continued from page 8.)

Most of the foliage will now have fallen off the Vines in the early house, and when this is the case lose no time in pruning; but care must be taken in performing this operation not to split the shoot in cutting. Avoid using scissors for pruning the Vine; these have a tendency to bruise the shoot for an inch or more below the cut, and when the Vines are syringed afterwards in the course of forcing, the water often runs down the shattered wood, and in many instances destroys the bud at the base of the shoot, and with it the prospect of a crop. The bud that would in due course have shown one or two bunches of fruit is by these means destroyed, to be replaced by two or more wood-buds. I am no advocate for the pruning-scissors at all, except for very rough pruning, such as Roses, and in this case I always use a sharp knife after them, taking care to cut off all the part that has been shattered by them. The safest way is to first shorten the shoot down to about the fourth or fifth eye; the remainder of the shoot can then be taken off with less fear of injury to the fruit-bud. I invariably keep a sharp knife for finishing off with. After I have gone over one Vine and shortened all the shoots as described above, I commence at the base of the Vine, holding the thumb and forefinger of the left hand firmly pressed against the shoot, pressing the thumb firmly against that part of it where the cut is finished. If this is not done a portion of the shoot is often split off, and with it one of the best buds. I mention this particularly here, so that those who have not had sufficient practice may save themselves a large amount of disappointment. I always prune down to the best prominent eye.

In about three weeks after the Vines are pruned, if the house is intended to be started in the first week in December, the border should have a good soaking with tepid water, and if the roots are outside, 18 inches or so of leaves should be laid on the border to encourage root-action, before the house is shut up, and the Vines should be syringed; this will cause them to break with greater regularity and stronger.

The leaves should be turned and well shaken about once every fortnight to prevent their becoming too hot, and if the heat in them is decreasing too rapidly, more leaves should be added. Something in the shape of wooden shutters, or a tarpauling should be placed over the leaves for the purpose of keeping out the rain from them. A trial stick should also be pushed in the bed, which should be frequently examined to ascertain the temperature. Towards the spring the leaves and other fermenting material should be turned as often as once a-week to prevent the roots from coming up from the border into them. If this is not well looked after the Vines may suffer much injury in consequence of their making so many of those fleshy roots which only feed the Vine with more sap than it can make use of; then loss of colour, shanking, and many other evils follow.

I should have stated before, that I do not see any necessity for daubing the Vines over with the usual mixture of clay, cow-dung, &c.; if a little of the old bark is peeled off, that I consider is all that is necessary, and great care should be taken in performing this. I have often seen people scraping and poking out the little bits of old bark at the base of the shoot; the only good this does is to make the Vines look a little better. More or less of the buds are sure to be sacrificed during this

operation, according to the skill of the operator. This, then, should be avoided by all means. Should any of the Vines bleed, which is sometimes the case as soon as their roots begin to work, a little dry Portland cement dashed over the cut once or twice will stop it.

The Vines, as soon as the house is shut up, should be liberated from the trellis, so that the top of the Vine may be a little lower than the base. This prevents the sap from flowing too rapidly to the top, and causes them to break more regularly. As soon, however, as the shoots are 2 inches or so long, the Vines should be gradually tied-up, still leaving the point a little the lowest, providing there is head-room. As the Vine progresses, breaking from the base upwards, raise it higher and higher until you have it in its proper position. The house should be frequently syringed when first shut up, and the temperature should range between 45° and 50°, giving during this time all the air possible, but scrupulously avoiding direct draughts and currents of wind through the house. This temperature may be continued for three weeks, when the Vines will begin to show symptoms of pushing very slightly; the temperature may then be increased a few degrees in the middle of the day. Keep all the air on that can be given with safety. About the first week in January they will show unmistakable signs of moving, green leaves will soon be visible, and after these the short, stubby, bunches of fruit. After this the temperature should never be allowed to sink below 50° at night, and 55° in the day; with the sun it may be allowed to rise to 65° or 70°, providing there is plenty of air on at the time. The syringe should be freely used up to this time, and twice or thrice a-day up to the time of flowering, when syringing the Vines should be altogether discontinued, but the passages, walls of the house, &c., should be syringed freely.

I know that I am treading on dangerous ground here, for some advocate the use of the syringe up to the time of the Grapes colouring—my friend Mr. Whittle, to wit, to whom I am greatly obliged for his kind invitation, and I assure him that I appreciate his kindness very much, and shall most certainly accept his offer on the very first opportunity.

I had great hopes that his and my disagreeing to agree in our opinions on syringing and other matters connected with Grape-growing, would have brought out many letters in *THE JOURNAL OF HORTICULTURE* from our champion Grape growers. I still hope that they will favour us with their views on the subject, for it is a most interesting one.

The wonderful display of Grapes at the Edinburgh Show will be the means of trying the mettle of our Grape growers for the next few years, and I believe that, however great the results that have already been obtained, still greater are obtainable by applying our minds more fully to the subject. Constant practice, with keen watchfulness, will make many a mystery clear, and open the door of success to those who are at present labouring under difficulties in cultivating the Vine.

I think, if my memory serves me right, Mr. Whittle said he would give us a paper on the cultivation of the Vine in pots. If he would kindly do so I am sure it would be read with pleasure and profit by many.

If it is intended to propagate a stock of young Vines, the cuttings of the kinds to be propagated should be tied in bundles and their ends put into the soil. The first week in January is a good time to put in the Vine eyes. They will require a brisk bottom heat, and should be shifted into larger pots as they advance in growth, still keeping them plunged where they can have the benefit of a bottom heat of 75° or 80°. When it is desirable to have well ripened canes for early forcing next year, they should be shifted often, and receive all the heat that can be given them. If they have their final shift into 12 or 14-inch pots early in April, they may be placed where they can have the benefit of as much sun as possible. They must on no account be allowed to become sufficiently dry so as to cause them to flag. After they have made their growth they may be placed in a cooler house, where they can have the benefit of as much light and air, as well as surface heat, as can be given them; this will soon harden them, and by the end of July their wood will be as hard as well-seasoned oak.

For a late Grape, in my opinion, there is none to equal Meredith's Black Alicante, the more I see of it the better I like it.—J. WILLS, *Huntroyde Park, Burnley, Lancashire.*

THE CZAR VIOLET.—I am anxious to make known to all the lovers of Violets who may not have met with Mr. Graham's Czar Violet, that I have now (November 3rd), some splendid

plants with full-blown flowers, which, from their wonderful size and sweetness, cannot be surpassed; nor indeed can any Violet come near the Czar. I feel myself greatly indebted to Mr. Graham for the trouble and patience which he has exercised in order to produce such a treasure for our gardens.—  
PROSPERO.

### STRIKING CUTTINGS OF THE VERBENA.

SINCE August I have read in the Journal of various methods of striking Verbena cuttings; and in one Number I saw the reply to a correspondent, that those who succeed in striking the Verbena from cuttings cannot fail in striking other bedding plants, making it appear that the Verbena is difficult to strike. As I have found it not only an easy but a very simple matter, perhaps the plan I pursued may be of some use to those who find a difficulty in the operation.

About the second week in August I took as many cuttings from the old plants as I thought I should require, and put two cuttings into a four-inch pot, pressing the cuttings firmly in, and watering them out of a can with the rose on. The soil I used was common soil out of the kitchen garden, mixed with a little Reigate sand. After I had potted all I wanted I placed them in a corner of the garden that was overhung by large trees; the trees effectually kept the hot sun from scorching the plants. I watered them occasionally, just keeping them moist; and did nothing more to them till the 13th of October, when I nipped the tops off, took the plants into the greenhouse, and placed them near the glass, where they can have plenty of air and light.

I may add in conclusion, that out of two hundred cuttings I only lost four; and a gentleman's gardener called to-day to see me, and he said he had never seen finer and healthier-looking Verbenas.

I may also state that all my bedding plants have struck without the aid of any artificial heat, including Verbenas, Geraniums, Loth common and fancy, and variegated, Ageratums, Salvias, &c.—JOHN BOWLEY.

### TRANSPLANTING FROM RUSHTON.

IF I lacked the Roman toga, and the still more rare Roman virtue, to make me fancy that I was Marius sitting amongst the ruins of Carthage; if the monogamist character of my views and sundry other small matters forbade me to fancy that I was Boabdil, as he stood on the hill still called "*Oltimo sosprio del Moro*," and looked for the last time on the proud walls and glittering minarets of his loved Grenada; and if my aversion to that nasty weed, almost equal to that of James I., of blessed memory, prevented me from imagining myself to be Macanlay's New Zealander, as he sat smoking his calumet, looking over the ruins of once proud London—I had the other day, when standing in Mr. Radclyffe's garden at Tarrant Rushton, one thing in common with them all, I was looking on glory departed or departing. I felt that I was standing where, probably, I should never stand again, for, alas! Rushton is doomed, and however its worthy rector may be designated hereafter, he will no longer be known as Rushton Radclyffe. He hands over the living either in March next, or March twelvemonth at the latest, to a younger rector, and he will be fain to pitch his tent elsewhere, and what he can take with him of his loved pets will migrate too.

Already I seemed to see the new "*Inenmhrance*," as an old dame once said to the late Bishop Blomfield, sending his men into the very sanctum of our friend. What in the world could he want with all those great sprawling trees? Wouldn't the house look much better well cleaned and whitewashed? And so away would go Solfaterre, Celine Forestier, and Triomphe de Rennes; and then, who would take the care of those Peach trees, from which the present rector has gathered upwards of 4500 Peaches in nine years, that has been taken of them? No one, I fear; and so I thought I would just say a few words anent this garden, ere it passes away from the notice of the horticultural world for ever.

I think that Mr. Radclyffe would be the last to let it be supposed that there were no such Rose trees in England as his, or that the growth which they manifest is something new and above that which other growers accomplish. No, it is simply this: In every point that can benefit the Rose grower the garden at Rushton is deficient; the soil is poor and hot, the situation exposed to the violent south-westerly gales, which so prevail in Dorsetshire; moreover, it lies in a valley where

frosts are much more severe than on higher ground; and all these things have to be combated. Yea, they have been and are fairly beaten, the Roses equalling those of more favoured localities, and all this from the determined perseverance, intelligent gardening, and constant care of the rector of Rushton.

The Strawberry plants, notwithstanding the hot season, looked full and vigorous, but then they had been watered incessantly. I never, said "Stephen," was "tired of anything than I wor of watering this year." All the first-rate kinds were here, and giving promise of great things, the most vigorous being Sir Joseph Paxton and Wonderful. Then there are the Peach trees looking so clean and bright, with well-ripened wood, close cut, which seemed to say, Only take of me, and see what I will do for you next year.

Mr. Radclyffe is so constant a correspondent of THE JOURNAL OF HORTICULTURE, that he leaves but little for me to say, and I am sure that he would not like that I should say all I heard of his open-handed liberality and kindness as a neighbour, clergyman, and friend. All about him hope that he will not move far away, and that if Rushton knows him no more, he may find a garden (for I do not think he cares much about the home), where under more favourable auspices he may yet achieve greater things as a rosarian. Let all who complain of soil and situation take a lesson from him, and their motto will be, "*Nil desperandum*."—D., Deal.

### ARCHERFIELD.

THE rapidity with which the traveller is now carried over the country allows him but little time to contemplate the character of each district until it has been left behind, and other features present themselves. Thus it is only when the journey is prolonged amidst scenery of a uniform kind that the mind begins to realise the certainty of distance; but then the monotony soon becomes more tiring than change. A railway skirting the ocean is at most times agreeable, while a moor or morass becomes wearisome, and even the well-cultivated tracts of country, known as the fen districts, lose all interest after the first sight has been obtained. There are, however, large tracts of level country which have been brought into the highest possible state of cultivation, and which will at all times claim attention; for instance, the market gardens in the flats which border the river Thames, both above and below London, cannot fail to attract attention, and so with the more extensive tracts of level country in agricultural crops, when their cultivation is of the highest order. It is to a district of the latter description that I have now to introduce the reader, it being an extensive plain bordering on the German Ocean and its tributaries, and one which for many years has stood in the foremost rank of agricultural progress. For at least two or three generations the Lothians of Scotland have held a high reputation for their agriculture, and particularly the East Lothian, or Haddingtonshire, to which I now refer. It is a flat country, the portion having the Frith of Forth for its northern, and the German Ocean for its eastern boundary, being level, or nearly so, for many miles inland, yet not the dead flat of the fen districts of Lincolnshire and adjacent counties, but destitute of eminences of any importance, excepting in such solitary cases as that of the remarkable mass of rock, called North Berwick Law, which is a huge mis-shapen mass of basalt, rising abruptly out of the plain. This prominent feature, visible for several miles, is, in some respects, the counterpart of its near neighbour the Bass Rock, only the latter rises out of the ocean, and possesses no small historical interest. The aspect of the country is more in accordance with what a farmer would admire than what the man of taste would wish for: large fields, with only moderate-sized hedges in straight lines, and but few trees, give the idea rather of a wholly agricultural district than of a picturesque one; and if we add the fact that dwelling-houses are but thinly scattered, and those that do exist present more the appearance of usefulness than of ornament, we have but little for the lover of varied landscape to admire in the picture. This flat country is divided into fields of from twenty to fifty acres or more, and the farm buildings are substantial, including that which forms so striking a contrast with most English homesteads, the building for the steam-engine, with its tall chimney, a number of corn stacks surrounding the whole. It may be remarked that in most cases the farm-house is on the south side of the building, and farther, that the farms are large, and not more than one-fourth of their acreage, if so much, is devoted to perma-

ment meadow or pasture, the remainder being wholly in tillage. In the early part of September the harvest was being just concluded, and fields of Margold, Turnips, and Potatoes showed unmistakably what good land or good farming, or rather both united, were capable of doing. These features of the country are here given preparatory to introducing the reader to one of the best-managed gardens in the kingdom—Archerfield, which is situated in this well-cultivated district.

From the general character of the country it will be at once understood that picturesque scenery does not form a main feature of this place; nevertheless, it is not without its advantages. The southern shore of the Frith of Forth forms the boundary to the park on that side, and the fine turf, level as a bowling-green, runs down to the water's edge, while at a little distance from the shore two or three island rocks, on a smaller scale than the Bass Rock, give great diversity to the scene. The Frith of Forth is from fifteen to twenty miles wide at this point, but the opposite coast of Fife is distinctly visible, and the size and shape of its fields easily traced. This view, of which the broad expanse of the Frith constitutes the finest feature, is to the north of Archerfield; looking eastward we have the black and precipitous rock of Berwick Law, almost on a line with the Bass Rock, already referred to. The coast in that direction is some miles distant, and not seen from the grounds. The immediate neighbourhood of the mansion is well clothed with timber, and the park and its surroundings are plentifully supplied with trees. Some thriving woods of mature age intersect it in various directions, and afford shelter where such is wanted. A noble avenue, stretching in a straight line from the west front of the mansion to a great distance, appeared to be 150 or 180 feet wide, and the ground being level it had a fine effect. On other sides plantations of irregular form connect the mansion with the ruins of a former residence at some little distance off, named Dirleton Castle, which will be noticed hereafter; there being walks through these woods, and ever and anon some opening displaying a Pinus or other important tree, differing from those forming the rest of the wood. The mansion is a large commodious structure, built, I believe, about the middle of the last century, when comfort and convenience were regarded as of more importance than external appearance, although in the latter respect it is not without its merits. In its immediate vicinity are a closely-shaven lawn, shrubs judiciously planted, singly and in masses, and here and there a Conifer, but few or no flowers. We must look elsewhere for those flower-garden plants which Mr. Thomson has the reputation of cultivating with so much skill and success, and arranging with such taste.

It has been explained that the mansion of Archerfield is situated on a plain, having the estuary of the Forth about a mile and a half or more to the north of it. The kitchen garden and forcing department, with Mr. Thomson's dwelling, are nearly a mile to the south-west; and the ruins of Dirleton Castle, with its beautiful flower garden, are little short of a mile off, in an opposite direction. These two places, nearly two miles apart, but of course connected by well-kept walks, &c., form independent flower gardens, and will be treated of separately. The kitchen garden, as being the head quarters and possessing other objects of interest, will take precedence. This garden is a parallelogram, and walled all round, the north wall, about 500 feet long, being occupied with glass structures, and some Pine-pits, and others are at the north side of the wall, with the usual offices. The garden, I may remark, instead of being divided in two by a walk across the centre, has two such walks, which, with the walks near each end, divide the central portion into three equal parts, and each of these walks gives scope for variety in that mode of ornamenting flower-borders which Mr. Thomson practises.

Before entering on this, however, let us take a peep into the houses and see some of the specimens of those noble fruits which Mr. Thomson exhibited so successfully at Edinburgh. The houses, though symmetrical, are mostly old, and the end ones, especially, are narrow. The whole length of range is divided into eleven houses, which, for distinction, I shall number from the west end. The two end houses, Nos. 1 and 11, are only 5 feet wide, merely glass cases in fact; Nos. 2 and 3, and 9 and 10, are about 7 feet wide; while Nos. 4 and 5, and 7 and 8, are about 11 feet; and the central house, which is span-roofed with a door in the front, is 15 feet wide; so that these houses, presenting a great length, it is true, have but little standing room for plants. I will, however, describe their contents more in detail, and beginning at No. 1, at the west end of the range, make a few notes on each.

1. Vinery, as stated above, only 5 feet wide inside, planted mostly with Lady Downe's, in excellent order, fruit being good.

2. Peach-house; fruit, which had been good and abundant, had been gathered; there were, however, some Figs in pots still having fruit on, and some plants for decorative purposes were coming on.

3. Vinery; mostly Black Hamburgh, excellently coloured, and in other respects good, as evidenced by the success which Mr. Thomson had at the Show. There was no appearance of withering or shanking, and the whole of the Vines were in most excellent health.

4. Vinery; mostly of the Muscat class, well ripened off, and equally well finished with the Hamburgh. The Duchess of Buccleuch was coming on, but was not so far advanced as to enable a judgment to be formed of its merits, but the whole of the Muscats were excellent.

5. Forcing-house, where Vines had been forced in pots, and it had been used variously. At the time of my visit, plants for rooms and other decorative purposes were its principal occupants.

6. Greenhouse with a span-roof and door in front, containing most of the popular plants of the day, not the least interesting being specimen plants of some of the best bedding Geraniums—such as Excellent, Chimax, Amy Hogg, Paul L'Abbé, Cybister, Rose Rendatler, Conspicua, and others. There was also an excellent specimen of *Statice profusa* and *Solanum capsicastrum*.

7. Vinery; Black Hamburghs, mostly cut, but had been good.

8. Vinery, recently planted, promising. Several new kinds had been introduced here, and in a year or two, doubtless, this will be very interesting. Some Figs and Vines in pots were also allowed a place for the time being.

9. Vinery; Vines mostly newly planted and choice kinds, including one or two seedlings; one, a White Grape, promised well. There was also a Black one that appeared likely to be useful and good.

10. Peach-house; fruit gathered; but trees in good trim.

11. Vinery; mixed kinds of Vines.

These houses, as will be understood, entirely occupied the north wall of the garden, leaving only two openings for ingress between the houses, Nos. 3 and 4; and also between Nos. 8 and 9. These walks, crossing to the opposite side of the garden, end at doors in the south wall, and between these doors on the south side is a Peach-house, 132 feet long by 12 wide. This house had not been forced like the others on the north wall, and, consequently, there was still some fruit hanging in the beginning of September, and both it and the trees were in excellent order. In winter Mr. Thomson here keeps a great portion of his bedding plants, as a couple of pipes run along the front. This house was also gay with good specimens of Geraniums and other flowering plants.

When describing this house I must also mention, that on the north side of the wall Morello Cherries were bearing excellent fruit, and a border about 12 feet wide was planted with Currant and Gooseberry trees, which at the time of my visit were in bearing, and a net fastened to the top of the wall, in a sort of lean-to fashion, protected the whole from the depredations of birds. The Gooseberries were still good and in tolerable abundance, while the other fruits promised to hang some time. I believe that Plums are retarded in a like manner, but this fruit is liable to drop off, and little can be done to keep it on the tree. This mode of keeping small fruits I noticed in one or two other places, and it seems a plan worthy of adoption.

In some Pine-pits behind the garden wall, Mr. Thomson had some excellent fruit of Smooth-leaved Cayenne Pine Apple, a variety to which he is very partial, and certainly, judging from the very excellent specimens here produced, it is deserving of greater attention. Mr. Thomson grows all the plants in pots, and in pits not by any means remarkable, either for their construction or facilities for heating, and yet he had fruit weighing upwards of 9 lbs., and the weight of a quantity that were in fruit or coming on would seem to average about 7 lbs. The fruit has a handsome appearance at table and is much admired. I do not think the variety often exhibited at the London shows is the same as this, as the London one is more tender as a plant and seldom attains the size above mentioned. Mr. Thomson also grows Queens, but less extensively than the Smooth-leaved Cayenne. There were some very good fruit of 4 and 5 lbs., and I learned it was customary at Archerfield to calculate the weight by the number of pips in depth in each fruit. A Queen Pine was expected to be half a pound in weight for every pip

in depth. Thus a fruit ten pips deep was expected to swell out to 5 lbs. in weight. The Smooth-leaved Cayennes were calculated at 1 lb. per pip. Thus a fruit 8 pips deep was expected to weigh as many pounds when ripe, and so on. The healthy appearance of the plants, and other circumstances, proved beyond doubt that the soil and treatment suited them, for it would be impossible to look on plants indicating a higher degree of health, and yet at the same time the foliage was not of that gross character I have frequently seen, when fruit only half the size was produced. The plants did not appear to have had any coddling, as three fine plants which Mr. Thomson had exhibited at the Edinburgh Show, and having fruit on, but which had not begun to colour, were returned to their places without appearing to have sustained any injury. The whole seemed to be growing away with but very little attention.—J. ROBSON.

(To be continued.)

## THE INTERNATIONAL HORTICULTURAL EXHIBITION.

It will be seen by our advertising columns that the great international project is now fairly launched, and at the head of it is Her Majesty, who has been graciously pleased to aid it not only with her royal patronage but with her purse. In like manner His Royal Highness the Prince of Wales has given his patronage, and has accepted the position of President; and we are happy to be able to state the adhesion of other members of the Royal Family is daily expected. With such support, and the support of those, the long list of whose names is announced, the prospect of success is most cheering. Already £2711 have been subscribed, and £3845 guaranteed, and every day brings its contribution. It is quite evident that the movement has been taken up most cordially by all classes and representatives of the horticulture of the country, from the Queen herself to the professional gardener, and one has but to glance over the list to see how all have, according to their means, done what they could to promote this laudable object. But there are many who have not yet sent in their support; some from the feeling of doubt as to whether the object would be carried out to completion, and others from a desire to see what their neighbours have done. There is no reason now to hesitate on either ground, and we would strongly advise all those who intend to identify themselves with this great national movement to send in their adherence as early as possible, that the Committee may know on what they have to depend.

The opening-day is now fixed for Tuesday, the 22nd of May, and the Exhibition will last till the evening of Friday following. The opening ceremony, to which none but the subscribers and the holders of privileged tickets will be admitted, is expected to be of a very attractive character, and will be conducted with all the importance befitting such an occasion.

The arrangements that have been made with the Council of the Royal Horticultural Society are such as will conduce much towards the success of the Exhibition. It is intended that the site be either the western annex—that is, the open space on the west of the Society's garden, or the vacant space to the south, where the Great Exhibition building stood; and the Committee of the International Exhibition are to have the entire use of the Society's garden for the week in which the Exhibition is to be held as an extension of their own exhibition. The terms which have been arranged will be gathered from the following correspondence:—

"1st November, 1865.

"DEAR SIR,—We are instructed to make the following offer to the Council in respect to the terms on which the garden of the Royal Horticultural Society is to be made available for the purposes of the proposed Exhibition.

"1. The Committee are to have the free use of the western annex, for the purpose of holding thereon such portions of their Exhibition as they may find it convenient or practicable to place there.

"2. To have also the use of the conservatory and of the western and upper arcades so far as they may require them, with permission to pass through the southern arcades in case the Show is held on the vacant space south of the gardens.

"3. To have the loan of the Society's staging if required.

"4. That the Committee of the International Exhibition undertake the arrangements in the gardens for the week in which the Show is to be held, and regulate the admission thereto of their subscribers and visitors, and of the public, from Tuesday to Friday inclusive. The admission of the Fellows to be regulated as hereafter explained.

"5. To have during the week of the Show the services of the staff employed in the ordinary business of the Society.

"6. To have all moneys taken for admission to the garden during the continuance of the Show.

"7. The Fellows are to give up for the week their privilege of admitting friends. They are themselves to have personal admission to the garden throughout the week, excepting to the conservatory and arcades on the Monday and Tuesday, during the staging and judging of the plants; and they are to have free access to the Exhibition in the western annex (or in the southern spot of ground belonging to the Treasury, should it be found more convenient to erect the tent thereon), only on the Wednesday.

"As an equivalent for this accommodation the Committee engage, in addition to the admission of Fellows and debenture-holders as already stated, to pay £300 to the Society on taking possession, to provide on each of the show days three bands of music, and to restore the western annex to the state in which they found it.

"I am, dear Sir, yours very truly, for self and co-Secretaries,

"ROBERT HOGG, *General Secretary.*

"To Capt. Cockrell, Assistant Secretary, Royal Horticultural Society."

"4th November, 1865.

"SIR,—I am desired by the Council of the Royal Horticultural Society to signify to you, in answer to your letter of the 1st November, their acceptance of the proposal of the Committee of the International Horticultural Exhibition therein contained.

"The Council desire me to express to you their earnest wishes for the success of the undertaking, and request me to inform you of their anxiety to afford you every assistance in their power for the carrying out of the scheme.

"I am, Sir, yours obediently,

"J. COCKERELL, *Assistant Secretary.*

"Dr. Hogg."

## THE ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 7TH.

FLORAL COMMITTEE.—As might be expected at this late season of the year, there were not many plants sent to this meeting for examination. Mr. Bull exhibited a very interesting collection of forty-eight plants used for either medicinal or official purposes. For this a special certificate was awarded. Mr. Bull also sent other specimens, and among them a large plant of the well-known hardy garden shrub, *Aucuba japonica variegata*, thickly covered with bright scarlet berries, for which a special certificate was awarded. *Selaginella Martensii albo-variegata*, from the same exhibitor, received a second-class certificate; and to *Cuscuta* sp. (*chilensis*?) growing on a plant of Ivy, producing white bell-shaped flowers very highly scented, a first-class certificate was given on account of its being a botanical curiosity. *Machærium firmum*, Pallisander Wood, supposed to be the Rose wood of commerce, was also exhibited by Mr. Bull.

