From observations taken near London during the last thirty-eight years, the average day temperature of the week is 75.1°, and its night temperature 50.6°. The greatest heat was 97°, on the 5th, 1852; and the lowest cold, 33°, on the 9th, 1863. The greatest fall of rain was 0.82 inch.

GLEANINGS FROM ROCK AND FIELD TOWARDS ROME.—No. 1.

LEFT England in February, but before my departure the Editors of THE JOURNAL OF HORTICULTURE kindly promised me space, on my return, for the account of any

Ferns or plants I might meet with; and though I fear my success will not be deemed very great, I venture once more to write of what it has been, as I have journeyed to and from Rome, with eyes always turned longingly to rock, bank, and watercourse, seeking for the tufts of bright waving green, which ever and anon would call forth a cry of "Restate!" and a plunge from the carriage, trowel in hand, to dig up the treasure and transfer it to the tourist's bag, which I carried on my shoulder, or, rather, round my neck, at the imminent peril of suffocation when the booty was large and heavy.

I left England on February 22nd, in bitter cold, with snow many inches deep on the ground. We left snow at Lyons on February 25, and as we neared Marseilles we were told that the "mistral" was blowing there; and blow it did! The Olive trees bent their supple limbs to it—the fair pink bloom of the Almond trees fled before it; women did fierce battle with crinoline, and men drew their long cloaks about them, and all the time the sky looked intensely blue and innocent of the riot, and the sun shone brightly, and his rays burnt like fire. Happy England! happier Englishmen, to whom "mistral," "tramontana," and "sirocco" are unmeaning words. Alas! for those who shudder at their names, as they bring back to memory the blasting, blighting effect of these terrible scourges. An east wind is bad enough, with the dust and the chill it brings with it; but what of a scorching hot east wind that seems to burn up and shrivel all life in man and nature, and to blow Cayenne pepper and Chili vinegar down your throat? Yet in spite of the "mistral" we saw tokens of coming spring everywhere. Vine-dressers were busy in the vineyards pruning every spare branch, Olive trees were being banked up—the whole creation seemed watching and waiting for the resurrection so surely coming from the winter's grave.

In the market we found Violets, Camellias, Carnations, Anemones, Daffodils, Narcissus, Roses (China and red), and large beautiful Heartsease. The flower market of Marseilles is very curious and pretty, each market-woman having a stall covered with a huge umbrella under the shadow of a tree. In one of these stalls I saw a woman making a large flat bouquet of dark Violets as a cross with white flowers round. I asked, "Is that for a church?" "Oh no," she replied; "it is for a lady who is dead."

These large bouquets are placed on the bier when the body is carried to its last resting-place, and left on the grave, as gentle witnesses of the fleeting nature of all that is most fair on earth. Sometimes the grave is entirely bordered with flowers: sometimes there are only vases of flowers decked with ribbons and beads. The vegetables were such as we should see in a south-country market in England, with the exception that in Marseilles the first crop of Peas was being gathered, and we had some for dinner boiled and sweetened to (French) taste.

The first Fern I saw was at Nice: on my way to the English church I passed a cart filled with blocks of stone, and peeping at me from their crevices I saw Ceterach and Trichomanes. The churchyard was full of Roses in bloom (red and white), and the scent of Oranges and Lemons filled the air. Summer seemed at hand, and we bought dust-coloured parasols and overcoats in expectation of its near presence. *En route* from Nice to Mentone we saw by the wayside hedges of Roses, the pink wild Anemone (*Anemone hortensis*; the *memorosa* I have seen but very rarely in Italy), Scillas, Jonquils, and I believe the pink Cyclamen, with many other common flowers; there were also huge Aloes, Cactus, and Palms, with Orange, Citron, and Lemon trees loaded with flowers and fruit. Often when the road was high up on the rock we looked down on precipices made golden with the Orange boughs, and as we drove on our glorious way little black-eyed children threw branches of Orange trees, covered with fruit and flowers, into the carriage windows.

It was Shrove Tuesday, and the villages we drove through were alive with groups of merry laughing peasants gaping at the processions of mummers, who, in every sort of grotesque costume, paraded the streets. Entering Mentone we heard voices singing a chant. "Oh," said I, "here is a church procession. Let us wait." Presently we saw a party of men in white (in imitation of priests), bearing aloft a man, who spread out his hands as if blessing the people. "Pio Nono! Pio Nono!" shouted the crowd as they rushed headlong on in their mad gaiety. To an English eye the Carnival must ever seem a strange vestibule to Lent.

*Cheilanthes odora* is to be found at Mentone, but it was too early to hope to find the small fragrant fronds on the steep mountain sides, where later in the year it grows. The flora of Mentone is a very beautiful one: in April the hedges and rocks are a mass of gay and varied bloom; but there are few weeks during the winter months when the botanist may not find ample material for his tin and book.

Shortly after leaving Mentone I noticed the first tuft of *Adiantum capillus-Veneris*, and as the limestone rock and trickling water increased, the little tufts became vast masses; clefts in the rock, like miniature caverns, were covered with the fairy-like foliage, which in some places seemed to line the entire face of the rock. At rare intervals I found the *Ceterach* also, but no other Fern. *Cineraria maritima* grew in great quantities, its soft grey leaves waving to the sea breeze, which blew upon them over one of the fairest scenes to be met with on this most beautiful earth. Yet even the exceeding beauty hardly repaid me for the more exceeding fright the pass of the Cornice always gives me.

NEW YORK  
BOTANICAL  
GARDEN.

1910

The road in many places is hewn on the face of the living rock, which stands in grand defiance, frowning on steep precipices going down, down, oh! so very far down into the surging billows beneath. For a great part of the way there is no protection—literally none; and every now and then you are greeted with pleasant remarks from the outside, such as—"Dear me! we were all but over when that carriage passed; the horses jibbed, or swerved, or something, and we were just over." Or, perhaps, it would be, "We had better wait a few minutes; they are blasting the rock ahead, and if a thundering piece came down the horses might take fright." Whatever the courage of the horses might be, I knew of one trembling passenger who was ever and anon reduced to study the geology of the steep rock rather than the botany of the precipice. Yet what a glorious sight it was! as we wound along our perilous way. On one side the blasting of the rocks showed all their grand colouring and veining, and the sunlight seemed to glint them with a thousand rich and varied hues. Beneath lay the deep blue Mediterranean, with white and red-sailed vessels here and there; while, stretching far away, before us and behind, lay soft blue distances with picturesque villages; now high upon some mountain side, now peacefully lining the shore, where fishermen in red caps and jackets stood about mending their nets, and little children played in and out amongst the boats. Every few miles we made perilous descents into these sea-side towns, and while the horses were rested we walked, gathering wild flowers, about the neighbouring *podère*, the *contadino*, pruning the Olives or Vines, only looking up to give a friendly glance at the stranger. On March 1, beneath the Olives or by the wayside, we gathered Daisies, Thyme, Wood Buttercups, Pellitory, Wood Mercurialis, purple and scarlet Anemones, Narcissus tazetta, Hawkweed, Rosemary, and Celandine; also very fine specimens of *Polygala vulgaris*, much finer than the English Milkworts. The weather was so genial we required no fire, and at San Remo we sat with windows open to the sea.

To engineers, the Cornice is just now specially interesting, from the magnificent line of railway they are uaking from Nice to Genoa. It seems almost too grand to be a human undertaking, chasms of such a tremendous depth have to be spanned over with giant viaducts, and rocks of such enormous proportions have to be bored through, rocks ending in precipices, with rocks again beyond. Everything seems to fall before the magic of the railway, or rather before the vast intelligence it embodies; old customs, old prejudices, old faiths are uprooted with the uprooted trees, and pass onwards and away with the advancing line. It is a strange thing to note the change a railway makes in an old Italian town. Life, energy, and purpose, side by side with inertness and decay, vast heaps of iron rails lying on beds of Myrtle and Lavender, causing the crushed and broken boughs to give out a delicious perfume; groups of peaceful-looking nuns passing quickly by where rough-looking and rougher-spoken "uavvies" are at work. A mass of blasted rock lying by the roadside with Maiden-hair Fern trailing over it; smart Parisian bonnets, worn by the smart wives of the railway contractors passing down narrow streets, with none but Italian peasants in their fanciful costume to look upon and envy (?) them! Everything has a disjointed, out-of-place look, and it will be many years before the graceful pleasure-loving Italy of old will be able to adapt herself to the requirements of her more active and useful step-children, for born Italians the new generation does not seem to be.

On March 3rd, I found between Savona and Genoa, what I believed to be the Dunraven variety of *Adiantum capillus-Veneris*; the rachis is of stiffer growth, and the pinnules smaller than they are in the ordinary form. I also found what I believe to be a variety of *Asplenium adiantum-nigrum*, the form of fronds is more obtuse than in acutum, and the pinnæ more divided than in simple nigrum; but I grieve to own that one of our best Fern authorities has only dubbed it with the name *A. adiantum-nigrum*. I, however, venture to enter a trembling protest against this ignominious treatment. We were detained at Genoa by snow, and this on the 7th of March. It came stealing on the earth at nightfall, and, lo! in the morning every mountain lay glittering like diamonds beneath the rising sun, every vessel, every house, each bye-way, and marble path wore alike the same pure covering, beneath which poor Italy trembled and shivered as we never shiver in England. At night there was a sunset! our room looked over the noble white marble terrace, upon the harbour of Genoa, bristling with a thousand masts, a resting-place for vessels of every nation upon earth; the setting sun glorified the mountain tops, and light, fleecy clouds hung like lamps of fire above the gorgeous scene. Yet,

like all of earth, how fleeting was the glory! A moment and the fading light fell like a meteor on the lower banks of cloud, another instant and the tall masts rise like gloomy spectres against the clouds, the waters lie calm and silvery beneath, and here and there a quiet star looks down.—*FILIX-FEMINA.*

### LIQUID MANURES.

Liquid manure enters largely into the art of plant and fruit-tree culture in pots and borders where the amount of root-action is limited to a small space. That which I have chiefly used has been the drainings of a dunghill, not necessarily what might accumulate from the washing of the manure heap by the ordinary rainfall, but it was our practice to have the fresh litter, during the summer particularly, thrown up every ten days or fortnight, either preparatory to the formation of hotbeds or for manure, into a square heap, which was afterwards well saturated with water and covered with a layer of soil or road-scrappings, if not wanted for hotbeds. In this way the litter was more readily converted into manure, and the manure tank was never long empty.

These washings, whether artificial or natural, were the kind used, being the washings of horse, cow, and pig's dung in about equal quantities, for the horse droppings were mostly collected for Mushroom-growing. This liquid being used up, is made fresh every fortnight; it never had a noxious smell, and never, to my knowledge, fermented, consequently it was never very putrescent. The liquid was used for watering, and sprinkling the walls, paths, &c. of the houses; for watering, it was diluted with an equal volume of hot water, so as to make the temperature of the liquid equal to 90°. It was given to all plants after growth recommenced, always making sure that the drainage was good, and that there was an abundance of roots to absorb the food thus furnished. No plant was watered with the liquid unless the soil was full of healthy roots, nor whilst in a state of rest; and if fresh potted or top-dressed it was not watered until new and healthy roots and new growth had been made and were a little advanced. For instance: Calceolarias and Cinerarias, were not watered so long as they remained out of their blooming-pots, and not then until the roots reached the sides of the pots, but afterwards at every alternate watering up to the time of their blooming. Geraniums were treated in like manner. Pelargoniums were not watered so long as they grew sufficiently strong, for applications before the bloom shows or trusses form have a tendency to encourage growth at the expense of the bloom. On the other hand, when the growth was weak, the plants still having healthy roots, they were watered with the liquid diluted with four times its volume of water. After the trusses were visible, the plants were watered at every alternate watering with liquid manure up to the time of their coming into bloom generally. This was the treatment pursued with all kinds of soft-wooded plants, no liquid being given so long as they grew sufficiently well without it, for I am persuaded that soils are, or ought to be, made sufficiently rich to maintain the plant up to its showing its trusses or bloom-stems; the liquid given after this goes to strengthen the flower-stalks, contributing to the size, not number, of the blooms of the flower-head; whereas, when it is given at an earlier stage gross or strong growths are often formed, and these are often produced at the expense of the bloom, for a gross plant is seldom prolific of flowers. I make it a rule to water no soft-wooded plant until it has been long enough in its blooming-pot to fill it with roots, that being the only time when I have found watering with manure water of any advantage. To all bulbs after the spike appears or the foliage attains its full size, it is given to strengthen the truss, and increase the size of the flower. Such, however, as have the pots full of roots may be watered whilst the foliage is forming, which will improve in size, and then it is only reasonable to hope for finer flowers, to say nothing of the bulb becoming stronger by higher feeding. It very often happens that highly fed plants, and those of a bulbous nature are no exception, do not flower so finely as those not so strong; but this is only due to the extra feeding retarding the ripening process. Bulbs that are highly fed must be very well ripened, otherwise they will not flower satisfactorily. I may note in passing that plants highly fed require more light, at least a longer continuance of light and heat, to perfect or ripen the growth made, whether it be eyes or buds on a plant or the concentration of the current year's growth in a bulb for another year.

There are certain cases in which it is desirable to further growth by copious manure waterings, and particularly does this apply to fine-foliaged plants. Caladiums would, I believe, live with their roots in a manure tank: I have known Caladium argyrites treated as an aquatic, planted in water fully 3 inches deep, and it thrived amazingly. All the Caladiums like liquid manure, and a brisk heat, with slight shade. Alocasias revel in moisture and liquid manure when growing. Marantas, and all that have thick and fleshy roots, as Dracenas, the Palms generally, Aralias, Ficuses, Coleus, Billbergia (though half epiphytal, some quite so), Echmeas, Pandanus, &c., though many have fibrous roots, are improved in foliage by liquid manure when growing. There are indeed few plants to which it may not be given with advantage, but they must be in a healthy state—not necessarily vigorous, for then it is not needed, but having healthy roots. It benefits those most, however, that form thick roots, and those especially that require a loamy soil wholly or in part. Those plants that never form such roots, as Heaths, Pimeleas, Leschenaultias, Eriostemons, Correas, Azaleas, and Rhododendrons, it does not seem to improve much if at all, and unless given very weak, it is certain destruction to many of them if persistently applied, and that even when weak. I fancied Azaleas had finer flowers, and made finer wood with a little weak liquid manure than others supplied with water only, but I am not certain, and would therefore advise others to be cautious in applying liquid manure to any plant that requires peat soil for its successful growth. Their roots are so very delicate as to be soon destroyed; Camellias, however, care nothing about it, except when healthy, they like it both when the buds are swelling in winter or spring, and again when making their wood. It is necessary, however, that the soil be well drained and porous, and the roots healthy. It is useless giving strong food to a sickly person without an appetite, and so with plants. Weak but nourishing food is required by sickly plants; a sweet soil and atmosphere, and thorough cleanliness, are what they require until they gain strength, and are able to take and make the most of stronger food.

Annual plants as Balsams and Cockscombs, succeed better with liquid manure than with very rich soil, and so do Gloxinias, Gesneras, Achimenes, &c., from the time of their first showing their buds to that of their coming into bloom.

I have an impression that Ferns, Mosses, and the lower orders of plants are no finer in consequence of the application of liquid manure, or indeed manure in any form. Though many of them will grow and appear none the worse of weak doses, not too frequently given, say once a-week, they do not seem to grow any better, and they are not improved, nor can I say injured in a "manured atmosphere," whilst Orchids become more luxuriant, and have healthier and better-coloured foliage in such an atmosphere.

Now drainings of the dunghill will do wonders in a garden during a dry season. The Roses will bloom finer in consequence of watering them with it, from the time of the buds forming to that of the flowers expanding, applying it cool, though it would be none the worse of being boiled to destroy the eggs and larvæ of insects, even if allowed to cool afterwards. Roses in hot weather like the liquid cool, and so do all plants that are required to grow slowly and remain long in bloom. It may not be generally known that cold pump water will cause a plant to continue longer in bloom than were it watered with water exposed to the air. It is best, therefore, to use the liquid at 90° when we wish to forward, and cool when we desire to retard the flowering, fruiting, or perfection of vegetables. The liquid may be given to all out-door plants when diluted with an equal quantity of water.

Whether is hard or rain water the better? This is a question well worth considering. We frequently see rain water recommended as the best for watering. I have known a large establishment successfully managed with no water except pump water, and no matter how dry the summer there never was any scarcity of water. I think a pump and a deep well capital things in a garden. Spring water is the best of agents for keeping the roots of plants cool, and, much as I like soft water, it is a fact that plants in a hot summer do better with pump than with warm or aired soft water, particularly those delighting in coolness and moisture, as Roses, Calceolarias, and any others of which we wish to prolong the blooming. It is also good for Strawberries in hot seasons. I may add that pump water is soon aired by pumping it into an open cistern, and if this be elevated the water can be run where wanted by means of pipes, and hose to distribute it will obviate much of

the drudgery of watering. For tender plants pump water is not good, or rather rain water is better.

To return. The drainings of a dunghill may be given to all out-door plants that are healthy, though weak, whilst growing, which it is desired to invigorate; the liquid being diluted with an equal quantity of water for the strong, and with four times that quantity for the less-growing kinds of plants, except such as Rhododendrons, Azaleas, Kalmias, Andromedas, Ericas, &c. There are other exceptions, as the majority of the Coniferae. Of all plants to which I have used liquid manure, tree Pæonies are those which show the beneficial effects perhaps more than any other, an application being afforded twice a-week from the time the buds are first visible up to flowering.

Passing on to fruits, I may say they all like copious waterings with liquid manure. I water Pines regularly with it, from the time that the suckers become well rooted up to fruiting—in fact from March to October. We water them with half drainings of the dunghill and half soft water, at a temperature of from 90° to 100°. During the winter months they are watered seldom, and with aired soft water only. To Vines in pots the liquid manure is given at every alternate watering, from the time of the buds breaking up to that of the fruit ripening; to Figs in pots, from the leaves appearing till these change colour—but it should be borne in mind that our Figs are always under-potted, for if Figs are liberally treated with pot room they grow too freely, and cast their fruit; and all stone fruits, from their setting up to ripening, are freely supplied with liquid manure. Musas in pots and tubs may have liquid manure every day when growing freely; Oranges too, may receive it when making new wood, and throughout the summer once or twice a-week. There is not a fruit tree grown in pots that is not benefited by frequent and copious waterings of liquid manure whilst in active growth, always excepting those of which the growths are already too luxuriant, or gross to an extent that interferes with their bearing.

Pines in beds are watered with liquid manure the same as those in pots; Figs, also, if the borders are filled with roots, and other fruit trees in borders, at every alternate watering. It ought to be borne in mind that, so long as the border is sufficiently rich to furnish strong wood and good crops of fruit, liquid manure is not likely to improve; for, though it might render the crop larger, it might produce rank growth, and imperfectly ripened wood. On the other hand, it may safely be given to trees whose growths are fruitful, the wood strong and close-jointed; and it may be given advantageously to those that are weak from want of nourishment in the soil, always making sure that the roots are in a healthy state. I was formerly of opinion that roots were more freely formed, and ran more readily through poor soil than rich. This, I find, is only in part correct; for, if we plant a tree in rich soil, roots will not be so readily emitted as when it is planted in poor ground; but when once emitted they ramify and extend more rapidly in rich than in poor soil. It is really astonishing how the roots will rise in pots surface-dressed with rich soil, even up into the top-dressing itself. I have nothing to urge against liquid manure, but I very much question whether it is as safe as top-dressings of manure. After the fruit has set, top-dress a fruit tree—say a Peach in a 15-inch pot—with an inch of fresh cowdung, so as to form a depression to hold water, and fill this with about two quarts of water every day, and renew the dressing of cowdung, an inch each time, at intervals of six weeks, up to the fruit taking its last swelling; give another tree an equal quantity of liquid manure daily, up to the same period, and which will be the healthier tree, and yield the finer fruit?

Of other liquids, I have used guano, at the rate of 2 ozs. to a gallon of water, for plants in the open air, and not frequently watered, or, if in pots, at the rate of 1 oz. to the gallon; and this last is the strength used for all plants of limited root-action in pots, tubs, and borders. The guano is best dissolved in a wooden tub, pouring the water upon it the night before using it. If placed in a watering-pot it quickly brings the paint off, and corrodes the iron. A peck of fresh sheep's-dung, mixed with forty gallons of water, was a favourite liquid with the man in charge of the houses where fruit and vegetable forcing was carried on, whilst cowdung—a peck to twenty gallons of water—was much valued by the flower gardener. Horse-droppings, in the same proportion, were not thought much of. Soot-water, made by pouring, or rather pumping—for all the tubs were in a shed at the back of the forcing-houses, and a pump in the rain-water tank enabled all the barrels to be filled by the simple turning and shutting on or off of the water—forty gallons of water over a peck of soot, was much used.

In conclusion, I may state that I have used several chemical manures in a soluble form, but I never found one of them of any use, except to bring the leaves of the plants down. Remember, I do not include, in this condemnation, some of the sulphates, muriates, and phosphates, which are manurial agents, but concentrated liquids, which are said to answer the same end as the pills of the Seythians, which would answer for food during a six-months campaign. The gluten of a bread loaf, brought into the compass of a pea, will no more satisfy and feed a hungry man than will a drop of the manurial constituents of a cartload of dung, condensed into an ounce phial, added to a bucket of water, be beneficial to plants.—G. ABBEY.

### CONIFERE PRODUCING CONES AT LINTON PARK.

THE fine dry autumn of last year seems to have exerted a fruitful influence on some of our trees, which this season have produced cones, and possibly some of these may arrive at maturity. I must, however, remark that the blooming of ordinary forest trees and shrubs was not so abundant as last year, and some of them have not the appearance of being loaded with their usual heavy crop of seeds. Walnuts will be thin, and the common Hawthorn will bear anything but a heavy crop. These things are, however, of little importance compared with the crops of edible fruits which form so important a feature in the general cultivation of the district, and which in most cases fall short of the expectation once entertained. My purpose, however, is to point out some Conifers which have here this season produced cones for the first time. Might I ask if they have done so elsewhere, and with what result?

**ARACARIA IMBRICATA.**—A fine tree of *Aracaria imbricata* has this season produced three large cones, which, from their manner of growth, promise to arrive at a size hitherto unknown amongst specimens furnished by other trees; the tree is upwards of 30 feet in height, and in outline more cylindrical than conical, the diameter of its branches at the height of 25 feet being about the same as at bottom. The top is gracefully rounded, and though the bottom branches for about 3 feet are gone, the next tier sweep the ground, so as to give that uniform outline so much admired in trees of this and similar species. The cones are near the top, are globular in form, and, as a lady justly observed a few days ago, are like hedgehogs in size and the bristly manner in which they are set with leaves, or rather spines, on all sides. Their size is quite equal to that of a full-grown hedgehog. From these cones appearing so early in the season there is reason to hope that they may arrive at perfection, the situation of the tree being favourable for maturing them, being dry, sunny, and sheltered. Indeed we have long thought the site drier than is wanted for a tree of this kind, but not having a tree of equal size growing on a situation of opposite character, although we have several smaller ones, it is, perhaps, premature to condemn the site, especially when it is known that the tree has never suffered from the severest winter, and promises so well.

**PICEA NOBILIS.**—A specimen of this fine Conifer which had lost its leader some fifteen years ago, and remained without one for several years, growing slowly in a lateral direction, at length sent up two leaders; and one being taken off, the other has pushed on as straight as a gun-barrel, and for the last four or five years the growth has averaged fully 3 feet. The tree is now upwards of 20 feet high, and as healthy-looking as could be desired, presenting that rich glaucous hue so much admired in this genus. This season several cones have been formed, and they promise to arrive at perfection. They are now upwards of 7 inches long, of a pale green colour, and to all appearance look as if they would attain a large size. The tree is on a dry stony situation, well sheltered from the north and east, and I hope the cones, from showing themselves thus early, may ripen.

**PICEA CEPHALONICA.**—A specimen of this has also shown cones this season in numbers. I am not certain whether it has done so before or not; they are, however, short and small compared with those of *P. nobilis*. The tree is more bushy, and has not the tall upright form of the last-named. An accident deprived it of its leader about twelve months ago, but it is making an effort to replace it by another, which will give the tree that conical form of which it is so good a representative.

Besides the above, *Pinus insignis* is this season loaded with a more than usual number of cones, it having borne a quantity for several years in succession. It is too early yet for those of

*Cedrus deodara* to show themselves, but abortive ones have for some years been produced on our largest specimens. More perfect ones, black as Sloes, or rather of a beautiful purple black, have here been produced by *Picea Webbiana* each year, and this year is no exception to the rule. Some other *Pinuses* have also produced cones; but I have not seen any indication of *Wellingtonias* becoming fruitful, neither is such a state of things to be wished for, it being in some degree the precursor of disease and a premature death. I believe, however, it has shown fruit in some places, but I have not seen it. Some of the *Thujas* are also bearing cones, I am told, in places, but I have not perceived in that state any of those introduced within the last twelve years; but a second hot summer following on the dry autumn of last year may, perhaps, throw into a bearing condition some of those which have not hitherto produced cones; but there are many things more desirable than a young tree doing so.—J. ROSSOX.

### DINERS À LA RUSSE.

AND THEIR EXEMPLAIRES AT KENSINGTON.

WHAT is a "diner à la Russe?" This would seem to be a question as yet undecided, if one may judge from the character of the tables set out at Kensington on Saturday week. Is it a dinner for the advertising of china and glass? Is it a slice of a bad ribbon-border cut out and laid on a white cloth? or what is it? My inclinations do not lead me into society much. I do sometimes, it is true, dine with friends who, I believe, know what is correct; and I must say it seems to me that there was in many of the tables laid out on Saturday the 24th inst. a want of taste, a vulgarity and inappropriateness, that none of my friends would have tolerated at their houses.

What is a diner à la Russe? then, I repeat. My idea of it is, as compared with the old style of dinner parties, that it consists in this—that the dessert is laid upon the table at once, that the old *épergues* and *candelabra* give place to a lighter and more elegant ornamentation in the shape of flowers, and that the dinner is cut up at the side table and handed round. If I am correct in my ideas, then, I should have disqualified some of the tables, and certainly not have judged them as they were judged; and without wishing to say one word of disparagement either of the ladies who undertook the arduous task or the Academicians who assisted them, I cannot think they have tended to increase good taste amongst our dinner-giving friends. It must have been no slight matter to judge, for in defiance of all ideas of comfort and convenience, the tables were laid, some on one side, some on the other of the conservatory; so that, having decided on the merits of one half of the tables, the Judges had to cross the whole length of the conservatory, keep in their minds what they had seen, and compare them with the other half. When we remember that even in judging a few boxes of Roses you have often to take one stand and put it alongside of another, and that even then it is often a difficult matter, one can estimate what a task this must have been. It only illustrates what many besides myself think—that a really effective show of any kind can never be held under the present state of things at Kensington.

And now to the prizes. "Surely," I said to a friend as I approached the table that took first prize, "this must be a china dealer's," little thinking how near the truth I was. My objections to this are—First, that I think white china is a decided mistake. It may do all very well for a warmer climate, but in ours it is cold and chilly-looking; and as winter is the chief season for dinner parties, that ought to be considered. Second, The table was overloaded: it matters not whether this be with silver or china, it is contrary to the elegance that belongs to this new style of dinner table. Third, The dessert was not well arranged. The double butter-boats in which the fruit was placed, while pretty in themselves, were awkward. I do not know how Cherries were to be got out of them except by one's hands; and Strawberries must have been inevitably smashed before they found their way to one's plate. And then there was an absence of those pretty *glacé* fruits and fanciful *petits fours* which are indispensable to a handsome dessert. Then, fourth, It was a decided mistake to put the dessert plates on the table. While the centre of the table is laid out for a dessert, the covers should be arranged for the dinner itself—knives, forks, spoons, but no plates. And what can be more babyish than to have holes in the rims of the plates for water and flowers?

So far for the first. As to the second, fair ladies! what could have persuaded you so to honour it? There was neither taste nor beauty flat as a Chaldean plain. And then the lines of yellow, blue, red, and white! It is quite true there was no obstruction; but people do not generally talk across the table, and now that the old fashion of drinking wine together has gone out there is no need of this flatness; so that I do not see the force of the objection which this table apparently was intended to meet—that the view is generally too much obstructed. There is a medium in all things, but the extremes of flatness and overcrowding were to be seen in the second and first prizes.

As to the third, the elaborateness of the design and the minuteness of the details were contrary to that simple elegance in which true, genuine, refined taste so much consists. A mirror set in a gilt frame with glass stands placed on it, and crowded with Ferns, Stephanotis, and Orchids, is not to my mind the sort of thing one wants to see. Indeed, amongst the unsuccessful tables were many which in my poor opinion were far beyond those which were honoured; and were I asked to sit down at one of them I should most fervently hope that the taste of the *chef* was better than that of the dresser of the table, for if not, I should look for a fit of indigestion. It sometimes happens that when people imagine that there is something extra required of them, that they fail through excess of painstaking. I have known preachers to whom one has listened often with pleasure, when called upon for some special occasion become so unnatural, so unlike themselves, that one could only regret they had ever been called upon to undertake the sermon. The young lady whom you have listened to with such pleasure as she performed her morning's practice, when called upon before a large number surprises you not so much by the brilliancy of her singing as by the unnatural and stilted character of her performance. And so the other day in Paris at Lady ——'s, the dinner table, arranged doubtless in its ordinary method for a *dîner à la Russe*, was far more effective and elegant than anything I saw at South Kensington. In these observations I am only uttering my own individual opinion. My eunuchs of taste may be wrong, but judged by them I say that all the tables exhibited were defective.—D., Deal.

### ROSES AND STRAWBERRIES.

**ROSES.**—The Editors and "D.," of Deal, are right about Duchesse de Caylus. It is a splendid first-class Rose, of great substance, beautiful clear colour, and excellent outline and folding. It bloomed on Sunday, the 25th of June, and has stood the broiling sun for three days without impression. Its colour is rich brilliant scarlet crimson. Its declining colour is rich clear pink. Mr. Adolphus Kent is here, and we cut up the plant and budded it on briars. Rushton Radclyffe is a fine, well-formed, full Rose, a strong grower, with good foliage, and an abundant bloomer, opening easily. These are very beautiful Roses: Lords Herbert, Macaulay, and Clyde. The first is full and beautifully folded, and of correct outline. The last two are of greater substance, and very beautiful and good. Lefebvre, Lords Macaulay and Clyde, Senateur Vaisse, and Gloire de Santenay are of great substance, and resist the sun well. The above five new Roses may be added safely to the five previously recommended. The next best and good are Alpaide de Rotalier, a larger and improved "old Cabbage" Rose, Leopold I., George Prince, and Madame Derroulx Douvillé. I should like to see them bloom once more before confidently recommending them. All that I have named in this paper are good growers.

I cut twenty-four trebles to please Mr. Kent on Tuesday morning at 5 A.M.; they were good. The trebles of Charles Lefebvre, Gloire de Santenay, and Senateur Vaisse were fine.

**STRAWBERRIES.**—As regards Lord Clyde, I had only two plants of it, and being under a hot south wall, the blooms happened to come out early, and were destroyed by a very severe frost. I was amused at M. Van Houtte's very flattering notice of me in his catalogue. He says of me, "He is the most experienced and best judge of Strawberries in England." "He is the most caustic and picturesque writer, sparing no one; neither in prose nor in verse." "Till this great judge says, 'To be, or not to be,' raisers are in a state of the greatest anxiety." I can only say that "from the sublime to the ridiculous there is but a step." What I said of Lord Clyde and John Powell was this:—"They were the best novelties here, and were rich and good." Of John Powell I have about forty plants, and can now speak of it

confidently. The form of plant is excellent; it has set its fruit well. The berries are of good size, beautiful clear crimson, and of delicious flavour. It has cropped well.

In a few days, after I have tasted Mr. Ingram's No. 10, I will send to 171, Fleet Street, a short Strawberry treatise, as requested by a clergyman.—W. F. RADCLYFFE, *Farrant Rushton, Blandford.*

### WATERING MELONS TO AVOID THEIR DECAY.

My Melons have hitherto succeeded excellently and are now ripening; but instead of ripening all over at one time, they decay at one end before the other end is ripe, so that the fruit are scarcely fit for table.—P. D.

[In watering give water to the roots without pouring it on the surface, and even then if the weather continues equally sunny place a piece of thin paper over the Melons during the hottest hours of the day.]

### THE KITCHEN GARDEN.

FEBRUARY.

Thus, if the weather is at all favourable, will be a busy month, but it is bad practice to work the ground when snow or rain has made it sloppy. During frosty weather, should it occur, the manure can be wheeled without injury to the walks, and the Pea-rows all pointed and stored separately in their different lengths. The pruning of the fruit trees, if it has not been done before, should also be performed, and when all are pruned I generally paint them over with a mixture of lime, sulphur, and soot, of a very thin consistency, in order to keep down the moss, and to act as a preventive against the ravages of the small birds on the fruit-buds. A handy man with an ordinary whitewash brush will soon go over a great number of bushes, after which, the ground between them being forked, all will look neat and clean. During very bad weather one can get the labels made, painted, and written to each separate packet of seed, which ought to be in by this time. I generally obtain mine from an old-established firm a good distance off, where I know most of the seeds are home-grown, and all to be depended on, as I consider it is a very good plan to procure them from a distance, for the change of soil and climate is beneficial. I seldom attempt to save seed of any kind myself, except a few Potatoes, which it is almost impossible to buy properly matured and greened ready for planting for an early crop.

Everything must now come up that can possibly be spared, such as Turnips, Colewort stumps, Savoys, &c., and the ground be manured and trenched, or dug, ready for the main crops, not forgetting when clearing off the Turnip bed to lay a few in some sheltered corner, where, with a little protection, they will yield a good dish or two of Turnip greens, which will afford an acceptable variety in the vegetable supply at this season. Savoys, too, may be kept on some time longer with a little management. A very good plan with them is to place two rows of Pea-rows opposite to each other, at an angle of 45°; throwing over them a little rough litter, and placing more sticks crossways to keep on the protecting material. As the Winter Spinach bed will now be the mainstay, it must be well looked after by loosening the ground between the rows, &c; autumn-planted Cabbages the same. All intended plantations of Horseradish, Mint, and herbs, ought now to be pushed along, if not done before. In fact, we must seize time by the forelock and hold him fast till the beginning of May, when, if you have nothing else to do, you may rest and contemplate your handiwork of the two preceding months.

The supply at this time generally consists of Brussels Sprouts, Spinach, Savoys, Turnip Greens, Coleworts, Kale of sorts, Sprouting Broccoli, and Winter White Broccoli, if so fortunate as to have any that have stood the severity of the weather. With salading very little can be done, except with that under protection, as Celery, Lettuce, Endive, and Mustard and Cress. Several things may now be sown with a chance of success. Should some of them fail, sow them again directly, a good gardener is never down-hearted; but be sure to select dry sunny days for sowing.

I generally sow a pan of Cole's Crystal White Celery, and a pinch of Cauliflower seed, and put them in one of the pits. In the beginning of the month I sow two rows of Dickson's Favourite Peas, and, before the month is out, two rows of

Veitch's Perfection, sowing them but 3 feet apart in the rows, as by the time they are done with the ground can be prepared for autumn Broccoli, and, if possible, I sow my Parsnips before the month is out, also a few rows of spring Spinach on the ground that will be required for the second lot of Dwarf Kidney Beans. The above are all sown in the open quarters, and on the border I sow a few small beds of such things as Early Horn Carrots and Red Dutch Cabbages, and plant a few rows of Robinson's Golden Kidney Potatoes. Some Radishes may be sown on the top of them, not forgetting to take the necessary precautions against the weather and the birds, which are very fond of Radish seed; sowing, in addition, a row or two of Parsley in some convenient quarter, is about all that can be ventured on in this month.—BRENTWOOD, P.D.

(To be continued.)

### SIPHOCAMPYLOS BICOLOR.

THE *Siphocampylos* is a most useful plant for in-doors, seldom being out of bloom; but it is more adapted for a large conservatory than cultivation in pots. Its rambling habit renders it rather difficult to grow in pots to form a neat specimen, but when planted out either against a wall or pillar in a cool house its true character is at once developed. A plant in our conservatory at this place has bloomed beautifully all through the winter, and is still in fine condition; and I believe the same plant to have occupied the same place for the last fourteen years, and shows no signs of death, but is as healthy and vigorous as it was ten years ago. It strikes freely from cuttings at any season, and thrives remarkably in good loam, leaf mould, and an addition of a handful of sand. I have tried to grow it in pots, but never succeeded in making what I call a respectable-looking plant. Others may be more successful.—(J. E. in *Scottish Gardener*.)

### THE ROYAL HORTICULTURAL SOCIETY'S ROSE SHOW.

This was held on Saturday the 1st inst., and was decidedly the best Rose Show which we have seen, or, indeed, we believe, that has taken place this season. Not only was the number of boxes exhibited very large, but the quality was excellent. Beneath the roof of the conservatory a light canvas awning extended from end to end, serving the double purpose of breaking the force of the sun, and preventing the height of the building dwarfing the blooms. Under this two rows of stands, one on each side, extended from end to end of the conservatory, and the exhibition was prolonged into the adjoining arcades.

Class I. was for seventy-two kinds, one truss of each. Here there was a close competition between Messrs. Paul & Son and Mr. Mitchell of the Pitdown Nurseries for the first place, both collections being very evenly balanced as regards the number of first-rate blooms. Messrs. Paul & Son, however, carried off the palm. Among their blooms we noticed fine examples of Maurice Bernardin, Gloire de Santenay, Vainqueur de Goliath, Madame C. Crapelet, Lælia, Senateur Farre, Madame Furtado, Duc de Rohan, Comtesse de Chabillant, Pierre Notting, Monte Christo and Praire de Terre Noire, Caroline de Sansal, Madame Alfred de Rongemont, Queen Victoria, the new yellow Tea, Maréchal Niel, Anguste Vacher, Gloire de Dijon, Alba Rosea, and Louise de Savoie. From Mr. Mitchell, who was second, came many of the above, Madame Masson, Madame Charles Wood, Wilhelm Pfitzer, Vicomtesse Douglas, Leopold Hausburg, Maréchal Souchet, Madame Julie Daran, Charles Lefebvre, Victor Verdier, George Prince, Senateur Farre, Madame Boll, Duc de Cazes, Madame Caillat, General Washington, and Duc de Rohan. Mr. Keynes was third with La Reine, François Premier, Cloth of Gold, Alfred de Rongemont, Louise Peyronny, Devoniensis, and many others very good; and Mr. Cant had the fourth prize—Rubens in his collection was very beautiful. Mr. Fraser, of Lea Bridge Road, had also an excellent exhibition.

In Class II., forty-eight kinds, three trusses of each, there was a very rich display, and, as in the preceding class, Messrs. Paul & Son again took off the first prize with fine trusses of Madame Charles Wood, Devoniensis, Lælia, Comte de Nanteuil, Vicomte Vigier, Lord Clyde, Maurice Bernardin, beautiful; Oliver Delhomme, very fine; Madame Villermoz, Vicomtesse de Cazes, Senateur Vaisse, brilliant; Madame Furtado, Gloire de Santenay, Madame Rivers, &c. Mr. Keynes was an excellent second with beautiful trusses of Souvenir de la Malmaison, Virginal, Comte de Nanteuil, Alpaide de Rotalier, Lord Macaulay, Sœur des Anges, Vicomtesse Vigier, Monte Christo, Triomphe de Rennes, L'Eblouissant, Gloire de Santenay, America, Madame Rivers, and others scarcely less fine. Mr. Francis, of Hertford, was third; Messrs. Lee, of Hammersmith, fourth.

In Class III., twenty-four kinds, three trusses, a beautiful exhibition from Mr. Keynes took the first prize. Particularly noticeable were Madame Charles Wood, Madame Boutin, Général Jacqueminot,

Madame C. Crapelet, Madame Vigneron, Charles Lefebvre, Maurice Bernardin, Maréchal Souchet, a fine dark-shaded crimson; Madame Furtado, and Gloire de Vitry, the last very fine. Mr. Cant, who was second, had fine examples of Victor Verdier, Madame Vidot, Madame Furtado, Prince Camille de Rohan, Jules Margottin, John Hopper, Queen Victoria, Colonel de Rongemont, Général Jacqueminot, Madame Clemence Joigneaux, &c. From Mr. Fraser came John Hopper, Maréchal Vaillant, Impératrice Eugénie, Madame Vidot, Gloire de Santenay, and Madame Julie Daran, all of them fine. Mr. Fraser had a third prize, and the fourth was taken by Messrs. Paul & Son, in whose collection we noticed Duc de Rohan, very brilliant in colour; Louise Magnan, very pretty, nearly white, and Madame Vidot.

Class IV. was also for twenty-four kinds, single trusses. Mr. Keynes took the first prize with Senateur Vaisse, Madame Charles Crapelet, Souvenir de la Malmaison, very large; Triomphe de Rennes, Alpaide de Rotalier, Charles Lefebvre, Louise Peyronny, and Comte de Nanteuil, very large. Mr. Fraser, who was second, had also some excellent blooms, particularly Madame Vidot, Beauty of Waltham, and Devoniensis. Mr. Cant was third, and Mr. Clarke fourth.

Class V. was for Amateurs only, single trusses of forty-eight kinds. The first prize went to Mr. Hudge, Reed Hall, who had, among others, fine blooms of Sœur des Anges, Madame Bravy, Olivier Delhomme, Victor Verdier, George Prince, Caroline de Sansal, Queen Victoria, Gloire de Dijon, Louise Magnan, Niphotos, Madame Boll, President Lincoln, and La Ville de St. Denis. From Mr. Ingle, gardener to G. Round, Esq., Colchester, came also a good exhibition, in which we noticed Comtesse de Chabillant, Senateur Vaisse, Beauty of Waltham, Cloth of Gold, François Premier, and several others very good.

In Class VI., single trusses of twenty-four kinds, Mr. Ingle was first; Mr. Moffat, Easton Lodge, Dunmow, second; Mr. Hedge third; Mr. Exell, gardener to J. Hollingworth, Esq., and Mr. Sawkins, Hertford, equal fourth. In this class there were very good examples of General Washington, Charles Lefebvre, Jules Margottin, Madame Furtado, Louis XIV., Victor Verdier, and Louise Magnan.

Class VII., was for eighteen single trusses. In this Mr. R. B. Postans, of Brentwood, took the first prize with Triomphe de Caen, bright purplish scarlet; Senateur Vaisse, Jean Gonjon, Duc de Rohan, Madame Vidot, Maurice Bernardin, Vicomte Vigier, and Souvenir de la Malmaison, all of them fine. The Rev. V. Child, Little Easton, was second; Mr. Marlow, gardener to J. Wigan, Esq., Mortlake, and Mr. Cruckshank, gardener to W. J. Loyd, Esq., being equal third.

In Class VIII., for twelve trusses, Mr. Postans was again first; Mr. Marcham, Hanwell, second; and Mr. Smith, gardener to F. Moxon, Esq., Leyton, third.

Class IX., was for eighteen new Roses of 1863 and 1864, but these were generally not in the best condition to judge of. Pierre Notting, deep violet-shaded crimson; Rev. H. Dombraïn; Charlemagne, deep rose; Paul de la Meilleray, Maréchal Niel, Alpaide de Rotalier, Leopold, Premier, and Maréchal Souchet (Damaizin), rosy carmine, were the most noticeable of those in the collection of Messrs. Paul & Son, who took the first prize. Mr. Cant, who was second, had Sœur des Anges, a very beautiful pale rose, almost white; Maréchal Niel; George Paul, a fine bright red; and Madame Victor Verdier, all of them fine varieties. Mr. Fraser was third. Joseph Fiala, Paul de la Meilleray, Duchesse de Morny, and Madame Victor Verdier in this collection were fine. Mr. Francis was fourth; and in an excellent collection from Mr. Keynes, which unfortunately contained two blooms of Laurent Descourt, and was, therefore, disqualified, Maréchal Souchet (Guillot), was a fine, deep, velvety crimson. There were besides very good examples of Pierre Notting, and other kinds named above.

In Class X., twelve trusses of any new kinds of 1863, Messrs. Paul and Son were first with beautiful blooms of Lord Clyde; Mr. Cant second with the same kind.

In Class XI., twelve trusses of any kind, Mr. Cant was first with Devoniensis, most beautiful; Messrs. Paul & Son second with François Louvat, fine lilac-shaded crimson; Mr. Keynes third with Madame Charles Wood, very large; and Mr. Cattell fourth. Beautiful boxes of Charles Lefebvre, Senateur Vaisse, and John Hopper were shown by Mr. Francis and Mr. Cant.

Among yellow Roses shown in Class XII., the beautiful new yellow Tea Rose, Maréchal Niel, was conspicuous; and of others, Louise de Savoie, Cloth of Gold, Vicomtesse de Cazes, L'Enfant Trouvé, Narcisse, and Celine Forestier were well represented. The exhibitors were Messrs. Cant, Paul & Son, and Hedge, who took prizes in the order in which they are named.

Class XIII., for twelve Tea-scented and Noisette Roses, exhibited considerable sameness owing to the want of high-coloured flowers in these sections. Mr. Exell was first with good examples of Isabella Gray, Vicomtesse de Cazes, Triomphe de Rennes, Sollaterre, Madame Bravy, Comte de Paris, Niphotos, Madame Villermoz, and Gloire de Dijon. Mr. Ingle was second. In the corresponding class for Nurserymen, Messrs. Fraser, Cant, and Paul & Son were respectively first, second, and third.

In Class XV., single blooms of twelve kinds, Mr. Keynes, who was first, had beautiful examples of Devoniensis, Gloire de Santenay, Alpaide de Rotalier, Maurice Bernardin, Gloire de Vitry, and Madame C. Wood; Mr. Francis was second, and Mr. Cant third with good blooms of several of the above, Charles Lefebvre, Madame Furtado, and some others.

Vases of Roses, shown in the succeeding class, were almost identical,

March's stands being used by all the exhibitors, and in the first and second prize vases, the stem of the stand was twined round with *Lonicera arbo-rotundata*, the Roses at the base and in the top dish in each case, resting on Ferns. Mr. Ingle was first, Mr. Marlow second, and Mr. Bousley, Twyford Abbey, third, *Isoplexis gracilis* being employed by the last named in the top dish. In six bouquets of as many kinds, Mr. Keynes was first, Mr. E. P. Francis second, Mr. Hedger, third; and for Moss Roses, Messrs. Paul & Son were first, with, among others, the White Bath and the Crested very good.

Roses in pots were not in good condition. Messrs. Paul took Mr. Kell's prize for those in six-inch pots.

Of miscellaneous objects Mr. W. Paul sent a collection of Roses raised by him from seed, or introduced by him, consisting of *Glory and Beauty of Waltham*, *Cœur de Lion*, Lord Herbert, Prince de Joinville, Princess of Wales, Dr. Lindley, and Lord Macaulay, all different shades of crimson and scarlet; *Queen Victoria*, delicate pink; *Madame Emile Boyau*, a very promising light Hybrid Perpetual; and *Elizabeth Vigneron*, blue-shaded rose. Many of the above require no comment, their merits being already recognised. Messrs. Jackman sent numerous blooms of their beautiful new Clematises; and Messrs. Naylor, glass and table ornaments.

SYRINGING GRAPES.

I beg leave to differ very much from your correspondent, Mr. Whittle, respecting the syringing of fruiting Vines, unless called for by some unusual occurrence, as red spider, making its appearance; then I say by all means use the syringe freely for a few days until it is all washed off. My principal reason for not syringing is, that it is impossible to do so without leaving a mark on the berries from a deposit in the water, which quite spoils their appearance for exhibition or table, where it is necessary they should be perfection, not that it injures the Vines in any way, or does them any good, as is proved by the fine Grapes exhibited at our London shows, without ever having a drop of water thrown on them. I quite agree with his remarks on stopping. N. W. D. P.

COLOUR AND SOUND.

In all specimens of good colouring there is a key colour, and that colour predominates. In the historic pictures of the old masters that colour is usually crimson or violet, and these answer to C and B, root notes, especially C, in the musical scale. It is curious that Professor Sanderson, who was born blind, and had no conception of colour, said that he thought red must be like the sound of a trumpet.

On this connection of music and colour a well-known man of science some years ago wrote to us as follows:—

“Taking the seven colours of the rainbow as equivalent to the seven notes of the natural musical scale, the order will stand thus:—

Red.	Orange.	Yellow.	Green.	Blue.	Indigo.	Violet.
C.	D.	E.	F.	G.	A.	B.

The red here sounds the key colour of the prismatic series, and corresponds to C, the root note of the musical scale in the natural key, and both would of course be again repeated as the octave or eighth degree of the gamut. Red, then, must be just as prominent in well-conceived pictures as C in musical pieces composed in that key; and the remaining sounds and colours have corresponding functions in the two sciences.

“Every one knows that, for the convenience of musicians, the notes of the scale are both numbered and lettered—the first seven letters of the alphabet and cardinal numbers being used. Thus, in the key of A, the scale is numbered and lettered as follows:—

A.	B.	C.	D.	E.	F.	G.
1.	2.	3.	4.	5.	6.	7.

Now, it does not signify what note we may start from, for the constitution of every key is the same, and only differing in the pitch being high or low, as the case may be. The key of C, however, is chosen by musical men as a standard, and hence called the natural key. As such I shall adopt it in the present notice. The order will then be as in the following table, to which I also add the equivalent colours:—

C.	D.	E.	F.	G.	A.	B.	C. (octave*)
1.	2.	3.	4.	5.	6.	7.	8.
Red.	Orange.	Yellow.	Green.	Blue.	Indigo.	Violet.	Red.

“Now, in harmonising tunes composed in this key, four grand chords are employed—that is, four combinations are chosen out of these seven notes, and severally used when they

\* The first note, in effect, is repeated eight notes higher, and hence called the octave.

will apply as accompaniments to the notes of the subject or air. These chords, then, in letters, numbers, and colours being known, the scientific or artistic gardener may modify them, invert them or change their position, and alter the arrangement of their fundamental constituents at his own pleasure. The chords are as follows in their natural position:—

I.—THE COMMON CHORD OF C, RED.

Natural position.	First change.	Second change.
5. G, blue	1. C, red	3. E, yellow
3. E, yellow	5. G, blue	1. C, red
1. C, red	3. E, yellow	5. G, blue

II.—THE COMMON CHORD ON F.

Natural position.	First change.	Second change.
1. C, red	4. F, green	6. A, indigo
6. A, indigo	1. C, red	4. F, green
4. F, green	6. A, indigo	1. C, red

III.—COMMON CHORD ON G, BLUE.

Natural position.	First change.	Second change.
2. D, orange	5. G, blue	7. B, violet
7. B, violet	2. D, orange	5. G, blue
5. G, blue	7. B, violet	2. D, orange

“The fourth table may in the same manner be constructed on the key of F, green.”

Now all this was brought to memory by the wonderful Handel Festival just concluded at the Crystal Palace. It was objected that this Palace is not an appropriate place for oratorios, but the retort was a silencer—“Music and flowers are associated with our ideas of Paradise,” and a lady added, “I never hear the trumpet notes in ‘Let the bright Seraphim,’ without my eye resting unconsciously on some very bright colour.”

There is, therefore, in cultivated minds an association of colour with sound—a harmony between certain tints and certain notes; they may be, and are enjoyed together at the musical celebrations in the Crystal Palace; and the combination is not without applicability even to the gardener. “Optics associated with Acoustics,” might form the theme for an additional chapter in “The Connection of the Physical Sciences.”

VINE CULTURE.

(Continued from Vol. VIII., page 411.)

If all has gone on well, the Grapes will be done stoning by this time; all berries that are not likely to swell off kindly should be cut away at once; the temperature may be increased a little, and a moist atmosphere maintained by frequently syringing the floor and paths of the house. If the stopping of the Vines has been carried out according to the directions given at page 410, there will be sufficient leaves left on the Vine for all purposes. All laterals that make their appearance should, therefore, be pinched out as soon as they are produced, in order that the whole force of the roots may be directed towards the Vine for the purpose of giving it sufficient strength to mature its present crop, and to provide for the crop of the following year. If the laterals are allowed to extend beyond the limits before described, much of the strength of the Vine will be wasted. From the time the Grapes have finished stoning till they begin to colour, they should be well supplied with water two or three times a-week, in such a dry season as the present, and when water is given it should not be with a sparing hand. To give a Vine-border a small quantity of water is worse than useless, better withhold it entirely. My plan is to sprinkle a little guano over the border, on this the water is poured, not by scores of potfuls at a time, but by hundreds. I generally put five or six men on with two pots each at one watering, for a border 35 feet by 10 or 15 feet wide I use a tank of water holding about four thousand gallons. Between the time of stoning and colouring I generally give my borders about four such soakings as this, using a little guano each time. Besides this, they are watered two or three times weekly, as stated above. From the time of stoning till the Grapes begin to colour, avoid sudden changes of atmosphere as much as possible. Give air as early in the morning as possible, by opening the top lights a little to allow the foul air to escape, and to dry the condensed steam that settles on the foliage during the night. If this is neglected the foliage is often burned up by the sun.

As a preventive is always better than a cure, paint the whole of the hot-water pipes over with a thick coating of sulphur. If this is mixed with a little soft soap it will stick to the pipes

better, and will not be so easily washed off by the syringe. Smear the walls and every available place in the house with the sulphur brush; this will prevent the appearance of two of the Grape-grower's worst enemies—namely, mildew and red spider. As soon as the greater part of the berries have partly changed colour give all the air possible night and day, this will help to impart a fine flavour, and assist the colouring process very much. Fire heat should not be dispensed with until the Grapes have finished colouring, and in damp or dull weather they should have the benefit when ripe of a little artificial warmth to keep them dry, and to cause them to retain a sweet and brisk flavour. After the crop of fruit has been all gathered give the borders another good soaking with water, using a little guano as before. Give abundance of air by opening all the lights as wide as possible, but by no means take off the top of the house. I mention this particularly, as I know it is often done with the idea of ripening the wood.

If the top lights are taken off the foliage cannot possibly be preserved, it is blown about against the wires by the wind, and by that means becomes very much mutilated. Its decay is, therefore, brought on much earlier than it ought to be, and the Vine suffers very much in consequence of losing a large portion of its foliage before its proper time, or before it has fulfilled its natural functions of storing the Vine with food as long as the sap was in circulation.

I am very glad my previous article is likely to provoke a little discussion on the cultivation of the Vine. This is what I was anxious to promote. I did not wish it to appear that the plan described and adopted by me was better than that of any other Grape-grower, personally knowing as I do many of our celebrated Grape-growers. I was in hopes that a description of the simple plan pursued with a fair share of success by myself, would be the means of inducing some of the more successful growers to favour the numerous readers of THE JOURNAL OF HORTICULTURE with their system of cultivating the Vine. The Editors would, I am sure, gladly open these pages to all who would communicate their ideas on the cultivation of the Vine, or any other subject connected with practical gardening.

Mr. Whittle is quite right in thinking that I did not allude to the cultivation of Vines in pots in my last article; that will form the subject of another communication. I fear Mr. Whittle's views will not be very well received with regard to stopping the Vine. In the first place, Mr. Whittle says he would not stop at all until the fruit were set. The evil to be expected in this case would be this: By the time the fruit had set the shoot would have, perhaps, six or more leaves above the fruit-joint, and would have grown 18 inches or 2 feet above that joint. This being the case, it is natural to suppose that it will have very much exhausted the Vine, and a great portion of the strength of the Vine, which would have been directed into the bunches had the shoot been stopped at the proper time is thereby lost, and the size of bunch and berry very much reduced. Then, again, to cut off a strong shoot when it is nearly the size of one's finger just above the bunch, must cause a very sudden check to the whole system of the Vine; and I must, until I am further convinced, beg most respectfully to differ in opinion from Mr. Whittle with regard to stopping. I consider that when the shoot is stopped at the joint from which the bunch grows, and that when the bunch is just formed, a greater quantity of sap flows to the point than the bunch and one leaf can make use of. In my opinion the two leaves above the bunch are necessary to absorb the superfluity of sap until the fruit is set, when the bunch can take without injury all the sap that can be spared by the Vine, and the atmospheric food supplied by the foliage above the bunch as well.

Mr. Whittle says he differs with me *in toto*, as to syringing after the Grapes are set, and that no one would think of syringing whilst they were in flower. Mr. Whittle may, perhaps, think me mad when I tell him that for many kinds of Grapes that is the most proper time to syringe them for the purpose of causing them to set freely, especially in the case of Lady Downe's and Muscat of Alexandria. I admit the treatment adopted by Mr. Whittle was quite right with regard to the Vines he described the first year he undertook the management of them; but if he would subject them to the same treatment on the two following seasons—namely, to syringe the Vines, fruit and all, up to the time of the berries changing colour, the water he is using must be clear indeed. Lastly, Mr. Whittle must allow me to differ very much in opinion from him with respect to aiding fertilisation. He may have been fortunate this season, and nature may have done much for him without his aid, but he may find another time, when other natural

agencies are not at work in his favour, that nature could be very much assisted by art; but more of this anon. In the meantime I hope Mr. Whittle will favour us more fully with his views on the cultivation of the Vine.—J. WILLS.

(To be continued.)

#### PASSION-FLOWERS NOT BLOOMING.

"E. M." has two Passion-Flowers (*P. cœrulea*) trained against a south wall. They have grown about 20 feet, and were shifted last year into tubs 15 inches in diameter. Should "E. M." give liquid manure to induce them to bloom which hitherto they have not done, or what treatment would be most likely to lead to that result?

[You may give manure water and plenty of it with great propriety. If the wood of last year was well ripened, almost every shoot that comes from it this season, will give you plenty of bloom. Nothing is easier managed afterwards, you have only to cut back these flowering shoots in spring to two or three buds, and these will throw out the summer flowering-shoots next year.]

#### PEACHES AND GRAPES SWELLING SLOWLY.

THE Peaches in my orchard-house are at a stand-still, they are now just the size they were a month or five weeks ago. They appear to be quite hidebound and do not swell at all. The stone is getting quite hard, the kernel looks perfect, and the trees are quite healthy. I turned one out of the pot to see if anything was amiss with the roots, they were looking well and not at all dry.

I also have a house of Muscat Grapes that do not stone as they ought.—F. K.

[The Peaches are most likely all right, you must give them time, they stand still a long while at the stouing period.

As with the Grapes you must either have too many on the Vines, or the roots are in a soil they do not like.]

#### NEW BOOK.

*Hardy Ferns: how I collected and cultivated them.* By NONA BELLAIRS. London: Smith, Elder & Co.

"ONE of Nature's simplest pages—I had almost said one of its prettiest—is that which I have made the subject of this small volume.

"The common hedge-row, the old wall, the rock by the sea-coast, and the wild moor, provide for us the little kingdom of Ferns, whose peculiar habits of life and growth form a pleasant study for our hours of recreation.

"We should begin our collection from those which grow near our own homes, bringing first one root, then another, finding out to what family they belong, what soil suits them, and their distinctive characters and habits.

"The cottage garden may always have room for its fernery; a few plants by the old well, by the wicket-gate, will supply subjects for thought and study; helping to turn the child's heart to the love of the pure and beautiful instead of the vile and the debasing."

To lead to and to aid in effecting the good thus depicted, the authoress has laboured attractively and ably. Our readers will recognise in the volume contributions that have been admired in our pages, but they are now collected in a form so tasteful that no lover of Ferns but will be glad to possess the volume.

#### ROYAL HORTICULTURAL SOCIETY.—JUNE 27.

FLORAL COMMITTEE.—Although the subjects for examination were not quite so numerous on this occasion, there were several novelties and plants of considerable interest. Mr. Rust, gardener to the Earl of Abergavenny, sent a collection of cut *Antirrhinums* of no merit; also a seedling *Myosotis*, with dark blue flowers. Mr. Herbst, Kew, sent a seedling *Amaryllis grandis*, with dark scarlet flowers, of good substance, but wanting in form—not nearly equal to *Amaryllis Unique*. Mr. Williams, Holloway, sent *Statiee pulverula*, also a nice specimen of the beautiful New Zealand Fern, *Toodea superba*, which had received a first-class certificate at a former meeting; *Lilium* species from Japan, small bright yellow spotted flowers—second-class certificate; *Trichopilia picta*—second-class certificate; *Lilium* species, semi-double, dull red, spotted flowers; *Phalenopsis amethystina*, very small and insignificant; a cut specimen of *Odontoglossum laeve*, the flowers with remarkably narrow segments.

Mr. Gill, Bradfield, exhibited a white seedling *Verbena Beauty of England*, a plant of great merit; the truss very large, the flowers that and smooth, very pure white; a first-rate *Verbena*. It was awarded a first-class certificate. J. Day, Esq., Tottenham, exhibited a new *Orehid*, *Palumbina candida*. This curious plant seemed much to interest *Orehid* amateurs. It was awarded a first-class certificate. Also, *Aerides Lindleyana*, very beautiful—first-class certificate; *Polychilus cornu-cervi*, well named from the flower-spike while in bud resembling a stag's horn—first-class certificate; *Promenau citrina*, was awarded a first-class certificate in May; *Cypripedium*, new species. A special certificate was awarded to Mr. Day's general and beautiful collection. Messrs. Jackman, Woking, sent three seedling *Clematises*. They were *Prince of Wales*, a very fine, large, dark purple flower, the petals striped with red, very distinct—first-class certificate; *C. rubella*, smaller flower, but equally good in form, with more red mixed with the purple, distinct and beautiful—first-class certificate; *C. Princess of Wales*, a paler-coloured flower, not so perfect in form nor so full. H. Walker, Esq., Horsey, sent *Phytolacca glauca*, a new, distinct, and handsome Fern—first-class certificate; and *Polystichum* sp., a half-hardy Fern—first-class certificate. Mr. Wimsor exhibited seedling *Zonale Pelargonium Pink Perfection*. Mr. George Smith, Horsey, showed seedling *Zonale Pelargonium Chieftain*, a very bright orange scarlet flower, of excellent form and good truss—first-class certificate; *Zonale Pelargonium Christabel*, pure white, with small salmon centre—this will probably improve as the season advances; *Zonale Pelargonium Alpha*, something like the first in colour, but not so good in form; *Zonale Pelargonium (Nosegay) La Grande*, a very fine truss, distinct in colour—carmine crimson; this will be a very useful plant for hedging, both on account of its bright flowers and general habit. Mr. Townsend, Horsey, sent four seedling *Clematises*. Lady Georgina Fuller was the best, a large pale lilac flower, very similar to *Clematis lanuginosa*, for which it was taken; *Souvenir de Cardinal Wiseman*, dark purple flowers; *Rev. Canon Oakley*, paler in colour; and *C. Hollandii*. These were deficient in form, and not equal to the hybrids lately sent out. He also sent *Thujopsis dolabrata variegata*—this plant was awarded the silver Banksian medal in 1861; and *Convolvularia variegata*, an old and well-known plant. Mr. Veitch exhibited another of Mr. Dominy's hybrid *Orechids*, *Cattleya quinquecolor*; the parents were *C. Acklandia* and *Forbesii*; a very handsome variety. It was awarded a first-class certificate. Mr. Mackintosh sent *Solanum vesicatum*, a new out-of-door ornamental plant very useful—second-class certificate. Mr. Holland, gardener to R. W. Venke, Esq., sent seedling *Zonale Pelargonium*, a variegated form, not equal to the *Comtesse of Warwick*; *Asplenium trichomanes Harrovi*, a very beautiful dwarf-habited Fern—first-class certificate; *Cyclamen Peckianum*, a very useful plant, an evergreen, and continuing to produce its rosy pink flowers all the year through; one of the plants exhibited was brought before the Committee three years ago, and has continued in flower ever since—first-class certificate.

Mr. Wills, gardener to Sir P. De Grey Egerton, Bart., sent *Mimulus cupreus* improved, but the improvement was not discovered by the Committee. The Rev. W. H. Girdlestone, Ryde, Isle of Wight, sent *Athyrium Filix-femina fissidens irregularis*, a variety discovered last year in the Highlands, a very distinct and beautiful Fern—first-class certificate. Mr. Batley, Rugby, contributed twelve seedling *Verbenas*, some of them pretty flowers, but not distinct or new. Mr. Fleming, Cliveden, sent cut specimens of several very beautiful seedling *Zonale Pelargoniums*, *Nosegays* and others. It was requested that these should be seen again; when in better condition some of them will take a good position. Mr. Wm. Paul, Waltham Cross, sent *Zonale Pelargoniums (Nosegays)*, *Duchess*, light scarlet, dwarf, compact habit, large truss, which was awarded a first-class certificate; *Mrs. Wm. Paul*, not a *Nosegay*, pale rose, good truss, but not equal to *Beante de Surennes*; also, *Indian Yellow Nosegay*, distinct in colour, very useful—first-class certificate; also, *Donald Beaton*, too coarse for a *Nosegay*, and not possessing the good qualities of the other section of *Zonales*; and *Nosegay Waltham Seedling*. Mr. W. Paul also sent four boxes of cut *Roses*, consisting chiefly of his own seedlings, which have all been noticed before. *Lord Macaulay* appears to be the best, but this *Rose* too much resembles *Charles Lefebvre*, they are both very fine *Roses*. Mr. Eyles sent from the Society's Gardens, a seedling *Gladiolus*, collected by Mr. Cooper; also a very small *Lilium*, from seed, from Dr. Regel, and a cut specimen of *Amaryllis reticulata*.

FRUIT COMMITTEE.—Mr. John Lee, in the chair. Mr. Tillery, of Welbeck, sent a tray of magnificent British Queen *Strawberries*, the last of the forced *Strawberries* of the season. They were the admiration of the Committee, and of all who saw them, both for their splendid appearance and their rich flavour, which was, indeed, that of a Pine. Mr. John Wills, gardener to Sir Philip M. De Grey Egerton, Bart., Oulton Park, sent a seedling *Melon*, which the Committee named *Oulton Park Hybrid*. It is of medium size, round, and with a salmon-coloured flesh, not quite a scarlet flesh. The flesh is wonderfully tender and melting, and very rich in flavour. This was considered a great acquisition, and received a first-class certificate. Mr. Thomas Ingram, of Frogmore, sent a seedling *Cherry*, called *Frogmore Early Bigarreau*. It is of large size, almost white where shaded, and with a brilliant crimson cheek where exposed to the sun. The flesh is remarkably tender and richly flavoured. This also received a first-class certificate. Mr. Cutbush, of Highgate, sent a branch of a seedling *Strawberry*, remarkable for its lateness, the fruit being not

more than the size of peas, while the *Prince of Wales* was fully ripe. Mr. Cutbush intimated his intention of bringing it forward when ripe at a subsequent meeting.

SCIENTIFIC MEETING, Lord Henry Gordon Lennox, M.P., in the chair.—The Chairman announced that J. M. Strachan, Esq., had made a present of a long list of valuable books for the library, which the Society was trying to collect, and added that further donations would be very acceptable. A bequest of books had likewise been made by one whose name commanded their respect and esteem, Sir Joseph Paxton, who had stood by the Society through good report, and, it might almost be said, through evil report, and he the Chairman asked the meeting to express in their vote of thanks to Lady Paxton, the deep regret which they felt for the loss which she and the Society had sustained. The vote having been unanimously passed, the Rev. Mr. Dix, and Mr. G. F. Wilson, the Chairmen of the Floral and Fruit Committees, read over the list of awards, and briefly commented on some of the objects exhibited.

Mr. Bateman, in the unavoidable absence of the Rev. Mr. Berkeley, offered some observations on the plants exhibited. Among those which came under notice were *Clematises*, especially those raised by Messrs. Jackman, of Woking, offering in the flowers purplish metallic tints like those of some *Ipomceas*, and being quite a new race, and the best for out-door purposes. A plant of *Jackmanni* on a south wall in his own garden in North Staffordshire, was growing vigorously, and he had no doubt would soon cover the wall, which was 6 feet high, with an indefinite number of flowers, quite as fine as those exhibited. Between Messrs. Jackman's varieties and those from another exhibitor, there was no discoverable difference. *Clematis lanuginosa*, another hardy kind, would have a fine effect when planted along with *Jackmanni*, so as to combine the blue of the former with the deep purple tints of the latter. A *Viburnum* discovered by Mr. Fortune was stated to be perfectly distinct from the common *Snowball Tree (Viburnum opulus)*, the leaves being entire and the flowers of a purer white. It was found to be perfectly hardy in the climate of North Staffordshire, but would, doubtless, be finer in more favoured localities. Mr. Bateman next introduced to the meeting specimens of purple and golden foliage. The purple foliage was that of three hardy trees, the *Purple Nut*, the *Purple Beech*, and the *Black Maple*, which, he said, deserved to be well known. It was introduced by some foreign nurseryman from Japan, and has small, cut, reddish purple leaves, transparent when seen with their proper background the sun. Contrasting the richer tints with light ones, what could be better than *Golden Yew*? Other plants offering such tints were the *Golden Holly*, *Golden Ivy*, *Lonicera arctocaulata*, and one of the most effective of all, the *Golden Bramble*. The variegated *Acer negundo*, and many more, might be employed, and these, he it remembered, were not hothouse plants, but hardy trees, which all might enjoy. Doubtless, if attention were turned in that direction, there would be no lack of suitable materials. Mr. Bateman then pointed out *Kalmias* as suitable plants for enduring the heated atmosphere of crowded rooms at this season, and related an anecdote of *Linnaeus* being cured of an attack of the gout on the return of his pupil Kalm, after whom the genus was named, with a rich collection of *Kalmias*, and so-called American plants. Attention was then directed to a singular plant, named by Professor Reichenbach, *Luisia Psyche*, having the flowers close to the stems, and presenting a striking similarity to some insects. It was mentioned because the genus had been said to consist of none but uninteresting plants. Mr. Bateman exhibiting a *Trichopilia*, which he had bought at one of Stevens's sales, and stated it had been named by Professor Reichenbach *T. turralba*, being found at the foot of a high mountain capped with snow, so as to resemble a white tower; but since he (Mr. Bateman) had come into the room he had seen another and better variety of the same *Trichopilia*, shown by Mr. Williams, called *picata*, under which name it had been figured in "L'Illustration Horticole," by M. Lemaire. A summer-flowering variety of *Lycaste Skinneri*, exhibited by Mr. Veitch, was stated to have smaller and neater flowers than that commonly cultivated, and *Govenia liliacea* (?) was pointed out as being useful for bouquets. In reference to *Dendrobium Pierardi*, which was exhibited by Mr. Stone, gardener to Mr. Day, Mr. Bateman remarked that though it had been known for fifty years, it still held its ground, and no collection was complete without it.

Major R. Trevor Clarke then offered some observations on the objects which he had brought to the meeting. Among them was a tall stem of *Lilium testaceum*, otherwise excelsum, from his garden in Northamptonshire, where he had cultivated it for years as a perfectly hardy plant, hardier than the common *Lily*. It had the unjust reputation of being somewhat tender. There was also a specimen of a climbing parasitical *Aroid* of the tropics, of which he did not recollect the trivial name, but the plant was figured by Dr. Wallich. For its generic name the choice lay between *Philodendron*, *Scindapsus*, *Pothos*, and *Monstera*. Its curious ripe fruits were on the table, and were said to be eatable, particularly that of the larger sort, called *deliciousa*, and to be convertible into a cooling drink. It had an ancient jungle-like tropical smell, and would probably give to cream ice a sensational flavour. The species now exhibited had a quality which would prevent it from being a practicable fruit for European palates, being filled with the same irritating spicule which existed in the hep of the *Briar*. He had also brought two inconspicuous objects—a shabby-looking garden *Stock*, and a spike of *Gladiolus* in a bottle, with its three poor

terminal flowers left blooming alone. The one was a seedling from a curious old plant, *Mathiola fenestralis*, crossed with the common garden Stock, *M. incana*, but it had not yet flowered; the other was the produce of one of the handsome rose-coloured Gladioli, crossed with the brilliant scarlet African species, *Gladiolus cardinalis*. It was interesting in this case to be able to confirm an observation made by the late Dean of Manchester, to the effect that the splendid colours of cardinals were not fully transmitted to the offspring, which the Dean attributed to the interbreeding having taken place in a cooler climate. The influence of cardinals, however, had produced a favourable effect in the present instance. The seedlings appeared to be early summer flowers, with the large and handsome habit of the autumnals. The two objects in question were authentic hybrids between two known plants, and he (Major Clarke) urged his horticultural brethren to lose no opportunity of bringing such instances to the Tuesday meetings. No person who had not really worked at scientific subjects could have a notion how valuable such contributions were—valuable because they were facts. A cross which might seem comparatively unimportant, being authentic, might supply a link in the chain of the evidences in an important investigation. "I call upon you," said Major Clarke, "to bring to these meetings objects of scientific interest of every kind, whether the results of individual experiment, or gleanings from hill or valley, river or forest, illustrations of nature's wild and wondrous changes. Such objects are too rarely seen on the tables of the Horticultural Society. Why is this? I believe because the horticultural mind, improved as it is in the present day, has not been sufficiently turned in this direction. In the early part of the season the observation was made by my friend, Mr. Bateman, that there was a lack of horticulturists at the present day. Now, this remark was, I believe, utterly misunderstood by some of his auditors or readers. We have clever gardeners, both in the nursery profession, and in the gardens of our country gentlemen, so clever that no country on the face of the earth can find their equal; but the man who will devote time and

money during a lifetime to legitimate horticultural experiment, both within and without this Society, who will from time to time take the trouble to produce his results in this room, who will initiate and perfect revolutions in our art, who will raise generation after generation of the fruits of the earth, season by season, improving and improving—this man will have deserved well of his fellows. These are the men alluded to by my friend, Mr. Bateman, and I believe with him that they are rare. But such men are rising, must be rising, in this almost over-intellectual age."

Mr. Bateman prefaced his lecture on *Rafflesia Arnoldi*, by remarking that when any one gave a lecture, or put his name to a paper read before any learned society, it was generally supposed that there was some fresh information to communicate, or progress to report, but he had nothing to add to what had been previously known; his object was simply to recall attention to what was the wonder of botanists—a plant of which an account was published in the "Transactions" of the Linnean Society, in 1820, and which was called *Rafflesia Arnoldi*. The generic name was given in compliment to Sir Stamford Raffles, and the specific name was in honour of its discoverer. Dr. Arnold, who was attached to Sir Stamford Raffles's mission to Sumatra, and who, about a fortnight after its discovery, fell a victim to fever caught in the woods where it grew. The biographer of this plant, the celebrated Brown, who wrote an account of it in the "Linnean Transactions," had also passed away. It appears that after having resided awhile in Sumatra, Dr. Arnold had ventured some way into the woods, when one of the Malay servants came running to him with wonder in his eyes, and said, "Come with me, Sir, come, a flower, very large, beautiful! wonderful!" He immediately went with the man about 100 yards into the jungle. The rest of the party hastened on, and here, growing apparently on a stem, was a flower a yard across. The whole flower was of very thick substance, the petals and nectary being in but few places less than a quarter of an inch thick, and in some places three-quarters of an inch; the substance of

*Rafflesia Arnoldi* with bud, growing on the stem of a *Cissus*.

it was very succulent. When Dr. Arnold first saw it, a swarm of flies was hovering over the mouth of the nectary, and apparently laying their eggs in the substance of it. It had precisely the smell of tainted beef. The centre of the nectarium gave rise to a large pistil, at the top of which were about twenty processes, somewhat curved and sharp at the end, resembling a cow's horn. Now for the dimensions, which are the most astonishing part of the flower. It measured a full yard across; the petals which were sub-rotund, being 12 inches from the base to the apex, and it being about a foot from the insertion of the one petal to the opposite one. The nectarium was estimated to hold twelve pints, and the weight was about 15 lbs. In order to ensure the size being accurately taken, four large sheets of paper were pinned together, and cut to the precise size of the flower. The soil where it was found was very rich, and covered with the excrements of animals. A guide from the interior of the country informed Dr. Arnold that such flowers were rare, but that he had seen several, and that the natives called them *Krübü*. What was this wonderful plant? Was it a fungus or an ordinary flowering plant? Brown with his usual sagacity decided that it was not a fungus but a true root parasite; and Mr. Bateman then explained at some length the distinction between parasites and epiphytes. Dr. Arnold had thought that the stem on which the flower was produced, was the root or stem of the *Rafflesia*, but it was the stem of a *Cissus* or Vine which wound round the trunk of a tropical tree. According to Brown, it takes three months from the first appearance of the bud to the full expansion of the flower, and the latter appears but once a-year, at the conclusion of the rainy season. The plant "has no stem of its own, but is parasitic on the roots and stems of a ligneous species of *Cissus* where it appears to take its origin in some crack or hollow of the stem, and soon shows itself in the form of a round knob," at first like an egg, then resembling a Drumhead Cabbage, and finally becoming a flower such as represented and described. It was not enough, added Mr. Bateman, to see a flower

represented in that room, but it was an object of natural ambition to have the plant. Mr. Loudon, when he drew a plan for the Birmingham Botanic Garden, had a tropical-house in the middle of the garden in which he hoped *Rafflesia Arnoldi* would succeed, but thirty years had elapsed and it was not yet in the country, though it ought to be in the stoves of Kew. He had no doubt it would be flowered in this country, but whether such a result would be obtained in the lifetime of the present generation of horticulturists he could not venture to say, unless the Chairman would use his parliamentary influence to induce the Government to take some steps in the matter. It appeared from an article in a Belgian periodical, that *Rafflesia* had been flowered in Java. The article stated that the *Rafflesia Arnoldi* "is parasitic on the roots of certain species of *Cissus* in the isles near the Sunda Strait, especially those of *Cissus scariosa*. M. Teysmann has tried, in the garden of Buitenzorg, in the isle of Java, to sow the plant which produces these gigantic flowers on the roots of *Cissus*, after having made an incision to divide the bark. The experiment has been perfectly successful, and at the end of eighteen months, M. Teysmann has had the satisfaction of seeing many flower-buds of *Rafflesia* burst from the roots, whose size varied from that of a Pea to that of a middle-sized Apple. From the observations which the Dutch gardener has had an opportunity of making on spontaneous *Rafflesia*, these buds will require a year or more before expanding the flowers, which are frequently not less than a metre in diameter. It has also established this singular fact, that the parasites spring some distance above or below the point at which the seeds were inserted. We may then hope to obtain in a cultivated state this remarkable vegetable." Mr. Bateman concluded by urging all who had friends in Java, to take steps to send home this remarkable plant; and moved a vote of thanks to the Chairman, who in returning thanks expressed the gratification which he felt in attending the Society's meetings whenever it was possible for him to do so.

THE MODERN PEACH-PRUNER.—No. 12.

LONG PRUNING.

THERE are various methods of pruning the Peach which can be classed under the head of "long;" but it is unnecessary here to illustrate more than one, which may be taken as a good specimen of this method. It is not more complicated in practice than the others, which are founded on the annual supply of young branches.

In this method the shoots spring from spurs which are calculated to last several years, and which are renewed whenever a new shoot springs conveniently from the base of the spur. A good succession of young wood is obtainable in this way.

All modern experience tends to show that systems founded on any considerable annual cutting-out of branches, however small these branches, must end in causing disease in the Peach tree. There is not, in reality, any good reason for this dangerous practice, which has already caused so much less; far

from this, the day seems at hand when leading branches will not be shortened at all, and the chief pruning of the tree will be effected by the summer-stopping of the shoots, allowing a comparatively small amount of regulation for the winter season.

When these ideas are fully carried out, the difficulty of Peach pruning will become small, and theory and practice will agree more fully together.

It is necessary now to go back a little, and remember that our young tree is supposed to have made a certain growth during the summer next after its being planted. Many pruners, at the winter season, shorten this growth made by the leading branches by one-third; the reason they give is, that the lowest third part of each branch frequently fails to develop its buds. This is, however, but a visionary fear, if the roots do their duty.

Fig. 11.—Third Summer Pruning.

Fig. 12.—Winter Pruning.

The next summer all the branches will extend freely, and the buds upon them will begin to develop themselves. The buds situated on the lowest third portion of each leading branch not receiving, especially if placed on the under side, much sap, will generally not extend much, and if the season be very favourable, some will become converted into cluster-spurs (class 5). These must, therefore, be retained untouched. Their character is discernible by May. Should they extend more freely they will pass out of class 5, and become rather slender shoots, and should not be stopped at all, not being in a position to become gross shoots (class 4). The buds situated on the central third portion of each branch will extend freely, and be

the principal fruit-bearers of classes 2 and 3. They should be stopped at 12 inches as soon as they have made 15 inches of growth, and be lightly tied-in during the season of growth, at regular intervals, and at nearly the same angle as the branch. The buds situated on the upper third portion of the branch should be treated in the same manner; and should any exhibit the appearance of becoming gross shoots, of class 4, they should be cut down at once to two eyes, from which one new shoot is to be selected (the best-placed, and the weakest) to fill up the vacant place. This will be a shoot of a valueless character, long between the joints, and of class 1; but it cannot be avoided.

Fig. 13.—Fourth Summer Pruning.

Fig. 14.—Fourth Winter Pruning.

The extension, or new growth, of each leading branch must be allowed to develop freely. Care must be taken to guide these branches in the proper direction, by means of light rods, and none of them should ever be lowered into the place it is destined eventually to fill, until it be well constituted, and in good balance with the corresponding branch of the other side. This is done by raising or depressing, according to circumstances. As no fruit is expected at this stage, blossom-buds may be rubbed off. Should any of the wood-buds be seen to be double, and to put forth two shoots, some little discernment may here be required to select the proper one, and to do so at the right time. Passing over the shoots of the lowest third of each branch, which are not troublesome, of those placed higher up the shoots nearest to the wall must be selected, and the outer ones removed, whether on the upper or lower sides of the branch. But, on the upper third portion, which receives abundant sap, all the weaker shoots should be selected for fruit-bearers, no matter where placed.

At the winter pruning of this the second year, should any cluster-spurs appear, one or two may be selected to bear the third season's fruit—that is, if it be so desired, because the

tree is yet very young to bear. All the other shoots should now be cut back to two good eyes. The leading branches in this style of pruning are now shortened by, say, one-fifth. To shorten more would be to throw the tree into inconveniently long lateral growth, requiring much interval between the branches. Of course, this interval varies with the style of pruning. Twenty inches is considered a moderate interval.

At the spring of the ensuing, or third season, the tree will have acquired certain proportions and form, and the shoots shortened last winter to two eyes will each speedily develop two new shoots, which shoots must now be carefully attended to, as destined to bear a moderate crop of fruit in the fourth season. We come thus to consider the branches and shoots as they appear at the third season.

The two shoots during this summer will gradually assume the appearance indicated in *fig. 11*. They are there named respectively *a* and *b*, as being the two original shoots proceeding from the spur *e*. If we keep to this nomenclature it will avoid confusion. No doubt the term "spur" is the most appropriate here, and has been received as such before by reviewers of cordon training. Spur is the correct rendering of the

synonymous continental word, and it certainly is produced by manipulation. Both shoots will be allowed to extend to 15 inches, and be stopped back to about 12 inches. At Montreuil about 14 inches is the general rule.

Many pruners abjure summer stopping altogether, which is a great error, and the cause of overgrowth and weakness in the tree. The winter shortening is immense and needless, because it is well known that the buds of the lower portion of each shoot can be readily distinguished in June, and a good guess then made as to their quality. If the lower buds be then prominent, and well established, what need can there be for any superfluous length of shoot beyond them? But, let us suppose *a* and *b* to make a good summer growth, and to have been stopped at 12 inches, as seen in *fig. 11*, and then to have made an additional second growth, which is only of use so far as it occupies the superabundant sap. During the season they will have been secured to the wall, avoiding enclosing any leaves, at the proper angle, and if weak it is proper to raise them somewhat more. At the winter pruning, when the leaves have dropped, they will look much like *fig. 11*. *e* Represents the original shoot, now called a spur.

It will now be proper to consider which shoot should be preserved long for fruit, and which cut back for a replacing-shoot. In *fig. 12* it is supposed that *b* has been found, by reason of its groups of triple buds, to be the best, and therefore it is cut down to above the second group of triple buds. Many pruners, however, would have left it half as long again. Some retain thereby space for a couple of fruit. This may be done when there is generally little fruit on the tree, or if the tree have few shoots. *a* Is cut down to two good wood-buds for a succession; the long shoot *b* is attached closely to the wall at rather an acute angle with the branch. The spur *e* continues to preserve its original form. These simple operations complete the year's work; great care having been taken, by syringing copiously, &c., the leaves during the summer, so as to keep down insects and favour growth. Practical Peach-pruners, such as Mr. Radclyffe, continually tell us this.

At the fourth summer, in *fig. 13* we see that the original shoots *a* and *b* are still the basis of the work in hand. *a* From its two wood-buds puts forth two summer shoots *c* and *d*, which are likewise stopped at 12 inches, and make a second growth. *b* Now bears a fruit at *r*, and the wood-bud accompanying the fruit extends a little, and is pinched in at three or four leaves. The terminal group sends forth another shoot from its central bud, and this is also pinched to three leaves. These two small shoots are amply sufficient to attract sap to the fruit below them, and this is their use. It will be observed that the fruit grows in this case on the lowest triple group, which is always the best to select. Should the shoot *b* have been laid in at much greater length than here shown, and disbudbing the intervening buds be practised (as so many do, some leaving only the bud accompanying the fruit, and another at the base to succeed), then it can only be considered an unnatural and useless custom. Moreover, some of the very best practical pruners agree that it is not proper to depend on the same shoot to bear fruit and to produce a replacing-shoot for the next season. It cannot be depended on, and requires far more attention in bending the shoot at just the proper time than the present plan. If this bending down of the shoot is omitted it will be blind the following year. The new shoots *c* and *d* are treated as before described, and if neatly secured to the wall will not present any confused or crowded appearance.

At the fourth winter pruning either of the shoots *c* and *d* are selected according to their character. Supposing *d*, the lower shoot, to be selected as the fruit-bearer, it is cut above the second or third group of buds as before; *c*, the upper shoot, then becomes that destined to produce the two new succession-shoots, and is accordingly cut back to two wood-buds. The upper portion of the original spur *e*, together with the whole of the shoot *b*, are now cut away as smoothly as possible, leaving the whole as it appears in *fig. 14*. By this time one or more buds will have appeared at the base of original spur *e*, and these if developed will form the basis of future work. Should several appear, one at least should be closely pinched in, so as to form a cluster-spur, and thereby increase the chance of fruit.

There are several other ways of managing the shoots, but none better than this one, nor in reality more simple. Some manage to work with alternate shoots. Others dispense even with this, and are content with single ones. Much overlying of shoot and branch and considerable winter amputations are

the consequences. Long pruning on the whole wastes the vitality of the tree by producing much needless wood. All recent experience points to a modification of this system, which shall form my next subject.—T. BRÉHAUT, *Richmond House, Guernsey.*

## THE LATE DUKE OF DEVONSHIRE AND SIR JOSEPH PAXTON.

ABOUT twenty years ago, by the direction of the late Duke of Devonshire, I copied the following from the original in his Grace's handwriting:—

"Joseph Paxton was born the 3rd of August, 1803. I made his acquaintance at the Horticultural Society's Garden at Chiswick, where he was placed in 1823. He was chiefly employed then in training the creepers and newly introduced plants on the walls there, which first excited my attention; and being in want of a gardener at Chatsworth, I asked Mr. Sabine, who was then at the head of the establishment, whether he thought that young man would do? He said, 'Young and untried,' but spoke so favourably that I had no doubt.

"The young man had made a large lake in 1822 at Sir Gregory Page Turner's place near Woburn. He came to Chatsworth in 1826. You shall have it in his own words: 'I left London by the Comet coach for Chesterfield, and arrived at Chatsworth at half-past four o'clock in the morning of the 9th of May, 1826. As no person was to be seen at that early hour I got over the greenhouse gate by the old covered way, explored the pleasure-grounds, and looked round the outside of the house. I then went down to the kitchen garden, scaled the outside wall, and saw the whole of the place, set the men to work there at six o'clock; then returned to Chatsworth, and got Thomas Weldon to play me the waterworks, and afterwards went to breakfast with poor dear Mrs. Gregory and her niece: the latter fell in love with me, and I with her, and thus completed my first morning's work, at Chatsworth, before nine o'clock.'

"He married Miss Sarah Bown in 1827. In a very short time a great change appeared in pleasure-ground and garden: vegetables of which there had been none, fruit in perfection, and flowers. Twelve men with brooms in their hands on the lawn began to sweep, the labourers to work with activity. The kitchen garden was so low and exposed to floods from the river, that I supposed the first wish of the new gardener would be to remove it to some other place, but he made it answer. In 1829 the management of the woods was entrusted to him, and gradually they were rescued from a prospect of destruction. Not till 1832 did I take to caring for my plants in earnest. The old greenhouse was converted into a stove, the greenhouse at the gardens was built, the Arboretum was invented and formed. Then started up Orchidaceæ, and three successive houses were built to receive the increasing numbers.

"In 1835 the intelligent gardener John Gibson was despatched to India to obtain the *Amherstia nobilis* and other treasures of the East. The colossal new Conservatory was invented and begun in 1836; the following year Baron Ludwig was so charmed with its conception, that he stripped his garden at the Cape of the rarest produce of Africa. Paxton had now been employed in the superintendence and formation of my roads: he made one tour with me to the West of England, and in 1838 contrived to accompany me for an entire year abroad, in which time, having gone through Switzerland and Italy, he trod in Greece, Turkey, Asia Minor, Malta, Spain, and Portugal. In absence he managed that no progress should be checked at home. A great calamity ruined the expedition he had set on foot to California; the unfortunate Wallace and Banks, young gardeners from Chatsworth, having been drowned in Columbia river. He went with me in 1840 to Lismore, and in that year the Conservatory was finished. The village of Edensor was new-modelled and rebuilt between 1839 and 1841, and the crowning works have been the fountains and the rock-garden."

After I had copied what precedes, I inquired of the Duke if he knew the amount of wages Paxton was receiving from the Horticultural Society in 1823? the answer was, "Only 18s. a-week, as I was informed by Mr. Sabine." As I knew that the Duke of Devonshire (by whom I had been most kindly aided for the last eighteen years) would not be offended by the question, I asked what wages he had himself given the "young and untried" gardener in the first instance? and his reply was, "I think 25s. a-week, and a cottage." Of course, his Grace afterwards rapidly advanced Paxton's wages; and eight or ten

years subsequently, the young labourer of 18s. a-week, and the now gardener of 25s. a-week, was often seen dining at the Duke's table.—(J. PAYNE COLLIER, in *Notes and Queries*.)

### NEW EARLY PEAS.

On the 7th of February I sowed the following varieties:—Dickson's First and Best Early, Sutton's Ringleader, Dillistone's Early Prolific, Sangster's No. 1, Daniel O'Rourke, and Maclean's Princess Royal, and on the following day Dickson's Early Favourite, Wonderful, and Maclean's Dwarf Prolific. In consequence of a long period of severe weather which set in just after they were sown, it was at least seven weeks before any of them appeared above ground, and then in the following order:—1st, Sutton's Ringleader, and Carter's First Crop; 2nd, Dickson's First and Best, and Dillistone's Early Prolific; 3rd, Daniel O'Rourke; 4th, Sangster's No. 1; the other three kinds coming through together a little after the last named. The time occupied in the Peas appearing above ground was from ten to twelve days. On the 5th of May, I noted that Carter's First Crop, and Sutton's Ringleader, were in full bloom; Dickson's First and Best Early was four days later; while Sangster's No. 1, and Daniel O'Rourke, bloomed together about two days later than Dickson's. Dillistone's Early, the seed of which was had direct from Mr. Dillistone, of Sible Hedingham, started off into a strong growth just as it was coming into bloom, a very heavy rain having fallen a few days previously. It reached the height of between 5 and 6 feet, came into bearing the last of all the early kinds, and produced a good crop, but the pods were rather small, and as I grew it, did not seem to present any special claims to favour.

On the 1st of June, I gathered a good dish of Peas, the majority from Carter's First Crop, and Sutton's Ringleader, and some from Dickson's First and Best Early; from the last, two days later, I was enabled to gather an abundant dish. Some time after the Peas had been sown, I was informed by Messrs. F. and A. Dickson & Sons, of Chester, that the seed of their First and Best Early Pea, was of the crop of 1863; in fact, that all they sent out, in the past spring, was of that harvest. I am, therefore, of opinion, that when new seed of the First and Best Pea can be sown against Carter's and Sutton's, it will be found quite as early, and a much better cropper, as it really is. I fully believe that the First Crop, and Ringleader, are identical in every respect, and this is not only my own opinion, but also that of all others who saw them, and it was noticeable that whereas Dickson's Pea was entirely free from "rogues," or "stragglers," there was a number of them amongst the other two varieties. The three were grown in a good deep loam, well manured last year for Onions, the average height being from 2 to 2½ feet. Sangster's No. 1, and Daniel O'Rourke, were ready for gathering about a week later, and their good qualities are too well known to need comment here.

In succession to these came Dickson's Favourite, Princess Royal, Wonderful, and Maclean's Dwarf Prolific, all were in bearing at the same time. Dickson's Favourite is a well-known variety, an abundant bearer, with long well-filled pods. It will grow from 5 to 6 feet high. Princess Royal is a large, white, round, Marrow Pea, growing about 3½ feet in height, and an abundant cropper, having large pods filled with fine Peas of good flavour. Wonderful is similar to Princess Royal, excepting that it is a white wrinkled Marrow, and scarcely so robust a grower. Both of these are first-class Peas, and they deserve to rank A 1. in the seed catalogues. Maclean's Dwarf Prolific grows about 2½ feet high, is an abundant cropper, rather smaller in the pod than the other two, and not quite so hardy. I may mention, that I grew Maclean's Advancer last year, and that I have this season seen it growing in the garden of Sir W. Heathcote, Bart., M.P., at Hursley, Hants, and while I admit its claims as a very early wrinkled Marrow, yet I find, that in southern localities at least, it grows so dwarf, and crops so sparsely, that I do not think it can long hold its own.

I am also growing Veitch's Perfection, Yorkshire Hero, Hairs' Dwarf Mammoth, Prince of Wales, and Lord Raglan, but they are not yet sufficiently advanced to make notes of at present. I know from last year's trial that they are all excellent varieties.

I should like to recommend, as best dwarf Peas for succession, Dickson's "First and Best Early," Sangster's No. 1, Princess Royal, Wonderful, Veitch's Perfection, and Lord Raglan.—ALEX. DEAN, *Maybush, Shirley, Southampton.*

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

The weather during the past few days has in many parts of the country been particularly favourable for planting out the autumn and winter crops, which may have been delayed in consequence of the previous dry weather. *Beans*, some *Mazagans* may yet be put in, which will produce late in the season if the weather prove favourable. *Broccoli*, *Cape* and *Grange's* may now be planted where the early Peas have been removed; the main crops of the other sorts should be got in as early as possible. *Cabbage*, sow a little more seed, if the sowing we recommended last month has failed. *Chevil*, another sowing to be now made for succession. *Cucumbers*, put in a few cuttings or sow a little seed, so as to have a few plants to plant out for a succession till Christmas. Continue to pay every attention to those in frames; they must have a liberal supply of water twice a-week, and should be sprinkled every afternoon. *Endive*, continue to plant-out a few about once a-fortnight, to keep up a succession; another sowing should be made. *Dwarf Kidney Beans*, the last principal sowing should now be made; earth-up the advancing crops. *Leeks*, those sown in drills should be thinned to a foot apart in rich ground, the thinnings will do to plant out. *Parsley*, make a sowing, so as to have strong plants by the winter. *Peas*, earth-up and stick the advancing crops; a few more may be sown, which will come into bearing if the autumn is favourable. *Radishes*, make a sowing of the various sorts; the Turnip-rooted, however, are generally preferred at this season. *Vegetable Marrow*, these plants will require a liberal supply of water; stop the main shoots to cause them to throw out laterals. Immediately a crop is done with either remove it to the char-heap or dig it in, in either case sprinkle the ground with lime to destroy slugs.

#### FRUIT GARDEN.

Grape Vines against walls to have the young shoots trained from the lower part of the wall for bearing next year. See that *Peaches*, *Nectarines*, and *Apricots* are nailed, if not already done, as the wind is sometimes very strong about midsummer and makes sad havoc with the shoots. *Currants* and *Gooseberries* require all watery useless shoots to be thinned out. It is a good plan for keeping Red Currants till the latest period for tarts, &c., to select some of the best bushes on a dry day, and thin all the shoots from the fruit; drive a strong stake in the middle of the bush, and tie all the branches to it, then wrap one or two garden mats around it.

#### FLOWER GARDEN.

Remove suckers from *Roses*, and clear the stems of wild shoots. Strong shoots of *Chrysanthemums* may now be layered in pots to produce dwarf compact bushes. Those in pots may soon receive their final shift. *Ranunculuses* may be taken up as soon as the foliage has turned yellow; for should wet weather continue they might emit fresh fibres, and if taken up then they are likely to be worthless. Plants growing in baskets or vases should now have a final stirring at the roots before the surface is entirely covered with foliage, likewise put on a layer of moss to prevent excessive evaporation, and thus save some labour in watering, which they would otherwise frequently require, as they are generally elevated above the surrounding surface, and therefore more exposed to the sun's rays. Bear in mind that *Fuchsias* in vases should be attended to daily as regards watering, it is inattention to this that causes the bloom to drop, and in the course of time renders the plant unsightly. Remove all decayed flowers and seed-vessels from American plants. Now is a good time for layering *Rhododendrons*, *Belgian Azaleas*, &c., just as they are coming into full growth. Shrubs grown to embellish Italian and geometric flower gardens, terraces, &c., should now be cut into the figure they are to assume; in many cases wires will be necessary to keep the branches in their proper places at first, when afterwards the knife and shears will suffice to keep them in proper form. *Portugal Laurels*, *Cypresses*, *Arbor Vitæ*, *Yews*, *Bays*, and *tree Box* are the plants most commonly used for this purpose, and when cut into architectural figures are good accompaniments of the above style of gardening. They should, however be clipped in two or three times during the season to preserve correctly the desired outline.

#### GREENHOUSE AND CONSERVATORY.

While out-door flowers may soon be expected in abundance, nothing should be brought here but what is well grown and bloomed, nor should any plants be allowed to remain that are at all shabby, for it is a waste of means, and certainly betrays

had management to occupy glass houses with plants of interest inferior to such as are plentiful in the open air. It is not desirable, however, to crowd the houses with flowering plants, the aim should rather be to have a moderate number of handsome specimens effectively arranged, which will yield more pleasure than a greater amount of floral display from plants of no individual merit. A thin arrangement of pot plants will also be advisable on account of the permanent occupants of the beds in the conservatory, which at this season should be allowed plenty of space in order to secure strong and well-ripened wood, without which they need not be expected to bloom finely. Use every means to keep down insects. Give clear weak liquid manure to young growing specimens, and repot any that are intended to have another shift this season, so as to have the pots well filled with roots before winter. Maintain a moist growing atmosphere in the greenhouse, and syringe vigorously any plant at all infested with red spider.

#### STOVE.

Encourage backward plants of Orchids with plenty of heat and moisture while that can be done safely. See that plants on blocks and in baskets are properly supplied with moisture at the roots. To prevent any mistake in this matter carefully examine every plant at least once a-week, and immerse any found to be dry in tepid water until the material about the roots shall have become well soaked. Syringe lightly morning and evening, and sprinkle floors, &c., in order to keep the atmosphere thoroughly moist. Here a number of Clerodendrons and such like softwooded plants, will now be showing bloom, and with the late-blooming Ixoras, Dipladenias, Echites, &c., this house will be very interesting for some time to come. Weak clear manure water should be used here once or twice a-week, as well to sprinkle the house as to water the plants.

#### PITS AND FRAMES.

Alpine plants in pots should now have a little attention. They should now be collected together; some will require division at the roots to increase the species. Many will require weeding and top-dressing, and others shifting into larger-sized pots; finally plunge the pots up to the rim in sand or finely sifted coal ashes. They should now be regularly syringed with clear water early in the morning and late every evening.—  
W. KEANE.

## DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

*Watering.*—Our chief work has been to render our little water as useful as possible, by applying it close to the roots, and either mulching or throwing dry soil over the moist surface as soon as possible. Mere surface watering, in such weather, is of very little benefit, except for newly-planted-out things, so as merely to refresh the foliage, as alluded to last week in the ornamental department. There have been signs of a refreshing rain, but as yet none has visited us; but on this morning of the 29th the barometer has fallen rapidly, and we hope that at last we shall have rain, which will greatly benefit all field and garden crops. In our stiffish, deep-stirred, moderately-enriched soil, the crops, especially those helped with mulching, are standing well; but in many cottagers' gardens the Beans are refusing to be more than bare stalks, and the Potatoes are ripening their haulm with but few tubers, and these refusing to swell to any size. Too many persons are slow to learn the advantage of surface-stirring in such weather, and deep stirring before planting. We lately saw some beds of vegetables and flowers with the surface cracked all over, and what was not cracked, pretty well as hard as iron; and the wonder was that, with almost constant evening sprinklings of water, the plants refused to grow. A good forking on the surface would have been better than all the drizzling from the water-pot. The watering, if given to reach the roots, would have been useful, and then, if the surface had been stirred to keep it in, the one watering would have been worth a dozen or a score of these drizzles on the surface, which merely encouraged roots to come to the surface, to be burned up by the next day's sun.

An old friend of ours is a great advocate of the sprinkling-overhead system, and wonders, though the plants seem refreshed by his kindly-meant process, that next day, if anything, they look the worse from it. As to getting our walking-stick into the ground, that was out of the question; we might as well have tried a plate of iron. Good stout arms would be needed to break it with a fork. No wonder that Cabbages and Cauliflowers

bolted, instead of laying a good foundation for good heads; no better plan could be devised for causing them to flower and seed early. As a rule mere surface watering, except for refreshing foliage, and chiefly of freshly-turned-out plants, is of little or no benefit, and often does harm even in well-stirred ground, because it breaks the line of conduction and evaporation, so that the roots are deprived of the moisture from beneath which they would otherwise receive. We have great faith in the moisture that is stored up in the earth, and which will be absorbed by the roots of plants, as it passes them, in proportion to the heat applied at the surface. The mere damping of the surface arrests, for a time—that is, until the surface is again dried—the line of communication between the moisture beneath and the sun and atmosphere above: hence it often happens that, after a slight shower in summer, which merely refreshes the foliage, and slightly damps the surface, if followed at once by a bright hot sun, the plants, as soon as the little sprinkling has evaporated, will seem to suffer more than before for a few hours, because, for a time, the roots have been deprived of their supply of moisture from beneath. Hence, also, the difference between natural and artificial watering. In the former case the whole atmosphere, with its clouds, seems as refreshing as a shower bath. In a bright sunny day the atmosphere, if we do not do anything in the way of mulching or surface-stirring to prevent it, will hasten to take away the moisture which we give. A dull or a drizzling day, or late in the evening, are, therefore the best times for watering. Sprinkling overhead in the sun, as alluded to last week, is merely an exceptional process, when, having secured enough of moisture at the roots, we keep down or lessen evaporation from the foliage until the plants become used to their new position. Plants in general would have been benefited by such foliage-sprinkling in these dry hot nights, where the amount of dew deposited would not have soiled a satin slipper in the early morn; but that sprinkling is a very different thing from thorough watering, and then letting well alone until your services are again required.

Among the uninitiated few things are less understood than watering, and the dribbling system is that which generally obtains. Let us take a Fuchsia plant in a pot as an illustration. We find the leaves and blooms unmistakably drooping, and, as the readiest way for averting disaster, we throw water with a fine syringe over the leaves and branches—a very good thing, it must be allowed, but then the remedy is a very temporary one. Finding this to be the case, we give a little water—enough to penetrate an inch or two below the surface—and that does a little more good. Keep on with this dribbling, and you might as well, or rather better, have grown your plant in a shallow saucer. The lower roots will die, in time, from having no moisture to feed on. Placing such a plant in a bucket, to be thoroughly soaked, would be the best means for insuring its safety, and then water it thoroughly when you do water. We are supposing the plant to be standing on a shelf or stage; but if you plunge the pot in a bed, or in the earth, the very plunging, though the plant be in a pot, makes it more independent of your care. The top-sprinkling, the surface-drizzling, would be ineffectual as to lasting effects as before, and would so far just deprive the roots of the moisture that would reach them from the bed or the earth; but then the roots, in self-defence, if permitted, would endeavour to look after themselves, by getting through the pot, and down into the earth, after the moisture. In such a dry summer as this the fields of Wheat often look extremely flourishing. Whence do the roots obtain their moisture? From great depths, for the surface is like driven dust. A mere drizzling on the surface would do more harm than good, as it would do no good to the roots, because it would not reach them, and, until evaporated, the raising of moisture from beneath would be arrested. On the same principle, plants thoroughly established, and with deep roots, will often do better without mulching than with it. Until we saw through these matters, one fact often surprised us. In a dry summer we have noticed how refreshed the fields looked after the foliage was even slightly washed with a passing shower; but if that happened in the morning, and the day proved sunny and windy afterwards, then, in the afternoon, the plants would hang their heads and look more distressed than before. The rain had done nothing for the roots, and the supply of moist vapour, by capillary attraction from beneath, was temporarily cut off. The balance was restored as the surface became dry. The shower, on the whole, did good, by cleaning, refreshing, and swelling out the stems and foliage; but it could not do what a soaking rain would do, that reached the roots. Let us

syringe and surface-water if we will, but we must not expect the results of a good watering that reaches every fibre of the rootlets. We think we have previously mentioned about a gardener being found fault with for watering his dry flower-beds in a dull drizzling day, when the barometer showed there was no likelihood of much rain. He ought rather to have been commended. Watering in hot sun should only be resorted to when it cannot be avoided. Unless care, by mulching and surface-stirring, is used, the moisture we give will soon rise as vapour to improve the general atmosphere: hence one advantage of surface-stirring and of loose mulching, is that, whilst the great heat is excluded, the air, with its vapour, can enter.

Made arrangements for soon sowing the last Peas. Planted a good space of Dwarf Kidney Beans. Will make another sowing, and then will sow where protection can be given. We have thus frequently gathered up to November. Sowed the main crop of Endive and Lettuces for succession. We always look upon early Endive where there is plenty of Lettuce as something like waste. Though very pretty in the salad-bowl, we consider Endive as merely a substitute for, and not a competitor with a crisp Lettuce. We lately saw splendid specimens of Carter's and Sutton's Champion Lettuces, excellent where size is an object. The flavour also was very good. The London and Paris Cos are useful for small gardens. Planted out more Cauliflowers, shading them and Celery with tree branches. The bulk of winter stuff we must leave a little longer in hopes of having rain, as the plants are easier kept in the beds and in the rows where thickly pricked out. Regulated Cucumbers. Spawned *Mushroom-bed* in open shed, and could we spare the time, would make some fresh spawn as it now dries quickly, and the spawn would run but with little trouble. We have had as yet a fair supply in the house, which is a lean-to to the north, by syringing all the walls and floor, and giving air so as to promote coolness. Heat is the great enemy to Mushrooms in houses above ground in summer, and draughts of air do not suit them so well as an open shady shed. We have had them very good under the shade of Vegetable Marrows and Gourds, but the spawn should not be placed nearer than a yard from the main stem of the Gourd or Marrow plants. Sometimes when we have spawned a ridge used for such plants, the spawn injured the roots of the Marrow; but if placed near the outside it did no harm, and the large leaves kept the Mushrooms cool and also delicate in colour. All such fungi require rich organic matter to thrive in, otherwise the Mushroom will grow in any rich ground. A friend of ours had some fine gatherings last season on a north border. He placed the droppings from his pony about 4 inches thick on the ground just as he got them, put some bits of spawn in it about 9 inches apart, and covered with an inch of soil, beat it down, and covered with a sprinkling of litter to prevent rapid drying. He had plenty and to spare before the cold weather came. As fine a bed as ever we saw was in the corner of a stable. With a little covering the farmer had plenty all the winter and spring months.

#### FRUIT GARDEN.

Proceeded with watering Strawberries, stopping the shoots of fruit trees, regulating Melons, banking-up linings round frames with litter to prepare for a change in the weather, and attending to other things with watering, thinning, much as detailed in previous weeks. At length some red spider has appeared in the lean-to orchard-house, and as a preventive have daubed all open spaces on wall with a paint formed of soft soap and sulphur. The fumes of both when the sun shines are disliked by these insects. Out of doors the birds are troublesome, getting at fine Cherries under the closest netting, and a lesson may well be learned from the patient and persevering scrutiny they evince, to find the slightest break or hole in your defences; but, poor things, they are objects of pity this season. Many of the larger birds—as blackbirds and thrushes, are perfect skeletons from their inability to find worms, and grubs, and snails in this dry weather. The word "quinine," in second column, page 491 of the volume just concluded, should be "quassia."

#### ORNAMENTAL DEPARTMENT.

Without any watering the Roses on our stiff soil have been large and good. In lighter soils even with watering they have not been so good as usual. Gathered a great many when full blown, for drying for *pot pourri*. We question if the gathering system is not the most economical on fine lawns, as when they shed the flowers and there is the least wind the sweeping-up is endless. On this account alone we should incline to banish them

altogether from a nice-kept lawn, and place the Roses in a roseroy, or in front of a shrubbery where a few shed flowers would be of less consequence. To our eye nothing disfigures a lawn more than being dotted over with tree Roses with small mop-heads on the top of a walking-stick stem. Such tree Roses are only tolerable when they are trees—that is, when the head has a diameter of from 6 to 12 feet, and droops gracefully. Many pretty gardens are quite spoiled by these puny mop-heads rising out of the turf.

With the exception of a little filling-up when we thought the plants would be rather thin, finished all our bedding-out last week. All the earlier-planted will now pretty well look after themselves. The *Caleceolarias* are producing huge cauliflower-like heads of bloom, but where much exposed, as on raised beds, they are not making such growth for succession as we would like in this dry weather, and with the ability to give them none but a minimum of water.

*Mulching.*—For these and Geraniums not covering the ground, and indeed for things in general, and as the ground is warm enough for anything, we have proceeded to mulch to keep the ground cooler and moister about the roots. We are not well off for materials this season, and have been obliged to use it rougher this season. For the centre of large beds we have used half-rotten leaves from the Vine-border, breaking them well up with the points of a five-tined fork, until they are pretty well as loose and flossy as the hair that is prepared for hair mortar. Even then this would be tempting for the birds, if placed near the sides of the beds, as they would soon pick it over the lawn. They have little chance of doing it from the middle of the beds, in consequence of the thickness of the plants, and the twigs to keep them all right and safe from winds. The front of the beds and borders will be slightly mulched, as far as the material goes, with from half an inch to an inch thick of a mixture of leaf mould and old Mushroom dung, passed through a sieve with openings an inch wide. This makes a nice finish, and is a great help every way, rendering much watering unnecessary, and economising what is used, and, in raised beds, preventing the rumming of the soil when watering is resorted to; whilst, if rain comes, the nourishment in the material is washed down to the roots. A little soot and lime, in the outside mixture, would help to keep the bills of the birds from it. But for scarcity of the material we would have used this riddled mixture alone, for the sake of neatness, and for most of the beds in this dry weather. By promoting surface-rooting it also promotes free flowering, instead of extra luxuriance, which much manure dug into the beds is apt to do. Moss is also a capital mulching, and gives a nice ground colour, if kept green, until the leaves hide it; and so is the cocoa-nut fibre. Some of our amateur friends write of it to us in ecstasies, and ask why we do not commend it for general use for this mulching process. Well, we agree in much of their enthusiasm; but then the expense of so mulching a large garden!

*Lawns.*—In such weather, the less mowing and grass-cutting with the machine the better, so long as neatness is secured. A deep cut with the mowing machine is sure to promote brownness and a rusty appearance. If the lawn looks flossy and a little rough, and pieces are long, especially round the sides of beds, a man who takes a pride in his work will so hold and regulate the machine as to knife the long points, and will soon, with a 14 or 16-inch machine, go over a large space of ground. When a few Bents, Plantains, and Daisies appear, the daisy-knife is the tool to remove them with, and the sun will make short work in sending them out of sight. The beautiful low yellow *Lotus corniculatus*, which would make a capital yellow bed, has been rather prominent on the lawn here this year, and the extreme dryness is also giving us lots of white flowers of the Dutch Clover; and the yellow and the white are apt to stud the green of the grass, and yet be so low that neither knife nor scythe can get hold of them; but as soon as they rise the least above the level of the short grass the knife soon settles them. A visitor told us, some time ago, that in a public garden he saw seven men toiling away with daisy-rakes on a lawn, and that they did not do half as much work as one man was doing easily with the daisy-knife. As yet our lawns are pretty green, but a good cutting with the machine, without rain, would make them brown enough.

*Florists' Flowers.*—*Anriueas*, *Polyanthuses*, and *Pansies* will now do best in a shady place. The last two may be divided and planted out or potted. *Pansies*, to be kept good, should have a shady place, plenty of rich top-dressing, and abundance of water to keep them moist and cool. Cuttings of favourite kinds may now be inserted in sandy soil in a shady place;

seeds be collected, and those used for flower-beds in spring be divided and grown on in beds for next season. Daisies we will divide as we get time. Pinks and Carnations need supporting, and green fly should be brushed off if it make its appearance. A fine brush and weak quassia water are better than using the fingers and thumb. Pricked out seedling Cinerarias. Planted out a lot of these done flowering to yield suckers. Put a few branches over them. Herbaceous Calceolarias done blooming should be placed out in a shady place to form suckers and shoots. One of these shoots rooted or struck as a cutting in the autumn will make a better plant than could be made of the old plant by any coddling whatever. These are invaluable for display chiefly in April and May. After that the air is too dry and hot except they are kept in a cool place. Tulips, cut off flower-stems, and the roots of fine ones should be taken up as soon as the leaves decay. Lachenalias and many early bulbs should be now in a state of rest, and may remain in the reversed pots, or be taken out and be placed in saucers covered with dry sand.

Went on potting stove and greenhouse plants. Cockseombs, especially feathered ones which promise to be fine, and Balsams, giving the latter mostly rotten dung and loam in equal proportions. Some of the Balsams had a little fly, and the tops of the plants were, therefore, dipped before shifting into a liquid of soft soap and quassia water, but not so strong as that recommended by Mr. Rivers. Even in rather small pots they promise to be strong and fine. The pots are plunged but the heads receive plenty of air. All our large Chrysanthemums are plunged to save water chiefly, but the plants are more easily kept in a uniform comfortable state. Dipped baskets of Stanhopeas in manure water, and kept all plant-houses in a moist state by damping the floors and stages. Clear weak manure water suits almost every thing now, if the drainage is all right. —R. F.

COVENT GARDEN MARKET.—JULY 1.

The market is now well supplied with everything. The late warm weather having driven all kinds of fruit forward, prices have consequently fallen considerably. Some good Apricots and Plums are now arriving from the continent. The first cargo of West Indian Pines has arrived, but the fruit is not very good.

TRADE CATALOGUE RECEIVED.

Osborn & Sons, Fulham.—Catalogue of Hardy Trees and Shrubs.

TO CORRESPONDENTS.

PLANTS SUITABLE FOR THE WALL OF A STOVE (*J. Bayley*).—Wistaria chinensis; Virginia Creeper; Lonicera xnoxosa, L. aureo-reticulata; Clematis montana, C. flammula; Aristolochia siphio; Bignonia radicans major; Hedera (the Ivy), Gold-blotched Irish, maculata, palmata, Silver-striped. Climbing Roses Ranga (this will grow in the coldest situation), Amandia, Grevillia, Felicite perpetuelle.

PRIZE MELON.—The scarlet-fleshed Melon with which I took first prize at the Royal Botanic Society's Exhibition should have been named Mounsdin's Moreton Hall instead of Malvern Hall.—THOS. PATON, Charl-cote Park.

STOPPING VINE LATERALS—BUDS BURSTING (*W. D., jun.*).—The cause of the buds bursting prematurely on your young Vine is very luxuriant growth and rapid root-action. We had a young cane of Duchess of Buccleuch this season that burst in a similar way. It is unfortunate when this happens, as the Vine will have to be cut back at the pruning season to the first good eye below the first primitive bud. If this is not done the Vine will always look very unsightly, as the spurs will be obliged to be left long, and will go on increasing in length each year; but if the Vine is strong and can be well ripened, the best way would be to take five or six good bunches of fruit from it next year, and encourage a young cane up from the base of the Vine for the following season.

MUSCAT VINE LEAVES TURNING BROWN (*A Young Gardener, Lincolnshire*).—Your Vines are very likely infested with the red spider. If so, keep the atmosphere moist, and put a thick coat of sulphur on the pipes, walls, or any other available part of the house.

AZALEA LEAVES INFESTED WITH BROWN THRIPS (*X., Stilmouth*).—The foliage of your Azaleas is very badly infested with brown thrips. Dip them two or three times in a mixture of Gishurst compound and water; put about two ounces of Gishurst to one gallon of water, and syringe the plants two or three times daily with clean water. This will soon clear them.

GRAPES DISEASED (*J. R.*).—The berries of the Lady Downe's Grape are very severely affected with what gardeners call "spot." It is an ulceration caused usually by the roots not obtaining a sufficient nutriment from the soil, owing to their descending too deeply or into an ungenial subsoil. We would remove the surface down to the first roots, put over them a little rich compost, and water with tepid water, at the same time ventilating night and day freely.

IRON GREENHOUSE (*P.*).—Any of the bothouse manufacturers who advertise in our columns could supply what you require. A similar structure might be made of wood, equally removeable and cheaper.

GARDEN TURF WEEDY (*M. E. H.*).—The Plantain and the Milkfoil (*Achillea*), which you enclose can only be eradicated by uprooting with a chisel or knife. Then sift over the whole a mixture of thoroughly decomposed stable manure and earth to the depth of a quarter of an inch; then sow it with Suckling seed (*Trifolium minus*), and pass the roller over.

APPLYING SALT TO ASPARAGUS-BEDS (*W. E.*).—We apply it at the rate of four ounces to the gallon, dissolved in house sewage, by means of shallow trenches made between the rows of plants. We apply it once a-week throughout the growing season—from April to October. We cover the surface of the beds with about an inch in thickness of thoroughly decayed stable manure.

CALCEOLARIA SEEDLINGS (*Knowsthorpe, Leeds*).—Your seedling Calceolarias are some of them of first-rate quality. These with a light cream-coloured ground are especially good, the circular markings distinct and novel. We should much like to see the plants. The dark flowers, though of good form, are not new in colour. Some of them are very promising, and of fine form.

MILDEWED PEAR LEAVES (*Chilworth*).—The leaves so severely visited by patches of fungi, turning black eventually and falling, indicate the border requires manure, mixing on the surface, and abundance of moisture. We should syringe copiously the leaves and the wall every evening during dry hot weather.

CUCUMBERS DEFORMED—VEGETABLE MARROWS FALLING (*Prospera*).—Cucumbers have large stalk ends, and dwindle towards the other extremity, usually because the roots are defective in action, owing to too little or too much bottom heat, or because there has been an irregular or deficient supply of water. The Vegetable Marrow fruit would fall from similar causes, or from air not being admitted sufficiently freely.

AN ORNAMENTAL CONIFER—PROPAGATING FLOWERING THORNS (*P. B.*).—You may take your choice for your mound and screen of Wellingtonia gigantea, Abies Douglasii, and Pinus insignis. The latter makes a noble tree, but you had better inquire whether it is perfectly hardy in your neighbourhood before you decide. Abies Douglasii is sure to be hardy. Flowering Thorns are best from buds, which may be put in during August and September.

PLACING VALLOTA PURPUREA IN WATER (*P. P.*).—We have not tried this Anuryllid in the open air, placed 2 or 3 inches in a shallow reservoir of water, but have repeatedly had it in a saucer of water from April to September, and it seemed none the worse of this semi-aquatic treatment. We have kept it in the open air plunged in a sunny place; and we doubt not it would do with the pots placed 2 or 3 inches deep in water in a large shallow reservoir, very much exposed to the sun, as you propose, taking in the pots the end of September. If you try the experiment we should be obliged by your stating the result.

MELONS TURNING YELLOW (*R. Allen*).—The usual reason is that not giving air early destroys the pollen, and the Melons consequently do not set. Another cause is too much moisture, which destroys or hinders the distribution of the pollen, and prevents the stigma receiving it in a fit state for fructification. The fruit sometimes turns yellow from a deficiency of bottom heat preventing a supply of sap sufficient to insure the swelling of the fruit, and at times through a deficiency of moisture in the soil. Keep the shoots thin, so as to admit light and air; give air early, and keep the surface of the soil rather dry at the time of setting, still quite moist beneath the surface; impregnate the flower, and stop above the fruit at the second joint; maintain a brisk bottom heat, and then keep the atmosphere dry. Avoid watering or wetting the surface whilst in bloom, and, if necessary to give water at that time, do so through drain-tiles inserted in the soil, or make holes, and pour the water into them.

CUTTING ASPARAGUS.—At page 468, second column, line 19, for "finer," read "fewer."

ROSE NEWS.—I cannot this week give the gossip that I gathered upon my late visit to Paris, but I may give all Rose-growers a good bit of news—that Lacharme, the well-known raiser of Charles Lefebvre, Louise Darzins, and other excellent Roses, has a genuine YELLOW Hybrid Perpetual, of the Centifolia type, to be let out in 1866.—D., Deal.

**MANAGING A NEWLY-PLANTED THORN AND BEECH HEDGE** (*An Amateur Gardener*).—You did quite right in cutting the Thorn or Quick plants down after planting the hedge. It would strengthen the Quicks, causing the shoots to come stronger, and a good bottom would be obtained at once, which is a main point. So far, then, your hedge will have a good foundation, which you must retain by trimming in the sides slightly early in August, and keeping the bottom clear of weeds, so that the fence may grow thick and close to the bottom. At any time after the leaves have fallen up to that of their reappearance the top may be taken off to 1 foot 6 inches, if it has made so much growth; if not that height, do not cut it down until after the second year's growth is perfected. Continue to trim the sides in in August in future, and when the height of hedge is attained take off the top at a few inches below the height required; trimming during the summer in June, and another run-over in the end of August will keep it very neat. The Beech will need no trimming this year, and only at the sides until the height of hedge is gained, when it should have the top taken off 9 inches or a foot lower than ultimately required. It is best to clip Beech hedges during the winter, though they may be cut, like Quick and Privet hedges, once or twice during the summer.

**RAISING BROMPTON STOCKS** (*Idem*).—Sow the seed forthwith in an open situation, and water if dry weather ensue. When large enough to handle plant out where intended to bloom, selecting a sheltered situation, and affording a little protection during severe weather by means of furze and fir or other close-branched evergreens. The Stocks may be planted close together, so as to require thinning in March; but the safest plan is to pot them in small pots, and place in a frame on a dry bottom on the approach of frost, plunging the pots in coal ashes, and giving air in mild weather, and planting out with the balls entire in March.

**EARLY PEAS**.—We have received (June 30th), from Messrs. Carter & Co. a sample of their variety, "First Crop." The Peas are an excellent sample, dry and hard—evidence that the harvesting was not hurried.

**WORMS IN VINE-BORDER** (*Witten Lodge*).—The earth worms were attracted to the border by the manure. They will be beneficial rather than otherwise by making perforations in the soil.

**AIR IN VINERY** (*A Subscriber*).—It requires to be kept well supplied with moisture by pouring water on the paths, &c., freely, but the ventilation must be good also by night and day, for stagnant damp air induces mildew. A dry hot atmosphere insures the introduction of red spider.

**SEEDLING CARNATIONS** (*Eaton M. D.*).—There is nothing remarkable in your seedling Carnation but its size; it is what is termed in floral language a monster. It is not unusual for seedlings when they first come into flower to produce these gigantic forms. The flowers are totally useless; the superabundance of petals always causes the pods to burst, which is very objectionable.

**DOUBLE FUCHSIA** (*A. R. McGuire*).—Your seedling double Fuchsia is not at all new, the bright colour of the sepals is a great recommendation, but it is not better than Hercules, Universal, and many others. The value of the seedling would depend on the habit of the plant. We have no recollection of receiving an Anemone flower from you in the spring.

**INARCHING VINES** (*An Amateur, Southampton*).—Unite green wood of the scion to green wood of the stock when the shoots of each are 2 or 3 feet long.

**SELECT CARNATIONS, PICOTEES, AND PINES** (*A. T. C.*).—The tastes of northern and southern growers differ, but the following are good and suitable for the northern and midland counties:—*Carnations*: Admiral Curzon, Lord Rancliffe, Black Diamond, Lord Milton, Fanay, Sarah Payne, Premier, Squire Meynell, Firebrand, Sportsman, Ariel, Friar Lawrence. *Picotees*: Mrs. Norman, Isabella, Amy Roberts, Lord Nelson, Mrs. Dodwell, Robin Hood, Mrs. May, Finis, Mrs. Barnard, Venus, Bertha, Mrs. Fisher. *Pinks*: Beauty, Catherine, Climax, John Bull, Lord Chancellor, Lucknow, Lucy, New Criterion, Mrs. Enfield, Mary Ann, Purple Perfection, Purple Gem.

**WHAT CAUSES THE WINDS** (*Ellen*).—We cannot reply better than by the following quotation from one of the best of our magazines:—"Regarding them in the simplest way, they are evidently produced by the successive heating of those parts of the earth most directly exposed to the sun's rays, the consequent expansion of those heated portions of the atmosphere in contact with the warm earth, and the replacement of these warmed and expanded portions by cooler air from north and south. The operation going on incessantly, a steady current would be produced at all times from both poles to the equator. This, indeed, soon ceases to be a north and south current from the poles to the equator, for the heated air rising and passing to the poles is moving with the velocity of the earth's surface at the equator—or a thousand miles per hour—while the air starting from the poles has no initial velocity. Thus each hot current as it advances northwards or southwards passes beyond the longitude of the place from which it started, and each cold current as it travels toward the pole lags behind the parts of the earth over which it successively travels. The north and south winds thus become at length east winds at the equator. While approaching the equator they are north-east and south-east winds for a considerable distance, and in this state, within certain latitudes, are called trade-winds, from their usefulness in navigation."—(*The Englishman's Magazine for July*.)

**VINERY** (*P. O. Whitehead*).—With plenty of heating power, which we presume, you can easily have in your part of the country, we do not consider that your house is too high; and the angle 45°, is a good one, either for early or late work, or any work. If you feared the wind very much you might have the height 2 feet less, but, with plenty of heat, we would do as you propose. For the border, inside, we would advise from 20 to 24 inches in depth, over a foot of rubble, and that drained beneath. It is much in your favour having the floor of the house, inside, so much above the outside level, as drainage will be an easier matter. We would make the border on the top of the present floor.

**NAMES OF PLANTS** (*Cumberland*).—1, *Lastrea Filix-mas incisa*; 2, *Polystichum angulare subtripinnatum*; 3, *Lastrea dilatata grandidens*; 4, *Athyrium Filix-fœmina pyramidatum*; 5, *Lastrea Filix-mas paleacea*; 6, *Athyrium Filix-fœmina*. (*H. T. K.*)—1, *Pedicularis sylvatica*; 2, *Gilenea trifoliata*; 3, *Polygonum aviculare*; 4, *Nepeta Mussinii*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending July 1st.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

FACTS ABOUT EGGS.

It is thought by naturalists, that the eggs of our domestic hen of the present day are, on an average, very nearly a third larger and heavier than those of the hens of the ancients.

The proportions of the yolk to the white of the egg are very nearly the same in each of the different races; but in proportion as the egg diminishes in size, does the relative proportion of the white to the yellow of the egg diminish—that is, small eggs have more yellow than large ones in proportion to their size, but the weight of their shell is also greater in proportion.

Eggs which contain the largest yolk or yellow, like those of the Brahma and Cochin-China hens, produce the largest chickens.

The weight of sterile, or unfecundated eggs, is less than that of those that have been fecundated; and their nutritive qualities are less.

The eggs of the wild hen have a superior flavour. The proportion of the yellow in them is greater than in the eggs of ordinary domestic fowls; they have a higher colour, also, and cooks esteem them on this account, for the preparation of certain sauces in the proportion of one to three.

Barley is said to increase the proportion of the yellow of the egg, and rye is said to favour the development of the white.

Eggs lose a slight portion of their weight day by day, when left to themselves, the contents becoming dried up gradually, and reduced, so that there is left a solid residuum withdrawn towards the small end of the egg, the opposite end being filled with air. Eggs which weighed 2½ ozs. when fresh, weighed but a very small fraction over 1 oz. at the end of two years. During incubation the diminution of weight is pretty rapid.

Aristotle taught that round eggs contained male chickens, and elongated eggs females. Scientific men have both combatted and sustained this opinion, but the general opinion of naturalists at the present day is, that both males and females come from both round and elongated eggs. Fecundation exercises no control over the figure or form of the egg. The most exact and scientific experiments upon these points, conducted recently at the Jardin d'Acclimatation at Paris, have led to these conclusions.—(*Massachusetts Plowman*.)

VERY LIKE SWINDLING.

Can any of "Our Journal" readers give me any information respecting a person who advertised in your columns for good poultry in exchange for foreign birds? Having many of the

former, and being fond of the latter, I was induced to answer the advertisement. This led to a correspondence, in which the advertiser undertook to send me some Californian Quails and other Australian birds (*sic*), on my sending her a pen of Buff Cochius which I had mentioned. My birds were sent to the address named, and after some delay I was informed that the lady had moved from Croydon to Brompton. The result is that I have never recovered birds, price, or equivalent; and after repeated threats at length I instructed my solicitor to proceed against the person, but this was too late, as we find the bird has flown and cannot be heard of. Perhaps some one else has been victimised in the same way; and if so, you may be doing a kindness to our poultry fraternity by stating that the name of this "lady" is Mrs. Firebrace, late of Croydon, since of Ovington Square, Brompton.—T. C. H.

THE FIFTH TOE OF DORKING FOWLS.

Is this really an essential? Mr. Baily, in his little book entitled "Fowls," when speaking (pp. 112, 113), of the points required in exhibition birds says nothing about it. The largest and most symmetrical birds I ever saw had all the Dorking characteristics except the fifth toe. I am further inclined to believe that it is not an essential, because you see it of all kinds of shapes, pointing in different directions, and even nailless, without having any influence over the awards of the judges.—NEWPORT.

[This is one of the most heretical letters we ever read, and if Mr. Baily knew the writer we are quite sure he would excommunicate him. The fine birds alluded to by "NEWPORT," are known as "Sussex" fowls. They are thus mentioned in "The Poultry Book"—"The breed now known as the *Sussex* fowl, has only four claws, and is a less compact though larger bird than the true Dorking, which it otherwise much resembles." In fact, the fifth toe is an essential characteristic, and can no more be disregarded than can the white face in the Spanish, or blue legs in Hamburgs. It is quite true that a distortion of the fifth toe is not held to be a disqualification any more than a distortion of one of the other toes, and would only be taken into account in case it was the only inferiority apparent in two otherwise-equally-excellent competing pens. At the same time there is no doubt that there is a form and position of the fifth claw, which is the most desirable, and it is as thus represented by M. Jacques.

"The claws," he says, "should be strong, clean-jointed, five in number;" and "The Poultry Book" says, in detailing the characteristics of excellence, "Claws five in number on each foot, and well defined."]

BEE-KEEPING IN DEVON.—No. XXIV.

A PROSPEROUS APIARY.

WHEN publishing to the world the misfortune which overtook me in 1863,\* and relating my experience of that terrible disease foul brood, which had caused my hapless apiary to dwindle to the very verge of extinction, it was not a little amusing to observe how many were prone to attribute my ill-success to the adoption of a scientific and experimental system of bee-management. "An OLD-FASHIONED BEE-MASTER" of Finchley, openly rejoiced over my discomfiture; Mr. Lowe authoritatively pronounced that "an experimental apiary can never be a thoroughly prosperous one," and published an amusing article which riled me not a little at the time, and in which he appeared to hold up to ridicule all that he either knew or imagined of my apiarian proceedings; whilst Jonas Jackson attributed my downfall to the neglect of certain popular superstitions. These Job's comforters were, however, vastly outnumbered by the multitude of correspondents who aided and cheered me by their sympathy and advice, and even in one instance (that of "J. E. B.," whose personal acquaintance I have recently had the pleasure of making), presented me

\* *Vide* JOURNAL OF HORTICULTURE, Vol. V., page 59.

with a strong colony of bees in the hope that it might aid in stemming the torrent of destruction which, at that time, threatened to overwhelm my entire apiary. Nor were there wanting those who, while giving expression to their kind sympathy, did not hesitate to express their conviction that I should in the end triumph over all my difficulties, and ultimately re-establish my apiary, and perchance raise it to a higher state of prosperity than before. To all such I may now return my warmest thanks, and I feel sure they will participate in the pleasure I have in informing them that their kind anticipations have been more than realised. Never since I first commenced bee-keeping (now just a quarter of a century ago), have apiarian matters progressed so pleasantly and prosperously with me as during the glorious summer of this year of grace 1865.

It may be remembered that last autumn I possessed twenty stocks; of these I unfortunately allowed one to starve by an oversight for which I can now scarcely account. The whole of the nineteen remaining stocks survived the winter, albeit some were much weakened from loss of bees during their protracted confinement, and breeding was also much delayed by the cold and late spring. Notwithstanding these drawbacks my account now (29th June) stands as under:—

PARTED WITH.		REMAINING IN MY APIARY.	
Stocks.....	14	Stocks.....	11
Swarms.....	3	Nuclei with impregnated queens	4
Queens.....	4	" " unimpregnated "	1
		" " royal cells.....	9
Total parted with.....	21	Total remaining.....	25
		Total parted with.....	21
		Grand total.....	46

As nearly all the stocks which I have sent out were despatched during the spring, they have, of course, been of little or no assistance in multiplying those that remained, so that in point of fact almost all this increase has arisen from the five remaining old stocks, aided by combs and brood from three purchased black swarms, which swarms were allowed to remain undisturbed in the country for about a month after hiving, and then plundered of nearly all the combs which they had constructed.

I esteem myself particularly fortunate in having had but one natural swarm, which issued on the 9th of June, settled in a pear tree, and was soon safely hived; but as if it were impossible for a natural swarm to issue in my apiary without being the harbinger of some mishap, the only young queen I have lost this season happens to be the one which just five days afterwards emerged from one of the only two royal cells which existed at the time of the departure of the swarm. Her death occurred in this wise: On June 17th, I was looking over, and rectifying, as is my wont, any irregularities in the formation of the new combs of the swarm, upon one of which I had just seen the queen, when I was horror-stricken by discovering, as I supposed, the beautiful matron I had seen in full health not a minute before lying lifeless, and evidently stung to death on the floor-board. Bitter was my mortification at believing that some inexplicable clumsiness in my manipulations had resulted in the premature decease of what was certainly my most beautiful and favourite queen—a mortification mitigated only by the reflection that she had attained the mature age of three years, and, although evincing as yet no sign of waning fecundity or decrepitude, not likely much longer to continue capable of maintaining the population of a strong and flourishing colony. Having accordingly allowed three days of mourning over my defunct favourite to elapse, I reflected that it was of no use to waste the time and energies of so large a multitude of bees in raising a young queen and waiting her impregnation, when I had it in my power at once to place a competent sovereign at their head, and therefore proceeded again to examine the combs with the view of taking preliminary steps by eradicating such royal cells as might have been started in the interim. Judge, then, what must have been my joyful surprise at discovering my yet queen perambulating the combs in the enjoyment of full health and vigour, and perceiving that she had evidently "not been dead at all," although I had mourned her as such. I was for some days much puzzled to account for the presence of the dead queen on the floor-board, and although this mystery ultimately received a partial elucidation by the discovery of the loss of the young queen from the old stock, I am still unable satisfactorily to account for her straying into the hive containing the swarm, especially as a third colony intervened between the two.

I may here say a few words with regard to the supposed

inferiority of what are called "artificial" queens, which are by some supposed to be so deficient in instinct as to be more prone to go astray than natural queens, to which, indeed, it is imagined they are also inferior in fecundity. My experience, which is now a pretty extensive one, satisfies me that there is no foundation whatever for this belief. "Artificial" queens, so called, are really as natural as what are generally denominated "natural" ones, from which they do not, moreover, differ in the slightest respect. Their fecundity is the same and their instinct by no means inferior. It will be observed that the only "natural" queen that has been produced in my apiary during this season was also the only one to go astray.

So abundant has been the honey harvest that one of my old stocks compelled me, rather late in May, to put on a super.

Notwithstanding repeated deprivations of bees and brood for the purpose of stocking "nuclei," honey poured in so rapidly that the breeding space was fast reaching the vanishing point when I tardily afforded them the much-required accommodation. This was at once taken possession of, and all went well until the 13th of June when a swarm emerged, but did not cluster, and presently returned to the parent hive. Knowing that the queen was disabled in one wing through ill-treatment by a swarm of black bees which were united to her subjects in the autumn, I instituted a diligent search; but failing in finding her, hoped she had not attempted to take wing, and turned my attention to the old hive, which I examined likewise without success, but from which I excised every royal cell I could find. On the 19th of June I repeated my examination, again excised whatever royal cells I could discover, and introduced a young queen hatched on the 11th and which had exhibited signs of fecundation. A subsequent examination, five days afterwards, revealing hundreds of eggs in the first comb lifted out was so satisfactory that it was not further proceeded with, and the stock working vigorously has now nearly completed its super, the nett contents of which when filled will not be much under 40 lbs. and which I hope to be able to allow Messrs. Neighbour to exhibit at Plymouth during the forthcoming show of the Royal Agricultural Society.

In conclusion I would invite such of the readers of "Our Journal" as may be disposed to doubt the possibility of an experimental apiary being also a thoroughly prosperous one to pay a visit to that of—A DEVONSHIRE BEE-KEEPER.

### BEEES IN YORKSHIRE.

As reports from this district are very rare in the Journal, it may interest your apiarian readers to know that the season so far has been a favourable one for bee-keepers. Swarms have been numerous, and there is no lack of honey. We have had more than five weeks of fine weather, interrupted only by three days rain; and although the excessive heat and drought are not very favourable to honey-gathering, yet the continuance of so many fine days without a break, adds continually to the stores of the hive. The cold nights also have induced frequent heavy dews, which always tell well.

The hives here stand rather thick on the ground, there being upwards of forty within the radius of a mile; but I believe all are doing well. As soon as our chickens are hatched and may be safely counted, I hope to give some account of my own proceedings and those of one or two of my neighbours. Meanwhile, for the sake of comparing with other districts, I note the large number of double swarms which have occurred this season, the union taking place without fighting, except in the case of the queens; also, the prevalence of drone-comb in the supers. Am I right in attributing this to an abundance of honey, which can be stored more rapidly in this way than in worker cells?—F. H. WEST, *Potternewton, near Leeds.*

[We shall be obliged by reports of the results of the honey harvest from different localities. The ingathering from the lime-tree blossoms is now at its height near London.—Eds.]

THE TOAD A BEE-EATER.—I have heard that our common toad would devour bees, but I would not believe the assertion until last week. I was then watching my bees as they were coming in and out of the hive, and to my surprise I saw a large toad in front of the bees, in a bed of cabbages, devouring them as fast as they flew down or near where he was. Will you inform me whether this is a usual occurrence?—JAMES N.—

[It is well known, and has been long known, that the toad is a most determined apicide.—Eds.]

### THE MASON WASP.

On the front of the gentleman's house where I reside as gardener, I was ataking some sweet peas, when my attention was drawn to something like earth on the ledge outside the window, but upon closer examination it proved to be a nest of larvae, like little caterpillars. There were four closed tubes rather larger than tobacco pipes, one of which I broke off to see what it was like. I took the top off one of the other tubes and stood looking at the minute grubs. In a few minutes a large wasp came humming up and alighted on the top where I had made the hole. It looked very closely at the hole which I had made, then flew away, and I thought no more of it till looking on the gravel there was the wasp. Up it flew to the tubes and deposited some very fine dust or sand, and then formed it into a puddle, and filled the little hole up which I had made, and then flew away.—J. B.

[The wasp which formed the mud cells described above, is one of the Solitary Mason wasps (*Odynerus*), of which there is a considerable number of British species. We shall be glad to see a specimen of the wasp itself, as the cells were rather unusual in form.—W.]

### BEEES IN NEW BURLINGTON STREET.

THE *Times* of Friday last says:—"On Wednesday afternoon, about five o'clock, not a little excitement and astonishment was caused in New Burlington Street by the circumstance of a swarm of bees alighting on a cab which had just drawn up at a restaurant. A man having procured a hive, set to work, and with assistance succeeded in securing the whole of the unexpected visitors, and took them away. A swarm of bees is rarely if ever seen in the streets of London, but it is not an uncommon occurrence for a swarm to stray considerable distances." Referring to the foregoing paragraph, Mr. Alfred Neighbour writes us as follows:—"The bees were ours. A swarm, being ordered to be sent into the country the following morning, was placed temporarily on the leads at the back of this house (149, Regent Street). The sun shining hot on the hive, or some other cause, induced them to decamp. Some one told us that the bees had arrested the progress of a cab, and we sent our man to bring the truants back, which he succeeded in doing, followed by a crowd to this door, who were evidently amazed at the sight of the "oney bees," as the cockney lads called them. Cabby had to be compensated for the loss of his fare, and so you may imagine that not a little commotion was caused. I thought that from the circumstance of the paragraph appearing in the 'leading journal' you might make an extract for THE JOURNAL OF HORTICULTURE, and that it might be as well to put you in possession of the real facts. New Burlington Street is the next street to this going towards Oxford Street."

### CAUTION.

THE following advertisement has appeared in several recent Numbers of the *Times*:—

"How to Take the Honey out of the Hive without Destroying the Bees. Full particulars will be sent to any part of the United Kingdom on the receipt of 12 postage stamps and a directed stamped envelope. Apply, &c. Warranted perfectly safe."

Least any of our apiarian readers should be induced by the above to part with a shilling in the hope of learning "something to their advantage," we may state that the operation prescribed by the advertiser is neither more nor less than that of stupefying bees by means of chloroform, a process which has already been fully tested and most emphatically condemned by several of our ablest apiarian contributors.

### OBTAINING AN ARTIFICIAL SWARM.

I PURCHASED a swarm of Ligurian bees on the 5th of last month, and put them into a full-sized Woodbury bar and frame hive. As far as I can see, the hive appears to be full of comb; I would like to have an artificial swarm from it. I intend taking the swarm off in the following manner, which has been recommended in the Journal—viz., by taking a brood comb out of the hive, and putting it into a smaller hive, and placing the empty hive with the brood comb in it on the place where the other hive stands. I suppose I must do this in the middle of a

fine day. Will you inform me what the brood is like at two days old, as I never saw a brood comb? I suppose the bees can form a queen if they have brood of that age.—A NOVICE.

[In choosing a comb for the purpose of rearing a queen you should select one containing brood in all stages, from the newly laid egg to the sealed grub, and take also the bees that adhere to the comb. An egg two days hatched becomes a minute white worm, which lies at the bottom of the cell surrounded by a milky-looking fluid.]

#### WEIGHT AND PROBABLE UNION OF SWARMS.

THE other day my bees swarmed in my absence, and on my return my neighbour had had a swarm, and mine had vanished. With his permission I weighed my neighbour's hive and found the swarm alone weighed 7½ lbs. Both my neighbour and self are young beginners, and wish for your opinion as to whether they have united. The hives were about 12 yards apart.—HERBERT LONDON.

[7½ lbs. is a very unusual weight, and we should, therefore, be inclined to believe that the two swarms have united. There is, however, a well-authenticated instance of a swarm of Ligurians weighing 8 lbs., but the heaviest that ever came under our own immediate observation was at Edgbaston, and weighed 6 lbs.]

#### CAPRICIOUSNESS OF BEES.

BEES are very uncertain in their behaviour, as sometimes a peaceful union is accomplished without any trouble or preparation, and again when circumstances are apparently exactly similar a deal of fighting and disturbance takes place. I stocked my unicomb-hive this summer with a second swarm made by driving, and secured a moderate-sized swarm and a fine young queen only just at liberty. She turned out a drone-breeder, no doubt owing to the difficulties experienced in finding her way out of the hive. I returned home early one day when she was about sixteen days old—i. e., about 3.30 (the morning had been very fine and bright), and on looking into the hive failed to find the queen. It occurred to me that she might be absent in quest of the drones, and shortly afterwards a send came on, which caused the bees to return home in vast numbers, and on looking on the alighting-board there stood the queen, surrounded by a few of her subjects; she remained almost motionless for some time pluming herself, and then very deliberately marched into the hive. I could see no marks of fecundation, but thought she might possibly have been more fortunate in a previous excursion. The next day proved cloudy, and the day after she began to lay. I soon noticed that she was unusually tardy in laying, remaining a long time in a cell, and on inspection found that she constantly deposited two, three, or more eggs in single cells, and this convinced me that I again had before me a case of parthenogenesis.

As the summer wore on the population not being replenished with workers, rapidly diminished, and although I furnished them with a fertile queen, for a short time I feared they would fall a prey to robbers, and so, on leaving home for a fortnight, removed the queen, a valuable one, and left them to rear a successor from her brood. On my return the young queen, a small dark-coloured one, was at liberty with a small population; but as the cottagers were taking down their bees, I drove a hive, and brought the natives home to strengthen the waning colony. I sprinkled the strangers with peppermint-syrup, and also anointed the aborigines with the same compound, and as I was quite indifferent to the fate of the queen I knocked the bees out in a mass in front of the hive, having secured the queen and placed her in limbo, and left them, making sure that they would make good an entrance; but on my returning home, to my astonishment, I found that my bees, relying on their strong intrenchments, had compelled the strangers to beat a retreat, leaving a vast number of their comrades dead in front of the stronghold. But where had they retired to? I supposed they had returned home, but on inquiry found not one had been seen at the accustomed stand, and on examining a bar and frame hive, containing previously a strong population, I was satisfied that the exiles had joined the community, and this had been effected without the slightest opposition from its inhabitants.

I afterwards drove another cottager's hive, and proceeded in exactly the same manner, but before knocking out the bees in front of the unicomb-hive compelled the sentinels to retire from the entrance by giving them a few good puffs

of tobacco smoke; the strangers marched to the entrance with great alacrity, gained possession of the entrance, and very soon entered the hive *en masse*. No fighting took place. The bees were in a great state of agitation all night, as the strangers were evidently searching for their queen, and in the morning I found that the young Italian monarch was under arrest, she was not, however, very closely confined, and would, I doubt not, have soon been set at liberty. To hasten her liberation I dispersed her persecutors with a whiff or two from the pipe; the bees still continued to search for their own queen, but did not again molest the Italian princess, who was proclaimed monarch by universal suffrage before evening set in.—J. E. B.

#### BEES IN A CHIMNEY.

A SWARM of bees have settled in an unused chimney in a large stack in my house. The chimney is a great height from the ground, the house being too storeys high, and the swarm is some distance down the inside. What means would you advise me to adopt in order to capture the colony?—T. H. F.

[We confess ourselves puzzled, and should be obliged if any of our correspondents who have had experience in the capturing of errant swarms would advise "T. H. F." in his difficulty.]

#### BEES FIGHTING IN A COLLATERAL.

A SMALL straw hive being crowded, I added a collateral box. After about a week the bees entered it, but only to fight furiously, so that the ground in front of the hive is strewn with dead bodies. I cannot tell what they were doing in the hive, but they worked very peaceably in a super.—H.

[We cannot tell why your bees fought in the side box. Are you sure they did so? We have known bees die in great numbers owing to being unable to find their way out. In this case a small aperture allowing the bees to escape into the open air is all that is necessary to set matters right.]

#### DRIVING BEES, AND TAKING THEIR HONEY.

THIS is the second year I have had them, and I have been most successful this year in driving them. I drove a hive last week, which swarmed May twelvemonth, and obtained 40 lbs. of fine honey, and did not lose one bee. They are all working away merrily now in another hive. In the case of a swarm of bees which I took on the 2nd of June, finding the hive so full of comb, I drove the bees on the 22nd, and have 10 lbs. of beautiful white honey. I mention this hoping it will encourage young bee keepers, and save the bees from the painful death of suffocation.—PROSPERA.

#### OUR LETTER BOX.

COCHIN-CHINA CHICKEN DYING SUDDENLY (*Eboracum*).—Staggering after feeding, and falling dead, demonstrates that the chicken died of apoplexy. A blood-vessel ruptured on the brain. Cochin-Chinas are voracious feeders, and excess of food is one of the most common causes of apoplexy both in man and animals. Less food both in quantity and at any one time is the best preservative.

FATTENING CHICKENS (*Idem*).—We cannot reply better than by this quotation from our "Poultry Book for the Many." Oatmeal and barley-meal alternately, mixed with milk, and occasionally with a little dripping, is good food. The feeding-troughs, which must be kept constantly scoured, should be placed before the birds at regular intervals, and when they have eaten sufficient it is better to remove them, placing a little gravel within reach of the coop to assist digestion. Keeping the birds without food for some hours after they are put up frequently induces them to take it more readily afterwards, but sufficient attention is rarely bestowed on the various details of preparation and supplying the food; hence complaints of the fowls deteriorating in the fattening-pen are far from uncommon. Access to water should be allowed at all times. Fattening must be completed in ten days, for after that period they begin to lose weight. The best age for table birds is when they are from four to six months old. The coop should be 3 feet high, 2 feet wide, and 4 feet long. This will admit from six to eight birds, according to their size. The bottom and front should be of bars 3 inches apart. A board outside the bars in front, 6 inches wide, will serve as a stand for the food and water-troughs. The coop should be in a warm, well-ventilated outhouse, and if kept dark between the times of feeding all the better. Sleep and warmth promote fattening.

JAVA SPARROWS (*B. B.*).—It is a very usual thing for birds, although not paired, to lay eggs and sit on them for a short time, and such was the case with your Canary. A Java Sparrow will not pair with a Canary, as the former bird will not breed in this country. We do not know of any distinctive marks between the sexes of the birds.

STOCKING A HIVE (*R. W.*).—The best mode of stocking your improved hive is with a swarm from the old colony. Transferring a stock of bees from a common to a moveable comb hive is by no means a simple operation, and one which should only be undertaken by a skilled bee-master.

WEEKLY CALENDAR.

Day of Month.	Day of Week.	JULY 11—17, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun rises.		Sun sets.		Moon rises.		Moon sets.		Moon's Age.	Clock before Sun.		Day of Year.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 75.5°, and its night temperature 50.8°. The greatest heat was 94°, on the 17th, 1834; and the lowest cold, 34°, on the 16th, 1863. The greatest fall of rain was 1.60 inch.

FIG TREES IN POTS.

As regards Fig trees for pot culture these may be of two kinds—dwarfs, and bushes on short stems. The former have the shoots close to the soil, and very often spring-

ing from the stem beneath it, and are readily obtained. These have from three to five shoots generally, and are grown on the system of never stopping the shoots, but the wood done bearing is annually cut out, and the young shoots that spring from the base of the plants are retained, thus keeping the tree furnished with bearing and young wood without encumbering it with that which is old and useless.

The bush trees have straight stems 9 inches or a foot high, with a bush-like head above that. Trees, to form these, should have a single or straight stem, cutting off the side shoots, and that must be cut down in the spring to within 9 inches or a foot of its base, disbudbing the shoots to three or five shoots, according to their strength, allowing three to a weak and five to a strong plant. When they have made five full-sized leaves pinch out the points of the side shoots, allowing the upper one to grow three weeks longer, then pinch out its point in like manner, and the tree is formed; but it will not fruit that season, unless it be grown in a forcing-house, when the spring shoots may give fruit in autumn, still it is as well not to allow them to do this, but rub off the fruit if any be shown, so as to throw more vigour into the second or midsummer shoots on which the first crop is produced in the ensuing season.

We have now provided Fig trees of two kinds—one in which the shoots are never shortened, but when the old shoots become too long young shoots from the base are prepared to take their place and the old cut clean out, by which system we keep up a succession of young bearing wood, and dispense with the old. These are the kind of trees to be selected for forcing. In those of the second description the shoots are systematically shortened to five joints whenever that number of leaves is made, the shoots being disbudbed so as to prevent crowding, notwithstanding which the shoots will become too much crowded in a few years, rendering it absolutely necessary to thin-out the shoots with a sharp knife close to the branch from which they spring, or to the stem itself. These trees may be bushes on very short stems, or standards from 1 foot to any height of stem desired. They are most desirable for cool houses or those occasionally heated.

The Fig makes two growths in a year. The first is the spring growth, on which the second or autumn crop of fruit is produced, the shoots being made before midsummer in heated structures and the young fruit will be prominent

in the axils of the leaves. The second growth is made after midsummer, and such shoots are usually termed the midsummer shoots, and on such the fruit is produced that furnishes the first crop the following season. Owing to the Fig making two growths in a year two crops are obtained in a twelvemonth and occasionally three, but though three may have been obtained I am inclined to believe from my own experience that two crops are the limit. I readily admit that I have had a crop produced from May up to July by trees started in January, when the trees would rest until the end of August, then commence ripening a crop from the spring shoots, and continue to do so until October. Now this is to me conclusive that the non-stopping of the shoots has a tendency to cause continuous bearing rather than the production of two crops or three in a season; yet there is evidence of two crops, for there is a cessation from bearing between the first and second crop on the same trees. The Brown Turkey or Lee's Perpetual is very nearly a continuous bearer, whilst in most others the fruit is ripe in a much shorter time, and the evidence of one or two crops more is apparent. Have any of your correspondents had the Fig produce three distinct growths and ripen three distinct crops in one season? If so, When were they started? at what time were the respective crops ripe? and when were the trees put to rest? also, what kind or kinds?

By stopping the spring shoots the flow of sap is arrested and impelled into the fruit then swelling on the shoots of the previous year. Stopping thus increases the size and forwards the ripening of the present crop, and assists the ripening or perfecting of the shoot just made, so that the second crop is likely to be produced sooner than were the shoots not stopped. There is then a likelihood of two crops being obtained in the season without much, if any, artificial heat. The midsummer shoots should in turn be stopped if they make five joints (which is not always the case, far from it, for they oftener make but a few short joints from which the growing point must not be taken), in order to hasten the maturity of the autumn or second crop, and to ripen the wood producing the first crop next year.

In all cases of Fig-training nothing is a greater obstacle to the production of fine fruit than crowding the shoots. Every shoot should be at such a distance from the others that its foliage may not be deprived, nor deprive them, of light and air. Allowing too many shoots to grow after stopping, or without stopping, at the spring or midsummer growth, is only making work for the knife, which is only necessary in Fig pruning for cutting out old shoots; by disbudbing or not allowing more shoots to grow than are absolutely required, the vigour of the tree may be directed towards the few shoots that bear, instead of being wasted on the many that are not wanted. If any shoots have a tendency to become over-vigorous tie them down, which will lessen the crowding considerably, arrest the rapid flow of the sap, and conduce to increased productiveness. Stopping the wood when the trees are leafless is not only useless but is detrimental to bearing. Any knife-shortening of Fig trees is bad; when the knife is used for shortening it should be to cut off the branch altogether. In fact, we only want a knife once a-year, in spring, to cut out any old branch long

and destitute of bearing wood, for Figs never bear on spurs. Dishud during the growing season instead of permitting a shoot to grow in order to cut it out, and use the nails of the finger and thumb for pinching out the points of the shoots.

The most suitable soil is hazel or yellow loam, from turf 3 inches thick, cut up roughly, and one year old. To this it is hardly possible to add anything that would improve it, unless the loam is very strong, when the addition of sand would be good, and if light, strong loam and well-rotted manure would be an improvement. Drain the pots effectually. No plant will do well in a badly-drained soil, neither will the Fig.

Fig trees may be fruited in six or seven-inch pots, and though the fruit is small it is much superior in flavour to that produced where circumstances are more favourable to growth. Six-inch pots are only suitable for very small plants, and at the best afford but a scanty supply of fruit. They will, however, do in the second year for those raised from eyes, when they will give two crops. Deep pots are to be preferred, and the Fig should always be kept under rather than overpotted. If treated to "plenty of pot-room" the trees acquire an excess of vigour prejudicial to their fruiting with certainty, and are more apt to cast their fruit than plants which grow but little and are pot-bound. Nine and ten-inch pots are very convenient sizes for trees intended for forcing, eleven and thirteen-inch pots for those intended for growing in vineries and comparatively cool houses. Larger pots may be employed, but they are inconvenient.

The time of potting is a matter of some nicety. If the trees are potted in winter, or a short time before forcing or growth commences, most, if not all, the fruit will fall, and, if potted whilst in active growth, in all probability a plentiful supply of wood, and the fall of the second crop prematurely will be the results. It is, indeed, hardly possible to pot the Fig without losing a part, if not all, of the succeeding crop. One exception is when the pots are plunged in a bed of leaves or other fermenting materials, so as to get the roots to the sides of the pots before any leaf growth of moment takes place; and the other exception is when the trees are potted immediately after the last crop of fruit has been gathered, and the leaves are assuming their autumn tints, for the fibrous roots are sure to be emitted rapidly in spring, and the succeeding crop will seldom fall in consequence of the shift. It is a good practice to pot Figs seldom, but to top-dress with rich compost, removing the old every year just when the leaves begin to fall, and to keep the pots half plunged in leaves, or standing on a bed into which the trees can root through the holes in the pots. The roots in this case should be cut off annually at the time of top-dressing.

In addition to top-dressing, the trees may be fed with liquid manure, weak applications once or twice a-week being of great service during the swelling of the fruit. I have occasionally covered the surface of the soil with a layer of fresh cowdung about 3 inches thick, so as to form a basin round the stem, and into this the water was poured; a healthy tree in full growth would require this basin to be filled twice a-day in hot weather, and once daily in dull periods. I may venture to state that there is not a fruit tree in a pot that will not do well with a top-dressing of fresh cowdung, and the roots come up into it. Among the trees that like it best, the Bananas or Musas are conspicuous; they will take three dressings of the fresh dung in a season, and every time the roots will come through begging for more. The Vine, Peach, Nectarine, and all stone fruits, and the Fig, flourish in it.

As to water, the Fig requires a good supply, but the soil should never be deluged, nor allowed to become dry, or the fruit will fall. It is a nice point neither to under nor overdo the watering of Fig trees; they should be kept well and regularly supplied. The Fig seems to be very impatient of changes, for I have found that a change of the waterer would be sufficient to cause the fruit to fall. I never could understand this, but such is the fact; only one person, when it is practicable, should water Figs. When the fruit is ripening the soil should then be kept rather drier, still well supplied with water, but when the second crop is ripened off the water should be given sparingly, and altogether discontinued after the leaves have fallen.

After bearing, the trees may be kept in any cool house or shed, and the cooler the better, if only secure from frost. Though the soil in the pots is usually allowed to remain dry from the time of the leaves falling to that of the trees being placed in heat or in the house where they are intended to fruit, I am certain that this drying process may be carried to

extremes. The soil should be dry, no doubt, to a certain extent, but there is a difference between keeping it dry to guard against frost, and so dry as to cause the roots to shrivel. The soil should be so moist as to maintain the roots in a healthy state; dry, but with a certain amount of moisture, though dry to all outward appearance.

During the seasons of growth (the Fig having two), the foliage should be syringed forcibly on the under side to keep down red spider, its greatest enemy, twice daily from first to last, except when the first crop swells for ripening, when the air must be dry, otherwise the fruit will crack and split before fully ripe, and after the second crop begins to ripen no more syringing will be needed, in fact, syringing should then be discontinued, the atmosphere kept dry, and well ventilated.

The Vine is not unlike the Fig in the treatment which it requires as to temperature, and Fig trees in pots may be successfully grown in vineries, whether forced or not, and will succeed in a common greenhouse; but to secure two crops it is necessary to grow the Fig in a heated structure. Fig trees will also succeed in a slightly shaded position, but when too much in the dark, though they grow well, they fruit but little.

I shall have occasion to write of temperature, and other matters relating to Fig culture, in treating of the tree in Fig-houses, and on garden walls.—G. ABBEY.

### GOSSIP ABOUT ROSES.

ALTHOUGH my recent run through Belgium brought before me many subjects of interest, which I should be glad to introduce to the readers of THE JOURNAL OF HORTICULTURE, yet as we are now in the very height of the Rose season, and so many and so widely distributed are the subjects of the queen of flowers, I cannot do better, I think, than just have a little quiet loyal chat with them on the matter of our common sovereign; and while the "free and independent" all through the country are discussing the relative merits of blue and orange, pink and purple, we can, without the excitement, the cold brandy and water, and pots of beer, which seem, alas! intimately connected with political strife, decide as to the merits of the candidates for our constituency; and as it seems to me that the measure of a candidate's suitability is what can be got out of him, so, I think, we have something of the same standard to go by. If we cannot get out of our new Rose enjoyment from its personal appearance (a point in which, by-the-by, many would-be M.P.'s are singularly defective), pleasure in seeing its fine foliage and steady growth, and comfort in its having a good constitution, we at once say it won't do for us. It may represent other constitutions—it may do for the suburban porch of our friend Tomkins or the wilderness gardens of Sawkins, but it will not do for our more fastidious eye; so that after all, though we talk very loudly, I am afraid that we are actuated by something of the same spirit as the free and independent electors who have the prospect of a good berth or so for Master Tom or Harry in their minds before they give their votes.

Any one who goes to Paris in the expectation of seeing first-rate Roses will be disappointed. I had a good walk through several of their grounds, and I feel confident that neither Margottin, Verdier, nor Levesque could put up such boxes of Roses as we are wont to see at our shows. Nor is it difficult to see that this must be so. The great heat and dryness of the soil is injurious to good blooming, while the absence of that stimulus that a good prize gives with us makes itself felt. Again: Any one who has tried knows the difficulty of seeing the new Roses. You are either too soon or too late: so that, although I have gone over at various times in June, yet I have never seen many. I do not say that this is intentional—far from it; I believe the growers wished to let me see their Roses; but as the new varieties are cut up so much for propagation they are always a good deal later than the established plants, and thus until the end of June you would hardly see the new Roses there; and at that time all the Lyons Roses, some of our very best, will have passed. Indeed, Lacharme told me that the best time to see the Roses of the South of France is September; and the mention of his name induces me to notice what perhaps many of your readers may have omitted to see last week, as it was amongst the notices to correspondents—that he has been fortunate enough to obtain a genuine yellow Hybrid Perpetual Rose. I had best give his own description of it:—"C'est un Hybride très remuant, arbuste vigoureux; fleurs de la forme la plus parfaite des centfeuilles (Centifolia), très

bean jaune." He says, moreover, that he has others with yellow flowers, which he is propagating. This is great news for us, and opens out the prospect of other accessions. He has also a very pure white in the style of Louise Darzins. These are not for next autumn. He intends to send out four varieties in the autumn of the present year, one of which I have seen, the other I hope to see before then. The one he did send me was a very fine flower of the *Senateur Vaisse* and *Duc de Rohan* type. It is called *Alfred Colomb*. The flowers are large, full, and well-shaped; the colour, a lovely scarlet crimson, not shaded. He says he is very rich in seedling Roses, and he is no mean judge, although he has made a sad blunder in one matter. I heard the story in Paris, and also from several the other day at the Crystal Palace; and as I knew it was incorrect I determined to sift the matter to the bottom, and I believe every Rose-grower will acknowledge the correctness of the view I have taken. It is this: Lacharme was walking in the garden of Mons., a celebrated Rose-grower at Paris, and, seeing a Rose in bloom, asked what it was. He was told John Hopper. "Ah!" said he, "that is one of my seedlings. The year that Charles Lefebvre was sent out this Rose was growing alongside of it, and in executing an order for England my man took it up by mistake and sent it over." Now, I know Mr. Ward. I know him to be too honest a man to have acted such a lie; and I at once said, "This cannot be true, for I saw John Hopper before Charles Lefebvre had left Lacharme's nursery, for I well recollect Mr. Ward sending it up to the Floral Committee in 1860, and how disappointed he was at its non-recognition by them. I then told him that I was convinced it was a first-rate Rose, and to keep it and show it again. This he did, and with what result the world of rosarians knows full well." On my return to England, finding that the statement was being disseminated, I wrote to Mr. Ward, and his answer, which I have now the pleasure of placing before Rose-lovers, completely settles the matter. It will be seen that I sought the fullest information on the subject. "I do not wish to be robbed of the honour of raising John Hopper, and I much feel the position such a statement would place me in with the public if not contradicted. I shall be very glad to show any one the original seedling plant and parent of every John Hopper in existence, and my own production. I will now answer all the questions you have kindly put, and shall be glad to answer or prove any other any one may feel respecting the original of the plant.

"1. I raised the plant from seed in 1859.

"2. You saw the first blooms in September, 1860.

"3. I sent it out in the autumn of 1862.

"4. At the time I let it out my stock consisted of six thousand saleable plants and several thousands in a dormant state.

"5. I never in my life received a plant of any description from Lacharme or any other raiser or individual in France.

"Charles Lefebvre came out in 1862, at which time I had six thousand plants blooming of my John Hopper. I should have shown my Rose again in 1861, most likely have sent it out in the autumn of 1861 or spring of 1862; but I had a long illness—for four months in bed, which prevented it."

I think that this is quite overwhelming evidence, and I have every reason to think that when Lacharme knows it he will be quite ready to say he is wrong. I felt that our poor fame is injured by such misrepresentations, and hence my desire to sift it to the bottom. I have no doubt that, to my mind, the unwise custom of buying the stock of a Rose in France, and then sending it out here with an English raiser's name attached to it, leads the French Rose-growers to believe all our new Roses are of the same character: it is a very misleading practice.—D., Deal.

### EARLY PEAS.

SOME of your readers have, I see, favoured you with the results of their experience concerning different sorts of early Peas, and therefore it may not be out of place to give you mine also.

I sowed early in March last, within the same half hour and on the same ground, six rows of early Peas, each row 9 yards long, three rows of Carter's First Crop, two of Sangster's No. 1, and one of Dillistone's Early Prolific.

The Early Prolific seemed to be more affected than the others by the cold winds of our late and lingering spring, and did not thrive nor do well. I do not think we gathered from it a quart of pods, and I shall not grow it again. It was perhaps a couple of days earlier than Carter's First Crop. Carter's First Crop yielded also very badly, scarcely more than the

Prolific. These also I shall grow no more. They were ready, I think, two or three days before Sangster's No. 1. A serious circumstance attending their culture was that after a time their first growth made no further progress, but a fresh growth took place from the roots, reaching to be a foot high, but resulting in small blossoms and insignificant pods. The two rows of Sangster's No. 1 yielded five or six times more than all the other four, and were very little behind them in time.

Mine is a garden of good soil, entirely unshaded by trees or buildings, wholly open to the south, east, and west, but sheltered by a high bank of fully 20 feet high from the north. Last year I grew for the early crop only Sangster's No. 1. Half of the seed I steeped as recommended by one of your correspondents, the other half I did not. The steeped Peas were ready for gathering fully a week before the others. I may add that with this year's crop no sticks were used.—THEA.

### PROPAGATING STAUNTONIA LATIFOLIA.

WE have a beautiful evergreen creeper, the *Stauntonia latifolia*, which seems to be little known, at least neither we nor our friends can procure any plants. Our plant nearly covers the front of our house, has had blossoms during the last three springs smelling deliciously like Orange flowers. In vain we have tried to give our friends cuttings. We have pegged down suckers near the root which we are told may in two or three years produce plants! We are trying also to bend some of the shoots into pots on a balcony, but these all wither away, so do the wooden branches which we try to bend down into the earth in the pots; yet every gardener who hears of this creeper and wishes to have some of it, says nothing is easier than to propagate it in this way. Can you give us any more instructions? This season for the first time, some little green pods like short caterpillars have appeared, but they seem to fall off without ripening.—A. A. Y.

[Select some of the finest flowers and disperse the pollen about the pistil. This is best done with a small camel's-hair brush. If the blooms are carefully fertilised they will readily produce seed, which is the surest way of propagating it, and the way is to select half-ripened shoots, cut a small nick just where the shoot is bent, then peg it firmly into the ground using plenty of sand about it. This will cause the roots to work freely. In fertilising the blooms select a day when there is plenty of electricity in the air.]

### MY PLANTS,

AND HOW AND WHERE I FOUND THEM.—No. 6.

I HAVE always combined a slight account of natural history with my botanical rambles, and the description of the knight in the "Ingoldsby Legends" would equally apply to myself. My delight as a girl was to pore over some unknown chrysalis, with two or three works upon butterflies and moths by my side; to bind up the broken limb of some unfortunate fowl; to refresh the leeches, newts, and beetles in a large wooden tub (in which I had made an imaginary island), with a shower of water from a large garden pot; or to watch the change of the tadpole into a frog, the same tadpole being kept for closer inspection in a water-bottle upon my dressing-table. I was up at six o'clock in the morning after the various kinds of cabbage butterfly, through the woods in the heat of the day for the highflyers, and out after dusk in the evenings with a lantern in search of moths. Cats, dogs, dormice, and hawks completed my small menagerie. These latter were the aversion of a favourite sister, and often would she laughingly prognosticate for me the ignoble fate of "Sir Thomas the good," who,

"Be it well understood,

Was a man of a very contemplative mood.

He would pore by the hour

O'er a weed or a flower,

Or the slugs that came crawling out after a shower.

Black beetles and humble bees, bluebottle flies,

And moths, were of no small account in his eyes;

An 'industrious flea' he'd by no means despise,

While an old 'daddy longlegs' whose long legs and thighs

Pass'd the common in shape, or in colour, or size,

He was wont to consider an absolute prize.

Nay, a hornet or wasp he could scarce 'keep his paws

Off.' He

Gave up, in short,

Both business and sport,

And abandon'd himself, *tout entier*, to philosophy."

Now having introduced you to the daily life of the "good

Sir Thomas," allow me for one moment to put before you the ignoble closing of his philosophical career, and also the moral, or a part of it, with which Thomas Ingoldsby dismisses his story. After waiting for "a fortnight or more" for her spouse, who had gone out upon one of his exploring expeditions, the Lady Jane's serving men discovered Sir Thomas's dead body in the adjacent pond.

"'Twas e'en so, poor dear knight, with his 'spees' and his hat  
He'd gone poking his nose into this and to that;  
When close by the side  
Of the bank he espied  
An 'uncommon fine' tadpole remarkably fat!  
Ho stooped; and he thought her  
His own—he had caught her!—  
Got hold of her tail, and to land almost brought her,  
When—he plump'd head and heels into fifteen-feet water!"

MORAL.

"All middle-aged gentlemen let me advise,  
If you're married, and have not got very good eyes,  
Don't go poking about after bluebottle flies!  
If you've spectacles, don't have a tortoiseshell rim;  
And don't go near the water unless you can swim!"

There is no doubt that natural history and botany are most absorbing subjects to those who delight in them, and that we have a world of interest which is not enjoyed by mankind at large. I was forcibly reminded of this the other day when seeking of a bookseller a small work upon Ferns and Grasses. In answer to my inquiries I was informed that "the subject was so unpopular it was useless to keep such books in stock, but that with pleasure he would order the work for me." Who does not know how the charm and freedom of some long-looked-for expedition have been marred by the presence of some uninterested individual, who, always foreboding evil in some form or other, becomes at length a perfect Jonah in the vessel, until he or she is got rid of?—not exactly by pitching the said personage out of the vehicle, because the finale might not be so satisfactory as it was in the case of the prophet of old, and to be indicted for manslaughter would be a sad termination to even such unsatisfactory beings as monomaniacal botanists—but by the quiet dispersion of detachments of the party to some devoted spot, leaving the aristocratic individual who eschews dirty hands, hard names, and uncomfortable-looking caterpillars and flies to the charity of some kind-hearted friend, and to lemon-coloured kid gloves and Byron.

Strangers in Jersey, nothing of this kind troubled us. Independent of everybody, we daily took some new walk, either in the interior of the island, through the lanes with their Ivy-clad banks, or towards the seacoast. The sea-weed is so abundant on the rocks around Jersey, that the inhabitants at certain times collect it for manure and fuel; and "vraicking," as it is called, is quite a gala time, men, women, and children all being engaged in it. I have seen whole families returning home late and wearied with their carts laden with sea-weed or "vraick." No hay-making scene in England can be more picturesque. Fish is exceedingly plentiful. Congers of different species abound amongst the rocks, some of them of an immense size and strength. A shell-fish, the *Auris marina*, or "Ormer," as it is called by the natives, is considered a great treat, although I think we did not appreciate it as much as our Jersey neighbours. The Alderney cows, of which we hear so much in England, are chiefly sent from this island; these with a few sheep and goats appear to comprise the short list of domestic animals of which the place can boast. We found it most difficult to obtain good English mutton whilst we were residing in St. Saviour's; and I feel sure that a good deal of that which was brought to us had more properly been designated "goat," the flavour was so strong and the meat so unpalatable.

There is one plant which immediately catches the eye of the newly-arrived visitor to Jersey. It is called the Jersey Cabbage. The plant grows to the height of 6 or 7 feet, and upon the top of this high stem is the Cabbage. A garden planted with these vegetables has the appearance of a miniature grove of trees. I believe they use the stems of the trees as walking-sticks. A most detestable combination which rejoices in the cognomen of "Jersey soup," was pressed upon us one day by our voluble French hostess. We politely refused the proffered luxury, as from the details of the ingredients therein used, we were more disposed to take her word for its merits than to try it; but she would take no nay. It was "très bonne." "Mais, Madame! You English are so much for dee roshif! Every day it is meat of some kind. If I have the soupe I am content." I conclude it is the "soupe maigre" of the continent;

and soupe maigre it certainly is, being nothing but the water in which a piece of fat bacon and a Cabbage have been boiled.

One morning in strolling about the garden I saw what I considered was a humming moth flitting from flower to flower. It eluded all my attempts to catch it, and finally I lost sight of it altogether. I have since my return to England read of an insect which is peculiar to Jersey, and which "resembles a humming bird so much in its habits that it is considered of the same species. Its size is that of a large humble bee. It does not light on any plant, but continually fluttering with a loud humming noise, it introduces a long proboscis into the emp of a flower, and thus sucks out the moisture." I still am inclined to think that it is the same moth which goes under the name of "Humming Moth" in England, and which we see occasionally in our gardens flitting and dancing over the flower-beds like a fairy thing. Whilst speaking of beautiful things I must not forget to mention the lizards which are found upon the sunny banks of Jersey. I am just now alluding to that bright green kind which one sees, with its piercing eyes, peering out from between the stones, or lying basking at full length in the sun. They are exceedingly vigilant, and disappear upon the slightest approach of danger. They are, however, to be bought of boys, who stealthily lie in wait for them, and secure these pretty creatures. The tremendous size of the toads in the island is, I suppose, well known: the size of a breakfast saucer is about the usual circumference. I could even excuse the lady in the light kid gloves if she fainted at the sight of these hideous monstrosities. I would go even farther, and bathe her face with eau de Cologne, and read Byron to her during the process.—ALICE.

ROYAL BOTANIC SOCIETY'S SHOW.

JULY 5TH.

This was the last of the Society's Shows for this season, and despite of the hot weather of the previous fortnight, the flowering plants were still in good bloom, though not looking so fresh as they did in May. Ferns and other ornamental-foliaged plants were in fine condition, whilst of fruit there was a very extensive and excellent display. The day being fine there was a large attendance of visitors.

STOVE AND GREENHOUSE PLANTS.—Although several very good collections were shown, the plants of which they were composed were nearly the same as at former shows. Of *Ixora salicifolia*, Mr. Whitbread exhibited a remarkably fine specimen covered from the base to the top with large heads of orange flowers; and a very good specimen also came from Mr. Peed. The white-flowered *Ixora alba* was likewise well represented in several collections, as well as *Ixora coccinea* and *javanica*. *Allanandus* consisted of *grandiflora*, *Schottii*, and *cathartica* in good bloom; and a *Stephanotis* from Mr. Fraser was covered with a profusion of its white blooms. Among other plants we noticed *Dipladenia splendens*, and *D. acuminata* with numerous flowers of a deeper rose; *Mussaenda frondosa*, *Kalosanthes*, *Hæmianthus panicus*, with sixteen of its showy orange scarlet heads; *Cyrtocarpus reflexum*, *Statice*, *Heaths*, *Aphelaxes*, *Pleroma elegans*, *Vincas*, and *Dracophyllum gracile*.

Awards.—For sixteen: first, Mr. Peed, gardener to Mrs. Tredwell; second, Mr. Whitbread, gardener to H. Collyer, Esq., Dartford; fourth, Mr. Kaile, gardener to Earl Lovelace. For ten (Nurserymen): first, Mr. Fraser; second, Mr. Rhodes; third, Messrs. Lee; fourth, Messrs. A. Henderson & Co. For ten (Amateurs): first, Mr. Chilman, gardener to Mrs. Smith, Epsom; second, Mr. A. Ingram, gardener to J. J. Blandy, Esq., Reading; third, Mr. Page, gardener to W. Leaf, Esq.; fourth, Mr. Wheeler, gardener to Sir F. Goldsmid, Bart., Regent's Park. For six: first, Mr. Wheeler, gardener to J. Phillipot, Esq., Stamford Hill; second, Mr. Kemp, gardener to Earl Percy, Albany Park; third, Mr. Smith, gardener to A. Anderson, Esq.