Messrs. Osborn, Fulham, sent a plant of *Parochetus communis*, a trailing plant with a deep blue pea-like flower, almost a hardy plant, and useful for rockwork or baskets—second-class certificate; and Messrs. Downie, Laird, & Laing two cut flowers of *Chrysanthemum Queen of England*, striped, one of the many forms of sports of this flower. Three plants were brought from the Society's gardens which had been sent home by Mr. Weir, and which were probably *Philodendrons*; they were referred to the Rev. M. J. Berkeley for further examination. Major Clarke exhibited two plants which were raised in some earth sent to him from South Africa; their names, &c., were not decided upon. Mr. Fleuning, Cliveden, sent some specimens of Chinese *Primulas* with yellow variegated foliage; also some fine variegated *Pelargoniums*, the merits of which at this late season could not be determined, and it was requested that they should be sent again. There were also some specimens of bright red varieties of seedling Chinese *Primrose* from the Society's garden, one of which was very much admired and noticed. Mr. Salter, of Hammersmith, sent seven fine seedling *Chrysanthemums*, some of them first-rate flowers. Those of 1865 were:—Hereward, with fine incurved flowers much like the old *Argenta*, but better formed—second-class certificate; Golden Beverley, a very beautiful sport of the white Beverley; the flowers were not fully blown, but from its delicate and bright yellow colour and excellent form it will be much prized—second-class certificate; Gloria Mundi, a very fine incurved flower, deep golden yellow, forming almost a ball, very fine—first-class certificate. The seedlings of 1861 were Golden Ball, a fine incurved variety; the colour when the flower first opens is a dull buff or bronze, but as the flower expands the colour becomes of deep golden hue—first-class certificate; White Trevenna, a sport from pink Trevenna, a pretty hybrid with neatly-formed flowers; and Prince of Anemones, flowers pinkish white, but rather coarse. Those seedlings which received certificates will not disappoint the public; they will most probably be frequently exhibited next year, and to much greater advantage. The hot summer, or rather the scorching month of September, when the buds are formed, proved very prejudicial; and *Chrysanthemums* are not so fine this year as usual, the flowers being small and deficient in substance.

FRUIT COMMITTEE.—Mr. George F. Wilson, F.R.S., in the chair. Two bunches of Grapes were sent from the garden of the Society, which had never before been exhibited; one was Diamant Traube, a fine large form of Chasselas, with a pure Sweetwater flavour. The bunches are large, and the berries unusually so. It is a valuable early

Grape, ripening in a cool house in August, and it will hang as long as the Barbarossa without exhibiting any symptoms of decay. This was awarded a first-class certificate. The other was Laterode Noir, a large oval Grape, with dark black purple skin, and covered with a thin grey bloom. The flesh is tender, but has not a very rich flavour. On comparing it with Lady Downe's it was found to be much inferior. There was also a good dish of Belle Agathe Cherry, but in consequence of the late rains the flavour was gone.

Mr. H. Downing, gardener to Thomas Grissell, Esq., of Norbury Park, Dorling, sent a dish of magnificent Pomegranates, grown against a wall in an orchard-house. They were equal to the finest imported, perfectly ripe, and, in consequence of the highly meritorious production, they received a special certificate.

Mr. Challis, gardener to Lady Herbert of Lea, sent a fine specimen of Charlotte Rothschild Pine, and Lady Dorothy Nevill sent fruit of *Monstera deliciosa*, perfectly ripened, and excellent in flavour.

Messrs. Stuart & Mein, of Kelso, sent specimens of a small Savoy, which is not so good as the Early Ulm, and has the disadvantage of being too open. The Yellow Blumenthal Savoy was not considered so great a desideratum in this country as it is in Germany, where its yellow colour recommends it as the best of the Cabbage tribe for saurkraut. The Miniature Drumhead Cabbage, exhibited by the same gentleman, was a coarse form of the Chon Joannet, or St. John's Cabbage.

Mr. C. J. Perry, of Birmingham, exhibited a dish of dessert Apples, the name of which was unknown. A large collection was received from the Society's garden all correctly named.

Mr. Henry Dewar, of Newcastle-on-Tyne, sent stalks of very excellent white solid Celery, and roots of his new seedling Beet. The latter is a very handsome root, with a small neck. The flesh is a brilliant dark red, and the leaves are bronzy or greenish. When baked (not boiled—never boil Beet), it was delicious. This received a first-class certificate.

**SCIENTIFIC MEETING.**—W. Wilson Saunders, Esq., F.R.S., in the chair. The awards having been read over by the Rev. Joshua Dix, and G. Wilson, Esq., the Chairmen of the Floral and Fruit Committees, Mr. Saunders said that he was glad to observe a collection of interesting economic plants from Mr. Bull, and stated that it was the intention of the Society to gather together such plants, so that its Fellows should have a knowledge and appreciation of their nature and uses. He then called upon the Rev. Mr. Berkeley to make his remarks on the subjects exhibited.

Mr. Berkeley said, that before doing so he would take the opportunity of stating, that a scarlet Quamoclit, exhibited by Mr. Earley at the last meeting, and which, contrary to the usual habit of the species of Quamoclit in this country, was a perennial, proved to be a form of Quamoclit phœnicea. Dr. Thomson told him that several of the species of Quamoclit were perennial in India, though annuals in this country. Referring, then, to the subjects before the present meeting, he stated that of two plants sent by Major Clarke, one was supposed to be a species of *Jatropha*, or Manihot, with peltate, digitate leaves, which had peculiar stipules at the base of the petioles; and the other, Mr. Gibson had suggested, might be one of the Piperaceae, and, probably, an *Artanthe*. A *Cuscuta*, from Mr. Bull, exhibited last year as *Cuscuta chinensis*, if not identical with *Cuscuta reflexa*, was very like it. Mr. Berkeley then directed attention to a collection of Gourds which he had brought from his own garden. They had been raised from seeds sent him from Paris by M. Naudin, who had rendered all the varieties experimented with there to four species—namely *Cucurbita Pepo*, *maxima*, *moschata*, and *melanosperma*, and to these every variety which was before the meeting could be referred. The first was distinguishable by the grooves on the stalks. *Maxima*, which was represented by a fine specimen of the Large Yellow Gourd, was distinguished by the roundness of the foliage and the stalk being never grooved. The rind, too, was generally soft, while in *Pepo* it was hard, still there was a variety, *durissima*, which had an excessively hard rind. People, generally, were not aware of the great utility of Gourds. In France they were made into soap, as a *purge* nothing could be better, and they remained in use till the end of March. Of *Cucurbita moschata* there was also a specimen, but this species seldom ripened in England, though in Egypt and other hot countries it was grown almost exclusively. The fourth species, *C. melanosperma*, had black seeds; and of this the collection contained two varieties, that known as the Malabar Gourd, and another which he had first seen noticed in Lowe's "Flora of Madeira." Among the Gourds were two *Lagenarias*. It was important to distinguish the difference, for they were not wholesome. The *Lagenarias*, or Bottle Gourds, were known by the flowers being white, and like gophered calice. Mr. Berkeley concluded by reading a letter, stating that a branch from an old Black Frontignan Grape had been sent, bearing from one eye a bunch of black and another of white Grapes, but the branch had not arrived.

Major R. Trevor Clarke having been requested to make some remarks on the plants exhibited by Mr. Bull, said it was one of the finest collections of economic plants that he had ever seen brought together. The Allspice, Arnotto, Arrowroot, Cichona, Peppers, Teas, Cinnamon, Coffee, Indiarubber, Nardoo, Patchouli, Sarsaparilla, Vanilla, &c., were each noticed, and some of their leading peculiarities pointed out. The Chairman then adverted in terms of deep regret to the death of Dr. Lindley, stated that the Council had that day passed

a vote of condolence to his family, and asked the meeting to join to it an expression of their feelings of regret for his loss. This having been unanimously voted the meeting closed.

### TAKING IMPRESSIONS OF FERNS.

The materials used are nitrate of silver, hyposulphite of soda, a flat camel's-hair brush, printing frame, one or two porcelain dishes, and paper, all of which may be obtained of any photographer.

First, as regards exciting. Dissolve I drachm of nitrate of silver in two ounces of rain water. When dissolved, pour the solution into a saucer. Pin a piece of paper on a board held horizontally; then with the camel's-hair brush, carefully brush this solution on till the paper will imbibe no more; then hang up to dry in a dark room. This process had better be performed by candle-light, as if the paper is exposed to the sunlight or to daylight, it will turn black. It will be as well also when the paper is being prepared, to mark it in the corner on the prepared side, that it may be better distinguished in the after-process.

Printing. Supposing there is good diffused sunlight, and the glass of the printing frame is cleaned well on both sides, place the object to be copied on the glass, face upwards, the excited paper on this, face downwards; then the back-board, which must be screwed down tight. The frame may now be carried into the light, and placed facing the sunlight; care must be taken that no shadow falls on the frame, otherwise it will present streaks. The time of exposure will be about five minutes.

As to fixing, when the printing has gone deep enough, take the paper out of the frame and immerse it in the fixing solution, made by dissolving three ounces of hyposulphite of soda in one pint of rain water; let it be immersed for about five minutes, then place it in a pail of water for about six hours, changing the water two or three times, so as to completely wash away every trace of the soda, which, if allowed to remain, would cause the impression to fade completely away, after which, hang up to dry as before. When dry, if the natural tint is required, colour picture like the original.—(*American Gardeners' Monthly*).

### CLOTH OF GOLD GERANIUM.

In reply to your correspondent Mr. Flitton, I beg to offer my experience with the Cloth of Gold Geranium. I have now used it for three seasons for bedding-purposes. In the south of Derbyshire, where I grew it the first season, it proved a complete failure, the plants being no larger at the end of September than they were on the day on which they were planted out, although they were planted in good soil, and were favoured with the best situated bed on the lawn. As nearly as I can remember they were planted out about the 16th or 17th of May, and this I am confident was the sole cause of failure, for in a few days came a most bitter cold east wind, which continued for three or four successive days; and though I took the precaution to fix mats up with strong flower-stakes at the exposed sides of the bed, yet, with all my care, my much-prized Cloth of Gold was deprived of most of its beautiful leaves, and they continued to have a very poor appearance throughout the season. I have also seen beds of Cloth of Gold this season having just the same appearance that mine had in 1863, and on inquiry I found that they had been turned out about the 20th of May, which is far too soon for Cloth of Gold in the south of Durham, where I am now living.

Since 1863 I have never ventured to turn out Cloth of Gold until the first week in June at the soonest, and then it has been planted on a south border, and the result has been that the success for the last two seasons has been as complete as the failure was in the first case. I also planted some this year about the end of June, or the beginning of July, on a piece of ground that was walled on the east and south sides, and having many trees very near on the north and west sides, consequently they received very little sun, and to my great surprise these grew far more vigorously than the former, the leaves being nearly twice the size, but the colour was not nearly so good, and the flowers were very poor. I suppose this was owing to the situation being moist, and not receiving much sun. The only preparation that the ground received previous to planting was a good dressing of well-decayed stable manure and fresh loam, in equal parts. If treated as above I firmly believe that Cloth of Gold will answer in any situation that is not exposed to high winds.

I always find Cloth of Gold one of the very best Geraniums

to propagate. This season I have not had a single cutting of it that has failed. They were treated as follows:—About the 20th of August I took the number of cuttings that I required, and put each in a separate thumb pot; they were then placed on ashes in a sheltered corner of the garden, and in a fortnight or three weeks the little pots were full of roots. I only wish some of the best silver-edged ones would do as well with me as the Cloth of Gold.

Perhaps it may not be out of place for me to mention that I found a sport from the Cloth of Gold, above a year since, with an entire gold-coloured leaf, of which I have now a good many plants, and it does quite as well with me as its parent, but I fancy it is of a more spreading habit, and, as yet, it has not shown the least signs of going back to the original.

In conclusion, I trust that these remarks and those that have come from others in favour of Cloth of Gold may induce Mr. Plitton to "try again."—WM. LAWRENSEN.

Mr. R. Fish, in his "Doings of the Last Week," asks if any one has experienced the same facts as he has with Cloth of Gold Geranium as a bedding plant; and as I have grown it largely in three different positions during the past summer, I may, perhaps, be doing some good by stating the results.

1st, In May of this year I planted two beds in the parterre, which were fully exposed to the sun's power, and from that time until the plants were taken up last month these had not grown an inch, but, on the contrary, they gradually became less, until they were unsightly objects.

2ndly, I planted another bed under a terrace wall, where the sun did not reach it until just after mid-day. Although this bed has done much better than the last-named, the plants only made slow progress, and were by no means up to the mark.

3rdly, I planted a quantity on a border, backed up with trees and shrubs, and situated so as to receive the morning sun up to eleven o'clock, and there I found the plant quite at home, thriving and making foliage of a splendid colour: consequently doing good service as a bedding plant.

The facts here stated not only coincide with those of Mr. Fish, but prove that in order to have this plant in perfection in our gardens it must have a partially shaded position. Golden Chain I do not grow largely enough to give an opinion of.—THOMAS RECORD, *Gardener to Colonel Loyd.*

METEOROLOGY OF OUR FRUIT-HOUSES.

THERE has gone abroad somehow an opinion that a Peach tree grown in a Peach-house should be treated in a different way from a Peach tree grown in an orchard-house, and also that a bush tree grown in an orchard-house is, in some unexplained way, stronger and hardier, and able to stand greater vicissitudes than one grown in a Peach-house. Now, I think that if these two systems are fairly examined it will be proved that there is only one treatment applicable to them, and that if this is not followed success should not be expected.

In my previous letters I tried to show the possessors of lean-to vinerias and Peach-houses that by keeping the sun's rays out they lost in summer what was equal to the value of their pipes; and, again, to prove to those who had large orchard-houses in the south, that they, whether they knew it or not, had as much heat as is required in any forcing Peach-house or vinery. As the correctness of the temperatures I gave as obtainable in these two classes of houses—viz., lean-to houses, where the sun's rays were not obstructed, and large span-roofed orchard-houses, has been called in question, it may be interesting to some of your readers, as well as satisfying my own desires, if I give a few meteorological facts to show that my assertions were not made at random.

The following table I have taken from Mr. J. C. Morton's "Farmer's Calendar," and he gives the Astronomer Royal as his authority:—

	Greatest heat.	Lowest max. heat.	Highest min. cold.	Greatest number of cold.	Average number of rainy days.	No. of years' observation.
May.....	86.2	65.0	45.3	28.3	13	} 90
June.....	94.5	72.7	52.7	36.2	12	
July.....	93.5	72.7	54.0	38.9	12	
August....	92.0	70.8	49.9	40.0	12	
September	86.4	66.7	53.5	32.0	13	

The mean between columns 1 and 2 must, I think, be taken as a fair criterion of the temperature on a sunny day, and that

between 3 and 4 as an average of the night temperature to be expected. I have also given the number of wet days. I will now contrast this with the Chiswick return for the month of September last—the highest was 85°. I find one day the thermometer is marked as 80°, and fifteen others are above; I shall therefore assume that this figure 80° is not too much for a fair average for the month this year, and that Mr. Rivers was unfortunate in his choice of a day to obtain an average upon, as, if it were correct, instead of proving his large orchard-houses to be equal to the climate of Toulouse and the south-west of France, it would only show that they are the same as the open air at Chiswick.

We also differ in our estimate of the increase of heat on a fine day. Perhaps if we notice the variations out of doors it may help us a little; I will take the month of June. Between the maximums on the 2nd and 6th, are 16°; between the 9th and 12th, 17°; 12th and 14th, 12°; 16th and 18th, 21°; 18th and 21st, 30°; 23rd and 26th, 21°; 28th and 29th, 14°. I will then reduce my estimates a little, and say that, taking an average of the five hottest months, a large orchard-house placed at Chiswick should have for eighteen days in each month a temperature, with fair ventilation, of from 90° to 110°, and I am still of the opinion that this heat is more than it would be safe to have if it were obtained by any other means. Let me now examine the minima and see if I am supported in saying that narrow span-roofed orchard-houses are only fitted for retarding-houses. Columns 3 and 4 will give the average night temperature according to the return of the Astronomer Royal, but I will also take the Chiswick register. During August I find eighteen nights below 51°, but including 41°, and seven below 41°; in September sixteen below 51°, but including 41°, and seven below 41°. This leaves only six nights in the first month, and seven in the second, that were over 50°.

Trees that have been growing in a warm climate—that is, with the ventilators closed till July, are more easily acted upon than those which have always been in a colder climate, and, therefore, will be sooner brought to a standstill, though they may not lose their leaves and go to rest till they have had their usual time of growth. But what does Dr. Bennet say?—that the deciduous trees were kept at rest till April at Mentone by a night temperature "in fine weather of from 40° to 48°, in bad weather sometimes below 40°." The average maxima he gives as, January, 52.4°; February, 53.8°; March, 58.6°; April, 64°. Perhaps it will be the most satisfactory if I also add the average minima for each month, January, 43.3°; February, 45.4°; March, 46.3°; April, 49.2°; the April table only includes to the 15th, at which date Dr. Bennet returned home.

I gave in my letter a range of from 95° in the day to 45° at night, and some may have thought this was a greater alteration of temperature than would be wise to permit. Mr. Rivers wonders that the trees were not killed—Peach trees are natives of a climate where there are greater vicissitudes than we have in ours, but let us see what we have as shown by the Chiswick report for September. I count six days upon which the difference between the maximum and the minimum was 40° and over, the highest being 46°; twelve had 35° or over, but under 40°; four had 30° or over, but under 35°; four had 25° or over, but under 30°; four had 15° or over, but under 25°; by this we see that upon eighteen days of last September there was a change, during the twenty-four hours, of more than 35° at Chiswick in the open air. The exact average of these eighteen days is 39°.

This subject, the meteorology of hot-houses and orchard-houses, is one that merits the attention of all who desire the advancement of horticulture. I am glad to testify that I have studied with great advantage the works of Messrs. Rivers, Brchant, and Pearson on orchard-houses, and shall order with renewed interest the next editions if they will add a chapter on this subject. I believe it is the one thing needed to make orchard-houses universally successful, and I advise all who have trouble with theirs to look to the night temperature, for with ventilation the atmosphere is soon changed, and unless there is a back wall that has been warmed by the sun, to give out its heat all night, they may find that they are unwittingly engaged in retarding their August and September Peaches in a manner that, if they have pipes enough, will enable them to ripen them in November.—G. H.

PLUMS.—Too much praise cannot be bestowed on Rivers's Early Favourite. A few years ago I purchased of Mr. Rivers a few trees, one of which I planted against a south-west wall;

it now covers a space of 8 feet by 9, and this season I gathered nine gallons of Plums from it, and sold them at 1s. per gallon to a wholesale dealer in fruit in the country; moreover it is a good dessert Plum. I can also speak favourably of Coe's Late Red, also from Mr. Rivers, which, if permitted to hang late, is most delicious, as all my neighbours can testify.—JOHN STROVELD.

### MAKING THE MOST OF A HOUSE.

HAVING frequently noticed your willingness to impart information, and to render service to the numerous subscribers and correspondents of "our Journal," I venture to ask your advice under the following circumstances.

At the sale of glass by order of the executors of the late Mr. Veitch I purchased what was an old propagating-house. It is 33 feet in length, and 13 feet 6 inches in breadth, a three-quarter span-roof, the front slope being 9 feet, and the back 6 feet. There are at present no front lights. The house, which was only used for propagating-purposes, was divided lengthwise by a brick wall, which served to support the ridge of the roof, and a portion at one end was also divided off, and used as a potting-shed. Now, of course, I wish to dispense with all these superfluous walls, and wish to know the best method of supporting the ridge of the roof.

Next, I want you to advise me how to fit up the interior, and will, therefore, tell you what I require to grow. My chief object is to grow good Grapes, and perhaps a few Peaches on bushes, and some flowers, such as Camellias, Azaleas, Roses, &c., and Ferns. I presume you will advise me to have front lights added, in which case I thought of having a slate bench, 2 feet wide in front, for my flowers, and a raised bricked-up bed in the centre, in which I might plant or plunge Vines, trees, or Roses, &c.; and it has occurred to me that I might secure two crops of Grapes by planting Vines in an outside border, and keeping them out until these growing in the inside bed were well advanced. If you consider this plan practicable please say how the Vines should be trained. Can my back wall, which will be some 6 feet 9 inches in height, be put to any account?

I also want you to advise me how to keep the frost from my Camellias, &c. Of course I have no intention to force. I am inclined to believe that a flue, which can be easily managed by my groom-gardener, will effect my object. Should the flue be placed in the front part of the house, or should it run round the raised centre bed?—that is, provided you approve of this bed. My object is to make the most of my glass, and to work it in the most economical manner.

I shall be compelled to have a new east end, which will be the entrance, would you place the door close against the back wall, or in the centre?

Will you advise me how to ventilate my house? I thought of introducing some wooden shutters into my front wall, but do not see my way clearly to admit air through the roof. What Grapes would you recommend me to grow? I see the Muscat Hamburgh is much recommended in your columns for a cool vinery.—AMATEUR.

[We have read over your letter carefully. With all due credit for your particularity, you have left two particulars of moment unnoticed—1st, the height of the house where the unequal spans meet, and the height of the present front wall, or what you intend to make it. We shall suppose the height at the apex or ridge-board to be from 9½ to 10 feet; and as you propose having a slate shelf 2 feet wide along the front we presume you mean the height there to be between 5 and 6 feet, so as to secure you plenty of headway. In that case, for the general purposes you propose, we would recommend you to have three out of five parts of the front glass, either moveable sashes, or fixed if you have ventilators in the wall below your shelf. The first would be best; the second would scarcely cost half the money.

2nd. For fixing and keeping up the ridge-board there would be the support at each end; and then the simplest plan would be oak, or, better still, two or three neat iron pillars set on a pediment of brick or stone.

3rd. With merely keeping frost from Camellias, and nothing like forcing, you could not have two crops of Grapes in the house in the season by any arrangement of Vines in the house and others started outside; but you could have some early kinds, as Sweetwater, Royal Muscadine, &c., in pots, which would come in earlier than those outside, and which need not interfere much with those on the rafters.

4th. Our proposed arrangements would be the doorway in

the end, in front of the ridge-board, which would bring it near the centre of the house as respects its width. Then we would have a shelf, 2 feet wide as you propose, at front and ends, a shelf or border at back the same width, a pathway all round 2½ feet wide, and a pit in the centre 4½ feet wide. If the shelf were 2½ feet from the ground level the pit should be a few inches higher if there is plenty of head room. We would prefer Peaches, Nectarines, Figs, &c., in such a pit to be in pots or tubs rather than planted out, as you could move them out and put in other things in winter. To make much of the back wall the lower this pit is, say 18 inches, and the lower the plants grown in it the better.

5th. A flue starting low enough to come under the ground level until you passed the doorway, going along that end above ground, along the front, and across the other end, all beneath the shelf, and, therefore, out of the way, and then out into a chimney, would be quite sufficient for the keeping of the plants as you propose, and even forcing the Vines a little if you thought proper. By keeping the front outside Vines out of doors until they began to break naturally, you could also have Vines and Peaches pretty forward before you introduced them, but not forward enough with a due regard to your plants to give you two distinct crops in the year.

6th. A very neat and pleasant way of heating such a house, would be to take the flue all round under the pathway; the top of the flue, 9 inches wide, would thus form the top of the pathway, and furnish very pleasant walking all the winter. In this case the flue might be in the centre of the pathway in front, and close to the pit at back, which with some rough matter at the sides of the flue would give 2 or 3 feet for a border against the back wall.

7th. In this border Figs and even Peaches would do very well; but nothing will do well if the plants in the centre bed grow to the top of the house, or if the roof be densely clothed with Vine foliage. The continued success of trees in the bed and on the back wall will depend on the Vines being kept to the rafters, and the lowness of the bed plants permitting the sun's rays to reach, not unobstructed, but pretty freely, the back wall.

8th. To combine the greatest floral beauty and utility in such a house without useless crowding, we would plant the back wall with Camellias and Oranges, which would be a fine sight all the winter and spring months. We would keep the centre bed low, and fill it with a few Vines in pots, but chiefly Peaches and Nectarines, and would just give as much heat as would keep the flowering plants safe and help on the Peaches, allowing the Vines to break almost naturally.

9th. We had so far anticipated the last two questions, which we received in a second letter, by alluding to openings in the front wall for ventilation. We had made some wooden ventilators, pivot-hung, in the middle of the wall, as you propose, but considered afterwards that we would have had iron ventilators if we had thought of it in time, as they could have been slipped in at either side of the wall. The kind we allude to is on the same principle as ventilators for asphalt doors. For instance, suppose that the ventilator is 18 inches long and 9 inches wide, that space being divided from top to bottom into quarter-of-inch openings, and a quarter-inch space between, an inner plate fixed in the same way, with similar openings, and moveable by a little handle, will shut up the outside openings, or leave them more or less open. Of these you would require eight in the front wall. The simpler plan we adopted, was to leave spaces—say eight, in your length, 1 foot square, in building the wall, and in each of these have a ventilator of the requisite size, pivot-hung, in the middle of the wall, as by that means the ventilator would not extend much outwards when open. If the pivots are fixed at about the third of the depth, the ventilator will always shut itself by its own weight. Two screws act as pivot and hinge to each ventilator. If your back wall is not already built, we would have had similar openings, with similar ventilators, just below the coping, and if hung as we said you could open them, by a string attached to the upper part, less or more as you wished; and whenever you wished to shut the ventilator you would have only to give free play to the string. Such ventilators, if placed in the middle of the wall, as respects thickness, would always be out of the way, and interfere with nothing inside or outside. In one sense they would not be so good as the iron ventilators with the slide, as with the latter, and not more than quarter-inch openings, a mouse even could not pass in. Four or five of such ventilators would do in the back wall, if you had an opening at each end in the angle under the ridge-board—say a base of 18 inches, and the perpendicular of

the triangle other 18 inches. As we presume that the ridge and rafters to it are complete, if you have not the means readily of making these holes in the wall, you had better have openings—say five at the ridge of the roof, 2 feet by 1 foot, and these openings at each end, and then on very hot days you could open the door wholly or partially. Perhaps the easiest plan would be to raise the wall plate at back from 6 to 9 inches, and have that space for ventilation by wooden shutters, as you like. If openings were made in the roof, at the apex, they also could be pivot-hung, the lower two parts resting on the bars, and therefore above the general level, and the other third narrower, so as to fall down between the bars or rafters when a string was applied. The only objection to this simple mode is that the two parts of the ventilator stand up above the roof when fully open, which does not answer well in a windy day. The front and back wall is best, and if the top is high above the ventilators, an opening at the ridge at each end.

10th. The Muscat Hamburg will do in general seasons, but on the whole we would recommend for a cool house Royal Muscadine and Buckland Sweetwater, and Black Hamburg and Esperione. Of course it would make all the difference if you proposed heating.]

### THE CHRYSANTHEMUMS AT MR. SALTER'S, HAMMERSMITH.

MR. SALTER is not a grower of specimen plants for exhibition, and the would-be visitor to the Versailles Nursery must not expect to find there the huge bushes which are to be met with at the shows; but he has a collection which, for the number and perfection of the varieties of which it is composed, is unrivalled in this country. It contains, in fact, every good known variety, besides multitudes of seedlings, which are annually raised, and out of which not a year passes without some striking novelty or further advance on existing kinds being selected. Although not arrived at their full perfection when we saw them the other day, the show-house or winter garden was filled with hundreds of Chrysanthemums of every shape and size, from the little button of the tiniest Pompon to the large, full, and beautifully incurved Prince Alfred, with blooms  $4\frac{1}{2}$  inches across, and 3 inches deep, and so perfect that in their natural state they almost look as if they had been dressed. Add to this that the blooms offer an infinity of shades of white, yellow, orange, red, and combinations of each of these with the others, that the whole of the plants are arranged with excellent taste, and that other plants are judiciously introduced to give variety and tone down the colours, and it will readily be conceived how charming is the scene.

The arrangement of the house does not differ materially from that adopted last year; fruiting Orange trees in pots are grouped here and there, and the oval beds in the serpentine central walk are filled with *Centaurea candidissima*, Maiden-hair and other Ferns, a *Wigandia* occupying the central bed; and elevated at various points opposite these beds are standard plants of *Centaurea gymnocarpa* on stems about 2 feet high. *Woodwardia radicans*, grown in cinders and loam drenched with water, is suspended in a basket from the roof, and on the right, near the entrance, is a small group of *Cannas*, the almost-hardy *Chusan Palm*, *Pteris argyræa*, a *Polypodium aureum*, &c., and on the shelf on the same side Mr. Fortune's pretty and useful variegated Bamboo. On the left, opposite the entrance, is a small piece of rockwork, or mound, on which *Saxifraga hypnoides* minor forms a pretty dense green carpet along with *Sedum glaucum*, diversified with patches of the yellow variegated *Arabis procumbens*, *Sedum Sieboldi*, and *Echeveria secunda*, which was used with such good effect by Mr. Gibson at Battersea Park.

Having noticed these minor matters, we now come to the Chrysanthemums; and it may here be observed that the season has been extremely unfavourable, at least round London, to their blooming in perfection. The hot weather and drought stopped growth, and hardened the shoots; these, with many growers, have lost their leaves, and the blooms are not up to the average degree of merit. Mr. Salter, however, by dint of much labour and perseverance has succeeded in preserving his plants with good foliage, and the show is fully equal to that of last year, and when at its perfection will, probably, be superior.

The seedlings of the present year being of most interest we shall take them first. A good many were only opening, and had not as yet been named, and among these were several which were very promising, especially *Crimson Velvet*, which

Mr. Salter describes as the brightest crimson ever raised, being half a dozen shades brighter than *Julie Lagravère*, and not being very closely incurved, it shows the colour well. *Gloria Mundi* is of the same colour as *Jardin des Plantes*, but much more free, and will, therefore, be a great acquisition. *Golden Beverley* is another fine flower; it is a bright yellow sport of *Beverley*, and, only differing from it in colour, will doubtless take a high position as a show flower. Hereward is a fine lilac crimson, with the back of the florets rose, a close flower, and perfectly double; and *John Salter*, a finely incurved chestnut, Mr. Salter considers one of the finest seedlings he has ever raised.

The new varieties of 1861, sent out this year, were mostly noticed last November, and conspicuous among them this year is *Prince of Wales*, a magnificent beautifully incurved show flower, and being of branching habit, fine for specimens as well. *Pink Pearl* is very pretty in colour, and makes a fine pot plant, and *Virgin Queen*, is a beautiful pure white. *Golden Ball*, which received a first-class certificate from the Floral Committee on the 7th inst., was noticed last year; it is remarkably fine in shape, and the back of the florets is of a beautiful golden amber colour, but when it first comes out it is brown, which has led some persons unacquainted with this peculiarity to suppose that they had not received the true sort. *Golden Dr. Brock*, a sport from *Dr. Brock*, is another finely incurved golden yellow flower. Mr. Wynness, a rich mulberry, which we saw last year, was not fully out, and so, too, was *Venus* one of the most beautiful flowers of last year. Others consisted of *Ranunculus*, *Ingo*, *Blanche of Castille* in the way of *White Queen* of England but more free; *Princess of Wales*, most beautiful in colour, pearly white, exquisitely tinted more or less with rosy lilac; *Mr. Brunlees*, a striking variety, brown tipped with yellow; and *Prince of Anemones*, large lilac blush, with a very high centre. The last, however, which belongs to the anemone-flowered section, should have been included among the varieties of 1865.

Of older varieties there was an endless succession, comprising *Alma*, *White Queen* of England, *Lord Clyde*, *Sir Stafford Carey*, *Alfred Salter*, *Hermione*, *Vesta*, *St. Patrick*, *Florence Nightingale*, *General Slade*, *Mr. Murrey*, a very free-blooming conservatory flower; *Little Pet*, also free blooming; *Bernard Patissey*, *Little Harry*, &c. *Tasselled Yellow* and *Duc de Conigliano* are showy kinds for conservatory decoration, especially the latter, which is large, and of a rich red colour.

Among Pompons were a seedling darker than either *Bob* or *Brilliant*; *Lucien Cabouche*, a new shade of rosy lilac; and *White Trevenna*, a very free-flowering white sport from *Rose Trevenna*. This last, however, has already been sent out.

In the lean-to house at the back of Mr. Salter's house were some new continental *Zonale Geraniums*. The best of those in flower were *Jules César*, light scarlet with a white eye, the petals broad, and the habit dwarf; *Eblouissant*, deep scarlet, with a white eye; and *Madame Reudatler*, rosy salmon, with a lilac tinge, and very brilliant in colour. The truss was close and round, and the individual flowers about  $1\frac{1}{2}$  inch across, with broad rounded petals. This variety was very striking. Another pretty variety was *Madame Werlé*, white, with a little pink at the base, and running up the side of the petals. In the same house was a new variety of *Cineraria maritima*, which it is expected will be less lacinated and not so rambling as the common form. There was also a variegated *Hedera algeriensis*, a seedling of Mr. Salter's, with the foliage of that large-leaved Ivy variegated with white.

Out of doors the Chrysanthemums had suffered little from frost, except a few of the whites, and the borders were gay with both large-flowering and Pompon varieties; there was also a large batch of seedlings in bloom from seed sown in March of the present year. We noticed a little white Pompon called *Marabout* which is beautiful for bouquets, being like a fringed Pink, and which is largely employed at Covent Garden for that purpose. *Laciniatum*, one of Mr. Fortune's Japanese varieties, Mr. Salter kindly pointed out as being of a similar character, and even preferable to *Marabout*.

### OUT-DOOR FIGS RIPENING AUTUMN FRUIT.

You may remember a short discussion under the above heading, commencing at page 91 (August 1st). I stated in a succeeding Number, that we were getting fine, ripe, out-door Figs here in plenty, in the last week in July. I think it now worthy of remark, that the same trees are yielding a second

crop. We have gathered a basket of fully ripe Figs this afternoon (November 3rd), and they are as fine in flavour, but not so large as the first crop. There were fifteen in the basket; many more could have been added, but the invitation to proceed further was declined. These are, of course, the Figs that are not expected to ripen in the autumn, and but rarely escape the frosts of winter.—A. T., *Noirmont, Jersey.*

We have gathered here (near Horsham), the second crop of Figs out of doors. Such a thing has not been seen by an old gardener that has been in this place twenty years. They are the White Marseilles.—B.

STAKES FOR PLANTS.

The staking of plants, &c., had been an eye-sore to us for some time, and a few seasons since we adopted a plan to which we desire to draw your attention; it is that of making stakes of galvanised wire, and shoeing them with wood for out-door work, but using them unshod for Pelargoniums, &c. They are scarcely observed when a plant is nicely tied to them, and we have, since we adopted them, used nothing else. The shoes will last several seasons, and the wire perhaps twenty years. We make them thus:—

The wires may be stout, thin, or medium, at pleasure. The shoe is of red wood, and a hole is bored, the wire put into a vice, and the shoe struck on. Any person fond of neatness will be pleased at their appearance, or rather non-appearance, the foliage generally hiding them.—GEO. BURTON & SON.

MANGO AND GUAVA CULTURE.

In reply to the letter of "G. S." in your last Number, I beg to say, that the Mango will grow from cuttings if they are taken from the half-ripened wood, cut through a joint, and placed in a gentle bottom heat, as I have reared the tree myself in this way. At the same time I quite agree with your correspondent that it would be far better to procure healthy plants of some of the best varieties from Bombay or Madras, as well as seeds, which if brought over in damp earth grow readily.

I have no doubt but that "G. S." is right in what he says about the Mango, and I should be the last person to lay down rules for the cultivation of a tree whose habits I understand so little. At the same time I must say I never succeeded in fruiting it in any ordinary stove, although I have often tried, and it was not until I kept the trees dry and hot in winter that I did so.

With regard to the Guava, I have grown Cattley's Guava (*Psidium Cattleyanum*), and it has the double advantage of bearing well, and being very ornamental, but I do not consider it equal to the White Guava (*P. pyriferum*), which has a finer-flavoured fruit, about as big as a duck's egg, of a beautifully golden yellow colour. The latter tree is very shy of bearing in England, unless grafted on the *P. Cattleyanum*, when it fruits plentifully. If both varieties are allowed to grow together on the same stock the effect is very good, the deep claret-coloured fruit of *P. Cattleyanum* contrasting beautifully with the golden *P. pyriferum*. All the Guava tribe grow readily from either seeds or cuttings.—J. H.

CONSTRUCTING STRAW COVERS.

In compliance with the request of several correspondents we repeat the directions given by Mr. Fish in Vol. XIII. for making these effective and inexpensive coverings.

Measure the length and breadth of the sash to be covered, so that in covering a pit the covers fit closely to each other all the way along. Then to make a single cover, get three slips of wood 1 inch thick, and from 2 to 3 inches broad. Two of these form the sides of the cover, and one goes right in the centre. You will perceive that these three pieces will sustain the whole weight of the cover. Being set out to the requisite width,

cross pieces are nailed to these three longitudinal pieces, first at the two ends, and then at 15 to 18 inches apart in the intermediate space. This forms the skeleton of the cover. You now turn it upside down, so that all the cross pieces are downwards, as these, independently of supporting the straw, keep it also at a distance from the sash. As it is desirable not to strain the three longitudinal pieces, these cross pieces are only half the width of the long ones. The spaces between the longitudinal pieces are now neatly filled with straw; so that when firmly pressed it will be as thick as the longitudinal pieces—namely, 1 inch. The straw is put in so as to mix the upper and lower ends regularly. Then, beginning at the middle of the corner, a tar-string is fastened to one of the side longitudinal pieces, opposite one of the cross pieces beneath, is pulled firm to another tack in the central longitudinal piece and taken from thence to another tack on the opposite side, piece. A string goes across, opposite every cross piece of wood, until the bottom and upper end pieces are reached, when a cross piece of wood is nailed on similar to the one on the opposite side, as being better for taking hold of when covering and uncovering than the straw fastened with a string. In a cover rather better than 4 feet wide, it will at once be perceived that there will be fully 18 inches of string from the side longitudinal piece to the central one, and that space is too much to enable the string to keep the straw firm in the various vicissitudes from dryness to wet. In the centre of each of these spaces, therefore, a loop is put over the string, passed through the straw, and fastened firmly round the cross piece on the under side. Firmness would at once be secured by placing cross pieces of wood over the straw, similar to those underneath it, and I did so for some time; but then the covers were more expensive at first, and did not last so long; because, in the first place, they were heavier, and strained the longitudinal pieces more; and secondly, because in wet weather the wet lodged at the cross pieces, and thus occasioned rotting there. I may add, that I like the straw to be drawn before it is thrashed. The soft ears are thus got rid of, and the straw tubes are not bruised by the flail or thrashing-machine.

PITS FOR BEDDING PLANTS.

A VERY common complaint amongst gardeners is that in spring they have a great deficiency of accommodation for their young stock of bedding plants, and it is certainly very disheartening for a gardener, after having successfully managed to keep through the winter a good stock of *Calceolarias*, *Verbenas*, &c., in boxes, when spring comes and vegetation becomes active, not to know what to do with them to give them the needful additional room. He is often obliged to huddle them together into pits, almost as closely as they were in the boxes, and the consequence is they become drawn up to long spindly shoots, deprived of their lower leaves, and so become weakened.

I think it would be lost money for any gentleman, whose gardener has much to do with bedding plants, to erect in a neat and substantial manner, and in extent according to the requirements of his establishment, a range of pits similar to that of which I enclose drawings.

Besides being useful for bedding plants, by good management and forethought they could be doing good service all the year round. A crop of Melons and Cucumbers could be put in at the beginning of June after the bedding plants had been cleared out; and after the Melons and Cucumbers were done, I think, provided the pits were closely fitted up, it would not be impossible to carry on the forcing of Dwarf Kidney Beans, Lettuces, Radishes, &c., during the winter months, but, of course, in this case judicious firing and careful matting over would be necessary for success in frosty weather.

Fig. 1.

In Fig. 1, *a a* is the ground level; *b*, a line of pillars, on the tops of which is laid a strong beam for the support of the planks on which rests the soil of the bed; *c c*, hot-air chamber,

with flow and return hot-water pipes; *d d*, pipe in connection with the hot-air chamber for the regulation of atmospheric heat; *e e*, a connection between the pipes *d* and the evaporating-pans on the hot-water pipes, by which moisture can be poured into the pans, and moisture admitted to the atmosphere at pleasure.

Fig. 2.

Fig. 2 shows the way in which the sashes are tilted up for bottom ventilation, by means of a plate of iron fixed with a joint to the coping of the wall of the pit, and pierced with holes for the admission of a peg, fixed into the centre of each sash. The ridge at the top, which may either be of glass or board, is intended to be raised by some simple mode of lever power from one of the ends, which will secure abundance of top ventilation.

Fig. 3.

Fig. 3 shows the means by which the sashes are secured from shifting when tilted up. The pivot on which they work may either be an iron rod running the entire length of the pit, or merely pegs fixed into the rafters. When soil is being shifted the sashes may be taken off and laid aside.—A JOURNEYMAN GARDENER.

[There is not, we think, much that is new in your proposed pits, but they would be none the less useful on that account, and the mode of ventilation, especially, is simple and good. We have repeatedly given utterance to the idea that so much cramming of bedding plants, &c., under glass in winter and spring involves a vast amount of labour in shifting plants from place to place, and that the expense of that labour would ere long provide mere glass, so as to avoid the necessity of so much moving. Many gentlemen see this as well as we do, but the extra labour is only a small annual per-centage on what the cost of houses would be at first, and therefore here, as in many other respects, the first expense is the difficulty to be surmounted. Perhaps our correspondent's arguments will have success when ours have often failed. One standing argument amongst ladies and gentlemen is shortly this, that providing they were to build these ranges of pits ostensibly for bedding plants, only a short time would elapse before they would again be requested to do the same thing, the pits having proved themselves so useful for general purposes, that as much convenience for bedding plants is wanted again. We must confess that there is no little truth in such arguments, as most gardeners who wish to do as much as they can to please their employers, use one such concession as a sort of fulcrum for resting their lever arguments for securing another and another improvement. Most servants are careless about increasing what would add to their labours; but gardeners, as a class, leave this out of sight, and will even encounter the additional labour when told they can have no more labour power to help them. In the management of such proposed pits there would often be less labour than is now involved from the necessity of constantly moving, to suit the wants of the denizens in houses and the merely temporary occupants.]

For mere bedding plants pits would do very well without a chamber and bottom heat, with merely a pipe round them, or the pipes in front, and would cost much less than sunk pits, and hundreds of gardeners would be glad of such structures. But for the extra expense, however, we would much prefer pits like those of our correspondent, and to have a platform instead of soil or ashes for setting the plants on, as such pits enclose a much greater amount of air, and therefore are less liable to sudden fluctuations of heat and cold. We are supposing that the platform is sufficiently open to allow the air above and below it freely to commingle.

Such pits with bottom heat, and means by drain tiles or other openings for that heat to pass upwards when necessary, would do admirably for Cucumbers and Melons in summer, and for Radishes, Lettuces, Rhubarb, Sea-kale shaded, and Asparagus with plenty of light, in winter and early spring, and would be first-rate for bedding plants—say from the end of February,

or as much earlier as might be convenient, or all the winter through; but our practice would lead us to say that if Kidney Beans are attempted in winter, there should be two pipes in addition for top heat, as assuredly in severe weather, even with mats on the glass, the two pipes in the chamber will not be enough to keep the plants healthy. True, we have grown such Beans successfully in the common dung-pit and frame in winter, but all who have done so know the trouble it involves in dull muggy weather, and how nicely a hot-water pipe would keep all dry and sweet.

After saying so much, we may add, that not having such pits as our correspondent so well recommends, we use common earth-pits, or turf-pits, with any little protection we can obtain from calico, mats, hurdles, &c., for thinning our bedding plants, and in these pits we begin to plant out the hardiest in the beginning of March, planting them, according to kinds, from 4 to 6 and 9 inches asunder; and although the plan gives trouble, there is no drawing up and weakening of the plants, as would be sure to be the case if the plants were placed close together in a cold pit, &c., without this planting out. One word more; in the southern counties these span-roofed pits of our correspondent will answer very well. In very cold exposed places it might be desirable to revert to the old lean-to roof, merely for securing more warmth, even if there should not be quite so much direct light.]

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

Much as there has been written on the utility of trenching the ground in kitchen gardens, and bringing up a portion of the subsoil to mix with the surface soil, when the latter is said to be "worn out" with constant cropping, some persons are still blind to its advantages. If the subsoil is a stiff loam, they are fearful of mixing a small portion of it with the surface soil, although the latter may be like an ash-heap, and as rich as dung can make it. We are aware that it requires some judgment as to the quantity of the subsoil to be brought up, as the texture of the soil may be materially injured by a large quantity at one time; but it can rarely so happen with a small quantity, and as very many old gardens would be greatly benefited by this operation, we hope the present favourable weather will be taken advantage of for the purpose. *Artichokes*, immediate steps should be taken to protect the roots from frost, if not already done. In some situations this may not be necessary, but it is best to be on the safe side. *Cabbages*, all that are sufficiently grown to admit of being earthed-up, should have it done before frost sets in. Red Cabbages for spring use may still be planted. *Cucumbers*, the plants should be kept as near the light as possible, nothing can supply the want of it, while heat, air, and water can be given as required. *Endive*, take up and plant in a frame some of the most forward, so that should severe frost occur there may be a supply. *Dwarf Kidney Beans*, add soil to the last sowing as they grow, until the pots are nearly full. Keep those in bearing well supplied with water. *Mushrooms*, take advantage of wet days for making fresh beds, and clearing out those that are spent, also collect and prepare droppings for forming fresh beds, by spreading them in a shed and turning them over frequently until they are sufficiently dried to prevent excessive fermentation after putting up. *Radishes*, these are sometimes required all the year round, where this is the case, it will now be necessary to sow in a slight hotbed. After they are up air should be given at every favourable opportunity. If they are sown immediately they will be ready to draw in the latter end of January. *Rhubarb*, a few old roots may be taken up and planted in boxes or pots, which may be placed in a Mushroom or forcing-house where the heat is about 60°. Clear up all decaying leaves, &c., and on dry days stir the surface of the soil among growing crops, as Cabbages, Spinach, &c. No vacant ground should now remain undug, it is sometimes the practice to leave the whole of the digging till frosty weather sets in, but by so doing half the benefit the soil would receive is lost, and independently of this it makes the garden look very untidy.

### FRUIT GARDEN.

Pruning and nailing should now be proceeded with every fine day, even although it should delay some other work which can be done with more comfort in bad weather than nailing. It is most important to have the latter done while the weather is mild. Nailing is a cold enough job for even a warm winter's day, but to turn men out to it in very cold or wet weather, and

expect them to do a fair day's work indicates bad management. If any transplanting or root-pruning of fruit trees has yet to be done, let this be attended to without further loss of time, and see that those exposed to the wind are securely staked before leaving them.

#### FLOWER GARDEN.

The weather is still favourable for executing alterations, and where these are in hand they should be carried on with dispatch. Take advantage of frosty mornings for wheeling dung, &c. Planting, or the removal of large trees or shrubs, should be attended to, for it is of importance that the plants should be afforded some chance of making fresh roots before the trying winds of March. See to even small plants being secured against wind, for these are often greatly injured by being blown about after planting, which a small stake and a few minutes work would prevent. Collect a stock of briars for budding upon next season. As tree leaves are always in request, either as fermenting material or for leaf soil, they should be collected at this season; if they are required only as manure they may be stowed away in any byplace and left to rot, but if, as is generally the case, they are in demand as a cheap mode of furnishing bottom heat for forcing, some pains should be taken to keep them dry. For this purpose they should be stacked up in some back place, or behind the garden walls, where access can be had to them at all times, and after allowing time for them to settle put on a coat of thatch to effectually secure them from rains. By these means they will be found in a state fit for use for twelve months.

#### GREENHOUSE AND CONSERVATORY.

While the principal collection of Chrysanthemums is in bloom, a selection should be made of the best and most useful sorts, for there are many worthless varieties in cultivation, and it is better to grow duplicates of the really good kinds, than to retain such as are indifferent, merely for the sake of having a long list of names. Give timely attention to providing a succession of bloom with which to keep the conservatory gay, and avoid as far as possible the expense of hard forcing, which is, moreover, very injurious to most plants. Be careful not to let things in bloom suffer from the want of water, giving weak clear manure water to Chrysanthemums, Salvias, Camellias, &c., and use every means to preserve the beauty of specimens in bloom as long as possible. Damp and mildew are the great enemies to be guarded against in the greenhouse, and these must be sharply looked after, especially in the case of plants that have not well ripened their growth and are in a rather soft state. If the former is troublesome it must be dispelled by means of free ventilation on mild days, using a little fire heat at the same time, and for the latter a dry airy atmosphere is the best preventive; but the plants should be frequently examined, applying sulphur on the first appearance of the enemy. Very little water will be required here at present, but the plants to be carefully looked over twice or thrice a-week, so as to make sure that nothing may feel the want of it. If not already done, let the plants be tied with the least possible delay, for it is difficult to tie a plant so that it will not look stiff and unnatural, and the sooner all this kind of work is done the better the specimens will look when in bloom. Above all, avoid crowding plants. It matters not how good the potting may have been, or how careful the waterings, those who will huddle the plants together must be content with leggy stock, and, what is even worse, with insects.

#### STOVE.

Let the resting section of Orchids settle quietly down towards their winter's rest, by withholding water at the roots, by diminishing the amount of atmospheric moisture, and by permitting a much more liberal ventilation than in the growing season.

#### PITS AND FRAMES.

All stores intended to be wintered in these structures should now be finally arranged as soon as possible. A dry atmosphere with a considerable amount of ventilation day and night are the requisites. An observant person may take a hint from the Verbenas which remain out in the beds. How often do we see them green through a great part of the winter. They are well established, however, at the root, and would infinitely prefer a moderate dry frost to a moist confined atmosphere.—  
W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

VERY much the same as last week. The rains have made Cabbages grow so freely that we shall earth them up at the first

opportunity, not only to protect the stems, but also to keep them from being moved by the wind. We prefer leaving a slight gutter in the ridge, in case it be necessary to apply manure water in spring. Nothing in dry weather is more benefited by sewage or other manure water, and when such is applied the produce will be tender and sweet instead of hard and stringy. In the whole range of vegetables nothing will beat a sweet tender Cabbage well cooked, and we never consider them well cooked unless they are bright in colour and pretty well as melting as marrow. Summer-planted Coleworts after the frosty mornings are just now at their best, and best they are. The quarter of Cabbages planted in the autumn of 1864 is still a mass of young Cabbage Coleworts after being cut over so often, and we generally leave them until exhausted in spring, as in common winters they furnish nice cuttings all the winter. After such hard work for the ground, we generally follow with Celery. At one time we fancied that the sproutings from the Cabbage were not so tender as young Coleworts planted in summer; but after many trials, and especially if the old Cabbages had the help of a soaking of manure water in summer, we have failed in detecting any difference between them. There is, no doubt, something in the cooking; but one great cause why vegetables are often unsavoury, and in a condition to bring on indigestion with all its attendant horrors, is their being kept too long, and wetted or heated before they are placed in boiling water. No wonder that in many large establishments vegetables are sent away scarcely touched, the sight of them being quite enough. Even a young Cabbage to be served up in perfection should be cut only a short time before it goes into the pot. A first-rate judge of what was good would not have his Marrow Peas gathered longer than just to give time to shell and boil them. Just imagine the difference after being well heated in close-packed sacks, or lying about a day or more in a hot kitchen.

*Cauliflower.*—The weather being somewhat uncertain, and a little frost being rather telling after so much wet, removed some of the larger lower leaves from a nice lot of Cauliflowers just showing little heads, took up the plants with what ball could be secured, and planted them thickly in trenches in an earth pit, on which we could lay some old sashes and other protection. In placing the plants in the trench we laid them slanting rather than upright, so that their own leaves would give a good deal of protection. We also gave a good watering when the trench was half filled, and when settled placed the dry earth over it before cutting back the next trench. That watering will be all that they will require in the way of moisture; and with dryish soil on the surface and plenty of air in mild weather, we have no doubt that they will do well if we can manage to keep rats and mice at bay. They have hitherto been our greatest enemies, and if much covering-up is required they make great havoc amongst Endive as well as Cauliflower. Where game is made a matter of first consideration, rats and mice will be sure to increase too much at the farm-stead and the garden.

*Lettuces.*—Did the same with this necessary for salads, though much less is used in winter than was wont to be the case. People are beginning to think that all such cold ingredients are most suitable for summer. If never used at all in winter it would save much trouble and room to the gardener. We also took up plants with good balls, and planted them rather closely together, watering as in the case of the Cauliflower, and choosing some not only fit for use for a month or two, but younger ones coming on in case they should be wanted.