FINE-FOLIAGED PLANTS AND FERNS.—Foremost among the former was a collection from Mr. Veitch, of Chelsea, containing a magnificent specimen of *Alcacia zebrina*, the dark green sagittate leaves about a yard in length, and the stalks beautifully marbled; also, two *Crotons* of large size and with the foliage beautifully coloured, the golden colour predominating in *C. variegatum*, whilst in *picturnus* the red variegation was conspicuous, especially round the margin. Among the others were the variegated *Pandanus javanicus* with the leaves beautifully striped; the graceful *P. reflexus*, a noble *Dicksonia antarctica*, *Cyathea dealbata*, *Theophrasta imperialis*, *Chamaecrops exelsa*, and *Lutania borbonica*. From Messrs. A. Henderson & Co. also came *Alcacia zebrina*, and their fine *Alcacia macrorhiza variegata*, *Maranta Porteana*, the leaves prettily marked with white; *Anthurium lenocentrum*, with deep green leaves veined with white; *Croton angustifolium*, very ornamental from the weeping appearance which is offered by the narrow pendulous leaves; and a fine variety of *Caladium bicolor*. Mr. Bull likewise contributed a good collection, consisting of Ferns, Dracenas, and Palms. In the Amateurs' Class, Mr.

Baines exhibited a remarkably fine collection in which *Caladium Lowii*, *Aloesia metallica* and *microchiza variegata*, and the variegated *Croton* were the most striking. *Dicksonia antarctica* had a stem 8 or 9 inches in diameter, the head forming an umbrella; *Gleichenia speciosa* was also very fine. Collections containing large well-grown specimens were likewise exhibited by Mr. Taylor and Mr. A. Ingram, and smaller ones came from Messrs. Young and Carr. Among them, besides several species already noticed, were *Nepenthes Rafflesiana* with several pitchers, and a very good pan of the red-veined *Gymnostachyum Verschaffeltii*, from Mr. A. Ingram.

Of Exotic Ferns, excellent collections of healthy well-grown plants came from Mr. Barnard and Messrs. Young, among Amateurs; and Messrs. Bull, Williams, and A. Henderson, among Nurserymen. Of British Ferns, interesting collections were exhibited by Messrs. Ivory, containing many curious forms, especially of the Lady Fern and Hart's Tongue; two pretty varieties of the former being *Athyrium f. f. diffusum-multifidum* and *A. f. f. Pursonianum*.

Awards.—For ten Fine-foliated Plants (Nurserymen): first, Mr. Veitch; second, Messrs. A. Henderson; third, Mr. Bull; fourth, Mr. Rhodes. For ten (Amateurs): first, Mr. Baines, gardener to H. Micholls, Esq., Boydon; second, Mr. Taylor, gardener to J. Yates, Esq., Highgate; third, Mr. A. Ingram; fourth, Mr. Young, gardener to R. Barclay, Esq., Highgate; fifth, Mr. Carr, gardener to P. Hinds, Esq., Byfleet. For twelve Exotic Ferns (Amateurs): first, Mr. Barnard, gardener to J. Taylor, Esq., Woodbury Down; second, Mr. Young, gardener to W. Stone, Esq., Leigh Park; third, Mr. Young, gardener to R. Barclay, Esq.; fourth, Mr. Taylor, gardener to J. Yates, Esq. For twelve (Nurserymen): first, Mr. Bull; second, Mr. Williams; third, Messrs. A. Henderson. For twelve British Ferns: first, Messrs. Ivory; second, Mr. Holland, gardener to R. Peake, Esq., Isleworth.

HEATHS were well grown and bloomed, but little can be added as regards the varieties to what has appeared in former reports. Of *Parmentieriana rosea*, Massoni, *Siumonia*, *Shavilleana*, *obovata*, *eximia*, and others, very good specimens were shown.

Awards.—For ten: first, Mr. Rhodes; second, Messrs. Jackson; third, Messrs. Lee; fourth, Messrs. F. & A. Smith; fifth, Mr. Baxendale. For eight: first, Mr. Peed; second, Mr. Wheeler, gardener to J. Phillpot, Esq.; third, Mr. A. Ingram; fourth, Mr. Chilman.

ORCHIDS were not so numerous shown as on the last occasion, nor, indeed, in such perfection. In collections of twenty, Mr. Bullen again sent *Brassia Henchmanni* in good bloom, several *Cattleyas* and *Aerides*, there being among the latter a very good *Aerides Lobbi*, *Oncidium ampliatum majus* and *Lanceanum*, *Cypripedium barbatum majus*, *Lycaste Skinneri*, *Lelia elegans*, *Trichopilia crispata*, in fine bloom; and *Uropedium Lindenii*, with two flowers, one of which had a tail 9 inches long. From Mr. Page came *Cypripedium Stonei*, with two of its handsome flowers; *Saccobolium Blumei*, with a fine spike of flowers; good *Phalænopsis*, including a small plant of *P. rosea*; *Vandas*, bearded *Cypripediums*, and *Aerides*. Mr. Penny had in his collection of twelve, *Cattleya Mossie*, in fine bloom; *Anguloa Ruckeri*; *Aerides Lobbi*, fine; *Trichopilia picta*; fine varieties of *Cypripedium barbatum superbum* and *Saccobolium guttatum*; the rich-coloured *Oncidium Lanceanum*; and *Aerides Lindleyanum*. In Mr. Wilson's collection, which was also excellent, *Trichopilia picta* was blooming freely, besides which there were *Cattleya superba*, brilliant in colour; *C. Schilleriana* and *C. Leopoldi*, both beautiful in colour; the brilliant *Disa grandiflora*, *Aerides odoratum*, &c. *Calanthe veratrifolia*, and *Renanthera coccinea*, in fine bloom, came from Mr. Hill.

Awards.—For twenty: first, Mr. Bullen, gardener to A. Turner, Esq., Leicester; second, Mr. Page; third, Mr. Peed. For twelve: first, Mr. Penny, gardener to H. Gibbs, Esq.; second, Mr. Wilson, gardener to W. Marshall, Esq.; third, Mr. Wiggins, gardener to W. Beck, Esq., Isleworth; fourth, Mr. Young, Leigh Park; fifth, Mr. Chilman. For six (Nurserymen): first, Messrs. Jackson. For six (Amateurs): first, Mr. Hill, gardener to R. Hanbury, Esq.; second, Mr. A. Ingram; third, Mr. Whitbread; fourth, Mr. Wheeler, gardener to J. Phillpot, Esq.

PELARGONIUMS were good, considering the heat and the period of the season. Mr. Fraser had *Pericles*, *Bacchus*, *Lord Clyde*, *Bessie*, *Royal Albert*, *Prince of Prussia*, *Landseer*, *Perdita*, *Festus*, *Regina formosa*, *Marabout*, and *Desdemona* in good bloom; and in the Amateurs' class, Mr. Bailey had by far the best. They consisted of *Guillaume Severens*, *Desdemona*, *Beneon*, *Royalty*, *Etna*, *Pericles*, *Mademoiselle Patti*, *Scarlet Floribunda*, *Regina formosa*, and *Confagration*. In *Fancies*, Mr. Fraser was the only exhibitor. His varieties were *Cloth of Silver*, *Madame Sainton Dolby*, *Miss-in-her-Teens*, *Bridesmaid*, and *Roi des Fantaisies*. Mr. Catlin exhibited some very good *Scarlets*.

Awards.—For twelve: first, Mr. Fraser. For ten: first, Mr. Bailey; third, Mr. Wiggins. For six *Fancies*: first, Mr. Fraser. For six *Scarlet*: first, Mr. Catlin, gardener to Mrs. Lermite, Finchley; second, Mr. Pettit, gardener to G. Powney Esq.; third, Mr. Hawes, gardener to J. Noble, Esq., Fortis Green; fourth, Mr. Weir; fifth, Mr. J. Logan.

FUCHSIAS.—The plants of these were not large, nor was the bloom first-rate. Among the best of the white-sepaled varieties were *Rose of Castille*, and *Minnie Banks*; of those with white corollas, *Madame Cornelissen*; and of dark kinds *Sir Robert Peel*. Messrs. E. G. Henderson exhibited several of Mr. Banks's varieties, as *Puritani*, white

corolla, *Charming*, a fine dark kind; *Loerzia Borgiu*, very large flowers; *La Favorita*, and *Sunshine*.

Awards.—Second, Mr. J. Weston, gardener to D. Martineau, Esq., Clapham Park; third, Mr. Gardiner, gardener to J. Stutter, Esq.; fourth, Mr. Green, East Greenwich.

ROSES.—There was a good display of cut blooms, among which were some of the new *Tea* *Maréchal Niel*. Of others there were very good examples of *Charles Lefebvre*, *Gloire de Saintomy*, *François Louvat*, *Madame Charles Wood*, and *Isabella Gray*.

Awards.—For fifty: first, Mr. Turner, and Messrs. Paul & Son; second, Mr. Fraser. For twenty-five: first, Mr. Exill, gardener to J. Hollingworth, Esq.; second, Mr. Ingle, gardener to G. Round, Esq., and Mr. Wright, Twickenham. For twenty-four: first, Mr. Turner; second, Messrs. Paul & Son; third, Mr. Fraser.

NEW PLANTS.—Interesting groups of these were furnished by Mr. Veitch, and Mr. Bull. Mr. Veitch had his new *Rhododendrons*—*Princess Royal*, and *Princess Alexandra*, both of which are very fine; *Leptopteris superba*, very beautiful; *Bertolonia*, *Urceolina aurea*, *Cattleya quinicolor*, noticed last week; *Osmunthus ilicifolius*; *Sciadopitys verticillata*, a handsome plant; *Anthurium Scherzerianum*, *Calathea Veitchii*, and some others. Mr. Bull had a singular plant, stated to be an Indian Radish, with edible pods having the same flavour as a Radish. These, it is stated, grow 3 inches in a night, and attain the length of 3 feet or more. *Globba radicans variegata*, the leaves streaked with yellow; *Spharogyne cinnamomea*, *Cycas Ruminiana*, *Bertolonia margaritacea*, variegated *Verbenas*, and *Clayanthenum*, as well as several Ferns, and a pretty *Lobelia* called *Silver Gem*, with white and blue flowers, the white largely predominating, came from the same exhibitor. New Clematises were shown by Messrs. Jackman, and Mr. Townsend; and *Trichium Manglessii*, a pretty Swan-River plant by Mr. Thompson, of Ipswich. This was described in these columns some time ago, and a representation of it was given in the "Florist" of October. Mr. Thompson states that it will succeed out of doors. Messrs. E. G. Henderson sent *Fuchsia Enoch Arden*, with a large dark corolla, and bright scarlet sepals, and *Gardenia florida variegata*; Mr. Smith, Horney Road, La Grande Pelargonium, a promising scarlet *Neoseguy*; Messrs. F. & A. Smith, *Orion Zonale Pelargonium*, with salmon flowers; Mr. Morse, Epsom, *Scolopendrium vulgare Copardi*, a fine crested variety; Messrs. Ivory, *Athyrium f. f. diffusum*, *Lastrea f. m. grandiceps*, and *Polystichum proferum Holeia*, all of which are desirable additions; and Mr. Williams, a fine *Dracena lineata*, Ferns, and Aloes.

MISCELLANEOUS.—Mr. W. Paul sent his new *Neoseguy Pelargonium* in fine bloom; Messrs. Saltmarsh, some of the tricolor-foliated class; Mr. Fraser, *Kalosantes*, in fine bloom; Messrs. F. & A. Smith, a showy collection of Balsams; Mr. Baines, gardener to H. Micholls, Esq., *Sarracenia Drummondii*, purple, *lava*, and *variolaris*, fine *Anacothils*, and the curious *Dionaa muscipula*. *Carnations* and *Pineets* from Mr. Turner were very fine; Messrs. Downie, & Co., had fine *Hollyhocks*; and Mr. Perry, seedling *Verbenas*, of which Charles Turner, *Mazeppa*, *Cleopatra*, and *Glowworm*, were excellent. *Caladiums*, and hanging baskets, neatly filled, came from Messrs. A. Henderson & Co.; and from Mr. Barnes, Bieton, a fine collection of cones, produced this year at Bieton, including those of *Araucaria imbricata*, *Picea Nordmanniana*, *Abies domosa*, and many others.

#### FRUIT.

The display of Fruit was very large, and most of the objects were characterised by great excellence. It was, to a large number of visitors, the most attractive feature of the Show; the plants, many of them, had been seen before, but such fine fruit, and in such quantity, has rarely been seen.

In collections, Mr. Sage, gardener to Earl Brownlow, Ashridge, was first with fine bunches of *Black Hamburg* and *Muscata Grapes*, the latter well ripened, a good *Queen Pine*, a *Melon*, *Royal George Peaches*, *Elruge Nectarines*, *Brown Turkey Figs*, and *British Queen Strawberries*. Mr. Miller, gardener to Earl Craven, Combe Abbey, sent two fine *Queen Pines*, *Black Hamburg* and *Trentham Black Grapes*, *Canon Hall*, not sufficiently ripe; a large *Melon*, fine *Peaches*, and *British Queen Strawberries*. Mr. Ruffitt, gardener to Lord Palmerston, had a fine *Providence* and two *Queen Pines*, excellent *Peaches*, and *Black Tartarian Cherries*. Good collections likewise came from Mr. Bannerman, Mr. Dawson, and Mr. Lynn, Hedsor.

Awards.—First, Mr. Sage; second, Mr. Miller; third, Mr. Bannerman, gardener to Lord Bagot, Rugeley; fourth, Mr. Dawson, gardener to Earl Cowper, Panshanger.

PINES were not very numerous, but some good fruits were shown. For a collection of four Mr. Barnes was first with a fine *Providence*, a *Priekly Cayenne*, *Queen*, and *Ripley Queen*; Mr. Young, Leigh Park, was second with two *Providences*, a *Queen*, and an *Enville*; Mr. Dawson third. Mr. Barnes sent, in addition, a collection of *Pines* ripened in the open air, and, to all outward appearance, well ripened. They consisted of *Brown Antigua*, *Enville*, *Queen*, and *Lemon Queen*. Though the climate of Devonshire is doubtless favorable to such an attempt, and so excellent a *Pine-grower* as Mr. Barnes is well known to be the most likely to achieve success, it would be interesting to know the mode of culture which he adopted in this particular case. Some very good *Queens*, upwards of 4 lbs. in weight, were shown. Mr. Young, gardener to Crawshay Bailey, Esq., was first with a large and fine fruit; Mr. Davis, gardener to W. Booker,

Esq., Cardiff, second with one of 4 lbs. 3 ozs.; and Mr. Kemp, gardener to E. Bentall, Esq., Maldon, third. Good fruit were also shown by Mr. Carr, Mr. Barnes, and Mr. Bailey. Providence, though of good size, were not handsome. Mr. Young and Mr. Deville were equal first; Mr. Allen, gardener to J. B. Glegg, Esq., second with a cocks-comb-crowned fruit; Mr. Dawson third. In the class for Any other variety the first prize was withheld; the second went to Mr. Bailey for a Prickly Cayenne; the third to Mr. Godfrey, gardener to H. Chuck, Esq., Ware.

GRAPES.—Rarely, if ever, have finer bunches than those shown been collected together at any one exhibition.

The Black Hamburgs were magnificent. Mr. Sage, gardener to Earl Howe, was first with large beautifully finished bunches with very large berries of a jet black; Mr. Meredith second, with magnificent bunches, the centre one in particular, the three weighing 8 lbs., but a still more extraordinary exhibition was that which was put up by the same celebrated grower in the Miscellaneous class, being a single bunch with six shoulders, each as large as an ordinary bunch, finely coloured, and weighing 9½ lbs. Such a weight in a single bunch of this variety has never, to our knowledge, been recorded before, and the Judges awarded it the highest prize which it was in their power to bestow. Third prizes were awarded to Mr. Wallis, gardener to J. Dixon Esq., Astle Park; to Mr. Henderson, gardener to Sir G. Beaumont Bart., Cole Orton Hall; and Mr. Speed, gardener to Sir E. Walker Bart.; and fourth prizes to Mr. Sawkins, Mr. Jackson, and Mr. O. Goldsmith, all of whom had good well ripened bunches. Mr. Rawbone, gardener to C. Campbell Esq., Ashbourne, had three very fine bunches weighing 9 lbs. 5 ozs., but they were unripe. A splendid basket of the same Grape, also from Mr. Meredith, had a first prize, and one of 14 lbs. from Mr. M. Henderson a second, and the third was taken by Mr. Wallis.

Muscats were not sufficiently ripe; the best were fine large-berried bunches from Mr. Turner, who received a second prize. There were, however, several good bunches from other exhibitors. In Three dishes of different varieties there were several fine exhibitions. Mr. Meredith was first with Trentham Black, Black Hamburg, and Black Prince, magnificent bunches of the largest size and beautifully coloured. A second prize was given to Mr. Hill, Keele Hall, for Black Prince, fine, the three weighing 8 lbs. 2 ozs.; Black Hamburg, 5 lbs. 7 ozs.; and Black Alicante (Meredith's variety), 5 lbs. 12 ozs., one of the bunches remarkably fine. Another second prize was awarded to Mr. Osborne, Finchley, for Black Hamburg; Buckland Sweetwater, finely ripened; and Muscat Hamburg, very fine. Mr. Peachey, gardener to R. Hole, Esq., Loughborough, was third with Red Frontignan, Golden Hamburg, and Black Hamburg; and Mr. Wallis, fourth, with Black and White Frontignans, and Black Hamburgs. Several other good dishes were set up by other exhibitors.

Of other kinds, fine bunches of Black Prince were shown by Mr. Allen, Mr. Sage, Mr. Pottle, and Mr. Hill, those from Mr. Pottle weighed 9 lbs. 5 ozs., but were not sufficiently ripe. Mr. Allport, gardener to H. Akroyd, Esq., Doddington Hall, had Ingram's Prolific Muscat and Black Frontignan, very good; and of Buckland Sweetwater remarkably fine bunches were shown by Mr. Meredith, but they were apparently not ripe enough. From Messrs. Lane came good bunches of Chavonsh and Royal Muscadine. For the above the following awards were made:—For Black Prince: first, Mr. Allen, gardener to E. Hopwood, Esq.; equal third, Mr. Wallis and Mr. Sage. For other kinds: first, Mr. Allport; second, Mr. Hyde; third, Mr. Goldsmith; fourth, Mr. Peachey; fifth, Mr. M. Henderson.

PEACHES AND NECTARINES consisted of Royal George, Bellegarde, and Violette Hative Peaches, and Elruge and Violette Hative Nectarines. Several of those to which prizes were awarded were large and highly coloured.

Awards.—For four dishes: first, Mr. Allen, gardener to J. B. Glegg, Esq.; second, Mr. Hill, Keele Hall; third, Mr. Rawbone; fourth, Mr. Enstone. For two dishes: first, Mr. Carr; second, Mr. Sawkins; Mr. Roberts, gardener to Hon. A. Barry, Tullamore; and Mr. Sage, gardener to Earl Brownlow; third, Mr. Ward, gardener to F. Martin, Esq., and Mr. Ruffett; fourth, Mr. Ford, gardener to Rev. T. Hudson, Watton; Mr. Young, Leigh Park; Mr. Enstone; and Mr. Budd, gardener to the Earl of Darley.

MELONS.—There was a good show of these, and they were for the most part well grown, but many of them we are informed were rather inferior in flavour. Gem was the principal variety shown in the Scarlet-fleshed class.

Awards.—For Green-fleshed: first, Mr. Enstone, gardener to Sir J. Duckworth, Bart.; second, Mr. Earley, Digswell. For Scarlet-fleshed: first, Mr. Gadd, Dorling; second, Mr. Weir, gardener to Mrs. Hodgson, Hampstead.

CHERRIES.—Several excellent dishes of Bigarreau and Elton were shown, and of the Black Tartarian or Circassian, beautiful examples came from Mr. Turner and Mr. Ruffett.

Awards.—For Black: first, Mr. Turner and Mr. Ruffett; second, Mr. Pottle, Mr. Carr, Mr. Marcham, and Mr. Sawkins. For White: first, Mr. Enstone and Mr. Widdowson; second, Mr. Turner, Mr. Perkins, Mr. Ross, Mr. Sage, and Mr. Marcham.

MISCELLANEOUS.—Figs consisted of good dishes of Brown Turkey and White Ischia; Plums, of Jefferson and Victoria. Of Strawberries, Sir Charles Napier, Filbert Pine, Admiral Dundas, British Queen, Bieton White, and some others were very good. Raspberries

came from Mr. Young and Mr. Cutbush, of Highgate, the latter showing Prince of Wales and Princess Alice; excellent baskets of Peaches from Mr. Osborne, Finchley; and some fine Nectarines from Mr. Henderson, and Mr. Masters, gardener to the Earl of Macclesfield. Messrs. Lane had a good collection of fruit trees in pots, and Mr. Turner contributed a seedling Strawberry called Dr. Hogg, for which a first-class certificate was awarded.

Awards.—For Figs: first, Mr. Orman, gardener to R. Holland, Esq.; second, Mr. Sage, gardener to Earl Howe; and Mr. Hutt. For Plums: first, Mr. Robins, gardener to Sir G. Kerrison, Bart.; second, Mr. A. Ingram. For Strawberries: first, Mr. Bailey; second, Mr. Widdowson; third, Mr. Budd; fourth, Mr. Kaile.

## THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE Anniversary Meeting was held at the London Tavern on Friday the 7th inst., J. R. Jeffery, Esq., of Woolton Hall, Liverpool, in the chair. Among those present were Mr. Serjeant Atkinson, Colonel Scott, R.E., Colonel Burnaby, Grenadier Guards, Donald Nicoll, Esq., Colonel Jeakes, Captain Fox, G. F. Wilson, Esq., G. Child, Esq., R. Wrench, Esq.; Messrs. J. & C. Lee, Fraser, Williams, Turner, Gray, Ormson, and Taylor.

THE CHAIRMAN said that he proposed, with much pleasure and heartfelt sincerity, the health of the Queen. The next toasts were the Prince and Princess of Wales, and the rest of the Royal Family; and the Army, Navy, Volunteers, and Naval Reserve, coupled with the name of Colonel Burnaby.

COLONEL BURNABY, in returning thanks for the Army, said that it had been the custom of his regiment for two hundred years to have a dinner once a-year, and His Royal Highness the Commander-in-chief had then said that the efficiency of the Army was all that he could desire. Mr. Cutler, the Secretary, returned thanks for the Navy, in which he had served when a youth; Col. Jeakes and Captain Fox for the Volunteers; Captain Shaw for the Naval Reserve.

THE CHAIRMAN then proposed the health of the Patron of the Institution, the Duke of Buccleuch, observing that nothing could be more encouraging than to have among the promoters of the Institution gentlemen of such extensive landed possessions.

THE CHAIRMAN said he had next to propose to them the toast of the evening, "Prosperity to the Gardeners' Royal Benevolent Institution," but before proceeding to do so he had to apologise for having left at Liverpool a large per-centage of his voice, but what was left was at their service. The Institution was one of an unpretending character and had not to contend with poverty, nor was it embarrassed with too much riches. It was blessed with one of the most persevering and industrious of Secretaries. When Mr. Cutler called on him (the Chairman) his diffidence and modesty induced him to decline the honour of filling the position which he held that evening, but such were the Secretary's persuasive powers and perseverance, that he (the Chairman), at length accepted the post, believing that the duties he would have to perform would be light. On second consideration he found that the task he had undertaken was by no means so easy, for he found he was called on to strike with Aaron's rod that hard rock their pockets, to cause them to flow in a refreshing stream to those who were dependant on the Institution. He was given to understand that there were fifty-seven of these, of whom thirty were females, and that they averaged the great age of seventy-six. If those present, or, indeed, the most wealthy in the kingdom were asked to forego indulgence in the fine arts or in the pleasures of a garden, there were few who would not prefer to give up the former in preference to the latter; and if so, was it not a duty, was it not necessary and desirable, to make the latter days of those who so ministered to our enjoyments happy? The Institution was, *par excellence*, a benevolent institution, not one of those which there were too many instances in which the sober man was chained to the drunkard, the frugal to the improvident, and he urged its claims to support. Each person present could contribute one stone to the edifice. The stone might be called by any name they choose, a coin of the realm if they liked, and each would have the satisfaction of contributing to the support of an institution which did a great amount of good. He found that the annual expenses were £800, and though the balance sheet was £316 in favour of the Institution, £300 of that sum must be forthwith dispensed to those who were dependant on the funds. The Institution was established in 1838, but scarcely came into life till 1842, when the present Secretary came into office. He (the Chairman) was surprised to find the large amount which had been distributed in that time, some £12,700, and yet there was a reserve in the Stocks of £5,700. He believed those present would agree with him in the hope that this sum would be doubled in half the period to come. He commended most ardently, most sincerely, the claims of the Institution to support.

The healths of the Chairman, Mr. Wrench (the Treasurer), Mr. Cutler (the Secretary), were then drunk; and among other toasts given were the Nursery and Seed Trade, the Stewards, and the Ladies. The amount collected was about £380, of which the Chairman and his friends contributed £80. The proceedings were enlivened by some good music from Miss Poole and Mr. Perren. There was a handsome dessert, and a variety of ornamental plants for the decoration of the room, these last coming from Messrs. Leo and Smith.

## ROYAL HORTICULTURAL SOCIETY.

JULY 8.

THE Show of Ornamental and Variegated-foliaged Plants and Scarlet Pelargoniums, on Saturday last, was probably the most extensive and best of the minor shows held this year, though, doubtless, the general effect would have been improved by the introduction here and there of flowering plants, to relieve the monotony of so much green foliage.

In Class I., twelve stove and greenhouse plants with ornamental foliage, Mr. Baines, gardener to H. Micholls, Esq., was first with a remarkably fine collection, nearly the same as that which he exhibited at the Regent's Park, and which is noticed in another column. Messrs. Lee were second with an excellent collection, in which were *Aloesia metallica*, very fine, *Theophrastus*, *Rhopala*, *Dracena indivisa*, variegated *Yucca*, and *Ananassa*, a fine Bird's-nest Fern, *Alsophila australis*, *Oreopanax dactylofolium*, and *Cordyline indivisa*. Mr. Bull was third with a collection, in which we noticed tall specimens of *Dracena australis* and *Rhopala corcovadensis*, *Dicksonia antarctica*, and other Ferns, and the cinnamon-stemmed *Spharogyne*. Mr. Carr, gardener to P. Hinds, Esq., Byfleet, had an extra prize for a collection in which were a magnificent example of the Sugar Cane, *Saccharum officinarum*, *Cissus discolor*, *Spharogyne lufifolia*, and *Musa Cavendishii*, in the culture of which he is an adept.

In Class II., six plants, equal first prizes were given to Mr. Donald, gardener to J. G. Barclay, Esq., Leyton, and Mr. Baines, the latter exhibiting his fine *Sarracenia*s and *Amætochils*, noticed in the report of the Royal Botanic Show. Mr. Donald had a fine specimen of the white variegated *Aloesia macrohiza*, variegated *Croton*, *Maranta zebra*, *Aloesia zebra*, and *Dicksonia antarctica*. From Mr. Young, gardener to R. Barclay, Esq., who was second, came a large and fine *Aloesia metallica*, the pretty white-blotched *Caladium argyrites*, a *Rhopala*, and *Dieffenbachia*; and in a collection from Mr. Taylor, gardener to J. Yates, Esq., Highgate, were the Rush-like *Littæa juncea*, *Cirenligo recurvata*, and *Maranta zebra*.

In Class III., six plants (Nurserymen), Messrs. Lee were first with a fine *Aloesia Lowii*, *Dracena indivisa*, *Croton pictum*, *Latania rubra*, *Rhopala corcovadensis*, and *Cyathæa Smithii*; and Mr. Bull second with, among others, a handsome *Araucaria* called *gracilis*.

Classes IV. and V. were for *Dracena*s and *Cordylines*. These chiefly consisted of *Dracena terminalis*, *ferrea*, *draco*, *rubra*, *australis*, *stricta*, *arborescens*, *Cooperi*, *heliconifolia*, *Veitchii*, and *Cordyline indivisa*. The first prize in the Nurserymen's class was taken by Mr. Bull, the second by Messrs. Lee; and in the Amateurs' class Mr. Donald was first, Mr. Barnard, gardener to J. Taylor, Esq., second, and Mr. Young third.

In Class VI. nine Palms, Mr. Bull was the only exhibitor; among those which he exhibited were *Euterpe edulis*, *Seaforthia elegans*, *Brahea dulcis*, and the *Date Palm*.

In the Amateurs' Class VII., very fine specimens of *Cycas revoluta* were exhibited by Mr. Taylor, who also had a gigantic *Sabal Blackburniana*; and Mr. Young had the *Date Palm*, *Chamærops chinensis*, and a large plant of *Thrinax elegans*.

*Caladiums* shown in Class VIII. were not remarkable for their novelty. Of kinds with red markings, we noticed *Chantini*, *Wightii*, *peccile*, *bicolor splendens*, and *Schmitzi*; and of others *argyrites*, *Belleymeii*, and *Lowii*. Mr. Carr was first, Mr. Young second, and Messrs. Lee third.

For a collection of twelve hardy variegated plants, a first prize was awarded to Mr. Salter for the variegated *Sedum Sieboldi*, Japanese Honeysuckle, *Ivies*, *Coltsfoot*, *Fortune's Bamboo*, *Jasmine*, *Sedum telephium*, and others; and the second to Mr. Bull for *Aucubas*, *Eurya*, *Enonymus*, and his variegated *Chrysanthemum* and *Verbena*.

The show of *Zonale* and other *Pelargoniums*, was tolerably effective, though the plants were not at their best as regards bloom. For twelve kinds of any colour, Mr. Fraser was first with good plants of *Herald of Spring*, *Clipper*, *Roi d'Italie*, *Amiral Protet*, *Malakoff*, and *L'Abbé Krensi*, scarlet; Mr. Rendatler, *Engéline Mezard*, *Souvenir de Naney*, and *Henri Etienne*, different shades of salmon; *Virgo Marie*, white, and *Rose Rendatler*. Among those from Mr. Salter, who was second, were *Amelina Grisean*, a fine large white with a large salmon eye, *Mulle*, *Marie Mezard*, white, *Germania*, orange scarlet, and *Beauté de Suresnes*, a very good deep rose.

In the Amateurs' Class for six, Mr. Ward, gardener to W. G. Wilkins, Esq., Leyton, was first; Mr. Hawes, gardener to J. Noble Esq., Finchley, second.

Among variegated *Geraniums*, Mrs. Pollock, *Glowworm*, and *Sunset* were the best of the tricolor-leaved varieties; *Alma*, *Mountain of Snow*, and some others of the white-variegated kinds were also exhibited in good bloom. The only collection of *Nosegays* entered for competition came from Mr. Salter. Mr. Fraser and Mr. Hally were first and second for variegated *Geraniums*, and Mr. Ward first for six in the Amateurs' Class.

Of Miscellaneous objects, Messrs. Lee exhibited good mixed collections of *Heaths*, *Orchids*, *Ferns*, *Ixoras*, and *Statice*s; Mr. W. Paul and Mr. Clarke, several boxes of *Roses*, the former also showing *Beaton's Geraniums*; Messrs. Downie, Laird and Laing, fine *Hollyhock* blooms; Mr. Salter, hardy *Ferns*; Mr. Bartlett, *Hamorsmith*, very fine pans of *Adiantum cuneatum*; Mr. Bull, the *Radish* noticed in another column; Mr. Thompson, Ipswich, *Trichium Manglesii*; Mr. Catleugh, Chelsea, *Lilium auratum*; Mr. Hooper, Bath, *Carna-*

*tions* and *Picotees*; and Mr. Taylor, Highgate, the singular fruit of *Dion edule*, a cone measuring about 17 inches by 9 in diameter. Messrs. E. G. Henderson had new *Fuchsias* of 1865, consisting of *Father Ignatius*, *Enoch Arden*, *Roderick Dhu*, and *War Eagle*, all having violet purple corollas and reflexed scarlet sepals; *Light Heart*, with a blackish purple corolla; and *Rose of Denmark*, and *Lucey Mills* light kinds. A *Rose* bearing *Verhena* called *Ariel*, and *Pink Stella Geranium* also came from the same firm.

Fruit was represented by a good *Queen Pine* from Mr. Ford, gardener to W. Hubbard, Esq., and three dishes of *Black Currants*, one kind being a seedling which is said to hang a month later than any other sort; and from the Society's garden came a collection of forty sorts of *Gooseberries*.

Miss Smith, Footing, exhibited some beautifully-executed artificial flowers, and Mr. Lowe, Maida Hill, a neatly-filled plant case. A fine *Phenocoma prolifera Barnesii* came from Mr. Baines, and a variegated *Aloe-leaved Yucca*, an excellent specimen, from Mr. Bull.

## POTTED VINE UNFRUITFUL.

I HAVE in a large pot a Vine which I am growing in a cool greenhouse. It has made shoots from about 1½ to 2 yards long. It has no fruit on. Last year the wood did not get well ripened, and I want to be sure of ripening it thoroughly this year. Would it be advisable to turn it out of doors, exposed to the air and sun now, to ripen the wood? I do not alter the temperature of the house in the least on account of the Vine, but keep it as cool as possible and moderately shaded. The Vine will be two or three years old, and I suppose I might get some fruit next year.—*EBORACUM*.

[As your house is kept cool and shaded, the best thing you can do, is to choose a dull day and take your Vine in its pot and place the stem against a south wall or fence, giving all the sun possible, and lessening the application of water after September.]

## CHINESE GARDENING IN AUSTRALIA.

THE class of Chinamen most useful to their European neighbours, next to the miners, who are adding to the wealth of the country, are the gardeners. There are few townships in the colony the inhabitants of which are not mainly dependant on the Chinese for a constant and regular supply of fresh vegetables of the very finest quality. Such, at least, may be said to be the case on the gold fields. Any idea of competing with the Chinese among our gold-fields townships, in the production and sale of vegetables, appears to be pretty generally abandoned; and although farmers will bring *Cabbages*, *Pumpkins*, and such like to the weekly markets, the Chinamen may be seen moving from door to door, by seven or eight o'clock every morning, laden with fresh green esculents. At all seasons, and in every description of weather, the Chinese gardener has some kind of vegetable for sale. Neither heat nor cold, drought nor rain, affects this regular supply. There are a great many of those vegetable gardens in various parts of the Castlemaine district, being so distributed that it would seem as if it had been arranged that enough of vegetables should be reared by Chinese, in each locality, to supply the whole of the surrounding neighbourhood. The number of Chinamen employed in each is generally about from four to six, and all appear to have an equal interest in the business. Each has allotted to him the particular duties which he has to perform. One hawks the vegetables and collects manure; another is employed chiefly in weeding; a third in watering, and a fourth in digging, preparing the plots and sowing the seeds. These arrangements once made are rigidly adhered to, and are universally carried out in the most amicable spirit. In this respect they set an example worthy of imitation by many Europeans. There is never any wrangling or jealousy among them, and one is not to be found complaining that he has too much work to perform, and that his partners do less than he. You will never find the Chinaman in a hurry; but, at the same time, he never loses a minute, and works on steadily from early morning until the light fails him at night, for he has never dreamed of an eight-hour movement.

The Chinese are most successful gardeners, or rather farmers; for in their gardens in this colony we really get a specimen of Chinese agriculture. Although we make a distinction between farming and gardening, and conduct them differently, there is no such distinction made in China, every foot of which is cultivated with as great carefulness as we find displayed here

on the land on which they grow vegetables. The Chinese are universally acknowledged to be the best agriculturists in the world. They may not be able to understand the chemical properties of the soil or of manures, but a Liebig could not surpass them in selecting the one, or in choosing and in preserving and improving the qualities of the other. Probably, for more than a thousand years, they have carried on the same systems that they carry out now, and have learned, by experience, what modes of culture and what manures, &c., are most effective; and the analyses of the European chemist confirm the practices they have adopted as being the best. The Chinaman does not know what are the scientific causes, but he knows that, by certain processes, he can produce certain results. If any unexpected difficulty arises, the Chinaman endeavours to overcome it by the most natural and simple means, however laborious. If blight afflicts his Cabbages, he washes it off the leaves with soap and water; if he be troubled with grub, caterpillars, beetles, or other insects, he does not attempt to destroy them by any solution, or with kerosene and other substances that have been tried by Europeans, but he gathers them all carefully and destroys them; sometimes before sowing or planting, putting blades of any vegetable into the ground to entice them, in order that they may be caught. Steady, patient labour is the only means of which he can conceive by which to overcome such obstacles. He has never thought of adopting means to save time and labour. The necessities of the case, no doubt, led the Chinese to discover methods by which they could get their country to grow a sufficiency of agricultural products to feed the teeming millions of their population. Agriculture has received much encouragement from the Chinese Government, and at an early period in Chinese history the various modes of cultivation were taught to his subjects by an emperor named Nung, so that a husbandman, or farmer, is designated in Chinese by the word Nunggin. As every one is aware, the Chinese are divided into a number of grades, castes, or classes, in accordance with the profession or trade in which they are employed. The second place on the list was given to agriculturists, "the learned men," or members of the learned professions, as we would say, alone taking precedence of them. This fact shows with how much respect the husbandman is regarded by the population who are dependant on his labours for the means of subsistence. Every house or tent in the district inhabited by Chinamen is supplied by the gardeners with jars, to be used for the same purpose as the tanks referred to in China. The gardener goes round every day and collects the contents; and, so much is it valued, that serious quarrels will sometimes arise if one gardener attempts to appropriate anything of this nature which another considers to be his.

While on this subject, it may be mentioned that such liquid manure as the Chinaman collects in his jars is, perhaps, more valuable than any other description, the quantity of nitrogen contained in 100 parts of it being, according to chemical analysis, equal to 1300 parts of stable manure or 600 parts of manure from the byre. The latter kinds of manure are likewise used by the Chinese gardeners, and when they come into town after disposing of their vegetables, they collect the compost, and carry it home with them. Wherever they can find any, they pick it up, and may sometimes be seen gathering it on the commons. The bulk of their supply, however, they obtain from such of their countrymen as keep horses for working their puddling machines, giving some vegetables in exchange. It is used chiefly as a top-dressing, and the effect of its being so used, along with the straw in it, is that, as is well known to most horticulturists, it prevents the surface of the soil from being baked by the heat of the sun, and cracks and fissures formed. It likewise assists in retaining moisture.

The Chinese display much skill and intelligence in the choice of their garden ground, both as regards the character of the soil, and the nature of the situation. The first consideration with them is the supply of water, and they choose a site therefore on the bank of a creek, in which they may obtain water in the driest seasons. Failing this, they must have wells dug in their gardens, from which they can get a constant supply of pure water. The gardens are models of neatness, and *ex uno disce omnes*, for they all exactly resemble each other. They are thoroughly clear of weeds, and all the vegetation is so fresh and verdant in appearance that, in a warm season like the present, they are most refreshing to the eye. The ground is prepared by being trenched to a depth of from 2½ to 3 feet. The garden is divided by a number of narrow walks into long beds or plots, which are of such a width that the gardener, sitting,

or rather crouching by the side of it, as the Chinese do, can easily stretch half-way across the plot, so that he can weed it without having to step on the plot. The beds are raised to a height of about 8 inches above the level of the walks. It has to be observed that the soil is always beautifully pulverised, and it may be presumed that it would be sufficient to drive a Chinese gardener frantic if any one were to tread and leave a footprint on his plot. If the reader would wish to see how a Mongolian can run, and how thoroughly his habitual equanimity can be disturbed, he must have an opportunity of seeing a goat break through the fence and get into his garden. They have a pride in their gardens, and respect for them amounting almost to reverence, and will take off their shoes before walking through them. A careful housewife could not be more proud and jealous of the furniture of a fashionable drawing-room.

An observant visitor to a Chinese garden might observe what would appear to be a careless mistake—namely, that while the most of the paths dividing the plots are of unswerving straightness, a few are slightly curved. The intention appears evidently to be that each series of plots should, by the nature of the lines that divide them, represent the character or symbol which is used for the Chinese word signifying a "field." The outline of the symbol referred to is a square with two lines running from side to side and from top to bottom of it, and crossing each other at right angles. The upward line and the sides of the square are perfectly straight, but the horizontal line is slightly curved, corresponding in this respect exactly with the curved paths referred to in the garden. There can be no doubt as to the intention of Chinamen in this respect, but when questioned as to their motive or object for adopting such a fanciful arrangement, they either cannot or will not understand. Indeed, although naturally polite and apparently frank, at least to an acquaintance or customer, the Chinese gardener is not a communicative gentleman. Probably he fancies that, having been from childhood familiar with all those things on which he is questioned, his interrogator must also know of them, and he may assume that the ignorance is feigned. If surprise be expressed or displayed, it is amusing to observe the curious smile which lights up the face of the Chinaman; good-humoured it is undoubtedly, but there is a certain air of condescension, mingled with satisfaction, and he seems to be amused with the idea that his immense superiority should so astonish the ignorant "barbarian."

The most of the Chinese gardens in the Castlemaine district are on land that has been alienated from the Crown, and for which they pay tolerably high rents. They do sometimes occupy Crown lands under business licenses, and their objection to doing so more generally is that they consider the charge for a business license to be too high. They cultivate most of the vegetables with which Europeans are familiar, and some novelties which they have introduced from China. They prefer, however, such vegetables as the Lettuce, which come rapidly to maturity, so that they may have a number of crops off the same ground every year, and get rapid returns for their outlay and labour. For example, they would rather grow and sell green Onions, or, as they are termed sometimes, "young Onions," in preference to the same esculent brought to maturity and dried. They will not plant fruit trees, because they would have to wait too long for the fruit, and besides they all entertain the hope of being able to return to China in a few years, and will not invest capital in this colony on "permanent improvements." But this is not their only objection. A gentleman recently offered to let a large and excellently-stocked orchard to a company of Chinese gardeners, on very advantageous terms, as his chief object was to get them to take proper charge of the garden; but they obstinately refused to have it at any price, for they did not think one crop of fruit a-year would pay them for the labour that would have to be bestowed on the trees, although they could also grow vegetables. In the same way they are averse to growing Potatoes, as they occupy the ground too long before the crop is obtained. They are very successful in growing Cucumbers, Pumpkins, Vegetable Marrows and such like, and their Melons are specially remarkable for their superior excellence. It may be mentioned that the Chinese preserve the seeds of the Melon, salting and drying them, and they are afterwards cracked between the teeth and eaten by Chinamen as Europeans eat nuts. When a Chinaman has had a few whiffs of opium, or is otherwise enjoying a leisure hour, it becomes as natural to him to crack and eat Melon seeds as it is for an English gentleman, after dinner, to associate Walnuts with wine.

Among the best known of the novelties which have been

introduced by the Chinese gardeners is what is called the China Cabbage, a vegetable which is not much esteemed by the English palate, because, when boiled, it becomes tasteless and flavourless, and reduced to a pulpy mass, as if it were decayed. This, however, is not the case if it be properly cooked in the same way as it is by a Chinese Soyer. The China Cabbage ought to be boiled, or rather stewed, in a small quantity of water, not sufficient to cover the vegetable. The Chinese usually cook it in a frying-pan after cutting it into small pieces. When it has been so boiled for a short time—no cover being put over the vessel—the water is partially strained off, and some oil or pork fat added; probably to most tastes, except those of Chinamen, butter would be preferable. So prepared, the China Cabbage would please the most fastidious *gourmet*. The China Pea is another excellent vegetable, being remarkable for the great length of the pods and its prolific crops. The Chinese use the Pea before the pods are thoroughly filled, as they cook the Peas in the pod and eat both, in the same way as French Beans are used.

Probably the chief secret of the success of the Chinese gardener, in addition to the liberal manuring, is that the vegetables are kept constantly supplied with water. They are watered three times a-day—in the morning, about midday, and in the evening. A large number of barrels, sunk in the ground at the end of the plots, are distributed throughout the garden. These are filled from the wells or creek during the intervals between the hours for watering, by the partner whose duty it is to perform this work. From there the watering-pails are filled at the proper time, and the liquid poured copiously over the vegetables, for they consider it most essential to water the plant as well as the soil, although English gardeners will frequently be seen pouring in only a little water at the roots of a flower or other plant. The plots are likewise frequently and regularly saturated with the liquid manure. English gardeners think it injurious to water any kind of plants during the day while the sun is shining; and so, indeed, it is, if the watering be not continued regularly. A Chinaman's vegetables are kept constantly moist, and he would water them at the appointed hour, although it were evident that a perfect torrent of rain would descend in a few minutes. The Chinese are quite as diligent in weeding as in watering, and the former is carried on as constantly as the latter, for they will not allow their manure to be exhausted by a profitless crop. No trifle is considered beneath notice, and a gentler and more careful cultivator than the Chinese gardener it would be difficult to imagine. He seems to be passionately fond of his plants, and nurses them most affectionately. For a picture of patience, nothing could surpass a Chinese gardener washing blight from the blades of his Cabbage. With a keg of soapy water, and a piece of stick with a rag tied to the end of it, he moves slowly along the side of the plot, tenderly lays hold of one blade after another, and carefully rubs off the blight with the cloth after he has dipped it in the water. To wash many hundreds of Cabbages in this fashion seems an extraordinary undertaking, but the Chinaman thinks it the most natural thing in the world, and, persistently persevering, it is astonishing what rapid progress he makes. In no respect are the wisdom, foresight, and accurate calculation of the Chinese gardener more wonderfully displayed than in his arrangement of his crops, so that he has always some description ready for sale, and yet never has a glut; or is compelled to sell immature vegetables, or allow them to become overgrown. He sows and reaps something every day all the year round; with him it is always seed time and always harvest. In the garden are to be seen vegetables in all stages of development; and as soon as one plant is taken from the ground new seed is put in its place. The soil is never allowed to remain a day idle, but it is too liberally treated ever to get exhausted. It ought not to be omitted to mention, before closing, as many may be ignorant of the fact, that Chinese gardeners always steep the seeds they are about to sow in liquid manure, until they are considerably swollen and have begun to germinate. The effect of this is that they spring up very rapidly, and escape the ravages of insects to which seeds and tender blades are so liable. Our best horticulturists and agriculturists could learn many a valuable lesson from the Chinese gardener.—(*Australian News*.)

### STRAWBERRY CULTURE.

There seems to be a prevailing opinion that the Strawberry crop this year is a failure. I never had a better, and I think if

my system were carried out there would be no complaints. My ground is well dug and heavily manured, the Strawberry plants dug up and put in with a trowel in July, 2 feet every way from plant to plant, the surface of the ground covered with manure in the end of March, no spade or fork ever allowed near the beds after they are made till they are destroyed, the weeds hand-picked, the roots kept single instead of being allowed to run one into another, and the barbarous mowing the leaves off strictly prohibited. I have had as many as seventeen clusters of fruit on a root the first June after planting. After the second year they are dug up and a fresh piece of ground planted.—J. W. CHALONER, *Newton Kyme, Tadcaster*.

### CUTTING ROSES AND TAKING THEM TO A DISTANT EXHIBITION.

Would one of your contributors, skilled in preparing Roses for exhibition, give a few hints as to the best means of conveying them to the place of exhibition? Should they be arranged beforehand in the boxes as they are to be exhibited? I mean in case of having to convey them one hundred miles or more. Or, if carried to the place of exhibition and arranged there, would a basket or close-fitting box be the best in which to convey them? Now that this flower is becoming so generally exhibited at our horticultural shows, a few hints on this subject will, I have no doubt, be acceptable to many of your readers, and especially so to—A COUNTRY CURATE.

[In answer to the above two questions I reply, that I live more than one hundred miles from London, and that, by careful attention to blooms, I have carried them sufficiently fresh to win two first prizes against the amateurs, and a second prize against the nurserymen. The distance of one hundred miles entails night travelling. I, therefore, cut from 5 to 7 p.m., and leave the box sufficiently open to take in the moist evening air from 7 to 9. At that hour I start for Wimborne Station, seven miles distant, and travel about three miles and a half an hour, pulling up at every dip, and driving in the centre of the road to keep the box level. At Wimborne I water the Roses, having a quarter of an hour to do so. I arrive at Waterloo Station at 4.30 a.m. They are then watered again and hoisted as level as possible on to the cab. Having arrived at Kensington I water them again and shut the box as close as I can to keep out heat and prevent evaporation. In this case I place over the box a wet cloth to prevent the action of heat on the box. I have always arranged them beforehand, but I also take a number of supernumeraries. I may say, that as decay is sometimes rapid, Roses just relaxing their petals will oftentimes be better next morning than Roses that left home fully expanded. It is best to take both, but futile to take blooms that have been wetted. The stems cannot be kept too wet, nor the blooms too dry, as heat and wet are the elements of decay. It is a great help to Roses that are to travel to keep the plants watered previously. Before putting the blooms into the box dip the stalk into water and sponge the leaves, but do not wet the blooms. On arrival at the exhibition cut off a small slice at the bottom of the stem, as they will suck the better for it. This is my reply to the first question.

In answer to the second question, I have an opinion that the following would be the best way of all for cut flowers to travel:—The mischief, of course, is evaporation. When a bloom is open it is at its zenith. It must, therefore, more or less decline. Our painted boxes draw the heat. The top, therefore, of the show-box should not be painted. Mine is painted; but to counteract heat I travel with a wet sack over the box. I have never travelled with cut flowers in a box, or basket, but I imagine that a box lined with lead, and having ice at the bottom, with a newspaper between the ice and the flowers, would be the best way of all. The flowers should be laid thinly in layers, with wetted grass, or moss, over their stems, and a bit of paper between the blooms. I have often sent Roses to London in linendraper's boxes without ice, but treated as above, with success. The great point is to prevent evaporation or the action of heat. Camphor is a very cooling thing, and, therefore, if travelled with water-cups a little spirit of camphor would help to keep the water-cool.

Finally, having put your Roses on the stand and having removed the cover, keep your eye on the box as long as you can, and, above all, keep your temper. As Mr. W. Paul justly observes in his admirable book on Roses, page 177:—"Let us ask ourselves again, if there is any disgrace in being beaten?" Certainly none. Every place here is honourable. If our plants

(or blooms), be good, never mind those of our cotemporary being better.

I recommend to "COUNTRY CURATE" an admirable article printed in the "Gardeners' Annual," which contains ten excellent rules to guide the Rose exhibitor. The direction given in one of those rules—namely, to cut the Roses in the morning with the dew on them is a good direction for Roses grown on the hills where the dew is moderate; but in valleys the dew in summer, which is in the same ratio as the solar heat, is so copious that it is very little short of rain. It penetrates into interstices between the petals, and when the Roses are exposed to the heat of exhibition the colours fly. Whether, therefore, I exhibit far or near, I cut overnight as late as I can, and leave the lid of the box trigged open, but sufficiently close to prevent the dew from falling on the blooms. They will thus absorb quite sufficient moisture. I have always observed at shows that my Roses stand the heat and keep their colours better than those of many others.—W. F. RADCLIFFE, *Tarrant Rushton.*]

#### CUTTING ASPARAGUS.

I WILL reply to your correspondent, "J. K.," page 488, from a totally different point of view. When a garden is much infested by the Asparagus beetle, it is obvious that by cutting off all the sprouts, you deprive them of a place to lay their eggs, and thus diminish them. On this principle I cut my beds clean, but find great difficulty in forming a new bed, from the impossibility of cutting, and the trouble of hunting after the grubs, which become beetles.—G. S.

#### FROGMORE EARLY BIGARREAU CHERRY.

THIS production of the Royal Gardens is one of Mr. Ingram's most successful efforts in raising new fruits, and will prove a great addition to our varieties of early Cherries. The original tree is growing against a north-east wall, and the fruit was ripe this season on the 17th of June. Unlike the class to which it properly belongs, it has a tender melting flesh, and furnishes another instance of Nature rebelling against the devices and systems of men. In every respect this is a Bigarreau in habit, leaf, and appearance of the fruit, and must be classified along with these varieties; but as if to set at nought all human arrangements, it persists in having a delicious melting flesh instead of one that is hard and crackling.

Frogmore Early Bigarreau Cherry.

The fruit is large, obtuse heart-shaped, with a very shallow suture. Skin with a brilliant red cheek, dotted with minute yellow points, and of a remarkably pale almost pure white

where shaded—so susceptible is it of shade that the point of a leaf or the shadow of a twig would be photographed on this brilliant red. Stalk 2 inches long with a very small receptacle, and set in a shallow and narrow cavity. Flesh very delicate and translucent, perfectly tender, melting, and very juicy, with a rich sweet flavour. Stone small.

The tree is a great bearer; clusters of a dozen and a half to two dozen large handsome Cherries being produced on a small spray.

#### AUCUBA JAPONICA.

Now that in our gardens this Aucuba perfects its brilliant berries, or drupes, to speak botanically correctly, it has acquired a very great additional interest, and, indeed, when loaded with its coral fruit it has such a novel aspect, that we heard a lady inquire "where this new species came from?" and, as this query led to others, and as the information elicited is not devoid of interest, we will arrange and detail it.

There is no doubt that Kämpfer was the first European to see it, describe it, and pourtray it. In his "Amoenitates exoticæ," published in 1712, he describes the "Aükuba" very accurately as having "red oblong fruit, rather larger than that of the Laurel; flesh slight, white, slightly sweet; nut inclosed, rather hard and harshly flavoured."

More than half a century later, Thunberg also noticed it when in Japan. He says, in his "Travels," that in 1776, when travelling near the Japanese town called Kokura, "I found near the hath at an inn a tree which is called *Aukuba*, and another called *Nandina*, both of which were supposed to bring good fortune to the house."

That benign influence did not extend to its European discoverers and the introducer to our gardens. Kämpfer returned from Japan with shattered health, and died four years after he had published his description of the Aucuba; Thunberg lingered for years suffering from accidental poisoning; and John Grafer, who first cultivated it in Europe, was murdered.

This last-named botanist is so little known that a few relative particulars deserve recording. He was a native of Germany, and came to England about the year 1760, to be a pupil of Philip Miller, by whose recommendation he was advanced to be gardener to Mr. James Vere, of Kensington Gore, one of the originators of the Royal Horticultural Society. After a few years he became a partner with Messrs. Thompson and Gordon in the Mile End Nursery, but he left the concern when Mr. Gordon died, and accepted a high appointment in Italy. On the title page of the only book he published he is designated "Botanic Gardener to the King of Naples," and to this he was appointed at the recommendation of Sir J. Banks. In the preface to the same work, published in 1789, he is mentioned as favourably known to our Admiralty for his "invention of prepared vegetables." This, and perhaps the influence of Lady Hamilton, who had a taste for gardening, and whose husband was then our ambassador at Naples, obtained for Mr. Grafer the superintendency of Lord Nelson's Sicilian Estate at Bronte.

Then came the Neapolitan revolution; the Royal family were driven from the throne, and Murat became King of Naples. Unluckily for himself Grafer still retained his appointment, for he was assassinated near his residence at Caserta in 1816.

Mr. Aiton in his "Hortus Kewensis," states that the Aucuba was introduced by Mr. Grafer in 1783. For some years, with praiseworthy care, our gardeners preserved it in the stove, whence, says Mr. Curtis, it was removed to the greenhouse or conservatory, and is now (1809) found to be as hardy as the Laurel or Laurustinus. The drawing of it in the "Botanical Magazine" for that year is excellent. Unfortunately only a female plant was introduced, and no one had the good thought to strive for the acquisition of a male plant, until Mr. Fortune visited Japan in 1861. He sent it with other valuable acquisitions to Mr. Standish, and it was thus noticed by our reporter soon after its arrival in 1862:—

"There is a plant—familiar even to those least versed in plant-learning, which is to be seen in the smoky squares in London, or breathing the clear air of the country; dingy it may be in the first case, and showing a fresh morning face in the other; which is to be found in every garden, and which succeeds well in all, alike resisting cold and heat, wet and dryness. This is the *Aucuba japonica*, or rather a variegated variety of that plant, for that which has been so long known under this name is merely one of many such varieties only now brought to light.

<p>“The true <i>Aucuba japonica</i> is not variegated, but has beautiful shining green leaves, which, when young, are of the</p>	<p>brightest colour; and when the female plants are impregnated, it will possess an additional charm in being covered with its</p>
--	--

*Aucuba japonica.*

<p>large red berries. It may safely be predicted of this new introduction, that in a few years it will be planted in every</p>	<p>shrubbery, where it will be quite as valuable as the common Laurel, and, like it, will form admirable hedges. For planting</p>
--	---

near London and other large towns it will prove invaluable, for the leaves will not look dirty so soon as those of the blotched-leaved sort.

"Such a shrub as this is alone an ample recompense for Mr. Fortune's journey, being, as it undoubtedly is, one of the greatest acquisitions among hardy shrubs that has been made in our time.

"The male *Aucuba*, which is also in Mr. Standish's possession, is, as far as its general appearance is concerned, but little if at all different from the female. Its great value lies in its producing flowers, by means of which the female plants may be fertilised and enabled to produce their beautiful berries. It is very scarce even in Japan, where it is only propagated for this purpose." We recommend purchasers of berried plants to sow the berries, for the chance of having, among the plants so raised, one that has male flowers. Those plants now bearing berries will not, of course, bear them next year, unless male flowers are close by during the blooming season.

## PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

**FOURCROYA LONGEVA** (Long-enduring Fourcroya). *Nat. ord.*, *Amaryllidaceæ*. *Limn.*, Hexandria Monogynia.—"The stately plant here represented is *Fourcroya longeva*, one of the most marvellous productions of the vegetable world. It belongs to the family of *Amaryllidaceæ*, and has the habit of a gigantic *Yucca*, its stem being frequently 50 feet high, and its flower-spike 40 more! It was originally discovered on Mount Tanga, in Oaxaca, at an elevation of 10,000 feet above the level of the sea. Mr. Skinner has also met with it on the high mountain-ridges in the interior of Guatemala. Plants of the species exist in our nurseries, but, contrary to expectation, it seems to suffer severely from the cold and changes of our climate. With us and in the Regent's Park garden, the temperature of a common greenhouse is sufficient for it; but the largest of our plants in cultivation are, of course, but pigmies in comparison with its height on its native mountains."—(*Bot. Mag.*, t. 5519.)

**DENDROBIUM SENILE** (White-haired Dendrobium). *Nat. ord.*, *Orchidaceæ*. *Limn.*, Gynandria Monandria.—Native of Moulmein. Flowers yellow and long-lasting.—(*Ibid.*, t. 5520.)

**MARIANTHUS DRUMMONDIANUS** (Drummond's Marianthus). *Nat. ord.*, *Pittosporaceæ*. *Limn.*, Pentandria Monogynia.—Native of Western Australia. Flowered in May at Messrs. Veitch's. Flowers blue.—(*Ibid.*, t. 5521.)

**DRIMIA ALTISSIMA** (Lofty Drimia). *Nat. ord.*, *Asphodeleæ*. *Limn.*, Hexandria Monogynia.—The finest of all the Drimias. Native of Natal. Flowers green, anthers yellow on purple filaments.—(*Ibid.*, t. 5522.)

**PHALENOPSIS LUDDERMANNIANA** (Lüddemann's Phalenopsis). *Nat. ord.*, *Orchidaceæ*. *Limn.*, Gynandria Monandria.—Native of the Philippine Islands. Introduced by Messrs. Hugh Low and Co., Clapton. Flowers white barred transversely with lilac at the base, and cinnamon on the upper parts.—(*Ibid.*, t. 5523.)

**PRIMULA CORTUSOIDES** var. *AMENA*.—Introduced by Messrs. Veitch from Japan. Flowers crimson with white eye.—(*Floral Mag.*, pl. 249.)

**ANDROMEDA TETRAGONA**.—Native of North America. Flowers white. Suitable for rockwork.—(*Ibid.*, pl. 250.)

**ANEMONE FULGENS**.—Imported by Messrs. Backhouse and Sons from the mountains of Greece. The flowers quite single, and intensely crimson.—(*Ibid.*, pl. 251.)

**BERBERIS STENOPHYLLA**.—Hybrid between *B. Dorwintii* and *B. empetrifolia*. Raised by Messrs. Fisher, Holmes, & Co., Handsworth Nursery, near Sheffield.—(*Ibid.*, pl. 252.)

**PELARGONIUM**.—*John Hoyle*: "We mentioned this flower as being, at the time we wrote, the flower of the season, so far as show Pelargoniums were concerned; and such it proved to be. None of the many fine sorts which made their appearance during the blooming season came up to it either in quality or in beauty. We may now add that, for distinctness and richness of colouring, and for all the properties desirable in a flower, none of the varieties of the present season will be found to surpass it."—(*Florist and Pomologist*, iv., 137.)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE principal business here for the next three weeks must be the introduction of the various winter and spring Greens,

and the thorough cleaning of the kitchen garden. Indeed, those who do not or cannot make earnest war against all weeds at this period must not look for abundant produce through the autumn and winter. *Artichokes*, when the heads are used the stems should be cut off close to the roots, clean the stools of decayed leaves, and loosen the surface of the soil about them with the hoe. *Brussels Sprouts*, let every nook be now filled with these and Green Kale, Savoys, Cabbages, and, of course, with a due supply of *Broccolis*. The *Wilcove*, the *Somers*, particularly *Late White*, the old *Sulphur*, and *Snow's Winter* should be got out immediately. The middle season, as the *Grange's Impregnated*, the *Protecting*, the *Walcheren*, and the *Cauliflower* must speedily follow, and these again followed by the *Capes* and some more *Cauliflowers* on a warm border for heading until Christmas. *Celery*, the beds should be planted speedily, as fast as land comes to hand. If the plants get gross when they are "pricked-out" they will run to seed if the weather is sunny. *Cucumbers*, keep the linings of the frames made up, so as to transmit a gentle warmth through the bed; for however warm the weather may be, this is necessary to procure fine handsome fruit. *Garlic* and *Shallots*, as soon as the tops begin to fade pull up the roots; after allowing them to remain on the ground a day or two to dry, tie them up in bunches, and hang them in a dry place. *Lettuce*, another sowing may be made in drills where the plants are to remain; a little of the *Paris* and *Bath Cos* may be sown at the same time. *Mushrooms*, save and prepare horse-droppings for beds to produce through the autumn and winter. Take care that newly-made spawn-bricks are thoroughly dry before being stored away. *Spinach*, sow a few rows to keep up a succession, thin the preceding crop, and keep it watered in dry weather. *Tur-nips*, thin-out the last sowing to a foot or 15 inches apart, and as the weather is now favourable the main autumn crop may be sown. Where the *Broccolis* are planted between Peas a narrow space should be dug for them if the ground is very hard, the rest of it can be dug and the intermediate rows of plants got in when the Peas are off. Do not forget a good breadth of *Leeks* immediately, and I may add, do not forget to put plenty of manure to them.

### FRUIT GARDEN.

Proceed with nailing the young wood of wall trees, and see that they are perfectly clear of insects, also stop any gross shoot, and endeavour to secure a fair supply of bearing wood all over the tree. Gross shoots that were stopped early in the season should be divested of all the laterals except one, or if it can be spared, remove it altogether. Keep the breastwood on Pear and other wall and espalier trees closely stopped in, and attend to thinning the fruit where the crop is too heavy for the strength of the tree. Look to preparing *Strawberry* runners for forcing next spring. Prepare ground for fresh plantations by heavily manuring and trenching it, or if land cannot be obtained at once, select the strongest runners and plant them on a shady border in rich soil, to be transplanted with balls next month.

### FLOWER GARDEN.

Go over the beds frequently, and keep the young shoots of *Verbena*, &c., nicely regulated and pegged down until the ground has got fairly covered, after which greater freedom of growth may be permitted. On light dry soils two or three applications of weak manure water, given at intervals of a few days, and when the ground is moist, will greatly assist in getting the beds covered without loss of time. See that *Dahlia*s, *Hollyhock*s, &c., are securely staked and kept properly tied. Remove decayed flowers and seeds from *Roses*, and give autumn-flowering varieties plenty of manure water in order to keep them in vigorous health and to secure plenty of blooming wood. Such as are budded on the *Dog Rose* must be kept clear of suckers. Budding may be proceeded with when the weather is cloudy. Give plants infested with green fly a liberal washing with the engine, or syringe them with tobacco water. *Mildew* sometimes becomes troublesome after this season; it may, however, be kept in check by applying sulphur to the parts affected the moment it makes its appearance, first wetting them with water, in order that the sulphur may stick. Where required proceed with propagating herbaceous plants, selecting for the purpose the small shoots not furnished with bloom. A north border is a suitable place to strike them, and a hand-glass will facilitate their rooting quickly. *Pansies* for autumn blooming may be treated in the same way. Climbers generally should be looked to. *Russian Violets* may be separated, and fresh plantations made. *Tulips* may now be taken up, allow the skin and roots, after carefully removing the soil, to remain,

these can be better taken off when the bulb is dry. Push Dahlias on by watering freely when the weather is dry, also assist them by mulching the ground with decayed stable-manure; take care that the plants do not chafe where attached to the blooming-sticks. Trap earwigs and other destructive insects. Mow and roll grass. Trim edgings. Attend to the walks, the weather at present encouraging the growth of weeds.

#### GREENHOUSE AND CONSERVATORY.

During the time when the creepers are in an active state make it a rule to go over them frequently, that they may not grow confused. The same may be said of creepers in pots which require attention, for the same reason, every few days. Any shoots which have done flowering to be cut back, and a crowded growth avoided. A number of hardwooded plants which were cut back some weeks since will now have recovered themselves and be commencing a fresh growth. This is the proper time to shift into larger pots any plants requiring it. Carefully loosen the outside roots. After potting, keep the plants close for a few days, and syringe them daily, but avoid giving any more water to the roots than is sufficient to preserve the old ball moist. Stock for autumn and winter flowering will now require some care to get it sufficiently forward to be useful at the proper time. Chinese Primulas, especially the double varieties, if at all backward, may now be placed in a close frame and shaded from the sun, when they will be found to make satisfactory progress. Cinerarias for early flowering should also be potted and started at once, choosing the strongest suckers for the purpose, and placing them in a close shaded frame until they have become rooted.

#### STOVE.

The stock here will now be growing rapidly, and must be allowed sufficient space to permit the perfect development of the foliage and the formation of compact handsome specimens. The atmosphere of this house can hardly be kept too moist, and the plants should be sprinkled overhead morning and evening, and every available surface kept constantly moist. Plants that are known to suffer from the direct action of the sun's rays should be placed in a shady part of the house, or kept together at one end where they can be shaded without interfering with plants that require plenty of light. If previous instructions have been properly attended to there will be little to do to the Orchids, besides attending to the ordinary routine of affording them a thoroughly moist atmosphere, repotting any specimen that may require it, and sponging the foliage as may be necessary to keep it perfectly clean.

#### COLD PITS.

The stock here will now be growing freely, and should be examined frequently in order to see that all is right, for plants growing rapidly speedily suffer from neglect in watering.—  
W. KEANE.

### DOINGS OF THE LAST WEEK.

The rain which we anticipated last week came, greatly enlivening the appearance of vegetation wherever it fell, and falling more freely, we believe, in the southern and eastern counties than with us. As a general rule, however, what are great general advantages to the many are often obtained at the expense of the inconvenience and discomfort of the few. The weather prophet was no fool who kept a well-lined pocket, and a successful popularity, by assuring his dupes he could send them rain at any time, whenever they were all agreed as to the propriety of having it on a certain day. This agreement was never realised—one wished dry weather for hay, another a fine day for pleasure, another fair weather until he returned from a journey, and so on; and, from the want of unanimity in his supporters, the prophet maintained his ascendancy and reputation.

Few could deny the advantages of the downpour on the 30th ultimo, but thousands wished that it had been on some other day than that set apart for a great out-of-door horticultural fête, which had been eagerly looked forward to, especially by the youth of both sexes. Of this we shall have something to say, if we can find time and space. Meanwhile, it was highly gratifying to find even so many braving the discomforts of the deluging rains, and the long wet grass, to see the flowers, and to listen to the strains of the best music. They must have felt that "music has charms," even when given in a tent, along with the heavy, discordant, pattering of the rain.

On Thursday, the 6th, we had a delightful rain, attended

with thunder, which is likely to lessen the great amount of heat, which has lately been making labour very trying to some of us, and attempting to take things a little easy more trying still. We can feel sympathy for a man who is working sharply in one of these broiling days, with the thermometer close on 90° in the shade; but we can feel the sincerest pity for the man who crawls about at work, or otherwise, on such a day. The active workman will get ease from perspiration, and the breezes which his own active motions make; whilst the lethargic man will feel as if he were going to be choked up in his own laziness and immobility.

#### KITCHEN GARDEN.

Proceeded with getting in winter crops of Savoys, Brussels Sprouts, Scotch Kale, Broccoli, &c., after the rains. Those pricked-out were lifted with balls, and planted in trenches with the spade. Those from seed-beds were planted with the dibber. See directions for dibbling last season. Transplanted Beetroot which has come badly, have a lot coming on under protection, hardly large enough to transplant yet; will so sow and transplant in future, as even under nets the birds nip them up as soon as the red seed-leaves appear. Sowed a few more Beans, Kidney Beans, in the open air, and a few Dwarf Fan Beans to come in in October, if the weather is fine. We often succeed better with good rows of early Beans, cutting them over when pretty well gathered about 3 inches above the ground, and the shoots that are thrown out from below often fruit better than those sown in June or the beginning of July. Sowed almost the last Peas, as Dickson's Favourite and Sangster's No. 1. Will most likely sow some early dwarf kinds about the middle of the month, in a warm sheltered border. Will proceed with winter stuff, as soon as we clear Potatoes, and early Peas. Watered the Peas in full bearing with sewage water, and mulched with short grass and litter. Mulching we find a great advantage, even if we could water more than we do. Sowed Carrots and Onions for drawing young, and planted out Leeks, giving them some good stuff to grow in, as Leeks when well cooked are a dish for a prince. They are also said by some of our learned medical men to be as cooling for the system as Onions are generally heating.

#### FRUIT DEPARTMENT.

Much the same as in previous weeks. Gathered Raspberries, Strawberries, and Currants for preserving. Have as yet been unable to plant out the spring-forced Strawberry plants, or to do much in preparing for next year's forcing. After this rain, will proceed with both operations. A little spider having appeared in the Peach-house, smeared the pipes with sulphur and put a brisk fire on for two or three hours, and then gave air, as a continuance would have been apt to throw off the ripening fruit before they were perfectly roasted, and much sulphur fumes in a close house with heat would tell upon the flavour. There is so little spider, and so little chance of its increasing much before the fruit is all gathered, that unless care is used, it would be better to dispense with fire heat and sulphur on the pipes when the fruit is so far advanced. In answer to an inquiry we would here state that we know of no better plan for sending Peaches long distances safely, than to gather before they are over-ripe, and pack in boxes divided into partitions of 3½ inches square, wrapping each Peach in stout silk paper, placing bran below it, and bran all round it and above it—shaking a little to keep all firm.

*Vinery Borders.*—We have only been able to remove our thin covering of tree leaves; this season we wish it had been done a fortnight ago to have gained the advantage of the strong sun heat. In general, for early Grapes, and the roots outside, and the border covered so as to keep heat in and frost out, even if little heat is thrown in, we think it safer and better every way to remove the covering in the end of June, instead of, as is often advised, in the beginning and middle of May. If the days are warm in the end of May the nights are generally cold enough, and the soil parts with its heat so rapidly by radiation as to cool the roots and check them if near the surface. If cold weather should succeed this thunder, it would be good policy to throw some litter or other protecting material over the border, as soon as the sun left it.

What we and others have said about Vine-borders is all right enough, and it is well to use such precautions for success; but, since we mentioned the fine Vines in Mr. Lane's orchard-house, we have been told of some dozen of instances of great success where no border-making had been resorted to, but the Vines were planted at once in the natural soil. A gentleman, or an amateur, may well do such a thing, and risk the consequences;

but a gardener, whose living and character depend on success, can scarcely risk such a primitive way of doing work. Not seldom, however, have we seen a great hole made, by taking away excellent soil, and the place filled up with a heterogeneous mixture of road scrapings, pond mud, and all sorts of rubbish, in which the Vines could not be made to flourish. If dryness is secured at the root by drainage, it would often be a rational plan to let well alone. Young Vines are much more often ruined by excessive early cropping than by bad soil or unsuitable borders. Of course the one influence will act and react on the other. No Vines will flourish in stagnant moisture; and we were going to say that they will not flourish with their roots deep; but we have known cases of fine Grapes—not early, but ripening well in July—where the bulk of the roots were some 20 inches below the surface, with fine open soil about 15 inches below that. For extreme fertility it is better to have them within a few inches of the surface.

ORNAMENTAL DEPARTMENT.

Here our work has chiefly been a repetition of that of last week. We are glad we have covered a good portion of the beds with a little mulching of rotten dung before the rains came. The most of the beds will now look after themselves, with but little care except tying, regulating, and pegging. We have several times described our wholesale way of doing the latter with little sticks, or prunings, cracked in the middle, and then both ends inserted in the ground, just as we might do with long hairpins of the ladies. The lawns are now getting nice and green, so as to give a good contrast to the flowers. We will, however, use the mowing machine but lightly until the vigour is regularly restored, as a brown lawn is a great disfigurement, and only less trying to the gardener than a withered grass field is to the farmer. From the heat and drought many grass fields never helped to blunt the scythe this season. Proceeded with potting all kinds of plants, and the cold pits now emptied of bedding plants are capital places for new-potted things, as, merely by the difference in air-giving and shading, we can make every two or three lights into a hot-plant stove, a cool-plant stove, a greenhouse, a warm pit, or a cold pit, at will.

*Placing Plants Out of Doors in Summer.*—There are few plants that are the better of this process. We adopt it with Azaleas, Camellias, New Holland plants, Pelargoniums when done blooming, &c., but just because we can find no room for them under glass. With light houses, and abundance of air, or, rather, part of the glass removed, we have no doubt all would be as well, or better, if kept under glass. When set out temporarily there is always danger from storms, from soaking rains, and the chance of leaving them a night too long, or taking them out too soon; but the practice is general, and we must make the most of it. The position should be sheltered, but not too much shaded, and, provided the heads are inured gradually to the sun, they will seldom suffer from all that this country can give them. It is from the roots that injury proceeds, especially when the roots are matted at the sides of the pot, and the pot is exposed to the force of a powerful sun. Plunging the pots, or surrounding them with some substance, to break the force of the sun's rays, is of great benefit to the plants, besides securing economy in attendance and watering.

*Plants Drawn from Shade.*—We have had numerous complaints that Geraniums, Fuchsias, &c., well grown, were, on account of their being drawn—that is, lengthened out by shade—thrown back in the prize lists at some country exhibitions. The gardeners say what is perfectly true, that it was impossible to have them otherwise in the only place they had to grow them in—under the shade of Vines, &c. Some have asked if that circumstance should not be taken into consideration by the judges in awarding the prizes. We do not see how that could be well done, unless all who grew in similar circumstances were to compete with each other. As a rule, judges never trouble themselves as to how the articles are produced; their work, for the time, is to single out what they consider the best—a not-very-easy task frequently—and, in the matter of plants, other things being equal, they will give the preference to stiff stubby plants over those that are weak and drawn. We quite sympathise with one gardener, who says his master is dissatisfied that his plants, drawn from shade, do not take the first place, because the disadvantageous position ought to be taken into account. It would be better every way not to grow such plants for exhibition in such a place at all. The gardener should explain the matter courteously to his employer, and either give over showing against more favoured competitors, or obtain from his employer equal facilities for

growing them well. Even then every one cannot take the first place; and there are many instances of fine culture that do not appear in the prize list. As our opinion is asked, we do not hesitate to say that, though the samples of plant culture turned out of fruit-houses are often wonderfully good, such plants as Pelargoniums, Fuchsias, &c., where much depends on the compactness of the plants and the richness of the colour, can never be made to equal those grown in light open houses, where the plants are the chief or only thing to be attended to. One amateur, who year after year failed with Geraniums from this cause, has taken to grow Ferns and Mosses with great success, and here, in his own neighbourhood, stands pretty well alone. Is not this much better than vainly striving to beat or equal a neighbour with so many advantages over himself? The gardener who competes will act wisely if he show what his circumstances will enable him to give every justice to. In the show alluded to we saw some wonderful Pelargoniums, to which we will refer at a future time, and we were informed that these plants did not even stand on a stage or a shelf, but that every plant had a pedestal for itself, with plenty of room all round it, and the light striking every part without obstruction. We also noticed some Pelargoniums and Petunias unrivalled for the brilliancy of their colouring; and we ascertained that they came from a gentleman who has taken out a patent or patents for glass-house building. We had the privilege of examining the houses and manufactory, and will give a short description ere long. Meantime, if the matter of expense at first can be properly got over, there can be no question of the great improvements. The houses are entirely of iron and glass, the iron either enamelled or galvanised, so as to dispense with painting—at least it will seldom need to be resorted to. Large squares of glass are used—no rebates, no laps, no putty, no bother; but the house can soon be put up, and soon taken down, and the squares packed again in crates; and yet so securely is the glass fixed that no wind or change of weather will cause it to move or rattle, and so loosely that there can be no breakage from expansion, as we some time ago mentioned took place here, when glass was put edge to edge without a lap. Except the small bars that are used to keep the glass down, the whole surface is a plane of glass, and, though the squares are joined to each other in the same plane, without lap or anything between them, there is no drip. Of course ventilation is duly secured.—R. F.

COVENT GARDEN MARKET.—JULY 8.

THE late refreshing rains have improved both the quantity and quality of the supplies to our market, which comprise all the articles usually to be had at this season. Among the foreign imports are Green Gage and other Plums, Apricots from France, and Pique Apples from the West Indies.

TRADE CATALOGUE RECEIVED.

William Dillistone, Munro Nursery, Sible Hedingham, Essex.  
—Catalogue of Choice New Plants of 1865.

TO CORRESPONDENTS.

\*.\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

CHAMBER SLOPS (*South Norwood*).—You had better not apply these to your Cucumber plants. It is of too uncertain a composition to be employed by any exact practical men. You may apply the slops to Cabbages, Rhubarb, Sea-kale, and Asparagus without fear of injuring them.

ROSE CUTTINGS IN COLD FRAME (*B.*).—They are best put in singly in small, two-and-a-half or three-inch, pots, in light sandy loam, plunging them in ashes, shutting up close, and shading from bright sun, never opening the frame for the first six weeks, except to sprinkle them with water every morning during bright weather. In September admit air by tilting the lights at back, and during the winter protect from severe frost, admitting air in mild weather. The cuttings should be from wood of the current year, and are best taken just after the bloom is past. They should have three joints, one being inserted in the soil, and the others left with their leaves entire.

PANSIES AND PINES PROPAGATING (*Agnes*).—Your plan is the right one. Keep close and shaded for a fortnight or so, or until the cuttings begin to grow, showing plainly they have struck root; then admit air and sun by degrees, gradually inuring them to full light and plenty of air. They like plenty of air after they have struck root, and that they usually do in a fortnight to three weeks or a month, during which interval they require no air. Shade from strong light and sun, and sprinkle with water now and then, to keep the air and soil sufficiently moist, but not wet or saturated. We have no knowledge of covering the cuttings with a box for weeks during the day, taking it off at night only. We have long ago struck them by the hundred in a shady border, covering with mats during the day, and only then during sunshine or hot dry weather, from 9 A.M. to 5 P.M. We think the covering with boxes is simply a modification of this—shade from sun, and protection from drought. We do not know of any difference in the Nosegay from other Geraniums, except in the petals, they having three broad and pointed and two narrow and toothed; but Nosegays are now so crossed with others of the Zonale section as to have lost much of their original character. Nosegay Stella is one of the best bedding Geraniums. We have more than twenty kinds bedded out, and it surpasses all the others in colour. It is decidedly worth having; and, though Mr. Beaton, its raiser, thought little of it, it rivals all others that we have tried in the profusion and continuance of its bloom. The old Monthly Rose will grow freely in warm situations, but is usually cut down to the ground by frost in open exposed places. Cut out the old wood, and manure like other Roses. Prune in March. We have beds of them, which are cut to the ground every year. They are now, and all summer, masses of bloom.

SEEDLING PELARGONIUMS (*A. R. M'Guire*).—Your seedling Pelargoniums are of no use; they did not arrive in a condition for judgment; the hot weather had caused the petals to fall. They may be pretty varieties, but not of first-rate quality.

PLANT BOXES FOR WINDOW SILLS (*F. A. Forbes*).—Hayman is the name of the maker, but we do not know his direction. He should advertise them, for they are of very good design.

FIGS FALLING (*A. B., Wallington*).—Does your Fig tree have plenty of light? Want of light is a fruitful source of failure. If your tree has enough of light, and plenty of air, we can attribute the mischance either to dryness at the extreme roots, stagnant water there, or too great luxuriance. If very luxuriant try a little ringing now. We have had the points suffer in dull weather from deficiency of air.

LILIU ACRATUM CULTURE (*G. S.*).—Sound loam and a little peat and leaf mould suit all these Lilies. We would give little water after the leaves decay, but we would keep the roots active by just keeping them moist. If you set the pot on a moist floor, and cover the top with 2 or 3 inches of moss that will do. The moss if the pot was set on the ground would save all your Lilies in the orchard-house.

CACTUS PROPAGATING (*T. Barnes*).—In the short article on the Cactus to which you refer, Mr. Fish forgot to state that it was an answer to a correspondent, and, therefore, no more was alluded to than merely met his case. He would feel a pleasure in helping you to increase your stock, and he would do this better if he knew what kind you have. Most of the singular Echinocacti and Mammillaria, &c., are increased by division, and taking off suckers, and little tubercled offsets. We suspect, however, that yours is one of the Epiphyllum or Cereus breed, as these are what are most generally grown in house windows, and the easiest and best way to increase them is to take off a piece or pieces as cuttings, and place the cut end among rough gravel and a little leaf mould, damping the mixture a little occasionally. All of these kinds will soon root under this treatment, and then you may pot and grow on. This is a more certain and easy way than putting the cutting in a pot. We are glad you took so many prizes at the flower show out of your spare room, and regret you have no kitchen garden to take your Calceolarias and Cinerarias to give them rest. When cut down they would do in the back part of the room, and might remain there until they made fresh shoots and suckers, and needed potting. They would do better, however, out of doors, and any shady place by the side of the house or the yard, would suit them as well as the kitchen garden. A common little yard can hold very many things in the rest period, as you term it. If even such advantages are denied you, and you object to having such faded plants in your room, we would advise you to depend on a pinch of good seed instead of the old plants. The old plants would give something more certain. If such plants are put in the yard, though they would do well enough in the pots, they would do better if these pots were plunged in ashes. As soon as the suckers were big enough divide and pot into small pots, and then into larger, and get them into the room before frost comes.

WINTERING BEDDING PLANTS (*A Rev. Subscriber*).—In your lean-to house 16 feet long and 9 feet wide, you may keep a great many things. The best arrangement would be to have a walk in the middle, and a platform on each side, and then beneath the platform you can keep many things in winter that do not need much light. To make sure in such a house you would need from 48 to 60 feet of three-inch piping for the hot water.

ALANTHUS GLANDULOSA (*A. R.*).—It is not unusual for this tree to flower in England. It has ripened its fruit here, which is like that of the Ash, but much smaller.

VARIEGUS (*E. J.*).—*Daactylis glomerata variegata* is a hardy perennial grass, and may be propagated by division. *Reineckia (Sansevieria) carnea* is a hardy bulb, if grown in well-drained light soil, with a little protection over the bulbs in winter. Of the daisy-knife, mentioned by Mr. Fish, there is a drawing in our No. 113, which you can have by post, if you enclose four postage-stamps with your direction.

ARRANGING GARDENS, &c. (*J. D., Bristol*).—If you write to Mr. Chapman, Hermitage Road, Richmond, Surrey, he will furnish you with the information you need.

NAMES OF PLANTS (*A Kent Subscriber*).—It is quite impossible for us to spare the time which would be required to determine the names of the trees from which your bundle of leaves was taken. Two or three specimens of plants in flower we readily name. Your Grape appears to be *Marchioness of Hastings*, but it is so unripe we cannot say confidently. (*A Subscriber, Wigan*).—We cannot name the scrap sent. The true Breadfruit tree is not a *Musa*, but *Artocarpus incisa*. (*A Youngster*).—1, *Gaultheria shallon*; 2, *Calceolaria* (dried up); 3, *Galega officinalis alba*; *Spiraea salicifolia*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

PETERBOROUGH EXHIBITION OF POULTRY AND PIGEONS.

No doubt the Show held on Wednesday and Thursday last at Peterborough was quite equal to any of those of former years held in con-

nection with this agricultural Society. The proposed arrangements of the managing Committee, had they been fulfilled, would certainly have proved as near perfection as possible; but, on the contrary, the neglect of the contractors well nigh upset the exhibition altogether. So far as we could glean the circumstances, by inquiries made on the spot, it appears that the well-known exhibition pens of Messrs. Turner, of Sheffield, were engaged a month prior to the time of holding the show, and it is but justice to state that so far as that firm was concerned

all the pens were ready on the ground fully forty-eight hours prior to the time of wanting them. Another local contract entered into by the Peterborough Committee, was for a sufficient supply of timber to form a basement for the pens to stand upon, and also for the support of an awning, to provide against the vicissitudes of weather during the time the Show remained open to public inspection. In this department of the contracts it was that the shortcoming arose, to the prevention of going on with the erection of the pens, and thus entailing an amount of difficulty few persons inexperienced in such matters would accredit. For this no excuse can be deemed sufficient, as the contract had been signed fully a month previously, and we will, as briefly as possible, give the results consequent on its non-fulfilment. The Committee had to pay away ten carpenters, actually "waiting (from time to time) for the timbers." Comparatively a very few of the pens were erected at the time of opening the Show to the public; and even the whole of them were not finished at 3.0 P.M. of the first day. Besides the annoyance to all parties concerned, the absolute loss to the Peterborough Committee must have been considerable; and numbers of the exhibitors, who had been waiting in the broiling sun for hours to pen their poultry, were by no means particular in the expression of their individual opinions on the subject. We would here suggest to all committees the absolutely imperative necessity, in such contracts, to insert a clause entailing a heavy fine in all cases of non-completion. It would be justice to all parties concerned, and would more surely enforce promptitude and compliance than the united remonstrances of a committee, though persisted in for hours. Luckily the weather was favourable during the time the pens remained unfinished, and, consequently, as the poultry in the meantime were carefully and sufficiently supplied with food and water in their travelling packages, we hope no injury may arise to any of them.

The *Grey Dorkings* were classes of considerable merit, though the majority of the birds exhibited were suffering materially in appearance from being now in the midst of their annual moult. We exceedingly regretted that decidedly two of the best pens shown of this valuable breed were disqualified altogether from the fact of the birds being marked with tape sown round the legs. It leaves no alternative to a Judge but to disqualify, and two first prizes were lost entirely from this cause only, for, as the Judge stated at the time, "the marked birds were infinitely superior to the winning ones." Some very good *Spanish* fowls were exhibited, but the number of entries was few. The *Game* classes were very good, and the class for *Cochins* was also praiseworthy. We had almost supposed the day far gone, however, when any exhibitor would have hoped to gain prizes by sending a Buff Cochins cock mated to a pair of excellent dark Partridge-coloured hens in the same pen, yet such was the case at Peterborough. The show of *Hamburghs* was a poor one, though an open class to all varieties. The Golden-spangled were the best, and Silver-pencilled next in order of merit. Some very excellently feathered Silver-spangled *Hamburghs* were also shown, but the hens possessed combs as pendant as *Spanish* fowls—a defect rendering success an impossibility. The class for Any other distinct breed was very good, and the commendations numerous.

In *Geese* and *Ducks*, both *Aylesbury* and *Rouens*, and again in *Turkeys*, Mr. Fowler, of *Aylesbury*, fairly ran away with the premiums, with birds such as would support the credit of even that gentleman's far-famed selection at any show, whilst many of the agricultural visitors at Peterborough seemed scarcely able to believe the evidence of eyesight, that they could be bred to such perfection.

The *Pigeons* were not numerous, being shown in pens of three varieties, for a sweepstakes only—a plan but ill-calculated to promote a spirited competition.

Notwithstanding the "disheartening" effect on the Committee of the pens not being ready until so long after the time of public admission, those gentlemen struggled diligently when the time came that they could pen the poultry, but we fear as so many exhibitors were then suddenly called into requisition as assistants, at the last moment, mistakes in penning may have arisen, particularly as several pens were "disqualified" as being wrongly entered.

**DORKINGS (Cock and Two Hens).—**First, T. Tatham, Kingsthorpe. Second, R. Wood, Clapton, Thrapstone. Third, J. K. Fowler, Aylesbury. Fourth, T. Rushin, Ravensthorpe. Highly Commended, R. Wood; T. Tatham; J. Archer, Hemingford, St. Ives. Commended, J. K. Fowler. (Two Hens).—First, J. Longland, Grendon. Second, J. K. Fowler, Aylesbury, Bucks. Highly Commended, T. Tatham, Kingsthorpe Norths; T. Rushin, Ravensthorpe, Norths; T. Hardy, Postland. *Chickens* (Cock and Two Pullets).—First, T. Tatham, Kingsthorpe. Second, R. Wood, Clapton. Third, J. K. Fowler, Aylesbury. Disqualified, Marchioness of Exeter, Burghley House, Stamford. (Two Pullets).—First, J. Longland, Grendon. Second, T. Hardy, Postland. Highly Commended, J. K. Fowler. Disqualified, Marchioness of Exeter, Burghley House, Stamford.

**SPANISH (Cock and Two Hens).—**First, J. Biggar, Northampton. Second, C. Wright, Northampton. Third, J. W. Smith, Oundle. Commended, X. Y. Z., Peterborough. (Two Hens).—First, J. Biggar, Northampton. Second, C. Wright, Northampton. Highly Commended, J. W. Smith, Oundle. *Chickens* (Cock and Two Pullets).—First, J. Biggar, Northampton. Second, C. Wright, Northampton.

**GAME (Cock and Two Hens).—**First, J. N. Beasley, Chapel Brampton. Second and Third, H. Shield, Northampton. Highly Commended, J. H. Smith, Horton. Commended, S. Deacon, Polebrook Hall, Oundle; Capt. T. Wetherall, Loddington, Kettering.

**COCHIN-CHINA (Cock and Two Hens).—**First, T. Tatham, Kingsthorpe. Second, J. K. Fowler, Aylesbury, Bucks. Third, Marchioness of Exeter, Burghley House, Stamford. Highly Commended, Capt. T. Wetherall, Joddington, Kettering. Commended, Rev. R. Montgomery, Holcot Rectory;

T. Tatham, Kingsthorpe. *Chickens* (Cock and Two Pullets).—First, Rev. L. H. Gandy, Stauwick Rectory. Second, T. Hardy, Postland.

**HAMBURGHS (any variety).—**First, T. C. Mansoll, Thorpe Malsor, Kettering (Golden-spangled); Second, T. Dance, Peterborough. Commended, J. Barber, Millfield, Peterborough.

**ANY OTHER DISTINCT BREED (Cock and Two Hens).—**First, Capt. T. Wetherall, Loddington, Kettering. (Black-breasted Red Game Bantams); Second, A. Storar, Peterborough (Duckwing Game Bantams). Third, Rev. R. Montgomery, Holcot Rectory (White Japanese Silk Fowls). Highly Commended, Capt. T. Wetherall, Loddington, Kettering (Black-breasted Red Game Bantams); H. B. Spurgin, Northampton (Brahma Pootra); J. Hill, Oundle (Brahma Pootra). Commended, Rev. R. Montgomery, Holcot Rectory; H. Shield, Northampton (Black-breasted Red Game); E. Fullard, Abbey Farm, Crowland (Silver Polands); H. B. Spurgin, Northampton (Black Bantams); J. K. Fowler, Prebendal Farm, Aylesbury; (Brahmas); J. Lound, Peterborough; (Black-breasted Red Game).

#### SINGLE COCKS.

**SPANISH.**—First, J. Biggar, Northampton. Second, C. Wright, Northampton.

**GAME.**—First and Commended, H. Shield, Northampton. Second and Third, J. H. Smith, Horton.

**DOCKING.**—First, R. Wood, Clapton. Second, T. Tatham, Kingsthorpe. Third, J. Louland, Grendon. Highly Commended, The Ladies Westworth Fitzwilliam, Harrowden House. Commended, J. Longland, Grendon.

**GEESE.**—First, J. K. Fowler, Aylesbury. Second, W. Hetty, Orton, Longueville, Peterborough.

**DUCKS (Aylesbury).—**First and Second, J. K. Fowler, Prebendal Farm, Aylesbury. Highly Commended, The Marquis of Huntley, Orton, Peterborough. Commended, J. Craig, Fotheringhay.

**DUCKS (Rouen).—**First, J. K. Fowler, Aylesbury. Second, The Marquis of Huntley, Orton, Peterborough.

**DUCKS (Any other variety).—**First, J. Beasley, Brampton, Northampton (Buenos Ayres); Second, S. Shaw, Peterborough (Muscovies). Highly Commended, S. Deacon, Polebrook Hall, Oundle (East Indian).

**TURKEYS (Cock and Two Hens).—**First, J. K. Fowler, Aylesbury. Second, J. Beasley, Brampton, Northampton. Highly Commended, W. Brown, Thorney. Commended, E. Fullard, Abbey Farm, Crowland.

**PIGEONS.**—Prize, T. Adams, Northampton (Carriers, Tumblers, Bald-heads). Highly Commended, A. Patson, Peterborough (Red Mottled Tumblers); A. Storar, Peterborough (Dan Carriers, Croppers Magpies).

Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, Birmingham, officiated as Arbitrator.

## SNATH (YORKSHIRE) POULTRY SHOW.

(From a Correspondent.)

OUR annual meeting for the exhibition of poultry, &c., was held this day, July 6th, and was one of the most successful hitherto held; the several pens contained some really superior birds, and there was an increase in the number of entries. The cock and hen Game fowls shown by Mr. F. Sales were universally admired for their symmetry and colours.

The following are the several awards made by J. Richardson, Esq., Thorne:—

**BEST COCK AND HEN IN THE SHOW, A SILVER CUP.**—First, F. Sales, Crowle. Second, C. Brierley, Roads House, Middleton.

**BEST GAME COCK, A SILVER CUP.**—First, E. Aykroyd, Bradford. Second, F. Sales, Crowle.

**GOLDEN PHEASANT.**—First, Messrs. R. & C. Burch & Bolton, Sheffield. Second, R. Tate, Leeds. Third, H. C. G. Holmes, Driffield.

**SILVER PHEASANTS.**—First, J. B. Hepworth, Bears Wood Green. Second, Miss Cawthorne.

**SPANISH.**—First, Robson, Brotherton. Second, J. Mann, Howden. **GAME.**—First, F. Sales, Crowle. Second, G. Morley, Barlow.

**DOCKING.**—First, Lord Hawke, Wormsley Park. Second, A. Young, Driffield.

**HAMBURGH (Silver-pencilled).**—First, G. Holmes, Driffield. Second, Halliwell, Sheffield.

**HAMBURGH (Golden-pencilled).**—First, O. A. Young, Driffield. Second, Messrs. Burch & Bolton, Sheffield.

**COCHIN-CHINA.**—First, R. J. Wood, Browsdale Hall. Second, H. Merkin, Driffield.

**BANTAMS.**—First, R. Tate, Leeds. Second, W. Brierley, Roads House, Middleton. (A severe contest.)

**ANY BREED.**—First, W. Brierley, Roads House, Middleton. Second, A. Young, Driffield.

## RIPON AND CLARO POULTRY SHOW.

(From a Correspondent.)

THE fifth annual Show, in connection with this Society, took place on the 4th inst., in a field at Bishopton. The entries were not quite so numerous as those of the preceding year, owing, probably, to the prizes being reduced in value; but the birds exhibited were equal to, if not better than, those shown on any former occasion, and the competition very close in some of the classes. In the *Game* there were many entries, but many of the birds were very inferior. Of *Spanish* both first and second were very loose in feather. *Dorkings* were very poor. *Cochins*, shown by Mr. Joseph Walker, of Hay-a-Park, were very good. The show of *Hamburghs* was good, especially the Spangled birds; Mr. Walker held his usual place in Silvers. *Bantams* were expected to see muster in good force. There was a very good show of *Pigeons*.

**GAME.**—First, T. Hench, Bedale. Second, W. Elliott, Thirsk. **SPANISH.**—First, W. Jndson, Ripon. Second, Bown and Greenwood, Harrogate.

DORKING.—Prize, J. Bell, Thornton-le-Moor.  
 POLAND.—First, Bown and Greenwood. Second, J. Dalton, Sleningford Grange, Ripon.  
 COCHIN-CHINA.—First, Bown and Greenwood. Second, J. Walker, Haya-Park, Knaresbro'.  
 GOLDEN-SPANGLED.—First, J. Walker. Second, J. B. Topham, Borough-bridge.  
 SILVER-SPANGLED.—First, J. Walker. Second, T. Hough.  
 GOLDEN-PENCILED.—First, G. Cryer, Hartwith, Ripley. Second, Bown and Greenwood.  
 GOLDEN-LACED BANTAM.—Prize, G. Nicholson, Sharow.  
 GAME BANTAM.—Prize, Bown and Greenwood.  
 ANY OTHER VARIETY OF BANTAM.—First, Bown and Greenwood. Second, J. Cartwright, Thirsk.  
 TURKEYS.—First, J. Greaves, Clothorholme. Second, S. Gothorp, Nunwick.  
 GESE.—First, J. Hattersley, Abel Grange, Thirsk. Second, S. Gothorp.  
 DUCKS (Aylesbury).—Prize, H. Walker, South Stainley.  
 DUCKS (Rouen).—Prize, J. Greaves.  
 DUCKS (Any breed or cross).—Prize, T. Renton, Ox Close House, Ripon.  
 PIGEONS.—Carriers (of any colour).—Prize, J. Hattersley. Tumbler (Almond).—Prize, R. Gray, Borobridge. Tumblers (Any other variety).—First, R. Gray. Second, T. Hammond, North Stainley. Pouters.—Prize, J. Hattersley. Jacobins.—First, J. Hattersley. Second, G. Petty Borobridge. Fantails.—First and Second, J. Hattersley. Snets and Trampeters.—Prize, J. Hattersley. Barbs.—First and Second, R. Gray. Turbits.—First and Second, J. Hattersley. Dragons.—First, J. Hattersley. Second G. Petty. Balbs or Beards.—First, T. Hammond. Second, J. W. Wood, Ripon. Any new or distinct variety.—First, J. Hattersley. Second, J. Malthouse, Ripon.

### ITALIAN MODE OF FATTENING ORTOLANS.

SIR HUGH LYON PLAYFAIR, in his lectures on the application of physiology to the rearing of cattle, gives a very remarkable illustration of the influence of rapid alternations of light and darkness, without reference to the diurnal revolutions of the earth, in inducing sleep and inclination for food, in the Italian mode of rapidly fattening Ortolans. "At a certain hour in the morning the keeper of the birds places a lantern in the orifice of the wall, made for the special purpose of darkening and illuminating the room. The dim light thrown by the lantern on the floor of the apartment induces the Ortolans to believe that the sun is about to rise, and they awake and greedily consume the food upon the floor. The lantern is withdrawn, and the succeeding darkness acting as an actual night, the Ortolans fall asleep. During sleep, little of the food being expended in the production of force, most of it goes to the formation of flesh and fat. After the birds have been allowed to repose for one or two hours to carry on digestion and assimilation, the keeper again exhibits the lantern through the aperture. The mimic daylight awakes the birds again; again they rise and feed; again darkness ensues, and again they sleep. The representative sunshine is made to shed its rays four or five times every day, and as many nights follow its transitory beams. The Ortolans thus treated become like balls of fat in a few days."

[It is not improbable that chickens and other poultry might be similarly deluded into frequent voluntary feeding when put up for fattening. If they could be so induced to feed, it would be far better than cramming, so often and cruelly adopted. —Eds.]

### THE STORIFYING SYSTEM.

Your esteemed correspondent "J. E. B." asks me in No. 213, to detail my mode of procedure with storified hives, and I append the following remarks in the hope they may prove alike useful to him and the brotherhood generally.

First, then, as to hives. From a lengthened experience of square and octagon hives kept side by side, I have no hesitation in giving a decided preference to the latter. I invariably find, should hives be at all weakly in spring, that the bees congregate in one side of square hives, gradually but slowly extending as they increase in strength to the other; while in octagon hives they stick to the centre, increase in numbers, and go ahead much more rapidly—easily accounted for by the better concentration of heat in the octagon form. At the same time I by no means disparage square hives for other purposes: these during the working season retain no insignificant place in my apiary, and, from the greater number of frames they contain, possess advantages to the scientific apiarian clearly apparent; still I seldom employ them as storifiers, except when I run short of an octagon box, and for which reason I take care to have both sorts of uniform width—viz., 14 inches, and, that I may transfer a frame or bar handily from one to the other, have them also of the uniform depth of 7 inches.

The usual depth of Stewarton hives is 6 inches. The enlarged size I find advantageous, enabling me to employ them singly for second swarms, or for beat-out bees at the end of the season. They also afford space for a larger window for observation, 5 inches from top to bottom, 4 inches across; the glass is let in from the inner side of the box, bedded in putty or sunk to the flush, secured in addition with a few small sprigs; the outside edge of the cut is bevelled off in imitation of putty externally. I adopted this plan of fixing windows, from finding frames each on the edge of the cut when letting down into the hive, and also combs, when frames were not employed, being carried out into the window space, and of course broken when the bar was raised. Each hive contains eight bars with the usual 7-10ths slides, the six central bars are 1½, and the two end ones 1¼ inch broad. The four central bars carry frames; all are kept in their place by means of half-inch brass screws; the entrance full width to dovetails, half inch deep, with the usual moveable door.

So much for the hives, now for their management. Two of the deep or breeding-boxes are firmly tied together with cord attached to the little weighing-hooks, the slides withdrawn from the lower, and the little pegs inserted; then give the earliest and largest prime swarm to be had; so soon as the two boxes are filled, nadir with a third breeding box. A swarm so treated in the north is not expected generally to yield any honey harvest the first season, it being more important to the storifier for the following season's procedure if possible to get the lower box combed. From the greater earliness of swarms and richer pasturage of the south, glasses or, a small super might possibly be taken in addition.

To ensure honey the first season here, the following plan is almost invariably adopted. Eight or ten days after the first swarm is hived in the boxes as above mentioned, a second good prime swarm is secured in a single breeding-box, and set down close to the other. At dusk the same evening the swarm in the two boxes is raised, and the new swarm in its box placed under the slides of the lower, which are then drawn, and the morning reveals a peaceful union, with the lower box empty, which had better be at once removed, and a super placed on above for access thereto, drawing only one slide on either side, the outermost of course. The pressure of the combined force has generally the effect of compelling a detachment to be told off to take possession of the super. So soon as comb can be seen therein through the windows, the third or lowest breeding-box, formerly withdrawn, is now reinstated; as the super gets well filled, place a second empty one above the first, at the same time withdrawing all the slides of the lower so as to afford free access between the two. The first super can be removed complete, when the cells of the central combs are observed to be all sealed; the upper super then takes the place of the under, and in like manner a fresh one takes the place of the upper. All supers must be well wrapped up with old woollen or other warm material. Meantime, the population may have increased to such an extent as to require a fourth breeding-box added below to avoid the escape of a swarm. "J. E. B." will find as he becomes more experienced in this system, that a little nadir space afforded a full hive, instead of diverting attention from the super, will on the contrary only stimulate to greater activity, while withholding it, in all probability, forces a swarm to the desertion of one or more supers, possibly for the season.

In young hives standing in three breeding-boxes at the end of the season, so soon as it is observed that the bees have vacated the lowest, it had better be removed, the slides run in, and after wrapping it up in paper, it can be hung up in a dry loft or garret, and in its room a shallow eke for ventilation inserted, that eke to be removed so soon as breeding fairly sets in in spring.

After work has been fairly started in a super, or even earlier, the lower combed box can be locked out and once more set beneath the hive. As a rule bees in these hives are generally wintered in two boxes set on a shallow eke. Older hives in four or five breeding-boxes, during the working season, will generally in addition to the removal of supers and the lowest box empty of comb, be able to spare, should the season be favourable, the upper breeding-box filled with honey. As in the case of my friend "R. B.," alluded to at page 478, a hive overloaded with honey, particularly at the beginning of the gathering season, is a decided disadvantage.

Sometimes, should the second prime swarm intended to be added be available sooner than the prescribed eight or ten days, it may be advisable to retain it for a few days in the box before uniting it to the other, so as to gain the advantage for that

time of the breeding of both queens. This, the timeous supply of space, and many little points of management too numerous to go over here in detail, will suggest themselves as the operator becomes experienced.

I cannot draw these observations to a close without attending to the remarks of Mr. S. Bevan Fox at page 391. That excellent contributor, I am afraid, rather misunderstood me when he concludes I reprobate the principle of his plan of placing shallow ekes between the super and stock hive. Were I to do so I would reprobate the very mode by which in days gone by I have taken my largest hauls of honey. On the contrary, I am thoroughly convinced that by no device can bees be induced to store up a greater weight of honey than by a gradual enlargement of one honey-storing compartment as in the adjuster hive, or by very shallow ekes; or by a similar enlargement, by deeper ekes, of one breeding-space, the queen's production is greatly stimulated, as has been already pointed out in the adapter hive, described by me in one of the early Numbers of the new series; each plan alike offering a strong temptation to increased storing and breeding, and avoiding altogether the hesitation often observable in taking possession of a fresh separate adjunct. Still, if we except some rare stupendous supers for ornamental purposes, the honey-dealer is ready to offer a proportionately larger price for the smallest and most completely sealed packages; and breeding in separate compartments offers considerable inducements for a more ready lightening of stocks overburdened with honey, besides employing such separated portions with facility for other colonies. Then again the recent improvements of the Woodbury bar and embossed wax sheets do much to overcome now-a-days twisted combs, and the consequent blocking up a free communication between the several portions of hives.

What I did deprecate in "J. E. B.'s" practice was the very limited fixed breeding-space (a too-common error, I am afraid, in the south, where the storifying system is not so generally adopted), and extended ckeing of unfilled supers, manifestly tending to force the queen to ascend and convert such enlarged supers into second breeding-boxes or lead off a swarm.

Mr. Fox might find it worth his while giving the plan of placing an empty super above an all-but-filled one a second trial. Both points may be well illustrated by a case from my own apiary. I had this spring a Ligurian colony in two seven-inch-deep breeding-boxes; when the honey season set in put on a full-sized super; as comb-building progressed therein, nadired with a third breeding-box (empty, I was sorry to have no combed one to supply); as the super got well filled, put on a second above, drawing all the slides between the two. Shortly thereafter the first super was completed and taken off; the second, by this time well combed, was set down on the stock in its stead, and a third empty super put on above as before; the second now only wants a few cells to be completed, and the third is fully combed. I have to-day (3rd July) given a fourth empty super above all; yet, notwithstanding, should the present heat continue, I must nadir with a fourth breeding-box below to avoid swarming, as a yellow mass of idlers lie upon the board and crowd up into the cover-porch. To nadir a hive now 34 inches deep requires a little management. For any one person to attempt to raise it, besides the weight, from its top-heaviness there is a great risk of its toppling over. Such is best effected by securing the boxes together with stout cord passed round the weighing-hooks, and a strong pole slipped through them on top, borne on the shoulders of two men. With the air afforded by this additional breeding-box, to see the immense body of workers contained in a hive, then 41 inches deep, in full work is a treat of no mean order anticipated by—A RENFREWSHIRE BEE-KEEPER.

[In conclusion our Renfrewshire friend refers for further details to his reply to "J. E. B." which appears in another column.]

### THIS YEAR'S HONEY HARVEST.

AFTER twenty years' experience as an apiarian, I have no hesitation in stating this to be a most extraordinary year both for honey and swarms. Owing to the late swarming of last year I succeeded, by feeding liberally, to commence this spring with nineteen hives, many of them, of course, very light, whereas now they are all full of honey to the bottom, notwithstanding the glasses, boxes, and caps I have obtained. Fourteen hives have thrown off twenty-seven swarms, five of which went together, the remainder I put into ten hives by uniting, in

which I succeeded in all cases but one, when by neglecting to put perforated zinc over the top in lieu of the cork, they were all smothered. My first swarm was on the 10th of June, but, late as it is, many hives are full of honey, all will live. The five swarms that went together were the best-behaved mob I ever saw, no riot, none wounded, none killed.—T. W. CHALONER, *Newton Kyme, Yorkshire.*

### THE MANAGEMENT OF STEWARTON HIVES.

I SHALL be glad of your opinion on my management, and the present position, of my two Stewarton hives. The annexed rough outlines will help you to understand me the better.

	A	A
	B	B
In the early spring they stood thus—		
As the season advanced I inserted a box between each of the above, and then they stood thus—		
I was afterwards told I ought to have put c at the bottom, and was advised to remove it.	A	A
I did so, and now they stand as on the left.	C	C
	B	B
To give more room, I afterwards placed a top box on each, and this became the position of them—		
The first of these swarmed (I believe) last Saturday week, unobserved by any one. The second showed signs of swarming, and, to prevent it, I added, yesterday, a fifth box from below, and beneath is now the position of affairs with regard to this one.	D	D
	A	A
	B	B
	C	C

I did not remove either c or d, because neither of them seemed to be filled with honey, although in both the bees were working well. Have I done right in the past? and what do you advise as to the future?

I have two large square glazed supers very nearly filled. The cells are sealed over, with the exception of a very small space at one end of the comb—the outer comb, I mean, as I cannot see the inner ones. Would you advise my ekeing these now, or waiting till completely sealed over? An answer in the next Journal will much oblige—T. R. D.

[Your letter has been submitted to "A RENFREWSHIRE BEE-KEEPER," who, in reply, says:—"The management, on the whole, was not amiss, excepting the blunder of placing an empty between his stock-boxes. That, as a rule, causing a vacancy to any extent between the portions of storified hives, is bad practice—all additional breeding-space should be given below, all honey room above. His further procedure will, in a great measure, depend on the strength of his stocks. If the first swarmed, it has, in all probability, room enough for this season; if they come to sufficient force to afford a prospect of their completing the super, then a second might be tried above. The other stock should have a second super on at once, in like manner. One can form little opinion of such storified hives without seeing them."]

### BEEES IN LINCOLNSHIRE.

I BEGAN the season this year with five stocks, one pure Ligurian (which I have multiplied into four as pure as the parent, and three others that I cannot at present tell the purity of), one hybrid Ligurian, the queen of which was kindly sent me by "J. E. B." last year, and three black stocks, one of which, a very old one in a cottage hive, being rather weak to begin with, has afforded me no assistance in forming swarms. On transferring it into a bar and frame hive on May 20th I was surprised to find the queen to be a well-marked Ligurian, and the progeny are decidedly hybrids. Being only weak, possibly I had noticed it but little, for certainly before the transfer I had not observed a trace of Ligurian blood about it. The stock has now, however, become very strong.

I have gone entirely upon artificial swarming this year, and have thus increased my five stocks into fourteen, all strong and thriving, and, including four absolutely pure Ligurians, all but one having more or less of Ligurian blood in them. I hope yet to increase the purity of the hybrid stocks. I have also abandoned the use of all hives not fitted with frames, as I find the command this gives over the stocks is very great. The season here has been a very good one thus far, but natural swarming has been unusually late and slow. In an average of

apiaries in this neighbourhood not 15 per cent. of the stocks have swarmed at all. I had a capital natural swarm last Thursday (29th of June), from a hybrid stock, from which I had previously taken two artificial swarms, the last of which was during the preceding week. This is the only natural swarm I have had.

A curious aberration of nature has taken place with the first pure Ligurian artificial swarm, and which for some time puzzled me exceedingly. It was made on May 20th, and is as strong a swarm as ever I saw. Somehow they seemed to work very hard, but yet make very slow progress in filling the box. In about three weeks I examined them, and found the queen to be a beauty, and breeding well (I might say that in forming the swarm the queen escaped into the parent stock again during the transfer of combs, so that the swarm formed the nucleus and raised nine royal cells, six of which I excised when sealed for other stocks); but on examining the combs themselves I discovered that all the new ones were constructed with circular cells instead of hexagonal ones, and I consider that this requires fully four times the quantity of both wax and labour. On June 20th, a remarkably hot day, two small combs in this hive fell, having been partially melted at top, this caused a great commotion. Of course I replaced them when I got home, and was surprised to find that after this hexagonal cells have been constructed for a few days, but now again they have gone back to circular ones. I have never heard of a similar instance. Is it a common occurrence?

The above may, perhaps, tend to strengthen the faith of some of your readers in the superiority of so-called "artificial" swarming, though it really seems to me a perfectly natural operation.—G. F. B., *Spalding*.

P.S.—I should have had one more swarm, but in removing the stock I stumbled, and down came self, and bees, and all. This caused a great commotion, and the greater portion followed the parent, so of course I sacrificed the swarm.

[Combs with circular cells are a phenomenon I never met with, and I should therefore be greatly obliged by a specimen of this description of abnormal comb being forwarded to—A DEVONSHIRE BEE-KEEPER.]

#### DISSECTION OF A DRONE-BREEDING QUEEN.

About the middle of August last year, I reared, artificially, a queen, which with a numerous colony of bees was put into a Woodbury frame-hive containing combs partially furnished with honey. On the 24th of the same month I joined to this virgin queen and colony a swarm headed by a fertile queen. The queens fought; one fell, to all appearance the fertile one, but not having marked her I cannot be certain. The hive, however, seemed to prosper, and but for drones continuing to be sent forth from it late in autumn might have been pronounced the most flourishing in my apiary. It got through the winter beautifully, kept up its large population till the arrival of spring, and showed great activity on fine days by diligently collecting pollen.

On March 24th, lively drones issued from it, but being of a small size I at once concluded all was not right. However, I determined to leave matters alone for the present, fancying that if the weather proved favourable, my virgin queen, if still a virgin, might incline to take an airing in the company of the drones. Some of the days that followed were warm and summer-like, the drone population increased, but no young workers appeared.

On April 6th, I made an inspection of the combs (which, by-the-way, did not contain a drone cell originally), and found the central ones filled with drone-breed, all in worker cells, which the bees had been at some pains to enlarge and elongate.

In some cells two and three eggs were laid, and placed at random in the apex or on the sides. Replacing the combs, I allowed matters to remain as I found them till the 7th of June, when about three-fourths of the population would be drones, the working part having sadly decreased. The result that would follow was sufficiently obvious. So without loss of time I removed the unprofitable queen and despatched her to Mr. Woodbury for dissection, requesting him to tell me whether or not she had made a successful wedding trip. I told him not one word regarding her age or history, my object being to test as far as possible the truth of parthenogenesis. On June 10th, Mr. Woodbury replied as follows:—"I have dissected out the spermatheca of the queen sent by you, and find it destitute of

the slightest trace of spermatozoa. If a young queen, she has, therefore, never been impregnated; if an old one, she has become completely exhausted, and if she laid eggs they would (like those of a virgin queen), produce drones only." I have thus stated a few simple facts, and I leave the apiarian readers of the Journal to draw their own inferences.

The hive though destitute of a queen still survives, and as none of the bees were hatched subsequent to the 22nd of August, the youngest of them is rather more than ten months old. They are all black, but I have a few Ligurians which I know, certainly to be still older.

From several circumstances I am led to think the average age of bees is six months. Those hatched in spring dying off late in autumn, and those hatched from about July keeping in vigour till spring is a little advanced.—R. S.

#### VOLUNTARY UNION OF SWARMS.

I MENTIONED in my note at page 19, the frequent occurrence of double swarms in this neighbourhood, or, more properly speaking, of swarms that voluntarily unite, either from both coming off at the same time, or the noise and excitement of a subsequent swarm rousing the new settlers to turn out again and join their fortunes with those on the wing. I am now able to record the case of a triple swarm, which may serve as a precedent to that of Mr. Stuttle, recorded in the Journal of June 13th.

On the 14th of June my neighbour, Mr. S., had an after-swarm from one of his hives, which was secured about noon. Very shortly afterwards a prime swarm from another hive joined it, but some little fighting must have taken place, as a hundred or two of dead bees were found strewn in front of the hive. The double swarm worked briskly, for on the 25th the hive was quite full of comb, and four large glass supers were progressing fast. The hive was already inconveniently crowded, but on the 27th an after-swarm from a hive which had been removed to a little distance, joined it at 8.45 a.m. Both the fact itself, the long interval that had elapsed since the second union, and the hour at which the third union was effected, are, I think, somewhat remarkable. The bees for the last three or four days have been hanging out in a great mass, looking more like swarming than a swarm. I shall be glad to take note of the proceedings of this colony, but thus far no such ill-luck has befallen it as in the instance recorded by "T. G.," and it seems new beyond the reach of harm.—F. H. WERT, *Potternewton, Leeds*.

#### DYSENTERY IN BEES.

THIS complaint has been very prevalent this last winter in all sorts of hives, and as some of the books say it is caused by dampness and some by feeding on certain flowers, &c, I should be glad to hear from your correspondents what they consider is the cause, as I cannot think dampness has to do with it, although it may help to cause it, as most of my bees were in straw skeps. A hive of common bees that I had joined a small Ligurian swarm and queen to had it very bad, and I thought it would have died out, and had it not been for the Ligurians being stronger, it certainly would, as the black bees died out at least a month before the Ligurians or some hybrids that I joined at the same time. If the "DEVONSHIRE BEE-KEEPER," "B. & W.," and some of your able Scotch correspondents would be so kind as give your readers their opinion on this complaint, we might find out some preventive or remedy.—A. W.

#### ADDING A LIGURIAN QUEEN.

HAVING examined the hive into which I put a Ligurian queen and finding her safe and healthy, with larva in abundance in the cells, I need not say that I am well satisfied at the result. They travelled to me from Devon remarkably safe, as there were only two dead bees. When I ventured to allow the bees to get beside the queen, I uncovered the box and opened the hole at the top of the hive, when they immediately crowded into the little box, amalgamating with the Italians and queen in a very friendly manner, with that unmistakeable hum when they discover what they are in search of—a sovereign.

I thought all was now quite safe and just placed it mouth down on the top of the hive to allow them to go down at their leisure during the night. However, contrary to my antici-

pations, in the morning I found a severe internal warfare, and a great number of bees stung and cast out, and still evidently at war amongst themselves. At first I could scarcely judge of the cause of the contest, but it had originated in the main body of the bees in the hive not following up those which went up into the box; and, consequently, after being separated for a short time, apparently those that were in the box with the queen were attacking every one that attempted to go in from beneath. I immediately used smoke thinking that this would at once put an end to the contest, but found it only had the effect of a cessation for a short time; and although I repeatedly used it throughout the day, they stung a considerable number, and in case war should continue during the following night, I forced those in the box to go down into the hive, and kept them running together in the hive among a slight smoke until they got completely mixed together and the quarrel was then at an end; but they were a few days before they were quite satisfied. Although there were not a few bees killed, I think there would be fully 4 lbs. weight left, so that there is no fear of them as to strength.—S.

### THE PREVENTION OF EXCESSIVE SWARMING.

I AND others would be glad to have a little more information from "B. & W." on preventing excessive swarming, and the best plan of preventing it, as giving them room will not always suffice. I have adopted the plan of returning the third, fourth, fifth, and sixth swarm to the stock in the evening; but I should be glad to have his idea on this plan—that is, to take the queen and a few bees from the swarm, and in the evening join her and the few bees to the parent hive, and, as soon as the bees find their queen gone, they would return to the hive again. This, I think, will be less trouble than returning the swarm in the evening, as they sometimes enter very slowly when there is a number. I also find, when hives are close together, that, putting the swarm in the stock's place, the bees will not enter and stay, but go to the next nearest hive or stock, and stay there. This I have had them do twice this season; but I should like to have "B. & W.'s" opinion a little fully on this subject; and would he also say how he uses the brown paper in expelling bees from the hollow trees? as the paper will not smoke unless dipped in nitre.—A. W.

### BEEs IN THE HOLLOW TRUNK OF A TREE.

HAVING derived much information from the several articles of late in your Journal on the subject of bees, I am induced to send you some notes I have made on points lately discussed in your paper, and also to request your kindly answering one or two queries. Precisely a similar case occurred to me as to "B. B." On the 7th of June a very fine swarm settled on the bough of a beech tree, at a farm which I hold some four miles from my apiary; but whilst I was making preparations for their capture they again took flight, and finally chose the hollow of an ash tree for their permanent abode. I saw at once that there was nothing for it but to fell the tree, which I set to at once, having at hand the valuable assistance of a man who had spent seven years in the backwoods of America, and whose skill in handling the axe stood me in good stead. I found, when the tree was down, that the bees had ascended at least 3 feet, and that it would be necessary to channel out the tree for that length. This we finally accomplished late in the evening, and secured one of the finest swarms I have ever seen. I conveyed them home, a distance of four miles, in a common straw skep, and transferred them the next day to one of Neighbour's Scotch hives, in which they have since worked so vigorously that on the 18th of June I put on a glass top, which is now more than half full of pure virgin honey.

Curious to say, in the very next tree to which I have alluded above, there has been established a colony of bees for the last fifteen years. How can I secure the honey from them? The tree is too ornamental to admit of being cut down, and the entrance is about 20 feet from the ground. Of course the bees would have to be smothered.

From a stock hive I this year had two swarms, the second in my absence and much against my will. I afterwards put on the stock hive a large bell-glass 10 inches in diameter, which is now literally packed with the finest honey. What is the best way of removing this? and would it be advisable to put on another glass at this period? What is your opinion of Natt's collateral box-hive as compared with the super system? Could

not bees hived in an old single straw hive be made to work on this principle by placing another hive or box on the table by the side of the hive, and establishing a communication by means of a groove in the table covered with glass, and the passage to which could be commanded by a zinc slide?—Scrib.

[We know of no means of securing the honey without injuring the tree by laying bare the cavity occupied by the bees. Insert an empty box between the super and the stock hive. The former will be found comparatively deserted the next day, when it may be taken off, conveyed to a little distance, and the remaining bees permitted to return home, a bright look-out being kept in the meantime to guard against robbers. Putting on another glass can at any rate do no harm, but take care that the stock hive is sufficiently well stored to stand the winter. We prefer the storifying to the collateral system. You will find several modes of adapting the latter to common straw hives described in Taylor's "Bee-keeper's Manual."]

### OUR LETTER BOX.

**GAPES IN YOUNG POULTRY (Loose Box).—**Give those affected a pill of camphor, the size of a small pea, daily until cured. Keep a piece of camphor in their water-trough.

**MARKINGS OF COCHINS (Coloured China).—**It is common for Partridge Cochins to have coloured breasts, but it is by no means desirable. Our experience is, that it is hardly possible to breed them all with purely black breasts, even from the best strains. Some should, however, have them. Where the chickens have only a few brown feathers, we should decidedly keep them till they attained their adult plumage, in the hope they would moul them out; but where it is a decidedly variegated breast, black and brown, we should get rid of the bird. The work you name will have coloured plates, but we do not place implicit dependence on such plates. You will see that the classes at most shows are for "Buff and Cinnamon." This has caused a laxity in lotting and matching which would not have been allowed formerly. There were originally three classes of Cochins, which are now intermixed:—the Buff, which should be uniform in colour; the Cinnamon, the cock of which was the colour of wetted cinnamon, the hens' bodies a lighter shade of the same, with very dark hackle; the Silver Cinnamon, the cock with a very light body, while the tail and hackle were of very pale red brown. The hens of this breed, when they were kept pure, were among the most beautiful of the tribe, the whole body was a most beautiful French white, giving a soft silky appearance to the feathers, and which was not belied on bandling. The only variety of colour was a lemon-shaded hackle. These have all inter-bred, and have originated the colours you describe. The third bird you describe, being all Buff, seems to us the best coloured; but the others would pass with well-matched Buff hens.

**GAME FOWL MOTIONLESS (M. P. C.).—**Your fowl had a cramp or a temporary vertigo from blood to the head, or some injury to the back. In either case your treatment was the right one. We have known a slight blow or a fall to injure the spine, and cause the apparent paralysis you mention for a few minutes, or sometimes for a longer time, and a perfect cure has been effected by the struggling of the fowl when caught.

**DISEASES OF PIGEONS (D. O.).—**Are you sure that there is not something unwholesome in their food? Has any of the corn ergot, or has it been otherwise damaged? Peas are not good for laying-pigeons; they are apt to lay soft eggs on them. Hempseed is too exciting. They should have access to chalk or old mortar. Or does their weakness arise from diarrhoea? You may try pills containing one grain of calomel, one-twelfth of a grain of tatar emetic, and follow it by pellets of cod liver oil and flour.—B. P. B.

**NOTES OF BRITISH BIRDS ARRANGED IN MUSIC (E. M.).—**We do not know of any book in which such music is noted.

**HIVES (An Amateur).—**We consider Neighbour's improved cottage hive rather too small, but it is unquestionably large enough for sustaining a swarm through the winter. Zinc ventilators are not essential to the successful working of bell-glasses as supers. It is better to remove one of the queens in uniting, but the bees will generally do this for themselves. We have, however, known instances in which both queens have been sacrificed, and stock lost in consequence.

**HONEY (A Bucks Bee-keeper).—**Apply to Messrs. Neighbour, 127, High Holborn, and 149, Regent Street, London.

**PAYNE'S IMPROVED COTTAGE-HIVE (F. H.).—**We do not know where this can be obtained, if not of Messrs. Neighbour. Why not buy our "Bee-keeping for the Many?" You can have it free by post from our office for five postage stamps. In that there is a drawing of Mr. Payne's hive, and any maker of the common straw hive could make one from that drawing.

### LONDON MARKETS.—JULY 10.

#### POULTRY.

THE supply increases, and the trade declines earlier than usual on account of the dissolution of Parliament. We may look for low prices, if the heat of the weather moderate. If it remain as it is now, a few fresh goods will every day make good prices, while there will be loss on the bulk of poultry sent.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 73.2°, and its night temperature 51.1°. The greatest heat was 91°, on the 18th, 1853; and the lowest cold, 27°, on the 16th, 1853. The greatest fall of rain was 1.37 inch.

SELECTION OF STRAWBERRIES AND THEIR CULTURE.

UT a few days ago I met at Blandford the Rev. Joseph Mansfield, Rector of Blandford St. Mary's, who occasionally visits my garden. He said, "I wish you would

write a treatise on Strawberry culture, and also give a selection of Strawberries that are good and easy of cultivation in lands generally." I assured him that Mr. Underhill's and Mr. Cuthill's treatises were excellent and amply sufficient. Still, as these may not be generally known, it may not be amiss to say a few words through a periodical of wide circulation.

It is difficult to make a suit of clothes to fit the whole species of man; and it is not less so to select Strawberries to suit every man's taste and widely different circumstances. As regards tastes—one man likes the Hautbois flavour; another likes a vinous juicy Strawberry; another prefers an acidulated flavour; another likes the Pine flavour; another does not care what the flavour is as long as he can get quantity, plenty of sugar, and Alderney cream. My taste is set to Hautbois, Pine, and Alpine flavour. As regards soils, there is a great difference between clay or deep loams, and sandy or chalky soils like mine. Moreover, as regards some sorts, aspect and situation (high or low) make a difference. You will see, then, by these circumstances and considerations what a difficult task lies before me to make a suit of clothes which is to fit everybody. I will, however, do my best.

I will commence by naming Strawberries of great excellence, suitable only to first-class lands and painstaking cultivators. I doubt whether they can be depended upon year after year in any land. When they succeed, you hear of it; when they fail, people hold their tongues! 1, British Queen and her synonyms, respectively in shape and flavour, or both, Magnum Bonum and La Chalonnaise; 2, Carolina Superba; 3, Filbert Pine; 4, La Constante; 5, Myatt's Pine Apple; 6, Crimson Queen. The last is late, good, and the surest.

I now come to Strawberries that do well for me and are excellent for the purposes for which they are designed. 1, Sir J. Paxton, the earliest that is good, a hardy plant, great cropper, and handsome show fruit. 2, Eclipse, the best early sort. 3, Rivers's Eliza, delicious, and lasts a whole season; I never knew it fail from any cause. 4, The Royal Hautbois, cropping well for the third season. 5, Scarlet Pine, the highest-flavoured and most pined sort that has ever been here; the plants are stalwart, and resist frost and drought. 6, John Powell, good plant, good cropper, good colour and form, and delicious. 7, Wonder-

ful, a heavy cropper and very good; it requires plenty of water in a torrid summer, or it would become hard. 8, Empress Eugenie, large, handsome, a heavy cropper, and of fair flavour, but not equal in flavour to some of the above. 9, Bieton White Pine, the best white; it is not ripe till it is yellowish. 10, The Frogmore Late Pine, a noble late sort, and liked here by all. 11, The old Red and White Alpines. These eleven sorts are on the whole the best out of more than 130 sorts that have been sent here for trial. They seem to combine all that we want. If we can get better of course we shall be glad, but in their different lines and seasons they will take some beating. If more than these are desired, these are good and good croppers, but not equal to some of the above:—President, Alice Maude, Trollope's Victoria, Marquise de la Tour Maubourg, Marguerite, Ingram's Prince of Wales, and Sanspareil.

The following are on trial, planted late in the spring. Of course, some allowance must be made. They were kindly sent by Mr. Ingram, Her Majesty's gardener. The Fairy Queen is nicely coned, handsome, sweet, and delicious. The plants have stood the heat very well. More I cannot say at present. It is a great favourite at Frogmore. No. 10 is a strong and quick-growing plant and runs freely. It was pegged June 24th. The berries are coned, large, and handsome. It is late. Mr. Ingram says it will be superior to the Frogmore Late Pines. Its seeds are prominent. I have a heavy crop of noble Frogmore Pines, by which I have tested it. It is delicious, and though it is not so large or highly pined as the Frogmore Pines it is sweeter. John Powell, the Frogmore Pines, the Fairy Queen, and No. 10 do great credit to the raiser. I should, however, like to see the last two go through a severe winter—a severe spring they could not encounter. To the two former I will give a first-class certificate, as I have had them here in scorching summers and severe winters, and, what is worse, in a severe spring. I have this morning (July 5), received a kind and complimentary letter from Mr. Ingram, asking me to name it, and expressing a wish to call it after me. I have no objection to its being called "Mr. Radclyffe," or "Rushton Radclyffe" if he like it better. The Rose called after me does me great honour, and this Strawberry will do no less. They are both a credit to the raisers. I think it safer to call it the above name than on limited trial to call it "Frogmore Pine Improved." Time will prove this. I beg to thank Monsieur Verdier and Mr. Ingram for this high compliment.

I now come to cultivation. There are very few cultivators of Roses and Strawberries in the kingdom. Even those who manure them do little or nothing towards watering them.

1. Preparation of the Soil.—Whether land be light or strong it should be trenched. Though Strawberries like great moisture and heat they also like free drainage. If water lies on the surface, and zero bites, the roots will be injured; and though the plants may flower well and set their fruit, they will not complete their crop. After trenching, the land should subside. Mine is light land; and if the land is dry I beat it down with a spade to prevent

its subsiding from the plant. Strong land does not require so much preparation previous to planting on account of its gravity.

2. *Planting.*—The plants should be planted to their base, or collar, and no deeper. The roots should be spread out on all sides like a duck's foot. The soil should be moderately pressed down on the roots and watered, and if the weather is hot, a flower-pot should be put over the plants by day, and removed at night. If they are planted from pots, the pot-soil should be slackened with the hand. If the roots are matted round the ball of earth, they should either be cut off with a sharp knife or carefully spread out on all sides. The best time to plant is, when the glass falls. The best seasons here to plant, with a view to cropping the next year, is from January to July. Eliza and Wonderful will crop well, even if planted very late. In this case you must put the plants in thicker, and after cropping remove every other one. Every plant of them will flower however late the runners are taken. As regards distances, it is a matter of judgment, resting on the quality and condition of the land, and also on the rate of growth of the plant. I am inclined to think, that in light land 18 inches every way is the best distance. Plants intended to stand over two crops should be planted wider. I do not recommend more than two crops. The British Queen, Filbert Pine, and La Constante will rarely bear more than one crop. If they can be got in early, I think with Dr. Roden, annual plantations of these sorts are best.

3. *Treatment after Planting.*—The soil should be continually surface-hoed (shallow), and the runners cut off. Water in dry weather should be constantly and liberally poured on the plants. Of course, the weeds should be kept down. The necessity of protecting young plantations during their first winter depends much upon the nature of the soil and their establishment. Strong land does not need so much winter-mulching as light porous soils. If young plantations winter badly, the best way is to keep the runners off and dis-flower them, they will then repay you manifold in the following year. I never break the soil of my Raspberries at all, and merely scratch lightly the soil of my Strawberry plantations. My crops are always heavy and complete their final production.

I must here pause to observe two errors that seem to be prevalent. The first is, the belief that a runner taken from a plant that has not fruited will be barren. If it is taken from a staminate plant (a male plant), of course that will be the case *ad infinitum*, but it is not true of hermaphrodites, which are the sorts that I keep, prefer, and recommend. Indeed, I believe that most of our European sorts are hermaphrodites. The other error is, that only the first runner on a string will bear fruit. If the Strawberry were to run a mile, the last runner would bear fruit, but the first runner would bear best, because it would be earlier established, and have more time to make crowns.

4. *Treatment under Flower and Crop.*—Do not water them when in flower, at least do not water the flowers. As soon as the berries are set, till they redden, in dry soils you can scarcely put on too much water. In their last stage water or rain acidulates them and spoils the flavour. After the first production is ripe pick clean off, and water the plants picked copiously. For lack of this, in many places the Strawberry crop and season will be short. As soon as they are in flower, put clean straw in the ranks and between the plants; and when they begin to redden put a net over them, which will cost you 1*l.* per yard. I have bought 800 yards this spring in addition to my previous stock. Blackbirds and thrushes being "hungry bestead," for want of worms and slugs, have been very busy; but "John Edgington" has baffled them. I like to see and hear them, but every "twit" of a blackbird disarranges the "ganglionic process" of Stephen, who seems to find relief in saying, "I wish I could lay hold of you, I would twist your neck for you!"

5. *Treatment after Cropping.*—I always, except when I want runners, cut off the runners and bury the straw with black dung, and water the ranks and whole surface copiously after cropping. I have given up the dangerous practice of cutting off the leaves. The above treatment brings up new leaves, which harden before winter sets in, fold over each other, and protect the crowns and roots. To this treatment I attribute my good crop this critical season. In natural soils it might not be a good plan to manure so highly close after cropping; but the plants should be watered and encouraged to make new roots from base or collar. The sooner they do it the better they will winter and crop. A large volume of perpendicular and horizontal roots is absolutely necessary to heavy cropping.

The failure of the crop this year, which I hear is general, must not altogether be attributed to spring demolition, but to deficiency of water during and after cropping last season. The earth was like a fryingpan, and the plants thus neglected suffered damage at their crowns and base. This neglect was followed by an hyperborean winter, and by a septentrionie spring. Add to this a torrid droughty summer and an inadequate supply of water, and you see why people have no Strawberries! I live nearly at the base of a steep chalky hill, where the land is chalky and without clay (equal chalk and clay is what we call "white land," it is the best in the world), and very dry. I cannot water the plants from the rivulet, as stated by "D." There is a nine-feet Thorn hedge between my garden and the rivulet. Everything here is watered from the pump! I keep two men at it with extra pay and beer. By following the rules I have given you, both this year and last, I have had a splendid crop. My annual Strawberry party was June 22nd. Eighteen came and tried to eat me out, but I beat them by several dishes. All the fruit used was fine and fit for Covent Garden—viz., Royal Hautbois, Scarlet Pine, Rivers's Eliza, Wonderful, Eugénie, and Trollope's Victoria.

6. *Procuring Runners.*—If they are intended to be cropped the ensuing season, and require a long time for establishment, which is not the case with the sorts that I keep, you must have two runners per plant during the fruiting season, pegged into pots, and removed as quickly as possible; or you must keep plants of the sorts required for running purposes entirely. It is absolutely necessary to plant the Queen early in any kind of soil. It is advisable to get the Frogmore Pine in early—a hardy plant when established. Early establishment is a grand ward in the key of Strawberry success!

7. *Manures.*—The grand constituent of a Strawberry plant and berry is potash. Good clay soil abounds in potash, and, therefore, it is the best soil for Strawberries; cow manure liquid and solid, is the best manure because it abounds in potash. All animal manures, liquid and solid, contain it. I use chiefly black dung, nitro-phosphate, soot, liquid manure, Peruvian guano, and strong beer grounds. They are all good for the purpose.

For strong land unfermented manure is best; for light lands the converse is best. Strong land does not require to be so highly or so frequently manured as light land. In my light land I find that I can never manure a Rose tree or Strawberry plant too highly, or too often. The plantations that are now picked clean are manured over the straw, and a fine thunder shower patters the manure into them.

In conclusion, keep a few things in your garden, and have them all well done. Keep only such things as are suitable to your land, situation, and circumstances. Do things at the right time, and multiply only those things that are good, and that do best for you year after year in this variable climate. When Stephen passes Jules Margottin and Eliza, he frequently cries out, "That's the sorts after all!" Above all, establish a sufficient number of pumps and a willing pumper. The former is of no use without the latter. Stephen and Fred have done good service, and my "Isachars may now yield their shoulders to the burden," for there is "a sound of abundance of rain!"—W. F. RADCLIFFE, *Tarrant Rushton.*

## GOSSIP ABOUT ROSES.

I was indebted this season, as I was last, to the kindness of M. Eugène Verdier in bringing to the "Mirabeau" (an hotel which, by-the-by, I can conscientiously recommend to any visitor of Paris), some blooms of his new Roses, and also some of those of last year; and as I believe my estimate of those he sent out last autumn was tolerably correct—viz., that Maréchal Niel and Rushton Radelyffe were the cream of the set, so I think, unless he has others which he may offer by-and-by, I can lay my hand now on the best of those of the present season. He has one flower which will be, I think, a decided acquisition. It is a large pink flower of the Louise Peyronny style, somewhat of a lighter shade of pink, perhaps, but having the same size of petal and the same bold and fine-looking outline; it is of fine vigorous habit with rich-looking foliage. I am not quite sure that the name for it is thoroughly decided, but shall know this before the time comes for the lists to be looked over (it is numbered 134). Then there was another flower of the Souvenir de l'Exposition type, like it in foliage, very fine and large, having, doubtless, a grand appearance on the tree; but it is not a style of Rose much in favour with us

in this country. The *Souvenir de la Reine de l'Angleterre*, *Madame de Cambacères*, and such like *Roses*, must eventually be pushed on one side, to give place to *Roses* of a better class, combining size with shape. It is, I fancy, a great mistake to suppose we have what we want in *Roses* as yet; this will not be until we get crimson reds, dark crimsons, and whites, with the shape and general contour of *Comtesse Cecile de Chabrillant* or *Coupe d'Hébé*. A third *Rose*, that promises well, was of the growth and foliage of *Jules Margottin*, fine in form, not very large, and very sweet-scented. I have placed these in the order in which I conceive their merit entitles them to.

As I have already said, it was too late for the Lyons *Roses*, and, consequently, I could only obtain information by letter. M. Guillot, fils, has four *Roses*, one of which seems very much to resemble, if one may judge by description, the *Rose* of M. Eugène Verdier, which I have already alluded to. It is called *Josephine de Beauharnais*, and is described to me as of a very beautiful delicate rose, with silvery white edge to the petals, a seedling of *Louise Peyronny*, of which it retains the character, both in wood and foliage. He has also another which seems to bear a striking analogy to the second *Rose* of M. Eugène Verdier, as it, too, is a seedling of *Triomphe de l'Exposition*, very well formed, superb velvety red, shaded with violet. A third *Rose* is *Pline*, a seedling of *Mère de St. Louis*, of which it is said to have retained the character in nearly every particular. Besides, he has a seedling Bourbon from *Louise Odier*—*Madame J. Gay*—I should imagine, from the description, very similar to *Emotion* and *Louise Margottin*. Of the four, one would have little hesitation in adopting M. Guillot's own view—that *Josephine de Beauharnais* and *President Mas* will be the best. From neither M. Charles Verdier nor M. Levesque did I obtain any information.

Of course I paid my old friend *Margottin* a visit, and, as usual, obtained a great deal of interesting *Rose* information from him; and, although his *Roses* (of which, I believe, he has a couple), to be let out this season were not in bloom, yet I had a long and broiling walk through his grounds on one of the hottest days I experienced during my trip. He has a plant of *Jules Margottin* this year which has come all marbled; a curious state is that marbling, for it seems, in nearly every instance, to affect the style of the flower, as well as its colour. I have myself this year a plant of *Anna de Diesbach* so marbled, and I can see that the style of the blooms is evidently altering. Whether it will be permanent I cannot yet decide; the autumn will tell whether these marbled flowers will remain true to their character. As a general rule, *Margottin* considers that the shaded *Roses* come better in France, and the bright ones in England. Certainly these violet-tinted and *ardoise* flowers are not general favourites on this side of the channel. In speaking of white *Roses* he said that he believed that *Made-moiselle Bonnaire* was a seedling of *Général Jacqueminot*, and that he had had numbers of white *Roses* from that most prolific parent, but none of them worth retaining.

I endeavoured to obtain from M. *Margottin* and other French *Rose*-growers their opinion of the *Roses* of last season, and I think that they have arrived pretty much at the same conclusion that we have. Thus *Duchesse de Caylus* was by all acknowledged to be a *Rose* of great merit, as was also *Rush-ton Radclyffe*, both of which I anticipated would prove to be gems. Of *Duchesse de Medina Celi* the opinion was not so favourable, and as I have seen but one flower of it this year I cannot say whether they are correct. Of *Charles Margottin*, I saw hundreds of blooms at the raiser's, and a very remarkable *Rose* for brilliancy of colour and substance of petal it is, in the style of *Count Cavour*, but brighter still; it is most certainly one of the brightest *Roses* out. At *Levesque's* I saw large quantities of *Madame Eliza Vilmorin*, but although brilliant in colour, it is wanting in that neatness of form and smoothness of petal we look for. *Denis Heyle* is a very fine and large flower in the style of *Anna de Diesbach*, but deeper in colour. *Xavier Olibo* was also considered to be a good *Rose*. It is somewhat difficult to keep in one's mind the *Roses* of the different seasons, as they come so rapidly one on the other; and in the metropolis, at any rate, one is struck with the few *Roses* of the present season that one sees. In the class for new *Roses* you get the *Roses* of three or four different years, and rarely more than five or six of the present season. Of those flowers which were distributed to the great bulk of *Rose*-growers in the autumn of last year I have noticed, as especially good, the following:—*Pierre Notting*, a deep violet burgundy-purple rose, of good form and substance; *Madame Victor Verdier*, a fine deep rose, of exquisite build, and great depth;

*Duchesse de Morhy*, a sweetly-coloured rose; *Baron Pelletan de Kinkelin*, purplish crimson; *Kato Hausburg*, bright rose, and prettily-cupped flower; *Madame Derreux Douvillé*, rich deep pink; and *Souvenir de Maréchal Serrurier*, deep crimson purple, cupped and full. Of the others that I have seen, *Amiral Lapeyrouse* has not enough stuff; *Bernard Palissy* is a very effective flower, but not of the shape to please a great many; *Centifolia rosea*, a pink rose, but nothing remarkable; *La Reine de la Pape*, rose shaded with violet, not good; *Louis Van Houtte*, too full, does not open well; *Madame Macker*, delicate in habit; *Maréchal Forey*, rough and bad. Further acquaintance may modify these views, but at present this is the estimate I have been led to form, and other *Roses* that I have not seen may take a good place.

The season generally, while favourable in the early part of the year, did not fulfil its promise. The intense heat of June fairly beat some of the most experienced growers, and in many grounds milder set in with great force. The cool weather and few rains we are now experiencing will give a good second growth, and we may possibly have a fine autumnal bloom. And so for the present ends my *Rose* gossip.

As several letters have reached me about the yellow *Rose* of *Lacharme's*, I may say here that it will not be let out till the autumn of 1866.—D., Deal.

### DINERS À LA RUSSE FOR THE MILLION.

"WHAT is a diner à la Russe?" asks your correspondent "D." of Deal. "D." answers his question, at least so it seems to me, very correctly, except in saying that the old *éperges* and *candelabra* must give place to a lighter and more elegant ornamentation in the shape of flowers. Now I dine very constantly, and I think very prettily à la Russe, with an *épergne* of ancient date and pattern in the centre of the table. This *épergne* is composed of silver, it has a bowl for flowers raised considerably above the table in the middle; while lower down eight silver branches spring out, each holding a small vase. When tastefully ornamented with flowers and Ferns, few things could look more graceful and light than this old *épergne* with the dessert arranged in plates of valuable china around it.

But many people may not possess an old *épergne*, and every one having a tolerably well stocked garden may enjoy this prettiest and most economical way of dining. I will suppose, that besides my garden I have a small farm with a trout stream running through it; I wish to have a few friends to dinner without much expense in this month of July. I have in common with most farm-houses, a few old china plates, that belonged to my grandmother, and a small stock of glass. I place a small saucer topsy-turvy on a soup plate, on the saucer I put a tumbler, and in the tumbler a champagne glass or old-fashioned rummer. Round the soup plate I dispose the fresh green fronds of the *Polystichum angulare*, or *neuleatum*; they should be all of the same size, so as to lie down evenly in a circle on the fair white tablecloth. I dispose smaller Ferns so as entirely to hide the saucer and tumbler, and then I fill up the soup plate with a wreath of white *Roses* and blue *Corn-flowers*, or the *Verbenas Purple King* and *Snowflake*. From the tumbler I depend my finest *Fuchsias*, white *Calceolarias*, *Jasmine*, and blue *Salvia*, with a few fronds of *Polypodium dryopteris*. My best Ferns and *Pelargoniums* I keep for the champagne glass.

This arrangement can be varied in a hundred ways—*Spiræa arifolia*, mixed with *Humea elegans* and a few Fern fronds, has a very good effect. I place this bouquet in the centre of the table, bending the circle of Ferns to make them lie on the tablecloth—then I put specimens of all my best *Roses* with fronds of Ferns in six rummers, and dispose them between the outer circle of fronds. My dessert of *Cherries*, *Strawberries*, *Raspberries*, *Gooseberries*, with *Currants*, white and red, I put in six of my old china plates, with a delicate frond of some of my favourite Ferns here and there.

The trout stream furnishes the fish, which my husband gets up an hour earlier in the morning to catch, and is rewarded with one fried for his breakfast, which I need hardly say puts him into a good temper till the hour for company smiles arrives. I can spare this delicacy with the greater ease because I need only have just enough fish to satisfy my friends; dining à la Russe saves much waste, and my fish is brought in hot from the kitchen, instead of waiting on the table to get cold while the company seat themselves. If the fish is preceded by soup,

I would have the latter made of green Peas, for which I have an excellent receipt, requiring no meat. Being an early riser, I should make this soup while my husband was catching the fish, but I would take care and be tidy by the hour for breakfast. The farm would provide a couple of chickens and a leg of lamb.

My second course should be toasted cheese—that is, cheese *boiled* with a little cream, put on toast, and sent to table very hot. This dish insures good temper for the rest of the evening. The sweets—Malvern pudding (fruit boiled, sweetened and put in a basin lined with slices of thin bread—to be eaten cold with thick cream poured over it), and a baked plum pudding; this is good both hot and cold, and therefore more economical than a boiled plum pudding. The vegetables should be early Broccoli and first-rate Potatoes.

Strictly speaking, none of these things, with the exception of the fruit and flowers, (some people only have flowers) should be put upon my table, but they might all appear there, and yet the dinner not have the appearance of a cannibal feast. The expense of this little dinner would be small, very small, and its festal appearance would show my friends that I esteemed their company an honour, and that it did not require any great outlay to dine à la Russe, and bring to a homely life some of the elegancies of society, supposed, erroneously, to belong only to the rich.

In a churchyard near my old home, there is an epitaph recording that—amongst other virtues, supposed to be a sort of passport to heaven—the lady whose remains rested beneath “contrived to make a very good appearance on a small income.” I always felt quite hot when I read that epitaph, in sympathising with the great exertions of the poor lady, but it was no small praise after all; I know something of that lady's life, and the trying to make a good appearance is an amiable as well as a very pleasurable excitement, and causes me oftentimes to forget that I am (what the “WILTSHIRE RECTOR” declares I am not)—AN OVERWORKED WIFE.

### STOCKS AND THEIR INFLUENCE.

WHERE the soil and climate are suitable for the growth, the perfection of bloom, and for the maturity of the seed or fruit of any tree, there can be no doubt that the organs, naturally provided for the supply of sap, will afford it of proper quality and sufficient quantity for every want of the tree. Then, if trees and shrubs succeed best, are more productive, and freer from disease, when supplied with sap from their own roots and passing through a stem of their own peculiar kind, why do we graft or bud on a stock of another species or variety? We do bud and graft, however—1st, For the increase of a particular kind of tree, and on stocks of a different species or variety, because they are the more readily obtained; 2nd, To fit the kind for some particular soil; 3rd, To produce some alteration in the habit of the tree or shrub. There is a prevailing impression among gardeners that the stock communicates to the species or variety of tree or shrub grafted upon it a portion of its own power to bear cold without injury. This idea, however, is wholly erroneous, as is amply proved by the tender kinds of Roses on the Briar being destroyed by severe frost, and also by the circumstance that the branches of every variety or species of tree are much more easily destroyed by frost than its roots. Physiologists agree in their views as to our grafting on stocks which are of less growth than the scion, and consider the practice wrong where extensive growth and durability is wanted, but eligible whenever it is desirable to diminish the vigour and growth of the tree. Mr. Knight draws these conclusions from his experience—“That the stock of a species or genus different from that of the fruit to be grafted upon it can be used rarely with advantage, unless where the object of the planter is to restrain and debilitate; and that where stocks of the same species with the bud or graft are used, it will be found advantageous generally to select such as approximate in their habits and state of change, or improvement from cultivation, to those of the variety of fruit which they are intended for supporting.” Mr. Johnson, in the “Science and Practice of Gardening,” p. 200, states “The only situation in which we can believe that the stock of another can be advantageously employed, is where the soil happens to be unfriendly to the species from which the bud or graft is taken.” I have no doubt as to the general conclusions of Mr. Knight being correct so far as the health of the tree is concerned; but I find him all at sea as to grafting or budding on a different species or genus restrain-

ing the vigour of the scion. I find the Apricot much less vigorous grafted on a stock of its own species than on the Plum, it being a well-known fact that all varieties or species take much more tardily from buds or grafts on stocks from stones or seeds of their peculiar kind, than on those of a different species or genus nearly enough allied to permit of the operation succeeding. It is also remarkable that the scion or bud of any tree will take much more readily on another part of the same tree, the tree itself being budded or grafted on a stock of another species or variety, than when budded or grafted on a stock of the same variety. Generally all trees and shrubs seem to take better on a stock of a different species or variety than on one of their own peculiar kind.

Now, by budding or grafting on a stock of less or slower growth than the bud or graft, as in the case of the Peach and Nectarine on the Plum, the aim seems to be to restrain vigour, and render the tree more productive. Apart from any influence of the stock, grafting alone has a tendency to increase fertility and lessen the vigour of the tree. It acts in the same manner as ringing, or removing a ring of bark from a branch or stem of a tree; both act by arresting the downward flow of the sap. Mr. Knight writes on this point—“When the course of the descending current” (elaborated juice or sap), “is intercepted, that necessarily stagnates and accumulates about the decorticated part, whence it passes into the alburnum, is carried upwards, and expended in an increased production of blossom and fruit.” Though this was written with reference to ringing, yet it may be taken as having the same bearing on grafting; for Mr. Johnson, in “Science and Practice of Gardening,” page 195, when writing of the influence of the stock, states that “the sap becomes more rich, indicated by its acquiring a greater specific gravity in some stocks than in others,” instancing a Black Cluster Vine stock on which a Black Hamburgh had been grafted. According to this dictum we ought to find the Pear on the quince more prolific, and giving larger fruit, of better flavour, than on the pear stock; and the same results should attend all grafting or budding on a stock of less growth, and of a different species or genus. It is, indeed, verified by practice; the Pear on the quince, the Peach and Apricot on the Plum, arrive at a fruiting state earlier, fruit-buds are more abundantly formed, the blossoms set better, the wood and fruit ripen earlier (simply from the more abundant deposition of cambium, which we term the ripening of the wood), and the fruit is larger, higher-coloured, and richer-flavoured than when on their own stocks.

Grafting or budding, therefore, on stocks of less vigorous growth than the scion or bud, restrains the growth, rendering it more productive, though it may endure for a short time only ere disease commence, and the parts decay; or it may be permanent, and of this I only know one instance—the Pear on the quince. The reason, in this case, is not because the quince does not restrain the growth of the scion, but because the head or tree is kept close-pruned or stopped, the growth of stock and graft being made culturally corresponding. It is a common error to conclude that, because Peaches on the Mussel Plum are short-lived, Pears on the quince must be short-lived also. Nothing can be brought to bear showing the parallel in these cases. No doubt the Pear on the quince is short-lived when it is allowed to outgrow its stock, as the Peach on the Plum always does, in consequence of being allowed to make shoots a yard long, to be cut down at the winter pruning to 9 inches or a foot. Were close-pruning or stopping practised on the Peach, I have every reason to believe it would be as long-lived as the Pear on the quince, of which I know trees as dwarfs, close-pruned or stopped, upwards of half a century old, which annually produce good crops of large, fine-coloured, full-flavoured fruit. Now that I have Peaches on the Plum producing their fruit on spurs, I have every reason to think that they will prove as healthy, as fruitful, and as long-lived as the Pear on the quince, “close-pinched” so that the growth of stock and bud, or graft, correspond. Perhaps Mr. Rivers may have some of his original Peaches on the Plum close-stopped so as to produce their fruit on spurs that even yet produce crops of large-sized and good-flavoured fruit? If it be so it would go a great way to prove that fruit trees on stocks of slower or less growth are only short-lived when the scion is allowed annually to outstrip its stock in the growth made.

Further, in budding or grafting on a species or genus different from that worked upon it, we find that the bud or scions take much more freely, and make stronger growth for a few years (the Peach on the Plum losing its vigour through the formation of fruit-buds at the third season of growth), than on a stock of

its own from seeds. Peaches when budded in the latter way take badly compared with those on the Plum, make less growth, and never outgrow the stock, both thickening alike; and, unlike the former, the trees annually become stronger, the sap flowing more freely into the small or lateral shoots, and are in every way more healthy, less fruitful, and the fruit deficient in size and flavour. I am persuaded that, however wrong grafting on a stock of a different species or genus may be physiologically, it yet serves our purpose better than when a stock of the same kind is employed—we obtain an earlier and larger produce of finer fruit, in a shorter period of time; the question of longevity being of secondary importance when trees are so easily replaced by others equally productive with their predecessors.

The greatest evil of grafting on a stock of a different species or genus is that disease is likely to ensue. I think it is in some measure owing to the increased specific gravity which the sap of an Apricot on the Massel Plum acquires, that the disease called gum, which so disfigures the Moorpark by the dying of the main branches, is brought on. It is certain that working on a stock from a stone of the same Apricot renders the tree free from this disagreeable malady. The buds, however, take very unkindly, and grow much more slowly for the first year or two, and seldom attain so vigorous a growth as when on the Plum. The Peach, too, on the Plum is liable, like the Apricot, to gum on light loams on gravel, and on all soils the sap does not flow so freely into the lateral shoots: hence an old shoot does not continue either healthy or vigorous for any length of time, but requires to be renewed with a younger shoot or branch. Peaches on the Almond stock succeed better than those on the Plum in soils free of stagnant water; whilst on a very light loose gravelly soil I am inclined to think they would do admirably on the Apricot stock. I am not certain whether the drain on the resources of the Plum stock, by our present system of growing Peaches on what I may term the "long-rod" system, is not altogether at variance with the nature of both stock and scion. The nature of every tree is to grow freely whilst young, and afterwards to grow less and fruit more. By reducing the branches of any tree considerably at the winter pruning we obtain more vigorous growth, but it is certain that this does not contribute to increased productiveness, the tree frequently remaining unproductive until the balance between the head and roots is restored. Whatever may be the result of the Peach producing its fruit on spurs, I am led to think highly of the Apricot stock for the Peach, though it is of another genus; whereas the Plum is perhaps only another species of the same genus as the Apricot. I am also certain that the Apricot would do better on a stock of another genus if one could be found that would act in the same beneficial manner as the quince for the Pear.

I have already alluded to the fact that grafting in itself directly checks the growth and vigour of a tree. This is strikingly apparent with seedling trees, which, when allowed to grow at their free will, require a lengthened period before they arrive at a flowering or fruiting state. I find them flower sooner even when a scion is worked on its own stock annually, repeating the operation on the last-budded or grafted part with a scion or bud from that inserted in the previous year, and this continued will bring the most refractory seedling into a flowering and fruiting state; and the object in view is obtained sooner by grafting or budding on a stock of slower growth. Thus, seedling Roses bloom the third or fourth year when budded on the Dog Rose, but not until the fifth or sixth year when budded on their own stock, or on a stock improved by cultivation. A knowledge of these peculiarities suggests to us that many trees valuable on account of their flowers or fruit, but which are shy in producing these, might be so far changed, by grafting or budding successively twice or thrice, or oftener, as to produce their flowers and fruit abundantly.

I have often thought it something strange to see a Pear on the Pear stock strong and healthy, but devoid, for the most part, of fruit, though covering many square yards of wall; whilst a very small tree, not one-twentieth the size, gave double the quantity of fruit, in an open border, close by, on the quince stock. The Easter Beurré, Beurré de Rance, Beurré Bosc, Gansel's Bergamot, Gansel's Late, Broom Park, Aston Town, Marie Louise, Eyewood, and other Pears, are all too vigorous to fruit on the quince profusely, but they are most prolific when double-worked on it.

Whilst the repetition of grafting or budding conduces to the early production of blossoms and fruit, the stock in the first instance having a tendency to increase the specific gravity of the sap impelled into the scion, and the grafting hindering or

restraining the downward flow of the elaborated juice, and rendering the sap twice as rich as it would be naturally, still we find productiveness and early bearing soonest attained by working on a stock of another genus less closely allied than the quince to the Pear, as, for instance, the Pear on the Hawthorn. This, truly, is grafting on a stock of less and slower growth than the scion, and yet it is attended with the best results as regards the early production of blossoms and fruit. I think many kinds of Pears that grow too vigorously on the quince, or so much so as to require biennial removal, might be so far restrained in growth by double or treble working as to bear annually without removal. Though the quince is an admirable stock for Pears generally, it restrains the growth of some so much as to render them unhealthy. Thompson's, even, when double-worked, is not healthy on the quince; Knight's Monarch (one of the very finest of Pears, of peculiar flavour), is neither healthy nor fruitful on it; nor are the Seckle and Ne Plus Meuris at all benefited by working on the quince. They probably require a stock of slower—certainly one of corresponding growth.

I would observe, further, in relation to working on stocks of slower or less growth than the species or variety to be increased, that the fruit produced is not only larger, but higher-coloured, and of better flavour. This is strikingly apparent, in addition to the examples already named, in Digurreau and Heart Cherries on the common Cherry stock. On stocks of their own kind from the stone they are not nearly so productive, nor so fine either in size or flavour. Dukes and Morellos on the Cherry stock are extremely fine, but remarkably improved in flavour on the Mahaleb. With regard to the healthiness of Cherries on stocks of either slower or inferior growth, we know that working on such has a tendency to induce gum, but not of so virulent a nature as in the case of the Apricot on the Plum. No one will doubt, that the further we remove anything from its own natural course the more susceptible it will be of disease; at the same time we cannot but see that budding or grafting on a stock of another genus or species, nearly enough allied to maintain productiveness, and the existence of the tree for an average lifetime, does away with large annual growths and planting an orchard for another generation; and that by this practice the largest produce, of the finest quality, is obtained in the shortest time.

It has been suggested that, by working trees below the surface, the evils of grafting on a stock of another genus, species, or variety of slower or less growth, would be obviated by having the tree on its own roots. Now, this is something very absurd. If the soil is suitable for that particular variety, well, even then a stock is of no use; for, whilst planting, we might as well plant a tree on its own roots in the first instance. If the soil is the reverse of natural to the plant, then common sense would tell us to allow no roots except that of the stock to find their way into it. If we could give every tree the soil and climate natural to it, then we might safely adhere to the fact that every tree is best nourished by its own roots, and grow them on their own stock, approximating as nearly as possible to a natural state of things. Notwithstanding, seedlings of even herbaceous plants are finer when continued by cuttings—less vigorous as a plant, but having finer flowers, or it may be fruit. In like manner the seedling Pear, Apple, Plum, Peach, &c. are seldom so fine on the original as on a stock of another genus, species, or variety; and all this goes to show that grafting or budding on stocks of slower and less growth furnishes food that becomes richer in the scion, tends to productiveness and quality, but renders the subject more liable to—may, induces—disease, resulting in early maturity and death.—G. ABBEY.

(To be continued.)

#### DICKSON'S EARLY PEAR, FIRST AND BEST.

IN Messrs. A. Henderson's report on Early Pear, in No. 221 of your Journal, they make a statement to the effect that Dickson's First and Best and Sangster's No. 1 Pears are identical in all respects excepting a slight difference in the colour of the flowers. That statement is so contrary to my experience of those kinds this season, that I am tempted to send you the following as the result with me.

Both kinds were sown in boxes on the same date (first week in March), placed in heat until they came up, then hardened off, and finally planted out in rows, across a south border, on the 29th of March. Dickson's was gathered from on the 1st of June in good condition. Sangster's No. 1 not until the 13th,

and then not in so good condition as the former was on the 1st. Dickson's was also a fortnight earlier in coming into bloom, and did not grow so high as Sangster's by a foot.

I consider Dickson's First and Best Pea an excellent early variety, being a good cropper, bearing good-sized, well-filled pods, and one from which several gatherings can be made.

I am not in a position to speak of its qualities as an early Pea, as compared with some of the other early kinds, such as Carter's First Crop, Dillistone's Early Prolific, &c., not having grown those varieties. Probably some of them are as early, or perhaps earlier, and another season I may test them.

Dickson's First and Best is decidedly the best early Pea I have yet grown, and I consider Sangster's a good variety to succeed it when sown at the same time.—J. H. MASON, *Stouton Castle Gardens, Staffordshire.*

## THE POTATO SCAB—YOUNG POTATOES SPROUTING.

I SHALL feel glad if you can give me any information respecting Potatoes being scabby. I have, growing in a garden, Rivers's Royal Ashlen Kidney, which are splendid croppers, and now quite ripe, also Daintree's Seedling, which are the size of a Walnut, but so scabby that a few that I took up for trial had to be peeled. White Kemps are similar. The Kidneys are not so much scabbed; but I am afraid the scab coming on the Daintree's and Kemp's whilst they are so young will prevent their attaining their full growth.

I have also some Lapstone Kidneys which are now in flower. I found, when looking at them to-day, that the young tubers are growing, one I found with a sprout above an inch long, and roots starting from the base of it. Can you give any reason for their doing so? Perhaps it is a peculiarity of the Lapstone, as I have found none of the others doing so.—J. W.

[The origin of the scab in the Potato is undetermined. It is merely an eruption, confined almost entirely to the skin of the tubers, and, probably, is occasioned by lime, or some other ingredient in the soil which causes decomposition in the tissue of the Potato's skin. Soils manured with coal ashes have been observed particularly liable to cause the scab in the tubers. We shall be obliged by any of our readers sending us the results of their experience relative to this disease.]

The cause of the young tubers sprouting is more easily accounted for. When checked in growth and prematurely ripened by long-continued drought, when rain occurs they vegetate instead of increasing in size. They usually emit fresh runners, and produce on them fresh tubers, which has been called super-tuberation.—Eds.]

## ROYAL HORTICULTURAL SOCIETY.

JULY 11.

SCIENTIFIC MEETING.—W. Wilson Saunders, Esq., in the chair. The Rev. Joshua Dix, after reading the list of the awards of the Floral Committee, and briefly commenting on some of the objects for which they were given, called attention to the Pelargoniums and other bedding plants at Chiswick, and particularly those of Mr. Bull; and the collection of Larkspurs and Poppies, he said, would also well repay a visit. Mr. G. F. Wilson, F.R.S., stated that no certificates had been awarded by the Fruit Committee; but mentioned the fruit of *Dion edule* from Mr. Taylor, gardener to J. Yates, Esq., of Highgate, Messrs. Cathush's Raspberry, and a new Pea from Mr. Graham of Cranford.

The Rev. Mr. Berkeley said, that before remarking on the objects before the Meeting he wished to draw attention to a pamphlet by M. Bonchet, of Montpellier, giving an account of the results of experiments in crossing Vines, and the substance of which had appeared in the "Comptes Rendus" of the Academy of Sciences. With one Vine in particular, *Le Teinturier*, which was used for colouring wine, some difficulty had been experienced in crossing, on account of its flowering eight or ten days earlier than the kinds which were employed as the female parents; but this difficulty having been overcome, several varieties had been the result, some of which had colourless, others coloured juice like the male parent; and some were so early that it would be possible to have the vintage in the South of France in August. It had been doubted whether cross-breeding affected the character of the fruit or seed of a plant the same year; but Mr. Standish, who had made numerous curious experiments in cross-breeding Vines and other plants, had informed him (Mr. Berkeley), that he had noticed a change of form in Grapes which had been crossed in the first year; and Mr. Standish had promised to give the Society some observations on this point. Mr. Berkeley then read a

letter from Mr. F. T. Moore, enclosing two leaves of Vines which had been raised from the seeds of Malaga raisins purchased seven or eight years ago for making wine. The raisins had been boiled, the juice pressed out, and the residue thrown on the garden, and in a short time hundreds of young Vines had come up, some of which were now 4 feet high. In reference to this, Mr. Berkeley remarked that the same thing had happened to himself, with this difference—that the marc had not been boiled for some hours, but treated with boiling water, and from the refuse thousands of plants had come up. Mr. Berkeley then proceeded to review the plants, &c., exhibited. A double variety of *Geranium sylvaticum* was said to be an ornamental plant for shrubberies; and General Grant Pelargonium, from Mr. Reid of Sydenham, to be a cross between a zonate variety and some Cape species, and therefore never likely to be useful for bedding. Elizabeth Vigneron Rose, from Mr. W. Paul, was described as a most exquisite variety, and even finer than its parent Louise Peyronny. Of *Podophyllum Emodi* an account would be given by Mr. Short, who had succeeded in making the plant produce fruit. There was also a species, the May Apple, *P. peltatum*, cultivated in America, where it was known as the Wild Lemon on account of the fruit being acid. The leaves were said to be poisonous, but the plant possessed valuable medicinal properties, the rhizome being much used in America in the shape of a powder for fevers and affections of the liver. In reference to the Castle Kennedy Fig he had omitted to remark at a former meeting that he believed that a great many valuable fruits that were probably unknown in this country might be found in old gardens in Scotland; for in former days the intercourse between Scotland and France and Flanders, was closer than between these countries and England. In confirmation of this, Mr. Berkeley observed that when at the Marquis of Huntley's in Aberdeenshire, he had noticed magnificent Green Cherry trees scattered over the country, and which had probably been imported from France, as they were certainly not indigenous. They attained the size of Oaks, and had a very picturesque appearance. A large Puff Ball which had been exhibited at one of the shows was stated to be *Lycoperdon bovisia*, and, remarked Mr. Berkeley, though almost every one seemed prejudiced against Fungi, some of them had curious properties. This one for instance was excellent for taking bees, had powerful anæsthetic properties, and when young the flesh looked like bread, and was most excellent when properly dressed, being more tender than any sweetbread. In Italy, where it grows abundantly, it was kept in a cellar and a slice cut off when wanted, but here it soon changed colour, and when it had an unpleasant smell if became unfit for human food.

Mr. Short, having been called upon to give an account of his mode of cultivating *Podophyllum Emodi*, said that it was by no means a new plant, but he believed that he now exhibited it for the first time in fruit. He had turned his attention to its cultivation for the last ten years, and no plant that he knew was so impatient of removal and disturbance as it; if only a small piece were separated, the plant would be three or four years before it arrived at the same stage again. The flower to a casual observer appeared like that of the Black Helichore, but was more like that of one of the Nymphaceæ; the plant, however, belonged to an order of its own—*Podophyllaceæ*. It did not remain in flower more than two days, and if the flower were not impregnated within the first few hours all chance of fruit was hopeless. Having removed some seedlings he found that some of them had only two thread-like roots 2 or 3 yards long. The plant was difficult to propagate—the best way to grow it was to let it alone. He thought that the fruit would be either insipid or intensely bitter. The Rev. Mr. Berkeley having tasted the fruit declared it to be not at all acid, but insipid, and not particularly nice.

Mr. Wilson Saunders begged to direct attention to what some of his friends called ugly-looking plants. They were the next relatives to Figs, and were called *Dorstenias* after Dorsten, and through them the fructification of a Fig could be better explained than by the Fig itself. Every one knew what is commonly termed the Fig, but that was not really the fruit, but merely a hollow fleshy receptacle bearing the true fruit on its inner surface in the shape of numerous small seeds. Taking one of the *Dorstenias* it would be found to possess a square flat receptacle set with numerous insignificant green flowers, each of which became a fruit. Now a Fig was nothing more than this rolled into a bag or turned outside in, with an aperture at top through which the air passes, and causes the pollen to fall on the stigma. The *Dorstenias* had been long in the country, but had not received the attention which they deserved. The forms which the receptacle assumed in some of the species were very curious, as would be perceived by the examples which he had brought. One species was said to possess very active properties as an antidote to the poison of snakes, but the principle, whatever it was, ceased to be active in the dried state of the plant. Passing from the *Dorstenias*, Mr. Saunders differed from Mr. Berkeley as to crosses of the Cape *Geraniums* being too tender to be used for bedding. Some of the Cape species there were that would only do in a greenhouse, but there were others, particularly the hard-wooded kinds, that in hot seasons like the present might be expected to stand out of doors when the temperature was not under 40°. Mr. Saunders then adverted to the important influence of ground temperature on the growth of plants taken in conjunction with the heat of the atmosphere, the latter being too frequently considered without any reference to the former. A *Brassavola* sent home by the

Society's collector Mr. Weir was then noticed, and Mr. Saunders stated that it did not differ much from *B. nodosa*; and in commending the charming *Bignonias* from Mr. Fleming to the notice of the meeting, Mr. Saunders strongly recommended them for covering the roofs of greenhouses and conservatories. To flower well, however, the plants should be old, and have plenty of room.

**FLORAL COMMITTEE.**—The entries were not very numerous, although several very interesting plants were brought before the Committee. Mr. Fleming, Cliveden, exhibited some of his seedling *Nosegay* and *Zonale Pelargoniums*, which were of a very promising character. *Nosegay* Dowager Duchess of Sutherland, having a fine large truss of deep carmine flowers, very distinct and beautiful, had a first-class certificate; also *Nosegay* Lady Constance, brilliant scarlet, large showy truss, leaves deeply zoned. Mr. Fleming also brought out specimens of several other seedlings of good quality and new in colour. Mr. Stone, gardener to J. Day, Esq., brought several *Orchids*, among which were a fine specimen of *Cypripedium Stonei*, with three flowers in perfection, for which a special certificate was awarded; and *Eriopsis rotundobulbon*, a very beautiful *Orchid*, with spikes of brown flowers, with a delicately-marked light rosy-notted lip. A first-class certificate was awarded for this; and *Bolbophyllum psittacoglossum* had one of the second-class. *Phaleonopsis Wightii*, a very small-flowering species, very unlike some of its magnificent relatives, was also shown by Mr. Stone. Messrs. Osborn, of Fulham, exhibited a plant of *Podophyllum Emodi*, which had never fruited in England before; the flowers are produced singly, resembling those of *Helleborus viridis*, and the fruit resembles that of the common Passion-Flower in form and colour. It is a hardy plant, difficult of cultivation, and when once planted should not be removed. *Geranium sylvaticum duplex*, from the same firm, is a useful and ornamental plant, growing where few other plants will succeed—under the shade of trees; the flowers were too much faded to judge of its merits. Mr. Bull sent a plant of *Stauranthus grandiflora*; *Phegopteris sancta*, a small and pretty stove Fern—second-class certificate; *Lobelia Silver Queen*, which was very similar to *Lobelia speciosa alba*; *Pandanus ornatus*, requested to be seen again; *Dicksonia cinnamomea*, a fine tree Fern, the stems clothed with a rusty brown wool-like substance—first-class certificate; *Cissus amazonica*, not nearly so good as *C. discolor*; *Costus zebrius*; *Aspidium* sp., a stove Fern; and cut specimens of a striped *Verbena* Gem, the colours not distinct, and spoiled by the green centre. Mr. Thompson, Ipswich, exhibited a very pretty greenhouse perennial, *Trichium Mangeshii*, with tufts of purple flowers, growing on feather-like footstalks, which give the plant an elegant appearance. It was much admired, and will, doubtless, become quite a lady's plant, and be in great request. It is nearly allied to the *Amaranthus* and *Celosias*. This received a first-class certificate. From Mr. Williams, Holloway, came *Gleichenia* sp., probably a glaucous variety of *G. macrophylla*—first-class certificate; *Gymnogramma* sp., to be seen again, as it much resembles *G. Parsonsia*; *Anacochilus Turneri*, a very fine form of this genus—first-class certificate; *Lilium* sp. from Japan, the yellow-spotted variety, exhibited before, and a small collection of *Lilium auratum*. Mr. Wilson Saunders sent a collection of very curious plants—nine distinct varieties of *Dorstenia*, with varied and singular form of inflorescence. A special certificate was awarded for them; also a special certificate for the general collection. Mr. Reid, Sydenham, exhibited a seedling *Pelargonium* of the *Nosegay* section, General Grant, hybridised with a Cape variety; the plant produced a truss of bright red flowers, and the foliage, instead of being circular, was much lobed, and without any zone. Messrs. Downie, Laird, & Laing had, for a collection of cut Hollyhocks, a special certificate. Mr. Ansell, Kentish Town, exhibited a collection of cut *Antirrhinum*s, the usual varieties which are produced from packets of seed which may be purchased anywhere; and Mr. Smith, Hornsey Road, a seedling *Zonale Pelargonium* Mrs. Box, pale salmon and white flowers, of which we have already too many. Mr. Brown, Sudbury, sent specimens of his new scarlet Sweet Pea, called *Invincible Scarlet*, advertised by him in the spring. This is a very fine and distinct variety, really worth growing; colour deep scarlet, blended with carmine, flowers large, and very highly scented. It received a first-class certificate. Mr. Wm. Paul sent specimens of new Hybrid Perpetual Roses Dr. Lindley, Elizabeth Vigeron, Madame Emile Boyau; and Mr. Fleming, cut specimens of two superb *Bignonias*, *B. grandiflora* and *B. chirera*. The plants were growing in a conservatory at Cliveden, forming extremely ornamental specimens. Mr. Eyles placed before the Committee an *Orchid* sent home by Mr. Weir, a variety of *Brassavola nodosa*, to be called *B. nodosa grandiflora*. There appeared to be two distinct varieties on the stump on which the plants were growing and were sent home. A first-class certificate was awarded. A collection of Sweet Peas was sent from the gardens, many good and distinct varieties, but not one equal to the *Invincible Scarlet*, which is a great acquisition to its family.

**FRUIT COMMITTEE.**—Mr. G. F. Wilson, F.R.S., in the chair.—Mr. Cutbush, of Highgate, again brought forward his seedling Raspberry Princess Alice, a late variety, which was then just coming into use. The flavour is more brisk than in the Prince of Wales, fruit of which was shown along with it. Mr. Fleming, of Cliveden, brought a bunch of a seedling muscat-flavoured Grape, raised from a cross between White Frontignan and Royal Muscadine. The bunch was of good size long, and well set; the berries as large as those of the White

Frontignan, and the flavour was decidedly good, notwithstanding the fruit was far from being ripe. Mr. Bradley, of Elton Manor Gardens, sent a seedling Strawberry named "Dr. Hogg," a fine handsome fruit, in the way of British Queen, but highly coloured, and giving indication of being a highly-flavoured and excellent variety; but the fruit had suffered so much by carriage that the flavour was damaged, and Mr. Bradley was asked to send it again. Mr. Myatt, of Deptford, brought samples of early Potatoes—viz., Myatt's Prolifer, Milky White, and Mona's Pride. Of these Mr. Myatt gave the preference to Mona's Pride, as being the best early Potato he has met with in his experience.

**SNOW OF LILLACE.** July 15th.—This was chiefly confined to the different varieties of *Lilium lancifolium*, of which some well-grown beautifully-flowered specimens were shown by Messrs. Cutbush and Young, of Highgate. We noticed the names of speciosum, rubrum, roseum, cruentum, and album, which were the only lance-leaved kinds shown on this occasion. Others consisted of *Lilium auratum*, among which was a pretty variety with reddish bands from Messrs. E. G. Henderson. This was named *rubescens*. The others came from Messrs. Bartlett, Cutbush, Bull, Young, and Cuttough. The only other *Lilies* shown were the *Tiger*, *longiflorum*, and *martagon*, of which there was a pretty dark variety under the name of *umbellatum*. *Vallota purpurea* and *Amaryllis alba ignescens* came from Messrs. E. G. Henderson; and *Vallota eximia* from Mr. Bull. Miscellaneous subjects consisted of six stands of Hollyhocks from Messrs. Downie, Laird, & Laing, together with a spike of a delicate pink seedling, called Mrs. Laing. Roses came from Mr. Clarke, of Brixton; hanging baskets, *Achimenes*, and variegated-leaved *Begonias* from Mr. Young; Cockcombs from Mr. Taylor, gardener to J. Yates, Esq., Highgate; and a beautiful plant of *Adiantum emarginatum* from Mr. Bartlett. Cones of *Pinus excelsa* were contributed by Mr. Carson, gardener to W. F. G. Farmer, Esq., Nonsuch Park, Cheam; and Figs and a Queen Pine Apple by Mr. Ford, gardener to W. Hubbard, Esq., Horsham.

## THE UNITED HORTICULTURAL SOCIETY.

THIS Society again held a show in the garden of Finsbury Circus on Wednesday the 12th inst., and as a whole for the season there was a good display. The centre of the principal tent was devoted to flowering and ornamental-foliaged plants, tree Ferns being placed along the centre and two fine *Draecenas* from Mr. Williams one at each end. Of Heaths some excellent specimens were exhibited by Mr. Rhodes, who has been very successful with them at different exhibitions this year; and other plants from Messrs. Page, Rhodes, Fraser, Williams, Wheeler of Stamford Hill, and Chilman, consisted of *Ixoras*, *Dipladenia splendens*, *Lescheaulia formosa*, *Cyrtoceras reflexum*, *Staticee*, *Pteroma elegans*, *Tillandsia splendens*, *Sollya linearis*, *Kolosenanthes*, *Fuchsias*, and scarlet and variegated *Pelargoniums*.

Fine-foliaged plants comprised *Dicksonias* and other Ferns, *Draecenas*, *Caladiums*, *Maranta zebra*, and *Warewiczii*, a few Palms, a variegated *Ananassa* in fruit, and a collection of *Cannas*; the exhibitors being Mr. Williams, Messrs. Low, Mr. Wheeler, Mr. Wilson, gardener to W. Marshall Esq.

Some good *Orchids* from Messrs. Wilson, Page, and Baker, occupied a small tent by themselves, along with a collection of hardy Ferns from Mr. Holland, gardener to R. Peake, Esq., Isleworth. We noticed good examples of *Cypripedium barbatum*, and *superbum*, *Angulica Clowesii* in good bloom, *Phalenopsis*, *Vandas*, *Acridies*, *Cattleyas* *Leopoldi* and *superba*, *Oncidium lanceanum*, and the brilliant *Disa grandiflora*.

Of other plants tricolor-leaved and other bedding *Geraniums* came from Mr. Aldred, Kilburn, Messrs. Smith of Dulwich, Buxton, Wandsworth Road, and Williams of Holloway; the last named having among others *Annie Williams* and *Golden Nugget*, two pleasing varieties. Mr. Smith of Tollington Nursery sent *Zonale Pelargoniums* *Chieftain*, and *La Grande*, both of which have been certificated by the Floral Committee and described at p. 9; likewise *Petunias*, and *Fuchsias*. *Lilium auratum* was shown in good bloom by Messrs. Carter & Co. and Mr. Williams, who had also the beautiful *Todea superba*; *Anacochilus*, by Mr. Aldred; *Balsams*, by Messrs. F. & A. Smith; *Aurea floribunda Calceolaria* in excellent bloom, by Mr. Forsyth of Stoke Newington; dwarf *Tropaeolums* for bedding, by Mr. George; and seedling Sweet Williams by Mr. Wiltshire.

Foremost among cut flowers were twelve boxes of beautiful Roses from Messrs. Paul & Son; and six from Mr. Turner of Slough, who also had large and beautiful *Carnation* and *Picotée* blooms. Mr. Holland likewise contributed good boxes of Roses. From Messrs. Paul & Son, and Messrs. Downie & Co., came excellent stands of Hollyhocks; *Verbenas* and *Roses*, from Mr. Vockins; and cut *Fuchsias* from Mr. Crute.

Fruit consisted of Peaches, Nectarines, and Strawberries from Mr. Tillery, Welbeck, and Mr. Young, gardener to W. Stone Esq., who also had two Pines: some excellent Currants and Gooseberries, from Mr. Newton, gardener to G. J. Graham Esq., Enfield Chase, and Mr. Mortimore, gardener to W. Pott, Esq., Carshalton, who also sent a good Queen Pine and two Melons; Black Hamburg Grapes from Mr. Lewis, Stamford Hill; and fruit trees in pots from Messrs. Lane.

Some good Cucumbers were shown, also herbaceous plants from Ballymounagh, Ireland; and we noticed a pretty Cape Heath, called *Exquisita*, exhibited by Messrs. Low.

#### TODMORDEN BOTANICAL SOCIETY.—JULY 3RD.

DR. W. P. H. SCHIMPER, G. et M. Pr. Ac. Sc. J. G. M. C., &c., "Bryolog. Enrop. Auctor." was admitted an associate member. In proposing the above-named gentleman the Chairman took occasion to pay a high compliment to the character and abilities of Dr. Schimper, remarking that he had a world-wide and also a well-earned reputation, and that the Todmorden Botanical Society, in conferring an associate-membership on such an individual received a far greater honour than it conferred. We noticed on the table a plant of a splendidly ramiflose var. of *Polystichum aculeatum*. We understood the plant in question, along with some twenty others equally characteristic, had been collected in Devonshire within the last few days by Mrs. Thornton, of Holdsworth rectory, North Devon, and lately of Rawtenstall, Rossendale. Mr. H. Halstead contributed a friend of a new *Athyrium*, with curiously-ovate pinnales, and which, if quite permanent, promises to be a valuable acquisition. The plant in question had been gathered near to Castle-Carr, in Yorkshire: several very rare and curious plants and flowers were sent from other sources. The Hon. Sec. read a communication from Mr. Fielden Hartley, Alton, Illinois, N.A., reporting the discovery of *Botrychium virginicum* and other rare plants, and enclosing a fine specimen of the one first-named.

The Vice-President (Mr. Nowell) having accompanied Drs. Schimper and Wood to Snowden, reported the discovery of the following rarities, none of which had ever before been seen in a growing state by the celebrated Schimper: *Aretoa fulvella*, finely in fruit; *Edipodium Griffithianum*, splendidly in fruit; *Racomitrium ellipticum*, do; *Bartramia arcuata*, this is altogether unknown on the continent; *Andraea alpina*, abundantly in fruit.

#### WORKING-CLASS FLOWER SHOWS.

WE visited, during the past week, one of these in Bloomsbury Square, and another in the Royal Horticultural Society's Garden at South Kensington, and well gratified were we to find the competitors so numerous. Great excellence is not to be expected, but there were many specimens very creditable to the growers, and evidence unmistakable of an increasing fondness and seeking after these beautiful adornments of a house.

The Earl of Shaftesbury, who distributed the prizes at the Bloomsbury Show—and let us add that the Bloomsbury window gardeners keep ahead in this race which they originated—observed that he was glad that the movement, originating as it did in Bloomsbury, and so well carried out by the Rev. E. Bayley assisted by Mr. Bosanquet and others, had now spread all over London. He thought, also, they ought not to forget the inventor of the movement, the Rev. H. Parkes. He held that a man who invented a movement like that, which was accomplishing so vast an amount of moral good, was a benefactor of the age. He went much about the town, and he saw the good effect of such shows amongst the people. The Bloomsbury folk ought to be very proud of originating a movement which was spreading all over London. He had three flower shows to attend that week; last year there were not above two such flower shows in the metropolis, this year there were twenty or thirty, and next year he hoped there would be a hundred.

There are a few minor points about these exhibitions which deserve alteration. We think, for instance, that a little more regard should be had to neatness; and if two plants showed equal good cultivation, and one was exhibited in a pot rendered inoffensive to the eye by being enclosed in a piece of crenulated green paper, we would give its opponent in a bare stained pot the second place in the award.

Labels or patches of white paper, even if all of a size and well-written upon, we would banish from the sides of the pots.

Then we would have distinct prizes for trellised plants and plants untrellised. A Fuchsia, we think, looks best trained as a pyramid rather than as a fan. A Geranium we consider more difficult than a Fuchsia to grow meritoriously. Lastly, a plant taken out of a border or a large pot, cut down, and then grown in a small pot in a window for next year's exhibition, is not "a plant raised and flowered within twelve months." A plant to come within this definition should be raised from the cutting in one year and exhibited before the close of the next.

These concluding notes are in answer to some queries we have received.

#### BROMUS SCHRÖDERI—ZIZANIA AQUATICA.

I SEE that Messrs. Carter advertise this Grass amongst their novelties, and give a glowing description of it in the advertising columns of your Number of April 11th. I have known and had it for some time, but never sowed any till this spring. Having just returned from London, I am glad to find a fine bunch of it about a yard high and in full ear. It was sown long after the general corn crop, so that Messrs. Carters' remark as to its peculiarity in sending up seed at a very early stage of its growth seems to be correct. Probably, if I had been at home and pushed it on with liquid manure during the late unprecedented hot weather, it might have been higher, but "the Derby," and such like, must be seen—"ruat cœlum."

Being a member of Council of the Acclimatisation Society, I have devoted much time and attention towards introducing such hardy shrubs and Grasses as will afford food for game; and my respected friends, P. Lawson & Son of Edinburgh, who in the kindest manner always send me anything they meet with tending to that object, forwarded me, some time ago, a spike of this Brome Grass. I distributed it among a few members of our Society, and a fine head of it was shown at the council meeting last Thursday. I believe Messrs. Lawson had it long since from Berlin, but I think it is a native of Virginia. There is no doubt it will be excellent food for game or poultry, but I doubt its perennial character, as well as its hardness, as it grows so fast.

Respecting the *Zizania aquatica*, or Wild Rice of Canada, with the re-introduction of which my name has been so much coupled, I am sorry to state that we have utterly failed in raising it. Mr. Thomas Moore of Chelsea and I have tried it all ends up without getting it to show the least vitality. I have gallons of it left, but it is no good giving it to any one. We are going to try to get young plants of it over.—JACKSON GILLBANKS, Cumberland.

#### THE KITCHEN GARDEN.

MARCH.

THIS, the busiest month of the twelve in the kitchen garden, must be made the best use of if the weather is at all propitious; but in the last season or two, owing to the inclemency of the weather, it has been impossible to keep to any method as to time of sowing, &c.; but on the proper use of any opportunities occurring during the month, will, in a great measure, depend the vegetable supply for summer, autumn, and winter.

The first day the ground is in a proper state for sowing, which may be ascertained by its crumbling beneath the tread, the main crop of Onions should be sown in drills 9 inches apart, the earth being well trodden and neatly raked after sowing. I lay great stress on getting them in as early as possible in the month, as they will be fit for drawing young sooner, and the main crop will be superior in every respect to those later sown, with the additional advantage of being ready to be taken off earlier in the season, thus leaving the ground at liberty for Winter Spinach, Cabbage, &c. Mine were sown this year on the 3rd of March, after which time, if I remember aright, we had some rather severe weather, and they are now looking first-rate, owing, I believe, in a great measure to their having had a good start before the dry weather set in.

The Cauliflowers, too, should receive immediate attention. Presuming that the trenches are thrown out between the Peas for Celery, these can be used for the reception of the surplus stock from the hand-lights, which will be off by the time the trenches are wanted for Celery. As regards those that are to remain under the hand-lights, of course, selecting the most forward, they should be watered, earthed-up, and the lights raised by placing bricks under them, but by no means coddle the plants too much, or they will ultimately assume too much the appearance of a flower. Next to the Cauliflowers, the Asparagus-beds should receive attention. I generally cover mine all over with about 6 inches of manure the first frosty day in the autumn or winter, and let it remain on till this month when the littery portion is forked off and the rotten part is merely loosened with a fork, digging the alleys to make all look neat and clean; but I never earth it up any more than I have now stated.

The main crop of Carrots and Beet should now be sown in the same way as advised for Onions, but before sowing be sure to make up your mind what crop is to follow; by so doing you will be better able to determine how much ground you

can spare for each crop, and prevent much confusion afterwards. It will be as well to sow a very small bed of Early Horn Carrots for summer use, as they often stop a gap, especially in such dry summers as it appears we are doomed to have. In fact, there are so many things to sow this month that it is no easy task to enumerate them all with remarks; but as one generally has to give up a frame or pit to half-hardy annuals, a part of it can be devoted to sowings of Brussels Sprouts, Broccoli, Lettuce, and Celery, not forgetting to prick the first sowing out as soon as large enough to handle, and again place somewhere under glass. Where Dwarf Kidney Beans are grown under glass now is the time to work them, as with ordinary attention they will repay the labour and come in now very useful. Besides these the supply will be much the same as last month, with the addition of the thinnings of the autumn-planted Cabbages, as I generally plant them so thickly in the rows that I am able to cut at every other one for greens, and the Radishes from the pit will make a nice addition to the salad for the month, with Cucumbers if you have them.

In this month I sow two rows each of Yorkshire Hero and Veitch's Perfection Peas, sowing Radishes between the rows and rolling all over to protect the seeds from the birds, after which I sow no more long Radishes but rely chiefly on Turnip Radishes, of which I make a sowing before the month is out. In addition to the above, sowings should be made of Vegetable Marrows, Tomatoes, Leeks, spring or summer Spinach, Turnips, and herbs. Plant Potatoes, and gravel the walks if necessary.—

BURNTWOOD, P. D.

(To be continued.)

### MY ORCHARD-HOUSE ON MIDSUMMER DAY.

THE late dry weather severely taxed our tanks. Getting-in the luxuriant hay crop, and watering the flower-beds, prevented due attention to our Strawberry-beds and Peaches in-doors and out. Out of doors I never saw them so spidered; anything more abnormal than the leaves one could not conceive; also, mildew on the young shoots, and remains of spring-blistered leaves. All this arose from neglect of syringing and applications, but it was out of our power. Guernsey is the land of monopoly, close borough, and dissent! Thus, at times there is much inconvenience in the labour market. The clergy, if not actually reduced to "drive cabs," must work their garden engines themselves if they wish to conquer the aphid tribe. In-doors, little spider, less mildew, but a great amount of brown aphid. If overlooked for a day the leaves curl up and defy all syringing. After many applications which injured the tender leaves, I decided on the "very close pruning" off of the diseased shoots, but there is little danger, for the buds for next year's crop are now plainly prominent and abundance of "May clusters" are visible, only in the case of an extension of a branch it is very trying to see it curled up and crooked. However, they are all cut off, being second growths.

Mr. Rivers presented me last year with about three dozen new trees, many unnamed seedlings. These with other new sorts make up about one hundred splendid varieties, and, I believe, my good friend alone could show choicer sorts. The interest created by watching them, noting their blossoms, habit of growth, and fruit, as yet unnamed, is unbounded. Among newer sorts Alexina Chaupin is a remarkably dark Peach, darker than any Bellegarde. The shoots are of a dark purple. Heath's Northern Tree, an American Peach, is very prolific, and seems good. Bergen's Yellow, said to be a shy bearer, is doing well. Then there are a number of seedlings all to be tried. Of the Victoria Nectarine I have two trees both bearing. The fruit is the largest Nectarine in the house after Chauvidre. The Princess of Wales Peach is truly fine. Another unnamed seedling white Nectarine will be first-rate. Of older sorts, Early York is still a very great favourite; so are the American varieties, Canary, Stump the World, and Golden Purple, all free-setting and good. No Peach is more prolific than Stump the World. Tecumseh, a new Georgian Peach, said to be very late, has also fruit. Pool's Late Yellow is finer this year. The Comet Peach is promising well.

My Apricots have not done much this year; why, I cannot say. Neither have they succeeded in a friend's house who has wonderful Plums, and such Apples and Pears!

My Figs I have removed from pots and planted against the wall inside the house. They require too much attention to watering.—any neglect and the crop is in danger; but trained *en cordon*, as diagonals, and closely, very closely indeed, pinched-

in, they make a goodly show. Some are nearly ripe, others of the size of a Pea, and many between these sizes. Let me recommend close pinching-in for Fig trees. We are coming to this style for everything.

As to the general crop, it is about 1500, as last year, besides plenty of Grapes along the rafters; but we are fatally crowded owing to my good friend's liberality, and as this is a common fault with beginners, let me say here how dangerous it is. The shifts we are put to to save room, the way we turn the plants to the light, the accidents from erimoline, the injurious comments of our many visitors, irritating to a degree to our self-respect, and the consciousness that our best trees are becoming fast out of proportions, all these and other good reasons induce me to recommend amateurs to construct their houses with a good width, and plenty of ventilation and means of irrigation. On the subject of visitors and their remarks, some curious chapters might, indeed, be written.—T. C. BRÉNAUT, *Richmond House, Guernsey.*

### IDIOT GARDENERS.

A STRANGE title!—yet fully justified by the truths leading to its adoption.

Who has not known a family with an idiot member?—sometimes an idiot filthy in its habits; resolute not to use muscular exertion; drivelling sometimes; sometimes uncontrollably violent; voracious in appetite, and careless of the quality of food partaken; without discernment of good from evil, and in fact loathsome, and a total sorrow, and an incubus upon the family?

We have known many such—nay, more, we have known a family with all the children idiots—and we, in common with the parents, and, probably, in common with a majority of our readers, looked upon them as incurables, and thought that Luther was not far wrong in concluding they should not be allowed to live. Yet, how totally this is at variance with the path that should be pursued, and how totally incorrect the conclusion that such imbeciles are incurables!

We ask of our readers, emphatically and urgently, to read a contribution to the just-published "Edinburgh Review," entitled "Idiot Asylums," and they will marvel to find that *all* idiots are teachable, *all* may be rendered happy and useful, and "that some actually possess special powers, above the common standard as relates to music, the art of drawing or modelling, and in powers of memory and arithmetic, and instead of dulness, imperfection, and deprivation, have in some direction or other a strange exaltation."

It is the mode of treatment—the adapting the teaching to the deficient powers of the mind, the associating with minds on a level with each other, and gradually leading each other on, that effects such a wondrous change. All the details are interesting, but we can afford space only for one extract—many trades are successfully taught—but we must confine our notice to the idiot cultivators of the soil.

"No idiot asylum should be without a farm and a garden, and if the number of pupils is large they should be of considerable extent. There are between twenty and thirty farmers and gardeners at Earlswood, while at Essex Hall the employment of pupils able to do the work assigned to them in the garden has long been found most attractive and beneficial. In the first-named place the garden consists of about 8 acres, and is admirably kept by the young gardeners under superintendence. The vegetables required in the establishment are well and abundantly grown, and in the flower borders, which are in excellent taste, it is almost impossible to find a weed. There is a greenhouse, and also there are some frames for preserving the plants to be bedded out in the summer, and every part of them has been made in the place in a workmanlike manner. Now and then at both the asylums just named, prizes have been gained for Cucumbers, Celery, and other produce, at the neighbouring horticultural shows, to the great joy and triumph of their growers. Such an occupation has a most happy influence on the imbeciles employed in it, while it secures abundance of excellent fresh vegetables and summer and winter fruits for their use, a part of their diet of great importance.

To see the poor fellows watching their plants and trees, and in summer parading near the Peas and Currants, with their clackers to frighten the birds, is a most exhilarating spectacle when contrasted with the uselessness and wretchedness of their previous lives. The great object of ambition, however, is to be

a farmer. 'I am a farmer now,' is the proudest boast of some poor fellow promoted to that post. The attention paid to the live animals of the farm is unflinching; whatever danger of neglect keepers of cows might fear from the boys who tend them, there is none from the idiots. The cows are the special object of their regard, and when a calf comes, or a litter of pigs, they are welcomed and cared for with enthusiasm, and they will run eagerly to the house to tell of the addition to the stock; only perhaps in mistaken terms, as one boy did out of breath—'Sir, sir, the pig has calved.' All the hay of a large acreage is easily made by the idiots, only they would fail without guidance in constructing the ricks. Idiot haymakers are a joyous company, and the hay-field is a source of pleasure to those too feeble to do any work in it. Nor is this labour without profit, for the farm produce has been sold at Earlswood for more than £1,000 in one year. Some boys are trusted with milking, and nothing in the way of pleasure would keep them from this duty, to which they go just before the tea is ready. Somebody asked one of them who sat tugging at a cow's dug after all the milk seemed to have been exhausted, 'How do you know when to leave off?' 'Oh,' said he, 'when the tea-bell rings.' It is a pleasant sight to see them come in from the farm to a meal; how carefully they wash their hands, and clean their shoes, and take off their working clothes to go into the common eating-room neat and with all propriety. It would have been considered as utterly impossible to have achieved such order and decorum with pupils whose previous habits tended to the reverse, but it may be witnessed daily.

Indeed the sight of a large company of well-trained idiots at table is most remarkable, and none are allowed to dine in the principal dining-hall, till they have achieved all the acts of feeding and sitting at their meals with due decorum. When they first come into the establishment, unless they belong to

the class who mope and are sluggish, they are as greedy and ravenous as wild beasts, seizing and bolting everything brought near them in the way of food, with a tendency, if not checked, to gorge themselves to excess. In time, however, they are brought to enter the apartment in regular order, the females arranging themselves on one side, and the males on the other. By means of apparatus for the purpose, the room being close to and upon the level with the kitchen, the dinner with the portion of each on a separate plate is served in a very short time. No one begins till all are served, when they sing under the leadership of their master, a short grace, and then commence. There is no apparent greediness, no unseemly feeding, but they form a cheerful and well-conducted company, much gratified by the notice of visitors. The dinner concludes, as it began, with another grace, and the room is quitted in a quiet and orderly manner. Some of the pay cases at Earlswood have a dining-room apart, where the meal is served as nearly as possible in the way they would have it at home, and thus when restored to their friends they are not excluded from the family dinner because of any improprieties. The preparation for dinner in the kitchen is a lively scene at Earlswood, for there are about a dozen of the pupils engaged as cooks in a subordinate capacity, and they are dressed in white with the usual caps, looking the perfection of cleanliness and neatness. They work with the greatest delight in this employment, and are very fond of it. This occupation does not interfere with the work at any trade, and it is one of those beneficial changes in the daily routine which are found so desirable. One boy has extreme pleasure in washing the plates and dishes, doing it well. So absorbed is he in this undertaking, that it is his principal thought; and when asked which he liked best, his present or former residence, he replied 'Oh, this, because there is a better sink here.'

#### POCKET FERN TROWEL.

Your fair correspondent "ALICE'S" remark, in a late Number of the Journal that she found a common screwdriver a useful accessory to her botanising knapsack, has induced me to forward a sketch of a very useful form of trowel, well adapted for the removal of tenacious-rooted plants, Ferns, &c., from walls. Indeed it will be found a very useful implement wherever the common trowel might be required, by any one of our botanising friends to whom unnecessary baggage would prove a great drawback in their customary rambles.

Pocket Fern Trowel.

The pocket Fern trowel is made wholly of steel, the whole being polished, with the exception of the surface portion of the handle, which for greater ease to the hand in working, has affixed a piece of leather. With this exception the handle is identical with the blade running the whole length of the same, which gives it greater strength. The trowel is enclosed in a neat leather sheath, and the whole being only 6½ inches in length, can readily be carried in the pocket. They are manufactured by Messrs. Numm & Son of Hertford.—WILLIAM EARLEY, *Digswell*.

#### GLEANINGS FROM ROCK AND FIELD TOWARDS ROME.—No. 2.

We left Genoa on March 8th, passing through snow, which was lying thickly on the ground, and which gave to mountain and valley a character of almost unearthly loveliness. The road continued for the most part on the edge of a precipice overhanging the sea, from which you looked upon the fair villages, stretching as far as the eye could reach, along the sea-coast, and nestling in groves of Oranges and Lemons, with Olive-crowned hills at the back. Through all the towns we passed there were such signs of life as I had hardly hoped to see in Italy: in many places the seashore was lined with vessels in every stage of progress and completion; there seemed to be quite a swarm of men, women, and children around these ships, some working, others talking, while the little children played in and out, making labour appear a very holiday task in these beautiful regions. In several of the towns there were large potteries, the sides of the houses being stuck all over with pots and pans of clay, drying and hardening in the sun: I could fancy that the captivity of the "Sleeping Beauty" was over, and the Prince arrived at last.

We rested in the middle of the day at Ruta, a very fair type of these Cornice towns. The inn was built on a terrace, with vineyards and oliveyards in terraces sloping down to the sea. From the stone walls of these divisions I gathered *Ceterach* and *Asplenium ruta-muraria*, with *Polypodium vulgare*, in large quantities. I fancied that the *Ceterach* was more divided

than is usually the case in England, but not so much so as to make it worth while to bring away any roots. Under the Olive trees I gathered large and beautiful Violets, which I took back with me to adorn the dinner-table. Before the inn door there was an alcove with stone seats, and wooden trellis adorned with the leafless tendrils of Vines woven in and out like lace-work; sitting in the alcove were men—working men and beggars—women and children; these all gather round a new arrival, talking, and watching, and begging. The dining-room of the inn was at the head of a flight of rambling stone stairs; beyond the dining-room, opening from it, was a bedroom, and opening from the bedroom a large arbor-like room, roofed only with a trellis-work of Vines, and commanding a magnificent view of earth and sea; from the arbor you could descend by wooden steps to a garden, and such a garden!—Olives, Vines, chickens, children, flowers, and weeds all mingled together in hopeless confusion, and yet amidst all the untidiness and ruin, preserving its own wild luxuriance of beauty—a beauty that in summer and winter is alike there.

On the 9th of March we left Sestri de Levante with six horses for the ascent of the Bracco Pass, which is even more terrible in its unprotectedness than the Cornice. There is, indeed, no railway, and there is plenty of room—mountain seems piled on mountain, with every shade of colouring adorning them, up to the very heavens. The different stages of vegetation on the

Bracco is most interesting. Myrtles, Arbutus, Adiantum capillus-Veneris give place to Ericas of several beautiful kinds, Asplenium adiantum-nigrum, and Polystichum angulare (seen to-day for the first time), and these are changed into Pines and the Heather of our native land; but after a while all vegetation ceases, and you are as if were alone on the bleak rugged mountain, with such blasts blowing round you as make you shiver and tremble lest carriage and horses and you should be blown down the two thousand feet that are between you and your last night's halting-place.

About Barghetto we gathered Lithospermum purpureum-corneum, Crocus vernus, Aquilegia vulgaris, and a very curious species of Potentilla with a rough woody stem, from which was formed a dense tuft of leaves and flowers. The leaves were ternate and very hairy, the petals white, with a pretty brown tinge. I had never met with this Potentilla before, and its woody stem distinguished it from any species I knew. We drove by fields bright with the common lilac Anemone, and others again gay with the Anemone hortensis. The only Fern I saw on this day's route that appeared strange to me was a very fine variety of Asplenium trichomanes; it was growing high on the Bracco Pass, its fronds measuring quite a quarter of a yard in length, the pinnules large and very far apart. It did not look the least like the English trichomanes, but yet there was no particular feature to distinguish it from it.

Although I missed strange Ferns from the Bracco, their loss was in some sort made up to me by the strange variety in the beggars; they troop down the hill in parties to meet you; you hear them laughing and chattering as they run, but the minute they approach you the laugh gives place to a low whine, which they will keep up for a great distance. I usually started in the morning with as much money in small coins as I meant to give away during the day, and when it was all gone I began to beg of the beggars, when the whine would cease, and the dark eyes twinkle with fun, and sometimes they would pelt me with flowers in return. There is in the Italian character so much child-like simplicity and aptitude for fun, that even the very beggars win their way into your heart as no other nation has the power to do.

From La Spezzia we journeyed to Siena by rail, staying a short time at Pisa to gaze once more upon its unrivalled piazza, where the baptistry, the cathedral with its leaning campanile, and the Campo Santo stand out white and glorious against the sky. Our way wound at the foot of mountains, the highest of which were covered with new-fallen snow, and looked dazzlingly bright as if with the light of life—the Carara mountains, rich with a hundred varied hues, worshipped at the feet of their white sisters, who seemed so near to heaven that the reflection of its purity fell on them. Siena is chiefly to be noticed for its academy, which contains very fine examples of what is called the Siennese school of painting. Some of these pictures are said to be of the thirteenth century. Duccio of Siena was an established painter at Siena in 1282, and there are several of his pictures still existing to be seen: real artists fall into ecstasies about them, describing their merits in glowing terms, but to my untutored eye most of them were but unnatural, almost grotesque, performances, hard in outline and unmeaning in expression; but I looked at them as I look at the old China Rose, feeling that out of them has been developed all that is beautiful in art, and much that is lovely in nature.

Looking out of the inn window at Siena, I saw the dead body of a poor man being taken to the mortuary—a house for the dead provided by nearly every foreign town for the receptacle of the poor whose small dwellings can ill spare a separate, decent space for their dead. Brothers of, I believe, the Benedictine order, habited in the brown suit of their order, with the hoods drawn over their faces, carried a black bier to the door of the house. Four priests, dressed in surplices, came out, preceding the brother bearing the corpse. This was placed instantly, but with all possible reverence, in the bier, covered with a pall on which was embroidered a gold cross, and the small procession formed, the priests heading it: four brothers carried the bier, while four others walked at the side bearing lighted tapers. The whole ceremony was so quiet and reverent, that I could not help wishing that every parish in England could have its mortuary and its Protestant confraternity to perform offices of love, such as I have described, for its poor.

March 12th was piteously cold, and it was Sunday, so I went to the Duomo or Cathedral to listen to a famed Jesuit preacher, and to gather what flowers of Italian rhetoric I could find. Sermons in Italy are not like sermons in England. The gene-

rality of the people go to mass early in the morning, and to the sermon, if there be one, in the middle of the day; they do not sit, as we do, but are content to stand for an hour together listening in wrapt attention to the eloquence for which Italian preachers are famed. Oh! how wonderful it was to watch that vast multitude of upturned faces eagerly drinking in the rich and varied tones! Hundreds were standing—soldiers, priests, old men and young children, the lame and the sick, the sister of charity in her white hood, side by side with the poor amongst whom she ministers—all listening, all wrapt up in the exceeding interest of the subject; there came a pause, the preacher wiped away the hot perspiration, the multitude murmured loud in assent, then a few finishing words, and it was over. It was a scene, striking in its deep simplicity and in the unrivalled beauty of its surroundings. I wish I could say that the subject of the sermon made it deserving of the attention it met with. It was on the gradual decay of England, in prosperity and prestige since she became Protestant! Few of the Italian poor are educated in any way, nearly all their knowledge comes to them through their priests; and if the source of the fountain be polluted, where shall those who long for knowledge be able to slake their thirst?

The cathedral of Siena is in part unfinished—that is, a proportion of it is left as the builders left it when the plague burst over the town destroying 80,000 of its inhabitants, and all the church revenues were taken to support the poor. What is finished is very perfect, the very floor itself being of inlaid marble figures, the pillars are of rich marbles, and the roof magnificently carved.

Siena is a queer-looking old town with very steep paved little streets, leading up and down and in and out in a most surprising fashion. The cold was intense, and the wood for the fires—so called in mockery—was green, and the chimnies smoked; but it is a place for summer, and very fashionable for Florentines in the hot season.—FELIX-FÆMINA.

#### STOPPING AND SYRINGING VINES.

Your able correspondent Mr. Wills does me injustice. I have not the paper by me containing my article, neither have I a copy of my letter, but I well remember the observations I made on the stopping of Vines on the spur system. Mr. Wills, in the article before me, sets forth as if I made it a general rule not to stop at all until the fruit is set. I will take up your worthy correspondent's words, and say I must be mad should I attempt to allow a shoot to proceed on in its course without stopping until the fruit were set. I advocated no such system; on the contrary, Mr. Wills advocates two joints, I advocate one, and I stated in some instances that stopping even at the bunch's joint I considered not impracticable. Mr. Wills may well say I should have few advocates if I entertained any such notion; I should consider myself a complete simpleton. I said there is no general rule for stopping, there are exceptions, but N.B., the exception I here name is confined to pot Vines.

In some instances we have no occasion to stop at all. I know not the distance your correspondent and myself are apart, but I should indeed be very happy, and esteem it a great favour, if he would call upon me; I could then show him instances, more than one, where I have had no occasion to stop, and now the shoot is not more than two or three leaves beyond the bunch. In our second house of pot Vines the bunches are mostly cut, yet some good bunches still remain; the third batch is progressing nicely, and he would see in both houses examples I have before named.

And now I must give a double invitation, should it be required, for Mr. Wills's visit. Whatever his experience leads him to follow, I adhere in every respect not only as to two following seasons, but two multiplied by ten, to my system of syringing. I have now a house, that named in my former communication, two years planted out; the syringe has not been stayed more than three weeks, there are bunches hanging from the top to the bottom of the house nicely colouring, and not a stain or discoloration to be seen on any of the berries (Muscats and Black Hamburgs). The pot Vines I treat, so far as regards the syringing, exactly in the same way, and the bloom that is upon the Black Grapes cannot be surpassed. But it appears that your correspondent and myself have disagreed to agree; for most assuredly I perfectly agree with him in reference to the water being clean. Undoubtedly the water must be perfectly clean, or the Grape will be discoloured. I can speak to this from

experience, for when I was at Bangor Castle, Co. Down, Ireland, I commenced my old practice of syringing, as I have done in England. I remember one morning, just as the Grapes began to colour, going through the houses I observed, as I thought, an appearance of mildew; I called the young man who had charge of them, and told him to smear the pipes over with an admixture of black sulphur and milk, but to my surprise I saw the discoloration continue. I then had the water with which they had been syringed analysed, and was told it was chalky water; this caused the bunches to have an appearance of mildew, but otherwise they coloured very well, and when on the table in the evening the defect was not discovered. The following year I had the water brought more than two miles to syringe with, but the same thing occurred again; and from further inquiry, I was informed that no water could be obtained in the county of Down without an admixture of chalk; and there, from sheer necessity, I was obliged to discontinue my favourite practice of syringing the Vines whilst fruiting. I must say that many years experience indorses the statement that where the syringe can be applied, it is followed by the Vines being more healthy, and consequently the Grapes in every respect better and free from that horrid pest red spider. I cannot leave this subject without making a further observation on Mr. Wills's recommendation, and to me very remarkable—namely, using the syringe when the Grapes are setting, not but that I perfectly agree with him that it assists setting (but no one but an experienced Grape-grower can say this). I leave off, not from being afraid, as just said, of the berries setting, but from fear of causing discoloration. The young Grapes when setting are very susceptible of being injured. I believe, I will not say positively, if the person who thins the Grapes should at the time have a nauseous breath, it will cause the rust; the touch of the hand, or the hair coming in contact with the berries, is also, in my opinion, more or less injurious. Having seen the berries nicely set, the bunches thinned, the syringe immediately commences its work, and continues till I see the first appearance of colour.

In respect to fertilisation, I will not disturb Mr. Wills in his opinion, but this much I will say, I never missed setting a Vine yet, neither Muscat nor any other; therefore having done well by nature having its course, I will not, for my part, attempt to disturb her, and I feel very thankful she so kindly favours me with her assistance, and whilst she does so I will in no wise interfere.

In conclusion I will just state that I grow and propagate our own pot Vines, this year about 150, all from eyes, with the exception of about thirty cut-down ones, which are now ripening their wood, to be ready to commence forcing with in October or November. I am glad to see Mr. Wills is going to favour us with his system of pot culture, I shall read his articles I trust with interest, but somehow I am vain enough to fancy if he saw ours at Bush Hall, he would be pleased with them. I have given a challenge to grow six of my own Vines against any six in the kingdom, placing them in the hands of some good disinterested Vine-grower, and letting him have the fruit for his trouble.—A. WHITTLE.

### APPLES—THE DEMOCRATIC FRUIT.

"POPULAR" is a word which is much despised, but may be made respectable. In this country wealth is obliged to pay respect to popular opinion, and of all fruits the Apple is the most democratic—the true democratic—for some democracy that we are acquainted with sprung from the first Apple. This popular favour of the Apple arises from the nature of the tree and the fruit. Any man who can grow corn can raise Apples.

In every soil, and under the most discouraging circumstances, the Apple tree lives and thrives. It can bear high or low cultivation. It is not dyspeptic like the Peach, or apoplectic like the Pear, or scrofulous like the Plum. The Apple is among the fruits like the cow among animals, like the camel, and like all good things, uncommonly—for beauty is only the mask which covers everything that is evil. In the beautiful, evil has struck in and affects the whole vital organism, while in homely women it is on the surface.

Have you never seen the maiden who, in a whole family of girls, remains unmarried, so homely that the lovers have all passed by her, who was the nurse, the mother, the story-teller, to a generation of little ones—the Virgin Mary of the household—the mother of God to little souls, in teaching them the better life—who was more fruitful in all except children, than any of her kindred?

My perfect idea of woman is my dear old aunt Esther, who will spend ages in heaven wondering how she ever got there, and the angels will wonder why she was not always there. What such a one is to the household is the Apple among fruits. Not the least among its excellences is its hardness.

We should as soon think of coddling our forest trees as the Apple tree. It will thrive in the stony lot too steep for the plough, or grow in the meadow, and repay us for the more abundant nutrition.

Where a Mullen stalk or a hill of corn will grow, the Apple will continue to secure an existence. It can be plain or ornate, always able to take care of itself—what I call democratic. It is emphatically the people's tree. In Florida or Canada it is equally at home, and equally good; while on the Pacific slopes it is portentous in size. Newton's Apple, which originated in his brain the science of gravitation, had it grown in California would have for ever put an end to his discoveries, and have opened the heavens to his gaze.

The health and longevity of the Apple tree are unsurpassed. Healthier than the Pear, no blight or disease affects it; worms and insects may lodge upon it, but unbuckling its bark, it exposes them to the wind and storm. An acre of Potatoes will not produce as much as the same area in orchard, with five times the labour. The grub only is a formidable enemy, but is so easily exterminated by a flexible wire, that if you have borers you deserve to be bored.

Farmers never think of nursing their orchards. And as for longevity, I have a tree now growing on my farm at least five hundred years old. Two ladies, now eighty years of age, say that in their childhood it was called the old Apple tree. At 12 feet from the ground it is 14 feet 10 inches in circumference; the fruit sweet and pleasant, though not large. I do not expect to live to see my young trees reach that size. I cannot resist a feeling of respect and awe when I stand in the presence of this gigantic tree, which heard the cannonading of the revolution; underneath whose branches Washington may have walked, musing upon the great task to which he was devoted.

The wood of the Apple tree has uses which we are not accustomed to credit it with.

For firewood it is equal to Hickory, and for cabinet work it is unsurpassed in beauty by any other wood. My best bureau is made of the Apple wood, and resembles Cherry. In Europe the roads are bordered with Apple trees, and the fruit is free to the public, except where wisps of straw fastened to a tree indicate that the fruit is reserved for the owner of the land.

How adapted to such a use is the upright Apple tree; planted along our roads, there would be no temptation for those juvenile saints to rob our orchards. Of all the contrivances to prevent stealing this is the most certain and easy.

The origin of the cultivated Apple is still uncertain; the wild-crab theory is unsettled, for no one has evidence that the seed of the Crab Apple ever produced an improved fruit. No Van Mons ever did for the Apple what has been accomplished for the Pear. Although probable, the theory must remain uncertain until, if by some horticultural Sunday school the Crab Apple has been converted into a good Christian tree.

No other fruit has such a range of ripening and of use. In good cellars it is kept from July to July. Kinds so delicate—and as the General Grant of the Vine would say, "so refreshing," even the Pear cannot rival, not even the Peach can surpass.

The various culinary uses of the Apple, its value in raising and fattening stock, were touched by the reverend lecturer with great humour, and for an hour he held the audience delighted with his picture of country life, interposed with wit and pathos, until he closed with, "And let me not omit to speak of cider. Temperance has banished it from the table, but it is creeping back again, not in its own old homely name, but under the guise of champagne."

As a temperance man I cannot advise you to make cider, but I can say that if you will make cider, I hope you will make it good.

I will not consume mere of your time with those eloquent periods with which I intended to close this address, for two reasons—first, it is already too long, and second, because I do not have them at hand.—(BEECHER in *Prairie Farmer*.)

PRESERVING FLOWERS BY GLYCERINE.—Mr. C. R. Tichborne states, in the *Artisan*, that, being desirous of preserving a vegetable *lusus nature* for some time, he submerged it in some weak glycerine, considering that that fluid would be less

likely to destroy the tender organism, and also remembering that it had been found most efficient in the preservation of animal tissues. The glycerine answered its purpose most admirably, preserving the delicate parts of the plant and preventing decomposition. He immediately saw that the property of glycerine might be made available for certain pharmaceutical purposes, where it was desired to preserve or extract the aroma of vegetable products, such as Elder, Orange, or Rose flowers, and also might be substituted for the oils and fats used in the purest process termed enfleurage. The glycerine need not be especially pure, but should be devoid of odour. The Elder flowers should be gathered when the corolla is fully expanded, but not too far gone; they should then be plucked from the stem, and packed firmly in wide-mouthed bottles or jars, without crushing them; and the whole should then be covered with glycerine. Mr. Tiehborne states that he has thus preserved flowers for two years, and, on distilling them, procured a water the perfume of which has equalled the most recent product. For the preservation of the aroma of the flowers he considers the employment of glycerine far superior to the system termed enfleurage, in which heat is used.

THE FLOWER FARMS OF FRANCE.

THE growing of flowers for the production of fine essential oils and for medicinal purposes, is an important branch of horticultural industry in those departments of France bordering upon the Gulf of Lyons and the Mediterranean Sea, and especially in the southern portion of the Department of Var, adjoining the former Italian, but now French, province of Nice. There are extensive factories in Nismes, Montpellier, Morbihan, Nice, and some lately established about the sea in Algeria. Smaller establishments are found at Mentone, and all along the Genoese Riviera; but the great and acknowledged centre of this branch of industry, is the town of Grasse, situated about seventy-five miles E.N.E. of Marseilles, a few miles inland, and its seaport Cannes, well known as the winter residence of Lord Brougham. It would be difficult to state, with any degree of accuracy, the product of the flower-fields of this interesting region. There are over sixty factories in Grasse, which is a flourishing place of 12,000 inhabitants, giving employment in the various departments of field and in-door labour, to fully 5,000 persons. Many manufacturers grow their own flowers, others buy them daily in the market, and still others are supplied by contract. The latter system prevails among the leading houses. Contracts are made, at a fixed price for a term of years, for the total product of a farm, at rates varying from 8 to 10 cents per kilogramme (2½ lbs.) of Rose leaves, up to 1 dollar for Tuberose leaves, and even higher for Violet leaves: the latter being mainly produced at Nice. The average prices are about as follows:—

Rose leaves, 8 to 10 cents the kilogramme.	Acacia buds, 60 to 80 cents the kilogramme.
Jasmine leaves, 40 to 50 cents the kilogramme.	Tuberose leaves, 1 dollar the kilogramme.
Orange leaves, 50 cents the kilogramme.	Violet leaves, 80 cents to 1 dollar 30 cents the kilogramme.

These are the leading garden-flowers used in Grasse; only small quantities of the Jonquil, Narcissus, Hyacinth, Mignonne, &c., are produced. A great breadth of land is devoted to Lavender, Rosemary, Thyme, Sweet Marjoram, Cherry Laurel, Sage, Balm, and other medicinal and culinary plants, which are sold at much lower rates than the products of the above-named flowers.

The preparations derived from all these plants divide themselves into four classes:—essential oils, distilled waters, pommas and oils, and dried leaves and flowers. It is true that considerable quantities of extracts of the pommas are manufactured and sold, but they are generally of inferior quality, and will not compare with those produced by the great perfumers of Paris and this country.

The great bulk of essential oils produced consists of Lavender, Rosemary, Thyme, Sage, Spike Lavender, and Sweet Marjoram, all of a terbinthine nature. The most valuable products, of any considerable amount, are the essential oils of Neroli and Petit Grain. The former is the result of the distillation of Orange flower water, from the petals of the flower of the Bigarade or Bitter Orange (the sweet or Portugal Orange yielding a somewhat inferior product), and the latter is obtained from the green leaves of the same tree. The price of Neroli varies with the season from 30 dols to 45 dols. the pound, of Petit

Grain from 8 dols. to 12 dols. These two oils are used extensively in the composition of Cologne water, and in combination with Bergamot and Rosemary, give its distinctive character. The Orange flower water is consumed in immense quantities in France, in the "eau sucrée," so universally drunk in the hot seasons; this, by the way, is the only form in which a Frenchman will drink water at all.

The Bigarade Orange tree also furnishes a rough-skinned, bitter, inedible fruit, from the rind of which is expressed an inferior oil called "Essence Bigarade," often used for adulterating the finer oils. The tree requires ten years to mature, and twenty to attain perfection, and yields an average of 17 lbs. of flowers per annum.

Rose water is also distilled in large quantities. A result of its distillation is a very minute proportion of otto of Roses of the very highest quality; it appears in small supernatant grains or drops, which are carefully skimmed off and rectified. It is superior to the famous Kizaulik or Turkish otto, and, like it, congeals at ordinary temperatures in beautiful, transparent crystals. I saw, at the celebrated manufactory of Mr. Antoine Cliris, who was in all things the leader of his profession, a bottle containing about three pounds, which he valued at 550 dols. or over 11 dols. the ounce. It is not an article of export, the quantity produced being very small, but is reserved for use in unfavourable seasons, or a failure of the flower crop, to give strength and finish to the Pommas and oils. The "Rose de Mai," (*Rosa centifolia* provincialis), or double May Rose, is the one universally grown.

Another very costly article of which less than an ounce had been produced in Grasse at that time, is the essential oil of Jasmine. Its existence in the flower was long and stoutly denied by the distillers, although they failed to prove what other principle caused its fine odour. In 1853 an Algerian chemist obtained a minute quantity, which cost him, we were informed, at the rate of 17,000 francs the kilogramme, or nearly 100 dols. the ounce. It has, since then, been produced at a cheaper rate, but still too dear for commercial purposes. The wild Arabian Jasmine is grafted on the cultivated plant of the same species, acclimated, and bears for many years, if not winter-killed, yielding from 90 to 150 lbs. of flower-petals per thousand plants. It is closely trimmed in spring and deeply covered in winter. The caterpillar is its most formidable enemy.

A most important branch, and one in which great rivalry exists, is the preparation of perfumed pommas and oils, which have a twofold use: first as bases for the finer kinds of hair oils and pomatums, and next as a medium for obtaining spirituous extracts for the handkerchief and the toilet; such as Lubin's well-known "Extraits pour le mouchoir." Their preparation is the most curious and interesting feature of the Grasse establishments.

The pommade "body," which is prepared in winter, is composed of 1 part of beef-suet, and 2 parts of beef-lard (except for Jasmine and Tuberose, which is mainly lard, hardened by mutton or veal suet), thoroughly hashed, washed in several waters, and, among the best manufacturers, washed several times in Rose water to deprive it of all unpleasant odour, then carefully melted and stored away in huge tin cans, in airy, cool vaults, for use in the season of flowers. Another preparation, called "corps dur," or hard body, is made of beef tallow only, and is used in the manufacture of stick pomatums. For the oils, the inodorous virgin olive oil is used, expressed from olives just before their maturity.

The busy operations of the year commence with the Rose season.

There are two processes for impregnating the pommade body, and the oils with the floral odours—one by infusion and maceration, the other by what is termed 'enfleurage.' The first is employed for the strong, less volatile odours of the Rose, Orange, and Acacia; the latter for the sensitive, ethereal perfumes of the Jasmine, Tuberose, Jonquil, and all the bulbous plants, which will not endure the application of even a moderate degree of heat.

And, first, by infusion. About 100 kilogrammes (220 lbs.) are put into a tin planished copper vessel, placed in a copper water bath, melted at a low temperature, and charged, at day-break, with a certain quantity of the freshly-gathered flowers, which are stirred constantly during the day and night, the mass being kept only warm enough to maintain a semi-fluid state. About midnight it is removed from the fire, poured into strong bags, made of fish cord, and subjected to heavy pressure in large perforated iron cylinders, standing vertically upon marble bed plates, which are gently warmed, to prevent

the congelation of the exuding mass. Next morning fresh leaves are added, and the process repeated daily, until the desired strength of perfume is attained; the pommade is then poured into cylindrical tin boxes, and sealed up for shipment.

The oils are treated in the same manner as to maceration, but are filtered instead of being pressed.

The process of "enfleurage" is as follows:—Large numbers of "chassis" or sashes are prepared, about 2½ feet long by 1½ wide, the frame itself being 2 inches wide and 1½ thick, holding a stout plate of ground glass, and resembling in construction a large school slate. Those for the oils are about 4 by 2½ feet, proportionately heavy, and, in place of the glass, have coarse iron-wire network. The large factories have several thousands of each of these frames.

Upon each side of the glass the pommade is thinly spread, and the surface is channelled or furrowed with a four-tined square-pointed wooden fork, so as to present the utmost surface for the absorption of the odour from the flower-leaves, which are thickly sprinkled upon it. The frames are successively charged with flowers, and piled one upon another, up to the ceiling. The leaves, confined between two strata of pomatum, wither, and yield up their odorate principle, which is rapidly absorbed. Daily renewals of the flowers are made, until the proper strength is obtained. The perfumed pommade is then scraped off gently, melted in a water bath, and poured into cans.

In preparing the oils, coarse, heavy, spongy, cotton cloths, made especially for this purpose at Marseilles, are saturated with olive oil, and spread upon the netted frames; flowers are then strewn thickly upon them, and they are piled up in like manner as the pommade frames. When sufficiently charged with the odour, the oil is expressed from the cloths by powerful levers.

Many hundredweights of flowers and herbs are dried annually, are variously used in medicine, in cookery, and in the composition of scent-bags, cachous, fuming-pastils for the sick chamber, and kindred compounds of the perfumer's art.

The Parmesian or double Violet is grown mainly at Nice, under the shade of trees, and yields a delicate and delightful perfume. It was the favourite odour of the Athenians under Pericles, and is now one of the most fashionable scents of the Parisian *beau monde*.

The flower-farms receive the highest culture. Underdraining was not practised at the period of my visit, but great attention was paid to irrigation. In some fields at Cannes there were complete networks of irrigating-tubes substantially laid in cement. A constant warfare is waged upon insects, and each plant has its particular borer, grub, or bug. Continual vigilance is the price of success.

The heat in summer is intense, though tempered by the sea breeze; and the winter is, at times, as rigorous as at Washington or Richmond.

Male labour costs 35 to 40 cents per day, and female 15 cents.—(*American Gardener's Monthly*.)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

At the time of planting Celery, Endive, or any other culinary vegetable, they should by no means be deprived of any portion of their leaves. This practice is still continued by some persons; but it is evidently a bad one, and may be proved as such by trying both methods. In planting great care should be taken to press the soil close to the roots. *Cabbages*, plant out some of last-month's-sown plants, for use in the autumn as Coleworts. Make a sowing at the end of the week for the first main spring crop. *Capsicums*, the plants should be kept watered in dry weather; if a little litter is laid round them they will not require it so often. There is a frequent complaint of their not fruiting sufficiently early to ripen. We know not how it can be expected when the plants receive no attention whatever, and consequently do not begin to grow till the autumnal rains set in. *Carrots*, thin the late-sown crops, and loosen the earth between them where they have been sown in drills. *Celery*, the earliest planted will now require to be gone over, and divested of their small lower leaves and side-shoots. The trenches should afterwards be thoroughly soaked with water, previously to the plants being earthed-up, which should take place the following day as soon as they are quite dry. *Cucumbers*, as the plants on the ridges spread, cover the soil with short litter. This will keep the earth moist and the fruit clean. *Endive*, transplant a few more, and make

another sowing. A few days' difference in transplanting, at this season, sometimes proves of great advantage. *Dwarf Kidney Beans*, a last sowing should now be made in a sheltered situation; the drills should be watered if the soil is very dry. *Herbs*, those for drying or distilling should be cut before the flowers expand, as they afterwards lose those qualities for which they are most valued. *Sorrel* should be cut down if required for use in autumn. *Tomatoes* require constant attention to cause them to ripen their fruit; the shoots should be thinned, and those left kept closely nailed to the wall; they should also be watered and mulched in dry weather.

### FRUIT GARDEN.

Attend to the previous directions in regard to the thinning and stopping the young shoots of all trained trees; and now make the final thinning of Peaches and Nectarines, of course leaving the heaviest crop on the most vigorous trees and strongest branches. As a general rule no two fruit should be left together. Plums of the large kinds, as well as the finer sorts of Pears, should also be thinned, if the crop is too heavy. Young Peach and Apricot trees, when making over-vigorous leaders, should have the points of the branches shortened, to encourage them to make other shoots less vigorous, and of a fruitful character. This will obviate the necessity of shortening them back at the winter pruning. Strawberries will require frequent waterings during dry weather. Layer the runners intended for pot culture, as well as those required for making plantations. All spare runners may be cut away, and keep the plants free from weeds. Thin and stop shoots of Figs as soon as they have made a growth of about 6 inches. Remove all useless growth from out-door Vines. Keep fruit close to the wall, and shaded by the foliage from the sun.

### FLOWER GARDEN.

Strong shoots of *Chrysanthemums* may now be layered in pots to produce dwarf compact bushes. Those in pots may soon receive their final shift. All seedlings should be marked, noticing their various properties as to form, colour, and substance. There are few persons, we believe, who are fond of horticultural pursuits but save seeds from some favourite flower, they raise them and watch their opening blossoms with anxious but pleasing expectations of procuring something different from what they have yet seen, but how many are disappointed in their expectations! The cause of this is that no attempt is made to artificially impregnate distinct species or varieties having good qualities, or if it is done, it is done carelessly, and new varieties are not more likely to be produced than by the common practice of saving the seed indiscriminately from every plant that produces it, whether having bad or good properties. This we believe to be the chief reason of so much disappointment in seedlings. One person, by care and attention to impregnation, will have more good flowers from fifty plants than another who has saved seed indiscriminately will from a thousand. Now is the best season for observing the effect of the arrangement of the colours, &c., and if any alteration is deemed necessary it should be carefully noted, which will greatly facilitate its execution at the proper season. Seedling *Polyanthuses* should be carefully shaded from the sun's rays, and watered with a fine rose, this will prevent the ravages of the red spider. *Ranunculus* roots will be better out of the ground as soon as the foliage is withered; the roots to be gradually dried, when this is done too rapidly it is detrimental to those which happen to be in a weak state. Continue to propagate *Picotees*, *Pinks*, and *Pansies*. Clip Box-edgings in cloudy weather. Bud Roses. Mow and roll lawns, and follow up assiduously the extirpation of weeds.

### GREENHOUSE AND CONSERVATORY.

Hardwooded plants, including most of the genera from New Holland which bloom early in the spring, and which after blooming received the necessary pruning, &c., will now be so far advanced in their new growth that any requiring to be potted should at once have a shift. After turning them out loosen the outside roots before placing them in their new pots, to enable them to take to the fresh soil more readily. Keep them close for a few days, especially if the roots have been much disturbed, and damp once or twice daily overhead, water carefully at first, taking pains to insure the old ball having its proper share until the roots get established in the new soil. Continue *Epacris* under glass till their growth is complete, but more air and light should be allowed, then increasing it as the wood gets firmer. In the beginning of next month they may be placed out of doors in an open situation where they can be protected from heavy rains. Some of the stove plants

that have recently been brought into the conservatory will require attention to prevent their being injured by damp during cloudy weather, and it will probably be necessary to use slight fires occasionally for the purpose of drying the atmosphere of the house. Continue to carefully regulate the growth of the twiners, but avoid tying them too close, and allow them to grow according to their natural habits as much as circumstances will admit.

## STOVE.

The plants that are intended for the decoration of the conservatory in autumn should now be carefully looked over, shifting such as are likely to want more pot-room, with a view of getting the pots well filled with roots before the plants are required to be in bloom. Keep, also, the shoots tied-out rather thinly and expose the plants to as much sunshine as they will bear without scorching their foliage in order to keep them low and bushy. Give clear weak manure water to young growing specimens, and report any that are intended to have another shift this season, so as to have the pots well filled with roots before winter. Maintain a moist growing atmosphere, and syringe vigorously any plant at all infested with red spider. Growing Orchids should be encouraged with plenty of heat and moisture while that can be done safely. See that plants on blocks and in baskets are properly supplied with moisture at the roots. To prevent any mistake in this matter carefully examine every plant at least once a-week, and immerse any found to be dry in tepid water until the material about the roots shall have become well soaked. Syringe lightly morning and evening, and sprinkle floors, &c., in order to keep the atmosphere thoroughly moist.—W. KEANE.

## DOINGS OF THE LAST WEEK.

On Saturday, the 8th inst., we had a severe storm of thunder and hail, which riddled a good many broad-leaved plants. We notice it in order to record the fact, that large squares of 16-oz. glass were uncracked and unbroken, but we observed that many of the hailstones rebounded from the glass fully 3 feet in height, and that the glass waved and bent considerably. There would be less risk of breakage with stouter glass, but then it would bend and curve less to the stroke of the hailstones. On Sunday, the 9th, we had some three and a half hours in the afternoon of continuous thunder and down-pouring rain, which seems to have well soaked the ground, and has laid the best fields of Barley considerably, but several cattle and sheep were killed. No ordinary spouting could accommodate such down-pouring, and, therefore, we received much less in our tanks than we expected. The heavy rains shot quite over the spouts. There is now in this neighbourhood little likelihood of being so dried up as we were last season. Wednesday, the 12th, was a beautiful dry day, and even the flowers with a little cleaning were opening freely to look as bright gems over the now fine green of the foliage and lawns, but the weather became wet again on Thursday, and if it continue the very best flower-beds will have a wobegone appearance. When the beds are full of leaf and bloom at this season, it tries the patience and equanimity of the gardener to find the results of his skill and unwearied care, little better to look at by visitors of the family than so many mounds of drowned mice. Who will have the honour of being the first to cover an acre, or even half an acre of the finest modern flower garden with glass, so ventilated by leverage power that even the rains and dews can be admitted at will, and rains and boisterous winds also be excluded at pleasure? We venture to say that such a garden would yield more continuous satisfaction than a dozen acres of flower garden in our uncertain climate. Probably, however, there may be a bewitching charm in the very uncertainty of being able to see such modern flower gardens at their best on a certain day, just as there is, at least, some test to the depth of that love which is not permitted to develop itself in the smoothest of channels. Well, there is no accounting for tastes, but we would be quite willing to make a present of our share of the pleasure arising from the thorough uncertainty of having a flower garden brilliant against a certain day, with the likelihood of our changeable climate marring all our expectations. In one thing we must rejoice, the beautiful luxuriance that is now spreading over the brown parched pastures.

## KITCHEN GARDEN.

Proceeded with planting out Winter Greens as we could get ground cleared for them. Planted more Cauliflower, Lettuce, &c., these being always indispensable. Staked late Peas, the

medium crops being richly flavoured after the rain. In some hot days gave the slightest shading to Cucumbers to keep them sweet. In such weather as we have lately had, Cucumbers, fully exposed out of doors, or even with air on under glass, are apt to be a little bitter, though in some seasons where they had unobstructed sunlight they were always crisp and sweet. The bitterness, we consider, is not so much owing to unobstructed sun as to the fierce sun and dryness combined. In many cases the complaints of Cucumber-eaters arise from having the fruit sent to them when it is too large and old. If sent in the young state there would be fewer complaints. The mistake has arisen from country societies too generally patronising length and size. Some time ago we heard an exhibitor very wroth because his Cucumbers were passed by. The judge, to silence him, took hold of the Cucumber by one end, and the other end at once pretty well joined it, the body of the Cucumber making a beautiful arc of a circle. There was no reply to the question, "how long such specimens had been cut and kept in the cellar." The person who would venture to eat such Cucumbers, after a due allowance of salt, vinegar, oil, and even young Onions, might as well have presented so much leather to the organs of digestion. Even Cucumber-eaters would be wise if, after attending to all the usual preliminaries, they sent such huge specimens of growth to be duly digested in the rubbish-heap, or followed the receipt of Dr. Johnson, and pitched them out of the window. Cucumbers grown in frames will now also be better of a little bottom heat from linings. A strong sun heat and a cold wet soil will be next to certain to make the fruit hard and bitter, and to militate against healthy luxuriance. We are short of material for this purpose, but anything that will keep cold out and send a little heat in, as a mixture of short grass and litter, will be of use, and will add to the future manure-heap.

*Tomatoes.*—Mulched, and fastened these against fences, walls, &c. They do pretty well, if well thinned, on sloping banks. They are but little used in this country in the green state as salads; but they are largely used in this way in America. Some time ago, an Englishman who became, as he said, a thorough Yankee told us that when green and small, Tomatoes made an excellent ingredient in salads, along with green Capsicums, Cucumbers, &c., and ended with telling us that "You old-country folk do not know how to use the blessings that Providence gives you."

*Mushrooms.*—Earthed up a piece of the bed in shed. The first part is now coming in. Will clear the house as soon as possible, as the decayed dung will do when riddled for mulching the remainder of the flower-beds. When cleaned out, we will smoke well with burning sulphur and a little turpentine to kill all insects, and woodlice in particular. We generally in this lean-to house to the north, get on very well during the winter—but as the warmth of the end of spring comes, so do the shoals of woodlice visit us; though we trap and kill myriads, we can never clear the place of them entirely until we take away the beds and burn sulphur as stated above, with all crevices shut up. It would never do to adopt such a system with the beds in bearing. Sulphur, as well as lime, is a great enemy to the whole, or nearly the whole of the fungus family. We believe we get the woodlice intruders in spring from taking them in with the dung for the beds, and in old gardens it is scarcely possible to find a place completely free from them. They multiply also very fast in a warm place. In some cases we have seen myriads of them when they seemed to care nothing for anything but warmth and dryness, never touching a Mushroom at all. In other cases we have known them assail every Mushroom that came when not much larger than pin heads, and in other cases we have found them roosting and eating among the laminae of a large specimen, like bees clustering among their combs. One advantage of beds in open sheds, or even out of doors in summer, is that there is little temptation for such intruders to go there. Warmth and dryness are what they chiefly like—so much so, that one wholesale way of getting rid of them, is to water the surface of a bed, and place a little dry hay along the back and front. In a few hours every one of the woodlice will have taken refuge under the thin layer of hay, and boiling water poured on with one hand whilst the hay is gently lifted with the other, will make short work of them; and as death must be next to instantaneous, there can be no great charge of cruelty, when once we have resolved to destroy if we can. We often think that the whole practice of snaring and trapping larger animals well deserves legislative consideration. The amount of torture thus inflicted is next to incalculable, and has a tendency to

deaden human sympathy and feeling. There was much humane appositeness, though blended somewhat with the paradoxical, in the exclamation of the young lady when frightened with a sight of what she deemed a loathsome reptile, "Oh, kill it, but do not hurt it." If we claim the right to kill, we have no right to cause unnecessary pain to any living thing.

#### FRUIT GARDEN.

Proceeded with gathering small fruit in fine days. Unless people particularly wish it, there is little economy in preserving Gooseberries, Currants, or even Morello Cherries to the latest possible period on the bushes and trees. We have had Gooseberries pretty good in the end of October, and Currants and Cherries until long after Christmas; but we rarely found such fruit, especially of the last two, sufficiently used and partaken of either for dessert or for puddings, tarts, &c., to compensate for the covering, &c. They might as well have been bottled, or preserved, or brandied at once when ripe, and thus saved all the attacks of birds, and the trouble and expense of protecting them. If they are to be kept, we and others have already stated how it may be done most economically with straw hands and matting, and most efficiently with waterproof tops and air at the sides. A bush may be well protected with a cover like a huge hand-light; the top, tin or zinc, and the sides galvanised iron pierced with holes, or even of stout book muslin, or something like thin tiffany. Some of these modes we advise for those who pride themselves on having fresh-gathered Currants at Christmas. The Morello Cherries are just beginning to ripen—just soft enough for the birds to begin to nibble them. All the best Cherries have been unusually early this season. With the exception of the Florence and other late ones, few will hang much longer on the trees to please us.

*Wall Trees.*—Went over Apricots, shortening in the breast-wood of that which had been shortened previously, and eased the fruit where too thick or too firmly set between wood to swell freely. Did the same to Peaches and Nectarines. In the first and subsequent thinning of such fruit preference should be given to those which stand on the front of the shoot instead of those on the side; but even then some fruit on the side and sometimes on the back of the shoot may be left, and unless these are eased, and kept from the wall or trellis, they will be injured as they approach maturity. The dry summer hitherto has given us but few strong shoots on Peaches out of doors; but where these have been stopped early to equalise the strength of the shoots, it will be desirable to choose one or two of the lateral shoots produced for the permanent ones, according as there is room for them, not forgetting that one shoot of medium strength—that is, about the thickness of a quill—well ripened by exposure to sun and air, is better than half a dozen similar shoots crowded up into a bundle, so that they cannot possibly get enough of either sun or air. There is scarcely one of us that has not too much young wood on his trees in summer.

*Apples and Pears,* dwarf standards and pyramids out of doors.—Went on shortening the points of the young shoots as we could find an opportunity. In many cases nipping out the point is better than cutting well back just now. The latter mode tends to make a fresh outburst of young shoots that will not ripen before winter. The former mode arrests mere growth, and even if a few wood-buds break the backward buds on the shoot are almost sure to be changed into fruit-buds for the following year. As the autumn approaches we must be thinking more of ripening wood than of increased and prolonged growth. What applies to fruit trees on walls and borders outside, applies still more to trees in cool and forcing-houses. Strawberries, commenced taking good runners for next year's forcing. The drought and little growth prevented us doing so sooner. We shall, therefore, for our first crop, use a few of the plants that were forced this spring.

*Peach-house, Fig-pit, and Vinery.*—Gave a good manure-watering to the first two, and having removed all the shallow litter covering from the last as respects the outside border, threw a dusting of soot and lime over it, expecting it to be washed in by the rains that did come. We observed some worms near the surface of the border from the fresh cowdung that had been applied last autumn, but the lime and soot would soon make short work with them, though in moderation they are good cultivators, instead of doing much harm. Probably it was the worms that enticed some moles that have rather troubled us in the garden, to make their runs all through the surface of the Vine-border. We had no fancy for them driving their tunnels among the Vine-roots, and we hope we have stopped them. The roots are so near the surface that we found

we could not plant a row of different kinds of Scarlet Geraniums along the front of the border without injuring the roots. To trap the mole successfully, a little spud of wood should be used, and even the trap should be set with a gloved hand, and if the glove has been rubbed with the skin of a dead mole all the better. The animal, if somewhat deficient in sight, is so powerfully gifted with smell, that the scent of the hand about the trap will generally cause him to avoid it, either by retreating, shoving more earth against it, or driving a tunnel underneath it. But for the injury it might do in such places, and the unsightliness of the mounds in dressed grounds, we incline to think that as respects cultivation, the mole, like worms, does more good than harm.

*Melons* that had no shade, except a little given to the changing fruit on the very hot sunny days, have been ripening very kindly. If this wet weather should continue, and the atmosphere become and continue colder, linings round frames will be desirable, and the surface of the bed must be kept dry, though moisture be communicated to the roots, otherwise there will be danger of cracking, bursting, and rotting. The fruit in no case should lie on the soil, and if moved frequently as it approaches maturity, it will be more regularly ripened all over. The last crops for frames and even for hot-water pits should now be planted. The advantage of the latter is, that you can obtain dry heat in autumn. For the generality of our summers, nothing beats a good dung-bed and frame for summer Melons, and they generally give less trouble than when in pits. Our own opinion is, that for weight and flavour in proportion to size, the best results are obtained from Melons, when the head is trained to a trellis, and the fruit is suspended until it begins to reach maturity, when it must be supported by a net or otherwise.

#### ORNAMENTAL DEPARTMENT.

Here the work was much as last week. Mowing, mashing, rolling walks and lawns, pegging Verbenas, tying herbaceous plants, regulating flower-beds, trimming broad rows of Cerasium so as to make them uniform, potting, and preparing cuttings of Pinks, Wallflowers, Cloves, &c. We have, however, filled our space, and must be content with noticing that this season as yet we are disappointed with

*Cloth of Gold Geranium.*—We turned out fine, strong, young plants, and on the whole they seem to have become less. Similarly treated on a contiguous border in a similar line we turned out young plants of Golden Chain, and they have done beautifully. Cloth of Gold did well with us last year, but this season where it does well is in a place protected from much wind, and also from the afternoon sun. We thought last year that we would dispense with Golden Chain, but we must give it a higher place in our regard. We would be glad to know how Cloth of Gold has done in other places, and as far as possible the circumstances under which it does well. Two little beds of Mrs. Pollock, with an edging of Baron Hugel, have as yet done well, although quite as much exposed as Cloth of Gold. It strikes us that the latter is tenderer than we thought, as, with the exception of the sheltered place referred to, it has not as yet done first-rate with us in any other position. We shall be able to dispense with it when once we get plenty of Miss Watson (Mr. Watson, of St. Alban's), Lady Cullum, Lucy Gieves, and other fine seedlings of Mr. Gieves's that as much excel Mrs. Pollock as that pretty kind excels Golden Chain and Cloth of Gold.—R. F.

#### COVENT GARDEN MARKET.—JULY 15.

LARGE importations continue to arrive from abroad, consisting of Green Gages and other Plums, and Apricots. Of home-grown fruit there is a heavy supply of Grapes and Peaches and Nectarines, particularly the last two. For Pines of English growth the demand is not brisk, owing to large quantities, of very good quality, having come in from the West Indies. Vegetables of all kinds are fully equal to the demand, and of new Potatoes there is an abundant supply.

BRAIN CORAL.—PETRIFIED MOSS (J. L.).—"Brain coral" may be got at any shell shop. "E. B." got his petrified moss from a brook near Tenbury, Worcestershire. "G. G." says, "They are to be procured at Buxton and Matlock. If your correspondent has any friends in that locality nothing is easier to obtain."

NARDOO SOWING (St. Bortier).—We had this germinating in a pan filled to within half an inch of the rim with peat, and chopped moss, the spores being sown on the surface, and covered with about a quarter of an inch of water, and kept so for six months after sowing in a close moist stove. The next six months the pan was kept sprinkled with water every morning; the pan stood in another pan of water, but not so as to keep the surface covered. Here our experience ends. We should be obliged by any of our correspondents stating their experience of the successful culture of this plant.

MANAGING CALADIUMS (Bessie).—Pot them in March in turfy peat, loam and leaf mould, in equal parts, with a free admixture of silver sand Water sparingly at first, and plunge the pots in a mild hotbed. When growing freely water copiously, and shade from very bright sun. Give plenty of pot room, free drainage, and liquid manure at every alternate watering. They like a brisk moist heat of 65° to 85° when growing, and the heat of a stove in winter. When the leaves begin to turn yellow, diminish the supply of water, and stand the pots on a damp floor, so that the soil may not become dust dry during the winter—that is, after the plants go to rest, which will be in October. They should have a temperature of from 60° to 70° in winter.

BUDDING ROSES (S. D. R.).—After inserting the bud you may cut the shoot down to 6 inches above the bud, and as much nearer as you please, only leave a growing point above the bud. The part left should not be removed or cut down to the eye or bud until the latter commences to grow in the ensuing spring. When the bud makes a shoot the same season as budded, that shoot should not be pruned until the beginning of the following March. When they push in the spring they should be allowed to grow until July, when they will mostly flower, and after blooming they may be cut-in to six or eight eyes, or, if no flower-buds form, stopped at the sixth bud for a weak, and at the eighth for a strong shoot. It is best to bud on the main stem of the Manetti, removing the soil so as to bud about an inch below the surface. You may bud on the side-shoots, and when the bud grows place earth against them, so as to cover the union; but this is a ready mode of obtaining suckers. The shoots, after budding, should be shortened to three or four joints above the bud. After the bud grows replace the soil, covering both stock and bud, and cut down the bud in March.

MANAGING VINES (A. M. T.).—We think the course pursued by your gardener is quite right. No harm can come of syringing the Grapes with soft water up to their colouring; and his thinning them three weeks ago, and again now, shows they were too thick. Provided the thinning is not done so as to make the bunches too loose and open, you will have finer berries, and they will keep much longer. There is no fear of the berries bursting, and, if there were, thinning would only aggravate an evil of that kind. If there be any sign of mildew, it is altogether wrong to continue syringing. They should have a drier atmosphere, and be dusted with sulphur at the infested parts. We suppose they are infested with red spider, and that is why the gardener syringes them. Syringing with soft water, accompanied with fresh air early, can do no harm, but is often necessary to keep down attacks of red spider, which is this year unusually troublesome.

PLANTS FOR STOVE AND GREENHOUSE (A Constant Reader).—*Aphelandra cristata* and *A. Leopoldi*, *Burchellia capensis*, *Ardisia crenulata* and *A. fructu-alba*, *Eranthemum rubrovenium*, *Franciscoa confertiflora* and *F. Hopeana*, *Meyenia erecta* and *M. erecta alba*, *Poinsettia pulcherrima*, *Sonerchis margaritacea splendens*, *Thyrseanthus rutilans*, *Rondeletia speciosa major*, *Medinilla magnifica*, *Luculia gratissima*, *Ixora acuminata*, *I. coccinea*, and *I. javanica*; *Hebeclinium atropurpureum*, *H. aurantiacum*, and *H. inthimum*; *Graptophyllum pictum*, *Gardenia Stanleyana*, *G. radicans*, and *G. citriodora*; *Euphorbia jacquiniiflora*, *Cyrtoceras reflexum*, *Clerodendron Fallas* and *C. Kämpferi*, *Centradenia grandiflora*; to which may be added, of climbers suitable for training on wires, *Stephanotis floribunda*, *Cissis discolor*, *Clerodendron Thousonia*; *Echites splendens*, *E. crassicauda*, and *E. magnifica*; *Hoya bella*, *H. carnosa*, *H. carnosa variegata*, and *Schubertia graveolens*. The above are all free-flowering or ornamental stove plants. There are many others equally, or more so, but we give these as reasonable in price for you to choose from. Greenhouse Plant: *Chrozema cordata splendens*, *Boronia Drummondii*, *Cassia corymbosa*, *Aphellexis macrantha purpurea* and *A. proflera Barnesii*, *Acaëti Drummondii*, *A. armata*, and *A. grandis*; *Abutilon venosum*, *Cornifolia glauca*, *Crowea saligna*, *Cytisus Atteana* and *C. racemosa elegans*, *Eriostemon intermedium* and *E. buxifolium*, *Monochæum ensiferum*, *Indigofera decora*, *Rhytidodendron jasmminiflorum*, *Swinosia Ferrandi*, and *Tremandra cricoides*. *Camellias*, *Azaleas*, *Heaths*, and *Euphrasies* we omit, as they are well-known plants, though quite indispensable.

VINES FOR EARLY AND LATE VINERY (Idem).—Five for early vinery: One Foster's White Seeding, one Buckland Sweetwater, two Black Hamburg, and one Pope's Hamburg. Four for late vinery: One Lady Downe's, one Alicante, one Bowdoin Muscat, and one Royal Vineyard.

VINE CULTURE—GREENHOUSE (M. R. C. S.).—"The Vine Manual," 2s. 6d., and "Greenhouses for the Many," 6d., may be had free by post from our office, if you enclose 3s. 2d. in postage stamps with your address.

HYBRIDISING (H. T. A.).—We know of no publication confined to this subject. Johnson's "Science and Practice of Gardening" contains much upon the subject. You can have it free by post from our office for 3s. 4d. in postage-stamps.

ORANGE TREE (S. T., jun.).—In the "Cottage Gardener's Dictionary," under the head "Citrus," there are full directions. Cranston's is a good system of ventilation.

EARLY PEAS.—A Subscriber has written to us about Dickson's "First and Best." If he will furnish us confidentially with his name, we will publish his communication. Such communications from anonymous writers are of no authority.

MOWING MACHINES (W.).—We cannot recommend one in preference to others. They all do their work well if properly managed, and taken care of. No specimens arrived in your letter.

TO CORRESPONDENTS.

\*.\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BACK NUMBERS, &c. (Man of Kent).—You can have all but Nos. 41, 42, 49, 50, 51, and 52; and you can have covers for any of the volumes.

RAISING TREES, &c. (A Young Nurseryman).—There is no very modern book devoted to this subject. You would find Abercrombie's "Gardener's Vade-Mecum" serve your purpose, if you can meet with a second-hand copy.

ONION GRUBS (G. V. S.).—The bulbs of Onions suffer from the grubs of two genera of flies—*Anthomyia* and *Eumerus*. There is but one remedy—burning every bulb attacked, and sprinkling a little gas lime on the surface between the rows, to keep the parent flies from approaching to deposit their eggs.

ROSES MILDEWED (C. Hamilton).—Syringe them with lime water, to destroy the fungi, but nothing you can do will restore leaves so virulently attacked. Water the roots copiously; mulch the surface; and continue watering abundantly during dry weather. Weak liquid manure once a-week will benefit the trees.

AVICELLA CULTURE (W. E.).—To answer your queries would require us to detail the whole cultivation. You can purchase the good varieties of any of the florists who advertise in our columns; and for four postage-stamps you can have, free by post from our office, No. 201 of our Journal, which contains full directions for their successful management.

SELECT ROSES (A Young Subscriber).—The following Hybrid Perpetuals will probably suit you, and are not expensive:—*Sensation* Visse, *General Jacqueminot*, *Jules Margottin*, *Madame Rivers*, *Anna Alexicoff*, *Caroline de Sansal*, *Eugene Appert*, *Geant des Batailles*, *Madame Donage*, *Maurice Bernardin*, *Louise Odier*, *Catherine Guillot*. All the above may be had as standards.

GROWING-POTATOES SPROUTING (H. L., Ozon).—It is very usual for Potatoes in the ground to sprout (shit or sprit, as some term this growth), when rain occurs after long-continued drought. As the tubers of your crop are a good size, we should take them up at once and sell them. We should try planting again, if we needed Potatoes, and could obtain some of last year's Potatoes for sets. We have known a July-planted crop very productive, and ready for taking up in October. We would even try, as sets, some of the sprouted tubers of your crop, taking care not to rub off the sprouts, or allow them to wither.

NAME OF CHERRY, &c. (An Old Subscriber).—It is the Royal Duke. *Hedera Regneriana* is an unjustified name for *Hedera colchis*, discovered more than a century and a half since in Japan, by Kämpfer, the discoverer, as we mentioned last week, of the *Aucuba*. Mr. W. Paul, who has paid much successful attention to the genus, describes it as having its upper leaves narrow-elliptic; flowers in simple racemes; pedicels and calyx covered with yellowish scales. It is found in the Himalaya, Northern China, Loochoo Islands, &c. See "Names of Plants."

VARIEGATED PLANTS—*FUCHSIAS* AND *GERANIUMS* (Miss H.). *Bambusa Fortunei variegata*, *Arundo donax variegata*, *Dracæna australis*, *Yucca filamentosa variegata*, *Aralia Sieboldii variegata*, and *Alchornea cornovadensis*—these are good green-house variegated plants. *Fuchsias*: *Comet*, *Emperor of the Fuchsias*, *Henry Abts*, *Minnie Banks*, *Universal*, and *Rose of Castile*. *Geraniums*: *Ariel*, *Excelsior*, *Symmetry*, *Modesty*, *Confraction*, and *King of Scarlet*. Now is a good time to obtain them to grow into specimens for exhibition next year.

MILDEW ON GRAPES (T. H.).—Have a soup-plate full of flowers of sulphur; dip each bunch into the sulphur, so that every berry may be dusted all over. Leave the sulphur on for a week, and then syringe. If mildew still appear apply the sulphur again. Admit air freely; this and the syringing will drive away the spiders.

**EARWIGS (J. H. H.).**—We know of no mode of destroying them except by inducing them to conceal themselves in inverted pots containing moss, hollow stalks, &c. Are there any flowers which earwigs would prefer to Dahlias, if grown in their vicinity?

**NAMES OF PLANTS (Mittida).**—1. Starved completely out of character—perhaps *Lastrea glabella*; 2, *Platyloma rotundifolium*. (*John Boyd*).—1, *Pteris aquilina*; 2, *Nephridium molle*. (*H. L.*).—Wretched specimens, some of which appear to be—3, *Selaginella Martensii*; 4, *S. uncinata*; 5, *S. cordifolia*; 6, *S. denticulata*. (*H. L., Leeds*).—1 and 2, *Blechnum spicant*; 3, *Polypodium droopteris*; 4 and 9, *Lastrea dilatata*; 5, 6, and 10, *Lastrea Filix-mas*; 7 and 8, *Athyrium Filix-femina*. (*R. H.*).—Your

climber is the purple-flowered variety of *Clematis viticella*, or *Vine-bower*. (*A Young Beginner*).—It is *Aretotis reptans*, which the late Mr. Beaton so prized for an edging, and named "The Frosted-silver Plant." (*E. C. T.*).—*Cotyledon orbiculatum*. (*Harry*).—1, *Rhododendron hirsutum*; 2, *Viburnum lantata*; 3, *Euonymus latifolius*; 4, *Magnolia tripetala*; 5, *Escallonia rubra*; 6, *Xanthoxylum speciosum*. (*Old Subscriber*).—1, *Lagurus ovatus*; 2, *Clematis erecta*. (*W. Earley*).—*Epipactis purpurata*. (*R. S.*).—1, *Gaultheria shallon*; 2, *G. procumbens*; 3, *Vincetoxicum officinale*; 4, *Anigozanthos coccinea*. (*J. M.*).—1, *Villarsia nymphæoides*; 2, *Digitalis lutea*; 3, *Pernettya mucronata*; 4, *Echinops ritro*. (*Orchidophilus*).—*Oxalis cernua*. The Orchid was entirely crushed.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending July 15th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

DUCK-FOOTED GAME FOWLS.

SEEING in your Journal that a pen of Game fowls, otherwise meritorious, lost all chance in competition from the "fatal defect" of being "duck-footed," or "duck-heeled," may I ask you to tell me what the defect is?—whether there is too much web between the toes, as "duck-footed" would seem to imply, or whether the hinder toe is inclined too much downwards and forwards (as I have seen it in some Game fowls), instead of being set on well behind the foot, and projecting straight and flat, as the term "duck-heeled" would lead one to infer, and whether either or both of these conditions of the foot in Game fowls are fatal to success in competition? These are niceties which are not mentioned in books; neither Mr. Baily nor the "Poultry Book," mentions the term, and yet from such defects a pen is often passed over at shows, much to the disappointment of their owners, who being young hands like myself, or "exhibitors in a small way," begin to question the honesty of the judges.

I keep a few fowls and like to encourage shows by exhibiting occasionally, but one tires of sending them, where the item of carriage is a considerable one, unless having some prospect of success. My own time is too much occupied to allow me to get far from home to gain practical knowledge at shows by scanning the winners, there being no shows or next to none near London, nor have I any neighbours learned in poultry, nor a "WILTSHIRE RECTOR" near me, who seems always ready to impart knowledge on his favourite subject.

Having neither of these helps near me I am obliged to fly to books, and "Our Journal," and the latter, I think, does not quite sufficiently consider the class of poultry amateurs of which I am one, for in its articles on the points of excellence in fowls, the exhibitors of Game fowls are generally thought to possess all the knowledge that is required, and are usually dismissed with some such generality as the following:—"Exhibitors of Game fowls have nothing to learn." Granted: as a body they send their stock to exhibition as perfect as can be, but we must all have a beginning, and we can only arrive at that knowledge which many have attained by degrees; and if you do not assist the beginner, where is he to look for information? and I am satisfied the more you tell us of the way to try to attain excellence, and of the points of excellence in poultry, the more will amateurs possess themselves of good specimens, and the more will poultry shows flourish. I have several times hesitated about sending fowls to exhibitions, and I have known several other amateurs similarly unwilling to exhibit, because I did not know whether they were good enough to stand any chance of success. I trust I have written in no complaining spirit, but have only expressed what I have felt as a want, and I am sure I am not singular.—MAN OF KENT.

[We never expected to be charged with giving curt replies, for we fully appreciate the good effected by full and correct

answers, and spare neither expense nor effort to obtain them. We sent your letter to Mr. Hewitt, and this is his reply:—"I have taken the enclosed drawing of the leg and foot of an otherwise excellent young Game cockerel; but, unfortunately, labouring under this fatal defect in the right foot only, rendering him as useless for fighting as he is for exhibition.

"Of course, this is a great annoyance to the owner of the bird, as undoubtedly in all other respects, as to feather and also in hand, he is one of the best cockerels I have met with of this season, being hatched as early as January. A bird thus faulty, more particularly where the malformation exists in both feet, if closely and quickly pressed when fighting, invariably falls backwards, having no support from the back toe—a position highly favourable to his antagonist, and a most critical moment for himself. I may add, that a cock only partially 'duck-footed,' if greatly excited and exhausted, becomes even more so as weakness steals on.

"The plain outline shows the foot as it should be, the dotted one the defect known as 'duck-footed,' or 'duck-heeled.' Of course it is not intended to represent two toes, but the same single toe in the two different positions, 'right and wrong.'"

AMONG THE MENDIPS WITH MR. ROBBARD.

No. 1.

"TICKET for Yatton, please?" "All right, thank you. Now, then, an insurance ticket?" "Sorry to say we have none left." "Indeed! why, then, I must go without one, W. R. will be as valuable to his family while alive as ever, but not so valuable to them as he might have been should the Great Western kill him." Ticket for Yatton! It is twenty-three years since I took a similar ticket. I remember the little station well, the scent of flowers hung about it from the pretty beds among the gravel. I arrived there even before my college days—it was my first start in life—the first leaving the parental

nest, when the fond and family christian name was no more heard by me, and the cold Mr. was in its place.

Full of these thoughts I pass Bath the beautiful, and then, not very long afterwards, Bristol the bustling. Catching a glimpse, after Bristol smoke (choking, horrible it is), has been passed, of that fairy-like work, the Clifton Suspension Bridge, if not the finest bridge in the world, its situation is certainly second to none. Soon I arrived at Yatton, and there on the same side, in the same place where I had been met twenty-three years ago, sat my friend Mr. Rodbard. After a hearty greeting, we are soon driving through Yatton village, with its old church and stump tower, a sort of miniature St. Mary's Redcliffe. We diverge to the left to visit, on our way to Aldwick Court, some chickens which are being brought up at a cottage. We turn down a narrow lane, with those large orchards here and there, which make one feel at once to be in Somersetshire. By-the-way, an orchard country is a good one for poultry, as orchards give both grass runs, always available, not being mown, and also abundance of shade. Somersetshire cottages are still, as of yore, poor places, though occasionally picturesque-looking. We pull up at one, and a girl with a west-of-England face comes to hold our horse, but back she starts, as if afraid. On seeing her fear, her mother, with true motherly feeling, took the reins from her hand. We enter an odd place—the roof of the cottage had been lengthened, and a slight edifice added on, open, however, at the gable. This afforded a space light and dry for the chickens to run into in case of wet, and it was a good place for feeding. There sat the hens, and in, upon hearing our footsteps, scrambled, as if to show themselves, a number of Partridge Cochins of various ages. But let me not forget the old lady who was their care-taker, and very careful she seemed of them, and not a little proud of them, pointing out eagerly the best birds according to her judgment. Poor old woman! once she was tall and straight, perhaps she had been upright as a willow wand, and graceful too; but now she was bent double, though, happily, there was little trace of feebleness in her countenance. Poor thing! she reminded me of Wordsworth's "Cumberland Beggar," for

"On the ground

Her eyes are turned, and, as she moves along,  
They move along the ground. One little span of earth  
Is all her prospect. Thus from day to day,  
Bow-bent, her eyes for ever on the ground."

Yet let me waste no pity upon her, she seemed happy enough, and the Providence that tempers the wind to the shorn lamb gave her pleasures all her own, in spite of bodily infirmity. Passing through this elongated cottage, we entered the old body's orchard, and I admired, with admiration unfeigned, many promising Partridge cockerels and pullets. A fine strain, a very fine strain, is yours, Mr. Rodbard. We take our leave of the old woman. By-the-way, many such an old body has reason to bless the love of poultry which prevails now-a-days in England, as it adds many a comfort to their slender stores.

Again we are threading the narrow lane, and now we return to the main road. On our right, Congersbury spire, in the heart of the rich valley, glitters through the trees. Now, straight on for Wrington. I cannot forbear turning my eyes westward, for there across the valley stand the beautiful Mendip Hills, not bleak and bare as are northern hills, but their sides covered with verdure, and in some instances the enclosures run almost to the top.

Beautiful Mendips! the first hills I ever saw! for I came straight from flat Cambridgeshire, when a mere youth, to Somerset, and my eyes were enchanted with the Mendips. I recollect scarce being able to dress the first morning (at any rate it was a lengthened toilet), from the admiration with which I paused and gazed upon the gently swelling hills, those lines of beauty; and although, since those days, I have looked upon the Grampians year after year, and gazed upon our lake mountains week after week, yet my first hill love is the strongest. I compare all hills with the Mendips. But, we are at Wrington, which is a kind of village metropolis to the surrounding district. Here was born John Locke the philosopher, and a tablet marks the spot, while a monument in the church perpetuates his memory. Nor is this the only literary honour of which Wrington has to boast, for close by lived for many years Hannah More, a good woman who did a noble work in her day and generation. There to the left was her residence, Barley Wood by name. Bishops, nobles, statesmen (among them good Mr. Wilberforce), clergymen, ladies innumerable here visited Mrs. More in her thatched-covered picturesque cottage.

We drive on, chatting pleasantly, albeit the dust is terrible;

I feel to be taking snuff upon compulsion every minute, and that not of the best kind. A pull on for two miles or so, and Aldwick Court is before us, standing on the spur of a hill pared flat to receive it. By the way, that small thatched cottage to our right was Hannah More's home before she grew rich enough to tenant Barley Wood. Pretty Cowslip Lodge! here the authoress planned many of her works, and, better still, carried out her plans. From yonder gate she sallied, with thick shoes on, to persuade the thicker heads of the poor to let her have their children on a Sunday to teach.

A little further on, a gate, a lodge to the left of it, a short avenue, then ivy-covered stables to the left, then a square of bright gravel, and we are in front of the pretty mansion, yeleft Aldwick Court. One side of the house looks up the valley and takes in a view of the sea, breaking on the coast at Weston, and on a clear day the Steep Holmes island is visible, and also the Welsh hills. The other side takes in the Mendip range. Behind is a thick wood, coming up to the very house without even a dividing fence. Sunny, airy, bright, pleasant Aldwick! and better than all, it has such an English-home look about it. To-morrow morning I am to see the renowned poultry, so let me enter the hospitable door in haste, for in half an hour dinner will be ready. The hall is filled with cases of stuffed birds and smaller animals, some in pairs, others in groups. Surely these and old oak furniture are a hall's best ornaments. I linger round the cases, noting this bird and that; I am then shown a painting in oils of the first Spanish cock possessed by Mr. Rodbard—his first prize-taker,<sup>C</sup> ancestor of a fine and fortunate race. The dressing-bell rings, and I obey its summons, and I more gladly obeyed the summons of that eating-and-drinking-inviting bell which rang twenty minutes later.

Dinner! how welcome after hours of dusty travelling—welcome cool dining-room, welcome the pleasant talk, and welcome Somersetshire eider. Now, during dinner, in spite of the fair ladies, in spite of interesting talk, in spite of the good pictures on the walls, in spite of all and everything, my eyes would wander to the sideboard, on which stood an almost innumerable host of silver cups of various sizes and shapes, not one alike. What was going to happen? Were the haymakers coming in to quaff eider from out of these cups? Was it the Queen's birthday? No. Was some hæcchanalian Somersetshire festival to be celebrated? Well, I knew not. I was sure in that well-bred household nothing wrong could occur—that was my comfort. But, oh! those cups. Time proceeded, the ladies retired, the cool claret was moistening my lips, but curiosity was uppermost, and I approached that glittering sideboard. "Whatever are these?" said I. "Only my poultry prizes," was the reply. "Poultry prizes! why here are the contents of a Milsom Street silversmith's shop!" I counted the prizes, they numbered about fifty. Silver salvers at the back, then cups of all kinds and grades—tall cups, short cups, slender cups, fat cups, plain cups, embossed cups, Grecian-shaped, Roman, mediæval, all shapes; cups with covers, tankard-like, cups without, and with inscriptions on each and all. Then there was a grand muffinier (that bird was not a muff that won it), also silver asparagus tongs, cream jug, and—and I know not what else. As the new servant girl, a very young one, said to her mother, after seeing the dinner-table laid out in the dining-room the first day of her service, "Lor me! mother, my eyes was right dazzled." Among the cups lay also, like nest eggs, a number of medals from Birmingham and other shows. Well, poultry fanciers, if successful, have something to exhibit to their friends worth showing.

After a pleasant evening stroll among the haymakers, and raising my eyes ever and anon to watch the shadows on the lovely Mendips, I retired to rest, and dreamed I was a Spanish don, with something odd about my ears, which were very white—then that a great number of medals were hung on my breast for distinguished service—then that I was keeping a silversmith's shop—then I was buying cases of stuffed birds—then I was reading Hannah More's "Life" and tracts—and then I dreamed that I was the real shepherd of Salisbury Plain—and then I awoke and found that I was the real—WILTSHIRE RECTOR.

(To be continued.)

## BELFAST POULTRY SHOW.

(From a Correspondent.)

THE above Show took place on the 6th and 7th inst. and met with more than usual success. The weather with the exception of a few

smart showers was all that could be desired. The Belfast Committee give a ten-guinea challenge cup to the exhibitor who obtains the greatest number of first prizes, the cup having to be won three years in succession before it becomes the property of the winner. This cup has proved such an inducement that it brought the best collection of poultry together that has ever been witnessed in Ireland. Last year the cup was won by Mr. Beldon, of Yorkshire, who beat Mr. Boyle of Dublin, by a single point, and the same two exhibitors again tried their strength this year, but the Yorkshireman proved too much for his opponent, being the winner by two points; but it certainly is highly creditable to Mr. Boyle when it is considered that he only exhibited fifteen pens to his opponent's twenty-five. Mr. Beldon has but to be once more successful to win the cup.

Of the various breeds first on the list came *Dorkings*, all the prizes going to Silver-Greys. The cock in the first-prize pen was a really fine bird. In Dorking chickens there was only a moderate display. In single Dorking cocks the quality was only moderate. Next came the *Spanish*. Here Mr. Beldon was an easy first with a pen shown in beautiful condition, and with fine pure faces; but they should have been larger. Mr. Boyle's third-prize pen, I thought, was much better than the second. In Spanish chickens Mr. Boyle was first with the best pen of youngsters that I have seen this season. In single Spanish cocks Mr. Beldon was again successful with a very fair specimen. In Spanish hens Mr. Boyle won with a really fine pair.

Next came the *Cochin-Chinns*, in which all colours competed together; the first prize went to a pen of Partridge-coloured, the second prize went to a middling pen of Buffs, the third went to a splendid pen of Whites. The *Drachmas* afforded another triumph to Mr. Boyle's yard, this gentleman winning both first prizes with splendid birds. His first-prize pen contained the best pair of hens I remember to have seen. The shape was equal to the best Cochins, and the pencilling the best I ever saw, the cock was a beautiful bird in size, purity of feather, and magnificent condition; the bird was perfection. Then came that beautiful variety the *Hamburghs*, these classes afforded easy triumphs for Mr. Beldon, that gentleman taking all the prizes. The *Game* was very indifferent; the class in my opinion did not contain a single good pen; the same may be said of the single cock class. In *Game Bantams* Mr. Boyle was first with a remarkably small pen. In *Bantams*, any other variety, Gold and Silver Sebrights took first and second. There were three classes of *Polands*; here again Mr. Beldon won the first in a very easy manner. There was also a class for the best six chickens for the table, Mr. R. P. Williams took first with *Dorkings*.

Next on the list came *Turkeys*; here Mr. Zurhorst was more fortunate, winning the first prize with large good birds. In *Geese* Mr. Boyle was unapproachable, winning first and second with birds of large size. In *Aylesbury Ducks* Mr. Boyle was first, hard pressed by Mr. Williams; the latter gentleman, however, made up for it in young *Aylesburys*.

**DORKING.**—First, F. H. Lewis, Nettlefield, Belfast. Second and Third, Col. Leslie, Glasslongh. Highly Commended, W. C. Seymour-Hill, Dunmory. **CHICKENS.**—First, W. C. Seymour-Hill. Second and Third, Col. Leslie. **COCK.**—First, J. Borthwick, Prospect, Carrickfergus, Second, F. H. Lewis. Highly Commended, R. P. Williams, Clontarf, Dublin. **HENS.**—First and Second, F. H. Lewis. Highly Commended, Col. Leslie.

**SPANISH.**—First, H. Beldon, Gilstead, Binsley, York. Second, C. E. McClintock. Third, R. W. Boyle, Galtrim House, Bray. Highly Commended, R. P. Williams. **CHICKENS.**—First, R. W. Boyle. Second, C. E. McClintock. Third, R. P. Williams. **COCK.**—First, H. Beldon. Second, R. W. Boyle. **HENS.**—First, R. W. Boyle. Second, F. Lewis.

**COCHIN-CHINA (Any colour).**—First, F. Lewis. Second, H. Beldon. Third and Highly Commended, F. W. Zurhorst, Belville, Donnybrook. **HENS.**—First and Second, F. Lewis. Highly Commended, F. W. Zurhorst.

**BRAHMA POOTRA.**—First and Third, R. W. Boyle. Second, H. Beldon. Highly Commended, H. Hawkins, Sydenham, Belfast. **HENS.**—First, R. W. Boyle. Second, F. Lewis.

**HAMBURGH (Silver-spangled).**—First and Second, H. Beldon. Third, R. W. Boyle. Highly Commended, F. Lewis.

**HAMBURGH (Silver-pencilled).**—First and Second, H. Beldon. Third, F. Lewis. Highly Commended, H. Hawkins.

**HAMBURGH (Golden-spangled).**—First and Second, H. Beldon. Third, F. Lewis.

**HAMBURGH (Golden-pencilled).**—First and Second, H. Beldon. Third and Commended, F. Lewis.

**GAME (Any colour).**—First, H. Beldon. Second, F. Lewis. Third, C. E. McClintock. Commended, C. Peacock.

**GAME (Single cock).**—First, C. Peacock. Second, H. Beldon. Commended, F. Lewis.

**GAME BANTAMS.**—First, R. W. Boyle. Second, H. Beldon. Commended, F. Lewis.

**BANTAMS (Any other breed).**—First and Second, F. Lewis.

**POLANDS (White-breasted).**—First, H. Beldon. Second, F. Lewis. Third, G. Martin, Glenview, Belfast.

**POLANDS (Silver-spangled).**—First and Highly Commended, H. Beldon. Second, F. Lewis. Third, R. P. Williams.

**POLANDS (Golden-spangled).**—First and Third, H. Beldon. Second, F. Lewis. Highly Commended, R. P. Williams.

**BEST SIX CHICKENS SUITABLE FOR THE TABLE.**—First, R. P. Williams. Second, C. E. McClintock.

**TURKEYS.**—First, F. W. Zurhorst. Second, R. Mehaffy.

**GEESE.**—First and Second, R. W. Boyle.

**DUCKS (Aylesbury).**—First, R. W. Boyle. Second, R. P. Williams. Third, J. Wilson.

**DUCKINGS (Aylesbury).**—First, R. P. Williams. Second, R. W. Boyle. Third, W. C. Seymour.

**DUCKS (Rouen).**—First, G. Martin. Second, R. W. Boyle. Third, H. Beldon. Commended, J. Dickson.

**DUCKINGS (Rouen).**—First, R. W. Boyle. Second, R. P. Williams.

The names of the Judges did not transpire.

[We are obliged to our correspondent for his communication; but we have omitted all the laudation and vituperation, because too apparently coming from friendly bias towards one of the exhibitors.—Eds.]

## BEE-HOUSE—APIARIAN'S VEIL.

ANSWERS to the following questions in THE JOURNAL OF HORTICULTURE will oblige. My bee-shed is 6 feet 8 inches high at back, and 5 feet in front, with a width of 5 feet from front to back, and 6 yards long. I want more room: will it be better to double the length of the shed, or have outer covers made for the hives? The latter will be by far the most expensive plan. My present shed is closed only at the back, and in hot weather I have an opening of a foot the whole length. If the shed be best, should there be any partition between the hives, such as a thin board on edge? What distance should there be between the hives? In the case of nucleus-boxes would it be desirable to place some distinguishing mark in front, say some decided colour, until the queen is fecundated? If my hives are all brought to one form there will be much sameness for returning bees. How do you prepare rags or paper for smoking bees? I have used brown paper steeped in a weak solution of saltpetre. Do you usually take advantage of a guard for the face? What is best! I do not care much about my hands, cats in gloves, &c. Hitherto I have used nothing. In looking for queens I want to have a clear vision.—E. B.

[We think you cannot do better than double the length of your present bee-house. At the same time it will be well to keep the hives as far apart as possible (say, if practicable, not less than 3 feet), and it will also be advisable to vary the appearance of neighbouring entrances as much as you can by diversifying them both in shape and colour. We do not deem it necessary to interpose any partition between the hives unless the bees themselves should prove it to be so by travelling from one hive to another. Whenever we find it convenient to use a little smoke we charge our fumigator with cellar fungus, and protect our face when necessary by means of a bag of black net, of a taper form, put on over the hat, and buttoned under the coat. Gloves we very seldom require, but photographer's indiarubber ones are by far the best.]

## FORMING STOCKS FROM CONDEMNED BEES.

A BEE-KEEPER in my neighbourhood who keeps to the old-fashioned mode of destroying the bees for the honey, has offered me the bees this autumn if I can take them by any other process, he being the recipient of the honey of course. Would you kindly tell me in your next impression how to go about it, whether, should I succeed, it would answer my purpose, and what food to give them during winter? I am thinking of building a house of my own after the fashion of a successful apiarian here, with boxes attached to one another, but with communications between them to allow of artificial swarming, &c., and supers or bell-glasses to each, &c. Can the bees be at once placed in them? They will be perfectly protected from frost and cold. Can the old combs be saved in the abstraction of honey, and will they be useful in the boxes? Or, again, had I better winter this lot in straw hives, and wait until the spring before I put them in the box-house? Whose is the best book for a bee-keeper who wants to study the art deeply?—W. C. D. *Calverton*.

[We drive condemned bees into common hives in the way described by Mr. Woodbury, in page 423, of Vol. V., bring them home in the same, and transfer them to frame-hives the next morning by knocking them out on the top of the exposed frames, having previously removed the crown-board and deepened the hive about an inch by a square frame of that depth and the same diameter as the hive laid on the top. This prevents crushing the bees when the crown-board is replaced, which should be done almost instantaneously after the cluster is knocked out and before it has time to spread. One or two more swarms should be added to each hive in the same way a few days afterwards, and the stocks fed\* up to from 16 lbs. to

\* Lump sugar and water in the proportion of 3 lbs. of sugar to 2 lbs. of water, is a cheap food and will answer the purpose.

20 lbs. nett weight each before winter sets in, at a cost of about 10s. to 12s. a-piece for sugar. Any portions of worker comb which are found empty and in good condition may, probably, be purchased for a trifle if not given to you, and will be a great assistance to the bees if attached to the bars in the way described in page 18, of the fifth edition of "Bee-keeping for the Many" (price 4d., or free by post from this office for five stamps). If the combs be new, all artificial supports may be removed within two days; if old, a day or two longer will be required. The best bee-house for one who wishes to study the subject deeply, is either a verandah or a similar construction built against a wall, either perfectly open or merely closed with pleasant wire (in which is a good-sized aperture opposite the entrance to each hive), in front, and with sufficient height and room to operate behind; whilst the best hives are those which have been named after Mr. Woodbury, and which are fully described in page 14 of the same edition, of "Bee-keeping for the Many." We prefer them made of straw, in which material Messrs. Neighbour, 149, Regent Street, and 127, Holborn, turn them out in first-rate style. These gentlemen will also supply you with Mr. Langstroth's book, which is the best work we are acquainted with for the purpose you require.]

### FERTILE WORKERS.

YOUR correspondent Mr. Wm. Carr need not be at all sceptical as to the existence of fertile workers, neither do I believe are they of such rare occurrence as our Editors would seem to suppose, having met with three separate instances this summer, and had them under my observation at the same time. I must say I rather entertain the idea that at certain seasons, and under particular circumstances, workers may be induced to become fertile as a matter of course, and I have no doubt that many cases of drone-production ascribed to virgin queens are all the while due to fertile workers.

The first case was that of a queenless stock presented me by a friend, and, on breaking it up, I discovered drone brood in worker cells, and in all stages of development, and which I have not a doubt was produced by workers. The other instances occurred in two of my earliest batch of nuclei—these failed to raise royal cells. In the one instance within a fortnight, before a queen could have been raised, or indeed ere the latest brood were much more than half matured, I was struck at noticing a good many eggs deposited in the cells, and rather hastily concluded that my assistant, to whom I had entrusted the peopling of the box, had stupidly run off the queen along with the workers at the out-lying apiary. A thorough search failed to show her, while a subsequent examination of the stock afforded ample proof of her most productive presence—whence the eggs? A subsequent minute examination not only revealed eggs in the cells, but many, even up to six, deposited in a single cell. By way of experiment I allowed matters to take their course, and the other day along with a most experienced apianian friend, took a survey of the box—found egg-laying going on and a good many drones at liberty; it was most interesting to note, that both the older blacks, as well as their more youthful Italian sisters, had alike the power to produce the males of their distinct varieties.

The brood in the other nucleus, above referred to, was all hatched out and yet no fertile workers. Feeling confident from what I had seen in the other case, that I had merely withheld the material to raise another monarch, and I could as it were compel them to become fertile, it was even so, and the drones have since been duly hatched.

I may here relate, as not altogether foreign to the subject, a curious coincidence which I met with in the early part of the present season—viz., the simultaneous issue in every flight of young bees from a stock possessing a black queen, not only attendance of her sable progeny, but a goodly proportion of splendidly marked Italians. There was no mistaking it, there they were rotating side by side on the landing-board, and commingling in their merry gambols, marking the site on their first flight of their common home. How could this be? I put forth my riddle to many apianian friends, and was not a little tickled at the many "guesses at truth" which came to hand.

To appreciate my riddle, I must go more into detail. The hive was a common straw one, a "second" of last season, from which I had expelled the black bees to make way for my old Devon queen and her train, after having been purified from foul brood through the double "purgatorial process." What

black brood existed in the hive at the transference was duly hatched, followed by lots of young Italians. Winter came; it was half over, when one day I had the mortification to find my valued monarch lying dead upon the landing-board. It was the 8th of March before I met with a spare black queen to take her place. In the interim, during mild days, when airing, the bees got into no agitation, as I had anticipated, on missing their queen. Pollen was carried liberally, and young Italians issued till I at last began to suppose, like Jonas Jackson, that I had taken a distended defunct worker for my valued monarch; this could not be, I knew her too well. By-and-by the offspring of the black queen emerged in abundance, invariably escorted in every instance by their glittering Italian sisters. I was non-plussed and sought advice.

A valued contributor of this Journal suggested a strain of Ligurian blood in the black queen. This could not be: her progeny in the stranger hive from which I removed her were, equally with her more youthful offspring, free from the slightest tinge, indeed as thoroughly black bees as I had ever seen. The "old-fashioned bee master" from whom I procured her prided himself on the blackness of his stock; besides, these fine-marked yellow jackets were emerging regularly before she was introduced. Another correspondent suggested they were late-bred bees, while I was sure they were fresh from the cell; and another was confident they were young Italians from an adjoining stock, or eggs carried from such—I know I saw them take their first flight; besides, unfortunately for me, I had no stock in my apiary capable of producing young bees at all up to the brilliancy of my old queens. I puzzled my correspondents—I equally puzzled myself.

Latterly, every other explanation failing, could it be possible they owed their origin to the existence of fertile workers? but then I was reminded they only produce males. Nature had endowed them with this power surely as a preliminary to a higher end, otherwise their drone-production could in no wise save their extinction. Might it not be that the long confinement of their queen had induced some of her progeny, as in the above cases, to become fertile, and on a par with virgin queens? that the performance of the maternal duties so far might incite the desire to go forth to seek the drones, who at that period abounded, thereby becoming converted into worker queens and save stocks so situated from impending ruin? In a spirit of rivalry might they not have risen in rebellion and destroyed the old queen, their new powers satisfactorily accounting for their strange quiescence? My pretty little theory was gradually abandoned with the decreasing numbers of the young Italians, till the new hypothesis was forced upon me as the only solution of the mystery, that the extreme fertility of my old queen had so far overshot the number of her followers, that she had dropped eggs into cells far in advance of their ability to attend to, that these had been preserved from chill by the genial warmth of the hive, and with the increasing temperature of the advancing season were gradually overtaken and hatched out.

Possibly some reader may be able to afford a clue to the better elucidation of what for many weeks proved to be one of the most singular and striking phenomena ever met with by—  
A RENFREWSHIRE BEE-KEEPER.

### EXPERIMENTING WITH LIGURIANS.

The following is extracted from the apianian journal of a clergyman in one of the northern counties of England:—

June 3rd.—Received a stock of Ligurians from the apiary of Mr. Woodbury. Took out all the frames in order to remove the strips of wood. Succeeded well until I came to the last frame, which slipped to the ground; soon re-adjusted without much damage; did not get a sting worth mentioning, and saw the queen. Saw a Ligurian on the alighting-board of uncomb hive dressing a young bee; both went into the hive quite pleasantly.

June 14th.—Beautiful hot day. Examined my Ligurian hive, and was much pleased to find that the bees had filled the two empty frames in a few days. Found the queen on the first frame I lifted out, and at once resolved to form an artificial swarm. I did so by putting two frames from the middle of the hive into the nucleus box. Removed Ligurian hive for fifteen minutes and put nucleus box in its place. At night placed nucleus box in apiary next to the Ligurian stock. They had been in the dark several hours. Supplied empty space in Ligurian by a brood comb from a Taylor's bar hive. It did not

seem to have much sealed brood, but there were several drone cells. Gross weight of Ligurian stock after the above operation, including floor-board, 36 lbs.

June 15th.—8 A.M.—Went to see my nucleus box place a yard from Ligurian stock. The bees did not seem in any hurry to leave the box, but, as I had feared, scarcely one of those leaving returned up to 1 P.M.; doubtless they would return to parent hive. Towards noon could see a difference in their conduct. The bees ran up to and touched each other, as if to communicate something. Could not resist a peep into the box, and found a busy scene. The bees were busy and had built four small pieces of comb. During the afternoon swept the bees from another brood comb into the nucleus box. Saw common drones in the Ligurian, probably from the comb put in yesterday. They had already begun to work well from the empty frame put in yesterday.

June 17th.—Hottest day we have had; temperature 80° in apiary. Examined nucleus, and hardly fancied there were sufficient bees. Could find no signs of preparation for a queen. Began to be dubious. Determined to add another brood comb. Found the queen on the sixth frame with eggs; remove her with a feather, and place comb in box. Also brush bees from another comb into box. Feel more comfortable after. This makes three frames taken from the Ligurian stock, besides the young bees swept from two other combs. Notwithstanding this rough treatment the Ligurian stock weighs 42 lbs.—viz., 6 lbs. increase in three days. Find the handling of frames rather delicate work, and calculated to make one nervous; the very slightest breathing excites the bees.

June 19th, Monday.—Ligurian stock 47 lbs.—viz., 11 lbs. increase in five days. Nucleus box, found two queen cells, but not yet sealed. They were on the frames first put in. This the sixth day. Felt some measure of satisfaction.

June 21st, Wednesday.—Nucleus-box: Put in a brood comb from a Taylor's bar, the result of an accident. How convenient these compound Woodbury frames are!

June 22nd, Thursday.—Nucleus-box: One queen-cell approaching completion; the other the same as before. The third frame, put in on the 17th, does not contain so many eggs as I had thought. Begin to doubt the desirability of putting in any fresh frames until full preparation had been made for the queen.

June 24th, Saturday.—Examine box, and find royal cell quite sealed and beautiful: only one, however, as no further progress has been made with the second. Form another nucleus-box. Commenced at 2 P.M., and found that I had this time caught a Tartar. Day rather gloomy, and a little wind from the north. The hive was one moving mass. For better light took the frames outside, and fancy the wind blowing on them must have excited them. Determine to proceed, although it is Saturday. Found my lady on the eighth frame, and felt thankful. All doubt about Ligurians stinging is now at an end, as I had half a dozen stings on my head and face. Put two well-filled frames in box No. 2; also a third frame with a little comb. Took a third frame from Ligurian stock beautifully filled with honey—5 lbs. Nett weight taken away, 10 lbs. Weight before operations, 52 lbs.—i.e., 16 lbs. increase in ten days, besides losing a brood-comb on the 17th. Weight after operation, 41 lbs.

June 25th, Sunday Evening.—Put box No. 2 in apiary, having had it in the dark since yesterday evening.

June 26th, Monday.—Ligurian, 43 lbs.

June 27th, Tuesday.—To my utter astonishment the Ligurians swarmed. Weight of swarm, 3 lbs. Weighed Ligurian stock at once, and found it to be 40 lbs.—i.e., just 3 lbs. lighter. Nucleus-box No. 1: Found a queen-cell on the comb last put in on the 17th. Tried bottle-feeder, made out of a pickle-jar, on box No. 2; answers well.

June 29th, Thursday.—Gross weight of Ligurian swarm, 20 lbs.

June 30th, Friday.—Examine box 1, and find the first queen-cell just vacated; the queen quite close to cell, and her wings not yet expanded well. Will there be piping? listened at night, but heard none. The other cell sealed sixteenth day. Ligurian stock, 42 lbs.

July 1st.—Got severely stung by Ligurians by removing cover too soon after unscrewing it. The hive had not been steady, so that they had been shaken. How interesting always to get stung on a Saturday!—nice preparation for Sunday! Box No. 1: Found second queen-cell empty; she must have been disposed of by her rival. For first time examined box No. 2. Three queen-cells sealed seventh day.

July 3rd, Monday.—Nucleus-box No. 2: Saw queen-cells all right.

July 4th, Tuesday.—Ligurian stock, 48 lbs.

July 5th, Wednesday.—Took about one-third of bees and frames, with one queen-cell, from Ligurian stock. Only one queen-cell left in the hive. Neither of them sealed eighth day from swarming. Examined natural swarm from Ligurian; found queen on the very last frame. Eighth day swarm weighed 26 lbs., as against 20 lbs. six days since. Took queen from a second east of black bees, with a view to putting in one of the sealed queens out of box No. 2. Put the captive queen, after much consideration, into the Taylor's bar-hive, which swarmed on Saturday last.

July 6th, Thursday.—Transferred a comb from the deprived hive to box No. 2, with a view to putting in a sealed queen. To my great grief and astonishment found all the cells open! only the twelfth day from the forming of the nucleus box: Cannot understand it. Thunderstorm with rain in the evening.

July 7th, Friday.—Dull rainy day for the most part.

July 8th, Saturday.—Morning dull, but bees flying much in the afternoon. The weather cooler, and do not deem it expedient to examine hives. Still feel anxious about my queen cells being open so soon. Query, Is it possible that the queen from box No. 1 can have mistaken her home, got into box No. 2, and rifled the queen cells? The boxes are exactly alike in all respects, and present the same outward appearance, but they are at least 3 yards asunder.—E. B.

[We never heard queens pipe in a nucleus, owing, probably, to no opposition being made under these circumstances to their destroying the remaining royal cells, which they proceed to do in an incredibly short time after they are themselves hatched. We consider one brood-comb \* sufficient in each nucleus box at first. When this has hatched out, and before the young queen has commenced egg-laying, then, and not till then, a second may be advantageously introduced. The population at the outset is usually far too scanty to cover more than one brood-comb properly. Superfluous royal cells should be utilised by being transferred to other nuclei on the ninth or tenth day, as they sometimes hatch out so early as the eleventh, although we have known them delayed until the twentieth day. The young black queen transferred on the 5th of July would, if unimpregnated, be very likely to return to her old hive, and would in this case at once destroy the inserted royal cell.]

#### FLOOR-BOARDS—FEEDING-HOLE.

THE floor-board three-quarter-inch thick, under a hive was firmly nailed to a pedestal. The floor-board is now beginning to warp and crack. When will be the best time to put a new one in the place of it? and how must I proceed? Would it be a good plan to cut a hole in the top of the hive through which to feed the bees with a bottle or pan in the autumn and spring, and to let out the moisture? If so, would it not be best done soon, and what size should the hole be?—A. R.

[Your new floor-board should be 1½-inch thick, and keyed to prevent warping. As soon as it is finished let some one raise the hive gently at dusk some cool evening and slip the new board under it. A hole of from 2 to 3 inches diameter for feeding, &c., may be cut at once.]

\* This brood-comb should, however, have either an empty comb or a honeycomb on each side of it.

#### OUR LETTER BOX.

AYLESBURY DUCKS (*J. C. Rose*).—We have made inquiries; and think that you will be quite safe in breeding from the Ducks, though one of the eleven has a dark patch of brown feathers, for this proves no more than that some generations ago there may have been a Honen cross. Do not breed from the Duck having the brown patch.

PAYNE'S COTTAGER'S HIVE (*M. A. Williamson*).—Your Payne's hive will not require the straw cap if stocked so late in the season as this. The hole in the top should be closed by laying on it the loose round straw mat, without interposing an adapter, which should be used only when a super is put on; the bees will fasten the cover in their own way. Bees frequently appear unwilling to work in glasses; there is, therefore, nothing extraordinary in one of your stocks refusing to do so. The glass should be taken off when seen to be filled, and the combs severed by means of a fine wire drawn across under the glass, or under the adapter if there be one. The bees may be got rid of in the manner described in our reply to "SQUIR" in page 40.

WEEKLY CALENDAR.

Day of Month.	Day of Week.	JULY 25—31, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.
			Day.	Night.	Mean.	Days.	m. h.	m. h.	m. h.	m. h.	Days.	m. h.

31	M	Flax flowers.	75.0	50.6	62.8	14	24 4	48 7	41 1	14 11	9	6 6	212

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 74.9°, and its night temperature 50.6°. The greatest heat was 92°, on the 25th, 1844; and the lowest cold, 35°, on the 30th, 1866. The greatest fall of rain was 1.30 inch.

PROPAGATING AND AFTER-MANAGEMENT OF BEDDING AND OTHER PLANTS.

(Continued from page 443.)

Fresine Herbstii I stated in my last article that it was likely to prove one of our very best bedding plants, but I must now retract what I said in its praise. It had

then all the appearance of being a really good plant for bedding purposes, and promised to far surpass the Amaranthus, but the excessively hot and dry weather we have had since has proved it to be quite unfit for the decoration of the flower garden. The beautiful crimson appearance it had in the spring has given place to a dirty brown, whilst the Amaranthus is one of the most beautiful objects we have here this season.

If managed in the following way the *Amaranthus melancholicus ruber* cannot fail to give every satisfaction. The seed should be sown about the third week in April on a moderate hotbed, and as soon as the young plants have made the second set of leaves, they should be pricked off into boxes filled with a good rich soil. They may be pricked out in the boxes nearly as thickly as they can stand together; then place them in a close frame for a few days, when they will soon emit fresh roots and start growing very freely. They should then have the benefit of all the air that can be given them for the purpose of hardening them off. By this time there will be spare frames, into which they should be pricked out; about 3 inches of good soil should be placed in these, and the plants should then be carefully turned out of the boxes, taking care to disentangle the roots without injury. The plants should then be pricked out into the frames about 2 or 3 inches apart. If there is plenty of partly decayed leaves at hand, put 6 or 8 inches of them into the bottom of the frames before putting the soil in. This will give a little heat to start them into growth. As each light is filled water with a fine rose and shut them up; they should be kept close for a few days, and if the weather is bright must be shaded. Syringe them every afternoon just before the sun is off the frames, and shut them up closely. Continue this treatment for ten days or a fortnight, by which time the plants will be well established, when they should be gradually hardened off, leaving the lights off them altogether about the third week in May. By the first week in June they will be sufficiently hardened and may be planted out where they are wanted. They should not be planted out earlier than the first week in June, unless the weather is very favourable and the situation where they are to be planted is a sheltered one.

Here a large bed of *Amaranthus*, with an edging of

*Viola cornuta*, is one of the finest objects I have ever seen; it lights up every bed near it, and, when seen at a distance, when the sun is shining on it, the effect is grand in the extreme. This Violet is perfectly hardy, and will, I think, prove one of the most useful plants for edging we have; it is of a shade of colour we are very short of amongst the numerous plants suitable for bedding purposes—it is a beautiful violet-shaded mauve. It flowers very freely all through the summer and autumn months—in fact it is seldom out of bloom summer or winter. In damp soils it grows very freely; it will, therefore, want frequently pegging down, and some of the young growths will have to be pinched out. The plants should be divided in the spring, and pricked out in beds; or they may be planted out at once around the margins of the beds where they are intended to remain during the following summer.

*Verbena Velvet Cushion*.—A large bed of this, edged with *Geranium Manglesii*, is truly a magnificent sight. This *Verbena* I consider one of the most beautiful plants we have for flower-garden decoration. It is a hybrid I succeeded in producing several years ago from the old *Verbena venosa*, crossed with some of the garden varieties. This was, I believe, the first hybrid *Verbena* ever so obtained from *venosa*. I was several years before I succeeded in ripening seed, and it took several years more to establish the plant. The first year it grew very weakly, and I had almost given up all hopes of ever having it sufficiently strong to propagate from, but now it grows with vigour. This has originated quite a new strain of *Verbenas*. I have them now in a great variety of colouring. Amongst the most beautiful of my last year's seedlings is one I have named *Scarlet Cushion*. This does not grow more than 5 or 6 inches high, and produces immense trusses of bright scarlet flowers, of wonderful substance for so small a plant.

These varieties will become great favourites with the public as soon as they become better known, and the treatment they require understood, as they are such small-growing plants. The soil most suitable for them is a very rich one. When the beds or borders in which they are to be planted are prepared in the spring, a thick coat of well-decomposed manure should be spread over the beds, which should be dug two spits deep, and the manure placed in the bottom. This will encourage the roots to go down in search of the manure. The sun does not then affect them; and, as they are free-rooting plants, it causes them to throw up a constant succession of young growths from the base of the plant all through the summer, and up to the latest period in the autumn. They do not trail along the ground like the garden varieties; neither do they emit roots as the young shoots come in contact with the ground. One of the greatest advantages which they have over the other varieties, is that they retain their perfect, symmetrical form all through the season; whereas the others, by their habit of rooting as each joint comes in contact with the ground, are constantly spreading further from where the plant was first planted, leaving the centre quite bare. This propensity of the plant for rambling occasions constant trouble, and the use of almost innumerable pegs, where a large quantity of *Verbenas* are grown. The *Cushion*

varieties, of which Velvet Cushion is the type, do not require any pegs, and very little trouble to keep them in order all through the season, if the beds have been well prepared for them before they are planted. Cuttings do not very easily strike in the autumn; some of the old plants should, therefore, be taken up early in autumn, and all the old summer shoots cut away, leaving nothing but the young growths that have been lately made by the plant. They should then be potted into large 60-pots, and placed in a frame where there is a gentle bottom heat; keep them close for ten days or so, until they have made fresh roots, and as soon as the roots have taken good hold of the soil, place the plants in a cooler frame, and encourage root-action as much as possible, so as to have the plants thoroughly established in their pots before they are placed in their winter quarters. It is, perhaps, the best plan to strike a lot of cuttings very late in the spring, and box them off, and let them remain in boxes till August, when they should be trimmed and potted as described above. In the spring they should be repotted, and placed in a genial atmosphere, where they will grow very freely. Fresh free-growing cuttings of these will then strike as freely as those of the commonest kinds of Verbenas.—J. WILLS.

(To be continued.)

### ASPECTS, AND THEIR INFLUENCE.

EVERY garden ought to be sheltered from exposed points of the compass by belts of trees at such a distance as to break the force of the winds, as well as protected by walls. I am aware that both these shelters are considered superfluous by some; but I know very well that the removal of trees does make vegetation later, and exposes it to the wind to such a degree that we are not able to view it after strong winds with that satisfaction which we always feel in the case of gardens protected by belts of trees and walls. "I am surprised to find how little damage had been done by the late high wind, which shook the buildings to their foundations!" is by no means an uncommon exclamation; "but the trees in the plantation are torn and battered, some have lost large arms, completely disfiguring them, others uprooted, &c." Hills and trees are Nature's shelters. The hills protect the valleys, the trees protect the shrubs, the shrubs the plants; the grass even shields the lovely Lilies, and the Fern the moss at its foot. "Trees create a confined atmosphere, harbour insects, and interfere with the growth of crops." Granted—what of the crops in a cold winter and spring? what of the fruit of trees in a windy season? Those who advocate open exposed situations for the growth of fruit and vegetable crops, only aim at cultivating the commoner kinds. I agree with them so far, but no farther. The plants which we chiefly cultivate in gardens are exotics, or, if not, are rendered so tender by improvement as to be equally or nearly as much in need of protection as if they were. More than this: we want crops early and late, we want to catch the sunbeams, and to retain them when we get them. In short, we want light, air, and warmth in gardens, but we want these without confinement, and equally without exposure. Shelter with openness is very different from shelter with overshadowing. Isolated trees, as hedgerow timber, are almost valueless, and are frequently situated where they will not give shelter but divert the force of the current in the direction of the point exposed. Were they planted in masses opposite the part sought to be sheltered it is certain they would serve the object in view, and become profitable after a while, which they rarely do when isolated. Besides, they are more ornamental in a mass, grow more rapidly, and consequently make a shelter sooner.

Few will deny that our climate is too cold for the majority of fruits to be grown in open situations; all agree that we need something to aid us in retaining the solar heat, and this, whatever it be, must absorb heat, and radiate it when the atmosphere becomes cold. Walls of brick have long been erected for this purpose, and they become heated sooner than stone, and also radiate the heat more rapidly. They have their evils, however, the chief one being that they do not constitute a sufficient protection against occasional severe spring frosts, and in very inclement seasons the fruit does not ripen well upon them. To remedy this defect glass coverings have been erected over the trees in some cases, and with good results, and latterly glass houses have been employed. I do not think that either walls, or glass houses without walls, fully answer the purpose for which they are intended, but both are good aids; the glass structure having the advantage over a wall in ripening

the fruit and wood during a wet season. A wall is certainly necessary to secure fruit of some kinds in our climate, whilst for others it must be covered with glass, or a glass house must be provided in order to have them in perfection, whilst some require not only glass structures, but artificial heat. It is foreign to my purpose, however, to enter into the merits of detached glass houses.

A garden walled all round, and having one face to any cardinal point, whatever it be, and all the others at right angles to it, will have four aspects—east, west, north, and south; it may also happen that the walls may not directly face any of the principal points of the compass, they may then be north-east, north-west, south-east, and south-west. I will take it for granted, however, that the position of the walls is met by one or other of the above cases, and will first deal with that in which the aspects are north, south, east, and west.

A south aspect is that wall on which, if you turn your back to it, the sun will be full in your face at twelve o'clock at noon. The other side of that wall is a north aspect, and so with an east and west aspect. An aspect is that side of a wall facing the point of the compass from which it derives its name.

The south wall or aspect receives the most light, absorbs the greatest heat, and is the best for the more tender fruit trees, and those required earlier than on aspects where they would otherwise do well. This wall is the only one suitable for Peaches, Nectarines, and also Apricots, to have them plentifully and with certainty. Apricots on east walls sometimes do fairly, but though the trees grow freely they are not to be depended on for a crop. A south wall enables the trees against it to ripen their fruit about a fortnight earlier than on an east wall. For earliness a tree or two of the early Cherries, as Early Purple Gean, and one or two of the May Duke, may be planted against south walls. For the same reason some early Plums may also be planted, as the *Précoce de Tours* now superseded by Early Favourite (Rivers), decidedly the best of the early Plums, July Green Gage or Reine Claude Hâtive, and Green Gage; likewise some of the early Pears, as *Doyenné d'Été*. Unless the walls are extensive it is not worth while occupying south walls with Pears, Plums, and Cherries. It is worthy of note that fruit grown on south walls is much earlier than that produced on any of the other aspects, and the juices being more highly elaborated the fruit is better flavoured though less juicy. The fruit on south walls comes in a fortnight earlier than that on east and west walls, and it is on this account that it is desirable to have fruit trees upon them that would do well on other aspects. Generally, however, south walls should be occupied by Peaches, Nectarines, Apricots, and Figs, which last are a precarious crop, and are best grown under glass. They do, however, sometimes bear well. Where there is much wall it is worthy of consideration whether a part might not be advantageously covered with glass on all the aspects, covering alike the wall and border, and growing bushes or pyramids in the borders, so that they may not interfere with the trees on the wall. There would not only be more fruit, but a larger continuance of it.

It is also worthy of consideration, whether we now make the most of walls—I mean devote them to that most likely to pay. For instance, a south wall 12 feet high, now exclusively devoted to Peaches, Nectarines, Apricots, and occasionally Figs (which is the greatest waste of space that I know of), might, together with from 12 to 18 feet of border, be covered with glass at a cost of £1 per foot run; and if planted with Vines would it not make an excellent and profitable viney, and be a good substantial structure equal to any used for horticultural purposes? Vines at 3 feet apart would certainly pay a good percentage for the outlay. If the length were 300 feet, 100 Vines might be planted, and they would be poor indeed if they did not each give £1 worth of Grapes after the second year, which, taking first cost and wear and tear into consideration, would be at least equal to 25 per cent. profit. Another part of the wall covered in like manner with glass for Peaches, Nectarines, and Figs, would surely pay, in consequence of something like double the amount of fruit being obtained from the space, besides being fully a fortnight earlier. I have seen this idea practically carried out, and with great results. The trees did quite as well on the wall as when exposed, and derived more fully its benefit, whilst the radiated heat was not lost as before in space, but expended on the trees that occupied the border.

Glass coverings applied to the other walls would simply make an east wall suitable for Apricots, Plums, and Cherries; the west being used for the same, for those Pears that are so liable to crack through the humidity and cold of our climate,

and for the better kinds of Apples. There is a great advantage in these lean-to houses with walls—viz., that the fruit on the walls comes into use earlier than that on trees in the borders. I am certain that covering walls with glass is one of the very best systems that can be adopted in any garden, in order to ensure certainty of crop, earliness, and the cultivation of fruits that do not ripen well on open walls. I am equally certain that such coverings need not be constructed as a matter of necessity; for the fruit trees which I have mentioned for south walls, and shall name for the other aspects, have been, and can be, successfully grown on walls now as in days of yore. There should, however, be some limit as to latitude and elevation: I may, therefore, observe that these remarks are based on observations made between 52° and 54° of north latitude.

To resume. A south wall receives and absorbs the greatest amount of heat, it is, consequently, the warmest. Fruits ripened on it are sweeter, more sugary, of whatever description they may be, including those that grow on the other aspects—as Plums, Cherries, Pears, and bush fruit as Currants and Gooseberries. The heat absorbed by day is radiated during the night, and a thermometer with its bulb exposed towards the wall indicates a temperature of from 6° to 10° higher than one in the open ground at the same distance from the ground. I have found that the blossoms (never so tender as the young fruit), are uninjured by 6° of frost when unprotected on a south wall. In addition to this, the ground and air for some distance in front of the wall are warmer than in an open situation, and the crop close by it is a fortnight earlier, whilst that on the rest of the border for a distance equal to the height of the wall is earlier by ten days.

The evils of a south wall, like the benefits, are great. The bricks absorb the sun's heat so rapidly as to become quite warm during winter, and this warmth excites the bloom-buds to swell and flower too early in the spring, and there is then a danger of the fruit suffering from spring frosts: hence it has been found necessary to protect the trees with nets, branches of trees, &c., by day, to prevent the bloom-buds swelling during any bright weather that may happen in early spring; and after the blooms expand to protect them at night from frost until the foliage becomes large enough to shield the fruit, or until frosts are past. The first of these evils—namely, the too early swelling of the bloom-buds, may be prevented to a considerable extent by having wires to train the trees to at about 1½ inch from the wall, this being the only form of trellis to be recommended. When fastened to the wall with shreds and nails the trees are literally roasted at noon, the buds swell much too early in spring, and the nailing destroys the face of the wall in a few years. Another evil is, that the wall is exceedingly hot in summer, but the heat is lessened, however, and does no great harm when the trees cover the wall. The bricks, too, are continually absorbing and giving out moisture. In dry weather they rob the trees of moisture, for they have a greater absorbing power than the leaves, and attacks of red spider are encouraged, whilst in wet weather they add to the wetness by remaining saturated, consequently we have attacks of mildew. Bricks absorb heat and moisture more rapidly than stone does. A dry brick will take up a pint of water, and be apparently dry, whilst from the surface of stone moisture hangs in drops. Bricks, I may remark, do not heat so quickly when covered with moss as when the surface is clean, and stone is influenced in a like manner. I may state that Peaches against a brick wall are some days earlier in ripening than against a stone wall, and Apricots are earlier still. Sometimes walls are painted with boiling coal tar, which closes the pores of the bricks, renders the wall hotter, and prevents the absorption of moisture. I cannot affirm that any benefit arises from this, from a coating of tar painted white or stone colour when dry, nor from whitewashing. There may be, but I have not experienced any difference worth mention. There cannot be a doubt that washing walls with lime, soot, and sulphur, mixed to the consistency of paint with boiling stale urine, destroys the eggs of insects. I have always been puzzled to find that Peach trees are the most infested with insects at the lower parts of the walls, whilst at the upper part they are free, not through the season, but at the first attacks. Green fly and red spider always begin at the lower branches, and extend upwards. Thus I have often noticed that the dwarfs were severely attacked, whilst the standards or riders were free, and this more especially for the first three or four years after planting.

East walls are chiefly employed for Cherries and Plums. In some instances I have known Apricots answer pretty fairly, but they are not to be depended upon. Cherries succeed fairly on

east walls, better even than on western aspects. With regard to Plums I cannot say that they do well on east walls, but fairly, though not so well as on a west wall. Pears, too, do not do so well on this as on a western aspect.

A west wall is the second best aspect, and should be planted with Pears, for they are liable to set badly on an east wall, when east winds prevail in spring, and they swell much better, and are never so gritty on a west aspect. Plums also succeed well. A west wall is never so much subjected to the injurious effects of the elements as an east wall. The air is often very cold and dry from the east, blights the trees, and does much mischief to the leaves, especially when these are young; but the west wall, on the contrary, is shielded from these evils, is warmer, and the wind it receives is more mild and humid. The trees are not so liable to have the bloom injured in spring by cutting winds and the insects which these bring. The only objection which I have to advance against west walls is, that the winds from that quarter are the strongest, and unless protected or sheltered by trees at a distance, the fruit is apt to be seriously bruised or blown off.

East and west walls are not acted on by solar heat to the same extent as south walls, consequently there is little danger of the buds being excited too early in spring, and the blossom being injured by spring frosts, against which the wall is usually sufficient protection. The two aspects are about equal as regards the crops on the borders; but the east, being the drier, is usually employed for herbs, and is, if anything, the earlier. The west border is certainly better adapted for Turnips, Lettuces, and the like. The earliness of all the borders is best tested by growing on all some of the same kind of crop. I found Keens' Seedling Strawberries were gathered on a south border on the 15th of June; on an east one on the 24th; on a west on the 28th; and on a north on the 16th of July. I also found that May Queen was gathered on the 28th of May on a south border, not further from the wall than 7 feet; Black Prince in a similar position on the 10th of June; and Keens' Seedling on the 15th of June. I also found Keens' Seedling in a bed 10 feet from a south wall was ripe on the 21st of June. Ash-leaved Kidney Potatoes close to a south wall were ready for use on the 1st of June, at 1 foot from the wall on the 10th, and at 10 feet from it on the 21st. Peas, again, sown on the 10th of November, at 3 feet from a south wall, were fit for table on the 7th, at 8 feet from the wall on the 18th, and sown at the same time on an east and west border on the 28th of June, and 2nd of July respectively, whilst those on a north border did not come in until July 18th. With these facts before us, and many more that might be adduced, it is evident that walls have a protective and retarding power. Walls may not shelter a garden, but they make some part of it warmer, and break the force of the wind.

North walls are the worst of all aspects for the growth of fruit. Morello Cherries, Currants, and Gooseberries, are the fruits which succeed best upon them. I have seen north walls planted with Plums, Cherries, Pears, and Apples, but the fruit of the first was scanty, and that of the last two scantier still, Cherries doing the best, and forming a good succession to those on the other aspects. I have known Morello Cherries kept until a very late period, and Currants matted up until the fall of the leaf. For retarding Broccoli in early summer, and Turnips to come in with forced Carrots, to have Strawberries late, and Currants and Gooseberries when those on the other aspects are over, and for retarding many other crops, north walls and borders are of great value. The most remarkable fact which I know in connection with north walls is, that if a Pear tree be planted on the south side and trained over the top and down the northern side, it will bear fruit equally well on the north as on the southern aspect. I have known Plums treated in the same manner, and with the same results, the fruit being some days later in ripening, and I have been told of the same result taking place in the case of an Apricot, but it did not come under my own observation.

Now as to the other aspects. A north-east aspect would grow Cherries, Currants, and Gooseberries; the north-west, Pears of the hardier kinds, but not so well as a west wall; the south-east, Plums and Apricots; and the south-west, Peaches and Nectarines, but the more choice Pears much better. If there is any necessity for houses for Peaches and Nectarines, these aspects not being good enough, houses are the sure road to success.

It seems to me, apart from all points not commercial, a pity to cover any part of a garden wall with glass. I say this guardedly. Where there is no obstacle in the way to the crea-

tion of detached houses for the growth of fruit it seems an error of judgment to cover the wall with glass. I think that glass houses should be erected for those fruits that do not ripen well on walls; and if they are not sufficiently warm through solar heat, heat them artificially without any hesitation. Let everything be done in order that success may be certain if proper care and attention be exercised. Grow on walls such fruits as do well, and those that do but indifferently as standards, bushes, and pyramids, in the open exposed ground. Where expense is everything, then covering a wall with glass would be the best plan to adopt. This would answer the purpose in a cold climate; but it would be a pity, for there is no finer sight in a garden than walls of Peaches covered with blossom in spring and loaded with fruit in autumn, or a Pear wall covered with a carpet of leaves throughout the summer, and hung with large handsome fruit in autumn. Covered walls never afford so agreeable a promenade as a large detached house, or, if they did, the pleasure of breathing the fresh air and viewing the trees on the walls is gone. If we are to be, and I suppose must be, modernised in our notions, let us not adopt half-measures.

I am persuaded that those who have gardens, whether proprietors or those in charge, would confer a benefit on themselves and offer a great stimulus to fruit culture if they were to keep a register of the fruit trees in cool houses or those without artificial heat, on walls, and in the open ground, beginning 1st, with the soil; 2nd, description of tree and how trained—bush, pyramid, or standard; 3rd, age of trees where practicable; 4th, time of flowering, noting whether injured or not by frost; 5th, the time of the fruit being ripe—Pears, when gathered and fit for table, and the same of Apples, with the continuance of their season; 6th, size, obtained by measuring round the middle of the fruit and also round by the eye and stalk, also weight of a single fruit, and half a dozen of a fair sample. If grown on walls, the aspect and other particulars should be named, and the whole tabulated like a meteorological table, there being a column for general remarks not coming within the range of the separate headings. It would add much to the value of the observations if the highest and lowest daily temperature were registered with the rainfall and hygrometrical condition of the atmosphere. I think these observations would be highly interesting and valuable to all growers of fruit, and the mutual exchange of observations could not fail to be of considerable advantage. A few shillings annual subscription would be all that would be needed to carry the project into effect—to defray the expenses of forms and the publication of annual reports. I have already done a little in this way, and gleaned a few facts which memory fails to furnish when wanted accurately and promptly.—G. ANNEY.

## THE BEDDING-OUT IN KENSINGTON GARDENS AND HYDE PARK.

KENSINGTON PALACE is an irregular pile, chiefly built by William III., but considerably altered and enlarged by succeeding monarchs. The structure is composed of brick, and the principal division inclines in shape towards a square, and shows three fronts on the garden side. The offices attached to the main building are very extensive. Only the south front is favoured with flower-beds, which are planted in the following order in pairs to match at each side of a broad walk leading up to the Palace. The first, third, fifth, and seventh are planted alike with three rows of *Stella Geranium* in the centre, then two rows of *Flower of the Day Geranium*, then a row of *Lobelia speciosa*, edged with *Gnaphalium lanatum*. The second bed, a circle, is planted with *Christine Geranium* in the centre, then blue *Lobelia*, edged with *Cerastium tomentosum*. The fourth, also a circle, is planted with *Madame Vaucher Geranium* in the centre, then blue *Lobelia*, edged with *Cerastium tomentosum*; and the sixth bed the same as the second.

When I say that the Palace has no hall or front door, and that the walk is at the end of the portion of lawn devoted to flowers, I am sure that this will appear incongruous to the eye of taste. The ribbon-border is composed of *Lady Plymouth* and blue *Lobelia* alternately, then *Jenny Lind Heliotropes*, *Perilla nankinensis*, a row of *Flower of the Day Geranium*, and yellow *Calceolaria* planted alternately in the row, then a row of *Punch Geranium*, and then a row of white *Feverfew*, backed by *Monkshood* and *Chrysanthemums*. On the west side, in front of the offices, the beds around the square piece of lawn look gay, but there seems a want of balance and some-

thing of a framework to separate it from the broad expanse of the park scenery.

Having passed along the broad avenue of Elms we enter what is called the Long Walk on the south side of Kensington Gardens; it is planted ribbon-fashion with an edging of *Stachys lanata*, then a yellow *Calceolaria*, said to be received from Hampton Court, then *Punch Geranium*, then *Ageratum mexicanum*, backed with shrubs. It is an improvement upon the planting of last year, and looking along the rows you are led to expect that it is well filled, but during your progress you are surprised to find that every plant is 18 inches apart in the rows. When you reach the end of the walk bear a little to the left leaving the bridge that spans the Serpentine on your right, and there, on a gradual slope, stands a low, Ivy-clad, castellated lodge, the residence of the foreman, with a semicircular grass plat in front, not surpassed for its floral beauty and retired scenery of wood and water by any other place with which I am acquainted. The small plot is furnished with five circles of different sizes—the largest, in the middle, planted with *Cloth of Gold*, two with *Christine Geranium*, two with *Madame Vaucher Geranium*; and a band surrounds the half circle composed of eight rows of different plants, and eleven or twelve No. 1 pots, filled with plants in flower, set on the grass and walk. There are, besides, two stages, 8 or 10 feet high, filled with plants in pots against what may be called the Ivy-clad wings of this pigmy castle. Much taste is displayed in the arrangement of the colours in the pots and beds, and it is a scene well worthy of a visit.

The gardens are three miles and a half in circumference, and contain a circular basin called the Round Pond, near the Palace, with three straight avenues diverging to three different points eastward. Two main gravel walks, each half a mile long and 21 yards wide, intersect these beautiful gardens from north-west to south-east with a broad circumferential and other gravel walks communicating with different parts of these thickly wooded and extensive landscape scenes. Nature in the undulations of the ground, and Art in the hands of the landscape gardener, have contributed to their beauty by presenting to the spectator distant views through long vistas of stately trees, and the Serpentine river winding through the valley. Placed near the city's western extremity, between its two principal thoroughfares, which here approximate so closely as almost to embrace it, and from which it is just sufficiently separated to protect it from the annoyance attendant upon a too close approximation to a great highway, and approached through the parks and its own grounds by beautiful walks it is a spot visited by all for its own sake, and to which we would with pride and pleasure conduct the footsteps of a stranger. The air of tranquillity which reigns around the spot itself, embraced as it is within the circle of the most populous capital in Europe, is almost marvellous. The trees in some parts of the grounds have been planted in masses of a sort, in other parts they are gathered into thick groves of mixed kinds, and intersect by long avenues from different points. An Elm tree that I measured was 151 feet, a Horse-Chestnut 127 feet, a Hornbeam 7 feet 8 inches, and a Spanish Chestnut 18 feet 8 inches in girth 3 feet from the ground. On a narrow strip of ground, about 150 yards long, running parallel with Rotten Row from Hyde Park Corner, I noticed some mounds and clumps that have lately been made and planted there. It is the first instalment of an improvement which I hope to see extended along the now-neglected site of the ever-memorable Exhibition of 1851.

From Stanhope Gate to Grosvenor Gate, beside Park Lane, the beds and borders are planted in the following order:—1st bed: centre, *Stella Geranium*, then *Purple King Verbena*. The opposite bed: centre, *Commander-in-Chief Geranium*, with two rings of variegated *Mint* and blue *Lobelia* planted triangularly. 2nd bed: centre, *Christine Geranium*, then *White Ivy-leaved Geranium*. Opposite bed: centre, *Commander-in-Chief Geranium*, then *Purple King Verbena*. 3rd bed: centre, *Trentham Rose Geranium*, then *Mangles' Variegated Geranium*. Opposite bed: centre, *Punch Geranium*, then *Purple King Verbena*. 4th bed: centre, *Tom Thumb Geranium*, then *Flower of the Day Geranium*. Opposite bed: *Tom Thumb Geranium* centre, then *Purple King Verbena*. 5th bed: centre, *Stella Geranium*, then *Madame Vaucher Geranium*. Opposite bed: centre, *Prince of Orange Calceolaria*, then *Verbena Purple King*. 6th bed: centre, *Stella Geranium*, then *Bijou Geranium*. Opposite bed: centre, yellow *Calceolaria*, then *Purple King Verbena*. 7th bed, centre, *Tom Thumb Geranium*, then *Madame Vaucher Geranium*. Opposite bed: centre, *Horseshoe Geranium*, then *Purple King Verbena*. 8th bed: centre, *Tren-*

tham Rose Geranium, then Flower of the Day Geranium. Opposite bed: centre, Stella Geranium, then Purple King Verbena. 9th bed: centre, Christine Geranium, then Ivy-leaved White Geranium. Opposite bed: centre, Commander-in-Chief Geranium, then Purple King Verbena. 10th bed: centre, Tom Thumb Geranium, then Purple King Verbena. Opposite bed: centre, Commander-in-Chief Geranium, then two rings of variegated Mint and blue Lobelia planted triangularly. All the beds are edged with two rings of *Cerastium tomentosum*.

The next compartment contains a ribbon-border at each side, planted with two rows of *Tropaeolum lobbianum elegans*, then *Heliotrope Jenny Lind*, Punch Geranium, then white Feverfew, backed with shrubs. Opposite: an edging of variegated Mint, then Purple King Verbena, Punch Geranium, yellow *Calceolaria*, then *Perilla mankinensis*, backed by shrubs. The next compartment from the Oak tree is planted with *Tropaeolum lobbianum elegans*, then scarlet Geranium, backed with *Ageratum*. Opposite: Robinson's *Deliance* Verbena and variegated Mint alternately, then Stella Geranium, *Ageratum*, and *Perilla*, backed by *Aucubas*. The next compartment is also planted ribbon-style with *Gazania splendens* as edging, then Madame Vaucher Geranium, then Stella Geranium, Bijou Geranium, and *Perilla*. Opposite side: two rows of Purple King Verbena and Mint triangularly, then Tom Thumb Geranium, then Flower of the Day Geranium, then *Perilla*, backed by shrubs. The last compartment is composed of two rows of variegated Mint and *Lobelia speciosa* triangularly, four rows of Christine Geranium, backed by white Feverfew. Facing the park is a long ribbon-border, planted with an edging of variegated Mint, two rows of Purple King Verbena, two rows of yellow *Calceolaria*, and a row of *Perilla mankinensis*, backed by *Aucuba japonica*. It is a splendid ribbon-border, forming a gentle slope from the back to the front.

From Grosvenor Gate to the Marble Arch is a long piece of pleasure ground laid out in beds (pairs to match at each side of the walk), on grass. The first is planted with *Colerus Verschaffelti*, edged with *Centurea candidissima*; circular beds with Christine Geranium alone, also beds of Madame Vaucher Geranium, then circle beds of Cloth of Gold Geranium, then a pair of beds of *Centurea candidissima*.

In the shrubberies north and south in Kensington Gardens are large iron labels stuck in front of the trees and shrubs, with the botanic and English names thus:—

RHES BANGUENEA,  
A blood-coloured flowered Currant.  
A Grossulariaceous Shrub,  
Native of North America.  
Introduced 1826.

The late Mr. London suggested the advantages of naming the trees and shrubs, and also of removing the wall on the north boundary of Kensington Gardens. After years of perseverance he lived to see his suggestions carried into execution, and to be universally admitted as improvements. To attach labels with the names to the bedded-out plants would be a boon to the public; it would also save nurserymen from the trouble of guessing the names of plants described by customers who have seen them in the parks. Five pounds would cover all the expense of so doing, a very small item out of the £24,774 allowed for St. James's, Green, and Hyde Parks, and £5956 for Kensington Gardens. Very great credit is due to the Hon. Wm. Cowper, Chief Commissioner of the Woods and Forests, for the many improvements that have been made in the parks—the people's parks—and for which the many thousands that enjoy them feel grateful.—W. KEANE.

#### HEATED VINE-BORDERS.

The question of heated Vine-borders has lately often been discussed in my hearing, and I have taken every opportunity of forming a correct opinion on the subject, except building a vinery with borders artificially warmed. Where the subsoil is cold and wet it is easy to see the advantage of an open chamber under a Vine-border, whether heated or not; but on warm and dry soils it is not so easy to perceive the advantage. The expense of making a chamber and putting pipes under it is considerable, and we ought to be quite sure of the advantage to be gained before such expense is incurred. I have seen magnificent crops of Grapes on Vines grown in warm borders, and I think quite as good on those growing in unheated ones; the latter I have fancied were better flavoured and less inclined to turn into raisins. This may only be a fancy of mine, but

we want to hear from those who have tried both plans. The question appears to me to be this—on a warm dry soil does a Vine-border covered with litter early in autumn get so cold during winter and early spring as to be unfit to afford nourishment to growing Vines? If this can be proved to be generally the case, which I much doubt, I would put another question—Is the heating by artificial means of a soil intended to grow Vines the best and cheapest mode of keeping such a soil at a proper temperature? Before answering this question I think the effect produced by covering a large surface of ground with glass ought to be investigated. I have a house, 100 feet by 24, kept warm all summer and most of the winter for the growth of Vines in pots; under the floor of this house is a large soft-water cistern, and though of course the rain caught during winter and melted snow are cold enough, I believe water was never pumped out for use during the coldest weather at less than 70°. How can a large surface of land covered by a hothouse get cold? Suppose vineries were built 30 feet wide and the trees planted inside, would their roots not be warm enough? A house for trees as bushes may be too wide, because if they are planted thickly they shade each other, but for Vines trained under the roof this is no objection. The best flavoured black Grapes I tasted last season were so grown in a house without fire heat.—J. R. PEARSON, *Chilwell, Notts.*

#### CUCUMBERS OUT OF DOORS.

We believe in warm situations the best plan to grow Cucumbers out of doors is to sow them in the open ground about the end of May, and then thin out as you would a row of Turnips, leaving 6 or 7 feet from row to row. The huge baskets of short Cucumbers and Gherkins that find their way from Sandy and Biggleswade to the London market, are thus managed. The plants receive one or two stoppings, and sometimes none at all, and the gathering continues until the cold nights come in the autumn. Though the Cucumbers look somewhat rough and gnarly, they are very sweet and crisp when cut young, when so managed. In such circumstances the plants do much better to be sown where they are to grow, than when raised in heat, hardened off, and then transplanted, as they are apt to show the effects of the codling.

The next best plan, and necessary in cold places, is to make a slight hotbed, by making a hole sufficient to hold two or three barrowloads of hot dung, placing the earth on it in a mound, bevelled down, and then sowing half a dozen seeds on each mound close together, and thinning out to three or four plants afterwards. If these can have a hand-light placed over them it will be all the better, giving air as soon as the plants are up; and as soon as the plants are large enough to run beyond the glass, tilt the glass up on four bricks, four pieces of turf, or four lumps of soil. The glass will keep the collars of the plant from heavy rains, and thus save them from gangrene. Many dispense with the glasses altogether after June, but in wet districts we deem them useful for the above purpose. In all such cases, the Cucumbers will thrive better if the vines are stopped, and the laterals stopped back, and not too many fruit allowed to remain, just as those in frames are generally managed. Where grown on a large scale in a field, the constant gathering renders such care less necessary, as the gathering every other morning or so prevents the plant being exhausted prematurely.

Even in cold places we have grown Cucumbers very successfully, and long kinds, too, by training them to a couple of stems against a wall or paling facing the south. In this case a hole was dug, a little hot manure given, and fresh rich soil added to the natural soil; good strong plants were brought from a cold pit. These plants had the point nipped out at the third rough leaf. Two shoots were allowed to come, all others were nipped out, and these shoots were trained up the fence about 2 feet apart, and were not stopped until they were from 3 to 4 feet in length, or sometimes longer, the object being to have a strong plant before the Cucumbers appeared. After stopping almost every side shoot would then fruit at the second and third joint, these side shoots were stopped the joint beyond the fruit, and thinning the fruit and this stopping was almost all that was required, with good warm waterings in hot weather, to insure continuous bearing until the weather got too cold. Protected thus by a fence the plants will bear longer than when on the ground in the open air. This will be especially the case if a mat or a piece of calico is suspended over the plant during a cold night. Beds in the open air will also continue bearing longer

if the lateral shoots are kept thin, and the bed is covered with flat red tiles placed firmly on the ground. We prefer the common red, as having a medium capacity for the absorption, and the radiation of heat. Painting the tiles in summer with sulphur paint, made of sulphur water and a little soft soap, will keep off mildew and red spider.—R. F.

### ROYAL HORTICULTURAL SOCIETY'S FRUIT AND VEGETABLE SHOW.—JULY 22.

ALTHOUGH the classes in which competition was invited were very numerous, the number of exhibitors in each was rather small; the show consequently was not so extensive as the amount offered in prizes ought to have brought forth; and of the productions themselves it may be stated that whilst on the one hand they offered no extraordinary excellence, they did not on the other exhibit any considerable falling off from an average degree of merit. The attendance of visitors, although the day was fine, was very small.

Only one collection of fruit was exhibited, by Mr. Carr, gardener to P. L. Hinds, Esq., Byfleet Lodge. It consisted of a Queen Pine, Tegg's Scarlet-fleshed Melon, Sweetwater Grapes, Moorpark Apricots, Gooseberries, and fruit of *Musa Cavendishii*, and the Papaw. Pines were not numerous; Mr. Young, gardener to Crawshay Bailey, Esq., Aberdare, sent two fine Queens, an Enville, and Black Jamaica; Mr. Standish, eight well grown fruit; and Mr. W. Thomson, gardener to the Duke of Buccleuch, Dalkeith Palace, a very fine Enville, Lord John Manners, and a Smooth Cayenne. A Providence of 11 lbs. 4 ozs. came from Mr. Allen, gardener to J. B. Glegg, Esq., Withington Hall, and excellent Queens from Mr. Grant, Finchley, and Mr. Young. The only two prizes given in the class for any sort went to excellent Envilles from Mr. Thomson and Mr. Young.

Awards.—For three kinds: First, Mr. Young; second, Mr. W. Thomson; third, Mr. Standish. For Providence: First, Mr. Allen. For Queens: First, Mr. A. Grant; second, Mr. Young; third, Mr. M. Higgs, gardener to Mrs. Barchard, Putney Heath. For Any sort: First, Mr. W. Thomson; second, Mr. Young.

Only two collections of Grapes were brought forward. That from Mr. Hill, gardener to R. Sneyd, Esq., Keele Hall, consisted of very good Black Hamburgs, Black Prince, not equal to what he usually brings; Black Alicante (Meredith's); Royal Muscadine; Lady Downe's, very good; Buckland Sweetwater, finely ripened; excellent bunches of Ingram's Hardy Prolific Muscat, and Black Morocco, under the name of Horsforth Seedling. The other competitor had Black Hamburg, Canon Hall, and Muscat of Alexandria. Of Black Hamburg excellent bunches, with large well-coloured berries, came from Mr. Sage, Mr. M. Henderson, and Mr. Wallis; and Mr. Brown, gardener to the Earl of Chesterfield, and Mr. Cruickshank, gardener to W. J. Loyd, Esq., Watford, also sent good bunches. Other Black Grapes consisted of Muscat Hamburg, from Mr. Osborne, Finchley; Mill Hill Hamburg, with fine large berries, but reddish in colour, as this variety is apt to come, from Mr. M. Henderson; excellent Black Prince, from Mr. Hill, the three bunches weighing 7 lbs. 12 ozs.; Trentham Black, very good, weight 4 lbs. 2 ozs., from Mr. Wallis; and Black Frontignan from Mr. Squibbs.

Muscats as usual were generally too green, but those from Mr. Sage were beautifully ripened. Mr. Tyler sent very large bunches of Bowood Muscat, weight 9 lbs. 3 ozs.; and fine bunches came from Mr. Standish. Of Canon Hall good bunches were shown by Mr. Budd, gardener to Earl Darnley, Cobham Hall; whilst Golden Hamburg was also well represented. Duchess of Buccleuch, a variety raised by Mr. W. Thomson, Dalkeith, and possessing a Muscat flavour, was also shown.

Awards.—For a collection: First, Mr. Hill; second, withheld; third, Mr. Tansley, gardener to Mr. Moss, Chadwell Heath.

For Black Hamburgs: First, Mr. Sage, gardener to Earl Brownlow, Ashridge; second, Mr. M. Henderson, gardener to Sir G. Beaumont, Bart., Cole Orton Hall; third, Mr. Wallis, gardener to J. Dixon, Esq., Astle Park, Congleton.

For Muscat Hamburg: First, Mr. G. Osborne.

For Mill Hill Hamburg: First, Mr. M. Henderson.

For Black, any kind: First, Mr. Hill; second, Mr. Wallis; equal third, Mr. Squibbs and Mr. Brown.

For Muscats: Equal first, Mr. Sage and Mr. Tyler; second, Mr. Standish; third, Mr. Tansley.

For Canon Hall: First, Mr. Budd.

For White, any kind: First, Mr. W. Thomson; equal second, Mr. Beasley and Mr. Cross; third, Mr. Busby.

Peaches were not numerous, but we remarked some beautiful dishes of Grosse Mignonne, Bellegarde, and Violette Hative; also a seedling from Mr. Ingram, very beautiful in colour, rich orange yellow where shaded, dark crimson next the sun; fruit rather small, and with a shallow suture. Of Nectarines but few dishes were shown, and of these the best were Elrage and Violette Hative.

Awards.—For Peaches, two dishes: First, Mr. Tillery, gardener to the Duke of Portland, Welbeck; second, Mr. Osborne; third, Mr. Bain and Mr. H. Whiting. For single dish: First, Mr. Tillery and Mr. Wallis; second, Mr. Osborne; third, Mr. W. Lane, gardener to J. Miles, Esq., Fryern, Barnet. For Nectarines: First, Mr. Sage;

second, Mr. Lane; third, Mr. Rogerson, gardener to E. Brown, Esq., Acton, and Mr. Tillery.

In Figs an excellent dish of Brown Turkey, from Mr. Whiting, The Deepdene, had a first prize; the same kind, from Mr. Rogerson, was second; and White Marsilles, from Mr. Cross, gardener to the Dowager Lady Ashburton, Romsey, had a first prize in the White class.

Cherries consisted of very good dishes of Morello, from Mr. Marcham, Mr. Squibbs, and others; Black Tartarian, very fine, from Mr. Whiting; Florence, from Mr. Higgs; Bigarreau Napoleon, from Mr. Tillery; Elton, and May Duke.

Awards.—For Black: First, Mr. Marcham. For White: First, Mr. Cruickshanks; second, Mr. Higgs; third, Mr. M. Henderson. For a single dish: First, Mr. Tillery and Mr. J. B. Whiting; second, Mr. R. Marcham; third, Mr. Squibbs.

Of Plums only a few dishes were shown. Mr. Squibbs was first with Black Morocco; Mr. Beasley, gardener to T. Wood, Esq., Acton, second; Mr. Whiting third.

At this late period of the season Strawberries could not be expected in quantity. The only exhibitor in the class for four dishes was Mr. Tillery, who had a first prize for Empress Eugénie, Welbeck Seedling, Rifleman, and Frogmore Pine. Mr. Earley, gardener to F. Pryor, Esq., Digswell, had a second prize for Elton; and a third was awarded to Mr. Phipps.

Of other subjects, some good Gooseberries were shown by Mr. Carr, and Mr. Young, gardener to B. Barclay, Esq., Highgate; some of those from the former were very large. The first prize was awarded to Mr. Carr, the second to Mr. Young.

Of Currants, Red, White, and Black, excellent dishes were shown by Mr. Carr, Mr. Ford, gardener to W. Hubbard, Esq., Horsham, and Mr. Beasley, Twyford Abbey, who had prizes in the order in which they are named. Raspberries were chiefly confined to the Fastoff; Mr. Moffat, gardener to Viscount Maynard, was first, and Mr. Clarke, gardener to Colonel Long, second, both exhibiting that kind. In Green-fleshed Melons the first prize went to Mr. Wright, gardener to the Earl of Normanton, Kingwood, for Sir John Sebright's, and the second to Mr. Squibbs, for Hybrid Perfection, prettily netted. In Scarlet-fleshed Windsor Prize from Mr. Weir, gardener to Mrs. Hodgson, Hampstead, took the first prize. Mr. Standish exhibited Vines in pots, each bearing from five to nine good bunches; the kinds were Black Hamburg, Golden Lady Downe's, and two seedlings, one from Chasselas Musqué, but with black berries, and the other called Citronelle, a white kind. Mr. Fraser, Lea Bridge Road, sent orchard-house trees; Mr. Carr, Peaches; and Mr. Rogerson, Figs in pots; Mr. Carr, fruit of the long Mango Papaw, somewhat resembling Vegetable Marrow, green changing to yellow; some good Apricots came from Mr. Whiting and others; Apples from Mr. Young; Muscat Champion Grape, an excellent variety, raised by Mr. Melville, Dalmeny Park, from Canon Hall and Muscat Hamburg, from Mr. Veitch; an excellent basket of Golden Hamburg Grapes from Mr. Cross, and a very good one of Black Hamburg from Mr. M. Henderson.

#### VEGETABLES.

The show of vegetables had a much better appearance on this occasion than such shows usually present; and most classes of vegetables were well represented.

In collections of not less than eight kinds, Mr. Budd, gardener to Earl Darnley, was first with Globe Artichokes, Parsley, Onions, Veitch's Perfection Peas, Kidney and Broad Beans, Dawe's Kidney Potatoes, Cabbage, Vegetable Marrows, Cabbage Lettuce, Cucumbers, Mushrooms, Beet and Carrots. Mr. Earley, Digswell, was second; and Mr. Whiting and Mr. Exell, gardener to Mrs. Sweetlove, third. A good collection also came from Mr. Veitch.

In collections of not less than six kinds, Mr. Exell, gardener to J. Hollingsworth, Esq., Maidstone, was first with Carrots, Potatoes, Broad and Kidney Beans, Peas, Onions, Lettuce, Globe Artichokes, Rhubarb, Cabbage, Herbs, and Horseradish; Mr. Hill, Highgate, was second.

For four kinds of Peas, Messrs. Hooper & Co., Covent Garden, were first with Hooper's Incomparable, King of Marrows, Veitch's Perfection, and Imperial Wonder, with beautifully filled pods; Mr. Veitch, second, with Veitch's Perfection, Mammoth Dwarf Green Marrow, Early Emperor, and Nonpareil Wrinkled Marrow. The best single dish was Veitch's Perfection, from Mr. Carr.

Of Potatoes, both Kidney and Round, excellent, sound, clean tubers were shown by most of the exhibitors. For four kinds of Kidney, Mr. Whiting was first with Sutton's Early Racehorse, Rivers's Royal Ashleaf, Jackson's Ashleaf, and Eugénie, white flushed with red. Mr. Moffat, gardener to Viscount Maynard, was second. In Round kinds, Mr. Whiting was again first, with Napoleon, Early Shaw, Palmahoy, and a large kind unknown. The best twelve Kidneys were Edgcott Second Early, from Mr. Neale; the best twelve Round, Transell's Seedling, from Mr. Moffat.

Among Carrots some beautiful roots of the Intermediate were sent by Mr. Exell, gardener to Mrs. Sweetlove; also good Early Short Horn, from Mr. Exell, gardener to J. Hollingsworth, Esq., and Mr. Whiting. Turnips, Beet, Shallots, Onions, Cabbage, Cauliflowers, Lettuces, Kidney and Broad Beans, were also well represented; and there were exhibitions of Rhubarb, Mushrooms, Celery, but small; Pot herbs; a collection of different forms of Vegetable Marrows, from Mr. Veitch, and of edible Gourds, from Mr. Young, Highgate. For

The prizes awarded to the above subjects we must refer the reader to our advertising columns.

Hollyhocks were again exhibited by Messrs. Paul & Son, and Downie and Co., the former also sending out *Roses* and *Phloxes*; Mr. Clarke, Brixton, likewise contributed *Roses*; whilst Messrs. Cubb's fine *Liliums* also remained, the whole forming a tolerably good floral display.

### THE BIRMINGHAM ROSE SHOW.

The fourth of these interesting gatherings took place on Thursday and Friday the 6th and 7th inst. at the Town Hall; and in every point of view, except the financial one, it was a decided success. The entries were numerous—much more so than last year—and the quality of the floral display fully realised the expectations which we ventured to indulge respecting it. In the opinion of the most competent authorities, professional as well as amateur, it was quite equal to the best of the metropolitan shows. Every rosarian knows how trying has been the present season, more especially the heat of the last few weeks, to his favourites; and, taking the weather into account, the blooms generally, both in substance and colour, were surprisingly good. As a matter of course, those varieties which are the most deficient in the former property suffered the most. The arrangements, too, were praiseworthy; the ornamental-foliaged plants and garden ornaments being so disposed as to produce an admirable effect. The elements, however, were unpropitious; and if anything could demonstrate the strength of the allegiance to the queen of flowers which pervades the community in and around Birmingham, it assuredly was the considerable muster of visitors whose zeal to render her "suit and service" was not to be overcome by the almost incessant rain which fell throughout Thursday.

One of the features on this occasion was the quantity of new *Roses* in many of the collections, where they were better represented than in the divisions which were exclusively devoted to them. At their head we should, without scruple, place *Maréchal Niel*, which deservedly attracted much attention. It was sent out during the past spring; and is said to be one of the hardiest of the *Noisettes*, and a free bloomer. Of a rich golden yellow colour, with stout petals, and fine contour, it is altogether a splendid flower, bidding fair to supersede *Cloth of Gold*. It was seen to great advantage in the stand with which Messrs. Paul & Son took first honours for ninety-six varieties, which also contained *François Louvat*, crimson, shaded with lilac, hardy in constitution, and a free bloomer; *Leopold Premier*, a bright deep red, large and double; *Eugene Verdier*, a rich violet, large, full, globular, a strong grower, and not liable to "burn" as some of the dark-coloured kinds; *Lælia*, silvery shaded, a fine double *Rose*; *Lord Herbert*, bright rosy carmine; *Senateur Favre*, a deep crimson, grand in shape, with a thick petal; and *Emotion*, a large white, beautifully tinted with rose colour. This, although catalogued as a Bourbon, is, we understand, a cross between a Hybrid Perpetual and a Bourbon, and the exhibitors propose that, with others of the same origin, it shall be relegated to a distinct class, to be denominated Hybrid Bourbons. Among later acquisitions, the most noteworthy were *Alphonse Damaizin*, a weak grower, which, under favourable conditions, is magnificent; *Maréchal Vaillant*; *Pierre Notting*; *Duc de Rohan*; *Général Jacqueminot*; and *Madame Victor Verdier*. The following is the entire list:—

Anna de Diesbach, Madame William Paul, General Bissen, Maurice Bernardin, Louise de Savoie, Triomphe de Caen, Queen Victoria, Madame Boutin, Virginal, Lord Clyde, La Ville de St. Denis, Lord Herbert, Lamarque, Senateur Vaise, Baronne Gonella, Lord Raglan, President, Alphonse Damaizin, Madame William Paul, Eugene Verdier, Emotion, Madame Furtado, Souvenir d'Elise, Madame Valembourg, Madame Victor Verdier, Niphètes, Alphonse Karr, Maxine, La Duchesse de Morny, Comtesse de Kergolay, Victor Verdier, Narcisse, Alfred de Rougemont, La Rhone, Madame de Cambacères, Clement Marot, Maréchal Niel, Louis Van Houtte, Princess Mary of Cambridge, Paul de la Moilleray, Madame Willermoz, Rev. H. Donbrain, Comte de Nanteuil, Olivier Delhomme, Celine Forestier, Maréchal Souchet, (Damaizin), Madame Freeman, Paul Desgraud, Souvenir d'un Ami, Lælia, Mlle. Emain, Madame Caillat, Devoniensis, Modèle de Perfection, Triomphe de Rennes, Bernard Palissy, Alpaide de Rotalier, La Fontaine, Laurent Descourt, Senateur Favre, Gloire de Dijon, Louise Odier, Louise Darzins, Turenne, Duc de Magenta, Monte Christo, Duchesse d'Orleans, Pœury d'Orleans, Madame Rivers, Leopold Premier, Comte de Paris, Baronne A. de Rothschild, Madame H. Jaquin, Beauty of Waltham, Impératrice Eugénie, Pierre Notting, Souvenir de la Malmaison, François Lacharme, La Reine, Maréchal Vaillant, Comtesse de Chabillant, Mrs. Charles Wood, Solfaterre, Madame Julie Daran, Madame Pauline Labouté, John Hopper, Charles Lefebvre, Allia Rosa, André Leroy d'Angers, Sœur des Anges, Duc de Rohan, Madame Vidot, François Louvat, Madame Boll, Marquise de Foucault. In the excellent stand of Mr. Keynes the best specimens were America, a fine yellow *Noisette*; Jamie d'Or, a large hardy yellow, full and globular in form; Victor Vigier; Madame Charles Wood; Lord Herbert; Docteur Spitzer, a bright red, and symmetrically-built flower; Centifolia Rosa; Gloire de Vitry; Alfred de Rougemont; Baronne de Rothschild; Paul Desgraud; Prince Henri de Pays Bas; and Abbé Reymond. In Mr. Cranston's collection were fine examples of Lord Raglan; Souvenir de la Malmaison;

Maréchal Souchet; Madame Charles Crapelet; Senateur Vaise; and Madame Pauline Villet.

Awards.—Ninety-six varieties, single trusses (Nurserymen):—First, Messrs. Paul & Sons, Cheshunt; second, Mr. J. Keynes, Salisbury; third, Mr. John Cranston, Hereford; fourth, Messrs. F. & A. Dickson, Chester.

Among the nurserymen who showed forty-eight varieties (three trusses), Mr. Keynes took the lead, with a collection in which the most prominent items were Louise Peyromy, Charles Lefebvre, Louise Margottin, Gloire de Vitry, La Phœcène, Baronne Gonella, Duchesse de Morny, and John Standish. We insert the names of all the *Roses* in this stand:—Maurice Bernardin, Comtesse de Chabillant, Gloire de Vitry, Senateur Vaise, John Standish, Madame Vignerot, La Ville de St. Denis, Laurent Descourt, Madame Charles Wood, Clement Marot, Triomphe de Rennes, Paire de Terre Noir, La Brillante, Centifolia Rosa, Sœur des Anges, Baronne Pelletan de Kinkelin, Duc de Rohan, John Hopper, Duchesse de Morny, Baronne Adolphe de Rothschild, Louis Van Houtte, François Lacharme, Baronne Gonella, Monsieur de Montigny, Celine Forestier, Gloire de Santenay, General Jacqueminot, Comtesse Onvaroff, Alpaide de Rotalier, Souvenir de Charles Montault, Maréchal Vaillant, Lays, La Reine, La Phœcène, Devoniensis, Madame Furtado, Anna de Diesbach, Victor Verdier, Gloire de Dijon, Louise Margottin, Belle de Bourg-la-Reine, Alfred de Rougemont, Prince Henri de Pays Bas, Mademoiselle Bonnaire, Souvenir de la Malmaison, Beauty of Waltham, Charles Lefebvre, Louis Peyromy. The second prize went to Messrs. Paul & Son, of whose collection we may specify Maréchal Niel; Leopold Premier; Baronne Adolphe de Rothschild; Souvenir d'Elise Vardon, a white, with a yellowish centre, and one of the finest Tea varieties in cultivation; Celine Forestier, the best hardy yellow, perhaps, with the exception of Maréchal Neil; Arles Dufour, a most desirable dark purple; and Madame Emain, one of the Hybrid Bourbons to which we have already referred.

Awards.—First, Mr. Keynes; second, Messrs. Paul & Son.

For stands of twenty-four varieties (three trusses), Mr. Keynes again stood first, with superior blooms of John Standish, Duc de Rohan, Gloire de Vitry, François Lacharme, Prince Henri de Pays Bas, and Beauty of Waltham. Of Mr. Cranston's stand, we may particularly note Duc de Rohan, Souvenir de Malmaison, Gloire de Dijon, Comtesse de Chabillant, and Charles Lefebvre. The premiums for stands of twenty-four singles were smartly contested, Mr. Keynes being first with, among others, La Reine, Virginal, Lord Macaulay, Pœury d'Orleans, a noble reddish-purple imbricated flower. In Mr. Batley's collection were Anguste Mic, Madame Pierson, Mlle. Bonnaire, and Mère de St. Louis, which seems to be replacing Virginal.

Awards.—Twenty-four varieties, three trusses:—First, Mr. J. Keynes; second, Mr. J. Cranston; third, Mr. G. Batley, Rugby; fourth, Mr. R. Smith, Worcester. Twenty-four varieties, single trusses:—First, Mr. J. Keynes; second, Mr. G. Batley; third, Mr. R. H. Vertegans, Edgbaston; fourth, Mr. T. W. Condy.

In the classes limited to nurserymen resident in the counties of Warwick, Stafford, and Worcester, the contributions were highly creditable to the growers. Among the best flowers were *Deuil de Prince Albert*, Madame William Paul—a purplish crimson and a first-class *Rose*, Comtesse de Chabillant, Senateur Vaise, and Madame Damaizin. Messrs. Perkins showed *Souvenir de Charles Montault*, Madame Furtado, Madame W. Paul, Madame Victor Verdier, Joseph Fiala, Gloire de Dijon, Docteur Spitzer, Madame Caillat, President Lincoln, Charles Lefebvre, Prince Camille de Rohan, John Hopper, Beauty of Waltham, Madame Vidot, General Washington, Victor Verdier, Senateur Reveil, Comtesse de Chabillant, Jean Bart, Madame Boll, Louis XIV., Lælia, Deuil de Prince Albert, Mlle. Bonnaire. In the stand of Mr. Hewitt, which obtained the first prize for twelve varieties, three trusses each, the most commendable were Comtesse de Chabillant, Madame Charles Wood, General Washington, Général Jacqueminot, La Reine, and Madame Vidot; and in that of Mr. Vertegans, who was second, John Hopper, Triomphe d'Angers (a lovely carmine), Charles Lefebvre, and Prince Camille de Rohan.

Awards.—Twenty-four varieties, single trusses:—First, Messrs. T. Perkins & Sons, Coventry; second, Mr. J. Parker, Rugby; third, Mr. G. Batley; fourth, Mr. T. Hewitt, Solihull; extra, Mr. R. H. Vertegans. Twelve varieties, three trusses:—First Mr. T. Hewitt; second, Mr. R. H. Vertegans; third, Mr. J. Parker; fourth, Messrs. T. Perkins & Sons.

The Amateurs mustered in great force, and the competition for precedence was very strongly maintained. The awards are appended; and we select from the principal exhibits the blooms most worthy of mention.