*Endive.*—Did much the same with Curled and Plain-leaved. The Moss-curl has been very compact and good. At this season we often take up the Endive and trest like the Lettuces, as when blanched and protected where grown more or less litter is always an accompaniment. A flat slate or tile is as good a way of blanching as any; a covering of dry tree leaves or dry straw also answers very well. Those who are fond of Endive may have it all the winter through in first-rate order, if they can secure a dry cellar, a dry close shed, anywhere provided it be dry, darkish, and frost-proof. From such positions, placed on the ground, or on benches, or in boxes, we have had it very fine until the end of March. The essentials are—taking up the plants when dry, with fair-sized balls, packing them closely, and for two-thirds of the height of the balls, in moist earth, or made rather moist without wetting the leaves, and covering up the other third with dry earth, or dry ashes. So treated the plants would grow very slowly, the moisture being enough to keep them from shrivelling. They would also blanch in the darkness; and the dry atmosphere around them, and

cool withal, would keep them slowly moving in their blanched state without damping or decaying. We have had Endive very good until the new year, by merely taking up the roots with a ball, and setting them in a dark place without any packing at all, but to keep them later requires a dry surfacing, and a dryish atmosphere, to prevent the blanched leaves damping.

*Chicory* and *Dandelion* roots may be packed in pots and boxes in a similar way, and the leaves will thus blanch as they grow. In their case it is best to take away all the leaves, and just keep the crowns as in the case of Sea-kale. A very simple and pretty way for securing such medicinal salads in winter, is to take an old barrel capable of holding soil. Begin at 6 inches from the bottom, and bore a row of holes, half an inch in diameter, and 6 inches apart, all round. Six inches above that make another row, and so on to the top. Then place dampish soil rather firmly in the bottom of the barrel up to the level of the first row of holes, then place a layer of roots all round, bringing the buds or crowns of two or three plants, according to their size, outside the barrel through the holes. Cover up with earth rather firmly to the next row of holes, and so on to the top, finishing with a layer of moss, old hay, chaff, or other nonconducting material, so as to keep the moisture from evaporating. Any dark place rather dry, and with a temperature ranging from 40° to 45° and 50°, will answer. The head or leaves may be cut as soon as they become long enough, and if the place is dark they will be sure to be a yellowish white as they grow. The same heads will yield two or three cuttings. If the leaves are seldom beyond 6 inches in length they will be firmer and more juicy for the salad bowl. After thus serving a salad purpose, we have known cases of the roots being used medicinally, or even dried and ground to be used as coffee, but after cutting the salad we should think that very little virtue of any kind would be left in the roots.

*Dwarf Kidney Beans*.—Gathered all the Beans worth anything from our last plants under protection out of doors. As it is, they have been very useful. The plants have been taken up, and the position occupied by them came in for the Lettuce and Endive. Turned a lot of young plants out of pots into a bed where they can have heat, and will keep a lot more in six-inch pots until we can find a little more room for them. But for the room and the heat they require, few vegetables are to be preferred in winter to Kidney Beans. Sometimes it is as well to have a few weeks' interval between the last out of doors to the first forced ones. It is not bad policy at times to keep in mind what the late Mr. Beaton, with characteristic shrewdness, said about new Potatoes in December. In the middle of January and onwards they would have been differently estimated.

*Potatoes*.—Went over those in bins, and found a great many diseased that seemed perfectly sound and a fine sample from a very heavy crop at taking-up time. The proprietors of cottage gardens, in low level districts, have suffered severely this season at taking-up time and since; and a nurseryman told us the other day, that some of the newest kinds suffered with him to the greatest degree, in some cases not even returning the quantity of seed in sound tubers, though producing rather heavily. This tendency in apparently fine healthy crops to go wrong after being carefully housed, is one of those things about the Potato disease which make it still more difficult to understand anything about either cause or cure.

*Sea-kale, Rhubarb, Asparagus, &c.*—We are having a fermenting heap of dung, grass, and leaves put in readiness to enable us to start these vegetables ere long. For want of other means at times, we have had these vegetables good in a hot-house. Sea-kale we have had very early and good in the coolest part of a Pine-stove, by planting the roots in a 12-inch pot, setting a second pot reversed on the top of the first, running a straw rope daubed in clay paint round where the pots met to exclude light, and securely stepping up the hole in the bottom of the upper pot.

*Mushrooms*.—The first piece in the Mushroom-house, though spawned and beaten down, seemed rather too loose on the surface to please us. It was, therefore, well daubed all over with the fists and mallet, levelled, and then made smooth by watering a little on the surface, and drawing a clean spade firmly over it. On the whole we like a firm smooth surface best. In this house we shall most likely introduce Sea-kale, Rhubarb, &c., with just enough of fermenting material below them to set them going. We shall try to have a one or two-light box set to work before long with Asparagus, but we have so overdone our Asparagus for several seasons, that we do not wish to have it before Christmas this season, and, if all is right,

with a mild heat, a month or five weeks will be quite enough of time for bringing it in.

From what is stated above as to Potatoes, though no other vegetable will ever take their place, it would be wise policy for our cottage gardeners to grow less of this root and more Carrots, and, especially, Parsnips. The latter if grown in fresh, well and deeply stirred soil are seldom attacked by disease or other evils, whilst they have highly nourishing qualities. For Celery, &c., see previous weeks.

#### FRUIT GARDEN.

As all the lights were taken off the Peach-house to allow of rafters, &c., being repaired, pruned and washed the trees, scraped off an inch or more of the surface soil, fresh surfaced with maiden soil, and prepared for filling the floor with bedding plants, and setting Strawberries on the shelves. These who wish to have Peaches and Grapes in May, must shut up the houses now, but should give little fire heat except on frosty nights for a fortnight or three weeks to come. The trees in the orchard-house are throwing off their leaves nicely as they turn yellow, showing that the ripening process is complete. We have no fruit left now, except Plums and a few Grapes. Of Grapes, we planted several of what we had for Buckland Sweet-water, but the little fruit we left proves the Vines to be Chasselas Musqué, or Jesling's St. Alban's. The flies were very keen at it, though they seemed to have a little difficulty in penetrating the skin; but in this cool position, and not over-supplied with water, not a berry cracked, and the flavour was delicious. We are inclined to see what they will do, as the flies could be mastered or excluded. Pruning all the hurdier fruits may now be proceeded with, and fruit trees of all kinds may be planted forthwith, and if there are a few greenish leaves on the trees all the better. For general routine see last week. In lateinery kept a good fire, with air on, in the damp foggy days.

#### ORNAMENTAL DEPARTMENT.

At page 389, second column, forty-second line, in the words "pruning and striking old Geraniums," the word "striking" should be "sticking." The fine, vigorous Geraniums being well snagged or pruned in as stated, and the roots shortened, are stuck into the pots as closely as the roots can be packed, from twenty to twenty-four being placed in a 12-inch pot, the heads, however, extending a little beyond the rim. These will please us well enough, if they just keep alive and do not make a fresh leaf until March. Of course, not a leaf is left on them now. The weather has been so unsettled, and so many things in hand, that this work is not yet finished, nor are all our *Calceolaria* cuttings in.

We would have liked as well if all these *Calceolaria* cuttings had been in before November, but they will do any time this month, if not frosted, and we have had no frost as yet to injure them. The failures with old Scarlet Geraniums and these cuttings of *Calceolarias*, most generally take place from want of patience. In the case of the old Geraniums, people are anxious to see them grow, and, therefore, they water and coddle them, and every sign of fresh growth in winter makes them more sensitive to cold and damp. Then in the case of *Calceolarias*, the cuttings are taken up every week or so, to see if the roots are coming, and because they do not appear, heat in some way or other is applied, and a close, warm atmosphere is kept about them, encouraging, at any rate, a weak elongation upwards, if not rooting downwards, and making them more liable to feel every change and vicissitude of the weather. If our cuttings in the cold pit remain pretty stationary for two or three months we shall like it quite as well. We believe many stood as long as that before they showed a root last year, and yet they looked as upright, hold, and robust as if they had had a lot of roots. Such little side shoots as were recommended, if firmly dibbled in, and watered at the time, will stand a good amount of air, and even of sunshine afterwards, without finching. After this planting, they generally receive little attention from us, except protection in frosty weather, and a light skiff from the syringe in very sunny days. When very sunny just now, we also keep the sashes generally shut. In dull weather a little air is given, and always at night if mild.

We were led by degrees to put in *Calceolarias* late from finding, first, that they always did better and were more free from diseases and insects if they never had the slightest artificial heat; and then, secondly, from finding that the more forward the plants were in cold pits and frames the more easily were they injured by frost and continued shutting-up in winter. We have frequently in continued frosty and bad weather had the *Calceolaria*-bed shut up from a fortnight to a month. There

ought to be no growth inside if the temperature is low enough to be only a very few degrees above freezing; but in practice we have found that the plants fairly struck and growing would sometimes change their colour a little, at other times have damped leaves upon them, which would require to be taken off; whilst those with not a root, or one or two about an eighth of an inch in length, would look as green and stubby after being shut up a month as when they were only a week inserted. Patience, then, with *Calceolaria* cuttings, we advocate to all who wish to make a fine display with hardy plants next season. We shall be quite content if they make roots in as many weeks as they would require days, or even half-days, in a slight hotbed in March and April. We have done exceedingly well with spring-struck plants, but we like those from cuttings inserted in autumn better. As a recommendation to patience we may add that cuttings inserted in the beginning of November last year, and that had scarcely more than the sproutings of roots in the beginning of January, were amongst our best plants this season. The very simplicity of the whole affair is against it with all those who will not have patience to wait.

If we cannot take up most of the Dahlias soon, we shall place a little earth against their stems. Most of the beds have now so much lost their beauty that we have commenced clearing away slowly the summer residents. We say slowly for two reasons—first, the weather being in general so unsuitable, and then on a dry day the bulk and weight to be removed being so much out of the common, owing to the great heat of the summer, and the warm rains in the autumn. The material, as *Geraniums*, *Pentstemons*, *Calceolarias*, *Verbenas*, *Ageratum*s, &c., has been largely used in banking up lots of frames, to keep frost from them, part will be used for covering a lot of rubbish, which we will attempt to char and burn, and the rest will go to the rubbish-heap, and be sprinkled over with earth.

Among a variety of other matters we may mention potting and shifting. We planted a pit with *Violets* for winter and spring gathering, potted bulbs, made fires in the conservatory in the day to dry up extra damp, and were busy in filling all gaps and holes in the glass, as every such opening admitted water and cold air. It is of little use for the gardener being disturbed if named Jack-of-all-trades, for though holding that every man will do that best to which his attention is chiefly devoted, there are many things that must be done when it would not be convenient to wait for a regular tradesman. In our younger days we have not seldom turned glazier in our dinner hour, when we had the misfortune to break a square or two of glass, and the chief point was to get the putty coloured so that the particular superintendent should not see that an accident had occurred. If there was a spice of concealment it might receive a little justification, because it kept matters smooth, and injured no one, as after the glass had been broken it could not be helped. No, the helping must be done by carefulness in preventing an accident, and not by excuses afterwards. In all gardens not large enough to keep a painter and glazier, the gardener should never be without a cutting diamond, glass, and putty. Hardly anything looks more dismal than sashes abounding in holes.

"STELLA" wishes to have an answer in this place on two matters. First, as to *Cineraria maritima*. Let the edgings of two beds remain as they are, and if they stand the winter well, cut them freely down in April, and they will shoot regularly for the summer. As respects the other two small beds, take the plants up carefully, prune them well back—say, within 4 or 6 inches of the soil, pack the plants lightly in pots, and keep them in a dry place as recommended for *Centaureas*, and next season you may plant them out; but our chief object in advising you to cut the plants in is, that thus you may obtain myriads of nice, firm, young shoots, which, slipped off when from 3 to 4 inches in length, will strike fast in a little heat, and for moderate edgings will be far superior to old plants, and not throw up flower-stalks as older plants do. Secondly, as to *Japan* and other *Lilies* which were potted last autumn and have flowered pretty well, and of which the stems are now withered, the best plan you can adopt is to take a portion of the surface soil away, top-dress with rich compost, and place the pots on what you say is the damp floor of your little cellar. Supposing the soil is dampish now, from the moist stones the pots will take up enough of moisture for the winter, and may remain there until the shoot begins to show above the soil.—R. F.

TRADE CATALOGUE RECEIVED.

F. & A. Dickson & Sons, 106, Eastgate Street, Chester.—  
Catalogue of Roses.

COVENT GARDEN MARKET.—NOVEMBER 11.

The supply is moderate, and a fair amount of business is being done, prices remaining pretty nearly as last week, with one or two exceptions. Foreign imports are light as compared with what they have been in some seasons, Pears and Apples not keeping any better on the other side of the channel than they do on this.

TO CORRESPONDENTS.

PLANTS FOR CONSERVATORY PILLARS (*A Subscriber, T. H. S.*).—Twelve of the best plants and climbers for the pillars of a conservatory are *Jasminum gracile variegatum*, *Lapageria rosea*, *Plumbago capensis*, *Rhynchospermum jasminoides*, *Cestrum aurantiacum*, *Luculia gratissima*, *Habrothamnus Aubletii*, *H. elegans*, *Sollya linearis*, *Tacsonia Van Volxemi*, *Tecoma jasminoides*, *Bignonia grandiflora*, and none of these is more graceful than *Mimosa prostrata*.

POTS AND POTTING STRAWBERRIES FOR FORCING (*A Subscriber, Cosham, Hants*).—For runners of the present year we prefer pots 4 1/2 inches in diameter, well drained, and filled with rich turfy loam beaten firm, and the runners are laid in these in July. We detach the runners from the parent plants in September, keeping off all runners prior to and after this, and place the pots, in double lines, on boards 1 foot from a south wall. These are for the early forcing to give fruit in March. Our second lot is prepared in the same manner, only we use six-inch pots because we employ larger kinds of Strawberries—namely, *Keens' Seedling*, *Eclipse*, &c. All after the first and second lots are fruited in six and seven-inch pots. We never pot or plant after September, and place them first in small pots for the successional crops, thence transferring them into fruiting pots as soon as the small pots are filled with roots. We presume your plants are as yet unpotted. The pots we should use would be 6 inches in diameter, and we take up with balls, and pot firmly. A bed of leaves about 18 inches high being made, a gentle heat would rise; in this bed we would plunge the pots about half their depth, which would excite a speedy root-action, and the materials becoming cold in ten days or a fortnight, a frame and lights might be placed over the plants to protect them from wet and severe weather. They will require to be started in January to fruit by the 1st of April. *Cinerarias* require blooming pots in proportion to their size. Small plants should have six-inch pots, and good plants those of 8 or 9 inches in diameter, up to 12-inch pots for very fine specimens.

LIFTING, PLANTING, AND PREPARING FOR VINES (*Idem*).—You may safely lift the Vines ten years old, only be careful not to injure the roots more than can be helped. March is the best time to plant young Vines. Your house will accommodate seven Vines, the two end ones should be planted 18 inches from the ends, and may consist of two *Black Hamburgh*s; the others may be one *Muscata Hamburgh* worked upon the *Black Hamburgh* stock, on which it is excellent for outside planting; if not worked, omit it and plant two *Trentham Black*, or one if a worked plant of the *Muscata Hamburgh* be planted, one *Buckland Sweetwater*, one *Foster's White Seedling*, and one *White Frontisman*. The border should be dug out 2 feet 6 inches deep, and the width of the house, the bottom sloping to the front, where there should be a drain to carry off the water. The bottom should be covered with 3 inches of lime riddlings beaten quite firm, except over the drain, which is not to be concreted. On the concrete place 9 inches of rubble, as brickbats and rough stones, and on this lay a turf grass-side downwards. Upon this place 2 feet of the following compost well incorporated—viz., turves 4 inches thick from a good loamy soil, light rather than heavy, chopped with a spade but not much, and add to each cartload two bushels of boiled half-inch bones. If the soil is heavy, add to each cartload the same quantity of old mortar rubbish as of half-inch bones. Make the border now, and it will settle to 20 inches deep by March. Let the border be made during dry weather. Avoid manure and leaf mould, which become a soapy mass in a year or two. You can at any time enrich the border by top-dressings of manure. The Vines will grow sufficiently strong for a year or two without manure.

**DRSPONTANIA SPINOSA NOT BLOOMING (E. D.).**—Your plant will never bloom so long as it grows so vigorously; and why prune it in autumn? Let it alone for one year, and it will bloom in the next, if kept in a light, airy, cool house and merely protected from frost. Be very careful to have the drainage free, and not to pot the plant so long as it is growing so vigorously. Water freely when growing, and at other times keep the soil just moist.

**SOLANUM CAPSICASTRUM BERRIES (Idem).**—Although, perhaps, not positively deleterious, we should yet be inclined to regard them with suspicion. Dr. Hogg, in his "Vegetable Kingdom," page 551, states—"The fruit of *S. pseudo-episcium* has been supposed to be deleterious, but M. Dunal says they are not so, for a dog which swallowed thirty of them, out in pieces, sustained no injury." This is a near ally of the *S. capsicastrum*, and whether the berries are poisonous or not, their taste is such as not to recommend their use. Be cautious.

**CELERY WITH SOLID STEM (Goddess).**—You do not say where and how your Celery has been treated, or when it was sown, whether in February, March, or April. You simply state "My Celery is large, sound, but solid-rooted half way up the stem." If it is the common Celery, and sown early, we should not be surprised to hear of its beginning to bolt, or run, by this time—that is, if it was sown in February, particularly after this hot ripening season, and the more so if there has been any lack of moisture at the roots. Celery sown in February, and properly treated, ought to be ready for use in August and September, and that sown after the middle or end of March ought to be ready to succeed the February sowing. From the March sowing we prick and plant out finally at several times, making our final planting about the end of August or first week in September, and we never have observed a plant bolt, or run to seed, before the following year. We have known it in some mild seasons begin to start in the February of the following year, towards the end of that month. The early earthing-up would not of itself cause the Celery to run to seed, but, of course, after the Celery was banked up finally for blanching no more water could be given to it, and it would be a long time before the rains could penetrate to the roots. We are much inclined to think from the words "my Celery is sound, solid-rooted half way up the stem," that it is the Celeric or Turnip-rooted Celery that has been grown and treated like the common Celery. If so, we should not be surprised at the earthing-up early having some effect upon the plants, and causing the knobs or roots, which ought to be round or nearly so, to become elongated half way up. Celeric may be treated like common Celery, as far as sowings are concerned, and nursing up the young plants for final transplanting; and for this final planting the soil cannot be too rich and good. Plenty of good decomposed manure should be well incorporated with the soil before planting out either. Celeric is generally planted on the flat surface, or in very shallow drills from 2½ to 3 inches deep, and from 12 to 14 inches from drill to drill. The plants are lifted with care from their nursery-beds, the tap roots shortened, and all side shoots carefully rubbed off, and the plants are then inserted in the shallow drills at the same distance from plant to plant as the drills are from each other. Water copiously after planting, particularly in dry weather, and pay attention to hoeing, rubbing off any side shoots occasionally. The Turnip-like knobs are taken up, on the approach of sharp frosty weather, and stored away in sand, or otherwise, like Carrots, and are used in stews, soups, salads, and in other ways. The leaf-miner, or Tephritis Onopordium, or Celery fly, has been very numerous this hot season, not that the grubs do much harm to the plants, except to disfigure their appearance for a little time, the Celery being a strong grower and making plenty of leaves. The soft larvae are very easily destroyed by a pinch between the finger and thumb. Hundreds can be destroyed thus in a very little time.

**COMPOSITION FOR FELT-ROOFING (J. M. R.).**—We have had several hundreds of yards of felt-roofing, and found nothing answer so well as what your carpenter recommends—viz., coal tar and Norway pitch, a lump of the last equal to one-fourth of the former being put in the pan, and, when boiling hot, applied to the roof when it is quite dry. Immediately afterwards sprinkle it with sharp sand, which will prevent its running and take away its glossy appearance. Black varnish is also an excellent preparation, superior to paint for out-door wood-work, resisting wet longer and better. Coal tar and powdered chalk we tried, but it did not answer. The main point with a felt-roof is to make it waterproof at the commencement, and to keep it so by renewing the composition every second year. If wet ever penetrate, the felt rots directly, and the water comes through it as through a strainer.

**VARIOUS (A Subscriber).**—No book specifies prices, the other information is in the "Garden Manual," which for twenty stamps; "In-door Gardening," twenty stamps; and "Out-door Gardening," twenty stamps; can be had free by post from our office. Turfy peat if decayed, or the bottom of an old wood stack may be substituted for leaf mould. The Sensitive Plant (*Mimosa pudica*) is an annual.

**SHAKESPEARE'S FLOWERS (Mrs. W.).**—The Editors regret that they must not indulge in notes upon the well-known flowers of Shakespeare. They only can find space for communications elucidating the names now not clearly defined. Can Mrs. W. decide what flower Izaak Walton meant by "Culverkeys?" It certainly was not the Columbine.

**OMISSION.**—In our notice of Dr. Lindley last week we stated that the editorship of the "Gardener's Chronicle" had fallen on Dr. M. T. Masters. We have since been informed that Mr. Moore is associated with him, and that the paper is under the joint editorship of these gentlemen.

**MANGO (C. McC.).**—We have forwarded your note.

**AZALEA LEAVES BROWNED (A Constant Reader).**—The leaves sent do not show the slightest trace of mealy bug, and nothing beyond the effects attendant on keeping the plants in a warm badly ventilated structure after their growth has been made. They do not seem infested with any insect. The majority of the leaves, if at all like those sent, will fall, but the bloom-buds are sound and will flower well, though the trusses will be small.

**LAPSTONE AND DALMAHOY POTATOES (F. K.).**—Any Potato dealer could supply you with these varieties. As you wish to plant an acre, advertise for as many bushels as you require.

**SMALL HOTHOUSE (M. W.).**—If you give us the size of your house, and tell us the chief of your wants and wishes, we shall be glad to advise; at present the matter is too indeterminate. What is the object in filling the pit partly with lime?

**TROPICAL FRUITS (T. Easterson).**—The Mangosteen (the *Garcinia mangostana*), is a very fine fruit, something like an Orange in size, and after passing the hard rind, divided something like an Orange, with seeds in the centre, and the pulp of a delicious flavour. This is, however, not the fruit alluded to at page 340, under the name of the Mango (*Mangifera indica*), which bears its bunches of small flowers on the points of the shoots, more resembles a flattened Plum with a thick rind, and has a most agreeable perfume and a rich pulp when ripe. The mode of successful cultivation, detailed at page 340, is most interesting, and, for success and the age of the plant, we believe it is quite unique. We have no doubt if you follow out "J. H.'s" system you will succeed, especially if you place your tub further from the back wall, so as to secure the benefit of the hot-water pipes, and to give you room to pack tan or other material round the tub, or large pot, in the growing season. We should have more faith of success if the trees, instead of being placed along the back wall, were trained some 15 inches below the glass over the pathway.

**PEACH TREES IN POTS (Pond-ohu).**—There has been a good deal written lately on Peach trees in pots. From your description we would be inclined to believe that you have not stopped them enough in summer; and from being plunged in the border of the orchard-house, most likely the extra vigour and large size of the trees are to be attributed to the roots running in the border beyond the pots. This vigour of growth, attended most likely by unripe wood, is the chief reason why you have not had more than two or three fruit to a tree. In similar circumstances we generally manage to allow too many to remain. It would have been better to have raised your trees, and root-pruned them a month ago, but better late than never. Take up the pots carefully now, and prune off most of the roots that have extended beyond the pots, replacing the pot again after putting some nice fresh rich soil below it and round it, to encourage the fresh fibres to run a little in it, then remove a good deal of the surface soil of the pot, as much as you can do without injuring the fibres, and replace with fresh loam, with a fourth of rotten dung or leaves, firming it well, and then give a good watering so that the buds may sustain no sudden check from cutting the most of the roots beyond the pot. During the winter the soil is to be kept dryish rather than wet, but not too dry, as when that is the case the buds are apt to be thrown off by a liberal watering in spring. Fibres will be forming in the top-dressing all the winter, and the shoots will come healthy and less vigorous in spring; and if stopped when they have made five leaves, and stopped again when they have made two or three, you will insure nice stubby well-ripened wood near home, the trouble with which will generally be sufficiently thinning the fruit that will show.

**FRUITS FOR AN ORCHARD-HOUSE TRELLIS (C. E. M.).**—The following will do for the trellis in your orchard-house:—Peaches: 1 Early York, 1 Early Victoria, 2 Noblesse, 1 Barrington, 1 Walburton Admirable; Nectarines: 1 Balgowan, 1 Elrune, 1 Hardwicke Seedling, 1 Violette Hative.

**VINEY TO BE A GREENHOUSE IN WINTER (Jardín).**—We have repeatedly stated that for more greenhouse treatment there is no necessity for turning out the Vines in winter after the fruit is cut, as if the temperature of the house is not raised by artificial heat above 45°, high enough for the generality of greenhouse plants, there will be no danger of starting the Vines before they do so pretty well of their own accord. We know many places where every viney, Peach-house, or Fig-house, is a greenhouse in winter before it is desirable to start the fruit-houses in earnest. If, however, you are resolved to have what temperature you want in winter in the house, and yet keep the Vines at rest, your best plan would be to have in front, two walls, two sills, and two wall-plates, from 2½ to 3 feet apart. In this place plant the Vines, and when pruned bring them down and train them in winter. For this purpose you would require double front sashes, the inner ones to be removed in summer. In most cases one pair of sashes would do, as the front ones might be placed behind the Vines in winter, and the Vines be open to the weather then, with the exception of being protected from wet by the glass roof above them. With double sashes the Vines would be more secure, and many things, as salading, might be kept beneath them in winter. By this mode, too, enough of heat could be admitted from the house into the space between the sashes to break the Vines before placing them against the rafters. But for the expense of the double sashes, this plan is in every way the best, and these inner sashes, if deemed advisable, may be used for other purposes as soon as the Vines go up against the rafters. Many modes have been resorted to, by board shutters and otherwise, to make one set of front lights do, and still give the Vines a little protection, for it should not be forgotten, that Vines grown in a house are never afterwards so hardy as those grown out of doors. One of the simplest of these modes we have met with is the following:—The front sashes, with studs between them in the usual way, were hung to the front of the wall-plate, on the hook gate-hinge fashion, so that the sashes could be easily put on or taken off. The sashes were 3½ feet in length. Similar hook hinges were fastened on the inside of the wall-plates. Three feet from the front sill, inside of the house, a piece of wood, 1½ inch thick and 15 inches in depth or height, went all the length of the house. Into this space, and as near the ground as possible, the Vines were bundled. The front sashes then were moved and hung on the inside of the wall-plate, the lower end sloping inwards to the boards, and resting on it, and fixed to it by a single screw. The space between the sashes occupied by the studs, between the sill and wall-plate, still remained to be filled up. That was done by a three-quarter-inch piece of wood as long as and an inch wider than the opening, either slightly tacked on at top and bottom, or fixed at bottom to the board with a screw, so that, though a little tight, the board would move on the screw so as to admit what front air was deemed advisable. In severe weather a little fern or litter was wrapped among the Vines. For common greenhouse plants, as already stated, however, there is no necessity for moving the Vines.