Forty-eight varieties.—Rev. S. R. Hole:—André Desportes, which resembles in style Victor Verdier; Triomphe de Rennes, which was better on the second day than the first, having developed more fully in the interval; Souvenir d'un Ami (very fine); Gloire de Santenay; and Prince Camille de Rohan. Mr. Evans showed Anna de Diesbach, Comtesse de Chabillant, and Vicomte Vigier. Mr. Hole's stand contained—John Hopper, Turenne, Alphonse Karr, Gloire de Santenay, Victor Verdier, Princess of Wales, Madame Vidot, Prince Camille de Rohan, Sophie de Coquerelle, Madame Furtado, Gloire de Dijon, Le Rhone, Caroline de Sausal, Maurice Bernardin, Coupe d'Hebe, Olivier Delhomme, Madame Bravy, Louise Magnan, Celine Forestier, Jules Margottin, General Washington, Madame C. Wood, Gloire de Vitry,

Wilhelm Pfitzer, Duchesse d'Orleans, Souvenir d'un Ami, Professor Koch, Pierre Notting, Auguste Mié, Maréchal Vaillant, Baronne de Heckeren, Charles Lefebvre, Triomphe de Rennes, François Lacharme, Lælia, Robert Fortune, America, La Brillante, Rubens, Baron Gonella, Senateur Vaisse, Vicomte Vigier, Devonicensis, Comtesse Cecile de Chabillant, Madame Clemence Joigneaux, André Desportes, Madame Charles Craplet. Of the twenty-four varieties, the finest were—Rev. S. R. Hole:—Gloire de Vitry, Souvenir de Comte Cavour, Gloire de Dijon, Juno, John Hopper. Mr. Hunt:—Baron Gonella, Comte de Nanteuil, Madame Craplet. Eighteens (three trusses), Mr. Evans:—Niphotos, Madame Victor Verdier, and Queen Victoria. The stands of Mr. Perry were of uniform merit, though it was evident the show would have suited him better had it been held earlier in the season. Through a mistake, Mr. Brown, of Elmton, had entered eighteen single trusses for this section, and although they were necessarily disqualified, they deserved and received great commendation. Twenty-four varieties, single trusses, open only to amateurs resident within fifteen miles of Birmingham. The Rev. P. M. Smythe:—Victor Verdier, Charles Lefebvre, Maréchal Vaillant, Madame Knorr, François Lacharme. The flowers in this stand were—Comte de Nanteuil, Baronne de Heckeren, Triomphe de Rennes, Maréchal Vaillant, Vanqueur de Gohiab, Maurice Bernardin, Anna de Diesbach, Madame Knorr, Charles Lefebvre, Céline Forestier, Louis XIV., Baronne Gonella, Jules Margottin, Beauty of Waltham, Acadie, L'Eblouissante, Madame Clemence Joigneaux, Louis Margottin, John Hopper, François Lacharme, Victor Verdier, Senateur Vaisse, Vicomte Vigier. Mr. Brown showed Gloire de Santenay, (very fine); and Coupe d'Hébé. Twelve varieties—single trusses, open to amateurs within fifteen miles of Birmingham—Mr. Brown:—Madame Caillat, (fine); Gloire de Santenay, Louise Maguan, and La Reine, (fine). Rev. P. M. Smyth:—Anna de Diesbach, Vicomte Vigier, and Baron de Noirmont. Mr. Brown's stand contained—La Reine, General Jacqueminot, Comtesse de Chabillant, Duchess of Norfolk, Madame Vidot, Beauty of Waltham, Anna de Diesbach, Gloire de Santenay, Louise Maguan, Madame Caillat, Triomphe de Rennes, Senateur Vaisse.

Awards.—Forty-eight varieties, single trusses: First, Rev. S. R. Hole, Newark; second, Mr. S. Evans, Arbury, Nuneaton; third, Mr. C. J. Perry, Castle Bromwich.

Twenty-four varieties, single trusses: First, Rev. S. R. Hole; second, Mr. Ebenezer Hunt, Leicester; third, Mr. E. Sage, Gopsall Hall, Atherton; equal fourth, Rev. P. M. Smythe, Solihull, and Mr. S. Evans, Arbury, Nuneaton.

Eighteen varieties, three trusses: First, Mr. S. Evans; second, Mr. C. J. Perry, Castle Bromwich; third, Mr. E. Hunt.

Twelve varieties, single trusses: First, Mr. E. Hunt; second, Rev. S. R. Hole, Newark; third, Mr. E. Sage; fourth, Rev. P. M. Smythe, Solihull.

Twenty-four varieties, single trusses (open to amateurs resident within fifteen miles of Birmingham only): First, Rev. P. M. Smythe, Solihull; second, Mr. William Brown, Elmton Hall, near Birmingham; third, Mr. C. J. Perry, Castle Bromwich; fourth, Robert Garnett, Esq., Moore Hall, Sutton Coldfield.

Twelve varieties, single trusses (open to amateurs within fifteen miles of Birmingham): First, Mr. W. Brown; second, Rev. P. M. Smythe; third, Mr. C. J. Perry; fourth, Robert Garnett, Esq.; extra, Mr. T. B. Wright, Perry Barr, and Mr. John Moor, Sparkhill.

No class was more satisfactory than the contributions of amateurs resident within four miles of Stephenson Place, Birmingham, as it afforded an illustration of the extent to which Rose cultivation is spreading in the neighbourhood, and the judgment by which it is directed. The stands, as a whole, would have been excellent for any locality, but they were still more extraordinary when it is remembered that some which took prizes (as for instance those of Mr. Field) were grown at Balsall Heath. In the first-prize stand of Mr. Cooper was the magnificent Tea-scented variety, Madame Willermoz, a white with salmon-coloured centre. It also comprised—Gloire de Dijon, Le Rhone, Madame Willermoz, Jules Margottin, Comtesse de Chabillant, La Reine, Général Jacqueminot, François Lacharme, Madame Vidot, La Ville de St. Denis, Louise de Savoie, Madame H. Jaquin. In the successful collections for six varieties, Mr. Cooper had La Ville de St. Denis, and Queen Victoria; Mr. Mapplebeck, Senateur Vaisse, La Reine, Madame Wm. Paul, and John Hopper; Mr. Sansome, Céline Forestier and Gloire de Dijon; and Mr. Lloyd, Mlle. Bonnaire, Duchess of Orleans, and Senateur Vaisse.

Awards.—Twelve varieties, single trusses: First, Mr. C. Cooper, Mosely Wake Green; second, Mr. G. Dymond, King's Heath; third, Mr. E. W. Field, Balsall Heath; fourth, Mr. G. Sansome, Moseley; extra, Mr. W. B. Mapplebeck, Woodfield, Moseley.

Six varieties, single trusses: First, Mr. C. Cooper; second, Mr. W. B. Mapplebeck; third, Mr. G. T. Sansome, Moseley; fourth, Mr. John Moore, gardener to Thomas Lloyd, Esq., Sparkhill.

The offer of special premiums for Moss Roses brought only a small collection of very moderate pretensions, the single award being given to Messrs. Paul & Son, for the subjoined collection, of which Cristata, a good white Perpetual with a cluster of buds, was the most conspicuous:—Cellina, Gloire des Mousses, Bath White, Cristata, Baronne de Wassanac, Perpetual White, Prolific, Aristide, Captain Ingram, Hortense Vernet, and Eugène de Savoie.

The new Roses were as usual interesting; but owing to most of the imported ones being over they did not include many of the present year.

The stand of twenty-four varieties with which Mr. Keynes gained the first prize included the following varieties:—Souvenir de Charles Montault, Madame Victor Verdier, La Phocenne, Sœur des Anges, George Prince, Lord Herbert, Paul Desgrand, Joseph Fiala, Alfred de Rougemont, Laurent Deseourt, Leopold Premier, Vicomtesse Douglas, Centifolia Rosea, Prince Henri de Pays Bas, Baron Adolphe de Rothschild, Alphonse Bélin, Claude Million, Docteur Spitzer, Alpaide de Rotalier, Bernard Pallissy, Madame de Stella, Pierre Notting, Duchesse de Morny, Louise van Houtte. Souvenir de Charles Montault is a vivid and showy garden flower; and both Paul Desgrand, a dazzling red variety, and Centifolia Rosea, a bright clear rose, will no doubt be seen to better effect in a less dry season. Sœur des Anges is a had opener, but fine when it does open. George Prince is a good-shaped, free-blooming, and effective Rose; and Lord Herbert has gained for itself a good character this season. Pierre Notting, a blackish red with a violet tint, and Vicomtesse Douglas, a lilac, are both fine; while Docteur Spitzer presents a distinct shade of crimson, and is good in form. The following were included in the collection of Messrs. Paul & Son, who were second:—Louis van Houtte, Duchesse de Morny, Madame de Stella, Eugène Verdier, Madame Freeman, Baron Pelletan de Kinkelin, Emotion, Lord Macaulay, Jaune d'Or, Bernard Pallissy, Pavillon de Pregny, Claude Million, Alpaide de Rotalier, Madame Valenbourg, Duchesse de Caylus, Alphonse Bélin, Alla Rosea, Triomphe de Villecermes, Lord Clyde, Maréchal Niel, Madame Boutin, Senateur Revel, Seeding No. 11, Leopold Premier. Of Maréchal Niel we have already spoken in terms of eulogy. Alba Rosea, with a rose centre, full and fine in form, is a splendid Tea-scented sort, useful for pot culture; and Claude Million, a deep dark vermilion, is also pleasing. Duchesse de Caylus, a vivid carmine, introduced during the present year, is a vigorous grower and excellent in form. Jaune d'Or, as its name imports, is an addition to the yellows; and Duchesse de Morny, a clear rose colour, with silvery under petals, though a little thin, may be expected to take a prominent position; and Pavillon de Pregny, a dark violet crimson, with white under petals, is very distinct. Mr. Batley of Rugby was third; Messrs. Perkins fourth.

The first prize for six trusses of a new Rose sent out in 1863-4 or 5 was adjudged to Mr. Keynes, for six blooms of Prince Henri de Pays Bas, a very bright crimson, full and globular in form, and Duchesse de Morny; the second to Mr. Cranston, for Madame Boutin; and the third to Messrs. Paul & Son, for Madame Victor Verdier, a vivid carmine, and reckoned one of the finest Roses of last year.

The designs for dinner table decorations formed a new feature; and we hope in future years to see a considerable increase in the number of competitors. Those sent on this occasion were arranged with admirable taste. The bouquets were an improvement on what we have hitherto seen, but did not quite come up to our expectations.

Awards.—Best basket or vase of Roses and Rose foliage: First, Miss Cole, Birchfields; second, Mr. Evans, Arbury; third, Mr. Parker, Rugby; extra, Mr. R. H. Vertegans.

Best bouquets for the hand, entirely of Roses and Rose foliage: First, Mr. J. Cranston, Hereford; second, Mr. J. Parker, Rugby; third, Mr. R. H. Vertegans; fourth, Messrs. Paul & Son.

Best design for dinner-table decoration (open to ladies only). Roses to be the only flowers used. Foliage not restricted to that of Roses, but left to the taste of the designer. First, Mrs. Brewer, Broad Street; second, Miss Cole; extra, Miss Garnett, Moor Hall, Sutton.

A number of ornamental plants for the decoration of the Hall were kindly lent by Mr. E. Wright, Mr. Bent, and Mr. Joh Cole; and, in addition, Mr. E. W. Field, of Balsall Heath, lent a very praiseworthy stand of Verbenas, for which no other reward was available than the favourable notice they obtained. The decorations were arranged by Mr. Cole and Mr. Tye, and were all that the most fastidious could desire.—(Midland Counties Herald.)

## DICKSON'S "FIRST AND BEST" PEA.

WITH reference to our new early Pea First and Best, it is due to the numerous friends who last season spoke so highly of it in their published testimonials, as well as to ourselves, that we should endeavour to remove the incorrect impression regarding its character, which Messrs. A. Henderson & Co., of Pine Apple Place, London, have unwittingly created by their published report on the new early Peas.

We obtained our First and Best Pea some six years ago from a gardener in this neighbourhood, and in successive trials season after season we found it some days earlier than the earliest known Pea. In 1863 we grew it extensively for the purpose of sale, but afterwards hesitated to send it out until we had subjected it to a scrutinising and decisive trial. We therefore sent a package to some fifty of the leading gardeners and others throughout the country, and from all of these the most unequivocal testimonies to its earliness and excellence were received, many of which were published in our seed catalogue for the current year. These testimonies were so satisfactory and decisive, that we resolved to send it out last spring, but as the seed had been held over a year, for the reason

before stated, this circumstance will to a great extent account for its not having exhibited still earlier characteristics than it has already done. In our own trial grounds, in two different localities near Chester, the one sheltered, warm, and early, the other exposed, cold, and late, our First and Best Pea was in each case about two days later in blooming and coming into bearing than its two rivals, but the crop was much heavier, and the pods larger and better filled. We found Sutton's Ring-leader and Carter's First Crop to be identical in every respect, and inclined freely to sport, whereas our own was very true. First and Best is also a little taller, and a more vigorous grower; and while it yielded three and four copious gatherings, but barely two pickings could be obtained from the two former. Dillstone's Early was some days later than ours, and Sangster's No. 1 and Daniel O'Rourke later than Dillstone's. Carpenter's Express we were unable to obtain; Eley's Essex Rival appears to be a good second early Pea, coming into bearing between our Early Favourite and Champion of England. We are growing our First and Best Pea very extensively this season, as we are certain it will be found and pronounced to be the best early Pea in cultivation.—FRANCIS & ARTHUR DICKSON & SONS, 106, Eastgate Street, Chester.

### GOLDEN VARIEGATED BALM.

By what means can the golden blotches in Golden Balm be preserved? In my borders it looked promising when first put out, but now it is quite green.—DISAPPOINTMENT.

[The Golden Balm preserves its colour best in poor unmanured soil. Rich loamy soil is almost sure to send it back to the original green. There is always a tendency to this when much transplanted. This and golden-striped Mint always look best in spring. We have given them up as ornaments, because towards autumn in heavy ground they either became green or had a dirty variegation worse than green. In light poor soils they do better.]

### NEW ROSES OF 1865.

I AM always delighted with a "Rose gossip" from "D." of Deal. I agree with him it takes time to find out really good Roses, especially if you are to speak of endurance and general good manners under adverse circumstances. Let it be understood that Roses are sent from France to England upon sufferance. Roses are, more or less, volatile things. It takes years to find out Roses that are good at all points, and good under adverse circumstances. To those previously recommended by me, I now beg to add Leopold the 1st, a fine, full, and well-shaped red Rose; also Duc de Wellington (Granger), a most beautiful Rose. It is thus rightly described: "Very vigorous, large, vivid velvety red, dark shaded, fiery to the centre." I have two blooms out. They are very beautiful. Duchesse de Caylus, Rushton Radclyffe, and Duc de Wellington, are the three best of 1865 as yet, and I can conscientiously recommend them. As you may have new subscribers, and as memories are frail, I repeat the names of those I have recommended lately in the Journal:—Madame V. Verdier, Pierre Notting, Lord Macaulay, Lord Herbert, Lord Clyde, Rushton Radclyffe, Duchesse de Caylus, Duchesse de Morny, Eugène Verdier, and Baronne Pelletan de Kinkelin, to which may now be added Leopold the 1st and Duc de Wellington. You cannot burn your fingers with the above. I must, however, make one observation with regard to Lord Clyde—namely, sometimes it is rough at its edges.

To-day I have sent a lot of Roses to Mr. Kent for his Blechingly Cottagers' Allotment Exhibition. I was much tempted to send two blooms of the Duc de Wellington; but I resolved at last to chop up the plant, and bud briars with it. I have two very healthy plants, and good growers, about to bloom—namely, King's Acre and Achille Genod; of these more in a few days. I have had one very nice bloom of King's Acre, but wish to see it once more. The last two are of excellent growth and habit. The last is evidently a seedling from Jules Margottin. As yet, not one of its children is equal to it, neither Victor Verdier, L'Esmeralda, or Bernard Palissy. Phoo! "Jewels," as we call him, is not going to the rear yet awhile! I have many infants yet to introduce to your readers. I will never tell you what Rose is bad, but if I say it is good you may buy.

I never knew Roses sport so as they have done this year. Had

the blooms been bad, "abnormity" would not have surprised me. I never had such a good season. Prince Léon and Lord Macaulay have occasionally been striped exactly like Triomphe d'Amiens. Alfred de Rougemont has been brilliant crimson and deep purple on the same plant. One of the blooms of Triomphe de Rennes was deeply red-tinted. I have read what is said of Mlle. Bonnaire. It is not a good grower, but no white Rose is equal to it. Its being a sport from Général Jacqueminot has much amused me. If a man marries a white woman, and she produces a "little black boy with curly hair," I fancy that he would hardly be satisfied with the explanation that it was "a sport!" Excepting Sénateur Vaisse, there has not been one Rose raised from this old sporting General that has been worth a "stump!"—W. F. RADCLYFFE, Tarrant Rushton, Blandford.

### SOFTENING HARD WATER.

Mr. Robson has called attention to the unsuitableness of hard water for plants; and, doubtless, almost all spring waters possess in a greater or less degree the property termed hardness—a property which depends chiefly upon the presence of super-carbonate of lime, or of sulphate of lime, or both; and the quantity of these earthy salts varies very considerably in different instances. Mr. Dalton long since demonstrated that one grain of sulphate of lime contained in two thousand grains of water converts it into the hardest spring water that is commonly met with. If about twenty drops of a solution of oxaliate of ammonia added to half a wine-glass of water causes a white precipitate we conclude that the water contains lime. By means of this test one grain of lime may be detected in 24,250 of water. If this test occasions a white precipitate in water taken from the pump or spring, and not after the water has been boiled and suffered to grow cold, the lime is dissolved in the water by an excess of carbonic acid; and if it continues to produce a precipitate in the water which has been concentrated by boiling, we then are sure that the lime is combined with a fixed acid. Hard waters may in general be cured in part by dropping into them a solution of sub-carbonate of potash. If the hardness of water be owing to the super-carbonate of lime only, mere boiling will greatly remedy the defect; but if the hardness be owing in part to sulphate of lime, boiling does not soften it at all. When spring water is left exposed in shallow reservoirs for some time, part of the carbonic acid becomes dissipated, and part of the carbonate of lime falls to the bottom. Such reservoirs, however, should not be constructed with bricks, unless covered with cement, as they render soft water hard.

The question of soft or hard water probably affects some of your worthy contributors much more than others. For instance: Mr. Fish, having a rather stiff retentive soil, would not require a tith of the water for out-door purposes that Mr. Robson would with a light soil and chalk subsoil; but, of course, the houses would all require the same amount of watering. I therefore think that any information on the subject would be acceptable to a large number of your readers.

I should much like to know whether the sub-carbonate of potash is at all injurious to Pears when used in sufficient quantity to soften hard water, or to any class of Pears, and whether the water would not require modifying in temperature after being rendered soft by a solution of sub-carbonate of potash.—F. FRITTON.

### WHAT IS A TRUSS OF FLOWERS?

Will you explain what is meant by a "truss of Roses, three blooms on a truss?" The Glasgow and West of Scotland Horticultural Society offered prizes for a certain number of trusses of Roses. For one of the prizes I competed, exhibiting three blooms growing from the one shoot. The prizes were in every instance awarded to bunches of three separate blooms tied together. Was this correct?—A. ROBERTSON.

[In the prize list quoted from by our correspondent, the words are, "Six Roses, distinct varieties, to be shown in trusses of three blooms each." To satisfy this condition the three Roses of each variety exhibited ought to have been in a truss. "Truss" is the florists' name for what botanists call an umbel, in which several flowers have their stalks united at one common centre, or, as in Roses, from one common stalk. Three separate Roses tied together are not a truss, but a bunch.—Eds.]

MINIATURE ORCHARD-HOUSE.

With this you will receive the framework necessary in the erection of a miniature orchard-house, sufficiently large to give you a general idea of the principle of construction.

The framework consists of four straight galvanized-iron rods 3 feet in length, and ten of slighter thickness bent at a right angle, about 2 feet from one end.

I shall suppose you are about to erect a house of which the slope of the roof from ground to apex shall be 24 inches. To do this, I shall presume you have at hand six sheets of glass 24 inches long by as great a breadth as you have a choice of, not exceeding 30 inches, and of a weight per square foot of not less than 21 ounces. If the sheets are as large as 30 by 24, a weight of 25 ounces will be preferable. The slope of the roof required I shall suppose to be an angle of 45°, and the house a span roof, covering therefore a base of about 34 inches (see *fig. 1*). If the erection is to be a very lengthy one you are not

Fig. 1.

*a, a*, Glass, 24 inches: *b, b*, 17 inches = total base, 34 inches.  
*c*, Perpendicular = 17 inches.

necessarily confined to a flat surface; some of mine run up and down a slight fall in the ground, and would equally suit a hill-side. For the experiment try a flat surface.

Suppose *A B C D* (*fig. 2*), to be the plot of ground to be covered, the lines *A C* and *B D* being each 34 inches, and the dotted line

Fig. 2.

to represent an imaginary line drawn from end to end equidistant from the sides. 4 inches or so from the line *A C*, and 5 inches or so from the line *E F*, fix the point *G*. 16 inches to the right of *G*, and at the same distance from *E F*, fix the point *H*. I say 16 inches on the supposition that your sheets are 24 by 24. If the second dimension is not 24, then alter the distance between *G* and *H* to the length of your sheet less 8 inches. Now, beginning at the other end of your plot, measuring 6 feet or so, fix two other points, *K* and *L*, on like principle to *G* and *H*. Fix a wire similarly about opposite *H*, say at the point *X*, taking care that before raising the longer half of the wire, it shall be so inserted as to point towards *C*. This wire of course must be raised so as to press upon the central sheet at the overlap.

A few minutes' practice will tell you more of the fixing of these wires than I can in an hour. The wires I send are unfortunately too powerful and therefore needlessly expensive,

but by taking the following variable properties into account you may make your wire suit its purpose:—

1. Thickness and elasticity of wire.
2. Angle at which wire is bent.
3. Depth to which the wire is sunk in the soil.
4. Tenacity of the soil.
5. Angle of the slope of the roof.

No. 2, the angle of the wire is the most readily convenient if you find your power of pressure either too weak or too strong.

Your wires fixed on the side *C D*, you can now proceed to lay your sheets on the other side. I could have done all the foregoing four or five times over whilst I have been telling you how to do it.

As for the gables, the most elegant are triangles of glass slightly larger than the opening at the ends, but this is not needful, save that it is also cheaper than most other plans. I shall suppose that in your experiment you use a square sheet, as in *fig. 3*.

Fig. 3.

The odd corners can be trimmed off with the diamond, and the pieces *A B* used as gables for smaller houses for Radishes, Carrots, &c., or for cuttings or seedlings. I have all sizes, from Pea and Potato houses down to Tom Thumb size, with a slope of roof of only 4 inches.

In fixing the gables use the remaining two wires, one to each, using the wires as before, but in the case of the gables inserting them not quite perpendicularly, or else at the distance of a few inches from the glass.

At each of the points *G, H, K, L*, (*fig. 2*), push one of the straight iron rods perpendicularly into the ground about half its length. Take now one of your sheets of glass, and standing in

Fig. 4.

*a*, Glass, 24 inches.  
*b*, Ground, 17 inches.  
*c*, Iron rod.

front of the plot put one end at the point *C*, (*fig. 2*) and the edge along the line *C D*, with a hammer or mallet in your right hand gently tapping the tops of the rods *G* and *H* till such time as by resting the sheet against them you get the slope of 45° or any other required angle. (See *fig. 4*.) Repeat this by laying

Fig. 5.

another sheet against the iron rods at *K* and *L*. Take now sheet No. 3, and place it so that it shall overlap sheet 1 and 2 about an inch and be supported by them. (See *fig. 5*.)

So much for one side of the house. You will see that no iron rods are required for the other side, on which the sheets have simply to be placed along the line *a b*, their upper sides resting upon the edge of the sheets of the other side of the house, leaving about an inch overlap as under. (See *fig. 6*.)

Fig. 6.

*a*, Glass. *b*, Ground. *c*, Iron rod.

However, before meddling with the side *a b*, we must first properly fix the side *c d* as follows:—At the point *m* (*fig. 2*) about opposite the iron rod *c*, and close to the edge where the glass meets the ground, insert perpendicularly into the soil the smaller half of one of the bent wires in such a position that by pressing it down to the angle the longer half shall lie close along the lower edge of the glass pointing in the direction of *d* (*fig. 7*.)

Fig. 7.

Now gently raise the longer end of the wire *w* till you get it in the position of the dotted line *x*.

For ventilation I have nearly a dozen modes all in use to-day, within view of my desk, and, except in large houses, none of them adding one penny to the expense. When you recognise the immense power of the bent wires, some of these modes will at once occur to you. Meanwhile spare me the naming of them till I hear your opinion of the main plan of erection.

I may say in advance of objections that I have never lost a sheet of glass from wind or frost, my only loss occurring from incautiously handling the wires before I knew their power. If properly fixed they never slip. Of course the overlap at the ridge should, in windy situations, face the mildest quarter.

I have given measurements, but after a little practice they are very immaterial. I stick my rods and wires in any way to a few inches, and make them accommodate each other by raising or lowering as seems required.

The fixing of the gables will best illustrate what I meant in a former letter by metallic reflectors. The backs of my lean-to are sheets of glass, upright, with the metallic reflector (of which further if you wish it) coating the surface. This acts as a substitute for a low brick wall, and I have a theory that solar light has properties in relation to vegetation when reflected as *light* very different from those of solar heat radiated from substances that have absorbed it.

I feel quite sure that using four-foot brick walls as a back, cheap sheets of very large glass might be specially made to render Peaches frostproof, but this is travelling a little out of the region of my own practice.—Wm. McGOWAN.

### A NEW HEATING APPARATUS.

DURING our brief visit to Washington, we stopped for a few minutes at the garden of the Agricultural Department, which is in charge of Wm. Saunders, Esq., one of the most accomplished of American horticulturists. Since our last visit here, a new propagating-house has been erected, combining advantages in the way of heating desired by Mr. Saunders, that are at once efficient and economical.

It is well known that the old mode of flue-heating has been in a great measure superseded by the hot water system. One

great drawback against its more general introduction, is its expense. Boilers and pipes are costly, particularly so since the advance in the price of iron; frequently it costs more to procure and fit up the apparatus, than it does to build the houses, and, after all, there is a great waste of heat passing off at the chimney.

For producing what is technically known as bottom-heat in a propagating-bed, there is no way of distributing warmth over a large surface so equally and economically as through water. The conducting power of water gives it the superiority in this respect, while it must be admitted that so far as economy of fuel is concerned, the old flue has the advantage. To combine the two modes has long been considered a desideratum, and this seems to be done in a very effectual manner in the house alluded to. The house is about 80 feet in length, divided by a partition across the middle. In one end is a propagating-bed, 35 feet by 8½ feet. The other end is fitted up with staging for pots, the object being to heat the bed without heating the atmosphere further than will be provided by radiation from the surface of the bed, while the atmosphere of the other portion is heated by a flue.

The furnace is placed opposite the middle of the house, and has also some peculiarities of construction, which we did not have fully explained, but our attention was attracted to the simple mode of heating the water in the tank which underlies the bed. Within a few feet of the furnace, a small piece of bent four-inch pipe is inserted with two arms, one of which is the flow and the other the return. This pipe altogether is about 15 feet in length, 9 feet of which lies in the flue; and the heat, as it passes this pipe, is sufficient to maintain an average temperature of 110° in the water, with moderate fire. If required, we understood that it could be raised to 120° with ease. The

shape of the pipe is as shown in this sketch, the bent portion being in the flue, which is represented by the horizontal lines. The simplicity and cheapness of this arrangement is manifest. Any plumber can make the boiler (for such it really is), and any labourer can fix it in its place. Its cost can always be readily ascertained, being little more than the cost of so many feet of three or four-inch pipe. It can also be extended, and several tanks heated from the same fire. A side tank 40 feet by 2 feet is in this case warmed by a small piece of two-inch pipe, let down through the top of the same flue that contains the four-inch pipe above illustrated.—(*Sorgo Journal*.)

### VINES FAILING—RED SPIDER.

We have an old viney heated by flues. We formerly had prodigious crops of Grapes from a double set of Vines, half planted outside, and half in, those inside against the back wall. Some time ago we changed our gardener, and as the old Vines were in a bad state, and had not borne well lately, we thought it right to replant the house, which was done, putting double the number of Vines in the outside border, and leaving the old ones inside, to continue bearing until the young Vines were strong enough to fruit. Last year we had a very good crop on the old Vines, but this year all the Vines had the red spider, and the young ones much the worst. Our new gardener says it was owing to the flues being so close to the openings where the Vines come in, and wants to have the flues lowered a foot all round the front of the house; but before we have this done, I thought I would ask your advice, as the old gardener always obtained as good Grapes as to size and quality as any in the neighbourhood. The Vines come into the house just 10 inches above the flue. The Grapes were started last year the middle of January.—F. W. S.

[It is just possible that were you to lower the flue you might much injure the draught. The hot weather has been much in favour of the red spider this season, and it will easily obtain the mastery if not combated with a little sulphur, and plenty of moisture. Ten inches is a good distance for the Grape

Vines when they enter the house to be from the flue. Were we in your case, we would let the flue alone, but we would have a dozen of evaporating-pans, zinc or earthenware, placed on the flue, and these we would keep filled with water, and a handful of sulphur in each, renewing it now and then, until the Grapes approached maturity, when little fire heat was necessary. We would have more faith in this than merely lowering the flues a foot. That, however, would secure a more uniform heat to the Vines. On a flue within 2 inches of the Vine stems we placed a sheet of zinc, separated from the flue by half an inch, and coated the upper part of the zinc with sulphur. This divided the heat better, and the zinc was never too hot for the sulphur fumes. We have then no objection to the sinking of the flue, but we would try the evaporating-pans.]

#### MEN AND MANURE REQUIRED FOR A GARDEN.

Do you consider the winter dung of eight horses, from November to April, sufficient for a kitchen garden of an acre, two Melon-lights, a hotbed for cuttings, and two lights for Potatoes?

Also, how many men would be required for a garden of same extent—a vinery 35 by 16 feet, a small Heath-house 16 by 10 feet, a conservatory 40 by 18 feet, two terrace gardens 90 by 30 feet, kept with bedding plants? The garden has no wall.—H. B.

— [We consider the dung amply sufficient, but most likely care will be needed to prevent the later-made dung from fermenting, in order that it may come in when required for linings after April. Placing it thin will secure that object, and then it may be placed together to heat when required. Instead of five we do a score or two of lights with half the quantity, but, then, much care and economy of material are required.

Roughly we should estimate your place requires about three men; but that will much depend on the way your terraces are kept or planted. As there are no walls there will not be much to do in winter. We have a great dislike to take men on for the summer; but there are cases in which men can obtain regular work in winter and can turn out in summer, and they just suit many gardens where there is less to do in winter. We have known places about your size tidily done by two men, and we have known four and five employed, and plenty to do. It so much depends on the plants grown and the finish of the keeping. For instance: in a terrace garden we know a border of *Cerastium* has been passable for some three years, and but little touched, but it has no artistic finish in comparison with another border planted every season, and nipped and clipped some half a dozen times during the summer.]

#### BROMUS SCHRÖDERI, ALIAS ANTHISTIRIA SPECIES.

As I have had some experience with this species of Grass, permit me to occupy a small portion of your columns in giving it. In January, 1864, I was in New South Wales, and had the pleasure of meeting with a large landed proprietor living near Sydney, who is not only an extensive cultivator, but has much of the energy of the "old country" in his experiments. He has cultivated this Grass extensively for several years, and has found it in his hot and dry neighbourhood a most valuable forage Grass, cutting heavy crops twice a-year. I saw one enclosure cropped with it, and was much struck with its vigorous growth. On making inquiries about it, I found its popular name at Sydney was "Californian Prairie Grass." I happened to meet with an old Californian digger who assured me that it was very common on the hills of California, and was not injured by the severest frosts. A botanist friend at Sydney said that it was a species of *Anthistiria* (Willdenow), and recognised as such by Leichardt. I did not hear of it in Queensland or at Melbourne. My English experience of it has gone thus far—I returned from Australia in the autumn of 1864, and brought with me a quantity of seed, which I sowed in October, the plants came up in November, and although so young and tender, they stood through the rather severe winter of 1864-5 well. I had early in the present summer a good crop of its Oat-like seed, and after cutting it when thoroughly ripe, the roots have put forth a promising crop of forage. I have read the advertisements of the "*Bromus*" (which I believe to be the same as my *Anthistiria*), at 1s. a-packet with some amusement, for I could have reaped a tolerable harvest of shillings had I not thought it more prudent to see how it suits our climate before offering it

for sale. I may add, that in New South Wales it seemed to give abundant forage, for the crops I saw were, as far as my memory serves me, 2 feet high, and very succulent. The proprietor above mentioned is a large dairy farmer, makes much cheese, and finds this Grass very nutritious for his stock. It seems to be much earlier than Italian Rye Grass, and may prove a very valuable addition to our early-spring fodder.

I almost fear those people who disbelieve the Cambridge-shire transformation of Oats into Barley will smile when I state the fact, that some roots of this Oat-Grass, the flower-stems of which I cut off to observe the effect on the forage, if thus treated have thrown up ears of Barley—odd, but true, for the roots were taken up, washed, and found intact, not being wedded to a stem of Barley, which I at first suspected. As to its perennial character, I can testify as to the variety I possess being so in New South Wales, for I saw one enclosure which had been laid down with it five years. The crop was abundant. From this source my seeds were gathered.—JOHN RIVERS, *Sawbridgeworth*.

Your correspondent doubts the hardiness of this forage plant. A gentleman who imported it from South America to Australia some years since, lately informed me that its being hardy was to him one of its greatest recommendations; and added, as the result of his experience, that spring sowing did not prove its utility, but that he had been in the habit of sowing in the autumn for winter food for stock, and, notwithstanding the cold at that season, it proved perfectly hardy—indeed, of rapid growth; and coming into use when there is no other green food attainable, he considers it one of his most valuable plants for winter forage.—C. H. S.

#### THRIPS ON PEACH TREE LEAVES— PRESERVING FINE NET.

BE so good as to inform me in your next Number what causes the Peach and Nectarine leaves which I now enclose to look so silvery. The leaves are not at all curled, and the trees are healthy in other respects. They are growing in an orchard-house, and are regularly syringed. I have noticed on the leaves many insects such as I now enclose. Do they injure the trees? If so, what is the best way to get rid of them?

Can you inform me the best way to treat Nottingham cotton net, not stiffened, one-sixth-of-an-inch mesh, so as to preserve it from the effects of the weather? What process does net go through that is tanned?—B.

[The insects on your Peach trees are the thrips, but not the worst kind to eradicate. Two tolerable smokings with tobacco and a good syringing would most likely vanquish them. These little insects give the silvery appearance to the leaves, increased a little by water resting on them when the sun is powerful. If you dislike smoking, wash the leaves with quassia water of the strength frequently mentioned, or with gum or glue water sufficiently strong, and yet weak—just enough that when you dip the finger and thumb in it there will be felt the least stickiness as you pull them asunder when the liquid is cool. For this purpose glue or gum water fastens and kills the insects, and a good syringing in a day or two removes them all. We have heard people complaining about insects, and submitting to great annoyance, when a small painter's brush and a little gum or glue water would have enabled them to go over every leaf of the plant. The same principle is illustrated every day in a garden, such as when a man plods and treads backwards and forwards for a fork or a hoe, when, if he had used the natural tools with which Providence had gifted him, he might have done all the work and saved much shoe-leather. A gentleman told us the other day, that if a job required three tools to do it nicely in his place, it required three journeys to the tool-house. Just so with insects. A brush and the fingers used in time might dispense altogether with a number of applications. A vast improvement would be effected if it were once established as a cardinal truth, that if once insects obtain the mastery it is lost labour, lost time, and lost money to attempt to clear them away. The best remedy is burning the whole lot. We think a little tobacco or a little gum water will make our correspondent's trees all right.

We are very doubtful of the success of any means of rendering Nottingham netting more enduring. Tanning it would be attained by placing it in a tannin lake netting. Steeping in oil with a little sugar of lead is advocated by some persons;

but after some experience with this netting, with calico, and other materials, we have come to the conclusion that all attempted means of preservation are only so much labour and money thrown away. All such preparations render the material more brittle and liable to crack; and we do believe that if kept as it comes from the manufactory, and put away in a nice dry state, it will last longer than when treated with preserving liquids, &c. That is our candid opinion after considerable experience.]

### MILDEWED SEEDLING PINUSES.

I HAVE had some heavy losses this year among my seedling Pinuses, from what appears to me to be a kind of fungus attacking the young growth. I have tried various means to prevent it, such as keeping dry, giving plenty of air, &c., but to no purpose. Perhaps some of your readers can give me information how to remedy the evil.—T. W. W.

[Our advice is to prick them off as soon as they appear above ground, and use pure loam that has no streaks of fungus in it. Probably the seedlings, too, are growing rather crowded. Dusting them with flowers of sulphur from a large pepper-box may do good. Your chief remedy will be pricking-off as soon as you can handle them, and giving plenty of air after they begin to root freely.]

### NEW EARLY PEAS.

I BEG to give you my experience of one of the new early Peas sent out last spring. I sowed this season Dickson's First and Best, Dillistone's Early, and Sangster's No. 1, and found the first fully nine days earlier than either of the others; the quality is excellent, and it is a most prolific bearer, very hardy, a strong grower, and pods from top to bottom. I gathered a much larger crop from Dickson's First and Best than I did from either of the others, and for the future I shall sow only this for my first crop.—W. LANDON, *Downton Castle Gardens, Ludlow.*

BEING much interested in the discussion on early Peas, which has appeared in your columns for the past few weeks, I may, perhaps, be allowed to say that I sowed Dickson's First and Best on the last day in February on a south border, and that I gathered the first dish on the 6th of June, and dishes on every subsequent day during the week. The crop was most prolific, the quality excellent, and the period they continued in a bearing state was much longer than any early Pea I have yet grown. I therefore do not hesitate to affirm that it is the earliest and best Pea in cultivation.—R. ROBERTSON, *Stoke Edith Park, Ledbury.*

SEVERAL communications having already appeared in your columns respecting early Peas, and much difference of opinion seeming to exist among gardeners as to what Pea ought to be styled the earliest, I venture to give my experience this season.

On the 8th of February I sowed Paul's Tom Thumb, which Pea I had hitherto found to be the earliest, on a south border. Dickson's First and Best was sown at the same time on an open flat, and I gathered Peas from that variety on the 3rd of June, Tom Thumb not being ready for several days, although accommodated with so favourable a situation. I have never gathered so many Peas and so early from a single row as I have done this year, and I can confidently recommend those who have not tried this valuable new Pea to do so, as, in my opinion, it is very properly named the "First and Best."—G. POVEY, *Doveridge Gardens, Uttoxeter.*

### TOMATOES.

A good medical authority ascribes to the Tomato the following very important medical qualities:—

1st, That the Tomato is one of the most powerful aperients of the liver and other organs; where calomel is indicated, it is one of the most effective and the least hurtful medical agents known to the profession.

2nd, That a chemical extract will be obtained from it that will supersede the use of calomel in the cure of disease.

3rd, That he has successfully treated diarrhoea with this article alone.

4th, That when used as an article of diet, it is almost sovereign for dyspepsia and indigestion.

5th, That it should be constantly used for daily food; either cooked or raw, or in the form of catsup, it is the most healthy article now in use.

*To Preserve Tomatoes.*—Professor Mapes says:—"If Tomatoes are slightly scalded and skinned, and put into bottles, and those set in boiling water for a few minutes, and corked and sealed, the fruit will keep as long as desired, and if eaten when first opened will have the same taste as when just picked from the vines."

Probably a better way is to peel the Tomatoes and boil slightly so as to expel the air, then put in heated bottles and cork at once. All depends on the exclusion of the air. The more perfectly this is done the longer fruit may be preserved.

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

ERADICATE all weeds before they shed their seed; pull them up by hand, as cutting them up with the hoe and allowing them to remain on the ground is nearly as bad as letting them stand; for although the seed may not be ripe at the time, the sun will soon ripen it. We allude particularly to Groundsel, Shepherd's-purse, and Sow Thistle. *Cauliflowers*, the main crop for autumn use should be immediately planted on a rich piece of ground. This vegetable, when planted at this season, becomes very useful after the Peas are over. *Cucumbers*, if they are required through the winter, seed should be sown, so as to have strong plants by the beginning of September. Carefully attend to those in frames, remove decayed leaves from the plants, and about twice a-week, in warm weather, give them a liberal supply of water. *Herb-beds*, where new ones are required may now be made; the ground to be previously manured and dug, slips of some sorts and rooted plants of others should be immediately planted in them. *Lettuce*, thin and transplant a sufficient quantity for use; keep them watered during the continuance of dry weather. *Onions*, the early-planted ones from the autumn sowing will probably be fit to pull up; if the weather is fine let them lie on the ground a day or two before they are housed, but if showery, they had better be laid in an open shed. *Parsley*, let a sowing be made immediately, if it was not done at the beginning of the month. If any has been left for seed let it be gathered as it ripens, or the best of it will be lost. *Peas*, earth-up and stick the advancing crops; the sticks from the early crops will now be out of use. *Potatoes*, plant some that have been saved from last year to produce new ones in the autumn; the rows may be closer together than for spring planting. *Radishes*, the Black and White Spanish should now be sown for winter use; also sow the common kinds for successional crops. *Spinach*, continue to keep up a succession, a larger space of ground may now be devoted to it, as it will not now so soon run to seed.

#### FRUIT GARDEN.

A systematic application of the principles of pruning should be continued to fruit trees during the summer months. The tendency to excessive luxuriance frequently exhibited by espalier trees renders the operation of disbudding, stopping, and shortening shoots more particularly essential. The whole principle of pinching is merely this—in the first place, to pinch all young shoots not necessary for the framework of the tree; secondly, to stop those shoots which threaten to overgrow their neighbours, by which means a due equilibrium of the branches will be maintained; and finally, having commenced a system of repression, to continue it in regard to lateral shoots which are developed by this system of stopping. Keep the Vines carefully tacked in, and the laterals constantly stopped; both branch and stem will be benefited by sharing abundantly the advantages of a free exposure. Let the free-growing shoots of Plums be regularly laid in, as they are apt to become awkward in training if left too long. The sooner the ground is prepared for Strawberries the better, let it be well manured and trenched to the depth of 3 feet.

#### FLOWER GARDEN.

Cuttings of Roses may now be taken and planted in a close frame in a northern aspect. In about a month they will have shown a disposition to strike root, when they may be taken up carefully, potted and plunged in a slight bottom heat. Treated thus they will make nice plants in a short time, and if kept under a slight protection during winter will fill their pots with

roots and be ready for planting out next May. Pink pipings put in early will now be ready for transplanting, and if so, this should be done at once, as they will require time to establish themselves so as to prevent frost from injuring them. If the situation ultimately intended for them is vacant, they may be planted there at once, but if occupied at present by something else, let the young Pinks be planted 4 inches apart on reserved beds in an open situation, the soil of which should consist chiefly of light loam. Climbers on walls must be attended to as they advance in growth, keeping the young shoots neatly laid-in. The climbing Roses will also require to be gone over occasionally for the purpose of cutting off decayed blooms, and any weakly old wood should be cut out at the same time to allow of laying-in the strong young shoots, which will bloom much finer next season than the old wood would. Any of the Perpetual-blooming Roses that have flowered very freely should be assisted by a liberal watering with manure water from the stable or farmyard tank; indeed, too much of this can hardly be given to any of the autumn-flowering varieties. Keep them free from insects, and have the budding finished as soon as possible. Also have Carnations and Picotees layered without loss of time. These are exceedingly useful border flowers, being so much prized for cutting; therefore, see that a good stock of them is prepared for next season.

#### GREENHOUSE AND CONSERVATORY.

Specimens that have matured their season's growth should now be more sparingly supplied with water at the root in order to promote the ripening of the wood. Some of the larger specimens will soon become exhausted, and preparations having been made securing a good reserve stock, such should be well attended to in regard to timely shifting, watering, &c. If such a course is duly followed up good specimens will always be at hand to fill up blanks occasioned by declining stock. Let young-rooted *Pelargoniums* be potted off in due time and protected. *Cinerarias*, too, whether seedlings or suckers, should have regular attention; those intended for autumn work should be potted forthwith. The forward *Achimenes* will have produced abundance of suckers, these taken off and encouraged in a propagating-frame will produce a very late display. Now, that *Camellias*, *Azaleas*, and other plants will be removed to their summer quarters out of doors, painting or other repairs required by any of the plant-houses will be more conveniently done than at any other season.

#### STOVE.

Let shading be used with caution. As plants should now or soon be ripening their young wood they want as much light, and even moderate sunshine as possible. In the case of Orchids this is especially necessary, in order that the young leaves and pseudobulbs may be thoroughly ripened. Plants already in this condition, or nearly so, should be removed forthwith to a cool-house, and care taken not to induce them at present to push again, as a fresh start would interfere with their flowering next year. *Dendrobium nobile*, and others of that class sufficiently advanced in growth, should also be moved to a house where they could have a moderate and steady temperature, abundance of air, and little water till their stems are ripe, and their flower-buds formed. Those Orchids which are still in a growing state should be placed in the most favourable positions, and encouraged by a nice growing temperature while the weather continues favourable for ripening and hardening any growths which they may yet make. Afterwards let them be put gradually to rest.

#### COLD PITS.

The stock here will probably require re-arrangement at this time, as some of the specimens having completed their season's growth will be better in a shady situation out of doors. Cut down *Pelargoniums* as soon as the wood is properly hardened, and keep them very sparingly supplied with water at the root until they start into growth, but sprinkle them overhead frequently, which will cause them to break more strongly.—  
W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

*Peas Blighted*.—Proceeded in dry days with removing stakes from the most forward Peas, and staking the later and latest-sown ones. A heavy fog a few mornings back was attended with a blight on the Peas. Many of the just-formed pods on the top, which would have come in for succession, became mottled and black, so as never to recover. We have suffered a

little on the height, but the crops have been next to destroyed in several gardens in the valleys. Some of the Potato haulm was also changed in colour. The fog was not at all cold, but there was something in it that thus injuriously affected vegetation. The soil was, perhaps, more than usually wet owing to the rains, but a short check to free evaporation could hardly have produced such a result. The pods seem much more affected than the haulm or foliage. A few fine rows of our favourite *Pea*, *Jeyes' Conqueror*, or *Ne Plus Ultra*, will be stopped in succession, but we have forked the ground, and as soon as drier will give a good soaking of sewage water to induce them to break afresh. Such blights derange our calculations as to autumn Peas for the table. Has the like happened in other neighbourhoods?

*Early Peas*.—We hope the trials on this subject will be productive of good. We want not an increase but a reduction of the number of varieties. The earliest with us this season is one obtained from an old gardener under the name of *Sebastopol*. We have already stated that we judged it to be the same as *Dillistone's Early*, but though sown the same day, and the appearance of both was much alike, we found we could gather a good dish of the *Sebastopol* some five days before we could gather one from *Dillistone's*, whilst the latter was fully eight days in advance of *Sangster's No. 1*. The last with us, however, is a wonderful cropper, and we use it, therefore, for our main early crop, following with that wonderful cropper, *Dickson's Favourite*, and the also fine cropper and sweet, though small, *Pea*, *Harrison's Perfection*. This last is a fine *Pea* for those who prefer flavour to size. In the latter respect it is nothing to *Veitch's Perfection*, *Mammoth*, and *Ne Plus Ultra*. Of a lot of others we have tried, we find nothing in the new in advance of the old. A few of the new earliest we have not tried, and, therefore, like many more, will note the results stated by so many correspondents. One fact we may mention, *Dillistone's Early* does well with glass laid over it, as in a cold earth-pit, or an open orchard-house. *Sangster's* and others do not come kindly. *Tom Thumb* as a dwarf does pretty well. From *Dillistone's* we had some nice early gatherings from a row sown near the front of an orchard-house, and allowed to spread to the front without stakes or support of any kind, pulling them up as soon as the crop was plentiful out of doors. A few days difference in the time of gathering is, therefore, a great point in early Peas, and well-authenticated statements of kinds sown near each other on the same day, and in similar circumstances, are very valuable. A few in an orchard-house do little harm, and they gratify the craving for this vegetable when they could not be had for two or three weeks out of doors. A good spoonful early is more thought of than a huge dish at a later time.

*Celery*.—Planted out as we got the trenches cleared of bedding plants, Turnips, Potatoes, &c. Plant as soon as we will, unless we give shade in bright weather, the *Celery* will not grow freely until helped by the cool nights of autumn. Our most forward *Celery* has been cleared of suckers at the roots, but has not needed tying as yet. With the exception of a sprinkling of dry earth from the sides after watering, we shall not do much, or rather nothing, in the way of earthing-up, until some three weeks before we wish to take it up for use, and even then will only do a little piece at a time, according to what we judge will be wanted. As stated some time ago, the bit-by-bit earthing-up is the fruitful source of bolted and run plants. We had not a single run plant last year, though we had it in use much earlier than we shall have this season. One word more. Those who grow for shows may feed it as much as they like to grow it of a huge size; but those who wish for sweet crisp *Celery*, and that which will stand good in the beds, or rows, until they want it, will be satisfied with smaller heads. Without a protecting awning it is scarcely possible to keep large heads when earthed and blanched from rotting in the centre. The most careful tying and banking-up will not prevent the rain and heavy dews trickling down into the centre of the plant, and then the size and the many layers of the footstalks of the leaves keep the water in the centre without allowing it to escape, and there in time it putrefies and rots the centre.

Pricked-out more Lettuces and Endive, and sowed successions of these, Onions, and Cabbage, the latter for the second spring crop. In a fortnight will sow again. Planted out Greens, Coleworts, and Broccoli, as we could find room, also a good breadth of Cauliflower for autumn use. What we plant afterwards will chiefly be taken up for winter use. The rains have done good to all these things, and those planted a week or

a fortnight have been greatly benefited by stirring the ground all over with a fork in a dry day.

*Cucumbers.*—These on ridges and on beds with little or no protection, having now had the soil well heated, will be benefited by being mulched with litter, or some hay grass, which will keep the fruit cleaner, and preserve a more equal condition of temperature and moisture about the roots. When nice Cucumbers, however, are wanted for the table, it is advisable to keep some in beds, pits, or frames, with glass over them, and where the soil can be kept warm. It is often advisable to give regular Cucumber-houses a rest during the summer. One of our most successful growers in a span-roofed house in winter and spring, allows his house to stand empty during summer, so as to be thoroughly sweetened and cleaned before he plants again in autumn. Few of us can thus spare glass; but even a few pot plants in such a place would be better than continuing on the Cucumbers, when they can be had very good in frames, &c. A few weeks ago we found traces of the disease in a two-light box, and as we had plenty more we cleared out and destroyed the plants, removed the soil, washed the frame, and planted again. It will be recollected that this spot and gum disease troubled us some years. In honesty we must add, that we do not know what brought it, or occasioned it, or what has happily kept it away. Nothing would conquer it when once it appeared. Fresh soil, frequent planting, and plenty of heat and air, just enabled us to get on. This season with the above exception we have seen nothing of it, but our treatment has not appreciably varied. We should be glad if some one would do what we are unable to do, after numerous experiments and much patient watching and noting—tell us the cause of, and the remedy for this disease, or these diseases. The spot on the leaf is worse than gum on the fruit. For Mushrooms, Tomatoes, &c., see previous Numbers.

#### FRUIT GARDEN.

Proceeded with stopping and shoot-removing as we could find time. Some Plums would be benefited by thinning if we could get at them. The dry weather kept the Strawberry runners back, and now they come freely. We have taken a lot with little roots and potted them singly in small pots at once; others we shall layer in small pots, both to be potted afterwards. As stated the other week, we will also report a few of those fruited last in pots, to come in the earliest; we shall shake the most of the earth away, and repot firmly in six-inch pots, and give all the sun possible after they begin to grow. We are now planting out the first-foed, and expect a crop in the autumn. Many are showing bloom freely now. Our crop in the open air though tolerable, has not been at all up to the mark. We believe the fruit-buds were starved by dryness last autumn, and, therefore, the bloom was not sufficient this summer. We were, however, much better off than some of our neighbours. We believe the shortness of the crop was more owing in such circumstances to the peculiarities of the last summer and autumn, than to anything connected with the sterility of the plants. Even then, however, it would be advisable to take runners from fruitful plants, rather than barren ones, and those who wish to be extra careful and sure of fruit, may as well choose the second layer that comes from the plant, instead of the first. We can scarcely get such minutiae attended to, but a number of experiments years ago convinced us, that though the plants from such layers were less vigorous in growth, they were on the whole more distinguished for fertility.

*Vine-borders.*—In addition to the sprinkling of lime and soot alluded to the other week, threw a sprinkling of superphosphate of lime over them to be washed in by the rains, as the crops are as usual too heavy. All Vines like a little of this application of bones, and a good dose will not be so liable to injure as guano, and other concentrated manures.

*Melons.*—In addition to what has lately been stated, the chief points to be attended to now are—setting the fruit on young plants, keeping swelling fruit from contact with the soil, thinning the laterals and leaves sufficiently so that what is left may have plenty of light; and for fruit advancing to ripeness, making sure that the roots shall be moist, and the surface and the atmosphere dry. If we would have a first-rate Persian Melon, we must imitate the Persian atmosphere. The very heat and dryness of the air there give an extra relish and sweetness to the juicy Melon. A travelled gentleman said of a really good Melon, "Ah! to make it perfect it should be partaken off under a broiling sun in Persia." No doubt this lends a charm to the Water Melons, which after many attempts have scarcely become at all relished in this country.

#### ORNAMENTAL DEPARTMENT.

Jobs here too numerous to mention, in changing plants, potting plants, training, &c. Stanhopeas have flowered all the stronger and better from having been dipped several times in manure water, and strongish manure water being poured gently on the baskets. In smallish baskets, tigrina and others have been large and fine. Our little plant-stove is becoming too cold for the Caladiums. They made the most splendid leaves when they were treated to a little bottom heat. No plants enjoy that privilege more. Give plenty of heat and moisture and a subdued shaded light, and fine foliage must be the result. The same may be said of the fine-foliaged varieties of Gesnera zebрина, though less heat suits them. For hardwooded plants see previous weeks, and for some time back. The most forward Pelargoniums may now be cut back for making shoots. For early-blooming Cinerarias and Calceolarias see former directions and practice.

*Chrysanthemums* now require plenty of manure water, and the tops must never be allowed to shrivel or flag. Every time a plant becomes so, a layer of leaves will fade next the base of the stem, and thus make the plants bare at the bottom. Now is a good time to layer young shoots into small pots for flowering in a small dwarf state. If the top of the shoot is twisted before laying in the small three or four-inch pot, it will soon strike root. Tonguing in the usual way can scarcely be resorted to, the shoots are so apt to snap; but a good plan is to run a sharp penknife along the middle of a shoot for 2 inches in length, and then put in a small bit of pebble or a little chip of wood to keep the sides of the cut separate from each other. The exposure of the bark and albumen soon secures plenty of roots, and when the pot is thus filled the connecting shoot can be cut off. Such dwarf little plants are useful for filling small flat vases. A vase of Chrysanthemums may thus be obtained of any conceivable height. The large pots and large specimens should now have plenty of manure water.

Out of doors the chief work has been mowing, machining, rolling, sweeping, &c. Two things may be worth special notice. The first is, the necessity from the rains, of training, and removing many leaves from flower-beds, so as to give more light to flowers and flower-beds. This was especially the case with strong-growing Scarlet Geranium-beds trained in the pyramidal form. These, though not equal to those at Bentley Priory last year, are still very fair, and all the ground completely covered. The removing of a few prominent leaves near the points of the shoots does not interfere with the clothing of the beds, whilst greater strength is thrown into the flower-stems. Of course, it must not be overdone, as the flower-stems, even, would be starved for want of correlative action. The second has reference to the treatment of several lines of Cerastium in front of ribbon-borders. We lately cut a long one rather wide, but as it was then only 1½ inch from the grass, we could do nothing but leave it straight. The others had been planted in May, and required some pegging and cutting to make it uniform and straight from end to end. When thus nicely finished, the Cerastium would be about 6 inches from the grass verge. We have already stated how nicely a row of Cerastium looked at Trentham, with rather more than that distance of black-coloured earth between it and the grass. Our soil is not black enough for the purpose, but we did not like to give up the idea of a contrasting colour between the green grass and the whitish Cerastium. We, therefore, had some dust coal passed through a sieve to get rid of a lot of the dust and the largish pieces, and by a little breaking and then washing all well in a fine sieve in a tub of water, much in the same way as the best sand is washed for cement, we obtained a lot of coal shingle ranging in size from that of small peas to that of fair-sized horse beans. The narrow strip of ground was levelled and beaten firm, and then the coal grit was laid thinly and evenly over it. At a little distance you might easily mistake the deep bluish-black for a narrow row of the darkest Lobelia speciosa. It certainly makes a better figure than the mere bare earth. We should like to see all flower-beds nicely bordered, and with something better than coal grit. Disapproving of mixing flowers and coloured earths or minerals in one uniform combination, there is not the same objection as to surrounding one figure, or group, or border, with some coloured earth, not much beneath the height of the row of plants next to them. In our case the bluish sparkling black diamonds come in as a narrow line between the green and the white. If not liked it could easily be put out of sight. The washing is essential, for, otherwise, rains would splash, and winds drive the black dust.

—R. F.

## COVENT GARDEN MARKET.—JULY 22.

MARKET well supplied. Soft fruit in excellent condition. Strawberries nearly over, Elton Pine being the only variety. English and West Indian Pines are both on hand in large quantities. Inferior samples of the former quite unsaleable except at a very low rate. Vegetables good and abundant, comprising the usual varieties; good Peas, however, are more inquired for, the sorts most in demand being Ne Plus Ultra and Champion.

## TO CORRESPONDENTS.

\* \* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

VINE LEAVES BULLATED (*J. Stevens*).—The warts on the back of the leaves are produced by rich feeding at the roots, with too much moisture, and closeness in the atmosphere of the house. Give more air, and more dry heat, and make your Grapes, and not the plants in pots, the chief object of your cultivation.

VINE AND MELON LEAVES MILDEWED (*A Constant Subscriber*).—There is a slight appearance of mildew on the Vines. Use a little flowers of sulphur. Give dry heat in moist weather, and plenty of air. Air and dry heat will, we hope, make all right. Use lime water in watering the Melons. You might strew some lime on the bed with advantage. Give also plenty of air, and paint the back of the pit or frame with sulphur and lime, and if that is too white add a little soot. It was a pity to use soil so full of fungus.

ANIMATED OATS (*H. N. E.*).—These are the seeds of *Avena sterilis*, and commonly called the "Animal Oat" and the "Lively Oat." It is a native of Barbary, but was introduced here more than two centuries since. Of course you are aware that the cause of these seeds moving about like a mass of insects is the extreme sensitiveness of their awns to dryness and moisture. We do not know the Clematises you mention, but they probably require greenhouse culture.

NAMES OF ROSES (*E. S.*).—The white Rose is *Noisette Grandiflora*, but the other was too decayed to be recognised.

TRANSPLANTING GOOSEBERRY AND CURRANT TREES (*A Subscriber*).—With care you can readily transplant these when six or seven years old. Prune the bushes as soon as the fruit-bearing is over—that is, cut away a good deal of the branches which will not be wanted. As soon as the leaves begin to change colour a little, open a trench some 3 or 4 feet from the bole of each shrub, and then pick away the earth, but carefully saving the roots. If you can secure to each a ball of earth all well, if not it matters but little. Spread out the roots nicely in the new soil, and stake the trees, and mulch the surface before frost comes. The shrubs will make good roots before spring.

STOVE PLANTS FOR DRAWING-ROOM (*An Old Subscriber*).—This subject will be discussed fully in the course of a week or two.

PELARGONIUMS DONE BLOOMING (*W. B. W.*).—After blooming they should be rested for a period of six weeks, by thorough exposure, and withholding water, or, if rainy weather, by turning the pots on their sides. When the plants are cut down it is not necessary to plunge the pots, but stand them on a hard floor or boards. They should be repotted after the new shoots are half an inch in length, removing most of the old soil, and potting into smaller-sized pots. After potting place in a cold frame, shading from bright sun, and keeping close for a few days; then give all the air possible, and protect from heavy rains.

PLANTS FOR WALL OF STOVE (*J. Bayley*).—We presume your wall is shaded. In that case you could not do better than have a trellis made for it, and cover that with *Cissis discolor*, and thus have a tapestry of the richest and most beautiful kind. In case you wish for flowering plants, *Hoya carnosa* and its vars. *piota* and *variegata*, *Mikania scandens*, *Manettia bicolor*, and *Bignonia venusta*. If there is no trellis, then *Cereus grandiflorus*, *C. Macdonaldi*, and *C. flagelliformis*. Our choice would be two plants of *Cissis discolor*, and a *Sphaerostemma marmorata* in the centre, with suspended baskets, from the upper part of the wall, of *Pothos argyrea*. If the wall is not shaded, then *Passiflora quadrangularis*, *edulis*, *racemosa*, and *alata*, or *Ficus barbata*, *Vanilla aromatica*, and *Renaudera coccinea*.

SCALE ON PEACH TREES (*Inquirer*).—It is difficult to tell what causes trees to be attacked by insects. Your trees on the greenhouse back wall do not, probably, receive sufficient air, and that may render the leaves favourable to attacks of scale. As the fruit is ripening, you can only pick off the scale with the point of a knife, which certainly is a slow but sure method of clearing off the pest. After the fruit has been gathered, syringe the trees with water, at a temperature of 160°, in which soft soap or Gishurst compound has been dissolved at the rate of 4 ozs. to the gallon. Allow this to dry, then wash it off with water at 140°. After the leaves have fallen (clear them away immediately they fall), wash the trees with a composition which we have used for the last twenty years, without any appearance of scale afterwards. It is made as follows:—Take 7 lbs. sulphur vivum, and 7 lbs. quick lime, and boil for fifteen minutes in three gallons of soft water; then add 2 lbs. soft soap, and 1 lb. of the strongest tobacco, continuing the boiling half an hour longer. Strain, and apply whilst hot (140°) to the trees with a brush, taking care not to injure the buds, and yet to go into every hole and crevice. Keep in a close-stoppered bottle for future use, and in case of attacks of red spider, thrips, and green fly, in summer, put a pint in three gallons of water, and syringe the trees with it. We know this old remedy, for the ailments of the Peach, to have been in use for three-quarters of a century with the best results. The trees should be washed before the buds begin to swell.

HIMALAYAN CEDAR AND CYPRESS SEEDS (*Dorset*).—Sow the seeds next March in a cold frame, in light good loam, or sow in pans, keeping moist, and rather close, until the seedlings appear; then give air day and night in mild weather, protecting only from deluging rains and severe frost. Water freely, but never sdden the soil; and in winter give air daily, protecting with mats in severe weather. When the seedlings are a year old, prick them off in the frame in rows 6 inches apart, and 3 apart in the lines. They may be potted, and grown in an airy greenhouse, if sown in heat, and hardened-off after the young plants appear. In the spring of the second year from sowing they may be transplanted into a sheltered situation, yet open, in lines a foot apart, and 6 inches in the lines. Two years from this they may be planted out in their final positions. We suppose that the "Gigantic Cypress" sent to you from the Himalaya is *Cupressus torulosa*. What is the "Rayen Cedar" or the "Blue Cedar," we do not know.

PEACH TREES OVER-LUXURIANT—FRUIT FALLING (*H. C.*).—We should think that your Peach-border is very rich and deep. If not deeper than 24 inches, and the roots cannot get below that, we should not mind how rich the border was; but disbud the young sappy shoots, so as to leave them 9 inches asunder, thereby allowing them light and air, in order to get the wood well ripened. When the wood is so ripe as to perfect the fruit-buds for blossoming and setting, it is hard to tell how the falling of the fruit afterwards can be attributed to the imperfect ripening of the wood. Your fruit falls when undergoing the stoning process, and it fails to do this generally—1st. When the trees have been too heavily cropped; 2nd. When there is not sufficient moisture in the soil; 3rd. When there is not sufficient air or ventilation; 4th. When the atmosphere is too dry, and there is too much heat at that period; 5th. When there are sudden changes of temperature, and alternations from little to much air, coupled with extremes of dryness and moisture. Providing the border is not deep, we would not root-prime or take up the trees, but disbud to shoots at every 9 inches distance along the main branches, and have them at that distance from each other. We would shorten the leading shoots but little at the winter pruning, and leave the bearing shoots longer than usual—say 1 foot. From the first swelling of the buds give air day and night, lessening it, of course, by night, and continuing this until the leaves fall. Peaches like plenty of air. After setting syringe the trees morning and evening, up to the time of the fruit ripening, when a little fire heat will do all that is necessary for ripening the fruit and wood. From first to last the border should be well supplied with water, particularly when the fruit is stoning; and for want of this, and sufficient ventilation, we think your Peaches fall without stoning. We presume your trees are young, and that they will lose their luxuriance when they commence bearing. If the border is rich and deep, then we would recommend lifting the trees in preference to root-pruning, reducing the border to 20 inches deep, and planting rather near the surface, just covering the roots. We have some that would not set their bloom, and we took them up last November, and found the roots like so many bare sticks at a depth of 2 feet or more. They were planted nearer the surface, and are now loaded with fruit. They were in a rich deep border. The trees are best lifted and transplanted when the leaves are falling, November and December being the best months.

GERANIUMS (*S. S. S.*)—Mrs. Pollock, Sunset, Italia Unita, Lucy Grieve, Mrs. Benyon, and Countess were raised, we believe, by Mr. Gieves. The others were also sent out by Messrs. E. G. Henderson, to whom you had better apply for information as to when the variety which you name will be sent out.

AZALEA STOCKS (*J. P. F.*).—*Versehafieldi*, called by some persons rhododendroids: this is without doubt by far the best stock known. If sufficient quantity of the above is not to be had use the following:—*Holfordii*, *Marie Louise*, and *Phœnicia*.

**HOUSE FOR PLANTS (P. O).**—If we understand you aright, your house is to be more of a plant-stove, or plant-forcing-house, than a greenhouse. We should, therefore, advise you to have your pit for pot-plants, instead of specimens planted out. You will thus secure your object better. *Passiflora princeps* and *P. kermesina* would suit the dome part of the house. For twenty climbers the following would be good:—*Combretum purpureum*, *Jasminum sambac flore pleno*, *Ceropegia elegans*, *Bignonia venusta*, *Quisqualis indica*, *Passiflora alata* and *P. Buoniaparuta*, *Ipomoea Learii* and *I. Horsfallii*, *Pergularia odoratissima*, *Hoia carnosa*, *Thunbergia fragrans*, *T. coccinea*, and *T. Harrisii*; *Allamanda cathartica* and *A. Schottii*, *Torenia asiatica*, *Echites* of sorts, *Banhiina scandens*, *Solanum grandiflora*. These are recommended on the presumption that the house is not to be below 60° in temperature; if a colder house others must be used.

**SEEDLING ANTIRRHINUMS (Barr & Sugden).**—There is a great variety among your seedling Antirrhinums, many of them good varieties, though nothing new, and we have seen many seedlings this year as good; yet no one can be disappointed who purchases seed saved from them. (*T. Ansell*).—Your seedlings are like many others we have had sent to us this season. Whilst writing we have three or four dozens quite as good before us. There is nothing new in colour or form; and though some of them are pretty varieties, they are only such as we should expect to be produced from any packet of good seed.

**ROSE TREES DYING (Lex).**—Your Rose trees have died off from some other cause than the insects you have seen at work, which are a species of bee belonging to the genus *Osmia*. They only burrow in the pith of the dead dry snags, and not into the living part, and the injury they commit extends no further down.—W.

**PLANTING STRAWBERRIES (Agnes).**—I presume when Mr. Chalouet speaks of taking up and putting in with a trowel in July, he means runners of the year. It is not a good plan to remove old plants. I do not keep the Black Prince, so cannot compare it with Sir J. Paxton and Eclipse. An earlier Strawberry than Sir J. Paxton would probably not be good out of doors unless covered with ridge-vineries' glass. It was ripe here this year on Whitsunday. Eclipse is not quite so early. When I said the planting season is from January to July, of course I presumed the January planting of runners is of runners supposed to be kept over the winter and planted the spring previously. The July runners of courses are to be had from one's own plants. The nurserymen cannot supply them so early. All my new plantations are now made, July 21. The fault of the Black Prince is that in mild winters it goes into flower, and its blooms are killed. It is otherwise a sweet, hardy, and good early Strawberry.—W. F. RADCLIFFE, *Tarrant Rushton*.

**NAMES OF PLANTS (M. D.).**—*Mesembryanthemum sessilifolium*, (*Lady King*).—A Cucurbitaceous plant; send it again when it flowers. (*A. J. T.*).—1, *Anchusa italica*; 2, *Sedum sexangulare*; 3, *Mesembryanthemum forficatum* (?); 4, *M. virens*; 5, *Sedum dasyphyllum*; 6, unrecognisable.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending July 22nd.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

DISEASES OF FOWLS.

We have had many queries about maladies and ailments among chickens that pass our philosophy. Prevention being better than cure, we can only tell our readers that which we do with uniform success. If the chickens are well, we let well alone; but if there appears a listlessness and discontent among them, a contempt for food, and an apparent inclination to go what our man calls "the wrong way," we give them wormwood and camphor in their water, not mixed, but each in a separate vessel. Both are very valuable. Our man gives them "nettle tea," because he finds it good for his children. We have no faith in it. We are becoming sceptical about tainted ground for chickens; we have reared on six acres hundreds for twelve years, and have no taint. We change the spot for the hens under the rips with the chickens every year, so far as the space will admit, and we allow the chickens to roost out and about till the long cold nights come, when they all go into an old barn. Every rip is shifted every day, and when the grass is laid up for mowing, each spot shows by its redundant crop where one has been. We share in the old superstition about June chickens—

"Chicks that are hatched, when there's making of hay,  
Will never grow up—they pine away."

It may be that while haymaking is about the chickens miss some of the care they require, and therefore decline; be that as it may, ours have always done badly in June, and we have, therefore, timed them this year to come out in July; they are doing gloriously. The rain has freshened the newly-mown land, and we know no run better for the young broods. Of course we are not speaking of exhibition birds, but good fowls are handy in the winter, and the July chicks will prove it.

THE POULTRY CLUB'S PROPOSED ANNUAL SHOW.

The Poultry Club having at its last general meeting decided on holding an annual show, moveable year by year, on the principle of the Royal Agricultural Society, the Stewards invite the co-operation of all exhibitors (whether members or not) in furtherance of this object.

The prize list is guaranteed by a fund subscribed to by individual members of the Club, and the Stewards propose to hold the show in one of the leading towns of the northern or midland counties. They now request suggestions from exhibitors, as to which town would be most eligible and offer the greatest facilities. It would be necessary to form a local Committee, and obtain the services of a good local Secretary.

If arrangements can be made in sufficient time, it is proposed that the Show be a chicken show, that being the want which the Stewards conceive to be most felt. The prize list will be liberal, increasing with the amount of guarantees received from members, and will include Pigeons. Two silver cups have been promised, and more are anticipated.

All communications or suggestions addressed to the Hon. Sec. of the Club will be thankfully received, and any local Committee formed in any eligible place can be at once arranged with. Signed by order,—F. W. ZUMWORT, *Hon. Sec., Donnybrook, Dublin*.

SULTAN FOWLS.

A FRIEND sent me three fowls to take care of during his absence from home, as he dreaded a want of care on the part of his man-servant. He calls them "Bashi-Bazouks." To me they appear to be neither more nor less than bearded White Poland fowls. They are quite white, with large topknots, a sort of beard under the throat, a small horned comb close on the upper portion of the beak, legs greenish yellow, or willow as it is called; good layers of average-sized eggs. They are certainly curious in appearance. Can you from my description tell to what class they belong? I am very desirous of the information, as he gave a very high price for them.—A VERY OLD POULTRY FANCIER.

[We should be disposed to believe the birds you name are the "Serai-ta-ooks," or "Sultan Fowls," imported some years since by Miss Watts. They were much like what you describe, very good layers, and most pleasing as tame and familiar pets. We can hardly name their value, as we were not aware there were any left, on account of the difficulty of procuring fresh blood. A cock and two pullets of last year should be worth from £5 to £6.]

ELECTIONEERING INTELLIGENCE.—The Light Brahmas have been elected to separate classes at Bingley Hall, Birmingham

by a large majority. We trust at the meeting the last week in November, they will by their presence justify the preference shown to them.

### PLYMOUTH POULTRY SHOW.

This was held on Monday, the 17th, and four following days. The entries were not very numerous (156), but the quality of the birds sufficiently compensated for any deficiency in quantity. The Show has been well visited, the weather being brilliant.

The following were the awards of the Judge, R. Teebay, Esq., Fulwood, Preston:—

**DORKING (Any colour).—**First, W. R. Peacey, Chelworth, Gloucestershire. Second, F. T. Parker, Rosewarne, Camborne. Third and Fourth, J. K. Fowler, Aylesbury. Commended, E. Burton, Truro. *Chickens.*—First, Miss J. Bartar, Plymouth. Second, Rev. P. W. Storey, Charwelton House, Daventry. Commended, J. K. Fowler.

**DORKINGS (White).—**First and Second, H. Lingwood, Needham Market, Suffolk.

**COCHIN-CHINA (Any colour).—**First, H. Tomlinson, Birmingham. Second and Third, F. W. Zurhorst, Donnybrook, Dublin. Fourth, J. K. Fowler, Aylesbury. *Chickens.*—First, R. Rodbard, Aldwick Court, near Bristol. Second, Rev. S. Taylor, Kenstwick, Kirby Lonsdale.

**COCHIN-CHINA (White).—**First and Second, F. W. Zurhorst, Donnybrook, Dublin.

**GAME (Black-breasted and other Reds).—**First, Rev. G. S. Cruwys, Morehard Court, Tiverton. Second, E. Burton, Truro. Third, J. Barter, Totnes. Commended, J. Collacott, Tavistock; Miss S. Northeote, Upton Pynes, near Exeter.

**GAME (Any other variety).—**First, S. Dupe, Everereech, Somerset. Second, Rev. G. S. Cruwys, Morehard Court, Tiverton. Third, J. Barter, Totnes. *Chickens.*—First, H. Doney, Mutley, Plymouth. Second, H. Adney, Remberton, Collypump. Third, Rev. G. S. Cruwys, Morehard Court, Tiverton. Highly Commended, H. Doney. Commended, H. Adney.

**SPANISH.—**First, J. R. Rodbard, Aldwick Court, near Bristol. Second, J. K. Fowler, Aylesbury.

**POLANDS (Any variety).—**First, J. Hinton, Hinton, near Bath. Second, D. Dohrie, Forest Rectory, Guernsey.

**BRAMA POOTRA.—**First, R. W. Boyle, Dunderm, Dublin. Second, H. Hinton, Hinton, near Bath. Third, E. Pigeon, Lymstone, near Exeter. Highly Commended, E. Pigeon; J. Pares, Childown Hall, Chertsey.

**HAMBURGH (Golden-pencilled).—**First, B. Mills, Mannamead, Plymouth. Second, J. Duustan, Wendro, Cornwall. Third, N. Barter, Plymouth. Highly Commended, N. Barter. Commended, T. Edwards.

**HAMBURGH (Silver-pencilled).—**First, A. K. Wood, Burneside, Kendal, Westmoreland. Second, Miss J. Barter, Plymouth.

**HAMBURGH (Golden-spangled).—**First, A. K. Wood, Burneside, Kendal, Westmoreland. Second, J. Roe, Hadfield, near Manchester. Third, C. Benwell, Baywater, London. Commended, R. Tate, Leeds.

**HAMBURGH (Silver-spangled).—**First, A. K. Wood, Burneside, Kendal. Second, G. Miller. Third, W. Miller, Sherborne, Dorset.

**GAME BANTAMS (Any variety).—**First, J. K. Fowler, Aylesbury. Second, W. H. Oxland, Plymouth. Third, Rev. G. Raynor, Rectory, near Brentwood. Highly Commended, G. Manning, Springfield, Essex.

**GOLD AND SILVER-LACED.—**First, Rev. G. S. Cruwys, Tiverton. Second, G. Manning, Springfield.

**SELLING CLASS.—**First, D. Dohrie, Forest Rectory, Guernsey (Crève-Cœur). Second and Third, R. H. Nicholas, Malpas, Newport (Spanish and Silver-spangled Hamburg). Highly Commended, Miss S. Northeote, Upton Pynes, near Exeter (White Game). Commended, Rev. P. W. Storey, Daventry (White Bantams); G. Manning, Springfield (Brown Red).

**SINGLE COCKS.—Game (Any variety).—**First, G. S. Cruwys, Tiverton. Second, R. Rodbard, Aldwick Court, near Bristol. *Bantam (Any variety).*—First, Rev. G. Raynor, Rectory, near Brentwood. Second, E. Cambridge, Bristol. Highly Commended, S. Lacy.

**DUCKS (Rouen).—**First and Commended, E. Burton, Truro. Second, J. K. Fowler, Aylesbury.

**PIGEONS.—Carriers.—**First, E. E. M. Roys, Ashby-de-la-Zouch. Second, H. Doney, Plymouth. Highly Commended, C. Cole, Bradford; H. Yardley, Birmingham; C. Bulpin, Bridgewater. Commended, C. Bulpin. *Pouters.*—First and Second, C. Cole. Highly Commended, E. E. M. Roys; H. Yardley; C. Bulpin. *Fantails.*—Second, H. Yardley. Highly Commended, C. Bulpin. *Tumblers.*—First, H. Yardley. Second, C. Cole. *Turbits.*—First, C. Bulpin. Second, E. Pigeon, Lymstone. Highly Commended, H. Yardley. *Any other variety.*—First, E. E. M. Roys. Second, E. Pigeon (Mappies). Highly Commended, E. Pigeon (Hyacinths); H. Yardley. Commended, H. Yardley; C. Bulpin.

### STOWMARKET POULTRY SHOW.

This exhibition was held on the 14th inst., and was remarkable for the fine collection of Game fowls, there being no less than twenty-nine pens exhibited. The number of entries, 140, was greater than last year, and there was also a marked improvement in the quality of the birds exhibited. The Society is evidently becoming better known to the best breeders of fancy fowls and more appreciated by them. The Society is fortunate in having so celebrated a breeder of Game fowls as Mr. Samuel Matthew near at hand, and his yards alone would be sufficient at any time to furnish a good show of Game birds. He was beaten in Piles by the Rev. F. Watson, and the competition between him, Mr. Fletcher, and Sir St. George Gore was very sharp. Mr. Reason Goodwyn had also two or three pens of fine Game fowls in the show. Mr. Lingwood, a well-known breeder of *Dorkings*, is another near neighbour, and he sent birds of a quality to run the most celebrated breeders of the county very close. Mr. James Frost's pen only winning the first prize through being in somewhat better condition of plumage. Mr. Henry Payne, another local Dorking breeder, had a pen of beautiful chickens, cock and two pullets, which took the first

prize, and were immediately sold at the price put upon them in the catalogue—£2 10s. Mr. Henry Lingwood came into competition with Mr. Rust and Mr. Rodbard in the Cochinchina classes. Mr. Rodbard's pen, which took the second prize for Cochinchina chickens, was a remarkably good one. This gentleman had also a fine pen of *Spanish*, beating Mr. R. Postans. The Spanish are a new feature in the Stowmarket show, and four finer pens than those sent on the 14th can scarcely be hoped for at any show. The Judges commended the two pens which did not take the prizes. Mr. Jeremiah Wright, as usual, took the first prize for *Brahmas*, but the class was not quite so good as in some shows. The *Hamburgs* were represented in all the varieties, but not numerously. The Spangled were very good, and the pen of Black Hamburgs shown by Mr. Jeremiah Wright, and which obtained a first prize, were very fine birds. *Lantams* were in great force. Mr. Henry Payne again carrying off a first prize for Game Bantams.

In *Ducks* there were some of the finest, or, at any rate, the largest Aylesburys that we have seen at any local show, and the Geese were equally meritorious, being large, handsomely made, and in beautiful plumage.

*Pigeons* were shown in great numbers and variety, and so good that the Judges highly commended every pair that they could not award a prize to. They were in a similar position with regard to the Rabbits.

The following were the awards:—

**SPANISH.—**First, J. R. Rodbard. Second, R. B. Postans. Commended, W. Hewitt, jun.; E. D. Mills.

**DORKINGS (Coloured or White).—**First, J. Frost, Parham. Second and Highly Commended, H. Lingwood, Needham. *Chickens.*—First, H. Payne, Stowmarket. Second, R. B. Postans, Brentwood. Highly Commended, H. Lingwood.

**COCHIN-CHINA (Any variety).—**First, F. W. Rust, Hastings (Buff). Second and Highly Commended, H. Lingwood. *Chickens.*—First, F. W. Rust (Buff). Second, J. R. Rodbard. Highly Commended, H. Lingwood. Commended, Mrs. M. Seamons.

**BRAMA.—**First, J. Wright, Woodbridge. Second, Mrs. M. Seamons. *GAME (Black-breasted and other Reds).—*First and Highly Commended, S. Matthew, Stowmarket. Second, Sir St. G. Gore, Bart.

*GAME (Duckings and other Greys and Blues).—*First and Highly Commended, S. Matthew. Second, Sir St. G. Gore, Bart.

*GAME (White and Piles, Blacks and Brassy-winged).—*First, Rev. F. Watson. Second and Highly Commended, S. Matthew.

*GAME (Chickens).—*First, E. Pettit, Colchester. Second, S. Matthew.

**HAMBURGHS (Golden-pencilled).—**First, Sir St. G. Gore, Bart. Second, W. B. Webb.

**HAMBURGHS (Silver-pencilled).—**First, Sir St. G. Gore, Bart. Second, W. B. Webb.

**HAMBURGHS (Golden-spangled).—**First, Sir St. G. Gore, Bart. Second, Mrs. Pattison.

**HAMBURGHS (Silver-spangled).—**Prize, Sir St. G. Gore, Bart.

**GAME BANTAMS (Black-breasted and other Reds).—**First, R. B. Postans. Second, Sir St. G. Gore, Bart.

**GAME BANTAMS.—**First, H. Payne. Second, R. B. Postans.

**BANTAMS (Any other variety).—**First, G. Manning (Golden Sbright). Second, Sir St. G. Gore, Bart. Commended, F. Ellis; H. Riley.

**ANY OTHER VARIETY.—**First, J. Wright (Black Hamburgs). Second, J. Pares (Andalusian).

**DUCKS (Aylesbury).—**First and Second, Mrs. Seamons.

**DUCKS (Rouen).—**Prize, C. Punchard, Haverhill.

**DUCKS (Any other variety).—**First, T. C. Harrison, Hull (Brown Call). Second, W. Hewitt, jun. (White Decoy). Commended, H. A. Oakes (White Teal).

**GEESE.—**First, Mrs. M. Seamons. Second, W. B. Webb. Commended, Mrs. E. Roe.

**TURKEYS.—**First, Miss J. Millward, Cambridge. Second, T. Taylor, Combs.

**PIGEONS.—**First, H. A. Oakes (Carriers). Second, G. E. C. Poyd (Pouters). Extra Second, D. Greengrass (Carriers). Third, H. A. Oakes (Carriers). Extra Third, D. H. Feltham. Highly Commended, F. Disney; J. W. Pountney; E. E. M. Roys; J. J. Hazell; D. H. Feltham; W. B. Webb; Wiggins; W. Feltham.

**RABBITS.—**First, E. E. M. Roys. Second, W. Howell. Highly Commended, H. Welshan; G. Mann; G. Gudgeon; G. Jones; C. W. Pettit; F. Roper; G. Stedman; Miss N. Hamilton.

**JUNGES.—**The Rev. Thomas Lyon Fellowes, Beighton Rectory, Norfolk, and Mr. James Monsey, Norwich.—(*Ipswich Journal.*)

### RIGHT AND WRONG.

AN advertisement appeared in your paper a short time since offering for sale a pen of birds which had gained a certain distinction at a certain show. I wrote to have them sent to me on approval. They came. The cock had lost half his tail, and the whole pen looked as if it could not, in any show, have gained the distinction named. The sender informed me by letter, marking under the words, that he was *selling for a friend*. I returned the birds, carriage paid, on the same day, telegraphing their departure, and asking for an animal, included in the advertisement, to be sent on approval. It came, backed with a pedigree, and a description of the purity of its breed, which showed that the advertiser was either a knave or a fool. Disgusted at my second disappointment, I returned the animal carriage paid, stating my objections, and remonstrating with the sender for putting me to expense and trouble by his misrepresentations.

Between three weeks and a month since, the above-mentioned advertiser wrote to me for a Game Bantam cock at a small price. I sent him one from a commended pen for 12s. 6d. He had probably seen my birds at a show held in his neighbourhood. The cock being of the same strain as the hens I did not care to keep him. I forwarded the bird instantly, according to request, as it was to be seen and approved of by some person who was to leave the advertiser's house on that day. The bird was carefully packed in a lined poultry basket. For nearly a fortnight I heard nothing of the bird. I wrote to this effect. A letter, purporting to be the copy of a letter written ten days before, then came. This inadvertently admitted that, as a copy, it was a falsehood, or else it was so clumsily put together as to make it appear like one. The letter contained an abuse of the bird, and an offer of 7s. 6d. for it. This I declined, stating that, even after so long a delay, the bird might be returned at once carriage paid. No notice was taken of my letter, neither did any bird arrive. In the meantime I wrote to the exhibitor of a pen which gained the distinction said to belong to the pen advertised, and sent to me on approval, offering to buy his pen if still for sale, and asking if it were the same pen which had been advertised by my correspondent. With much incivility, or with some knavery, I have not received any answer; therefore I conclude that two persons, *arcades ambo*, were concerned in the advertisement. When I answered this advertisement, I wished to possess the pen that I might put the cock bird into my own pen. When I wrote to the supposed owner of the advertised pen, I wished to possess it for other and obvious reasons. After waiting another week without receiving any answer from either the advertiser or his friend, and without receiving my bird, I directed my man to write for payment of the price. He did so. In two days after this I received the bird, packed, not in my own lined poultry basket, but in a broken fruit basket, without lining, and ill-secured. In consequence of this carelessness, to use the mildest term, the bird's tail feathers are so damaged that he will be useless until after the moult.

In mentioning this matter to a friend, I found that the same person who has victimised me obtained from him a pair of hens on approval, which he unwarrantably kept during the time of, and until after, a certain show, when they were returned with a string of unreasonable objections.

Who can have done this? Can this be right? many will exclaim. I know who has done it, and I will not say that it is right. Truth is a libel if damage can be shown; but I shall be glad to know by what means, not actionable, the unwary can be put upon their guard against advertisers of this stamp.

The person in question is a tradesman, who deals in other things, probably, as he deals in birds.—EGOMER.

### DYSENTERY IN BEES—PREVENTING EXCESSIVE SWARMING, &c.

DYSENTERY in bees appears to me to be owing rather to the want of pure air in the hive than to dampness, although I think the combination of both evils aggravates the mischief greatly. Not seldom it arises from the entrance becoming accidentally choked up with dead bees during a long continuance of cold or bad weather, when the living insects have been unable to carry off the corpses. Depend upon it, that in roomy hives (if not quite full of comb so much the better), with good-sized entrances, and containing plenty of wholesome food stored up in good time, there will be little experience of this complaint. It is important to avoid all feeding from October to February or March. A neighbour of mine suffered greatly last winter from this disease, owing to the constant drip of liquid food into his hives from the inverted bottles at the top. "Damp" certainly "helps to cause it." Some persons recommend that a current of air be made to pass through the hives all the winter, by leaving a hole open at the top of the hive. I have tried this plan myself with good result, but the hives ought not in this case to face any quarter whence cold winds blow prevalently. I would recommend the excision of a comb or two at the close of the honey season, which would make the hive more airy.

With regard to the prevention of excessive swarming, it is sometimes impossible to avoid it, but it may be much checked by the plan I recommended at page 497, No. 222. I am quite aware that up to the time that an artificially-formed swarm is placed in lieu of the driven parent stock, there will be more or less secession to the neighbouring stocks, if near at hand, in

which case, however, they will mostly return the same, or the next day; but I cannot imagine the bees thus succeeding in the case of a natural swarm, when substituted for the parent stock. I presume that the swarm is immediately placed where it is to remain, for when the swarm has had time to establish its distinct individuality, the bees of the two families will often not peaceably unite.

The following recent experience of mine may not come amiss in this place. I was much vexed to see a swarm issue on the 22nd of June last from one of my Tasmanian hives, which I had considered out of danger of such calamity. Although it was a very large swarm, it was too late in the season to do anything for itself. I, therefore, returned it after cutting out of the parent hive every royal cell I could see. I also gave the bees abundant room in a large straw super, besides cutting out some honeycomb from the hive itself. This answered perfectly, but I do not think it a good plan to "join the queen and a few bees taken from the swarm to the parent hive in the evening." How much better and simpler to put the whole swarm, queen and all, in the old stock's place at once.

The brown paper I use for smoking bees is the same as that in which my seeds come to me from the Messrs. Sutton and Sons. It smokes very freely without being dipped in nitre.—B. & W.

### ENTRANCE TO JOINED HIVES.

We have a hive of bees in a common straw hive that seemed too full. Lots of bees hung outside, so we put a piece of wood on the top, with a hole cut in the middle, and another hive with a hole cut in the bottom. Now the bees are working in both with two outlets—one as usual at the bottom of the low hive, and one at the bottom of the top hive on the wood platform. Some of my friends who profess "bee-ology," advise me to step up the top hole, and let all the bees go in at the bottom and work upwards. I think the two holes are best, ventilate the hives, and save the top workers lots of trouble in getting all through the bottom hive to the top.—AN AMATEUR.

[We should close the upper hole, leaving the bees but one entrance, and that at the bottom.]

### CONSEQUENCES OF DEFECTIVE VENTILATION.

HAVING obtained a Woodbury straw hive I screwed fore and aft a flange with a groove in it, so that a square of glass was kept firm, but not tight, on the top of the hive, and on Monday June 5th I hived a swarm in it. On the 26th (three weeks after), the bees had filled eight of the frames, or nearly so, and had begun on the 9th and 10th, on which day I took out a maiden swarm, consisting of the two outside combs on the left hand as the bees enter, for they had begun upon the outside, not the middle, combs. I was lucky enough to find the queen on the first (the outermost) comb; so I had no difficulty, and did not disturb more than the two I removed. They were put into a bar-and-frame hive of native make, of which more anon, and were placed on their original site, and began to work vigorously, seeming scarcely disturbed. The Woodbury-hive was then placed about 2 yards from its old position, but facing south-west instead of south-east, with two spare frames in the vacant notches, and the entrance closed with perforated zinc.

Relying somewhat upon the Woodbury-hive being specially adapted to the making of artificial swarms, and also that the glass cover admitted air on both sides at the top, I concluded that there would be ventilation enough; and wishing that the bees should commence royal cells and settle down sufficiently before they were liberated (see answer to my letter in your Journal of April 18, page 315), I did not remove the zinc till 9 p.m. on Tuesday, thirty-two hours from having made the transfer. When I did so there was a rush of bees about the entrance, and they were active under the glass at the top. Judge, then, my surprise when at 6.30 on Wednesday morning I found the entrance choked up with dead bees, and I scooped out about half a pint before there was a passage for any living bees, which, when they did come, only for a moment hovered around, and then returned to their original home. This went on till at 1 p.m. I became alarmed. The parent hive with its six full frames had scarcely a bee in it, while the maiden swarm in the original position had all the bees. To remedy this I changed the position of the hives: the consequence was that there was a second desertion from the maiden swarm back to the original stock, which set to work on the

whole well, yet showing a disturbance from the want of a queen. But I was again alarmed, for the second desertion was carried further than seemed fair; and as two rainy days followed I gave them a quarter of a pint of syrup each night for four nights, and they did very well, as the young bees from the two frames were then beginning to come out, and they repulsed robbers which were beginning to take advantage of their weakness.

One point I have purposely omitted. A great many of the bees that first deserted from the original hive to the maiden swarm died, and were carried out by the other bees; this happened before the exchange on Wednesday at mid-day, and I would ask, Why did they die? Surely not for want of food, for there were plenty of sealed cells of honey, which they never touched, and I had syringed about a quarter of a pint of syrup among them during the day. Would partial suffocation act fatally some hours after their liberation?

My bees are on a shelf about 4 feet above the ground, under a roof, but open to weather on all sides; now in inspecting the frames, taking them out to see how royal cells are progressing, &c., is it better to remove the hive or manipulate as it stands? I should also be obliged if you would inform me if a nucleus hive is a Woodbury with fewer bars, or is it a smaller hive on the same plan? or what?—M.D.

[The great mortality among your imprisoned bees was owing to the non-observance of our caution regarding the necessity of ample ventilation. Had the crown-board been removed, and a square of perforated zinc been substituted for the glass on the top of the hive, all would doubtless have gone right. The bees which first returned to the old hive had probably acquired some distinctive characteristic during their absence which caused their brethren to destroy and expel them as strangers. Partial suffocation would certainly not be attended with fatal results some hours afterwards. As there appears to be plenty of room for bees that take wing to escape into the open air, it will be much more convenient to them as well as to yourself if you manipulate the hive *in situ*. A nucleus-box should accommodate four full-sized Woodbury frames, and measure 14½ inches long by 6½ inches wide, and 9 inches deep inside.]

### BEEES FORMING COMBS OUTSIDE THEIR HIVE.

A NEIGHBOUR of mine has a hive of bees which he placed, when swarmed, upon a shelf in a dark room, with the entrance of the hive against a hole in the wall; and as soon as the hive was full, the bees commenced building combs underneath the shelf, and now there is a nice lot of combs and bees. Will you inform me how I may drive the bees up into the hive? as I contemplate purchasing them, and fixing some of the combs, which are under the shelf, in a frame-hive, into which I intend to put the condemned bees of two or three hives. I may add that the bees do not get underneath from the inside of the hive, which is a common straw one.—A. R.

[Commence by affording more room by raising the hive on a uadir, slightly wedged up on one side. Then puff a little smoke among the combs attached to the shelf, and, having donned a bee-dress, cut them off one by one, and sweep the bees off each comb with a feather on to the shelf close to the wedged-up side of the uadir, which they will rapidly enter with vibrating wings. The uadir had, perhaps, better remain until autumn, when it may be removed, as the diminished population will then find ample accommodation within the hive itself.]

### BEEES IN A CHIMNEY.

As no answer appeared in your last Number to an application made the previous week by "T. H. F." for information as to how he might secure a swarm of bees which had settled in a chimney in his house, I think I may not yet be too late in rendering him assistance by giving him my experience of a method which I have known to be adopted with success in a similar difficulty.

The mode of procedure on the occasion to which I allude was as follows:—A rope, with a light weight attached, was let down very gently from the top of the flue in which the bees had settled, and when this made its appearance at the bottom of the chimney, a bundle of fresh grass well damped and as

nearly as possible the size of the flue, was attached to it, and the whole was then drawn gently to the top of the chimney, upon which an empty hive had been already properly placed; into this the bees at once ascended, and were removed to their destination without further difficulty. No doubt "T. H. F.'s" bees, if he has not already secured them, have before this formed no inconsiderable quantity of comb, but although this may cause the loss of a few bees, they may still lay up a sufficient store for the winter. At all events he might unite them to another swarm.

On the 10th of June I was presented by a kind neighbour with a magnificent first swarm, which had unfortunately lived in "an old straw" ten days previously. As I was anxious to try one of Nutt's hives I undertook the removal of them, and although they had an immense quantity of young comb formed, I conveyed them safely a distance of two miles, and transferred them with very little loss. They have ever since flourished apace.

The very sudden change in the weather which we have lately had here, has given a great check to one of the finest honey seasons ever known. On examining my cap-glasses yesterday I found nearly all the bees had forsaken them and retreated to the body of the hive; I attributed this to cold at night, and immediately covered each of them with wool, closely wrapt round between the glass and super. To-day, although very cold, on peeping in I found them working away in the glasses as busily as ever.—SQUIB, *County Kildare*.

A FEW weeks since a swarm of bees settled in my next-door neighbour's chimney (a very high one), and after having been there two days, my unskilled friend, without any preparation in the way of dress, took a long fishing-rod and agitated them with it. About half of the bees came down the chimney into the attic, and my friend swept them up with a hand-brush and dust-pan, shovelled them into a hive, and placed them in the garden, where they are now working well, although few in number. The remaining half settled on the roof over the engine boiler, and we placed a hive over them, but when the engineer lowered the damper the sulphur from the flue killed them.—A. R.

[Agitation by means of a fishing-rod might of course disturb a swarm of bees, and cause them to forsake a chimney in which they had just taken refuge, but would be worse than useless, if not absolutely fatal in its effects, if resorted to after combs had been built and stored.]

### OUR LETTER BOX.

GAME FOWLS (*Man of Kent*).—Very glad are we that we met your wishes satisfactorily. We did not feel aggrieved by what we considered intended as an awakener. Editors, like policemen, require inspectors to keep them alert when on duty.

LEG WEAKNESS (*W. H. Fell*).—Your Cochon-China cockerel resting on his hocks is suffering from leg weakness, caused by over-rapidity of growth. It is a common occurrence. Feed him on bruised oats, bread and beer once daily, and plenty of green food. Give him also, daily, two grains of sulphate of iron mixed up with his bread and ale, until he is stronger.

CHICKEN FEATHERLESS AND BLISTERED (*T. S.*).—We are afraid there is no cure for the case you mention, but we have known adult fowls live for a long time in a similar condition. Try the effect of pricking one or two of the bladders, closing the opening with any sort of ointment as soon as the air is expelled.

COCK'S FEET AND LEGS SWELLING (*H. B. W.*).—You would materially assist us in answering if you would describe the breed of the bird. Dorkings are very subject to it, while it is rarely met with in other breeds. If it belong to the breed named, there is no cure, the great weight of the body resting on the feet keeps up the inflammation. If the bird is an old one, the best advice we can give you is to kill it. If a young one it arises from weakness—perhaps from over-growth. Feed very generously; give cooked meat, ground oats slaked with milk, and boiled egg. Keep the bird in confinement, with hay to tread upon. Let it have a large sod of growing grass every day. If the swelling extends above the knee-joint, and the flesh of the thigh, close to the knee, is uneven on the surface, and feels to the touch as if filled with small air-cells, you may kill it at once. It will be a loss in every way, even if it live.

LICE ON POULTRY (*W. B. A.*).—You have two bad things—first, instead of being cleaned once per week, the houses should be cleaned every morning. If the floor is, as it should be, of loose gravel, a birch broom, drawn over the surface, under the perches, and the places, corners, &c., where the birds congregate every morning, will entirely remove all the lice, or can be, in any way offensive. It is a great mistake to have sitting hens in a roosting-house. We believe attention to this will remove the nuisance.

LIGURIAN BEES (*Una*).—Write to T. Woodbury, Esq., Mount Radford Exeter.

WEEKLY CALENDAR.

Day of Month	Day of Week.	AUGUST 1-7, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock before Sun.	Day of Year.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 74.9°, and its night temperature 51.2°. The greatest heat was 92°, on the 2nd, 1856; and the lowest cold, 36°, on the 1st, 1862. The greatest fall of rain was 1.23 inch.

THE GREAT INTERNATIONAL HORTICULTURAL EXHIBITION OF 1866.

THE Belgian horticulturists have for a number of years held a triennial International Exhibition of Horticulture and a Botanical Congress to which the most eminent horticulturists and botanists of Europe are invited.

Last year we reported in the pages of this Journal what took place at one of those meetings held at Brussels, where there was such a gathering of horticulturists and botanists as had not been witnessed, perhaps, in Europe before. With laudable rivalry and noble hospitality Holland stepped forward, and this year gave a welcome to the nationalities, who flocked to Amsterdam to assist at a similar ovation there; and it was at this last meeting that the British representatives were good-humouredly reminded that they had not yet held out the hand of hospitality to their continental brethren, and invited them to a great exhibition in their metropolis.

At the great meeting held at Brussels last year the proposal was made among some of the British representatives to give a return invitation, and they opened a subscription among themselves for the purpose of carrying out that idea; but it remained an idea, and it was not till the return of those who attended the Amsterdam meeting this year that a Great Exhibition of Horticulture in London, to be held in the year 1866, was determinedly resolved upon. That there will be such an exhibition in London next year there can be no doubt. Already a committee has been formed which has held numerous sittings, and at which not only a general programme has been formed, but an exhibition schedule drawn out offering prizes amounting to £2500. In this schedule every class of horticultural skill is represented, and is encouraged on a scale which has never yet been acted upon in this country. The Committee will be composed of all the leading amateur and professional horticulturists in the United Kingdom, and already the list of Vice-Presidents bears such names as those of the Dukes of Buccleuch, Rutland, Marlborough, and Newcastle; the Marquis of Exeter; Earls Granville, Vane, Cowper, Craven, Ducie, Grosvenor, Manvers; Lord Henry Gordon Lennox; the Bishops of Winchester, Oxford, and Bath and Wells (Lord Auckland); Hon. William Cowper; J. Jackson Blandy, Esq.; W. Wilson Saunders, Esq.; Hon. and Rev. — Curzon, &c. The Executive Committee is composed of some of the leading horticulturists about London, obviously with the view of securing efficient aid on the spot in such an arduous undertaking. The Secretary to the Exhibition is Mr. Moore, of

Chelsea, Dr. Berthold Seeman takes the Congress, and Dr. Hogg is General Secretary. Up to the present time, without any effort on the part of the Committee and without any apparent publicity being given to the movement, the sum of £4200 has been subscribed and guaranteed. The intention is to obtain, if possible, the co-operation of the Horticultural Society of London as being the metropolitan representative of national horticulture, and to hold the Exhibition somewhere in the region of South Kensington in a structure to be erected for the purpose, and which will occupy an area of from an acre and a half to two acres. Failing negotiations in this direction the Committee will then turn their attention in some other direction, wherever they may find it convenient to carry out their arrangements.

Our object in directing the attention of our readers to this great national movement, which is to show the nations of Europe the combined horticultural skill for which this country has as yet no equal, is that they may each and all unite in promoting this desirable undertaking, and if there are any who are desirous of rendering local services we shall be glad to be furnished with their names, so that the Secretaries may be placed in communication with them. Copies of the programme, with lists of the supporters and subscribers, are now ready, and are being distributed with all expedition, and those who are willing to receive them may obtain them by applying to the Secretaries. A great undertaking of this kind cannot be carried out without funds, and we trust that all who have the welfare of horticulture at heart will come forward and contribute, according to their ability, in furthering this very laudable and important national movement.

VISITS TO GARDENS PUBLIC AND PRIVATE

BATTERSEA PARK.

For once in my life I am a radical reformer: and although I showed my devotion to the old orange and purple by travelling nearly a thousand miles to record my vote in its favor, I now beg to propose, as a representative of the horticultural interest, the most out-and-out radical I know — Mr. Gibson of Battersea Park; not that I have the pleasure of knowing him personally, for unfortunately he was out when I paid my visit there, but, judging of a man by his fruits, I hesitate not to say he is that. Farewell to your flaming reds and yellows, a long adieu to your three or four kinds of flowers to produce effect; here is a gardener who lays hold of everything he can that will be effective, who ransacks the stove and the warm greenhouse for plants to produce the most beautiful combinations, and who has, moreover, succeeded *à merveille* in so doing. I daresay there are some who say, "All this is very fine; but you know we have been accustomed to see such things done on the continent, and this is no novelty to us." My good *habitué* of the Champs Elysees or the Parc de Monceaux at Paris, of the Coursal at Homburg or the Casino at Florence there is not one of these that can for a moment compare with the sub-tropical garden at Battersea; and *blaze* as one is

with garden sights, here is the man to whom Alexander might have given his prize, for he has invented a new pleasure for gardeners, the surprises of which are not exhausted, but, on the contrary, will every day be increasing as new plants are brought into notice and experimented upon for out-of-door purposes. I had travelled all night from Dublin, and having a few hours to spare before going south, I betought me of Battersea; and taking a boat up to Chelsea was enabled, through the kindness of Mr. Bull (to whom and to Mr. Veitch I paid a flying visit and saw, as one always does, much in both places of novelty and interest), to spend a short time there. As I drove along through the Park I could see that the ordinary bedding-out style was carefully attended to, and hundreds of thousands of plants arranged in the most effective manner; but it was to the sub-tropical garden I was bound, and these were, therefore, but slightly noticed, and, indeed, so hurried was my visit, that I can only briefly tell of what I saw. And I would here say that, beautiful as this now is, in a very short time another and a larger piece, including some water, will be added to it—a portion I did not see, but which I hope some day to ask Mr. Gibson to show me.

On first entering there was before me a long oblong bed of Mrs. Pollock, which effectually answers the question often put as to whether it is a good bedding plant or not. Here it was most beautiful. It was arranged in bands lengthwise in the bed with *Lithospermum fruticosum*. This latter, I think, might be improved upon. It was, I dare say, when in full flower a beautiful contrast; but that was over, and I have no doubt something will be found by Mr. Gibson, if his opinion agrees with mine, to take its place. On the other side of the walk was a bed of the variegated-leaved Vine, edged with a basketwork in which the golden-leaved Japan Honeysuckle (*Lonicera*), was trained. Then one came to beds and borders of Cannas of various sorts; of *Caladiums*, especially the fine large-leaved *esculentum*; *Solanums* looking bristly and formidable, especially *citrullifolium* and *robustum*, but producing a grand effect. But what is that bed in the distance shining with the most resplendent fiery crimson, almost dazzling one's eyes—a bed which I hesitate not to say it is worth going a hundred miles to see? *Coleus Verschaffeltii*, about which many have doubted as to whether it was of any use at all. Here it is the finest thing one can imagine. How it is done I know not; but I looked over the whole bed, and did not see one green spot on any of the leaves. Entering into conversation with one of the gardeners, he told me that it was watered carefully every night overhead, but I rather opine it must have some other treatment to come out as it does here. The bed was edged with *Centaurea gymnocarpa*. The contrast between the brilliant crimson of the *Coleus* and the pure white of the *Centaurea* was admirable. There was another bed of it on the other side equally good, but the effect of which had been, I think, spoiled by placing a row of *Coleus atropurpurea*, a coppery-looking one, between the centre and the edging. Passing along, one came to a large border in which were plants of various kinds—*Senecio Ghiesbreghtii*, Cannas, *Wigandia caracasana*, edged with a border of the *Lonicera* mentioned above. Here again was another bed with a long row of the Indiarubber tree, *Ficus elastica*, with its bright glossy leaves and the purplish red of its young growth. Now one came on a row of *Canna purpurea*, very striking; and I would remark of these and other large-foliaged plants grown here that the shelter for them has been so admirably managed that they have not that torn and tattered appearance they sometimes have even abroad, but are all beautifully fresh and green. The border was edged with a long row of *Iresine Herbstii*, a plant which I think will be found effective, and indeed is more so in another part of the Park than here, as it seems to do better in the shade, and in a bed, than in the sunny aspect it had here. Another small bed was filled with *Centaurea* in the centre, edged with Mrs. Pollock *Geranium*; in fact there was no end to the combinations, while single plants of *Dracænas*, *Wigandia*, and other plants of a similar character were introduced wherever practicable to produce effect.

My object in giving this short notice is not to describe the sub-tropical garden, for I should be ashamed to attempt that after so short a visit to it, but just to give my impressions of it as one of the most successful pieces of modern gardening that I know, and to induce any of the country subscribers to THE JOURNAL OF HORTICULTURE who feel an interest in such things to lay out for one of their days of sight-seeing Battersea Park; and I am sure that they will, when they see in the estimates a round sum for Battersea Park, say, "And never

was money better laid out than it is there. Vote it by all means, and add another hundred if you can to increase Mr. Gibson's stipend."—D., Deal.

## STOCKS, AND THEIR INFLUENCE.

(Continued from page 45.)

Stocks of slow and small growth, also those of a different species or genus from the kind which is to be worked on them, furnish richer sap than a stock of the same kind as the scion, and in such cases a swelling is formed at the point of union, which arrests the sap, and this is then expended in an increased production of blossom and fruit. Thus the scion receives a greater amount of sap than would be supplied by its own roots. Moreover, we may safely conclude that the deposition of cambium is also greater, and this secures the ripening of the wood: hence we find such trees have a tendency to make little wood, the sap being expended in the production of blossom and fruit.

Whilst stocks of restricted and slow growth, and those of a different species or genus, add to the production of blossom and the size of the fruit, as well as its quality, it is certain that the increased productiveness is permanent; indeed, the crops annually increase, the greatest care being needed to prevent overcropping, and hastening the death of the trees. The increased productiveness is so permanent, indeed, that when the tree ceases to be productive it dies. It has been contended that trees so worked are short-lived; this is, undoubtedly, the case when they are compared with those on stocks of their own kind, still I think that in most cases they will be found equally durable as fruit-bearing trees, if we consider that they arrive at a fruiting state earlier, and continue in bearing whilst those worked on stocks of their own kind are only undergoing a preparatory process. We may conclude that such trees are only short-lived when the stock grows in rich soil, and the pruning is too severe. An excessive use of the pruning-knife, especially for the reduction of parts not wanted to produce fruit, generally causes disease, which is one of the greatest objections raised against stocks of slow or less growth, and of a different species from that worked on them. I shall not contest the point that they debilitate, but will admit the soundness of this view of Mr. Knight and all physiologists since his time. Granted that such unions do debilitate, we have to inquire into the cause of the debility or premature decay of the tree, or a part of it. Now, the ascending sap being richer, and the descending current arrested, it follows that there will, to a marked degree, be a greater deposition of matter in the scion than in the stock. This matter, from the increased quantity of blossom and fruit, is certainly cambium, which will be either gummy or mucilaginous; gummy in stone fruits, as the Apricot, Peach, Plum, and Cherry; and mucilaginous in the Pear and Apple. Any addition to the natural deposition of this matter must necessarily lead to a closing of the ascending and descending channels of the sap. Hence the sap will flow less abundantly into the old shoots than in new wood, and they will in time have the sap-vessels so small as to cause the total exclusion of the sap from that part, resulting in its death, or becoming so weak as to be incapable of producing fruit of the usual size and flavour. Of fruits exhibiting this disease in a marked degree, the Apricot affords an example; the Peach also, but to a less extent; and they are on stocks of another genus. Next in order come the Cherry on the common Cherry stock, and the Plum on its Brussels stock. With the Apricot there is an exudation, sometimes also in the case of the Peach, but in the latter it is more confined to the wearing out of the shoots, and on this account we have the bearing-wood of Peach trees annually replaced, though this is by no means necessary to obtain fruit, as such is readily produced on spurs. The Plum and Cherry occasionally lose their branches, and those of the first remain weak and unfruitful in consequence of a deficiency of food, rather than from any debility of the tree arising from the stock. There seems to be no permanent remedy for this evil other than working the Plum on a stock of its own peculiar kind.

From some experience, I am led to draw the following conclusions in respect to stocks of smaller and slower growth than the trees grafted or budded upon them. 1st, They are desirable for early-producing trees, and when the space for their heads is limited. 2nd, The trees grow more freely on them than on stocks of their own kind, but such growth is of short

duration, and can only be maintained by rich soil, and considerable reductions of the annual growths, which are a fertile source of disease and early death. 3rd, Any great reduction of the head at the winter pruning causes increase of wood, exhausts the energies of the stock, and is obtained at the expense of a plentiful crop of fruit; it also induces disease and early death. 4th, The grafting or budding on stocks of slower and less growth, and also on those of a different species or genus, though it renders trees very fruitful, may be carried too far, as, for instance, in the case of the Apple on the Pear. 5th, The trees should not be induced to make large annual growths to be cut away or reduced considerably at the winter pruning, growth only being needed until the allotted space is covered, after which the vegetation of the stock and scion should be balanced by judicious summer pruning. 6th, The trees worked on them produce fruit or flowers at an earlier age, but not at an earlier season, and the fruit is more abundant, larger, and of higher flavour than on stocks of their own kind.

Now as to budding or grafting on stocks of a growth approximating to that of the scion, it is certain that we follow a more natural process; but then we must provide for each kind space for the full development of its head, otherwise it will prove unfruitful. We must give the Apple and Pear their place in the orchard, and have walls and houses sufficiently large for the full development of all trees requiring protection in our climate. We must be content to see trees growing, but seldom fruiting or blooming; to plant an orchard for another generation, and to plant a vineyard and let another eat of the fruit thereof. It really seems contrary to the order of cultivation itself. We invariably like the animal with small bones and abundance of fat, and we of the sister art surely do not want large boughs without flowers, long branches without fruit. I am not prepared to state that this is the result of grafting or budding on stocks approximating in growth to the variety worked, for I know the best results attend such a union of favourable influences; but we must not limit the ultimate growth of the kind to one-third or one-half the space that it would require when it arrives at a state of maturity. When we employ a stock for grafting or budding upon approximating in growth to the scion, we must provide space for it the same as if it were growing in a state of nature, annually increasing until the natural size be attained. I think the prevailing opinion that the "graft overruleth the stock quite" is an absurdity, for it is pretty certain that the stock will continue to grow up to the age natural to it, and then it will take a downward course irrespective of any influence of the scion. We see the Pear on the quince luxuriant for a time and requiring biennial or triennial removal to keep it in a fruitful state, but after a time the Pear does not need this removal, the growth being small and the tree very productive. If the graft overruled the stock, the Pear would go on growing until it became a tree 40 feet in height, yet it remains a fruitful tree at the height of a quince. The Apple on the Paradise is generally a productive tree, but when it is limited to a small space it is for the most part unfruitful after that space becomes covered; in a word when we employ stocks of approximate growth with the scion we must provide space for the full development of their heads or restrict the root-action in a corresponding degree with the limits of the branches. Such stocks are then injurious, inasmuch as they supply more nutriment than can be expended in the production of blossom and fruit, and the consequence is abundance of sap wood in the place of either. The main characteristics of a stock approximating in growth to the scion are, that the stock and scion remain nearly of the same size at the point of union, the sap flows more freely, both ascending and descending, consequently the trees have a tendency to grow upwards, leaving the lower parts of the tree weak and bare, to which I may add that the trees are remarkably healthy, but are more impatient of the knife than those on slower and smaller-growing stocks. From a tendency to grow upwards we frequently find the Apple on the Paradise losing its branches when trained horizontally, and shooting strongly from the upper part of the trunk and espalier. So long as there is space for the annual increase in size, the growth of stock and scion correspond, but after the space becomes occupied it is no unusual occurrence for the scion to grow in advance of its stock, and exhibit all the evil of a tree on a stock of stronger growth, the tendency to make wood instead of fruit.

Grafting or budding on stocks of stronger growth is rarely practised, and only in cases where it is desirable to give increased vigour; the stock in this case grows in advance of the scion, but the tree is no stronger after all, and its fruit is not

increased in size, and is less plentiful. It is in truth planting a tree with its roots upwards, for the scion having smaller sap-vessels the sap does not flow freely into it, and the result is an abundance of suckers from the stock; the scion receives no more sap than its vessels will admit of, and that of the thinnest and poorest description. Then the descending sap is not arrested, but flows downwards freely into the stock, causing a greater deposition of cambium in it than in the scion. The tree, it is true, is for a time rendered more productive, but its fertility is of short duration, and the branches in a short time become decorticated as if ringed, and roots are emitted from these parts if they are covered with moss and kept moist, or placed in the soil, just as if nature sought to provide what is necessary for the existence of the tree.

Finally, if we wish for healthy trees, long-lived and continuously productive, we must select stocks of similar habit, and earliness of growth, and not prune or limit the annual growths much at the winter pruning. When stocks of slower and smaller growth, or of a different species or genus, are employed we must keep up an abundant supply of sap by high feeding or manuring, and not prune excessively if long-lived trees are wanted, pruning having a tendency to cause the production of young wood and finer fruit for a time, but its effects are temporary and end in early debility and death.—G. ABBEY.

### THE MODERN PEACH-PRUNER.—No. 13.

#### THEORY OF CLOSE PRUNING.

The history of this part of our subject is somewhat obscure, and though interesting in itself, a brief notice will suffice. The present style is, no doubt, only a revival of what had been touched upon by Keith in this country, and De La Quintinie in France, nearly at the same time—that is, about 150 years ago. For a certain period no progress seems to have been made, though the matter was freely discussed in both countries. We may, therefore, take the late Mr. Knight, a very competent authority, as a fair exponent of closer pruning in more recent times. The passage is quoted by McIntosh, and is as follows:—"Instead of taking off so large a portion of the young shoots, and training-in a few only to a considerable length, as is usually done, as I should myself do in every favourable situation, I preserve a large number of young shoots which are emitted in the early spring by the yearling wood, shortening each where necessary by pinching off the succulent points, generally to the length of 2 or 3 inches. Spurs, which lie close to the wall, are thus made, upon which numerous blossom-buds form very early in the ensuing summer; and, upon which, after most unfavourable seasons, and in situations so high and cold, that the Peach tree in the most favourable seasons had usually produced only a few feeble blossoms, I observed as strong and vigorous blossoms as I usually have seen in the best situations and seasons, and I am quite confident that had the Peach trees in gardens round the metropolis been pruned in the manner above described—that is, upon spurs, in the last season, abundant and vigorous blossoms would have appeared in the spring."

Mr. Knight then proceeds to recommend a mixed system of long and close pruning, which when judiciously carried out is very successful. It indeed requires some experience in the selection of the proper class of shoot. Mr. Knight seems to be disposed, however, not to trust the whole crop on spurs formed by close summer pruning. In "warm situations," the ordinary long pruning, he says, may answer; but "in cold and late situations then try the spur method. A mixture of both modes, in every situation, will generally be found to multiply the chances of success, and, therefore, neither ought to be exclusively adopted nor rejected in any situation." This is sound and practical counsel, and comes from an excellent authority; and McIntosh, alluding to these remarks, says of them, that they are "well worthy of the attention of Peach-growers in all situations, even in favourable localities, but especially so in cold and late ones."

Since these opinions were published, Peach-pruning has considerably advanced, and it is not too much to assert that orchard-houses have revolutionised the whole system. A similar change seems to be imminent in France and elsewhere.

In France, especially, close pruning has at present numerous advocates. Though, as we have seen, this system is only a revival, there is no doubt that the Imperial Society of Horticulture of France is justified, in its report of 1862, in speaking as follows:—"We must leave to M. Grin, of Chartres, the

honour of having at least popularised the original idea; a fact which has the real merit of a veritable initiative." Speaking of close pruning, Professor Dubreuil says—"I saw in M. Grin's gardens such excellent results from this method, that I hesitate not at present to recommend it to the exclusion of every other." In Professor Gressent's late work (which has the sanction of the Minister of Agriculture and Commerce), it is stated that M. Grin, being convinced of the many disadvantages resulting from the old system of long-pruning, applied himself for a lifetime to work out a newer and more profitable way, and finished by obtaining a complete success. The shoots, he says, being so short the branches may be double in number, and each of the closely-pinched-in shoots bears at least as many Peaches as the *coursommes de Montreuil*. Professor Gressent then adds, that the complete success which attended M. Grin's labours, caused him much envy and resistance in his native country, but that having, like M. Dubreuil, visited Chartres, he was so convinced of the advantages of the new style that he has ever since adopted it. In his work of 1863 he describes it, and says that he has followed it on a very large scale, and introduced some important modifications, which, being similar to some tried in my own garden, shall be noticed presently.

M. Grin has laboured under some disadvantage in having his ideas first presented to the world in the works of others. Though fairly enough described, the actual experience gained is not represented, nor his latest ideas, and it is with a certain pleasure that I am able to state, that these lines are the only authorised exposition of the whole system in its latest development, and that by them alone the originator wishes English gardeners to learn it. Having myself followed the system for ten years with some success on the open wall (the first occasion on any scale in which it has been thus tried in this country), and having applied it to the back wall of an orchard-house, with diagonal cordons (also a novelty, as described in a former work), a certain experience has been gained not without value.

On the practical advantages to be derived from close pruning, M. Grin thus speaks—"Whatever form may be selected for the trees (his were horizontal cordons with a single central stem, and single diagonal cordons), first establish well your principal branches. On these, by close pruning to two leaves, short spurs are formed which bear fruits of equal size in every part of the tree year after year. It is true that M. Lepère by a different system (long pruning), produces good crops, but nine out of ten fail because they do not possess the constant practice and special science required for such a style of pruning. Some eight or ten successive operations are required in long pruning, all requiring an exact appreciation which does not belong to the generality of gardeners. On the other hand, close pruning has the immense advantages of simplicity and economy of time and money. There are no tedious tings-in of the summer or winter wood. The main branches are only 10 inches apart (and here let me observe that 6 inches would be better), therefore, without a given amount of wall space we can obtain a double amount of crop. Lastly, there are few or no amputations of important branches, and this alone constitutes an appreciable gain, even to suppress 'gourmands' (gross shoots of Class 4), or to shorten extensions where needed. Every amputation however well performed causes a perturbation in the economy of the tree. Why not anticipate the causes which necessitate amputations, rather than have the merit of curing them? Besides this, even clever gardeners cannot always succeed in remedying the evil effects of wounds on the tree."

The above are the chief reasons given by M. Grin for adopting very close pruning or summer-stopping of the shoots. In fact, there seems no reason whatever why a well-furnished main branch should ever be shortened at all. If the shoots are kept regularly and closely summer-pruned, the prolongations of the branches may, with the exception of equalising them, be left to themselves. How simple would Peach-pruning become under these new forms! Plant the tree carefully in a well-chosen and well-drained spot, allow it to grow, only balancing it, keep the summer wood short, thin out in winter a little; this, with shelter and destroying insects, &c., is really all.

We thus perceive how really simple and easy to perform Peach-pruning is. Good pruning should not differ much in principle whether in the open air or under glass. In either case if we take care of the shoots the branches will take care of themselves. The exigencies of space, of course, require that we should direct the growths in the most convenient manner; but a branch 20 feet long in the open air can be made to form

a compact spiral cordon, occupying little space, round three vertical wires, and no style of training is more beautiful or more productive.

To the above cited well-known names, which are now connected with the success of close pruning, I may add that of Mr. Rivers. Orchard-houses have, indeed, done much for the Peach. Their multiplication induced corresponding developments in training. The great object was, of course, to economise the valuable space, and to do this close pruning was required; and, in consequence, we find the principles of close pruning well described in Mr. Rivers's works on the management of these houses. There need, therefore, be little doubt as to the solidity of the foundation of these truths. As was stated at first, the chief object of these papers was to point out the utility of a system which should serve, with obvious changes, both for the house and for the open wall, and each succeeding season has proved that this is possible.—T. BRÉHAUT, *Richmond House, Guernsey.*

## ONION GRUBS.

VERY often it is easy to prevent the occurrence of a mischief, whereas to remedy it is very difficult. The Onion grub is a case in point, if the information just imparted to us be correct. When the grub has begun to eat the bulb, no remedy is available; the bulb had better be pulled up and burnt, thus immobilising the marauder. The parent of these grubs begins to deposit her eggs just within the sheath of the young Onion plants early in May. A preventive of this, we are told, is to sprinkle *fresh* pine or deal sawdust all over the surface of the Onion-bed, as soon as the Onions are well above the soil. The sawdust need not be put on thickly; but a little fresh might be sprinkled on once a-week until the bulbs are safe. We have faith in this preventive, because the turpentine fumes emitted by the sawdust are obnoxious to all insects, and might keep away the flies.

## BEARD'S PATENT METALLIC GLASS HOUSES.

WHEN I wrote the hurried note at page 34, I had just been visiting the excellent Bury St. Edmunds Horticultural Show, held by the kind permission of Lady Cullum in the grounds of Hardwicke House. Without saying anything at present of the fine subjects exhibited, I would merely mention that I was much struck, as already stated, by the rich bright colouring of some Pelargoniums and Petunias, and on inquiry ascertained that they were exhibited by Mr. Beard, a retired tradesman of Bury St. Edmunds, and came from houses of his own designing and constructing, for the peculiarities of which he had duly protected himself by several patents. Of the patents and the chief particulars patented, I can do and say nothing. I had previously seen several houses put up without putty, and but little painting, but had failed to see any improvement in them, or that they had much except novelty to recommend them. I had heard these houses of Mr. Beard spoken about, as presenting a sheet of light to the plants inside; but I knew that some of our modern orchard-houses admitted rather too much light, in connection with the heat from the sun's rays—at least for the amount of ventilation that could be given. I was also well aware that light was the first essential, provided the ventilation was ample, and that that ventilation did not unduly dry up and parch the plants under the glass. I, no doubt, seemed a retrogressionist to some keen go-forward gardeners, when I said that fine plants could be grown in lean-to and span-roofed houses, built with large squares in the usual modern manner, and that the want of high colouring and robustness in plants was more owing to crowding and growing under the shade of creepers, Vines, &c., than from any deficiency of light transmitted by the glass. I make these statements merely to show that I was not predisposed to approve of these new houses, and now, in reply to a number of inquiries, I would repeat, after having more time to think over the matter, just what was stated at page 34, that the matter of first expense got over, there can be no question of the great improvements.

Through a friend, I was introduced to Mr. Beard, who kindly showed us his different houses, and introduced me to his relative, Mr. E. J. Sanders, of the Victoria Works, Bury St. Edmunds, who manufactures the houses in question, and he took us over the works here. Several houses, lean-to and span-roof, were in the process of building.

I need not at present say anything of the old, heavy, wooden houses that kept out more than a fourth of the light, and entailed a constant expense to keep them slightly and in repair. I need not calculate what even the cheapest modern orchard-houses will cost for glazing and painting after the few first years' wear. I need not speak of the objections to iron houses glazed in the usual way, from the expansion and contraction of the metal, glass, &c. I need not tell of the breakage by expansion, when glass was placed edge to edge with out laps, from the putty becoming too hard to permit of expansion. I need not describe how, when large squares were fastened without putty by means of screws and elastic bedding beneath the screws, the glass rattled in a windy day as if it resolved to dance merrily to the inspiring music of the gale; but I must add, that all these drawbacks seemed to be avoided by the simple plans adopted by Mr. Beard.

Light and elegance are secured by making the house an almost continuous plane of glass from the top to the ground level, whether the house be lean-to or span, the sash-bars being strong, elegant, but light, and without any rebates. Ventilation is secured by openings at top by various modes—as lever, rod, &c., and in the front close to the ground, which might be modified in peculiar circumstances. No lap with its accumulation of filth is seen, as the large squares are cut to butt close against each other. No putty is used, and here, I think, will be found the great feature of the plan. A strip of non-conducting elastic material, as asphalt, is placed on the flat upper side of the bar and as wide as the bar, these bars being generally 2 feet apart. The glass squares rest by their edges on this asphalt, another strip is placed over the glass, and then a neat thin iron rod, flat below and rounded above, is laid on the top of the upper strip over the glass, and is connected with the bar with screws, holding all firmly in their place, and yet the elastic material prevents all injury from expansion and contraction. If the glass were fitted edge to edge crosswise, and glazed with hard putty at the sides, there would be danger of cracking by expansion. I should be afraid of the same thing happening if the glass were placed edge to edge crosswise, and the end of one square came close to the end of the other square on the middle of the bar, without rebates, even with the assistance of the elastic material below and above, as the glass could neither expand laterally nor longitudinally. But, now, in Mr. Beard's plan, is a simple but distinct feature. The ends of the large squares do not meet on the middle of the bar, but about a quarter of an inch or so is left between them, and this room for lateral expansion is found sufficient that I was assured that not a single square had been cracked for three years, and that even the lowest squares that abutted over the water-trough passed through the winters unharmed. It will be seen that the system not only does away with puttying at first, but it does away with all chipping and hacking when a square is broken. The thin rod that secures the glass and its bedding to the bar is in several pieces in a roof at all wide, and when a square is broken the two opposite pieces of rod are unscrewed, the damaged square removed, and a fresh one slipped in and screwed down. No glass is proposed to be used under 21-oz. per foot.

Painting, one of the most expensive operations connected with the building and keeping up of glass houses, is hoped will be avoided—first, by the use of galvanised iron. It would be well to obtain evidence as to how long the galvanising would last when exposed to the atmosphere. Even if it proved pretty lasting, the dark dingy colour might be unacceptable to many people, as it will get darker as it becomes older. To remedy this drawback, I was shown iron undergoing a process of enamelling. The pillars, bars, &c., are first painted with red lead and undergo a process of baking, are then several times painted with peculiar white paint, and baked or roasted in a high temperature. Some sash-bars shown me were as hard and bright as white china. Of course, it will have to be proved how long this enamelling will last.

And, lastly, the first inspection showed me that such houses would be valuable for tenants who did not wish to put up what they could not take away. The houses, whether lean-to or span, are supported at the sides by neat iron columns of any requisite height. Each of these columns is hollow, and not only supports the roof and water-spout, but takes the water into a drain or other means below, or a number of the hollow tubes may be stopped if the water is to be taken to either or both ends. Everything is made to fit, and screwed neatly together, so that when all is in readiness a house is soon put up and soon taken down.

I may add, that I know nothing more than what I saw in a short visit, that I did not take a single note, and merely write from memory, that I never heard of the patentees before, that I write this without their knowledge, and having no other object than to make a novelty in the right direction generally known, convinced, if the system answer, it will be used for many purposes besides houses for growing plants, and other horticultural uses.

Perhaps, as already hinted at, the best practical idea involved, is not only the elastic substance beneath and above the glass but more particularly the *open space* between the squares on the sash-bars. No doubt that looks a very simple matter, and so it is when we see it. Anything is simple only when understood. We neglect too often to make valuable discoveries because we look beyond simplicity. Intending builders may now consider and make inquiries for themselves. I have stated all I know at present.—L. FISH.

## MY PLANTS.

AND HOW AND WHERE I FOUND THEM.—No. 7.

BUT shall I ever be forgiven for wandering so long from my subject of "Plants," to toy amongst the animals and fish of Jersey? Let me at once refer to my notes and *hortus siccus*, and see what were the results of a day spent at Grève de Lecq, in June, 1860. We had long heard of the charms of this beautiful little bay, and determined upon judging for ourselves of the same, and we looked forward with much pleasure to our trip from St. Saviour's to the north-western coast of the island. Rising early and packing up our basket of provisions for the day's need, we started off in a small pony carriage, which had been kindly lent us for the occasion. The sun was shining brightly, indeed, it was one of those gorgeous mornings which, all radiant with the sun's smiles at their birth, so often ere half his race be run, leave us in sorrow and tears. Foreseeing what was likely to occur, we fully provided for the impending rain, and safely packed our waterproofs and umbrellas at the bottom of the conveyance, forming impromptu seats for the two children, very unaristocratic no doubt, and quite unconventional! But bear with us awhile, good reader, for we are unconventional people, and ours are unconventional children, and I may state, that during our return home the horse became unconventional enough to run away.

Our drive was chiefly through narrow lanes, for we were travelling from east to west, and the principal roads in the island run from south to north. The orchards were white with blossoms, fainting in the heat of the mid-day, soon a breeze sprang up, and like a shower of snow in summer, the petals fell thickly upon the green grass. Enjoying the increasing coolness of the air, and pleased that the beautiful blossoms we were watching, and the lowly flowers by the wayside, would alike soon be equally refreshed, we urged our pony forward at a quick pace. Large and heavily fell the tardy rain-drops, the branches of the trees waved to and fro in grateful acknowledgment of the coming benefits; all nature seemed stirred, like children who, having received a promise of some long-looked-for gift from a parent, are now about to realise the fulfilment of their wishes. Passing St. John's Church we were not long in arriving at St. Mary's. As we did so, the rain poured down in torrents, and continued all the time we were descending the lovely valley which leads to the bay. Much to our disappointment, we scarcely saw anything of the banks on either side of us; therefore, an old historian shall take you through the defile. He says—"On quitting St. Mary's Church we soon enter a romantic valley, serpentine between lofty swelling hills richly clothed with Fern and other wild shrubs, that, if less profitable to the owners of the gritty soil than the golden treasures of Ceres or the juicy gifts of Pomona, display a lively verdure on which the eye rests with pleasure. The valley is likewise shaded in different parts with groves of Oak and Fir. At length the winding path descends rapidly to a beautiful cove called Grève de Lecq. This inlet in its full compass may be said to reach from the promontory of Sorel to that of Pleumont." Just as we reached the bottom of the valley the rain ceased, and closing our umbrellas the full beauty of the little bay stood out in the sunshine; I thought it one of the most lovely spots we had visited.

Putting up our horse at the hotel, and drying ourselves and the children, we started off to the beach. My husband climbed the almost perpendicular cliffs to obtain a good view seaward, whilst I was searching the sands for Grasses. I had no sea-

side Grasses in my collection, and my delight was great when I came upon the *Elymus arenarius*, Upright Sea Lyme Grass; also, the *Triticum junceum*, Sea Wheat Grass; and the *T. cristatum*. A little further inland I found the *Lepturus incurvatus*, Hard Grass of Soverby, or the *Rottboellia incurvata* of Withering. There also, was the *Poa loliacea*, and close to it the *Carex intermedia*, Soft Brown Sedge; and *Carex ampullacea*, Slender-beaked Bladder Sedge; with some poor starved specimens of a *Bromus* and *Hordeum*, the latter, probably, the *H. maritimum*, and the former, I believe, was the Soft Brome Grass, and I do not know how many kinds of *Festucas*, but I have marked the *F. miqumis*; and beside it are several others the names of which I am fairly puzzled to decide. In the same sheet also are two dilapidated specimens of *Bromus maximus*, peculiar, I believe, to Jersey, and rather celebrated from the extreme length of the awns. Nearer the road, about halfway between the beach and the hotel, we come upon the *Poa maritima*, Sea Meadow Grass; and the *Glyceria maritima*, Creeping Sea Sweet Grass; also, some good roots of the *Hordeum maritimum*, better nourished than those growing entirely in the sand and closer to the sea. I considered myself very fortunate in securing so many varieties of my favourites. Saving the falling of my little boy into a gully formed in the sands, which immersed him above the waist in salt water, and the restiveness of our borrowed pony on our return, we met with no very untoward event.

Another day we started on foot to witness a review of the militia belonging to the island. They comprise both artillery and infantry; they are clothed by Government, but receive no pay. Being drilled very frequently they have become a very efficient body of men. There is, also, a juvenile corps, the boys of which are exercised weekly in summer time. It was a pretty sight to see the men collecting from all parts of the island, St. Helier's being their rendezvous. From the top of "Gallows Hill," or Le Mont Patibulaire, which rises above the sandy plain on which the town of St. Helier's stands, we had a fine view of their evolutions.

Wearying after a time of gazing down upon the beach in the full blaze of a scorching sun, I turned my attention to a low wall which was running along the top of the hill at my back, and extracted from it roots of *Festuca rubra*, Creeping Fescue Grass; and *F. ovina*, Sheep's Fescue; and lower down amongst the light sandy soils, the *Poa loliacea*. The damp air of evening was slowly rising ere we turned our steps, tired and fagged as we were, to descend the hill towards St. Helier's, but I was not too tired to notice a, to me, new Grass growing under the wall on the eastern side of the town. I sought for it subsequently in several botanical works, and have considered it the *Festuca myurus*, Wall Fescue Grass; I will not be certain that I am correct, it is a slender Grass with smooth shining stems of about 2 feet in height, rather roughish leaves, the panicle from about 6 to 7 inches in length, unilateral; flowers very small and shorter very much than their long awns; spikelets containing about six flowers. The general appearance of this Grass has something extremely elegant about it; the root, leaves, awns, and flowers, all being exceedingly fine and delicate.

Whilst writing of strolls about this island, my mind again sees a picturesque group by the wayside. A donkey, goats of all ages and sizes, from the ancient, important, and grey-bearded *paterfamilias*, upon the rock above, to the tender kid quietly cropping the sward below, perhaps thirty in all. And whose keen eye and quick voice reigned over this united family? Who so hastily chid the straying kid, or if wearied took it up in her arms with the affection of a mother? In the midst of her pets stood, with all the authority of a queen, a dark-haired, strange-looking woman. That her eye was wild, her hair undressed, but beautiful; that her manners were those of a lady, all this was seen at a glance, and one was fairly puzzled to guess what delight she could have in passing days, and weeks, and months in the society of creatures of instinct, rather than with rational beings; seldom noticing the passers-by, or if she did so, merely giving an uninterested or cursory glance, she busied herself with her pets, or sat quietly upon a stone, or portion of rock, knitting. Her handsome face was bronzed with exposure to the sun, and rendered coarse with years of battling against the wind and rain. Kind friends there were at home, a room prepared, and affectionate welcome, but seldom did she return thither. Wandering! ever wandering! night and day o'er rock and hill, or down the deep and silent valley midst the roar of the tempest, through the drenching rain, those poor feet, so small, so pretty, so well fitted for the dazzling ball-room, and the comforts of home, foot-sore and

weary, plodded their restless way. Hair falling straight and long from beneath her brown hat, dress bedabbled, jaded as she was, on she went; beneath the parching sun of mid-day, or the chills of night, it was always the same; the morning dew and the evening mist alike saw her pressing on and on into an unseen future, ever striving and never attaining that object of affection, whom years long back (so told the cottagers), some sudden and fearful calamity had torn from her. It was a sight to make all those who saw her, with tearful eyes offer up a prayer that her wandering spirit might, ere long, leaving behind it this unsatisfying earth, with its sorrows and unquiet, attain unto that never-ending "rest which remaineth for the people of God." Nothing would give me purer or more saddened pleasure than to smooth the pillow and comfort the last hours of that most afflicted of earth's children.

"God rest thee!  
We shall go about to-day  
In our festal garlands gay;  
Whatsoever robes we wear,  
Not a trace of black be there.  
Well, what matter? None is seen  
On thy daisied-covering green,  
Or thy maiden pillows, hid  
Underneath a coffin lid,  
God rest thee!

"God take thee!  
Ay! no other. Sleeps beneath,  
One who died a virgin's death;  
Died so slowly, day by day,  
That it scarcely was decay,  
Till this English churchyard kind  
Opened, and we leave behind  
Nothing but a little dust.  
God is tender. God is just.  
God take thee!

"God keep thee!  
Nevermore above the ground  
Be there relics of thee found:  
Lay the turf so smooth, we crave,  
None would guess it was a grave,  
Save for grass that greener grows,  
Or for wind that gentlier blows,  
All the earth o'er, from this spot  
Where thou wert, and thou art not.  
God keep thee!"

—ALICE.

## THE GENERAL REJECTION OF TOADSTOOLS.

I FEAR my letter on that species of Agarics called commonly "Toadstools" must have escaped your attention, being satisfied that the importance of the subject has not been underrated by me. I believe this is the only civilised country in Europe where Toadstools are not eaten with relish both by rich and poor, more especially the latter, for whose especial benefit the Rev. Mr. Badham, in his excellent book on "English Fungi," seems to think a kind Providence intended them, spreading them out in waste places, by roadsides, in forest nooks and corners where the poor might gather them without trespass. Mr. Badham, too, gives in his book excellent recipes for cooking the different species of these Toadstools, and in language graphic enough to make the mouth of a London alderman water for a taste. This, too, and August and September, is about the season for these Toadstools; not above one in a hundred being poisonous in England, whilst in the vicinity of Rome, where a much larger per-centage is poisonous, many hundredweights are sold daily in the markets at about 3d. per lb., and bought alike by rich and poor, and eaten as nutritious and palatable food.

Surely it would be a great boon to the poor of this country if the foolish prejudice against these Fungi could be got rid of. In September, after the harvest had been secured and work became slack, the labourer might with little trouble gather a plentiful meal for his family, which would, well cooked, delight the palate of an epicure in Paris.

Mr. Badham tells us the clergy of Confucius in China have published a book enumerating over four hundred vegetable articles of food that the poor might have recourse to in times of dearth—such as the inner bark of certain trees and shrubs, and various leaves, berries, roots, &c., of weeds and plants that grow wild in the fields. Why should not your Journal open the campaign against the foolish prejudice relative to Toadstools and all the Agaric tribe save Mushrooms?—WASOX.

[We are doing the utmost that we can by publishing, for 1s. monthly, four coloured drawings of the "Eatable Funguses;" but we cannot recommend the indiscriminate consumption of "Toadstools." Orfila's "Toxicology," the "Transactions of the London College of Physicians," the "London and Medical

Physical Journal," and other works contain too many painful records of poisoning by Fungi to justify any one in publishing an indiscriminate use of them as food. We published more than twelve months since (No. 138, page 395), the details of a family being poisoned by eating the *Agaricus fertilis*, and gave a drawing of the species.]

### ROYAL HORTICULTURAL SOCIETY.

FLORAL COMMITTEE, July 25.—But few plants were sent on this occasion, and none of any particular interest. Messrs. E. G. Henderson, of Wellington Road, sent their collection of new Fuchsias, two of which received first-class certificates—viz., Enoch Arden and Father Ignatius, the former a neat compact flower, bright crimson sepals, reflexed, large deep purple corolla; the latter with a much lighter corolla. The others consisted of Rose of Denmark, a pale colourless variety; Rhodoric Dhu, dark purple corolla; War Eagle, Village Pet, and Lucy Mills. There was no advance or improvement in many of the older varieties, and it will be long before a more elegant or free flowering variety is exhibited than Souvenir de Chiswick. Mr. Salter, Versailles Nursery, sent a seedling Nosegay Pelargonium, *Impératrice des Nossegays*, bright red flowers forming a large globular truss. The merits of this seedling will be better known when it is seen bedded out. The plant exhibited had evidently been grown under glass. Messrs. Smith, of Dulwich, sent a pale light blue Delphinium, *Madame H. Jaecot*; a small collection of Balsams; seedling Phloxes, *Chancellor*, a dark red, and *Beauty of Dulwich*, pale lilac with dark centre; *Fuchsia Eva*, with a double white corolla; *Fuchsia L'Africaine*; *Fuchsia multiflora*, a good market variety; and *Fuchsia Enoch Arden*, which must not be mistaken for Messrs. Henderson's variety bearing the same name. *Zonale Pelargonium*, *Golden Dwarf*, *Aureum*, and *Bronze Shield*, also came from the same firm. Mr. Townsend, Hornsey, sent two Japanese Liliiums, the flowers were faded and appeared to have been a dark chocolate, the other a tawny yellow. Mr. E. Davis sent four single flowers of *Lady Sherburne*, double white *Fuchsia*. As no plants were sent, notice could not be taken of them. Mr. Cox, gardener to Earl Beauchamp, exhibited a white seedling *Lobelia*, probably of *L. ramosa*. If suited for bedding purposes it will be a desirable plant—first-class certificate. Messrs. Veitch exhibited *Dendrobium* species, from Australia, sent homo by Mr. John Veitch. The same *Dendrobium* was exhibited by Mr. Wilcox, gardener to Dr. Pattison, of St. John's Wood. Mr. Bull exhibited *Allamanda Hendersonii*, a very fine free-flowering plant with large yellow flowers—first-class certificate; also *Bigonia argyrea* violescent with beautifully marked foliage; the plants were exhibited under glass—first-class certificate. Mr. Cross, gardener to the Dowager Lady Ashburton, sent a *Polypodium vulgare* with forked fronds, or the fronds in pairs on one footstalk. Mr. G. Smith, Hornsey Road, sent two seedling *Fuchsias* with double white corollas, the sepals pale and deficient in colour, and not attractive. Mr. Smith's single white-corolla *Fuchsia Complicata* is far superior to these pale varieties. Mr. Rivers sent a specimen of the Climbing *Devoniensis* Rose, with a shoot more than 10 feet long. Mr. Rivers kindly explained how this vigorous growth was obtained. A drawing of a fine variety of *Lilium auratum* with dark red leaves, grown by Messrs. Cutbush, Highgate, was exhibited by the Chairman, and was much admired.

SCIENTIFIC MEETING—J. J. Blandy, Esq., in the chair. The Rev. Joshua Dix, the chairman of the Floral Committee, read over the list of the awards made by that Committee, and pointed out some of the subjects exhibited. Amongst others he drew special attention to the Climbing *Devoniensis* Rose sent by Mr. Rivers, who made the *Devoniensis* assume that form by budding a strong growing *Perpetual* on the *Manetti* stock, and then budding the *Perpetual* with *Devoniensis*. It was also found that buds from *Devoniensis* thus treated, when single-worked in the usual way, did not differ in habit from the ordinary form of *Devoniensis*. Next year Mr. Rivers hoped to apply a similar process to other Tea Roses with the like result.

Dr. Hogg, the Honorary Secretary to the Fruit Committee, said that before proceeding to consider the subjects brought before that Committee, he would call attention to the report on the early Peas grown this year at Chiswick. It was the practice of the Committee to obtain seeds from the parties who send out the varieties, if possible. Dillistone's Early Prolific, Carter's First Crop, Dickson's First and Best, and Sutton's Ringleader, were so procured. They were all sown in the same piece of ground and on the same day; they all came up on the same day; they all flowered on the same day; they all podded on the same day; they all were fit for table on the same day, and the result of the experiment was, that they must be considered identical. The variety which had the priority of name was Dillistone's Early Prolific. Those who are accustomed to study Peas consider a good sample of Dillistone's nothing but a pure stock of the old Early Kent, a variety very difficult to obtain and to keep true. Of other Peas tried, Laxton's Seedling was very similar to the Avenge and Dickson's Favourite, whilst Carpenter's Express proved to be none other than Sangster's No. 1. Princess Royal was thought to be an improvement on the old Dwarf Marrow. Blue Excelsior struck the Committee as being a remarkably distinct Pea. A number of others

were found to be exactly synonymous with Veitch's Perfection. Passing on to the subjects submitted to the committee, Mr. Rivers had sent a collection of White Grapes, all of them belonging to what the French call "Muscats" and the English Frontignans, as they have round berries, whilst in what are called Muscats in this country the berries are oval. The Frontignans possessed a Muscat flavour, a quality which was highly developed in *Chasselas Musqué*; the great advantage of this *Chasselas* was its being earlier than the true Muscats, and ripening in a cooler temperature; it had, however, the evil quality of cracking, but within the last few years a new race had been introduced which did not offer this drawback, and of such Mr. Rivers's Grapes consisted. Of Muscat Salomon of the French, or Early Golden Frontignan, the great recommendation was that it was three weeks earlier than the Black Hamburg, and produced bunches from 12 to 18 inches long. The colour, as he could affirm, was much more golden, in fact he had seen it deep amber. Early Smyrna, Muscat de Smyrna of the French, was also a form of White Frontignan, not so early as the preceding but hardier, and would probably succeed out of doors, at all events it would ripen well in an ordinary greenhouse. Early Silver Frontignan had a larger berry, a very thin skin, and was eight or ten days later than Early Golden Frontignan and the same number of days earlier than the Black Hamburg. The Black Bordeaux, received by Mr. Rivers under the name of Muscat à gros grains, was much more sugary than the Black Hamburg, and a month earlier. Muscat Champion, sent by Mr. Veitch, was stated to be a most valuable acquisition, possessing berries as large as those of the Mill-Hill Hamburg, with a strong admixture of the Muscat flavour, the latter quality in particular rendering it highly desirable. A Raspberry from Mr. Graham, of Cranford, was remarkable for its large size, but as it had not as yet been subjected to careful cultivation the Committee wished to see it again before deciding on its merit. There was also a Black Currant from Mr. Ford which was stated to hang a month later than any other kind, but the berries were small and acid. A Raspberry came from Messrs. Cutbush, of Highgate, the merit of which consisted in its coming into bearing after all the other red summer Raspberries were past, but as regards flavour it was not considered fit for table, and seeing that autumn-bearing varieties of better flavour already existed, no award was made. Some Cherries were also exhibited by Mr. Rivers. Of these the Large Purple Gean came in after all the Bigarreaux were over; and the Love Apple Cherry belonging to the Late Duke class was very large, being an inch across, had a colourless juice, and was furrowed like a Tomato. Mr. Ingram exhibited a seedling Peach called *Frogmore Golden*, but it was not so large as Crawford's Early, which was a freestone, and it was not so delicious as that and some others. It was therefore doubtful whether the variety in question was required. In conclusion Dr. Hogg directed attention to two Apricot trees in pots which Mr. Rivers had sent, first to show that fruit trees in pots bearing ripe fruit can be transmitted to a distance, and second to prove that Apricots can be grown in pots. The whole secret of their culture in that way was very simple—it simply consisted in giving them plenty of ventilation whilst in bloom, even 3° or 4° of frost would not injure them then. The rationale of this was, that when the orchard-house is kept close whilst the trees are in bloom there is such an amount of moisture in the air that fertilisation cannot take place. Mr. Rivers stated in a communication addressed to him (Dr. Hogg) that chalk existed in the soil which was used for potting, but in what proportion he (Mr. Rivers) did not know, as he had sent the soil to be analysed; but one-twelfth or one-tenth would not be too much.

The Rev. M. J. Berkeley said there were not many plants to comment upon, but he had an interesting fact to communicate in reference to hybrid Ferns. Every one knew that in cultivating Ferns vast numbers of *Gymnogrammas*—golden, silver, and grey—were freely produced in the same house, and they were believed to be hybrids, but no one had proved them to be so. He had now, however, a veritable case of a hybrid Fern. Mr. Robinson Scott enclosed a frond of an *Asplenium* which he had found in a rocky place about eight miles from Philadelphia, on the banks of the Schuylkill river. It was surrounded by *Camptosorus rhizophyllus* and *Asplenium ebeneum*, had some of the characteristics of both, and was distinct from anything described by Dr. Asa Gray, in his "Flora of the Northern United States." Sir Wm. Hooker had declared it to be new. Mr. Berkeley then described the leading characteristics of *Camptosorus rhizophyllus*, *Asplenium ebeneum*, and the hybrid. The production of such a hybrid was not of botanical interest only, but of horticultural importance; for if any horticulturist could obtain hybrid forms, there was no doubt that it would prove very profitable. He had prepared a set of drawings to show that it was possible to do so. The spore of a Fern consisted of an outer and an inner case, and if placed in proper circumstances of moisture, &c., the envelope would split and a rootlet be thrown down. Every healthy spore produced anthridia containing a slender filament, which, on the anthridium bursting, floats about; and on coming in contact with the embryo sac containing the ovule, it penetrates the sac and the development of a fresh plant commences. Impregnation between two different Ferns, therefore, could not take place unless there was a drop of water present by which these filamentous bodies could be carried to the embryo sac; and by a little delicate manipulation it might, therefore, be possible to bring the contents of the anthridia of one Fern in contact with the ovules of another, and so produce a hybrid. After briefly noticing a few of the plants, and two monstrous forms of *Plantago major*, Mr. Berkeley observed, that from

several quarters he had received mildewed Peas and Beans, and that there was a great probability of the Wheat crop being attacked this autumn, though it might escape if the weather were fine.

**SHOW OF FERNS AND THEIR ALLIES, July 29th.**—This, the last of the special shows for the season, was rather extensive, and had a pleasing effect, though, from the absence of plants with coloured foliage, the Ferns, graceful as they were, did not appear to such advantage as they otherwise would have done. Large masses of bright colour unrelieved by green foliage are wearisome, almost painful, to the eye; and foliage of the same hue and general character in like manner becomes monotonous. In natural scenes, indeed, green foliage predominates, but it is varying in tint, in outline, and in size, is exposed to the play of light and shadow, and is seldom entirely motionless. A long stretch of level green pasture without a flower, or tree, or animal upon it, however beautiful the green, if viewed apart from surrounding objects would not be pleasing, and even the wide fields of golden grain soon cease to please if dissociated from surrounding objects and from the ideas of peace and plenty to which they give rise. The great fault of the Show was, that when viewed as a whole there was too much sameness in colour and general character, but this was a fault inherent to the very nature of the Show and not to Mr. Eyles's arrangement, for he produced the best effect which it was possible to obtain from the materials at his command.

Class I. was for twelve exotic species. Here Mr. Bull took the first prize with well-grown plants of *Marattia elegans*; *Dicksonias calceata*, *antarctica*, and *cinnamomea*; *Gleichenias fabelata*, *microphylla*, *hectistophylla*, and *dichotoma*; *Cyathæa medullaris*; *Alsophila australis*; *Blechnum corcovandense*, and *Platyterium alicorne*.

In Class II., nine exotic kinds, Mr. Cross, gardener to the Dowager Lady Ashburton, was first with good examples of the Bird's-nest Fern, *Dicksonias*, the pretty *Cheilanthes leadigera*, *Cyathæa Smithii*, *Cibotium Schiedei*, and *Lygodium scandens*. Mr. Barnard, gardener to J. Taylor, Esq., was second, and Mr. Young third.

In Class III., for six kinds, Mr. Young was first with fine plants of *Woodwardia radicans*, *Phlebodium aureum*, *Adiantum formosum*, *Stenochlaena scandens*, *Blechnum brasiliense*, and *Platyterium alicorne*. Mr. Bull was second, having among others the beautiful *Gleichenia spluncea*, *Cibotium princeps*, and *Alsophila australis*; and Mr. Barnard, third.

Variogated exotic Ferns, shown under Class IV., were confined in the three successful collections to *Pteris argyræa*, tricolor, and *cretica albo-lineata*, of which good plants were exhibited. Mr. Bull had in addition, *Pteris nemoralis variegata*, *serrulata variegata*, and *argyræa sublobata*. Mr. Barnard was first; Mr. Weston, gardener to D. Martineau, Esq., second; and Mr. Young third. ¶

In three tree Ferns there were only two competitors, Mr. Bull and Mr. Young, who were first and second: those from Mr. Bull consisted of *Cyathæa medullaris* and *dealbata*, and *Dicksonia antarctica*. Mr. Bull likewise exhibited *Hymenophyllums*, and Golden Ferns. The best of the latter, however, came from Mr. Young, and consisted of *Gymnogrammas chrysophylla*, *ochracea*, and *Lauchæana*.

Of British Ferns very excellent collections were shown by Messrs. Ivery & Son, and Messrs. A. Stansfield & Sons of the Vale Nurseries, Todmorden, who had equal first prizes for twelve. Messrs. Ivery had *Athyrium Filix-femina Fieldiæ diffusum*, *Frizellie nanum*, *plumosum*, *ramo-cristatum*, *Lastrea Filix-mas Bollandiæ*, *cristata*, the crested Royal Fern, Limestone and Welsh Polypody, *Polystichum angulare decurrens*, *proliferum Wollastonii*, and *Scolopendrium vulgare crispum*. Messrs. Stansfield had *Asplenium marinum*, *Athyrium Filix-femina Fieldiæ*, *plumosum*, *Vernonia*, *Lastrea Filix-mas Barnesii*, *Lastrea montana Nowelliana*, the crested Royal Fern, *Polystichum angulare Wollastonii*, *contractum*, *lineare*, *oxyphyllum*, and *plumosum*. Extensive and excellent collections containing many rare and curious forms were shown by the same exhibitors, Messrs. Ivery receiving a first and Messrs. Stansfield a second prize. Mr. Bull and Mr. Kilmister likewise exhibited British Ferns. The latter was first for six, Mr. Young being second, Mr. Earley, Digswell, third.

Of Lycopods, numerous fine pans of the usual kinds were shown by Mr. Higgs, Mr. Young, and Mr. Barnard. For nine, Mr. Higgs was first, and Mr. Barnard second. For six, Mr. Young was first with large pans, and Mr. Higgs second.

Other subjects consisted of some moderate-sized *Fuchsias* in very good bloom, from Mr. Weston, gardener to D. Martineau, Esq.; *Petunias*, from Mr. Macintosh, Hammersmith; *Acrides odoratum*, grown in an average winter temperature of 45°, and the brilliant *Echmea fulgens*, from Mr. Earley; a fine plant of *Caladium argyrites* from Mr. Young; and *Lilium auratum*, fine pots of *Adiantum cuneatum*, *Leptopteris superba*, and a beautiful example of *Todea pellucida*, from Mr. Bartlett, of Hammersmith. Some good Hollyhock blooms were shown by Mr. Porter, gardener to the Hon. A. Ashley, Epping; cut Roses by Mr. Clarke, Brixton; a collection of ornamental Grasses by Mr. Turner, Notting Hill; and the beautiful new *Geranium*, Dowager Duchess of Sutherland, noticed at page 47, and several unnamed seedlings, by Mr. Fleming, of Cliveden, who also sent flowers of *Bignonia chirere*, excellent Black Hamburg Grapes, Peaches, and Nectarines. Mr. Merrett, gardener to H. Whiting Esq., Battersea, also exhibited excellent Peaches, and Mr. Earley good Apricots. *Adiantum Farleyanum*, a handsome new Fern, had a first class certificate.

## ENTOMOLOGICAL SOCIETY'S MEETING.

The July Meeting of this Society was held on the 3rd ult., the President, F. P. Pascoe, Esq., being in the chair. Fourteen new members and four annual subscribers were elected into the Society. The Secretary announced that a new part of the Society's "Transactions," consisting entirely of the commencement of Mr. Baly's descriptions of the plant-feeding species of Beetles captured in the islands of the Eastern Archipelago by Mr. A. R. Wallace, was ready for distribution among the members.

A vote of thanks was unanimously passed to W. Wilson Saunders, Esq., for the handsome entertainment given by him to the members of the Society at Reigate.

Mr. Frederick Bond exhibited specimens of *Toxocampa Cracca*, bred by Dr. Knaggs; also, of *Eupethicia pulchellata*, reared from the Fox-glove; and *E. campanulata*, a new species bred by the Rev. H. Harper Crewe, from larvae found in a Beech wood near Tring, feeding on the flowers of *Campanula trachelium*.

Mr. Stainton exhibited the curious broad and flattened cocoons of *Pyralis glaucinalis*, bred by Mr. Edwin Brown, of Burton-on-Trent; also, the very minute larvae of *Cemistoma Lotella*, found feeding within the leaves of *Lotus major*, near Scarborough, by Mr. Wilkinson.

Dr. Armitage exhibited specimens of both sexes of a remarkable Moth, allied to *Oiketicus Kirbii*, from Monte Video, the female of which is destitute of rudiments of legs and wings, and never quits the cocoon or even the chrysalis skin.

The Rev. Hamlet Clark read a letter from the *Ceylon Examiner*, respecting a remarkable species of Firefly, having a considerable number of luminous patches on each side of the body, and referring to the simultaneous flashing and extinction of the light by numerous Fireflies, as alleged by him at a former meeting, but which had been opposed by several entomologists who had been in tropical countries—namely, Messrs. Sallé, W. W. Saunders, A. R. Wallace, and Bates. Mr. Clark read the following letter from Mr. Alexander Fry:—"I can confirm your observations, that the Fireflies of the genus *Aspisoma* of Castelnau (corrected into *Aspidosoma* by Lacordaire), flit at night in great numbers over low-lying damp fields, chiefly near water, emitting light by short dashes, at intervals of three or four seconds, the majority keeping time with each other, as if in obedience to the baton of a leader. I think it is only the Fireflies of that genus which practise it, the numerous Fireflies common in Mexico and North America, belonging chiefly to the genera *Ellichia* and *Photuris*, whose habits are different, so far as I have had opportunity to observe their congeners in Brazil." Mr. Clark also exhibited a considerable number of minute insects collected in central India, by Lieut. Hobson, transmitted by post in small tubes to this country.

A note was read from the Rev. Douglas Timmins, containing an account of a month's collecting of Lepidopterous insects in the spring, in the neighbourhood of Cannes.

A note was communicated by Mr. W. F. Evans, relative to the luminosity of the genus *Fulgora*, confirmatory of the statement of Madame Meriau, which had been opposed by Mr. W. S. McLeary, and others. Mr. Evans had sent a figure of the *F. latermaria* to his son, who is in the commissariat department in British Honduras, and received in due time the following statement from him:—"Belize, May 17, 1865.—I have succeeded in my entomological researches about the Lantern Fly. I had one given me, caught here, alive, and I saw it myself giving light. I kept it under a tumbler for about a day, and it sometimes did not give it, but at others it did."

The Secretary read a notice containing the statistics of "la Gatine," a disease to which Silkworms are subject in the great silk-producing establishments in the south of France.

Mr. Pascoe stated, that eggs deposited by some of the female Dog Ticks, exhibited at one of the spring meetings of the Society, by Capt. Cox, had recently hatched.

## GREAT ROSE SHOW AT BRIE-COMTE-ROBERT.

On the 9th of July, for the first time in France, we had the treat of admiring a special Rose Show. It took place at the small town of Brie-Comte-Robert, the centre of the fertile Brie, where Roses are so extensively grown in fields by about eighty cultivators. It was apprehended after such an unusually dry and hot season, that the day appointed for the Show would be rather late, but thanks to the efforts of the principal growers, and to the skilful management of more than a million of trees, the exhibition was a decided success. Whoever has not had the good fortune to witness this most gorgeous display of the "queen of flowers," cannot form an idea of its grandeur. The Show was held under a vast tent of about 150 feet long by 50, in the middle of which were large beds, and all around, upon stages, were set the various collections. Imagine the effect thus produced by upwards of 60,000 Roses. There was one bed consisting of about 5000 blooms of that old but still much-valued Rose du Roi, and a show it was of itself, well deserving the gold medal awarded.

The finest collections were shown by Mons. Granger, at Suisnes, near Brie-Comte-Robert, consisting of 380 splendid

varieties; by M. Scipion Cochet, of the same place, 375 varieties; and by M. Aubin Cochet, of Grisy, Suisnes, 220 varieties.

Of smaller collections, not less admired, there was M. Gautreau, père, and M. Cochet, père, both of Brie-Comte-Robert, 120 varieties, and M. Ladechaux, of Villeceresnes, 180 varieties.

Of seedlings, M. Granger, had Exposition de Brie-Comte-Robert; and M. Gautreau, père, Camille Bernardin, both very fine Roses, universally admired, and which will, no doubt, be welcomed on the other side of the water when sent out.

For bouquets and table decorations, several prizes were given, as well as for smaller collections of Roses, which, though small, were not without interest. I subjoin a list of some of those which may be considered the cream of the exhibition. They were all represented in beautiful specimens. Maréchal Niel, Anna de Diesbach, Kate Hausburg, Baronne Pelletan de Kinkelind, Maurice Bernardin, Président Lincoln, Impératrice Eugénie, John Appert, Sénateur Vaise, Duchess of Norfolk, Madame Furtado, Comtesse Cecile de Chabillant, Madame Victor Verdier, General Washington, Madame Eliza Vilmorin, Souvenir de la Reine de l'Angleterre, Eugène Appert, Madame Eugène Verdier, Charles Lefebvre, M. Alphonse Eclin, Denis Helye, Madame la Baronne de Lassus St. Genies, Madame Boutin, Charles and Louise Margottin, Maréchal Vaillant, Monte Christo, Prince Camille de Rohan, Deuil de Prince Albert, Victor Verdier, Reine des Violettes, Madame Boll, Empereur de Maroc, François Lacharme, Vicomte Vigier, M. Charles Crapet, Sœur des Auges, Baron Rothschild, Bernard Palissy, Maréchal Souchet, Duchesse de Morny, &c.

The Censors were the following highly respectable gentlemen:—M. Charles Baltet, of Troyes; Guillot, père, of Lyons; Eugène Verdier; Dupuy-Jamain, and Lesvesque, fils, of Paris; Desfosses-Thuillier, of Orleans; and Saffray, of Rouen.

I understand that henceforth an annual show of Roses will be held at Brie, and I, therefore, earnestly advise British rosarians to come next year and see for themselves such a sight as they will never see at home. Those who call from time to time upon the Parisian Rose merchants, have no idea of the extensive cultures of the real growers at Brie.—FERNAND GLOEBE, *Les Sablons, Seine et Marne*.

#### PRESENTATION TO MR. INGRAM OF FROGMORE.

For some months past a movement has been in progress among the friends of Mr. Ingram, at Frogmore, to raise a subscription for the purpose of presenting the respected gardener to Her Majesty, with a tribute of their affection and esteem on this the fiftieth anniversary that he has presided over the Royal gardens at Windsor and Frogmore. The subscription list having been closed, the Committee of Management appointed a deputation of their number to proceed to Frogmore on Saturday last, and present the testimonial. The deputation consisted of Dr. Hogg, Chairman of the Committee; Mr. John Lee, of Hammersmith; Mr. Edward Brown, of Slough, Secretary to the Committee; Mr. Charles Turner, of Slough; Mr. Stains, of Harewood Square; and Mr. John Fleming, of Cliveden. The testimonial was presented by Dr. Hogg, in the name of the subscribers, and consisted of a handsome silver tea and coffee service, manufactured by Messrs. Garrard, the Crown jewellers of the Haymarket; a gold watch made by Frodsham, of the Strand; and a purse containing 150 guineas. The watch bore the following inscription:—Presented to THOMAS INGRAM, Esquire, by his friends on the 50th anniversary of his services in the Royal Gardens, Windsor, July 1865." Accompanying the presentation was a list of the subscribers neatly engrossed on a roll of vellum. Dr. Hogg, in presenting the testimonial, said:—

"Mr. Ingram,—It would be affectation on my part if I were to assume that you were unaware of the object of our visit to you to-day. I have reason to believe that you are not ignorant of the fact that for some months past a number of your friends have entertained the idea of presenting you, on this, the fiftieth anniversary of your services at the Royal Gardens at Windsor and Frogmore, with a substantial testimonial of their esteem for your personal worth, and their appreciation of your professional ability. That idea has become a reality, and we are here to-day—a deputation from the subscribers to that testimonial—to perform the pleasing duty of presenting it to you.

"I am flattered, sir, that it has fallen to me to perform this

pleasing act; but I feel, also, that there are others to whose hands the work might have been more advantageously committed. There are those present, and there are among those whose names are inscribed on this roll some who have known you far longer than I have done, and on them I should have preferred that the office had fallen. But although my personal acquaintance with you may not have extended so far back as theirs has done, yet, connected as we are with the same country—nay, even with the same locality—my knowledge and appreciation of you extend to a lengthened period; and, therefore, I feel that I am not entirely out of place in performing this service.

"For fifty years you have served the Royal Family of this country, with fidelity to them and honour to yourself—for fifty years you have occupied a prominent position in an arduous situation—one requiring the exercise of the greatest discretion, coupled with decision and courtesy. In that situation you have, doubtless, had to exercise much self-denial, and, while in the performance of your duty and your high trust, to give offence when you would rather have conveyed pleasure. For fifty years you have adorned the profession of horticulture, and assisted in no small degree in promoting and fostering its pursuit; and for far upwards of fifty years you have lived a life that has endeared you to many friends, and made you respected by all who know you; and it is for these reasons that we are now here to present to you these testimonials from your friends, whose names are inscribed on the accompanying roll.

"In the good providence of God you and Mrs. Ingram have been spared to live far beyond the allotted span, and it is our earnest wish, and that of all your friends, that you both may yet be long blessed with the enjoyment of each other's society, and to receive the hearty congratulations of all those who have the privilege of your acquaintance."

#### OUT-DOOR FIGS RIPENING AUTUMN FRUIT.

As you are publishing some articles upon the cultivation of this fruit, let me add one little jotting as to the ripening of autumn Figs.

As a rule, it is doubtless true that of out-door Figs the spring crop alone ripens, the autumn Figs dropping off at the approach of winter; but in our Undercliff there are exceptions to this rule; and not only do autumn Figs remain on the trees during the winter, but sometimes they are ripened in the ensuing summer. I have repeatedly heard that this latter was the case; but on Monday, the 24th ult., I had positive proof, having, on that day, gathered and eaten from a tree in the open ground, grown freely, and without any particular cultivation, a full-sized, fully-ripened, and full-flavoured Fig—I believe a Brown Turkey—of as good quality, in all respects, as I have eaten Figs in Jersey at the end of August. This Fig, as well as others on the same tree, now approaching ripeness, was, of course, grown upon last year's wood. This tree is in the grounds of Dr. Leeson, at Banchurch. In all the books on fruit culture that I have seen, it has been assumed that autumn Figs (out-door ones) must necessarily fail; and as there is here a plain and distinct exception, I believe you will not think it troubling you unnecessarily to communicate the fact.—H., *St. Boniface Cottage, Centnor*.

#### BEDDING GERANIUMS.

Our Cloth of Gold Geraniums are doing well, as usual, which we think in some measure due to very light soil—namely, as stated last year, a good supply of leaf mould or bog soil worked into the beds. We took all our old plants up last autumn, potted them with a mixture of fibrous peat, leaf mould, and sand. They stood in a pit amongst other kinds. We thought they were the strongest of any, as they made much growth before bedding-out time. By-the-by, I wish our nurserymen would not overwhelm us with bedding Geraniums. I have had hundreds of cuttings of Madame Vaucher to give away for four or five years past, and consider it too bad to be charged 3s. 6d. each for White Tom Thumb and Snowball, when no one can tell them from it. However, I obtained some good ones out of a batch that I bought, so I must be thankful. I would like every one to have Amy Hogg, Wooton's Indian Yellow, and some others which I have bedded-out, and which are promising, but think it almost too early to report on them.—W. C.

MINIATURE ORCHARD-HOUSE.

(Continued from page 73.)

My primary object in the erection of miniature orchard-houses on the plan I have described, being the production of early crops of Strawberries, and the protection of Pear blossoms from spring frosts, most of my ventilation experiments have been in these two directions. The plans I have followed will, when explained, give the key-note of the system, and enable variations suitable for Vines, Peaches, Tomatoes, or other crops, to be made.

With Strawberries, up to the time at which the flower-scape appears, I have hitherto, perhaps improperly, given no ventilation whatever; but after that period I have arranged the sheets of glass somewhat as in plan 1, which is a lazy way of work-

Plan 1.

ing, though suitable for Strawberries not wanted very early. For the two years I have tried it I seem to have lost nothing by frost. I have shown neither the ridge-wires nor the upright supports, but it will be seen that as there is an interval of an inch or two between each sheet, all the sheets on the first side erected require each two supports, instead of each alternate sheet being supported by its neighbours as in my description last week. The dotted lines represent the sheets of glass forming the other side of the house, and it will be seen that the interstices are placed not opposite those on the other side. This prevents too great a draught and distributes it when the wind blows. This is a plan contrived to save any alteration after once re-arranging the house when the blossom begins to show bud, and also as facilitating the gathering of the ripe fruit, which with Strawberries is a daily operation. This is done of course by shifting the sheets which overlap at the top, leaving the other side fixed as at first, till the end of the fruit season.

Watering in this and all other plans I have found best effected by the hydropult, with extra delivery hose, inserting the rose at the gables, or in very long houses through the interstices. A dry hearth-brush in dusty weather is of service in keeping the glass clear.

Plan 2 is a modification of plan 1, adapted to protect Pear blossoms from spring frosts. Fig. 2 represents it in its closed state, the sheet b resting upon and overlapping a and c. In fig. 1 it will be seen that by driving an upright wire into the ground so that its top b shall press against the sheet B, there is the means of using the sheet B as a sliding shutter, which may be completely closed during the night and opened during the day as wide as may be desired.

Plan 2.—Fig. 1.

driving an upright wire into the ground so that its top b shall press against the sheet B, there is the means of using the sheet B as a sliding shutter, which may be completely closed during the night and opened during the day as wide as may be desired.

Plan 2.—Fig. 2.

during the day as wide as may be desired.

revolve on their angle very readily, as in the accompanying diagram. In moving the ridge-wires grasp them firmly. I have broken glass and injured my fingers from incautious handling.

Plan 3 is very suitable for small houses of ridges not exceeding 24 inches. The ridge-wires opposite the sheet b must be inserted in the ground at such a distance from the straight line A to c as the ventilation required renders necessary. By drawing the bottom of sheet b outwards, the top of course gives

way and leaves a gap in the ridge between, the air entering below in the direction of the bent arrows. At night the sheet b is pushed up to its place closing up both top and bottom ventilation. The ridge-wires will hold the sheet b quite tight whether closed or open, even if inserted in the ground several

Plan 3.

Plan 3.—Vertical section.

inches in front of the bottom of the sheet when closed. If the sheet exceed 24 inches either way, it will be necessary, or at least safer, to place two uprights behind the sheet b, as the points e and f are too slight for support without breakage. These uprights are so yielding that if properly placed they will not be in the way when the glass is closed.

Plan 4 I would like to commend to very special attention and experiment. It literally costs less than a house without ventilation.

The double lines represent the ridge-wires. Fig. 1 is for permanent ventilation, as in Mr. Rivers's ground vineries. On experiment it is surprising how easily and firmly the small sheet of glass c is held in its place with the same ridge-wires that keep the others in position.

Plan 4.—Fig. 1.

The ventilation may be varied according to the size of the sheet c. Fig. 2 is the arrangement of wires I adopt so long as frost may be apprehended. The wires are so placed in order to allow a sheet of glass (b fig. 3) to rest (without any wire to fix it) against the opening below c. This shuts the house up almost as effectually as any other method I have tried, and a hundred sheets like b may be removed each morning and replaced each evening in "no time." During the day, as they do not much obstruct the light, they rest conveniently against the slope of the ridge near the opening they cover at night.

Plan 4.—Fig. 2.

Plan 5 is a modification of plan 4, adapted for the ripening period and admitting of free ventilation both above and below the sheet c, which may be elevated or depressed as more or less free escape at the top is desired. The double lines represent the ridge-wires which, unless the sheet c be very narrow, answer very well as placed in the engraving.

Plan 4.—Fig. 3.

Plan 5 is a modification of plan 4, adapted for the ripening period and admitting of free ventilation both above and below the sheet c, which may be elevated or depressed as more or less free escape at the top is desired. The double lines represent the ridge-wires which, unless the sheet c be very narrow, answer very well as placed in the engraving.

Plan 5.

Plan 6 is for gables only, and answers very well as the only ventilation given short houses of a few feet for propagating, or forwarding annuals, Radishes, &c. before their out-door season. The gable by proper arrangement may be raised or lowered without slipping the wire, by simply holding the wire with the one hand and moving the glass with the other.

Closed.

Plan 6.

Open.

The gable by proper arrangement may be raised or lowered without slipping the wire, by simply holding the wire with the one hand and moving the glass with the other.

Plan 7 is for the ends of Pear tree miniature orchard-houses. During frosty weather the sheet c should be gently pulled back each evening and the triangle n inserted between it and the other glasses. The pressure is sufficient to retain it in its place. It might be

Plan 7.

advisable to adopt this plan for all large gables, as there is thereby a great saving in being enabled to cut large gables out of small sheets.

Plan 8 is another, but not so good plan for gable ventilation.

Plan 9, for gable ventilation, is accomplished by inserting a rod of wood or iron between the gable and the glasses behind it at such height as will leave the size of aperture required.

Plan 10 includes several modifications for lean-to houses, which I need not particularise. I shall need a few months' further experiment before I can speak of lean-to miniature orchard-houses as a success. I have tried low brick walls without mortar and this year glass walls with metallic surfaces as reflectors. The glass walls are nearly perpendicular. In the following en-

Plan 10.—Back of a Lean-to.

graving of the back of one, the lines A A are uprights, the double lines are wires after the manner of the gable wires. Most of my other plans I have rejected for some of the foregoing. Throughout the whole of the twelve months in a well-regulated garden there need not be a sheet of glass out of use except for a day or two. I find it will be convenient to have racks of galvanised iron fitted up at different parts of the garden to save trouble in carrying large sheets. After the Strawberries ripened this season I used the glasses for Cucumbers and Tomatoes,

Plan 11.

as well as Cherries about to ripen. In the latter part of the year, more especially in a wet September, they may be used to cover choice Strawberry-beds and secure well-ripened buds. I shall, however, this year experiment at that time mainly on late Apples and Pears, but my way of treating these is too outrageous a violation of natural laws for me to say anything of it at present, so let it rest.

Plan 12.

In spring, spare glasses answer admirably for double-glazed miniature orchard-houses for Apricots and Peaches, somewhat after this fashion (a vertical section), the double line being an upright. (See Plan 11.)

Plan 13.

The interval will not be quite air-tight, but will at all events exclude a few additional degrees of frost. To carry the idea even farther, as there is little use for many ridge-wires, except on the outside of all, excellent protecting-houses for bedding-out and other tender plants may be very readily formed, thus, (Plan 12, or even as in Plan 13.)

If the last one does not keep out the frost I must give it up, and though I do not on the instant see my way to an effective ventilation for these and the Apricot-houses, I feel sure that half an hour's thinking will resolve the problem. Should the subject be thought worth experiment I shall be glad from my two-seasons experience to reply on any point wanting further elucidation, but my hope is that if I have struck a useful chord I may hear of useful applications and improvements effected beyond anything my short gardening experience can evolve.—Wm. McGOWAN.

ERRATUM.—From a transposition of the sheets of the copy the article at page 72 in our last Number has been rendered all but unintelligible. On reaching the close of the sentence terminating with "to c and n" in column 1, on the ninth line from the bottom, the reader must pass on to the paragraph in the middle of column 2, commencing with "At each of the points," and on reaching the close of the paragraph in column 1 page 73, terminating with "of the dotted line x," he must turn back to the sentence near the foot of page 72 column 1, beginning with "Fix a wire, &c."

HOW TO GROW VARIEGATED GERANIUMS.

MANY persons say they cannot grow some of the new and very beautiful Geraniums, such as Mrs. Pollock and Sunset. Thinking it a great pity that these beautiful plants should not become common, I will give my experience in the hope that it may be of assistance to some who have not succeeded so well as they wished.

We have always a heap of rich soil prepared in the following manner:—A foot of good sandy loam covered by a foot of good stable-manure, again covered with soil, and again by manure, and so on till the heap is finished. The heap is turned several times during twelve months, and always comes in useful whenever soil is required for potting. Having removed the soil of the bed intended to be planted with Variegated Geraniums a good spade's depth, an equal quantity of compost was prepared by mixing a little white sand and cocoa-nut fibre with the soil of the heap before mentioned, and with this the bed was filled. A variety of Geraniums, amongst which are a good number of Mrs. Pollock and Sunset, are growing in this bed almost as freely as Tom Thumb. Some few older varieties, planted with them for contrast, are twice as effective as those planted on common soil. It appears as if a rich open soil is what these new Geraniums require. Perhaps those who have tried cocoa-nut fibre, and been dissatisfied with it, have forgotten that its effect is merely mechanical, and if added to a poor soil, it of course makes it still poorer. My bed is so beautiful I feel quite proud of it, and seeing what can be done with these new Geraniums, am anxious others should grow them successfully.—J. R. PEARSON, *Chilwell, Notts.*

POTATO SCAB.

I HAVE grown a large number of unusually fine Ashleaf Kidneys on some new ground this season. The tubers are very large, and excellent when cooked, but they are so scabby as to be quite disagreeable to look at when dug. My gardener tells me it is caused by the little thread worms which abound in the soil, owing to its having been manured with some rotten stuff from an old Cucumber-frame. I should be very glad to know the real cause of this scab, which is, as you say, only skin deep.—T. C. H.

I QUITE agree with the Editors in their answer to the query of "J. W." as regards lime causing the scab in Potatoes. Some years ago, in the vale of the Humber, we had very fine Potatoes manured with farmyard dung, and generally free from scab. Leading into our fields was a long lane always repaired with limestone, the scrapings from which one winter were spread over about an acre and a half, and ploughed in; the following season was rather dry, and the Regents and other rough-skinned kinds were scabbed very much, but we thought they were no worse in quality, and not much less than usual. The Kidneys and other smooth kinds were very little scabbed. We thought, but might be wrong, that the lime passed into the rough parts of the skin and caused the eruption. I would advise "J. W." to obtain a change of seed from a distance, and from a different soil from his own, to manure moderately with farmyard dung, and perhaps a little guano, but to use no ashes nor lime.—W. C.

## CLIMBING DEVONIENSIS ROSE.

Mr. Rivers states, "This was originated from budding a strong-growing shoot, what is called a 'sport,' and thus continuing the inclination to a vigorous habit. Such sports are not uncommon with Roses; the climbing Géant des Batailles, and the climbing Aimée Vibert, are Roses in point. The climbing Devoniensis reverts to its normal condition if buds or cuttings are taken from the blooming shoots. The specimen sent to the Floral Committee of the 25th of July would, if not confined in so small a pot, have doubtless put forth blossoming-spurs from its stem, as is the case with plants in the open ground. The extraordinary vigour of the specimen exhibited was probably owing to its culture. It is double-budded, after the flowering method. A strong-growing Hybrid China Rose, Madame Pisoni, was budded on the Manetti Rose stock, and the following August a bud of the climbing Devoniensis was budded on the young shoot of Madame Pisoni. This method of culture gives most remarkable vigour to Tea-scented Roses, the Rose Gloire de Dijon making shoots from the buds thus inserted of from 8 to 10 feet in length. It is also highly successful with delicate-growing varieties of Hybrid Perpetuals." Rose-growers will have much cause to thank Mr. Rivers for his valuable remarks on this subject.—X.

## EARLY PEAS.

HAVING heard a good deal in favour of Messrs. F. & A. Dickson & Son's First and Best Pea, I purchased some of the seed, in order to give it a trial and prove its merits, and I now give the results of my experience. I have been in the habit of growing for my first crop Dillistone's Early, Daniel O'Rourke, and Sangster's No. 1, but having this year added to my list Dickson's First and Best, I am happy to say that I have not been disappointed with the high character I had with it.

I selected an open and early quarter in the kitchen garden, which had been previously trenched, and was in capital heart. The soil is a good, deep, and rather stiff loam, the very soil to withstand the great droughts which we have experienced for the last two seasons, and which, in my opinion, greatly affects success in growing the Pea. The four varieties named above were sown on the 3rd of February in rows about 6 yards apart, so that they would have the benefit of the sun on either side. I grow all my Peas in single rows; I always think they crop better, and I fancy that it is a saving of ground, as you only lose a row of the crop growing between. I gathered the first dish from Dickson's First and Best on the 30th of May, and from Dillistone's Early on the 1st of June. Daniel O'Rourke and Sangster's No. 1 were a few days later. Dickson's First and Best is not only a better cropper, but continues much longer in bearing, is very superior in quality, and is in every respect a very valuable early Pea—indeed, the earliest with which I am acquainted. I have made up my mind to grow for my first crop no other Peas than Dickson's First and Best, and Sangster's No. 1, and for succession Dickson's Early Favourite, Veitch's Perfection, Lord Raglan, and Hairs' Dwarf Mammoth.

To grow the Pea successfully you must trench deeply, manure well, and have the ground in good order before sowing; for no crop suffers more than the Pea from a long continuance of dry weather, and in doing as I have described, it will be found that the trouble will be well repaid by the increased production.—W. DAVIDSON, *The Gardens, Benington, Leominster.*

My belief is, that the seasons exercise a great influence on the earliness of Peas, as in the case of fruit and flowers. Some of your correspondents assume that Dickson's is in reality the earliest and best Pea, but how can they fairly make such an assumption, when we find that two or three other early sorts have not been put to the test? My experience proves that their conclusions are rather premature, inasmuch as Carter's First Crop produced me Peas on Saturday, the 3rd of June, in the open ground, and under no peculiar advantages. I would further assert, that had I been living on the spot instead of in London, Peas might have been gathered at least three or four days earlier than I received them, and, furthermore, a neighbour of mine, expecting great results from his Pea—Dickson's First and Best, made careful observations, and on comparing his with mine (Carter's First Crop), it was proved that his Pea was more backward, and the pods much smaller. I, therefore, do not admit that Dickson's First and Best has proved itself

worthy of that cognomen, and from what I have read, and my own experience, I should certainly give preference to Carter's First Crop.—JOSIAH LOVELL, *Overton, Hants.*

My experience is confined to three varieties only (as early ones) which I have grown here—namely, Dickson's First and Best, Dillistone's, and Sangster's No. 1. All were sown on the same day on a border due south. Dickson's First and Best came into bloom ten days before the last-named varieties, which bloomed together, and kept the lead, giving me a crop in every way satisfactory, fully ten days earlier than either of the others. For the future I intend growing Dickson's First and Best as a principal first crop, as I find it here does admirably.—J. GARDNER, *The Gardens, Little Aston Hall, Sutton Coldfield.*

[We have inserted the above and other communications respecting early Peas in order that the opinions and practice of correspondents in different parts of the country might be made known; but on reference to the report of the meeting of the Royal Horticultural Society it will be found that three of the so-called new Peas are not distinct from Dillistone's Early Prolific, and that that kind is nothing but a pure stock of the Early Kent. This, the result of careful trial, is confirmatory of the conclusions arrived at by Messrs. A. Henderson, and stated by them at page 467 of our last Volume.]

## MR. PERRY'S SEEDLING VERBENAS.

MR. C. J. PERRY is now well known as the raiser of some of the finest Verbenas yet sent out, all of which have been introduced by Mr. C. Turner, of Slough. Taking advantage of my visit to the great Rose Show at Birmingham, I visited Mr. Perry's garden at Castle Bromwich to see what seedling Verbenas he had for next year, and I am sure the following will be hailed as great acquisitions, but of course they will not be sent out until next spring.

*Charles Perry.*—This is an improvement on Charles Turner, and a decided improvement on L'Avenir de Ballant and any others of the same class. Very fine pip and truss.

*Cleopatra.*—Rich deep rose, with clear lemon eye, beating Rosy Morn and all of that class. Very fine truss.

*Maceppa.*—A decided improvement on Lord Leigh and all of that class, having a white instead of a yellow eye, and very fine pip and truss.

*William Dean.*—A great improvement on Black Prince, Lord Elgin, and others. Very rich shaded purple, with clear white eye; fine truss.

*Harry Turner.*—Shaded lilac; very fine pip and truss. An improvement on Magnificens.

*Mrs. Dean.*—Blush, with pale crimson centre, the centre being more clearly defined than Madame Herman Stenger. Fine pip and good truss.

*Admiral of the Blue.*—Distinct lilac blue, with large white centre. A great improvement on all of this colour.

*James Walton.*—Bright rosy carmine, with darker shade towards the centre; light eye. Very fine pip and truss.—W. D.

## WORK FOR THE WEEK.

## KITCHEN GARDEN.

AFTER the first shower of rain earth-up Brussels Sprouts, Savoys, Broccoli, and whatever requires it. Keep the ground free from weeds, remove the crops that are done with, and prepare it for winter crops. We strongly recommend mulchings to be applied between the rows of vegetables; for wherever the ground is at all stiff and exposed at this season to the powerful action of the sun, it is apt to crack or rend in several directions, by which the roots of vegetables are, in very many instances, destroyed. *Broccoli*, any now planted out should have the roots dipped in puddle of soot, earth, and water, and immediately after planting should be again watered. The Cape and Grange's intended for use in the autumn should also be watered. *Cabbage*, the principal sowing for spring use should now be made, if not already done; Barnes' Early Dwarf and the Vanack are the best sorts for private gardeners. *Carrots*, some of the Horn may now be sown to stand the winter, but another sowing should also be made towards the end of the month. *Celery*, abundance of water should be given to that newly planted, and also to the earliest crop, which, if watered early, should be earthed up. Continue to plant out, observing to take up the plants with as much soil about their

roots as possible. *Lettuce*, make a sowing of Cos and Cabbage for late use. *Onions*, a few may now be sown to draw young for winter use, or to stand the winter for transplanting in the spring. *Turnips*, as ground becomes vacant another sowing may be made; if the weather continue dry water the ground after the seed is sown, and cover with mats.

## FRUIT GARDEN.

Water trees not fully established if the weather is very dry. Remove badly placed or crowded shoots. Take suckers and weak shoots from Currants and Gooseberries; cuttings of half-ripened wood strike readily in a shady place. Remove suckers and weak laterals from Figs. Water Peaches and Nectarines freely in dry weather, thin the leaves, and cut out all coarse growth. Thin weak Raspberry suckers, leaving only the number wanted; stake them clear of the bearing rods. Keep Vines free from useless wood, and allow plenty of air to the fruit, but do not expose it too much.

## FLOWER GARDEN.

The rockery, a valuable adjunct to the flower garden, should now have a thorough cleaning, clear away all decayed flower-stems and dead leaves. A few stones had better be placed in front of the tender-rooted species to afford a little shade and protection from the powerful rays of the sun. Half-hardy plants put out here in June should have their shoots spread out and pegged down. Nail the shoots of Fuchsias and Petunias to old stumps or roots that may have been introduced among the rockwork. Managed in this way they produce a gay and pleasing effect during the autumn months. Top-dress Auriculas. Layer Carnations and Picotees. This is performed by cutting through the second or third joint, bringing the knife about half an inch up the centre of the shoot, making "a tongue," the small portion of stem beyond the joint is cut back to it, and when pegged down in the soil, which should be fine and light, it will soon emit roots. The Dahlias to be looked over, and if any of the ties are too tight for the shoots, to be removed and retied. The old-fashioned plan of placing small pots, with a little moss in the bottom, on the top of stakes to trap earwigs, should not be forgotten. Seedling Pansies put out now in a moist rich soil in a shady situation will flower freely. The seed-pods on the old plants to be gathered as they ripen, and dried in a shady place; seed only to be saved from flowers of good form and stout petals. Holly-hock seed to be sown in an open border, and the stock increased by cuttings.

## GREENHOUSE AND CONSERVATORY.

This is generally a critical month with greenhouse plants out of doors. The heat is sometimes so great as to produce the tropical winter of vegetation, when the parching heat of the sun acts upon and produces in some degree a dormancy in the system of plants; and at other times when occasional showers fall, and we see the surface of the soil in the pots moist, we are satisfied until the drooping or withering foliage shows our neglect, and perhaps with Heaths, New Holland, and similar plants it is noticed when too late to save them. The ill-effects may be avoided by plunging the pots in coal ashes, and by syringing the plants overhead of an evening, and, when doubtful of the ball being moist, by gently turning one or two plants out of their pots to see the state of the ball, as it requires some experience to distinguish whether a plant wants water or not from the ring produced by rapping the knuckles against the side of the pot. Azaleas and Camellias that have done growing may be placed out in a dry airy place to rest and harden their wood. Calceolarias and Cinerarias should be shifted as they require, and kept cool. Pelargoniums that were cut down some time since, and have been standing dry, should be shaken out of the soil, their roots trimmed, potted in small pots in sandy loam, kept close for a week or so, and watered sparingly. Polygala and other such hardwooded plants which have done blooming to be pruned pretty closely, and placed in a cool situation to start again. The conservatory will now be gay with Balsams, Globe Amaranths, Fuchsias, Pelargoniums, Cockscombs, Thunbergias, Japan Lilies of sorts, and the creepers on the rafters and trellises arranged in festoons or in any other manner to give a pleasing effect to the whole. Grow on the late Achimenes, Gesneras, &c., freely. Keep the succulents exposed to light, with plenty of heat and air, but gradually reduce the supply of moisture, so as to get the growth firm and ripe. Leave plenty of air all night to the greenhouse; all houses should be freely ventilated, especially early in the day. Regularly train, water, and syringe window plants, and protect the pots from the scorching rays of the sun.

## PITS AND FRAMES.

All the cuttings of Geraniums that can now be obtained should be put in, they will make fine strong plants for keeping over the winter. They will succeed very well in a bed of light soil in the open ground, but we prefer to strike them in good light soil in a frame, where they can be protected from heavy falls of rain or thunder showers. Sow Chinese Primrose seed in light free soil, and place in a pit or frame; water sparingly. Propagate largely from those half-hardy plants which cannot be quickly struck in the spring. Sow Mignonette and a few showy annuals for decorating the conservatory during the autumn and winter.—W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

NEVER had warmer weather, and the showers did good to everything, except some of the most forward grain. Everything promises a good harvest time. Went through most of our kitchen garden where we could use the Dutch hoe, as where no weeds were to be seen a short time ago, these appeared to be coming up in myriads. When cut up young a few hours of bright sun will thoroughly settle them. This refers even to such succulents as Groundsel, Sow Thistle, &c., and such bad root weeds as Dandelions and Convolvulus. Cut the latter often enough, and the roots will die. Of course, it is more effectual to get the roots up, but then the labour! A good plan with Dandelions on carriage roads, walks, &c., is to cut the root below the surface as deep as possible, and then put a pinch of salt on the top of the root. The drier the weather is afterwards the better, and the more destructively the salt will act, as it is absorbed more gradually into the system of the root. Groundsel and things of that kind in bloom, and seeding commenced, it is of no use to cut and leave, as the juice in the stems will be sufficient to ripen the seeds, unless the sun is very scorching. Such should be pulled up by hand, placed in a basket, and safely transferred to quarters where they cannot seed, or do injury. The best plan, however, if we could always do it in time, is to cut up all weeds before they are an inch high. The necessity of pulling makes weeding a nice process only when a gardener does not know what to set his men to. There may be a few such places, but the generality of us have to rack our brains as to what must be done first, and to contrive that no second step shall be taken by a man, where one can be made to do. The Dutch hoe in time is the great weed-eradicator.

Well-kept walks must be weeded, but many walks when very green may be hoed, raked several times, and then levelled and rolled with advantage. Salt is the most ready agent for cleaning walks, but then if the walks are fine on the surface, it will make them soft and damp in winter, so that weeding after all is the best plan; but after such warm rains the labour is apt to be excessive. With walks and borders clean and in good order the garden will always have a neat appearance. Care must be exercised in such dripping weather that men do not walk from quarters on to walks with shoes uncleaned or hanging with mud and soft earth. No walks can be tidy under such treatment.

We lately alluded to a neglected garden so overrun with Groundsel that it would have been a little fortune to those who sell green food for "dickey" birds in London. We passed it lately again, and there were second and third crops seeding, old and younger plants, forming a dense carpet. One year's neglect will, we are confident, give pretty good work for twenty or thirty years to come. The seed of the Groundsel is very tenacious of life, but it will vegetate only when brought near the surface in contact with air. In fact, it never seeds more freely than when it is permitted to sow itself on the surface. Every fresh digging for many years will bring a number of these hardy seeds near enough the surface to vegetate, and when these are early destroyed, the garden may be pretty free for that season; but the fresh digging of the next year brings another lot of seeds nearer the surface, and another carpet of weeds, and then having seen no plants seeding, some friends just beginning to thread the enticing labyrinths of science, take up all sorts of notions about spontaneous generations, and other wild ideas of what can be accomplished in forming organised existence out of peculiar combinations of matter. True, in the Groundsel, the Thistle, and the Dandelion, seeds can be wafted to great distances by their downy wing-like appendages. Two years ago in a windy day, we were enveloped by a clothing of Thistle down, and found no Thistles nearer than a mile, where they formed a perfect *chevaux de frise* in a hedgerow. Making

all such allowances, there can be no question that the seeds of such plants as Groundsel dug down into the ground, retain their vitality for a long period, and will vegetate whenever they are placed in suitable conditions, especially as to air, as most other conditions the earth freely supplies to them.

In connection with this subject, we lately met with a striking example of the tardiness with which in general we prosecute any pursuit closely allied to that which engrosses our attention as a matter of business. In walking through the fields of a young scientific farmer, and admiring his fine crops of Barley a little laid by the rains, Oats, and Wheat with splendid heads, and Swedish Turnips pretty well covering the ground, Mangold with the leaves meeting, and all so nicely hoed and cleaned that we failed to find a single weed even an inch in height;—we observed a wonderful contrast when we entered the garden and found Cabbages, Strawberries, &c., almost concealed by masses of seeding Groundsel and Sow Thistle. Our young friend agreed with us that the vegetable garden was too near akin to field culture to exercise much of a fascinating interest over him, and hence the neglect. It brought to our mind a rule in some country societies as to *cottagers' prizes*, by which those who work as labourers in a garden are excluded from competing with those engaged in other handicraft operations. We have always looked on the propriety of such a rule as doubtful. True, the garden labourer has some advantages; but then there is the great counterbalancing disadvantage, that working for himself of an evening in his garden presents nothing to him of the charms of change and variety. It is the same thing from morning to night, and he can feel little of that buoyancy that the tailor, the shoemaker, the carpenter, and bricklayer experience in their gardens of an evening merely from the change of occupation. If we are physically tired we feel a sort of pleasure in writing these notes of an evening, when a couple of hours at the hoe or the spade would be irksome and wearing-out. Hence the proverbs about the slovenliness of the good farmer's garden, the bad state of the shoes of the shoemaker's wife and of the blacksmith's nag. There are reason and nature for the foundation of the proverbs, from the simple fact that we work most heartily for ourselves when the work is most different from that by which we gain a livelihood. Hence our best florists have generally been men engaged during the day in sedentary pursuits. Hence in villages the best gardens more frequently belong to shoemakers, blacksmiths, and other tradesmen and mechanics than to garden and farm labourers. Hence, too, in farmers' gardens you will generally find, that if enthusiastic in gardening at all, it is the flowers and fruit, and not the vegetables, with which the farmer troubles himself. Of course there are exceptions. Many farm and garden labourers have gardens of their own worthy of all commendation, and farmers' gardens are frequently to be met with models of neatness and of good culture. In the latter case, however, the result is often less owing to the zeal of the farmer than to the energy and determination of his partner in life, who, if a prudent woman, will generally gain her purpose, though there may be a little grumbling about labourers going too often to the garden, and too frequently to the dungheap; but the good man of the house never turns his head away from a dish of green Peas or a plate of Strawberries.

We allude to the matter thus prominently because, though believing that gardens have a good influence on garden and farm labourers, we also believe that they have still a greater and more elevating effect on mechanics, artisans, and other labourers, on the simple principle that every human being has a longing for variety, and that, as a general rule, that change is most pleasing that is farthest removed from our usual daily avocations.

Kept removing first Peas, staking late ones, planting out more Celery, also Coleworts, Cauliflowers, Lettuces, and Endive, and planted about eight days ago a lot of Potatoes in our bedding earth-pits, to come in late for very early Potatoes for those who may like them. All these things fresh planted wanted a good watering in this warm weather, in addition to the warm showers.

Here we may note a particular fact with respect to the *wireworm*. In an earth-pit or bed that had grown well temporarily lots of Calceolarias, Geraniums, &c., we planted a lot of Lettuces, &c. In the neighbouring bed nothing could have answered better, but in this bed more than half the plants were eaten up with wireworm. In the roots and underground stems of some Lettuces we found fully half a dozen of these hard-skinned insects. How came they there? might be a moot question, as we noticed not a single specimen in lifting the Cal-

ceolarias. We have found baits of Potatoes, Turnips, or even leaves of vegetables of no use in the present case, as the Lettuce stems and roots proved the most enticing. They, however, formed good baits, and every unhealthy or dying one being examined, the place could soon be cleared of them. "Catch and kill," is the best remedy. Tar water, and tar itself sprinkled on the soil may make it unpleasant for them, but it will not kill them. We recollect reading in some old book that the wireworm was the larvæ state of *Elater obscurus*, and that it generally remained in the larva state for five years. Would that some one learned in these matters would give us the whole history of the wireworm. In some popular works it is not even mentioned. We once kept wireworms in a box of earth for three years and a half, giving them roots of vegetables to feed on, and there was no change in them in that time. By an accident the experiment was ended, the box being cleared out when we were absent.

Sent some boys with a branch in their hands in pursuit of white butterflies, that have come in a cloud since the warm rains. If not struck down, every time they alight and rest on Cabbages and Cauliflower they will deposit eggs that will soon be hatched into hungry caterpillars. Dusting vegetables with soot and lime will keep them from inserting their eggs in them, but the dusting will be almost as disagreeable as the caterpillar. A clever boy that takes the matter easily—that is, does not become flurried, will soon knock down a hundred of such gay visitants. But for the shoals of caterpillars that succeed them, the butterflies would be ornamental in the garden rather than otherwise.

*Deodorising sewage*.—More than a twelvemonth ago a little box of whitish brown powder was sent to us from the office of THE JOURNAL OF HORTICULTURE, with a request to try it. Ignorantly we supposed it was a kind of manure, and tried it on Strawberries, Vines, and various vegetables, but found the effect was *nil*, the application producing no result beyond that of common water. Some time ago we saw the same powder, we suspect, alluded to by our valuable coadjutor, "UPWARDS AND ONWARDS," and the benefit he derived from it in deodorising sewage water. We tried what little we had left in the same way, and found it very effectual, even in small quantities, in removing unpleasant smells. Even now we do not know what the powder is named, or who is the manufacturer, or who sent it to the office. We have no doubt that many would be glad to put a little in their cesspools, house sewage, &c., before using the liquids on their gardens. We fully believe that porous earth will soon deodorise all liquids committed to its care; but all of us have not noses so suited to ammonia, &c., as those who are nearly constantly employed in throwing up and working dunghills, and to some of us the application even of sewage water is distressing before the smell goes off. On this account nothing but the great drought of last season would have reconciled us to using such sewage to flower-beds near a mansion, or to plants, or fruit-pots under glass. In many cases we would decidedly prefer the sewage to pond or river water, if the scent were removed before using. The smell is apt to make some men ill, and it would be advantageous every way if the odour were removed by throwing a little of the powder into the reservoir. Something of this kind would be simpler and safer than trusting to acids, gypsum, &c. If some such powder easily applied, and cheap withal, cannot be applied, most of us, notwithstanding our knowledge, will go on applying sewage and dunghill drainings in their unpleasant natural condition.

#### FRUIT GARDEN.

Went on with Strawberry plants as detailed last week. Gathered most of the small fruit needed for preserving, the birds after all having left us a pretty good share, for which we should thank them, if we thought our thanks would reach them and make them better-behaved in future. We fear their moral sense of *meum* and *tuum*, would scarcely be so fine as that of a man, who was the terror of all the gardens in the neighbourhood. One morning a quaint old gentleman met him, thanked him for taking only a portion of his Apples and Plums, and said very good-naturedly, that whenever he wanted any more, he would have no more to do than ask for them as long as they lasted. This quite took the man by storm, he could have stood any amount of scolding and browbeating, for he was used to it, but the words of kindness went home, and from that day he turned his naturally good abilities into the laudable pursuits of honest industry. We fear our feathered friends would not be quite so amenable to kindness, and their troubling us less may be owing to the warm showers bringing snails and worms to the surface. In the dry weather it was pitiable to see the

blackbirds and thrushes reduced to skeletons. However, they have had more of their own way, as for several reasons this season we have fired no shots at them, but instead sent a boy with good lungs and a rattle among the bushes, to keep them moderate in their meals, and, perhaps, the absence of the gun has made them more moderate, from a principle of gratitude.

Unless very secure, netting is no avail, the birds will actually from mere curiosity find their way under the netting to see what is there. We have had ample proof this season, that the tomtit is a great enemy to buds in the spring, he is a great insect-devourer all the rest of the season. He is pretty well as active now in nipping up insects from bushes and trees, as the swallows are in their way among the flies in our atmosphere.

Went over the trees on walls and orchard-houses, thinning later fruit, which after all we constantly manage to leave too thick. Some time ago we grumbled that a few trees on the back wall of an orchard-house did not set thick enough to please us, but the trees acted more wisely than we would have advised them to do, as we have had to thin considerably what we thought would be a thin crop. Went over the ripening Peaches, removing shading leaves, shortening laterals, and seeing if the fruit had full room to swell. It is very annoying when a fine fruit is mature, to find that one side is marked or cut into by ligature, wire, or wood trellis.

Trees from which all the fruit was gathered, we syringed forcibly with soap water and clear water alternately, and gave the driest a good watering. Gave also a good watering to Peaches swelling freely. Too much water whenever they begin to ripen spoils the flavour, but they need a good watering in general at the second swelling, to give plumpness and size.

Thinned the shoots of Fig trees in low house, and in pots, and gave plenty of water and air to those ripening freely. None but a Fig-grower can have the satisfaction of eating ripe Figs in perfection, as when at their best it is next to impossible to pack them so as to take them safely for long distances. Plenty of air is necessary to prevent them cracking prematurely, and in dull, moist, muggy weather, a little fire heat is useful to prevent them ripening on one side before they become soft on the other. Plants in pots must never now be dry, and they must never be water-logged. In very bright days, such tender-skinned ones as the best White Marseilles are all the better of the slightest shade.

Looked after a few damped berries among Grapes, and gave a little fire heat to the late house, shutting it up early. A little extra heat now will do more good than in September or October. Melons have been all that could be wished in such bright weather. Without sun and at all shaded much under glass, they are apt to be little better than large ripe Cucumbers. We presume that in such matters people change, but we find once regular Melon-eaters at all meals of the day now scarcely touch them at any time. Several gardeners have lately told us that they have given up growing them, as they were never used. The glass in many places could well be used for other purposes. It often happens, however, that fruit and vegetables neglected for a time are again taken into favour, and we cannot produce too much of them. We notice to-day, that a heavy crop of Apricots, swelling freely, are being marked already on the most forward parts, which marking we attribute to ants and earwigs, both of which are more numerous than usual this season. We shall take an early opportunity of lashing the trees and fruit with clear lime and soot water, which is not liked by these pests, so as to bring them to the ground, and then we shall paint the wall at the bottom with a mixture of tar, grease, and oil, the latter ingredients preventing the tar drying, and, therefore, keeping the intruders from passing over. A small space as to width would do—say three-fourths of an inch. The syringing is essential, as what insects are left on the trees will be apt to remain there.

ORNAMENTAL DEPARTMENT.

Potting, staking, mowing, regulating, much the same as last week. The heavy rains have rendered it necessary to remove many leaves of Scarlet Geraniums from the flower-beds, to give more room and light to the flower-trusses. Picking decayed flowers gave also more occupation than we wanted. In fine settled weather this is less needed, as the flowers decay, and the receptacle drops off and is lost sight of; but in such warm weather with frequent heavy rains, if there are a few decayed blooms in a large truss the rains wash the colour out, and spoil the rest of the truss and other trusses near it. Borderings of Nasturtiums have been freely disleafed. Hollyhocks have been secured by taking stout string from stake to stake—say 6 feet apart, and then the individual stems were secured to the string,

Rows of Gladiolus were secured in the same way, which is a much neater and more economical plan than a more general staking. Rows of Ageratum, Purple Verbenas, &c., in borders, were secured in their places by very small string or thread, strained between stout little sticks, neither sticks nor string being seen a few days after being used.—R. F.

COVENT GARDEN MARKET.—JULY 29.

SUPPLIES of most descriptions of fruit and vegetables are very heavy. Peaches and Nectarines are not so plentiful, but quite sufficient for the demand. English Pines realise very low prices, large importations of West Indian Pines continuing. Currants are good, and in great request; Strawberries are not yet over, some good Eltons being still to be had. Spinach chiefly consists of the New Zealand, or *Tetragonia expansa*, which is found very useful. The best Peas at present at market are the No Plus Ultra and Champion of England.

TO CORRESPONDENTS.

\* \* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

PEACHES AND NECTARINES FRUITING ON SPURS (*An Old Subscriber*).—Peaches and Nectarines do not generally produce fruit on spurs, in consequence of their being disbudded to a single shoot to replace that producing fruit during the current season, and the formation of spurs is therefore prevented. They bear fruit on spurs, commonly on the Plum stock when disbudding is confined to removing the shoots not wanted for extension, and those which would crowd the trees if allowed to remain stopping the shoots taking the place of general disbudding, the side shoots being close-pinned throughout, in the first instance to three and at the most five joints, and ever afterwards that season at the next joint. On the Peach stock the trees are as much given to produce their fruit on spurs as when on the Mussel Plum, if not more so; the main cause of their bearing on shoots of the previous year is their being made to do so by an excessive use of the pruning-knife. We apprehend there will be less unfruitful trees when all pruning of fruiting trees or of an age fit for bearing is confined to summer pruning.

ANTS ON WALL TREES (*Idem*).—Smear the inside of a flower-pot with honey, and place it near the ants' nests and haunts, and when crowded with them put pot and all in boiling water. The most effectual remedy, however, is to mix arsenic with honey in equal parts, place in a saucer with two thin sticks across, inverting another saucer over it resting on the sticks, so that the ants can get in but other animals be kept from it. We had some fly-destroyer, or fly-paper, from a chemist, and we found it of great service in thinning them.

**POTATO SCAB (M).**—When manure is largely mixed with either lime or ashes we find the Potatoes liable to scab. It is also prevalent where the sets and tubers are in contact with the manure. We find Potatoes less liable to scab on newly-broken-up land than on that which has been long cropped, and that they are never so much affected in ground where the manure is applied some time previous to planting and well mixed with the soil, as where it is applied immediately under or upon the sets.

**TAKING UP POTATOES (Idem).**—Potatoes are ready to take up—1st, when the tubers have attained their full size. 2nd, when the leaves begin to fall and the haulms turn brown. 3rd, when the tubers come freely from the vines without having to jerk them off violently. 4th, when the skins are firm and will not come off easily when rubbed. Your Potatoes are not fit to take up whilst growing and blossoming. They will be best left alone until done growing. Last year Dalmahos and many others ripened earlier than usual in consequence of the unprecedented dryness of the season. Judging by the appearance of our second early Potatoes we think they will not be ready to take up for storing before the end of August, and the main crops not until the middle or end of September. They promise a good crop.

**CROPPING A GARDEN (Idem).**—Generally two crops are as much as can be taken from the same ground in one season, because they take up a certain time from sowing or planting to arriving at maturity. You being informed by a gardener of high standing that a garden ought to have five crops in a season may be correct as to Lettuce, Spinach, and similar crops that are frequently sown, and soon come into use. The assertion does not hold good as regards Carrots, and Onions, to say nothing of Peas, and all the Cabbage tribe. Manure after every crop; never leave anything on the ground a single day after it ceases to be of use; plant or sow something upon it the same day; never let it be idle, and you will then obtain all that can be had from the ground in a season. The papers now appearing by "BURNWOOD P.D." contain much relating to cropping a kitchen garden.

**APRICOTS ROTTING (Marston).**—We have not experienced any annoyance from Apricots rotting off as they ripen. In the absence of any particulars of the disease we are unable to assign a reason or point out a remedy.

**VERBENA PEGS (Idem).**—They may be obtained from the principal London seedsmen, but we can tell you how to make them cheaply and expeditiously by the thousand. Procure some thick bamboo canes. Saw them into six-inch lengths. Split these into thin slips about the eighth of an inch thick, and place in water for a few days. When thoroughly wet split with a knife to the thickness of lucifer matches, and they are then ready for use, still keeping in water to render them pliant. In using them the ends are brought nearly together and thrust into the ground, with the shoot to be pegged between them. In this way they form so many wood-like hairpins, and are much cheaper. An expert hand can make several thousands in a day.

**BANKSIAN ROSES NOT BLOOMING (E. Hicks).**—The reason these Roses bloom so seldom is that people cut away the small twiggy shoots on which they for the most part bloom. Such shoots should not be shortened, and but little pruning is required in any part until the wall be covered. Banksian Roses flower more freely in dry soils than in those which are wet and retentive. If the branches be shortened they put forth a profusion of strong shoots and do not bloom. Old plants towards the end of summer often produce immensely thick and strong shoots. Early in autumn these should be removed, that the flowering twigs may not be exhausted by them.

**APPLES, PLUMS, AND PEARS FOR A NORTH-WESTERN ASPECT (T).**—The fruits you wish to grow on an aspect which is north-west by north do not generally succeed well there. They would do fairly, but would not be equal to those on more favourable aspects. The fruits which you do not wish to grow—viz., Currants, Gooseberries, and Morello Cherries, would be more profitable than Apples, Plums, and Pears. The kinds of Plums most likely to bear moderately, are Pond's Seedling, Kirke's, Coe's Golden Drop, and Guthrie's Late Green. These at 20 feet apart, the first at 10 feet from the end of the wall, will occupy 80 feet of the wall, and if more Plums are wanted Green Gage and Jefferson may be added. Apples—Hawthornden, Maxx Codlin, Koswick Codlin, Norfolk Bearcr, Blenheim Orange, and Scarlet Nonpareil. Pears—Louise Bonne of Jersey, Bergamot, Gansel's Late, Colmar d'Eté, Alexandre Lambré, Beurré Superfin, and Thompson's. The Apples on the Paradise should be 15 feet apart, and the Pears on the quince at 12 feet apart.

**CONSTRUCTING ROCKWORK (L. J. E.).**—Some notes on the subject will be found at pages 333 and 372 of the last volume. The construction of rockwork is a matter of taste; keep in view boldness of feature and distinctness, and rugged outline. In forming these rocks on the islands you will make a footing for them below the level of the water so that they may appear to rise from it. On these the remainder of the rockwork may be constructed. It is not necessary to cement the stones together unless small, when doing so would impart massiveness to fragments. The whole of one or more of the islands may be converted into rockwork with green patches here and there. In others it should be confined to the water's edge with stones jutting out in places, forming ledges level with or a little below the water, others rising abruptly from it in parts, and to some height, whilst at the other side they may rise little, and be confined to the edge of the water. The stones will hold together without any cement, only make every stone firm before placing another upon it. Use few and large stones, and aim at a natural effect.

**SEEDLING HOLLYHOCKS (M. Smith).**—The flowers are good, but there are many like them, and many better. No judgment can be formed of the merit of a Hollyhock unless a whole spike can be seen.

**CRICKETS (J. Acton).**—In No. 222, published June 27th last, we gave all the information we possess relative to destroying crickets.

**VARIED FORMS OF CONIFER LEAVES (Man of Kent).**—We consider the specimens you enclosed are from a Juniperus chinensis, or Chinese Juniper. The prickly leaves will cease to appear as the tree becomes older. The others are only the mature leaves of different ages.

**CUCUMBERS OUT OF DOORS (Pease Hill).**—We refer you to page 67, but will see what more can be done. Very correct information, however, is not so easily obtained, unless you are on the spot and can see for yourself. The Sandy growers have long been the earliest in the country, but that holds true also in general of Peas and Potatoes, except those brought from Cornwall and Devon. The light warm soil is the chief cause of the early success.

**FLOWER-BEDS NOT THRIVING (An Old Subscriber).**—The remains of an old Melon-bed will be good for manuring flower-beds next season, after it is well rotted and sweetened by exposure to the air, and several turnings. The exposure and the turning dissipate a portion of the manuring principles, but this is more than compensated by the sweetness and friability obtained. Beds can only be over-manured when the plants grow too much to leaf and too little to bloom, and beds that would scarcely be rich enough in a hot dry summer, will be much too rich in a wet moist season. We often must make a risk in these matters, as we cannot know what the season will be before it comes. We are, however, just a little in doubt whether what you call your failure is owing to the manuring, or to the winter planting of your flower garden. If you had a good show from bulbs, annuals, &c., in spring, you must not expect that the bedding plants will answer first-rate, unless you can give them extra attention, and have the ground well stirred before planting them out. Some of our own beds that had some old hofed dung tinned into them looked better three weeks ago, before the heavy rains came. If a dry autumn come they will be fine again. If it should be dull and wet we shall have too much foliage, and the leaves will be so large that a portion of them will have to be removed. But, on the whole, extra growth is more pleasant to look at than extra stuntedness. On light poor soil, all the twelve plants you mention would be the better of a little sweet rotted manure. In soil moderately rich, and where the climate is at all moist, we would give manure, as above, to Calceolarias, Verbenas, Lobelias, Linum, and Gazanias, but we would give little or none to Phlox Drummondii, Saponaria, Amaranthus melancholicus, Petunias, Scarlet Geraniums, Tropaeolums, and Mesembryanthemums. In rich soil all the latter will grow too much to leaf. Mesembryanthemums, Portulacas, &c., and things of that kind, do best in poor sandy soil, and better still if the rows are planted on little hillocks so as to escape damp. Three weeks ago we had a beautiful Petunia-bed allied to the old Shrubland Rose. The bed was raised in the basket style, and the outsides were bordered with a blue Nola. The soil having become exhausted, fresh and richer soil was given, and nothing could have looked more lovely and compact than these Petunias. The heavy warm rains have left abundance of bloom, but it has more than doubled the length of the plants, and to prevent their falling or being swept by the wind into unseemly bundles, we have had to stick the bed all over with branches some 30 inches in length. Could we have been sure of such heavy warm showers, and the ground hotter than we have ever experienced, the poorest fresh soil would have been the best for these Petunias. As it is, it required some hours' labour to make and keep the bed handsome. We may mention that the plants had been at first pegged down regularly, and then, as the plants grew, the bed was stuck all over with twigs some 14 inches in height, that being thought sufficient; and it would have been so in a dry season like the last. We would wish to oblige "AN OLD SUBSCRIBER" more definitely if we could, but the season makes such a difference in growth, that an unvaried rule of manuring or not manuring can scarcely be given.

**GRAPES NOT COLOURING (J. H.).**—We are no great advocates for dulled plate glass for forcing-houses, though we have not met with any want of colouring in the fruit grown under it, when, as in your case, plenty of air and heat were given, and the roots kept in such a nice condition. We incline to think that the very heaviness of the crop and the size of the berries have been too much for the colouring matter. Here we may remark that lately in a meeting of gardeners, and with specimens of Grapes before them, alike well grown, but some imperfectly and others perfectly coloured, it was agreed by a majority that the somewhat reddish Black Hamburgs were sweeter and more luscious than the black ones. There is a secret about colouring besides heaviness of crop. We have had very heavy crops well coloured, and a few bunches on a Vine that yet never became black.

**STRAWBERRY CULTURE.**—In answer to an "ORIGINAL SUBSCRIBER" I reply that if a plant, being either pistillate or hermaphrodite, does not fruit the first season, it will fruit the more abundantly the next in consequence of having a year's grace. I frequently disfruit weak plantations and deprive them of runners, and always find that they will repay me the next season. I have received the thanks of Mr. C. Turner for the Strawberry article, and I beg to acknowledge the thanks of an "ORIGINAL SUBSCRIBER." The season lasted here from Whitsunday till July 16th. I ended well with the Frogmore Pines and John Powell, two admirable late sorts; they are both long in bearing. The former has a nice briskeness, not amounting to acidity; the latter is sweet, rich, and delicious. Both are handsome.—W. F. RADCLIFFE, Tarrant Rushton.

**PROPAGATING LYCOPODS—EVERGREEN CLIMBER FOR A PORCH (Peep).**—Most Lycopods may be propagated by cuttings and divisions. The smallest will grow in a moist warm place. We do not think there is any little work on the subject. The British Lycopods and Mosses would be the best in a closed porch. Such kinds as the Swiss denticulatum which creeps very freely, would stand well on such a closed porch when the adjoining hall had a fire in winter. The North American apodium, and rupestris we think would also do, if kept moist and often moved, as the first is apt to give way in the middle. Such British kinds as alpinum, clavatum, and selaginoides are very interesting, but they will not spread, nor look so green as denticulatum. For covering a dark back wall nothing is better than Cissus antarctica. You do not give us so definite a statement about the porch as to enable us to state whether a Vine would do in it, or what other evergreen creepers would be most suitable. You speak of a window south-west. Well, has it a roof of glass with merely a window or two? Unless large, you could not do much with evergreen creepers, except the variegated Ivy perhaps, but if you will give us the width, length, and height of the porch, and whether it has a glass or an opaque roof, we will do what we can to meet your case.

**HEATING A GREENHOUSE AND DETACHED HOUSES (J. P. Liverpool).**—If you can go low enough, we would recommend a conical boiler of middle size, say 2 feet in height; if not, a saddle-back of similar size. There will be no difficulty in heating the two houses, though the one is 25 yards apart from the other—that is, if the level admits of it, but you will be able we presume to make little use of the 50 yards of piping which will be required between the two houses. The heating of each house may be quite independent of the other, and but for the connecting-pipes, there need be no difficulty if the ground from the first to the distant house rises a little all the way. The pipes of connection may be packed in sawdust in a dry drain; or better still in an open drain, with an open end into the house, and the heat will thus be conveyed from the pipes. If you gave us more definite particulars we should be happy to help you all we can. We are surprised at the fuel not answering.

**HEATING A GREENHOUSE, VINERY, AND STOVE** (*An Old Subscriber*).—To heat three houses 31 feet by 12 you would require a boiler about 2 feet in length, and dimensions of fireplace, 13 inches wide and the same in height. A saddle-back of 20 inches in length would do, but very small boilers are economical only at the first purchase. You do not tell us whether your houses are to be lean-to's, or span-roofed, or whether the vinery is to be forced early. For a lean-to house you would need from 120 to 130 feet of four-inch pipe. For a vinery to commence in November or December you would require as much. To begin in the end of February, some 90 feet would do. For the greenhouse 60 feet at least would be required to keep out frost, and from 90 feet if you wished the house to be from 45 to 50 in winter. You had better err on the safe side and have more instead of less, as the less heat there is in the individual pipe, to keep a requisite temperature, the better it will be for all things grown in the house. The position of the boiler is also a matter of importance; supposing the stove to be in the centre, the boiler had best be placed near that house.

**WANTED VINE LEAVES** (*Wm. Lucas*).—The warts on the back of the leaves are produced partly by a damp border, but chiefly by a close moist atmosphere. Nothing will remove those affected this season. More air and heat may prevent anything of the kind next year. The spider has nothing to do with it.

**ENTOMOLOGICAL WORK** (*G. G.*).—Humphrey's and Westwood's "British Moths and their Transformations" gives all the British species known at the time of publication, with the caterpillars; also Humphrey's "British Moths" and Morris's "British Moths," but all these works contain the Microlepidoptera, none being restricted to the families you name.—W.

**NAMES OF PLANTS, &c.** (*Hyson Green*).—*Erodium moschatum*; *Excelsior Marrow Pen.* (*S. T.*).—We are sorry to trouble you again, but your letter did not reach us along with the fruit, and the connection between the two was consequently lost. (*C. P.*).—1, *Galopsis ladunum*; 2, *Galopsis tetrahit.* (*G. B. J.*).—*Plumiera alba.* (*S. H.*).—1, *Galium verum*; 2, *Portulaca oleraceae.*

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

ARTIFICIAL INCUBATION.

I THINK it possible that some of your readers may like to hear the record of a young poultry fancier's failures and successes. For three or four years I had kept a few fowls, but my supply of eggs and poultry was so scanty and precarious that I balanced for some time whether I should attend to them personally myself, or give them up altogether. At the beginning of last year for five months I had not had a single egg. I then purchased Mrs. Fergusson Blair's "Henwife," and followed her directions as to a more generous and regular system of feeding. The result was that I quickly had a fair supply of eggs, which went on continually increasing. I purchased a few pure-bred fowls at the Birmingham monthly sales, and procured some first-rate sittings of eggs from friends at a distance. I had tolerably good luck with them, and sent three pens of birds to the Birmingham Show last November, putting a guinea-a-head on them. They were all sold the first day, and I replaced them with other birds at the same price, so as to give myself a change of breed. At the close of the year I found that my expenses had been £49, and my receipts (including the home-consumption at market price), had been £48 15s.

At the beginning of this year I had six cocks and about fifty hens and pullets. My supply of eggs never failed. I had four or five dozen weekly, even when the ground was covered with snow; but my early sittings were almost all failures, and both my own eggs, and those I purchased, brought forth miserably small broods; and even those small broods were decimated by the weather and accidents. As I had seen incubators praised and advertised in your columns, I determined last Easter, being in London, to buy one. I set this to work immediately on my return, in the beginning of May. In the first week of that month I placed forty eggs in the incubator, and set five hens at the same time. Day and night I watched the incubator; but I could not keep the thermometer from rising sometimes to 112°, and at another sinking to 85° or 90°. Most anxiously, as the twenty-first day drew near, did I listen for any sound of life, but in vain. Day after day, as the chicks became due, did I watch and turn the eggs; but when my five natural hatchings had succeeded, two bringing forth every egg in their nests, I broke one by one all the forty eggs. They all showed the same appearance, one-third being empty, and the rest without any signs of a living chick, but also without any offensive smell. This has been a great disappointment, and I shall be glad to hear from any amateur how far they have succeeded with an incubator. Mine was constructed to burn a new lamp with artificial gas, from naphtha or some like

spirit. It consumed two gallons (price 12s.), in twenty-eight days; so that, even if I had succeeded, the cost of incubation was something considerable. My idea in ordering the incubator was to try the experiment now, and, if tolerably successful, to set it to work early next year with my first sittings, so as to give me an additional chance of early chickens; but if I cannot make it succeed in May, how can I expect it to answer in February? I have inquired for some work on incubation, but can hear of none, and I cannot tell from what cause my recent experiment failed. I have never met with any one who has tried an incubator, so that I have no means of judging whether I should have better luck next time. Should you insert this letter in your Journal it might bring some answer as a guide to a future trial, otherwise I must own my previous experience has given me but little encouragement to try again.—A COUNTRY PARSON.

[The letter which we print from "A COUNTRY PARSON," is that which we some time since promised to answer next week. It will, probably, seem to our correspondent, that the next week is like the schoolboy's "to-morrow," or the debtor's "very shortly." We have been waiting for every experiment to be tried, and are now in a position to say an incubator will be shortly offered to the public that has never failed. We have not only closely examined the machine, but have seen the results at every age. We have seen Ducks and chickens hatched and hatching with a general average of three-fourths. They have come out strong, clean, healthy, well-formed chickens. The heat is so regulated that the machine may be left for forty-eight hours, if necessary, without the fear of variation. The application of it to the egg has been as nearly as possible assimilated to the natural process of the hen, to which we attribute the unusual strength and health of the chickens. The artificial mother, hitherto the bane of all these inventions, has really become a very useful and successful thing. It is patented, and will be immediately brought out by a company (limited).

The advantages of such a machine are incalculable to the poultry world, whether they be amateurs or dealers. We can all recollect last year, the total absence of broody hens from November till March; and the consequent disappointments to the first class, and loss to the second. It will be a most valuable adjunct to a yard, and our excellent correspondent, the "COUNTRY PARSON," was acting on sound principles when he put eggs under hens, and in the machine on the same day. It is one of the advantages of an invention like this, that it enables us to put a full brood to every hen. In Surrey, Sussex, and the parts of Kent that devote themselves to poultry, these machines will be of eminent service in increasing the supply of early chickens, now so scarce and dear during the months of April, May, and June.

Their utility will not, however, be confined to poultry. They

will be inestimable to the Game breeder during the Pheasant season. Considerable breeders ourselves in each department, we do not hesitate to say, that we anticipate unqualified success and benefit from the introduction and use of this hatching-machine. Our advertising columns will shortly give our readers full particulars, and also the address where it may be seen in action.—B.]

### CAMBRIDGESHIRE AND ISLE OF ELY POULTRY SHOW.

THE first Poultry Show which has been held for many years in this county, took place in the Parade Ground, Ely, on Wednesday, the 26th of July. The weather was extremely fine, and there was a very large attendance of visitors. The *Spanish* fowls were good specimens; but the Coloured and also *White Dorkings*, were of superior merit. The *Cochin-China* fowls were very creditable; and the *Game* were largely represented, and all of them were first-class specimens. However, Mr. S. Matthews, of Stowmarket, took both the first and second prize with *Brown Reds*, and the other with *Black-breasted Red*. The *Golden-pencilled Hamburgs* were all good specimens, as also were the *Silver-pencilled*. The *Gold* and *Silver-spangled* were not so well represented as many of the other classes; but in the *Silver-spangled* class we observed some magnificent birds, and this class, although small, must have given the Judge a good deal of trouble and anxiety. The *Dantam* class was large, but chiefly represented by *Game Bantams*, which were generally of superior merit and beauty. The *Ducks* were exceedingly fine. There was but one pen of *Geese* exhibited, and that was a beautiful pen of the *Cravat Goose*, or *Anser canadensis*.

Altogether the Show must be considered a complete success, and being in connection with the Agricultural Show, many thousands flocked to the ground in the course of the day, and we congratulate the Committee of Management on their success.

The following are the awards:—

**TURKEY.**—Prize, Mrs. G. S. Hall. Highly Commended, Mrs. G. S. Hall; J. Jessup, Littleport.  
**SPANISH.**—First, Mrs. G. S. Hall. Second, A. Rac.  
**DORKING (Coloured).**—First, H. Lingwood. Second, W. T. Everard. Highly Commended, Capt. Colthrop.  
**DORKING (White).**—First and Second, H. Lingwood. Highly Commended, W. T. Everard.  
**DORKING (Any other variety).**—Prize, H. Lingwood. Highly Commended, Capt. Colthrop. Commended, J. H. Chambers.  
**COCHIN-CHINA (Any variety).**—First, H. Lingwood. Second, J. Wright. Highly Commended, Mrs. G. S. Hall.  
**GAME (Any variety).**—First and Second, S. Matthews. Highly Commended, T. Everard. Commended, C. Clarke.  
**HAMBURGH (Gold-pencilled).**—First, Rev. H. J. Carter. Second, Mrs. G. S. Hall.  
**HAMBURGH (Silver-pencilled).**—First, A. K. Wood. Second, J. S. Saltmarsh. Commended, J. A. Dimmock.  
**HAMBURGH (Gold-spangled).**—First, J. Wright. Second, A. K. Wood. Highly Commended, R. Tate.  
**HAMBURGH (Silver-spangled).**—First, A. K. Wood. Second and Highly Commended, C. Bamford.  
**BANTAMS (Any variety).**—First, G. Manning. Second, J. C. Lowndes. Highly Commended, G. Clarke.  
**ANY OTHER VARIETY.**—First and Second, J. Wright. Highly Commended, C. Ambrose, Peterborough.  
**DUCKS.**—First, G. Comins. Second and Highly Commended, C. Bamford. Commended, Capt. Colthrop; J. O. Fison.  
**GOOSE.**—Prize, Mrs. G. S. Hall.

Mr. James Monsey, Norwich, officiated as Judge.

### THE SCARBOROUGH, HACKNESS, AND NORTH AND EAST RIDINGS POULTRY SHOW.

JULY 22ND.

SO far as the weather and company could contribute to make it a successful exhibition, we should say this was second to none of its predecessors.

**SPANISH.**—First, W. Massey, Fulford, York. Second, W. Charter, Driffield. Commended, J. Hadfield, Cottingham. *Single Spanish.*—Prize, O. A. Young, Driffield.  
**DORKING.**—First, W. Hunter, Green Hammerton, York. Second, J. Hatfield, Cottingham. Commended, Mrs. Dale, Scalby. *Chickens.*—First, W. Hunter, Green Hammerton. Second and Commended, Mrs. Dale, Scalby. *Single Dorking.*—Prize, Mrs. Dale, Scalby.  
**COCHIN-CHINA.**—First and Second, T. Barker, Hovingham. Commended, O. A. Young, Driffield. *Single Cochin-China.*—Prize, R. Smith, Norton. *Chickens.*—First, T. Barker, Hovingham. Second, H. Merkin, Driffield. Commended, O. A. Young, Driffield.  
**GAME.**—First and Second, G. Pounder, Kirby Moorside. Highly Commended, M. Hunter, Green Hammerton. Commended, G. Cartwright, Seamerlane, Scarborough. *Single Game.*—Prize, W. Dawson, Scarborough. *Chickens.*—First, M. Hunter, Green Hammerton. Second, G. Pounder, Kirby Moorside.  
**HAMBURGH (Golden-spangled).**—First, J. Hall, Willerby, Hull. Second, J. Dobson, Pickering. *Single Golden-spangled.*—Prize G. Holmes, Great Driffield.  
**HAMBURGH (Silver-spangled).**—First, Miss Hawson, Pickering. Second, R. Drummond, Scarborough.

**HAMBURGH (Golden-pencilled).**—First, G. Holmes, Driffield. Second, F. Stubbs, jun., Snainton. *Single Golden-pencilled.*—Prize, O. A. Young, Driffield. Commended, F. Stubbs, jun., Snainton.  
**HAMBURGH (Silver-pencilled).**—First, G. Holmes, Hull. Second, Miss A. Charter, Driffield. *Single Silver-pencilled Hamburg.*—Prize, G. Holmes, Driffield.  
**POLAND.**—First, —Loft, Woodmansey. Second, O. A. Young, Driffield. *Single Poland.*—Prize, O. A. Young, Driffield.  
**ANY DISTINCT BREED.**—First, —Loft, Beverley. Second, O. A. Young. *Single Bird.*—Prize, O. A. Young.  
**BANTAM (Black and White).**—First, R. Smith, Norton. Second, Lady Londesborough, Grimston Park. *Single Black and White Bantam.*—Prize, R. Smith.  
**BANTAM (Neither Black nor White).**—First, G. Holmes. Second, J. Pickering, Driffield. *Single Cock.*—Prize, G. Holmes.  
**ANY OTHER VARIETY.—Chickens.**—First, R. Smith, Norton. Second, Miss E. Charter, Driffield.  
**GEESE.**—Prize, O. A. Young. *Geesings.*—First, Mrs. Elsworth, Yeddingham. Second, Mrs. J. Darrell, West Ayton.  
**DUCKS (Aylesbury).**—First, O. A. Young. Second, Mrs. G. P. Dale, Scalby. *Ducklings.*—Prize, O. A. Young.  
**DUCKS (Rouen or any other breed not Aylesbury).**—First, A. Catley, York. Second, O. A. Young. *Ducklings (Rouen).*—First, Miss E. Charter. Second, R. H. Boyes, Aislaly. *Any other variety.*—First, Mrs. J. Darrell, West Ayton. Second, O. A. Young.  
**TURKEY.**—First, Mrs. Dale. Second, Mrs. Hopper, Wykeham Grange. *Turkey Poult.*—First, O. A. Young. Second, Mrs. Dale.  
**GUINEA FOWLS.**—First, O. A. Young. Second, H. Merkin.  
**SELLING CLASS.**—First, Miss E. Charter. Second, G. Holmes.  
**PIGEONS.—Croppers.**—First, —Dotchen, Whithy. Second, —Nicholson Carriers. —Prize, —Dotchen, Whithy. *Trumpeters.*—Prize, E. N. Roysde, Asby-de-la-Zouch, *Jacobins.*—Prize, —Cooper, Weaverthorpe, *Fantails.*—Prize, F. B. Lockwood, Scarborough. Highly Commended, R. Esh, Helperthorpe, Malton. *Tumblers.*—Prize, —Dotchen, Whithy. *Barbs.*—Prize, —Dotchen, Whithy. *Nuns.*—Prize, G. Holmes, Driffield. *Balds.*—Prize, —Dotchen, Whithy. *Drolls (Blue or Silver).*—Prize, W. Glaves, Ayton. *Turbits.*—Prize, J. Hodgson, Scarborough. *Dragoons.*—Prize, O. A. Young.  
**ORNAMENTAL WATER FOWL.**—Prize, Mrs. J. Hopper, Yedmandale.  
**RABBITS.**—Prize, R. Dobson, Fulford, York, and O. A. Young, Driffield, divided the money.

### CLEVELAND AGRICULTURAL SOCIETY'S SHOW AT GUISBOROUGH.

THE Show of this Society was held July 25th, at Guisborough, on ground provided, as usual, by Capt. Chaloner. The weather was beautifully fine, and, consequently, a large number of visitors assembled.

**SPANISH.**—Prize, W. Milburn, Guisborough.  
**DORKING.**—Prize, J. White, Warlaby, Northallerton. *Chickens.*—Prize, W. Leason, Driffield.  
**GAME COCK.**—Prize, J. Richardson, Middlesborough.  
**GAME (Any age).**—Prize, P. Sturdy, Ingleby Mill, Stokesley.  
**ANY BREED OR CROSS.**—Prize, Rev. J. G. Milner, Bellerby, Leyburn. *Chickens.*—Prize, R. Easby, Ormesby, Middlesborough.  
**BANTAMS (Any age or breed).**—Prize, J. Pickering, Driffield.  
**DUCKS (Aylesbury).**—Prize, W. Smith, Peyton-carr, Stokesley. *Duckling.*—Prize, Miss Smith, Peyton-carr, Stokesley.  
**DUCKS (Rouen).**—Prize, J. Farrington, Crossbeck House, Normanby. *Ducklings.*—Prize, J. Farrington.  
**DUCKS (Any breeds not Aylesbury).**—Prize, Rev. J. G. Milner.  
**GEESE.**—Prize, O. A. Young, Driffield.  
**PIGEONS.—Carriers, Nuns, Turbits, Archangels, Jacobins, Trumpeters, Fantails, Barbs, and Dragoons.**—Prize, T. C. Taylor, Middlesborough. *Tumblers (Almond).*—Prize, J. Wetherell, Hartlepool. *Owls.*—Prize, T. Rodham, Guisborough. *Any other New or Distinct Variety.*—Prize, A. Donaldson, Lackenby, Redcar.  
**RABBITS.—Length of Ears.**—Prize, O. A. Young, Driffield. *Coloured.*—Prize, O. A. Young. *Forciga or any other Variety.*—Prize, W. Lawrenson, Eaglescliffe, Yarm.

### BELFAST POULTRY SHOW.

BEING one of those who strove to win the cup, but did not, I am afraid of being mistaken for your "vituperative" correspondent, and beg to state that I had nothing whatever to do with the report of the Belfast Show published in your Number of the 18th ult. It is impossible for the Judges to please everybody, and I would like better proof of their incompetence than the mere assertion of a disappointed exhibitor. Mr. Beldon was fairly entitled to the cup, having had the greatest number of first prizes; still the Nettlefield birds require no "laudation" from me, having carried off a greater number of prizes of all sorts at this Show than those of any other exhibitor, except Mr. Beldon, and only for him would have won as many first prizes as any two of their opponents put together, the gross numbers being—

H. Beldon . . . . .	19 prizes of all classes, and	1 Commended.
F. H. Lewis . . . . .	15	4 Do.
R. Boyle . . . . .	15	1 Ditto.

Still I hope Mr. Beldon and other English exhibitors will continue to compete at our Shows. I will give them a hearty welcome, and every assistance in my power, and if I cannot beat them I will do the best I can.—FREDERICK H. LEWIS, *Nettlefield, Belfast.*

## CANKER IN PIGEONS—COLOUR OF EYES.

A PIGEON of mine had, as I suppose, canker just above the beak, a tumour opening into a very unpleasant-looking dark yellow cavity. For this complaint Moore advises the application of burnt alum, and Roman vitriol. Mr. Brent suggests caustic, and scraping with a spatula shaped for the purpose from a bit of wood. For the benefit of those who do not happen to have Roman vitriol in store, and have, perhaps, an inadequate notion of a spatula, I can recommend a third process—viz., letting the bird alone, which mode of treatment resulted in a complete cure. I was led to this discovery by having invariably failed in doctoring all previous ailments in my columbarium.

I saw the other day a curious sport from a pair of Archangels of an inferior colour throughout, which the dealer called yellow, but which I regarded as red. The regular form was preserved, but not the glossy lustre that should belong to that variety. It seems a pity that Pigeon-fanciers' standards of taste are so conventional. The brilliant red and yellow iris is ignominiously described as "gravel," while the pinky white passes for "pearl." Now, the former colour harmonises exactly with a blue-necked bird, and is a relief to a black or white one. On the other hand, I cannot concur with the author of a paper on the Archangel, who prefers a "rich golden eye" for that bird. The gold, I imagine, kills the orange hues of the neck, and would be well replaced by as pure a white as might be attainable.—F. TURNER.

## REMOVAL OF SUPERS.

HAVING seen occasional inquiries in the "Journal," as to the best way to take off supers and to expel the bees, and also having frequent applications made to me personally for information on this point, perhaps it may not be amiss, now that the time for the removal of supers generally has come, or is at any rate drawing near, to give the results of my own experience. It used formerly to be with me a task of very great difficulty, and as my time for these and most other manipulations connected with my apiaries is almost entirely confined to the mornings and evenings, I have often dreaded the commencement of the operation, fearing lest there should be insufficient time for effecting it thoroughly before the "shades of evening" should close over us, or the usual business hour of the morning approach ere the stubborn bees were induced to leave their own well-filled storehouse. Occasionally it has been necessary to confine the bees in the super for the day or night, or until a further opportunity presented itself. The plan usually recommended, is to remove the super with its adapter as gently as possible to a distant part of the garden, or to a room partially darkened, having one aperture only for the admission of light, and to afford exit for the bees. The super is then to be tilted on edge, and the bees allowed to find their way out gradually; then flying to the light they are supposed to go quietly home.

This is a plan I have adopted with success in many instances, but occasionally the bees would not go; then various means had to be resorted to to make them. Patience at length would become exhausted, and as the bees came to the surface of the combs, or wherever they could be reached with a feather, they were remorselessly brushed off on the floor. The majority would fly or crawl towards the light, but a great number would fail to reach their homes, from having filled themselves to repletion with honey filched chiefly from the unsealed cells. I also found that this plan was certain to attract robber bees, and that, notwithstanding the darkened room, hundreds would enter to endeavour to share the spoil.

I have found when bees were unwilling to leave a super, that shutting them closely in until they became really inconvenienced from the confined air, and then affording them means of exit, they would tumble out with a great rush; this repeated several times would at length prove successful in nearly clearing the combs. Still there were a few that would stick to their colours, nailing them closely to the mast, resolved never to yield. To get rid of these was often a work requiring great time and trial of patience. The most difficult cases are those of bell-glasses, when it is desirable that the bottom of the combs should not be severed from their attachments to the adapters. The small central aperture affords a very contracted space for the departure of the inmates. A considerable amount of time is usually requisite under such circumstances. The glass must be wrapped up, so as to show but one aperture (that by which the bees ascended for work) whereby light can be seen. Gradu-

ally, provided it is not assailed by robbers, the bees will leave it, and it is desirable that no shaking of the super, or brushing of bees, be resorted to.

I have, when the communication with box-supers could be shut off by slides, occasionally had them completely cleared of bees in a few minutes without removing the supers from their stocks. Having pushed in the slides, the bees are allowed to remain undisturbed until they begin to show unmistakable signs of excitement; the super is then gently raised in front about half an inch, or an entrance aperture is opened, a stream of bees will pour out and descend the front to the entrance of the stock-hive. The owner must watch, and if a cessation occurs before all the bees have left, he must again confine them for a bit, carrying off the super so soon as he thinks it tolerably cleared of them. I have taken away well-filled straw hives worked on Taylor's doubling-board plan, perfectly cleared of bees in two or three minutes, by pushing in a zinc slide between the two boards and opening an unused entrance in the hive to be appropriated. As slides are almost entirely abolished in my apiary (one good hive only is retained, which is so worked). This last plan is now very seldom resorted to by me.

Of late years I have adopted the use of large-sized supers, capable of containing from 35 lbs. to 75 lbs. of honey, of which some are of glass, some almost entirely of glass, being framed glass octagons, and others simple wooden boxes. My apiary having largely increased, and the time at my disposal for attending to the requirements of the bees having become more and more limited, I was at length led to adopt a far more summary method of dislodging bees from the supers, and this was the all-powerful persuasion of *driving*, which up to this date I have never found to fail in effecting the desired end in an incredibly short space of time. At first it was tried on wooden supers only, as I thought it would be almost a matter of impossibility to handle glass supers in a manner sufficiently rough for the purpose. But finding that the bees could be so readily induced to ascend into an empty hive from the ordinary box supers, I was not long in making the attempt with a large mahogany-framed glass octagon.

I choose a hollow-sounding deal table, or fix a board with its ends resting on two hives or similar support. The glass super is removed as gently as possible, and immediately inverted on this table or board. A straw hive is placed over the combs, and without tying round with a cloth, a gentle drumming is kept up on the board or table, the super itself not being touched except to steady the straw hive. As the bees ascend I usually tilt the straw hive on edge, watching them as they go up. If the straw hive is larger than the super, I hold it on with one hand, so that, perhaps, only one part of its edge comes in contact with that of the latter. It seems to have no effect in preventing the ascent of the bees. It is advisable to select a hive that is free from dirt, which may be shaken down with the vibrations, otherwise the appearance of the combs may be sadly marred.

When all, or nearly all the bees, have been forced to ascend into the receiving-hive, I remove them at once. A cloth is fastened so as to rest partly on the floor-board in front of the entrance of the old stock; the other end is secured to the ground. The cluster of bees is shaken out with a few smart concussion between the open hands; falling in front of their proper home they rapidly crowd into it. With a frame-hive the cover can be removed, and the cluster knocked out on the top of the frames; but I usually adopt the plan first described.

When supers are too small to allow of a receiving-hive resting over them, I fix up a temporary stand close to the parent stock, of such a height as to allow the edge of the inverted super to be on a level, and to come in contact with the floor-board. I then drum gently on this stand, endeavouring not to shake the stock-hive, and usually find the bees run up and into their proper entrance in one continuous stream. If they do not all go at first, it may be advisable to remove the super to a darkened room for a little time, or there may be some difficulty in keeping off an attack on its contents by the bees which may pour out from the stock. Still, with a little management, I have found this plan answer very well.

In about an hour and a half of one evening during the summer of last year, I succeeded in dislodging the bees from four large supers, varying in size from 73 lbs. to 20 lbs. In the largest of these, an octagonal glass box, there remained after the operation one solitary drone, which was liberated subsequently. The others were cleared in an equally effective manner, and in addition to this, the adapters were all removed from the stock-hives, the proper tops put on, and all made snug for the

autumn and winter. About the middle of June this year, I took off a beautiful glass-box super of 35 lbs. carrying it into a rather dark arbour. At first I tried whether the bees would leave without my having resort to driving, but after waiting an hour, and finding the bees apparently almost as numerous as at the commencement, I proceeded to drum them out, and in five minutes the majority of the bees had ascended into the upper receptacle.

I think, then, that enough has been said to demonstrate the fact that driving can be safely resorted to for the purpose of freeing supers from the bees, provided due care and precaution be taken, that much needless waste of time may be saved, and the operator be preserved from all apprehensions of the coveted stores being appropriated by the bees instead of by himself. I shall be pleased if the foregoing hints be of use to other apirians.—S. BEVAN FOX, *Exeter*.

### BEES IN 1865.

I COMMENCED bee-keeping about the 20th March last, when I purchased a hive of bees, a last year's swarm, and at that time very light, but with plenty of bees, and half full of comb. I fed them for a short time and soon they began to work. As in May they increased very fast, I wrote to ask you how to make an artificial swarm in order to stock a set of Nutt's boxes, when you replied that it was too difficult a task for an inexperienced bee-keeper. My bees, as I stated, were so situated at a distance that I could not watch them, so that if they swarmed I should be very likely to lose them. I, therefore, resolved to make the attempt. May 25th, between one and three o'clock, I took the old stock off the stand placing an empty hive in its stead. The full hive or stock I carried some distance off, then turned it upside down in a bucket, placing the pavilion over it, first securing the zinc slides and covering them with straw. I then tied a cloth round where the hives met and began tapping the old one. They buzzed awhile and then began to march up the sides of the pavilion and clustered at the top. I tilted the hive and saw the combs were quite deserted. I then placed the pavilion on a cloth and took the old hive back to its stand. The bees that had mustered, laden with pollen, &c., rushed in. They seemed disturbed for a time and searched the hive all over. The swarm I took a mile and a half off and left it.

The old stock went on well, all busy carrying honey but very few pollen. They each day increased in numbers and soon showed signs of swarming by hanging out, so I tried again on June 20th, and drove the bees in a flat-topped empty hive, but in turning the old hive down on the stand I dropped a large piece of comb filled with honey; I took it away, but the sun being so hot caused more to drop, so that the bees could not get either in or out. I then thought it would be best to take the old hive away and put the driven bees back on their old stand. They have now quite filled the empty hive with comb. I strained 20 lbs. of beautiful honey from the old hive, but found no brood. The swarm went on increasing in numbers and stores, soon filling the pavilion with comb and honey.

I went to see them on the 2nd of July, when I found them hanging out in a great cluster at the front; so on July 3rd, I smoked them in, but during the day they had commenced working in two glasses that I put on, and at night I brought them home and put the hive together, opening one of the end boxes which they soon took possession of, and commenced comb-building. I then perceived a quantity of dead bees in the side box and several bees fighting, and as I had just read an answer given by you in a similar case, advising an opening in the end box for the exit of the bees, I made one three-quarters of an inch long by three-eighths of an inch high, but that night turned out cold and wet. The wind from the south-west so blew through the opening I had made that next day there were not so many bees in the side box, but they had cleared all the dead out, and have since quite deserted it. I have stopped the hole with a cork. The weather is still cold and showery, so I suppose it is too cold in the box, but they have almost if not quite filled two of Neighbour's bell-glasses, so I should like to hear if I have done right. I should also like to know the best way to join bees to others, if by fumigating and securing the queen, or driving; and whether it matters securing the queen, and how, if driven; and what respecting queen encasement, for I cannot see the inside of my hives as if they were bar-hives.—A NEW BEGINNER.

[Your question and answer referred to transferring an old stock of bees to a Nutt's hive, not to stocking it with an arti-

ficial swarm, in which you appear to have succeeded admirably, where a beginner might well have failed. Your attempt to force a second swarm on the 20th June, was a mistake. As you found no brood in the old hive on that occasion, the probability is that the young queen had not begun egg-laying, so that the falling of the combs was very likely the best thing that could have happened, as without eggs or brood no queen could have been reared. Unfavourable weather was, probably, the sole reason of your bees deserting the side box. The best mode of effecting autumnal unions is by driving, as recommended in page 59 of the fifth edition of "Bee-keeping for the Many." We always remove one of the queens, but it does not appear to be very essential, as it is only in comparatively rare cases that we have found both sacrificed.]

### NUTT'S COLLATERAL BOX-HIVE VERSUS STORIFYING.

HAVING read at page 40 of "our Journal" "SOUB'S" letter asking your opinion respecting "Nutt's collateral boxes" as compared with the storifying system, I may perhaps be allowed to make one or two remarks respecting both methods as they have answered with me. I have three stocks in three different kinds of hives. No. 1 is in a set of Nutt's collateral boxes. Last season I took about 20 lbs. of pure honey from one box, and 15 lbs. from the other box, leaving the breeding-box untouched, and I shall obtain as much from it this season. No. 2, is on the storifying principle, in a square box 16 inches square by 10 inches deep. I have given both the same attention in every respect, and as far as the season has passed I feel sure I shall not have half so much honey from No. 2 as from No. 1, for at present they have not quite filled a glass super of 8 inches diameter. No. 3 is a hive I had sent me from Germany in a straw skep last February, and when it reached me it was in a sad state, suffering from dysentery; but following your directions, for which I beg to thank you, and keeping the floor-board scrubbed every morning with boiling water and soda, they recovered, and increased so rapidly that at the end of May they were stronger than No. 1, which is three years old; and I was compelled to place a frame-hive alongside of the straw skep, and so let them pass through the latter to prevent their swarming. I tried to drive them in the spring, as directed by Mr. Woodbury, but failed, and I find they are more reluctant in leaving a straw for a box-hive. This German hive is also placed in a collateral position with the frame-hive, which last they are also filling, and from them I shall not have much less than 40 lbs. of honey. But much depends on the management, and I admit I am not so well versed in the piling system as in the collateral; but what may answer with one person may be a total failure with another. All I can add is, that I find the bees prefer working on a level in preference to carrying their stores up two lives; and therefore I would recommend "SOUB" to try both ways, as being the best advice of one who uses Nutt's hives.—T. S.

[We are very glad to "hear both sides;" but in order to give the storifying system a fair chance you should try it with a stock-hive of reasonable size. A box 16 inches square by 10 inches deep is much too large for the purpose.]

### OUR LETTER BOX.

BUTTERFLIES AND MOTHS (*T. R. Drake*).—Stainton's "Manual of British Butterflies and Moths," in two small volumes, will suit your young friend. It is published by Van Voorst, and is cheap.

STEWARTON HIVE (*Yorkshire*).—Mr. Eaglesham, we believe is dead. Apply to Mr. Paton, Joiner, Stewarton, Ayrshire. We are informed that more than two hundred sets of these hives have been sent from Stewarton this year.

INFERTILE QUEEN (*A Reader*).—An examination of the spermatheca of the queen bee which accompanied your letter, proves it to be, like that of the queen submitted to me by "R. S.," destitute of the slightest trace of spermatozoa. She may, of course, be either a young queen or a very old one. If a young queen she has certainly not been impregnated—if an old one she has become completely exhausted, and if she laid eggs they would (like those of a virgin queen) produce drones only. A few lines stating how far the actual history of the defunct queen either corroborates or contradicts the conclusion at which I have arrived will greatly oblige—A DEVONSHIRE BEE-KEEPER.

DIMENSIONS OF WOODBURY FRAME-HIVES (*J. Coward*).—Woodbury frame-hives are 14½ inches square by 9 inches deep inside. Full directions for constructing them, from the pen of Mr. Woodbury himself, are given in the fifth edition of "Bee-keeping for the Many" which you can obtain from this office by sending five postage-stamps.

UNITING BEES (*R. C.*).—The best mode of condensing your ten stocks into five is by driving and uniting adjoining stocks as recommended and described in page 59 of the fifth edition of "Bee-keeping for the Many."

WEEKLY CALENDAR.

Day of Month	Day of Week.	AUGUST 8-14, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock before Sun.	Day of Year.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 74.6°, and its night temperature 50.8°. The greatest heat was 92°, on the 10th, 1842; and the lowest cold, 32°, on the 13th, 1839. The greatest fall of rain was 1.14 inch.

ON AND ABOUT THE ROCKS AND SANDS OF TENBY.—No. 1.

T will be a comfort to many to read, as most comforting is it to me to be able to write, that there is one enjoyable seaside town—though railways have done

all they can—still very difficult to be arrived at. This difficulty of access keeps away those pleasure-and-ease-destroyers—stuck-up personages, who think the coat makes the gentleman, and expensive dressing the lady. There are none of these at Tenby; but every one owns Common Sense as the ruler of the place, and lives, and jounies about, and wears costumes conducive to mental relaxation and bodily invigoration. They come to obtain these remunerators, and are wise enough to pursue them without needless encumbrances and hindrances.

No place was ever better described by its name, for Tenby (written Dinbych in old MSS.), is only a southern mode of pronouncing Denbigh, meaning a little fortress on a hill; and such it always was from the earliest record when the Danes were here, just one thousand years since, until its fortifications were finally shattered by the Cromwellian cannon in 1648. The hill is of mountain limestone, and is a long narrow peninsula—so narrow, that the houses on one side its main street look over the southern sands, and the houses on the other side similarly look across the northern. Those sands and their enclosing rocks yield a rich ingathering to the naturalist.

Geology is not among the special objects of this Journal, yet I will crib a little of its space to tattle a few sentences about the fossil plants of the Tenby geology. The mountain limestone on which Tenby rests passes inland, and that limestone supports all the coal strata of Wales. Some of those strata, or "coal measures," are of anthracite coal; those not anthracite are rich in fossil Ferns, Equiseta, and even of those princes of the vegetable kingdom, the Palms. Near Hean Castle is that vein of black clay from which is formed the best of firebricks. In that clay are found the roots of Palms, telling of an age before the Flood, when our climate must have been tropical. Passing along the coast towards Tenby a portion of the rocky strata is passed, so rich in some fossil cryptogamia as to be known as Fern cliff. In the opposite direction is Saundersfoot, where on the shore are found the "beetle stones" polished at Tenby for ornamental purposes. They are black nodules of clay ironstone, having in their centres white vegetable petrifications, the sections of which sometimes approach an insect form.

There are evidences that the sea is receding from some parts of the adjacent coast, and that it has encroached

upon the coast in other neighbouring parts. Thus, opposite to Amroth Castle, about six miles to the north-east of Tenby, visible at low tides, are the remains of the forest known in the days of the bards as Coed Traeth. The wood of the submerged trees for the most part is decayed and crumbles when pressed between the fingers, but some of it is quite sound.

Four miles to the west of Tenby the sea has receded. There is the Vale of St. Florence—a name bestowed by the earliest Flemish settlers in our island, but known to the Britons as Tregyor; and those are still living who remember when boats rowed to the village, which is now more than three miles from the sea. Its waters, however, have left one evidence of their former presence, for the Samphire (*Crithmum maritimum*), still grows near a bridge not far from the village.

The soil in every direction is extremely light, and I am struck by the evidences of the prevalence of deep tillage and liberal surface-stirring both in the fields and the gardens. Such good cultivation has been taught to the farmer and gardener by practice alone; but it is perfectly consonant with the suggestions of science, and has long been advocated in this Journal. Last year Professor Church carried on a series of experiments instituted specially to prove or disprove the benefits alleged to be the result of deep tillage and frequent surface-stirring. After long-continued drought he ascertained the quantity of water retained in the thirteenth inch of soil, measuring from the surface. In one case, where the soil had been deeply cultivated during the previous autumn, no less than 28.6 per cent. of the apparently dry layer examined was water. In another, where the subsoil was taken from uncultivated land, which had not been disturbed within memory, the per-centage of water was 19.2. In a third case, the subsoil of a kitchen garden, which had been deeply trenched in autumn, yielded 26.2 per cent. of water. In a fourth, the subsoil in the same garden, where the bed had only been half dug, yielded 20.5 per cent. There had been no rain to speak of since the spring, and yet these enormous quantities of water still remained in the subsoil. The soil experimented on is "a light calcareous clay loam, resting on the forest marble."

Whilst writing the concluding word I was summoned from my desk to see the uncovering of the statue of "Albert the Good," in the presence of his youthful son Prince Arthur. I shall not pause to detail the ceremony, nor dwell on this evidence of how thoroughly, even to its furthest verge, loyalty pervades our Queen's home islands; but I will give expression to my oft-recurring thought—What a testimony it is to the unrivalled beauty of the objects of the gardener's art, that they alone are selected as the best decorations on all festal occasions. Nay, more; no artist designs, or could design, an ornament without copying some vegetable form, and that no such ornament was ever suggested of which the type and the superior could not be gathered from among our plants. It is true that the yachts and even the very smallest Tenby fishing-boat is decorated with flags of bright and many colours; but how poor and monotonous are they compared to the

flower-decorated windows and arches which edge and span the street of Tenby this day! The climate, like that of the Channel Islands, is so tempered by the surrounding sea, and the gardens on the south-western slope of the limestone hills are so sheltered, that the Fuchsias, Hydrangeas, and other plants of similar nativity and habit are almost trees instead of being the potted pets they are in colder districts. Hence branches of these, with their floral honours thick upon them, have been sacrificed to do honour to this day with a liberality that would appal a more inland gardener.

This floral decoration carries me away to notes on the use in this neighbourhood of particular plants on particular days; and the first among those notes is of a custom—rude and barbarous, but now abandoned—for the men and boys on St. Stephen's day, to carry twigs of Holly, and to beat with them the bare arms of the women whom they could find thus unprotected! What could be the origin of this misuse of the evergreen which but the very previous day had been used to do honour to Christ's nativity? Was it intended by our forefathers to prefigure that that birth, though a subject of rejoicing, caused suffering to the jubilant as it did to the proto-martyr?

New Year's-day had, and still has, a more grateful custom; for boys and girls, bearing a cup of spring water, dip into it a sprig of evergreen, and sprinkle with it the inmates of the houses where they call. This may well be accepted as a gentle monition to purity during the newly-born year; but how shall we explain all the details of these verses they chaunt during the sprinkling?—

"Here we bring new water from the well so clear,  
For to worship God with, this happy new year;  
Sing levy dew, sing levy dew—the water and the wine.  
With seven bright gold wires, and bugles that do shine,  
Sing reign of the fair maid with gold upon her toe;  
Open you the west door, and turn the old year go.  
Sing reign of the fair maid with gold upon her chin;  
Open you the east door, and let the new year in."

There is no reason for doubting that "levy dew" is really the Welsh "*Llef i Dhew*," a cry to God. The first "fair maid" we may accept as intending the last day of the old year, which departed amid the usual rejoicing over its last hour, or "gold upon her toe;" and the other "fair maid" we may similarly accept as the first day of the new year, the very commencement of which was welcomed, or had "gold upon her chin." "Turn the old year go," is a Welsh form of speech; for when the field-gate is opened for any animal to enter, that animal is "turned go," according to the farming man's vocabulary. But who will explain the gold wires and bugles?—G.

### SHADE, WHAT IS IT? AND THE THERMOMETER.

ALTHOUGH this question may appear very simple, yet there is a wide diversity of opinion as to what constitutes shade in the case on which the present article is intended to dwell; and even in the more general sense in which the term is used in gardening shade differs more or less in degree; at the same time its influence on vegetation entitles it to most careful attention. It is not, however, my intention to enter upon that part of the subject, but to speak of what is commonly called shade in describing the heat of any particular day. There is evidently much diversity of opinion on this point; consequently, the registers of those who take meteorological notes lose much of their value from their not being conducted according to one uniform rule. As matters of this kind have of late been considered of more importance than heretofore, and as some of the most eminent men in the kingdom have given their attention to meteorology, something like a uniform rule as to what constitutes shade, when this term is used in describing the heat of a summer day, ought to be settled by general consent. As we possess no other means of registering the various amounts of heat in our atmosphere than by instruments more or less correct, let us at least try to avoid giving a wrong figure by adopting a universal rule as to how and where that figure has to be denoted.

Taking for granted that thermometers are the only instruments for measuring the variations of heat in the atmosphere, where ought these instruments to be placed so as to simply give a true index of that heat? "In the shade," is generally the answer at once. But what is meant by shade puzzles many, and the different records of extreme heat given by those who now and then report in the public prints certainly indicate that the observations are taken under different circumstances.

Heat, unlike water, is not distributed alike in all places to which it has access; certainly its tendency is to rise upwards instead of to descend as the heavier fluid does, but even then it does so in waves that do not penetrate everywhere in the same degree, even though acting on one level. Many upstairs rooms that are lofty and allow of a large hourly influx of external air never become heated to the same degree as the air out of doors, but this is probably due to the walls and various articles of furniture abstracting heat from the atmosphere; and until they have acquired the same temperature as the external air (which doubtless requires longer than the twelve or fourteen hours' heat of our summer days) the atmosphere of the room must be colder.

When the earth has become to a certain degree warmed by the bright sunshine of preceding days, and the evenings probably seldom offer a lower temperature than 55°, we may look for the hottest day in the year somewhere between the 20th of June and 20th of July. Not that the period here stated always presents the highest temperature, for I have known this occur in May, and on one occasion in September, but such cases are unusual, the period above given being usually the warmest; and as comparison with the heat of former years is always interesting, those having the means usually endeavour to ascertain the degree of heat, and if their instruments be correct, and the mode of using them the same each year, the difference, if any, will be easily seen. It is, however, not so easy to compare notes with others who may take their observations under widely different circumstances, and, consequently, comparison in such a case is useless, for A perhaps keeps his thermometer in an upstairs window facing the north, where perhaps some overhanging trees assist in completing the shade and encourage the eddying wind to play on the instrument, reducing the reading much below what it ought to be; while B, anxious to have his readings correct, runs into much the same error by boxing his instrument up from almost all connection with the external air, giving it in fact a case all round or nearly so of some non-conducting material, and thereby preventing that access of external air which ought certainly to be allowed if anything like the true indication be wanted. C, again, places his instrument in the open, or I might almost say in the full sun, and, consequently, falls into an opposite error by recording too high a temperature, and seems surprised on looking at the published returns in the daily papers to find his district so much hotter than any other recorded. In fact, so vague is the term "shade" that unless some explanation be given of what is meant by it we must expect to grope in the dark. I therefore venture to give my views as to what I think we ought to regard as the day and night temperature, or in other words the maximum and minimum of the thermometer.

Assuming that the object is to ascertain the precise temperature of the external air where not acted upon by the direct rays of the sun, the least possible amount of shadow that intervenes between the sun and the instrument would seem to be all that is wanted. At the same time such intervening object ought to be of a non-conducting material, and for general application I know of nothing better than a plain timber post set perpendicularly in the ground in a perfectly open situation; this post ought to have a flat side to the north considerably wider than the instrument that is to hang against it on that side, whether horizontally or vertically, the former way being on the whole preferable. Against such a post, and say at 4 feet from the ground, hang up one of the best maximum registering thermometers, and about a foot from the ground you may hang up the minimum one in the same way; care being taken that nothing like shelter intervenes to prevent the cool air of the night acting upon this instrument. A more open exposure may be made if necessary for the latter, but this is sufficient for most purposes, and the convenience of having the two instruments together is an object when only ordinary observations are required. I prefer having the two instruments separate, as the double ones are so liable to become deranged, and when the maximum and minimum thermometers are separate there is no more trouble in taking notes of them than if only one were in use. Tolerably good instruments can now be had at a reasonable rate, although I by no means affirm that perfection has been arrived at; on the contrary, I would like to call the attention of makers of such instruments to the fact that bubbles of air or some other foreign fluid often pass into the quicksilver or spirit, and thereby render the reading incorrect. This misfortune is by no means confined to low-priced thermometers, for I have had two or three thermometers from a celebrated London firm which cost 2ls. each, and they

all went wrong in about a month, while a common one of simpler construction has been in use for some years. In fact I hope to see a great improvement in thermometers and other meteorological instruments, and until such is really the case, the public can hardly be expected to buy the expensive article when its merits are only in its outward adornment.

Notwithstanding the heat of the present season, the thermometer has not yet reached the maximum of 1856, 1857, and 1858, as will be seen by the figures below, which indicate the hottest days in each year, as taken in the manner described above:—

1854.	July 25th .....	thermometer	87°
1855.	June 29th .....	"	93
1856.	July 31st and August 1st .....	"	95
1857.	June 26th and 28th, and Aug. 23rd .....	"	95
1858.	June 15th and 16th .....	"	97
1859.	July 12th .....	"	92
1860.	July 2nd .....	"	78
1861.	August 12th .....	"	88
1862.	May 6th .....	"	86
1863.	August 9th .....	"	87
1864.	July 20th .....	"	87
1865.	June 21st and 23rd .....	"	92

It is somewhat remarkable, that the heat attained on the 21st and 23rd of June in the present year was not approached by 8° in any of the days before or after these dates, and up to the time I write, July 28th, the thermometer has only once reached 86°, and that was on the 15th of July; but a long period of dry hot weather may occur without any extreme being approached, and it is questionable whether an unusually hot day amongst others of medium character is beneficial. One of the most remarkable instances of this kind occurred on May 6th, 1862, which, as shown above, was the hottest that season. I may, however, remark, that the present season has presented a longer period without rain than any previous one, for none fell here (Staplehurst), for twenty-six consecutive days in June. The rainfall, however, of the six months ending the 30th of that month is a full average. The early months were wet, and during July nearly 3½ inches of rain have fallen.—J. ROBSON.

MILDEW ON ROSES.

JUDGING from what I have seen, as well as from complaints I have heard from others, this pest to Rose-growers seems to be unusually prevalent this season; and from recent inquiries in THE JOURNAL OF HORTICULTURE I conclude that some information on the subject will be acceptable to many of your readers. Though I may not be able to advance anything in my present communication that is not known to most Rose-growers of experience, I may be able to convey some useful information to such of your readers as are, like myself, beginners in this most pleasurable branch of floriculture, by selecting and condensing what has been advanced by some of our best writers and most experienced Rose-growers.

With regard to the cause of this disease, we find that, as with diseases affecting the human frame, "doctors sometimes disagree;" and the fact seems to be that, as to this part of the subject, we are very much in want of certain and reliable information. Mr. William Paul, in his "Rose Garden," does not venture to allude to any positive cause of the disease, but says negatively, page 118, "If the situation (of the rosery) be airy and sunny, there is little to fear on account of this disease." Mr. Cranston, in his "Cultural Directions for the Rose," quotes the late Mr. Knight as saying, "The secondary and immediate cause of this disease has long appeared to me to be the want of sufficient moisture from the soil, and excess of humidity in the air, particularly if the plants be exposed to a temperature below that to which they have been accustomed." This, I conclude, refers to Roses in pots, or newly planted out from a frame or some such sheltered situation. An anonymous writer in your Journal of March 28th, page 243, says, "Mildew is seen under extremely different circumstances, but I think is generally caused by defective root-action, the roots not being able to supply the sap fast enough to the leaves, or sometimes from the leaves being in a higher temperature than the roots; . . . . . and it would seem as though mildew, attacking healthy young Rose shoots exposed to sun and air in the open ground, must differ very much from the mildew which attacks plants in cold damp houses in the winter, and yet I am still inclined to think the cause is much the same." The Rev. Mr. Radclyffe, perhaps our highest authority on Rose-culture, seems, indirectly at least, to ascribe its prevalence to extremely

high culture, or, in other words, to gross feeding; for in an article on the Manetti stock he says (see JOURNAL OF HORTICULTURE for April 22nd, 1862, page 63), "It cannot be denied that Manetti Roses, as a class, are more subject to white mildew than Briar Roses, and that the higher you cultivate the more you will be subject to it." To this latter remark I can fully subscribe; for while I confess myself unable to assign any certain cause of the existence of the disease, I believe it may always be developed by high or gross feeding. The soil in which I cultivate my Roses consists to a great extent of decayed turf from an old pasture mixed with the soil on the spot, which is moderately heavy and well drained; it is also well manured with decayed stable dung, and I find that the appearance of mildew always follows a liberal application of strong liquid manure. This consists of house-sewage, by which I mean the whole liquid refuse from the house, consisting of kitchen and chamber washings, soapsuds, &c. This, in wet weather, is diluted with an equal quantity of pure water, and in continued dry weather with double that quantity, and is applied in the proportion of a gallon to each tree on an average of once a fortnight from May to September.

Whatever may be the cause of mildew, as regards its existence in the rosery it is, I believe, developed or increased very much by circumstances over which we have no control—I mean, by atmospheric causes, as the existence of long-continued seasons of drought, or of dull, cloudy, wet weather. But while we can, perhaps, do little to prevent the existence of the evil altogether, we may do much to remedy it where it does exist. The remedies recommended for this disease are indeed manifold, and one or other within the reach of every Rose-grower. Mr. W. Paul, in the "Rose Garden," page 118, says, "Dusting the leaves with sulphur is the best remedy. Watering with a solution of nitre is also said to destroy it." Mr. Rivers, in the "Rose Amateur's Guide," recommends the same remedy—"sprinkling with sulphur." Both these instances, however, refer to Roses in pots. Mr. Cranston, in his "Cultural Directions for the Rose," recommends the same remedy, giving the preference to black sulphur over yellow; but adds, "Where sulphur has failed to arrest its progress, Gishurst compound has been applied, and with wonderfully good effect. The quantity used has been from 2½ to 3 ozs. to the gallon of water. The plants affected are syringed or well wetted with the mixture, and if the shoots are at all tender they must be syringed over with clear water in a few hours afterwards, otherwise the young buds which are formed at the ends of the shoots may be destroyed; also, when allowed to dry upon the foliage it has a disagreeable appearance. One or two applications in most instances will be sufficient; but when the disease has been allowed to establish itself it must be applied weekly until it is cured." The Rev. W. F. Radclyffe, in his lecture on Roses, delivered before the Royal Horticultural Society (see JOURNAL OF HORTICULTURE of July 26th, 1864, page 67), gives, as the most effectual remedy known to him, "2 ozs. of blue vitriol, dissolved in a little hot water, and then mixed with a stable-bucket of cold water, and poured from a watering-pot with the top (rose?) on over the leaves." Your correspondent "X. Y. Z.," before referred to, writing in the Journal of March 28th, says, "There is no more certain cure for mildew on Roses in summer than a thorough soaking of water at a temperature of 80° or 90°." "UPWARDS AND ONWARDS," I think, speaks of liquid manure heated to 140°; and in your answers to correspondents in the Journal of July 18th, you recommend syringing the plants with lime water to destroy the fungus, and then to water the roots copiously, mulching the surface, and to continue watering abundantly during dry weather; and you add that "weak liquid manure once a-week will benefit the trees."

Here, then, we have plenty of remedies to choose from. The two which I have tried myself are the Gishurst compound and the solution of blue vitriol, and I can answer for the efficacy of both. Of the two I give the preference to the Gishurst compound, and this I never use stronger than 2 ozs. to the gallon. My reason for the preference is, that while it is as efficacious as the blue vitriol, I find it does not mark the foliage so much. Indeed I find in applying the latter that any Roses wholly or partly expanded, but especially those which are white or light-coloured, become so covered with black spots that they have to be destroyed. The foliage also becomes spotted, though not to such an extent. In applying the Gishurst compound I mix it, if possible, two days or more before using it, and, choosing a dull day, syringe the plants about the middle of the day. I then syringe them over, about six or seven o'clock the same

evening, with clean water, which removes any deposit of the Gishurst compound, and leaves the foliage but little marked by the deposit. I am convinced that any remedy to be at all effectual should be applied immediately a trace of the disease is discovered. The old saying is emphatically true in this case—"A stitch in time saves nine;" and not only must some remedy be applied at once, but it must also be persevered in from time to time as the disease re-appears during the season. The remedies recommended are inexpensive and easy of application, and he who does not make use of them in case of their being required does not deserve to possess a good collection of the queen of flowers.

My remarks, although I fear already too long, will not be complete without mentioning what sorts I have found most subject to mildew. Out of a collection of about one hundred different sorts, chiefly Hybrid Perpetuals, I find none so subject to the pest with me as *Géant des Batailles*: I have three or four plants of it in different situations all on *Manetti*, and they suffer more than any others. *Blairi No. 2* and *Prince Camille de Rohan* are also much infested with the pest; but in these cases I am not sure that it may not be something in the situation, rather than any predisposition to this disease, that makes them worse than others. I must not close this communication without expressing a hope that the readers of it will contribute so far as they can to the elucidation of the subject discussed, especially by furnishing information as to the prevalence of the Rose mildew in their own locality, the remedies used for its removal, and the kinds of Roses most subject to the disease. Such information I cannot but think will be most interesting and valuable to many of your readers, and especially to—A COUNTRY CURATE.

#### PLANTS FOR ROOMS.

† THE atmosphere of halls and ante-rooms is so variable—sometimes close and stifling, often subject to draughts, and always much drier than plant-houses generally—that plants cannot be placed in such situations without sustaining a certain amount of injury, especially as there is usually a great deficiency of light. Drawing and sitting-rooms, likewise, are but ill-adapted for plants; for, though there is not so much danger of currents of air, the air is drier, the rooms are equally dark, and often so warm, especially in winter, that the plants begin to grow, become unhealthy, and flower badly. However desirable plants may be for the decoration of rooms, I can only regard growing them for this purpose as preventing the production of fine specimens, and taxing the patience and energies of the gardener to the utmost, particularly if he is at all proud of his plants, and grows them year after year from cuttings up to handsome specimens. It is, indeed, rare to meet with an establishment remarkable for its specimens, where plants are largely employed for in-door decoration. There is, notwithstanding, an increased demand for decorative plants for rooms, that demand being generally greater where there is no conservatory or greenhouse that can be entered or seen from the mansion.

It is by no means unusual for plants to be most in request where the conveniences for growing them are none of the best. Many structures are so ill-contrived for the growth of plants that an exhibitor would not know how to proceed in order to grow a plant worth looking at. Justice compels me to note the impracticability of growing fine specimens where the means are limited to vineries and stoves, the proper occupants of which require different treatment from the plants. More credit is due where good Grapes are grown in vineries in which every nook and corner is occupied with plants, than where every structure is used for its proper purpose; for plants and Vines may be grown well together at certain times, whilst at others the treatment which will suit one will not suit the other, and in the endeavour to grow both neither obtain justice. There may be no lack of skill, perseverance, and desire to make the most of the means at command, and yet the plants will never be so fine as those grown in light and proper plant-houses. Fruit-houses are the worst of plant-houses, for their occupants are so different from plants in their requirements that the cultivator, seeing that he can grow only one thing well, tries to do that, and makes the other a secondary consideration. Take, for instance, plants in a vinery. Up to May the plants may be grown without any great detriment, either to themselves or the Vines, but by that time the Vines will shade the roof too much for flowering-plants, which will,

consequently, be drawn up weak, producing plenty of leaves but few flowers. The plants must, therefore, be moved to more suitable quarters, and their place occupied by others requiring a certain amount of shade. After a time the Grapes will change colour, and the plants must then suffer, or the Grapes be defective in their colouring. I am perfectly aware that sometimes, and under certain conditions, plants can be grown fairly in vineries, and yet Grapes of average excellence be produced; but my experience leads me to doubt whether excellence in fruit and plants can be attained in the same structures. To have fine plants structures entirely devoted to them are necessary, and to obtain fine fruit nothing should interfere with it. Whatever, therefore, is grown in vineries, in addition to the Vines, should not remain there a day after they interfere with the Grapes, or are interfered with. I will assume that the correspondent for whom these remarks are chiefly intended wishes to have Grapes of average merit in addition to plants, and, bearing this in mind, I will proceed with the answer, led only by my own experience of plants in vineries where Grapes are the principal object, and of those plants suitable for or which have been employed for room decoration. I confess that I have no knowledge of growing plants in vineries, making the Vines a secondary consideration. The correspondent to whom I reply "has a stove and vineries, but no greenhouse." I will assume that he has two vineries, and pits or frames.

In JANUARY we may expect in bloom from the stove—*Eranthemum pulchellum*, and *E. strictum*; *Poinsettia pulcherrima*; *Euphorbia jacquiniiflora*; *Justicia speciosa*; *Begonias nitida*, *insignis*, *lucida*, and some of the variegated kinds, as *B. grandis*, and *Marshalli*; *Torenia pulcherrima*; *Gardenia citriodora*; *Epiphyllum truncatum* vars. *magnificum*, *purpureum*, *salmonium*, *cruentum*, and *violaceum*; *Thysacanthus rutilans*; *Ardisia erenulata*, for its red berries, and its white-and-yellow-berried varieties; *Aphelandra aurantiaca*; *Hebeclinium atrorubens*, and *H. ianthemum*; *Gesnera zebrina splendens*, and *G. cinnabarina splendens*. From vineries—*Camellias*; *Primulas*; *Cyclamens* *colum*, *Atkinsi*, *persicum* vars.; *Coronilla glauca*; *Daphne odorata rubra*, and its sub-variety *alba*; *Acacias hybrida*, *rotundifolia*, *oleifolia elegans*, and *longiflora magnifica*; and in addition *Snowdrops*, *Scilla brevifolia*, and *S. bifolia*; last, but not least, *Lilies of the Valley* brought into flower in a cool part of the stove, along with the two preceding, all on a shelf near the glass, and from the same a few *Hyacinths*, *Narcissus*, and *Crocus*, and a few pots of *Tulips*; nor must I omit *Andromeda floribunda*, and *Laurustinus* on short stems, that come from the vineries without any forcing.

In this month it is to be expected that one of the vineries will be thoroughly cleaned (this we shall term the early vinery), and forcing commenced so as to have Grapes in June. Such being the case, we may introduce plants of the dwarf *Rhododendrons*, as *R. caucasicum album*, *danicum atrovirens*, *clivatum*, *gemmiferum*, varieties of *Nobleanum*, and other hybrids, nice dwarf plants well set with bloom-buds; common sweet-scented hardy *Azalea*; *Kalmia glauca* and *latifolia*; *Deutzia gracilis*; *Dielytra spectabilis*; *Weigela rosea*; *Sweet Briar*; *Roses* (assigning them the lightest and airiest situation); also *Lilies of the Valley*, *Hyacinths*, *Tulips*, *Narcissus*, *Crocus*, *Scillas*, and a few pots of tree and Neapolitan *Violets*. Plants of the old *Hydrangea* will bloom the earlier if afforded a little heat, and it is one of the best plants for rooms. To the above we may add some of the most forward *Pelargoniums*, *Cinerarias*, *Calceolarias*, a few *Fuchsias*, *Salvia splendens*, varieties of *Azalea indica*, especially *amona*, and a few pots of *Lilium lancifolium speciosum*. A few *Gloxinias* and *Achimenes* may be potted and introduced into the stove, and also a few more bulbs to keep up a succession until those in the early vinery come in. If there is convenience, a bed of leaves or tan may be made in the early vinery, and this will be useful for the deciduous plants introduced for forcing, of which I find that I have omitted *Prunus triloba flore pleno*, *Rhodora canadensis*, standard and dwarf *Ribes*, and *Lilaes*, and the double-blossomed *Peach*; also, *Daphne cneorum* and *Berberis Darwinii*, which are evergreens. It will also be of service for forwarding *Begonias Evansiana*, *manicata*, *coccinea*, *Prestoniensis superba*, *Saundersi*, and *Martiniana*, and a few of the variegated-leaved varieties.

FEBRUARY.—In addition to the plants already mentioned for January, and they may be expected more or less up to March and April, from vineries we may expect *Solanum capsicastrum*, for its red berries all the winter; *Magnolia fuscata*; *Lachenalias quadricolor*, *pustulata*; *Oxalis fulgida*, and *O. tricolor*; *Linum trigynum*; *Hovea Celsi*; *Monochaetum ensiferum*;

*Daphne Fortuni*; *Cyclamens Atkinsi* and *persicum*, in great variety; *Mignonette*; and towards the end of the month from the earlyinery, *Epiphyllum Russellianum*; *Cytisus Alceana*, *racemosa elegans*, and *racemosa superba*; *Acacia armata*, and *Drummondii*, and some of the forced plants. The stove may furnish *Franciscana confertiflora*, and *eximia*; *Gardenia Fortuni* and *florida*; *Jasminum gracile*; *Centradenia grandiflora*, and *rosea*; *Rogiera cordata*; *Eucharis amazonica*; *Pancratium speciosum*; *Imantophyllum miniatum*; *Pycnostachlys urticifolia*; *Amaryllis aulica*, vars. *crocata*, *Johnsoni pnceox*; *Echmen fulgens*, and *Stenogastera concinna*.

Cuttings of *Poinsettia* and *Euphorbia* should be inserted, and of *Luculia gratissima* in the stove, for early blooming. Start more *Achimenes* and *Gloxinias*, also *Gesneras* of sorts, especially *gloxiniiflora*, *splendens*, *zebrina splendens*, and *Donckelaari*; and *Caladiums* to be potted forthwith. Cuttings of all winter-blooming plants should be inserted if the stock is short, and also to obtain small plants. A few cuttings of *Coleus Verschaffelti* put in now will prove useful. Pot *Tuberose*s, and place in the earlyinery in a little bottom heat. *Amaryllis formosissima* with others of the *Amaryllids* now showing for bloom, will do admirably plunged in the bed of the earlyinery. Pot a few Ferns, they will come in useful through the summer; and some *Lycopods*, *Otaheite Orange*, *Azaleas*, *Rhododendrons*, *Weigela rosea*, *Deutzias*, *Dielytra spectabilis*, and more bulbs to be introduced. *Datura humilis* and *chlorantha* (young plants kept over the winter), to be potted, and encouraged. Sow *Celosia pyramidalis*, *Cockscomb*, and *Globe Amaranths*, also *Amaranthus bicolor* and *tricolor* towards the end of the month, or early in next.

MARKS.—From the earlyinery many of the plants placed there to force will be coming into bloom, and these will in themselves be amply sufficient for frequent changes of the plants in the rooms during this and next month. We may, in addition, calculate on *Tropaeolum tricolor*, *Jarratti*, and *brachyceras*, which are handsome on trellises, and so is *T. azureum*; also, *Lithospermum fruticosum*; *Acacias grandis*, *ericarpa*, and *juniperina*; and *Chorozeas*. *Kennedys*, too, bloom finely on trellises at this season, and we may expect some this month from cool houses. The stove will afford a few forced plants, and the other winter-flowering plants will come in or continue in bloom until this period, it being understood that the stove is not so much occupied with summer as with winter-blooming plants.

All plants coming from the rooms should be again placed in the structure they were taken from. If from the stove, they should be rested for about a month, and may then be cut in, and have the pots plunged in the earlyinery, which will set them going. *Camellias* and *Azaleas* done blooming to be placed in the earlyinery to make wood for next year's early blooming, which, as regards the first, will, in the current year, occur in October and onwards. The first lot of *Gloxinias*, *Achimenes*, and *Gesneras* will be forward, and be placed in their blooming-pots, more being introduced for succession. Pot variegated *Begonias* and the better kinds of hardy Ferns; they are charming for in-door decoration in summer. A few more plants for forcing may be introduced to fill up blanks in the earlyinery. Sow *Primulas* and *Cinerarias* for an early bloom. See that *Aphelandra cristata*, *Porteana*, *Leopoldi*, and other winter or autumn-blooming plants are cut in, and cuttings made of all winter-blooming plants if still delayed. Pot those previously struck, and grow them on; many of them will do well in the earlyinery. Pot more *Fuchsias*, and put in cuttings of the early plants for autumn blooming. *Impatiens Jerdonia* is a good stove plant for autumn work; plants now potted and grown in the stove will be found useful. Select a few of the better kinds of bedding plants, as the different variegated and *Zonale Geraniums*, and especially *Nosegays*; also *Verbenas*, *Petunias*, &c., potting and growing them on in the coolinery. They will be useful when the *Pelargoniums* are over. A few plants of *Pinks* and *Carnations*, potted now, will, though they come in little earlier than those in the open ground, be none the less sweet in vases in the house. *Epacris* to be cut and placed in a cold frame. Cuttings of *Heliotrope*, to furnish plants for winter and spring blooming, to be inserted forthwith; also of tree *Carnations*. Sow more *Cockscombs*, *Celosia pyramidalis*, the first *Balsams*, and *Thunbergia alata*, for training to sticks in the form of pyramids, or any other shape. They will do now in the earlyinery. Encourage plants of *Sericographis Ghiesbreghtiana* in a cool house. Let them grow freely until June; then stop the shoots, repot, and grow on until October; then place in the stove. They will

bloom in November. *Fuchsia serrulata* and its varieties *floribunda* and *alba* are valuable winter-blooming plants. Cuttings put in now, in a little heat, soon strike root; grow on until July, place out of doors, then take up in September, and place in the earlyinery, which will by that time be cool enough for anything. Sow *Mignonette* in pots, for autumn blooming, in a cold frame; it will require to be potted when the plants are large enough to handle, and grown on in a frame until June, to be then placed outside in an open, but not very sunny, place. Remove to the frame in September, keeping stopped and potted through the summer as the plants grow. *Rhodanthe Manglesii* and *Acroclinium roseum*, are nice Everlastings for pots; seed may now be sown in a little heat. *Cypripedium insigne* and *venustum* are of the best of winter-flowering plants; plants of them should be potted and encouraged in the stove orinery now at work. The old *Plajus grandiflorus* is a glorious plant for blooming in early spring; it should have sweet soil, plenty of drainage, and a place in the stove to make growth, with abundance of water and moisture. The very best of room-plants, *Richardia athiopica*, should be potted, and increased, if practicable, by dividing the roots. It does well in a coolinery. Cuttings of *Chrysanthemums* to be put in; they make nice plants for autumn. *Inga pulcherrima* to be cut-in, and grown in a frame; endeavour to have the shoots well ripened before or by autumn. It will require potting after it breaks. *Hoitzia coccinea* to be cut-in, and potted after the new growths are an inch long; it is a stove plant.—G. ABBEY.

(To be continued.)

NORTHWICH GOOSEBERRY SHOW.

THE following are the weights of the prize berries at the Show held at the Angel Inn, Northwich, Cheshire, on July 29th.

			dwt.	grs.

## GLEANINGS FROM ROCK AND FIELD TOWARDS ROME.—No. 3.

LEAVING Siena by railway for Ficulie, we passed through many miles of country so desert-like, so bleak and bare of vegetation, that it looked as if just emerging from a second deluge which had left but few of the inhabitants, and they with the marks of sin and horror still upon their brow. We rejoiced when the railway journey gave place to a comfortable carriage drawn by four horses and two white bullocks with large, gazelle-like eyes, and we were once more ascending a mountain's steep side, where we could revel in nature with the breath of Violets scenting the air around us. We saw few habitations, but here and there peasant women in scarlet hoods, distaff in hand, were carding what seemed to be flax, as they minded flocks of sheep and pigs, wandering amidst the flowery wilderness of Myrtle and white Ericas. On this mountain I saw, for the first time in Italy, the *Pteris aquilina*. I also found *Polystichum angulare* and *Asplenium trichomanes*. I looked in vain for some form or variety unknown to me; and yet I had plenty of time to look, for we were upwards of five hours driving the twenty-one miles that divided the Ficulie station from Orvieto, which appeared before us on its grand elevation of rock, like the huge battlements of some giant castle; now close to us, now far away, as we wound round and round the glorious hill. As we entered the town, daylight faded, and the dimly-lighted houses showed us parties of men drinking at long tables such as one sees in Dutch pictures.

The next day was market-day, and the streets were filled with parties of peasants, gaily dressed in various costumes, driving in mules laden with wood and other commodities. The peasant women wore many-coloured and richly-embroidered stays, with white or coloured chemisettes and sleeves; the petticoat was short, and of some striped material; some wore on their heads flat towels, folded square, and others red hoods; while the men were attired in velvet jackets, made very fancifully, knee-breeches, bright stockings, and steeple-crowned hats. The bright and varied streets were a fitting introduction to the wonderful cathedral, the façade of which is a mass of richly inlaid mosaics, and basso-reliefs in white marble or alabaster; these latter were in compartments, each relating some Bible story. The interior is rich with treasures, amongst them some beautiful frescoes of Fra Angelico's. All the pictures and frescoes were photographed, and the priests sell copies of them in the cathedral, before the very altars, where a short time before the mass was celebrated. It is a long time before a Protestant travelling in a Roman catholic country can understand what is considered sacred in their churches. Not the church itself, for it is desecrated in every way—not the altars, for no knee bends before an empty shrine. As far as I have been able to break through the outer crust of much seeming irreverence, and to look beneath the surface, I should say that respect is alone paid to the blessed Sacrament and to statues or, so-called, miraculous pictures.

We left Orvieto for Viterbo on the 14th of March, driving through a very cold hailstorm. On our way we found the *Anemone appennina* (the only wild specimen I have ever met with), *Scilla obtusifolia*, Violets of several shades of colour, *Pteris aquilina*, *Polypodium vulgare*, *Adiantum nigrum*, *Polystichum angulare*, *Asplenium trichomanes*, *Ceterach*, &c.

The drive had but little of beauty to recommend it, though here and there a lovely scene of lake and tree, mountain and sky, would call forth an exclamation of delight; but the pervading atmosphere was wretchedness. The cottages—as I write the word, the dear whitewashed cottages of England contrast themselves with the miserable huts I saw on this route—huts in which no chimney was visible, no outlet for the smoke of the scant fire, save the hole of the unglazed window, or the door, from which a herd of half-naked children rushed at the carriage wailing piteously. I was dividing some bread amongst a group of three of these beggars—one a little child of three years old—there was but bread enough for two, the little child saw this at a glance, and gave a cry of such wild terror and hunger, that it pierced my very heart. Is there any cry on earth like that of a little child for bread? Its intense pleadingness haunted me into Viterbo.

I shiver when I think of Viterbo, and of the scowling handsome faces of its people, that seemed to demand of me as I walked along, "Your money or your life." "Of twenty brigands taken in the last two years," said a friend to me, "seventeen were from Viterbo." I had read of brigands all my life, but now I was, as it were, face to face with them, for

the road from Viterbo to Rome is a part of their most convenient hunting-ground, its numerous windings and abrupt turnings giving ample opportunity for concealment and escape. Whether we should meet the brigands or whether we should escape them; who should be the spokesman of the occasion; who would give up jewels, and who would hide them, were the questions to be decided while pressing the wild-flower specimens or encouraging wet logs of wood to give a friendly blaze.

By seven o'clock on March 15th we left Viterbo by a dreary ascent up steep hills covered with snow, protected at intervals by gens d'armes, who looked so lonely and miserably in their wretched huts that I fancied a brigand's friendly greeting would have been better than none. We lunched at Monterose. The inn is worth a visit on its own account. From a courtyard, filled with horses and carriages, you ascend a broad flight of dirty stone steps, and putting aside a dingy cotton curtain at the top, you find yourself in a large chamber, with a wide open fireplace at the end, and several dining-tables spread around. Congregated in this chamber is a miscellaneous company of wayfarers devouring as best they can tough cocks and hens, accompanied to the death by a band of fleas that hop about without ceremony or constraint. Different parties of travellers keep putting aside the curtain and entering on the scene, like players on a stage, save that the acting is to the very life. There is the Englishman, silent and reserved, melting, if ever he does melt, under a smile of protest, as though he should say, "Take notice, I give way under the exigencies of travel;" there is the American loudly "guessing" and "calculating" as only Americans can; there is— but no, I will not draw on my imagination, for I saw only English and Americans at Monterose. "I guess," said one, *en route* from Rome, "you'll find the Eternal City about as unpleasant for climate as any place in the world; fix it how you will, you must always wear two coats, and then I calculate you'll have bronchitis if you walk in the shade, and fever if you walk in the sun." "Where then," I asked, "is the 'unchanging blue' of the Roman sky?" "Well," was the reply, "I guess you'll about have left that at Torquay."

Not being able to eat the chickens, and wishing to escape being eaten myself, I set off to walk in advance of the carriage. The keen piercing wind came raving to meet me: the peasants, clothed in sheep skins and goat skins, looked out at me from miserable huts, roofed only with mud and leaves; there were very few wild flowers, only here and there a straggling Rose, doing its cheerful best to adorn the rough masonry of the bridges, which crossed the swamp-like road. On every side there appeared evidences of poverty, degradation, and misery. Hanging in festoons about one old bridge I found what I believed—from its long tendril-like branches of dark shining leaves, and clusters of pointed buds—to be the Banksian Rose: this seemed the more likely, as I afterwards found the Banksian growing all but wild in the hedges about Florence and Rome. Entering Rome by this route, I can imagine nothing more desolate: there were few crosses, and very few churches. "Verily," said I, "the shoemaker's children are the worst shod."

Entering Rome! Can any one enter Rome as they enter any other place on earth? What is it that gives to every traveller Romewards that intensity of anticipation that keeps the eye straining on the far distance for the first speck on the horizon that conveys the certainty of Rome? The air around one seems to vibrate to the echo of the old heroic deeds that make the schoolboy's veins tingle with enthusiasm; the wind that blows upon one's brow seems yet wailing with the last cry of agony wrung from the martyr's heart; your whole intelligence is wrought to the highest point as you wait in almost breathless silence for the first cry of—Rome! In a few minutes a cry came, but it was not Rome: only a poor man lying by the wayside, dead, in a pool of blood. Whether he had been gored to death by one of the wild bullocks that abound in the Campagna, or whether he had been murdered, we never discovered: the prelude to our entrance to Rome, as it has been to that of thousands, was blood. A few minutes more and another cry came, but it was not Rome, it was—St. Peter's!

Yes, there was St. Peter's! and forthwith the old grand thoughts of ancient Rome melted away, and in their place came the Triple Crown. How would it look near at hand? Were the jewels that adorned it diamonds, or only glittering paste? There, however, is St. Peter's, square, and squat, and round about the dome; there is the Vatican, looking, with its many rows of square windows, like Millbank Penitentiary; there is the Tiber, trailing its thick clammy waters along, not yellow nor yet brown, but very uncomfortable-looking in their

greyish brownish garb; there is the Porta del Popolo, through which a stream of fair-faced men and women are passing from the daily evening service of the English Church, held *outside* the walls; and here is—Rome.—FELIX-FEMINA.

### CLOTH OF GOLD GERANIUM—SPARKLER CALCEOLARIA.

"R. F." has told us how Cloth of Gold Geranium stands with him, and solicits information as to the success or the contrary of others. I have two circular beds of this variety edged with green foliage; the plants were all young and healthy when planted out, now, all that is left of them is about half a dozen leaves on each about the size of a shilling, and I have during the last week seen several almost as badly off as ourselves. I may add that the beds are fully exposed to sunshine, but sheltered from all wind except the south-west. Cloth of Gold will do very well in favoured situations in a soil composed of fine mellow loam and peat. Such, at least, is my experience.

I would like to say a word about Calceolaria Sparkler. It has the best habit of any bedding Calceolaria I have ever seen. Neither sun, wind, nor rain, has any effect upon it. Some small plants in thumb-pots were planted out, and are doing remarkably well. They are thoroughly shrubby; the colour is scarlet brown, with bright yellow caps. As so many of the bedding Calceolarias now grown have so much of the herbaceous strain in their constitution, I should like to hear how Sparkler is liked, and to be informed of any other variety of the same habit.

In my letter on softening hard water, page 71, the word "Pears" in the third and fourth line from the bottom should read "plants."—F. FLITTOX.

### VISITS TO GARDENS PUBLIC AND PRIVATE.

M. LOUIS VAN HOUTTE'S, GHENT,\* BELGIUM.

THE travellers who enter Ghent for the first time are no doubt moved, as in all such cases, by very various feelings. To one man it is the city of commerce, of linens and of calicoes, stuffs and cloths; and its tall chimnies and large factories are indications that his journey will not be in vain. To another man it is the city dear to him in its history, its achievements, and its sufferings—the city of Jacques and Philip Van Artevelde; the scene of Alba's brutalities, and of Egmont and Horn's sorrows and death; the city of turbulent burghers and sturdy citizens, whose ideas of liberty were too often that of some of our modern friends—full liberty and thought, provided you agree with them. They rejoice to see the towers their heroes gazed on, and the places where they met and harangued their fellow citizens, places from which Henry Taylor drew his inspiration in his noble poem of "Philip Van Artevelde." To the horticulturist it is the city of nurserymen *par excellence*; the city of Camellias and Azaleas; the home of Van Houtte, and Verschaffelt, and Van Geert, and the many others who have made a name for themselves throughout Europe and the world at large. Let me say that when I entered it it was with mingled feelings. In a former run through Belgium thirty years ago I had been obliged to pass Ghent by. There were no railways then, and I was hurrying home; but I had still enough of feeling to be moved by the story of Ghent, and its eventful histories and noble-hearted men; and though I had no calicoes to buy and cotton to sell, yet I did hope to see as a horticulturist much that might gratify my tastes and satisfy my curiosity; and it is a little of what I then saw that I now wish to lay before the readers of THE JOURNAL OF HORTICULTURE. I labour under one great disadvantage, for not long ago one of its Editors recorded his impressions of the same place; but as we view oftentimes in the same pursuit things from a different stand-point, I may perhaps notice some new point, or the same in a different manner, so as to give some fresh notions.

I found M. Van Houtte crippled in body by an attack of gout, but active enough in mind, and, as far as a brief interview would enable me to form an opinion, fully bearing out

\* I have used the names by which these places are known in England in preference to their true ones, although we lose much by substituting our anglicised terms. How few remember that "Old John of Gaunt, time-honour'd Lancaster" was so called because he came from *Gand*, which we corrupted into Gaunt, and then to Ghent.

the character given him by "G." His establishment is a vast one; but it must be borne in mind that it is not in a pecuniary point of view resting on his shoulders. The royal arms over the gateway are emblematic, not, as with us, that the establishment serves royalty, but that royalty serves it. In what way I do not exactly know; but it is, I was informed, considered as a Government establishment, and not at all corresponding to those great establishments in our own land which rest solely on the resources of the person or family whose name they bear. In my tour round the garden I could not but be struck with the sandy and apparently barren character of the soil. One would hardly imagine how plants could grow in it; yet by careful management not only bulbs, but Conifers, Roses, and the like seemed to be doing well.

The greenhouses are very numerous, and, generally speaking, low-pitched and very dark, the importance of keeping off the glaring sun in summer leading to the necessity of great shading. The quantity of glass is enormous, and the stock propagated and contained in them very large. Thus, there were at least 40,000 Camellias of various sizes, and of all the valuable kinds, as well as the older sorts. 8000 Imbricata and 7000 Fimbriata will show on which kinds the run is mainly made for decorative purposes; but there were quantities of such fine kinds as Lavinia Maggi, Anguste Desfosses, and Duchesse de Berri, and I must say in a very excellent state of cleanliness and health, affording a remarkable contrast to the French nurseries in this respect. The manner in which the various markets were catered for is somewhat curious. Here were large quantities of Pandanus, Dracenas, Cycas, and Palms of various kinds: most of these were for the Paris market, where, as every one knows, so much is done in the way of decorating houses, hotels, &c., with living plants—a custom which one would be glad to see adopted more in London. How much the dull character of the entrances even of such houses as the Langham and Grosvenor Hotels would be taken away if the use of these plants were more general. I was surprised to see at the "Mirabeau" the quantity that was purchased from day to day, and I cannot but think the same expenditure might be profitably made with us. To one house in Paris alone 1200 Pandanus had been sent during the last year. The Cycads found their way many of them to Saxony, where two, three, four, five, and sometimes ten and fifteen francs are given for single leaves of Cycas revoluta for carrying in funeral processions, where it seems to be the custom so to use them, and to strew the churches with branches of the common Yew. The *chef* informed me that these ornamental plants were more looked for in England now than formerly. Then, again, Gloxinias, Tydas, and kindred plants were grown in very large quantities, upwards of 20,000 Gloxinias alone being grown; and Amaryllids in large numbers, upwards of 60,000 bulbs in various stages of growth being in one quarter of the ground. This bulb ought surely to be more generally grown than it is, its showy character and easy culture fully entitling it to a place, and there are now many very beautiful varieties. Among the tree Ferns were some large specimens; a magnificent one of Alsophila glauca, sunk in the floor of the house, had fronds that extended 20 feet, and was said to be the largest specimen in Europe. There were also fine specimens of Cibotium princeps, the Cyatheas, and other members of this very fashionable family. It is well known that M. Van Houtte deals largely in novelties, comprising plants of all kinds, from the ordinary softwooded plants to the glorious Palms of the tropics. Amongst new Azaleas two were very highly spoken of—Charles Van Echlaute and President Victor Van den Hecke. The former was described to be of a very brilliant colour and good shape; the latter, white striped with carnation; but as they were not in bloom I could not decide as to their superiority to those in the same class already sent out both from Belgium and England.

Most horticulturists know that Van Houtte is the publisher and editor of "Flor des Serres," and the visitor may see the workmen engaged on it in the establishment, where it is all superintended by the watchful eye and keen judgment of M. Van Houtte himself. At another part of the ground is a steam-engine, which cuts laths, pumps water, grinds paint, and manufactures flour; while again you meet with gas-works for supplying all the gas used in the establishment. That such an establishment requires no ordinary mind to direct it may well be imagined, and all who come in contact with M. Van Houtte at once recognise him as such; and while he is, no doubt, seconded by able superintendents in the various departments, much of the fame and success of the establishment is to be attributed to him. There was not, certainly, such

a plethora of novelties as I met with at M. Linden's at Brussels, of which more hereafter, but in all the details of the nursery there was a great deal to entertain and instruct.—D., *Deal.*

MINIATURE ORCHARD-HOUSE.

(Continued from page 93.)

As regards the earliness of crops grown under my glass ridges as compared with those produced in the open air, I may mention that Prince Imperial Strawberries ripened under my ridges seventeen days before their neighbours of the same sort on the same plot without protection. In an ordinary season we should have gained fully twenty-one days. It was no little treat to have Strawberries to breakfast when Covent Garden quotations were 1s. per oz. In Peas we gained fully a fortnight, though not sown till late in March. In Potatoes, planted at the same time as the Peas, we gained about a fortnight. In Turnips, April sown, a fortnight; and in Radishes, likewise April sown, ten days. As the glasses were disused for Strawberries, they were re-erected over Cucumbers, Tomatoes, Pears, Apples, and young Vines which have not yet fruited. Louise Bonne and Jargonelle Pears are a long way a-head of their like in the open ground. Tomatoes, too, which rarely ripen with us here, I am trying to succeed with.

I will now add a very short supplement to my last letter. Take three triangles of glass of any convenient size, as in the accompanying figure, and which I shall call a, b, and c. Drive in an upright wire; lay a against it; complete a triangular pyramid with b and c, and to c, the last fixed of the three triangles, attach a ridge wire. No ridge wire is necessary

in sheltered gardens.

The cost of this substitute for a hand-glass, represented beneath, is very slight—from 2d. per one-foot slope, up to 8d. for a very large size, fit to grow a Cauliflower under. For cottage gardens, for Cauliflowers, half-hardy annuals, Vegetable Marrows, Cucumbers, protecting Fuchsias from damp in winter in the open ground, and fifty other things it may do. It has answered well with me for some of them.

Putting one up is only the work of thirty seconds.

Reverting to my glass ridges I omitted to mention, that the precaution should be taken to have the ridge wires bent before sending them to be galvanised, and to take care that the galvaniser does not return them too brittle. Bending the wires when galvanised peels the zinc off, and when too brittle the wire snaps at the bend.

I find a little annoyance in wet weather from birds entering to dust themselves with the dry earth; also, that some of my largest sheets of glass are troublesome from being not quite flat, and so leaving a slight gap in the top of the ridge, which will not do for frosty weather. Gidney's Prussian hoe is most effective in the removal of weeds from under the angle of the ridge, and is, indeed, the only tool I know that can reach them without having to remove the glass.

30 inches by 24 is not too large a size for the sheets of glass, and a little practice makes them very easily managed. With 30 as the slope of the roof, ventilation for Pears, at least, is ample when every fourth sheet on both sides is reversed, so that 24 inches of the upper part of the slope are covered with glass, and the remaining six left exposed for ventilation. Suppose the following to be a perspective view of a ridge:—

For short ridges no ventilation seems necessary except open ends, but this will vary according to the shelter or exposure of the ground.

With every care plates of glass will now and then be broken, and this more particularly in transport from

the dealer or manufacturer to the garden. With large sheets this is a serious drawback, but not so much so as at first sight it would appear. In by far the majority of cases the sheet is broken only into two parts, and usually right across. Now, such broken sheets may be used just as they are without any trimming with the diamond. Supposing a sheet to be broken as under, all that is necessary is to use the two parts for that side of the glass ridge where the glasses lean on the edges of the others, and not against the upright wires, making one half overlap the other, as in the dotted line.

Sometimes an additional ridge wire is required, sometimes not.

For a long time I have not broken a single sheet, except when, from a constitutional absence of mind, I forget that it is glass I am working with, and such an occurrence as breaking a sheet of 20 by 12, or less, I cannot recollect since discarding 16-oz. for 21-oz. glass. With 16-oz. glass the ridge wires require to be very weak in their tension. With glass of 30 by 24 inches, I am troubled with some sheets being not quite flat.

When uprights, more particularly if not galvanised, remain some months in the ground, they become so firmly embedded as to occasion considerable difficulty in their removal; but if caused to revolve on their axis by the use of a monkey-wrench, or a pair of strong pincers, they may be withdrawn from the soil by the hand with the slightest effort.

I have found it a saving of labour to have a store both for wires and glass in the portion of the garden where the glass is used. This need not be covered. Suppose you want to store glass of 24 by 20 inches after taking down a house till wanted for another, take a three-quarter-inch board 25 inches by 12 or so, drill holes in this as under, at 2 inches from each other.

Lay the board flat on the soil, and into each hole drive one of your upright wires. Slip your sheets edgewise between the uprights and no wind will harm them.

When wanted for a new house the glass is benefited by a coarse brush, such as is used for blacking, being passed over both sides to remove the soil, which in clay lands adheres in lumps where the edges have rested on the ground. This should be done before storing. The rain outside and internal dew will remove what remains, though in dry dusty weather a hearth-brush passed over the outside of the ridges is good.

I cut all my broken bits of glass into the longest sheet I can make, measuring 6, 9, 12, or 15 inches one way. This fits them ready for use in houses with that breadth of ridge. 15 inches is quite large enough for Cucumbers, though 12 inches may do with both ends open. The 9 and 6 inches are useful chiefly in spring for protecting Peas, Radishes, Turnips, &c., and annuals or cuttings. The six-inch ridge is a very cheap protection from birds for newly-sown Peas, or Cabbage seed.

As regards gables, you may save cutting up large sheets by having the triangle of two pieces, and making one overlap the other. The upper one is kept in its place by the pressure

of the under one, and may be removed after danger from frost is over.

Where the glass is stored the wire may, if galvanised, be left without shelter thus, A A being the surface of the ground—

The upright wires rest at each end in the hollow formed by the crossing of two uprights driven into the ground, as represented beneath. The ridge wires may be hung on the same apparatus, leaving the smaller end hanging down.

The smaller pieces of glass I cut into small squares of 3 or 4 inches. Of their use, however, I must speak some other day.

I am still in the dark as to the proper angle for the ridge, consistent with room for the plants inside and the covering, and therefore warming, of a good breadth of soil; also the right amount of ventilation, and where and of what height to make the ventilating-holes. All these will vary with the plants grown and locality.—WILLIAM MCGOWAN.

### THE KITCHEN GARDEN.

APRIL.

By this time the principal crops will be in, the alleys neatly marked out, the various beds properly labelled, and the walks and borders cleaned, making the kitchen garden very interesting indeed. At this time we must keep a sharp look-out to prevent the ravages of slugs on the various crops now appearing above ground. The means I generally adopt is to lay Cabbage leaves in various parts of the garden, and by examining them every morning large numbers may be caught and killed; and where convenient I strew soot on the ground, as on each side of the rows of Peas, and on the seed-beds, &c. Much has been lately written about the ravages of small birds on the young plants of Beet; now we have all kinds of birds here in abundance, and I have never, to my knowledge, lost a single plant of Beet through them, though I never think of protecting it from them in any way.

Onions and other small seeds will now be showing fairly through, and should be hoed at once, using a small four-inch hoe; and as I always sow in drills a man may soon run over a great deal of ground. In fact, from this time, and during the next three or four months, I never look whether there are weeds or not, but send a man with two or three different-sized draw-hoes once every week to go over all the ground, as in a small-sized garden you cannot spare any of it to grow weeds in. By strictly adhering to this system I seldom have any to chop up, and I think one can hoe ground with no weeds in half the time that it would take to hoe it once where these exist.

Some more Peas must also be sown, earthing-up and sticking the more advanced crops. I generally sow British Queen and Bedman's Imperial this month. The first lot of Brussels Sprouts and the second lot of Celery will by this time require pricking out on a well-prepared bed, giving them a little protection at night from frost, &c. A good bed of Lettuce should be planted on the south border, sowing more on the top of one

of the Asparagus-beds. Now is a good time to plant Potatoes between the rows of Cabbage; and towards the end of the month I sow my first batch of dwarf Beans, sowing Turnip Radishes on the top of them, netting it all over to keep the birds from the seed. Red Cabbage should now be planted out in well-manned ground, and what manure is wanted can be taken off the forced Rhubarb and Sea-kale, whilst any not required for digging-in can be thrown into a heap for the Vegetable Marrows, which should be sown on it as soon as possible, and they will do much better than plants raised under glass. Sow Winter Greens, Leeks, Celery, &c., thinly on the ground that is ultimately intended for the first batch of Savoys or Coleworts. Now is a good time for working Dwarf Kidney Beans in pots, giving them plenty of manure water to insure fine produce. Cauliflowers will be coming in for use; they, too, should be watered with manure water, mulching them if the weather is at all dry. I generally cut Asparagus out-doors before this month is out, which with Cabbage, Brussels Sprouts, Spinach, and Sea-kale, with perchance some Broccoli (not forgetting the Purple Sprouting Broccoli, which, if kept close cut will do wonders, and is invaluable for a winter and spring vegetable), form the main supply at this time. For salads, I have Cucumbers, Radishes, Lettuce, Mustard and Cress, &c. I always have the best Lettuce at this time of year from the plants that have been wintered under hand-lights. I think the sort I grow is called the Stansted Park Winter White Lettuce, than which it is impossible to have a better. The first lot of forced Sea-kale roots should receive attention at once as to cleaning, manuring, &c.—BURXTWOOD, P. D.

(To be continued.)

### VERBENA PEGS.

THE best and cheapest Verbena pegs are cut from the Fern. I send you a sample of one which I have just taken from one of my Verbena-beds. They are cut for me by children at 1d. per 100. Where the common Fern can be procured, nothing answers better.

I think that I have two beds of *Coleus Verschaffelti*, bordered with *Centanrea candidissima*, nearly, if not quite, equal to those of Mr. Gibson.—W. G. H.

[These are formed by cutting the fronds at the divarication of the branches, and are at once easily procured, easily made, and perfectly efficient.—Eds.]

### LILIUM AURATUM.

THE capabilities of this glorious plant are not yet known. Independently of the varieties in colour which have already been discovered amongst the imported bulbs, the free-flowering qualities of some of them are very remarkable. I saw the other

day at Mr. Veitch's a bulb with twenty-nine flower-buds half-grown upon it; it had two stems, one containing fourteen and the other fifteen flowers. But let not every one imagine that their auratum will be like this; I am persuaded, and in this Mr. Dominy agreed with me, that some varieties are much more free-flowering than others. I had myself this year two bulbs of precisely similar dimensions, they were both treated in the same way, and yet one produced five flowers, the other only one. This has been noticed long since in *Lilium lancifolium*, and I have no doubt it holds good with auratum. Still it is a glorious thing to imagine what this king of Lilies is capable of; and as it is now within every one's reach, we can welcome it as a noble addition to all our gardens, as easy of cultivation as it is beautiful in appearance.—D., Deal.

[The plant above referred to will be exhibited at the meeting of the Floral Committee of the Royal Horticultural Society this day. This, the finest specimen yet seen, was, we believe

grown by Mr. Constantine, gardener to C. Mills, Esq., of Hillingdon Court, Uxbridge, and certainly reflects great credit on the cultivator. It is, we believe, one of the original bulbs received from Japan by Mr. Veitch, and is most kindly lent to him for exhibition by Mr. Mills.]

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

In sowing crops at this season, which do not come into perfection till spring, and which are expected to grow more or less through the winter, the ground should not only be well manured but trenched to a considerable depth, that the rains and snows of winter may pass quickly beyond the reach of their roots, and that comparative dryness and warmth may be thus maintained around the roots of growing plants. Those who have observed how quickly snow thaws on well-drained land owing to its higher temperature, will at once understand how important the above conditions are to crops which are expected to make way in the winter. *Broccoli*, where there has been any planted between Peas, the latter should be removed as soon as they are done with. The ground should then be dug and the intermediate spaces filled up. *Cauliflowers*, plant out more in warm situations, and hoe through former plantings. *Cherrie*, make a sowing for autumn use. *Cucumbers*, those intended for house culture through the winter, must be shifted into larger pots as those in which they are become filled with roots. A few more seeds may be sown for the same purpose. *Endive*, continue to transplant as circumstances require. Let elevated beds of 4 feet in width, and having a bold curvature, be provided in an open and dry situation. Such beds should be a foot or more above the ground level, and must be made very rich. These beds may be hooped over in the end of October, and may be readily covered with mats when frost arrives. *Lettuce*, keep a succession sown and planted. They will require a good supply of water to make them crisp and fresh. *Spinach*, the Prickly or Flanders may be sown from the 8th to the 15th of the month according to the situation. The beds to be prepared as advised for Endive.

### FRUIT GARDEN.

It may be advisable to go over such trees as are over-luxuriant and stop about half the shoots, beginning, of course, with the strongest, for a general stopping at this time would probably be of little further service than to induce the production of a mass of useless spray, whereas stopping the stronger shoots or those which incline to grossness, will divert the sap into the weaker ones which will be strengthened, while the buds on the shoots that have been stopped will become full and plump without starting into growth. Should it be found, after stopping, that the roots incline to start into growth, it will be advisable as soon as the fruit is gathered to open a trench at a moderate distance from the stem of the tree, cutting the stronger roots. This will be of the greatest service in checking growth, and will, probably, do more towards securing ripe wood than anything else that could be adopted. Let the Strawberry plantations intended to, and for next season be trimmed as soon as convenient, cutting off and clearing away the runners so as to afford the leaves plenty of room.

### FLOWER GARDEN.

Go over the flower-beds frequently, and remedy any defects that may be perceptible without loss of time, for the hedging-out plants are enjoyed but for a comparatively short season, and now that they are in beauty every means should be used to render them as effective as possible by maintaining the most perfect order and neatness. The active growth of plants in the flower garden, encouraged by the prevailing humidity of the weather, will involve considerable labour, as it will be necessary to go over the beds frequently, pegging down where necessary, and cutting back such shoots as may incline to in-croach upon the edging of the beds. Dahlias are growing rapidly, and will require to be gone over frequently to keep the side branches securely tied in, for when left untied they are apt to be broken by a thunder storm. Hollyhocks must also be securely tied to their stakes. Continue to remove dead flowers from Roses, and give plenty of manure water to the autumn-blooming varieties. Plant out rooted cuttings of Pansies, &c., in nursery-beds in a shady situation, keeping them well watered, if the weather prove dry, until they become established. Finish hudding Roses at once if not already done; also let border Carnations and Picotees be layered without loss of time.

### GREENHOUSE AND CONSERVATORY.

It will be much to the advantage of the inmates of plant-houses to reduce the shading after this time considerably, to enable the plants to ripen their summer's growth, allowing more air to keep down the temperature, and to check any tendency to a second growth which may show itself, and which can only take place at the expense of next season's bloom. Remove *Achimenes*, *Gloxinias*, *Tuberoses*, and plants of the same habit from the conservatory when on the decline, and replenish to keep up the display. *Passifloras*, and, in fact, the greater part of conservatory climbers will be growing fast and will require frequent training. Thin out the weak and over-strong shoots, and reserve only sufficient to produce the desired effect; the blooms will be considerably finer, and the plants themselves more capable of producing well-matured wood, when these little attentions are performed regularly. *Epacris*, winter-flowering *Heaths*, and other plants requiring to have their wood ripened early may now be placed in a sunny exposure; as the wood is already formed nothing remains but to ripen it well, and although water equal to the demands of the plants must be given, a dry air and warm atmosphere are essential to the perfect ripening of the wood and consequent formation of bloom-buds. The different varieties of *Epiphyllum* (if the growth is not sufficiently advanced), should have the same treatment. Give a shift to Chinese *Primulas*, *Cinerarias*, and *Chrysanthemums*. If not done previously, *Salvias* and other autumn-flowering plants should be placed in their blooming-pots. Should the weather prove unfit for out-door work, take the opportunity to effect any changes in the arrangement of the plants. Cleansing the conservatory and potting may also be carried on. It is injudicious to defer this last operation, when at all necessary, until late in the autumn; the sooner new growth is encouraged the better chance there will be of having it matured. Plants arranged out of doors must be frequently examined and carefully secured against all chance of injury from ungenial weather. All kinds of soil used in potting and shifting should now be laid in without delay, except in cases where it is very wet and unfit for storing. Store them up neatly in narrow ridges so as to be safe from wet, and yet exposed as much as possible to the action of the air, and as success in plant-growing very much depends upon having suitable soil for potting, no trouble or expense that may be necessary to procure this should be spared where well-grown specimens are expected.

### STOVE.

Such of the inmates here as are intended for the decoration of the conservatory in autumn and early winter should be carefully looked over, shifting those likely to want more pot room without unnecessary loss of time, so as to have the pots well filled with roots before the flowering season; also, keep the shoots tied out rather thinly, and expose the plants to as much sunshine as they will bear without scorching their foliage, in order to promote stocky growth. Give clear liquid manure to young growing specimens, and repot any intended to have another shift this season, so as to have the pots well filled with roots before winter. Various stove climbers, as *Combretums*, *Quisqualis*, *Allamandas*, &c., will bloom for a considerable portion of the summer if the shoots on which the flowers are borne are slightly cut-in when the blooms decay, as anything which prolongs the period of beauty with these favourites is valuable. The growing season is far advanced, therefore encourage any backward *Orchids* with plenty of heat and moisture while this can be safely done. See that plants growing on blocks and in baskets are properly supplied with moisture at the roots.

### PITS AND FRAMES.

Young stock in cold pits intended to flower next season should be exposed as much as possible in order to ripen the wood. Some of the inmates here will want occasional shading with, of course, a free circulation of air. We need scarcely urge the importance of most regular attention as to watering. —W. KEANE.

## DOINGS OF THE LAST WEEK.

We have had evidence enough of 'late years, that a man who holds the position of a servant merely, should not be too free in giving utterance to his opinions, whatever these may be; for if at all of a nature to excite general interest, he is sure to be inundated with a number of letters, which sitting up into the short hours of a morning would not enable him to answer, even if his conscience would enable him to do so; and we say

this advisedly, because the conscientious man would not perform any labour, physically or mentally, that would interfere with the regular performance of his duty to those to whom he is ostensibly a servant. It is common to meet with some who make short work of such matters. They make it up to their own satisfaction that they are underpaid for their services, as most gardeners are, and they consider themselves justified in using a part of their working time for other purposes. Now, all such conclusions are in our opinion just so much treading on very dangerous ground. A servant is hardly safe in engaging in any such work without the knowledge of his employer, and if satisfied (and that often is easily done), that he is much underpaid for his services, it would be much more honourable to seek remunerative employment elsewhere, and to dissolve the connection in an honourable manner, than to keep grumbling at the circumstances of our lot, or endeavouring by other employment to add to an otherwise scanty income, by any modes except those which are patent and open to every inspection.

Almost every gardener that we have known, who has done anything for the gardening and general press, is a man distinguished for his attention to business, and who makes his writing hours a substitute for what many others spend in other recreations and amusements.

Hence, no doubt, the propriety of the law laid down by our Editors, that no one is to write to their coadjutors—a law, however, which a good many think may properly be broken in their own individual ease, and that, too, as our old friend Mr. Beaton used to complain to us, without even sending an envelope or a postage stamp!—a matter of no moment if such letters were to be numbered by units, but no trifle when they soon amount to scores and hundreds; and yet when your proverbial good nature and courtesy are appealed to, what can you do at times but write a few lines and disobey so far the excellent general rule laid down by the Editors, who knew human nature well before they saw the necessity of requiring all inquiries to be sent directly to them?

The writers of inquiries of a week or two past have mostly kindly wished that we would allude to the matters in this part of the Journal, which, they say, they always read, but which we heartily wish were more worthy of their perusal than ever it has appeared to us to be. These have chiefly reference to the following points:—

1st, *Patents.*—"Do they not retard, rather than advance, useful practice?" Well, on the whole, we think they do. We do not think that, in general, they do good to anybody except the Patent Office. Forgive the use of the authoritative editorial *we*, instead of the insignificant *I*, but we would give all the authority we could to our conviction that, in general, the public have come to have something like a horror of those inventions, discoveries, and improvements that are protected by patent. Did we discover something grand ourselves we would be disposed to throw it open to the public, and to trust to the general run of trade to remunerate us for the discovery. At the same time it is perfectly just and honourable, that the man who has spent much money in perfecting a system worthy of a patent should have the power of deciding as to the best means of rewarding himself for the outlay in money, and thought, and consideration. If, then, as a general rule, we would not recommend people to trouble themselves with patents, we have no right, and no desire, to find fault with those who thus protect themselves. In some cases it is the only plan by which the inventor can receive an adequate remuneration for his time, skill, and many experiments. We would wish it, however, to be clearly understood that, so far as we have the opportunity of noticing, the word "patent" has lost its charm—nay, more—that from the frequency of its use many people come to distrust what is recommended to them by such a high-sounding title. The inventor must be considered the best judge as to how he is to protect his own interests.

2nd, "Could we not use the same non-conducting materials, over and under the glass, as Mr. Beard uses in his iron houses, without infringing his patent?" We do not know, as already instanced, the particulars of the patent; but our belief at present is that you could not do so. If this constitutes a chief part of Mr. Beard's patent it might suit his purpose to sell the use of it, as, even on the score of glazing alone, many of those who build cheap wood orchard-houses might see the advantage of using the elastic substance under and above the glass instead of putty. That, however, is a matter between the builder and the patentee. We know no more than was stated last week.

3rd, "Much obliged for what you say of Mr. Beard's houses;

but it has annoyed me too. I thought I could manage a wooden house this year on the orchard-house or fixed-roof principle, and I cannot afford more. A friend of mine is putting up one with glass at from 1½d. to 1¼d. per foot"—more is the pity—2d. or 3d. would be cheaper in the end—"but then my next neighbour will have none of these paltry orchard-houses. If he has one at all, he will have one of Beard's, if it cost double or treble as much. What do you think will be the difference of the first expense?"

Here is a dilemma. Now, taking lean-to houses in both cases, we believe we could put up a wood-and-glass-house for about one-fourth of those metallic-houses of Mr. Beard's; and if we were short of cash, and wished to have all the enjoyment we could for some thirty years, with an annual outlay for repairs, we would do so; but if we wished our houses to be always nice, lasting, &c., and escape the horrors of chipping and painting, then decidedly we would join issue with your friend, and have houses of a more permanent character. We have not lost our senses in the matter at all. We have as much respect to-day for Mr. Rivers, for making glass houses accessible to the many, as we have for Mr. Beard in making these houses lasting, and without the common annual outlay which such houses generally involve. We would wish each system to stand on its own particular merits.

3rd, and lastly at present. "What an idea, the having a glass-covered flower garden! What and who could live in it with the heat in a bright day? Who could make a roof to shut close when you pleased, and to open vertically when you pleased, to let rain and dews in at pleasure?" After the Crystal Palace and the huge conservatories of Chatsworth, Kew, Enville, and the low ridge-and-furrow-roofed one at Trentham, there can be little doubt of the feasibility of such an achievement. By pivot-hanging and leverage power, and other modes which our great builders know so well how to use, they would tell you that the only difficulty in the matter would be to secure to them the order. The building would soon appear like a fairy scene. Only a short time ago we saw a small dome-roofed glass house, where the dome was thrown open at pleasure. A clever gardener said the ventilation was wrong, just because the rains would come in; but there is no reason why they should not be admitted or shut out at pleasure. Where there was abundance of water there would be no necessity for letting rains in at all. We alluded to it as being worthy of consideration in dry places, and as a saving of labour in watering, but the feasibility does not depend at all on the letting the rains and dews in, as all the water that falls on the glass can be secured in tanks to be used again by pail, engine, or hydropult. As to the heat, who has not felt a relief in moving from the terraces of the Crystal Palace in a hot day, into the Palace itself? With plenty of ventilation, and the help of climbers, and by-and-by of coloured glass, that will let light through and keep back part of the heating-rays, the atmosphere will be every way more mild and enjoyable under glass than in the open air.

The using of coloured glass in plant-houses is, as yet, only beginning to attract attention. What a charm it lends to the fernery of Mr. Bewley, near Dublin! How striking the azure-blue tint of the dome of the conservatory at Woodstock, in Ireland! Would that Mr. McDonald and others who have studied and experimented on the subject, would give us the results of their experiments. It is amazing that coloured glass has not become more one of the luxuries of the age. But, with or without such coloured glass, there need be no question as to the coolness that can be obtained under glass in summer, any more than of the warmth that can be secured in winter. The time will come when those possessing wealth will see the propriety of having an Italy, a Madeira, &c., at their own residences, instead of taking long voyages in seeking after the great boon of health. What a help to medical men would such covered gardens be if placed in connection even with hospitals, where those afflicted with the worst diseases are obliged to congregate!

Without, however, entering into such weighty reasons, we would advocate such glass-covered gardens for giving greater variety to a demesne; affording more space to hardy plants that, once planted, would pretty well look after themselves, and be growing in interest and beauty with only the slightest minimum of our help and interference; and lessening the great anxiety the gardener must now often feel about the weather. For instance: for a week or so, up to the 31st of July, our flower garden was very fair, and of a number of intending visitors we were anxious they would come then, but scarcely any made

their appearance. Since the 31st we have had heavy, continuous, drenching rains, and almost every day; and scarcely a day has passed without visitors coming to inspect the drenched beds and borders, and trusting their feet, and often with thinned-soled boots, on the saturated lawns. It would be the height of rudeness to say what, however, most gardeners would think in such circumstances, and that would be that they would have been as pleased that the visitors had stayed at home until the weather changed. Extra hours and extra care may have been exercised in anticipation of some particular company, and then some twenty or forty hours' rain and wind give all the flowers that would have been bright a woe-begone miserable appearance.

KITCHEN GARDEN.

Kept on much the same as in the previous week. Taking up Potatoes that were ripe, planting out Broccoli and other greens, staking Peas, cleaning Celery, and planting out lots of Endive and Lettuces, and banking up with grass and litter the sides of Cucumber and Melon-boxes to keep them comfortable.

FRUIT GARDEN.

Much as in the previous week. Chiefly thinning fruit and shoots, and exposing the fruit in the late orchard-house, and giving a good watering with manure water to help them in the last swelling. Our Peach-house is now nearly cleared of all but the Walburton Admirable, which will keep us on until the earliest in the orchard-house come in. Potted Strawberry plants, &c., and watered Fig trees.

ORNAMENTAL DEPARTMENT.

Thinned the plants of large Chrysanthemums, as they were standing too thickly. They are so strong and stubby that as yet they have received no tying, and we would dispense with it altogether if we could. All staking is just so much stilting, and instead of making stakes a prominent feature, as we have seen them stuck in in sheaves, and nicely whittled too, we would rather see the stickler show his taste by concealing every stick. Went over single plants of Mignonette in largish pots, training them and taking off the flowers, as such single plants, whether as standards or pyramids, bloom more freely in winter than pots of seedlings grown in the usual way. Top-dressed large plants of Balsams and Fuchsias to secure fine blooms, and though they do not continue long, few things are more striking than fine-grown Balsams. Proceeded with potting on wet days, and commenced putting in cuttings of Verbenas for next season. We have gone to them because they are at present healthy and clean, whilst in dry autumns they are apt to be interfered with by thrips, and the cleaning of the cuttings then is a troublesome affair. In such cases we draw all cuttings through tobacco or quassia water: at present that is not needed. In the flower garden the heavy rains have rendered more twigging-up with small branches necessary, or the beds would be deprived of their symmetry. Some rows of Geraniums also required fine string run along them to keep them in their place. No better time could be found for weeding, and rolling walks and lawns, and where the mowing machine could not be worked owing to the wet, the scythe was just in its element. Pelargoniums, pruned-in and breaking, were laid on their sides, to prevent extra soaking. Fine clear weather now would greatly advance harvest work.—R. F.

COVENT GARDEN MARKET.—August 5.

Hot-house Grapes, Peaches, and Nectarines are very abundant, and moderate in price. Cherries are now confined to the Morello, Strawberries are over, and Gooseberries are nearly so. Pears chiefly consist of Beurré d'Amanlis, Jargonelle, and Lammis. Plums are very plentiful. The vegetable market is well supplied.

TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

TIME REQUIRED BY PEAS TO COME INTO BEARING.—I wish to give you my experience of Veitch's Perfection and Hairs' Dwarf Mammoth, which, in a late Number, were stated to require fourteen or sixteen weeks to be ready for picking. I planted Veitch's Perfection on May 9th, and they were fit for picking on July 22nd—ten weeks and 4 days. Again, I planted Hairs' Dwarf Mammoth May 20th, and have to-day (August 1st) gathered a good crop from them—ten weeks 3 days. I should have preferred their coming in later, as, since the latter part of May, although my kitchen garden is only 84 feet by 42, and well stocked with other vegetables, I have had more Peas than my family could consume.—ROWLAND WHEELER, Ventnor.

MRS POLLOCK GERANIUM (*W. P. Sissinghurst*).—The difficulty of growing this well is more imaginary than real. The secret lies in giving it very rich soil, and such can hardly be too rich. See also Mr. Pearson's remarks last week.

INSECTS (*A. E. R.*).—The caterpillars sent are young ones of one of the species of *Agrotis* (probably the Heart-and-Dart Moth, *A. segetum*), which last year did so much mischief all over the country. There is no other remedy with which we are acquainted to prevent their present attacks than that of laying traps of sliced vegetables, or Cabbage or Lettuce leaves, just below the surface, and examining them every other morning. The caterpillars are produced from eggs, deposited in June by the parent moths, which were, of course, numerous this year; and if we do not have a considerable quantity of wet the caterpillars will be again very injurious.—W.

APRICOTS DECAYING (*John Richards*).—From your description, and without seeing them, we should think that the fruit had not ripened from a deficiency of nutriment, and that is most likely occasioned by the branches gumming. We notice that ants and earwigs have this year eaten holes in the fruit before it was ripe, and the rain penetrating into the holes has caused the fruit to rot in that part before the other was ripe. Perhaps your fruit is similarly affected. We have not seen a mildewed fruit during our practice. Surely your mildew is only the mould found on all decayed and decaying fruits.

ROSE CELINE FORESTIER NOT FLOWERING (*G. C. A.*).—We would try removing or lifting, and root-pruning. Do not prune much, and always to a good eye at the top of the matured shoots. It requires very little pruning, and never flowers much against a wall, or if it do the flowers do not open well.

CLUB IN CABBAGES, &c. (*Stenbury*).—Before planting your Cabbages, Brussels Spouts, &c., tread or roll the ground so as to make it solid, then with a dibber make good-sized holes; fill these up with a mixture of burnt soil and rubbish from the rubbish-heap, then put out your plants, and if the weather continues dry give them an abundant supply of water. We have often found this treatment succeed when every other stratagem has failed.

MAKING RHODODENDRON-BEDS (*Drina*).—You will best make the bed by digging out the light sandy soil, where the bed is to be formed, to the depth of 2 feet, and then filling in to the depth of a foot with your not-very-heavy clay. On this place a foot of peat, and then plant the Rhododendrons in it. The soil most suitable for Rhododendrons is bog soil, or black fibry peat. Your sandy peat will do, unless very sandy, when one-third clay mixed with it would vastly improve it. The best position for Rhododendrons is an open situation, sheltered by trees at a distance, so as not to shade the bed, and yet protect it from strong winds, which ruin the foliage.

BOOKS (*J. W. M.*).—We do not know when a new edition will be issued, or even that such is in contemplation. You might, perhaps, pick up a copy cheaper at some of the book-stalls. You will find nearly all the new plants which have been recently introduced fully described in the several issues of the "Gardeners' Year-Book," which is published at this office.

PROPAGATING BEDDING PLANTS (*G. L.*).—Verbenas, Heliotropes, Ageratum, Petunias, Cupheas, Fuchsias, and, indeed, all kinds of bedding plants may now be propagated so as to have them well established before winter. They will all readily strike without artificial heat. Keep the cuttings shut up close during the day, and pull the lights off early in the morning for a short time, also in the evening for an hour or two if the air is not too dry.

**PROPAGATING WEIGELA ROSEA AND IVY (J. H. H.).**—Take cuttings of the half-ripened shoots of the Weigela, those that are firm and brown; cut them below the lowest joint transversely; remove the leaves from that and the joint above; leave two joints, or at most three, above them, with the leaves entire, and insert the cuttings, in a cold frame, up to the lowest pair of leaves, about 3 inches apart every way, using light loam mixed with about one-half sand. Put on the lights after watering, and do not open them for the next month except to give water, sprinkling them slightly with water every morning in bright weather, and keeping shaded from bright sun. In six weeks they will be fit for potting, and should be kept in a frame during the winter; or they may remain where inserted, and be planted in spring either in pots or open borders. If it is the common Ivy you wish to propagate, cuttings may now be placed in a moist shady border, selecting those cuttings that are short, and have a few roots already in course of formation upon them; but if variegated they should be inserted in a cold frame, and be kept close and shaded as for the Weigela cuttings. The cuttings should be slipped off, and be inserted about half way in the soil.

**RAISING BERBERIS DARWINI FROM SEED (Idem).**—Place the berries in layers, in dry sand, in a box, with sand between each, and sow them next March in light sandy soil, with a little peat or leaf mould intermixed. Distribute the seeds in rows, 3 inches apart, or broadcast, and cover with half an inch of light soil. Water copiously during dry weather.

**POTATO SCAB (J. P. B.).**—We can give you no information as to the cause beyond what was stated in last week's and previous Numbers. In your case, from the lined portion being scabbed, and the tubers in the unlined ground sound, the disease is no doubt attributable to the use of lime, especially as the ground is light and sandy.

**FORMING A CROQUET GROUND (L. I. B.).**—The greatest fault of all cricket grounds that we have seen is that they are too small—not too small, perhaps, for the game to be properly played, but too small to allow of a change of ground; the consequence is, that when the ground is much used, it is soon worn bare, and too short of grass for playing the game well. The smallest we have seen was 12 yards square; this was too small for anything, and a mere mimicry of a cricket ground. We have seen lawns for croquet of all sizes, from the eighth of an acre to an acre in extent; but, from what we know of the game, we should not think of having one of less than a quarter of an acre or 35 or 36 yards square—certainly not less than 30 yards every way; and we would not have it larger unless we expected large parties, and the ground to be in constant use; for with such an area we could change the starting and ending posts. For instance, if the sticks were north and south, we would change them, when the grass began to be worn, to east and west, and thus give it a chance to grow by the time the other piece became worn. If the ground permitted, we would have the croquet lawn sunk about a foot or 15 inches, and form a terrace all round, with a slope of 2 feet to the croquet ground. This terrace to be 36 feet wide; 15 feet of grass from the slope, then a six-foot walk, and 15 feet of grass on the other side, and bounded by a Yew hedge. On the terrace we would plant different kinds of close-growing shrubs, and upright-growing Conifers, exactly in the centre, on each side, and along the ends. Steps of stone at each end, or on all four sides, should lead to the terrace walks; and on the terrace, at these points, we would have vases on each side of the walk, and either vases or statuary on half-terraces at all the corners, the latter being rounded for that purpose, and also at the corners of the outside, or on both sides of the walks, where the walks crossed at right angles. Between the shrubs there would be beds of circular form for bedding and other plants. This might be carried out either on a large or small scale. In forming the ground, make it level, and allow it to settle and become firm before turning. When there are many depressions to fill up, and heights to take down, hollows are apt to be formed, in consequence of the soil sinking. If the subsoil is of a strong tenacious nature, the turf should be laid on an inch or so of ashes, which will help to render it drier in damp weather. Some say the grass comes finer, but the reverse is often the case on dry subsoils. Form the ground so as to lay the turf by the beginning of October, and, when laid evenly, gently beat as the work proceeds; sprinkle a little soil on the turf after laying, but not much; and if the soil is at all poor give a good dressing of leaf mould and well-rotted manure in the following March. Let the grass grow up to May, or even June, before mowing, in order that it may form good roots, and then mow and roll regularly to bring it into order. It will require a year to do this, even if good turf be laid. Use it very carefully the first year, for if it become bare at the commencement it will show the effects for a long time. If grass seeds are to be sown the ground may be prepared during the winter, and the seed sown in April; let the grass grow until July, then mow, and mow regularly every fortnight afterwards, and manure, if necessary, in order to obtain a good turf earlier; this you will do in a year by sowing seed, and the same year by laying turf; but you must not expect to use the ground the same year, for grass requires time to make a bottom. Of course if it be merely taking up and relaying a lawn that has been some time under the scythe or machine, then the turf may be used in the following year, if laid in autumn, or in the same season, if laid in spring; still it will not endure dry weather so well as a lawn with the roots deep. The main points are—to make the ground large enough, to level a good depth of soil beneath the turf, have a good sward before using it much, and then not to play too long on one place.

**HEATING A CUCUMBER PIT (J. L. Stackhouse).**—Your Cucumber pit will answer very well. You will have enough of heating if you surround the bottom-heat pipes with pebbles. It would be well to place a layer of clean-washed gravel over all, and that will always give a nice bottom for the soil, and prevent any tendency of the roots to go down to the pipes. It will also be advisable to have a few upright drain-tiles communicating with the rubble round the pipes, through which you can pour water to give a moist bottom heat. The three-feet bed will do for the Cucumbers, but we would have made path and bed of equal width. Such a house, to have Cucumbers in January, should have a bottom heat ranging from 75° to 80°, and the top heat without sun should range from 60° to 65° for short kinds, and a little more, say from 65° to 70°, for very long kinds. In dull weather more fire will be necessary so as to permit of air to keep all sweet. Evaporating-pans would be useful on one of the top pipes. Strawberries will swell very well in such a house, after they are set. You must have a cooler place to bring them on in, until the fruit is set. The shelf against the back wall should be from 16 to 18 inches from the glass, according to the size of the pot and the thickness of the turf used.

**PROPAGATING CERASTIUM TOMENTOSUM, PINKS, AND CARNATIONS (A. A. S.).**—The *Cerastium* will live out of doors, it is perfectly hardy. Put in at once all the cuttings of it you can take off in a sandy soil on a shady border. Early in the spring propagate from these again. In this way from a few plants you may obtain a large stock by next year. Pinks and Carnations are perfectly hardy; they are best propagated by layers. To do this make a slit in the bottom side of the pipping, at a convenient distance from the plant, so that you may be able to bend the shoot down to the ground without breaking, fasten it with a small hook firmly into the ground just above where the slit has been made; then sprinkle a little sand round the layers and scrape a little soil about them, and if all go on well they will have taken root by the end of October, when they should be taken from the parent plants and planted in beds of rich soil rather elevated. Let them remain in this position till the spring, when they should be placed in their blooming-beds. The soil for them should be good, having a liberal supply of well-decomposed cow manure in it.

**DESTROYING ANTS (A. L.).**—We can only repeat what we have already stated in answer to other inquirers. To kill ants smear the inside of a flower-pot with honey; invert this over their nests, and when the pot is crowded with them plunge it in boiling water. Repeat this until the colony is destroyed. Another mode consists in placing a 24-sized flower-pot over the nest; the ants work up into it, and may be removed with a shovel, and thrown into a bucket of boiling water. The hole in the pot should be stopped up. Boiling water poured on the nests is a third mode; and the fourth is to mix arsenic with honey, or sugar and water, and place in saucers, covering with an inverted one or slate, and placing a stone on the top, and two thin pieces of wood between the saucers or slate, to admit the ants to the repast, which they will sometimes devour greedily, and at others not touch. To drive away ants pour strong lime water into their nests several times, and freely. Guano sprinkled over the nest largely, and the application repeated, will also sometimes drive them away; and so will a strong decoction of bruised Laurel leaves poured over the nest at night. Sometimes a decoction of Elder leaves will answer the same purpose. A line of gas tar near the base of the wall, and on the stem of the trees, prevents their ascending. Wool they will seldom cross, more especially when it is dipped in oil; oil, especially train oil, and turpentine, they greatly dislike.

**PREVENTING ANTS AND EARWIGS ATTACKING APRICOTS (R. B.).**—For driving away and destroying ants, see reply to "A. R." in the present Number, and Mr. Fish's remarks last week. Earwigs are best trapped; the traps may be had of any seedsmen. Broad Bean-stalks cut into six-inch lengths, the stems of Sunflowers, Jerusalem Artichokes, and of the Giant Cow-parsnips, or *Heracleum giganteum*, are good for the purpose of trapping them. These hollow stems should be placed horizontally in different parts of the trees, and examined every day or every other day, and the earwigs blown or shaken out into scalding water. A little dry moss placed at the bottom of a small flower-pot, and stuck on a stick or spur of the tree, will induce many to congregate in the moss, they may then be shaken out into scalding water or otherwise destroyed, the pots being frequently examined for that purpose.

**VINE LEAVES AND GRAPES SHRIVELLED (R. A. M.).**—The most likely cause of the leaves turning brown and shrivelling up before the Grapes are ripe, is red spider. Another probable cause is not giving air early; moisture is consequently deposited on the leaves, and the sun acting powerfully upon the drops scorches the leaves. It may also proceed from the bad quality of the glass, some glass burning the leaves very much. The Grapes shrivel through shanking, and it is caused by a defective root-action at the second swelling of the berries. The house not being shaded has nothing to do with it. It is not customary to shade vineries.

**DAISIES AND DANDELIONS ON LAWN (Idem).**—Grub up the Daisies by the root and the Dandelions also, with as much of the thick tap root as possible, dropping a little salt into the hole. It is best done in showery weather. Fill the holes with fresh soil, and slightly scratch the bare places, or level them if necessary with fresh soil, and sow lawn grass seed from now up to the middle of September during showery weather. Roll well after sowing, but not when the soil is so wet as to adhere to the roller. It is best sown a short time before rain.

**FUNGI DESTROYING FERNS (M. W.).**—We imagine that your rockery is constructed of roots and stumps of trees, or that there is a quantity of wood in the compost, which causes the fungus. In that case your only method of getting rid of the fungus would be to remove the pieces of wood, to reconstruct the rockery of stone only, and to replant the Ferns in compost free from sticks and pieces of wood. The present, however, is not a proper time to do this kind of work, the best time is spring; besides it may be impracticable from the absence of stone, and we may be altogether wrong in judging your rockery to be of stumps and roots of trees. We have always found that fungi were caused by wood either in the soil or in close proximity to the roots of the Ferns. Stir the soil, remove that where the fungus most abounds, and dust fresh lime wherever the fungus exists, replacing the soil removed with fresh compost. Whenever the fungus re-appears stir the soil frequently, and sprinkle with fresh lime, which is disliked by all fungi, and the only effectual mode of keeping them in check without seriously injuring the plants.

**BEECH LEAVES OF DIFFERENT KINDS ON THE SAME TREE (E. S.).**—The cut leaves are those of *Fagus sylvatica heterophylla*, which are sometimes in narrow shreds and at other times broader. This variety is very apt to return to its normal form, the common Beech, as in the present instance—hence the supposed Oak and Beech leaves on the same tree.

**COLOURING BRICKWORK (R. W. C.).**—The best plan you can adopt with your fine that is so exposed, is to colour it in the usual way with lime wash, and then place a wire guard along the exposed side to keep it from the clothes of visitors. This will be better than colouring that will not rub off.

**FUCHSIA BLOOMS PREMATURELY FALLING (—, Northalerton).**—We found no trace of insects on your Fuchsia blooms. We believe that the falling of the bloom is owing to one of two causes—the heart of the ball of earth is dry, notwithstanding your regular watering—and, if you suspect this, make holes with wires, or set the pot in a tub of water—or the bees have access to your flowers and fecundate them, and then the blossom drops. Many are obliged to use gauze coverings over the open ventilators to keep bees from Fuchsias. From this cause we have seen hundreds of blooms drop on a morning. Let us know what you think. We are obliged for the information about the *Chrysanthemums* and the *Lonicera*.

**RED SPIDER AND MILDEW ON VINE LEAVES** (*B. W. Stannus*).—Your Vines are very much infested with mildew and red spider. Procure some quassia chips, boil them for fifteen minutes, about 3 ozs. to two gallons of water. After it is cold syringe the Vines well with this two or three times. If the house is heated by hot-water pipes, give these a good coating over with sulphur mixed with soft-soap, give all the air possible, and soak the Vines well at the roots. We suspect they have suffered from want of water. The border is too shallow. Place 8 or 10 inches of fresh soil on the top of the border at once, but first give a liberal sprinkling of bones all over the border. See that it is well soaked with water before you do this.

**DESTROYING THRIIPS ON CUCUMBER LEAVES** (*A Subscriber*).—The insect is the common thrips—it changes colour as it becomes older. If the bulk of the leaves are as bad as those sent, the best plan is to smok the house with sulphur and kill plants as well as insects, clean the place, and begin anew. If those sent are the worst, and there is a good deal of healthy foliage, we would cut off all the worst carefully and burn them, then smoke with shag tobacco when the leaves are dry; next day keep shaded and close, syringe with quassia water or weak glue water, and repeat the dose. If the plants are as bad as the leaves sent, we would not waste the tobacco on them. Once we had a hed very much attacked

and we cut off all the leaves, washed with glue water, and let the plants break afresh, but this only answers with strong healthy plants.

**VERBENA VELVET CUSHION**, &c. (*E. P.* ; *G. L.*).—For plants of these apply to Messrs. E. G. Henderson & Son, of the Wellington Road Nursery, St. John's Wood, London. They will also supply the *Viola cornuta* in any quantity. It is not the common garden variety.

**NAMES OF PLANTS** (*N. B.*).—Hollyhock apparently worthless, but impossible to judge of certainly in the stage at which it was sent. The labels of both your Fuchsias were detached. (*A. K.*).—1, Do not recognise this leaf; 2, *Gasteria verrucosa*; 3, *Aloe serra*. (*Cheshmore, Waterford*).—*Eucephalartos pungens*. (*East Sussex*).—1, *Muhlenbeckia complexa*; 2, *Cyrtanthera Pohlana*; 3, *Begonia*; 4, *Begonia discolor*; 5, *Lastrea decurrens*; 6, *Convolvulus mauritanicus*; 7, *Asclepias curassavica*. (*D. Davis*).—1 and 2, (young), vars. of *Athyrium Filix-femina*; 3, appears to be *Hypolepis distans*; 4, *Nephrolepis tuberosa*; 5, *Scolopendrium vulgare crenatolobatum*; 6 to 9, vars. of *Scolopendrium vulgare*, not determinable without better fronds. (*T. W., A Subscriber*).—*Solidago virgaurea* and *Hemerocallis caerulea*. The *Pelargonium* not determinable. (*New Forest*).—The smaller is *Cystopteris bulbifera*; the larger, *Lastrea spinulosa*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending August 5th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

AMONG THE MENDIPS WITH MR. RODBARD.

No. 2.

On looking out from my window I found the morning was most brilliant. There had been rain during the night, and now it was "the clear shining after rain" mentioned in the Bible. On such occasions the state of the atmosphere is grateful to the senses of sight, and smell, and taste. Breakfast having been dispatched, Mr. Rodbard proposed a walk to inspect the poultry. I am, perhaps most of us are, fond of imagining before I see it what a place will be like, and then comparing the reality with the imagination. I thought that the poultry would be in specially built houses; I thought of the various contrivances to keep the breeds separate; what sort of laying-places; I thought of an infinite outlay of painted wood, wire-netting, newly invented food-pans, and water-bottles. All my thoughts and imaginings were quite unnecessary, and quite incorrect. The ground in the park around Aldwick Court was of the most undulatory description possible. I use the word "undulatory" in its original meaning "wave-like." A high mass of hill, then a valley, deep but not wide, then another wave of hill, then another valley, and so on. Now the consequence of this was that within what was really a short distance there might be two distinct walks for poultry, and the two lots of birds never met; then on further, other walks. Bearing this in mind, a great deal of trouble was spared. Then all being grass runs and such splendid air no wonder that I did not see one sickly bird. As to houses, Mr. Rodbard informed me that he had not built one. There happened to be a number of old buildings scattered here and there on the estate before it became his, some for cattle, others for tool-houses, &c., and these, without even much alteration, became his poultry-houses.

But now for our walk. Passing through a building filled with all manner of baskets which had been sent to many shows, and whose inhabitants had never been overcrowded, I come to walk No. 1, where were some Spanish fowls just returned from a show, having won a prize of course. We ascend a hill, but in ascending I stop to admire some Rouen Ducks whose marvellous length seemed to require that they should have an additional pair of legs. I throw out this hint to committees, "Rouen Ducks to take prizes are expected to have four legs, those having but the ordinary two will be disqualified." Doubtless four-legged ones would appear! We can breed to feather, why not to a foot? Up the hill—that wicked "B."

who said I was fat would have heard me pant at any rate, though I am not fat, I beg to state. We come to an aged tree round which a seat had been made; this is called "Hannah More's tree," and it is said the authoress loved to climb the hill and enjoy the prospect. "But what is this somewhat ecclesiastical building in the trees?" "Only my private chapel," said Mr. R. We enter the gate of the—is it a churchyard? Yes—no—yes—no—I think not, for I see no grave-stones, only fowls. It does look like a church of church-warden-gothic, tower and all. On going round to the south door I find it is not a church, but built to look like one at a distance. It was erected for the accommodation of cattle. Had I preached there, my text would have been "What meaneth this lowing of oxen that I hear?" But the cattle had given place to Partridge Cochins—I caught a cockerel, and a big baby he was—I then caught a hen, the largest I think I had ever seen. Unless I greatly mistake, Mr. Rodbard will do wonders with his breed of Cochins—other exhibitors, look out; cross your strains, hatch early, feed well, or you will be beaten. Nay, you must be beaten unless you have as large birds. Leaving the church with its congregation of sleepy (sitting) hens, and the larger congregation of lads and lasses (cockerels and pullets) walking about the churchyard—idle creatures, where is the churchwarden?—we dip down a valley, and come upon a tool-house divided by wire, with a most hopeful-looking lot of Spanish inside. Then on to a walled garden, in the corner of which was a gardener's cottage converted into a poultry establishment for early Spanish chickens. In a good-sized room, ceiled and with glazed windows, were a vast number of birds. Imagine three counters from drapers' shops running round the room, with upright boards nailed on the edges, thus turning the counters into troughs, and in each trough a quantity of chopped straw to keep the chickens warm. The said chickens when I saw them were advanced in chickenhood, and even sporting in an enclosed space, hiding beneath artichoke and rhubarb plants; they all seemed healthy. I stroll on and come to a farmyard, where I find some Game fowls; these gave me a headache, as I always want to keep them, but am unable. Further on, past a lodge, we came to the coachman's cottage, where, in the yard, we found a number of Spanish cocks living together in single blessedness, yet happy bachelors, neither moping nor pugnacious. A little further, and I am in front of Aldwick Court, and my ramble is done.

Now for a few reflections. Mr. Rodbard has singular facilities for keeping his birds—the ground, the air, everything in their favour. Then he thoroughly understands poultry, and most thoroughly enjoys the pastime. I have never seen such good Spanish, and never better Rouen Ducks; the Cochins and

Game were also excellent. A lunch formed a natural conclusion to my walk, then, for 'tis Saturday, I must away. We drive back to Yatton, and in the railway I meditate upon the pleasant visit I have had.

This second paper would have appeared earlier but for the illness of the writer; and now, if my memory has failed me and I have not noted anything that was noteworthy at Aldwick, the plea of an aching head and shaky hand must be given.—  
WILTSHIRE RECTOR.

### LUTTERWORTH POULTRY EXHIBITION.

THE number of entries for this Show were beyond question much curtailed, from the fact that the nearest railway station to Lutterworth is fully three and a half miles from the place of exhibition, nevertheless there were sufficient birds upon the ground to make a good show. It is certain, however, that had the Lutterworth meeting been of easy access by railway, the number of pens would have been doubled. The poultry were exhibited under a tent perfectly waterproof, a fact that was unfortunately tested during the whole of the first morning the Show was open by exceedingly heavy occasional downfalls of rain.