**WATERING ENGINE (H. Vaughan).**—Any one of the horticultural implement makers who advertise in our columns could supply such an engine on wheels. Write and ask them to send you a priced catalogue.

**NAMES OF FRUIT (Frank).**—1, Beurre Diel; 2, St. Germain; 3, Black Worcester; 4, Beurre d'Arcberg; 5, Puisse Colmar; 6, Glou Marceau; (H. W. P.).—Vicar of Wingfield. (F. L.).—3, Nonvau; Poiteau; 3, Beurre Diel; 5 and 7, Beurre Clairgean; 8, Beurre de Rance; 9, Ne Plus Meuris; 10, Beurre Bose; 15, Doyenne Defois; 17, Marie Louise. The others are not ripe, we shall keep them and let you know the names by-and-by. (B. R.).—1, Beurre d'Arcberg; 2, Crasanne; 3, Old Colmar. (H. H.).—1, Van Mons Leon le Clerc; 2, Beurre d'Arcberg; 3, Marie Louise;

### POULTRY, BEE, and HOUSEHOLD CHRONICLE.

#### LIGHT BRAHMAS AT CHILDOWN HALL, SURREY.

THERE is no change from the country so thoroughly and entirely a change as spending a few days in London. We country parsons need it at times. We are apt to get narrow, to move in too small an orbit, and to be unduly careful or troubled about village things and village people. London widens one's views, diverts one's thoughts, and completely shakes one out of oneself.

Thoroughly, then, do I enjoy a few days in the great metropolis; I get out of the danger of merely vegetating,—I live. "Better fifty years of Europe than a cycle of Cathay," sings Tennyson, and better to change the flow of thought to quicken the blood, by being in London for awhile, than to be always in our country homes, be they ever so pleasant. Still, art wearies in time, often in a short time, but nature never wearies for long. My eyes filled with London sights, my ears with London sounds, satisfied, just short of satiated, I turn back to the country.

A kind invitation lies before me to visit Mr. Pares at Childown, and inspect his Light Brahmans. I will go; more, I will record my experience; it will be but fair. I have seen and told of "Y. B. A. Z.'s" dark beauties, I will see and tell of Mr. Pares's light charmers.

Gliding off from Waterloo station, out south-westward, my eye catches sight of several pairs of fancy Pigeons on different houses, some caged in, mostly Tumblers, I think. I will not speak too certainly this time, remembering my mistake at Calne. Mistakes! who does not make them sometimes? This reminds me of my curate days. After one Sunday morning's service—I had been reading prayers—my rector, one of the best and most gentlemanly of men, but fidgety when the gout was coming on, said in the vestry, "Why, you made six mistakes in reading!" "Sorry," said I, "but I am not feeling well." In the afternoon it was my rector's turn to read. He began the morning Psalms, and read away to the end, the clerk reading his verses from the evening Psalms; the congregation was tittering. It was now my turn. I said in the vestry, "Rector, you read the wrong Psalms." "Ah! well," said he, "'tis a wonder we do not make more mistakes." And so it is.

Well, to return—on farther until one catches sight of "Clement's terraced heights and Esher's groves," as saith Thomson; and now the character of Surrey is coming out every few miles; I see here and there scrubby bits of heath. Strange it is, but yet I believe true, that close to London as is Surrey, yet, there is more waste land in it than in any other county. But, perhaps, this is well; if the parks of London are its lungs, surely additionally healthy for Londoners must be these large heathy spaces in a county so near as Surrey. There, on the heath, the air is uncontaminated, the same sharp clear air as in the days when London contained but its half million of inhabitants. Londoners, then, may thank God for the uncultivated wastes in Surrey. On, creeping on, very slowly, I come to Chertsey—no, only Weybridge. Further on to the right, flags and groups of people. Oh! I see, it is a ploughing match. The

sturdy arms are steady as iron, and the furrows straight as arrows. Well done, Surrey's sons, the best of all shares to hold is the ploughshare.

Chertsey at last; but in a drenching rain, which pens us all, and there are many, into the little station; a heavy, heavy shower. "Nature is paying her debts," says one near me. Never mind the delay, it cannot be helped. Let me watch the different characters around me, as revealed by this compelled imprisonment. There is a goodly number of English grumblers. "Grumble and grow fat, happy Englishmen," said once a lively son of France. Then there are the fidgets, poking their heads out into the rain ever and anon. Then there are those two young ladies in the waiting-room, who are quite pleased with the rain, for that waiting-room is to them, with that nice youth, quite "a flirting-corner." Oh, it is the old, old story. But grumblers, fidgets, flirts, you are not in my line. There sits that delicate-looking lady, I fear a case of recent illness, whom I had noticed huddling her cloak higher to her throat, and glancing timidly at the open windows of the carriage, and now sitting, evidently fearing a bad result from the rain. I will say a kind word to you. Ah! the rain is over, and there is my host that is to be. My curiosity regarding his personal appearance is at an end now, and his curiosity at mine, if he had any, is also over.

A drive through Chertsey—old quaint Chertsey, "a dead-alive place," as I was told in the railway-train. Yet to me there is a great degree of interest attached to all those little towns and villages to the west of London, and on the Thames. As to Chertsey, two names are connected with it in my mind. First, Cowley's, the poet; but who reads him now? I suppose no one. Artificial, yet learned, Cowley, your works cannot live, but your name will—"Stat nominis umbra." There is Cowley's house, part new, but one bit old: may that old bit never be taken down. But there is another and far greater name connected with Chertsey, that of Charles James Fox, for close by is St. Ann's Hill, that well-wooded eminence where the great statesman was wont to retire, and live a purer life than his London life. Rogers says of him—

"Not less happy, Fox, than thee!  
Thee, at St. Ann's, so soon of care beguiled,  
Playful, sincere, and artless as a child!  
Thee, who would'st watch a bird's nest on a spray  
Through the green leaves exploring, day by day;  
How oft from grove to grove, from seat to seat,  
With thee conversing in thy loved retreat,  
I saw the sun go down!"

Poor Fox! A great mind, an eloquent tongue, a heart full of noble aspirations, but the life ended all; as one said of him, "The statue is imposing, but the pedestal leans." On to Childown, rising higher and higher, until we arrive at

"A land of brown heath and shaggy wood."

Yes, actually within twenty-five miles of London here is a country like that lying at the feet of the Scotch highlands, such as I have seen in Kincardineshire. Heath, heather everywhere, with furze in patches; then rising above is the beautiful silver birch, most charming of highland trees; and here and there great belts of Scotch firs, with their brick red stems. The picture I beheld was unique. I was, alas! too late to see

the heather in bloom, but the trees were perfect. Wild scenery, indeed, exactly that described in Kingsley's "Winter Garden." No winter, as to foliage, reaches this place, for the firs are clad spring, summer, autumn, and winter too.

Apparently in the midst of a fir wood a space has been cleared, and on the south slope of hill the pretty modern mansion called Childown Hall, red brick cornered with stone, has been built; a hill behind and to the east keeps off the wind. Childown—well, all the chill is outside, for the reception I got was the reverse of a cold one. The much-needed lunch came first, then out to the poultry. First, those behind the house, where awaits, cornbasket in hand, master's man, to whom I am duly introduced. When he heard I was coming he had said, "I wish them chickens that the pointer pup killed last March had been here for 'WILTSHIRE RECTOR' to see." This I found was a sore subject, almost a heart-breaking one; the pointer pup, the wretch, had worked his way early in the night into the chicken-house, and there, hour after hour, he had mangled and mouthed away until thirty chickens were no more—the best of course, for he was a puppy of taste.

Well, a host of Light Brahmas are around me, some prize birds, others not. In the midst is the largest cock Mr. Pares has ever bred, and named by him "Samson," the hero of a hundred (show) fights. I watch these birds, I stoop down and bring my face level with theirs, for that is the best way to inspect poultry. I turn round, and within a wired enclosure, with roosting-houses made of furze (these looked in character, for the wild country was open to us as well as around us), I note some of the chickens of this year, not equal, I am told, to those the puppy killed. Chickens that meet with untimely ends, like kings who die in childhood, are always perfect. In another pen are Black Ducks and Brown Call Ducks, one very lame, quite a cripple and very spiteful, "*Mens curra in corpore curro.*"

We walk on further, no fear of wetting one's feet, for the soil is sandy, "a hungry sand," said the gardener. We find another fowl-structure, half hidden among firs. One hen I pronounced superb, large, full-chested, beautiful to behold. Strange it seemed to find these choice cultivated birds in so wild a spot. On still further, "To the monastery," said Mr. Pares. I start! "As an English gentleman I wish to be thoroughly obliging, but as to visiting a monastery—no, please; I have scruples, I do not like monks, I am a clergyman of the Church of England, besides, I have a wife and family." "Oh! I only call it the monastery because cockerels alone live there."

On my way I admire two Bretonne cows, and would have petted a lad's pony, but he, the pony, scorned it, as doubtless the lad would also have done. Over fields, for some part of the district has been made into pasture land, I see many pullets wandering. "There are the monks," said Mr. Pares, and I see, perhaps, fifty cockerels, of large growth, walking out of a rustic house made of rough fir poles. The monks come to call, for monk-like they love eating, and master's man is a walking refectory, as they well know. Gently, no driving, please, let them come naturally over; drive them, and they stretch up their heads and put themselves out of shape. Never drive fowls, especially Cochins or Brahmas. "This is the best bird," say I, and he is named "Rector," out of compliment to somebody I know. We now bend our steps back towards home, see some more Brahmas, one "Goliath," Sampson's son; then three cocks separated in different compartments, one a Frenchman, and not popular with master's man, who is true English, not less so because he is, like his master, a poultry enthusiast.

"Why, what have you got there under wire at the side of the house? Oh! I see, Andalusians." "Yes, my man would call them for a long time 'Master's delusions.'" Neat-looking birds they are, the hens especially—slate-coloured, quaker-like matrons—a new variety of fowls for a change. And lo! in the next enclosure are some Silkies, funny little fellows, beautiful in their ugliness like Scotch terriers. Their shape shows eastern origin, resembling that of other eastern fowls, and, passing strange, their having silky hair for feathers, they can scarcely be said to moult. These are the pets of the lady of Childown, and right proud she is that they have begun a distinguished career by a recent "highly commended." The Silky makes a nice lady's pet, being tame, willing to live in small space, and its neat form is pleasing. However, I should not like to eat one of the "blue noses;" if obliged, I should close my eyes.

So I have seen all the fowls, and a goodly number they are. Next a practical word. I set aside at once all disputes about the origin of Brahmas. They are fowls which will stand their ground because of their utility, and that is the right basis; they are excellent winter layers and not bad eating. I would

say that the two kinds, Light and Dark, should never compete against each other, they should each have a separate class at shows; this would be fair to the breeders of both varieties. Then, too, the Light should be really light; no suspicion of a cross shown by a patchy plumage. Let Light be light, and Dark be dark. As to the Light, there seem to be three special difficulties in their breeding—to keep the comb right, to avoid patches on the back, and not to get a yellow tinge over the whole bird, which greatly spoils the pearly hue, but is apt to come on in old age. Brahmas are useful birds, and like Cochins tame, and attractive in many ways. Breed them large and to a feather if you can.

There remained a little time before we needed to go in-doors, and like many a day in late autumn, the weather had improved. I ascend a hill, walking through ranks of red fir stems. On the top I stand panting and admiring; I feed upon the view; I enter into their feelings, of whom it has been said—

"On a fair prospect some have looked  
And felt as I have heard them say,  
As if the moving time had been  
A thing as steadfast as the scene  
On which they gazed themselves away."

What a wild view! And again I exclaim, "And so near London!" To the extreme right lie Virginia Water and Windsor forest, but too far away to come much into view; then nearer is Chobham common, where our poor soldiers played at being in the tented field, soon in the Crimea to be exchanged for work in which was no play. Some slight remains of the camp still exist—viz., ruins of earthworks. Beyond the common lies the village of Chobham, where Bishop Wilson, of Calcutta, was, in his youth, curate to Richard Cecil. Then further still are the Frimley ridges. Before me, and to my left, in dim distance, stretches the whole line of the Hog's-back. On the nearer hills the outlines of buildings are to be traced—viz., "The Dramatic College," called by the poor the "Rheumatic College," and an orphan asylum, and others, while nearer is the wild-heath-clad valley, broken up by knolls. Nearer are Scotch firs with breaks through them, showing bits of the valley, while close to me is a small lake. I stray round in front of Childown; I wish I had been here when the heather was in bloom. I find a goat tethered, for no enclosures are here, and she might wander away for miles. Poor nanny! though from another country, she must surely feel at home here. But I must hasten in, for the evening chills are coming on, and the horizon is narrowing minute by minute, while the cheerful blaze, throwing its brightness upon wall and ceiling and window, invites us to walk in-doors. A loll on a couch, and a cup of tea—'tis five o'clock. Oh! that blessed cup of tea, the best invention, a lady's it was, this twenty years, for those who dine late, for late dining takes away that real enjoyment of tea which early diners have; warming, cheering, five-o'clock cup of tea! Shall I need to add more? A dinner followed, at which neither teeth nor tongue was idle, the former we employed in eating a Brahma, the latter in talking of their living merits. I am bidden to invert the silver cup at my right hand before it is filled with ale; I fear some conjuring trick, but on the bottom of the cup I only read of the triumphs of Brahmas.

I scarcely need say I thoroughly enjoyed my visit, not less because we had a drive the next morning, and another in the afternoon to Virginia Water station. So the wild picturesque country remains fixed on my memory. I am asked, at parting, to make another visit. I hope I may be able some day or other.—WILTSHIRE RECTOR.

## GAME JUDGING.

YOUR correspondent "OLD COCHIN" seeks to enlarge the controversy on Game judging by introducing matters entirely foreign to the subject, and, while deprecating personalities, affords strong proof of his disinterestedness by a violent attack on the Birmingham Committee, and "a single individual" in particular. "OLD COCHIN" appears to be completely *au fait* on many matters connected with Birmingham, but being beyond the point at issue—"Game judging," it is not the intention of the writer to notice these at present; however, as "OLD COCHIN" takes exception to the statement that the dissatisfaction at the Game decisions last year was confined to one or two disappointed exhibitors, a few remarks are necessary. Your readers are aware that previously to the last two years, a certain peculiar notoriety obtained at Birmingham in the Game department, to which your correspondents "OLD COCHIN" and "AN EXHIBITOR" seem to wish to return, relative to which,

and the dictation on the subject, an explanation from the latter would be peculiarly interesting just now.

It is generally understood that two organs of the press indicate and reflect public opinion on poultry matters, and for confirmation or otherwise of the alleged mistake, a reference to the reports at the time will perhaps assist in elucidating the point better than all that may be written *pro* and *con.*; and for that purpose, if your readers will refer to your columns, New Series No. 193, page 459, they will fail to discover any mention of such dissatisfaction, or indeed any fault at all. For the report of your contemporary on the Game classes, it is well known the services of one of the Game Judges of 1862 were engaged, and what was the result? Had the Game Judges been at fault, would a solitary complaint have been made? Perhaps either "OLD COCHIN" or "AN EXHIBITOR" can explain this, and, failing that, the alleged dissatisfaction may be consigned to the limits previously stated.—JUSTITIA.

### MANCHESTER POULTRY SHOW.

SEVERAL exhibitors, without taking the trouble of looking minutely into things, or even of comparing them, having spoken disapprovingly of this Show, I will, through the medium of your columns, endeavour to prove the fallacy of their arguments not only to them, but also to those who may have been biased by their unthinking talk.

I have lately heard one or two remonstrate against the arrangements which Messrs. Jennison, of Belle Vue, have made with regard to their Poultry Show at Manchester, and, at the same time, regret their not having taken the Birmingham principle of entries as a criterion for their own. The Manchester system this year is just the same as the Birmingham, only not so expensive to large and, more especially, to small exhibitors of one or two pens.

At Birmingham a subscription of £1 must be paid for every four pens, and 2s. 6d. for each of the pens exhibited, thus making £1 10s. for the four entries, or 7s. 6d. per pen. Let us now investigate the Manchester system:—An exhibitor can enter in one form (which really constitutes the subscription mentioned for the Birmingham Show) five pens, for which he has to disburse £1 15s., thus each pen costs him to enter 7s. or 6d. less than at Birmingham; and an exhibitor of one pen at Birmingham has to pay £1 2s. 6d. for the privilege of showing, whereas at Manchester the same person can show the same pen for 15s.

Manchester is straining every nerve to make its Show the Show of Poultry and Pigeons, and there is very little doubt that it will be so, considering that the promoters are men of integrity, the Judges persons of undeniable character and honour, and that the Music Hall, where it is held, can be thoroughly warmed by steam-pipes which are laid down throughout the building.—JUSTITIA.

### SHEFFIELD COLUMBARIAN SOCIETY'S SHOW.

(From a Correspondent.)

THIS was held on November 6th. The pens for old and young birds numbered about 140, young birds only competing for prizes. The birds, competitive and exhibited, comprised every variety, and some were unequalled; among these, a Blue cock Pouter, owned and shown by Mr. Edward Brown, and a pair of Black and Dun Carriers, bred and exhibited by Mr. Thomas Colley, were declared premiers of the county, having won three silver cups this year.

The following is a list of the Judge's awards:—

CARRIERS.—First and Second, — Cottey. Third, J. Deacen.  
 POUTERS.—First and Second, W. Ashforth. Third, H. Brown.  
 FANTAILS.—First and Second, — Hawkins. Third, — Smith.  
 TURBITS.—First and Second, — Wilkinson. Third, — Benison.  
 OWLS.—First and Second, — Ashford. Third, — Benison.  
 TUMBLERS (Short-faced).—First and Second, — Smith. Third, H. Brown.  
 ANY OTHER VARIETY.—First and Second, E. Brown (Barbs).  
 SPECIAL PRIZE (Pouter Hen).—W. Ashforth.

NANTWICH SILVER GAME CUP.—It will be seen, on reference to our advertising columns, that the Committee of the Nantwich Poultry Show purpose next year giving a silver cup for the best pen of Game fowl of any variety, the competition in this case being open to the whole kingdom. Nantwich being so proverbial for the excellence of its Game fowls, no doubt the local exhibitors will strive to the utmost to prevent this coveted

laurel being wrested from their grasp, and from this cause, most probably, the competition will be a very severe one, and embrace entries from most breeders of Game fowls.

### MIDDLETON POULTRY SHOW.

IN the Journal of October 31st I find an effusion from the prolific pen of a Mr. Massey, of Fulford, York, in which he has taken the trouble to occupy himself, from about the 21st of September, with sundry small grievances, arising out of the business of our show at that date.

First of all he complains about a want of attention to his Pigeons (quite a new disease), and that he had occasion to bribe some unknown individual before their wants could be attended to, ignoring the fact, known to all exhibitors, that his appeal ought to have been made to the Steward of the department. From inquiries which I have made, I feel most positively certain that not only all the Pigeons, but the large number of poultry as well, were during the Show as well cared for, or perhaps better, than they could have been at home.

It is not worth while to notice the complaint of his call at my office, as he must be well aware that in the midst of multifarious business, circumstances occasionally called me to the various departments; I can avow, however, that I was not absent for any length of time all put together. In the payment of the prizes, I find that in copying out, the second prize, by mistake, was taken for Carrier Pigeons instead of first, so that at the date of his note he was entitled to 7s. 6d., but he only needed to have pointed this out and it would have received my best attention. The 1s. 6d., I believe, is fully stated on the note sent with his prize money to be for the carriage of his birds, and as the enclosed note will show, was quite in accordance with his own instructions. Of course he was also charged commission on the sale of his poultry, and the expense of remitting, which together amounted to 4s. 4d.

Lastly, about the mastiff. I can safely say that as soon as his telegram arrived it was dispatched to the Steward of the department and the dog forwarded immediately, after being well fed and cared for in every possible manner. But, may I ask, why should the trouble and expense of Mr. Massey's dog be thrown upon our Committee, when that gentleman was present at the Show, and ought certainly to have taken charge of and removed him at the close? Mr. Massey is not quite noteless, it appears, and perhaps would not be able to lead the way to the summit of perfection better or sooner than—THOS. MILLS, Secretary, Middleton Agricultural Society.

P.S.—I have omitted to state the reason why the dog was not forwarded earlier, he had lost his number, and no one could tell to whom he belonged until the telegram arrived.

IN your Journal of the 31st ult. there is a complaint of the want of management at the Middleton Poultry Show. I was very much vexed at the time with the state in which my birds were returned, as they exhibited great want of care, as well as want of food; I therefore feel called upon to confirm Mr. Massey's statements in those respects, and hope that there will not be ground for complaint next year.—CHARLES SIDGWICK, Riddlesden Hall, Keighley.

### WARNING.

A FEW weeks ago I sent to the Worcester Show some Ducks, which were commended, and a week had not elapsed before I received a letter, edged with black, from a gentleman (as I thought), and dated from Stanton Court, Herefordshire, inquiring what I would take for a drake of the kind he had seen at the Show. Upon this I sent him my terms, to which he agreed; but being a party of some standing, as I then supposed, I did not think it requisite to request the money before sending off the bird, but from that time to this I have heard nothing more from the person, although I have written to him several times requesting payment. A warning in your valuable paper to all amateurs will greatly oblige—A SUBSCRIBER.

ABERDEEN POULTRY, PIGEON, AND CANARY SHOW.—This will inaugurate the new year. The prizes are very liberal; and there are sweepstakes, as well as extra cups and medals. One

good feature is that the day is specified (January 20th), on or before which all prizes will be paid. The Poultry Club is to appoint the Judge of poultry.

### SIR JOHN SAUNDERS SEBRIGHT.

We have been applied to for a portrait of this first cultivator of the Bantam, and as we have a rather scarce portrait of the worthy Baronet, we have had it photographed, and copies may be had at our office. A few particulars of his not eventful biography will be a suitable accompaniment.

He was the eldest son of Lieut.-General Sir John Sebright, M.P. for Bath, and his mother was a daughter of Edward Knight, Esq., of Wolverley, in Worcestershire. He was born in Sackville Street, St. James's, Westminster, on the 23rd of May, 1767. He married, in 1793, a daughter of Richard Croft, Esq., of Harley, in Norfolk, and their offspring were one son and eight daughters. He succeeded to the baronetcy on the death of his father in 1794. In 1797 he was High Sheriff of Hertfordshire, which county he represented in eight parliaments, from 1807 to 1835, and he was also a Deputy Lieutenant of the same county. He died at Acton Green, April 15th, 1846, and was buried at Flamstead, in Hertfordshire.

The Sebrights are an ancient family in England, and were at Sebright Hall, in Essex, when the earliest Norman Kings reigned over us. Even then they were specially associated with country occupations and the hunting field, holding their estate by the service of "keeping the King's palfrey, or saddle horse, forty days at the King's charge, whenever he came into those parts."

The late Baronet did not depart from the traditions of his ancestors. It was about the year 1800 that the late Sir John Sebright first began to fashion the Sebright Bantam. The cross was between some common Bantam and the Polish fowl. These were bred in and in until the required marking and size were secured. Sir John then accidentally found a short-tailed Bantam cock in the country when he was travelling. This short-tailed bird he in-bred with his newly-manufactured Bantams, thereby giving their progeny the present form of the short tail.

In the "Poultry Chronicle" it is stated that Sir John obtained a buff-coloured Bantam hen at Norwich: she was very small indeed, with clear slate-coloured legs. On the same journey he purchased a cockerel rather inclined to red in colour, destitute of sickle feathers, with a hen-like hackle; and also, at Watford, a small hen resembling a Golden Hamburg. He afterwards had a white cockerel from the Zoological Gardens, by which he made his Silvers. This description of the origin refers back before the laced marking was achieved. They were then known as Pheasant Bantams.

Sir John also established a club for the fostering and improvement of his pets. It is thus mentioned in the "Poultry Chronicle" of 1855:—"The Sebright Bantam Club was formed some forty years ago by the late Sir John S. Sebright and several other fanciers, who endeavoured, if possible, to obtain the beautiful plumage of the Polish fowl on as small specimens as could be. They (the late Sir John, the late Mr. Stevens, the late Mr. Hollingsworth, and Mr. Garle, who still survives), began their labours by selecting the best kinds for their purpose of the Polish, and, by judiciously crossing them with Bantams, gradually obtained their end. They had to work out the top-knots, get rid of the hackles and long tail feathers, and reduce the size, retaining as much as possible the truly impertinent carriage of the Bantam. This has been most successfully accomplished, but not without the occasional re-crossing with the Black Bantam, for the constant breeding in and in has often brought the birds to a stand-still. The Club thus formed met annually, on the second Tuesday in February, in Brick Lane, but has of late years been transferred to the Gray's Inn Coffee-house, Holborn, when it has always been the custom to admit strangers, on application, after the award of the Judges. The Club is essentially private, and all members must be proposed and seconded by a member, and afterwards balloted for. The annual subscription for the Golden is two guineas, and the same for the Silvers, which forms the amount of prizes. All the birds must be the *bonâ fide* property of the exhibitor, bred by him, and under a year old. The cocks are allowed 22 ozs., the hens 18 ozs. The cocks must have no long hackles, no saddle feathers, no streamers in the tail; they must have rose combs, short backs, heads and tails approximating; their ground colour, whether Gold or Silver, must be clear, and every feather delicately laced (never spotted) with pure black. The

tail feathers should form no exception in their lacing (but this will be very seldom seen), and the bars on the wings should be black and distinct. The same rule applies to the hens."

### ATTEMPTED SWINDLING.

SOME time since, being in want of a few pairs of fancy Pigeons, I advertised for them, and the second day after the appearance of the advertisement I received a letter from a party who also signed himself a "Surgeon," offering me some birds, which he said had taken first prizes at the Crystal Palace and other principal shows, at marvellously low prices, and offering me a further reduction of 50 per cent. subject to my taking half-a-dozen pairs. These very liberal terms aroused my suspicions, and naturally prevented me from sending cash in advance, but I wrote to him and asked him to send me some that I mentioned, on approval, at the same time referring him to a gentleman who lived within a few hundred yards of the address given. From that day to this I have never heard a word from this most honourable "Surgeon," but from inquiries which I caused to be instituted I find that the address given is not a surgeon's residence, but a post office. I have not a shadow of a doubt but that this is the same person who, "if he could," would have imposed upon "CAXTUS" as well as myself.—J. J. H. S.