In *Grey Dorkings* the classes were very good. Henry Warner, Esq., of The Elms, Loughborough, exhibiting excellent adults, but at present in deep moult; and he gained the first prize also in Dorking chickens with a pen that proved a complete "walk over" to his opponents. The *Spanish* fowls were good likewise, but much out of condition. In *Cochins* (any colour competing), Buffs alone were the prizetakers, for though some excellent Partridge-coloured ones were shown, every cock proved defective. The White Cochins were well shown, and proved one of the best-filled classes in the Show. Some White Cochins competing with quite bright green legs were of course inadmissible. *Game* fowls during moult always show to great disadvantage, but some excellent birds were entered. With the exception of the Golden-spangled *Hamburghs*, the *Hamburghs* were perhaps one of the very worst classes in the Show. Some pretty Gold-laced *Bantams* were exhibited, and some very fair White ones also. The *Game Bantams* were superior, but moulting.

The *Aylesbury Ducks* were one of the best classes in the show; but, strange to say, not a single entry was made for *Rouens*.

The *Turkeys* were really capital, but there was no entry whatever of *Geese*.

The *Pigeons* were few in numbers, but the prize Carriers, Turbits, Pouters, Rants, Jacobins, and Fantails, were decidedly better than heretofore at this Society's meetings.

It is a pleasure to record the fact, that every arrangement was not only perfectly fulfilled, but also completed long prior to the time appointed for opening.

The fowls were liberally fed, and the pens used were the well-known exhibition pens of Mr. Turner of Sheffield. Had the weather been propitious, instead of the most disheartening that could be imagined at the break of day, the attendance of visitors would doubtless have been far greater, but heavy showers prevented numbers from taking tickets who actually had purposely attended at the various outlying railway stations to do so. Some of the more daring visitors, beguiled by an occasional gleam of sunshine, ventured even to walk from the Ullersherpe station to receive, in many instances, a thorough wetting through in return.

**DORKINGS.**—First, H. Warner, Loughborough. Second, M. Brown, Ab-Kettleby. Commended, H. Bond, Lutterworth. *Chickens.*—First, H. Warner. Second, M. Brown. Commended, H. Bond; W. T. Everard, Alton Grange.

**SPANISH.**—First and Second, M. Brown, Ab-Kettleby. Commended, E. Morley, Spocote. *Chickens.*—Prize, W. T. Everard, Alton Grange.

**COCHIN-CHINA** (Any colour).—First, J. Buckley, Desford. Second, H. Warner, The Elms. *Chickens.*—First, H. Warner. Second, J. Buckley, Highly Commended, A. Guy, Eaton.

**COCHIN-CHINA** (White).—First, F. F. Foster, Birmingham. Second, M. Brown, Ab-Kettleby. *Chickens.*—Prize, J. Pratt, Whetstone.

**GAME** (Black-breasted and other Reds).—First, R. Sansome, Lutterworth. Second, W. S. Ivens, Lutterworth. *Chickens.*—First, H. Warner, The Elms. Second, W. T. Everard, Alton Grange.

**GAME** (White, Piles, or any other Colour).—First, W. T. Everard, Alton Grange. Second, A. Guy, Eaton. Highly Commended, W. S. Ivens, Lutterworth. *Chickens.*—First, W. T. Everard. Second, H. Warner.

**HAMBURGH** (Golden-spangled).—First, H. E. Emberlin, Humberstone. Second, W. Draycott, Humberstone. Commended, J. Buckley, Desford. *Chickens.*—First, H. E. Emberlin. Second, W. Draycott.

**HAMBURGH** (Silver-spangled).—First, withheld. Second, J. Buckley, Desford.

**BANTAMS** (Gold-legged).—First, W. Draycott, Humberstone. Second, Lady Berners, Ketherpe Hall.

**BANTAMS** (Cleans-legged).—First, W. Draycott, Humberstone. Second, H. E. Emberlin, Humberstone.

**BANTAMS** (Black Cleans-legged).—Prize, W. Draycott, Humberstone.

**BANTAMS** (Game, Black-breasted and other Reds).—First, W. S. Ivens, Lutterworth. Second, A. Guy, Eaton. Highly Commended, H. Warner, The Elms.

**DUCKS** (Aylesbury).—First, H. E. Emberlin, Humberstone. Second, W. A. Kendall, Humberstone. Highly Commended, F. Gill, Narborough.

**TURKEYS.**—First, A. Guy, Eaton. Second and Highly Commended, J. Johnson, Braunston.

**PIGEONS.—Carriers.**—First, F. F. Foster, Birmingham. Second, W. Draycott, Humberstone. Highly Commended, F. W. Montgomery, Wals-

grave. *Turbits.*—First, F. F. Foster, Birmingham. Second, H. E. Emberlin, Humberstone. Commended, F. F. Foster. *Pouters.*—First, H. E. Emberlin, Humberstone. Second, F. F. Foster, Birmingham. Commended, F. W. Montgomery, Walsgrave. *Rants.*—First, H. E. Emberlin, Humberstone. Second, W. Reed. *Jacobins.*—First, F. F. Foster, Birmingham. Second, H. Emberlin, Humberstone. *Fantails.*—First, W. Draycott, Humberstone. Second, F. F. Foster, Birmingham. Commended, C. H. Gates, Lutterworth. *Magpies.*—Prize, H. E. Emberlin, Humberstone. *Any other variety.*—First, H. E. Emberlin, Humberstone. Second, F. W. Montgomery, Walsgrave. Highly Commended, F. W. Montgomery. Commended, C. H. Gates, Lutterworth.

**RABBITS.—Weight.**—First, W. Draycott, Humberstone. Second, F. W. Montgomery, Walsgrave. *Length of Ears.*—First, F. W. Montgomery, Walsgrave. Second, W. Read. *Any other kind.*—Prize, W. Draycott, Humberstone.

**SWEETSTAKES** (Game Geck).—Prize, H. Warner, The Elms. Highly Commended, W. T. Everard, Alton Grange.

Edward Hewitt, Esq., of Eden Cotta ge, Sparkbrook, Birmingham, officiated as Judge.

### BUDE HAVEN POULTRY SHOW.—JULY 28th.

THIS was the ninth annual Show, and there were sixty entries more than last year, the funds too are still increasing. The afternoon of the day of exhibition was very fine, though the morning was by no means promising, and the visitors, consequently, were very numerous. *Dorkings* took the lead for entries, and many of them were purchased from first-class yards. The first-prize White *Dorkings* were a beautiful pen, so too were the first-prize Golden-pencilled *Hamburghs*. In *Game* there were twelve entries of first-class birds. The *chickens* were rather too young but very handsome. Black *Cornish* were beautiful birds. Dark-pencilled *Brahma* chickens from H. Leworthy, Esq., but not entered for competition, were much admired. The *Ducks*, *Guinea Fowls*, and *Turkeys* were also very good.

**DORKINGS** (Coloured).—First and Second, Rev. G. De C. Guille. Third, Rev. A. G. Thynne. Fourth, Rev. J. R. Whyte. *Chickens.*—First, Rev. G. De C. Guille. Second, J. Brock. *Single Cock.*—First, J. Galsworthy. Second, J. Dinner.

**DORKINGS** (White).—First, W. Pickard. Second, J. M. Braund. *SPANISH.*—First, R. Hoskin. Second, J. Joce. Third, W. Leach. *Chickens.*—First, R. Hoskin. Second, J. Sluman.

**MINORCAS.**—Prize, W. Shearn. *GAME.*—First, J. Joce. Second, H. M. Bazley. Third, H. Parsons. *Chickens.*—First and Second, S. Pichard.

**COCHIN-CHINA.**—First and Second, W. L. Trewin. **MALAYS.**—First, and Second, H. Dureh.

**CORNISH** (Black).—First, D. Maynard. Second, W. Bromell. **HAMBURGH** (Golden-pencilled).—First, J. F. Delmar. Second, Mrs., Kingston.

**HAMBURGH** (Golden-spangled).—First, J. F. Delmar. Second, J. Banbury. **HAMBURGH** (Silver-pencilled).—First, J. M. Braund. Second, T. Legg. **HAMBURGH** (Silver-spangled).—First and Second, W. M. Lancaster.

**POLAND** (Golden-spangled).—First, F. Gloyne. Second, W. Hore. **POLAND** (Black, White-topped).—First and Second, W. L. Trewin.

**BARNDOR.**—First, J. B. Lyle. Second, —Barrott. Third, H. Francis. Fourth, J. Francis. Fifth, A. Seldon.

#### EXTRA PRIZES.

**COCK AND TWO HENS.**—First and Second, E. Hockin. **BANTAMS** (Black).—First and Second, W. Bromell.

**GUINEA FOWLS.**—Prize, Rev. G. De C. Guille. **DUCKS** (Aylesbury).—First, J. Bines. Second and Third, T. Barrett. *Ducklings.*—First, J. Bines. Second, W. Bines.

**DUCKS** (Common).—First, J. Cotton. Second, T. Trewin. Third, S. T. Pickard. Fourth, L. Coham. *Ducklings.*—First, W. Bines. Second, J. Wood. Third, J. Goad.

**DUCKS** (Rouen).—First, Rev. G. De C. Guille. Second, G. P. H. Paty. **GEESE.**—First, J. Heal. Second, W. Brock. Third, J. Woodley.

**TURKEYS.**—First, Rev. G. De C. Guille. Second, J. Heal. Third, G. Risdon.

**PIGEONS** (Common).—Prize, J. H. Cotton. *Jacobins*, *Trumpeters*, *Tumbler.*—Prize, J. M. Braund.

**RABBITS** (Lop-eared).—First, J. Cory. Second, F. Gloyne.

**RABBITS** (Common).—First, J. Brimacombe. Second, P. W. Bray.

**EXTRA PRIZES GIVEN BY WILLIAM MASSELL, ESQ.—DUCKS.**—Prize, H. Brimacombe.

**JUDGES.**—Dr. Scott, Exeter, and H. Leworthy, Esq., Newport Barnstaple.

### NEWMILLERDAM POULTRY SHOW.

THIS Show was held on Tuesday, August 1st, on the usual site in Chevit Park, kindly lent for the occasion by Sir Lionel Pilkington, Bart., and although the weather was rather unfavourable yet there was a large attendance of visitors.

The show of poultry was not so large as on some previous occasions, yet the quality of the birds shown was decidedly superior. The first prize for Black Red *Game* was won by Mr. T. J. Charlton, with perhaps the best pen Yorkshire can boast of; the first in *Ducklings* by Mr. W. H. Briggs; and the first for chickens, Brown Reds, by Mr. Aykroyd, with a pen of very extraordinary merit. The *Cochins*, *Dorkings*, *Spanish*, *Polands*, *Hamburghs*, *Ducks*, &c., were all of first-class character. The following are the awards:—

**GAME** (Black Red).—First, T. J. Charlton. Second, F. Vickerman. *Any other variety.*—First, W. H. Briggs. Second, F. Vickerman. *Chickens.*—First, E. Aykroyd. Second, F. Vickerman.

**COCHINS** (Buff).—First, W. Dawson. Second, H. Beldon. *Any other variety.*—First, R. J. Wood. Second, W. Dawson. *Chickens.*—First, W. H. Briggs. Second, H. Beldon.

**DORRINGS.**—First, H. Himsworth. Second, H. Beldon. *Chickens.*—First, J. Hirst. Second, H. Himsworth.  
**SPANISH.**—First, H. Beldon. Second, W. Whiteley.  
**HAMBURGS (Golden-spangled).**—Prize, H. Beldon.  
**HAMBURGS (Silver-spangled).**—First and Second, H. Beldon, Bingley. *Chickens.*—Prize, H. Beldon. *Any other variety.*—First and Second, H. Beldon.  
**BANTAMS (Black or White).**—First, T. J. Charlton. Second, S. Scholefield. *Game.*—First, F. Vickerman. Second, S. Scholefield.  
**DUCKS (Rouen).**—First, H. Beldon. Second, J. Hirst. *Aylesbury.*—First, J. Hirst. Second, H. Beldon.  
 The Judge was Mr. Thompson.

### HASLINGDEN POULTRY SHOW.

THE exhibition was held on the 28th of July in a large meadow, about five minutes' walk from the Town Hall; and though the rain had the effect of deterring many persons from visiting the show in the forenoon, before one o'clock the sun dispelled the watery clouds and shone forth with the heat and brightness usual to July. Visitors then began to arrive in large numbers, and during the afternoon the show ground was thronged with persons from all the adjacent townships.

The stock of poultry exhibited was not large, but included many excellent birds. The *Game* were in good feather and looked well. Many excellent single cocks were shown, and the chief prizes were won by Mr. C. W. Brierley, of Middleton. Mrs. F. M. Hindle, of Haslingden, took the first prize for *Single cock* belonging to the district, and Mr. W. Westwell, of Baxenden, the second. *Dorplings* were a capital show, and Mr. D. Parsons, of Cnerden, near Preston, took the chief prize, with a splendid pen. *Cochin-Chinas* were also a capital show, and the pen of Black *Spanish* belonging to Mr. Henry Beldon, of Bingley, near Leeds, were first-class, while those belonging to Messrs. Burch & Boulter, of Sheffield, which had the second prize, were really fine. A few good pullets were also shown. *Brahma Pootras* were in good feather, and some fine birds were shown. *Hamburghs* were very numerous, and the Golden-spangled ones shown were beautiful and well bred. In the Silver-pencilled class there were also some capital birds exhibited. The chief prize for *Any variety* was given to Mr. H. Beldon, for a pen of *Polands*, splendid birds. The show of *Game* and other *Bantams* was far above the average in number and breed.

*Turkeys, Geese* and *Ducks* were also of a very good class.

The show of *Pigeons* was very varied; Carriers were a very good class. The fancy classes were well represented, and attracted much attention. Mr. Yardley, of Birmingham, Mr. Cole, of Bradford, and Mr. Brown, of Sheffield, took the chief prizes.

Four pens of *Rabbits* were also shown, two of which were of the Long-eared class belonging to Mr. W. J. Corbridge, of Blackburn. For other varieties prizes were won by Mr. W. Graham, of Accrington, and Mr. Corbridge.

The following is the list of awards:—

**GAME (Single Cock).**—First and Second, C. W. Brierley, Middleton. Highly Commended, W. Gamen, Chester. Commended, J. S. Butler, Boulton-le-Fyde.

**GAME (Single Cock, limited to district).**—First, F. M. Hindle, Haslingden. Second, W. Westwell, Baxenden. Commended, J. Platt, Haslingden.

**GAME.**—First, C. W. Brierley. Second, W. Gamen.

**DORRING.**—First, D. Parsons, Cnerden. Second, W. Gamen. *Chickens.*—First and Second, D. Parsons. Commended, J. Stott, Rochdale.

**COCHIN-CHINA.**—First and Highly Commended, R. J. Wood, Brinscall Hall. Second, T. Stretch, Ormskirk. Commended, H. Beldon, Bingley.

**CHICKENS.**—First, C. Sedgwick, Keighley. Second, T. Stretch. Highly Commended, W. Bamford, Harpurley. Commended, E. Smith, Middleton; W. Bamford.

**SPANISH (Black).**—First, H. Beldon. Second, Messrs. Burch & Boulter, Sheffield. Commended, J. Wood. *Chickens.*—First, Messrs. Burch & Boulter. Second, W. Nicklin, Walsal.

**BRAHMA POOTRA.**—First, R. W. Boyle, Bray, Ireland. Second, W. Hargreaves, Bacup. Highly Commended, J. Wood. *Chickens.*—First, R. W. Boyle. Second, M. Seamons, Aylesbury. Highly Commended, J. Stator, Stand Hill; W. Hargreaves.

**HAMBURGH (Golden-pencilled).**—First, H. Beldon. Second, Messrs. Burch & Boulter. Highly Commended, J. Robinson, Garstang. *Chickens.*—First, H. Crossley, Halifax. Second, J. Robinson. Highly Commended, C. Tattersall, Waterfoot.

**HAMBURGH (Silver-pencilled).**—First, J. Robinson. Second, Messrs. Hindle & Pickles, Accrington. *Chickens.*—First, H. Smith. Second, H. Beldon. Commended, A. Nuttall, Newchurch.

**HAMBURGH (Golden-spangled).**—First, W. Driver, Keighley. Second, J. Robinson. Highly Commended, J. Newton, Silsden. *Chickens.*—First, J. Roe, Hadfield. Second, J. Andrews.

**HAMBURGH (Silver-spangled).**—First and Second, H. Beldon. Highly Commended, E. Collinge, Middleton. *Chickens.*—First and Commended, J. Fielding. Second, E. Collinge.

**ANY OTHER VARIETY.**—First, H. Beldon. Second, H. Carter, Holmfirth. Highly Commended, C. W. Brierley; C. Sedgwick.

**SELLING CLASS (Any variety).**—Prize J. Marchant, Halifax.

**BANTAM (Game).**—First, D. Parsons. Second, C. W. Brierley. *Single Cock.*—First, G. Maples, Wavertree. Second, C. W. Brierley. Highly Commended T. Holt, Linchome; T. Eastham, Preston.

**BANTAMS (Any other variety).**—First, S. & R. Ashton, Roe Cross. Second, E. Tate, Leeds.

**TURKEYS.**—First, E. Leach, Rochdale. Second, T. Houliker, Blackburn. **GEESE.**—First, R. W. Boyle. Second, M. Seamons. Highly Commended, B. Baxter; E. Leach.

**DUCKS (Aylesbury).**—First, E. Leach. Second and Highly Commended Mrs. M. Seamons.

**DUCKS (Rouen).**—First and Second, E. Leach. Highly Commended, Mrs. M. Seamons.

**DUCKS (Any other variety).**—First, J. R. Jessop, Hull. Second, T. C. Hamson, Hull. Highly Commended, E. Leach.

**PIGEONS.—Carriers.**—First, C. Cole, Bradford. Second, S. S. Stott, Haslingden. Highly Commended, W. J. Corbridge, Blackburn. **Tumbler.**—First, H. Yardley, Birmingham. Second, J. Fielding, jun., Rochdale. Highly Commended, C. M. Roys, Green Hill. **Barbs.**—First, E. Brown. Second, J. Fielding, jun. Highly Commended, C. Cole. **Owls.**—First, H. Yardley, Second, J. Fielding, jun. Highly Commended, C. M. Roys; J. Fielding, jun. **Croppers.**—First and Second, C. Cole. Highly Commended, E. Brown, Sheffield. **Fantails.**—First and Second, H. Yardley. **Turbits.**—First, H. Yardley. Second, E. Brown. **Dragons.**—First and Second, H. Yardley. Highly Commended, S. S. Stott. **Trumpeters.**—First, H. Yardley. Second, F. Key, Beverley. **Antwerps.**—First and Second, H. Yardley. Commended, W. J. Corbridge; W. Hill, Littleborough. *Any other variety.*—First, H. Yardley. Second, W. J. Corbridge. Highly Commended, C. W. Roys; W. Markland, Dean.

**JUDGES.**—Mr. R. Teabay, Preston, and Mr. R. Sergenson, Liverpool.—(Abridged from *Preston Guardian*.)

### ROSSENDALE POULTRY EXHIBITION.

THIS was held on the 4th inst., when the following awards were made:—

**HAMBURGS (Silver-pencilled).**—First, Hindle & Pickles, Wood Nook, Accrington. Second, J. Robinson, Vale House, Garstang. Commended, A. K. Wood, Burnside, Kendal.

**HAMBURGS (Golden-pencilled).**—First, S. Smith, Northowram, Halifax. Second, J. Robinson, Vale House, Garstang. Highly Commended, B. Thomas, Sheffield.

**HAMBURGH CHICKENS (Golden or Silver-pencilled).**—First and Second, A. Nuttall, Mill End (Silver-pencilled). Commended S. Smith, Northowram.

**HAMBURGS (Silver-spangled).**—First, A. K. Wood, Burnside, Kendal. Second, J. Fielding, Newchurch. Highly Commended, J. Fielding.

**HAMBURGS (Golden-spangled).**—First, A. K. Wood, Burnside, Kendal. Second, J. Roe, Hadfield, near Manchester.

**HAMBURGH CHICKENS (Golden or Silver-spangled).**—First, J. Roe, Hadfield, near Manchester. Second and Highly Commended, J. Fielding, Newchurch.

**GAME.**—First and Second, C. W. Brierley, Rhode House, Middleton. Highly Commended, T. Dyson, Pellon Lane, Halifax. *Chickens.*—First, J. Turner, Radcliffe. Second, A. Nuttall, Mill End. *Hen or Pullet.*—First and Second, C. W. Brierley, Rhodes House, Middleton. Highly Commended, W. Hargreaves, Bacup. Commended, T. Dyson, Halifax; A. Nuttall, Mill End.

**COCHINS.**—First, J. Wood, Brinscall Hall, Chorley. Second, J. Nelson, Heaton Mersey, Manchester.

**BRAHMAS.**—First, W. Hargreaves, Bacup. Second, R. W. Boyle, Galtrin House, Bray, Co. Wicklow, Ireland.

**BANTAMS (Game).**—First, D. Ashworth, Halifax. Second, C. W. Brierley, Rhodes House, Middleton. Highly Commended, R. Tate, Green Road, Leeds.

**BANTAMS (Any other variety).**—First, C. W. Brierley, Rhodes House, Middleton. Master C. H. Hutton, Pndsey, near Leeds.

**ANY OTHER VARIETY.**—First, H. Carter, Upper Thong, Holmfirth. Second, R. Tate, Green Road, Leeds (Black Hamburghs). Highly Commended, C. W. Brierley, Rhodes House, Middleton (Silver Polands); J. Stott, Healy, near Rochdale (Grey Dorplings).

**COCK (Game).**—First and Second, C. W. Brierley, Rhodes House, Middleton.

**COCK (Game Bantam).**—First, C. W. Brierley, Rhodes House Middleton. Second, T. C. Harrison, Hull.

**DUCKS (Aylesbury and Rouen).**—First, E. Leach, Greave House, Rochdale (Aylesbury). Second, J. Nelson, Heaton Mersey, Manchester (Rouen). Highly Commended, E. Leach (Rouen).

**DUCKS (Any other variety).**—First and Second, J. R. Jessop, Hull (Winter Teal and Wild Ducks). Commended, T. C. Harrison, Hull (Brown Call).

**TURKEYS.**—First, J. Wood, Brinscall Hall, Chorley. Highly Commended, E. Leach, Greaves House, Rochdale.

**GEESE.**—First, R. W. Boyle, Galtrin House, Bray, Ireland. Highly Commended, E. Leach, Greaves House, Rochdale.

E. Hewitt, Esq., of Sparkbrook, Birmingham, officiated as Judge.

### SULTAN FOWLS.

NOTICING a query respecting Sultan Fowls or Serai Taooks in your Number of July 25th, I venture to trouble you with a few lines, which may be interesting to the querist.

The original pen imported by Miss Watts was sold to, or exchanged with Mr. Dawson, of Hopton Mirfield, by that lady some years ago. Mr. Dawson bred them and exhibited them with great success. After a while Mr. Dawson finding a difficulty in keeping up without fresh blood, and wishing to give more room to his favourite White Cochins, by a friendly arrangement his entire stock, consisting of an old cock, a younger one, three hens, and three chickens, came into my hands. I was successful in exhibiting them at Islington, Newport, and Brighton, and two pens were claimed at high prices. This left me with only the young cockerel and one superb old hen, when fortune threw in my way a gentleman from the south of Ireland, who consulted me as to the name of a breed of which he had two hens given him by a lady who had them from a ship from the Mediterranean which put into Queenstown. "White-crested, feathered legs, bearded, larger than Bantams." The

description rang music in my ear. "Sultans for a thousand," I thought, "now for the much-wanted change of blood." My informant wanted Buff Cochins, and an arrangement was soon effected for an exchange; but, alas! I could get only one, my friend informing me that the other having become the intimate friend and associate of the mother of certain puppies, and sharing in the maternal cares, his daughter would not part with her at any price. My prize arrived, yellow with Shannon clay, with only half a crest, and generally delapidated, but healthy, and an unmistakably pure Sultan, not a long-legged, taper-bodied White-Poland-looking bird, or a Ptarmigan, by courtesy a Sultan, but the short legs, curiously square body, upright and abundant tail, and five claws of the genuine Sultan—a breed as distinct from White Polands as Game from Dorking. The peculiar hop in the gait of these birds is most striking, and their legs are the shortest in proportion I ever saw. I have twenty-five strong and healthy chickens running about fegged, and I hope to introduce some of them to notice as winners in the Variety class before Christmas has turned.—F. W. ZENROSSER, *Belville, Donnybrook, Co. Dublin.*

#### A PATERNAL BRAHMA.

Many years ago, when I was in conversation with the Rev. G. F. Hodgson, he told me that a Partridge Cochlin cock, which he had imported, would undertake the charge of a batch of chickens. I had never known any of my Brahmas thus anxious to show their paternal affections; on the contrary, if they take notice of the chicken it has been rather by an application of the beak, which tender mercy never appeared to be appreciated by the recipient. This year, however, my old bird had been placed in a yard, where some three or four hens were finishing their maternal duties. To my extreme surprise I found, after a short time, that when feeding was going on he would allow the chicks to take the food out of his beak. I imagine this commenced by his calling the hens, but it has been fully carried out since they have left the yard; and it is decidedly amusing to see him, surrounded by thirty or forty chickens, now picking up a grain for this one and now for another. Not satisfied, however, with this part of the performance, he first allowed the chicks to come against him for warmth, and ultimately to get under his wings—in fact, treat him as their mother. At night the same duty is thoroughly carried out, the united families making him the centre of attraction, some resting on his broad back, heads peeping out from under his wings, and a motley group around him. I had never, as I have already said, noticed this before, either in this cock or in any other, and the question in my mind is, Why is it so? Is old age affecting him? Well, he was hatched in 1862, and is, therefore, now in his fourth year. I am disposed to think this rather old either for a Cochlin or Brahma, and had almost at the beginning of this year made up my mind that the present should be his last year for the stud. His kindness to the chickens has made me waver. He crows as well as ever, is as attentive to any of his ladies admitted to the yard as of yore, and appears every feather to be "monarch of all he surveys," and I am, therefore, disposed still to retain him for another season. Should any of the readers of "our Journal" have had a similar instance I should like to know what they think.

His history during the last few months may offer some solution. Could an old *habitué* of the exhibition tent, as he was, tell whether or no the judge appreciated him, and whether his pen was or was not decorated as it should be? I will not decide this knotty point; but suffice it to say that at the close of the past year he was, for the first time in his life when shown, in first-rate condition, with two splendid partners, unnoticed. Why so I cannot tell. My man Friday "couldn't see the rights on it," and evidently thought it *fool* play. Friday never perpetrates a pun, so he meant it seriously. I will confess that with all my admiration for judges in general, and this identical judge in particular, I felt a shade of dissatisfaction, and can only suppose that his spectacles, if he wore any, dropped off just as he came to my pen; for I hold to this opinion, that though beaten, a thoroughly good pen of birds ought to be commended or more, even if there are a hundred. The next week I sent the same pen somewhat doubtfully to a large show, saw them there myself placed in the worst light of the whole class, still indubitably the best, and the coveted first-prize was there too, with good names not unknown at Birmingham following me. Since then by some accident, he and another

of my birds met on common ground, and, as often happens, age and worth had to succumb to youth and power, and I found my poor old pet crouched under some wood, looking the picture of abject misery, with his rival carrying plenty of marks of the fray, crowing triumphantly alongside. He never recovered his condition as to feather, yet was highly commended at a grand show soon after, where, however, in repucking, he and one of the hens were so roughly handled that a broad bare patch could be easily seen on the back of either, utterly devoid of feathers; so that until moulting is over his chances of prizes are at an end. To-day I introduced some cockerels four or five months old into the yard, but their intrusion he does not tolerate; so that, although he patronises cockerels of two months old, he does not admire strangers of older growth.—Y. B. A. Z.

#### LIGURIAN BEES.

The following is a brief account of what various writers have stated respecting the Ligurian bee:—Aristotle speaks of three different species of the honey bee as well known in his time; the best variety he describes as small in size, round in shape, and variegated in colour. Virgil speaks of two kinds, the better variety he states to be spotted or variegated, and of a beautiful golden colour. Mr. Langstroth gives the opinion of Captain Baldestein, as observed in their own country, that they differ from the common kind and seem to be more industrious, and among the points which he considered as definitely established by his observations on the Ligurian bee are these—1st, the queen, if healthy, retains her proper fertility at least three or four years. 2nd, the Ligurian bee is more industrious and the queen more prolific than the common bee, because in a most unfavourable year when other colonies produced few swarms and little honey, his Ligurians produced three swarms which filled three hives with comb, and together with the parent hive laid up ample stores for winter, the latter yielding, besides, a box well filled with honey, and the three colonies were among the best in his apiary. The workers do not live at most longer than one year; they do not sting so much as the common bee; they are more prolific, and consequently gather more honey; they are hardier, as many of the common bees under more favourable circumstances died out this last winter, and the Ligurians lived and did well. You can go among the Ligurians without being stung, as they seldom attempt to do so if not disturbed, and many of your correspondents who have procured them would not now be without Ligurians on account of their superior qualities.—J. ELMO.

#### AUTUMNAL UNIONS.

Will you kindly inform me how soon it is prudent to unite stocks, so as not to needlessly sacrifice brood? I observe in "Bee-keeping for the Many" that it is spoken of in the calendar under the head of August as well as September. My wish is to effect several unions as early as may be consistent with a due regard to the saving of brood, but I have not had sufficient experience to be competent to judge when this may best be done. May I further ask your kind advice as to the desirability or otherwise of sprinkling bees to be united with sugared beer? Taylor recommends it. "Bee-keeping for the Many" makes no mention of it, but says (I quote from memory), that after knocking the driven bees out and placing the stock hive to which they are to be united gently over them, they will quickly ascend, and all will be peace and harmony. If the sprinkling process may be safely dispensed with I should prefer it.—G. S. C.

[Unless you defer the operation until very late in the season you must expect to find more or less brood. We, therefore, never hesitate, but always utilise what brood-comb we find by giving it to some of our stocks to hatch out. In moveable comb-hives this is readily done by attaching it to bars in the manner described in page 18 of the fifth edition of "Bee-keeping for the Many," and placing it within the hive itself. Where there are no bars but merely a hole in the top, the brood may be placed in its natural position in a bell-glass or other super, and this being put over the aperture in the top of a strong colony, sufficient bees will usually ascend to hatch out the whole. Sprinkling with syrup is not always essential to a successful union, but we do not deem it advisable to neglect it. Simple syrup scented with a little peppermint water is, however, much better for this purpose than sugared b.e.r.]

## THE MASSACRE OF THE DRONES.

[From the German of KARL ENSLIN.]

By "A DEVONSHIRE BEE-KEEPER."

The insect monarch thus commands,\*

(Herself such idlers scorning),  
"Let ev'ry drone at once depart,  
Nor look for further warning."Her warlike amazons prepare,  
And from their tents proceeding,  
With lances keen the *mêlée* join,  
No second order needing."Turn out, turn out, ye idlers all!  
We feed you now no longer.  
The lazy ask in vain for food,  
Unless they be the stronger."The sturdy drones themselves defend,  
Their heavy weight opposing;  
But yield at length to arms and skill,  
And numbers round them closing;Whilst those who on the battle field  
Their latest breath are sighing,  
Are by the victors dragg'd away,  
The dead as well as dying.The remnant at the frontier wait,  
In vain imploring pity,  
Remorselessly they're left to starve,  
And die without the city.Now in the hive is sloth unknown,  
Of labour none are sparing;  
Some guard their home, some range the fields,  
Honey and wax preparing.

T. W. WOODBURY.

Mount Radford, Exeter, 3rd August, 1865.

## BEE-KEEPING IN SOUTH LANCASHIRE.

I HAVE nothing new to tell my fellow bee-keepers. I simply write because it may be interesting to some of your readers to know how "the busy bee" fares in South Lancashire, and because I want to ask you a question or two respecting the future management of my hives.

First, I ought to remind your readers that we are less happily situated as bee-keepers in this neighbourhood than our friends in agricultural districts. Within a circuit of ten or twelve miles five or six large manufacturing towns are included, of which Manchester is one; and then, also, our climate here in the north-west is very much less favourable than in the south or midland districts; though this year I must own we have had but little to complain of the rain, and fog, and dampness for which Lancashire is famous.

My apiary consisted at the beginning of the year of no more than three hives, of which two (swarms of last year) seemed pretty strong, the third, an old stock, quite weak. I intended to allow the stronger hives to swarm, and prevent the weaker one, in which plan I did not succeed. My first swarm, which weighed upwards of 4 lbs., was hived on the 23rd of May, and was the first of which I have heard in this neighbourhood. I placed it in one of Neighbour's common cottage hives, and it has twice filled the straw super with beautiful virgin honey, and has made some comb therein, and stored a little honey a third time. The second swarm from No. 1 issued June 7th, and was given away. I hear that it has filled a good-sized hive, and begun to work in a bell-glass. Hive No. 2, threw a swarm of 4 lbs. on June 6th, which I placed in a wooden-frame hive. They have stored a good deal of honey in their hive, and I have taken in bell-glasses about 6 lbs.

A second swarm from No. 2, weighing 3 lbs., was hived June 20th, and I think has done fairly, increasing in weight some 8 or 9 lbs. I put bell-glasses on No. 3, to prevent swarming, but unfortunately without success. They stored 3 or 4 lbs. in the glasses, and then on July 3rd threw a swarm of 4½ lbs. Happily bad weather prevented a second swarm issuing.

You will see that I have increased my stock from three to seven hives, besides giving away a swarm, and have taken 18 or 20 lbs. of honey. Do you advise me to be greedy, and try for some more, by sending my hives to the heather? I have done so three years in succession, and each year have

\* This is, of course, mere poetical license; most persons are now aware that the queen or rather mother-bee never really "commands" the workers.

received my hives no keener than when I sent them, and this has disposed me to keep them at home this year. Again, I have been accustomed to drive two hives together on receiving them from the moors. Can I do this if I keep them at home? Will not the bees which have been driven return to the place where their hive used to stand, instead of to their new hive?

My last question is on a point on which I should like to hear the opinion of some of your readers. We have had some very hot weather this month, and, consequently, a good deal of honeydew. Do the bees work on this? Books tell us they do, but I have never seen them do so, though I have watched pretty closely the trees where there seemed most. I am anxious to know if any bee-master has seen that which I have been unable to see.—A SOUTH LANCASHIRE BEE-KEEPER.

[We can scarcely advise you with regard to sending your hives to the heather, but after failing three years in succession we should be rather inclined to give it up. You need not hesitate about uniting your stocks by driving, merely taking care to "marry" those that are nearest to each other. Hives increase very rapidly in weight during honeydews, but bees are so seldom seen collecting the sweet deposit or exudation, that we ourselves have witnessed the fact but once.]

UNPLEASANT NEIGHBOURS.—In the garden of the Rev. Arthur Roberts, Rector of Barkham, Berkshire, is a rustic and movable dovecot, in which are domiciled a considerable family of beautiful white Fantail Pigeons. In one of its compartments may be seen a hen Pigeon sitting closely on her eggs, and in the compartment, immediately beneath her, a large swarm of hornets busily engaged from morning till night constructing their nest or comb.—(*The Age We Live In.*)

## OUR LETTER BOX.

LEG WEAKNESS (*W. H. Fell*).—In addition to the treatment so judiciously recommended by "our Editor," I would advise you to mix with the soft food, two or three times a-day, five or six grains of phosphate of lime, which you can obtain at any chemist's.—Y. B. A. Z.

AGE AT WHICH HENS CEASE TO BE PROFITABLE (*Isa*).—By laying, we understand the production of eggs irrespective of breed. For such a purpose we would not keep hens after their third season, but if the hen were valuable on account of her breed or beauty, or if she always bred good chickens, we would not hesitate to keep her for five or six years.

DORRINGS DYING SUDDENLY (*W. W.*).—If this is a common occurrence, you will, we think, find there is something poisonous about the place. If it has only occurred to two or three, it is merely one of those curious things we cannot explain. Your feeding is judicious and cannot cause it. Put some lumps of camphor in the water they have to drink.

POINTS OF ROSEN DUCKS (*R. M. D.*).—Size is a most essential point in Rosen Ducks; and they must be as nearly as possible the wild Duck in plumage of both sexes. The points in which exhibitors fail most, is in the colours of the bills. Blue, leaden, and green are disqualifications in the Ducks. That of the drake must be a mixture, as though the foundation were gamboge washed over with a light tea-green so lightly as to show the yellow through the green.

POLANDS LOSING THEIR TOPKNOTS (*G. I. N.*).—It is more than probable the birds pick the young feathers out of each other's topknots. They commonly do so, and the patient seems to like the operation. Rub heads with compound sulphur ointment. If that does no good, you must separate them till the feathers are sufficiently grown to hide the skin, you will have little difficulty afterwards. When the topknots are very large, and in damp and dirty weather, it is a good plan to confine them with an elastic band.

COLORS OF DORRINGS' EGGS (*F. H.*).—In a yard full of the purest Dorrings in England, we find every shade from dark cream, almost brown, to dazzling white. We know not the cause. The condition of the shell is entirely subject to the state of body and health of the bird. The same hen will sometimes lay soft eggs, and at others good hard shells.

GOLDEN-SPANGLED HAMBURGS (*Scotchman*).—A Golden-spangled Hamburger to have any pretensions to be a prizetaker, must have a white deaf-ear. There are all sorts of fowls in Yorkshire and Lancashire, offshoots of Hamburgs, that are called by all sorts of names; but if a man advertises "Golden-spangled Hamburgs," he is bound to sell them, and not "Moonies."

TREATMENT OF FOWLS BEFORE EXHIBITION (*Eboracum*).—Fowls for exhibition should, with the exception of Spanish, be allowed to run. They should be well fed on ground oats slaked with milk, whole corn occasionally, scraps of bread, refuse of cooked meat from the table, &c. Spanish should be shut up in a partially darkened place for a week before being exhibited. All birds should be scrupulously clean when they are exhibited. The basket in which they are packed should be large enough to prevent the feathers from being broken. The light Cinnamon cock would not spoil the chickens for exhibition.

TAKING BEES FROM A ROOF (*Dalton*).—Yours is just one of those cases requiring the services of a skilled bee-master fertile in resources, who would modify and adapt his proceedings to the exigencies of the moment. Speaking generally, we should say that the best plan would be to use only sufficient smoke to intimidate the bees, and then cut out and remove the combs one by one with the bees adhering to them. If, however, the queen should escape and the bees return to the old spot in consequence, they might possibly be induced to take possession of a box or small hive that would enter the aperture and might then be removed in the evening.

AVERAGE PRODUCE OF A CONDEMNED STOCK AND SWARM (*B. B.*).—If they average 20 lbs. of honey from each we think they will do very well.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 72.9°, and its night temperature 50.8°. The greatest heat was 92°, on the 18th, 1842; and the lowest cold, 32°, on the 21st, 1850. The greatest fall of rain was 1.12 inch.

THE CULTURE OF THE STRAWBERRY.

THROUGHOUT the land, except in a few places, the cry has been, "The Strawberry crop is a complete failure." With me it has been quite the reverse, for I never had, and never saw, such an ex-

traordinary crop as my beds have produced this season. The kinds I grow are Sir Harry, Sir Charles Napier, Comte de Paris, Keens' Seedling, Reeves' Eclipse, Carolina Superba, and Cuthill's Black Prince; these have all done equally well.

I think the cause of the failure may, in many instances, be attributed to two circumstances, each of them most important in the successful cultivation of the Strawberry. The first is, that in preparing the ground the soil has not been trenched sufficiently deep, and the manure, instead of being put into the bottom of the trenches, has been mixed with the soil near the surface. When this is the case most of the roots remain near the surface, and the consequence is they are soon dried up by the sun in a hot and dry season like the present. To prevent this, my mode of preparing the ground for the Strawberry is as follows, and I adopt the same principle with most kinds of vegetables, and for flower-beds as well. In the first place I trench the soil as deeply as possible; if I can go to a depth of 2 feet 6 inches or 3 feet without bringing any clay, sand, or other bad soil to the surface I do so. For Strawberries I put 2 inches of good rotten manure in the bottom of every trench, and this is done with the whole of the piece of ground intended for the Strawberry plantation. The manure being placed in the bottom of the trench the sun, however hot and dry the weather may be, cannot injure the Strawberry plants, for the roots will naturally go down in search of the food. They are therefore secure from injury; and the amount of moisture they receive with their food enables them to withstand any amount of dry weather, if the next important operation in connection with their successful cultivation has been properly attended to, which is mulching them in autumn to prevent injury from frost, and early in spring to prevent evaporation during summer. I find the best material for this purpose, is partly decomposed leaves at the autumn mulching, and for the spring dressing slate marl. I know this is not to be obtained in many parts of the kingdom, but where it can be had it is the finest substance possible for them, especially if the soil is light; it keeps the ground cool and moist, and if the lumps are put pretty thickly between the rows early in February or March they will become pulverised before the plants come into flower, when the small pieces of marl should be spread evenly all over the surface of the beds, taking care

that the ground is nicely covered all round the plants. This is best done by going over the beds after the marl has been spread, and holding the leaves of the plant in one hand, and scraping the small pieces round the plant with the other. Where marl cannot be had, use the same material for the spring mulching as that recommended for the autumn.

Now is the proper time to prepare the runners; these should be taken off, and pricked-out in beds of good rich soil, about 3 inches apart, in rows 6 or 8 inches asunder. They should remain in their nursery-beds till about the end of February or beginning of March, when they should be planted in the permanent beds. By this time they will have made good strong plants, and if enough young plants have been pricked-out in the autumn none but those really good and healthy need be put in the permanent beds.

When the beds are planted permanently in the autumn the young plants are not sufficiently developed; hence it often happens that many blind plants are seen in the beds, which makes these appear unsightly, besides causing a waste of space. In preparing the young plants it is a good plan to leave an inch or two of the runner attached to them. If they have not good roots when they are taken off this helps to keep the plants firm in the ground, if the soil is nicely pressed about them when they are pricked-out. I like spring planting too, for this reason—the slight check the plants receive does them good, and the number of roots which they emit after the second planting is double that of plants put in permanently in autumn. Nearly all the points of the roots are broken off in removal, so that the plant has double and treble the number of main roots to establish itself with when it is finally planted in the permanent bed.

I consider fresh beds should be made every year. I never allow a bed to remain after the third year. I arrange my Strawberry ground so that I can destroy two or three beds, and make the same number each year. Under this system the beds are always in the best possible condition.

In order to keep the fruit clean, instead of using straw or litter for the berries to lie on, I have a lot of sticks prepared; these are stuck in around the plants soon after they have done blooming, and some small twine is then wrapped around them in two places, of which one is about 3 inches from the ground, and the other at 5 inches. This plan, although it is rather more troublesome at first, saves time in the end, and it has many advantages over the old system. 1st, It saves the fruit from being spoilt by lying on the damp straw, and the fruit will also hang longer on the plant because the air can circulate more freely amongst them, and in damp weather it prevents their tasting of the straw; 2ndly, the Strawberry season is prolonged ten days or more, because the ripe fruit can be gathered more readily without injury to the young green fruit when they are resting on the strings in the manner described above; and 3rdly, a bed of Strawberries when tied-up in this way presents a most beautiful appearance. I should mention that in putting the string around the sticks it should be hitched once round each stick, and about five or six sticks are required for each plant. I use Willow twigs after they have been cut a few months, as they are more easily cut out,

and present a neater appearance. Another year I shall have the sticks and strings placed around the plants before they open their blossoms, for the scapes will the more readily take their proper positions, and the operation can be performed with greater care and with less injury to the scapes and young fruit.

Carolina Superba and Sir Harry are, in my opinion, the best two Strawberries at present in cultivation. The former far surpasses the old British Queen in point of flavour, and for the four years that I have grown it the plants have done well and cropped very abundantly. Sir Harry is the next best, it continues fruiting about ten days longer than Carolina. We have had very fine fruit of Sir Harry till very recently. The last dish was gathered only a week ago (end of July). From two-year-old plants of Eclipse we have gathered wonderful quantities of fruit. On many of the plants there were as many as thirty-seven fruit-stems.—J. WILLS.

#### AWARDS AT DONCASTER HORTICULTURAL SHOW.

I ENCLOSE you a schedule of the Doncaster Show, and will be much obliged for your opinion or that of any of your correspondents as to what the class for handsome-foliaged Geraniums should be. The words of the schedule are "a premier prize for the best twelve distinct varieties of handsome-foliaged Geraniums." I exhibited the following twelve sorts:—Roi d'Italie, Mrs. Kingsbury, Mrs. Pollock, Italia Unita, Fontainebleau, Glowworm, Countess, Adonis, St. Fiacre, Eugène Negrier, Picturata, and Sunset. These were disqualified for not being according to schedule, and I have not yet had anything like an explanation why.—G. EDWARD, *York*.

[Our opinion is, that if the line is correct "a premier prize for the twelve best distinct varieties of handsome-foliaged Geraniums," and there is nothing else in the schedule to render that statement more definite, then there could be no reason for disqualifying the varieties sent, though there might be reason for not giving them the prize. The words "distinct" and "handsome" leave a wide margin, and much to the taste of the exhibitor. We meet with people who prefer the bold horseshoe leaf of Village Maid, and the small dark leaf of Baron Hugel, to Mrs. Pollock, Italia Unita, and Golden Chain. The Judges might have good reasons for passing by a collection; but, without more than we know from the above line, we do not see the reasons for the disqualification.]

#### ON AND ABOUT THE ROCKS AND SANDS OF TENBY.—No. 2.

ONE more note in addition to those I gave last week, and then I will pass to other topics from the still-retained connection of plants with old British customs, and this last note is on the old Oak which stands on Penallt Common, far away on the banks of the Wye. It is a noble specimen of our representative tree, on a well-wooded eminence in the rear of the church. Beneath that Oak is a stone seat, and every corpse on its way to burial is set down on that stone whilst the mourners sing a psalm, significant that their dead friend has triumphed over man's last enemy. I have no doubt that this practice is a remnant of that wise accommodation of Christian to Druidical practices which tell of the earnest good sense which characterised the first promulgers of our faith in these islands.

Let me now jot down some notes on the climate of Tenby and its consequences. Lying high and extending out into the sea. Tenby has a more than average amount of wind; yet a good observer, and not locally interested, remarks, that being more exposed than Torquay to the influence of the gulf stream, Tenby has a slightly warmer midwinter, whilst from its high and more northern locality its summers are rather less hot. The differences between the day and night temperatures are also somewhat less. The mildness of the winters is sufficiently testified by the Hydrangeas, Fuchsias, Myrtles, and Verbenas, remaining in the borders uninjured throughout the year. The geniality of the whole year's climate is told by the general luxuriance of vegetation, and the numerous native plants not found where our winters are felt more severely. The Ferns are particularly fine and abundant, and searching for these I wandered on, during the first day of

my sojourn, through deep narrow lanes with luxuriantly-clothed banks, until I came to a residence where surely dwells some banished one, or some modern Timon, some misanthrope, some one disgusted with a world that has played him false.

At the bottom of a deep declivity I saw a stream rippling along; a little lower down it was crossable by a rustic bridge; but this was so tastefully constructed that I could not reconcile it with rusticity. On I went, and every step showed more and more of civility, a good well-kept road, mown banks, Fuchsias, evergreens, and then an unmistakable evidence that an Englishman was lord-paramount there, for on a board with bulldog brevity was inscribed, "PRIVATE." Thus brought to a standstill I sought and found a path permitted to be trodden, and this, one of the narrowest and deepest, I traversed until, passing under an old Ivy-clad arch, I emerged upon the sands of a little rock-enclosed bay. At the head of this, by the side of a waterfall, stood the cottage villa, none other near, and looking as if "Welcome," ought to be a more desirable word than "Private," to inscribe over its entrance-gate. It is a hermitage without the name, for it is known as Waterwinch. With rocks around and the sea in front, I had forced upon my memory the poet's query—"Does here some gloomy outcast sleep?" But the owner was saved from a totally unfavourable estimate (and "Y. B. A. Z." will say I am right), by my seeing on the grass plat a group of good dark Brahma Pootras. Then there is another pleasing association with the place, for Blechnum boreale, or Northern Hard Fern, is found in its hedgerows. I never saw finer specimens, and I never gathered any before, for it is not now as it was in Gerarde's time, when, he records, "on a heath by London, called Hampstead Heath, it groweth in great abundance." The fertile fronds of the specimens I gathered are 2 feet high, and the barren fronds 18 inches.

Let me here record, with commendable self-complacency, that there were twelve fertile fronds and ten barren fronds, and that I took only two of each. If collectors would remember that there are others having a similar need, we should not hear such complaints of species no longer to be found in certain localities, nor have to listen to such speeches as—"I dare not tell where I found it, for if I did it would soon be extinct there."

Contrasts are often as pleasing as harmonies, especially when you pass from the beautiful wild to the beautiful cultivated; and such I found the transition from the Waterwinch to Penally. This is a dot of a village of wide-apart cottages and residences scattered among many old trees on a steep declivity facing the south, open to the sea, and sheltered behind by the high limestone formation. What a place for blooming Camellias in the open air, one would think; but, strange to say, I could not discover one. Yet good gardening guided by good taste is there.

I was told that a fernery in this village was worth seeing, nor was the information deceptive. The gardener was not to be seen, but a young lady ceased from flower-gathering, and advanced and offered to be my guide with that sunny look and kindly speech which make the stranger feel he is not intruding. We passed up a slope, skirted a well-kept geometric flower-garden, by a small vinery and melony, caught a glimpse of some more than ordinary standard Fuchsias, and arrived at the entrance of the remains of an old chapel. Near it stands a portion of a ruin surmounted by one of those round chimnies, now mantled with Ivy, so numerous in Pembrokeshire, testifying of the architecture prevalent in the middle ages. The chapel is known as St. Daniel's. I hope that that Saint presided over Ferns—and I think he must, for never were they more luxuriant or better-growing than those now within his sanctuary.

I would only take a hurried glance at them, for my obliging guide was interrupted in arranging bouquets to decorate the inauguration ceremony I mentioned in my commencing notes; so I soon made my best bow of withdrawal, and begged my thanks and card might be presented to the proprietor. That proprietor, Miss Robson, most kindly invited me and mine to repeat the visit; and then I had full leisure to inspect not only the fernery, but the garden, and to search among the wild plants of the vicinity.

The walls of the old chapel are perfect—even the tracery of its east window remains, and that window with good taste is now partly filled with stained glass. No vestige of the old roof remains, and Miss Robson has had it replaced by one of glass. In the centre is a tank of water, around which is rock-work, between which and other rockwork and the border adjoin-

ing the walls is the path. Without a single exception the Ferns in tank, rockwork, border, and walls are more vigorous, and grow more as if they enjoyed growing, than in any other fernery I ever visited. The Ferns on the walls are the best evidences of this, for they are the progeny of the species cultivated in the border and rockwork. These have all ripened their spores, and wherever these are dispersed, there they vegetate; and the moist air, the subdued light, the genial temperature, and the good cultivation, make them flourish as well as they could flourish in their fatherland.

They are not merely Ferns of everyday occurrence, but many of them of the rarer and less easily cultivated species. However, that my readers may judge for themselves, here is a list of them:—

<i>Acerophorus hispidus</i>	<i>Gymnogramma chrysophylla</i>
<i>Adiantum capillus-Veneris</i>	<i>peruviana, var. argyrophylla</i>
<i>cultratum</i>	<i>Wetenhalliana</i>
<i>eucneatum</i>	<i>Hymenodium erinitum</i>
<i>curvatum</i>	<i>Lastrea Filix-mas, var. cristata</i>
<i>macrophyllum</i>	<i>glabella</i>
<i>pedatum</i>	<i>Lygodium japonicum</i>
<i>pubescens</i>	<i>volubile</i>
<i>rhomboidcum</i>	<i>Nephrodium exaltatum</i>
<i>trapeziforme</i>	<i>Onychium japonicum</i>
<i>varium</i>	<i>Phlebodium sporocarpium</i>
<i>Angiopteris erecta</i>	<i>Platyoma cordatum</i>
<i>Asplenium bulbiferum</i>	<i>Peleopteris leiobiza</i>
<i>dimorphum</i>	<i>Polystichum angulare, var. Wol-</i>
<i>flaccidum</i>	<i>lastoni</i>
<i>racibirizon</i>	<i>Pteris arguta</i>
<i>Cheilanthes dealbata</i>	<i>argyrea</i>
<i>elegans</i>	<i>cretica</i>
<i>Cyrtium falcatum</i>	<i>cretica albo-lineata</i>
<i>Davallia dissecta</i>	<i>longifolia</i>
<i>pentaphylla</i>	<i>tremula</i>
<i>tennifolia</i>	<i>tricolor</i>
<i>Gleichenia microphylla</i>	<i>Stenochleena tennifolia, var. na-</i>
<i>Goniophlebium appendiculatum</i>	<i>talensis</i>
<i>subauriculatum</i>	<i>Woodwardia radicans</i>

Of Lycopods there are—

<i>Selaginella cæsia</i>	<i>Selaginella obtusa</i>
<i>densa</i>	<i>stolonifera</i>
<i>delicatissima</i>	<i>Wildenovii</i>
<i>lepidophylla</i>	

What else I saw and gained must be left untold until I can again sit down to make further jottings.—G.

MILDEW ON ROSES.

I HAVE read "A COUNTRY CURATE'S" article at page 105. Mildew, or more properly white fungus, has affected my Roses this season but little, and that chiefly under hot walls. My Roses in both my gardens, respectively with west and north-east aspects, on the briar, on their own roots, and on the Manetti, have suffered immensely from orange fungus, which, as the nucleus is formed on the under side of the leaf, is more difficult to cure than white fungus, known as mildew—literally honeydew—which occurs chiefly on a new branchlet and foliage, on the upper sides of the leaves. As regards orange fungus, I at first attempted to stop it by the removal of the diseased leaf; but on examination of my plants I found it so abundant and universal that I gave it up. It ran its course; and though I had a magnificent first bloom, the fungus spread so thoroughly over the leaves as to destroy them in detail. The plants are now new-foliated and doing well, and I expect good and continuous full bloom. The Manetti Roses only ceased blooming about one week.

I pass from orange fungus, skipping over "black patch," of which I have had none this year, to speak of mildew. Mildew is called the "daughter of drought." Why so? Not because drought is a "creator of the fungus," but an assistant to its rooting and development. If Rose plants were always sufficiently supplied with water at the roots, and the spores continually washed off the leaves, the fungus could not take root. For lack of these two conditions mildew has been called the "daughter of drought." As well may we say it was the daughter of "the fortuitous concurrence of atoms." Drought predisposes or prepares the tree for its rooting; and the atmosphere, such as would be suitable for Mushrooms, aids its development. When the roots are not sufficiently supplied with water, the juices of the tree eliminated at the leaves (new leaves), become sticky, and cause the fungus to adhere; and in due time, the tender leaves being spongy, and not firm and close in texture, the fungus roots into the leaves. This is the real reason why mildew should be called the "daughter of drought." The leaves of some sorts are closer than others.

The glazed or semi-glazed leaves, such as Duchess of Norfolk, Solferriere, and Triomphe de Rennes, have suffered nothing from any kind of fungus. In both my gardens the hard-leaved Duchess has retained the beauty of her foliage. I cannot remember ever seeing her with blight or fungus of any kind. The Roses most subject to mildew of any here are the Géant and Baronne Hallez. Still, if the fungus is about or floating in the air, it will, if it pitches on the tender and sticky follicles of any Rose, abide there, unless washed off, till the atmosphere favours its rooting and development.

Prevention is better than cure: therefore keep the plants watered at the root and syringed over the leaves. I may say, in passing, that the miseries of trees or plants, whether out of doors or under glass, arise greatly from not keeping the foliage clean. Where people have only a few Roses to attend to, the best way to stop it is to rub it off with the thumb in its early stage before it has rooted deeply into the leaves. Even then you can destroy it by so doing, or it might be sponged off. Young pot plants reared under glass usually come with fungoid disease, imperceptible to the eye, about them. These should be kept well syringed, and should not be planted under hot walls, or in situations that are not airy. Sulphur, I see, is recommended; but sulphur, unless quickly washed off, will do the same mischief as the fungus: it will stop the pores of the leaves, and, if the weather is very hot, it will burn the foliage. An astringent lotion is best. The two ounces of blue vitriol should be thoroughly dissolved with hot water, and then added to the cold. I never knew it affect the leaves, as stated by "A COUNTRY CURATE." Gishurst compound I have never tried. I have seen high testimonials in favour of Toogood's liquid, but this I have never used.

As regards stocks, I imagine that there is but little difference. I have a lot of fine plants of Souvenir de Malmaison on their own roots, and also on Manetti, under my south wall. They suffered much and alike; I could see no difference. It depends, I believe, chiefly on the state of the plant, its foliage, and atmospheric circumstances. In the human body we know there are at times predisposing causes to fungoid diseases.

In conclusion, if "A COUNTRY CURATE" had not speedily washed off Gishurst compound he would probably have had to make a complaint; and had he thoroughly dissolved the vitriol with hot water, so as to leave no grit, he would not have had to complain of a simple, safe, and efficacious cure.—W. E. RADCLIFFE, *Tarrant Rushton.*

BEDDING ANNUALS.

In seedsmen's catalogues, and in your advertising columns, I have often seen annuals recommended for bedding purposes, but with the exception of one or two kinds, I myself have never been able to obtain satisfactory results with them. It was, therefore, with considerable anticipation of pleasure that I resolved to visit the collection of annuals which Messrs. Hooper advertise to be seen in "the gardens of the Royal Horticultural Society, South Kensington, where their beauty and adaptability as bedding plants is successfully illustrated." I have paid my visit, and return appreciating more than ever the force of that unrecorded heatitude, which blesses him "who expecteth little, for he shall not be disappointed." I doubt if there are many lovers of the well-abused bedding system who would be pleased with that modicum of success which satisfies the Messrs. Hooper; and yet I fear that as a rule greater success is not to be attained with annuals alone.

There is, however, among Messrs. Hooper's beds one filled with *Linum grandiflorum rubrum*, which, from its mode of cultivation, presents an undeservedly shabby appearance. The *Linum* appears to have been treated as a half-hardy annual, sown under protection, and planted out; it was planted too thinly at first, and it shows this all the more where plants have died too late in the season to be replaced. I find this *Linum* does best treated as a hardy annual; I sow in rows 12 inches apart, and if the seed does not germinate regularly, take plants from where they have come up thickly to where the rows are thin. Early in the summer, before the Geranium and Verbena beds are well filled up, the rows in my bed of *Linum* have ceased to be visible, and the plants are a mass of bloom; and late in the autumn, when other beds are bare, the *Linum* still sends out fresh crops of blossoms whenever the frosts permit. I know nothing more gorgeous than this plant on a bright sunny morning when it is properly massed, and it would, I am sure, be much more extensively used if it were only

customary to treat it as hardy, and to give it a chance of filling its bed. I have, probably, ten plants on the same space of ground that is occupied by only one of Messrs. Hooper's; but I can assure your readers that they will be well repaid their outlay of an extra shilling for seed by the difference of result which such an outlay will produce.—MONTICOLA.

### BATTERSEA PARK.

GREAT credit is due to the First Commissioner of Her Majesty's Works, &c., for the manner in which he has beautified the naturally low and swampy ground of Battersea Park. It is only a few years since it was the resort of wild fowl, and only celebrated as a shooting ground, with a trap at one end of a string, and a sportsman at the other ready with his gun to shoot the bewildered pigeon when it issued from its prison. Thanks to the ruling powers and to Mr. Gibson for the change that has taken place, we now see more intellectual recreations for all classes than the Red House provided.

Having entered the Park at the west gate we find seven long beds like the spokes of the half of a wheel, the centre being a circle representing the nut of the wheel. It is edged with *Stachys lanata*, then come two circles of yellow *Calceolarias*, and two circles of *Mountfordii Geranium*, with a dot of *Centaurea candidissima* in the centre. Two beds at opposite sides, to match, are edged with *Stachys lanata*; then there are two rows of Scarlet *Geraniums* at each side; and at the broad end, in the middle, variegated *Veronica Andersoni*. Two beds have two rows of *Coleus Verschaffeltii* at each side, next Flower of the Day *Geranium*, and then *Mountfordii Geranium*; and then there are two beds edged with white *Centaurea*, and then comes *Trentham Rose Geranium*. The centre bed is edged with *Daybreak Geranium*, and consists of *Coleus Verschaffeltii*, then *Magenta Geranium*, with two or three rows of variegated *Veronica Andersoni* in the centre. On the left is a splendid circle composed of *Iresine Herbstii* edged with white *Centaurea*.

On the south side of the refreshment-room is a fine display; standing in the centre on each side are match beds in this crescent-shaped parterre. The first two beds are planted with an edging of *Golden Harkaway Geranium*, then come a row of *Daybreak Geranium*, and four rows of *Lady Middleton Geranium*. The next are circles edged with *Bijou Geranium*, with the centre of *Scarlet Globe Geranium*. The next are two rows of *Mrs. Milford Geranium*, with four rows of *Lord Palmerston Geranium* in the centre. The circular beds have *Gold-leaf Geranium* as an edging, and *Lobelia speciosa* in the centre. The next consist of two rows of *Cloth of Gold* as an edging, two rows of *Coleus Verschaffeltii*, and four rows of *Christine Geranium* in the centre. Again, we have circular beds with a row of *Mrs. Milford Geranium* as an edging, and four rows of *Madame Vaucher Geranium* in the centre. The end beds are edged with *Lady Plymouth* and *Oriana Geraniums*, and have four rows of *Cybister Geranium* in the centre. The borders that surround this crescent, and at each side of the broad walk leading southwards, are planted ribbon-fashion with three rows of *Lobelia speciosa*, and three rows of *Daybreak Geranium* intermixed, then two rows of *Christine Geranium*, two rows of yellow *Calceolaria*, two rows of *Lady Middleton Geranium*, and two rows of *Stella Geranium*, backed by *Chrysanthemum pinnatum*. The golden foliage of the *Geraniums*, the taste displayed in the arrangement of the colours, and the correct knowledge as to the probable heights of the plants, have contributed to produce a gorgeous effect.

On the right is a bank planted with a serpentine border of *Cerastium tomentosum*, about 2 feet wide, with small circular and semicircular beds running through it in the middle planted with *Harkaway* and *Pink Geraniums*, and others. It is a new idea for bordering, which I have no doubt will be extended and improved upon. Mr. Gibson, although the last to enter the field, is the first to lead the fashion; his gold and silver leaves give to his beds and borders an oriental richness not to be found elsewhere. I recollect having seen at Chiswick (then under the superintendence of the late Mr. McEwen), a border of annuals in which the circles along the centre were planted with different sorts, and around the circles were squares of other colours. Mr. Miller was carrying out the same system last year on a border at Coombe Abbey.

I will now proceed on the broad walk leading south to the sub-tropical garden, but leaving its details to other hands, my remarks on this part of the grounds will be brief. There you see the *Banana* or *Plantain*, the *Indianrubber*, and the

*Brazilian Dragon Tree*, the *Rice-paper Plant* of China, and a host of other plants belonging to warmer climes than our own, but on these I will not dwell. In a long narrow bed I noticed several of *Beaton's* seedling *Geraniums* sent out this season by Mr. W. Paul, and among others *Black Dwarf*, flowers crimson scarlet, a true *Nosegay*, useful for small beds on account of its close dwarf habit; *Duchess*, flowers rosy lake, of dwarf habit; *Donald Beaton*, flowers orange scarlet, a good variety; *Amy Hogg*, flowers bright purplish rose, a strong, free-growing Hybrid *Nosegay*, the leaves slightly zoned, very distinct, and attractive; and *Scarlet Gem*, flowers bright orange scarlet with white eye, dark horseshoe leaves, valuable for the mass of colour it produces. The triangular-shaped portions were planted with *Queen of Queens Geranium*, scarlet flowers with white margin; *Sulphurea marginata*, *Variegated Beauty*, *Nymph*, and *Glowworm*, the latter has fiery scarlet top petals, lower petals magenta, flushed with crimson. To my fancy the handsomest bed in the place is a small circle planted with the *Dragon Tree* of Australia in the centre, then *Begonias*, four or five plants of *Dracana ferrea variegata* and *Cooperi*, edged with white *Centaurea*, and carpeted with *Sclaginella denticulata*.

It is delightful to see the interest the people take in the plants here, many with pencil and paper noting down the names. Mr. Gibson originated the happy idea of planting a sub-tropical garden in the open air, and the people flock to the park to see these inhabitants of foreign climes as, for a similar reason, they go to the zoological gardens to see the specimens there exhibited from all parts of the world. All tends to the enlightenment of the present generation. Many tropical plants, which at their first introduction were kept entirely in stoves, are now planted out without any abatement of growth or diminution of beauty; and from this we may reasonably hope that some tropical fruits may in time be so far assimilated to our climate as to ripen in our ordinary summers. Mr. Nickson, when at *Pepper Harrow*, turned out of pots in June some fruiting *Pine* plants into a prepared border of loam and leaf mould, and in September they were ripe. Although the weather that summer was unfavourable for the experiment, the flavour of the fruit was pronounced by competent judges to be considerably superior to any fruit grown under glass. Our hope now rests with Mr. Gibson, if sufficient means be afforded him, of seeing Sir Joseph Banks's prophecy fulfilled, that "ere long the *Akee* and the *Avocado Pear* of the West Indies; the *Flat Peach*, the *Mandarine Orange*, and the *Litchi* of China; the *Mango*, the *Mangosteen*, and the *Durion* of the East Indies, and possibly other valuable tropical fruits, will be frequent at the tables of opulent persons, and some of them, perhaps, be offered for sale on every market day in *Covent Garden*."

I hope to see the day when it will be considered safe to remove the iron hurdles in the sub-tropical and other departments of the Park, and allow the public to saunter around the beds and borders. To judge from what I see, I think the people seem to be so grateful for what has been done for their recreation, delight, and instruction, that they would protect the flowers and shrubs from damage in their own parks. The danger of mischief would arise more from the large circumference and sweeping trains of the ladies' dresses than from any other cause. I am glad to see the names attached to the plants in the sub-tropical department, but some are so far from the walks that it is almost impossible to read them.—WM. KEANE.

Although the general features of the sub-tropical department have been ably depicted by "D., Deal," at page 83—so well indeed that little more is left now but to describe the details; yet these may not be without a certain degree of interest as showing more fully the plants which Mr. Gibson employs, and the way in which they are arranged. The effect produced by hundreds of *Indianrubber* trees, *Caladimms*, and *Cannas*, by noble-leaved *Wigandias*, *Solanums*, *Aralias*, and *Tobaccos*, with tree *Ferns*, *Dracenas*, and many other exotic plants, is so different from that produced by ordinary bedding, so different from the garden scenes to which an English eye is accustomed, that any mere description must fail to give an adequate idea of the reality.

Starting from the entrance of the sub-tropical garden on the north, or river, side, and passing circles in which are *Bambusa gracilis*, a plant of graceful habit and so hardy that it has stood out of doors for two winters, and some other plants for trial; next comes a group of *Cannas* in a circular bed, *Canna discolor*, a noble kind with the ample green foliage barred with a dark copper colour approaching the hue of the *Purple Beech*, being in the centre, with *Canna floribunda* for an edging. Adjoining

this group is a bed of *Lomatia ferruginea*, a Proteaceous plant with very handsome bipinnatifid leaves of rusty or ferruginous hue, whence the specific name. The centre plants were 1 feet high, those at the outside about a foot less.

Turning along the walk to the right and passing the variegated *Bambusa metake* planted out for trial, and *Strelitzia angusta* displaying a noble expanse of foliage, we come to a half-moon bed of *Dracena terminalis*, backed with *Hibiscus rosa sinensis splendens*, and edged with *Centaurea ragusina*. In a group on the opposite or left hand side are *Aralia macrophylla* with large leaves with a yellowish tinge, *Alphophila australis*, *Imantophyllum miniatum*, and *Dracena rubra*, which is readily propagated and very useful. A crescent-shaped bed at the foot of a mound is carpeted with the purple and green *Tradescantia zebrina* and planted with Indianrubber trees, *Aralia papyrifera*, *Dracena brasiliensis*, *D. longifolia*, with long graceful leaves, *D. arborea*, *Grevillea robusta*, most elegant in its foliage and growing freely, variegated Oleander, very handsome, and variegated *Veronica* at the back; the whole edged with Golden-variegated Ivy.

In a group on the right, plants of *Aralia papyrifera* from 5 to 6 feet high, with leaves 2 feet across, form the most conspicuous objects, and are now making good strong growth, so that by autumn they will have attained much greater dimensions. Mr. Gibson has found no plant equal to this in the effect which its magnificent foliage produces. In the same bed are fine plants of *Dracena*, and the ground is covered with *Tradescantia* edged with *Gnaphalium laetum*. Near the *Aralias* is another fine bed of *Cannas*, *C. nigrescens* with dark copper-coloured leaves occupying the centre, *C. zebrina elegantissima* one end, and *C. hybrida grandiflora* the other. This is surrounded by *Fuchsia Tom Thumb*, a very dwarf free-flowering kind, which, when planted closely, makes quite a hedge, and produces its pretty little red flowers throughout the season. Next, there is a long oblong bed divided into lozenges along the centre, with triangles in the intervals at the sides, and edged with *Sempervivum montanum*. The triangles at each end are planted with Golden Harkaway Geranium; the central lozenges with Mr. W. Paul's new Nosegay Geraniums, Black Dwarf, Duchess, Donald Beaton, Amy Hogg, and Scarlet Gem; whilst the triangles at the side consist of *Veronica inema*, and Geraniums Variegated Beauty, Fairy, Nymph, Rival Nosegay, Glowworm, Queen of Queens, Bonnie Dundee, Ratazzi, and *Sulphurea marginata*. The principal object of this bed is to show that many different varieties of the same plant can be introduced into a single bed and yet produce an agreeable diversity without sacrificing the general effect. Beyond this bed, and further to the back, is one of *Epilobium hirsutum*, the variety with creamy white variegations, and which, being easily propagated by the roots, is, like the common Willow Herb, very useful for damp situations. The next bed to the oblong is filled with *Cannas Annæi* and *edulis*, and *Hedychium coronarium*.

On the opposite side there is a crescent-shaped bed facing the south-west with *Centaurea gymnocarpa* in the centre, edged with *Coleus Verschaffelti*, which makes a beautiful edging to the white, and this again with the Californian Houseleek the leaves of which, being tipped with dark purple, give the whole a novel but pleasing appearance. Near this is a bed of the Laurel-leaved Coral Tree, interspersed with *Cannas*, and edged with *Plumbago capensis*; and then the beautiful long oval bed of Mrs. Pollock Geranium noticed by "D. Deal," at page 84. This is 30 feet long and about 9 feet across, and is planted with a triple row of Mrs. Pollock along the centre and double rows at each side, divided longitudinally by bands of *Lithospermum fruticosum*. The colour of the foliage was beautifully developed, and had the *Lithospermum* been in full flower would have shone to even greater advantage, for Mr. Gibson finds nothing brings out the colour better than blue or a soft green. A circular bed adjoining consists of *Daphne pontica purpurea*, surrounded by a broad circle of the variegated Cock's-foot Grass, one of the most beautiful and effective of broadly white-striped Grasses, and edged with yellow *Calceolaria*, Scarlet Geraniums, and *Convolvulus mauritanicus*. This circle is very pretty.

Opposite the Mrs. Pollock bed is a large bed of *Canna zebrina*, backed with Castor-oil plants, the front row being the dull orange-flowered *Canna crocea*; and in a small circular bed close by the golden Japanese Honeysuckle prettily clothes the stem of a tree. The same beautiful plant is employed as an edging to an elegant group of *Vitis heterophylla variegata*, the leaves of which are much cut, and prettily variegated with pink and

white, and sometimes purple. Near the end of this bed is a very fine specimen of the Bird's-nest Fern; then follows a noble bed of *Cannas* 52 feet long by 8 feet wide. The centre is *Canna discolor*, with *C. crenulata* at back and *C. Sellowii* in front; and the whole is backed with a mass of *Ferdianda cminens* 6 feet high, with magnificent leaves nearly 2 feet across. In front of this bed is a long oval planted with seven rows of Mrs. Pollock Geranium, edged with one of *Christine*. This bed is 27 feet long and 6 feet across, and adjoining it is a circle of *Caladium cucullatum*, the centre plant in particular being remarkable for the great size of its foliage, one leaf made out of doors measuring 2 feet 11 inches long and 2 feet across.

On the opposite or left hand side of the same walk is another bed, 48 feet long, planted with *Canna Annæi* in the centre, 5 feet high, and *C. discolor* all round, with *Hedera multi-maculata* as an edging. In other beds on this side are *Ricinus variabilis splendens*, a Castor-oil Plant of vigorous growth, having *Acanthus mollis* planted underneath, and *Cineraria platanifolia* and the variegated Cock's-foot as an edging; the variegated Speedwell, edged with Smith's Excellent Geranium, not a good hedder, but a first-rate kind for pot culture; and in a crescent-shaped bed *Canna Liervalli*, a free-growing dark-stemmed kind, and *C. muscifolia*, with a pale stem and leaves.

On the right, again, is a mixed bed of *Solanums*, with some plants of *Canna rubricaulis*, which grows 5 feet high, and has very dark reddish purple stems and dark bronzy leaves. Other groups of *Cannas* consist of *C. discolor floribunda*, much darker than *discolor*, as robust, and said to be more free-flowering; *C. Annæi rosea*, with warm orange-scarlet flowers; and *C. muscifolia hybrida*, with leaves 2 feet 4 inches long and nearly a foot across; and dividing these are *Solanum Balbeis*, a white-flowered kind, having leaves 16 inches long, with white midribs, and set with ochreous spines; and *Solanum citrullifolium*, with deeply sinuated pinnate leaves and pale blue flowers, the whole plant covered with spines. It may here be remarked, that the *Solanums* are planted a good distance apart, for if this is not done the spines tear the leaves of neighbouring plants and spoil their appearance to a very considerable extent. Single plants of *Wigandia caracasana* with magnificent leaves, Japanese Bamboo, *Saccharum perenne*, New Zealand Flax, and Black Bamboo are dotted about at this point; also *Trepidanthus calyptrotus*, the leaves of which reflect the light falling on them. Again, we find another fine group of *Cannas* on the left, and then on the right a bed of *Caladium esculentum* 45 feet long and 10 feet wide; the *Caladiums* were about 4 feet high, and their wide expanse of foliage gave the bed a noble appearance. *Funkia undulata variegata* is here employed as an edging. Behind, sheltered by a Willow tree, are two fine specimens of *Alsophila australis* with fronds at least 6 feet across; and close by a fine group of *Seaforthia elegans*, with *Dracena brasiliensis* in front, and *Funkia subcordata* as an under-covering to the soil.

On the left is a series of serpentine beds worked as a chain round circles of Ivy, with *Euonymus radicans variegata*, and Golden Fleece Geranium as an edging, and *Stella* in the centre. Interspersed among these beds are fine specimens of *Dicksonia antarctica*, *Astrapea Walliellii*, and variegated *Yuccas*; and behind is a scroll bed 100 feet in length, for the most part planted with a double row of Indianrubber trees 8 feet high, *Hibiscus sinensis coccinea*, and a handsome double buff variety, and edged with *Centaurea ragusina*. Each end is planted with variegated *Crotons* and *Dracenas*. The vigour of the Indianrubber plants is most remarkable, and from the way in which the roots are running in the soil, it is evident that they are as much at home at Battersea as in the tropics.

On the opposite side, at the back of the *Caladiums*, and sheltered by an elevated bank, are *Dracena congesta*, *Monstera deliciosa*, *Grevillea robusta*, and *Polymnia grandis*, the last 10 feet high, though only struck from a cutting last year, and which when taken up in autumn had made a growth of between 6 and 7 feet. A short oval, 15 feet long, planted with *Coleus Verschaffelti*, and edged with the silvery *Centaurea gymnocarpa*, is here one of the most glorious sights that can well be imagined, the *Coleus* being a richer and more beautiful brownish crimson than we have ever seen it before, and, withal, even in height, and not a plant faulty. As "D." remarked, it is well "worth going a hundred miles to see." A raised semicircle at the back is planted with *Eucalyptus globosus*, one of the Australian Gum-trees, the timber of which was shown at the International Exhibition of 1862, but though it is not grown here for timber, it bids fair to attain the dimensions of a tree, for it has made a growth of 3 feet this season, and in the public

gardens and parks of Paris, where it is largely used by M. Barillet, it grows 10 or 12 feet in one season. Here, also, occur *Ficus imperialis*, with magnificent leaves a foot long; *Dracæna Ghiesbreghtii*, and seedling *Dicksonias*. Next the *Coleus* bed is a fine circle of Mrs. Pollock *Geranium* set off by a broad edging of blue *Lobelia*; then a bed 48 feet long of dwarf *Cannas*. The front is planted with *expansa*, one of the most useful of dwarf dark varieties, and the remainder with dwarf *indica*, *lutea picta*, *leptochila*, and *Warszewiczii*. Near this group is an elevated bed of *Seaforthea elegans*, and in front a beautiful circular bed 8 feet in diameter. In the centre of this is *Dracæna australis*, surrounded by *Begonia parviflora*, with pink and white flowers, then by a row of *Dracæna Cooperi* and *D. ferrea* variegata alternately, with single plants of the pure white *Centaurea ragusina compacta* between each; and the whole, except the central portion covered by the *Begonias*, is carpeted with *Selaginella denticulata*, and this is edged with a narrow line of *Saxifraga pectinata*. By means of slight shading when the sun is strong this extremely beautiful group is preserved in all its freshness. In another circle is *Aralia Sieboldii*, surrounded by *Cannas*; this *Aralia* has withstood two winters without protection. Next this, again, is another very beautiful circular-bed, and so fresh and bright in its colours that when first seen it seems more the creation of the imagination than *nota stern* but lovely reality. The centre is *Dracæna ferrea*, surrounded by three rows of *D. terminalis*, all of which are planted out in the soil, not plunged. Covering the ground in the centre is *Ficus repens*, and the whole is edged with *Centaurea* and *Tradescantia zebrina*.

On the opposite side to these beds, which are the gems of the place, is a mixed irregular bed at the junction with the walk leading southwards; it is edged with the Japanese *Honeysuckle*, and planted with *Coral Trees*, *Cassia corymbosa*, *Saccharum Maddenii*, variegated *Arundo donax*, *Amicia zygomeris*, *Wigandia caracasana*, *Solanum macranthum*, *giganteum* (a very tall-growing species), *macrophyllum*, *japonicum*, *pyracanthum*, *glutinosum*, and *violaceum*, the last having the under sides of the leaves of a violet purple colour. Turning the corner, a little further on is a round bed of *Aralia papyrifera*, with *Farfugium grande* beneath, and edged with *Fuchsia Tom Thumb*. Another bed is filled with *Solanum citrullifolium*, with a flat-growing variegated *Cock's-foot Grass* as an undergrowth, and *Salvia argentea* as an edging; and a sunk bed in a low position is filled with *Cyperus papyrus* and *alterifolius*, *Gunnera scabra*, *Hibiscus palustris*, the *Bull-rush* of the Nile, variegated *Arundo donax*, and other marsh plants. Other beds near this point consist of one, 60 feet long, of *Canna discolor*, edged with *C. floribunda*; one of *Canna erecta hybrida*, with *Castor-oil plants* at the back, and *Cassia floribunda* in front, edged with *Golden Ivy-leaved Geranium*; a circle of *Canna rubra superbissima*, *Funkia undulata variegata*, and *Golden Ivy-leaf*; and a splendid bed 30 feet long, planted with *Wigandias* and *Canna metallica*, one of the finest and most rapid-growing kinds, attaining a height of 8 feet. We also noticed a noble plant of *Ferdinanda eminens* in a circle, and a bed 30 feet long of *Polymnia grandis*, the stems of which are 3 feet high, and fluted like architectural columns, and the leaves bear a strong resemblance to those of the Bread-fruit tree. *Verbesina gigantea*, *Solanum robustum*, and *Sonchus laciniatus*, the last with a pretty Fern-like leaf, occupy another long bed; and in front of a semicircle about 64 feet in length, planted with *Cannas Anna's* and *discolor*, 7 feet high, and edged with *Festuca glauca*, is another beautiful bed of *Coleus*, with an edging of *Centaurea ragusina*. At the back of this and other beds is a mass of *Persian Lilacs*, *Aucubas*, and other shrubs, planted in lines partly for shelter, and in front are two rows of *Iresine Herbstii*, which, at least as exemplified here, is far from being equal to the expectations formed of it as an out-door plant, being of a rusty brown. Lastly, omitting mention of some beds of *Cannas*, *Caladiums*, and *Hollyhocks*, we arrive again at the north end of the sub-tropical garden, and conclude our inspection with a semicircle of noble *Wigandias* edged with *Farfugium*.

"How are such results obtained?" is a question that will naturally be asked. How are the denizens of tropical climes fostered and made to luxuriate in a climate so much colder than their own? Certainly not without the assistance of a great amount of horticultural skill and of scientific knowledge practically applied. Mr. Gibson makes no secret of the means to which he has had recourse. In the first place, he has provided shelter from strong winds from whatever quarter they may blow by groups of trees and shrubs, most of which have been

planted little more than three years, but they have made rapid progress and the shelter which they afford will in future years be even greater than it is at present, care being taken to prevent ground currents of wind by shrubs of lower growth. In the second place, and herein lies the great secret of success, the beds are formed on what may be termed geothermic principles. The beds are all either circular, oval, or oblong—if circles the diameter is not very wide—and are so placed that the sun may warm one or other of the sides throughout the day, and the heat thus obtained is stored up in the materials on which the bed is founded, and by them given out to the soil in which the plants are growing. The site for the beds is therefore dug out to the depth of 9 inches below the level of the rest of the ground, the soil excavated being placed all round so as to form a kind of box of the same shape as the bed, but 2 feet beyond its outside, and from 18 inches to 2 feet of brickbats are put in. These at the sides form a slope of 25°, and over them a thin layer of soil is placed, and then turf. In the interior of the bed turf is laid grass-side downwards over the brickbats, and then from 9 to 12 inches of a compost consisting of loam, leaf mould, and Thames sand. Thus not only is perfect drainage secured, but the brickbats, receiving a large amount of heat during hot days, give it off to the soil at night, and, indeed, whenever the ground is colder than they are.

Long as this account of Battersea Park may seem, much has been omitted that is well worthy of notice. The objects of interest with which it abounds are so numerous, and so bold and novel the idea which has been successfully carried out, that the visitor there will be well repaid for his journey, especially if he have the good fortune to meet with its talented and most courteous superintendent, Mr. Gibson, by whom the beautiful grounds have been laid out, and to whom belongs the credit of having inaugurated in this country the new and very effective style of gardening exemplified in the sub-tropical department.

#### NOTES ON THE ST. PETERSBURG FLOWER SHOW.

ONE reason, I think, why gardeners are a superior class of men is because they are constantly taking notes. Do you ever see a gardener (I am not now speaking of the lad of sixteen, but of the gardener proper), walking in some public gardens, or in a private park, without his note-book and pencil? Rarely, unless my observations are taken from peculiar cases. I have been to many flower shows in the United Kingdom and abroad, and I have noticed with pleasure gardeners taking the names of new flowers or descriptions of exotic plants; and then you see two comparing notes or shaking their heads over some new plant, or perhaps degenerate specimen of an old one. But I am running away from my subject, which is a slight account of a St. Petersburg flower show.

I ought to say that the show I saw was *the* show of the season, to the best of my belief, and therefore may be taken as a fair specimen of what they usually are. It was held on the 19th of May (7th, old style), being kept open for a few days, in a large, plain, oblong building in one of the open spaces with which the town abounds.\* The entrance is at the end of the building, up some twenty steps, from which a *coup d'œil* is obtained of the entire show. Your readers will imagine my astonishment when, instead of the long stages, &c., of our English flower shows, a perfect garden presented itself to my view—beds, walks, and a lawn, fountains playing, rivulets trickling over mossy stones, statues, and everything to give the appearance of a well-laid-out and neatly-kept *parterre*. But I should begin at the beginning. Each side of the platform on which I stood was lined by tall young *Spruce Firs*, looking as if they were growing; the walls beyond were painted to represent massive stone walls, covered partly by moss, and very cleverly they were done; on each side of the steps descending into the garden were pillars, made to appear like ancient marble, and broken, and chipped, and mossy to aid the delusion; then vases in the same style. The walls edging the steps were also made to look old and time-worn. To proceed. I descended into the garden; on my right there was a bed of an oval shape, in front a round one, and altogether ten beds, cut out of the artificial moss lawn, each being full of the plants for show, and the card hanging on the prize plants.

The plants exhibited were *Caladiums*, *Begonias*, *Palms*, all of which were fairly good. The *Rhododendrons* struck me

\* The *Karavans*.

as being very fine. The flowers were, generally speaking, well developed, and the plants nicely shaped and carefully grown: in these Minnie was striking, being a faint blush, with a rich golden tinge in the centre of each petal. Evelyn was almost a repetition, not so strong in colour. Mr. Standish's Perfection elicited general admiration, although I must acknowledge there were not so many gardeners proper in this flower show as you see in every English exhibition. Further on we came to some Heaths and Azaleas, nothing worth special mention. There were some fine specimens of *Arancaria exelsa* and *A. Cunninghamii*, and a handsome *Yucca* in a tub sent by a rich amateur. I believe the same plant had taken many prizes before. I noticed some Azaleas trained in the shape of an umbrella, which assuredly did not improve the plants. These, with some Camellias, Acaesias, Brooms, and Ferns finished the list, which your readers will remark was but small. The arrangement of the show was the point to be noticed, not the flowers. We certainly grow the finest specimen plants of every kind, and naturally enough when the time and money devoted to the object are considered. In a corner of the building there were a collection of pickled fruits and some fresh Strawberries (at 1s. 50c. the basket, about 4s.), and Raspberries. Here was nothing worth mention. I had tasted the fruits at home at a much more moderate figure. In the corresponding corner were some ornamental pots and vases; these were made of a white clay and with rings, and altogether neater and prettier than the common red pots in use in England. They were, however, too dear to compete with the old red ones.

Facing the principal entrance was a raised platform, reached by means of wide steps flanked by Roses, Gloxinias, &c., in pots. On this platform were chairs and seats, placed so that the *coup d'oeil* might be obtained, and it certainly was from this point very charming. With gaily-dressed ladies and officers promenading, and the flowers and foliage, the whole was worthy of some notice. Usually a good band plays in the building during the afternoon, but the death of the Czarewitch had put a stop to that and many other pleasures.

This is a slight and very imperfect sketch of the flower show; want of time compelled me to cut my memoranda very short, and were it not with the idea of contributing something to the pages of "our Journal" and amusing its readers, I should not have ventured so far as to present this sketch.

Whilst in Russia I made it my duty, as well as pleasure, to see the public gardens, the botanical houses, and some private establishments. If it is agreeable to your readers, I may, as time permits, attempt a further description of these.—PATELIN.

[We shall be glad if you will, for such descriptions are always interesting.]

NATIONAL GOOSEBERRY SHOW.

THIS was held at the Sir John Falstaff Inn, Market Place, Manchester, on Saturday, the 5th inst., and we believe the Gooseberries shown on this occasion will be found to be the largest exhibited in England this season. An extra prize was awarded to Mr. Peter Daine, of Currington, who exhibited a berry of Shiner (green), weighing 31 dwts. 19 grains. This is the largest green Gooseberry ever shown. The principal attraction, however, was a cup of the value of £5, offered by Dr. Hogg for the heaviest four berries, one of each class. For this all seemed to have reserved their most choice fruit, and, after a severe competition, it was awarded to Mr. Thomas Pilkington, of Scausbrick, near Ormskirk, Lancashire. The competitor who stood next was Mr. Moses Ainsworth. The whole of the fruit was in splendid condition, sound, and most beautifully coloured.

The first prize, a silver cup, value £5, the gift of Dr. Robert Hogg, LL.D., F.L.S., was obtained by Mr. Thomas Pilkington with the following berries, viz. :—

GROUND VINERIES.

It appears to me that in the construction of these there is a slight mistake in not providing ventilation, however small the

amount, at the top of the case. I would suggest a small louver board, say 4 inches wide, hung on a pivot in the centre, and running the entire length of the case. If it opened an inch at the top and bottom that would be quite sufficient, and the top part of the louver board should butt up underneath a lap in order that the wet may be carried off. I am induced to send you these remarks from having visited the excellent kitchen garden of Mr. Heywood at South Norwood, who takes great interest in ground vineries; but although he has followed out your instructions as given in No. 28, the whole of his Grapes inside these cases are scorched. This result I attribute to the moisture arising from the earth condensing on the berries, and in dull mornings the sun hursting out with sudden force upon the glass and stagnant air inside. The pigeon-holes in the bricks upon which the case is placed receive air that has passed along the ground only, and therefore laden with moisture, but ventilation at the top would create a current and dry the berries before the sun's rays struck directly on them. We know how beneficial this is for large vineries. A little air should be given at six o'clock in the morning, and the cases taken off at mid-day. For my own part I consider it a mistake to place the cases so low, they should be raised upon some dry material that would filter the air before it reached the inside of the case.

There can be no doubt that cordon training of the Vine is a great success, in this instance there were several cordon Vines not under cases completely covered with bunches, some of which, if they come to perfection, may average from 2 to 3 lbs. I forgot to inquire of Mr. Heywood if the Grapes ripened last season, but I have no doubt he will readily answer that, or any other inquiry your readers may wish to make through your Journal.—F.

## ROYAL HORTICULTURAL SOCIETY.

AUGUST 8TH.

**FLORAL COMMITTEE.**—The meeting held this day was a very interesting one. There were 124 entries of plants and flowers for examination, and among them were some very good things. The magnificent specimen of *Lilium auratum*, with twenty-nine flowers upon it, was alone worthy of a journey to South Kensington. Some idea can now be formed as to the character and value of this superb Lily. The seedling Hollyhocks were also very good, considering the hot and dry season: the only thing wanting was the Fellows to see them. It will be well for those members of the Society who are still in London to remember that, although the fashionable world is out of town, flowers and fruit are still to be seen at the Floral Committee meetings. Florists' flowers are now very numerous. Seedling Dahlias, Hollyhocks, Scarlet Pelargoniums, Verbenas, &c., are now in perfection, and are sent for examination to have their merits or demerits assigned them.

Many certificates were awarded at this meeting. Mr. Bull exhibited *Aucuba japonica medio-variegata*; *Spherosyne cinnamomea*, which was awarded a second-class certificate in June last; *S. ferruginea*—second-class certificate; a variety of *Lilium auratum* called *picturn*, one of the red-banded kinds; and *Verbena Fascination*, a white flower striped with dark red. Mr. Osborn, Fulham, sent cut specimens of *Rhexia virginica*, *Gantheria Shallon*, *Castanea pumila*, *Sophora japonica*, and *Cerasus rubra*, bearing numerous bunches of dark brown berries. Mr. A. May, Fulham, sent a specimen of *Opuntia vulgaris* grown in a window; the plant was covered with fruit, and had a very singular appearance. Messrs. Downie, Laird, & Laing sent a collection of cut flowers of Hollyhocks, and four seedlings shown in spikes; Charles Eyre was awarded a first-class certificate, Mrs. B. B. Todd, a second-class certificate. The Rev. G. Hawke sent three cut flowers of a seedling Hollyhock, Senior Wrangler, a very fine variety, dark chocolate with a reddish tinge. It was awarded a first-class certificate. Mr. Porter, Epping, sent a collection of Hollyhocks, and four spikes of seedlings—*La Brillante*, Shirley Hibberd, Volunteer Improved, a seedling of 1864; and John Laing, a light rosy earming, fine full flower—first-class certificate. Mr. Chater, Cambridge, exhibited a collection of Hollyhocks and five seedling *Zonale Pelargoniums*. Mr. W. Chater, Saffron Walden, sent a collection of Hollyhocks containing many of the best varieties, which was awarded a special certificate. He also sent nine seedlings shown in spikes—*Firefly*, a deep bright crimson—first-class certificate; *Hebe*, a pale silvery blush with deep rose centre—second-class certificate. The others, which were good flowers but not specially noticed, were *Nymph*, *Favourite*, *Desdemona*, *Orange Boven*, *Gem of Yellows*, *Aurantiacum*, and *Alice*. Mr. Chater's seedlings are not equal to those of 1864, but doubtless the hot and dry weather has had its influence upon them. Mr. Thompson, Ipswich, sent *Palafoxia Hookeriana*, a dull pink half-hardy annual, producing clusters of composite flowers—second-class certificate; and *Pectis angustifolia*, a dwarf, flowering annual with yellow composite flowers, the foliage strongly scented like Lemon Thyme, useful for bedding purposes—first-class certificate.

Mr. Apted, Galton, sent double red *Fuchsia Victory*. Mr. Veitch sent *Dendrobium tatoncense*, from Australia, exhibited at the last meeting—second-class certificate; also *Cattleya Sidnei*, a hybrid between *granulosa* and *crispa*; and a *Cattleya*, probably a variety of *Mossie*, with pale lilac flowers having a beautifully marked purple lip—first-class certificate. Mr. Veitch also exhibited the fine specimen of *Lilium auratum* grown by Mr. Constantine, gardener to C. Mills, Esq., Hillingdon, which was awarded a special certificate, and recommended by the Committee to the Council as worthy of a medal for good cultivation.

Mr. Davies, Bath, exhibited a seedling *Pelargonium*, said to have been grown from seed sown in March last, and now in flower. There must surely be some mistake in this statement. Mr. Williams, Holloway, exhibited several variegated *Zonale Pelargoniums*; they were very good, but it was requested they should be seen again to be compared with others. They were *Miss Eleanor Scott*; *Parity*, with a very white margin; *Mrs. Spicer*, and *Sally Miller*. He also sent an *Orchid*, a species of *Brassia*, probably *caudata*, with a spike of very fine flowers. Mr. D. Windsor, gardener to J. R. Ravcunhill, Esq., sent five seedling *Zonale Pelargoniums*—*Gladiator*, deep salmon; *Brightness*, scarlet with white eye; *Modesty*, white with salmon centre; *Great Eastern*, scarlet; and *Sir Robert Peel*, a bright orange scarlet, compact truss, and good firm petals; they were awarded a first-class certificate. Mr. G. Smith, Hornsey, sent double red *Fuchsia Gladiator*, dark corolla, bright crimson sepals. Mr. Cripps, Tunbridge Wells, sent the new *Colens Verschaffeltii aureo-marginatus*. We hear this golden margin does not last when the plant is grown out of doors. He also sent double scarlet *Pelargonium rannunculiflora plenissima*. These double varieties have never yet been exhibited in a condition to deserve the slightest commendation. *Zonale Pelargonium Lady Caroline Neville*; and *Lilium auratum*, a variety with a pale red band were likewise shown by Mr. Cripps. Mr. Turner, Slough, contributed two seedling *Phloxes*—*Edith*, white with crimson centre, a very finely formed and beautiful flower—first-class certificate; and *Phlox Herbert*, dark rose with shaded centre. He also sent *Dahlia Ely*, orange buff tipped with carmine; and a collection of *Lilium auratum*, containing several beautiful and distinct varieties—the finest collection ever yet brought together. It was awarded a special certificate, and was recommended to the Council for a medal. A very fine specimen of *Athurium cordifolium* from the Society's garden, one of Mr. Weir's plants, well grown, was exhibited. It was awarded a special certificate.

Messrs. Garaway sent seedling *Zonale Pelargoniums Queen of Tricolors*, a stronger-growing plant than *Sunset*, of better habit—second-class certificate; *Bronze Queen*, *Ophir*, *Unique*—second-class certificate; *Princess Lichtenstein*, and *Volunteer*. Mr. Dijkman, Haarlem, sent over some seedling *Gladioli*, hybrids from *Gandavensis*, far behind the flowers of the present day. Mr. Townsend, Hornsey, sent two varieties of *Lilium* from Japan. Mr. Press sent *Calceolaria Gem*, dark ruby; and *Calceolaria Fascination*, yellow ground, with dark crimson blotch. Mr. Hopkins, Brentford, sent seedling *Dahlia Lord Enfield*, deep claret, a very promising flower. It was requested that it should be shown again later in the season. Mr. Wills, Oulton Park, sent a cut spike of an *Epidendrum* which had never before flowered in this country. It was awarded a special certificate. Mr. Tillery, Welbeck, sent a seedling *Gladiolus*, bright scarlet, with a white centre, very pretty, but neither new nor distinct. He likewise sent *Lilium auratum gloriosum*, an inferior red-banded variety. Mr. Perry, Castle Bromwich, exhibited a collection of very fine *Verbenas*, which received a special certificate; also several seedlings. These were *Verbena Cleopatra*, a very deep bright rose, very fine truss, with extra large flowers—first-class certificate; *Wilham Dean*, deep maroon, the finest *Verbena* in this shade of colour—first-class certificate. There were five or six other good flowers, but not new or distinct. Mr. Perry also exhibited seedling *Dahlias Modesty*, pale lilac, tipped with a darker shade; *Miss Powell*, a striped crimson or red variety; *John Powell*, a deep yellow, a promising flower; and *Carnation*.

In the report of the Floral Committee, July 25th, in speaking of a drawing of Mr. Cutbush's *Lilium auratum* which was exhibited, it is described as having dark red *leaves*, it should have been dark red *bands*, terminating in yellow.

**FRUIT COMMITTEE.**—Mr. G. F. Wilson, F.R.S., in the chair. Mr. Rivers sent an interesting collection of miscellaneous varieties of fruit, consisting of *July Green Gage Plum*, a very early variety of *Green Gage* ripening in July. It is in every respect similar to a good, medium-sized, and highly coloured *Green Gage*, very richly flavoured, and the flesh separating from the stone: a very valuable early Plum. *Bacay's Early Gage*, another form of the *Green Gage*, a shade larger than *July Green Gage*, but not so early nor so highly coloured. It is a most delicious Plum, and is distinguished from the former by its flesh adhering very closely to the stone. *Rivine Claude de Berger* is not a *Gage Plum* at all, but synonymous with the *Peach Plum*, for the confirmation of which Mr. Rivers sent both these varieties to compare. *Minsterworth Plum* is a variety much grown about *Minsterworth*, near Gloucester, and appears to be synonymous with *Damas Violet*. It is a great bearer and a good, early, black, market Plum. *Cluster Damson* is a very prolific form of the English *Damson* grown about *Stroud*. It was of course still unripe, and was sent to show the great fertility of the sort. *Dragon's Yellow Bigarreau Cherry* is a fine large *Bigarreau* of clear sulphur yellow colour, far superior in size and flavour to

Buttner's yellow or Lady Southampton's. *Rival* is a valuable late black Bigarreau of medium size, somewhat larger than Belle Agathe, with which in its lateness it forms a good companion. It hangs till the end of August and beginning of September, is a profuse bearer, and a fine late Cherry. This was awarded a first-class certificate. *Late White Heart* is also a small late Bigarreau of a pale colour, about the same size as *Rival* and Belle Agathe, but inferior in flavour to both.

Mr. Rivers also sent a portion of a bunch of Duchess of Buccleuch (grape to show, as Mr. Rivers stated in his communication, that the berries of this variety are subject to crack and rot, while the White Frontignan in the same house exhibits no such tendency. Mr. Rivers sent, also, fruit of Williams's Favourite Apple, an American variety.

Messrs. Garaway & Sons, Bristol, exhibited a seedling Ridge Cucumber, which received a first-class certificate. The fruit was from 16 to 18 inches long, and were remarkably fine specimens of out-door culture.

Messrs. Osborn & Son, of Fulham, sent branches of *Prunus padus fructu-rubro* in fruit, and *Gaultheria Shallon* in fruit.

### THE RIPENING OF OUT-DOOR FIGS.

The ripe Fig noticed by "H." (page 91), is thus explained. In the axil of each leaf is formed a fruit. As winter approaches these fruits are seen of various sizes, from nearly full-grown specimens on the lower part of the shoot, to the size of a pin's point at the upper extremity. The more advanced are killed by the frost. The smaller survive. It is generally said that if under the size of a hazel nut they are secure—i.e., with moderate protection.

It will thus be seen that the security with which an embryo Fig passes through the winter is inversely as its size. If, under favourable circumstances, one a little larger than usual passes through the winter unscathed, of course it ripens earlier. Such was the Fig noticed by "H." In my garden, far north of Undercliff, I had a similar Fig on the 1st of August, and in a previous year had one on the 31st of July.

I was at Bonchurch last June, but had not the *entrée* of Dr. Leeson's grounds. Those Fig trees, however, which I saw in the Undercliff, were remarkably void of fruit. With natural advantages apparently far superior to Tarring, I was surprised to find the produce so inferior in quantity.—G. S.

SEEING it stated at page 91, that "H., *Ventnor*," had on the 21th ult., gathered and eaten a fully ripe Fig from a tree in the grounds of Dr. Leeson, at Bonchurch, as fine as he or she had eaten in Jersey at the end of August, I may mention that I had sent me on the 26th ult. (two days later than the above date), a pair of ripe Figs as fine and luscious as ever were eaten. They came with the dairy produce which is sent every morning from the farm of our worthy manor bailiff, and on Saturday the 29th, they were followed by a basket of the same—splendid, bursting, purple fellows, "a banquet for the gods." Not taking notes of these things, I was not aware that it was at all out of the usual course. If earlier than usual it is probably owing to the very fine summer we have had. At all events we have not had to wait until the end of August for our ripe Figs this year. I know the tree well from which these Figs were gathered, and I believe all the care that is taken of it is to prop up the branches.—A. T., *Noirmont, Jersey*.

### HEATING AND VENTILATING A GREENHOUSE.

In my former home I used to look after the garden, but we had a gardener who, of course, took his own way; now, I find myself with a large vegetable garden, a lawn, and flower-beds, I have made a porch, and have a greenhouse in course of construction. The garden is all in my own hands, with a boy for constant work, an itinerant gardener occasionally, and the men from my husband's farm when I want them.

What I particularly want to know is, how to heat the greenhouse? It measures 18 feet by 12, adjoins the house, faces the west, and has a south end, but that is rather blocked up by farm buildings within 20 feet or more. It is span-roofed, with fixed sashes and rather slight rafters, as described in "Greenhouses for the Many," the door is in the middle of the front, and there are three sashes on each side of it, all of which open, being hinged from the top. There is a potting-room at the back of the greenhouse, but not high enough I imagine to have

ventilators into it, as the wall only rises as far as the beginning of the span-roof of the greenhouse. A door opens from the greenhouse into this potting-room, which door is at the back, close to the south end. Shall I put ventilators in the south end at the top of it? The roof, south end, and west front are all glass except the 24-feet brick wall.

My second question is about heating. I was going to have a portable stove; but as the north end adjoins the house, and has at its back a fireplace where a fire is kept almost constantly, even in summer, it would be easy to put in a boiler and hot-water pipes, and it seems to me that it would be a good plan to run these pipes only round one end—that is to say, from the boiler under a corner stage at the west, and along the front shelf as far as the door, and back again to the boiler, then again from the boiler to the east corner, perhaps in a rockery for stove Ferns, and along half the east side under a shelf, and back to the boiler.

It appears to me that over my boiler I could have a place for propagating, that my warmed front shelf, which I could make a box or tray, would do for Gardenias, Gloxinias, &c., and the other and darker side would grow Ferns, &c. Then, I think, the centre stand, south shelf, and half the western shelf would grow Geraniums, &c., and I have an idea that I might by moving them have Vines in pots.

Being an invalid and not able to drive or go about, I can give more attention to my plants than other people, and I also turn my maids into under-gardeners! I should say, that I mean to have against the 24-feet brick wall of the south end of the greenhouse, a cold pit for storing bedding plants, &c. Will it do in that position?—O. D.

[We can well enter into all your little troubles and difficulties, as, independently of the extra claims to notice, as being somewhat of an invalid, you occupy just one of those positions in which we would wish to be serviceable if we could. We are certain that all your attempts to improve your garden, if you prudently do not overwork yourself, will not only improve your health, but vastly increase the comforts of your home. We have known men of rather sedentary habits, hard-thinking, intellectual men, who lived and procured the means for their family to live, by the hard work of the brain, who, after suffering dreadfully from neuralgia and various nervous affections, that made them appear in their studies as if they had taken farewell of their senses, after trying everything else, found complete relief and freedom from distracting pains through working in the garden. One of these gentlemen told us that his garden had been his great physician. "Whenever I feel the least signs of the hyps, the sure forerunner of the tic, neuralgia, &c., I shut up books and papers and off to my garden, and delve, hoe, rake, &c., as if my living depended on it; and now, since I have taken a regular spell night and morning, I have been able to say adieu to my kind worthy physician. I am sure there is a fund of health in the fresh-turned earth, and the balmy air of early morn." We have told and told of such cases, until many friends, male and female, have had reason to tell us since, "Ah! the garden was our best doctor." So may it prove to our correspondent.

Only the other week we dined on the causes that naturally rendered so many of our farmers careless about their gardens, especially the ornamental department, and that where appearances were very different, these appearances generally might be traced to our best friends the ladies. Now, here, as if to corroborate our words, is a lady, a wife of only five months' standing, keenly attentive no doubt to her household duties, and yet resolved to make use of her newly-acquired powers and opportunities to manage her large garden herself, with the help of a boy constantly, a jobbing gardener at times, and men from her husband's farm when she wants them. Now to the questions.

1. As to *ventilating* the house. As all the front sashes are made to move, we would, as you propose, have a part of the south end made to open—say a triangle of some 2 feet at base, and the same in height to the apex, and just beneath that point two or three small squares made to move would have the same effect. These in a common greenhouse might be fastened open night and day from the middle of May to the middle of October. Between these two periods they would have to be regulated according to the heat of the weather, keeping in mind that in cold weather in winter the ventilation would be safer by such openings than by the front sashes, and especially in the south part of the house, where you propose having no heating medium. So much for the south end. Now, if you had a space to open on the north end of your span, though not

more than 18 inches square, in such a short house of 18 feet, and even if in cold weather you opened each of these merely a few inches, you would secure at all times a sweet atmosphere, and prevent anything like scorching or burning from accumulated vapour. As already stated, they might stand open all the summer, and very little air given early in the day in cold weather, would prevent alike the evils arising from a stagnant or a moisture-laden atmosphere, and those different evils which come from allowing great draughts of cold air to pass at once among somewhat tender plants, which would be apt to be the case from a free use of the front sashes in winter.

If not convenient to make this opening at the apex of the north end, the next best plan would be to have an opening 2 feet by 1 foot at the top of the wall and the north-east corner of it, which separates the greenhouse from the potting-shed. If there were any objection to the ventilation in the south end, we would fix just such another near the doorway at the south-east corner. With the door or the window of the potting-room open in summer, and a little open, except in cold nights, in winter, the ventilators at the top of the back wall where the span springs from would be quite enough for ventilation, whether formed of hinged board, or swung on pivots, or of glass in a frame. These, too, we would leave open all the summer, and in winter, though less would be required, more air could be given than if the opening went at once into the open air, as the air in the potting-room in winter will be more mild, though, if the place is kept clean, it may be equally pure with that of the open atmosphere. Such ventilation into such places has much to recommend it in the case of beginners, as more air may be given and still less danger be incurred from cold dry draughts in winter.

2nd, *Heating*.—The ease and propriety with which you may manage to heat the house, from a fireplace in the room at the north end of it, will depend on the relative heights of the floor of the greenhouse and the floor of the sitting-room, or rather, more correctly, on the height of the little boiler around the fireplace, and the height of the pipes inside. Sad errors have been made in this respect—no doctoring or management can make the water that is heated in the boiler descend and circulate in pipes below the level of the boiler, unless, indeed, in some peculiar cases, when pipes at some distance rise to a much higher elevation than the boiler. If the boiler has an open lid, the upper pipes should be on the same level as the top of the water in the boiler; the pipes must not be higher, or the boiler will overflow. If the boiler is close on the top, and is either fed by an elevated cistern, or by a cistern placed on the highest point of the pipes, then the pipes may run in the house at any reasonable height above the boiler, provided no part is higher than the supply-cistern—in fact the action will be all the better if all the heating pipes, flows and returns, are on a level above the top of the boiler, unless at that point where the return joins the bottom of the boiler.

We are all the more particular on these simple points, because the neglect of attending to them often results in disappointment, and the blame is not always placed on the right person, as we sometimes know to our cost. Not so long ago we were told somewhat bluntly by a gentleman that he got into a scrape through us, when he did not succeed satisfactorily because he totally neglected these simple matters as to levels. A gentleman, partly by our advice, heated his neat conservatory adjoining the drawing or sitting-room from his kitchen boiler. The kitchen floor was at least 12 feet lower than the conservatory floor. The kitchen boiler was close on the top, supplied by a cistern and ball-cock higher than the floor of the conservatory. The connecting pipes from boiler to conservatory were of 1½-inch lead, and packed mostly in sawdust, in a neat wooden trough against the wall. The floor of the conservatory (span-roofed) was 4 inches lower than the floor of the drawing-room, and the same depth lower than the sill of the door that opened out on the little garden. We do not advocate this lowering of the floor in general circumstances; but here it answered by simplifying the heating, which was done by three-inch pipes, three in the front, and two at the back, going all round the house on the same level, and close together, and a neat piece of iron grating going over the pipes at the doorways, thus forming a step-down of 4 inches in depth. The other gentleman resolved to do the same thing from his kitchen boiler; but then the kitchen boiler was some 5½ feet above the floor of the conservatory, and, after a deal of worry and trouble, they found that all would be unavailing unless they fixed the pipes at that height against the walls of the house, where they not only looked ugly, but did the work wanted very

imperfectly, making the floor of the house too damp and cold, and the top, near the apex of the lean-to house, far too hot in general. Let the heating medium be low enough, and stagnation of air in a house is next to impossible. We have not the same faith in the applications of heat where the heating medium is as high as our heads. The last accounts we heard of this mishap, or next to it, because the owner wanted a propagating-bed from a part of the pipes, was to the effect that the pipes were to be taken down, and to be connected with a small boiler in a lean-to-shed potting-house, where at first we would have advised its being placed.

This leads us to say that, if, from the position of the fire in the room, there should be the above difficulty as to level, it would be the safest plan, if the floor of the potting-room was all that lower than the conservatory, or if it was easily practicable, to sink a stovehole deep enough; then pipes could be taken all round the house, stopping at the two doorways, and be placed on the floor, if deemed necessary; or, what we consider would be the most economical in such a house, a small five or six-inch shallow flue could be carried round below the tiles of the floor, if such a floor were resorted to. The advantage of having a fire here would be the independence of the lad that lighted the fire of all house servants, and their systems of management, which, somehow, do not often square well together. This last matter would be got over if the boiler would be suitable in the room at the north end; all that will be required will be to keep the boiler supplied with water, and a tap in the greenhouse to let the heat on when desirable.

Unless you place more than two four-inch pipes at the north end, and for less than a half along each side, we fear you will not have heat enough to keep out much frost at the south end, though, perhaps, quite enough to meet all that is generally prevalent near Cork in winter.

In such a short house as 18 feet in length, you will, we fear, fail to keep one end as a warm house for tropical and subtropical plants, whilst the unheated end would be devoted to the hardier greenhouse plants, requiring more air and a colder atmosphere. In such a space the heat would be apt to become uniform, unless, indeed, you made a division in the house, and then nothing would be more easy. Without that division you would find it equally difficult to make a propagating-box or pit over the pipes at the heated end, or to grow Gloxinias, &c., unless you shut in part of these places with cases covered with glass. With such contrivances as shallow boxes, covered with a pane or panes of glass, and moveable at pleasure, set on a bed formed over the pipes, the pipes being placed in a chamber, or packed round with stones, brickbats, &c., you might grow in them, and do in them, anything that could be done by more expensive cases. You could likewise readily harden-off gradually by giving more and more air to the cuttings, plants, &c., in these little cases, hand-lights, and then place them in the colder end of the house. Moreover, by having three pipes instead of two, where you would want most heat, you could have a few openings at the side to let the heat out, and then, whilst securing heat to your more tender favourites, you could also borrow enough from the pipes beneath, by slide or otherwise, to keep frost and extra cold from the unheated part of the house; but, without such contrivances to keep in the heat about your tender plants, we have no faith in your keeping distinct atmospheres in such a small house. A few simple wooden bottomless boxes, with a large square of glass at the top, would enable you to do wonders. Were the glass top, whether a simple square or a pane, moveable, you could then turn it in an instant—a matter of moment with young seedlings and cuttings.

3rd, As respects your Vines in pots, we are of those who believe that there are ladies by whom the word "impossible" is thoroughly unrecognised. Meanwhile, we would say, "Let well alone;" and if you would entice your spouse by a cluster of Grapes as he sits under his own Vine, we would advise you to plant two or three at the west front of the house, close to the flower-borders; they will give you less trouble, on the whole do better, and, if only two or three, will yield a nice shade to the house in summer. Too much, of course, would spoil and draw all plants beneath them. We shall never forget when, in our young days, we had Cucumbers, Melons, stove plants, Vines, Figs, and Peaches in one house, and that a steep lean-to, the late Joseph Knight, Esq., the predecessor of the present Mr. Veitch, looking very comically at us, and saying, "Why, you will beat nurserymen in cramming." We have always had enough of cramming much in little space; but here we advise no one to follow our example.—R. FISH.

## RUSSIAN VIOLET THE CZAR.

This fine flower was raised by F. J. Graham, Esq., of Cranford, and obtained first-class certificates in 1865 from the Royal Horticultural and Royal Botanic Societies for its mag-

nificent flowers and foliage, the plants exhibited being grown in pure loam without liquid manure.

The flower is of a deep blue colour, of great substance, at-

taining  $1\frac{1}{4}$  inch in depth, and on very stout footstalks 9 inches long. One of our highest authorities has publicly said of it, "The Violet is evidently a genuine seedling, and not only is the plant remarkable for its extreme luxuriance, but the smell surpasses that of any other Violet I have ever met with." Some

of the plants in pots produced 130 flowers to a root, and others had two flowers on one stalk.

The accompanying engraving of the flower was measured by compasses. The leaf is accurately copied from a tracing from life.

## WORK FOR THE WEEK.

## KITCHEN GARDEN.

CLEARING off all crops as soon as they are exhausted, and the destruction of weeds, tend not only to improve the appearance of the garden but are actually, with reference to the soil, of economical importance. *Broccoli*, the latest crops should now be planted out, if not yet done. *Cabbage*, another sowing may be made in the end of the week to remain in the seed-bed during the winter. A late sowing sometimes comes in very useful; also, make a sowing of Red Dutch for summer use. *Cauliflower*, make a sowing in the end of the week, for plants to stand the winter. The Asiatic is a large and excellent sort for this purpose. *Celery*, previous to earthing-up the first time give the trenches a thorough watering, as the plants will not receive much benefit from waterings afterwards. The earthing-up should be carefully done, the whole of the leaves being kept close together at the time. *Cucumbers*, the lights may be drawn off those that are in frames during gentle showers of rain, but not when it is sufficiently heavy to injure the leaves. Gather Gherkins for pickling. *Dwarf Kidney Beans*, keep the crop closely gathered, for if allowed to remain until they are too old for use they cease to bear as they otherwise would do. *Lettuce*, sow largely for standing through the winter. The Brown Cos, Black-seeded Bath Cos, and Hardy Hammer-smith, and Brown Dutch are the best sorts for sowing at this season. Plant out from the late sowings for autumn use. As regards prescribed periods of sowing, it is advisable to study both the soil and locality of a garden, that its advantages and disadvantages may be understood. There are localities where it is necessary to deviate considerably from ordinary practice to meet peculiarities. *Onions*, pull up and house those that have done growing. If the main crops have long necks the tops may be broken down; if not, there is no advantage in doing so. *Radishes*, make another sowing of Black and White Spanish, and also of the Turnip-rooted sorts. *Tomatoes*, let the most forward of the fruit be fully exposed to the sun. Remove some of the leaves which shade it. Keep all the shoots stopped immediately there is sufficient young fruit on the plants.

## FRUIT GARDEN.

The preservation of wall fruit from birds and insects should receive attention. The bean-stalk earwig-traps should be frequently examined. Worst of other small-meshed netting may be employed with advantage to protect Green Gage or other Plums. Look carefully over Peach and Nectarine trees, and remove nails that are too close to the swelling fruit. In stopping and arranging the wood let only as much as can be conveniently laid in be allowed to remain, and the quantity laid in should also be greatly regulated by due consideration for the perfection of the fruit and the proper ripening of the wood, which only the influences of sun and air can accomplish. It is also an error in another respect to retain a large amount of wood to be removed in the winter pruning, as undue excitement and extension is given to the roots, which, with a superabundant supply of sap, induces in the spring the growth of rank and unmanageable wood. Pear shoots which have been left or only partially shortened, should now be pruned back to three or four eyes. Proceed with Strawberry planting. Remove runners from established plants to relieve and strengthen them.

## FLOWER GARDEN.

Hollyhocks, Dahlias, and herbaceous plants must be made safe from the effects of high winds, by securely fastening them to their supports. The like attention should be paid to climbing plants against walls and trellises, standard Roses, &c. There is an appearance of negligence when plants are blown about by the wind, which should by all means be avoided. Remove daily dead leaves, bloom, and litter of all kinds, and frequently sweep and mow grass to give a clean well-kept appearance. Gravel walks should be frequently rolled during heavy rains to keep them firm. The general pruning of evergreen shrubs should now take place, reducing straggling growths within proper limits, but avoiding giving them anything of a formal character. The object is to assist, not deform, nature. By this the general characteristics of each plant will be as much as possible preserved. The case is different in pruning shrubs used as architectural embellishments, which will require trimming into the precise figure wanted. Cutting hedges should now be finished, using the knife for large-leaved plants. Keep the shrubby borders clean by frequent dressings.

## GREENHOUSE AND CONSERVATORY.

Should the weather continue unsettled it will be an advantage

to many delicate plants to introduce them early into the greenhouse. It is better always to anticipate an evil by precaution, than to supinely await its arrival. We shall soon have short, sunless, damp days, and long nights, therefore look over the stock of pot-plants, and see that none of them are suffering for want of pot-room, or other attention necessary to assist them to make young wood for flowering next season; also see that proper care is afforded any late-growing plants in the borders, for while in active growth much more water will be necessary. Large old specimens of *Camellias* should not be allowed to become too dry at the root after they have set their buds, for this is what generally causes them to drop their buds—a source of frequent complaint. Young vigorous plants, however, frequently require to be watered rather sparingly at this period, to prevent their making a second growth. *Cinerarias* for early flowering should now be growing freely; attend to these with shifting, &c.

## STOVE.

Many of the hardwooded spring-flowering specimens, when kept growing late in the autumn, when there is not sufficient sunshine to properly ripen the wood, seldom flower strongly; therefore give every encouragement to such as have not made their growth, and use the shading very sparingly after this time. The twiners here will now be in their glory. Keep them well supplied with water at the root, and give frequent attention to regulating the shoots and disposing the blooms in the most effective manner. *Allamandas* are fine plants for pot culture, but to have them in perfection they must be planted out in the border of the stove, and tramed to the pillars or back wall, where they flower magnificently during a great part of the year. The brilliant *Clerodendron splendens*, the *Combretums*, *Echites suberecta* and *splendens*, *Stephanotis floribunda*, and many other first-rate plants, do splendidly when treated in the same manner, and trained near the glass.

## PITS AND FRAMES.

Propagation of stock for next season must be commenced and carried on with expedition, so as to secure well-established plants before winter, and without the necessity of keeping them so close or warm as to induce weakly growth. It cannot be too often repeated that, to be able to winter bedding stock safely with ordinary care, the cuttings should be put in sufficiently early in the autumn to allow of their being well established, and fit to be exposed to the open air by the end of next month. Begin with variegated *Geraniums*, and such plants as are found to be most tedious to propagate and prepare for winter.—W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

HAVE been busy taking up *Potatoes*, and putting in strong plants of winter greens in their place. The *Potatoes* in open ground, and introduced on in securing plants between the rows, have been an extraordinary crop, literally covering the ground with tubers. We have tried nearly all plans with *Potatoes* and winter greens, and now chiefly approve of the system of pricking out the greens in an intermediate-bed, and taking up the *Potatoes* before cropping the ground. When greens of any sort are planted between the rows the ground is trodden in planting and watering, and it is rarely that the crop comes so nice and regular afterwards as it does on cleared ground. Of course such observations do not apply to those large gardens where gardeners can keep quarters in fallow until they turn out their winter vegetables. In few gentlemen's gardens can this be done, the demand being so much greater than the ground allotted for the supply; in no cottager's garden would it be advisable to pursue the fallowing system. Treat the ground kindly. Stir it well. Give the crops when growing all diluted slops and sewage, and it will scarcely ever say, "Hold, enough." In market gardens it is generally most profitable to have quick-rotation crops, and only one crop on the ground at a time; but then a piece can there be cleared at once and sent off to market. The gardener, on the other hand, must have a regular daily supply. A cartload, or even a barrowload, of any one vegetable at one time is rather a misfortune than otherwise, unless the establishment is so large as to need it all on one day, or the material will keep like *Potatoes* or *Carrots*. One of the best growers of *Broccoli* in this neighbourhood, and who finds that its culture pays him well, gives each plant a yard of ground—that is, they stand a yard apart each way, and little else is taken from the ground for the season.

This is another proof that plenty of space is, instead of wasteful, the most economical in the end. The labour now spent so often in moving plants from house to house and place to place before they reach their final resting-place would soon put up separate houses for such purposes, and the labour of frequent moving thus be saved. As we are on Potatoes, we may mention that in our limited room we find it most economical to grow Ash-leaved and its several improvements, as Early May, a beautiful Potato, Early Frames, Early Shaw's, &c., chiefly because they make small tops in comparison with their tubering below ground. In some cottage gardens we noticed lately some kinds of Rough Reds, and other sorts, with the haulm fully 5 feet in height; and the drawback to these is that generally they are so long in ripening that the winter greens are late in being put out, and planting between the rows is out of the question. Except in a frame, where the soil was too sandy and light, we have as yet met with no trace of the disease.

**Cabbages.**—The first sowings, owing to the rains, are becoming quite strong enough to stand well through the winter. The second sowing, though protected with a mat and net to keep out all marauders, came very thin, and we were half inclined to think there must have been something wrong in the seed; but to teach us charity as respects our seedsman friends, we find a succession is now coming up quite thickly, and it will answer our purpose better than if all had come together. We shall sow a pinch more for spring planting if we do not plant them in autumn.

It is now a good time to sow Red Dutch, for next year's pickling, in cold stiff soils. Savoy and Scotch Kale may also be sown to come in early next season; these, especially on north aspects, will be much earlier and yield a heavier produce than those sown in spring, in April and May. Scotch Kales are sown largely in Scotland for this purpose, and they are used there in early summer in a way they are rarely used in England. As the plants grow freely, even when they are of no great size the cottage housewife goes into her garden and cuts away about the half of the largest leaves, leaving the other half on the plant, so that but little check to growth is given. These parts of leaves are then divided into several pieces, and when placed in boiling broth, of which barley dressed and meat form a portion, the mess of savoury food turned out is what a king might well admire. These cut leaves are very tender, come in before the early Cabbages, and are popularly termed "stewings." These greens are little used in England until they have a little frost, but the stewings need no frost. The Scotch cottager has much to learn in gardening and cooking matters from his neighbours south of the Border; but in this one respect we think the southern may take a lesson. There is just this to be suggested, that in the warmer climate such Berecote if sown too early would be apt to run to seed early in summer, instead of continuing to grow on in bulk.

**Cauliflower.**—Sowed a little seed, but for next year's first crop prefer sowing in September, as then there is little chance of the plants bolting in winter or early spring before they come to any size. For general cropping nothing we have found beats the London Market. The Frogmore Forcing and some others are more compact, and stand a little forcing better, and are therefore better for pots. Kept planting out on spare ground, and will do so for the month, the latest to be taken up and protected.

**Spinach.**—Sowed the main winter crop on open ground well stirred and enriched, in rows 15 and 18 inches apart. In shady places, and confined for air, it is apt to damp off and become diseased in winter. Where it is much in demand the surface of the ground if at all stiff must be well stirred in winter. The surface-stirring is the great and simple safeguard against the evils arising from damp and also from frosty weather. The Prickly Spinach is the hardiest.

Sowed successions of Turnips, Radishes, and Lettuces, Onions for standing the winter; and planted out successions of Lettuces, Endive, &c. A good plan for late *Endive* is to throw the ground into broad ridges a yard or 4 feet from furrow to furrow, and then plant on the sides of the ridge, about an equal distance from the apex and the furrow. In such positions the plants often stand all the winter with but little protection, though it is safest to have a good lot set thickly under glass, giving them plenty of air. The evils that menace them there are damp in bad weather and attacks by mice and rats when frost sets in. Air for the first, and traps and poison for the last are the best antidotes. On uncovering a piece of *Endive* protected, after a severe frost, we have had the mortification

to find the greater part of the centres eaten out, and therefore rendered next to useless for salading. Lettuces will be attacked in the same way, but the mice are scarcely so fond of them as of *Endive*. One slight protection from them is afforded by letting the plants be frosted a little before covering them up. The mouse cares less for them when the leaves are hard. It is the heart or centre to which mice invariably go. Any one may have the outside leaves for what they care.

**Cucumbers.**—Sowed some for a late and winter crop, if they should be desired; planted out more to keep on in the autumn, and put lining of grass and litter round frames where the plants are still bearing freely. In the few cold nights we have had put on a mat over the glass at night. Gathered Gherkins and short Cucumbers for pickling; if the weather be sunny as well as warm there will be plenty more.

**Mushrooms.**—Prepared for another small bed in the shed; the first bearing heavily, and the second piece just appearing. Now is a good time for putting up a first-rate general bed, and also for making Mushroom spawn. The several modes of doing so we have frequently alluded to.

#### FRUIT GARDEN.

Proceeded much the same as noticed in previous weeks, thinning, shortening, and pinching the points out of shoots, gathering ripe fruit, and so as to prevent it falling. Plums, Morello Cherries, &c., are ripening very soon this season, and Gooseberries look as if they could not be kept long. Strawberries will want dressing as soon as we can find time, and the weaker summer shoots of Raspberries will want removing, to give more light and air to those remaining. Not a day but we see many things that want doing, which we cannot do so soon as we would like. Much, however, may be managed by system, and without the qualms that attend over-working.

A gentleman from the manufacturing districts lately expressed his surprise that the general run of labourers in this district did not seem to go at their work in the same spirit as they did in his neighbourhood. He alluded chiefly to agricultural labourers. We thought there was a reason patent on the surface. The labourers where he came from had some two, or three, or four shillings per week more as wages. To get the most out of a man, even as a mere physical machine, the machine must be kept up, and all its gearings well lubricated and in working order. Good food must be supplied as the fuel to make and keep up the working steam. It is worse than infatuation to expect that the Irishman will do the same amount of work in his own land for 1s. or 1s. 6d. per day as he would heartily do in some more favoured locality and circumstances where his wages would be from 2s. 6d. to 3s. 6d. per day. An Englishman cannot continue to do the work on 10s. per week which he could easily do, and also be fairly expected to do, on from 12s. to 15s. per week. Low wages will generally be found a great mistake for all parties concerned. One good effect of the new Union Chargeability Bill will be the greater equalising of wages over large districts, and a more general recognition of the simple principle, that before a man can do his best at even the simplest labour he must have a sufficiency of nourishing food. When first we came in contact with regular railway navvies we were astonished at two things—first, the amount of hard work they performed, and secondly, the quantity of good nourishing food they managed to put out of sight. No man could sustain such arduous continuous labour without being well fed. Without the fuel the fire must either go out, or merely maintain existence like a gathering coal smothered with ashes. The times are fast approaching when even the energies of the mere physical machine of humanity will have to be made the most of, and kept in first-rate working order. Without such care the employment of such energies will entail loss rather than profit.

#### ORNAMENTAL DEPARTMENT.

Went over stove, so as to relieve the shade, which was becoming too dense. Find we can grow but few plants in our limited room. Removed the decaying flowers from Stanhopeas and other Orchids, and gave abundance of water to Ferns. Plenty of drainage, good, sweet, well-aired, rough loam and peat, and plenty of water, so as never to allow the roots to become dry, are the chief points to be attended to in the successful culture of house Ferns. *Justicias*, *Eranthemums*, *Euphorbias*, *Poinsettias*, &c., to bloom freely in winter, should now be exposed to more light and air. The larger kinds of Cactus, as *Cereus*, *Epiphyllum*, &c., should now have all the sunlight possible, and no more water given than will keep them from showing signs of distress. Few of the larger kinds

will need much water after August. An inquiry has been made as to where Echinocacti, Mammillariæ, &c., are to be had for a small unique collection. No doubt there are many other places, but the chief place we recollect at present, where a nice select stock is for sale, is at the Bury St. Edmunds Botanic Garden. We often wonder why some of our amateurs, with but little room, and little time to spare, do not take more to this tribe of plants. Potted Cinerarias, Primulas, &c., for winter and spring, and commenced propagating for the flower garden next season. Nipped off the flowers from Geraniums intended for winter blooming. Gave more room to feathered Cockscombs, Balsams, and Chrysanthemums. Looked after the watering of the latter, as the rains are deceitful, the massive foliage throwing it past the pots, instead of into them.

The chief work, however, has been mowing, machining, and rolling lawns, and cleaning and regulating the beds in the flower gardens after the heavy rains. This work consisted chiefly in picking out decayed petals and blooms, picking out points of shoots in front of bloom-buds of Geraniums, and a plentiful disleafing of the larger-leaved Geraniums, which, owing to the wet, had become rather massive for the size of the flower-trusses, and keeping the plants in their right places by twigs and bands of fine string, which are generally concealed in the course of a day or two. This and lowering some buds which had grown rather high for the group, took up more of our time than we wished, and the result on the whole was very satisfactory as to appearances, the few days' sun having removed, with such picking, &c., all the effects of the pelting rains. But now, on the Thursday evening on which this is written, after being pretty well pleased with everything this afternoon, the barometer is falling rapidly, the lightning is flashing, and the thunder rolling as if presaging another storm, and if it come the beauty of the beds will be again impaired, all helping to give strength to the idea of having flower gardens under glass, as several times lately alluded to. At any rate whenever we have the chance, we would lessen rather than extend the space devoted to the grouping system of flower gardening out of doors.

Perhaps it is only fair that we should have the right of somewhat modifying our opinions as to the relative first expense of Beard's metallic houses, and a cheap, rough, but serviceable orchard-house, as we have it now on indisputable authority, that the patentees intend putting up such elegant houses at the expense of from 1s. 9d. to 2s. per square foot.—R. F.

COVENT GARDEN MARKET.—AUGUST 12.

INCREASING supplies and decreasing prices are the rule now, for such large quantities of Plums, and other fruit, have rarely been seen even here, the great emporium.

TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

VARIOUS (Mary C.).—Add salt and pounded allspice to your dried Rose leaves before putting them in the vases. (Tyro).—We would not advise you to cover your Vine border with glass for propagating bedding plants. The Currant is the Green-fruited Black; the blue-flowered plant is a variety of *Galaga officinalis*.

APRICOTS ATTACKED BY EARWIGS (An Old Subscriber).—The rotting of the fruit is evidently the result of the earwigs making holes, and wet lodging in these causes rotteness. Adopt the means recommended in similar cases in last week's Journal.

PROPAGATING-POT (T. Barnes).—If you send us one of your pots, carriage paid, and it appears to us to be an improvement on those already in use, we will give publicity to it.

KEW GARDENS (J. B., near Hull).—By all means embrace the opportunity. With care you can live on the sun you name.

HAIL-STONES (W. Gerrard).—We have seen much larger pieces of ice fall in storms, if the sketch sent represents the natural size.

AURICULA CULTURE (W. E.).—"Florists' Flowers for the Many," which you have free by post from our office for five postage stamps, gives all the information which you require. We never recommend dealers.

MRS. POLLOCK GERANIUM (One Not Used to Plants).—The mould from rotten sticks is decidedly bad, and so, too, was cutting off nearly all the leaves. Under these circumstances success in striking the cuttings is very questionable. Try what you can do by potting in sandy loam, leaf mould, and silver sand, in equal parts, with a little silver sand at top; then water gently, cover with the bell-glass, and it may yet succeed.

GLAZING WITHOUT PETTY (S. J., Salop).—We are unable to understand your mode of glazing from the photograph alone, and shall be glad to have further particulars.

FUNGUS ON LAWN (T. S. B., Streatham).—To kill the fungus give a sprinkling of salt. The ground is probably worn out; if so, an application of guano will make the grass grow stronger, and the fungus will then probably cease to trouble you.

TROPEOLUM SPORTS (Ruby).—We sowed the seeds sent us last year, as we were desirous to learn whether the seedlings would inherit the peculiarities of their parent. The plants have nothing to distinguish them from the varieties of *T. Lobbianum*, and the flowers are inferior and very different from the leaves and flowers sent us last season. Six seeds vegetated, and no two of them were alike.

ACHIMENES AND GLOXINIAS IN A COOL GREENHOUSE (Eboracum).—You may flower them in a greenhouse if the roots are forwarded in a hotbed, and kept there until well advanced for bloom. They cannot be grown well in a cool greenhouse, though they will flower well there, and may be kept in winter in the warmest part of the house with the soil dry. A dozen good Achimenes are Deuzle, Ambrose Verschaffelt, Longiflora major, Carl Wolfarth, Baumanni hirsuta, Mauve Queen, Sir Tcherne Thomas, Margareta, Carminata elegans, William Muller, Meteor, and Scepterum. Gloxinias: Sir Hugo, Angliana, Duke of Wellington, Most Beautiful, Lady Emily Williers, Wilsoni, Georgiana, Princess Alice, Evelina, Raphael, Tisona, and Lady Victoria Howard.

PLANTS FOR ROCKWORK (L. T. B.).—*Rhododendrons hirsutum* and *ferrugineum*; *Silene acaulis*, S. Schaffa, *Cistus formosus*, *algarviensis*, *roseus*, and *purpureus*; *Cerastium tomentosum*, *Cineraria nariflora*, *Alyssum saxatile*, *Acœna Nova-Zelandiæ*, *Aquilegia alpina*, *Arabis albidæ*, *A. bellidifolia*, *Bryanthus erectus*, *Cornus suecica*, *Campanula garganica*, *Linaria cymbalaria variegata*, *Lithospermum fruticosum*, *Iberis saxatilis*, *Litsea coniculatus flore pleno*, *Saxifraga oppositifolia*, *S. caryophylla*, *S. palmata*, and *S. affinis*; *Sedum pallidum roseum*, *S. sempervivoides*, *S. grandiflorum*, and *S. altaicum*; *Vinea major* elegantissima, *Statice alpina*, and *Oxalis tropeoloides*.

CARNATIONS CHANGING COLOUR (Felixstowe).—We have never known this to be the case as you say from dark to light. Light flowers frequently run and become dark, but we do not remember ever hearing of the reverse taking place.

PURPLE SPINACH.—We have not observed this at the Royal Horticultural Gardens and in the parks. Is it not either *Amaranthus melancholicus* ruber or *Iresine Herbstii* to which you refer?

INTERNATIONAL HORTICULTURAL EXHIBITION AND CONGRESS (Argus).—You may rest assured that no individual, or body of individuals, will be permitted to interfere with the management, except the Executive Committee which has already been appointed.

COTTAGERS' ALLOTMENT SOCIETIES.—A society of this description being in contemplation at Penzance, our assistance has been asked in procuring the rules of similar associations; we shall therefore be glad if any of our correspondents can help us in the matter.

SEEDLING GERANIUM (F. D.).—It appears to possess some good properties, but to form a correct judgment of it the plant should be seen. We would advise you to submit it to the Floral Committee of the Royal Horticultural Society.

**NAMES OF FRUIT** (*W. Wilson*).—The Fig is the Brown Turkey. The reason of its ripening earlier than the others is well explained by "G.S." in another column.

**NAMES OF PLANTS** (*J. S. W., Worksop*).—1, *Eunonymus europæus*; 2, *Rhus cotinus*. (*A Young Beginner*).—1, *Allamanda Aubletii*; 5, *Rhy-*

*cospermum jasminoides*. It is impossible to name plants from mere scraps of leaves. (*C. P.*).—1, *Athyrium Filix-foemina*; 2 and 3, forms of *Cystopteris fragilis*; 4, *Adiantum setulosum*. (*T. of A.*)—*Pteris serrulata*. (*An Old Subscriber, Berks*)—*Clethra acuminata*. (*J. B. H.*)—*Lycopsis arvensis*. (*C. F.*)—*Begonia gracilis* var.; *Gaillardia bicolor*.

**POULTRY, BEE, and HOUSEHOLD CHRONICLE.**

**SELECTING FOWLS FOR BREEDING.**

THAT like begets like is a proverb as old as the hills. As poultry breeders of old standing we know it, yet we are sometimes foolish enough to think we may now and then deviate from an established rule without penalty. It may not be. We have tried it this year to our cost. At a walk we placed a cock, such a beauty; but he had one fault, we tried to persuade ourselves it was a very trivial one, and might not be hereditary; but now, when the time is come for weeding the different runs, for consigning to the market or to the kitchen all that offend grievously, or that will not pay to keep, we find there is no exception in our favour, and that one fault is faithfully transmitted. We knew we were doing wrong, because the same result has happened before; but there is, we suppose, at times an inclination to forget experience and to try again. We know not what Darwin would say on the subject. A Goldfinch mated to a Goldfinch always produces a Goldfinch, but in many breeds of fowls it is difficult to breed chickens exactly like their parents. Take, for instance, Silver-Grey Dorkings—we have seen yards where every bird was the counterpart of his fellow, and where the uniformity was both marvellous and beautiful. The tie of Beau Brummel's neckcloth was the wonder and envy of all his admirers. A friend going to see him one day at his "lever" met the valet bringing down a large tray of neckcloths, little tumbled and quite soiled. "What are these?" said he to the valet. "Our failures, sir," replied the man. "My Lord," said a brother sportsman to Lord Rivers, "how is it, all your greyhounds are good ones?" "Because," answered his lordship, "I breed well, and hang well." Now, when we see these perfect yards, we want to meet the failures, and to see the kitchen account. We also find it much easier to hand down defects than virtues. A single comb in a Hamburgh or a Bantam is sure to be reproduced, a faulty toe in a Dorking or spikes in a Poland; but the great points and qualities appear only in some of the progeny.

We can only learn from these rather unprofitable facts that even from perfect birds we obtain only a proportion, and often a small one, of perfect chickens. It is, therefore, of paramount importance that in selecting our stock, we should take, if possible, perfect birds, and be inexorable if any one would have us overlook a real fault. Seeing also that where such is plainly to be perceived the bird is not a profitable one for stock, he should at once be got rid of. We say he because it is possible eggs may be wanted, and pullets kept for the purpose. The food consumed by useless mouths often makes the difference between profit and loss at the end of the year.

**ORMSKIRK AND SOUTHPORT POULTRY SHOW.**

The ninth annual meeting of this Society was held on the 9th inst., at Ormskirk. It was decidedly the best and most successful Exhibition which the Association has ever had. The entries were more numerous than upon any previous occasion, and the weather having proved fine there was a very numerous and respectable company upon the ground during the day. The collection of poultry was such as would have

done credit to exhibitions of far greater pretensions. There was a very numerous assortment of *Pigeons*, comprising nearly the whole of the well-known kinds. The pens of *Ducks*, *Geese*, and *Turkeys*, were also well filled. A very good pen of *Spanish* belonging to Mr. Rodbard was not delivered at the showyard until after the Judge (Mr. J. Hindson), had given in his awards, which were as follow:—

**DORKING**.—First, Admiral Hornby, Knowsley. Second, J. Blundell, Burscough. **CHICKENS**.—First, J. Holme, Knowsley. Second, Admiral Hornby.

**COCHIN-CHINA** (Buff).—First and Second, T. Stretch, Ormskirk. **CHICKENS**.—First, T. Stretch. Second, C. Sidgwich, Riddlesden, York. Highly Commended, T. Stretch.

**COCHIN-CHINA** (Partridge or Gronse).—First, R. T. Wood, near Chorley. Second, T. Stretch, Ormskirk. **CHICKENS**.—First and Second, T. Stretch.

**SPANISH**.—First, R. Teebay, Fulwood. Second, J. Holme, Knowsley. **CHICKENS**.—First, R. Teebay. Second, J. Holme.

**GAME**.—First, J. Wood, Haigh, Lancaster. Second, C. W. Brierley, Middleton. **CHICKENS**.—First, J. Wood. Second, J. Eaves, Knowsley. Highly Commended, J. Eaves. Commended, T. Bell, Bickerstaffe; A. Nuttall, Newchurch.

**HAMBURGH** (Golden-spangled).—Second, J. Newton, Silsden, Leeds. Highly Commended, A. K. Wood, Burnside, Kendal.

**HAMBURGH** (Silver-spangled).—First, R. Teebay, Fulwood. Second, J. Newton, Silsden, Leeds. Highly Commended, H. Birch (executors of), Aintree. Commended, J. Foster, Riddlesden, near Keighley.

**HAMBURGH** (Golden-pencilled).—First, S. Smith, Halifax. Second, R. Tate, Leeds.

**HAMBURGH** (Silver-pencilled).—Second, A. Nuttall, Newchurch. Highly Commended, J. Platt, Desn, near Bolton.

**BANTAMS** (Any variety).—First, T. Eastham, Preston. Second, Admiral Hornby, Knowsley.

**ANY OTHER DISTINCT VARIETY**.—First, R. W. Boyle, Wicklow. Second, C. W. Brierley, Middleton. Highly Commended, J. Heath, Nantwich, Cheshire.

**COCK** (Game).—First, Admiral Hornby, Knowsley. Second, C. W. Brierley, Middleton. Highly Commended, J. Holme, Knowsley.

**BANTAM** (Game Cock).—First, G. Maples, jun., Wavertree. Second, C. W. Brierley, Middleton.

**DUCKS** (Aylesbury).—Prize, R. W. Boyle, Wicklow.

**DUCKS** (Bouen).—First, R. W. Boyle, Wicklow. Second, Admiral Hornby, Knowsley. Highly Commended, H. Prince, Nantwich. Commended, P. Ryley, Searisbrick.

**GEESE** (Any variety).—First, Admiral Hornby, Knowsley. Second, R. W. Boyle. Highly Commended, J. Bryers, Ormskirk.

**TURKEYS** (Any variety).—Second, Admiral Hornby, Knowsley. Highly Commended, C. W. Brierley, Middleton; J. Bryers, Ormskirk.

**PIGEONS** (Any distinct variety).—First and Second, C. Cole, Bradford. Highly Commended, C. M. Roys, Rochdale; Countess of Derby. Commended, T. Stretch, Ormskirk.

**WOLVERHAMPTON POULTRY SHOW.**

SOME years ago a Society was formed at Wolverhampton called the St. John's Working Men's Club, and annual meetings have taken place for the exhibition of fruit, flowers, and vegetables. This year, however, is the first at which prizes have been offered for poultry, Pigeons, and singing birds. The promoters have evidently had steadfastly in view not only the encouragement among local working men of a taste for the breeding of poultry and Pigeons, but also actually extended their premiums to the best of many varieties of wild animals that had been domesticated and made pets of. Such meetings must always have a beginning; and when it is taken into consideration that competition in all cases was absolutely restricted to residents within five miles of Wolverhampton, it cannot be denied that, for a first attempt, it was a most successful one.

At break of day the weather forebode a series of heavy storms; the rain fell in torrents, and everything seemed to augur disappointment. About eight or nine o'clock, however, the sun broke out, and, luckily for the Show, a most favourable day ensued. Another year no doubt a more correct method of penning the birds will be carried out; for, on the present occasion, there were many irregularities, arising, most probably, from the hurried manner in which exhibitors brought their specimens to the show tent.

Among the pens shown were many of great merit. Some very good *Brahma* pullets, both dark and light-coloured, were exhibited, and some very nice *Grey Game Bantams*, and *Ducks* of unusual merit for table birds. A singular feature of the Show arose from the fact that, although two sets of prizes were offered for *Dorkings* (any variety), not a single specimen was shown. The district around Wolverhampton does not by any means seem favourable for *Spanish* fowls, if we are to judge those shown as a fair sample. The *Hamburgs*, on the contrary, proved not only a numerous entry, but also really good; some very early chickens were especially worth notice. It is a singularity of this Show that not a single specimen of either variety of Pencilled *Hamburgs* was entered. It is proved by experience that, they not being so hardy as the Spangled breeds, the district around Wolverhampton does not suit them. Some very fair specimens of *Cochins* were shown; and the *Rabbits* and *Guinea Pigs* proved so numerous an entry that they were quite a leading feature of the Show. The *Pigeons* were many of them good, but matched with great irregularity. To give every working man a chance of exhibiting his "hobby," prizes were offered for an indiscriminate class of what might fairly be called oddities. Among the more singular of these was a Badger, that seemed ill at ease under the inquisitiveness of the many visitors, though a broken fang, and other blemishes, told but too plainly that he had experienced far rougher treatment since leaving his natural wilds. A tame Hawk was exhibited among the Pigeons; the owner also sent a pair of Doves, with young ones very recently hatched out, and for which, in spite of the number of people crowding around, the old birds displayed the most careful solicitude.

The Society of the St. John's Working Men's Club at Wolverhampton now embraces more than four hundred members, and we are told that additions are of daily occurrence. As, by the aid of multitudes of banners, triumphal arches, bands of music, &c., the day proved quite a *fête* at Wolverhampton, and the Show a pecuniary success, there cannot be a doubt the exhibition now instituted will prove an annually increasing one.

The following is the list of the awards:—

**SPANISH.**—First, J. Malkin. Second and Third no competition. *Chickens.*—First, A. Picken. Second and Third no competition. **COCHINS.**—First, T. Bryan. Second and Third no competition. *Chickens.*—First, W. Catreece. Second and Third, B. Wiley. **HAMBURGS.**—First, J. Boucher. Second and Third, T. May. Commended, W. Ilsley; R. Wiley. *Chickens.*—First, R. Wiley. Second, T. May. Third, G. Shingler. Highly Commended, G. Shingler. *Pullets.*—First, T. Blakeman. Second, J. Ridze. **EXTRA VARIETY OF POULTRY.**—First, W. Johnson (Light Brahma Pullets). Second, E. Williams (Grey Game Bantams). Third, G. Shingler (Dark Brahma Pullets). Commended, C. Taylor (Game Bantams.) **DUCKS (White).**—First, J. Tudge. Second, T. Bryan. Third, no competition. **DUCKS.**—First, J. Davies (Black and White). Second, E. Painter (Muscovies). Third, no competition. **PIGEONS.—Carriers.**—First, E. Williams. Second and Third, W. Smith. Commended, W. Walker; B. Walford. *Fantails.*—First, T. Ward. Second, J. Burgess. Third, T. Ward. Commended, W. Smith. *Any variety of Pigeons or Doves.*—First, W. Smith (Antwerps). Second, R. Ling (Blue Owls). Third, W. Smith (Doves). **RABBITS.**—First, E. Butler. Second, W. Webb. Third, J. Lowe. Fourth, W. Webb. Fifth, J. Lowe. Highly Commended, Mrs. Carter; W. Andrews; J. Lowe. Commended, T. Skinner; J. Lowe. **GUINEA PIGS.**—First, C. Sage. Second, J. Causar. Third, J. Campbell. **HAWK.**—Prize, W. Smith. **BADGER.**—Prize W. Jenkins.

Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, Birmingham, kindly gave his services as Arbitrator on the occasion.

## THE YORKSHIRE AGRICULTURAL SOCIETY'S POULTRY SHOW.

THE above Society held their annual exhibition of poultry at Doncaster on the 2nd, 3rd, and 4th inst., and although in quality it was perhaps the best the Society has ever brought together, yet we think the prize list capable of considerable improvement so as to include classes for Golden-pencilled *Hamburgs*, *Brahmas*, *Polands*, &c., for there being no class for "any other variety," these kinds were excluded from competition. The weather was very unsettled, with frequent showers, during the three days, and as the birds were unprotected in open pens we fear some of them would suffer severely.

*Spanish* headed the list, and formed a good class, the first-prize pen being especially worthy of notice. *Dorkings* mustered strongly, but, with the exception of the prize pens, more particularly the first pen of chickens belonging to the Hon. H. W. Fitzwilliam, they were only an average lot. *Cochins* were weak in the adult class, but in chickens the competition was better, the prize being awarded to good Buffs. The *Game* classes were a disappointment, as, with the exception of a few pens, they were a very indifferent lot. There was a good show of *Hamburgs*, the adult Silver-spangled deserving most praise, the first-prize pen in that class we never saw excelled. *Bantams* were poor. In Single Game Cocks the cup was carried off by a splendid Black Red; a well known Brown Red, distinguished at many shows, here showed unmistakable evidence of "the white feather," by cowering in a corner and throwing up the feathers at the back of the head at sight of a competitor, in fact, as a bystander observed, he evinced considerable anxiety to be moving.

*Geese* and *Turkeys* were good, and the *Ducks* formed a splendid collection, Mr. Fowler figuring very conspicuously in nearly every class with birds of great merit.

The *Pigeon* show as regards entries was a failure, the prize of 5s. to each class not being a sufficient inducement to exhibitors to send their specimens, but, although small in number, some good birds were shown.

*Rabbits* were a nice lot.

**SPANISH.**—First, H. Beldon, Goitstock, near Bingley, Yorkshire. Second, J. G. Park, High Low Hall, near Whitehaven. Highly Commended, W. Massey, Fulford, York. *Chickens.*—First and Second, T. Greenwood, Dewsbury.

**DORKINGS.**—First, J. White, Warlaby, Northallerton. Second, H. Beldon, Goitstock. Highly Commended, J. Hatfield, jun., Cottingham, Hull. *Chickens.*—First, Hon. H. W. Fitzwilliam, Wentworth Woodhouse. Second, H. Savile, Manor Farm, Rufford, Ollerton, Notts. Highly Commended, J. K. Fowler, Prebendal Farm, Aylesbury.

**COCHIN-CHINA.**—First, H. Beldon, Goitstock. Second, W. Dawson, Hopton, Mirfield. *Chickens.*—First, W. H. Briggs, Bradford. Second, C. Sedgwick, Kiddlesden Hall, Keighley. Highly Commended, H. Merkin, Driffield, Yorkshire.

**GAME (Black-breasted and other Reds).**—First, H. M. Julian, Hull. Second, M. W. Stobart, Darlington. Highly Commended, J. Cross, Hodscock, near Worksop, Notts; C. Chaloner, Steeley, Worksop, Notts. Commended, J. Pearce, Sturton, Retford, Notts. *Chickens.*—First, F. Sales, Crowle, Bawtry. Second, W. Bentley, Scholes-in-Cleckheaton. Highly Commended, T. Greenwood, Dewsbury.

**GAME (Whites and Piles).**—First, M. W. Stobart, Darlington. Second, W. Sutcliffe, Throstle Bower, Mytholmroyd, near Manchester.

**GAME (Duckwings and other Greys and Blues).**—First, F. Sales, Crowle, Bawtry. Second, W. Warburton, Sturton, near Retford, Notts. Highly Commended, M. W. Stobart, Darlington. *Chickens.*—First, W. Bentley, Scholes-in-Cleckheaton. Second, G. Hartley, Gomersal, near Leeds.

**HAMBURGH (Golden-spangled).**—First, H. Beldon, Goitstock, Bingley. Second, Messrs. Burch & Boulter, Sheffield. Highly Commended, J. Newton, Silsden, near Leeds. *Chickens.*—First, R. Ellis, Underbank, Holmfirth. Second, Messrs. Burch & Boulter.

**HAMBURGH (Silver-spangled).**—First and Second, H. Beldon, Goitstock. Highly Commended, J. Newton, Silsden, near Leeds. *Chickens.*—First, H. Beldon. Second, J. G. Park, High Low Hall.

**HAMBURGH (Silver-pencilled).**—H. Beldon, Goitstock. Second, H. Savile, Manor Farm, Rufford. *Chickens.*—First, H. Beldon. Second, J. G. Park, High Low Hall. Commended, J. Preston, Allerton, near Bradford.

**BANTAMS (Gold and Silver-neck).**—First, J. Preston, Allerton. Second, Right Hon. Lady Lodesborough, Grimston Park, Tadcaster.

**BANTAMS (Game of any colour).**—First, R. J. Bentley, Funningley Park. Second, G. Hustler, Stillingfleet, near York. Highly Commended, J. G. Park, High Low Hall, near Whitehaven; Hon. W. Eden, Cantley Hall, Doncaster.

**BANTAMS (Black or White).**—First, H. Beldon, Goitstock. Second, H. E. Embleton, Humberstone, near Leicester.

**BANTAMS (Any other distinct breed).**—First, W. J. Cope, Barnsley. Second, H. Beldon, Goitstock, Bingley.

**COCK (Game).**—Cup, W. H. Briggs, Bradford. Highly Commended, M. W. Stobart, Darlington; F. Sales, Crowle. Commended, R. T. Bentley, Funningley Park; C. Chaloner, Steeley, Worksop, Notts.

**GESE.**—First, J. K. Fowler, Prebendal Farm. Second, O. A. Young, Driffield, Yorkshire. Highly Commended, Lord Hawke, Womersley Park, Pontefract; J. K. Fowler.

**DUCKS (Aylesbury).**—First and Second, J. K. Fowler, Prebendal Farm. *Ducklings.*—Prize, J. K. Fowler, Prebendal Farm, Aylesbury.

**DUCKS (Rouen).**—First, A. Cattle, York. Second, H. Beldon, Goitstock. *Ducklings.*—Prize, J. K. Fowler.

**DUCKS (Any other variety).**—First, J. K. Fowler, Prebendal Farm, Aylesbury. Second, H. Beldon, Goitstock. *Ducklings.*—First, J. K. Fowler. Second, J. R. Jessop, Hull.

**TURKEYS.**—First, Lord Hawke, Womersley Park, Pontefract. Second, J. K. Fowler, Prebendal Farm, Aylesbury.

**PIGEONS.—Carriers.**—Prize, E. E. M. Roys, Greenhill, Roehdale. *Beards or Mottled Tumblers.*—Prize, E. E. M. Roys. *Owls.*—Prize, H. Yardley, Market Hall, Birmingham. *Nuns.*—Prize, R. Tate, Green Road, Leeds. *Turbits.*—Prize, H. Yardley. *Archangels.*—Prize, H. Yardley. *Fantails.*—Prize, H. Yardley. *Pouters or Croppers.*—Prize, H. Yardley. *Dragoons.*—Prize, E. E. M. Roys. *Any other new or distinct variety.*—Prize, H. Yardley.

**RABBITS.—Length of Ears.**—Prize, J. Carnelly, Nottingham. *Coloured.*—Prize, S. Hardcastle, York. *Weight.*—Prize, E. E. M. Roys. *Any other variety.*—Prize, H. Hirst, Doncaster.

The Judges were Mr. W. Smith of Halifax, and Mr. M. Hunter of Greenhamerston, near York.

## ROSSENDALE POULTRY EXHIBITION.

THIS Show was first instituted many years back in conjunction with an Agricultural Society; for the last four or five years, however, it has been discontinued, on account of the widely spread distress of the surrounding district, dependant, as it almost exclusively is, on the cotton trade. The recent happy termination of the American war, however, having brought with it the resuscitation of local trade, the customary meeting again took place on Friday the 4th inst., and we rejoice to say proved one of the very best ever yet held by this Society. Although the weather for two or three days previously was wet in the extreme, portending nothing but failure to the exhibition, even so late as nightfall the preceding evening, a more beautiful day for holding such a show could not be imagined than that on which this one was held. The sun shone cheerily the whole time, yet a fresh breeze made all things appear cool and invigorated. The arrangements were carried out with the greatest possible promptitude and success by James Munn, Esq., a gentleman who, being himself an enthusiastic

poultry fancier, knew perfectly well all the requirements of a poultry show, and by energy and perseverance evinced his personal determination to leave no stone unturned to command success, and, consequently, the whole affair proved a matter of universal congratulation. The Show ground is one of singular beauty, being the centre of a perfect amphitheatre of hills, clothed to the summits in most directions with trees of many years' standing, thus giving quite a rural and picturesque character to the scene. It is a matter beyond question that the Doncaster Show, which unfortunately was this year held simultaneously, somewhat lessened the amount of entries that otherwise might have been insured, as not a single Yorkshire breeder competed at Waterfoot; yet, despite this drawback, the collection was one of a very superior character, and was evidently a most popular feature of the meeting to the visitors generally.

*Hamburgs* stood first on the prize schedule. In these classes first-rate birds were entered, but it is a universally recognised fact among poultry breeders, that *Hamburgs* and *Game* fowls always show to the greatest disadvantage during moulting-time, being especially birds of feather. The Golden-spangled and the Silver-pencilled (chickens) were the best specimens exhibited. The *Game* fowls generally were fast losing their feathers, for it is well known that all fowls are in heaviest moult this season fully three weeks or a month earlier than customary. Mr. Brickley, of Middleton, exhibited several pens of these breeds, which will prove very difficult to beat some two months hence; this gentleman seemed determined to sweep the prize list, and so he did effectually. The *Cochins* and *Brahmas* were in very rude feather, particularly the latter variety. The second-prize pen of Mr. Boyle's, from Ireland, should now have a few weeks entire rest, for they well deserve it, having been so pre-eminently successful the whole season. At this moment, however, the hens are entirely without tail feathers, and we regretted to see them fast eating away the exposed pen-feathers, at present only partially developed over the whole frame, a depraved habit that once fairly acquired is most difficult to cure.

We never have seen this season so good a display of *Roman Ducks*, as at Waterfoot. The *Aylesbury* young birds were but little inferior; whilst the *Geese* were prodigies of careful management. Some very beautiful domesticated *Teal* were shown, and proved an object of general interest throughout the day. Some good specimens of the common wild *Duck*, hatched this season from eggs procured from a wild bird's nest, were very good, but, most strange to say, one of the *Ducks* had a singularly faulty-coloured bill, a feature which we never before saw among hundreds of eggs thus treated, variations of colour, or "sports" as they are commonly called, being of very rare occurrence among wild birds.

It is with unfeigned pleasure that we record the success of the Show just held, and under the improvements of trade, we do not doubt that public support will be freely accorded to the future annual meetings of the Rosendale Committee.

A list of the awards made will be found in our last week's impression.

### TAKEN TO MALAYS.

Our friend, "WILTSHIRE RECTOR," writes that he has "taken to Cochins." I had hoped it would have been his experience of "taking to Brahmas" that he would have given, and I am sure he would be able to say more for them than for Cochins; but then we see there was our "maister's mon" in the way. He, good soul, was satisfied with the quiescence of the Cochin, his lack of curiosity, &c., and so as the Cochin "kips himself to his own place, maister's mon have made up his mind that maister better not kip any other zort, that's all," and "WILTSHIRE RECTOR," kind-hearted soul, as we all know him to be, gives in for the sake of peace and quietness. I can only recommend "our Chaplain" to take refuge under the wings of "our Editors," and introduce Brahmas to his "mon" as a new sort of Cochin. I do not think he will be sorry for the exchange. But I forget myself. I meant to write about "taking to Malays," but the old hobby-horse ran off with me. I can hardly say *revenons à nos moutons*, seeing that it was feathers and not wool I intended to dwell on. Taken to Malays, indeed! "And what if you have?" possibly some may say. Well, gentle reader, I beg pardon. My mission, self-imposed, a criticiser of schedules, as our friend "WILTSHIRE RECTOR" called me, is over, at least for the present, I am disposed to think satisfactorily. I have seen several schedules with a light and dark Brahma class. Even at Birmingham it has been found wise to throw aside the "rest and be thankful" theory, and adopt this division, whilst all shows of any stamp have offered fair premiums to my pets: and so my mission thus far, is, I fancy, accomplished.

Let me now turn to Malays, and give my experience of them. They appear rapidly going down the hill, and I would fain lend a hand to put the drag on. Soon, I fear, that this old breed, formerly so much thought of, must show up only in the "Any variety class," where too frequently the Judge "hates the

Malays," and accordingly high commendations reward them instead of prizes; the latter by far the most pleasant; the former always provoking my man Friday, he always declaring "he can't zee no good in recommending 'em."

Malays are certainly peculiar. Under certain conditions I call them shy birds. If they have the run of a field, and you take some friends to see them, ten chances to one they bolt like lightning through the outlet, and off. Shut them up in a few yards square with railing and they will allow you to examine them, looking you fearlessly in the face with somewhat an air of impudence, as if asking, "What do you think of me?" while the bright, intelligent, yet restless eye keeps you ever in sight. They have a peculiar knowing way of throwing their heads on one side, and taking a sight at you, as though they would return your searching glance. A good cock is a splendid bird. I think I have seen them brighter-coloured than the Game, with the metallic lustre of the black feathers more marked, while the hardness of feather cannot well be surpassed. Am I right in thinking they talk more to each other than other breeds? Certainly, if I am within hearing distance, he appears to me always to be saying something; and when at one time he was kept by himself, and the hens in an adjoining run, they would try every inch of the fencing to get through to him, and Friday persists "he would call them through anything." Both seem restless apart, nor does the presence of other ladies compensate for the loss of his own. So far as I have noticed, he will not tolerate a Brahma or Polish hen. If the cock will not tolerate other hens, his ladies are perfect vixens to the Brahmas; they drive them all over the run, gradually getting rid of the poll feathers from their pecks. This applies only to the Brahmas, for, strange to say, they never attempt to peck the Polish; whether alarmed by the unusual appearance, or what, I cannot say, but they give in at once. I have noticed the same amongst the young chickens. If there is this apparent pusillanimity as regards the Polish, this does not apply to the chickens amongst themselves. A lot of Malay eckerels have their set-to as fierce and as protracted as do Game eckerels, and the adult will take any amount of fighting before he will cry "enough." There is much in the chickens that grows upon you. They are the first to run towards you in greeting, and though, perhaps, somewhat gawky, if good coloured they have a beauty of their own, and now that I have taken to them I should not like to be without them.

Malays require high fences, for though heavy, with the wings short compared to Game and Polish, they have far greater powers of flight than the Cochin or Brahma. To many this is a disadvantage. I do not think they show to perfection in the exhibition pen. The hens are too restless, too intent on escape from their prison, and the cock's flowing and somewhat drooping tail is apt to suffer; moreover, they want freedom to remove the leggy appearance; added to this the hens may not be over-pleasant to each other. On this account I rejoice that Birmingham has decided to treat them as Game, and show cock and one hen. When "WILTSHIRE RECTOR" paid me a visit, he jokingly said that Malays were *Naylays*. Well, mine have behaved very creditably in this way, and I have heard no complaint of paucity of eggs. Some of the eggs are above the average size, others again are very small; the colour, too, varies considerably. On the table I have already said, I think the Malay A1, both as to flavour and appearance. On the latter point I have yet to convert "our Chaplain," and I trust this year I may do it. The chickens are certainly hardy.—Y. B. A. Z.

### BEE-KEEPING IN DEVON.—No XXV.

THE SEASIDE—TRUE HEROINES—HIVES WITH ENTRANCES AT TOP—REMOVING A SUPER—CHILLED BROOD NOT IDENTICAL WITH FOUL BROOD—A DRONE BRED IN A ROYAL CELL!

I've once more been by the seaside, but not again to my favourite little hamlet in the wilds of North Devon, nor have I any apiarian adventures to recount. This time my fortnight's sojourn has been at one of our South Devon watering-places, within easy distance by rail of the "ever faithful" city, and to which, indeed, I was once recalled by the necessities of distant friends who were impatient for Ligurians. During this fortnight's trip I think I saw but one bee, and that a black one, in the act of investigating a blackberry blossom. I immediately caught the little forager and conveyed it a short distance imprisoned in my bare hand, from which when opened it escaped right joyfully and flew merrily away, probably some-

what puzzled to account for its unusual adventure. All this was matter of intense astonishment to a juvenile relative who happened to accompany me, and who seemed to deem my explanation that bees were most inoffensive creatures when at a distance from their hives, a rather lame interpretation of what appeared to him so remarkable a phenomenon.

But, dear me! what am I saying? That I never saw but one bee? What a mistake! How could I forget that I paid a visit to two excellent maiden ladies (sisters), residing near a neighbouring village who, to their eternal honour be it spoken, devote the whole of their time and otherwise ample means to the gratuitous maintenance and education of a number of destitute orphan girls, children of officers who, having spent themselves in the service of their country, had been unable to provide for those dear ones that remained behind them. All honour, indeed, to these admirable women, before whose life-long labour and glorious self-abnegation, deeds of what the world is accustomed to call heroism appear but as puny and dwarfed abortions. By one of these estimable ladies was I escorted over the apiary, which I found to consist of about a dozen hives of various descriptions scattered about the garden—some swarms, some old stocks, some working-supers, and all doing well. But what most forcibly engaged my attention was two or three hives with entrances at the top, after the fashion advocated by Messrs. Williams and Stuttle, and one of which was working a couple of good supers. This my conductress informed me had been for some years a very favourite and successful plan of hers; and on my inquiring what became of dead bees and other refuse, she replied that she supposed they must be dragged out at the top, for there was no other means of egress.

Having returned from my fourteen-days holiday in the evening of the 13th July, my first care was to insert an empty box under the super adverted to in page 19, which was by this time well filled, with the exception of the outside of the two side-combs which the bees had not been able to seal completely over, but which, nevertheless, contained in the whole about 35 lbs. of beautifully white honeycomb. Most of the bees had deserted it by the next morning, when I took it off, permitted the stragglers to escape, and had it all ready for Mr. A. Neighbour, who made his appearance about one o'clock in order to convey it to Plymouth in time to be exhibited during the following week, at his stall in the show-yard of the Royal Agricultural Society.

The afternoon was devoted by Mr. Neighbour and myself to a trip to the residence of the clerical friend whose "mistakes" were related in No. 221 of "our Journal." Here we inspected his apiary, minutely examining the hive mentioned in page 477 of the last volume, and which at that time contained so large a quantity of chilled brood in all stages of decomposition. We found that the great bulk of this abortive brood had been removed by the bees, whilst that which remained appeared to have dried into a perfectly innocuous condition, nor was there the slightest trace of that fell disease, foul brood, with whose appearance I have unfortunately been so familiar that I could not fail to recognise it almost at a glance. The result of this "mistake," therefore, proves as conclusively as a somewhat similar experiment purposely instituted by myself, and frequently referred to during my discussion with Mr. Lowe on the subject, that chilled brood and foul brood are by no means identical.

Returning in the evening, I saw my friend and his weighty glass box off on their way to Plymouth, where I doubt not his stand has proved one of the most attractive features of the show.

Those who are familiar with the writings of the illustrious Huber may, perhaps, remember that during his experiments with drone-breeding queens, whose abnormal condition, erroneously attributed by him to retarded impregnation, has since been proved to be owing to parthenogenesis, since drone-breeding queens are undoubtedly virgin queens; he remarked the singular fact, that these defective mother-bees sometimes lay the eggs of males in queen cells, and was astonished at finding that the workers took exactly the same care of drone eggs deposited in royal cells, as of those that would really become queens. More than once, in the firm persuasion of finding royal nymphs, he opened these royal cells after they had been sealed, yet the nymph of a drone always appeared.

I am not, however, aware that any instance has yet been recorded in which bees, with the full opportunity of selecting from hundreds of worker eggs and young worms, have yet committed the mistake of choosing a male egg, giving to it a

royal cradle, and nursing it to maturity. It will, I think, be admitted that such an aberration in the instinct of the bee is extremely unusual, and I for one should be very slow to believe it, unless occurring, as in the instance which I am about to relate, under circumstances that preclude the possibility of either doubt or mistake.

It may be remembered that on the 19th of June, I introduced a young queen that had exhibited signs of fecundation, to a stock which, as related in page 19, had lost its queen in an attempt to swarm six days before. This introduction having been successfully effected, I supplied the "nucleus" from which the young matron had been abstracted with a suitable brood-comb on the 25th of June. This comb contained worker-brood in all stages, from the egg to the sealed nymph, as well as a patch of drone-brood at one end. Only one royal cell was, however, formed, and this, as is very frequently the case, was situated near the bottom of the comb, and just at the point of junction between the worker and drone brood. After vainly watching day after day for the expected appearance of a queen, and finding the royal cell apparently neglected by the workers, who, having denuded its apex of wax, seemed to pay no further attention to it, I cut it open on the 23rd day, and was at first quite confounded at finding that it contained a living inhabitant. My momentary impression that I had prematurely destroyed a queen nearly ready to emerge from her cell was, however, speedily dissipated on a more minute examination, which proved the individual thus reared "in the purple" to be neither more nor less than a full-grown and well-developed drone, which would probably have made a natural exit during the next (the 24th) day.

I should be glad if any of the apianian readers of "our Journal" would state whether a similar instance to that last related has ever come under their observation.—A DEVONSHIRE BEE-KEEPER.

#### BARS AND SLIDES OF STEWARTON HIVES.

MAY I trouble you or "A RENFREWSHIRE BEE-KEEPER" for a minute description of the bars and slides used with the Stewarton hives? A section, such as was given of the Woodbury bars and frames, would, I think, be valuable to many of your apianian readers in common with myself.—W. J.

[The six central bars in Stewarton hives are  $1\frac{1}{2}$  inch wide, the outer two are  $1\frac{1}{2}$  by  $\frac{1}{4}$  inch thick. If frames are intended to be attached, to make a more secure job, the thickness had better be increased one-eighth of an inch. On each side of the bar, one-eighth of an inch from the top, is run a groove, one-eighth square, to receive the feather of the slide; the lower corners are rounded off to the Woodbury rib. The slides are five-eighths of an inch wide on the under and three-eighths of an inch on the upper side, and a quarter of an inch thick, the upper side of the slide working flush with the top of the bar. The accompanying sketch, showing an end view of the bar and slide, may aid the description.]

The slides are left  $1\frac{1}{4}$  inch longer than the bars, to draw by, and should be slightly rounded on the lower edge that they may work very easily at the start. An obdurate slide or over-thick comb I can easily remove from one of my hives by simply bringing the others a little closer; this advantage is attainable by placing the bars on the top of the hive, a portion of their under side being removed to lower the edge of the groove equal in extent to the thickness of the hive; whereas in those hives in which are bars or frames sunk into notches, the bars do not offer the same facility, but are in a great measure fixtures.

When frames are attached to bars the notches are carried further on, so as to leave a quarter-of-inch passage between the end of the frames and the hive. The ends of the frames are of the same breadth as the bars, fully one-eighth of an inch thick when dressed, the lower corners are rounded off in imitation of combs, and kept together at bottom by a narrow strip of wood seven-sixteenths of an inch broad by a quarter of an inch thick. Frames so made are an improvement on those in which the bottoms are of the same width as the sides, such

keeping the hive much closer and impeding the progress of the bees.

Your correspondent's best plan would be to order direct from any of the Stewarton makers a single hive as a pattern (should he not require more), and if he wish to adapt bars and slides to the hives he at present employs, he could add to his order a quantity of bars and slides in length pieces, and these he could easily cut up to suit his purpose. These hives can be procured from Stewarton at a price at which no local tradesman will undertake to furnish them. James Allan, cabinet-maker there, supplies me.—A DEVONSHIRE BEE-KEEPER.]

### FECONDITY OF LIGURIAN QUEENS.

My apiary is looking more flourishing than before in consequence of the wonderful breeding powers of the Ligurian queen, daughter of one received from Mr. Woodbury. I made the first swarm from this hive by removal on the 6th of May; on the 9th of June a very large swarm was thrown off, which has filled a large super; on the 19th a good second swarm issued, and a large population was left behind, besides which I robbed it of two brood-combs to strengthen other swarms, and a great number of bees from this queen are working in two black hives, to which they seem to have been allowed entrance without opposition. I never saw anything like the multitude of bees this queen has produced, and drones are also very numerous.—J. L.

### SUPERING A SWARM WHEN HIVED. STRENGTHENING A WEAK STOCK—FEEDING.

I COMMENCED keeping bees this season by purchasing two first swarms, which were hived in Payne's flat-topped hives on the 6th and 7th of June respectively. I was absent from home at the time, and, mistaking my directions, a small straw super was placed on No. 1 two days after it was hived. On the 11th of July I took this super, completely filled with sealed honey, and weighing 9½ lbs. nett. On the 13th, having taken out the honey, I replaced the super in its former position, and it is now apparently nearly full of sealed comb again.

No. 2 was treated according to the direction in "Bee-keeping for the Many," the glass super not being put on till the eighteenth day after the swarm was hived. In the meantime I fear a swarm had gone off, which was lost; for the bees appear to be greatly reduced in numbers, and have refused to do anything in the super. The stock-hive, however, does not weigh less than 20 lbs. Do you recommend me to join another swarm to this by driving, or to let the hive stand the winter as it is?

On the 27th of July I purchased a stock condemned to be burnt, for the purpose of making an experiment in driving. The experiment was perfectly successful, and I took about 15 lbs. weight of honey from the hive from which the bees were driven. The weather being very fine at the time, I did not feed the driven bees; they seemed to work well in their new hive, and, after a day or two, began to carry in pollen abundantly. A wet morning, however, made me nervous about their having enough food, and I determined to give them the "bottle." I took up the volume of THE JOURNAL OF HORTICULTURE for 1863, and found that the right proportion of sugar and water was 3 lbs. of the former to 2 lbs. of the latter, simmered and boiled for two or three minutes. I made my food according to receipt, put it in the bottle, tied on the net, inverted it over the perforated zinc, and all seemed well; but the next morning a dark spot on the ground, covered with a cluster of flies, told a tale. The syrup must have poured down through the hive, causing great consternation to the inhabitants, and at length dropped on the ground, to the great delight of the flies. Since that I have given them half a pound of honey; and now I am feeding with barley sugar put in at the bottom, which, however, they do not eat very readily; in fact they seem to be in a very weak state.

If this experiment does not succeed, I am determined to try again with another colony of condemned bees; but I am anxious to have a good receipt for bee-food without honey. One person strongly recommends treacle and beer; another, sweet worts, &c. The cook says if she had to make syrup about the consistency of ordinary honey, she would put 5 lbs. of loaf sugar to half a pint of water. This is very different from the receipt in the Journal. I should also be glad to know whether the food ought to be given soon after the bees are

driven, or whether it is better to wait till night.—J. L. STACKHOUSE.

[Some persons recommend placing a small super on a swarm immediately after hiving, and your success would seem to indicate that the plan is a good one. If No. 2 appears weak, we should drive and add to it the bees from a condemned hive. The fault was not in the food, but in your management of the bottle, which you should test before using, by filling it with water and inverting it. If any run out after it is inverted there is something wrong—the mouth, perhaps, too wide—and another must be chosen. The inhabitants of two or three condemned hives should be united, and fed liberally until they have built combs, and stored them with a nett weight of from 15 to 20 lbs., if it be desired to form a strong stock, fit to stand the winter. Food is best given at night.]

### REMOVING BEES.

BE so kind as to inform me at what time of year and what hour of the day it will be best to move a hive of bees from one side of some buildings to the other, a distance, perhaps, of 40 yards, but not in sight.

[The best mode of removing a stock of bees so short a distance is, first to carry it to a new situation not less than a mile and a half off, shutting them up in the evening with due care for ventilation. In about three weeks time they may be brought back to a new position in the neighbourhood of their old stance. If moved direct it had better be done very quietly during the depth of winter.]

### RETARDING THE DESTRUCTION OF DRONES. REMOVING A QUEEN.

I SHALL feel obliged if you will advise me as to the best means of preserving the drones in one or more of my hives for the purpose of trying to breed a few late Italian queens. Although the doctrine of parthenogenesis seems incontrovertibly established, I should, nevertheless, prefer saving drones bred by my pure queen. This pure queen is now in a bar and frame hive furnished with a fair proportion of drone-comb, and drones are beginning to come forth pretty freely, so that by the middle of July it will contain a considerable number of these gentlemen. Would feeding in case of bad weather, or when the honey harvest begins to fail, induce the bees to allow the drones to remain unmolested? If the hive still retains the old queen, I would take steps for raising young queens about the 7th of August, as by the time they were hatched and ready for the drones the cottagers would have taken down their bees, and the annual massacre would be completed in almost every hive which remained. I should not like to risk my pure queen in these experiments by removing her to a strange hive and leaving her subjects to raise queens.—J. E. B.

[Liberal feeding when the natural supply fails may do something to retard the destruction of drones, which, also, bees possessing an old queen are not usually so prompt to commence as those presided over by a queen bred this season. Still it is more than probable that you will eventually be compelled to remove the queen, and this may be safely done by putting the comb on which she is found into a nucleus box, together with two or three spare combs, and then brushing into it the bees from two or three combs of her own hive. This little colony, being possessed of a fertile queen, may be rapidly built up into a strong stock by the gradual addition of brood-combs from other hives, and the queen will not run the slightest risk by the removal.]

### ARTIFICIAL VERSUS NATURAL SWARMS— DWINDLING STOCK.

I WAS amused at your correspondent "A DEVONSHIRE BEE-KEEPER" writing that he had had a misfortune in one of his hives swarming naturally. I always imagined natural swarms were best. I have not kept bees for many years and therefore am perhaps not competent to give an opinion, but I have tried artificial swarming twice and failed each time. The first time, my new swarm disappeared the day after driving. This year, having a large straw hive crammed with bees and more than 50 lbs. weight of honey, I determined to try for an artificial swarm, as the bees had been hanging out for two or three

weeks and would not go off. Accordingly, on June 9th, I obtained the help of an old friend who has kept bees for years, and done better than most, even in every kind of hive. We first put an empty hive on the full one, drummed till about half of the bees went up, and then put the swarm in its place. It was a large swarm, but decreased in a few days; the bees, I suppose, going back to their old place. However, they have done very well, but the old stock puzzles me, and I should like to know what to do with them.

This old stock is in a fair-sized bee-house with another hive by its side, and as far as I can ascertain the two have fraternised. I saw the morning after driving that they were inclined to do so, but I effectually separated them by putting up boards for a day or two. Now, however, they appear to me to run together inside the house; and although the bees in the driven stock occasionally carry in a little pollen, yet they are idle and listless, and there is not above half the number that there was a month ago, while the hive by its side is crammed, and a large super also full of bees. I do not like losing a stock in this way, and I should be glad of any advice. My friend here is puzzled, as he says it is too late to give them a piece of royal brood or a queen. Would it do to remove the super and put an empty hive in its place, so that if the queen went up it might be removed this autumn or next spring, and trust to the stock-hive (not the driven one), raising a new queen? In this case I should take the honey from the driven hive, and let the bees all go together.—A PUZZLED ONE.

["A DEVONSHIRE BEE-KEEPER," using only moveable comb-hives, and multiplying his Ligurian bees with ease and certainty by artificial swarming, may well deem the risk of losing valuable queens by natural swarms far too great to be willingly encountered. Your first failure was probably owing to the queen not accompanying the driven swarm, and the bees returning to the parent stock in consequence; whilst in the second instance the old stock either failed in raising a queen or some fatal accident happened to her afterwards. Similar misfortunes are by no means uncommon in natural swarming, but with moveable comb hives they can be soon detected and easily remedied. Your best plan will now be to drive some one of your neighbour's condemned colonies and add the bees to your dwindling stock.]

### TAKING SUPERS—HONEY HARVEST IN SHROPSHIRE.

You say the best way of taking a super is to put a box under it, but you do not state if the communication with the stock is to be cut off. I always find a difficulty in taking away supers, and any improved and quiet plan would be a boon. After placing the box under the super, do you cut off the communication with the stock?

The honey season here seems to have been good. I had three stocks this spring and have taken 60 lbs. in supers. One stock after swarming filled a glass super weighing 24½ lbs., and the swarm nearly 10 lbs., making upwards of 30 lbs. The honey harvest has been over here for at least a fortnight.—GEO. SMYTHE, Norton, near Shifnall, Salop.

[When a box is inserted under a super with a view to its removal, the communication with the stock-hive should be left open.]

TO MAKE CURRANT JELLY.—Set on the fire in a sugar-pan a pint of smooth clarified sugar; when it boils put in a quart of picked red currants, in which let them boil for an hour. Be careful to skim them well, and at times add a little cold water to raise the scum. When boiled enough run the liquor through a sieve into a basin, in which you have squeezed three lemons; then put in some isinglass, and set your jelly in a mould to ice as usual. Another mode consists in taking the ripest red currants that can be had, as the white are not so good for jelly; crush them, and press out all the juice into a glazed pan; cover it very closely, and set it in a cold place for six days; then with great care remove the thick skin which covers the juice, and pour it into another vessel, throwing away what remains at the bottom. When the juice is perfectly clear weigh it, and for each pound take half-pound of crushed sugar; put them on the fire together, and much scum will soon rise, which must all be taken off; let it remain on the fire for about an hour, and then try it as follows:—Put a small quantity on a very cold plate, and if when it cools it becomes thick and of proper consistence

take the pan from the fire; if it is not let it remain till that is the case. Pour the jelly whilst hot, and the glasses must be quite cold before you cover them with paper.

TO CANDY FRUITS.—Take one pound of the best loaf sugar; dip each lump into a bowl of water and put the sugar in your preserving kettle. Boil it down until perfectly clear, and in a candying state. When sufficiently boiled, have ready the fruits you wish to preserve. Large white grapes, oranges, separated into small pieces, or preserved fruits, taken out of their scrups and dried are nice. Dip the fruits into the prepared sugar while it is hot; then put them in a cold place—they soon become hard.

### OUR LETTER BOX.

POINTS OF ROUEN DUCKS (*J. McConnell*).—We do not remember having received your letter, but a similar question was answered last week at page 120. Streaks of white on the face, pale breasts, or the presence of white feathers on any part of the body, are fatal objections.

BREEDING COCHINS FOR EXHIBITION—POULTRY FOOD (*Valeria*).—Having assured yourself that the birds are in all respects such as you would wish, you may take hens of two or three years old, and put to them a cock of twelve months. If you are breeding for early chickens next year, you must recollect that there is almost always a large proportion of cocks in the earliest hatches; you must arrange accordingly. The best food for all poultry is ground oats; it is used all through Sussex; it is not oatmeal. It can be had from Mr. Agata, Slaughtam Mills, Crawley. The book is in the press.

VETCHES AS FOOD FOR POULTRY (*J. T.*).—Vetches are not considered good food for poultry; we do not advise you to give them. They are excellent for Pigeons. It may be well to say that if the quantity does not exceed one-tenth they may probably be given without injury, but it is hardly satisfactory to give food that will merely allow your poultry to remain stationary, without deriving benefit from it.

COOP FOR SITTING-HENS (*G. B.*).—Your coop will answer the purpose well; but such a box should be divided into three, be closed all round, and only the lid should be wirework. The hens should be shut in, and taken out to feed morning and evening. There should be no bottom. Sitting-hens cannot be too private, and nothing annoys them so much as other hens laying in their nests. It is also a great disadvantage at the hatching-time, on account of the irregularity it causes.

MANAGEMENT OF GOLDEN AND SILVER PHEASANTS (*W. H. W.*).—They are not very sociable birds. It may be some time before they become reconciled to their house, and attached to their owner. They would do better on the ground than in a loft. Their food should be barley. They are very fond of bread. They must be supplied with sods of growing grass. They are very hardy, and require no warmth, and very little shelter. Any kind of perch will suit them, but the best is a round one, about 1½ inch in diameter.

REMOVING EKES AND NADIRS (*A. B.*).—All the ekes or nadirs should be removed before winter.

TREATMENT OF A WEAK SWARM OF LIGURIANS (*A. Subscriber*).—The best, perhaps the only, chance of saving your Ligurians will be to drive a strong stock of common bees, and induct the Italians into their deserted habitation. If done at once, there will probably be sufficient brood hatched out during the next two or three weeks to bring them into a satisfactory condition.

TOMATOES (*W. G. S.*).—On the Continent, and in America, visitors have informed us that large quantities of full-grown green tomatoes are used as salads separately, and mixed with cucumbers; that great quantities of the young fruit are pickled and preserved, just as we pickle gherkins. We have made a very nice sauce in the following manner:—Put the ripe fruit for an hour in an earthen vessel into an oven, not hot enough to make them boil, but warm enough to cause the fruit to fall, and become soft; then pour off the thin liquid; squeeze the pulp through a cullender, keeping out the seeds; and to every gallon of this juice add a dozen fair-sized button onions, rather more shallots, less of garlic, or of cayenne pepper a little allspice and cloves, and salt to flavour. Simmer gently over a slow fire for an hour, stirring the mixture well all the time; and, as it gets cool, place it in wide-mouthed bottles; cork and secure with bladder. There are many other modes; and among these you will find directions for making tomato sauce; tomato catsup, tomato soup, tomato paste, and stewed tomato, at page 414, in No. 362, September 4, 1855; and these are but a sample of the many variations in the recipes as to keeping this fruit. The simplest mode is just to part with some of the mere watery fluid, boil the remainder sufficiently, and help to keep, and flavour to taste, with such condiments as pepper, salt, allspice, cloves, &c. Other receipts will be found Vol. VII., New Series, pages 324, 364, and 384.

### LONDON MARKETS.—AUGUST 14.

#### POULTRY.

There is a good supply of poultry, with a dull trade. Since our last quotations Grouse have come into season. We shall notice them next week, but at the time we go to press it is impossible to do so, very few having arrived.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 72.2°, and its night temperature 49.2°. The greatest heat was 89°, on the 25th, 1859; and the lowest cold, 32°, on the 21st, 1850. The greatest fall of rain was 1.32 inch.

HOW TO MAKE A CROQUET GROUND A GARDEN ORNAMENT.

AFTER all, gardeners must accept croquet. I suppose they have found this out for a year or two; before that time they might have hoped to escape, but now it is in

vain to dream of immunity from the universal game. A power to which all yield—monarchs and gardeners—is enlisted on the side of, and is ready to do battle for croquet—namely, the lady power; so therefore to yield is duty, propriety, yea, necessity.

Some four or five years ago a gardener had heard of the croquet invasion, but "he was quite sure that such nonsense would never captivate his ladies, they loved their flower-beds too much a great deal." He had, indeed, seen his brother gardeners with rueful faces turfing over their beautifully-shaped beds, and he had marked with sorrow how their lawns were blotched in dry weather with straw-coloured patches, or even had the bare earth peeping through; however, he should escape he knew. At length one fine day an ominous-looking long box appeared on his lawn, and was opened in his presence. He knew what it all meant, and his heart sank, but as it sometimes happens in dark circumstances, his wit grew bright. As the mallets were extended on the grass, he said, "I suppose ma'am you are going to have a party of little cripples to tea, and these (touching the mallets) are their crutches?" A faint smile was all that was vouchsafed in return. A few minutes after the hoops were planted in *terra firma* (I wish some other hoops I knew of were under *terra firma*). Then, "Gardener, these beds must be laid down in grass, that Deodar must be transplanted, and, of course, that border must be done away with." A few months afterwards that poor gardener was in the condition of the son of a spendthrift sire, who was accustomed to say, "The gout was the only inheritance left me by my father," for he had but the croquet ground left in its bare ugliness, in that part of his once-prized garden.

But gardeners are men full of resources. "Why," said some one to Dr. Johnson, "do Scotch gardeners excel English?" "Because," growled Ursa Major, "it's all gardening in Scotland." There was sound sense in this reply. The greater the difficulties, the more is energy called forth, and the more resources to overcome the difficulties are brought out. Attempt to hinder a persevering man, and he will persevere all the more. The farmers thought free trade would ruin them, but it only ruined the idle ones, while the industrious and ingenious rose to the occasion, and triumphed. The game of croquet is well known. Let me observe, in passing, that the original arrange-

ment of the hoops is the best—two, and then three on each side, and two again. The bird-cage is one of your too-clever-by-half contrivances. There is only one plan occasionally adopted which every master or mistress of a garden, and every gardener must protest against, and not allow for a single moment—viz., the third stick, or one placed in the centre space which every player is obliged to hit with his ball after he has gone through each quarter of the game—that is, hit it eight times during the whole game. This is difficult, and there are often six misses to one hit; hence the grass around this stick becomes worn down to bare earth very quickly. This third stick cannot be tolerated; every other part of the game may be allowed to pass, but this never.

Croquet is to us in the country a necessity. Londoners talk of their Crystal Palace, and say they could not do without it, and cannot imagine a time in London's history when there was not such a building, so available for all purposes and all weathers. Nay, it is said some Londoners aver that there always was a Crystal Palace, that it is all nonsense to say otherwise, at any rate that the first was not built in 1851, but rather in 1581, if not earlier. Now, I say, I cannot imagine the country without croquet, it must have always been played, or how could there have been any summer sociality? Besides, we know there have always been weddings going on, and how without croquet could the young people have met, and we know they must have met before they were married? Hence it follows there always was croquet. Two bachelors each of forty-five years fell before croquet. "Poor fellows!" exclaimed another bachelor, the last left of the set, "they played each once too often at that foolish game." Even supposing the bachelor correct in charging croquet with spreading the fatal snare, still, perhaps, his friends did right in choosing wives at croquet, surely it is a better plan than the old and somewhat vulgar cheese-paring one. Watch a lady at croquet, if she be persevering, if she play steadily, if she play perfectly fairly, not trailing her dress across her ball, of course quite accidentally, but somehow the ball is put into a better position, if she play in perfect good humour, not losing her temper whatever happens, not stamping her pretty foot, and this, above all, if she be obedient to her captain, it is only fair to presume that she will make a good wife. In a too artificial age, croquet brings out the natural character, this surely is well; besides, it affords exercise without fatigue, and all can play from seven years old to seventy. One only fault is to be guarded against, croquet is apt to become a ruinous runner-away of time. This I endeavour to avoid by never allowing a mallet to be touched in the morning. Time for exercise, time for amusement (all the better if both are to be had together), there must be, but a game must not take the place of the serious, earnest business of life. Permit, fair young friends, this word of caution, and do not play morning, noon, afternoon, and even by moonlight. If the Great Master asked you, "What hast thou been doing?" and the only answer you could truthfully give, was, "I have been playing croquet," that would be a poor reply in deed.

Some of our readers, perhaps, occasionally give, or wish

to give "a croquet," that is the ladies' short for a croquet party; but as all such things are not equally well managed, let me describe one at which I was, happily for myself, present a short time since. Suppose a lawn on which were placed hoops for three games to be played at the same time; the mallets and balls were tastefully arranged at each starting point. In order to know one ground from another, and to prevent any dispute in the games, each ground had been clearly marked out by a narrow line of scattered bran run round the edge. On a table were laid the prizes, these are frequently flower-vases, photographic albums, or anything elegant and durable. The party had been planned for some weeks, there were to be players and lookers-on. Three sets of eight had been chosen by one well knowing the play of all. Each captain of a side was presented with a paper, upon which the names of his party, and their opponents were written. A little time is consumed in getting the players together, at last a dilatory gentleman who comes panting in at half-past three, instead of three, has arrived, and then the lawn is alive with players. Gay silks and black coats are intermingled, happily those odious dress coats are not required to be worn. Dress coats, the horrors! making eyegymen look like footmen in mourning.

To return, the games proceed merrily. I thought I noticed a little flirting, and somebody looking across at another set, and wishing somebody had been playing in her set. Still all went on pretty well, and as each game nears its end, and that end is often long in coming, spectators gather round the stick almost as eager and as excited as the players themselves. The glorious uncertainty of croquet is now seen, for the skill that had been behind all the time now makes a spurt. A good hit follows, by which the best player of the hitherto successful side is knocked out of the game. All is excitement, and, lo! the lately depending ones win. So the eight are reduced to four. But just at this juncture dinner is announced, and here a croquet party is again seen to advantage. It is a cold dinner, and what so suitable in summer time? Long narrow tables extemporised for the day by the carpenter, run along the sides of the room, leaving a hollow square in the centre, and making a small dining-room a large one, or at least capable of containing a great number of guests, which is just the same. Brightly glisten the viands, being for the most part glazed marvellously, there are the substantial viands, there are the lighter viands, with dishes of juicy fruit interspersed, semi-transparent Grapes, Blooming Plums, and downy Peaches. But commend me (after I have dined) to the flower decorations, shapely Ferns in rustic-looking pots, Fuchsias with Chinese-lantern-like flowers, with the earth hidden by many a rare device; then the cut flowers, to arrange which employed the morning of the young ladies; care and time well spent, for the result was giving happiness to all who beheld them. Oh! the exquisite taste shown in arranging the colours, and the dainty sprays of Variegated Ivy made to climb the narrow stems! Man! man! thou art a very bungler in such matters! I could only look on and wonder at what the slender fingers had wrought. "What would any entertainment be without flowers?" Granted, but what would the flowers be without woman's arranging hand? The dinner is over, that portly old gentleman has finished at last. How some old gentlemen do enjoy their dinners! Back to croquet; the games of four, two on each side, are soon over; then come the duels, when the two firm friends all through, who have advised each other in soft accents, now become deadly enemies. Now they are at it, the lady is croqueted, but she does not despair; up she comes again. The gentleman bumbles at the first stick, the lady advances; he is after her. Another miss—ah! but she has artfully wired herself. "He will win." "No, she will." "Hurrah! the lady has it." The other games are advancing to their end. Mamma's sip their tea, and hope the grass is not damp; the daughters say, "Oh dear no." but it is, though the young ladies are incredulous. The last game is over, the heroes of the day are congratulated, and advance for their prizes. They draw lots for the best, and receive them in order, with a heightened cheek, and a tremulous hand. Evening is now advancing rapidly, and all praise to health-giving croquet, its parties end when others begin. Croquet causes no late hours, and brings no headaches. The groups are thinning, and soon the last carriage wheels out of the gate.

One final remark. I think it is a mistake to give prizes at croquet parties. Like chess, croquet should stand as a game on its own merits. The pleasant gathering, the kind hospitality, the good game are enough. Prizes make feelings too keen, and a little mar the general pleasure. Human nature is

human nature, even when dressed in crinolines, or black frock coats. Dear me! how I have run away from my text, which on turning back I see, for I had forgotten it, is, "How to make a croquet ground a garden ornament." Well, I am not the first clergyman who has run away from his text, that's a comfort; besides, does not Miss Augusta Gushington declare that such run-off sermons (I have not run off the line, I hope) are freer, more natural, more earnest? &c.

But now to my text in all earnestness. A croquet ground with the earth at the edges running any way, is ugly—it is no ornament, that is certain. The prettiest I know is oval, this shape suits the game, it opens out beyond a small geometric garden, and has a grass bank all round save at the entrance and exit, this bank varies in height, but the average is 2 feet, then on either bank is a flower-border planted with standard Roses, Geraniums, Asters, &c., the side near the road has at the back a thick row of *Convolvulus major*, neatly trained as a screen. Some one asked a few weeks since, "How to make a croquet ground," but I purposely did not read the reply, and so speak simply my own ideas. The bank around is a great feature, the oval shape meets the eye pleasantly. Besides the bank prevents the balls rolling too far, and as ground has usually to be levelled, the spare earth is used on the spot. If flowers are not thought advisable, there are flowering shrubs in abundance for choice, or have old-fashioned border plants, why not? Croquet cannot be allowed to become a garden destroyer, and little square fields with nothing round them are very objectionable.—WILTSHIRE RECTOR.

#### DESTROYING MILDEW—PREVENTING THE SPREAD OF THE POTATO DISEASE.

THE article of "A COUNTRY CURATE," at page 105, appears to call for some remarks from myself. One side of this house is covered with *Esperione Vines*, of which I am excusably proud, and I have never allowed other hands than my own to interfere with their management, excepting once last year when I had nearly blinded myself by the frequent application of flowers of sulphur. In 1862, 1863, and 1864, these Vines were very subject to the mildew. In the first year of their being attacked, a muslin bag was made to do duty as a sulphur-duster; but in the spring of 1863, passing through the Pantheon, in Oxford Street, I stopped short at a stall to examine a sort of little mop with a cotton-wool head that caught my eye, and which was called a bottle-cleaner. I thought that it would do to dust flowers of sulphur over my Vines, and bought it. The bottle-cleaner answered the purpose, but it was so tiresome to be constantly clinging to a ladder by one's legs, with a soap-plate in one hand and flourishing the little mop about and under the fruit and leaves with the other, that it made me determine to carry out a threat I made against the Vine mildew, in Vol. XIX., page 368. In the beginning of July I filled the washing-copper with pure sewage from the tank and heated it, between nine and ten o'clock at night, to a temperature of more than 140°, and with this heated sewage I syringed the Vines most thoroughly without any dilution at quite 140°. I dislike a bad smell quite as much as our good friend Mr. Fish himself, and the heating process did bring out the fumes. I was awake by daybreak next morning, and eager to witness the effect. The blue mildew had turned quite black, and so it remained to the last on both the fruit and the foliage. The hot syringing with the sewage had entirely killed it, and what is better, not one particle of the disease has been seen upon the Vines this season.

As regards Roses, whenever I see a leaf disposed to mildew, and my Roses have been several times threatened with it this season, I place on the kitchen fire in the evening my special saucepan, which holds about a gallon of sewage, and when this becomes heated to 140°, I take the pot to the bush or tree affected, and syringe from it at once without any dilution of the sewage, which is the same as that mentioned by "A COUNTRY CURATE," at page 105, and then I can, in nine cases out of ten, say good-bye to the mildew. I do not usually now, and I did not in the case of the Vines, syringe with clean water afterwards, as the fine glaze of health on the foliage, after the overhead liquid manuring, seemed to indicate that such a course was unnecessary. It is, I conceive, the ammonia about the plant that benefits it and renders it distasteful to mildew and insects.

I have only used an ounce of tobacco this season for fumigating for brown aphis, which had attacked some Nectarines

in pots, and Peach trees against the wall of a lean-to orchard-house, when the leaves were very tender in the spring. The hot sewage is with me a remedy for all evils; but for dipping tender shoots in 125° is as hot as it should be. To dip or to syringe makes all the difference. I enclose you three specimens of Rose foliage which have undergone the operation that you may be enabled to judge with a powerful glass, how thoroughly the mildew has done its work on the cuticle of the leaves, and also how thoroughly the former has met with its death.

No. 1. Leaves of Empereur de Maroc, syringed sixteen days ago.

No. 2. Caroline de Sansal, syringed eight days ago. The most determined subject I have met with.

No. 3. François Lacharme, shoot dipped three days ago in sewage at a temperature of 125°. I syringed this bush also at a heat of 140°, and I cannot perceive that it has in the least injured some very fine blooms which it has upon it, and which I purposely allowed the liquid to come in contact with.

[On No. 1 the mildew was quite destroyed, but on Nos. 2 and 3 there were still traces of the mycelium.]

125° would be quite hot enough for syringing young tender shoots in spring in a greenhouse orinery, and for that purpose care must be taken that the sewage is diluted with half its bulk of plain water. For instance, as I could not wash the walls or clean the glass of my smallinery last autumn so as to protect myself from the evils that Vines are heir to, I resolved to syringe the house and Vines with sewage, just as the infant clusters were showing this spring. I employed the above dilution at a temperature of 130°, in the evening, and shut up close. Early next morning I perceived from the drooping appearance of the foliage that it did not like it, so before the sun could shine upon the house, I shaded the glass over completely with a sort of cheese-straining cloth which I have nailed to thin deal parallelograms, the size of Cucumber-frame lights. These were kept on till the sun ceased to strike on the house, and then I syringed the Vines well with clean lukewarm water. The foliage was all right next day, and I have never syringed the Vines but once since, and that was just as the Grapes had finished setting. Last year I kept on syringing the Vines till the Grapes began to colour, but they did not show the nice evenness of bloom that they do now from not syringing. Both mildew and red spider have left the place in disgust.

Hot sewage is certain death to the mildew and insect tribe, when used in time; in fact, I have purposely allowed a Haron's Incomparable Pear tree to become as badly attacked with red spider as it could possibly be, and two syringings at 140° have nearly destroyed the whole of the insects, and by constantly syringing the trees right and left of it on the wall, these have been untouched. I am certain that if we are content to suffer a little from the disagreeable smell, syringing with sewage is one of the most beneficial and economical operations that can be performed for the health of our trees.

Mentioning the hot syringing to Mr. Murray, of the royal forcing department at Frogmore, as we were walking through the houses there last September, in connection with the subject he pointed out to me a pair of sulphur bellows invented by Mr. J. Lipscomb, Thames Street, Windsor, and capital they are for the purpose, casting the *boite à houpe* quite into the shade. I procured a pair, costing 8s. 6d., this spring, but I am happy to find that I do not require to use the apparatus. It is excellent for distributing soot as well as sulphur, either of which is all the better for use if previously passed through a hair or finely-perforated zinc sieve.

I am in great anxiety just now about my Potatoes. The leaves became spotted three weeks ago, and the electrical state of the atmosphere since that time, along with prevailing rains, have kept me haymaking at the haulm at every opportunity—yes, haymaking, for I could not stand still and allow my Potato patches to become like a blackened, fetid dung-heap, which they presently would have done; and as to cutting away the haulm entirely that does more harm to the tubers than letting it alone, on account of the exuding sap from the close-severed stems running down and perpetually moistening the ground, and thus inevitably causing disease. Well, I cut away with the garden shears all communication between the foliage of the separate ridges, and cleared away the severed leaves; then with a Parkes's fork I turned and bore all the growing tops to the right-hand sides of the ridges, and with the fork slightly scratched the bare or left-hand sides, as well as the bottoms of the trenches. When the sun had dried the surface of the ground, and the uppermost side of the haulm, I imme-

diately turned the haulm over to the left-hand side of the ridges and again scratched the surface of the soil laid bare. Afterwards I took the opportunity whenever the sun had again dried the surface of the soil and the foliage to turn the haulm over. I believe that I shall save my crop from becoming diseased by the above method, and it makes me more in favour of the ridge-and-trench plan than ever. I could never have thought that Potato tops would have borne so much knocking about with impunity; and the sun soon converts the mildew-affected leaves, when these are turned over to meet its scorching rays, into tinder before the disease can be communicated to the stems. This rough mode of procedure, as regards the top, will, however, upset some nice calculations I was in hopes of being able to make this season to satisfy Mr. Abbey.

I have this instant come in from probing some roots on the ridges containing Fortifolds, Lapstone Kidneys, Hogg's Coldstream, La ntree's Seedling, and Daintree's Newest Seedling. The last I can speak of with unqualified praise this year, having grown it more largely. It is an improved early dwarf Lapstone Kidney, and it is entirely owing to the treatment that the original Potato suffered in the post-office three years ago, that I have been unable to fully learn its qualities till now. I cannot find a diseased Potato on those roots which I tried. They are all quite ready to be taken up. In fact, Hogg's and Daintree's Newest were ready to dig for store more than a fortnight ago had the weather permitted, and as soon as it proves propitious up they all come. The scab or rupture of the tissue of the skins of Potatoes which was the subject of inquiry lately from two or three correspondents, is, I conceive, brought on simply by the wetness of the soil, caused by the rain or otherwise.—UPWARDS AND ONWARDS.

## GARDENING AND GARDENS IN DORSETSHIRE.

THE REV. W. F. RADCLYFFE'S, TARRANT RUSHTON,  
NEAR BLANDFORD.

THE quiet and retired garden of the rectory of Tarrant Rushton, has become a classic spot in the annals of horticulture, and will long be retained in the recollections of the lovers of gardening—by those who have not had the opportunity of visiting it, from the large amount of solid information that has been imparted thence through the medium of various periodicals and direct correspondence with its kind-hearted owner; and still more strongly by those, who, like myself, have had the pleasure of seeing its "wonders," and have the happiness of sharing the generous sympathy and friendship of the good pastor.

A visit to Rushton has never failed to leave a vivid and enduring impression. Such would naturally be the case with any one who finds the subjects there treated identical with those to which he has directed his own attention. These subjects are both familiar and useful; and forming as they do items in all gardens, more or less, and, moreover, easy of comprehension, and within the reach of all, and hence the more generally diffused, the success achieved at Rushton stands out more prominently than if the plants under cultivation were rarities or less frequently met with than Roses and Strawberries.

The successful cultivation of the Rose and Strawberry, in connection with which Mr. Radclyffe's name has gained such a world-wide reputation, has not arisen from any accidental circumstances, such as favourable situation and suitable soil. On the contrary, at Rushton both are very unfavourable. Although a very inadequate idea of a garden can be gleaned from a written description, yet a brief account of Mr. Radclyffe's garden is necessary to enable your readers to form anything like a just estimate of the difficulties to be contended against in a spot of ground not altogether fitted for horticultural purposes.

The garden is rectangular in form, situated on the west side of the dwelling-house, the four sides nearly corresponding to the four cardinal points, and the longest sides are the north and south, which are walled. It slopes somewhat abruptly from east to west; the east side is bounded by the house and offices, and is partly overhung by some fine specimens of the Horse-Chestnut; hence that portion of the garden is deprived of the morning sun. These Horse-Chestnuts, I may remark, having been planted on the most elevated and driest part of the premises, have a remarkable growth and vigour, the foliage being particularly fine, and larger than I have ever before noticed. The west side of the garden, many feet lower than the opposite end, is guarded by a Thorn hedge about 9 feet

high. Close to it, on the other side, is a wide stream of water from the neighbouring mill, which in wet seasons overflows the adjoining meadows, and renders them little better than a swamp. All who have had any experience in gardening are aware how injurious and disappointing are the spring frosts which occur in our climate, to the detriment, and very often the total destruction of the tender shoots of our favourites; more especially do these frosts occur in damp and low places, and their effects are there more destructive. Owing, then, to the proximity of this swamp, the spring frosts in the garden at Rushton are an enormous difficulty to fight against.

The soil is light, with little depth, and naturally poor, and requires constant feeding with the best manures to enable it to produce a crop. Such is the place in which, in one of his quaint, good-humoured articles, Mr. Radelyffe tells your readers that he determined some years ago "to have a go at gardening." (*JOURNAL OF HORTICULTURE*, August 23rd, 1864.)

The subjects to which Mr. Radelyffe has devoted his attention are few—namely, Roses, Strawberries, and Peaches, to which may be added Raspberries, and latterly, chiefly, I believe, at the instance of Mr. Rivers, of Sawbridgeworth, Pears on the quince stock. His principle is, "keep a few things in your garden, and have them all well done." Keeping this simple axiom steadily in view he has brought to bear on the subjects he has undertaken an indomitable perseverance, an earnest search after the truth in connection with them, and an un-deviating consistency in the maintenance of it. No horticultural writer on these subjects enjoys a greater share of the confidence of cultivators. No one is more looked to as a guide and instructor in the selection of kinds, and the management of them. No one has done more to raise the public taste for good Roses, or to select with greater accuracy the best kinds of Strawberries out of the host of varieties continually sent out to tempt the unwary.

I propose to review each briefly as I found them on my late visit to Rushton.

Roses.—Owing to various circumstances I was unable to visit Dorsetshire in time to see them at the zenith of their first bloom; nevertheless, the evidence of what had been, from the quantity of flower-stalks left, and the excellence of the blooms remaining, was unmistakable. I was informed by Mr. Ford, a respected friend and neighbour of Mr. Radelyffe, that he had never seen such a mass of Rose blooms upon living plants concentrated in one spot before, a result the more to be admired from the great difficulties to be contended against in order to produce them. Mr. Radelyffe has made no secret of this success, the course pursued has been regularly and constantly imparted to the public. He may say of Roses and Strawberries as Franklin did of wealth—the way to obtain them is "as plain as the way to market," and others may have them as well, if they will but follow up the simple directions he has prescribed in his various articles.

The most important point connected with the Roses at Rushton, is the use of the Manetti stock, of which Mr. Radelyffe has for several years past been an unflinching champion. Having now seen them there three times in very different seasons, I can fully corroborate all that Mr. Radelyffe has said about it; and using it myself in preference to any other, I have had the truth of his observations confirmed in my own garden. In a recent article on the Manetti stock, Mr. Radelyffe enumerates the following points of advantage (I copy from the "*Florist and Pomologist*," of March and April of the present year):—

1. Roses will thrive on it with less water and less manure than on any other.
2. They may be grown in lands where those on any other stock would be hopeless.
3. They are earlier, more abundant, more continuous, and later.
4. They will stand more violation from the weather, from fungoid diseases, and from neglect of the owner.
5. They may be removed and transplanted at any time and become quickly established.

With these results before us, the adaptability of the Manetti stock is conclusive enough.

In addition to the garden above described, Mr. Radelyffe has a plot of ground about half a mile distant entirely planted with Roses. This plantation may be said to consist chiefly of the well-established kinds on the Manetti stock, planted in rows, such are *Senateur Vaisse*, *Comtesse de Chabrilant*, *Jules Margottin*, *Mrs. Rivers*, *Victor Verdier*, *Madame Knorr*, and others that will remain in the catalogues for years to come.

The entire stock of Roses, although numerous, does not amount to so many as might be supposed. Every inferior or worthless kind, as soon as it is proved to be so, is rigorously weeded out. While retaining only kinds worth cultivating and bestowing upon them every care, Mr. Radelyffe's Rose culture is also essentially experimental. Thus we find some appropriated to beds, and others trained as pillars, others as climbers; some, again, are allowed to grow attached to high poles. These experiments are not confined to single specimens, every promising kind is allowed full scope suitable to its habit. The following are worthy of remark:—Climbers: *Solfaterre*, *Triomphe de Rennes*, *Aristide*, *Gloire de Dijon*; and among the Hybrid Perpetuals, *Duc De Cazes* and *Louise Carique*. Pillar Roses: *Manrice Bernardin*, *Duc de Rohan*, *Souvenir de la Reine de l'Angleterre*, *Anna Alexieff*, *Madame Plantier*, &c. Attached to poles are three fine specimens of *Duchess of Norfolk*. I once saw these covered with bloom from top to bottom, and they were most beautiful. To remedy the damp and unfavourable situation of the home garden, Mr. Radelyffe has adopted a very simple and at the same time very successful expedient. He has formed raised banks from 1 foot to 18 inches high, and about a yard in width, composed of the soil with a strong mixture of thoroughly rotten manure and vegetable ashes. He has on several occasions alluded to these banks and explained their composition. It is now, I believe, three or four years since he first applied this method, and it is upon these raised banks that many of the new Roses are tried. Their arrangement is such that the plants have the best possible opportunity of a fair trial. At the time of my visit, *Rushton Radelyffe*, *Duchesse de Caylus*, *Lord Macaulay*, *Leopold I.*, and *King's Acre* were in bloom, and several others would shortly be so, some of which Mr. Radelyffe has since reported upon.

Notwithstanding the vast quantity of bloom that had already passed away, the robust health and vigour of the plants in sending out new shoots was so great, that the term "perpetual" was literally accepted and accomplished. Both gardens had every appearance of being gay with Roses for weeks or even months to come.

With the recollection of the Crystal Palace Rose Show fresh in memory (it was two days previous to my arrival), I found the quality of the bloom at Rushton fully up to the mark. Hot weather is an advantage to Rushton, it will stand it when many other gardens would be burnt up. To see what could be done in the way of cut blooms, we rose early on the morning after my arrival, and looked over the whole stock, consisting of about 2000 plants, of which not less than 1600 are on the Manetti. With ease Mr. Radelyffe filled a box of twenty-four trebles, which, had they been shown at the Crystal Palace on the Saturday before, could not have failed to have taken an honourable position. To show the varied character of the blooms in this box, I subjoin the names, reading from left to right:—1st row: *Solfaterre*, *Prince Camille de Rohan*, *La Ville de St. Denis*, *Duc De Cazes*, *Schrismakker*, *Gloire de Santenay*, *Wilhelm Tell*, and *Senateur Vaisse*. 2nd row: *Pius IX.*, *Victor Verdier*, *Caroline de Sansal*, *Comtesse Cecile de Chabrilant*, *Clemence Joigneaux*, *Duchesse d'Orleans*, *Charles Lefebvre*, and *Triomphe de Rennes*. 3rd row: *Devoniensis*, *Général Jacqueminot*, *Comte de Nanteuil*, *Souvenir de la Malmaison*. *William Griffiths*, *Gloire de Dijon*, *Napoleon (Gallica)*, and *Madame Knorr*.

It will thus be seen that the old summer Roses find a place in Mr. Radelyffe's garden, and very justly so, for they still afford variety of tint and beauty not yet obtained in the Hybrid Perpetuals. A long row of them on two-foot Briers under the north wall, in excellent bloom at the time of my visit, was a marked feature of the garden. It will be a matter of regret that the summer Roses should be lost sight of in the increasing demand for Hybrid Perpetuals. Mr. Radelyffe has always maintained the right of the best of them to a place in the Rose garden, and has frequently given lists of those deserving cultivation. To remind your readers who may be planting at the season now drawing near, I add a list of the twelve best summer Roses selected on the spot:—*Charles Lawson*, *Coupe d'Hébé*, *Napoleon*, *Boula de Nanteuil*, *La Volupté*, *Madame Zoutmann*, *Kean*, *Paul Ricaut*, *Obl.*, *Wilhelm Tell*, *Madeline*, *Transeau Goubault*, and *La Ville de Bruxelles*.

Of course, the Hybrid Perpetuals form the bulk of the Roses at Rushton, and these principally in proportion to their quality, hence we find here—*Senateur Vaisse*, *Comtesse de Chabrilant*, *Charles Lefebvre*, *Jules Margottin*, *Triomphe de Rennes*, and *Gloire de Dijon* by the score; nearly as numerous are *Duchesse*

d'Orleans, Prince Camille de Rohan, Caroline de Sansal, Maurice Bernardin, and Duc de Rohan. Mr. Radclyffe tells us truly—"To form a good rosety begin with a hundred each of Jules Margotton, Senateur Vaisse, Cœcile de Chabillant, Charles Lefebvre, and Prince Camille de Rohan, and you will have such a beginning as will take half a century to beat."—ADOLPHUS H. KEST, *Blechnigley*.

(To be continued.)

### SIR WILLIAM JACKSON HOOKER.

DEATH, in removing from us Sir William Hooker, has deprived us of one who has ranked among the most indefatigable and useful botanists of our time.

He was a descendant from "the judicious Hooker," author of "Ecclesiastical Polity," and other temperate works in divinity. His father was a brewer of high standing at Exeter, but Sir William was born at Norwich, in 1785. He concluded his education at one of the Scotch Universities, where natural history, to which he was devoted, was more fostered than in our English colleges. Eventually he became Regius Professor of Botany at Glasgow, and was the leader in forming the Wernerian Society of Edinburgh. Long is the catalogue of his literary contributions from his "Journal of a Tour in Iceland," in 1811, down to his last description, during the present year, of the plants in "The Botanical Magazine," of which he was the editor. Knighthood in 1835, and an Oxford honorary degree of D.C.L. in 1845, were well-earned acknowledgements of his services to botanical science. In 1841, upon the retirement of Mr. W. T. Aiton, he was appointed to the Directorship of the Royal Botanical Gardens at Kew, a fitting office which he ably filled and retained to the time of his death. He was a Fellow of the Royal and very many other British and foreign scientific societies. He died at Kew on the 12th inst.

### THE STRAWBERRY CROP IN YORKSHIRE.

As your correspondent Mr. Radclyffe has given you an admirable account of the various kinds of Strawberries he has this year cultivated in Dorsetshire, it may perhaps be interesting to your readers to learn what sort of a crop this fruit has produced in the hill country of Yorkshire.

Strange to say, many healthy plants of Keens' Seedling never flowered this spring. Eclipse, of which I had upwards of fifty well established plants, also refused to flower. Rivers's Eliza suffered so much from the dry weather that not one dish was gathered from about one hundred and fifty plants. Cox's Hybrid failed, for the first time since I received it from Mr. Nicholson, to produce an abundant crop. I still think this variety will continue in fruit a week later than Ingram's Late Pine. I am quite at a loss to account for the bareness of these most hardy and healthy varieties, as the plants were strong and well established. It is, however, right that you should hear of failures as well as of successes. Ingram's Prince of Wales produced as usual a most ample supply of fine fruit. It is decidedly superior to Oscar, Sir Harry, Wonderful, Empress Eugénie, Victoria, Eclipse, and Keens' Seedling in flavour, and it has never failed for the last nine years to give me an abundance of fine highly flavoured fruit both for dessert and preserving. For quantity combined with quality I have not yet met with its equal. Crimson Queen and Frogmore Late Pine have both produced a most remarkable quantity of large first-rate fruit. These two varieties are worthy of being extensively cultivated, especially the Late Pine, which is the best late pine-flavoured Strawberry in cultivation. My gardener tells me he can gather a dish of this variety to-day, the 11th of August.

My favourite, La Constante, yielded as usual a splendid crop of its most delicious fruit. It exhibited no signs of burning nor of not being summer-hardy throughout this most dry and scorching season. Here, in Yorkshire, La Constante does not require to be treated as an annual, for it continues to increase in strength and productiveness until it has reached its fourth year. My three-year-old plants gave me by far the best crop, while runners, obtained somewhat late last year, also flowered and bore fine fruit. I shall not throw away a single plant, but manure my whole stock heavily in the winter. This variety is also especially suitable for gardens which are exposed to late spring frosts. Last year the frosts of the 4th and 5th of June made sad havoc among my Strawberry plantations. The

flowers of La Constante alone escaped injury; being carried on short footstalks they were almost entirely covered and protected by the leaves. This variety cannot be said to be especially slow in making runners, as my gardener planted no less than two hundred and fifty fine runners on the 3rd of August.

Mr. Dean, of the Bradford Nurseries, Shipley, was good enough to pay me a visit this summer. He examined and tasted all my different varieties of Strawberries, and would, I am sure, gladly confirm the correctness of much that I have stated. Can any of your readers afford me any information concerning those seedlings of La Constante which were sent out last year by M. Gloele—viz., La Favourite, La Fertile, Bijou, &c. ?—A FRAGARIAN.

### VISITS TO GARDENS PUBLIC AND PRIVATE.

M. AMBROISE VERSCHAFFELT'S, GHENT.

EXTENSIVE and important as M. Van Houtte's establishment is, that of M. Verschaffelt is equally so; and to an Englishman perhaps more interesting, as it is more on the model of one of our home nurseries, dependant on private enterprise, and worked out with an energy and independence that reminds one of some of the foremost names in our own country. There was, too, a neatness and regularity in the arrangement of the whole place which is so very unlike what we see in the French nurseries, that to an eye with which these qualities find favour it was very refreshing. The same character appertains to all the establishments which I have seen in Belgium, leading one to the belief that their old connection with that clearest of all countries, Holland, has inoculated them with these properties.

Among the most interesting plants to a visitor are unquestionably the magnificent specimens of tree Ferns which M. Verschaffelt has collected, and these grown in a house which is sunk some feet below the surface. In this condition they were growing most luxuriantly, as it seems most conducive to the maturing of the stems. Besides the well-known forms of Cibotium, Cyathea, Dicksonia, &c., M. Verschaffelt had two very interesting specimens—one, Cibotium regale, far finer than even Schiedei or princeps, and another but unnamed species: these were said to be the only specimens in Europe, and were certainly very interesting. But alas! there are so few, comparatively speaking, who can afford room for these Goliaths of the Fern tribe, that the crowd must be satisfied with looking at them in other people's houses rather than their own; not so, however, with the Camellias and Azaleas, which are here grown to a large extent and in great perfection. It is known, perhaps, to many, that M. Verschaffelt is the editor and publisher of a work called, "Nouvelle Iconographie des Camellias," the publication of which has now extended over some years, since 1849, and which contains from that period up to 1860 no less than upwards of 500 Camellias, and this list is still going on. It may be imagined, then, what a *specialité* they form in his establishment: they are to be seen in thousands, from the little plants with two or three leaves up to large bushes 7 or 8 feet high, although the latter are now becoming very difficult to procure, the demand for them in all quarters having been so great. A little knowledge of M. Verschaffelt's extensive collection might be valuable to some parties nearer home, for I find that a variety received last year distinguished honours as a novelty which was figured in his "Iconographie" for 1850—fifteen years ago, and which he is now selling at two francs a-plant—certainly not to my mind a novelty, however beautiful it may be.

Azaleas, too, were to be seen in all sizes; the larger ones of a very different shape to the erinolines which we are in the habit of seeing at our exhibitions—a form which is an abomination in the eyes of the Belgian growers, and indeed in those of some nearer home. Their treatment of the Azalea is very different, too, from ours, and I suppose could only be carried out in their climate; certainly it would not do in ours. After they have done flowering they are clipped all over with a pair of shears, and then placed out of doors in order that they may the better break. When I was in Belgium, in June, they were then beginning to push vigorously all over, and would remain in the same quarters, mostly in sheltered alleys, during the summer months. I need not say how widely different this is from the plan adopted by our best growers of hardly ever allowing their specimen plants to go out of doors. Indeed, some never do; but then the drenching rains to which we are subject, and the lower temperature of our climate, make this necessary. Amongst the best and newest varieties were the semi-double Reine des

Beautés, Jacques van Artevelde, and Souvenir de Prince Albert; and of the single kinds, Charles Enke, Duc d'Arenberg, Souvenir de Miellez, and Madame Verschaffelt were highly spoken of. Some of these we have seen and appreciated on this side of the Channel, others we have yet to see.

M. Verschaffelt makes the same remark that others have done as to the paucity of amateurs, especially amongst the choicer plants, such as Orchids. He has himself a nice collection; but Belgium does not contain, any more than France, men of the Day, Warner, Turner, and Bateman stamp, who spare no pains or expense in order to procure their favourites, and whose growth of them is a marvel of skill and perseverance, and whose liberality has a reflex influence on such establishments as Veitch's, Williams's, and Low's; while, on the other hand, plants which are but little prized, comparatively speaking, by us, are there highly prized and find a ready sale. Zamiis, including fine specimens 8 or 10 feet high of lamuginosa, Altensteinii, and Lehmannii; Pandanus, including the sweet-scented odoratissimus and the graceful elegantissimus; Stephensonias and Palms of various kinds, Agaves, and other plants of a similar character, are all greatly run after for the decoration of houses, courtyards, &c.; and hence in all these establishments will be found a much larger collection of such things than we are wont to see on this side of the Channel.

Amongst the most interesting plants that I saw here was Clerodendron Thomsone, which hitherto we have only seen grown as an exhibition plant, trained and tortured on a trellis. Here it was planted out in a pit, and suffered to run along the rafters, the more luxuriant shoots being cut back, and nothing could be more telling than were its clusters of pure white and crimson flowers hanging down all along the roof. I hope to see it one day so grown over here. I am sure Mr. A. Henderson, of Wellington Nursery, could not do better than treat it thus; and he will as much please the numerous visitors to his nursery by it as he has already done by his successful treatment of Lapageria rosea and Clanthus Dampieri. By-the-by, he mentioned to me the other day that he believed the former of these would prove to be a hardy plant.

I here also saw Liliun Brownii or japonicum flowering freely, and a very beautifully shaped white Lily it is; one hardly ever sees it over here, it being said to be difficult to grow. M. Verschaffelt finds no difficulty with it, and I noticed that he had a piece of drain pipe laid round the stem almost 6 inches up and filled with light peaty soil, in order to encourage the growth of the young bulbs which are formed at the joints. Liliun auratum was of course grown and held in as much estimation over there as with us, while one, which has been snubbed here, but which I believe will eventually be looked after as a fine showy plant, is being brought out by M. Verschaffelt as Liliun staminosum at twenty-five francs a-piece. It is the variety which was pronounced a monstrous form of Liliun Thunbergianum, and considered worthless; and I can testify that it is far from that. I had a bulb which formed a corymb of flowers six in number, and I can safely say that it was a very bright and showy-looking plant. Since it went out of flower in the spring it has formed another shoot from the side of the old one, and this will be in flower in a week or two; its habit, too, is very dwarf, compact, and vigorous—in fact, I look upon it as likely to be a valuable decorative plant.

M. Verschaffelt has a large and fine collection of the Pelargoniums which we call French, but which are known in Belgium as Pelargonium Odier; they are much more valued abroad than our more regular flowers, owing to their showy character for room decoration. Amongst them are unquestionably many flowers of very striking colours and brilliant appearance. Amongst the plants suitable for bedding purposes, I saw a good quantity of Achyranthus Verschaffeltii, which we know on this side of the Channel better as Iresine Herbstii; it has been condemned in a contemporary's notice of the Battersea Park garden, but I think unjustly; it undoubtedly has not the fine brilliant crimson tinge of Coleus Verschaffeltii, which was in an equally hasty manner condemned at first, nor, perhaps, even of Amaranthus melancholicus ruber; but then one wants different tints, and this, I think, will afford an opportunity for variety. It has been warmly received on the continent, and will I think hold its ground amongst plants of a somewhat similar character, with odd colouring for out of doors. I noticed Teleianthera ficoidea versicolor, which rejoices in bright sunlight, and has a curious fashion of curling the edges of the leaves.

But I must forbear. Suffice it to say that I was most kindly received by M. Verschaffelt, who is a man of most genial spirit, and, as every successful horticulturist must be, an enthusiast in

his calling, and will gladly show all his treasures to any who can appreciate them. Besides being the editor of the work on Camellias, M. Verschaffelt is the publisher also of "L'Illustration Horticole," which is, however, edited by M. Charles Lemaire.—D., Deal.

## PLANTS FOR ROOMS.

(Continued from page 107.)

APRIL.—From the stove Amaryllises will come freely, and the variegated Begonias there will now be fine. They, with Achimenes, Gloxinias, and Gesneras, will do equally well in the early vinery, which must be cleared of the Calceolarias, Cinerarias, now blooming, and the Pelargoniums, by the end of the month, after which time it will be a stove, and may be employed for all stove plants that require to make a vigorous growth and then rest. There will be no lack of subjects for vases in this month, Cinerarias, Calceolarias, forced Deutzias, Dielytras, Weigelas, Rhododendrons, Azaleas, tree Violets, and many other plants already named will be in perfection, and soon afterwards similar subjects will come in from the cool vinery, which will now also be fast becoming a stove. Pits or frames must now be in readiness for the Cyclamens, Epacrises, Correas, and all plants that require a greenhouse temperature, except Camellias and Azaleas, which should be placed in heat to make new growth, and be kept there until the buds are formed. As the forced plants are taken from the early vinery take advantage of it to ease the stove of such plants as Gloxinias, Achimenes, Gesneras, Begonias, &c., paying strict attention to the plants in it for autumn and winter blooming, potting, and encouraging them with plenty of heat, moisture, and air, to make strong growths. Cyrtoceras reflexum does not suffer from a sojourn of a few days in a room, nor does Hoya bella, and both are charming plants for blooming in summer. They will now be in a forward state for that purpose. Justicia carnea will be showing its fine heads of bloom, and should be liberally supplied with liquid manure. The Otaheite Orange will be none the worse of being retained in the early vinery after flowering, for the fruit will then swell and be ornamental in winter. Pot Solanum capsicastrum, and grow as pyramids in a frame. Place Caladiums in the early vinery, and from receiving more air they will not suffer so soon when employed in-doors, which should only be on special occasions. Pot more Gloxinias and Achimenes, also Gesneras, they will come in late, and may be grown after a time in the cool vinery. Repot Celosias, Cockscombs, and other annuals, making sure of a few pots of Isolepis gracilis. Cyperus alternifolius, and its variegated variety, are charming for vases and dinner tables. Tradescantia zebrina is now to be potted and placed in a vinery; it will live in a room where nothing else will. Strong cuttings of Draena terminalis put in now in the stove will have fine foliage in winter, and not less ornamental is Ficus elastica. Clerodendron Dungei potted now and grown on will be useful in September; it will do in a cool vinery if it only have light. Pots of Liliun lancifolium, L. auratum, and Tritonia aurea will do very well in a cold pit, and the bulbs will bloom in August. Sow Humea elegans in the vinery for decoration in the June of the following year; it is the most graceful and elegant of room plants. Grow it in a cold frame after June, potting and treating it in every way like a Calceolaria or Cineraria. Seed of the last should now be sown, and old plants which have ceased blooming should be placed in a cold frame.

MAY.—We must now have Gloxinias in bloom in the stove, Achimenes close in their wake, Gesneras coming after them, Begonias and Caladiums in full beauty, and something to set in vases. We should also have Azaleas in a cool vinery, and Hydrangeas in the early one, Fuchsias in full flower, a few Pelargoniums, and Coleus Verschaffeltii as pyramids a foot high, with the point of every shoot pinched out. Pelargoniums for June and July will be in a cold pit along with Fuchsias for August, Celosias in the early vinery, and Cockscombs on a shelf in the stove. Pot-off Balsams now, and sow more. The time is, however, come when there will be plenty of flowers out of doors, or preparation made for having them, rendering plants in a room of less consequence. We must, however, look beyond this period of sunshine and flowers, and have plants for the vases in winter. Cuttings or young stock of various winter-flowering plants coming on, also old plants cut back and making vigorous growth, should be repotted, and encouraged to make their wood early and ripen it well. Cinerarias just potted off may be kept in a cold frame, along with Calceolarias, for autumn blooming. Besides these we must have young and

flourishing plants of *Chrysanthemum*, *Crowea saligna*, *Epacris* cut-in and shooting freely, *Mitraria coccinea*, and some of the better kinds of bedding *Geraniums* for July and August, as well as Tea and China Roses. All plants done blooming should be managed so as to secure their blooming another year by giving each the treatment necessary for it.

Early in May the lateinery will be cleared of all greenhouse plants that have not flowered, especially *Pelargoniums*, *Cinerarias*, *Fuchsias*, and *Calceolarias*, which do better in pits after this. It will then become a growing-plant-house, and will be useful for subjects coming on for autumn and winter blooming, as well as for *Camellias* and *Azaleas* to grow and form their buds. The very handsome *Bambusa gracilis* will now be fine in the cool house, and fit for any use, but keep it no longer in the house; it is very liable to red spider. *B. Fortuni variegata*, the very best of dwarf kinds, will be fine all the summer in a cold frame. All hardy plants which have been forced should be hardened off in a cold frame prior to being fully exposed; they may then be plunged in the pots in coal ashes in a sunny place. With a few exceptions, such as *Duetzias*, *Dielytra*, &c., they will require a year's rest; some, such as *Hyacinthus*, being of no further use, may be planted in borders. *Indigofera decora* now potted and placed in a cold pit will come in for August, and forward plants of it will now be in flower. *Erythrinas*, which well deserve more attention than they receive, if encouraged a little now will bloom well in two months, and they are best grown in pits. *Calceolarias* for blooming next spring should be now sown in a frame, or under a hand-glass in a shady place. *Primulas* for autumn blooming should be potted and encouraged in a cold frame. The earlyinery will now have no plants in it that require much moisture, its contents being chiefly confined to *Gloxinias*, *Achimenes*, *Gesneras*, and *Begonias* far advanced for flowering, and those plants that are fast completing their growth, as *Epiphyllum*, *Amaryllis*, and *Vallota purpurea*; the last if going to rest now will most likely flower in autumn. It will also suit *Bougainvillea* species when good growth has been made, and plants requiring the wood to be well ripened, but no others; for, when the Grapes change colour, though moisture may help to swell the berries these will not colour well; and if a growing moisture is kept up, the flavour of the Grapes, whatever the colour may be, will be poor, instead of brisk and refreshing. The end of this month is the best time for putting in cuttings of spring-flowering greenhouse plants, and as quantities of these are in request take the cuttings from the half-ripened shoots and insert them in sand under a bell-glass in a gentle heat. They will strike in about six weeks, and may then be potted off and grown in the lateinery until August, when a frame would suit them better. Repot *Epacris* after they have made new growths a few inches long. *Cyclamens* to be plunged out-doors in a sunny place at the end of the month, or early in the next.

**JUNE.**—The early *Camellias* should be taken out and placed in a cold pit for a few days to harden off, and the same with *Azaleas*. Nothing should be kept in this house after this time but what will accommodate itself to the Vines. All greenhouse plants in the coolinery to be placed outside in a sheltered place, and the house occupied with *Cockscombs*, *Celosias*, *Ferns*, *Lycopods*, *Begonias*, *Gloxinias*, *Achimenes*, *Gesneras*, and *Lilium lancifolium*, which will now be fine from the earlyinery. The stove will furnish but few flowering plants this month, but will contain *Caladiums*, *Marantas*, *Dracenas*, and other variegated plants, as well as plants advancing for autumn and winter bloom. The frames will give *Fuchsias* and *Pelargoniums*. The spring-struck *Fuchsias* should now be potted for the last time. Towards the end of the month, *Cyclamen europæum* must be potted and placed in a cold frame, it will certainly bloom in September if not in August. *C. neapolitanum* to be served in like manner at the end of the month, as we must have it in October. Look out for runners of *Violets*, and pot them forthwith. The double purple, tree, and Neapolitan are the best for scent and rough usage. The frames will supply any deficiency in the houses in the shape of variegated and Zonale *Geraniums*. Stop and cut *Nosegay Stella*, *Baron Licasoli*, and any others of that class, and also repot to have them in order for September. Pot early *Chrysanthemums*, stop them, and supply liquid manure at every alternate watering. Layer into six-inch pots shoots of *Chrysanthemums* with nice branching heads, layering as near the head as possible. They will root well in about six weeks, and should then be detached, but not until the pots are filled with roots; they make excellent dwarf bushy plants for small vases. Cuttings of the shoots pinched off now should be put in and never stopped, but

allowed to go on for bloom. Those struck in April should be stopped and potted for the last time, and any large specimens should be stopped and trained, after shifting into their blooming pots. *Witsenia corymbosa* will do admirably in a cold frame or pit at this season, and bloom finely in August. *Rhododendron jasminiflorum* will also do well in a frame in summer, and should now be potted. It will bloom next April in a coolinery, and is one of the sweetest and handsomest plants we have, the flowers being of so pure a white. *Gesneras cinnabarina*, and *zebrina splendens*, to be started for winter blooming; continue to pot off and forward *Gloxinias*, *Achimenes*, and *Gesneras* as they require it. For autumn bloom, seedling *Gloxinias* do best; they are now to be potted. *Cactus speciosissimus* placed in the coolinery now and kept there until August, then placed out of doors close to a south wall for a couple of months, will bloom next May. It is inferior to no plant at that season for the fine display which it makes. Cuttings of *Torenia asiatica* inserted in March will need potting into their blooming pots; elevate the pot and allow the shoots to hang over it. This plant will look well hanging over the sides of a vase when covered with its porcelain flowers in September and October. Pot *Statice brassicifolia* now, and grow in a cold frame; it may throw out its spikes in September and be in bloom all the winter in ainery. Young plants of *Statice imbricata*, *profusa*, *propinqua*, and *foliosa* should be encouraged with liberal pot room and a place near the glass in a coolinery. *Myrtles*, common and doubled-flowered, nice compact dwarf plants, may now be potted, and encouraged with moisture in a cold frame. Pot, train and encourage young stock, keeping the plants clear of insects.

**JULY.**—The most forward *Balsams*, *Cockscombs*, and *Globe Amaranthus* will be in flower, and the *Celosias* towards the end of the month, as well as *Rhodanthe Manglesii* and *Thunbergias*, *Gloxinias* and *Achimenes* being plentiful, and the summer-flowering *Begonias* in perfection. Zonale and variegated *Geraniums*, with *Verbenas* and *Petunias*, will supply the place of florists' *Pelargoniums*. There will also be *Fuchsias*, *Ferns*, *Lycopods*, and variegated *Begonias*. The majority of winter-blooming plants, such as *Eranthemums*, *Thyrseantius*, &c., young stock of *Poinsettia* and *Euphorbia*, will now require to be shifted into blooming-pots. *Camellias*, *Azaleas*, and the whole of the winter and spring-flowering greenhouse plants may be placed outside in an open situation, and if protected from the midday sun all the better. This should be done early in the month, or, if the plants are forward, a fortnight or three weeks earlier. *Correas* and *Epacris* should, however, still be kept in frames for protection from heavy rains, giving all the air possible. Pot the most forward *Primulas* in six-inch pots, and keep near the glass in a frame. *Cyclamen coum* and *Violets* to be potted at once in six-inch pots, keeping cool and moist. Pot *Calceolarias* into their blooming-pots, as they will soon show for bloom. *Cyclamen europæum* to be accommodated with a place in a frame; and *C. neapolitanum*, both red and white, to be potted if still delayed, and accommodated in like manner towards the end of the month, at which time stop some of the *Chrysanthemums* for a late bloom. Pot-off *Primulas* for spring blooming, also *Cinerarias*; the latter, if for autumn display, to be put in their blooming-pots at once. Now is the time to fill a frame with Tea-scented *Roses* that have been disbudded up to this; allow them plenty of air, using the lights only in very wet weather. This is also the time, and only time, to stop *Nosegay Geraniums* for an autumn bloom, and after they have made new shoots pot, and afterwards grow them in a frame. *Pelargoniums* to be cut in. *Mignonette* for winter bloom to be sown. Intermediate Stocks to be sown the first week in an open situation, there to remain until October, when they may be potted in small pots, and kept over the winter in a cold frame, potting in March into 24's for blooming in April and May. *Gesnera purpurea macrantha* to be potted and placed on a shelf in the stove. It will come in for winter and spring blooming. *Tuberose* will now come in. *Tritonia aurea* will be in fine bloom, and the *Liliums* in pits will soon follow. Continue to pay attention to late plants of *Gloxinias*, *Achimenes*, and *Gesneras*, they will do well in the coolinery, which towards the end of the month must be cleared of all plants requiring much moisture. It will answer admirably for any plants which have made their growth, and require their wood to be hardened. *Gesneras cinnabarina* and *zebrina* for winter bloom to be potted off, and grown on in the stove. Put in cuttings of *Coleus Verschaffelti* in the stove, and pot-off when rooted, growing on until October, then shift into six-inch pots. It is one of the finest plants for

winter decoration, and requires to be kept growing all the winter in the stove.

August.—Much the same as last month as to the materials at command for decoration, which it would be needless to recapitulate. Pot *Cyclamen vernum*, and place in a frame, also varieties of *C. Atkinsi*. *Cinerarias* and *Calceolarias* for autumn bloom should be placed in a frame where they can be protected from excessive rains, and do not allow them to suffer from drought. Pot a few *Chrysanthemums* for a late bloom, stopping them at latest by the middle of the month. Examine the state of the roots of the winter-blooming plants, and if any are inclined to become pot-bound give a shift: they will make a succession to the others, and be finer. The winter-flowering *Begonias* that have been rested to be shaken out, potted in smaller pots, and encouraged in the stove. In addition to those named already, I may note *B. prestoniensis* as a fine kind for winter. Plants kept growing slowly until this period and then placed in the stove make fine growth, and bloom a long time. *B. fuchsoides* and its variety *miniata* having now their old flowering shoots cut away, fresh-potted, and placed in the stove, will make handsome plants after awhile. *B. Dregei* potted now, and the old wood cut out, makes a fine plant for late autumn blooming. *Deutzias*, *Weigelas*, *Prunus*, and other plants intended for forcing to have full and free exposure to ripen their flower-buds. *Pelargoniums* headed back last month to be potted, and placed in a frame. Pot suckers of *Cinerarias*, and place in a frame, and continue to encourage *Primulas* by potting. *Celosias* and *Balsams* will do much better in frames than in vinerias at this season. *Impatiens Jerdoniae* will be coming into bloom, give it an airy light situation in the stove. Sow *Mignonette* for spring, and *Cinerarias* for a late spring bloom.—G. ABBEY.

(To be continued.)

### THE BEDDING-OUT AT KEW GARDENS.

On entering the gardens the first object worthy of notice is a pattern of scrollwork on grass in front of the Grecian conservatory. It is planted alternately with Sweet Alyssum and *Lobelia speciosa* as an edging; then two rows of Punch Geranium, and two rows of *Calceolaria amplexicaulis* in the centre. The next is a crescent-shaped bed planted with *Rhododendrons*, edged with Purple King Verbena; then Bijou and Christine Geraniums. This edging reminded me of two beds at Cremorne Gardens planted with Bijou Variegated Geranium mixed with Purple King Verbena, and edged with *Perilla nankinensis*—the best beds in that place.

By the long walk leading to the Palm-house the beds are circles and oblongs, match pairs at each side, and planted similarly. The first circles are planted with *Lobelia speciosa* edged with Sweet Alyssum. Next come beds planted with Purple King Verbena, edged with *Tropæolum elegans*; then beds divided into four parts diagonally by single rows of Bijou Geranium—the two sections east and west contain Tom Thumb Geranium, and the sections north and south Cerise Unique Geranium. Then come circles of *Coleus Verschaffelti* edged with *Gnaphalium lanatum*, and beds of *Calceolaria amplexicaulis* edged with Brilliant Geranium; and then beds of Roses, which would look better as dwarfs pegged down to correspond with the other beds. Next come circles composed of *Lobelia speciosa* edged with *Arabis lucida variegata*; then beds of Cybister Nosegay Geranium edged with white Centaurea: beds divided into four parts by Tom Thumb Geranium, the east and west sections being Bijou Geranium, and the north and south Golden Chain Geranium, edged with *Lobelia speciosa*; circles of *Gnaphalium lanatum* edged with *Amaranthus melancholicus ruber*; beds of Purple King Verbena edged with two rows of Christine Geranium; circles of Cybister Nosegay Geranium edged with white Centaurea; and then beds of Flower of the Day Geranium in the centre, then a row of Brilliant Geranium edged with two rows of Purple King Verbena.

At the cross walks are match beds of *Ageratum mexicanum* edged with Lord Palmerston Nosegay Geranium; then follow circles of *Gnaphalium lanatum* edged with two rows of *Coleus Verschaffelti*; beds of Purple King Verbena edged with Victoria Geranium, a good pink, larger and better than Christine; beds divided into four parts by Little David Geranium, the east and west parts being Bijou Geranium, the north and south Golden Chain Geranium, edged with *Lobelia speciosa*; circles of *Lobelia speciosa* edged with *Arabis lucida variegata*; beds of Cybister Geranium, edged with white Centaurea; circles of *Iresine Herbstii* edged with Variegated Mint (the *Iresine*

*Herbstii* looks well here); beds of *Calceolaria amplexicaulis* and *C. Westwood* edged with two rows of Brilliant Geranium; beds divided into four parts by Flower of the Day Geranium, Cerise Unique Geranium being in the north and south divisions, and in the east and west ones Tom Thumb Geranium, edged with a row of Bijou Geranium; circles of Sweet Alyssum, edged with *Lobelia speciosa*; and lastly, beds of Purple King Verbena edged with *Tropæolum elegans*.

At the end of the long walk is a magnificent circle. It is 36 feet in diameter, and has a rich, massive, moulded edging of terra cotta 15 or 18 inches high. The bed is raised up as a pyramid, and in the centre is a very handsome flower-vase with pedestal and plinth. This bed is divided into four sections by *Coleus Verschaffelti*, and planted with white Centaurea; then a broad band of scarlet Geranium, edged with *Lobelia speciosa*. On both sides are beds parallel with the walks, leading to the museum on one side, and to the Palm-house on the other. These very effective beds are divided into chain-like compartments by Purple King Verbena; the centre, Brilliant Geranium; and the sides filled up with Rose Queen Geranium edged with *Gnaphalium lanatum*. Then come circles of Purple King Verbena edged with Golden Chain Geranium; beds of *Calceolaria amplexicaulis* and *C. Westwood* edged with two rows of Brilliant Geranium; circles of *Gnaphalium lanatum* edged with *Coleus Verschaffelti*; and crescent-shaped beds with *Perilla nankinensis* in the centre, then Punch Geranium edged with Variegated Mint.

Standing in front of the Palm-house the terrace garden is seen to great advantage. Two vases in front and other vases at the head of the lake are all filled with scarlet and Nosegay Geraniums. The two large circular beds in the middle compartments are divided into eight sections, four of scarlet Geraniums, four of Flower of the Day Geranium, there being in addition a circle of *Lobelia speciosa*, and a broad band of *Gazania splendens*, with vases in the centre filled with Cybister Nosegay Geranium. The patterns at each side are duplicates and planted alike. The centre beds in the middle of the figures are planted with Bijou Geranium, with an edging of Lady Plymouth Geranium, and patches of *Coleus Verschaffelti* around the pedestals of vases filled with Scarlet Geraniums. The crozier-shaped beds are planted with Lord Raglan Verbena, then *Calceolaria amplexicaulis*, finishing with *Iresine Herbstii*. The saddle-shaped beds are planted with Christine Geranium; the pentagon beds with Purple King Verbena; the triangular beds with *Lobelia speciosa*, and the end circles with Cloth of Gold Geranium. The corner beds at the angles are planted with Tom Thumb Geranium. This pattern is tastefully arranged, well balanced, and not overloaded with scarlet, which is the prevailing colour in most places.

I was glad to see the bedding-out plants named. The large tallies and the beautiful writing of my friend, Mr. Greenhead, in the beds on the south side of the main walk, and in the terrace garden, were so conspicuous that you could "run and read," and at the same time they did not mar the general effect, but contributed to the information of the thousands of visitors who loitered about these lovely beds.—WILLIAM KEANE.

### LILIUM AURATUM.

HAVING seen at Mr. Veitch's nursery the plant with twenty-nine flowers, submitted to the Floral Committee of the Royal Horticultural Society on the 8th inst. as an extraordinary specimen of cultivation, I submit the following account of a plant of this Lily under my charge.

The flowers, it will be observed, are not so numerous, but are nearly double the size of those on Mr. Mills' plant. One bulb has this year produced two stems, each 24 inches in circumference at 6 inches from the surface of the soil, the highest stem measures 8 feet, the other 7 feet 9 inches, with a total of 185 perfect leaves and 20 flowers; this is one of the finest varieties I have seen. The first and strongest offset I had from the above has this year produced three flowers, each 13 inches in diameter.

Allow me to add that I shall feel pleasure in showing the above to any one interested who may favour Bow Bridge with a visit.—R. BULLEN, Gardener to A. Turner, Esq., Bow Bridge, Leicester.

SEEDLING PELARGONIUMS FLOWERING THE FIRST YEAR.—At page 128, a doubt is expressed as to the possibility of a *Pelargonium* raised from seed in March, being in flower in August.

I last year raised about a hundred seedlings, the seed being sown in February. Two of these seedlings flowered in the autumn, but I do not remember the exact date. They were raised in heat, but as soon as they were potted off they had only greenhouse treatment.—P.

### MY PLANTS.

AND HOW AND WHERE I FOUND THEM.—No. 8.

IN the spring and summer of 1862 we were sojourning in the proud old county of Norfolk, that county of noble families of "lang pedigree," and of broad and well-cultivated lands. It is not, however, of these that I am going to write, but of one small portion of that county in the neighbourhood of East Dereham. I daresay many in that locality think of it simply as a bog—a thing to be avoided on dark nights, especially when returning from the alehouse at midnight, for, I regret to say that, noble as this county is, it is by no means free from those ignoble pests of our English towns and villages, the public-house and low beershop. It is impossible to say how many aching hearts now at rest in that silent churchyard close by have lain them down out-wearied with the care, and anxiety, and grief brought to them on the wings of that unhallowed laughter and witless jesting within those curtained rooms at the village alehouse! A fine and handsome face is shadowed on the blind; laughter, songs, and swearing are within. A thin, anxious, and careworn form is watching from without; tears hot and fast fall down her cheeks. She kisses that small bundle within her shawl, and bitterly retraces her steps. Many a time she pauses and listens, listens for that one loved foot-fall—for him who is still her idol, though so ill deserving of her love. Late on in the night he stumbles home, falls across the bed, from whence proceed the infant's wakened cries and the mother's stifled sobs. In the morning he knows nought of the night's anguish, and, whistling, leaves his home and mixes with his fellow men. In the evening he "seeks it yet again." She, with a heavy heart, coldly and slowly labours out her day; and in due time, when grief has done its work, she, too, lies her down with her sorrow-laden sisters to await that last awaking and final reckoning which must come both to husband and wife alike.

But let me quit this sad subject for hours of happy memories, of pure delight amongst those much-neglected children of the water and the fen—beauties overlooked by the casual passer-by, but which had accidentally been mentioned to me. Hours and hours of the long summer days I spent in Scarning Fen, until it became quite a byword amongst some friends of mine. "Scarning Fen again?" Yes! I was mad about the place, for the time being there was no doubt of it. The heat of the morning certainly did not find me there; but still I was generally employed at home in drying and arranging specimens collected on the previous day. An early dinner, and off again; through the town, down a passage to your right, across the railway and some fields, and you are soon and almost imperceptibly upon the spot! I can scarcely describe the delight with which I always crossed the style separating the fields and the Fen. The moment you were over, had the fields been ever so dusty, you came at once upon the most beautiful wet mess and the charming Sundew. A carpet of moss and Sundew!—could anything be more luxuriously and botanically romantic? A pool of water stretched away to the right, containing that vestal queen of aquatic plants, the white Water Lily, in garments of green; and close by, its sisters with the golden hair and green drapery all floating on the water. Rushes and Sedges, handmaidens to the Lilies, waved their adulations, or whispered love songs to the winds which played between the leaves. Many a lecture did my prudent medical husband give me; and, must I confess it?—they fell unheeded. What was it that I returned home with wet feet? Had I not been to the shrine of the goddess of water flowers, and should I return with no sign of my mission? The moment I entered that Fen I forgot the world around. An ignis-fatuns seemed to be before me. From one spot to another I stepped, occasionally choosing an unsafe tuft and getting ankle deep in mud, but generally keeping pretty close to the pool in which were the yellow and white Lilies. Beyond the water, towards the Scarning side of the Fen, lay a large piece of turfy grass, and there, upon some of the little hillocks, we would rest for a while to look over our gathered treasures. Ling and the Erica tetralix were grouped around us, and the pretty Pinguicula vulgaris, or Butterwort, with its tuft of bright green leaves lying close to the ground, from the centre of which rise

its delicate purple flowers. I think this Fen contains a greater variety of really beautiful flowers than any place of the same size which I have ever visited. The *Menyanthes trifoliata*, Bog Bean, here flourishes in all its luxuriance; and beneath it the pretty pink *Anagallis tenella*, Bog Pimpernel. In another part of the Fen grew the *Parnassia palustris*, with its delicately white petals; and there also the common Cotton Grass waved its silky flowers. The gorgeous Marsh Marigold and sweet blue Forget-me-not ran riot amongst the reeds and rushes. The pretty little *Scotia spiralis* with its twisted spike, from which comes its name of Lady's Tresses, I gathered here for the first time, and also the Marsh Helleborine. Ragged Robin and Willow Herbs, striving and pushing their way through this mass of vegetation, assert their claims to a conspicuous place. The only plant which would not verify this description was the dwarf Red Rattle. Always stunted, and looking like a badly nursed child, this plant arouses somewhat of a feeling of sympathy in our hearts for its apparently neglected condition. Speaking of the Heath beyond the pond, I must not forget to mention the discovery of a very slender plant with a round stem and one spike at the top. I never found another root of the same, though I frequently returned to the spot. I believe it was the *Scirpus Savii*, Savis' Club Rush. It was the most slender and smallest Rush I have yet met with.

The thick mist which gathered so quickly over the Fen in the evening sent me homewards much sooner than I otherwise should have returned; and I own it was with something of the saddened tone of feeling with which one quits a dear friend that I took leave of my favourite haunt. The last train has whistled past, this last noisy sign of a bustling troublous world without has died away in the distance, and now I would fain remain here with the newly risen moon and the quiet shadows for my companions. The evening star is shining above the pool, and the Lilies gently stir with love as they turn their meek eyes upwards in answer to the starlight from above. And now the elves,

"Who slept in buds the day,  
And many a nymph who wreathes her brows with Sedge,  
And sheds the freshening dew; and lovelier still,  
The pensive Pleasures sweet,  
Prepare Eve's shadowy car."

The children who have been playing at a distance on the heath, like the wearied birds have sought their beds. A little under-song of settling warblers, and the solemn creak of the toad close by, are all the sounds which come to me as I take a parting look before I cross the style.

Farewell, Scarning Fen! Your treasures I leave for other and more able botanists to search out and to possess. As I look back, it is strange to think that I have dabbled amongst the Sundew in goloshes and a waterproof, the rain falling so slowly, so miserably, and so small! It sounds very absurd, no doubt, but so it was. Perhaps just then my heart was "cold, and dark, and dreary;" and is it not better to arouse oneself to some study in which you delight than to sit with your hands before you brooding over some trouble at home? At least, this is my peculiar theory. Again, I remember days which I have spent on the Fen, when the sun was burning, no air stirred, and the leaves of the pretty Butterwort were shrivelled and yellow. My heart was light enough then, and as cheery and glad as a fainting flower after the summer shower. The only remark which I remember hearing about the Fen was from a neighbour, who casually mentioned that "some gentleman had been from London to botanise in the Fen, that he had made as much fuss about it as I had, that he had found a very rare plant there which he prized very much." My informant believed the flower of it was green, and that it came in the month of September; however, of this latter fact he seemed uncertain. Often and often I hunted for the said "green flower," but ineffectually. Perhaps as we left East Dereham about the end of August we thereby lost the acquisition of some very rare addition to our hortus siccus. I feel that my account of this small spot has not done it justice, but I must now leave it for a stroll in quite a different part of England—namely, North Staffordshire. But before I quit Norfolk entirely I must jot down a fact with regard to the *Scelopendrium vulgare*: in no other locality have I seen the Hart's-tongue so fine as on the banks at Gressenhall, Scarning, and Hoe. They are quite a contrast to the meagre specimens I have met with in Staffordshire.—ALICE.

LARGE HIBISCUS.—Perhaps you may be able to afford space to chronicle the fact that at Wharf Bridge, Winchester, there is now in full bloom (a mass of rich rose tints), a fine, and

I believe in England unequalled, specimen of an Hibiscus, the trunk of which cannot be less than 8 inches in diameter. I have often observed the finest solitary specimens of rare plants in places where they might be least expected—amongst the cottages and gardens of the poor.—L. A.

EATABLE FUNGI.

Your correspondent "WASON" (page 88), is quite right as to the esculent qualities of many of our Fungi. I had the pleasure of Dr. Badham's acquaintance, and many dishes of the various Fungi from his table have I tasted. It is vain to try to uproot prejudice, especially where there "is poison in the pot;" but those who love a *bonne bouche* should purchase a work on the subject, and try for themselves. I would especially recommend to notice the Puff-ball—when the interior is perfectly white, stewed or fried, it is food fit for the gods; when the centre has a greenish hue it disagrees—only then. It would be worth "WASON's" while to write to the Rev. — Berney, Bracon Ashe, near Norwich, who sought information from me about three years ago, as he had commenced growing the various edible Fungi. He invited me the following year to go and see his progress, but other duties or laziness prevented. I do not know what success he met with, but fear that the excessive dryness of the past two seasons may have disheartened him. Dr. Badham was much pleased in consequence of my succeeding in preserving many specimens, some in Goadly's solutions, some in turps. I made an exquisite sauce of Champignons with sherry, if I remember rightly, and a quantity of catsup from *Agaricus rubescens*.—J. FISON, *Barningham, Suffolk*.

THE MODERN PEACH-PRUNER.—No. 14.

THE PREMATURE LATERAL.

As some of the most successful growers have devoted considerable attention to the proper treatment of this summer lateral (*anticipé* of the French), it would be improper here to pass it over; and, indeed, it constitutes a certain basis in very close or in-door pruning whereon to establish much after-work. In the open air it is also important, as helping much to keep the fruit nearer to the wall, and closer to the main branch when properly treated. The premature lateral springs directly from the wood of the year whenever that wood is of a certain strength. The gross shoot (class 4), with these summer laterals springing from it, has been already depicted. As an extension of a young and healthy tree it frequently attains a considerable size, and, provided due attention could be given to directing and controlling its growth, we should be glad to see it; but the laterals which spring from it, when so placed as to receive a great volume of ascending sap, are apt to be troublesome to manage. The *bourgeon anticipé* is naively called by M. Grin "the enemy of gardeners, and is either of a good or of an evil nature." In the first case it is known by the principal leaf being considerably longer and broader than the others. This is when it is quite young and manageable, for it very soon becomes vigorous, and is then easily recognised by its erect habit and darker colour.

During the months of June and July, especially after a favourable May, the growth of the Peach is considerable. The trees require constant attention and regulation of the summer shoots, for upon the exact performance of this depends the future appearance of the tree; but the growth of summer laterals, when placed on the upper side of the extension, is such that it is not easy to regulate it. The consequence of a neglect is, that the strong flow of sap will develop these laterals so fast as to carry away the first pair of well-formed leaves to a distance of 2 or 3 inches from the base in a very short time. This is evidently a defect, and if it should occur in many places must cause the loss of valuable space, and also of radiation of heat. On the other hand, to arrest unskillfully the growth of these laterals in a young and vigorous tree must check its progress and injure it. In the case of an established tree, to remove too great a portion of the laterals on the under side of an extension may end in their drying up entirely by the end of the season.

It requires, therefore, both experience and attention to transform these laterals into close-lying, and, at the same time, vigorous spurs for future bearing and growth. The general habit of the tree operated on must also be carefully considered. Some sorts of Peaches and Nectarines are naturally of weak

growth, and such should not be severely treated, but be allowed more freedom of growth, and to become well established before bearing regularly. Indeed the skill and attention required to manage successfully these laterals are such that Professor Dubreuil says, "This is the only portion of M. Grin's method which really presents any difficulty."

The object which we have in view is to avoid a blank space of more than an inch between the first pair of full-sized leaves (which have the bearing-buds with them), and the base of the lateral, for the reasons before stated. Passing over other expedients to check the growth of a too-vigorous lateral on the upper side of an extension, M. Grin's method may be recommended here. It consists in the suppression of one-third of the two small leaves which spring immediately from the base of the larger leaf. In *fig. 15* these small leaves are marked A,

Fig. 15.

and the line of suppression is shown by B. This operation is considered to be always successful provided—and here is the only difficulty—it be done at the proper moment. This is known by the relative sizes of the leaves as seen in the engraving. There is no doubt that in the case of an orchard-house cordon, which is more easy to watch, the sudden arresting of the sap will produce two or more buds, which will constitute a good basis for next year's work.

Should, however, the lateral have made its growth unchecked, and have carried off in its progress the leaves and buds to a distance of several inches, we may be induced to try Professor Gressent's remedy, which he highly recommends, for it is easy to perform, and the defect in our tree is conspicuous. The object in this instance is to cause the production of a cluster-shoot or spur ("May cluster"), at the base of the offending lateral. He proceeds in the following manner. By means of a sharp-pointed instrument or lancet he pierces the base of the already-developed lateral and the dormant bud near it, so as to produce a deviation of the vessels of the medullary canal, without, however, injuring the ligneous formation. The vessels being cut, a temporary concentration of the cambium is induced; a mass of cellular tissue results, and ends in the production of a group of flower-buds. By the next spring this group is well constituted, and the lateral may then be suppressed, leaving in its stead a group of buds as delineated in *fig. 5*.

In *fig. 16*, A represents the point of section; B, is the me-

Fig. 16

dullary canal, composed of the primitive cellular tissue enclosed within the wall-like formation of the vascular tissue, c, c;

n is the inner epidermis of the green shoot, through which the cambium descends; and e is the thin outer epidermis not yet become hard. The ligneous formation is seen between v and c; and f represents the blank portion of the premature lateral.

The method here described may be tried with advantage in certain cases, care being taken not to pierce beyond the point indicated.

I have thus endeavoured to point out how to recognise the character of a lateral which seems likely to become gross, and shown when and how to arrest its progress. In the next instance a remedy has been pointed out in the case of a lateral having been neglected or overlooked. It remains, then, only to describe the treatment of such laterals as are of fair growth and promise. In the case of maiden or young trees it is good practice not to check their growth, but only to direct it a little. We shall, however, suppose the tree to be somewhat established and formed. In this case the laterals on the summer extensions may be stopped to 6 inches to strengthen the buds at the base, of which, at the winter pruning, there will be left only two good buds. When these have pushed in the following year, in order to induce them to be fruitful, they should be stopped at four leaves as soon as they have made six full-sized ones. The second growths may be stopped at two leaves more, and the third growth may be stopped at one leaf, or allowed to extend during the autumn, according to the state of the buds at the base. If all go well, by August we may confidently expect to find the lowest two buds full and well established. Possibly another pair besides these may be developed nearer to the base of the lateral. The two upper buds will have extended, and on these the second and third growths will have been already stopped respectively at two leaves, and one leaf, as before said.

It is my practice in this case to allow the tree to make some more growth, unless the autumn be wet and sunless; if, however, the two lowest buds of the lateral are not satisfactory, then but very little second growth is permitted, and frequently it is good practice to cut back below the first stopping, and by a new check and concentration of the sap and diminution of the shade produced by the leaves, to endeavour to ripen these lowest buds.

Some of the finest fruit is produced in the ensuing season on the extensions. When, however, the tree bears freely, the laterals should be rather devoted to form new spurs for future use, and, if possible, they should be transformed into a group of two or three shoots.

In the case of very old trees no rules can be given, as these require less severe pruning, and vary considerably.

In fig. 17, we have a premature lateral drawn by myself from

Fig. 17.

nature early in August. The leaves are omitted. We notice the pair of buds at the very base of this lateral; they are prominent, dark in colour, and triple, which is not always the case. The lateral had been stopped at the fourth leaf, when it had made some six full-sized leaves, and two of these four buds have extended. That marked b has been stopped at the second growth, and has formed at that point a group of flower-buds which would ripen in an orchard-house; the other bud, marked c, has also extended, but it has not produced flower-buds. It would have grown freely, and so has been stopped at about two leaves beyond the first stopping, and, again, for the third time at one leaf; still it is growing, and it is no matter, for our lower buds are well constituted. The tree suffered also from insects, and will benefit by more growth during the rest of the autumn. Probably M. Grin would cut back, at the winter pruning, to the first pair of buds at the base; but I have found it well to

have plenty of shoots to select from. I should, therefore, cut back only to a, above the beautiful triple group there. This group having a central leaf-bud will be sure to extend. Should any fruit appear on this group it might be left on, if so desired, and the leaves beyond the fruit reduced to two or three. The pair of buds at the base may become "May clusters" by this process, which, indeed, is the principal aim of very close pruning. Nothing can be more successful than the production of this class of shoot, especially in pairs. Should, however, these buds at the base extend, they will very likely become fruit-bearers of class 2. As soon as the group at a has borne its fruit, it should be completely cut out. By this time the eyes at the base will have become strong, and will be ready to take the place, in some shape or other, of the group removed. At p, we see a group of buds on the other side of the extension, e. This group will be of service hereafter, probably as a May cluster.

The lateral represented is a fair specimen. Others more striking could as easily have been shown; some which by stopping have forked and become double shoots, which can be left as such, and others equally useful. Of course, the double shoot is nearer perfection provided it divide very near the base. In M. Grin's practice he does not, however, attach so much importance to having more than one shoot from the same base, but it multiplies the chance of fruit, especially in the open air.—T. BRÉHAUT, *Richmond House, Guernsey.*

## CLOTH OF GOLD AND MRS. POLLOCK GERANIUMS.

### MANAGEMENT OF AMARANTHUS MELANCHOLICUS RUBER.

WITH me for the last four years Cloth of Gold has put all other golden varieties into the shade. It both grows and flowers well. This year I have two large beds of it, with a ground-covering of *Verbena venosa*, struck from root-cuttings in January last. This I find a better plan than planting out seedlings, as the plants so propagated come into flower much sooner. The soil in the beds is a sort of chalky loam, and a little manure is annually given, but no peat. The beds are exposed to wind on all sides but the north. Cloth of Gold requires plenty of water when first planted out, especially in such dry weather as that which prevailed in the early part of the present season. Some plants used as edgings have not done so well; this I consider is owing to shallow soil and want of moisture. Golden Chain does very well with me as an edging plant, but is useless for the centre of a bed on account of its poor flower, while Cloth of Gold has a good bright scarlet flower, combined with a larger and better coloured leaf than the former.

*Amaranthus melancholicus ruber* has grown with me as strongly as *Perilla*. I sow in heat at the end of March, and as soon as the seedlings are large enough to handle, I prick them out into small pots, and when these are pretty well filled with roots turn the plants out in a cold frame, in a mixture of leaf soil and ashes. Afterwards I keep close for a time until they start into growth and then give all the air possible. I think the main cause of failure at some places with this and many of our bedding plants, is keeping them in small pots until planting-out time comes, then many of them grow less. I plant out some thousands of bedding plants every year, and find that nearly all of them are benefited, if they are well rooted, by being turned out of the pots into leaf or any soil out of which they can be well lifted. With *Verbenas* I find coal ashes answer well.

I can highly recommend turf pots for spring-struck Geraniums, but spring-struck *Verbenas*, *Variegated Alyssum*, *Ageratum*, *Heliotropes*, *Gazanias*, and *Petunias*, grow quite as well, if not better, tied up in soil and moss, and placed in a little heat until they start into growth; when they may be shifted where you like. It is the way to grow a great quantity.

*Centaura ragusina* has turned green with me this year and keeps running to seed. *Calceolaria Sparkler* does not keep its bright colour with me, it turns a dirty brown after being out a few days.—BAILEY WADDS, *Raywell, Brough.*

As Mr. Fish asks for a report of the above Geraniums, I may state that I have a bed edged with the former, which has always been a favourite of mine, and it does not seem to have grown at all this year. Last year in another bed it grew well, and was everything I could desire as an edging. I have come to

the conclusion that Golden Fleece is the best of that class. It is a good grower, and the foliage is of a bright good colour.

Mrs. Pollock has grown remarkably well with me. I treat it as follows:—At bedding-out time I pot the plants in good rich loam, with a liberal dash of good rotten manure in it, in 32-sized pots, without any crocks in them. I plunge the pots in the beds, placing about half a foot in depth of the same soil the plants have been potted in for them to rest on. The effect of this is that the roots come through the bottoms of the pots, and the plants grow as well as if they were in the bed without pots, and in October I can take them up without the risk of losing them. Considering the high price this *Geranium* still commands in the market this is of great consequence to me. I possess *Lady Cullum*, and consider it a great acquisition to our list of bedding *Geraniums*.—CALCAREA.

#### BEARD'S PATENT HOTHOUSES.

THESE HOUSES possess structural and cultural merits of the highest order. The most obvious of their structural merits are strength, elegance, simplicity, completeness, non-conductibility, elasticity, and durability. Their framework being formed entirely of iron, strength and elegance are easily combined. Their simplicity consists in the fewness of their parts, the ease with which they can be handled, put up, taken down, and removed from place to place. Thus the trouble, delay, and expense of hothouse building are entirely avoided. They are so complete in themselves that there are no extras; ventilating apparatus, water-troughing, &c., either form part of the houses or are sent with them in perfect working order. What in ordinary houses forms the roof plate, becomes also the water-troughing in these. The roof terminates in rather than on this gutter, so that it removes the condensed water from the inside of the glass as well as the external rain. The upright pillars that support the front are all hollow tubes and perform the office of water pipes as well. The bottom plate may either stand on a wall, or on wood, or even on a level surface of gravel. Either way the houses are complete without any addition beyond the ground line. If it is desired to raise them higher, of course they can be placed upon walls in the usual way. Another great merit of these houses is their non-conductibility. Iron is a rapid conductor of heat and cold. The extreme of either is a great practical evil in hothouses. Mr. Beard's mode of glazing breaks the conductive power of the iron. He accomplishes this by placing two layers of asphalt, or other elastic non-conducting material on the top of every sash-bar, one above and one below the glass. An iron heading is then bolted down over the whole to fix the glass in its place. One of these copper or lead bolts is inserted at each point where four panes meet, the corners of the glass being cut off to make room for it. Each sash-bar or rib, when finished, thus consists of an iron heading, a layer of asphalt, a thickness of glass, another layer of asphalt resting on the main bar below. This ingenious arrangement breaks the currents of heat or cold, prevents them from passing through, provides an elastic packing for the glass, and earns for the houses the character of non-conducting.

But these houses are also elastic—not quite like sponge or Indianrubber, but they give and take in a similar manner, if not to the same extent. The bulk of all substances is changed by the addition or subtraction of heat. Not only so, but every substance changes in a different ratio. Wood, putty, iron, glass—for instance, would all change in a different degree when subjected to the same amount of cold. The neglect of this fact has caused the most serious consequences in hothouses. The evil has not been so obvious in glass houses with wood frames, as wood is a sluggish conductor; but in iron-framed glass houses the breakage of glass from the operation of this natural law has been enormous. The usual mode of glazing is to fix the glass tightly between two iron sash-bars, with putty that speedily becomes almost as hard as either the glass or iron. On a frosty night the cold contracts the iron much more rapidly than it does either the glass or putty, and crack! crack! go the squares, like the report of small firearms all over the house. Mr. Beard's mode of fixing the glass prevents all this. He leaves a space of, say the eighth of an inch, between each two squares as they lay side by side on the top of his level sash-bars. Every square is also completely isolated from the iron above and below, by the intervention of the slip of asphalt. The removal of the corners from the squares of glass, also prevents the bolts that tie them in from touching them. The squares

also meet each other end to end, and are not lapped. Consequently when the iron suddenly contracts, the square moves, and this elasticity, slight though it be, prevents the possibility of breakage.

Perhaps the greatest structural merit of these houses is their durability. Inside and out they present an unbroken surface of iron and glass to the atmosphere. There is positively nothing perishable about them but the slips of asphalt, and they, protected as they are at most points by the iron or glass, will probably last thirty years or more. Besides, they are easily and speedily replaced by new slips. By the use of galvanised, enamelled, or japanned iron, and the new mode of fixing the glass, those incessant sources of worry and expense, putty and paint, are entirely got rid of. The great error of most builders has been that they have mixed substances of the most varied degrees of durability together in one and the same structure. Wood, iron, putty, paint, brick, and stone, have all been used to form one house. The time such houses could stand without expensive repairs, must be measured by the durability of their most perishable parts. They involve an expense of 3*d.* or 4*d.* per foot every third or fourth year, and would cost their original worth in repairs in a period varying from fifteen to thirty years, according to their quality. During the same period the only part of Mr. Beard's houses that could possibly need renewing, would be the asphalt, which in a house like that erected in the Botanic Gardens, might be done for less than £1. The enamelling or japanning process looks as hard as the iron itself, and is likely to prove almost as durable. Some objection has been made to galvanised iron. It is thought by some that this grand antidote to corrosion injures the texture and lessens the durability of the metal. I believe these views are mistaken, and that such iron is good for two or three lives at least, and we need not trouble to go beyond that. Neither does Mr. Beard confine himself to galvanised iron; he lays his enamel on common iron, and this, with the glass, which completes his houses, surely lasts long enough for all human purposes. The greatest possible durability, without repair, is a leading characteristic and a chief merit of these patent houses.—D. T. FISK, *Gardener to Lady Cullum, Hardwick.*—(Bury Free Post.)

#### REMARKS ON SOME SPECIES OF CONIFERÆ.

REGARDING *Pinus insignis*, how much it is to be regretted that so few plants of this beautiful tree now remain in this country. Our limited experience once led us to believe that its constitution was such as to resist uninjured the frost of our severest winters, but in this we have been greatly disappointed. The evidence produced during 1860 and 1861 has completely annihilated any hope that it will ever become a permanent tree in Britain. During these severe winters we had the misfortune to lose seventy-five plants, varying in height from 5 to 30 feet. Neither the situation nor the quality of the soil afforded any protection, although both were subject to considerable variations. Our largest tree still survives, but is only a mere fragment of what it once was; nor will it ever again acquire the same proportion, as the constitution has been so severely shattered. At the time to which I refer, it was 43 feet high, growing on the blue lias formation, and faultless in form, branched closely to the ground. In our parks and pleasure grounds we shall long miss the warm green colour and open graceful habit of this *Pinus*, as there is none possessing the same characteristics. The nearest approximation with which I am acquainted is *Pinus muricata*, quite as hardy as the Austrian Pine; the foliage, however, is a little lighter in colour, and the habit a little more rigid, still at the distance of 10 or 12 yards the difference is hardly perceptible.

Authorities differ greatly as to the hardihood of *Pinus Hartwegii*, and to some extent there may be space for these broad views, as we know what a large latitude different soils and situations afford for the production of dissimilar conclusions. The opinion usually entertained passes it off as being far too tender for our climate; this I am not prepared to endorse, as we have had it growing here for a good many years, and have not found it suffer in any way.

Our plant is growing among brashy sandstone, on a high situation fully exposed to every breeze. In a young state this is undoubtedly a handsome Pine, its long dark green foliage drooping gracefully. The young shoots are thickly covered with leaves, but after a few years they fall off, leaving a naked stem, the very reverse of ornamental.

Some botanical authorities, without the least scruple, classify

*Cupressus macrocarpa* and *Cupressus Lambertiana* as the same, while others again maintain that they are distinct species. I do not believe the difference is so great as to separate them thus widely, and this may account for the fact that nurserymen supply the one for the other. Setting aside conflicting statements, we are quite correct in saying that they are distinct varieties, and in no point more observable than in the difference of habit. *Macrocarpa* invariably preserves a close-growing spiral outline, while, on the contrary, *Lambertiana*, even as a seedling, pushes out its branches at right angles, and with age the habit becomes more set. But there is something more than this; the latter passed through the winter of 1860 and 1861 without being damaged in any way, while several plants of the former, above 20 feet high, were completely killed, quite irrespective of shelter or exposure—hence it is irrefutable that the constitution of the one is more resistible than the other. We may then, I think, legitimately infer at least, that they are distinct varieties.

We have the *Araucaria imbricata* growing on two formations—the mountain limestone and the red sandstone. On the former it does not refuse to grow, still the rate of growth is far from being so satisfactory as on the latter. In different parts of the park the *Araucaria* is planted in quantities, and invariably the same result follows. Our largest tree was planted in 1839, and is now 33 feet high, bearing cones on the south side. Age does not in the least diminish its progress, as it is now as vigorous as when I made its acquaintance thirteen years ago. No *Araucaria* can possibly possess greater symmetry of outline; the branches are evenly and closely arranged from the summit to the base, the lower tier is creeping so closely on the ground as to require protection against being covered with soil. Why it is so I know not, yet the fact is indisputable, fully tested during the winter of 1860 and 1861, that in a group of *Araucarias* planted in the same soil, and equal as to drainage, some were severely injured, others completely killed, while not a few escaped without any damage. Nor was the destroying agent confined to this situation, it passed over to other places, conducting its operations much in the same way. Now it is somewhat remarkable that plants of the same species, possibly seedlings of the same tree, and reared under the same treatment, should differ so greatly in resistive power. I believe the difference to be unexplainable, vegetable physiology refuses to answer the question—the subject is just as subtle as the doctrine of metaphysics. Conjectures innumerable might be offered, but they can be of no real value.

The *Wellingtonia gigantea* has beyond all cavil established for itself a position and reputation for hardihood; more than this too, it is the most ornamental Conifer ever brought from California. What renders it so much more acceptable, arises from the fact that it does not refuse to grow in any kind of soil, so long as it does not contain an excess of water, nor does it object to a dry situation. Our largest specimen was planted eleven years ago, and it is now 18 feet high, densely covered from the apex to the base with healthy foliage; the lower branches sweep the ground, and measure 14 feet in diameter. It is somewhat singular that it should grow so vigorously, as the depth of soil does not exceed 15 inches, overlying the mountain limestone, but no doubt the roots are creeping down between the crevices of the rock, secure against sudden and continued drought, such as we experienced last summer. We have also the *Wellingtonia* growing on the red sandstone quite as freely. Some years ago we planted a young seedling in a deep and rather, rather loam on the border of a marsh, where the soil is rather wet than otherwise, which is, unquestionably, the most appropriate situation, as it will ere long leave the others far behind, judging by present progress.

*Torreya myristica* has proved to be quite hardy with us, having passed through our severest winters without the slightest injury. Being so distinct from the generality of Coniferous plants, it is found to be no inconsiderable acquisition. The rate of growth is by no means rapid, so it will be a good number of years before we can expect to have even a moderate-sized tree. On the Sierra Nevada mountains it does not exceed 40 feet in height, so there is but little hope of it ever growing to half that height in this country. The long peculiarly-formed leaves of a yellowish green colour give it an interesting appearance. *Torreya grandis* will not submit to a British climate; in the truest sense it is a greenhouse plant, where it is not worthy of the space. We had it planted in the open air for three years, and I do no wrong in saying that it did not, during that time, grow more than an inch, although every possible care was taken as regards soil and situation.

*Pseudolarix Kämpferi* has withstood the frost of our severest winters, and may therefore be catalogued as quite hardy; but its dwarf bushy habit will, I fear, prevent it growing larger than a good-sized shrub; still in China it is said to attain the height of 100 feet. This dense low form is greatly to be regretted, nor have I been able to produce a free centre by keeping all contending side branches constantly shortened. Could we by some means cause it to produce an active leader, it would be a great acquisition, as no tree with which I am acquainted offers such a display of golden-coloured leaves during autumn.—(A. CRAMÉ, *Tortworth Court, in Scottish Gardener.*)

## THE ROMANCE OF THE VEGETABLE KINGDOM.

No very limited field of literature this, and if I, an old gleaner in the field, were to throw down my sheaf before you, many Journals would appear, each with a handful of the gleanings before the entire were gathered up. The "Book of Books," the mythology and the poetry of the Greeks and Romans, the tales of the Persians and Arabs, the Hindoos, the Chinese, nay, the American Indians, have all episodes and narratives in which flowers and trees occupy a conspicuous position. I could buzz about and among these flowers like an old "dum-blo-re," and add many a modern instance, such as "The Rose in January," that tale in the old "London Magazine," in Tom Hood's time, a tale that fascinated me in youth, and fascinates me now, for the frost though on my hair has not got to my heart. Then there was the *Fuchsia* of her "boy Ben," found in the old woman's window in Wapping; and the *Mignonette* in the Saxon coat of arms; and that lovely "*Picciola*, or the Prison Plant;" and the *Planta genista* of the *Plantagenets*; and the *Roses* of York and Lancaster. Put on the cockle-shell, take up your staff, and see how many years would pass before you could visit the Gospel Oaks, and other historic and romance-associated trees in our own land. Pass on to Germany, France, and Italy, and life must be protracted to a length equal to that of the wandering Jew before you could exhaust the legend-lore and historic events associated with members of the vegetable world.

I named Italy last, and from that land, to which God, not man, has been so bounteous, my last gleanings were collected.

The *Jasmine* was introduced from India into Europe early in the sixteenth century, and a duke of Tuscany was one of its first possessors. He was so jealously fearful lest others should enjoy what he alone wished to possess, that strict injunctions were given to his gardener not to part with a slip, not so much as a single flower, to any person. To this command the gardener would have been faithful, but for a fair but portionless peasant, whose want of a dowry and his own poverty kept them from becoming husband and wife. On the birthday of her he loved, the gardener presented her with a nosegay, and to render that nosegay more acceptable, he added to it a blossomed spray of the *Jasmine*. The "povera figlia," wishing to preserve the bloom of this "new flower," put it into the earth, and the spray remained green all the year. In the following spring it grew. It flourished and multiplied so much that the bride elect was able to amass a little fortune from the sale of the precious gift which love had made her. With a sprig of *Jasmine* in her breast, she gave her hand and wealth to the happy gardener of her heart. This may be only a legend, but it is certain that the Tuscan girls to this time preserve the remembrance of this event by invariably wearing a nosegay of *Jasmine* on their wedding-day, and they have a proverb which says a young girl wearing this nosegay is rich enough to make the fortune of a good husband.—G.

## NEW ZEALAND.

A BOTANICAL RAMBLE IN HOON HAY AND OTHER BUSHES.

GEOLOGISTS tell us that the body of the earth was once in a state of fusion—that is, it was once all in a melted state, glowing, burning, flaming, and that it gradually cooled until it became covered with a hardened surface. These bushes, in the convulsions of nature, seem to have been tossed up into all sorts of forms, and are now clothed with noble trees of the forest; some appearing in full view, others half-concealed behind the rocks and crags, and others with their rounded heads appearing above the summit of one range, as if they were

clumps of shrubs seated on the slopes of the more distant mountains. Such extent of ground as there is in these places; such variety in the disposition of it; objects of vegetation so interesting in themselves and ennobled by their situation; each contrasted to each; every one distinct, and all seemingly happily united; the scenery so beautiful, of a whole so great—compose altogether a landscape of some magnificence, and of great beauty, which it would be well for our landscape gardeners to try and imitate. These were my thoughts when looking around and entering a New Zealand Bush for the first time.

The indigenous timber, at any rate, at first sight appears to be grown to a towering height, and in a perfection, I think I may say, equalled by that of few other countries. Vegetation runs riot. Perpetual verdure and freshness is to be seen all the year round, which is very different to plantations and forests in the old country, which become deciduous one part of the year. No fall of the leaf, but varied and beautiful scenery. By-the-by, where nature has done the planting, it would be very difficult to find any straight lines or trees in rows.

If our bushes contained any prickly plants like our briars and brambles at home, or the prickly *Melocactus* of Mexico, they would be a jungle physically impenetrable; and even as it is, they present many obstacles to free steps and movements. Here we experience "Supple-jack" snares; and travelling inside is a very slow process, not without two or three falls at most. Such is the closeness of growth, the luxuriance of foliage, that sun and air, in some places, can scarce penetrate. The birds seem to enjoy your company, for in whatever way you wend your steps they follow, and warble melodious notes. In addition to this, see the stumps of cylindrical boles of trees which have been left after the havoc of the axe, some of them measuring 20 to 30 feet in circumference, which once reared their majestic heads in grandeur.

As I have already mentioned Supple-jack, I may state that whoever undertakes a ramble in the bush will find that the first plant to be met with is the one which I will now say a little about. It is a species of *Smilax* of enormous size. I found it both in flower and fruit; flowers white, and hanging in racemes, afterwards followed by red berries, which hang waving in the air. It is a gigantic climber, and most troublesome because most abundant. Its stems are amazingly strong and tough, and well known among us by the name of Supple-jack. There is another *Smilax*, which accompanies this, twining itself round the trees, which I will name *S. aspera*, or Rough Bindweed. I am glad to see two indigenous plants amongst us, belonging to the natural order of Sarsaparillas.

*Dacrydium cupressinum*.—This beautiful tree seems to love to grow in the shade. Its branches are more spreading, and begin at a less height from the ground, than those of the other New Zealand Pines. Its foliage is remarkably graceful and elegant. The leaves are only like small needles, and very thick on the shoots, and their united weight causes the branches to hang like the Weeping Willow. Its beauty is heightened by the liveliness of the colour and denseness of foliage, in comparison with the sombre hue of most of the other evergreens in the bush. It is in every respect in character like *Wellingtonia gigantea*, and its head in shape like an umbrella.

It will be as well here to state the difference between our New Zealand Pine trees and coniferous trees belonging to other parts of the world. Our Pines here are separated by their fruits not being collected in cones, each growing singly, unprotected by hardened scales; and nothing can equal the elegant appearance of their fruit, especially the fruit of the *Podocarp*, of which, when fully ripe, the drupes are carmine-coloured.

In the natural order Taxads, to which our Pine trees belong, there are only nine genera, and two of them are indigenous to the Cape of Good Hope. Out of these nine genera only fifty distinct species have been discovered as yet.

Man is, however, the most active agent in the dispersion of plants, and we must not overlook the important consequences. Sometimes, indeed, the causes are accidental, but more frequently intentional, as we have witnessed of late during the last two or three years in the numberless accessions to our gardens of coniferous plants from other countries.

I fear that the timber trees in New Zealand are by no means so abundant as to justify our regarding the supply inexhaustible, for I am sure it must be incredible the quantity of trees which fall beneath the axe at the present time.

*Cabbage Tree*.—A more appropriate name would be Dragon Tree. From a dry fruit which I found and examined, it was very clear to me that it belonged to the natural order Lilyworts. It attains a great height in the bush, more so than in a solitary

state on the plains. The beautiful creations which constitute the order of Lilies would seem to be well-known to all the world, for what have been so long admired and universally cultivated as they? Nevertheless, in my opinion, there are few great groups of plants which have been more neglected by the exact botanist, or which stand more in need of his patient attention. Even Phormium, our celebrated Flax, with its perennial leaves and panicles of flowers, belongs to this interesting natural order. For a certainty, our familiar Cabbage Tree, all over the plains, belongs to the genus *Dracæna*.

*Edwardia microphylla*.—I notice very fine trees of this, towering up much higher than the rest. The thousands of small pinnated leaves and wiry twigs contrast beautifully with the surrounding evergreens. Here it does not become deciduous, as in the old country. Stems equal in circumference any of the other large Pine trees. It belongs to the natural order Fabaceæ, or leguminous plants. The Locust Trees of the west belong to this order, and have long been celebrated for their gigantic stature; and other species are the colossi of South American forests. Martens represents a scene in Brazil where some trees of this kind occurred of such enormous dimensions that fifteen Indians, with outstretched arms, could only just embrace one of them. At the bottom they were 84 feet in circumference, and 60 feet where the bole became cylindrical. The tree mentioned is supposed to be older than the era of our Saviour. By counting the concentric rings of such parts as were accessible, he arrived at this conclusion.

*Fuchsia excorticata*.—better known by the name of Native Fuchsia. This tree, for so it must be called, seems to shed its leaves; but still I could perceive a great number of leaves pushing forth, which looked as if when one leaf drops another comes. The tree I saw had three forked strong limbs, and spreading branches in proportion. The bole was 5 or 6 feet in circumference, and the three limbs were about 20 or 30 feet high. It was not in flower or fruit. There is a great difference between this dwarf monarch of the forest, as I will term it, and the little pets grown in pots by florists. One can hardly judge which state of growth is to be liked better—a *Fuchsia* plant in a pot, or a *Fuchsia* tree in a state of wildness in the bush. This wild species of *Fuchsia* is more of a botanical curiosity at home than anything else, and is grown in collections for that purpose.—WILLIAM SWALE, *Arboretae Botanicæ Garden*.—(Lyttelton Times).

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

GIVE all possible encouragement to advancing crops by stirring the surface of the soil, and earthing-up such as require it, and keep a sharp look-out for seed weeds of every description in order to remove them before shedding their seed: care in this respect will save much weeding and hoeing next season. *Basil*, to be cut and dried just as it is coming into flower. *Carrots*, make a sowing for early spring use on a light, dry piece of ground that is only moderately rich. *Cauliflowers*, if seed was not sown last week, it should now be done, and another sowing should also be made in about a week; in favourable situations the latter sowing will be quite early enough, no advantage being gained by having the plants very forward before winter. *Celery*, plant some of the last sowing for spring use. As it will not be necessary to earth it up, the plants may be a foot apart. *Cucumbers*, if seed was not sown for plants for house-culture through the winter, cuttings should be immediately put in to produce plants for that purpose; those in frames and on ridges will now require attention in regulating the shoots, so that sun and air may be admitted to them. *Endive*, make a last sowing for spring use; continue to transplant from former sowings when the weather is favourable. *Lettuce*, if the sowing of the various sorts to stand the winter was made during the past week, another good sowing should be made in the end of the present one; the former will do for transplanting in the autumn, and the latter will remain in the seed-bed to be transplanted in the spring. *Mushrooms*, prepare the materials for making up beds next month. Clear out the old beds, and limewash the walls of the house to destroy insects, and give the whole a clean appearance. *Onions*, sow seed of Spanish, Tripoli, or Strasburgh to stand the winter. The Welsh may also be sown for drawing in the spring; the other sorts are best transplanted in spring for bulbing. *Spinach*, the winter crop should now be sown, if not yet done. Sow a small quantity of Cabbage Lettuce with the Spinach.

## FRUIT GARDEN.

Crevice formed between the soil and walls are the favourite lodgments of numerous insects, therefore, at this season, the soil adjoining walls should be frequently disturbed. A shallow trench may be taken out all along, and as this is being proceeded with, the soil adhering to the bricks should be removed with a hard broom. The portion of the wall thus exposed should then be sprinkled with lime water, which should be applied the instant it is made. Remove all superfluous shoots from wall trees, and expose the fruit of Peaches and Nectarines, but this must not be done by cutting off the foliage. If the leaves are in any case overcrowded, the fault is owing to the laying in of the shoots, and the remedy must consist in the proper regulation of these. Place dry bean-stalks, cut in lengths of about 6 inches, among the branches, and by this means most of the earwigs may be caught before the Peaches become ripe. The soft pithy lining of the bean-stalk is preferred by these insects to the finest-polished tuber. Apples and Pears require constant attention now, gather the various sorts as they ripen, and let the operation be performed with gentleness, for wherever an Apple or Pear is bruised it lays the foundation of premature decay. Peaches and Nectarines must be looked over daily, and gathered as they ripen, as a fall, even when nets are suspended to receive them, is fatal to the flavour and appearance if they have to be kept a day. The extreme humidity of the weather has in many instances operated unfavourably on wall fruit; Apricots, particularly, have suffered. Rotten fruit should not be allowed to remain on the trees, or the branches in contact with the affected fruit will be injured.

## FLOWER GARDEN.

The heavy rains and boisterous winds have caused considerable derangement among the flowers. Immediate attention should be given and all deficiencies from such injuries replaced. Look over rock plants, pruning back any that are overgrowing more choice kinds, in order to give them sufficient time to break again before autumn. Cuttings of choice kinds should now be put in for planting out in spring. Keep such plants cut back as have a tendency to overgrow Box and other edgings. Some of the earliest Carnation and Picotee layers will now be sufficiently rooted to take from the parent plant, they may be potted in four-inch pots, placing them in a frame for a few days, taking care only to water the soil, not over the foliage. Continue to plant out Pinks as they strike root, bearing in mind that those which are put out now in the place where they are to flower next season, generally lace much better than those planted in the spring.

## GREENHOUSE AND CONSERVATORY.

Large specimens which have been placed out of doors to provide room for other things will soon require housing. This, however, will depend greatly on the weather. The earthworm is a greater enemy to pot plants in general than low temperature, every precaution must be taken to avoid injury from this cause. Many Orchids maturing their growth will now be showing signs of ripeness in the leaf and plump pseudo-bulbs, and may be removed forthwith from the excitement of the growing-house. Any situation where a temperature averaging from 60° to 65° by night and day can be guaranteed will suit them well, a very moderate amount of atmospheric moisture will suffice. Look well after late-flowering plants. Late Heliotropes, Scarlet Geraniums, Petunias, &c., will now be somewhat pot-bound, and will in that state, with the application of weak liquid manure, produce abundance of bloom on a light shelf until the beginning of December. Lachenalias should be repotted, and Persian Cyclamens if planted out will now be fine bushy plants full of young leaves. They should be taken up forthwith with all the soil possible adhering to them, potted carefully, and placed in a close frame or propagating-house with a very moderate atmospheric temperature, a bottom heat of 55° would be an advantage. After three weeks of this treatment they may be introduced to the greenhouse, where they will produce blossoms in abundance from November until April. When Camellias, Chinese Azaleas, and hybrid Indian Rhododendrons were not potted in spring and require shifting, the present is the most favourable time, as the young wood is now becoming somewhat firm and the flower-buds are perceptible. As plants of this class require water to be very liberally supplied during one period of their growth, drain the pots well and use very turfy peat and sand, adding an equal portion of loam for the Camellias.

## STOVE.

The absence of bright sunlight will render it more especially

desirable to expose all plants to the little sunshine we have in order that the shoots may be ripened before the approach of winter. More air should also be admitted to these plants, as their preservation in a perfect state depends in a great measure upon the thorough maturation of the young wood. It is an error to keep plants that are required to produce a profusion of bloom during the following spring and summer actively at work late in the autumn. Summer is the season when rapid development should be promoted, and autumn the period when the young wood should be completely hardened and ripened preparatory to the approach of winter.

## PITS AND FRAMES.

Some of the first-struck cuttings will now be fit for potting off. Place them in a pit or frame, shade and keep them close until they are established in the pots, when they should be set out to harden previous to being stored up for the winter. Continue to put in cuttings, more particularly the best kinds of bedding Geraniums, which ought to be struck as soon as possible.—W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

Much the same as in the previous week. Sowed Brown Bath and Hardy Hammersmith Lettuce to stand the winter. Where there is the convenience of a two-light frame, it is as well to sow under that next month; the sowing, if the weather prove severe, will come in for planting out early in spring. The rains have brought up little weeds very thickly where none were seen before; and it is of little use to hoe until the ground is drier. Where the soil is rather open, the quickest process is to turn them in by a shallow spit, and they will help to manure the ground. Took up the remainder of Shallots, Garlic, and a portion of the Onion crop, where the necks were quite ripe, and the bulbs good.

## FRUIT GARDEN.

Proceeded with potting later successions of *Strawberries*, and cutting those laid in pots from the parent plants. As often stated, the principal points with potted *Strawberries* are to keep the bud well up, and to pot very tightly, ramming the soil with a rounded stick, or spatula, according as there is more or less room for soil. We like the soil to be fresh loam, rather stiff if we can obtain it, and mixed with about one-sixth part of sweet rotten dung, generally hotbed dung, of which tree leaves formed the principal part. If we had old, sweet, dried cowdung we should prefer it. Generally a little soot is sprinkled at the bottom of the pot, which helps to keep the worms out; no plants in pots will thrive with worms in the pot, as they soon clog up and disarrange the drainage. We have not yet been able to finish planting *Strawberries* in the open air, nor yet to clear those that are left of runners, &c.; but the sooner that is done the better for the plants, as admitting more light and air among the crowns and buds. From two to three years is generally the time we allow a plantation to remain; but we have kept them in full bearing for many years, by freely thinning out all the smaller buds and shoots from an old plantation, and giving a surface-stirring and a good rich surface-mulching. On ground naturally dry, or made so by draining, this plan does well with those who have only a small garden, and entertain something like a horror of the idea of making a fresh bed, and waiting until the second season for a full crop. There is no necessity for thus waiting if the runners are laid in pots, as if for forcing, or if the earliest runners are taken off, and pricked out into a bed of rich material, placing them 5 or 6 inches apart, so that they can be raised with nice compact balls, and turned out into well-prepared ground early in the autumn. By either plan a good crop is secured the first succeeding summer. The ground, if loamy, should be well trenched and manured, the surface pointed over afterwards, a little very rotten dung pointed in, and the plants turned out in rows, allowing 1 foot to 18 inches in the row, and 2 feet from row to row. If the soil is light and sandy, fully more dung should be used, and the ground should be well trodden before and after planting. Cracking may be prevented by slightly mulching the ground. *Strawberries* will succeed very well even on light ground if thus firmly trodden when damp, and a little mulching afterwards given. Of course stiff soils will become firm enough of themselves.

Apricots are ripening unkindly, owing to the quantity of wet and little sunshine, and many are showing signs of decay-

ing on one side before they are soft on the other. It is so far good that the heavy crops will render a few thus going of less importance. If the rains thus do a little injury to fruit and some of the most forward corn that cannot be garnered into store-house or stack-yard, they have produced wonders in the pastures, which may, in some measure, counteract the results of the cattle disease.

Looked over vineries, removing a few laterals, and any berry that showed signs of damping, and put fires on in the dampest days, giving plenty of air, especially at the top of the house. Melons, owing to the heat, have come in more together than we should have liked.

#### ORNAMENTAL DEPARTMENT.

*Lawns.*—Went on mowing, sweeping, and rolling. The rains have greatly increased work, by rendering the scythe more necessary, with all its attendant sweepings, &c. The grass grew so fast that we could not overtake it at all with the machines. The men like the machine much the better, and there is no comparison as to the labour; for the sweeping is so troublesome. To save this as much as possible, and thus gain time for other work, we are allowing parts of the lawn, more out of sight, to grow longer than usual, so as to give one mowing instead of two or three, as, though the weight to be removed is greater, the sweeping is just the same. Such rather longer grass, mixed with litter, is valuable for hotbeds, for packing round hotbeds as linings, or for placing in the rubbish heap, and covering with earth, as the refuse from potting-benches, &c. It thus gives a rich manuring-power to all such heaps. Tossed merely on the top, and allowed there to ferment, and ultimately shrivel and dry up, its good properties go to render impure the surrounding air. Some allow part of the lawn to grow so long as, when cut, the grass is useful for cattle. Such part then ceases to have the peculiar attractions of a lawn even as to sight. It may be as long as we have stated above, and yet look well to the eye, if all coloured weeds, as Plantains, &c., are swept down with the daisy-knife. In many places, where the lawns have originally been too large for the labour power to keep them nice, it is the best plan to select the most prominent portions near the house, and the like, and keep them first-rate, and merely mow the other parts when convenient. If the scenery in the latter case is wilder, the contrast will even be pleasing; and in pinetums, &c., we often think the longer and rougher grass is an attraction rather than otherwise. In such a case the grass might well pay for the cutting. Sure we are, however, that part of a lawn thus kept first-rate, and another part less conspicuous not in such first-rate order, will always be more satisfactory than a large lawn, none of which often looks quite satisfactory, from an ineffectual attempt to keep the whole well. Of course there is no objection—quite the reverse—to the having large lawns, and all well kept, if there is sufficient labour power to do it all; but if there is only labour to keep an acre nice, no screwing or managing, with the same help, will ever keep three acres equally well, though two of them might look different from the surrounding park. We wish to impress the truth—not so much on our great landed gentry as on our enthusiastic amateurs, who do so value their lawns—that these lawns, to be well kept, are the most expensive parts of a garden. True, the mowing machines have greatly reduced that cost; but still, running over lawns in general seasons twice a week, or once every four days, is not done for nothing. That will be cheaper than mowing once a fortnight. In such dripping weather as we have lately had, mowing once in ten days will never secure the conditions of a well-kept lawn, though it may please the owner; and, if that is the case, no one else has any right to interfere. It is just such little matters as these that make all the difference between places well kept and those that are merely passable: hence, when proprietors ask us what labour power should be necessary for such and such circumstances, we generally advise them to note how the men work, and act accordingly. It is true, system and careful management can do wonders, but the best system will not treble labour power.

Just as an instance of what people consider good keeping: this season our lawn has been praised by many; to us it is but passable, and just now we could employ a dozen pair of hands in weeding that alone for a month. A thoroughly good lawn ought not to have a Daisy or a Plantain, either of the round or long-leaved kind, in it. As to Daisies, we should feel the case almost hopeless, and we do not mind them so much, as they form a thick carpet with the grass. At this season the flowers do not show, and earlier in summer we can soon

send myriads of them out of sight with repeated strokes of the daisy-knife, but the Plantains are a complete annoyance; they will raise their flowering heads, and then the round-leaved kinds form so many large rough cushions on a velvet lawn, and nothing but taking them up by the roots will free you of them. Cutting the top off is of no use whatever, they will throw up as many heads as the fabled hydra, and if you allow them to seed you will have no want of progeny. After these rains would be a good time to take them up by the roots, sow the large space that the leaves cover with Dutch Clover and Bents, and roll all over nicely. We have seen several prongs for the purpose, but the great point is to take up with every bit of root, and if a pinch of salt is placed in the hole it will be all the better. The *Plantago lanceolata* is equally difficult to extirpate, but then its "rib-grass"-like leaves blend, like the Daisy, more with the grass, and do not form such unsightly cushions as the *Plantago major*. We would like to see the whole lot of them out of every lawn. Some time ago we noticed Tingarth Gardens in these pages. We have not seen it for some years, but the lawn there was about the finest we have ever seen. It is nearly thirty years since we first saw it, and Mr. Phillips, the gardener then, was having it rolled early in the morning to throw down the dew to enable the ladies to walk on it dry-shod, and we never can forget his offering half a crown for every weed above 2 inches in height that could be picked up anywhere. We did not then see a single Plantain on the lawn. Mr. Phillips, who is now to us one of our pleasant memories, with his characteristic noble-mindedness, told us, "Mind, it is no credit to me; my employer freely gave the means, and I merely employ them." There are few truly weedless lawns. The pulling out of prominent weeds, say some friends, is surely a very little matter; and so it would be but for other myriads of little matters demanding attention.

Here we may just instance one more reason why gardeners should be sure as well as diligent. A young gardener, not long in a place, has written to us asking our sympathy and help in what he considers bad usage. He had next to lost his place because he allowed the under-gardeners to give, for a certain consideration, some long-mown grass to a cowkeeper. Our only sympathy would be given in the old maxim, "What is worth the having is worth the asking for." When a gentleman meets with a good honest gardener, we believe it will be as well that such matters are left to his management, as he will be anxious enough to receive a *quid pro quo*; but, on the other hand, no gardener who values his character, would risk doing anything in an underhand way, even to oblige his labourers or under-gardeners. Right is right, all the world over, and everything about the garden and the pleasure grounds is as much the property of the proprietor as the money in his purse, and the plate in the strong room. Without his sanction or approval nothing about the place, be it as seemingly insignificant as the short grass from a lawn, ought to become the subject of barter or exchange. The gardener who in such matters trusts to use and previous custom, trusts himself on very slippery ground. The straightforward and open are best in the end. In other words, thorough honesty is ever the best policy. Instances are known to us in which certain privileges have been so abused, that it was deemed the better way to allow no privileges whatever. Even waste vegetables were taken to the piggeries, &c., because the taking of them by the men became a source of annoyance and abuse. Though anxious that nothing that is fit for food should be lost, there may be circumstances in which it may be proper even to consign that to the manure heap. However we may approve of employers granting privileges to their workmen, as a general rule, we think it is best for every one when all workmen are suitably paid at once for their labour, and are not partly paid by contingent privileges. We can easily fancy how even the disposing of short grass by men would cause much annoyance and disappointment; at any rate no gardener ought to permit such a thing for a moment, without the knowledge and the sanction of the employer. We advise our correspondent to make an apology and be more strict for the future. Every man may do with his own as he likes, provided his doing so does not interfere with the advantage or the morals of others; but no man has a right to do with his master's property except as that master may approve. Gardeners are often put to great straits in these matters. There are many applications made to them which they could not meet without a previous understanding as to the powers at their disposal. In such cases a man must be safe to be sure.

In potting, shifting, hardening, &c., see previous weeks. We shall now say a few words on propagating bedding plants, in answer to several remonstrances as to our overlooking simple matters of detail. These have been so often given that we deemed such next to unnecessary. Several friends kindly say they do not wish to be referred to some far-back article, but to be told how we are doing now, and that perhaps, will be best.

Our propagating has hitherto chiefly been confined to Verbenas, Lobelias, dwarf Ageratums, and the more tender variegated Geraniums, as we wish cuttings and plants that will stand in little room all the winter. For most of these we select four, five, and six-inch pots. The pots are filled to about a quarter of their height with drainage. The first crock is placed with its convex side downwards, so as to prevent worms entering, the other drainage is placed in an open manner over it, the smallest drainage being at the top. Through this the water percolates freely, and escapes, though nothing, unless it be very small and slimy, can get in. On the top of the drainage is placed either a slight sprinkling of moss, or of the roughest riddlings of compost, and in the first, and generally in both cases, a slight sprinkling of soot is placed over this bottom. The pots are then filled to within an inch of the top with soil that has been passed through a half-inch or three-quarter-inch sieve, consisting of four parts loam, one of leaf mould, and one of rough drift-sand, such as may be picked up by the sides of a highway after a heavy rain, the sand consisting of a mixture of soil and ground flints. If the soil is dry, these matters are pressed down, and then watered, and allowed to stand a day for use. If somewhat damp nothing in the way of watering is required; but the mixture is pressed down so as to be moderately firm, and some quarter of an inch of fine road-drift or other sand—silver sand is the best—is placed on the top ready for the cuttings to be dibbled in.

Now, suppose we take cuttings of Verbenas. We have no notion of having a barrowload from the beds brought in to the shed to select cuttings from, to the danger of hurting the appearance of the bed, and the as great danger of puzzling the cutting-maker as to whence he shall select his cuttings from the mass of branches. Cuttings cannot be taken without selection, and as a general rule we wish the selection to be made on the growing plants instead of in the shed. For this purpose small shoots, side shoots generally they are called, are selected, and these are slipped off with a sharp knife close to the main stem, and if not more than 2 or 3 inches in length, we like them all the better. These are more robust and more likely to make stiff stubby plants than mere points of long shoots. These are generally taken off and placed in flower-pots or little baskets, so that there shall be no danger of flagging, it being one of our rules that no cutting at any time should have the chance of flagging if we can prevent its doing so. Let beginners ever bear in mind, that though a cutting may revive after flagging, yet that the time it requires to do so is just so much time lost as to its becoming a plant on its own account. We, of course, except some succulents full of sap, which are often the better of a little drying, though even in their case they would often strike root sooner when no such drying was resorted to. With Verbenas, Lobelias, Petunias, &c., it is always best when there is no flagging. Now, here comes a matter of importance. Verbenas seem as yet quite clean this season, and so we have not done much to insure their cleanliness, but if we have a month of dry weather, thrips, &c., will be almost sure to assail them. It is a good plan, therefore, if thrips or fly be suspected, to draw all these little cuttings through weak tobacco water, or quassia and soft-soap water, as recommended by Mr. Rivers. The simple way of doing this is not without its importance. The small slipped-off pieces may be washed through the water and laid out on the board to soak and dry, or the cuttings may be made first by cutting off the lower leaves, cutting straight through at a joint, and shortening the other leaves a little; and then, holding some dozen or score by the bottom ends, swing the cuttings through the prepared water, and lay them down before inserting them. The object in either case is the same—to wash all the parts of the cutting in the mixture, except the lower end, which is held in the hand. We have long since proved that certain mixtures, as the above, will kill all insects on a leaf, joint, &c.; but similar mixtures absorbed by the root, or the cut end of a shoot, become prejudicial to the health of that shoot, cutting, or plant. The only care necessary is, that little or none of such liquid should be absorbed by the cutting. Some things are hardy enough to resist even this, but it is well to work on the safe

side, as even the filling of these pots involves considerable time and labour.

The cuttings, being thus prepared, may be inserted, in two rows, round or all across the pot, giving them from a half to 1 inch each, be fairly watered with a rose, and the water allowed to settle, the sand clinging to the base of the cutting, and preventing air entering to rob it of its moisture there. The next consideration is the position for the cuttings; anywhere under glass will do, or even under calico or paper, where you can maintain a rather close atmosphere, and prevent, by moisture in that atmosphere, and shading from bright sun, the tiny little bits being scorched or withered up. Nothing is better than a cold frame or pit, which can be shaded and kept close in sunshine, and a little air given at all other times, when the cuttings will bear it without flinching. Every bit of shade more than the cutting needs to prevent it flagging, is just so far an inducement for it to elongate itself upwards, and therefore to weaken it, instead of inducing it to throw roots downwards, and thus secure robustness by correlative action between the buds and roots. Sun that scorches and withers, or flags, is either to be kept out, or neutralised by moisture and syringing. Provided the cuttings can be made to hold their heads erect, the less shade they have from the sun the more quickly will they root, and the more healthy will the young cuttings be. The cuttings will give less trouble still if they are placed in the cold pit or frame, some 15 or 18 inches from the glass, as at that distance they will need but little shade, and that in the hottest part of the day. In one word, place pots of cuttings of Verbenas in such a position now, for all artificial heat will be injurious to them; if on rough coal cinders all the better. Keep the lights close for twenty-four hours, which will secure a damp atmosphere, and force the cuttings to absorb as much as they perspire. After the second night give about half an inch of air, by raising thus much the top of the sash of the frame; shut close down about 8 A.M. If the sun is strong and clear, give a dewing from the syringe about ten, as soon as the cuttings show the least sign of flagging; repeat, if necessary, again; and if that is not sufficient give a little shade for two or three hours, but no shade at all if the plants will do without it; and remove the shade as soon as the force of the sun is past. Give air again at night; shut up during the day, until the roots are formed; then give more air night and day, by degrees, and expose the plants ultimately to sun and air, to harden them off; and either keep in the pots, or pot off, according to your system of management. We generally keep ours as store pots, for cuttings next season. Some pot them off singly; in the latter case they should be established in the pots before winter. The chief point is to use as little forcing as possible, and to keep them as hardy as possible before winter. For summer planting we prefer spring propagating, but then, by some means, we must have the plants to propagate from. We may say the same of the blue Lobelias, Petunias, &c.; but if you manage Verbenas, you will have no trouble with other bedding plants. To beginners we would say again, Recollect what has been stated about the shading; give as little as possible, and, when given, do not let it remain on all the afternoon and evening. We have seen a mat put on for shade, but, ten to one, it remained on to six o'clock, seven, or later, when it was cloudy after 1 P.M., and that made the cuttings weak and drawn.—R. F.

COVENT GARDEN MARKET.—AUGUST 19.

SUPPLIES continue very heavy; and the demand at this season being far from brisk, the market would be completely glutted were it not for the large quantities of fruit and vegetables required by the northern towns. Good dessert Apples chiefly consist of Kerry Pippin, Nonesuch, and Red Astrachan; and Pears of Jargonelle, Williams's Bou Chrétien, Lemmas, and other common sorts. Peaches and Nectarines from open walls are very plentiful but small.

PROPAGATING CINERARIA MARITIMA, CENTAUREA, AND CERASTIUM (C. P. P.).—Take up the best of the old plants of *Cineraria maritima*, and winter them in a dry cool greenhouse, and the *Centauras* in like manner. In February place them in a house with a temperature of from 50° to 60° to make new growth, and when this is a few inches long take off the shoots of the *Cineraria* with two joints and the growing-point, cutting transversely below the lowest joint; remove the two lowest leaves, and the cutting is ready for insertion in pans half full of two-thirds sandy loam and one-third well-ried leaf mould, then fill to the rim with silver sand. The *Centauras* cuttings are to be taken off close to the stem of the plant with a short heel, the side leaves neatly trimmed off to the extent of an inch or two, leaving the growing-point with its leaves untouched. Insert these like the *Cineraria* cuttings with their bases just resting on the soil, the dibber taking a little sand down with it if it penetrates beyond the thickness of the sand. Put them in so as not to touch each other to any great extent. Water lightly to settle the sand about the cuttings, and place in a bottom heat of 75°, and a top heat of from 65° to 75°, with a close moist atmosphere and alight shade from very bright sun; water sparingly, still keeping just moist, but by no means wet, otherwise the cuttings will damp off. In a fortnight or three weeks they will be well rooted, and may be removed to a cooler house, and when a little hardened potted off. The old plants if continued in heat will afford three or more lots of cuttings for striking in the same manner as the first, all making good plants for planting out in the first week in June. Cuttings of *Cineraria maritima* and *Centauras* taken at this time of year root with much less certainty than in spring, but will strike in a mild hotbed. For this purpose take the growing shoots of the *Cineraria* with the base of the cuttings a little hardened, and the side shoots of the *Centauras* with a short heel. *Cerastium* will strike from March up to September in an open border, taking off shoots 3 inches or so in length, and dibbling them in in lines 3 inches apart in sandy soil, and to about half the length of the cuttings. We put our cuttings in in April where we wish to have an edging, line, or band of it, taking the cuttings off with a knife by the hundred, and without trimming insert them half way in the soil at 3 inches apart in double lines, and all they further need is a good watering should the weather prove dry. These are what we prefer for lines a foot wide to look well by July; but for panel work we prefer small divisions of the roots at 6 inches apart in single lines for a width of 1 foot, but double and treble lines in quincunx arrangement for wider hands or lines. *Cerastium tomentosum* does very well in this way, but *C. Biebersteinii* does not make a lie so soon nor so good if the cuttings are inserted where they are to remain, and divisions of the root are better. These if put in during April or May will make a splendid line by the end of June. Cuttings of *Biebersteinii* strike less freely than these of *C. tomentosum*, but take a longer time to form as good an edging. Cuttings of both strike freely in light soil in a gentle heat, as well as in the open ground or in a frame.

TO CORRESPONDENTS.

.. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

VINES IN POTS (*C. T. Culver*).—The "Vine Manual," published at our office, and the pages of this Journal, will supply you with the information which you require. Mr. Whittle's address is Bush Hall, Hatfield, Herts.

SEEDLING PETUNIAS (*C. C. Malton*).—Your seedling *Petunias* are very pretty, the white ground pure, and the stripes distinct. If they are free from the usual fault of most striped varieties, which is that of losing the stripes, and becoming selfs, they will be very valuable. It is not likely that they will remain true to their present condition; we do not know of any variety that can be depended upon.

DRAINING AND RAISING A BORDER (*Calcearia*).—After you have dug out the soil to the required depth, make a proper drain in the bottom. On this place the brick rubbish, cinders, or any other rubbish you may have. You may cut the soil straight down in front of the Ivy, leaving 18 inches or 2 feet next the wall. After you have made your drain secure, put the soil back again. In doing this shake some light rubble stuff, such as small lime rubbish, in about the stems of the Ivy. The plants will not sustain any injury if their stems are covered up 2 feet or more with any porous substance, if there is plenty of drainage below, so that the water may pass away quickly from their roots.

FRUIT-ROOM SHELVES—LANCASHIRE GOOSEBERRIES (*Rector, Kent*).—We should decidedly give the preference to the open spars, as they permit a better circulation of air about the fruit, and for the same reason, and to prevent the spread of mould, we would use no straw. Mr. Charles Leicester, of Crompton Road, Macclesfield, Cheshire, can supply the Lancashire prize Gooseberries true.

SCARLET RUNNERS NOT SETTING (*W. B.*).—Rapid growth, rain, and cold nights are most likely the cause. The bees, we think, would promote rather than hinder fertilisation.

BEDDING GERANIUM (*A Subscriber*).—We do not recollect of any one that meets your requirements as to shade, &c. *Rubens* has some of the properties you want, but the shade is very different, and the habit more vigorous.

FLOWER-GARDEN PLAN (*S. B.*).—We think your plan and planting for a simple, regular group will answer very well. If you put *Centauras* round the dial it will give you more variety. We prefer the *Cineraria* for the centre or edging of beds, rather than filling beds chiefly with it. We think, also, it contrasts better with purple and scarlet, as *Purple King Verbenas*, and *Scarlet Geranium*, than with blue *Lobelia*.

FAIRY RINGS ON LAWNS (*A Subscriber*).—Water the rings copiously with lime water made by placing 14 lbs. of fresh lime in a hogshod or tub, pour over it 40 gallons of water and stir well up. Allow the whole to stand for two or three days, and then water with the clear liquid; if when the ground is dry so much the better. Two or three thorough soakings at intervals of four or five days will generally be sufficient to destroy the mycelium of the fungus. The whole lawn we should think poor, and would be much improved by a dressing of well-rotted manure in autumn or early in spring.

EJECTION (*A. E.*).—No one without being informed upon what terms you took your house can say whether you can be ejected after a month's notice; but if you are discharged from the landlord's service as gardener, you cannot be so unwise, we hope, as to wish to retain possession of the house required for your successor.

EMIGRATION (*A Young Gardener*).—We readily insert all the communications we receive from our colonies, or elsewhere, if they give information at all relative to gardening. If we intended to seek for employment as a gardener away from our native land we should go to some of the older of our settlements, such as Tasmania or New Zealand.

CALCEOLARIA LEAVES TURNING YELLOW (*G. A.*).—The usual cause of the leaves of the herbaceous kinds turning yellow is a warm, close, and dry atmosphere, and the evil sometimes arises from defective drainage, or using very rich decomposing vegetable soil, which destroys the roots. Keeping the plants dry and warm during winter is a common cause; they should be kept as cool as possible, merely excluding frost. When their blooming pots become filled with roots weak applications of liquid manure will assist in keeping the foliage healthy up to the time of blooming; and a cool, moist, airy, and light situation at all times will also promote the same result.

SOEWING MIMULUS MACULOSUS (*Idem*).—Plants from seed sown now will bloom next June. When the seedlings are large enough to handle they should be potted off into small pots, and be placed on shelves near the glass in a cool airy greenhouse from which frost is excluded, using a compost of turfy loam two-thirds, and one-third leaf mould, with a little sand intermixed. They may remain in the small pots until March when they should be shifted into larger pots, and as soon as these are filled with roots shift again, and so on until in the size in which you wish them to bloom. They like moisture when growing, and require the same treatment as *Calceolarias*. If for bedding stop them in April, and harden off in a frame for planting out in May.

DESTROYING COCKROACHES (*J. M. W.*).—A hedgehog kept in the greenhouse will make quick work of all that come within his reach. They may be trapped by placing a basin, half full of water sweetened with a teaspoonful or two of honey, on the floor at night, with a few sticks half an inch or so wide resting on the edges of the basin for the beetles to walk upon. These tumble into the liquid and are drowned. The basin may be sunk to the rim in soil, and is then an excellent trap. Arsenic mixed in the proportion of one-fourth with boiled Potatoes, and laid on pieces of paper at night, will certainly kill all that partake of it, and to prevent dogs touching it invert over each paper a box or piece of wood so as to allow of the beetles entering, a heavy weight being placed upon the box. Arsenic and honey in equal parts if laid on scraps of paper at night will also destroy the beetles. Phosphoric paste spread on thin slices of bread is as good a poison as any, and not so dangerous as arsenic, which should never be used where it can be avoided.

FERNS EATEN BY INSECTS (*J. K.*).—Most likely snails or slugs eat your Fern fronds. You may ascertain whether this is the case or not by looking out for them after dark with a lantern. If fresh Cabbage leaves are laid down at night, and examined in the morning, the snails or slugs will be found beneath them and may then be destroyed.

ASPHALTING A WOODEN VINERY (*W. S. W.*).—We say decidedly that painting the boards so shrunk with gas tar would be injurious to every thing inside, unless you previously filled all the shrunk parts. When the joints from shrinking are some way apart, a good plan is to fasten along the joints slips of wood, say half-inch and 2 inches wide and bevelled at the sides, which keep all secure whilst the shrinking goes on as it may. This might dispense with your proposed plan of covering the outside of the boards as you propose with asphalt roofing. If you do use the asphalt you might tar that outside, and whilst wet throw on as much awdust or road dirt as it would take in. This will also cause it to dry sooner, and it will make it more lasting. No air should be given in front until the smell has gone off. We have met with several instances in which bulbs and tubers will retain their vitality and grow, though kept out of the ground, and at rest for twelve months. There are some tubers, such as *Tropaeolum*, very singular in this respect. They will rest sometimes for a year or two, and then grow strongly.

**PROPAGATING PHLOX DRUMMONDI (T. C. H.).**—Save the seed from the finest flowers. They will give a large per-centage of flowers equal to the parents, and many we doubt not superior to them, though they may not be of the same colour. Cuttings of the growing parts put in now will strike root freely in gentle heat, and may be potted off when rooted into small pots, and grown in an airy part of the greenhouse in every way the same as *Petunias*. Cuttings may be taken in spring from the plants struck in autumn, and they make good plants for bedding out in May. We were in the habit of growing *Phlox* Criterion for bedding out, and we treated it like the *Petunia*; but it gradually wore out, and for this reason we strongly advise you to save seed from your present strain, and from none but extra fine flowers, propagating by cutting when the colours are required separately and with certainty. Plant in beds of rich soil, otherwise the bloom will not be good.

**SHELTERING A GARDEN (A Subscriber).**—With so small a garden we should think a wall 8 or 10 feet high would be sufficient protection. Trees shade so much ground and occupy so much with their roots, that room cannot well be afforded them in a small garden. Poplars would grow the fastest, and the Lombardy Poplar would take up the least room. Next to that the Black Italian and Ontario are rapid growers, and would do better in strong soil than the Lombardy, though they all like moisture. The White or Abele Poplar is worthless for shelter, and equally so is the Aspen. Poplars are the worst of trees to be near a garden, their roots run so far and so near the surface. Beech is the best; and you may cut it into a hedge, and thus prevent the tops overshadowing or the roots extending too far. The growth, however, is much slower than that of Poplars; but Beech or Hornbeam, which will bear any amount of cutting, is to be preferred to Poplars.

**SUPPLYING A FOUNTAIN CONTINUOUSLY WITH THE SAME WATER (H. J. B.).**—There are miniature fountains a good deal on this principle, but they are chiefly toys, and would not be of any use for a fountain in a garden. For such we know of no plan by which you can use the same water over again, except collecting it in a tank or reservoir, and then pumping it up

into a reservoir sufficiently elevated, from which it should again flow to the fountain. The toy fountains are made on the principle of those of Hero, of Alexandria, two air-tight vessels being connected by tubes, and the upper vessel filled with water; and water pouring down through a tube into the lower vessel so compresses the air that the water in the upper vessel is thrown up through the jet; this continuing only so long as the water in the vessel lasts, and the pressure is kept up. For practical purposes, we know of no plan better than the force pump, however that may be applied.

**NAMES OF INSECTS (G. S.).**—We cannot undertake to name entomological specimens, except when they directly relate to gardening. (Y. Z.).—The insects are slimy grubs, *Selandria* athrips, and are killed by dusting with lime. (A. M. K.).—The caterpillars are those of the Goat Moth (*Cossus ligniperda*), which are very destructive to trees, attacking even those which are hard-wooded as the Elm and Oak, but preferring fruit trees and those with softer wood. Thrusting a wire into their holes would probably kill them, and the French have used chloroform with a like object.

**NAMES OF FRUIT (A Subscriber).**—The Apple is Kerry Pippin. Plums—1, Nectarine; 2, not known; 3, Gi-borne's; 4, Pond's Seedling; 5, Standard of England.

**NAMES OF PLANTS (J. M.).**—The globular fungus is *Sclerotinia vulgare*, common in woods, and of no value as an article of food; the other, an *Agaric*, but not in a state fit for determination. (*Alpha, Acton*).—1, *Nephrolepis tuberosa*; 2, *Pteris hastata macrophylla*. The Oak Fern is *Polypodium dryopteris*; the Parsley Fern *Asplenium crispum*. (*Inquirer*).—The *Caladium* is *Caladium bicolor*; the *Begonia*, *B. frigida* ? You can obtain No. 187 from our office by sending your address and four postage stamps. (*G. B. B.*)—It is impossible to name plants with certainty from mere leaves. (*A. J. T.*)—1, *Veratrum nigrum*; 2, *Eschscholtzia californica*; 3, *Tradescantia virginica*; 4, *Calendula officinalis*; 5, *Gentiana asclepiadea*; 6, *Veronica spicata*, var.; 7, *Veronica spicata*. (*Old Subscriber*).—One is *Polystichum proliferum*, the other *Athyrium Filix-femina*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending August 19th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

WITHHOLDING PRIZES.

As the approach of autumn, and the growth of chickens, and the receipt of schedules remind us of the season of shows, amateurs look at their stocks before they make entries, and ask themselves where they shall send, and what their chances will be of success. There are two classes of exhibitors. The first, and oldest class, sought and seeks to breed and exhibit only the very best and most perfect birds of the sort admired; the second seeks to take the first prize under any circumstances. Our best birds and most reliable information are derived from the first. Those who form it are chiefly men of education, leisure, means, and intelligence. Possessing these advantages it is not surprising that they should excel; yet, with these means and appliances to boot, they constantly need the help of the second to procure the fresh blood necessary for keeping their strain in the first rank. We recently had a letter from a correspondent who has bought a bird for this purpose, advertised as a first-prizetaker on three occasions. The bird is in many respects faulty, but has one fault that should disqualify him anywhere—of course he is worthless. Inquiry proved the truth that he had taken the first prize as represented. When the defects and disqualification were pointed out, the answer was a truthful and ready one—"he was not a very good bird, but he was the best bird in his class." So long as schedules offer prizes for the three best pens of birds shown in such a class, first, second and third prizes, and committees tell judges not to withhold prizes because it discourages exhibitors, so long will these anomalies exist; but if judges are desired to recollect that they may withhold prizes from pens that do not deserve them, it will induce a far better state of things. Cheap success, where it is not intended as an advertisement, is appraised at its proper value, and undeserved honour is lightly esteemed. "Showing, in many cases," said a good exhibitor to us, "has become an absurdity—I sent a faulty pen for sale, and it took first

prize." So far from being encouraged by it he is annoyed, and says at present he shall give it up.

We all know how difficult it is to attain anything like perfection. We would not, therefore, make a first-prize pen depend on the exploit of reaching it; but we would insist on its possessing sufficient merit to justify the awards in the eyes of one, who, needing such, and trusting to the judges, would send his money on the strength of it, in answer to an advertisement offering it for sale. We believe the effect of withholding would be to multiply shows and entries, because it would increase the sale of first-prize birds. It would make exhibitors more careful in their selection. It is notorious that at many of the small local shows the best birds are not sent, because inferior ones get first prize; but if it were found that on such occasions the first was withheld, better birds would soon be forthcoming. No pen that is not highly meritorious should ever take a first prize. Where there are not such, let the first be withheld; award the second and third. Again, if only one pen is shown, and it deserves it, let it have the first. When a good exhibitor writes from the north of England that a good white deaf ear in Spangled Hamburgs is seldom seen at the shows there; another that a first-prize Game cock had such a crooked breast that it was visible to the eye; and another that the first-prize Game Bantam had a squirrel tail; it is necessary either that more pains be taken in judging, or that more competent persons be employed in the office; or, and we think the mischief lies here, that first prizes be withheld from inferior birds, though they may be the best in their class.

GAME BANTAM PRIZES AT BIRMINGHAM.

Will Game Bantam breeders join me in subscribing for an extra cup to be offered at Birmingham for the best pen of birds in classes 82 and 84? I should also like to offer one for the best bird in classes 85 and 86, if we could obtain the necessary funds. If Cochin fanciers can raise £25 I think we ought to be able to get £15 together. I shall be glad to give a guinea, and to receive

the names of gentlemen willing to subscribe to a fund for the purpose. If preferred the amount might be divided into say three prizes, to be added to the Birmingham Council prizes, or competition for the cup or cups might be limited to the birds belonging to subscribers to the fund.—R. B. POSTANS, *Brentwood, Essex.*

### DURHAM POULTRY SHOW.—AUGUST 8TH.

The following are the awards made on this occasion:—

**SPANISH.**—First, J. Shorthose, Newcastle-on-Tyne. Second, J. Rickerhy, Durham. *Chickens.*—First, R. Tate, Leeds. Second and Highly Commended, J. Shorthose.

**DORKING.**—First, J. Gunson, Whitehaven. Second, Mrs. Clark, Chester-Street. *Chickens.*—J. Bell, Thornton-le-Moors, Northallerton. Second and Highly Commended, Mrs. Clark.

**BAHMA POOTRA.**—First, F. Powell, Knaresborough. Second, Rev. A. D. Shafto, Brancepeth, Durham. Highly Commended, H. Marshall, Durham. *Chickens.*—First and Second, H. Lacy, Hebden Bridge.

**COCHIN-CHINA.**—First, Rev. A. D. Shafto, Brancepeth. Second, J. Shorthose, Newcastle. *Chickens.*—First, Rev. A. D. Shafto. Second, Rev. J. G. Milner, Bellerby.

**GAME.**—First, J. Wilson, Tudhoe. Second, J. Sutton, Durham (Brown-breasted).

**HAMBURGH** (Gold or Silver-pencilled, or Spangled).—First, Second, and Highly Commended, A. R. Woods, Burnside, Kendal (Golden-spangled, Silver-pencilled, and Silver-spangled). Commended, T. Fairburn, Dunwellpit, East Rainton (Golden). *Chickens.*—First, A. R. Woods (Silver-spangled). Second, R. Tate, Leeds. Commended, T. Fairburn (Golden-spangled).

**BANTAMS.**—First and Second, J. Shorthose, Newcastle-on-Tyne. Highly Commended, T. C. Harrison, Hull.

**DUCKS** (Aylesbury).—Prize, Mrs. Clark. *Ducklings.*—Prize, Mrs. Clark.

**DUCKS** (Rouen).—Prize, O. A. Young, Driffield. *Ducklings.*—First, H. Marshall, Durham. Second, Miss Robinson, Pittington Hallgarth.

**GEESE.**—Prize, O. A. Young, Driffield.

**PEACOCK.**—Prize, H. Marshall, Durham, twenty years of age.

**PIGEONS.—Carriers.**—Prize, J. Emmerson, Durham. *Tumblers* (Almond).—Prize, G. Procter and T. Pringle, Durham. Commended, T. Rule, Birmingham. (Any other variety).—Prize, T. Rule. Commended, H. Yardley, Birmingham. *Fantails.*—Prize, H. Yardley. Commended, T. Rule. *Trumpeters.*—Prize, T. Rule. Commended, H. Yardley. *Barbs.*—Prize, H. Yardley. Commended, T. Rule. *Jacobins.*—Prize, T. Rule. Commended, H. Yardley. *Turbits.*—Prize, T. Rule. Commended, R. Tate, Leeds. *Owls.*—Prize, R. Thompson, Sunnybrow, Willington. Commended, T. Rule. *Pouters.*—Prize, J. J. Wilson, Darlington.

**RABBITS** (Best pair of any breed).—Prize, O. A. Young, Driffield. Highly Commended, J. Reed, Sunnybrow, Willington. Commended, H. Marshall, Durham; G. Meffatt, Durham.

### NORTH LANCASHIRE AGRICULTURAL SOCIETY'S POULTRY SHOW.

A POULTRY Show was held on the 10th inst., in connection with the annual meeting of this Society, at Acerrington. The *Dorkings* were, as a class, very good. Of *Spanish* the show was very small in numbers, but all exhibited were of a high quality; and the same might be said of the *Game* fowl. The Golden-spangled and the Silver-spangled *Hamburghs* were amongst the most attractive features of the Show, their excellence being indisputable. The following were the awards:—

**DORKING** (Grey).—Prize, J. Robinson, Garstang. *Chickens.*—Prize, D. Parsons, Cuerden.

**DORKING** (White).—Prize, D. Parsons, Cuerden. *Chickens.*—Prize, D. Parsons.

**SPANISH.**—Prize, R. Teebay, Fulwood. *Chickens.*—Prize, R. Teebay.

**GAME.**—Prize, J. Wood, Haigh, near Wigan. *Chickens.*—Prize, J. Wood.

**HAMBURGH** (Golden-pencilled).—Prize, T. Wareing, Preston. *Chickens.*—Prize, W. Bee, Goosnargh.

**HAMBURGH** (Silver-pencilled).—Prize, J. Robinson.

**HAMBURGH** (Golden-spangled).—Prize, J. Robinson.

**HAMBURGH** (Silver-spangled).—Prize, R. Teebay, Fulwood. *Chickens.*—Prize, J. Robinson.

**POLAND.**—Prize, C. W. Brierley, Middleton.

**BANTAMS.**—Prize, C. W. Brierley. *Chickens.*—Prize, D. Parsons.

**COCHIN-CHINA** (Chickens).—Prize, C. Sidgwick, Keighley.

**GEESE.**—Prize, T. Houliker, Rividge. *Goslings.*—Prize, T. Houliker.

**DUCKS** (Aylesbury).—Prize, E. Leech, Rochdale. *Ducklings.*—Prize, E. Leech.

**DUCKS** (Rouen).—Prize, T. Houliker. *Ducklings.*—Prize, T. Wareing, Preston.

**DUCKS** (Any other variety).—Prize, D. Parsons, Cuerden. *Ducklings.*—Prize, D. Parsons.

**TURKEYS.**—Prize, E. Leech.

### BEEES AND BEE-HIVES

AT THE ROYAL AGRICULTURAL SOCIETY'S MEETING AT PLYMOUTH.

LIVING bees at work are always attractive, not only to bee-keepers but to the general public; Messrs. Neighbour & Sons' exhibition formed no exception to this general rule, for their stand was at all times densely crowded. The chief object of interest was the Woodbury unicum observatory-hive, in which was a stock of Ligurian bees, with a very fine queen surrounded

by her yellow Italian subjects. Messrs. Neighbour also exhibited a square Woodbury glass hive stocked with English bees, in which the position of the bars and frames, with bees and combs, could be very distinctly seen. Both these colonies were brought from Mr. A. Neighbour's apiary near London. The bees obtained egress and ingress by means of a covered way nearly 3 feet long, which appeared but little to inconvenience them, whilst, being covered with glass, it added not a little to the interest with which they were observed. In the wall of the shed were small apertures, with alighting-beards fixed on the outside, and although the public passed in crowds before these unprotected entrances, no one was stung, nor were the bees themselves interfered with or molested—a warning notice appended to the outside being universally attended to, and a respectful distance maintained.

Amongst Messrs. Neighbour's collection were the Woodbury straw bar-and-frame, Neighbour's improved cottage, the ladies' observatory, cottagers', and many low-priced straw hives on the improved system. The impressed wax sheets, with specimens of combs partially worked therefrom, were interesting and curious. The bottle-feeder, bee-dresses, Indian-rubber gloves, and other apianian appliances also received, and were worthy of much attention.

By way of illustrating the fruits of the honey harvest of the present year, Messrs. Neighbour had a square super of fine white honeycomb from the apiary of our esteemed correspondent Mr. Woodbury, and an octagon glass super from our valued contributor Mr. S. Bevan Fox, both of which admirable specimens were most highly commended.

### BEEES CARRYING OUT YOUNG BROOD.

CAN you explain the reason why bees in a remarkably fine strong May swarm should, on the 3rd inst., have carried out of their hive at least one hundred bees fully formed with legs and wings, but all quite white? For two days they continued to remove them. The hive is straw, with a small hive on the top, which is covered by another straw hive, all fresh, clean, and free from vermin. The bees have always been busy and healthy.—K. S.

[This may arise either from the brood becoming chilled by a sudden fall in temperature, or from the bees themselves being near starvation. We should advise an immediate and liberal supply of food.]

### BEEES IN STAFFORDSHIRE.

CONDITION OF HIVES ON APRIL 9TH, 1865.

A		B	
Swarm May 15th, 1864. Hybrid queen July 2nd, 1862. Very strong.		Swarm May 19th, 1862. 1863 and 1864. Very weak.	
C		D	
Swarm June 1st, 1862. Very weak.	Storified in 1864.	Swarm May 16th, 1864. Pure Italian queen introduced October, 1864. Strong.	
E			
Swarm of May 18th, 1864. Strong, but no queen.		C and E were united, and the queen of C killed, April 16th, 1865.	

April 9th was a splendid day, and I closely observed the proceedings of the different hives. A great many beautiful Italians issued forth from n, proving that the pure Italian queen was safe; but a few of Mr. Lowe's puny drones were also visible. A considerable number of drones, the majority Ligurians, were issuing from e, but I could not discern a single young worker, and this excited grave apprehensions, so on the following day, Monday, I overhauled the combs, and found, as expected, a sprinkling of drone brood, not compactly arranged, but a few here and there, in different parts of two or three combs, chiefly in worker cells. After a long and rigid scrutiny, failing to detect a queen, and concluding that the brood proceeded from fertile workers, I determined to unite this hive to c, and thus form a strong colony. The union was successful as far as the bees were concerned, and only a little fighting occurred; but on the following day the fertile queen of c was cast out dead. The bees completed several royal cells, and a queen was hatched on the 24th; but as she had not commenced laying upon the 15th of May, I killed her, and on the following day gave the bees two frames of brood with the adhering bees from d, to enable them to raise a queen from pure Italian brood, and also to recruit their diminishing numbers. Three royal cells were completed, but only one queen arrived at ma-

turity, and she emerged from her cradle upon the 30th, and has proved amazingly prolific.

May 4th a nucleus was formed by taking three combs with the adhering bees from D, and placing them with a frame of sealed honeycomb in a four-frame box. The bees were confined, but with ample ventilation, until dusk. When set at liberty upon the following day a great number of the bees returned to the parent hive, but sufficient remained to construct three royal cells; in three or four days, as the colony was very weak, a fourth frame of brood and bees was substituted for the frame of honeycomb, and most of the bees remained with the juvenile colony, and when a young queen emerged upon the 18th, the hive had become quite populous. Only one royal cell was fully completed. On the 7th of June I found that the hive already contained a good deal of sealed brood from eggs laid by the young queen, so I at once removed the bees into a full-sized ten-frame hive. Two frames of ripe brood from A were added to them, but all the adult bees were first swept off to prevent any chance of casuality to the young queen. This hive soon became very strong, and was fully occupied by the end of June.

May 20th D was completely sub-divided. In the first place the queen (pure Italian), with one comb of brood, was put into a new hive (G) with several frames of empty comb, and this hive was then located on the site of the old stock. Two frames of bees and brood were then placed in another hive (H) containing six frames of empty comb, and the hive was then put upon the stand of a very strong stock (A), which was removed to another part of the garden. The remaining frames of brood from D (5) were then replaced with the adhering bees in the original hive, with two or three additional frames of comb, and were located upon a stand about a yard to one side of the one they previously occupied. The majority of the adult population returned to their queen in G; but a considerable number, recognising their old habitation, joined the queenless stock.

The bees in H made a great number of royal cells upon the two frames of brood with which they were supplied (three upon one, and ten at least upon the other). On the 30th of May I killed the black queen in A, and gave the bees one of the frames from H, containing three royal cells, two queens were ejected, and the third now reigns monarch of the hive. Five cells were then excised from the other comb in H, and three brood combs having previously been removed from A, which had again become very populous after its removal on the 20th, these cells were inserted in one of them, and the three frames of brood, with a frame of sealed honeycomb were placed in a four-frame nucleus-box, which was then put on the stand previously occupied by A, which was again removed to a new situation. From some cause or other, this nucleus failed to rear a queen, but on the 5th of June n sent out, as I anticipated, a maiden swarm under one of the young queens. They were hived in an ordinary straw hive full of comb, and containing also a good deal of honey, and promise to do well.

On my return home finding that piping in both keys was still going on in H, I opened the hive, and, leaving the queen already at liberty mistress of the hive, removed the remaining royal cells. A queen emerged immediately from one of them, and was at once put under a tumbler. The royal cells were then inserted in one of the combs in the nucleus. I then took the captive queen out of durance, and placed her upon one of the combs which I held in my hands, and watched to see the result. One of the bees came up, seized the tip of the queen's wings, and gave several hard tugs, but then quitted her without inflicting any injury; other bees subsequently came up and she underwent a severe scrutiny, which made her very nervous, but no further violence was offered to her, and in half an hour afterwards, upon again inspecting the hive, I saw the queen quite at ease, pacing the combs, and she was piping in the evening. The royal cells were destroyed, and their inmates ejected.

By these operations, with only two hives in a position to give me any assistance, five good swarms have been established, a drone-breeding stock has been reserved from destruction, and B, which contained a young but very indifferent queen, has been supplied with a monarch reared from the brood of a pure Italian mother.

I have now nine flourishing colonies, seven of which are headed by fertile young queens reared from the brood of the pure queen received from Mr. Woodbury last autumn. This queen is monarch of the eighth hive, and the ninth is, I believe, under the guidance of a queen nearly three years old, sole surviving daughter of the original Italian queen received from Exeter in 1861.

All the queens raised this season commenced to lay within a few days of the time of their emerging from their cells, and have demonstrated by their amazing fecundity, that what are technically called artificial queens, are in all respects equal to those originally laid in royal cradles; and I doubt not that Mr. Lowe will find that artificial queens raised in favourable seasons prove quite as fertile as those reared naturally by the bees, without interference from the bee-master. Since 1856, I have raised a great number of artificial queens, and only two out of the entire number have proved themselves drone breeders. A third, though kept a considerable time, did not lay, and would, I believe, have turned out the same; but all these queens were raised in a unicomb hive, from which the exit was rather complicated and contracted. All those produced in ordinary hives or boxes have in every case proved perfectly fertile.—  
J. E. B.

## THE OLD BEE.

[From the German of JOHANN BAUMANN.]

By "A DEVONSHIRE BEE-KEEPER."

How many journies hast thou travell'd  
To distant hills—to distant vales?—  
How oft the leafy maze unravell'd  
Where daylight into twilight pales;  
With wing untiring day by day,  
From morning's dawn till ev'ning gray?

With honey or with pollen freighted  
Often and often cam'st thou home;  
Brief was thy rest when overweighted,  
But prompt to fill the waxen comb;  
Sole end and aim of all thy zeal  
The progress of the common weal.

If when on guard before the city  
Thy post were threaten'd by the foe,  
Then undeterr'd by ruth or pity  
All hostile schemes thou'dst overthrow.  
He who attack'd whilst thou hadst breath  
Tro'd but the path that led to death.

To build the combs thy aid was given,  
To feed the brood, to rear the young;  
With willing mind and temper even,  
With active limb and pliant tongue;  
By day or night no rest for thee:  
Say, if on earth thy equal be?

Labour and toil thy portion ever,  
Thou faithful, clever, noble thing!  
What thy reward for such endeavour—  
What crowning blessing doth it bring?—  
Without remorse, when old and gray,  
To starve and die thou'rt turn'd away.

Thy wings that erst were full and rounded,  
By willing toil are chafed and worn;  
Yet with submission still unbounded  
Thou tak'st thy last sad flight forlorn,  
And slowly flutt'ring to the earth  
Forsak'st the home that gave thee birth.

T. W. WOODBURY.

Mount Radford, Exeter, 16th August, 1865.

## BEEES DYING—UNPRODUCTIVE STOCKS.

I HAD a flight of bees on June 18th, but another issuing on the same day I joined them, and they progressed well until the 11th, when I noticed several dead bees on the alighting-board. Having swept them off I left them till evening, when I found the board again covered. I determined to take up the hive immediately; it weighed 31 lbs., but the hive-board was covered with dead bees to from 1 to 2 inches deep. I had never noticed any fighting. The hive was on a post 5 yards from a weaker stock, and 50 yards from two others, all flights of this year. Can you give any reason for the death of so many bees? Honey is good, and everything seemed satisfactory?

I have also been unable to obtain a glass from a single old stock this year. I have a beautiful glass taken off July 8th from a swarm only hived on the 9th of June of this year. The glasses were put on principally on May 1st, the others on May 8th. There was a little comb in some, but they all sent out

strong swarms. Why do I not succeed? How large ought the supers to be?—**MINILYN.**

[Suffocation or dysentery are the only causes which appear likely to have produced such a catastrophe. If the entrance to the hive be very narrow, the accidental obstruction caused by the presence of a few dead bees may possibly have caused the former, whilst the latter would be indicated by the dead bodies being swollen to an unusual size.

The want of decay combs in your glasses would be a probable reason for your ill-success. Supers may be of any size from 3 or 4 lbs. up to 50, or even more.]

#### NOTES AND QUERIES TOUCHING BEE-KEEPING.

1. I can quite corroborate what Mr. Bevan Fox says in favour of the plan of getting rid of the bees from supers by driving. I have not had many glasses to deal with, the bulk of my honey having been taken from duplicate bar-frame-hives used as supers; but on taking off the last glass, being pressed for time, I bethought me to try the effect of driving: therefore, keeping the whole glass carefully covered, I turned it bottom upwards, tapping the edge of the adapter against a doorpost. In about five minutes there was the usual hubbub among the bees, and out they rushed in a steady stream, and I had no difficulty whatever. I had made a memorandum to try the plan more fully next season, and am glad to find my experience is correct so far as it goes.

2. Can any one explain how it is that one particular hive in a neighbouring apiary has not swarmed for six years? It is a good-sized hexagon, rather large certainly, but, I think, not sufficiently so to account for the fact. The hive has always been strong, and has worked well in glasses. The reason generally given—namely, that the queen is from some cause unable to fly—will hardly hold good here, as the hive is now six years old, and this exceeds the highest estimate of the age of a queen. My neighbour, who is a most successful apiarian, and generally contrives to have both honey and swarms, proposes to drive it, and add the bees to a swarm of this year.

3. In removing a double hive (one placed above the other), to or from the moors, it would be much more convenient to separate them, and pack each by itself with perforated zinc; but will the bees in the super travel safely for twelve hours if separated from the queen, and having no young brood with them? Notwithstanding every care, many deaths occur in the removal of a single hive, and I imagine that the agitation and excitement of the bees in the case supposed might produce much mischief. I ask the question, because it is a serious matter to remove a hive of 70 or 80 lbs. to any distance, and especially with new combs in the super. There are far more bees than the lower hive alone will contain.

4. Being inclined to experiment a little in various materials for hives, I should feel much obliged by any information as to similar trials. As between wood and straw, it seems to be now generally admitted that straw has the preference. The difficulty is, that while it is easy to have wooden hives made to any pattern, a square straw hive is beyond the skill of a country workman. Has cedar been fairly tried against American pine? The former seems to be a more porous and spongy wood, but the only plea which I have seen urged in its favour does not seem a sound one—namely, that the odour is grateful to the bees, but distasteful to the moths. Is this a fact? because, ordinarily speaking, what is favourable to the one insect is also favourable to the other, and *vice versa*. Also, has paper or millboard, 1 or 1½ inch thick, been tried? Many years ago hives seem to have been made of this material, and at a very cheap rate, but I have never heard how they answered; and there is tan, respecting which your valued correspondent Mr. George Fox has spoken most highly. May I ask if his hives stand well, and if he still thinks as highly of the material as he did at first?—**F. H. WEST, Potternewton, near Leeds.**

[Your neighbour's stock having worked well in glasses appears a sufficient reason for its not swarming. Bees shut up in a super would certainly not be likely to travel safely for twelve hours. We shall be glad to receive information in reply to our correspondent's last query.]

**STEWARTON HIVES.**—Referring to the notice regarding Stewarton hives from "YORKSHIRE," at page 102, allow me to state that I have recently had a complete octagon hive from Mr. Eaglesham, Stewarton, consisting of two boxes 9 inches deep,

with honey-box the usual depth; each box is fitted with four frames in the centre of the windows, 5 by 3½ inches. The hive is of superior finish, and is altogether the best idea (after using them largely for the last twenty years), I have yet seen of the Stewarton hives. The directions for managing these, with the aid of the diagram sent along with them by Mr. Eaglesham, are so simple and explicit, that the merest tyro in bee-culture could have no difficulty in working them with success.—**URBANUS.**

[We are very glad to find from the above, and from Mr. Eaglesham himself, that he is *not* dead.]

**WASPS.**—Has anybody seen a wasp since May? In April the queens were so numerous that it was supposed we should have in the autumn an overwhelming supply of these troublesome and destructive insects, and it is recorded that one gentleman paid more than £6 for the destruction of queens in his gardens and grounds during that month. He might have saved his money. The sharp frost of the 1st of May appears to have done its work in destroying these insects, scarcely one having been seen since; so that the swarms which have in some years infested our houses, eaten our fruit, and given animation to the grocers' windows, are this year nowhere to be found. The complaint this year is of earwigs, which infest every house in the outskirts of the town and in the country.—(*Daventry Express*.)

#### OUR LETTER BOX.

**CHICKENS DYING (Two Duns).**—We are at a loss to account for the death of your chickens, unless they find something poisonous about the premises. This, however, would not be the case everywhere. If you were to open one you would probably find the cause. We know nothing that would attack them at that age that would not do so earlier. Feed them generously on bread and ale, and put camphor in their water.

**DISTINGUISHING THE SEXES OF GUINEA FOWLS (Guinea).**—The reason why you get no produce from the eggs is because they are both hens. It is difficult to tell the sex, but the cock has longer wattles, and a larger coronet on his head. The hen only calls "Come back;" the cock utters a kind of wail. They pair as strictly as Partridges; and, unless an equal number of each sex be kept, there will always be many bad eggs. It is easy to tell the age. In the young bird the coronet or lump on the top of the head is covered with soft skin; in the old one the skin has become a hard brown crust.

**POINTS OF GOLDEN-SPANGLED HAMBURGS (Exhibitor of Golden-spangled Hamburgs).**—The distinction in question was in answer to a special case, in which a man justified a Golden-spangled Hamburgh with red ears by calling it a Mooney. We have always said, and we repeat, the white deaf ear is indispensable—one of the most positive and important points of the breed. Those who recollect the beautiful birds bred and shown by the late Mr. W. Worrall will at once admit that, although there may be difficulty in getting this, as there is all other marks of perfection, yet that gentleman never showed a pen in which the hen's ears were not the size, shape, and colour of a new fourpenny-piece. We have often heard Moonies and Spangled Hamburgs called the same breed, and we have agreed with those who thought so; but these birds are the old Montagnes and Capulets—Yorkshire wanted black breasts, Lancashire would have them spangled. Years before this controversy some contended for henny tails, others for full tails. Now this present question arises from the distinction drawn by an amateur or a dealer between Mooney and Golden-spangle. The local Yorkshire Red-cap, a Golden-spangle, with exaggerated comb and gills, should have a red deaf ear. Indeed there is little doubt that they acquired their name from the redness of all the flesh that constitutes part of head and face; also that they are offshoots from the Spangled Hamburgs; but we do not tolerate a red ear in a Spangled Hamburgh, nor, in our opinion, should such ever have a prize—certainly not a first one.

**CONTINUOUS USE OF POULTRY YARD (C. A.).**—There is no objection to your keeping fowls in the same yard for a succession of years, more especially as they have a three-acre orchard to run in. With a view to profit solely, keep Cochino-China or Brahma Pouter pullets and a Dorking cock. Have the floor of the hen-house covered with loose sand, rake off the dung every morning, and whitewash the interior once or twice annually with a creamy mixture of chloride of lime and water.

**CLITHEROE POULTRY SHOW.**—I sent a pen of Silver-laced Bantams to Clitheroe Show, and received back a pen of Brown Red Game Bantams, and would be glad if any one having received my Silver-laced instead of his Game Bantams will write to my address, or send them, when I will return the birds which I have received in mistake.—**S. J. ASHTON, Mottram, Cheshire.**

**ORMSKIRK AND SOUTHPORT POULTRY SHOW.**—In the list of awards published last week Mr. A. K. Wood, Burnside, Kendal, informs us that his name is omitted as having taken the first prizes in the Golden-spangled and Silver-pencilled Hamburgh classes, and a high commendation in the latter. The omission is that of the list which was forwarded to us.

**BEES GOING DAILY TO THE SEA (Rusticus).**—This superstition is wholly without foundation. It is, however, very generally diffused throughout the West of England.

**DRAINING HONEY FROM COMB—PREPARATION OF WAX (A New Bee-keeper and not a Farmer).**—Full directions for draining the honey from combs, and for rendering the latter into wax, are given in pages 28 and 29 of the fifth edition of "Bee-keeping for the Many," which may be obtained free from this office for five stamps.

**STEWARTON HIVES.—MR. EAGLESHAM.**—"In replying to a question about Stewarton hives, in No. 227, you say, 'We have reason to believe that Mr. Eaglesham is dead,' a statement which may do me considerable injury, as I never, in any season, sent more hives to England than I have done in this. It is only about three months since I advertised in THE JOURNAL OF HORTICULTURE, and am at a loss to know how you came to believe I was dead.—**WILLIAM EAGLESHAM.**"

WEEKLY CALENDAR.

Day of Month	Day of Week.	AUG. 29—SEPT. 4, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock before Sun.	Day of Year.		
			Day.	Night.	Mean.		m.	h.	m.	h.	m.	h.	m.	h.					
29	TU	Red Bryony berries ripe.	71.6	48.0	59.8	14	9	af	5	52	af	6	30	1	29	af	10	0 44	241
30	W	Meadow Saffron flowers.	72.0	48.3	60.1	9	11	5	50	6	25	2	16	11	9	0	26	242	
31	TH	Elecampau flowers.	71.1	47.2	59.1	16	13	5	48	6	17	3	13	0	10	0	7	243	
1	F	Partridge shooting begins.	70.5	47.5	59.0	19	15	5	44	6	2	4	13	0	11		after	244	
2	S	Autumn Gentian flowers.	70.6	47.6	59.1	16	16	5	43	6	45	4	17	1	12	0	59	245	
3	SUN	12 SUNDAY AFTER TRINITY.	70.3	47.6	58.9	16	17	5	41	6	19	5	28	9	13	0	50	246	
4	M	Berberries ripe.	70.4	46.2	58.3	16	19	5	39	6	50	5	46	3	14	1	9	247	

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 70.9°, and its night temperature 47.5°. The greatest heat was 85°, on the 1st, 1843; and the lowest cold, 32°, on the 29th, 1850. The greatest fall of rain was 1.50 inch.

THE SEASON AND ITS RESULTS.

Y many it is remarked, that if they had been acquainted with the character of the coming season, they would have acted differently; as, for instance, if they had been certain of a hot period,

many tender plants would have been trusted out of doors, or if the contrary, more hardy ones would have been brought into use. Unfortunately, or rather, perhaps, fortunately for us, our insight into futurity in this direction is very limited, notwithstanding that weather-prophets are numerous enough, and each prognosticating something different, one amongst them has a chance to be right, and is by no means slow in taking credit for it; but I am not aware of any one telling us in the early part of the season that we were to have such an exceedingly dry period in June, and that the latter part of July and early part of August would prove so wet. However, so it has happened: therefore, let us see how the season has affected the various products of the earth, more especially those we are most interested in. At the same time let us call to mind what were our expectations at its commencement, how far these expectations have been fulfilled, and what more we might have done had we known how it would turn out. Before we condemn ourselves, let us recall the disappointments of former years, and though we may regret not having risked more plants out of doors this year, the sad realities of 1860 are still fresh in our memory. The three hot summers preceding that year favoured the idea that our climate was approaching somewhat nearer that of the tropics; but the cold, wet, dull year which followed more resembled a prolonged autumn than a summer, and our farmers, whose grass and hay crops had threatened to fail, had recourse to a substitute, semi-tropical in its habits, which had done good service in the few places in which it was tried in 1858 and 1859, and was, consequently, rather extensively planted in 1860; but the Asiatic summer had a poor representative here, and the plant has been heard of very little since, otherwise I have no doubt that it would have done good service in other years. I fear it has been prematurely condemned from its failure at a time when success was impossible.

As already remarked, we must plod on in uncertainty as to the probable character of the seasons, and expect to meet with varied successes and reverses; but as the present one is not without interest, let us investigate in what way it has been favourable to the various crops which we wish to prosper.