### PIGEON MANAGEMENT.

I THINK it would be interesting to your readers to hear from fanciers of their successes and failures in breeding, and their mode of treatment. This has, I believe, been generally considered a bad breeding season, and comparatively few of our great breeders have succeeded in rearing many birds. This I hear from all quarters, but have heard no satisfactory reason assigned, and I shall be glad to hear what may be the probable cause. At this time my stock of Pigeons (mostly Carriers) are in perfect health and condition. I am feeding them chiefly on old tick beans, and occasionally give them Indian corn and small round peas by way of a change. Of course they are kept scrupulously clean, and have a constant supply of gravel, sand, and fresh water.

On cold mornings I give them a little hempseed, but I am not certain that this is a proper diet for Carriers, and that rape seed is not preferable. Will Mr. Brent, or any of our Pigeon-fancying friends, give an opinion, and of the effects of the different kinds of corn on the birds? So far as my experience teaches, sudden change of food is injurious, and Indian corn alone I should not recommend.

With regard to ventilation, I am giving a good deal of fresh air in the day, and closing the loft at night. I should like to know whether much fresh air is thought desirable at this time of year, and whether a pretty strong current through the loft would be beneficial or otherwise.—WILLIAM MASSEY.

[I think that a little hempseed, if given sparingly, will not injure Mr. Massey's Carriers, and I fear that they will not be able readily to pick up rapeseed on account of their wattle obstructing the direct line of sight. Indian corn and peas I consider good for flying Pigeons while in training; but for Pigeons confined I fear much Indian corn is too fattening, and peas cause them to lay soft-shelled eggs. Wheat is good for feeding young ones on, but causes the old ones to be soft in condition and feather. Sound old tares, small old beans, and a little good barley I think the best food for fancy Pigeons. Fresh air is good for the Pigeons, but a strong draught at this season is certainly not desirable.—B. P. BRENT.]

### SECOND AND THIRD SWARMS.

I BEGAN bee-keeping this year with a swarm, second or third from the old stock, in the first week of June. The hive is called, I think, "Neighbour's Improved Cottage." The bees have worked apparently very industriously all along; but they have not filled the hive, and of course have given no honey in the glasses above. The bees began to build on one side, and gradually approached the other; but a large share, I should think one-fourth of the whole, has not yet been filled up. They have been fed with syrup, equal to about 6 lbs. of white sugar, up to the present time. The drones, if any, have not to my knowledge been expelled, although I have watched the hive very closely, unless this event occurred about three weeks since when a few dead bees were found lying in front of the hive; there were, perhaps—say twenty of them. There seem to be, however, plenty of bees, and they are very industrious.

How is it the hive has not been filled? Why were the drones killed off so late, and then so few? Should they still be fed? and as I cannot weigh the hive, how shall I know when they are sufficiently fed? I suppose my beginning with a late swarm was a disadvantage; but will this still be a disadvantage next spring? Will this fact interfere with their early and vigorous swarming in the next spring?—B.

[A second or third swarm is rarely strong enough to fill its hive with combs the first season. The reason of this is, that after-swarms are later than first swarms, are seldom so numerous, and being led by a virgin queen, breeding is more or less delayed.

Few drones might have accompanied the swarms in the first place, and these would be destroyed immediately upon the queen becoming fertile, whilst none would be bred by a young queen at the head of a weak colony.

If you cannot actually weigh the hive, you can surely lift it in your hands, either with or without the floor-board, and thus form some idea of its condition.

The hive being stocked in the first place with a late swarm, and being, therefore, only partially filled with combs, must perforce be at a disadvantage next spring, as compared with a strong colony in a well-filled hive, and is not so likely to swarm early.]

### WOOD FOR HIVES.

ISRAEL TODD will find well-seasoned yellow pine much better than red deal as a material for hives. The latter is too close in its texture, and, consequently, too good a conductor of heat for the purpose, whilst bees will frequently refuse to remain in hives made of red deal, owing to the strong smell of the turpentine it contains.—A DEVONSHIRE BEE-KEEPER.

[We used well-seasoned red deal for several years, and never found the bees inconvenienced.—Eds.]

### STRENGTHENING A LIGURIAN CAST.

WHAT would you advise me to do with a cast of Ligurian bees, which I had much trouble with in getting them into a Woodbury hive? I sent them to the moors, but they came home very little better of the journey; indeed, the heather has been quite a failure this season. I have been feeding them, and this morning took off the cover to see what state they were in, and found that they were very weak as to combs, &c. They occupied the middle of the front of the hive; the two outside bars had nothing on them, and the others had combs only about half way across, or hardly that. Now, I do not want to join them to the others, which are very strong, but rather to feed them, and save them through the winter, if possible. I could put a frame or two in at the sides with empty combs, or nearly so, and feed them till they had filled them up, and had thus provided a good stock. Would it do to keep them in a greenhouse during the winter, taking care to supply them with plenty of food?—G. W.

[As stocks are found to winter better with the two outer combs removed, you will do well to abstract two frames of worker comb from your strong stock, brushing off every bee, and leaving a vacancy on each side. Insert these combs in the centre of the hive containing the weak colony, removing the two small side combs, and feed liberally at once until it is sufficiently heavy to stand the winter.

A greenhouse might, probably, be a good shelter for a weak stock, but the bees should not be confined, and care must be taken that there be no draught of air rushing in at the entrance. They should not be fed in winter, and if the present position of the hive be a little distance from the greenhouse, the removal may do far more harm than good, owing to the loss of bees returning to their old stance.]

### OUR LETTER BOX.

FEEDING BRAHMA POOTRAS FOR EXHIBITING (A. O. W.).—Ground oats form the best food for any kind of poultry. They may be mixed with water or milk. We do not advise you to shut up your Brahma cock unless you have a good-sized pen in which to put him, and if in company with the hens to be shown with him, so much the better. Give him twice a-day, morning and evening, as much of the slaked ground food as he will eat. In the midday feed him on kitchen scraps, the crumbs of the breakfast and dinner-tables, and if soaked in the beer-bottoms it is no injury to him, quite the reverse. Willow legs are admissible in Black Game. You can have "The Pigeon-Book" from our office, free by post for twenty stamps.

ROUP (J. C. M.).—Poultry have no disease called "croup." Cleanliness and good feeding prevent roup, which is what you mean. Bailly's pills, castor oil, camphor, and bread and ale, cure it in certain stages. It does not occasion great mortality, except when the fowls are debilitated from under-feeding or other causes. Among strong healthy fowls it is not infectious, nevertheless, some will always take it, being predisposed to it. It is not nearly as fatal as it was years ago.

INCUBATOR (E. M.).—We will shortly give a drawing or ample description of an incubator. We fancy your heat is not equally distributed.

SULTAN FOWLS (F. B.).—It may be that the crest of the Sultan cock was cut off before he began his voyage. Many people when sending known birds to connoisseurs divest them of every unnecessary feather, especially a crest or top-knot, as it is liable to get wet, and to incommode, if not injure, the fowl. Nothing will accelerate the growth, nor is it necessary. If, however, the feathers have been cut off, and the quills or stumps remain in the skin, they must be removed before others will grow. All birds will eat bread, our ordinary Guinea Fowls eat meal freely. On the continent they feed much with Indian corn and buckwheat. It is difficult to distinguish between the sexes, but the cock is supposed to have a larger horn and longer wattles than the hen. If by a greenish colour in the Spanish fowls you mean a green metallic lustre on the black plumage, it is not only correct but desirable. The plumage must be black. There is more latitude in Crève Cœurs. They should be quite black, but many of them have some coloured feathers. These last are not of necessity impure, but the mixture is not desirable.

WEIGHT OF COCHIN-CHINA COCKEREL.—BILLS OF BUENOS AYREAN DRUCKS (Yorkshire Exhibitor).—Eleven and a half pounds is a capital weight for a twenty-five-weeks-old Cochin cockerel; it is heavier than common. The bill of a Buenos Ayrean drake should be like a green yellow, washed with soot and water.

GOOSEBERRY TREES AND POULTRY (A. Z.).—We never heard that the trees are injurious to poultry, and do not think that they are.

FOWL-KILLING DOG (W. L.).—Give the owner a written notice that his dog does kill fowls; after which, if he allows his dog to be loose and unmuzzled off his own premises, he may be sued for any damage the dog may do to fowls, whether yours or belonging to any one else.

DISEASE IN PIGEONS.—Can any correspondent give me a receipt for the disease in Pigeons, which I believe is called "Going light?" The Pigeons become thin, lose their appetite, waste away, and die. A great many of my young ones have thus died this year at various ages, but no old ones have as yet been attacked. Generally there is no other appearance of illness, yet in a few it is accompanied with lameness in leg or wing. In a few there is a curdly appearance about the mouth, as in a feverish person, but it is not common; others have diarrhoea, some die soon, others linger for weeks. I have cured some with calomel and cod-liver oil, but many die, and I should be obliged if any one can tell me of a perfect cure.—B. P. BRENT.

JACOBS' EYES (An Old Gardener).—Baldhead Jacobins frequently throw young ones with dark or bull's eyes, which is a great blemish. All pearl eyes are dark at first, but they assume their right colour before the young birds are ready to pair.—B. P. BRENT.

ANATOMY OF BIRDS (Delta).—Dr. Carpenter's "Animal Physiology" will suit you. He gives a popular description of the structure of all the parts of birds, and abundance of illustrations.

DISTINGUISHING THE SEX IN CANARIES (F. W. B.).—The cock Canary is bolder-looking, stands more upright, and sings louder. Though hens sometimes sing their voice is less powerful, and their song shorter and more disconnected. You will find the English Finches particularised in the "Canary and British Finches," published at this office. You can have it post free for nineteen stamps. I do not know of any better book on foreign cage than Bechstein's.—E. P. BRENT.

WOODBURY STRAW HIVES (Fred. D. Mort).—We do not consider ventilation during winter necessary, or even beneficial, in the case of straw hives of any description.

COVER FOR EXPOSED HIVES (G. H. B.).—We use roofs and outside cases of this description. Both are made of half-inch wood well put

together and painted a light stone colour. The roof is moveable and fits loosely on the square case, which latter rests on the floor-board, and is retained in its place by the two-inch plinth fitting outside.

WEEKLY CALENDAR.

Day of Month	Day of Week.	NOVEMBER 21—27, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock atter Sun.		Day of Year.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 47.6; and its night temperature 34.1°. The greatest heat was 62°, on the 25th, 1863; and the lowest cold, 9°, on the 23rd, 1858. The greatest fall of rain was 0.88 inch.

A PLEA FOR TREES, SHRUBS, AND SOME OTHER PLANTS IN FLOWER GARDENS.

BEING desirous of assisting, however limited may be my power of doing so, in extending the taste for trees, shrubs, and other plants that are ornamental by their foliage, as tending to

remove the great defects of modern flower gardens, I beg to tender a few remarks quite as much to solicit as to furnish information.

One of the great defects of modern gardens is their uninteresting appearance in winter, spring, and early summer, and most cottage gardens are far more gay at those periods than places of greater pretensions; yet there is no deficiency of shrubs and other plants that are interesting and even pretty, to say nothing of the many recent and valuable introductions, several of which are of a character to afford gratification all the year, and some flower at an early period of the season. There is no lack of subjects that only need pressing into the service to put an end to the absurd system of having nothing of interest in the garden except in the height of summer. Another great evil is the generally monotonous character of gardens as at present arranged and planted. There is a monotony of form and outline, and a general sameness in all the details, affording nothing but a first impression. The plants employed are seen at a glance, and give an instant impression, and people seem pleased with them they know not why, and all we can learn from them is, that certain gardens are grand—grand beyond the powers of pen or pencil to pourtray. They comprehend many forms and many colours so well arranged as to be extremely pleasing; but, examined in detail, they will be found to be made up of the same forms and colours repeated. The forms are simply straight or curved lines little different from one another, and the colours are of the brightest and most dazzling description; these are wearisome to the eye; and what there is to learn is soon obtained in consequence of the small amount of variety that there exists in principle and material. There is an overpowering amount of colour, the gradations between warm, bright, and low tones are not accounted for; either the colours are too bright, lack warmth, or require toning down, and no one seems to be able to fix any laws by which the arrangement may be governed, or if any do promulgate a set of rules as has been done by Chevreul and others, they as often are beside as hit the mark. In short, our gardens lack variety and intricacy both as to form, material, and arrangement.

Flower gardens being rendered brilliant by employing flowering plants in masses, another striking defect presents

itself, and that is the want of repose or relief. The various shades of green constitute in nature the great relief to the colours of flowers. It is the blades of the Wheat that make red Poppies so telling, the green of the Barley that gives Charlock its peculiar richness in yellow, the green of the pasture that makes the Milfoil look so white; and the pink Centaury receives no small aid from the herbage around. In nature there is no such thing as positive colour, it is toned down by the foliage of the plant producing it, and it is not possible to find a more fitting contrast for any flower than its own foliage. The relief of masses of bright colour in lawns is found in the grass, and much more warmth of colour may be given there than can be done when the masses are in Box or gravel.

It is only now necessary to point out the essential difference that exists between geometrical and irregular flower gardens.

Geometrical gardens are regular and symmetrical, the paths are regularly curved or regularly straight, and the eye is only impressed by objects slightly varied; for, whether the lines are straight or curved, symmetry requires that the objects in one side or part should be repeated and correspond with those on the other. The result of this is, when all the principal parts are seen, which are never numerous, or if they are, mere repetitions, the spectator has seen everything that such gardens have to offer. They are usually planted either in varied masses of colours, separated from each other by unplanted intervals, which may be grass or paths of gravel, or they may be planted homogeneously when it is the intention to give an effect of individuality, the corresponding parts of which are identical. This style is the most simple, and affords on the most extensive scale scope for a few species of plants only, and is, as at present adopted, but a slight modification of the Dutch style, though the more polished gardens are after the French style. The extremely monotonous aspect of such gardens is the theme of universal comment, and their bareness in spring and early summer is the obstacle to their further extension. A slight variation of material pleases those who are fond of the gay and splendid, but to a lover of those plants which are possessed of charms other than forming carpets of bloom, gardens of this kind are of little interest, for there is nothing to study except what may be seen any day in a draper's shop-window. I do not wish to imply that I would seek to do away with the present mode of planting flowers in masses, nor lead any one to conclude that gardens in which that system is adopted are entirely devoid of interest; but I ask, Are they not deficient in interest for the greater part of the year, and monotonous at their best? and when the principal points of their composition are seen, what is there further to engage curiosity and keep awake the interest which is expected to be found in gardens? Simply nothing, the garden is a fixed unchangeable thing, and such it remains year after year, or is but slightly varied.

Now, to tone down the bright colours plants remarkable for their foliage have been introduced with good effect into such gardens, and particularly plants of which the leaves

are frosted, bronzy, or variegated with white or yellow, but with green entering largely into their composition. I may be told that blending these with other plants gives a tone which green foliage would not, and that by planting these flowers in proximity whose colours enhance each other we avoid, at least, the disagreeable effects produced by masses whose hues are mutually injurious; but plant as you will, the colours will never have so good an effect as when relieved by foliage distinct alike in form and colour—for example, a ribbon-border backed with evergreens, or beds placed in the intervals between beds of shrubs not in flower. The effect of beds should be such that the colours will be as agreeable to the eye of the spectator as music is to a musician whose ear is struck by a succession of harmonious tones. Verdure, in short, is the best and only relief to gaudy flowers, and green being a sober colour, intermediate between the deeper and brighter tints, consequently affords a foil to all. But then there are various tints of green in combination with yellow or white. Yellow accords well with blue, and with reds inclining to blue; white accords favourably with blue and orange; perfectly with red or rose, and is the only hue that possesses the advantage of heightening light tones of any colour, and separating those mutually injurious. Green, when deep, contrasts well with any colour, and it alone affords relief or repose. Enough, then, has been said to show that the want of repose arises from a deficient amount of green or verdure, and this I think must be apparent to all who take any interest in gardening.

It may be contended that there is sufficient green in the composition of geometrical gardens when the outlines are formed of Box. This is simply a mistake, as is exemplified by placing a primary colour in the centre of a bed edged with Box, and surrounding that colour with a band of white; the Box, it will be found, will produce but a feeble impression. The green of leaves not only serves as a ground without destroying the contrast, as might be supposed, of the flowers, but heightens their tone; but the green of Box, especially when the growths are young and of a yellow tint would irretrievably ruin the contrast of the colours were it not that green edgings produce a very feeble impression. Again, blue flowers as, for instance, *Lobelia speciosa*, accord badly with green, and are never pleasing next grass, but the reverse is the case when placed near a Box-edging; whilst a purple, as *Purple King Verbena*, accords well with grass, and so do blue flowers containing white, as *Lobelia Paxtoniana*. The green of Box then is no relief; it adds to rather than is destructive of monotony. Ornamental-foliaged plants, especially those with frosted or variegated leaves, afford slight repose, but are as frequently employed to heighten the tones of any colour, to separate discordant colours, and to give a regular gradation of tones, as with a design to afford rest for the mind. *Perilla*, *Orach*, *Amaranthus melancholicus*, and those plants of which the leaves are a mixture of red and green, act the part of neutrals and contribute to the same end as green, but in a less degree. Notwithstanding the assertion that neutrals should always be placed in the centre of groups, I may state my firm conviction that it is founded on no principle, for the most decided contrast that it is possible to form is that of *Perilla* next grass, separated from a centre of scarlet, rose, or pink, by a band of white. It does not then afford repose as it would if it were planted in the centre, and the gradations of tone in a downward order.

A word as to the colours of gravel or the paths by which the masses are separated. Grey associates well with green, blue, and orange; and where the colours accord badly, there is an advantage in separating them by white bands or edgings—for instance, blue next green. *Lobelia speciosa*, or even *Purple King Verbena*, next grass accords better separated by an edging or band of white *Cerastium tomentosum*. Black combining with sombre colours to produce harmony of analogy, and with light and brilliant colours to produce harmony of contrast, is preferable to white. Yellow-tinted gravels are even worse than white, for they do not harmonise nor contrast with green or verdure. Gravels of a russet hue contrast and harmonise well.

Since there is nothing to do away with the monotony of masses of flowers, and afford repose, or but to a very limited extent, we must look to something beyond flowering plants. Shall we turn to earths of various colours to give an interest to our gardens in winter and spring? Will they do away with the monotony, and afford repose? Or shall we revert to the barbarous system of cutting shrubs into the shapes of birds and beasts? Few will be found to admit any merits in these; but who will deny that beds of low spring-flowering shrubs, and specimens distributed singly, would be out of character in a

geometrical flower garden? Would they not at once give interest, and destroy the monotony, whilst combining with other, it may be principal or secondary, points to form a whole, the extent of which may be seen at one view, and at the same time afford repose? Certainly they would give variety, and add to the apparent extent. It is necessary that they should be evergreen, and all planted that there may be the same correlation which is required by flowers. The different hues of green must be judged as we judge of the harmony of the colours of flowers. The points that must guide us, are—height, form, variety, facility of development, distinctness of aspect, and harmony of arrangement, as well as of colour.

If the object in a garden is to produce brilliancy of colour and monotony, then my argument is useless, and the general practice of planting masses of flowers unrelieved, unvaried, or but slightly varied, admits of justification. On the other hand, if my conclusions are correct, then the generally monotonous effect of our gardens ought to be changed by introducing shrubs and plants that would form no impediment to the flowers attaining a high degree of perfection, but be rival objects of beauty, whilst heightening the effect of the whole.

To the shrubs most suitable for geometrical and irregular gardens, I shall advert in another communication.—G. ABBEY.  
(To be continued.)

### THE SWEET-SOP.

SOME years ago, while staying with a friend in Yorkshire, he received a large case of Orchids and other plants from Singapore, among which was a bundle of cuttings, all planted together in a large tin case, each cutting about 7 inches long, without name or any clue by which to recognise them. Some had rooted, it is true, and were just beginning to grow; but for the most part they were in a wretched condition, and looked very unhealthy. As I have always had a fancy for any new or unknown plants, and my friend evidently did not set much store by his "leafless plants," as he called them, I begged they might be given to me, and on my request being granted I took them home the next day, and carefully planted in separate pots as many as I thought had any chance of living, putting them into a new hotbed, and keeping them moist and shaded for a week or two. The few which remained I stuck into the bark-bed of the stove, where I had been working, pushing them into the tan behind a large Pine.

I took immense pains with my cuttings in the frame, tending them with the greatest care, with too much, in fact; for, do what I would, after they had rooted slightly and begun, as I hoped, to grow, all died off, one after another. I moved two or three into a drier atmosphere, but with no better result, and the upshot of the matter was I lost them all; much to my vexation.

Two months after this, having occasion to renew some of the bark in the stove, I was moving the Pines for that purpose, when lo! behind one of them was a plant which I recognised directly as one of the very cuttings I had stuck in there ten weeks before. Yes, there it was, sure enough, growing like a Willow, with shoots 6 or 7 inches long, and looking as healthy as ever I wish to see any plant, the sole survivor of my three-dozen ill-fated slips!

The next thing to be considered was what should I do with it? Move it I must; but with the fate of its companions still fresh in my memory I hesitated about taking it up. However, at last I got a large pot, drained it well, and filled it about half full of good rich garden soil, mixed with a little leaf-mould. I then carefully dug out the plant, putting it into the pot, tan and all, taking particular care not to injure or disturb the roots, and kept it close and warm for a few days until I saw that it was settled, giving very little water. Directly it began to grow I placed it in the hottest part of the stove, where it could have plenty of sun. It grew rapidly, filling the pot with roots in the course of the summer, and forming a nice bushy tree. I kept it dry all the winter, repotting it early in spring, when it started afresh, growing with great vigour, and in August it bore three large greenish flowers.

Up to this time I had not the faintest idea what my tree was; but one day, while I was showing my plants to a gentleman who had recently returned from India, he exclaimed, "Why, you have got a Sweet-Sop tree!" and so it was. My cutting had turned out to be the *Anona squamosa*, or, as it is commonly called abroad, the Sweet-Sop.

After this I had much trouble with it, as the fruit would neither grow nor ripen, dropping off soon after the flower;

and for more than two years, although I obtained plenty of blossom I did not get anything else. At last, however, I hit upon the plan of growing the trees (for by this time I had several), in smaller pots and poorer soil, and I then had the satisfaction of seeing the fruit grow and ripen.

When ripe the fruit becomes of a yellowish colour, and is covered over with large scales on a thick rind. It is about the size of a small Pine Apple, and when cut open is not unlike one in appearance, only instead of having a firm flesh, it is filled with a delicious pulp, tasting uncommonly like Strawberries, or Raspberries and cream, with the creamy taste predominating. Even in this country, when well ripened, the flavour is delightful, and I have little doubt but that in its own it is far better. The fragrance of the pulp, too, is remarkable, being like rosewater, or rather sweeter—more like the scent of an old-fashioned Cabbage Rose.

There are, I believe, several other species of *Anona*, cultivated for the sake of their fruit, particularly *A. cherimolia* and *A. muricata*. They are all natives of the tropical parts of Asia, Africa, and America; but, as I know little about them, I shall confine my remarks to the Sweet-Sop (*A. squamosa*). This tree, even in its own country, never grows above 7 or 8 feet high, and here it never exceeds the size of a bush. To grow it for fruit it should be planted in a 13-inch pot, and kept plunged up to the rim in a bark bed, as it will not thrive without plenty of bottom heat. The soil should be a good ordinary garden loam, not stiff, and by no means rich, as if the soil is too good the tree will flower but not fruit. Like the Mango, the Sweet-Sop delights in a very high temperature, with plenty of moisture when growing, and requires little air. Indeed, it is best grown with the Mango and Mangosteen, and treated in every respect as these trees are, excepting that the fruit requires thinning as soon as it is fairly set, leaving no more than ten or a dozen on each tree. When ripe it should be cut, although it will hang for some weeks by removing the trees into a rather cooler atmosphere. Like many other fruits, it is best when gathered fresh from the tree.

At dessert the Sweet-Sop should be divided into two or four parts lengthwise, never across, a very sharp knife being needed to sever the thick rind. This must, however, be done at table, and not before dinner, or the fine aroma will be lost. When first opened one fruit will perceptibly scent the whole room, and for this reason, when practicable, the Sweet-Sop should always be served along with the Durion, its delightful perfume completely overpowering the disagreeable scent of that fruit.

One point must be borne in mind, which is, that the flavour of the Sweet-Sop depends entirely upon the fruit being thoroughly ripened in all the sun possible. For this very reason the taste often varies, sometimes being all that could be wished, and at others quite tame and insipid, the least shade when ripening being quite fatal to flavour.

The Sweet-Sop grows very readily from either seeds or cuttings, but when raised from seed it is shy of flowering, and, therefore, in practice, the latter is the best mode of propagating it. Care must, however, be taken not to give the cuttings too much water, as they are exceedingly liable to damp off until well established. They will not bear fruit for two years.

The Sweet-Sop is rarely attacked by insects, and is not, I believe, subject to any disease; it is easily fruited if grown in a small pot, and kept constantly in a high temperature; and, when the exquisite flavour of the fruit and its delightful perfume are considered, I think I shall not be far out if I express the opinion that ere long this luscious fruit will be found in every tropical fruit stove.—J. H.

### BOILERS UNSET.

"PEOPLE have such a dread of pipes, and bricks and mortar." So writes your able correspondent "R. F.," at page 283. No one will ever dispute the assertion. I have gone through the ordeal of erecting new boilers with brickwork on three occasions. I can shudder at the remembrance of erecting the last. It was one that required the full exercise of the mason's ingenuity. It took him half his time to "scratch his head," and nearly as long to get his tools, &c., together. It was at last complete, and the account also. If I mistake not I was charged for about three hundred more bricks than were ever used; but that was nothing to the labour! Man, 5s. a-day; big boy, 3s. 6d.! All I could do was like unto that in which the mason "excelled"—viz., "scratch my head!" This I did very feelingly, having resolved to act differently if I ever "got

into a mess again." About eighteen months afterwards the boiler in question "gave up," and whilst scratching my head again, I thought I would do without brickwork. Now, if any of your readers should require a simple and efficient heating apparatus, one that can be put up or taken down quickly, and, above all, "no brickwork," let them get Bury & Pollard's boiler, Truss's patent piping, and half a dozen glazed drain tiles for a chimney. If these things are introduced to the gardener about "lunch time," the same may be in operation in time for "backing-up." This is possible, easily and pleasingly possible!—H.

### NEW ROSES.

Do our French friends want a motto for their catalogues? Let them by all means take "*Omne ignotum pro magifico*," for assuredly we must subscribe to it; and however false we may believe some, and however exaggerated others, of the statements to be, we cannot say they are not as they describe. I am now venturing into a *terra incognita*, or rather on a wide and extensive sea, or, if you will, a desert seemingly bright and fair—translucent waters, waving Palms, lovely flowers present themselves to my bewildered eyes. But alas! I have seen them before, and I have found out that it was only a mirage after all, that the tales were all too flattering, and that hopes disappointed and promises unfulfilled were all that I had to tell of. I know nothing of the Roses described in the following lists, and therefore all must be mere conjecture; still, much may be learned, I think, from the experience of the past. If a man tells me year after year that he will send me the very best, let me say, tea, and year after year I find that it is only sloe leaves, or some bad and inferior stuff, why, in the end I come to the conclusion that either he does not know what good tea is, or else—well, we will not say that hard word. If the tea were the produce of his own estate in Assam I should, perhaps, be charitable enough to hope that he saw in it perfection. I did not because it was his; and, indeed, this is a very ordinary way for people to act. They get into a strain of seed, the flowers are defective in some points, but they cannot see it; and so they go on and on, distanced by their competitors from the blind adherence to their own productions, although every one else sees the difference. Who does not know the frequenter of flower shows who has always finer Geraniums, larger Apples, and better Grapes than any there? He sees with his own eyes, and not with yours. One hardly blames a man for this partiality, although it may make us cautious in having to do with him. Let him think his geese swans, it does not harm us; but what I do dislike is the way in which some people will endeavour to make out that others' real swans are only geese. Show a country photographer one of Meunier's or Disden's cartes, and he will be sure to find out something wrong; and so there are some who, if a flower or fruit is not theirs or let out by them, see nothing in it. There is one French raiser to whom these remarks will apply—I mean Trouillard, M. Leroy's foreman at Angers. I verily believe he considers that his Roses year after year are good. They, provokingly, are only a little way off from being so—some, at least; but none will abide in our lists, Eugène Appert, perhaps, alone excepted. They want either a few more petals, or else shape. Marguerite Appert, Madame Standish, Reynolds Hole, Thérèse Appert, even André Leroy will not do for our English taste; and hence if any of Trouillard's Roses appear in our new lists one must feel a doubt about them. The same remark applies in a greater or less degree to others.

#### TOUVAIS.

17. *Comte Alphonse de Serenge*.—Very vigorous. Flowers very large, full; perfect form, and striking appearance; very sweet-scented, clear red, very lovely, slightly tinged with purple.

18. *Danica*.—Very vigorous. Flowers very large, full, of a beautiful rose-coloured cerise, transparent, and very brilliant.

19. *Mousseline*.—Very vigorous. Flower medium-sized, cupped, admirably formed, tender flesh rose; petals fine and transparent.

In 1864 this grower gave us Belle rose, Semiramis, Souvenir d'un Mère; in 1863, Centifolia rosea and Jean Touvais, but they have not been any great acquisitions. I have heard Centifolia rosea well spoken of, but have not seen it. Remembering M. Touvais' treatment of us in former years we have need to be cautious.

#### LIABAUD.

20. *Jean Cherpin*.—Vigorous. Flowers very large, full, red velvety purple; the centre clear fiery red.

21. *Marcella*.—Very vigorous. Flowers large, full, cupped, fine salmon rose, new colour.

22. *Purpurea*.—Vigorous. Dark foliage. Flowers large, full, reddish purple shaded.

Monsieur Boncenne of last year has been well spoken of, but I know nothing of it; and neither Arles Dufour nor Madame de Canrobert of 1863 have made for themselves a name or even a "local habitation;" and hence one is not over-sanguine as to these three Roses.

## DAMAIZIN.

23. *Abel Grand*.—Very vigorous, really Perpetual. Flowers large, full, beautiful silvery satiny rose.

24. *Frederic Biboret*.—Very vigorous. Flowers large, full, beautiful lively red, passing to cerise red bordered with lilac.

25. *Hippolyte Flandrin*.—Very vigorous. Flowers very large, full, well formed, fine lively rose, superb.

In looking through the lists of the last two years I do not see that any of this grower's flowers have been favourites. 25 sounds well, but so do they all.

## DUCHER.

26. *Abraham Lincoln*.—Very vigorous, having some similitude to Charles Boissière. Flowers very large, full, blackish purple.

27. *Gloire de Ducher*.—Very vigorous. Branches and foliage reddish, like Géant des Batailles. Flowers very large and full, having some analogy to Madame Masson, with the petals at the centre purple, those of the circumference slaty. Admirable.

28. *Louis Noisette*.—Vigorous, having some analogy to Baronne Prevost. Flowers full, globular, well formed, fine carmine rose, very beautiful.

Marie Perrachon, Rosa Mundi, and Vase de l'Élection were the production of this raiser in 1865, and Le Mont d'Or and Benoit Cornet in 1864. They are now unknown to our lists, and notwithstanding the glowing descriptions of this year, one must look with suspicion on them.

## OCER.

29. *Aurore Boréale*.—Very vigorous. Flowers large, full, globular, lively shining red.

30. *La Tendre*.—Very vigorous. Flowers large, full, cupped, fine rose Hortensia.

31. *Triptolème*.—Plant very vigorous. Flowers medium, full, globular, very lively scarlet red.

Who knows anything of Belle Normande, Général de Mian-dol, Marie Boissé, this raiser's productions in last year, and Charlemagne, George Simon, Madame Malherbe, Marquise de Briges, or Michel Ange of the year before, and applying this test, who is likely to see after the first year anything of those now advertised?

## GRANGER.

32. *Carl Coers*.—Vigorous. Seedling of Triomphe de l'Ex-position. Flowers large, full, shaded purple.

33. *Exposition de Brie*.—Plant vigorous. Flowers very large, full, well formed, lively shining red. This variety obtained the silver gilt medal at the Exhibition at Brie.

33 Sounds well, but we have only, as far as my memory serves me, some second-rate Roses of this grower's. If the Judges at Brie know good flowers then 33 ought to be a good one; but I have learned long since that their views and ours differ, and hence shall not be disappointed if even it fail to satisfy us. I may be, of course, wrong in applying the test that I have done, and a raiser who has never given us anything good may change his mind and give us good Roses; but we have had long experience and, I may add, many grievous disappointments, and hence are cautious. I hope to conclude the lists in my next.—D., Deal.

## VINEYARD UNDER GLASS.

The opinion that you have expressed of my Grapes is very encouraging. I have, probably, been too ambitious in attempting to cultivate such as the Muscat of Alexandria and West's St. Peter's. Next season, if favourable, will show whether the Trentham Black, Early Saumur, Sarbelle, Chavoush, Chasselas Musqué, Chasselas Violet, Chasselas Rose, and White Frontignan will ripen well without fire heat. The wood of these young Vines is thoroughly hard, and I have already pruned them.

Your correspondent "F. J. S." will find in Rivers's "Orchard-House" every information that he will require to build such a span-roofed house as my own. At first I followed Mr. Rivers's

directions implicitly; and the only alterations that have been subsequently made are, that the ventilating shutters have been lowered, so that they rest on the ground when open; that the space above them is now filled in with glass; and that I have strengthened the roof by binding the rafters together by two long, flat, and light bars of iron, one on each side, running the whole length of the house, and attached to the centre of each rafter.

My glass is 20 inches by 20. I think 20 by 16 would be preferable, as high winds will now and then snap the squares in two. The estimate given in Mr. Rivers's little book for the erection of a span-roofed house, 30 feet by 14, is £28. Mine cost me under £35. It would have been more had not I and my man Friday worked very zealously at it; the painting was entirely done by us.

Two years before the erection of the house the piece of ground on which it stands had been trenched 2½ feet deep; and when the Vines were planted some bone-dust and lime-rubbish were added. The subsoil being of very porous gravel, no drainage was necessary. The ventilators over the door and at the end of the house have been kept open night and day since the beginning of April last; and before next season I shall contrive to ventilate the middle of the house by framing one or two of the panes of glass next the ridge-board.—M. B., West Somerset.

## FLORAL DECORATIONS IN NEW YORK.

In the rapid development of the material resources of this country, Horticulture has not been neglected, but has rather led the van in the common march of improvement, and, as a natural consequence, refined the mind and elevated the tastes of all within its sphere of action. Even a casual spectator cannot pass through this city without being struck by the facilities afforded for the indulgence in the luxury of flowers, even by those of moderate means; for from the City Hall to Thirty-fifth Street, at every short distance along Broadway, may be found young boys and girls earning a good livelihood by selling to passers-by bunches of Violets, or bouquets, at from ten to twenty-five cents each. Sometimes an enterprising speculator may be met with a painful of beautiful white Water Lilies, in their season, for which he finds a ready sale; and should the means admit of a more expensive investment, a visit may be paid with much gratification to some of the tastefully-fitted-up florists' stores, where, at from sums varying from five dollars to 150, a bouquet or basket of flowers can be purchased, arranged with all the art and taste of a talented manipulator; and what with constant practice, extensive competition, and, I may add, liberal patronage, the florists of this city are in a fair way of adopting as their motto "Second to none," at least so far as the ornamental department is concerned.

Dining-room and parlour decorations have not been neglected, and here the natural taste of the ladies has directed the efforts of the florists, and produced many pleasing and telling tableaux. I well remember being present one morning at Kensington Gore, when Her Majesty paid an early visit to see all the gardeners busy at work arranging their various productions, one of the finest sights to be seen there; later in the day the late lamented Prince Consort opened the gardens, and showed himself a skilful horticulturist by planting a Wellingtonia, handling the spade as readily as if it had been His Royal Highness's daily occupation, and no dainty tool either, but a *bona fide* garden spade, and of which the owner (Mr. William Miller, now of Coombe Abbey) was so proud, that he declared it never should be used again, but be kept as a memento of the honour done his profession. Well, that same day prizes were offered publicly, for the first time, for dinner-table decorations, and I was much struck with the simple elegance of the successful stand, as compared with others arranged with more show but less taste; and here, sure enough, a lady showed her intuitive appreciation of what was at once natural and effective by carrying off the first honours. I have since then both seen and read a good deal of dinner-table "fixings," nor have the able staff of THE JOURNAL OF HORTICULTURE been behind in encouraging, by well-matured opinions, the taste for this refined luxury; but it is a very difficult matter to lay down rules, as is sometimes attempted, for this, when so much depends on individual taste, and the occasion for which that taste is exerted. The finest display in this line that has ever taken place in New York occurred last night, when that thorough specimen of an English gentleman, Sir S. Morton Peto, gave a farewell banquet to his

numerous friends and well-wishers on this side of the Atlantic at Delmonico's, Fifth Avenue Restaurant, and never have the capacities of that establishment been tested to such an extent as then. It is also generally conceded that there were the best and most tasteful of floral decorations that have ever been seen in this city, and as it may be interesting to the readers of THE JOURNAL OF HORTICULTURE, I will try and give some idea of the floral part of the entertainment.

There were five long tables running the whole length of the great banquetting-hall, and a raised dais at either end for the host of the evening and his principal guests. Behind Sir S. Morton Peto's seat were festooned the British and American flags, enclosing the British coat of arms, and at the lower end the same emblems of Liberty enclosed the American shield, and as the British lion growled out from underneath the folds of bunting, "*Dieu et mon droit*," the stary shield, with an eye to business, replied "*E pluribus unum*." Ornamental baskets and stands of flowers graced, but did not crowd the principal table, the elegant dinner service of which, I may state, was manufactured in honour of the Prince of Wales during his visit to this country, and was used at the reception dinner given him in this city. At proper intervals along the other tables were placed ornamental stands of flowers, with pendant baskets attached, all filled with the rarest flowers of the season, and each stand surmounted by a miniature Union Jack, and in the finger-glasses of each of the 400 guests was placed a small flat bouquet, fragrant with Heliotrope, Tuberoses, Jasmine, &c., backed with rose Geranium. The ornamental stands are made of cane, painted white and gilded, the tins for the flowers showing blue through the lattice work, and are much more effective and pleasing to the eye than glass stands.

Throughout the suite of rooms attached to the banquetting-hall were dispersed flowers in great profusion, every bracket and chandelier having a hanging basket attached to it filled with flowers, and dispersing the most delightful fragrance throughout the vast suite of rooms. But the great piece of the evening was a massive emblematical floral device of mosaic, at least 4 feet by 2½, placed on a table in the centre of the principal parlour, having the Union Jack and star-spangled banner plainly traced out with flowers, almost as distinctly as the painter's brush could do it, and with great fidelity in the harmony of colours. The staffs (transversed) were formed of yellow Immortelles, and the colours in the Union Jack were nicely brought out with red Carnations, white Eupatorium, and blue Ageratum. In the American flag the red and white stripes were formed alternately of Bouvardia and Sweet Alyssum, with single pips of Laurustinus for stars on a blue ground formed of Ageratum, the whole piece filled in with Camellias (white), Tuberoses, Safrano, Agrippina, and Hermosa Roses, Heliotrope, Carnations, Eupatorium, Neapolitan Violets, &c., edged with leaves of Cissus discolor, Dioscorea, Ferns, Lycopods, Tradescantia, &c., the whole forming a most appropriate international design, and, notwithstanding a lowering horizon, inwardly suggestive of harmony and peace, betwixt the two great Anglo-Saxon nations.

Mr. William Brower, one of the leading florists of this city, superintended the whole of the floral decorations, and the entire arrangement did much credit to his taste and judgment. Sir S. Morton Peto sails for England in the Scotia to-morrow, and carries with him the good wishes and goodwill of the American people, and were more men of his stamp to cross the Atlantic there would be much more cordial unity betwixt the two nations than has heretofore existed.—DAVID FOULIS, *New York, October 31st, 1865.*

#### RAINFALL IN OCTOBER, 1865.

In compliance with Mr. Robson's request, in No. 241, to know the amount of rainfall in October in different localities, I beg to inform you that rain fell here on twenty-eight days in that month, and the total amount was 6.14 inches, exactly 2 inches less than at Linton Park. The greatest amount in one day was 0.98 inch on the 22nd. In September there was only 0.19 inch; in August rain fell on sixteen days, and the amount was 3.47 inches.—CHARLES ROSS, *Gardener, Welford Park, near Newbury, Berks.*

SEPTEMBER was a very hot and dry month, rain fell on one day only, the 21st, to the amount of eighteen hundredths of an inch. The grass was much burnt in places, but vegetation would have received a much greater check had it not been for the remarkably heavy dews which we experienced here through-

out the month. On three mornings there was upwards of one hundredth of an inch of dew.

October commenced with much the same kind of weather up to the 8th, and from then till the 31st rain fell on thirteen days. The greatest amount that fell on any one day was 1.15 inch on the 9th. From the 8th to the 12th, 2.27 inches fell; on the 17th, another half inch fell; and from then to the 31st ninety-four hundredths more, making a total of 3.71 inches for the month, being less than half the quantity which fell at Linton Park.

I have not any record of so great a rainfall as that which Mr. Robson records, the nearest approach to it that I have is November last year, when I registered 7.13 inches, and that was registered within thirty miles of Linton Park.—A. READ, *Newark-on-Trent, Notts.*

#### MESSRS. PATERSON AND THEIR POTATOES.

On the 10th inst. Messrs. Wm. Paterson & Son were entertained at a public dinner in the Royal Hotel, Dundee, and presented with a very handsome silver épergne and claret jug, in recognition of the improvements they have effected in the Potato plant. The following inscription is to be engraved on the épergne:

"At a public dinner given to Messrs. Wm. & Geo. Paterson, this Épergne, along with a Claret Jug, was presented to

MR. WM. PATERSON.

(To descend to Mr. Geo. Paterson should he survive his father), in the name of the subscribers—landed proprietors, farmers, Potato merchants, and other friends—as a mark of their respect for him, and also of their admiration of his successful exertions during the past forty years to improve and renew the Potato plant.

Dundee, 10th Nov., 1865."

Upwards of one hundred gentlemen sat down to dinner, which was tastefully and liberally furnished by "mine host" of the Royal. A leading and most pleasant feature of the dinner was the presence of the giant Potatoes, "The Victorias, the Reds, and the Blues," boiled in their jackets, which were much too small for them.

After the usual premier toasts and some preliminary observations, the CHAIRMAN, Bailie Yeaman, said—Gentlemen, the subject of the toast which I am about to propose is one of the most important that the people of any town or any county could be called upon to respond to. The meeting has been brought together in the most spontaneous manner possible, and I believe on account of a thorough appreciation of the great services that the Messrs. Paterson, our esteemed friends, have rendered to the country, and I hope to the world at large. (Great cheering.) There are none that will challenge the great importance of the Potato in this country, in most of all points of view. We recollect that in the year '46, when the severe Potato blight first attacked this country, in the great calamity which befel the country generally at that time, but particularly the inhabitants of the sister isle, the plant was almost swept away. We are aware that no crop is of greater value to the agriculturist than a good crop of Potatoes, and we are all aware that no acre of cereals or any other produce, yields a larger amount of food than an acre of Potatoes. So you must calculate the great amount of good that this esculent does to the country; and while Mr. Paterson has been going on benefitting the country, I am sure it has not been for his own advantage. (Hear, hear.) I do not say it has been for the pecuniary profit of Mr. Paterson, but I am sure every gentleman here will be delighted to hear if Mr. Paterson's enterprise will at one time turn out to his advantage. (Loud cheers.) It has been said that the man who can make two blades of grass grow where only one has grown before is a benefactor to his country. But Mr. Paterson has done more than this, he has restored the Potato from its dead rot, from being almost extirpated from the country, to its present healthy state, and I say he has been a great benefactor. (Applause.) Gentlemen, he is not only entitled to the thanks of those here, or of this community, or of this country, but to the thanks of the British Government, and I have no doubt if this matter were brought before them, it would be taken notice of, and he would be rewarded in some way or other. (Renewed applause.) I believe, gentlemen, Lord Dalhousie has taken a very great deal of interest in this matter since he heard of what Mr. Paterson had done. And I would refer also to the great number of letters—complimentary and approving letters—to Mr. Paterson, who has received them from hundreds of persons of all stations in Scotland, England, Ireland, over the Continent of Europe, Australia, and New South Wales. You are all aware, gentlemen, of the prizes he has taken at the Dublin Agricultural Exhibition, International Exhibition, and the Horticultural Shows of Dundee. I do not see it necessary for me, in the presence of Mr. Paterson, on this auspicious occasion, to say more in regard to the benefits which he has conferred on the country, and with which, the great majority of you being agriculturists, you are better acquainted than I am, and I am sure you all appreciate these services. The next duty which devolves upon me before I propose the toast, is to present this very handsome épergne, which I now uncover—(loud cheers)—and also this solid

silver claret jug. I am sure that Mr. Paterson will duly appreciate these handsome presents, and will be proud of them, not only for their value, but as being an expression of the feelings of the gentlemen who presented them to him, and they will go down to his posterity as heirlooms.

Mr. PATERSON said he was almost unable to find words to reply to the toast which had just been proposed, and the substantial present which had been given to him. When a boy he began to experiment on the Potato plant, but he never thought the time would come that his experiment would arrive at such a result. He was then in his father's service, and for eight years he was his father's manager. As they knew, he was a market gardener, and thus he had ample opportunity for conducting his experiments. The Potato, like all other plants and animals, was subject to diseases, and required careful attention and renewal. (Hear, hear.) The method of procedure he adopted was to select the finest and healthiest kinds, and cultivate them. (Applause.) He begged to thank them for the honour they had done him, and he hoped their valuable present would continue in his family so long as they bore the name of Paterson.

Mr. GEORGE PATERSON also replied. He was sure all present who knew him would believe that he highly appreciated the honour which had been done him; and he could assure them, if it was the will of Providence that this valuable present should fall into his hands, he would value it as one of the most cherished articles in his possession. As he was not much accustomed to speaking, his father had drawn up a paper narrating the progress and result of his experiments, which he would read to them. He then read as follows: "From early life I have taken a deep interest in the Potato plant. My father being an extensive cultivator of fruit and vegetables in this quarter, it gave me a favourable opportunity of observing the cultivation of the Potato, from the delicate garden variety to the strongest kinds under culture in this country. My notice was first attracted by some of the earlier sorts weakening in constitution, and in the course of a few years becoming almost extinct or worthless as a useful and paying crop. I next turned my attention to the more robust field varieties then grown, and with the like result. I then formed an opinion (from which I have never had cause to depart), that the Potato plant was only designed to serve its generation, the same as in animal life, and that without a constant and successive renewal from the seed or apple it was quite probable this most valuable esculent might be lost to mankind altogether. About forty years ago a disease termed curl attacked the plant, causing it to become quite stunted both in haulm and tuber, and ever since then the plant has been liable to visitations of disease in one shape or other—such as soft rot in the ground, decay after storing, and some seasons it was not only difficult but almost impossible to find a regular braid, while whole fields were a total blank through this cause. Every preventive and restorative I could conceive I tried in order to regenerate the plant, but with little satisfaction. In 1846 we had the first visitation of the fatal blight, which nearly destroyed the whole crop of this country, and which has since then annually manifested itself all over to a greater or less extent. In 1847, in conjunction with Professor Johnston (who was commissioned by our Government to inquire into the cause of the epidemic, and if possible find an antidote), and other scientific gentlemen, we made various and extensive experiments in order to attain the end in view. As to the cause, many conjectures were put forth, but as to the remedy that never was arrived at. My own conviction regarding the Potato blight is that there is no direct cure for it, but that it is entirely an atmospheric action in the plant, it having the seeds of disease within itself, and that it will be always more or less subject to it. Before arriving at this conviction, I planted year after year all the varieties I could obtain from the coldest and warmest countries, used all the manures I could think of, tried by different processes of planting and lifting, by preparing the ground and seed, to arrive at some satisfactory result. During the growing season, I have microscopically examined the growth of the plant in all its stages, and I have remained in the field in July (the growing season), when the blight would overtake the plant with virulence, during sultry weather, and seen the moisture evaporate from the haulm, and the disease became stayed, and no recurrence of it took place until the like weather returned. From that time I determined on carrying out my original idea of raising and improving seedling varieties. The York Regent was the first Potato that answered in this quarter after the blight, in preference to varieties from Archangel and other cold climates; then followed the White Rock. This variety took my especial attention. With its strong robust constitution and vigorous habit, it proved the ablest variety to resist the disease of any then grown, but from its rough appearance and its then inferiority in quality, farmers would not take to it for years. Now it has become one of the most useful varieties grown, and of excellent quality. In 1854 I obtained from almost every country where the Potato is found a collection of the best sorts, and planted them side by side in the open field, in order to get as complete and fresh a variety as possible. The experiment was successful. Through the agency of insects and otherwise there was a thorough mixture, and from the seed or apple then produced sprung these improved varieties which I have now given out to the public. Through the medium of the newspaper press and otherwise, public attention has been very widely directed to my experiments, and orders for seed have been received from many parts of the world. We have sent considerable quantities of it to Australia, New Zealand, India, Germany, France, Russia,

Denmark, Sweden, &c." Mr. George Paterson then continued—I would like to mention to you an incident illustrative of the necessity of particular attention and care being given to the cultivation of the Potato. Five years ago my firm selected from among our seedlings a quantity of a blue variety, which yielded largely, and promised well. One fanit, however, they had, and this was, that while they were blue without, they were also bluish within. On this account we almost gave up the idea of cultivating them longer. We resolved to give them a last chance; and by mere accident in cutting them down for seed, I observed that some of them were quite white in the inside, though outwardly they appeared similar to the others. It struck me at once that here I had discovered a distinct variety of the blue Potato—a Potato which would become very valuable, I determined to experiment on it. I got out of the heap, after careful examination, a basketful of these Potatoes. We planted them; and at the end of the season we found that they turned out a large crop, and first-rate in quality. These, gentlemen, are now Paterson's Blues—(applause)—and I think they are destined to take a lead in the Potato field; and now we have at least 100 tons of them. The other Blues from which they were taken were at last rejected as faulty, as were many other varieties which we raised. Well, gentlemen, this accidental discovery of this fine blue variety shows that there exists great necessity for careful observation in the cultivation. How many good kinds have been lost to us from the want of care and attention. Many who have devoted much time and labour to the subject have given it up at last as vain. There is in the vegetable, as well as in the animal kingdom, a predominance of the inferior over the superior; and no wonder that, in trying to raise the breed, one retires from the task in despair. But after all, in my opinion, the task is not hopeless. Here I am led to make a remark. To me it seems that this matter of the cultivation of the Potato is one which might properly enough command the notice of a paternal Government. We all know the value of the Potato to the farmer for feeding his cattle; we all know its value to mankind; and we know the awful calamity which befel the country in 1846, when in one night the plant, through the length and breadth of the land, was struck with the fatal blight. Who knows how soon the scourge may come upon us again? Considering this, would it not be desirable that the Government should take up the matter and appoint parties of experience to adopt means to preserve the Potato from degenerating, and thus becoming more liable to disease? Even this season the blight in some districts has been severe, and the sooner steps are taken to avert it the better. It is a public duty to obtain and keep up the best and healthiest varieties from whatever source they can be got. The disease cannot, in my opinion, be prevented; but surely it is possible to mitigate it. (Hear, hear.) He concluded by saying that no manure was absolutely necessary for the cultivation of the Potato, but he advocated the use of a little light manure. Guano was the best, and soluble guano had been found by them in many cases to do as well as Peruvian guano.

Mr. LANGLANDS, in proposing "Success to Paterson's Seedlings," said he was one of the first who understood and appreciated Mr. Paterson's endeavours to improve the Potato plant. For a long time Paterson and his Potatoes were a standing joke among the farmers. I thought the thing a joke, I frankly acknowledge; but Mr. Paterson persevered. Wherever there was a piece of bad land there Paterson set down his Potatoes. There was one field in particular, in my immediate neighbourhood, which I noticed every time I went to Dundee. I saw there was an appearance of Potatoes growing and that was all, and I thought that little could come out of that field. At the end of the season no one seemed to be coming to lift them, and I imagined that it had been considered they were not worth looking after. But, one evening when I was returning home, I saw dimly through the mist several figures in the field, and they seemed to be digging. On coming up I noticed my friend Mr. Paterson amid a corps of Irish labourers, and I said to him, "Hilloa, what are you doing there? You can get nothing in that field." He replied, "What do you say, man? Just come and see this!" Well, I thought I would just stop, and on going into the field I saw him thrust his hand into several shaws and bring out Potatoes which, for size and promising appearance, certainly astonished me. The crop was abundant, and from that day to this I have been satisfied that Paterson's seedlings are no joke; and though many a farmer was, like myself, sceptical about them, I think every one has become a convert like myself. Having, as I said, been converted, I have been growing Paterson's Seedlings ever since, and I refrain from telling you the yield of some of my crops for fear that you would not believe me.—(Dundee Courier.)

## REPORT ON THE BRISBANE (QUEENSLAND) BOTANIC GARDEN.

THE following is an extract from the Report made to the local Legislative Assembly, by Mr. Walter Kell, the Colonial Botanist, and Director of the garden. It is dated, Brisbane, 5th August, 1865.

"Some tropical and semi-tropical trees and shrubs which have previously borne fruit in these gardens, produce a more abundant crop as they increase in size and age. Of these the Sweet-Sop (*Anona squamosa*), the Cherimoyer (*Anona cherimolia*), and *Anona muricata*, are, perhaps, the most desirable for cultivation. The useful Jaco Tree

(*Artocarpus integrifolia*) of the East Indies, had also produced a large quantity of fruit. The Cassava (*Jatropha manihot*), the tubers of which furnish a food much valued in the West Indies, &c., has succeeded well. The variety in the garden is that known as the sweet or blue Cassava, and is considered the best.

"Amongst recent introductions of useful plants, I have to mention the receipt of a large number of plants of the Cork Tree (*Quercus suber*), through the kindness of Mr. George Maclay. The whole of these have already been distributed to persons residing in different parts of the colony, and from whom the plants will no doubt receive the care and attention which they so well deserve. Also, the Java Almond (*Cunarium commune*), and the beautiful Indian *Mesna ferrea*, which will be well adapted for ornamental purposes. The Maltese Clover, or French Honeysuckle (*Hedysarum coronarium*), has not realised the expectations I had formed of its value as fodder. It does not flourish well in summer, and many persons whom I have supplied with seeds have attempted its cultivation without success.

"In my late journey to the north, I was enabled to collect many useful and interesting indigenous plants, which will prove valuable for cultivation in the gardens, but especially so for purposes of exchange. Of these, a Scitamineous plant may be regarded as particularly interesting, its fruit supplying the aborigines of the north with a food as highly prized by them as the *Bunya Bunya* by the natives of the southern districts. This plant was seen by Carron, in Kennedy's unfortunate expedition, and described by him as a singular Pine-Apple-looking plant. It is, I believe, new to science, and the great value of its fruit as an article of food has been hitherto unknown. I had also an opportunity of collecting seeds of a species of *Eugenia*, known to the settlers as the 'Cherry tree,' which produces a delicious fruit; of a new and very handsome *Cycadaceous* plant, as well as of *Cycas media*, the native *Banana* (*Musa Jackii*), and also the *Nelumbium Leichhardtii*, all of which furnish the natives with edible fruit. I also collected many fine Fern plants, some of which are new to the Australian flora. Many other valuable plants might have been procured, had the due discharge of my other important duties allowed sufficient time and opportunity to become acquainted with the rich and extremely varied flora of Rockingham Bay."

## THE UNITED HORTICULTURAL SOCIETY'S FLOWER AND FRUIT SHOW.

NOVEMBER 14TH AND 15TH.

THIS was held on Tuesday and Wednesday last in the Guildhall of the City of London, the scene of many a civic banquet; but on this occasion it was on a banquet for the eye, and not for the palate, that those grim giants, Gog and Magog, and armour-clad knights looked down. Unfortunately, from the murky state of the atmosphere, the recently completed noble gothic roof of the hall was invisible throughout the fore part of the day, and the hall itself presented a gloomy appearance; but in the afternoon, when lighted up, the general effect of the exhibition was very good. Fourteen fine specimens of *Dicksonia antarctica*, from 5 to 7 feet high, which stood sentry along the sides of the hall, and which were sent by Messrs. Low & Co., of Clapton, were, perhaps, the most striking feature of the Show, and in the intervening spaces along the sides were grouped specimen *Chrysanthemums*, *Heaths*, and fine-foliaged plants, whilst at the east end were various *Rhopals*, *Yuccas*, *Draecenas*, and other fine-foliaged plants, contributed by Mr. Williams, of Holloway, with large groups of *Chrysanthemums* from J. Crute, Esq., of Holloway, and J. Delvalle, Esq., of Stoke Newington. These, though well arranged, had rather a flat appearance, and would have been better of the introduction of some taller-growing plants, elevated among them, so as to be more in proportion to the height of the hall. In the central area were five tables, on which were arranged the cut blooms, fruit, and some pet plants. Considering that there was no inducement offered in the shape of money prizes, the Show on the whole was a good one; and though plants were not very extensively represented, any deficiency in this respect was made up by the abundance and excellence of the fruit.

**CHRYSANTHEMUMS.**—Of large-flowering kinds Mr. Forsyth, of Stoke Newington, had a very good group of six, consisting of Annie Salter, in fine bloom, Golden Christine, Vesta, Lady Harding, Christine, and General Bainbridge. A group of three, consisting of the two last named and Annie Salter, full of bloom, as well as groups of very well-grown large-flowering plants and Pompons, with some excellent standards of both, were also shown by Mr. Forsyth. In one of these groups the variegated Orange was introduced with good effect. Mr. George, gardener to Miss Nicholson, Stamford Hill, also exhibited six large-flowering *Chrysanthemums*, consisting of Jewess, very full of bloom, Alma, Beauté du Nord, Her Majesty, Vesta, and Annie Salter. In the class for three, Little Harry, from the same exhibitor, was beautifully studded with a profusion of its rich amber-coloured blooms, and Christine was also good. Mr. Rowe contributed finely-bloomed plants of Annie Salter, Christine, and Beauté du Nord; also an excellent group. Among Pompons were well-bloomed plants of Bob, Cedo Nulli, Lilac Cedo Nulli, and General Camrobert, from Mr. Forsyth and others.

Cut blooms were shown in considerable numbers, and though not generally so large and fine as in former years, in good perfection. The only exhibitor of 36 was Mr. Forsyth, whose stand contained good ex-

amples of *Plutus*, Anaxo, Princess of Wales, General Slade, Venus, Prince Alfred, Dr. Brock, Cherub, Golden Ball, General Bainbridge, and others. In 24's Mr. James, Rochester Castle, Stoke Newington, had a fine stand, in which we noticed Princess of Wales, Prince Alfred, Prince of Wales, Queen of England, Empress of India, large and fine, Beverley, White Globe, Rifleman, General Slade, Dr. Brock, Aimée Ferrière, Rev. J. Dix, King of Denmark, *Plutus*, and Oliver Cromwell. In 24's Mr. Morgan, Plymouth, had very fine blooms of Duchess of Wellington, Venus, Robert James, Oliver Cromwell, Beverley, Rev. J. Dix, Prince Alfred, Prince of Wales, Princess of Wales, very slightly tinged with that beautiful rosy lilac which makes the variety so attractive, General Slade, Nil Desperandum, and Cherub. Mr. Howe, Shacklewell; Mr. Rowe, Mr. James, and others also exhibited good stands. In the class for six blooms, those from Mr. Morgan, Plymouth, were remarkably fine; they consisted of General Slade and Rev. J. Dix, very large and perfect, Princess of Wales, large and fine, Prince Alfred, Prince of Wales, and Venus. Very good stands were shown by Mr. Wheldal, who was second, Mr. Delvalle, third, and Mr. Howe. For six blooms of varieties sent out in 1861 Mr. James was first, with Empress of India, Prince Alfred, Princess of Wales, Robert James, General Slade, and Rev. J. Dix. For six varieties sent out in 1865 Mr. James was first, with Mr. Bruneles, Sam Weller, Venus, Prince of Wales, Mrs. Kaines, and Lady Carey; Mr. Forsyth second, with King of Denmark, Golden Ball, Golden Dr. Brock, Venus, Sam Weller, and another. All the above have already been described in our columns.

Of the large Anemone-flowered varieties, those principally shown were Gluck, Margaret of Norway, Louis Bonamy, Queen Margaret, and Lady Margaret, from Mr. George, who was first for six; and George Hook, white; Madame Godereau, sulphur; Prince of Anemones, noticed last week, Gluck, and Miss Margaret, from Mr. Forsyth; and Mr. Howe was second with several of the above kinds and St. Margaret, Mr. Forsyth taking a similar position for *Chrysanthemums* of 1864, in which class his Anemones were shown. For 12 blooms Mr. James was first. Pompon Anemones, shown by Messrs. James, George, Rowe, and Cox, comprised good blooms of Miss Nightingale, Firefly, a fine showy scarlet, Mr. Astie and Antouis, yellow, &c.

FRUIT was chiefly confined to that of out-door growth, though a few Grapes and Pines were also shown. Among the last was a noble Smooth-leaved Cayenne, weighing 10 lbs., from Mr. Page, gardener to W. Leaf, Esq., handsome in shape, and in every respect highly creditable to its producer. A large Providence was also shown by Mr. Sparrow, gardener to Lord Ebury, Moorpark, Hertfordshire; a good Queen by Mr. Howard, gardener to J. Brande, Esq., Balham; and the fruit of Charlotte Rothschild, noticed last week, by Mr. Challis, gardener to Lady Herbert, of Lea. Three Pines were also exhibited by Mr. Young, Leigh Park. From Messrs. Lane & Son, Great Berkhamstead, came handsome bunches of Barbarossa, about 6 lbs. in weight; Buckland Sweetwater, in excellent condition, having hung since August, Chavoush, Foster's White Seedling, Esperiene, Black Hamburg, and Black Prince. Trebbiano was also shown by Mr. Tillery, gardener to the Duke of Portland, Welbeck.

Apples and Pears were numerous, and among them were many fine specimens. Of the former a very extensive and excellent collection came from Mr. Newton, gardener to J. G. Graham, Esq., East Lodge, Enfield Chase. Mr. Baker, gardener to A. Bassett, Esq., Stamford Hill; Mr. Rhodes, Mr. Kirtland, Stoke Newington; Mr. Grove, Mile End; Mr. Mortimore; Mr. Parsons, Acton Green, and Mr. McIndoe, were the chief of the other exhibitors. It was a matter of no little difficulty, in several instances, to say from whom particular dishes and even entire collections came, and we can therefore only enumerate a few of the varieties that were best represented. These were—Blenheim Pippin, very large and fine; Fearn's Pippin, finely coloured; Cox's Orange Pippin, Court-Pendu-Plat, Adams's Pearmain, King of the Pippins, Golden Reinette, and Beachamwell; and among kitchen Apples—Alfriston, Blenheim Pippin, Hunwell Souring, Beauty of Kent, Dumelow's Seedling; Reinette du Canada, Dutch Mignonne, and Holland Pippin, from Mr. Newton, very large and fine; Alexander Beauty of Kent, and Gloria Mundi, Alfriston, Alexander, and Dumelow's Seedling, from Mr. Baker, were also fine; and many of the above kinds, and some others, were highly deserving of notice in several collections.

Pears consisted of Forelle, beautifully coloured; Josephine de Malines, Prince Albert, Passe Colmar, and Beurré Diel, fine, and Easter Beurré, from Mr. Keeler, Woodhouse, Dulwich; the two last named, Winter Nelis, Bacon's Incomparable, and Glon Moreau, from Mr. Newton, were also very good; Forelle, from Mr. Groves, and one or two others, was beautifully coloured; and Mr. Turner, gardener to J. Hill, Esq., Streatham; Mr. Richell, Epsom; Mr. Williams, Bentworth Hall, Alton, and others, had fine examples of Chaumontel, Easter Beurré, Knight's Monarch, Bergamotte d'Espere, Glon Moreau, Beurré Clairgeau, Ne Plus Meuris, &c., whilst Mr. Mortimore, gardener to A. Smce, Esq., Carshalton, contributed Beurré d'Amaulis, Beurre Superfin, Beurre Prevost, Dr. Troussan, Josephine de Malines, and Peach, a showy kind.

Of kitchen Pears there were five specimens of Catillae, also Verulum, which is very brilliant in colour when cooked, shown by Mr. Keeler; and the first-named, likewise very fine, came from Mr. Rhodes and Mr. Groves.

In addition to the above, Mr. Turner, of Slough, also contributed

a large collection of Apples and Pears, Coe's Golden Drop Plums, a Capsicum in a pot, bearing pods 6 or 7 inches long by 3 or more across at the widest, and a cluster of Pears, consisting of at least forty fruit. Mr. Williams, Bentworth Hall, sent well-grown Shaddocks, Limes, and Oranges, and some very fine Medlars came from Mr. Hull, gardener to J. Scott, Esq., Blackheath Park, and the same fruit was also shown of good size by some others. There was also a dish or two of Quinces.

MISCELLANEOUS.—Messrs. E. G. Henderson and Son contributed *Anthurium leuconeurum*, *Spharogyne latifolia*, *Cyperus papyrus*, the Sugar Cane, and various other plants with ornamental foliage. Mr. Prestoe, Victoria Park; Mr. Wheeler, gardener to J. Philpott, Esq.; Mr. Rhodes, and Mr. Wilson, gardener to W. Marshall, Esq., Enfield, sent various flowering and ornamental-foliaged plants; and from the last-named came also cut Orchids, including *Cattleya labiata*, *Cypripediums Stonei*, *concolor*, and *Fairriacannum*, and *Odontoglossum radiatum*, one of Messrs. Low's recent introductions. Messrs. Low exhibited *Calanthes*, *Laelia præstans*, small plants of the brilliant *Sophronis grandiflora*, &c.; and Mr. Bull the economic plants shown at Kensington, and his new *Aucubas*, some of them in fruit. Mrs. Pollock and other variegated-leaved *Geraniums* were shown by one or two exhibitors; *Ivies*, and 63 dishes of different kinds of Potatoes, by Mr. Shirley Hilberd; and a collection of Gourds, both ornamental and edible, amounting, it was stated, to 1000 in number, by Mr. Young, gardener to R. Barclay, Esq., among which were very large specimens of the *Potiron janne*. From Messrs. Sutton & Sons, of Reading, came another large collection of Gourds, also one of Grapes; from Messrs. Catbush, Highgate, Nuneham Park Onion, noticed at page 212; and from Messrs. Barr & Sadgen, and Carter & Co. ornamental plant and Fern cases, in some of which, from Messrs. Carter, marble was used with good effect for the bottom. Several beautiful bouquets were exhibited by Mr. Howard, gardener to J. Brande, Esq. Tobacco tissue, or Tobacco rolled into a thin sheet for fumigating-purposes, was shown by Messrs. Roberts and Sons, of Clerkenwell, and will, doubtless, prove equally convenient with Tobacco paper, and more effective. Lastly, one of Wells's portable ground vineries was shown, together with thirty-one very good bunches of Black Hamburgh, the produce, less five, of the Vine planted therein.

### ENTOMOLOGICAL SOCIETY'S MEETING.

THE November Meeting of the Society was held on the 6th inst.; the President in the chair. The deaths of General Sir J. B. Hearsey (a gentleman who in the midst of arduous military duties had yet found leisure to extend our knowledge of Indian entomology and botany), and Mr. Benchard, who had gone to South America on an entomological excursion, were announced by the President.

Professor Westwood exhibited on behalf of Mr. S. Stone, a specimen of the Death's-head Moth, in which no rudiment of the right antenna existed. The pupa-case was also shown, in which, however, an antenna-case on that side of the body was present in a rudimentary state.

Mr. MacLachlan exhibited six bred specimens of *Stertha sacaria*, a rare Geometrideous Moth, all of which agreed in being much darker than the usual state of the species; they had been reared by Mr. Helling, on *Polygonum aviculare*; also, a female specimen of the Dragon Fly, *Calepteryx splendens*, the left fore-wing of which was coloured with steel blue as in the male; whilst in the right fore-wing only a few small patches of the same colour were scattered over the surface.

Mr. Ianson exhibited *Myrmedonia plicata*, a new British Beetle, found in the nest of *Tapinoma eratica*, a species of Ant, at Bourne-mouth, in August last, by Mr. Smith.

Mr. Crotch exhibited three species of Beetles new to this country, *Ægialea rufa*, *Lithocharis maritima*, and *Monotama 4-foveolata*; and Mr. Stevens a collection of insects of the various orders found in Damara Land, South Africa, by Mr. Anderson.

Mr. F. Bond exhibited a new British Moth, *Acidalia mancinata*, from the collection of Dr. Knaggs; also, a series of highly magnified photographic representations of minute parasitic insects, executed by Dr. Maddox.

Mr. Hewison sent some leaves of Oak densely covered with the gall, commonly called Oak spangles; also, some notes on the Indian variety of *Chrysophanus phleas*, resembling a variety of *Chrysophanus virginiae*, from Zermatt, published in the last part of the "Annals" of the French Entomological Society; also, descriptions of a number of new exotic species of Butterflies, belonging to the family Hesperidae.

Mr. Baly read descriptions of twelve new exotic species of plant Beetles, of the family Galeceidae.

A paper was read by Captain J. Mitchell, Superintendent of the Madras Museum, on the structure of the filament of silk as spun by the common silk caterpillar, which has often been asserted (by Rymer Jones, Dr. Carpenter, &c.), to be composed of a double-twisted thread, but which he had found to consist of two threads laid side by side longitudinally, and fastened together by gum.

A note by Dr. Jordan was read on the acclimatisation of the common Pontia Rape, in North America, during the last two or three years; it being now found plentifully for one hundred miles on each side of the river St. Lawrence, and where there are as many as three broods in a year, not more than eighteen days occurring between the

deposition of the egg and the arrival of the insect at the perfect state in the middle of summer.

Some notes were also read by the Rev. Douglas Timmins, on the advantages of collecting the Lepidoptera of Europe, instead of restricting collections to British species; also, a paper by Mr. David Sharp, on the British species of the Coleopterous genus *Agathidium*.

### GLEANINGS FROM ROCK AND FIELD TOWARDS ROME.—No. 8.

I FEEL that it is time I quitted Rome, and yet I linger on; what I have said seems so little and poor, what I have left unsaid so rich and great. Churches, monasteries, palaces, unnoticed by me, rise in numberless pictures to my mind's eye, in which the past and present are mingled together, and they seem to take voice and ask, Why are we forgotten? Now I am in the Forum Romanum listening to the thrilling eloquence of Cicero; or with wonder, open-mouthed, am watching Cæsar's first and greatest triumph, when, followed by a countless host of soldiers, people, and captives—of whom, perchance, a few poor Britons formed a part—he ascended the steps of the Capitol on his knees, between forty elephants bearing lights, while the common people were feasting at 22,000 tables placed in the streets. And now I am standing beneath the huge statue of Pompey, once red with the life blood of this same Cæsar; the voices that once proclaimed him a demi-god now raised in hoarse cries of "Perish the traitor to liberty!" Or it is evening, and I am ascending the wide flight of steps in the Piazza di Spagna, and entering the little church of La Trinita de Monti, where, in the fading light of the setting sun, the nuns of the Sacré Cœur sing sweet vesper hymns to the Light of Light. Or I am in the Pantheon hanging a wreath about Raphael's tomb, and wandering from shrine to shrine, now dedicated to the worship of Him who is God indeed, instead of the many gods in whose honour the altars were raised; for this nobly-proportioned edifice was erected by Agrippa, B.C. 27, and passed with but little alteration from a pagan to a Christian temple in the year 608.

That vision passes, and another takes its place. I am standing amidst the Cypress trees on the Monte Mario watching the Easter fireworks, which convert the entire population of Rome into a population of children, laughing, talking, and even screaming with delight, as each fresh artistic representation bursts into light, and the lower heavens glisten with a thousand meteors sent there by man's hand. Again the scene changes, and from the noise and bustle of the Roman streets I pass to the quiet studio of the great Christian painter Overbeck, and listen with reverent attention as the old man, with gentle voice and winning smile, gives his beautiful explanations of his yet more beautiful pictures, both speaking of something better and greater than the noisy world outside. My eyes are dim as I watch the painter sitting amongst his children, the creations of the intellect so soon to pass away to the Great Intelligence from whence it came.

Some one has said that "Architecture is like frozen music." Is it some thought akin to that that makes me never remember Overbeck without connecting him in some sort with the beauty and fragrance of flowers? The transition seems slight that transports me from the quiet studio back to my well-nigh forgotten theme of flowers. I seem to be once more gazing on the fair bouquets that all winter long are to be seen in the greatest profusion arranged on tables in the Via Condotti or the Piazza di Spagna. All day long the arranging of bouquets seems going on, and the flowers seem always fresh, the purple Violets still sweet, the white Camellias and Roses still fair; yet very few people ever seemed to do more than admire their beauty. Where the flowers came from was always a mystery to me till I took the best means of solving a mystery, and asked for information, when I was answered, "There are no nursery gardens as in England; but all these flowers come from the gardens of the Roman nobility, the gardeners sending them early in the morning.

The Romans have at all times been supposed to possess a very limited flora, so I may be excused if my actual floral gleanings in the Eternal City were small. Their principal garden flowers now, as in days gone by, seem to be Violets and Roses. They have now, as they had then, the Crocus, Narcissus, Lily, Gladiolus, Iris, and Poppy; while flowers, and plants, and climbing evergreens are still to be seen decorating the flat roofs and the windows of the houses. It does not appear that much alteration has taken place even in the laying

out of their gardens and pleasure grounds; for now, as then, the most striking feature in a Roman garden is the lines of large trees planted in regular order, with closely clipped hedges of Yew and Cypress, formed into walks, with statues, pyramids, fountains, and summer-houses interspersed.

A Roman garden at first appears like a very wilderness, beautiful indeed, yet still a wilderness; but after a time the eye becomes accustomed to the style, and is able to appreciate its fitness to the climate and to the habits of the people. Passive enjoyment is not in the nature of Italians; they always want to embody their thoughts, and with the lower minds talking takes the place of that action which in the higher shows itself in some noble work of art. The long alleys and walks suit the talkers; and alas! the day for that higher development seems clouded over for Italy, and the names of foreigners—Story, Gilson, Overbeck, and Platz occupy the places once accorded only to Italian Michael Angelos or Raphaelis. The skill of the ancient "topiarius," or ornamental gardener, used principally to be exerted in the cutting and twisting the shrubs into the figures of animals, &c., such as we may sometimes still see in the old-fashioned manor-house gardens in England. Specimens of this peculiar art are frequently to be met with in ancient paintings and in the bas-reliefs. Modern Rome is like a broken mosaic; it requires labour, but that labour of the most delightful kind, to gather up the fragments of precious stones here and there, out of which to restore the perfect picture of what ancient Rome was.

Before I take my reluctant farewell I must tell a pretty story that was told me about a wild flower. I may not remember it perfectly, but I will try my best. Beyond the Porta Pia, on the Campagna, a botanist went wandering in search of flowers. After a while he came on one peeping up from the grass that he had never met with before excepting when growing on a wall. Some theory or other was started, so he gathered the flowers and sent them to the Linnean Society. They, too, were astonished, and sent them back to some of their learned members then in Rome. They went to the spot, found the flowers, and dug for their roots, when they found traces of an ancient wall. Then archaeology put in a word. It was conjectured that long years ago some great man had been buried in that locality and the precise spot forgotten. The little flower spoke again, and guided by her voice they dug away, and discovered the ancient sarcophagus and the traces of a basilica, the tiny flower spreading all round where the walls lay.

As my first greeting on entering Rome was from the English church, my last greeting on leaving shall be to her. Amidst all the attractive dissipation surrounding the stranger in Rome there is a quiet witness for the truth daily pleading for recognition, and most touching in their pure simplicity do the English services seem to English hearts after the gaudy decorations of the Romish ritual. The little church is always crowded. One congregation is scarcely out ere another takes its place. Many have to go away for want of room; and when the hymns are sung it is like the voice of many waters ascending to the Throne

"Where Sandalphon, the Angel of Glory,  
Sandalphon, the Angel of Prayer,  
Is gathering the prayers as he stands,  
And they change into flowers in his hands,  
Into garlands of purple and red;  
And beneath the great arch of the portal,  
Through the streets of the City Immortal,  
Is wafted the fragrance they shed."

And so I quitted Rome.

The railway route from Rome to Civita Vecchia has left but one impression on my mind, and that is Roses—Roses everywhere, clinging to Vines, to trelliswork, to hedges, to houses—Roses ready for imaginary crowns for imaginary victors, when Rome, emerging from ancient and modern trammels, shall once more shine out with radiance worthy the Eternal City. Civita Vecchia has not much to recommend it; it savours on all sides of quarantine, and the people and sailors have a watchful look as if on the alert for fevers.

Early morning found us once more on the road, the noisy peremptory railway having given way to vetturina, and the shrill whistle to the driver's whip flourishing over the horses' heads in a frantic whirl of reverberating cracks. Now I could look at the dear country in peace; now I could walk up the hills gathering wild flowers, or have my lap filled with blossoms put through the window by the courier. From Rome to La Nunziatella I reaped a perfect harvest. *Asphodelus microcarpus* assumed shrub-like proportions; we cut down quite branches of it, only to let them fade away in the hot sun.

The temptation was so great I could not resist making up one lovely bouquet after another, intermixing the white *Asphodel* with the brilliant blue of the *Anchusa officinalis* and the rich amber of the *Cerintho aspera*, all of which grew in the greatest profusion. The *Cerintho* of the Campagna seemed different from the Roman one. The leaves were cordate instead of ovate; and though in both cases they were stem-clasping, yet in the Roman *Cerintho* this was not so observable, because the leaves were fewer and narrower at the base, and embraced the stem without opposition. I am inclined to think the Campagna *Cerintho* may be *C. major*. In both specimens the leaves are fringed with sharp white teeth; and the same sort of teeth or tubercular hairs are spotted over one side of the leaf, the reverse side being covered with raised white spots. The whole plant is exceedingly striking, and would be a handsome addition to English flower-borders. By-and-by the *Cerintho* and *Anchusa* would give place to the *Roseda phytiumma*, like our garden *Mignonette*, only more white and not so sweet; the little *Narcissus intermedius*; the brilliant *Lithospermum purpureo-ceruleum*, which is said to grow at Mary Church in Devonshire; with the *Helianthemum vulgare* and *guttatum*, and a lovely white *Cistus*, the name of which I do not know. Then the last bouquet would be thrown away, and there would be a *Teucrium* of brightest blue, a brickdust-coloured *Vetch* (*Lathyrus erythrinus*), *Ornithopus scorpioides*, with its very big toe in the centre of the ternate leaflets, together with *Erodiums* and a red *Convolvulus*.

These and a grand *Orchis* (*pyramidalis*), gladdened our route to Nunziatella. But even *vetturina* travelling has its drawbacks. If it were all up-hill it would be pleasant enough; but down hill, and level ground put botany to flight, and a passing glance and a cry of "Oh, look there!" was all I could give to many a rare bloom I longed to possess. Wherever it was practicable I grabbed up roots and bulbs, to the intense amusement of the contadini, who looked on, grinning approval of the "Inghlesi" who had such a strange fancy for weeds. I have promising plants of *Anemone hortensis* both from seed and bulb, *Grape Hyacinths*, and *Asphodels*. I have just planted my *Cyclamens*, which are not yet above ground.