In the first place, the past winter was shorter than usual; for, instead of dragging on through the month of April with frosts more or less severe, we scarcely ever had the ther-

monometer down to the freezing-point in the whole month, while, strange to say, it was three times at that point in May. The spring, therefore, might be regarded as a favourable, and certainly an early one; May being on the whole a growing month for most vegetation, excepting grass, which, as a hay crop, was lighter than for many years. The blossoming of fruit trees was, on the whole, favoured with fine weather, yet all did not alike benefit by it. Apples, though not deficient in bloom, are not by any means a generally good crop; but Pears and Plums are, in most cases, abundant. One grower only half a mile from where I write, calculates his crop of Plums at 1500 bushels, although the proportion grown by him of that fruit is comparatively small. Cherries have also been plentiful. The greatest falling off among small fruits was noticeable in the case of Black Currants and Strawberries; the latter being soon over in consequence of the hot dry weather we had at the time of ripening, but the early fruit was not amiss, and the crop was a fair average. The forcing weather hurried them on so fast that they might be said to have ripened before swelling.

Of the plants most generally cultivated in the garden, there are some whose origin most likely has been in a cool, or, perhaps, moist climate or situation, and these plants cannot withstand the parching heat of such a period as we had in June, consequently their progress is slow, or, perhaps, retrograde, and I am not certain but that the Strawberry requires a much cooler situation than those in which we are often obliged to plant it. Certainly it grows in the far north as well as near London. Celery, too, grows better when the long dewy nights of autumn set in. Such plants, it is scarcely necessary to remark, made little progress in June, except where moisture was supplied by artificial means. On the other hand, by far the greater proportion of vegetables make most growth in warm weather, more especially those imported from warmer countries than our own. Kidney Beans will flourish in the hottest and driest season, and the same may be said of Cucumbers, Onions, Shallots, some sweet Herbs, &c., and for which our hottest summers are never too warm. The crops, I believe, have this season been generally good, especially Onions. Lettuces have also been quite as good as usual, and Peas certainly better. On the other hand, Potatoes, which in June promised to be small, took a second growth in July, and in the early part of August exhibited unmistakable signs of disease in its worst form, and which threatens to be as bad as in any season we have yet had. The Brassica tribe has been about as usual. On the whole, in the outdoor department of the kitchen garden, the summer of 1865 may be pronounced favourable. Enemies to the well-doing of different kinds of produce, however, have not been wanting, and foremost amongst those now annoying us are earwigs, which prey on wall fruit to a most destructive extent, and red spider has also been abundant enough, both under glass and elsewhere, but wasps hitherto have not made their appearance in anything approaching the numbers that were expected in the early part of the season. The other plagues of the garden may be regarded as existing to about the average extent.

In the ornamental department the season has been the means of restoring some plants to favour that have been going out for some years. Verbenas have, in general, done well, and the same may be said of Petunias where they are grown. Calceolarias have also been pretty good, and there is a good prospect of their improving to the end of the season. On the other hand, Geraniums have become too gross to flower well, and the kinds that have done so were not the favourites last year; one of the greatest delinquents in this respect has been *Stella*, which, although good at the present time, was by no means so early in blooming as some other kinds. This qualification is, I believe, more due to the season than to the variety. Now that all kinds have attained so robust a growth, an abundance of bloom can hardly be looked for, unless we have very dry weather indeed for the remainder of the season. The silvery-edged class have done well, but I think the golden ones have sometimes been better; the Ivy-leaved varieties have presented us with scarcely any bloom, and the strong growers of the flesh-coloured and white kinds have been little better than a mass of foliage. The same may be said of *Tropæolums*, with the exception of *T. elegans*, which is by far the most dwarf in its foliage of any of the trailing class.

Among plants with remarkable foliage, *Perilla* is still pre-eminent for its general service in its particular colour. *Centaurea candidissima* has been pretty good, but I have been disappointed in a plant I expected much of, *Arctotis repens*. Though it is everything that can be desired in a dwarf plant in a young state, its leaves turn to a reddish brown when they become old, and, consequently, neutralise the silvery hue which it has in its early growth. I should like to know if this is the case elsewhere. *Gazania*, *Cineraria maritima*, *Variiegated Alyssum*, and others, may be pronounced to be about as usual. *Nierembergia gracilis* is better than in most seasons, and the same may be said of one or two *Mesembryanthemums*, while *Salvias*, *Ageratums*, *Chrysanthemums*, and other tall plants have become better and more robust than usual, and the same may be said of *Dahlias*, and several annuals. Perhaps one of the best of the latter as regards habit, is *Tagetes signata*.

The present season, I believe, presents us with as prominent an example as in any former one, of the partial way in which rain falls. In Kent we had a very dry June, the first three days and the last two in the month being the only ones on which rain fell, the rest being very dry and hot, parching the ground, and forcing forward all vegetation that could withstand it. Grass, however, even in the best pastures succumbed to the heat. Showers followed in July, giving us 3½ inches of rainfall in that month; the atmosphere, however, continuing warm things have grown rapidly, and rain falling still more abundantly in August, we begin to wish for dry weather to secure the ripening of fruits, &c., for up to the time at which I write (the 23rd) 5 inches of rain have fallen. Now, it appears that this abundant rainfall has not extended to London, and still less so to the north-western counties, where a dry season is complained of. I may, however, remark, that most of the rains we have had resembled thunder showers, although we have scarcely had any thunder; but as such showers only extend over a limited space, it is not unlikely that we may have had our full share. I have long been of opinion that "thunder weather," as it is commonly called, is most beneficial to vegetation, as well from the moisture that it affords to the earth and foliage, as from the properties which it imparts to the air; at the same time this benefit to vegetation in a direct sense is accompanied by another in what may be called a negative way, for myriads of the lower class of destructive insects fall a prey to the atmospheric influences they are unable to endure. On the other hand, I am not certain that this same condition of the atmosphere which imparts health and vigour to the higher class of vegetation, does not act in the same way on the lower grades, encouraging mildew, and the long train of evils which follow in its train; but I can hardly bring myself to attribute these evils to electricity, I would rather believe that they follow rain falling at a lower temperature than that of the air near the surface of the earth, or a period of continuous wet weather. It would be well if those interested in such matters would state their views.—J. Ronson.

WASPS.—Having seen in your Journal an inquiry as to wasps, I beg to say that we are much troubled with both wasps and hornets in the neighbourhood of Southampton, and, in spite of our protection against them, they are daily spoiling

much of our fruit; Apricots, Pears, and Plums, being their favourites. We have also an abundance of earwigs infesting both fruit and flowers.—A GARDENER.

### ON AND ABOUT THE SANDS AND ROCKS OF TENBY.—No. 3.

ALTHOUGH the bedding *Calceolaria* and *Verbena* are found to survive the winter in the open air at Penally, yet neither here nor at Stackpole Court are they exposed to the risk. Plants of those species accidentally left in the borders are those which have endured the exposure. Yet the climate of Penally and adjacent parts of this peninsula, especially those having a southern aspect, is strikingly temperate. An unmistakable evidence of this is a standard unprotected shrub of *Escallonia macrantha* in Miss Robson's garden. It is fully 9 feet high and 8 feet in diameter. The *Lilium giganteum* attained there to the same height.

The wild plants, too, about Penally are such as are unknown to the eye and gladden the heart of those to whom only our more northern flora is previously known. Among Ferns there is *Osmunda regalis*; but, in more striking abundance, *Lastrea thelypteris*, the Marsh Fern. I had been accustomed to look upon this as a rarity, but it is scattered liberally over the marsh between Penally and the sea. Among flowering plants elsewhere less abundant, are *Thalictrum minus*, *Lychnis vespertina*, and *Rosa spinosissima*, and I must remark on this Burnet-leaved Rose, that in places upon Penally Burrows it covers as with a carpet the sandy soil. *Sherardia arvensis* and *Asparagus officinalis* grow nearer to the sea on Giltar Point, the nearest land to Cady Island, where *Lavatera arborea* is found, *Gentiana germanica*, and *G. amarella*.

One of Miss Robson's guests informed me, that two years since a member of his family had found growing wild near Tenby *Isolepis gracilis*. I thought this must be a mistake, and the more so because "*FILIX-FÆMINA*," informed me that this would not endure without protection even the winters of Torquay. A plant of the Tenby species was obligingly given me, raised from that originally found on the marshy ground between the sea and the ruins of Amroth Castle. It proved to be *Isolepis setacea*. But when cultivated, as this specimen was, the leaves are as long and would be as ornamental on the dinner-table as those of *I. gracilis*.

Immediately in front of the marshy district at Amroth, is that submerged forest which I mentioned in my first communication. Mr. Gosse learned from an old man, resident at Amroth, that "People call it Sea-turf; they cart it away for manure, and it all goes to earth; they put it on the Barley and Oats. 'Tis light stuff, but 'tis the brine in it that's the good. They get it at low water, springs and neaps alike. Anybody can tell its wood by the look—the grain." Mr. Gosse afterwards saw specimens of the wood, some soft and decayed, other blocks perforated by, and with the shells ensconced within of *Pholas candida*. Other pieces are quite solid, resisting the knife and the saw as firmly as fresh wood. These last, Mr. Gosse observes, are evidently Oak. The soft specimens appear to be Poplar; but, he was told, Elm, Willow, and Alder likewise occur. Trunks and roots are occasionally laid bare after storms, having marks of the axe still fresh upon them.—(*Gosse's Tenby*.)

It is difficult to be quite satisfied with what one has said about the place where and those from whom one has received pleasure and kindness, but if I have said little, it is not because I appreciate coldly, and, having thus endeavoured to be self-exculpated, let me pass on to Penally's neighbouring village, Gumbreston.

I have already mentioned that the Sapphire is still found by the Causeway Mill, near this highly picturesque place. Embosomed by trees, in a secluded dell, far from the cottages, and covered with Ivy, is its church; and I know of not one other in Great Britain where the world is less likely to intrude upon those who kneel within its walls. But there are three springs whose water bubble up in that dell, which ought to bring thither a throng of those who are travelling to win back health.

It is a fact, incredible as it may seem, that those three springs with barely a yard's breadth of earth between them, yield unceasingly streams of water each totally different from the others in its qualities. The highest, they are on a hillside, is pure water; the middle spring is strongly chalybeate, like that of Tunbridge Wells; and the lowest spring, like that of Harrogate, is impregnated with sulphuretted hydrogen. There is no shade

of error in this statement; for although the nature of the two mineral springs requires for detection no other test than the palate, yet it is stated, as the result of analysis by Dr. Golding Bird.

Now, Gurfreston is only two miles from Tenby, and I do not know of any other place in the world that thus offers its visitors sea-bathing, and either chalybeate or sulphuretted mineral waters. Were I a medical resident at Tenby, the United Kingdom from north to south, and from east to west, should be made fully cognizant of the fact.

Before I leave, lingeringly leave, that never-to-be-forgotten churchyard, I would record a remonstrance against its stone cross being entirely enveloped and hidden by Ivy. Let that "rare old plant" mantle the church walls and tower unhindered and unpruned, but let it not hide one inch of this early standard, for each is characterised by some peculiarity, precious at all events in the eyes of the antiquary.

On and away through high-banked shady lanes superlatively rich in vegetation, especially Ferns. Let me pause awhile over these, and first to observe on the absence of one from this neighbourhood. The climate and the rocks seem to be peculiarly suited to the *Adiantum capillus-Veneris*, yet it is nowhere found. Some one—but the authority is unknown—has stated that it is at Castle Martin, not far from the southern shore of Milford Haven; but a collector and vendor of Ferns at Tenby, told me that he had thoroughly but unsuccessfully searched Castle Martin for the Maiden-hair. More than one amateur collector bore similar testimony. This Fern may be excused for objecting to dwell in this neighbourhood, since twenty-one of its relatives have made it their abode. I saw them and collected specimens of nearly all. They are these—

<p><i>Asplenium adiantum-nigrum</i>.  <i>Filix-foemina</i>.  <i>lanceolatum</i>.  <i>marinum</i>.  <i>ruta-muraria</i>.  <i>trichomanes</i>.  <i>Elechnum boreale</i>.  <i>Ceterach officinarum</i>. (This I was told was to be found scattered scantily over the walls of Carew, Manorbier, and other old ruins, but no one mentioned the churchyard wall of Bosheton, where I found it in greater abundance than I ever saw elsewhere.)  <i>Lastrea cristata</i>.</p>	<p><i>Lastrea cristata var. uliginosa</i>.  <i>dilatata</i>.  <i>Filix-mas</i>.  <i>Feniseel</i>.  <i>oreopteris</i>.  <i>thelypteris</i>.  <i>Ophioglossum vulgatum</i>.  <i>Osmunda regalis</i>.  <i>Polypodium vulgare</i> and several varieties.  <i>Polystichum aculeatum</i>.  <i>angulare</i>.  <i>Scolopendrium vulgare</i> and several varieties, <i>furcattm</i> being the most frequent.</p>
---	---

—G.

PLANTS FOR ROOMS.

(Concluded from page 148.)

SEPTEMBER.—Gloxinias and Achimenes done blooming may be dried off in the late vinery, and those coming on should be removed to the stove without delay. All stove plants should be moved out of the vineries by the end of the month. Roses intended for forcing must be potted and plunged in a sheltered open situation. The early vinery will now be cleared of its fruit, and the laterals and all spray not absolutely necessary ought to be cut away; this will be beneficial alike to the Vines and the plants, which must be introduced at once, more particularly if dull wet weather set in. The glass to be cleaned, and all made sweet and clean. All greenhouse plants to be housed here, except such as can be accommodated in frames, which, however, will soon have to be cleared for bulbs and plants required for forcing. A little discrimination will be necessary in assigning the plants the most suitable position. Primulas and Cinerarias blooming, or far advanced for it, will do best on dry shelves near the glass, whilst Epacris and Correas, with other plants of similar habit, should be near the points where air is admitted. Camellias and Azaleas if not crowded will do in the centre. All dwarf plants, especially those growing, will do best on shelves. Young growing stock of Cinerarias and Calceolarias should be kept in frames some time longer, having protection ready against sharp frosts, which may come any time about the end of the month. Growing-Primulas will do much better on shelves after the middle of the month, as the atmosphere of frames always tends to cause damp at the collar. The pots of all plants housed to be washed and the drainage examined and put right if needed, the surface of the soil to be stirred and cleared of moss and fresh-surfaced if necessary. The Begonias for winter blooming will be doing well in the stove, and will need shifting into their blooming-pots. Chrysanthemums for early bloom to be placed under a wall or fence, where they can be protected if frosts set in

suddenly. *Cyclamen persicum* and its varieties to be potted and placed in a frame. Pelargoniums may remain in frames some time longer with abundance of air. Those cut-in last month to be shaken out, potted in smaller pots, and kept close in a frame for a few days, then give air freely. The most forward of those first headed back may now be stopped and allowed to break before moving into the early vinery; but their removal will depend on the weather. If there be a continuance of dull damp weather they will be better in the vinery, as such weather is apt to cause gross growths, and in extreme cases the leaves to spot or damp. The best place for Pelargoniums in vineries is shelves near the glass. Any plants done blooming and requiring the wood to be hardened or ripened, may be placed in the late vinery, from which all plants not requiring a dry atmosphere should be removed forthwith. It will do admirably for *Amaryllis*, *Epiphyllum*, and similar plants. The Grapes in it will be ready for use early in September. *Lacbenalias* to be potted and placed on a shelf in the early vinery; also, *Ixia flexuosa*, *conica*, *viridiflora*, &c.; *Sparaxis tricolor*; *Oxalis tricolor*, *fulgida*, *sanguinea*, and *rosacea grandiflora*, which last is one of the best for spring blooming. Pot *Ornithogalum thyrsoides* into six or eight-inch pots in sandy fibry loam with a little leaf mould, giving the protection of a pit or frame. Violets to be placed in their blooming-pots without disturbing the roots much, and set in a frame with plenty of air. Take up clumps of Crocuses and Snowdrops for potting and plunging in a sunny place under a wall; also *Scilla bifolia*. Pot *Mignonette*, and thin out, as it never does well when crowded; the pots may be placed on shelves in the early vinery towards the end of the month. Pot the first batch of Hyacinths, Narcissus, and Tulips as early in the month as possible, and plunge in coal ashes in a frame, the lights being left off day and night, except in very wet weather, when they are to be drawn on and tilted. The Tea-scented Roses for late bloom to be protected from heavy rains, place them in a frame towards the end of the month, and draw on the lights in wet weather, but still keeping these tilted. *Jasminum nudiflorum* will now be showing for bloom; early in the month some plants of it in pots should be placed by a south wall. Plants on stems from 18 inches to 3 feet high are the most handsome, and form, with standard *Laurustinus*, charming objects for table decoration. They should be placed in sheltered situations and housed before severe weather sets in. Pot *Tropaeolum tricolor*, *Jarratti*, and *brachyceras*, and place in the early vinery, training before the shoots become too long.

OCTOBER.—Correas Brilliant, *pieta superba*, *delicata*, *magnifica*, and others will be coming into bloom, as will also *Epacris Lady Panmure* and *Viscountess Hill*, the two very best for winter-blooming. *Erica scabriflora*, *Lambertiana rosea*, *melanthera*, *colorans*, *mutabilis*, and *hyemalis* will be coming into bloom. They may be grown fairly in vineries, but must have the lightest and ariest situation, and be kept as cool as possible; they should be removed to cold pits early in spring, so that they may not become drawn. I have noted these plants as suitable for rooms, but they must not remain long, a week or ten days being quite long enough. Other decorative plants at this season will consist of *Primulas*, *Solanum capsicastrum*, and *Lueulia gratissima*, which, if not in flower, soon will be, if placed in a cool part of the stove or late vinery; and tree Carnations will continue to bloom more or less all the winter. Camellias will also probably be in flower; if not, one or two of the most forward should be placed in the stove, also a plant or two of *Inga pulcherrima*. *Monochatum ensiferum* and *Chrysanthemums* will also come in from vineries, improved by *Cyclamen neapolitanum*; *C. europeum* being over, if you have the right sort, and it is the sweetest of them all. From the stove we may look for *Poinsettia pulcherrima*, *Torenia asiatica* and *pulcherrima*, *Ardisia crenulata* for its berries, *Gesnera zebrina*, *Gloxinias*, and *Eranthemum striatum*.

The stove will be fully occupied, and the plants now require all the room that can be given. Ease it, therefore, by placing the Caladiums under the shelves or stage, and let Achimenes, Gloxinias, and Gesneras be placed in the cool vinery after their beauty is gone. *Amaryllis*, also requiring to be kept dry in winter, may be treated in a similar manner. These away, more room may be given the plants growing on, and plants requiring heat may then be accommodated. Among others introduce a plant or two of some of the varieties of *Epiphyllum truncatum*; they will bloom in December, if not earlier. Early in the month pot the second batch of Hyacinths, Narcissus, Tulips, and Crocus; also Lilies of the Valley, potting in small pots those that have thick crowns. They may be

plunged out of doors in a dry situation, and covered with an inch or two of sawdust, tan, &c. Deutzias, Weigelas, Dielytras, Lilacs, and other deciduous plants for forcing, to be kept dry and in a sunny place. Now is the time to procure, for forcing, dwarf plants (and the fuller of buds for bloom the better), of Rhododendrons, Ghent Azaleas, Kalmias, Andromeda, Berberis Darwinii, Daphne cneorum, and Rhodora canadensis. All these require peat soil, and should be taken up with good balls, and placed in pots just sufficient to hold them well. They may be plunged in coal ashes in a warm situation, or if there is a frame at liberty place them in it, as also the forcing-bulbs named above, which are all the better of protection from wet and severe frost. We can go any time and draft one or two as we want them into the stove, which is now our forcing-house. Cyclamens coun, Atkinsi, and verum to be placed on shelves in the late vinery, about half the stock of the two former, and all of the last, for if it is the true kind it will bloom in November. C. persicum and its varieties to be housed forthwith and placed on the shelves of the late vinery, as well as the Cinerarias, Calceolarias, Pelargoniums, &c., from frames, where they must no longer remain. Primulas, for spring blooming, to have a position near the glass, and to be shifted into their blooming-pots. Chrysanthemums to be brought into this house at or by the middle of the month, if no protection can be given outside. I would here remark, that in this month, the stove being for winter-blooming plants, a brisk heat must be maintained, and atmospheric moisture should be kept up more abundantly than in an ordinary stove. The temperature should range from 70° to 75° by day, and from 55° to 60° by night. Early in the month plants of Adiantum cuneatum, A. vcapillus-Veneris, Asplenium marinum, Lomaria Patersoni, L. I. Herminieri, Goniophlebium loriceum, Asplenium Veitchianum, A. bifidum, A. monanthemum proliferum, Blechnum gracile, B. polypodioides, Doodia aspera, Lastrea glabella, Nephrolepis pectinata, N. davallioides, and N. exaltata, Polystichum angulare proliferum, Pteris argyrea (small plants), P. cretica albo-lineata, P. scaberula, P. serrulata, Adiantum curvatum, and A. macrophyllum, should have the drainage looked to, some of the old soil removed, and the brown fronds taken off, replacing the soil removed, or repotting, if necessary. In the moist growing-heat of the stove they will soon become fresh, and be lively all the winter, and very useful for table decoration. Some of the Lycopods are also useful, as Selaginella Lyalli, Wildenovi, formosa, its near relation stolonifera, Martensi, Lobbi, umbrosa, and denticulata, the most useful of them all. The third and last lot of Hyacinths to be potted in the last week.

NOVEMBER.—Cyclamens will be represented by late plants of neopolitanum, verum, and, it may be, forward plants of coun and Atkinsi, but this is not general. Chrysanthemums will now be coming into fine bloom. In the late vinery every bunch of Grapes must be cut with an inch or two of wood to it, and the end of this dipped in boiling sealingwax or pitch and tar. The bunches may then be hung up by this piece of wood in a cool dry room, where they should be looked over twice a-week, and every tainted berry taken out. The Grapes may thus be sometimes kept till New Year's-day or even later. If the berries are very close together make a loop, and draw it tightly round the footstalk after passing it over three or four berries at the lower end of the bunch, and thus suspend. This will cause the shoulders to fall, and the berries will not hang so closely. If the shoulders are large it would be well to take them off. The Grapes being thus disposed of, the early vinery may be eased of the Chrysanthemums, and the shelves of the remainder of the Cinerarias, Calceolarias, Pelargoniums, Fuchsias (young stock to be kept slowly growing all the winter for early bloom), Primulas, Cyclamen persicum and C. Atkinsi, and Violets. Tea-scented Roses will also do in a light airy part. Mignonette to be kept rather dry and near the glass. Pelargoniums for an early bloom to be put in their blooming-pots. Thysanacanthus rutilans will be in fine bloom in the stove, Euphorbia jaquiniaeflora now or soon, and some of the Begonias. I am told that B. Digswelliana is the best of all winter-flowering kinds of Begonias, continuing in bloom all the winter, and being remarkably free. Any of the variegated-leaved Begonias which it may be desired to retain in beauty through the winter must have a place in the stove; the kinds likely to bloom, in addition to their being attractive by their foliage, are Marshalli and grandis. B. splendida with velvety crimson leaves and large trusses of bloom is well worth a place, for its flowers contrast extremely well with the foliage. A few of the first-potted Hyacinths, &c., may be introduced into the stove, placing

them on a shelf in a cool part, and where they can have air pretty freely; a few more being introduced at intervals of a fortnight up to February. One or two Deutzias, Dielytras, Lilacs, Weigelas, Rhododendrons, Azaleas, and other plants may be introduced into a cool part of the stove in the same way as the Hyacinths, Tulips, &c. If the plants of Salvia splendens, fulgens, splendens Soucheti, and gesneriflora are not showing bloom, they may have a shift, and will make fine plants for spring-blooming. Varieties of Tropæolum Lobbianum trained to an upright stick, and liberally treated to light and air, will bloom all the winter in the vinery. Oxalis elegans will be in bloom, or soon will be, on a shelf in the stove. All plants for forcing should have the protection of pits or frames. Roses for forcing to be pruned.

DECEMBER.—Previous directions being attended to, there will be no lack of subjects available this month for decoration. These will consist of Gesneras zebrina and cinnabarina, Poinsettia pulcherrima, Euphorbia jaquiniaeflora, Eranthemum pulchellum and strictum, Epiphyllum truncatum; Apelandras cristata, Portæana, Leopoldi, &c.; Torenia asiatica and pulcherrima; Echea fulgens; a Camellia or two; Lilies of the Valley for Christmas, and a few Hyacinths, &c., for the new year, in addition to others before noted from the stove. The vineries will afford Chrysanthemums, Primulas, Mignonette, Camellias, Correas, Epacrisces, Ericas, Coronilla glauca, &c. Pelargoniums to be potted, also Cinerarias, Calceolarias, and Primulas for spring bloom. Chrysanthemums done blooming to be placed in a cold pit, thereby making room for the hardwooded plants and those liking cool treatment, which will have to be taken out of the early vinery towards the end of the month, the plants for forcing taking their place in the early vinery. Gloxinias, Achimenes, Gesneras, Erythrinas, &c., will be at rest; they will do kept dry in any place with a temperature not below 45°. A few plants of the tall Cacti, as they are called, now introduced into the stove will prove useful. Continue to introduce more plants for forcing, selecting the most promising, it being vain to introduce any not well set for bloom. Fuchsias may be kept over the winter in a shed or cellar from which frost is just excluded. It must be here observed that in the vineries the temperature from fire heat must not on any account exceed 40° for the mere sake of having plants in flower. It is now too late to do by artificial heat what is best done by sun heat at an earlier period.

I have now gone over the whole year. It may seem to "AN OLD SUBSCRIBER" that I have named more plants than can be accommodated in his or her houses. My object was to make the subject as useful to as many of the readers of this Journal as possible, and if a difficulty of the kind alluded to arise with "AN OLD SUBSCRIBER," he will, by growing a few of such plants as he may have convenience for, attain his object. I should be glad to learn any additions that can be made to the list of plants, with remarks as to the periods when they can be had in flower, and the means to be adopted for securing this result.—G. ABBEY.

#### THE RIPENING OF OUT-DOOR FIGS.

UNDER the above heading, you inserted, in page 129, immediately after a letter from myself, another from "A. T.," of Jersey. The two communications have a more intimate connection than at first appears. Our Jersey friend states that on the 29th of July he received a perfectly ripe basket of the most luscious Figs, and we know that these Figs appear in the London market some three or four weeks before we can produce anything like them. Now, most people on reading this statement will content themselves with saying, that Jersey being south of England, and, therefore, having a warmer summer, might be expected to produce earlier Figs; but the fact is, that Jersey has not a warmer summer than London, the average temperature of July being (according to Pettermann) 63.5° in the former place, and 63.6° in the latter. Besides this, it is to be remembered that the comparison is being made between a standard tree in Jersey, and a wall tree in England. Now, if the extra warmth of a wall is equal, as Loudon tells us, to about 7° of latitude, it is obvious that a wall near London, is, in climate, superior to an open garden in Jersey. So we must discard the popular hypothesis, and seek for some other cause than a warm summer for the early ripening of Jersey Figs.

Now, I believe that my letter above referred to furnishes the clue to the satisfactory solution of the difficulty. The January temperature of Jersey is 41.6°, of London 36.2°; therefore,

autumnal Figs grown so large as to be cut off by the London frosts, survive the Jersey winter. What wonder, then, if fruit which starts in the spring with the advantage of four or five weeks' growth during the preceding year, should ripen earlier than those embryos which have had to make almost all their growth during the current year? Besides this, from the severity of London spring frosts, it is necessary to keep the trees matted up till late; while in Jersey, the standard trees, open to every ray of spring sunshine, awake earlier from their winter's sleep, and thus gain still more on their northern brethren.—G. S.

#### MR. STANDISH'S GLADIOLUSES.

HAVING just had an opportunity of visiting Mr. Standish's nursery at Ascot, and seeing some of his Gladioluses in bloom, for many had not yet shown flower, a few notes on them may not be unacceptable to some of the readers of THE JOURNAL OF HORTICULTURE who are lovers of this beautiful autumnal flower, which deserves more encouragement than it has yet received on this side of the Channel. In Ireland it is different; and Mr. Standish was just sending off his fine collection to compete for the ten-guinea cup which is offered by the Royal Horticultural Society at their autumn show to be held to-day (Aug. 24th), and which the Council had asked me to attend as Judge—an invitation I was obliged to decline owing to engagements at home.

My (what Mr. Standish calls) severe taste in these matters, leads me to regard with favour only those flowers which fulfil my ideas of goodness. They ought to be well-shaped, and not flimsy in petal, and showing the spike all on one face; not winged flowers, with so much of the oppositiflorus blood in them. Hence in my list No. 1 I have taken what our neighbours call the *crème de la crème*. Many in No. 2 are exceedingly beautiful and would satisfy the vast majority of people, although they may not come quite up to my standard.

##### LIST No. 1.

*J. W. Lane*.—A noble flower; bright vermilion, with a large yellow star in centre, and deep lake eye.

*Eleanor Norman*.—A lovely flower, of fine shape and habit; beautiful clear white, most delicately striped with purple. One of the best.

*Castor*.—Fine rose; with carmine stripes and pencilling. Very effective.

*Dr. Hogg*.—A brilliant, rich, scarlet crimson, with violet tint in the throat.

*Mrs. Dombrain*.—A remarkably beautiful flower; pale rose, largely striped, and washed with deep lavender. Very striking.

*Miss Howell*.—Light rose, pencilled with carmine; white midribs and yellow throat. Very fine.

*Susan Ingram*.—Buff, changing to white; purple feathers and throat. Fine.

*Scottish Chief*.—Fine peach, striped and spotted with carmine; purple feathers on damask. Very beautiful.

*Beauty of Bagshot*.—Fine creamy rose, with deep velvety markings.

##### LIST No. 2.

*Aurilian*.—Scarlet.

*Caroline*.—French white, with purple.

*Mr. Rucker*.—Fine red; purple feathers, and white markings.

*Mrs. E. Nott*.—Buffish yellow; long spike. Flowers too far apart.

*Juliet*.—Very fine white.

*Basil*.—Fine pencilled carmine. Flowers somewhat loose.

*Norma*.—Very pretty; white, striped rose; rosy carmine feathers.

*John Lecch*.—Salmon rose, striped with deeper rose; bronze tongue.

*Mrs. Hagg*.—Fine lavender-coloured flower. Very large.

*General Lee*.—Bright crimson scarlet, pencilled on the edge with deep lake.

*Sultana*.—Pale rose; yellow throat. A pretty flower.

*Excelsior*.—Bright salmon, buff-striped.

*Joseph Meston*.—Fine scarlet, with purplish-violet throat. Excellent.

*Samuel Weymouth*.—A most brilliant colour—scarlet, with yellow throat.

*The Ensign*.—A remarkably fine and brilliant flower, fiery red, with light crimson feathers.

*Carminata*.—Light carmine; very large and brilliant flower.

*Lord Clyde*.—Cerise; yellow throat; rich plum feathers, with yellow markings.

*Kathleen*.—White, striped and tinged with violet. Beautiful flower.

*Mrs. Standish*.—Clear white, with deep velvety feathers, very similar to Mrs. Dix.

*Lord Shaftesbury*.—Very showy flower, light rose or peach, striped with pink; pink feathers.

*Lucy Neal*.—Fine rosy crimson flower, with white stripes. Very distinct.

*Garibaldi*.—Very bright crimson; violet throat. Fine.

*Brian Boru*.—Large showy flower.

I hope to have the opportunity of adding to these lists before the season is over, and also of giving notes of some of the best foreign flowers, amongst which are some really splendid varieties, M. Souchet still maintaining the foremost position in France as Mr. Standish has done here.—D., Deal.

#### BLACK HAMBURGH GRAPES NOT COLOURING.

My Hamburgh Grapes planted inside my vinery seem to have forgotten that they ought to ripen this year. I started them on the 1st of March, and judging by neighbouring vineries, they ought to have been ripe in July, yet not a bunch is free from greenish berries (inside the bunch), and I have left so many bunches on, that I do not expect them to turn black. My house is seldom under 75°, and the temperature often mounts up to 85°, or even 90° with sun. The border is damp enough, if I may judge by the leaves and young spray, and the laterals are ripening their wood quickly, so that I have no idea why the bunches seem to have made no progress in ripening for a month past, and if you can tell me I shall be much obliged. I may mention that alternate plants of Lady Downe's last year as well as this (my plants are only three years planted) have been, and are, as finely coloured as possible, yet they have and had a heavier crop of Grapes than I left on the Hamburgs.—J. MacKENZIE, M.D.

[The heavy crop certainly had some influence in preventing the colouring, but the chief cause is the great heat—not under 75°. The sun beat will not hurt them, but Hamburgs will ripen and colour better if you do not have them above 60° at night, even 55° would be better than 75° at night.]

#### KITCHEN GARDENING.

##### MAY AND JUNE.

As these remarks on kitchen gardening are chiefly directed to cropping and keeping up a constant supply of vegetables, I think I may take May and June together; for in both months the work to be done is almost identical. The first crops will now be in a fair way to yield their produce.

As early in the month as the young plants of winter stuff are large enough to handle, I prick them out into beds to become strong for putting out between the rows of Peas or Beans. The spring Spinach being now fit to pick, the old bed of winter Spinach, which by this time will be running to seed, should be cleared, and the ground having been well manured, dwarf Beans are sown in rows at 5 feet apart, thus leaving room between the rows for Celery trenches, or whatever may be most in demand. The remains of the winter crops may now be cleared off, and the ground heavily manured, as it will have to carry two crops during the greater part of the summer.

I generally sow my Scarlet Runners in two successions, on the ground intended for winter stuff. I sow three rows at the end of April, or beginning of May, 5 feet from row to row, these will be staked, and in bearing in July and August; the winter stuff being planted some time in July. These three rows must be pulled up towards the middle or end of August to give the winter stuff the chance of establishing itself, though it will seem almost a sacrifice to pull up the Beans when in their prime; but they can be spared, as I sow three rows in the end of May, and they will take their place. The last-mentioned three rows I generally allow to stand over the winter, as the winter stuff between them being later, and, in consequence, not so hardy, will require the protection which the Bean-sticks with the dead haulm will afford; thus placing utility before ornament in this case at least.

As regards the Asparagus, which will be, so to speak, the most important vegetable in May, on no account cut any after the Peas are in, which will be in the end of May or beginning of June. The plan which I usually adopt, is to salt the beds and alleys as soon as the grass has grown about 1 foot high,

and Lettuces or other crops are cleared off, giving a coat half an inch thick, and washing it in with a good watering of liquid manure, not forgetting to give the Sea-kale a dose at the same time. This, independently of the good it does the plant, will act as a preventive against weeds for the greater part of the summer.

The Cauliflower will now need but little attention besides cutting and watering—in fact, the supply of vegetables at this time of year is almost unlimited, including Potatoes, Peas, Broad Beans, &c. All the seed-beds, such as those of Carrots, Beet, Parsnips, &c., should now be hoed, and thinned out according to the size required. The first lot of Cabbages may be cleared off, and the ground prepared for some other crop, as I think they are best off the ground directly they are not wanted, whether they are all used or not; but still I generally leave two or three rows of the second lot to make sure of a dish, if such should be required. The Turnip Radishes which were sown between the rows of Kidney Beans, should be cleared off, giving the latter a good soaking of liquid manure, and afterwards earthing them up. The early Peas, too, should be cleared off, giving the crop previously planted between the rows a chance; but if nothing has been so planted, put out at once some good strong plants of Savoys or Coleworts for early autumn use. The Peas which will be in bearing towards the end of June should be well watered and mulched, as without so doing it is almost an impossibility to grow a good dish of Peas, especially in such dry summers as those of the last two or three years. I find Yorkshire Hero do the best with that treatment.

The Potatoes will require flat-hoeing and earthing-up, but in a limited space of ground there will not be more than is required to last till autumn. I plant a few rows of Knight's Prolific, and Ashleaf, on the south border, and the others I plant between the Cabbages or Peas—in fact, wherever there is room to grow a few. Some that I had planted between the tall-growing Peas have turned out first-rate, and I think the Potatoes have acted as a natural mulching to the roots of the Peas, which are now (August) yielding capitably. Either towards the end of May or beginning of June, I sow my last lot of Peas, Knight's Dwarf Green Marrows, having previously sown the Champion, and others for successions to the second early, according to the demand. I find it a very good plan to note when the different crops are sown, and when they are gathered, and whether they worked in after other crops as they were intended, and by keeping a sort of diary of the cropping, year after year, I know the varieties to choose for this particular locality. This is a plan I would recommend to any of my readers to adopt, as the varieties that would insure a succession in one locality, would be almost useless in another: hence the utter impossibility of naming varieties and times of sowing to suit all parties. In the beginning of May a sowing of Cream-coloured dwarf Kidney Beans should be made—say two rows among and between the rows of spring Spinach, and a sowing of Dwarf Negro as soon as the first lot of Cabbages can be cleared off the ground. Salading will require attending to as to sowing, pricking-out, blanching, &c.—BURNWOOD, P. D.

(To be continued.)

### LILIUM AURATUM BULBIFEROUS—SEEDS FROM A WHISK BROOM.

I HAVE nowhere seen the *Lilium auratum* noticed as being bulbiferous. I have just removed five strong young bulbs from the axils of the lower leaves in my specimen. Another remains, not yet ripe enough to detach. The parent bulb flowered, for the first time, this month, having two main stems with a single terminal bloom on each. The buds before opening measured rather more than 7½ inches in length, making the fully-expanded flowers from tip to tip of opposite petals more than 15 inches across.

I enclose a leaf of a graminaceous plant raised by a neighbour from the seeds taken from a carpet broom. The plant is of fine appearance, between 4 and 5 feet in height, with leaves a yard long by 2½ inches in breadth, each having a prominent white midrib. For those who desire to mingle, at small expense, stately grassy foliage with their greenhouse specimens, this plant will be a desideratum. All that they require will be a moderate hotbed to raise the seedlings, and a few of the seeds obtained from amongst the fibres of a common carpet broom.—M. D.

[The leaf and panicle enclosed by our correspondent are from a plant of *Sorghum vulgare*, or Indian Millet. It is culti-

vated in Italy, and Ray mentions that brooms and brushes of it (known to us as "Whisks"), were in use in Italy, Venice, and elsewhere.]

### ROYAL HORTICULTURAL SOCIETY.

FLORAL COMMITTEE, August 22nd.—Another very excellent and extensive collection of plants and flowers was exhibited this day. Among Mr. Veitch's beautiful Orchids were conspicuous several plants of *Odontoglossum grande* in full perfection and very attractive. Seedling Dahlias and Scarlet Pelargoniums were the principal subjects for examination.

Mr. Bull exhibited a double Fuchsia with scarlet sepals and dark corolla, very free-flowering, and good, close habit. A label of commendation was awarded to this as being a decorative plant. Others consisted of *Xanthosoma violacea*; *Amorphophallus grandis*, in flower, a curious botanical specimen; and *Tapiocetes Caroline*, a very singular-looking plant, with pure white flowers resembling the Gesneras, the foliage a dark bronzy green, very glossy, and covered with hairs. This was awarded a second-class certificate.

Mr. Veitch sent a fine collection of Orchids, which contained groups of cool-house and stove Orchids; a special certificate was awarded to each section. Mr. Veitch also sent *Cattleya hybrida picta*, a seedling between *intermedia violacea* and *guttata*; this had remarkably handsome flowers, dark rose, spotted all over with a deeper shade. It was awarded a first-class certificate. Messrs. E. G. Henderson, Wellington Road, sent Fuchsia Rhoderick Dhu, much-reflexed scarlet sepals and pale slate-coloured corolla, too much expanded to be elegant; *Croton elegantissimus*; *Agalmyla staminea*, a well-grown plant with a splendid wreath of scarlet flowers, broad ovate foliage, very handsome, which was awarded a special certificate for its good cultivation; *Amorphophallus zebrinus* (?), said to be *Alcacia triloba*, with beautifully variegated stems; *Sauromatum asperum*, and *Medimilla farinosa*. Mr. Wills, Oulton Park, exhibited seedling Verbena Scarlet Cushion, very dwarf habit and free-flowering. It received a first-class certificate as a useful bedding variety. Cut flowers of three other seedlings of dwarf habit came from the same exhibitor, among them General Lee, which was much admired for its trusses of rosy purple flowers; seedling *Zonale Pelargoniums Gaiety*, yellowish green leaves with bronzy zone; and *Countess of Lincoln*, coarse foliage; as had also the other seedlings, *Neatness*, *Circlet*, and *Bridesmaid*. Mr. Salter, of Sydenham, sent *Zonale Pelargoniums Vermilion King* and *Sydenham Rose*; cut flowers of seedling Verbena Blue De fiance, a promising flower, requested to be seen again; and two seedling *Lobelias* of the *speciosa* kind.

Mr. Legge, Edmonton, exhibited three dwarf Dahlias in pots, and three seedling Dahlias—viz., Mr. Braham, Pride of the World, dark golden tipped with red—second-class certificate; and *Lilac Perfection*. Messrs. Smith, Dulwich, had *Zonale Pelargoniums Rev. H. Dombain*; *Crystal Palace Gem*, with rather pretty foliage, pale yellow mottled with green; *Premier*, *Bronze King*, *Gannet*, *Siren*, *Orange Belle*, *Glow*, many of them good varieties, but not first-rate, or differing from many others. Mr. Barker, Godalming, contributed *Asplenium erectum proliferum*, from the Island of Ascension, a very dwarf distinct Peru, first-class certificate; *Pteris flabellata ascensionis*, a fine Fern, first-class certificate; also a box of cut *Petunias*, with many good varieties among the single flowers, but not better than innumerable seedlings raised every season. Mr. G. Rawlings, Romford, exhibited seedling Dahlias Queen of the Dwarfs, and Firefly; and Mr. Turner, Slough, sent a collection of cut Dahlias, in very good condition. Mr. Walker, Chester, had *Pelargoniums Brookfield Pink*, a sport from *Trentham Rose*, a worthless variety. Mr. Pope sent seedling Dahlias Walter Newman, deep amber; Fanny Start, a fancy, white ground, heavily tipped with crimson; only one flower was exhibited. It was pronounced the best fancy Dahlia in existence, of perfect form. Mr. Kelway, Langport, exhibited several seedling Gladioli, among them one or two good varieties; the flowers were fading, and not in a condition for examination. Dr. Ainsworth, M.D., Manchester, contributed a small spike of *Dendrobium MacCarthiae*, very handsome—first-class certificate; Mr. Church, Brockwell, Dahlia Fire Meteor; Mr. Hopkins, Brentford, Dahlia Lord Enfield, deep maroon, Challenger, deep ruby, and Diana; Mr. Burgess, Dahlias Sir Eardley Wilmot, Lady Derby, and Mr. Lund, second-class certificate. From Mr. Keynes, Salisbury, came Frank Tiffin, second-class certificate; Lottie Atkins, first-class certificate; John Downie, second-class certificate; John Bunn, second-class certificate, Gladiator, Annie Austin, Ultimatum, and George White. Mr. Eckford, Cotes-hill, exhibited six seedling Verbenas—viz., Lady Jane Ellice, a very delicate flower, white ground, with a rosy circle round the centre—first-class certificate; Miss Annie Bouverie, John Keynes, William Dodds, Mr. Stevenson, John Stainer. Lastly, Mr. Butler, Clapham, sent two worthless double seedling Fuchsias.

FRUIT COMMITTEE.—Mr. George F. Wilson, F.R.S., in the chair. At this meeting prizes were offered for the best dish of Peaches grown in an orchard-house, which was obtained by Mr. Cox, of Rodleaf, with Early Grosse Mignonne; and also for the best dish of Plums, which was gained by the same gentleman with Green Gage, Jefferson, and Diaprice Rouge. Messrs. Lee, of Hammersmith, sent a dish of Gordon Castle Plum, a large obovate greenish yellow Plum which promises to be of considerable merit, but as it was not quite ripe Messrs. Lee intend exhibiting other examples at the next meeting. There were several

specimens of seedling Melons exhibited, none of which, however, possessed merit sufficient to entitle them to any award by the Committee; they came from Mr. Charles Hubbard, Woodcote Lodge, Carshalton; Messrs. Kelway & Son, Langport; Mr. John Willis, Oulton Park, and from Mr. Muir, Chilton Lodge, Hangerford. There was also another Melon from the Society's Garden, called Sirdur, which was also very deficient of flavour.

A Pine Apple was sent from the Garden of the Society which had been ripened out of doors on the geothermal-bed, which is now in such beauty at Chiswick. It was of the Queen variety, and was perfectly ripe and so well flavoured that it was remarked that fruit had often been eaten from under glass much inferior to that which was then exhibited. Mr. Richard Smith, Calderstone, near Liverpool, sent a fine specimen of Pine to be named, and which proved to be *Antigua Queen*. Mr. R. Laing, Twickenham, sent a very showy variety of seedling Crab about the size of a Golden Pippin but entirely bright red. It is a very ornamental sort, and in pleasure grounds cannot fail to form a striking feature. Messrs. Osborn & Sons, of Fulham, sent fine specimens of *Jambosa aqua* in fruit, which were much admired. Mr. Hale, of Harefield, sent a dish of a seedling Currant, which was so like Raby Castle as not to be distinguishable from that variety.

ANNIVERSARY OF THE LATE PRINCE CONSORT'S BIRTHDAY.—On Saturday last, the 26th inst., the gardens were thrown open to the public in accordance with Her Majesty's desire, and upwards of 129,000 visitors availed themselves of the privilege. They were a highly respectable and well conducted class of people, and the sum total of the damage done amounted to the turf being worn in places; but two or three days of this moist weather will put that right.

#### ROSE MILDEW AND GISHURST COMPOUND.

AFTER reading Mr. Rudelyffe's interesting letter on Rose mildew at page 123, No. 229, I could not help very much wishing that he would try Gishurst compound; it has the double action of washing as a soap, and of applying sulphur in its soluble and therefore most active form, and I believe in his experienced hands would prove a more certain remedy than others which he has used.

About a fortnight back an experienced Australian horticulturist gave me an account of the use of Gishurst in the neighbourhood of Melbourne, where blights appear to live and breed all the year through, and he wound up with the fact, which to my mind said great things, that the cultivators around proposed presenting him with a testimonial for having introduced Gishurst.—G. W.

#### MANAGING A HOLLY HEDGE—GARDENING IN NEW ZEALAND.

Will you oblige a New Zealand subscriber to your useful Journal, with an account of how a Holly hedge is to be managed, from the sowing of the berries until it has attained the full size of a hedge? The soil here is a light vegetable mould, from 10 to 15 inches deep; the subsoil a peculiar yellow earth, sufficiently tenacious to allow of wells being sunk 100 feet or more in depth, without boarding or bricking-up, but which becomes quite friable and light immediately upon exposure to the atmosphere, and without a stone to be met with. Our climate is a very equable one; during upwards of twenty years' experience I have never known frost remain on the ground after 9 A.M., unless in a shaded place where the sun's rays cannot get at it, and the heat in the summer is not so great as in England, although the season lasts longer, as we generally have fine warm weather until the end of May, corresponding to your November. Many of what are greenhouse plants with you remain in the open garden with us all the year round, and this summer I have had a plant of *Colletia bictonensis* in the open borders covered with its small white Heath-like blossoms. I mention this because I saw a notice in your Journal that this plant does not blossom in England.

We find great difficulty in finding a suitable plant for live fences. The White Thorn does not thrive excepting in sheltered situations in the bush; probably it does not thrive on the sea coast. The Furze grows very rapidly, but it is apt to be attacked with a fungus which kills it, and it is, besides, very troublesome from scattering its seed and encroaching on the land. I have a plant of Osage Orange, which for three or four years scarcely grew at all, but since I have removed it to a situation where a great deal of water drains on to its roots, it has made great growth, and this season has thrown out seven or eight shoots upwards of 6 feet long. This plant was at one time much talked of as a fencing plant, and many pounds of

seed have been sown here; but, I believe, not above fifty seeds vegetated out of the whole. Do you find this plant grow well in England? If you can suggest any fencing plant that you think would suit our soil and climate, I shall feel much obliged by your mentioning it in your Journal. The Holly hedge I wish to raise is for a garden, but this plant would be too expensive and too long in forming a fence to be available for agricultural purposes.

There appears to be a peculiarity in our soil or climate which does not suit some descriptions of fruit trees. Peaches fruit so abundantly with us in the open ground as standards, that I believe the fruit would be the cheapest food that could be grown for feeding pigs. Some are of excellent quality. They receive no cultivation: the trees are planted, and with very little attention to pruning, they bear such heavy crops in sheltered situations as to require to have the branches staked up to prevent their breaking down. Apples do moderately well, but are subject to the American blight, which spreads much more rapidly than in England. The common Cherry, like an inferior Kentish in appearance, fruits tolerably well; but the good cultivated sorts do not bear at all well—it is difficult, indeed, to make them fruit at all. The same remark applies to Plums, Pears, and Apricots. Pears bear tolerably well after the trees are from fifteen to twenty years old, but fruit is rarely produced until they are from twelve to fourteen years old. Plums and Apricots so seldom fruit that their cultivation is almost abandoned. Gooseberries do very well and yield heavy crops; but Currants of all sorts scarcely fruit at all. That the soil has all to do with it, I believe, evident, as in the neighbouring province of Nelson all trees fruit abundantly. There the soil is very stony, and what we should consider a hungry one, and the trees make very moderate growth. With us, on the contrary, the soil is very good and the trees make a great deal of wood, but bear no fruit. I have lately begun to remove my trees on Mr. Rivers's plan, hoping to check the growth of wood and throw them into bearing; but there is not sufficient time yet to test whether this plan will answer. If you could give any suggestions in your Journal to obviate our difficulties in this particular, you will much oblige myself and my fellow colonists. The removal plan may do in a small garden, but would not be applicable to fruit-growing on a large scale in a country where labour is scarce, and an ordinary farming-man's wages 6s. a-day.—A SUBSCRIBER, *New Plymouth, New Zealand*.

[We are very much obliged by the interesting information which your letter affords. We are always pleased to receive such communications. We trust that some of our more experienced readers will be able to enter more into the subject than we can do; but we will, at least, show our willingness to oblige if we can.]

From your description of the rich surface vegetable mould, we have little doubt but that the Holly would thrive well as a fence, more especially if some 12 inches of the yellow soil were trenched-up and incorporated partly with surface soil, say 2 or 3 inches mixed with the rich soil, and the rest kept mostly at the bottom. No plant makes a better hedge than the Holly, and after it is established it needs but little care, as the annual growth is so short and stubby. As to the management: As the seeds are a long time in vegetating, it is best to treat them much like those of the Hawthorn. Mix them with earth or sand in a heap, and turn them now and then until all the fleshy covering is rotted, which will take a good part of a season, then the seeds may be separated from the earth by sifting, and sown in nicely pulverised beds, and covered with half an inch of fine soil. If the weather should be very hot, after sowing it would be advisable to cover the beds with fern or other litter to keep the seeds moist and cool. Your heat will be the worst enemy to the young Hollies. We advise thus sowing in beds, as the seeds will be the more easily protected from birds, &c. If the seeds are imported, it would be best to wash them free of pulp, dry them well, and sow at once. In the second year after thus sowing, the young plants may either be transplanted for another year into rows 1 foot apart, or into the hedgerow at once, placing them about 1 foot apart. Before doing so we would bring some of the surrounding rich soil, slightly mixed with the under soil so as to give a depth of at least 2 feet, if more all the better. Thus treated, we believe the Holly will grow with great vigour. Little attention will be required except stopping the plants that grow more strongly than their neighbours, and any very strong shoot that threatens to rob or take the strength from the lowest tier of branches. These should be encouraged so as to stand out from 18 to 24 inches from the stem. The wedge-shape will thus be secured,

which will give the most impenetrable fence and with the least amount of trouble in the way of cutting and training. From 3½ to 4 feet across at the base, would do for a hedge from 5 to 6 feet in height, and some 12 or 15 inches wide at top. The hedge may be perpendicular on each side, and as wide at top as bottom if deemed advisable, as the plant may be trained to any shape. If cut or pruned often, the outside becomes impenetrable even to birds.

The Osage Orange (*Maclura aurantiaca*), we have no doubt would thrive with you, and it is easily propagated by layers, and by cutting the roots into pieces and planting them. We have never seen a good hedge of it. One circumstance might account for this. Like some other plants, it is apt to keep up a lingering existence if the first shoots are retained on the plant; but if after the first or second season's growth these shoots are cut down to a bud or two, strong shoots will be thrown out the next season, and these, if stopped when from 5 to 6 feet long, might form a dense fence. We should imagine your climate would be more suitable for it than either England or North America. Here it will not compete with the White Thorn in general, though, if we had nothing else, it might be coaxed into a good hedge fence.

For an evergreen fence, few plants would beat the Portugal Laurel, which hardly any amount of cold in England or Scotland will harm. Your summers would just be warm enough for it; but it has always a good appearance, and stands cutting well.

The common Laurel (*Cerasus laurocerasus*), would greatly exceed the Portugal in growth, and in your climate would mount up with great rapidity. The difficulty would be the annual cutting, to keep it in bounds as a fence, but the cutting would give a great amount of firewood. Multitudes of plants could be easily obtained, first by seeds, second by layers, but more quickly by cuttings. As soon as the summer's growth is over, take off the young shoots, with a little bit of the previous growth; shorten the cuttings to some 7 or 8 inches, and plant the half in the soil firmly, placing them in rows a few inches apart, if in a shady place all the better. By the following spring most of them will be rooted, and many fit to transplant in the autumn.

Near the sea coast, where no other fence would live, the Sea Buckthorn (*Hippophae rhamnoides*), will thrive, and even in poor soil. It is propagated by seeds, and also by suckers from the roots, which it throws out in great abundance.

The common Buckthorn (*Rhamnus catharticus*), grows freely in many places where the White Thorn will not flourish, and from its dense compact habit makes an excellent fence; it is best propagated by seeds, which come up shortly after being sown.

The common Sloe Thorn, or Black Thorn (*Prunus spinosa*), though delighting most in a chalky loam, will flourish in almost any soil, and will thrive in saltish soils, near the sea coast. It is easily increased by seed, gathered when ripe, mixed with sand and turned over several times for three months or so, and then sown; but when a few plants are obtained, it increases amazingly by suckers. One plant left to itself would soon monopolise all the surrounding ground. When used as fences, its spreading must be guarded against, but this property prevents the necessity of planting thickly at first to make a good fence.

In poor soils the Locust Tree (*Robinia pseudacacia*), has made good fences on the Continent and in America. The common Arbor Vite bears the knife and shears well when used as fences. The Spruce Fir and Scotch Fir do tolerably in exposed places. We have seen fair fences of the Willow, made by planting slips a foot apart, twisting the heads together when 6 or 7 feet high, and then interlacing the lower shoots. But for fences in fields, on a large scale, where the Hawthorn will not grow, few fences excel those of the Beech and Hornbeam. The Beech, when cut, becomes impenetrable, and the old leaves hang on until the new ones come. The Hornbeam also keeps the old leaves a long time, and in rich soil grows with great rapidity. A thick fence soon becomes quite impenetrable. Seeds require much the same care as Hollies or Thorns, and the ground should be well stirred and enriched before planting.

For field fencing we should think of the last two; but we throw out these remarks chiefly for the purpose of obtaining information from others, and especially from those who have themselves been in New Zealand. The local knowledge in these circumstances is generally the best. Hence it is that we have made no mention of Yew, Evergreen Oak, Privet (one

of the most quickly got-up fences with us, and which would be impenetrable if mixed with a little Black Thorn), Laurustinus, Junipers, &c., because we do not know how they might succeed there; or even of the Thorn Acacia, besides the Locust Tree. As so many thrive in Australia, any practical information on these matters we shall consider as a favour, not only to our correspondent, but to our readers generally.

The account given of the fruit trees is very interesting. With labour so scarce, the only course it strikes us as being desirable to follow, would be very shallow planting, and that, too, on hillocks, so as to lessen the vigour of growth, without the trouble of either lifting or root-pruning; and if the growth is less vigorous, there will be little occasion for top-pruning. If such means are taken to lessen growth, there will be no occasion, we hope, to wait ten or fifteen years for fruit.]

## GARDENING AND GARDENS IN DORSETSHIRE.

THE REV. W. F. RADCLYFFE'S, TARRANT RUSHTON,  
NEAR BLANDFORD.

(Continued from page 145.)

STRAWBERRIES.—Although too late to see the Roses at Rushton in the height of their first bloom, I was more fortunate in respect to Strawberries; they were in perfection, and a most agreeable sight they were, the beds of strong healthy plants being loaded with ripe fruit. At the same time accounts were coming in from all quarters complaining of failure or deficiency in crop; here there was no indication of deficiency. Witnessing in part the treatment of the Strawberry-beds at Rushton after the crop had been gathered, I think it would not be difficult to account for the shortcomings we have so frequently heard of this year. The drought of last year was doubtless the chief cause, to which may be added, in some instances, insufficient trenching and manuring of the ground before planting; and had Mr. Radclyffe allowed matters to go on in the usual way, his crop would, probably, have been little better than that of others. He says, "Establish good pumps in your garden;" and with his industrious and steady hands, Steve and Fred, of whose careful labours I was also a witness, the copious and constant watering of the beds during the dry time of last year secured a glorious crop for the present season.

It would be superfluous to repeat here the mode of treatment adopted at Rushton, so closely following the excellent Strawberry article that appeared in the Journal a few weeks since. It is sufficient to state that, to me, the principal features of the Strawberry-beds seemed to be—the strength and health of the plants; the abundance and size of the berries; and, when examined singly, their flavour, weight, and colour. I add the last, for there is much beauty in a well-grown Strawberry.

The following kinds may be certainly reckoned among the best—Rivers's Eliza, Eugénie, Wonderful, Scarlet Pine, Frogmore Late Pine, John Powell, Sir Joseph Paxton, and one not so frequently met with as it deserves, the Royal Hautbois. "It is difficult to make a suit of clothes to fit everybody;" and if the flavour of the Royal Hautbois may not be quite agreeable to the palates of some, there can be no doubt that others will have a different opinion of it, and myself among them.

PEACHES.—If the gardening world has heard frequently of Mr. Radclyffe's three old Peach trees, I can assure it that it has not heard too much. Never before had I looked on such a renovation of old material, and I will hazard the conjecture that no one else has. I am afraid to say how old the trees are, for my memory may be a little at fault; but that they are many years aged is certain, and evident from the stocks upon which they are worked. They occupy a space of about 50 feet of the west end of the south wall, 8 feet high, separated from the adjoining marsh only by the Thorn hedge before mentioned. The spring frosts are fearful antagonists of these fine old specimens, but with the aid of canvass covering judiciously managed, a crop is always secured. At the present time there are not less than 500 Peaches on the three trees, and so evenly distributed, that they have the appearance rather of being fastened on artificially, than growing naturally. There they are—upon the old stump wood, at the very bottom and close upon the old branches, as well as upon the newer wood about the extremities; and there also the hydraulic processes of Stephen are constantly called into action, to keep the beautiful foliage in health, and defend it from the attacks of the red spider and other pests.

RASPBERRIES.—This is a subject that may be considered by some as rather too common to be worth remarking upon. Everybody can grow them, and everybody does because of their

Usefulness. We find them occupying a space at the cottagers' shows, and very pleasing it is to find that our poorer neighbours know how to appreciate their value. There is a right way, however, of getting them in perfection, as well as an indifferent one in leaving them to themselves. At Rushton the Raspberry canes occupy the south-western corner of the garden, and bear, as all Raspberry canes should bear, in profusion, and berries of large size. The strength of the plants is maintained by efficient manuring, which is allowed to work in by the action of the weather. As little or no mulching is done between the rows, the ground was, of course, somewhat hard; but it effectually prevents suckers, which is one great cause of weakening the plants. The whole of the plantation was covered with netting to prevent the depredations of the feathered tribe, to which, by the way, Stephen is not so friendly as could be wished.

PEARS.—Surely Mr. Rivers must be prince among us to have devised so manageable a plan of growing one of the most grateful of fruits. If we have been in the habit of regarding a Pear tree, either as approaching the dimensions of timber, or, in the espalier form, stretching its long arms for many feet in either direction, our ideas may now be greatly modified in seeing the diminutive little trees, smaller than an ordinary Currant bush, and small enough to be put into a portable pot. No garden, however small, need now be without Pear trees, with the further advantage to the owner, that if he be a horticulturist his plants will cause an interest from their manageable form and size. It would be premature to state what has been done with Pears on the quince stock at Rushton, since Mr. Radcliffe has not yet reported upon them, and that a little longer time is still necessary to complete a fair trial. They were all of them (about fifty), in excellent condition, and many of them loaded with promising fruit. I have no doubt that in due time we shall have a proper account of them.

I cannot conclude these notes without expressing my deep sense of the kind feeling and hospitality shown to myself and other horticulturists to whom I had the pleasure of being introduced while in Dorsetshire.—ADOLPHUS H. KENT.

#### THE CALCUTTA BOTANIC GARDENS AND THE CYCLONE OF OCTOBER 5TH, 1864.

We have been favoured with a copy of the Supplement to the "Calcutta Gazette" of June 21st, in which we find an account so singularly and painfully interesting of the injury done to these celebrated gardens by the terrible cyclone of October 5th, that we do not hesitate to condense it for our own pages. A tropical botanic garden must of necessity be something very different from an English one. The stature and girth of the trees, the fine climate, the great multitude of species, must combine to give it an aspect of wonderful richness and splendour, and make it almost a terrestrial paradise, trying weather, and a thousand little difficulties with individual species, have no doubt to be encountered at times, just as in Europe; but the reward of toil and enterprise will be as much greater, one season with another, as an equatorial country is superior to a temperate one in respect to its adaptation to the growth of plants.

The Calcutta Botanic Garden was established towards the close of the last century, and has had the benefit from time to time of the superintendence of some of the most distinguished botanists residing in India. The number of species brought together was very considerable, comprising all the rare and splendid plants of the country, and large numbers from distant parts of the world, exhibiting a fair show of what tropical botany is, whether in the eastern hemisphere or the western. A large number of the timber trees in the garden were cut down by Mr. Griffiths about twenty years ago; the condition of the Garden, as appears from his report to Government in May, 1843, being that it was "choked with trees." Sufficient remained, however, to allow of the destruction of not less than a thousand in the terrible cyclone of the date above given.

The history and general character of the cyclone as it occurred in the city of Calcutta itself are well known to all readers of the public journals, having been fully narrated at the time. In the gardens this terrible visitation was far more severely felt, they being situated more in what was the centre of the storm—in the very vortex, so to speak, of this awful aerial whirlpool. It did not last long, but in the short space of its endurance there was done damage incredible to a European were it not described by a crowd of eye-witnesses. The

Garden suffered further from being near the river, across which the gale blew diagonally, and thus struck the trees and plants with a force unbroken for the space of a mile by any obstacle whatever. The damage appears to have been done between 11 A.M. and 1.30 P.M. The five hours and a half saw ships forced by the water on to the actual surface of the Garden; a large portion of the soil was submerged to a depth of 5 or 6 feet; and green trees were stripped not merely of their foliage but of their branches, so that what an hour previously were stately masses of verdure became bare poles, like those used to support scaffolding by builders. The most curious fact in the history of the destruction appears to be that the endogenous class of plants, speaking generally, suffered least, or at all events much less than the exogenous. So extensive was the destruction of exogenous vegetation, that the morning after the storm the country seemed to be inhabited almost exclusively by Palms and Bamboos. Not that the Palms were uniformly exempt from ruin; two species suffered severely—namely, the *Arca catechu* and the *Arenga saccharifera*. The Cycads also very generally escaped. Why the exogenous trees should have been victims to so great an extent while the endogenous were mostly spared does not appear; nor without experience of observations made on the spot, or at least in India, is it easy to speculate on the cause. Another very curious circumstance attendant on the devastation was the death of many trees through the mere force of the wind, or through the violent strain to which they were subjected during the chief pressure. During the height of the storm this was calculated to be 120 lbs. on the square foot. It is wonderful how great a strain trees will bear if it be administered gradually. In the winter, when the snow falls gently but steadily for many hours together, it is not unusual to see small trees bowed completely to the ground by the deposit upon their twigs and branches, and when the thaw has commenced they gradually return to their position unharmed. Coming, however, all at once, it is like the blow of a cannon-ball, and the tree can no more bear it with impunity than a human being. A third very curious circumstance was the complete upset of the vital economy of certain trees and plants. Several kinds flowered or fruited for the first time shortly after the visit of the cyclone; others, that ordinarily are deciduous, became partially evergreen; while others, accustomed to flower profusely, scarcely produced a blossom at the time when they were wont to be loaded with bloom. Nothing proper to the idea of a garden was visible the morning after the storm. Not a leaf or a flower or a fruit remained, and the paths and tanks were blocked with fallen branches.

Of individual instances of destruction, one of the most terrible and lamentable was the overthrow of the great *Adansonia*, the trunk of which was 12 feet in diameter. Out of sixty-seven Mahogany trees no less than thirty-one were blown down. Only four trees remain of the *Casuarina* avenue, and these are much mutilated. Of twenty-five *Araucarias* not one has been left with the main stem entire. In-doors there were destroyed of the fine collection of *Orchidaceæ* at least one-half; while the plants in the thatched conservatory were almost without exception annihilated. The only plants that seem to have defied the storm were the numerous species of *Ficus*, and these by virtue of their powerful aerial roots, which enabled them to hold on as if by anchors. The great Banyan tree, though injured, was not damaged seriously.

Such was the state of things produced by the awful cyclone of October 5th. The picture is in no respect overcoloured; it is below rather than above the reality. What should we think if the sweet lawns, and shrubberies, and grand old trees of Kew were, in the course of a short forenoon, to be totally obliterated? Yet this is the mournful condition of the best portion of the Calcutta Garden, which half a century will hardly restore to the beauty and richness it possessed on the eve of that fatal tempest. The climate is in its favour, and all that skill and devotedness to the work can accomplish will no doubt be given to the process of restoration; the loss is, nevertheless, one of the greatest that has ever been sustained in connection with a garden.

#### MR. BULL'S VINERY, KING'S ROAD, CHELSEA.

PEOPLE who have not been abroad sometimes imagine what a beautiful sight a vineyard must be, and conjure up all sorts of poetic visions as to the "clustering Vine;" but in the great majority of cases this is a mockery, a delusion, and a

snare. The vineyards of France and Germany are as much like plantations of Currant bushes as possible, and, let it be said, about as pretty. In Italy, indeed, where the Vine is often festooned from tree to tree, it is different; but without going so far south, lovers of beautiful sights may enjoy one by going to Mr. Bull's establishment at Chelsea. His winter garden is now a perfect show. The Vines are trained all along the roof, climb up the pillars and supports, and are festooned in all directions, and the side divisions of the house show a double

tier of finely-coloured Grapes. The Vines are now loaded with a beautifully regular crop of Black Hamburg and other Grapes, the bunches as regularly disposed as possible, fine in colour, and of good size. Nothing can be more charming than the aspect of this fine house; in fact, nothing of the kind is to be seen near London equal to it, and any one having time will feel himself amply compensated for his trouble. He will, moreover, have the opportunity of seeing some other remarkable novelties.—D., Deal.

### GLAZING WITHOUT PUTTY.

In accordance with your wish, I now try to describe my simple method of glazing without putty.

The bars are made of a new pattern T-iron, with a raised back  $1\frac{1}{4}$  inch each way, and the bar (a), represented in the accompanying section, is bent at each  $18\frac{1}{2}$  inches by machinery. Two pins (b) are riveted through in each length,

and on these pins is an indiarubber washer (c) at each end. These washers are three-quarters of an inch in diameter, and one-quarter of an inch thick, and just touch the iron. The sheet of glass (d) is inserted from the front between the iron and washer, the latter rolling round by the friction of the glass. A brass hook (e) is put on before one of the washers.

a, sash-bar; b, iron pin; c, indiarubber washer, four to each square; d, glass; e, brass hook, one to each square; f, f, water gutter.

Brass hook.

Top view of one sheet of glass 19 inches by 12.

which holds it fast on, and when the sheet of glass is up in its place the hook drops over the edge, and holds the sheet fast until released by lifting the hook up again.

I can put in twenty squares per minute, or take that number out in the same time. The cost of these roofs varies from 6d.

to 7d. per superficial foot. The house you have a drawing of is 24 feet by 11 feet. The upper board in front can be removed at will for ventilation. With a boy to assist, I can take the house down in three hours, and pack it, and I can erect it in the same time.—SAMUEL JUCKES, *Shrewsbury*.

### ADDITIONAL NOTES ON CONIFERÆ.

I HOPE the remarks of Mr. Cramb, at page 152, on Conifere will be followed by the comments of others having like experience. I am sorry, however, to learn that little hopes are entertained of *Pinus insignis* succeeding in the west central counties, where in general most trees thrive as well as in the more favoured coast districts. This fine species grows here (Linton Park), quite as rapidly as the Scotch Fir, and, so far as appearances go, is quite as hardy, the severe winter of 1860-61 not having had the least effect upon it, and it has borne cones for some years. The only Conifer of any size that suffered with us that winter was allied to *Pinus excelsa*—I believe *P. Montezumæ* or some other Mexican, which had suffered in hard winters before, and did so last winter also. *Pinus excelsa* seems quite hardy, and is this season bearing cones, as well as *Thuja borealis*, and some other Conifers mentioned in a former article; but I rather regret than other-

wise hearing of *Wellingtonia* doing so, for, like Mr. Cramb, I think this will one day become the monarch of our forests. The best specimens we have are growing on moderately dry ground, but by no means shallow, and their progress is rapid; the tree seems to accommodate itself to even a dry stony soil and exposed situation, and grows luxuriantly enough.

I am far from certain what description of soil or situation suits the *Araucaria* best, for, with the exception of the one at Dropmore, the next best I know of is in Northumberland, where it is growing in a deep moist soil; and a short time ago I saw a very healthy young plant, about 10 feet high, that was growing about 6 feet from the edge of a large pond, its collar being not more than 8 or 10 inches above the level of the standing water, and nothing could exceed the healthy condition of the plant.

Next to the *Wellingtonia* as a new plant I should be inclined

to place Thuja Lobbi, a fast-growing graceful tree, not a shrub like the ordinary Arbor Vite, but a plant starting with the evident intention of becoming a tree. Cupressus Lawsoniana has not a more promising appearance, although it was put forth as one of the tallest of the Coniferae. As to Cupressus Lambertiana, the only drawback to its general adoption as a garden ornament is its liability to be blown down by high winds, otherwise its deep green hue exceeds even that of Pinus insignis. Of the more recently introduced Conifers Retinospora pisifera promises well, but Sciadopytis verticillata and Abies Kämpferi will take centuries (if they survive so long) to become even second-sized trees. Of the broad-leaved species of Picea, Nordmanniana is unquestionably the finest of the green class, while the silvery hue of nobilis is equally striking, and both are free-growing when they succeed well; we have the latter bearing cones, of the other we have not a good specimen. I believe, however, that most of the Piceas prefer a somewhat moist situation, certainly the Silver Fir, which may be taken as a type, does so; nevertheless the experience of others may teach us different; and I trust any one having a fine specimen of any of this popular family will kindly favour us with the conditions under which it has become so. I am sure all growers of Conifers must be grateful to Mr. Cramb for his useful article on the subject.—J. ROBSON.

#### MR. DE JONGHE'S SEEDLING STRAWBERRIES.

I HAVE not had *La Fertile* or *La Favourite*, but I have had the following seedlings of Mr. De Jonghe:—

*Ne Plus Ultra*.—A hurdy strong plant, all large fruit, a heavy cropper, medium flavour; a good family and market sort.

*La Reine*.—White and roscate, tolerably hardy plant, very high flavour; a very interesting sort. I should like to see a cross between it and *Bieton White Pine*. It would give the latter more flavour and firmness.

*Lucas*.—This is the best of Mr. De Jonghe's high-flavoured sorts, so far as I have proved them, for general cultivation. It is hardy and a quicker grower, and quicker runner than *La Constante*. The fruit is level, and high-flavoured.

*Bijou* is a very small hardy plant of the same formation as *La Constante*. Its berries are beautifully formed, and beautifully seeded. It is a slow grower and slow runner. Its flavour is very good. The formation of the berries of this and *La Constante*, both much alike, is the best in any Strawberries known to me. It is suited to bedding purposes.

I cannot agree with "A FRAGARIAN," that the Prince of Wales is superior to *Wonderful* and *Eclipse*. It is the best style of sturdy dwarf plant, useful and good. I got rid of it because it exposed its beautiful white trusses to the severe hoar frosts.—W. F. RADCLIFFE, *Tarrant Rushton*.

#### THE CULTURAL MERITS OF MR. BEARD'S PATENT HOTHOUSES.

PLANT-HOUSES were originally erected for conserving, not growing, plants. They merely afforded protection from wind and rain, excluded the cold, and provided a medium of heat. The object was simply to preserve in life as many plants as possible in the smallest compass, and the semi-opaque houses then built sufficed for this purpose. The chief merit then was held to be in possession rather than in superior culture. To have plants, to know them, and to be able to marshal them in regular gradation according to their respective heights, comprehended much of the science and practice of gardening only forty years ago. Doubtless, gardening has changed and advanced wonderfully since then. If our tastes and pursuits are less ideal and lofty now, they are infinitely more useful. Perfection of growth, profusion and brilliance of flower, and quantity and quality of produce are the highly utilitarian objects aimed at by every lover of gardening. This change of taste and practice necessarily created the demand for different and better houses. The old plant-sleeping dormitories must be exchanged for living-rooms, where not only the heat but, as far as our climate permits, the light, air, and moisture of the tropics may be secured, if tropical produce is to be grown to perfection. The recognition of this fact arrested the erection of plant-houses for mere architectural effect, and the multiplication of those semi-opaque masses of ugliness, lumbered up, apparently, for the express purpose of absorbing spare timber, and oppressing the plants beneath into a living death, and

caused a new order of houses to be built on the principles of cultural utility.

Successful cultivation demands a sufficient supply of light, air, heat, and water, and that each of these be placed under the immediate and direct control of the practitioner. These, with suitable soil, are the elements which the transforming powers of plant life, and the skill of man, weave into every form of vegetable produce. Do Mr. Beard's houses furnish them in purity and plenty, and place each under easy control? I think they do. Mr. Beard offers no new plan of heating; but as these houses are, or may be, made closer than most, they will economise to the utmost extent both natural and artificial heat. The arrangement of the sash-bar will also favour an equable temperature. The entire structural arrangements are well adapted for the collection and stowage of water. The roof-plate collects it throughout its entire length, and every front pillar may convey it into tanks either outside or inside the house. These houses also cure, or reduce to the smallest limits, a great water-evil incident to most others—drip. Drip is caused more by the condensation of water on the inside of the glass than by the action of capillary attraction in drawing in the external rain, or dew, through the laps. Practically, this scarcely ever happens. But when the warm air of a hot-house impinges upon the cold surface of the glass, the air suddenly cools, and is unable to hold the same amount of water any longer, and, consequently, leaves it behind on the glass. So far, no harm is done. Presently, however, the water begins to run down the glass. In ordinary-lapped glazed houses, as soon as it reaches the bottom of the square it drops down in virtue of the change of level. Hence we have rows of drops all over houses, which prove a source of great mischief. From the very position of this water it is of necessity cold in cold weather. On ordinary metallic roofs, unless well painted, this water is generally impregnated with iron rust. Often such drops prove a chilling shower of death to tender leaves; more frequently they leave irremovable blotches on fine foliage. The mechanical arrangement of the glass in Mr. Beard's houses cures this evil. It presents a level surface inside and out; consequently, when the water begins to run, the chances are largely in favour of its flowing down to the bottom, where it falls into the roof-plate, into which the glass drips, and is conveyed away in company with the external water. It is said that no water gets through where the ends of the squares abut against or touch each other. The ventilation of these houses is very perfect. There is but little new in the mechanical arrangements by which it is effected, and in some minor details I think them capable of improvement; but the positions at which air is given are the best possible. The lowest and the highest points of a house are decidedly the spots at which air ought to be admitted and discharged, if the whole atmosphere of the house is to be renewed, and these Mr. Beard has chosen. It is of the utmost importance to change the entire air of hothouses. The rapid growth induced in them speedily exhausts the air of all its plant-feeding properties, and fresh air to them is, literally, new supplies of food. The quantity given must be largely determined by the amount of light and heat enjoyed, as air is not simply supplied as food, but as a controller of temperature.

There is another great advantage in admitting air at the ground level. In most cases, from 6 inches to 1 foot from the front wall is the most convenient place for placing the hot-water pipes. It is not only the most convenient, but the best, for they should always be situated at the lowest and coldest part of the house. Supposing that they are so placed in these houses, the fresh air will enter directly over them. It will thus get heated before it comes into contact with the plants. The rarefaction which the heat imparts will also cause a thorough circulation of the entire atmosphere of the house. If the pipes are furnished with evaporating-pans, kept full of water, the air as it sweeps over them will get charged with moisture as well. These arrangements are of the first importance in a cultural point of view. Cold air does not simply check, or chill, plants from its coldness, but also from its dryness. The colder it is the dryer it is, and if it is not moistened by artificial means, it will steal water from the first delicate foliage it touches. This loss of water causes a further depression of temperature, and often produces disease and death. All this may be prevented by warming and watering the air before it is admitted to the plants, and these houses admit fresh air at the best point for these purposes. They also allow the used-up heated air to escape at the highest point, where it is sure to be found in virtue of its lightness.

But the greatest cultural merit of these houses is, that they

admit more and purer light than any others I have ever seen. The superlative importance of light has only recently been recognised. Most of the old houses excluded a third, many one-half, of the direct light of the sun. What with pondrous rafters, heavy sash-bars, wide laps, with the usual accumulations of dirt on each side of them, and small squares of glass, I believe I have placed their illuminating power too high at half of their surface. Considering that Mr. Beard has abolished rafters and laps, and used only iron ribs of the smallest possible scantling consistent with the requisite strength, and that his glass is wide, I believe the transparent parts of his houses to the opaque would be as ten to one. It is impossible to exaggerate the immense importance of this great accession of light. Heat is not more useful in stimulating the vital forces of plants than is light in consolidating and moulding them into useful and ornamental forms. Light is the great manufacturing power of the universe. It works up the crude raw materials of nature into portable, beautiful, and edible forms, and lays at our feet, as trophies of its skill, flowers of surpassing loveliness, and that food which is the sustenance of our existence. Yes—

"All the world's beauty that delights our eyes,  
Is but of light the several livens;  
Thou the rich dye on them bestowest,  
Thy nimble pencil paints the landscape as thou goest."

If all this is true, and it is, it is surely of the first importance to secure every possible ray of light for the full development of tropical plants in glass houses. Some of Mr. Beard's have been erected long enough to prove their superiority over others in this respect. At our last show his plants were remarked upon for their compactness of growth and high colour of flower. Doubtless, part of this was due to the skill of Mr. Suelling, Mr. Beard's intelligent gardener. We all remember that he used to show good plants grown in ordinary houses in his last situation. Still some of the characteristics noticed were, doubtless, attributable to the houses in which the plants were grown. I saw at Mr. Beard's a row of Scarlet Geraniums that had stood for several months on the ground floor against the back wall in one of his houses. They continued as dwarf and compact as could be desired, and were one mass of bloom. In a similar position in one of our houses they would have been a yard high, with only a few flowers. This fact may convince many, whom neither theory nor poetry will influence, that light forms flowers and produces fruit, and that the more light there is given the more there will be of both, and the greater the brilliance of the former, and more luscious the qualities of the latter.

These houses also afford more space for their size than any others. The glass coming down to the ground line, every inch of the ground is available for cultural purposes. In a house 20 feet by 10, there is a clear gain of 20 feet cultural area from the absence of bricks.

The vital question of price remains to be noticed. Most things have an absolute and a relative value. The first is their intrinsic, the second their comparative, worth when pitted against other things that will serve similar purposes. Few care to discover the former, as the latter forms the basis of trade; Mr. Beard's houses can afford to be judged by both of these tests of value. Let us look at their absolute price first. Accepting the house in the Botanic Garden as an example of price, as it is of structural and cultural excellence, I find by measurement that it contains 580 square feet. It is glazed with sheet glass, weighing 28-oz. per foot; the price is £50, or barely 1s. 9d. per foot. I very much doubt whether ordinary wood-framed glass houses can be as well finished at the price. I am, of course, aware that the Paxtonian and other houses are offered for less, but it is well to bear in mind that there is a great difference in value between mere frames and elegant plant-houses. Looking at their relative value, compared with other houses, this price must be largely reduced. In this light their completeness and durability assume a money value, and become equivalent to a reduction in prime cost. The ventilating apparatus alone would cost £5; the substitute for troughing and piping, and the iron door-step, are worth another pound. A pretty lengthy experience has also taught me, that ordinary wood and glass roofs cannot be kept sightly and in repair for less than 1d. per square foot per annum. By the most economical management, the 14,800 feet of glass here cost us over £60 a-year. Then, surely, Mr. Beard's enamelling process, which prevents the necessity of this outlay, is worth six years' purchase of repairs, or 6d. per foot. This amounts to a reduction of £14 10s. on the house in the Botanic Gardens. All

these items put together would reduce the price of this house from £50 to £30, or 1s. 0½d. per foot, a price which can scarcely fail to astonish many, and satisfy all purchasers.

Perhaps I ought to state, in conclusion, that I have no pecuniary interest in these houses, that these letters have been written without Mr. Beard's knowledge or authority, and solely as a duty which I felt pleasure in discharging to a most useful invention, which promises to promote the prosperity of the town, the improvement of gardening, and the good of the public at large.—D. T. FISH, *Gardener to Lady Cullum, Hardwick.*

[The chief part of this communication appeared in the *Bury Free Press*, but has been sent to us for publication, with some additions by Mr. D. T. Fish.—Eds.]

## PLANTING VINES INSIDE OR OUTSIDE A VINERY.

Will you tell me which is considered by experienced gardeners to be the best mode of cultivating the Vine? Is it better to plant in a border outside of the house, or inside the vinery? The former is, I believe, the old-fashioned style, the latter came into vogue of late years. By best, I, of course, mean the most productive, and, therefore, the most profitable mode.

A friend of mine has planted his Vines in the house, but there are arches in the front wall of it, to admit of the roots going outwards if they choose. On a line with the frontage he has, perhaps, nine or ten lights heated by one pipe connected with those in the vinery. In these he grows his Cucumbers, and in winter keeps his bedding plants. His Vines, which are young, do not seem to me so healthy and strong as they should be, and I am rather inclined to attribute this to the absence of the good old-fashioned border outside, and to the cultivation of Cucumbers and Melons so close to the house, which I should fancy must draw a great deal of the "goodness" of the soil, and thus impoverish the Vines. This, after all, may be a prejudice on my part, and for this very reason (coupled with the intention I have of erecting a vinery upwards of 30 feet in length), I am induced to write and ask you for your opinion on the two modes of Vine culture.—W. B. A.

[We decidedly prefer planting Vines inside a vinery, even if the border chiefly be outside; but the inside border must be higher than the outside one, and the roots must not descend to get under the arches, or beneath the wall plate. Of course, if you use your outside border for Cucumbers, or preserving bedding plants, that is a different matter, and the soil must be rendered more or less unfit for the roots of the Vines.]

## GLEANINGS FROM ROCK AND FIELD TOWARDS ROME.—No. 4.

To strangers in Rome St. Peter's is the first great point of attraction—the sun, from which streams the light of the minor stars. I may never forget my first view of the interior of this great temple; it stands out alone in my memory, surrounded by a bright halo of its own. The exterior was at all times disappointing to me, and I entered the vast doors with a fear lest the same feeling might follow me within. The church was nearly empty, but I did not note it. There fell upon me instantly, and with wonderful power, a sense of my own utter nothingness, that bowed me to the earth with irresistible force. It seemed as if that mighty building, so vast, so unutterably magnificent in its tremendous proportions, awed me as the contemplation of eternity awes; and my whole being cried out for the God in whose honour this temple was raised—a temple that seemed almost worthy of being "the gate of heaven." I rose from my knees, filled with this same strange awe, to see a crowd of people hurrying in one direction. What great attraction was there? On reaching a given point they fell on their knees, crossed themselves, and, then rising, approached some object, which they reverently kissed, and pressed to forehead and lips with tenderest devotion. I went to the spot. There was no cross, no representation of the Crucified. I saw only a hideous black statue, said to have been that of some old Roman emperor, but now called St. Peter!

I was told that a Flora of the piazza of St. Peter's had been printed, but I have never seen it, nor did I gather one wild-flower specimen there. The shrine, beneath which the bones of St. Peter lay, was adorned by no bright wreath of fading

flowers; ninety-three lamps burned there night and day, and its *immortelles* are the prayers of thousands of burdened hearts which arise daily and for ever from kneeling multitudes up to the great white throne of God.

If St. Peter's is, as it were, the centre of Rome, this shrine is the centre of St. Peter's. From thence you can glance upwards to the incomparable dome, the immense magnitude of which the straining eye fails to realise, while its beautiful details are partially lost in the far distance; and from the dome downwards to the pavement of rich marbles, and along the vast nave to the great western doors, which, if you are fortunate, may be opening to admit a procession of Pope, cardinals, bishops, and clergy, who will pass through a file of Swiss guards in their strange amber red and black uniform, and fall on their knees to worship before the altar of the Blessed Sacrament. Or, it may be, you will hear in the distance the blending of many voices in a loud sonorous chaunt, and a procession of some confraternity will enter, headed by a cardinal, while some of the members bear a crucifix, others huge wax tapers, and all are covered by a loose white, black, or grey robe, with girdle and rosary round the waist, and a hood over the face, with holes cut for the eyes. Or the confraternity may be one of noble ladies, with attendants bearing kneeling-cushions, and every few minutes helping them to bear the weight of the huge tapers or crucifix. In Lent, procession after procession files in; at the door the chant ceases, and in silence they pass towards the altar of the Blessed Sacrament, and there fall down on their knees in lowly worship. After a while they rise and pass on, while another confraternity takes their place. Or, it may be, that you will hear soft music stealing on the air, and the echo of tutored voices rising and falling in measured harmony. Wandering away in the line of these vibrating chords—past many a noble statue, in marble or in bronze, of Popes long dead and gone—you will find yourself in the Capella del Coro, where you may listen to music of the sweetest from what is said to be one of the finest choirs in the world.

But what may you not see in this magnificent temple? At one time crowds will be worshipping a bit of the true cross, placed on high, surrounded by a hundred dazzling tapers; at another, Pope, cardinals, kings, and beggars will be kneeling before a handkerchief, said to have wiped away the sweat from the Lord's brow on His way to Calvary, and to have retained the impress of His features. At yet another time crowds will be marching up the magnificent Scala Regia to the Capella Paolina, to worship the Host, laid in a tomb, with many hundreds of tapers burning around, some of them hanging from the very roof of the chapel, which is draped in mourning. The whole ceremony has the appearance of the lying in state of some great person. None are forbidden entrance; and the motley crowd pass in and out in silence, kneeling and adoring, and then returning back to St. Peter's for other sights and ceremonies.

But the supreme moment in the annual life of St. Peter's is when the Pope, on Easter day, comes out on the balcony to proclaim to the world that Christ is risen, and to bless the assembled people in His great name. Then the tiny wayside flower, which lifts up its head from the masonry of the steps leading to St. Peter's, is crushed beneath the feet of a countless multitude of men and women, soldiers, horses, and artillery—every street leading to the piazza of St. Peter's is filled to overflowing by the crowd of people who can find no place in the piazza itself. The tumult and the buzz made by this concourse is so great, that even the roar of the cannon proclaiming the hour of noon seems to be in part stifled by it; but the instant the Pope, wearing his triple crown and borne on the shoulders of men, appears, every sound is hushed, every knee is bent, and nothing is heard save the distant barking of a dog or the neighing of a horse, while the Pope's magnificent voice rings over the enormous multitudes, calling down from on high the blessing of the Lord. And yet from most of these bustling spectacles of St. Peter's how refreshing it was to turn to the pure earth and sky! the one clothed in a carpet of many colours, the other wearing such hues of azure softness as I have never seen elsewhere.

One day, after a morning at St. Peter's, we drove to the Villa Pamfili-Doria, and had a lovely scramble after Anemones, Violets, and other wild flowers. This Villa is the Hyde Park of Rome on Fridays and Mondays, when it is most generously thrown open to the public, and its beautiful woods resound with the merry laugh of many a pretty English girl wandering amidst them, gathering bunches of dark blue Violets, much

darker and finer than our English ones. The grass was fragrant with the breath of Thyme; and here and there, amidst a profusion of Violets, I found the *Cyclamen latifolium* with its broad leaves so darkly and beautifully marked. The flowers had all been gathered, but I brought away the leaves to place in a bouquet of Anemones of many colours that I found growing in profusion. In places the ground was quite rose-coloured with the *Anemone hortensia*. The only Fern I saw was the *Adiantum capillus-Veneris*. It waved its tender fronds from many a stone of the rustic bridge placed over a piece of water, where stately swans were gliding about, persecuted by some Italian boys who were trying to rouse their anger, while two monks, very dirty and very slightly clad in brown serge robes with girdles of rope, looked on and laughed approval. These monks are to be met with everywhere—in the streets with a wallet on their back, in which they put the food they beg for their daily sustenance—on the stairs of the hotel, shaking a money-box in your face, and praying you to help souls out of purgatory—in picture-galleries, silent and observing, yet utterly apart from the busy world around them. I did not meet them, where, too, they may be seen, at the bedsides of the poor, consoling the dying, feeding the hungry, and ministering to the sick. Idle the many may be, but Italy without her monks would be in a worse state than England without her poor-house.

But to return to the Villa Pamfili-Doria with its untidy luxuriance of beauty, where Nature, left very much to her own caprices, riots and revels in superb indifference to all rules of horticulture, beautiful flowers and scarcely less beautiful weeds contending for pre-eminence; and amidst it all English lads were playing cricket, and English fair-haired maidens were having their croquet-match, near to the very spot where, in 1849, Garibaldi fought for what he deemed was Italy, and brave hearts bit the dust and ceased to beat for ever. There is a pretty orangery in the gardens; but Oranges in Rome are not like what they are in the Cornice—they seem to require care and looking after, and even with that many are sick and fruitless. In the garden of the Palazzo Rospigliosi I found some Orange trees almost without leaves on one side of the garden, while those planted on the sunny side were full of fruit and flowers. I asked the gardener about them, and he told me his Orange trees lost their leaves about every two years; but the situation was dry and not good for them, and the old man appeared to be thinking a great deal more of the expected pauls than of the neglected garden.

In the Rospigliosi Palace is the "Aurora" of Guido, a fresco painting that to my taste stands out immeasurably apart in its superiority from any profane picture I have ever seen. It tells its own story in a manner as bright as its colouring. Apollo drives through the air, his chariot surrounded by nymphs of surpassing loveliness. Aurora precedes the chariot, scattering flowers on the earth. The dark blue waters of a distant sea, bordered by hills, lie beneath, while over the entire scene there is the unmistakable look of nature just awakening from night to dawn. I wondered if the old gardener spent his time in peeping through the window at this incomparable work of art rather than in studying the indifferent page of nature that was his province.

One of the chief pleasures of modern Rome is its palaces, each containing some treasure, some glorious painting or choice piece of sculpture, that gives individuality to the building, and clothes it with a glory not its own. Who is there that, hearing of the Palazzo Barberini, does not instantly see before him the touching, childlike, pleading face of Beatrice Cenci? The glories of the Barberini family, Pope, and Cardinal, are alike forgotten, while the pictured story of innocence startled with crime haunts him, with its tender claim for sympathy, for ever. No copy of this most wonderful picture bears any comparison with the original. The white turban is there indeed, the white robe, the chestnut hair, the brown eyes; but they are as the clay figure of Prometheus—they lack the fire of life, the magic touch of the master's hand.—FILIX-FEMINA.

#### PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

*BERTOLONIA GUTTATA* (Spotted leaved Bertolonia). *Nat. ord.*, Melastomaceae. *Linna.*, Decandria Monogynia.—Received by Mr. Veitch, of Chelsea, in May last, as a native of Madagascar, but believed to be peculiar to Brazil. The foliage is most beautiful, being marked between the five parallel veins with

lines of distinct white or, more frequently, rose-coloured spots, giving the leaf the appearance of being studded with rubies. Flowers rose-coloured.—(*Bot. Mag.*, t. 5524.)

*SCUTELLARIA AURATA*, var. *SULPHUREA* (Sulphur-flowered Golden Scutellaria). *Nat. ord.*, Labiate. *Lim.*, Didymia Gymnospermia.—A variety of *Scutellaria aurata*, with smaller flowers of a pale sulphur colour.—(*Ibid.*, t. 5525.)

*PSAMMISIA LONGICOLLA* (Long-necked Psammisia). *Nat. ord.*, Ericaceae. *Lim.*, Decandria Monogynia. Native of South America.—A straggling shrub, with glossy, coriaceous leaves and bottle-shaped scarlet and green flowers.—(*Ibid.*, t. 5526.)

*PHALENOPSIS SUMATRANA* (Sumatra Phalenopsis). *Nat. ord.*, Orchidaceae. *Lim.*, Gynandria Monandria.—Native of Palembang, Sumatra, where it was discovered by Korthals more than a quarter of a century ago, but first exhibited in flower in this country by Mr. Day, at South Kensington, in the present year. Flowers yellowish white, barred transversely with broad streaks of reddish brown; the lip white, spotted with orange and streaked with violet or lilac.—(*Ibid.*, t. 5527.)

*PRIMULA CORTUSOIDES*, var. *AMENA*.—Introduced by Mr. Veitch from Japan. Flowers deep rosy purple, with white eye.—(*Ibid.*, t. 5528.)

*RHODODENDRON THIBAUDIENSE*.—Native of Bhootan. Flowers resembling those of a *Thibaudia* rather than of a *Rhododendron*, reddish orange, tipped with yellow.—(*Floral Mag.*, pl. 253.)

*AQUILEGIA CERULEA*.—Native of the Rocky Mountains, originally discovered by Dr. James, and raised by Mr. Thompson, of Ipswich, from seeds sent home by Dr. Parry. Flowers violet blue and white, with long spurs.—(*Ibid.*, pl. 254.)

*CLEODENDRON THOMPSONI*, var. *BALFOURII*.—Raised by Mr. McNab, of the Edinburgh Botanic Garden. Flowers large, crimson and white.—(*Ibid.*, pl. 255.)

*PRIMULA INTERMEDIA*.—Raised by Mr. Fuller, Headingley, and now in the hands of Mr. Bull, of Chelsea. Flowers resembling a small-flowered *Auricula*, mauve; trusses composed of numerous pips.—(*Ibid.*, pl. 256.)

*SKIMMIA OBLATA*.—"Imagine the bright-coloured berries of the Holly set amongst the glossy lively green leaves of the Laurel, and something like a picture of this new *Skimmia* will be brought before the mind's eye. In September, 1864, Mr. Standish exhibited before the Floral Committee of the Royal Horticultural Society a specimen, in fruit, of this new hardy evergreen shrub, when it received, as it deserved, a first-class certificate. As a decorative shrub it is immeasurably superior to the ordinary *Skimmia japonica*, as it is called, beautiful and interesting as that may be, in certain situations; for it produces berries of the brightest vermilion red, in contrast with rich green foliage, while that has both foliage and fruit dull-coloured. The plant, which was one of Mr. Fortune's discoveries, must become a valuable acquisition for our gardens and shrubberies.

"On examination it has proved to be obviously distinct from all *Skimmias* yet known, in the remarkably oblate figure of its bright red berries, so very different from the oblong fruits of the *Skimmias* we have heretofore possessed. It is also remarkably distinct in the form and texture of its foliage, as well as in habit. It is a free-growing plant, with dense clear green leaves, and erect terminal panicles of white flowers, succeeded by bright-coloured berries nestling amongst the foliage. We are assured by Mr. Standish that, unlike the other species we cultivate, this bears exposure to the sun without injury."—(*Florist and Pomologist*, iv. 161.)

#### ENTOMOLOGICAL SOCIETY'S MEETING.

THE August meeting of this Society was held on the 7th inst., the chair being occupied by F. Pascoe, Esq., F.L.S., President. Amongst the donations announced were the publications of the Royal Society of London, the Linnæan Society of Lyons, and the Zoologico-Botanical Society of Vienna.

Mr. McLachlan exhibited some specimens of the Ant Lion insect in the imago state, which he had reared in this country from larvæ which he had found at Fontainebleau.

Mr. W. W. Saunders exhibited a live Locust of a delicate green colour, of which he had received several specimens in a young state from Mr. Marshall of Edmonton, who had found them in his Orchid-house, where they had probably been imported with Orchids from Mexico. Mr. Saunders had found them very injurious amongst his Orchids since he had received them, a *Cyanophyllum* had been especially damaged; the

insects feeding by night so as to escape detection, their presence only being indicated by the holes which they had made in the leaves. On being secured in a glass vase their movements were very interesting, being almost incessantly engaged in cleansing their limbs and antennæ, which they draw through their mandibles.

Mr. Bates stated that during his residence in the Amazons he had never noticed any species of Locust to be nocturnal in its habits. He also described the apparatus by which the insects made the chirping noise so often heard, by means of a drum-like space at the base of one of the wing-covers, the opposite one having a serrated ridge, which is drawn backwards and forwards over the drum. The natives in some parts of the Amazon Valley kept these insects in cages for the sake of the noise which they make.

Professor Westwood stated that the insect in question did not belong to the family of the true migratory Locusts, but to that of the Grasshoppers with long slender antennæ (*Gryllidæ*); also that the apparatus by which the noise is made has a much greater resemblance to a tambourine than a drum, consisting of a single strong membrane stretched across a circular space with a raised margin. It was also stated that our British species, *Meconema varia*, which belongs to the same group, is often taken at night by sugar placed on trees for attracting Moths.

The President stated that he had received a particular account from a friend in Australia of the means by which the species of *Bolboceros* make a noise—namely, by the rotation and friction of the hind coxæ in their cavities, being furnished with a narrow groove.

Mr. Saunders, jun., exhibited a specimen of the very rare *Trachys pygmaea* taken in a marsh near Lowestoft; and Mr. D. Sharp a beautiful series of *Cryptocephalus 10-punctatus*, varying from red to black, taken at Rannoch in Scotland.

Mr. S. Stevens exhibited a box of beautiful Butterflies collected by M. Bouchard, Santa Martha, the extreme northern part of South America.

Mr. Smith communicated a note dated at the end of April last from Mr. S. Stone of Brighthampton, giving an account of the vast numbers of female Wasps which he had observed during the spring, notwithstanding the great destruction of Wasps' nests during the preceding autumn. The species which he had observed were *V. germanica*, *rufa*, *sylvestris*, and *vulgaris*. Many of these he had induced to commence building by making holes in banks, which they at once selected for their nests. It was, however, stated that up to the time of this meeting Wasps had been extremely scarce; and many nests which had been begun and partially tenanted had been destroyed from some cause or other hitherto unexplained.

Mr. Saunders suggested that possibly this might have been caused by the attacks of Earwigs on the young grubs in the cells of the Wasps' nests; whilst Professor Westwood considered that it was owing to the very violent rains which had several times fallen during the spring and summer. It was stated that Earwigs had this season been exceedingly abundant, probably in consequence of the long dry weather during the time when the eggs were being hatched. As many as a score of these troublesome insects had been found in a single flower of the *Oenothera macrocarpa*.

Professor Westwood gave an account of some peculiarities he had observed in the economy of the caterpillars of the *Ailanthus* Silk Moth, especially with reference to their feeding by night whilst young, their eating their cast skins, and the peculiar exudation of a white powder over their bodies previous to moulting.

The Secretary read some notes on the rearing of the *Saturnia* attar in France. Mr. Moore, however, stated that he had previously reared it in this country.

Mr. D. Sharp exhibited specimens of the larvæ of the beautiful *Lycus (Eros) aurora*, found in vast numbers at Rannoch under masses of chips of Fir trees.

Mr. Baly read a memoir containing descriptions of a number of new exotic species of Phytophagous Beetles; and the Secretary exhibited a remarkable specimen of *Bupalus piniarius*, which appeared to be intermediate between the male and female sexes; the body and antennæ being decidedly female, whilst the wings were marked like those of the male, being, however, suffused—the dark colours of the male being converted to a dull brown. He also made some observations on the classification of such monstrosities proposed by Mr. Newman, which was not sufficient to include the present individual.

## WORK FOR THE WEEK.

## KITCHEN GARDEN.

THE long-continued wet weather has favoured the growth of weeds, and rendered their destruction a matter of difficulty. The best plan to adopt, when hoeing and raking are not practicable, is to dig them down, especially the young generation. *Artichokes*, cut down the flower-stems and remove the dead leaves from the old plantations; those made last season will probably now produce a few heads. *Cabbage*, continue to plant out for Coleworts at every opportunity that is favourable. Prick out the young plants intended for the main spring crop. *Cucumbers*, those intended for house culture should now be potted into their fruiting-pots; the soil for the purpose should be composed of equal parts of loam, rotten dung, and leaf mould; good drainage should be given, the health of the plants depending, in a great measure, on this point. Allow one or two shoots to grow to the full extent of the house before being stopped. *Celery*, in earthing-up, the greatest care is necessary to prevent any portion of the earth from falling into the heart of the plant, which would prevent the upright growth of the inside leaves, and spoil the appearance for the table; nor should the earth be pressed too closely round the upper part of the plant, as, frequently, when such is the case, the latter bulges out below. The best practice is to tie each plant up loosely with matting, after having removed the suckers and small leaves, and then a little earth can be added every week as the plant increases in height. Another common error arises from earthing *Celery* up too soon: It should be allowed to grow to a considerable size before earthing-up is attempted, and be frequently soaked with water, as but little rain will reach the roots afterwards; it should likewise never be touched when the plants are at all damp. *Cardoons* will require similar treatment. *Leeks*, plant out the thinnings of the seed-bed as soon as the weather is favourable; this is a very useful culinary vegetable during the winter. *Onions*, no time should be lost in getting the crop stored when fully dry. As the ground is generally used for *Cabbage*, it should be immediately trenched up; if manure is necessary, let it be laid on the top of the trenched soil and fork it in; if, however, the ground was well manured for the *Onions* it ought to carry the *Cabbages* through, and they will always be the better thus, because, if too much manure come in contact with the roots in the autumn, it induces a succulent luxuriant growth, which renders them liable to injury from alternations of frost and thaw in the winter. *Turnips*, the last crop for the season to be sown; thin advancing crops. *Scarlet Runners*, let all the old pods be picked off, except a few of the best for seed, as they exhaust the plants for a succession. At the earliest opportunity earthing-up *Broccolis*, *Savoys*, and all other crops that require it; remove *Peas* that are mildewed immediately they are done with; destroy caterpillars that infest the *Brassica* tribe before they do much mischief.

## FRUIT GARDEN.

The following few necessary precautions are to be observed in the gathering and storing of fruit. *Peaches* and *Nectarines* should not be allowed to remain on the tree until they are what is technically called dead ripe. A little practice will enable a person to determine the degree of ripeness at which they should be gathered, without resorting to the common way of pinching. *Plums* should be allowed to remain until perfectly ripe; the large amount of saccharine matter in the fruit acts as a preservative, and although something may be lost in bulk by their remaining on the tree, the flavour will not be deteriorated. Such as the *Impératrice* and *Golden Drop*, if protected from wasps, may be kept until a very late period of the season. *Apples* and *Pears* generally fall as soon as they arrive at an early degree of ripeness; that period must be anticipated, and their removal effected as soon as it is ascertained. After gathering, the fruit intended for keeping should be laid out in the fruit-room for a week or ten days, and exposed to a free circulation of air. The fruit will be found clammy from perspiration; it should be carefully wiped and laid out thinly in the store-room, which should be kept, as soon as the fruit is introduced, securely closed and protected from material alterations of temperature. If *Apples* and *Pears* are gathered carefully without bruising, and at a proper period sorted, all defective fruits being removed, and the rest stored in the manner above described—if they are placed on paper, so much the better—they may be kept with very little loss, and in a plump, highly-flavoured condition throughout the winter.

## FLOWER GARDEN.

Unless some precautions are taken to keep the taller plants

in the beds of geometric flower gardens within proper limits, they will be likely, towards the end of the season, to become too high, and will destroy the uniform appearance essential to this style of gardening. A constant watch should, therefore, be kept on plants likely to exceed the standard height, and by frequently pinching back or pegging down, endeavour to keep beds of the same pattern at the same height. At this season, with beds of flowering plants, frequent cuttings-back and trimmings will be required to prevent free-growing plants becoming straggling, and the late rains will contribute to their becoming so; at the same time allow no dead flowers or seed-pods to remain on the plants. By careful attention to these little matters, the season of blooming may be prolonged till the plants are destroyed by frost. Lawns should be well swept in dry weather to remove worm-casts, and afterwards well rolled. Where worms are very troublesome, water with clear lime water of full strength, this will bring them to the surface, when they should be removed. Cuttings of various evergreens should now be planted, to keep up the reserve-garden.

## GREENHOUSE AND CONSERVATORY.

Directly *Japan Lilies*, *Glaboli*, and plants of like habit have done blooming remove them to the foot of a south wall to ripen their growth; water them moderately till their foliage show signs of decay, when they may be laid on their sides till potting-time. The earliest-struck *Pelargoniums* should now be potted off, exposing them on all occasions to the weather, except during heavy rains. The older plants first cut back, which have made shoots an inch or two long, should now be shaken out of the old soil, the roots trimmed, and repotted in smaller pots; if they can be plunged in a slight bottom heat till the roots are started it will be of assistance to them. Attend to *Chrysanthemums*, water freely with liquid manure; good specimens should be aimed at rather than a few fine blooms. The earliest winter-flowering *Heaths* and *Epaeris* must soon be placed under glass, as it will forward their blooming. *Hyacinths* and *Narcissuses* for forcing must soon occupy attention; about equal portions of good soft loam and decayed leaf mould, with a little sand, will be the best soil for them, if for forcing.

## STOVE.

The specimens temporarily disposed in other houses should now be restored to their proper position, and should generally receive the treatment calculated to ripen their summer's growth of wood, and so prepare them against the injurious effects of our trying winters. Let *Euphorbia jacquiniiflora* receive attention.

## PITS AND FRAMES.

Propagation of all the more important bedding plants should now be pushed on as quickly as possible. Let *Scarlet* and other *Geraniums* struck in the open ground be taken up, and potted immediately they have made roots; they will require a close frame for a week or two, when they should be placed on a dry bottom in a southern exposure to harden them for the winter.—W. KEANE.

## DOINGS OF THE LAST WEEK.

THIS day (Thursday), we have had a visitor that spent the most of Wednesday in the Crystal Palace, and was pretty well obliged to stay there. We have no regular rain-gauge, but judging from our tanks, more rain fell here yesterday than has fallen altogether since March. It will be of assistance to all fresh-planted things in the way of vegetables, but it will be almost sure to affect all the later kinds of *Potatoes*, and to bring us whole shoals of weeds, and so prevent our ever having the hour's idleness that used to be looked forward to in days of yore. We say nothing of the flower garden—that was rather radiant on Wednesday morning. This morning it was enough to give one a fit of the blues. Our finest ribbons and beds looked like faded washed-out finery, conjuring up much of the same class of mournful melancholy associations which we feel in witnessing in towns the cast-off garments of the rich torn to tatters by the poor and the unfortunate. Would that they too might be able to look up and rejoice, as the flowers will yet do if privileged with sunshine and calm. Many a tattered neglected flower of humanity, rough and uncouth to the eye, would yield a rich harvest of beauty and moral loveliness if only receiving that amount of cultivation which hearts thrilling with human sympathy knew so well how to impart. That seen-and-felt sympathy is everything in arresting and elevating the impulses of the stray waifs of humanity. Strive as you

will, honestly as you will, perseveringly as you will, and from as sincere a desire to do good as you will, but set yourself up as if much better than they—in one word, leave out the seen-and-felt sympathy with their condition, and your well-meant efforts will be as fruitless as the attempt to make flowers look their best amid the drenching downpourings of rain and the absence of the bright sun, with which they have so much sympathy that they ever look the best when basking in its rays.

We will allow that our friends the farmers, proverbial for their grumbling at all times and all seasons, have lately had some reason to be a little uneasy, though the chief harm should at present be confined to the blackening of the Barley, which will make it bring less in the market for malt, even though it should be none the less nourishing when ground as meal. In the extra labour and expense in securing the harvest in such a season as this, we thoroughly feel for and sympathise with them; and if we should pay a little more for our bread we would have no reason to complain, as it is best every way, that whilst every man should bear his own burden, we should also keep in mind and duly practise the precept, "Bear ye one another's burdens." But there is one matter connected with the present harvest in this neighbourhood which hitherto has not come so prominently under our notice—a practice which even now we hope is anything but general, and which we trust will ere long cease to be particular, and that for the benefit of all parties concerned, whether master or servant. A custom has long obtained in this neighbourhood that in consideration of the long hours something like double pay is given to the labourers in the harvest month. Sometimes a certain number of men engage to do all the harvesting for a certain sum, and the amount is generally such that in a fine season the men make a little more than the regular month's wages, and the having the work more quickly done is an advantage to all parties. In such a season as this it will tell against the men. The most general plan, however, is to engage men for the month at the increased wages agreed upon, generally the usual working men on the farm, with some additions if deemed necessary. Now it appears that, in many cases, farmers, who scarcely ever during the season send a man home on account of the weather if anything at all can be done, will send them home on these wet harvest days, and require the time thus lost to be made up at the end of the month, so that a man may have his harvest month extended for the same money into five weeks or more, instead of four weeks. It might not be fair to expect that when men could not go into the fields on account of the weather they should receive harvest pay, but it would tell greatly to the advantage of the men, and we think to the benefit of the farmer likewise, if the men were kept doing something about the homestead, and received for such days the common wages of the year, instead of constraining them to be idle against their will, and exposing them to the temptation of so spending that idle time as not to fit them over-well for the work of the following day; whilst much is apt to be spent that if unspent would have told on the comforts of home. Most facts may be used to bolster up opposite principles, but it requires no prophet's vision to foresee that if such modes become the general practice steam and horse power will ere long do what is now accomplished by human labour.

#### KITCHEN GARDEN.

Much the same as in previous weeks. Took up the remainder of the Potatoes. As we expected, a few are diseased, and a few signs of disease are appearing among those taken up early and harvested in good condition. Took up more Onions, as they are better out of the ground now, too much wet causing them often to mould, or rot at the points. Those sown to stand the winter are coming up nicely. The Spanish and Tripoli are good for this purpose, and so is the Blood Red for those who like it. Button Onions seem scarce, this season, unless where the plants were left thick on poor soils. Sowed the last Lettuces, &c., planted out a lot, and of Endive for succession, Cauliflowers, Coleworts, and a few of the earliest Cabbages, and will take the opportunity of the first dry day to run the hoe through every open spot, as a lawn might soon be formed, where a few days ago there was not the trace of a weed. We are constantly meeting with proofs that the earth to considerable depths is stored with the seeds of vegetation, that only require to come in contact with the atmosphere, &c., to grow and seed again. In sweeping the sides of kitchen-garden walks about a month ago, to make them look fresher, we threw along the sides a little sandy gravel, dug directly from the pit, and these sides where scarcely a weed was seen before, are sending up fine grass

like a carpet. We have known many instances of walks that scarcely showed a weed for years, yielding a plentiful supply when they were fresh-gravelled over the surface. Even in this respect, a fresh coating on the surface often makes much additional work afterwards, and in the case of these imported seeds of weeds, we know of no mode of preventing their growing unless some means could be resorted to for kiln-drying the gravel, and that would be an expensive process. There is a great difference in gravel pits in this respect, some scarcely contain a seed, and others are well supplied. It is advisable to use all gravels fresh dug; when the heaps lie long exposed many weed seeds are nestled in them. We recollect of a piece of gravel producing a rare crop of Sow Thistles, and yet not one could be found for a great circumference round the pit.

Made some Mushroom-bricks for spawning in a wet day; earthed-up another piece in our thatched shed, the first beds producing plentifully. Will smoke and clean the Mushroom-house, and begin there as soon as we can collect material sufficiently dry. Mushrooms, we believe have been plentiful out of doors this season, but they are not to be depended on like those grown at home. At the best they are ticklish things except for ketchup, and the boiling and the quantity of spice may make that harmless out of rather questionable materials.

#### FRUIT GARDEN.

Gathered fruit in fine days. Supported some Apple trees much loaded with fruit. Plums ought to have been more thinned. Melons have come in rather too much together. Watered the Fig-pit. Will clear Strawberry-beds as soon as the ground is dry. Potted more for forcing. Thinned out shoots, and shortened-in those of Peaches, &c. Gathered in the rest of the Apricots; though a heavy crop, the continued wet weather has made many rot and damp before they ripened. Thinned out part of the Raspberry canes, to give more room, sun, and air, for those intended to bear next year. Will continue these and other jobs as soon as the ground is drier. Looked over Vines to see that there were no damp berries. Kept fires in on these wet days, and gave air in proportion, and lest the red spider should appear, brushed the pipes over with thin sulphur paint.

#### ORNAMENTAL DEPARTMENT.

The less said of the flower garden the better for a few days, though a few hours' sun does wonders. Most of the beds will require picking as soon as the weather is drier. Fine trusses of some kinds of Geraniums have scarcely an open petal that is not drenched like a wet rag. Other sorts, as Rubens, Mrs. Vernon, &c., seem to brave the wet well, sending the deluges of water from their petals as if they were so many duck-wings. Stella stood well until this last drenching; now it will want a good deal of picking to make it bright again. Of all we have seen, for massive effect it is still No. 1. The usual routine of potting has been persevered in, on wet days especially. One row of Calceolarias had become too low, and we commenced raising it some 6 inches, but were stopped by the rains. We adopted the same plan some ten years ago, and the plants, lifted with a fork in large pieces, never felt the operation. We could not proceed, as the other rows becoming wet would have been discoloured by some of the earth that was necessary for raising the Calceolarias falling on them. A few hours' labour, when it can be spared, will thus often make a great difference in appearances. The growth of many plants is very different this season from what it was last, and thus people are apt to be deceived as to heights. Our chief work, however, has been mending up our small wooden boxes in wet days, washing pots, &c., limewashing the rough boxes, and putting in lots of cuttings, having fairly commenced with Geraniums, and taking the variegated kinds first. Of the common variegated kinds, there is a fine variety of Brilliant, called Improved, that we understand will be generally diffused next season. The foliage has more white in it, and the flowers are larger, and in larger and stronger trusses than the old Brilliant, whilst the compact habit is retained. We have, as yet, no reserve ground for cuttings—that is, plants to take cuttings from; and, therefore, they are carefully selected from the bottom of the plants in the flower-beds, so as to make as little appearance of being meddled with as possible. Short stubby pieces, from 3 to 4 inches long, are generally preferred. In such weather a good lot is taken when there is a dry interval of a few hours, and then the cuttings are made when it is wet. The boxes average 2 feet in length, 9 to 12 inches in width, and 3 or 4 in depth; enough riddings are strewn along the bottom, then we partly fill in with good fresh lumpish soil, giving a casing of

lighter sandier soil on the surface. The cuttings are dibbled in from 1 to 1½ inch apart. The variegated kinds may have a cold pit, and some old lights laid over them; the common Scarlets will mostly stand in the open air. The boxes we prefer at first, because it saves lifting and potting if the cuttings are placed first in the ground; and though we have no objection to using rather large pots for cuttings, we think we can move them about more quickly and easily in these boxes. The boxes are so roughly made that we do not need to trouble ourselves about drainage; the water escapes by the sides fast enough. There is just one disadvantage in the use of such rough boxes—they are apt to have fungus about them when standing in a damp place, hence the limewashing. Pots, however, will always be the favourites with many, and for scarce things three or four cuttings in a four-inch pot is a good plan for securing quick-striking and healthy plants. We have had numerous inquiries about striking Scarlet Geraniums from leaves. We have no faith in it as a matter of practice. Striking a leaf, with a bit of the stem at the bottom enclosing a bud in the axil, is a different thing, and is not leaf-striking. As a general rule, little is gained by using cuttings less than 3 inches in length.—R. F.

COVENT GARDEN MARKET.—AUGUST 26.

ALL kinds of fruit and vegetables in season continue to be abundantly supplied, and quotations are nearly the same as last week.

TRADE CATALOGUE RECEIVED.

W. Cutbush & Son, Highgate, London.—*Descriptive Bulb Catalogue for 1865.*

William Bull, King's Road, Chelsea.—*Retail List of New, Beautiful, and Rare Plants.*

B. S. Williams, Paradise and Victoria Nurseries, Holloway, London.—*General Bulb Catalogue, General Pelargonium Catalogue, and Fruit-tree List.*

TO CORRESPONDENTS.

HAMILTON ON THE PINE APPLE (*E. S. Jones*).—It is out of print. This mode of culture is included in "The Pine-Apple Manual," just published, and which you can have free by post for thirty-two penny postage stamps.

SCHINUS MOLLE (*A Constant Subscriber*).—Your plants are each worth about 5s.

CZAR RUSSIAN VIOLET.—Several applications have been made to us for information where this variety can be purchased; reference to our advertising columns of this and last week will supply the desired information.

PEA AND POTATO (*H. C.*).—We do not know the "Yorkshire Hero" Pea. "Rivers' Royal Ash-leaved" Potatoe is early, productive, and good.

PLAN OF GARDEN (*Rev. T. White*).—We know of no gardener who would give you a plan. You had better write to Mr. Chapman, Garden Designer, Richmond, Surrey.

STORING FILBERTS AND NUTS (*W. E.*).—Nothing more is required than to put them into stone jars, leaving all the husks on, and placing the jars in a cool cellar. If the cellar is damp all the better.

PROPAGATING LOBELIA SPECIOSA (*F. T. C.*).—We always propagate Lobelia from cuttings in preference to seed. You had better procure half a dozen plants of the true variety from some respectable nurseryman; from six good plants procured now and kept through the winter, you may easily propagate between the months of February and May 1,500 or 2,000 plants. To preserve plants through the winter the best plan is to strike some cuttings into in the spring, keep them in store pots till about this time, when they should be cut in closely and potted in large or small 60-pots. The potting-soil will be none the worse of being kept in a house, providing it is not kept too dry nor too wet. We should be glad if we could obtain from a rich pasture a few loads of the yellow-looking soil you name; if it is the kind we take it to be almost anything would grow in it. If the fibry part of it is used, when taking it from the pasture cut up the sods about 2 or 3 inches thick.

CUTTING DOWN PELARGONIUMS (*Agnes*).—The plants should be placed in a frame after they are cut down so that they may be easily sheltered from the rain, and exposed to the sun in fine weather. In about three weeks after they have been cut down they will have pushed out their young shoots. All the soil should they be shaken away from their roots; repot them in as small pots as it is possible to put them into, then place them in a frame, keeping them close for a few days till the roots have taken hold of the fresh soil; afterwards they should have all the air that can possibly be given them. When the young shoots have grown 3 or 4 inches long pinch out their tops early in February, and repot the plants, but they must not have too large a shift at once; it is better to pot them two or three times than to overpot them the first time. In a fortnight or three weeks after each potting pinch out the top of every shoot; by these means you will keep your plants stocky, and they will produce double and treble the quantity of bloom in consequence. At all times see that they are kept free from green fly; when the slightest trace of this pest is seen fumigate with tobacco at once. In the spring months the green fly may be kept down by syringing the plants with quassia water. This is made by boiling the chips for ten minutes; 1 lb. of quassia chips will make five or six gallons of water very bitter. The chips should afterwards be put into a tub or cistern and fresh water poured on them, into which any plant much affected with green fly or any other insect may be dipped; but it is not safe to syringe the plants in the winter months, unless you have plenty of heat at command so that you can give abundance of air and heat to dry the foliage as quickly as possible. If the foliage is allowed to remain wet long in the winter it soon decays.

PLANTING STRAWBERRY RUNNERS (*Idem*).—The Strawberry plants will be more likely to produce a crop of fruit the same year if they are planted in February or March than they would if planted in the permanent beds in autumn. The plants when taken up from the nursery beds in the spring must not of course be pulled up to them and be carefully planted, with nice balls of soil attached to them and be carefully planted, making the hole for each plant large enough to put the plant in without cramping its roots. The soil should then be carefully scraped in around the plants with the hand. If the weather is mild at the time of planting the plants will be all the better of a little water. This should be poured on them with a rose and not from the spout. If the plants are mulched with a dry light substance, such as leaf-soil, directly after planting they will be all the better, as it will shelter them from the drying winds; care must, however, be taken that the hearts of the young plants are not covered up with the mulching. If the plants are managed as described above, and in the previous article, they will never suffer from their removal. Almost any kind of Strawberry will produce a good crop of fruit in the first year if managed in this way.

CATERPILLARS AND SLUGS (*Query*).—Hand-picking is the most effectual and cheapest mode of clearing Cabbages of caterpillars. Dusting the surface of the ground and the plants with slaked quicklime will destroy the slugs. If the soil is rather clayey, and has been so long neglected, pare and burn the top 6 inches of the whole surface. It will effectually destroy the seeds of weeds as well as vermin.

GERANIUM CUTTINGS (*K. C.*).—We have not the direction of "W. C." who had given the cuttings away.

SYRINGING WITH HOT SEWAGE (*X. Y.*).—The urine you mention must be diluted with at least five times its bulk of water before it is used.

EATABLE FUNGUSES (*F. L.*).—The work entitled "The Eatable Funguses of Great Britain," is published at our office. The Editors are the Editors of this Journal and others. Three Numbers have been published, and they may be had free by post from our office for forty postage stamps.

AZALEA VERSCHAFFELTI.—"J. P. F." wishes to know where he can purchase some for grafting on.

SLUGS ON LAWN (*A Long-standing Subscriber*).—Water it well with lime water during an evening when the slugs are on the surface. This, repeated two or three times at intervals of a day or two, will extirpate the marauders.

TOMATO CULTURE (*A Learner*).—Sow the seeds early in March in leamy soil, and place in a frame with a gentle heat, such as a Cucumbrerame, or one used for raising half-hardy annuals. When the plants appear and have made a pair of rough leaves, pot them off singly into small pots, retaining them in the frame a few days longer until they become established in the pots. For convenience they may be removed to ainery or other house at work, and have a shift in about a fortnight into six-inch pots, using a compost of turfy loam with a little leaf mould added. Kept well supplied with water they will grow fast, and stiff and strong also if they have a due share of light and air. Towards the end of April or early in May, they should be hardened off by placing in a cold frame, and be planted out from the middle to the end of the month, in the intervals between fruit trees on south walls, which is the only aspect of any value for them. They should be well watered in dry weather, and have the shoots trained to the wall as they grow, and when the fruit shows they should be stopped at the joint above it. After a sufficient quantity of fruit is set, and, in fact, throughout the season, keep the shoots closely stopped to one joint above the fruit, and take off those shoots and leaves that cover the fruit so as to expose it as much as possible to the sun.

CLIMBER FOR NORTH END OF HOUSE (*H. N. Barnett*).—The Virginian Creeper (*Ampelopsis hederacea*), will do fairly on a north aspect, but it is deciduous. Ivy, being an evergreen, we should think preferable. Hedera Ragnieriana or Ragnier's Ivy with magnificent heart-shaped leaves would suit your purpose.

**THRIPS ON CARNATIONS—MILDEW ON ROSES (D. C.).**—Your only plan of removing thrips from your Carnation blooms will be to have a cap made to fit over the plants and resting on the ground. Fill the cap with tobacco smoke and allow it to remain on until the smoke vanishes. This, repeated once or twice, will generally clear them sufficiently. Your Roses, we should think from your description, are severely attacked with mildew. The cause is want of moisture at the root, and wetting the foliage in dry weather. The preventive is to keep well watered at the root, and to syringe over the leaves. The cure after disease gains possession is to dust the parts affected with flowers of sulphur, and to wash this off forty-eight hours after the application. Should any vestiges of mildew remain dust the parts affected as before, and syringe it off with a solution of Gishurst compound at the rate of 2 ozs. to the gallon of water. Black sulphur, or sulphur vivum, is the best. We have found that what will prove efficacious one time will not do so at another, but the Rev. Mr. Radclyffe's remedy we have found effectual when others have failed—viz., 2 ozs. of blue vitriol dissolved in a little hot water, then mixed with four gallons of cold water, and poured over the tree with a rose watering-pot so as to thoroughly wet every part. This is a certain remedy, and will root out the evil after it obtains firm hold, and so will sulphur; but Gishurst and lime water require to be applied in the early stages.

**PROPAGATING SINGLE AND DOUBLE WHITE BRUGMANSIA (A Lady Subscriber).**—Take the points of the shoots not flowering, and when about half ripe as they will be now, and with two or three joints in addition to the growing point, remove the leaves from the two lowest, and cut transversely below the lowest. Inserted in light soil with a large per-centage of sand and plunged in a mild bottom heat, they will soon root. Another method is to take off the shoots when a few inches long with a little heel to them, and after removing the lowest pair of leaves to insert in sandy loam and plunge in a bottom heat of 75 or 80°. They may also be propagated from eyes or cuttings of the old wood, put in after the manner of Vine eyes and cuttings, a brisk bottom heat being necessary to plunge the pots in. February is the best month for this mode of propagation; May for the second; and July for the first, but now will do, or when the cuttings can be had.

**STUART'S BEAN TREE SEEDLING, WHEN WILL IT FLOWER? (Idem).**—If by Stuart's Bean tree, *Stuartia virginica* is meant, it will not flower for the next six years, and may just as likely be longer before it does so. If it be the one we mean, it is a deciduous tree with white flowers, and nearly if not quite hardy, quite as much so as Camellias of the hardier sorts. It will be best grown-on for about three years, and after that kept closely pinched-in and pot-bound so as to induce bloom. It requires a compost of turfy loam two-thirds, and sandy peat one-third, with a free admixture of sharp sand. Water freely when growing, gradually withholding moisture in autumn, and keeping just moist over the winter.

**CUTTING-IN OLEANDER—STOPPING CRASSULAS (Idem).**—The Oleander done blooming, or if it has not bloomed, may be cut-in to the lowest shoots, it being best to cut to shoots at this late season. The cutting-in will not then injure the bloom of next year; but if you cut-in closely so as to cause shoots to come from the old wood, they will not be sufficiently ripened to bloom well, if at all, another year. It would be better to defer the heading-down until May or June next year, if it be found necessary to cut so that no young shoots may be left. The plants will not be injured in the least by cutting-in. The Oleander, however, is a bad-habited plant at its best, it being very difficult to form it into a shapely specimen. By stopping the Crassula now you will put an end to the bloom of next year for the most part, and those shoots that bloom will be late. They will, however, make bushier plants for blooming the season after next, any shoots showing next year being stopped.

**SOIL FOR CALCEOLARIAS AND FUCSIAS (J. Noctias).**—Loam from rotted turves (cut 3 inches thick, laid up for twelve months in alternate layers with fresh manure, and turned over twice), chopped with a spade but not sifted, two-thirds; leaf-mould, three-parts reduced, one-third; and one-sixth of river sand well mixed together. In speaking or writing of 13-inch pots or other sizes, the diameter at top within the pot is meant, and not the depth. If you will oblige us with a communication we shall then be able to decide what to do with it.

**FRUIT TREES FOR SOUTH-WEST-BY-SOUTH WALL (Bramley Oaks).**—Your wall will answer perfectly well for Peaches and Nectarines. Apricots on low walls do not do well from the necessity of pruning. If you have them the trees will need root-pruning or lifting to check their vigour and keep them fruitful. Peaches and Nectarines being what you chiefly wish, we will say ten of them at 20 feet apart, the first tree at 10 feet from the end of the wall. *Peaches*:—One Early York, one Early Grosse Mignonne, one Grosse Mignonne, one Royal George, one Noblesse, one Barrington, and one Walburton Admirable, the seven succeeding each other. *Nectarines*:—One Elruge, one Pitmaston Orange, and one Violette Hâtive. If Apricots are wanted, then you will have one Royal in place of Walburton Admirable Peach, and one Moorpark in place of Pitmaston Orange Nectarine. Copings have been advocated, but we find the trees are healthier, the fruit as plentiful, and equally fine on uncoped walls as on those whose coping projects beyond the wall. They are unnecessary, and in our case worse than useless, for they are injurious. We have a splendid crop on our Peaches this year on the south walls, and they are fully better where the wall is low (8 feet as in your case), than on the general walls, which are 12 feet. Our soil is light and gravelly, the reverse of a good Peach soil, and we find all they want in such land is to keep the roots near the surface and out of the gravel, or from going deep into it, liberal dressings of manure, syringing the trees in dry weather to keep down red spider, and copious supplies of water, in addition, to keep mildew under. When the roots penetrate deep into the gravel, the trees become stunted in growth, bear little, and are much affected with mildew, and the points of the shoots constantly die back in winter. Those having trees in this condition should take them up just when the leaves fall (it does not matter how old the trees are), and plant again with the roots about 6 inches below the surface, in the top spit of a pasture if it can be had, and in the year afterwards there will be more fruit than in the preceding ten years. We mention this for the benefit of those having Peaches on walls, and who cannot induce them to bear fruit plentifully and with certainty, and especially for those having a light gravelly soil to contend with.—G. A.

**FOUR-LEAVED CLOVER (J. H. T.).**—It is only a sport, and a rare one, of the Common Clover. When found by the peasantry in some parts of Ireland and Scotland it is used by them as a charm. The only English name we know of *Viscaria oculata* is "Dark-eyed Rock Lychnis."

**ERECTING VINERIES AND PIPING FOR (T. E.).**—If you want a house cheap at first cost, procure one on the orchard or Sir Joseph Paxton system; if you want one to be lasting, that will cost little or nothing for annual repairs, and which will always look nice and light, get one of Mr. Beard's—see last column of "Doings of the Week" a fortnight ago. It would not be fair for us to recommend builders. You will not err if you employ such as advertise with us, but make all sure beforehand, and that makes the best friends. To have Grapes in July you would need about 240 feet of four-inch piping. If you want them in May and June you had better have from 350 to 400 feet of piping. The greenhouse would require 200 feet of piping, and more if you wished the heat in cold weather to be from 40 to 45° and onwards.

**VARIOUS (Peppy).**—You would see that your case was mostly met in our last answer. A small boiler would have suited, and the expense at 9d. to 1s. per foot for piping would not be great. A brick Arnott's stove would answer well enough fitted either in the house or the shed behind, and the top could easily be turned into a propagating-box. A portable iron one you can carry out in summer. We think either would keep out the frost. The frigidome covering, however, would be useful on the roof and ends, and would do for shade in summer. But if you could do without the covering in winter, a little whitening in milk painted once over the glass would give you shade enough in summer. A couple of Vines on the roof, with greenhouse treatment, will not hurt the plants below. Of course if you covered the roof the plants would suffer. From one or two stems of Vines planted outside, and taken in through the front wall, we still think you will have more success than from Vines in pots, but try the pots by all means if you like that plan best. The glass roof will be a great addition to your porch. We admire your arrangements as to windows and boxes. As evergreens we would advise *Acacia armata* and *Iophanta*, and, as a sub-evergreen, *Passiflora coralica*. Your little propagating-boxes, &c., will do better if the top is not hinged, but merely laid on. We like to turn them over, which sweetens the air and presents a dry glass to the plants and cuttings, and saves all wiping of the glass.

**BLISTERED PEAR AND PLUM LEAVES (O. d Sons).**—The brown blisters on the leaves are caused by little caterpillars the larvae of a beautiful little moth, of which a coloured drawing is in the now-defunct "Gardeners Magazine of Botany," and where Professor Westwood thus described it:—"The moth measures about a quarter of an inch in the expansion of the fore wings, which are of a glossy silvery white colour, the terminal portion being orange with white fringe, but varied on the fore margin near the tip with two white triangular spots, edged with black lines, and with a trident-like black mark at the tip, and with the inner margin terminated by a black spot glossed with purple; the hind wings are silvery white, with long fringe. The history of this species, (under the name of *Tinea Clerckella*, but now called *Argyromyces scitella*), was first made known by the late Mr. Knight. The perfect insect generally appears at the end of May, when the female deposits her eggs on the under surface of the leaves, the young larva penetrating the under cuticle, and feeding on the parenchyma, leaving the two surfaces of the leaf untouched, and thus forming large oval or rounded patches, several of which often unite together, and thus the greater part of the leaf assumes a blistered appearance. Mr. Johnson states that the Chamontel is especially subject to the attacks of this larva, as he had observed a standard tree of this variety annually attacked, whilst a Swan's Egg, and an Easter Bergamot in the immediate vicinity were comparatively untouched. It is at the beginning of the autumn that the leaves are observed to be most affected by the ravages of these larvae, which are fleshy, yellowish-white, hairy, and with six pectoral, eight abdominal, and two anal feet depressed. When full grown the larva pierces the upper cuticle of the leaf, and comes into the open air, it then spins some longitudinal threads close together on the upper side of the leaf, and beneath these forms its cocoon, which Mr. Curtis describes as boat-shaped, with the keel upwards of a very close texture, and with a slit at each end, the cast-off larva skin being thrust through one of these slits, and the moth escaping by the other. Sometimes these insects abound to such an extent as seriously to affect the growth of the trees, and the size and flavour of the fruit; indeed, Mr. Knight's Pear trees were so much injured that he at one time resolved to remove them. The chief remedy for preventing the mischief caused by this species seems to be the picking off the blistered leaves before the larvae have left them, or by sharply pinching with the fingers the blistered parts, in the case of small and valuable trees. The collecting, also, of fallen leaves at the close of the autumn is serviceable, as the chrysalides will thus be destroyed, and the propagation of the species in the following spring prevented."

**BEDDING GERANIUMS BLOOMING INDIFFERENTLY (An Old Subscriber).**—We think, as your Geraniums make good growth and but little bloom, that the soil is too rich. Either the soil is too rich or the plants are planted too closely and watered too freely. Your remedy will be to make the soil less rich; add nothing to it at the winter dressing in the shape of manure or leaf-mould, unless the soil is heavy, when a dressing of sandy loam would be advisable. If the soil is very rich, and naturally moist or heavy, the plants would do better as to flowering if plunged in their pots so as to cover the rim three-quarters of an inch to an inch deep; this will check their tendency to produce foliage and cause them to bloom more freely. Pauch is a strong grower at its best, but free-blooming generally; the others named are free-blooming generally. Stella is the very best dark scarlet bedding Geranium. We have it edged with a dwarf variegated Grass (*Dactylis glomerata elegantissima*), and the bed is indeed gorgeous. Lord Palmerston, another of the Neseagy section with crimson scarlet flowers and a good truss, we think inferior to Stella as a bedder, though fine for pot culture. Cybister is a superior bedding variety. Paul l'Abbé is a white Zonale kind, good for bedding, but does not stand sun and rain better than Madame Vaucher. A good pure white Geranium that will endure sun and wet is much wanted for bedding. *Diadematum*, when it can be had true, and that is Beaton's variety, is a very free-blooming bedding Geranium with rose-coloured flowers.

**STORING FRUIT (L. T. W.).**—We shall publish some general hints on the subject before the time arrives for storing fruit.

**CRATEGUS PRUNIFOLIA VARIEGATA (J. Major d Sons).**—The variegation is well marked and very pretty, and the colour is really golden and not that sickly hue too frequently met with in so-called golden plants.

**ROSE GROWER (P.).**—You will be quite safe if you give the order to the florist you name.

**ONION GRUB (H. A. F.).**—There is no cure for this. See what we said at page 85 of our Number published on August 1st about prevention.

**PRIVET FOR A HEDGE UNDER TREES** (*A Subscriber*).—Neither the leaves nor fruit are injurious to cattle. We have a hedge of it between a plantation and a park to which sheep, cows, and horses have access, and we never knew them eat either the leaves or fruit, or if they did they were not injured by them. Birds eat the berries, particularly the bullfinch, and the leaves have an astringent bitter taste, and are sometimes used along with the flowers in the form of decoction for sore throat and scorbutic ulceration of the mouth. Privet does much better than Quicks under the shade of trees, but is somewhat difficult to establish after the trees are grown up. We planted it and Hollies to thicken a Thora hedge under trees, and the Hollies, if anything, had the best of it, but are much slower-growing than Privet.

**WINTERING COLEUS VERSCHAFFELTI, SOLANUM MARGINATUM, AND WIGANDIA CARACASANA** (*idem*).—By withholding water now from *Coleus Verschauffelti* the shoots would become harder or less gross, and not so liable, therefore, to suffer from damp in winter. It should not be suffered to become soddy as to cause the leaves to fall and the shoots to flag and shrivel. To keep it safely it requires a warm greenhouse. *Solanum marginatum* is a half-shrubby perennial. *Wigandia caracasana* is also perennial. They should be taken up towards the end of September, or before frost, potted, and kept in a greenhouse with no more water than is sufficient to keep them alive. After February they should be encouraged so as to secure free growth, and have it well hardened off before planting out early in June.

**FERNERY SHADING** (*W. H. Alger*).—Glass that can be seen through will not obstruct the sun's rays, and will, in fact, be no shade. Coloured glass will be sufficient shade; but as this is what you especially wish to avoid, a thin blind to draw up and let down would serve your purpose. It is only when the sun shines powerfully that the blind will be required, and that will equally be the time when the window could not be seen through, so that we do not see any objection to such a blind. But we may have misunderstood your case; if so, write us again.

**VINE LEAVES SHRIVELLED—BORDER-MAKING** (*S. T.*).—The leaves exhibit those appearances found on Vines in a cold wet border with the roots deep, and are besides scorched by the sun acting powerfully on the leaves whilst wet, probably from the deposition of moisture on them during the night, and not giving air sufficiently early to dry them before the sun strikes powerfully on the house. The paragraph alluded to, and quoted

from "Sanders on the Vine," refers to the particular houses of his planning and not to vineries generally. It is necessary and important, for the houses alluded to, that the border be exactly on a level with the interior flooring, as will be found on referring to the plans in the work. It is of no import, however, when the roots are wholly outside, and it would be better if the borders of all vineries were made not only level with the floor of the house but at least half its depth above the surrounding ground level, especially where the subsoil is wet and heavy. By all means raise the borders, and have nothing upon them that roots deeply, much less Rhubarb, &c.

**CALIFORNIAN PUMP**.—*West Croydon* wishes to know if any one has tried this pump, and if so, would he give some information about it? We never heard of a pump so named.

**NAMES OF INSECTS**.—*Dr. Stuart* is quite correct in supposing the insects which have destroyed the foliage of his Jargonelle Pear to be the larvae of the *Tenthredo Cerasi* of Linnaeus, or the *Selandria Ethiops* of Fabricius and recent authors. The larva, called commonly "Slimy Grub," at the surface of the leaves as well as the parenchyma. They are produced from eggs deposited by the black-winged Sawflies in June and July. Dusting with lime kills them. (*Fulham, S.W.*).—The earwigs are produced from eggs, which are deposited in the spring by the females. The young ones exactly resemble their parents, except in wanting the wings and short wing-covers. The long thin worms which you have found within them, are parasites of the genus *Gordius*, of not uncommon occurrence in the bodies of these insects.—*W.*

**NAMES OF FRUIT** (*A Constant Reader, Sydenham*).—Plums:—1, Jefferson; 2, Kirke's; 3, Early Orleans; 4, Royal Dauphin; 5, Downton Imperatrice. (*C. R.*).—Apples:—1, Scarlet Nonpariel; 2, Minchall Crab; 3, Lord Suffield; 4, Fearn's Pippin; 6, Golden Harvey.

**NAMES OF PLANTS** (*C. P.*).—1, *Pteris cretica albo-lineata*; 2, too imperfect, probably young and very weak *Pteris cretica*; 3, *Doodia caudata*. All three will do in a Fern case. If infested with brown scale they should be cleaned before introducing them among other plants. (*A. S. P.*).—1, *Todea hymenophylloides*, often called *Leptopteris* and *Todea pellicuda*; 2, *Dicksonia squarrosa*; 3, *Polystichum venustum*; 4, *Asplenium Coleusoides*. (*A. B.*).—1, *Paulownia imperialis*; 2, *Enonymus japonicus*; 3, *Quercus ilex*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending August 26th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
			Air.		Earth.				
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.			
Sun... 20	29.927	29.803	76	51	64	62	S.W.	.26	Fine; very fine; mild at night.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

OUR DAILY FOOD.

THE food question is daily becoming more important, and spite of the reluctance there has always been to entertain poultry as being part of it, we cannot help thinking that eggs and birds must at last assume the importance that belongs to them. We can easily dismiss the former question by repeating the thrice-told tale—we import a million every day in the year, and yet have not enough of them to be within the reach of a cottager for a sick wife or child.

Every country but England has statistics of these things. It is known in France how many eggs and fowls are produced in each department, how many are consumed at home, how many are sent to the capital or other departments, how many are exported. The result is that France receives from us annually millions of pounds sterling. They encourage and increase the amount; we care not for these things. We dabble at times with cookery, and tell of the good things that may be made with even an old hen, and we believe in many a house in the country and suburbs of London, at a time when some look askew at beef on account of the murrain, and "Paterfamilias" speaks ominously about the price of mutton, and seems to think that we consume too much animal food, the refuse of the poultry stock may be turned to good account. We have poultry companies and hatching machines (limited); they enjoy but small public favour. People pooh-pooh poultry, but things in connection with it are heaving themselves up, and will at last assume proportions that will intrude themselves on public notice, and, like the tax-gatherer, insist on being seen. Abstinence sharpens the wit as well as the appetite, and the present price of meat may make some look pleasantly at the rather

coarse fowl that was rejected not long ago; and in the absence of the lump of meat, the system that by plain roasting and boiling reduces that on a fowl to the smallest possible amount, may be exploded for judicious and delicate cookery, which makes that which would be a hard or dry fowl the foundation of a delicious and satisfying family dish.

EXHIBITING POULTRY UNSHELTERED.

WILL you allow me to draw the attention of the managing committees of many of our poultry shows to a most serious drawback to success, both as regards the permanency of such meetings, and also the amount of present entries likely to be secured, from the reprehensible practice of placing the competing birds fully exposed to all the vicissitudes of the weather? This really objectionable plan has, to my own personal knowledge, been a chief cause of the failure of many an exhibition that otherwise might at the present hour have been a well-established institution. Of course it is quite impossible for any one with certainty to predict the kind of weather that may arise during the continuance of a show, and it is well known that the greater portion of our exhibition birds are so carefully tended when at home as to render them even more susceptible to the influence of sudden atmospherical changes than birds would be if taken direct from the more hardy treatment of a farmyard.

The practice now alluded to occurs chiefly, I am glad to say, in the case of poultry and Pigeons exhibited in connection with agricultural societies; but as these combined meetings of cattle and poultry are annually increasing in numbers, a few brief hints to forewarn may not be out of season, more particularly as a goodly number of such meetings are now near at hand. Among many objections that might be named, a few of the principal ones are these.

The foreknowledge that any show of poultry will not take place under cover prevents many of the best and most valued specimens being entered at all, and this of necessity detracts materially from the interest of the exhibition.

In case of rain not only are the birds seriously injured for exhibition at all future meetings, but also, in the event of absolute saturation of the plumage, as I have myself again and again witnessed, the awards made under such adverse circumstances amount rather to a guesswork than otherwise, as perfection of combs and general outline are the only data a judge has then at command; for the all-important point, plumage, is temporarily placed beyond discrimination, and arbitrators are compelled to satisfy themselves by simply doing the best they can under so inextricable a difficulty.

Nor does the damage arise exclusively from rain, for long exposure to a burning sunshine enases as irremediable an injury to birds, if subjected continuously to its influences, as does the most boisterous weather. In proof: No doubt many of the readers of THE COTTAGE GARDENER well remember the truly magnificent Cochlin cock so frequently and so continuously shown by the late Mr. Gueldard, of Acrigg End, near Kendal. It was apparently a fowl of extraordinarily strong constitution, and the most protracted show, to use Mr. G.'s own words, "never seemed too long for him, nor was he ever exhibited without prizetaking." In fact, it was, I admit, one of the very best Buffs I ever yet saw, being a pure even gold colour throughout, with comb, face, and wattles brilliant as coral. At the last Anerley Show, this valuable specimen succumbed to intense sunlight, and that alone. After this exposure the comb suddenly blackened, the cock became inert, and altogether listless, and shortly afterwards fell down dead, to the great annoyance and irreparable loss of its owner. Nor was this the only bird by several, whose deaths took place shortly after this one exhibition. It is beyond question that birds, however much they may voluntarily enjoy bright weather, cannot endure constant exposure to an almost burning sun. It absolutely kills them, and the space of time requisite is but a brief one. These results can never ensue in cases where adequate protection is afforded to the imprisoned birds, for then every one connected with the exhibition has at least the honest consolation, that all things necessary to ensure success were provided, and even should the mishap of unpleasant weather ensue, still a Committee may reasonably calculate on at least a portion of those visitors, who, if the whole affair is "open to the sky," naturally abstain from coming at all.

I should not have intruded this long letter upon your space, but even this day two different amateurs have solicited me to give my own opinions on this important subject in connection with poultry exhibitions, supposing "it might carry more weight than their own," when labouring under the vexation of seeing several pens of their own expensive poultry utterly ruined, if not killed outright, by the incessant rains during a recent exhibition. I will merely add in conclusion, that simple justice to the exhibitors who confide expensive poultry to any committee's safe keeping, demands a suitable protection for the birds so sent, quite independently of the obvious cruelty to the fowls (or Pigeons, as the case may be), if a contrary course, so so "penny wise, and pound foolish," is pursued.—EDWARD HEWITT, *Eden Cottage Sparkbrook, near Birmingham.*

[Until we received this communication we were not aware that any Committee had been so thoughtless and barbarous as to have the poultry entrusted to them exposed to all the vicissitudes of our climate. No one having a pen of birds would allow them to be exhibited in this manner, unless he was entirely neglectful of his own interests, and regardless of his bird's sufferings.—EDS.]

### ROYAL AGRICULTURAL SOCIETY OF IRELAND'S EXHIBITION.

THIS took place on the 17th instant at Clonmel. The show of poultry was tolerably good in some of the sections. Mr. Williams had the medal as the exhibitor who won the greatest number of prizes, and Mr. Boyle and Mr. J. Hyland came off very well also. Mr. W. Magrath, Blesinton, won with his Silver-Grey Dorking cockerel and couple of pullets, in which section Sir Robert Paul, or, rather, his young son, who has in this way begun his apprenticeship as an exhibitor, was also successful, both of the winning lots being nice fowls.

DORKING (Silver-Grey).—First and Second, R. P. Williams, Glaslun, Clontarf. Highly Commended, J. C. Cooper. *Chickens*.—First, W. Magrath, Blesinton. Second, Sir R. Paul, Bart., Waterford.

SPANISH.—First, R. P. Williams. Second, Miss F. E. Prittie, Oakville,

Clonmel. [*Chickens*.—First, R. P. Williams. Second, R. W. Boyle, Wicklow.

BRAMA POOTRA.—First and Second, R. W. Boyle. *Chickens*.—First and Second, R. W. Boyle.

COCHIN-CHINA.—First and Second, R. P. Williams.

TURKEYS.—First, J. Hyland, Dublin. Second, S. Perry, Clonmel. *Poults*.

—First, Miss A. Hyland, Dublin. Second, J. T. Abbott, Cahir.

GEESE.—First, R. W. Boyle. Second, S. Perry. Third, J. C. Cooper, Limerick.

DUCKS (Aylesbury).—First, R. P. Williams. Second, R. W. Boyle. Highly Commended, R. P. Williams.

DUCKS (Rouen).—First and Second, R. P. Williams.

To the exhibitor who has won the greatest number of prizes in this class, the medal.—R. P. Williams.

JUDGES.—Messrs. Darker and Stanton.—(*Irish Farmers' Gazette*.)

### FULFORD POULTRY SHOW.

THE second annual Exhibition of poultry and Pigeons in connection with the Floral and Horticultural Society, was held on the 16th inst. The village of Fulford is of easy access from the city of York, and a numerous and highly respectable company were present on the occasion. There was a considerable increase in the exhibition of poultry this year; and the Pigeons, though not numerous, contained some very good specimens. The following is the list of the awards:—

SPANISH.—First, W. Massey, Fulford. Second, Miss Hustler, Stillingfleet.

DORKING.—First, T. Mason, Green Hammerton. Second, Miss Hnstler. COCHIN-CHINA.—First, and extra for the best pen of poultry, W. Massey. Second, J. Braddock, York.

GAME.—Prize, J. Barker, Dunnington.

HAMBURGH (Golden-spangled or Pencilled).—First, J. Darbyshire, Green Hammerton. Second, G. Hutchinson, York.

HAMBURGH (Silver-spangled or Pencilled).—First, — Cumberland, York. Second, H. Steward, Bishopthorpe.

ANY OTHER BREED EXCEPT BANTAMS.—First, Mrs. Carey, Heslington. Second, J. Warnford, Dunnington.

CHICKENS (Any Breed).—First, W. Massey. Second, Mrs. E. Ledgard, Poppleton.

BANTAMS.—First, Miss Hustler. Second, J. Barker.

SELLING CLASS.—First, J. Barker. Second, — Cumberland.

GEESE.—First, A. S. Perfect, Fulford. Second, Mrs. Ledgard.

TURKEY.—Prize, A. S. Perfect.

DUCKS.—First, J. Elsworth, Whixley. Second, A. S. Perfect.

PIGEONS.—*Carriers*.—First, J. Thackray, York. Second, W. Massey.

*Tumblers*.—First, J. Thackray. Second, A. Cattley, York. *Pointers*.—Prize,

E. Wilson. *Jacobins*.—First and Second, W. Massey. *Fantails*.—First,

J. Thackray. Second, A. Cattley. *Dragons*.—First, W. Massey. Second,

J. Thackray. *Any other Variety*.—First, W. Massey (Earbs). Second, J. Thackray (Swallows).

JUDGE.—Mr. Anton, York.

### UTTOXETER POULTRY SHOW.

(From a Correspondent.)

THE Uttoxeter Poultry Show, in conjunction with the Annual Floral and Horticultural Exhibition, was held on Friday, the 18th inst., and comprised a choice collection of different breeds of poultry from all parts of England. Great care was taken by the Committee that satisfaction should be given to exhibitors, and pens of ample dimensions were provided for the exhibition of their different specimens, both great and small birds alike occupying pens 3 feet wide by 2 feet 6 inches high, faced with two-inch wire netting, an arrangement which was highly applauded by those exhibitors who were present. These pens, we may add, were especially built for the occasion, and are the property of the Society, and will be used at future exhibitions, when more classes will be thrown open and higher prizes given for competition. On the part of the Committee, neither pains nor expense will be spared to place the show for poultry on a first-class footing, and to render it acceptable to intending future exhibitors, which they hope will secure a continuance of their valued support. Considering it was a new thing in this place, it was a decided success; the birds sent for competition were first-class.

SPANISH.—First, W. Bayliss, Walsall. Second, G. Walker, Sandon. Highly Commended, F. Bagshaw, Uttoxeter. Commended, E. J. Blair, Uttoxeter. *Chickens*.—Prize, E. J. Blair, Uttoxeter.

DORKING.—First, Sir St. G. Gore, Bart., Wirksworth. Second, F. Bagshaw, Uttoxeter. *Chickens* (any variety).—First, Sir St. G. Gore, Bart., Wirksworth. Second, J. McConnell, Lime Crofts.

COCHIN CHINA.—First, J. Stephens, Walsall. Second, J. Bakewell, jun., Uttoxeter. Highly Commended, Rev. S. C. Hamerton, Stafford. *Chickens*.—Prize, F. Bagshaw, Uttoxeter.

GAME (Duckwings and other Greys and Blues).—First, Sir St. G. Gore, Bart., Wirksworth. Second, W. F. Taylor, Doveridge Hall.

GAME (Black and Brown-breasted Reds).—First, W. S. Bagshaw, Uttoxeter. Second, Mrs. Hay, Sudbury.

GAME (Any variety).—Prize, Sir St. G. Gore, Bart., Wirksworth. *Chickens*.—First and Second, J. Bakewell, Draycott. Highly Commended, Mrs. Hay, Sudbury; C. Minors, Sudbury; Sir St. G. Gore, Bart., Wirksworth; T. Lowndes, Cheadle; W. F. Taylor, Doveridge Hall.

HAMBURGH (Golden-pencilled).—First, The Hon. T. W. Fitzwilliam, Rotham. Second, E. Tate, Leeds. Highly Commended, Sir St. G. Gore, Bart., Wirksworth.

HAMBURGH (Silver-pencilled).—First, A. K. Wood, Kendal. Second, C. Minors, Sudbury. Highly Commended, E. Bell, Burton.

HAMBURGH (Golden-spangled).—First, A. K. Wood, Kendal. Second, R. Tate, Leeds.

HAMBURGH (Silver-spangled).—First, A. K. Wood, Kendal. Second, Sir St. G. Gore, Bart., Wirksworth.  
 POLANDS.—Prize, S. Mills, Walsall.  
 HAMBURGH CHICKENS (Any variety).—First and Highly Commended, C. Minors, Sudbury. Second, S. Finney, Ashbourn. Highly Commended, H. Bagsbaw, Uttoxeter.  
 BANTAMS (Black or White).—First, Sir St. G. Gore, Bart., Wirksworth. Second, — Lasbrey.  
 BANTAMS (Any variety).—First, Sir St. G. Gore Bart., Wirksworth. Second, W. F. Entwisle, Yorkshire.  
 DUCKS (Aylesbury).—Prize, Sir St. G. Gore, Bart., Wirksworth.  
 DUCKS (Rouen).—First, Sir St. G. Gore, Bart., Wirksworth. Second, J. Bakewell, Uttoxeter.  
 DUCKS (Any variety).—First, Sir St. G. Gore, Bart., Wirksworth. Second, Mrs. Wolferstan, Tamworth.  
 GESE.—First, F. E. Richardson, Bramshall. Second, J. Bakewell, jun., Uttoxeter. Extra Prize, W. A. Rawlins, Stramshall (Chinese).  
 TURKEYS.—First and Second, F. E. Richardson, Bramshall.  
 GUINEA FOWLS.—Prize, J. Bakewell, jun., Uttoxeter.

#### SWEETSTAKES FOR SINGLE COCKS.

Game.—First, J. Bakewell, Draycott. Second, Mrs. Hay, Sudbury.  
 Spanish.—Prize, W. Newman, Walsall. Dorking.—Prize, C. Minors, Sudbury.  
 Game Bantams.—First, Hon. T. W. Fitzwilliam, Rotherham. Second, J. Bakewell, Draycott.

### MOTTRAM POULTRY SHOW.

THE first show of Poultry, Pigeons, &c., was held at Mottram, on Monday, the 21st of August, in the large room and yard of the Victoria Works, which were well adapted for the purpose. The prizes were not very large, but they brought together 130 peas, which was thought very good for a country village, and there were some good birds shown. The exhibition was acknowledged to be a success, and the promoters hope next year to add largely to the prize list.

The following awards were made:—

DOBKINGS (Any variety).—Prize, C. W. Brierley, Middleton.  
 SPANISH.—First, W. H. Gaskell, Matley. Second, S. and R. Ashton, Mottram. Chickens.—First and Second, S. and R. Ashton, Mottram.  
 COCHINS.—First, C. W. Brierley, Middleton. Second, T. Dearnley, Hadfield. Chickens.—First, A. Bamford, Middleton. Second, A. Kidd, Hadfield.  
 GAME (Black-breasted and other Reds).—First and Second, C. W. Brierley, Middleton. Chickens.—First, J. Ashton, Mottram. Second, Messrs. S. and R. Ashton, Mottram.  
 GAME (Any other variety).—First, C. W. Brierley, Middleton. Second, W. Reddish, Mottram.  
 HAMBURGHS (Gold-pencilled).—First, T. Walker, jun., Denton, near Manchester. Second, T. Wrigley, jun., Middleton. Chickens.—First and Second, T. Wrigley, jun., Middleton.  
 HAMBURGHS (Silver-pencilled).—First, A. K. Wood, Kendal. Second, Messrs. S. and R. Ashton, Mottram. Chickens.—First, E. Collinge, Middleton. Second, Messrs. S. and R. Ashton, Mottram.  
 HAMBURGHS (Gold-spangled).—First, J. Roe, Hadfield. Second, A. K. Wood, Kendal. Chickens.—First, J. Baneroff, jun., Ashton. Second, J. Roe, Hadfield.  
 HAMBURGHS (Silver-spangled).—First, A. K. Wood, Kendal. Second, Messrs. T. M. and J. Ashton, Mottram. Chickens.—First and Premium Prize, best pen in the show, E. Collinge, Middleton. Second, Messrs. T. M. and J. Ashton, Mottram.  
 POLANDS (Any variety).—First, C. W. Brierley, Middleton. Second, Messrs. S. and R. Ashton, Mottram. Chickens.—First and Second, Messrs. S. and R. Ashton, Mottram.  
 ANY VARIETY.—First, C. W. Brierley, Middleton. Second, W. McMillon, Glossop. Chickens.—First, Messrs. T. M. and J. Ashton, Mottram. Second, Messrs. S. and R. Ashton, Mottram.  
 BANTAMS (Game).—First and Second, C. W. Brierley, Middleton.  
 BANTAMS (Any variety).—First and Second, C. W. Brierley, Middleton.  
 DUCKS (Aylesbury).—Prize, Messrs. S. and R. Ashton, Mottram.  
 DUCKS (Any variety).—First, C. W. Brierley, Middleton. Second, J. Nelson, Manchester (Rouen).  
 GESE.—Prize, Messrs. S. and R. Ashton, Mottram.  
 TURKEYS.—First, C. W. Brierley, Middleton. Second, Messrs. S. and R. Ashton, Mottram.  
 PIGEONS.—Carriers.—First, C. M. Roysds, Rochdale. Second, H. Roberts, Mottram. Pouters.—First, C. M. Roysds, Rochdale. Second, W. H. Gaskell, Mottram. Dragons.—First, N. Tinker, Mottram. Second, C. M. Roysds, Rochdale. Jacobins.—First, C. M. Roysds, Rochdale. Second, W. Booth, Mottram. Almond Tumblers.—First, T. Wilkinson, Staley-bridge. Second, Miss J. E. Baneroff, Mottram. Owls.—First, C. M. Roysds, Rochdale. Second, Miss J. E. Baneroff, Mottram. Barbs.—First, N. Tinker, Mottram. Second, W. H. Gaskell, Mottram. Any new or distinct Variety.—First, J. Midwood, Saleybridge. Second, T. Walker, Denton.

Mr. James Dixon, Bradford, officiated as Judge.

### DEANE POULTRY SHOW.

THIS took place on the 23rd inst., when the following awards were made:—

SPANISH.—First and Second, N. Cook, Chowbent.  
 DORKING.—First and Second, S. Farrington, Astley.  
 GAME COCK.—First and Second, J. Wood, Moat House, Haigh. Highly Commended, J. Turner, Radcliffe.  
 GAME.—First, J. Wood, Haigh. Second, J. Turner, Radcliffe.  
 COCHIN-CHINA.—First, E. Smith, Middleton. Second, A. Bamford, Tonge Lane, near Middleton.  
 HAMBURGH (Golden-pencilled).—First, T. Wrigley, jun., Tonge, near Middleton. Second, N. Marlor, Denton, near Manchester. Highly Commended, J. Turner, Radcliffe.  
 HAMBURGH (Silver-pencilled).—First, J. Platt, Dean. Second, A. K. Wood, Burneside, Kendal. Highly Commended, Mrs. Price, Halliwell.

HAMBURGH (Golden-spangled).—First, N. Marlor, Denton. Second, W. Parr, Patricroft. Highly Commended, A. K. Wood.

HAMBURGH (Silver-spangled).—First, R. Walker, Westhoughton. Second, A. K. Wood.

POLANDS.—First and Second, S. Farrington, Chat Moss, Astley.

ANY OTHER VARIETY.—Prize, N. Cook, Chowbent.

GAME BANTAMS.—First, F. Abbott, Wallsuches, Horwich. Second, J. Turner, Radcliffe. Highly Commended, M. Kay, Horwich.

ANY OTHER VARIETY.—First, S. Farrington. Second, C. W. Brierley, Rhodes House, Middleton. Highly Commended, N. Platt, Dean.

DUCKS (Aylesbury).—Prize, E. Leech, Greave House, Rochdale.  
 DUCKS (Rouen).—First, T. Wakefield, Golborne. Second, W. Parr, Patricroft. Highly Commended, E. Leech, Rochdale.

DUCKS (Any other variety).—Prize, S. Farrington, Astley.

GESE.—First, L. Walls, Westhoughton. Second, W. Green, Wharton Hall. Highly Commended, J. B. K. Grover, Worley.

TURKEYS.—J. Wood, Brinscall Hall Chorley. Second, J. Wood, Haigh, Cambridge.

PIGEONS.—Carriers.—First, C. & E. Roysds, Rochdale. Second, A. Lowe, Over Hulton. Tumblers.—First, H. Yardley, Birmingham. Owls.—First, C. & E. Roysds, Second D. Bromiley, Over Hulton. Croppers.—First, H. Yardley. Second, C. & E. Roysds. Fantails.—First, S. Farrington, Astley. Second, G. Caldwell, Westhoughton. Dragons.—First and Second, D. Bromiley, Over Hulton. Antwerps.—First, W. Markland, Dean. Second, H. Yardley. Any other Variety.—First and Second, D. Bromiley. Extra Stock.—First, W. Green, Wharton Hall. Second, W. Markland.

### PREVENTING BROOD IN SUPERS.

IN taking off both glass and bar-frame supers this summer I have found in them much brood, and in one glass super a number of dead drones on the bottom. In another glass there was an immense quantity of brood comb, but the bees were hatched. All this spoils the appearance of both supers and honey. Will you kindly tell me if this arises from the openings in the adapting-boards being cut too wide? Is a quarter of an inch the proper width to allow the worker bees to ascend into the supers without admitting the queen or the drones? I have had very great trouble this summer in inducing the bees to leave their supers at all, and there has been great commotion and fighting amongst them. I see in "our Journal" that it is recommended to put an empty box under the super you wish to remove. Should the box be put on the day before you wish to remove the super? Must the box be open top and bottom? or will it answer to lift up the super from the adapting-board and put the box upon it? Still it appears to me that the latter must be open top and bottom. I have two hives with ekes; ought I to remove these before winter, and when? The bees in these two hives have worked the comb to the floor-boards, I mean the full depth of the ekes.—J. W.

[We do not know how entirely to obviate breeding in supers and at the same time insure free access by the bees. It has been attempted by permitting communication only through a number of narrow apertures, three-sixteenths of an inch wide, and about 2 inches long, placed close together, and looking something like a miniature wooden gridiron, but we have never seen the plan tried. The empty box should be open at top and bottom, and should be interposed between the adapter and the stock-hive the day before the removal of the super, which should be taken off before the bees get fully to work the next morning, when it will be nearly deserted. We find it a very good plan to use two adapters, which much facilitates removal.

In this case the empty box should be inserted between them, the upper one being raised with the super, and the under one remaining on the hive. We should remove all ekes in October, shortening at the same time such combs as require it. This is readily done by first puffing a little smoke under the hive, and then turning it up and cutting off as much of the combs as may be necessary.]

### REMOVING SUPERS—PREVENTING SWARMING.

HAVING a very heavy super to remove from a Woodbury frame hive, I was in considerable difficulty as to the best and quickest plan of removing it and expelling the bees, till the communication of Mr. Bevan Fox so opportunely appeared in "our Journal" of August 1st; he there gives us the results of his experience in such a clear and conclusive manner that I determined to adopt his plan, in which I succeeded beyond my expectation. The super was a heavy one, weighing 5 lbs., and crowded with bees, and by adopting the driving system I got all the bees out, with the exception of about a dozen stragglers, in from fifteen to twenty minutes. As you have many inquiries as to the best plan of performing this operation I wish in gratitude, to Mr. S. B. Fox, and for the benefit of other amateurs like myself, to add my little testimony to the excel-

lence of his plan. If Mr. Fox could favour us with any plan equally efficacious in preventing swarming, I, for one, should be greatly obliged to him, as I find it is no trifling matter to remove a heavy super from an immensely strong stock and search the frames for royal cells, an operation which the bees resent as a most unwarrantable liberty; and I have found that with plenty of room in the super and a nadir 3 inches deep a swarm came off in the latter part of July, and was lost to the great annoyance of—G. L.

### TAKING HONEY FROM SUPERS.

A FRIEND of mine keeping bees took off a super a few days ago, and upturned it for the sake of letting the bees go about 4 yards from the hives, and on going to it in about four hours he found the bees had carried all the honey back into the hive, leaving the empty comb.—S. T.

[In removing supers the greatest care is always requisite to elude the vigilance of the bees, whether of the parent stock or of neighbouring hives, all being equally alert and active in "looting" on these occasions.]

### REMOVING BEES IN THE AUTUMN.

#### DRONE SLAUGHTER—SUCCESS OF SECOND SWARMS.

I CONSTANTLY read of the autumnal purchasing of stocks for the establishment of an apiary, but have failed to discover from any author which I have consulted the exact period of the autumn at which their removal should take place. Will you kindly inform me on this point? also the best plan for conveying the bees with their plant a distance of two miles, and should the removal take place by day or night? I suppose a strong early swarm of this year, with hive full of honey, would be preferable to a stock of last season which has been allowed to swarm. I have my choice of either.

The very gloomy and wet weather which we have had in Ireland since the middle of last month has completely put an end to the honey season here, and, with the exception of carrying on an unmerciful war against the drones, my bees have almost struck work entirely. I was surprised the other evening in walking among my hives, after one of the few fine days we have lately had, to discover on the ground not only a large number of slaughtered drones but also several drones in the grub state which had evidently been torn from their cells and forcibly ejected from the hive. Not being an apiarian of long standing this surprised me, but I remembered reading of the circumstance in "Goldsmith's Animated Nature," and on reference I found the following: he quotes from the authority of Reaumur—"Nay, the working bees will even kill such drones as are yet in the worm state in the cell, and eject their bodies from the hive among the general carnage."

For the information of those who are doubtful as to second swarms flourishing during winter I may add that I hived on the 28th of June last a small second swarm in a Scotch hive. At this moment it is not only crammed with honey but a small super also, and I do not think I ever saw a larger colony. It was under this hive that the circumstance I mentioned above occurred.—SQUIB, *Co. Kildare*.

[Stocks may be purchased and safely removed to a distance of not less than a mile and a half as soon as the evenings become chilly. After dusk they should be tied up in a coarse cloth of open texture (cheesecloth), and all egress being rendered impossible by a string tied tightly round the hive about 2 inches from the bottom, conveyed carefully to their destination. A swarm of this year would have the advantage of new comb, but might have a very old queen, whilst a stock which has swarmed this season must have a young queen but old comb. Both, therefore, have their advantages and disadvantages; and it is only by balancing these, aided by inspection and a knowledge of the history of each, that a judicious decision can be arrived at.]

### DRIVING AND UNITING BEES.

I HAVE three stocks of bees in common straw hives. I have this season had one swarm from each of them, which swarms were hived respectively in a Woodbury-hive, one of Gale's hives, and one of Neighbour's hives. I now wish to do away

with the old stocks entirely, but think I ought to save the bees. How could I best put them into the three new hives which are now occupied by the three swarms, which I suppose would be worth doing, so as to increase the numbers in these hives?—BRAMLEY OAKS.

[Drive the bees out of the old hives, and unite the inhabitants of each to the nearest swarm in the manner recommended in page 59 of the fifth edition of "Bee-keeping for the Many."]

### HONEY HARVEST NEAR STAFFORD.

#### DRONE BRED IN A ROYAL CELL—FERTILE WORKERS.

UP to the end of June the present was a splendid honey season in this neighbourhood. Very little has been collected since; many late swarms are even suffering from want of food. Swarms generally were not very early, I only heard of two or three in May. I only kept three stocks last winter, but they were three good ones. From these, besides several brood combs, I have had one natural swarm and 123 lbs. of honeycombs in supers. I also took a super, containing 75 lbs. of beautiful honeycombs, off a Woodbury frame-hive belonging to a lady neighbour. During the present showery weather I notice that Ligurian bees are more attentive than the common ones to borage and other garden flowers. I have quite recently had a royal cell tenanted by a drone, which came to maturity, and issued from the cell in the usual way. The case, however, was not similar to the very interesting one related by "A DEVONSHIRE BEE-KEEPER," there having been none but drone eggs in the hive; nor was it quite like those recorded by Huber, the egg being that of a fertile worker, and the royal cell being, I think, formed round it after it was laid, as is usual in compulsory queen-rearing. It came about in the following way:—On the 17th of July I examined a small artificial swarm to which I had given a brood comb on June 17th to raise a queen from. I found very few bees remaining, and no queen. Two out of their three combs had each a small patch of drone cells in its lower corner, and in one of these I thought I saw eggs, but owing to my having a bee-dress on, and to its being late in the evening, I could not be sure, so I cut a small piece off to examine afterwards by a better light. I found that it contained several eggs in each of the cells, some had as many as a dozen each. On the 26th I examined again, and found three royal cells formed on the drone-comb along the cut I had made on the 17th. One was sealed over, another had a good-sized grub, the third was not tenanted. I examined them frequently afterwards, and at last on the 10th of August I found the royal cell open at the end, and a fine young drone perambulating the comb. The grub had disappeared from the other cell, and there was no other drone in the hive. Very few of the eggs had hatched, and those few were not in a forward state. I found that egg-laying had continued in the patches of drone-comb, but that none had been laid in worker cells. That they were the produce of fertile workers I have no doubt; it is not likely that I so often overlooked a queen among so few bees; while the formation of royal cells, and the continuance of egg-laying afterwards, are, to my mind at least, conclusive evidence.—JOHN P. EDWARDS, *Shirleywich, near Stafford*.

### OUR LETTER BOX.

SPANISH COCK'S FACE BECOME PARTLY RED (*Typo*).—It is not uncommon for a good Spanish cock to show red in his face when moulting. If formerly his face was entirely white, it will be so again, but you must not deceive yourself. If his face was not white before, it will not be so when he has done moulting. The fowls you mention are Black Hamburgs.

POULTRY IN A TOWN (*Old Subscriber*).—All your wants will be attained by your keeping either Cochin or the Brahma Pouter fowls. Both will thrive in confined spaces, both are good layers, and will furnish a meal.

POULTRY BASKET (*H. J. C.*).—There can be no doubt that Mr. Bartlett should have long since had a final settlement with you, but it is not a transaction entitled to notice in our columns.

CANARY CONTINUALLY MOULTING (*G. F.*)—I should think that there is something in the place where you keep your canary that is injurious to him. Do you keep him where gas is burned, or in too warm or close a place? Draughts are not good, but the birds do best with fresh air. Let the food be quite plain, as canary seed and clean water. Sand the bottom of the cage. He may have as much green food as he will eat, a piece of bread or biscuit to peck, or a few oat grits; but avoid sugar, cake, hump, or rape seed, and indeed all trash.—B. P. BRENT.

CLITHROE POULTRY SHOW.—I see the Judges have awarded me the second prize in Cochins at the Clithroes Show. This is an error, as I never sent my birds, the weather being so bad.—R. J. WOOD.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 67.2°, and its night temperature 46.9°. The greatest heat was 83°, on the 5th, 1848; and the lowest cold, 50°, on the 6th, 1850. The greatest fall of rain was 1.09 inch.

WHAT IS THE CAUSE OF GRAPES NOT COLOURING?

The art of horticulture it may be truly said we learn more every year we live. Many problems have been solved; many more remain unsolved; much has been accomplished by the lights that have gone before, but we still, and must ever, see through the horticultural glass darkly and imperfectly, finding something that a combination of scientific with practical knowledge has not before revealed to us. There is not one, even of the most experienced of modern horticulturists, that does not experience some imperfection in his crops which cannot be satisfactorily accounted for, and there is no reason why any one engaged in horticultural pursuits should withhold from the effort towards diminishing the obscurity under which we labour. It has been said that when any one fails in producing what others succeed with that he ought to be the last to say anything about it; but if our failures can be traced to no lack of skill, care, judgment, or management, surely too much cannot be said about it so far as regards the searching for the cause and the remedy of the failure experienced; and this leads me to endeavour to answer the inquiry

What is the cause of Grapes not colouring? It has been attributed to—1st, Heaviness of crop; 2nd, Too much atmospheric moisture; 3rd, Deficiency of heat; 4th, Insufficient ventilation; 5th, Leaves partially deprived of their powers of elaboration through attacks of red spider, scorching, &c.; 6th, Roots deep, or in a cold wet border. The essentials known, we can only attribute non-success to mismanagement. Certain it is, however, that under the very best treatment Black Hamburg Grapes are not always the colour of Sloes, nor Muscats like amber. Why? First, I am persuaded the reason of Grapes not colouring at times is not known, or if it is the defect cannot be avoided by pursuing treatment the opposite of the cause assigned; and second, the cause is not even seen until it is too late for remedy.

1. *Heaviness of Crop.*—This may be, and sometimes is, the cause of Grapes not colouring, but not always. I have known a very heavy crop of forty bunches on 20 feet of rafter colour perfectly, although the same Vine would not colour half a dozen bunches of less size in the previous year. In another instance there were upwards of thirty bunches on a Vine: a few bunches at the top were coloured, those in the middle were never otherwise than red and streaked, whilst half a dozen at the bottom of the same Vine were like Sloes in colour. It does occasionally occur that with a heavy crop the berries are larger than usual, and

all goes on well until the colouring process commences, and in this they fail; they swell well, but are longer before they change colour than where a less crop is taken, there being at least a fortnight or three weeks difference in the same house. The quantity of bunches left on a Vine should be regulated, so that it may not be burdened with more than it can bring to perfection; but the precise number to be left seems a point as yet undetermined, and is so dependant on the health and vigour of the Vine as to become a question of judgment rather than of rule. For a Vine in good health from twenty to twenty-four bunches, averaging 1 lb. each, are as much as it can be expected to bring to maturity on 20 feet of rafter. It does not matter whether we take by the rod-system half a dozen that will weigh 4 lbs. or more each, or six times that number of smaller bunches; for a given amount of rafter will not carry more than a certain weight of Grapes, and the amount above stated is the result of the experience of several consecutive years. More may be taken one year, and the Grapes may be all that can be desired, but it is not to the present only that we must have regard, but to the after-crops as well. The Vine may be so weakened by the demands of a heavy crop that it may not be capable of carrying one worth mention for some time afterwards, and then the Grapes may not arrive at the same degree of perfection that they would have done had the Vines not been overtaxed in previous years. Usually it is not in the year that a heavy crop of fruit is taken that the resultant evils are most manifest, and people think because a tree carried a heavy crop of fruit one year it ought to do so again. Nothing can be more at variance with the future well-being of a Vine than to overcrop it. When a heavy crop is taken the whole vital energies of the subject are directed towards its perfection, little remaining for the proper formation and maturation of those parts producing fruit in succeeding years.

That too heavy a crop will prevent Grapes colouring I take as proved by the fact that some Vines with a heavy crop do not colour well, but others in the same house with a fair crop do so perfectly. The solution of the question as to how many bunches a Vine will carry greatly depends on the health and vigour of the Vines themselves, on the size of the bunches, and the space occupied; but I think it may be laid down as a general rule that 1 lb. of Grapes to every foot of rafter occupied is a good crop, and as much as a Vine in full health and vigour can properly mature—if the Vine be weak, then less; if unusually vigorous, more. It is well, however, to be on the safe side, and make sure of a crop that will attain the highest degree of perfection. Experience will be the best guide in determining how many bunches should be left on the Vines when they show; one upon each shoot, and these at every foot along the Vine will be ample, and is very often more than Vines will properly mature. Heaviness of crop is a common cause of want of colour in Grapes; but when it occurs with a moderate crop, and the Vines are healthy and vigorous, we must look for some other cause, and may probably find it in

2. *Too much Atmospheric Moisture.*—This is certainly

very prejudicial to the ripening of fruit, inasmuch as it induces growth and the swelling of the Grapes rather than their ripening. It is no uncommon practice to keep the floors of vineries moist or sprinkled with water after the berries change colour, so as to assist in their second swelling. This, if not too long continued, is not much, if at all, detrimental to the colouring of the Grapes, and it adds immensely to the size of the berries. Sometimes, however, it does prejudicially affect the colouring, and that is when it is accompanied by much moisture in the border. Unless the atmospheric moisture is large in amount, and continued long after the first indication of colouring is observed, I think that it has very little to do with the imperfect colouring of Grapes, for I have seen them much worse-coloured in a dry house without a plant in it than in one crammed with plants, and moist enough for growing Ferns or Orchids. I have seen Grapes as red as Orleans Plums on the roof of a vinery kept dry enough for Caeti when at rest, and yet black as jet when trained to the roof of a moist forcing-house. How was this? The roots of the Vines in the first case were in a wet border, the berries were gorged with moisture, and the leaves exhaled considerably, as was evident by the deposition of moisture on the glass, even with air, and, as might be expected, the berries were larger than in the second case, where the border received no moisture after the berries took their second swelling. Atmospheric moisture, tending to retard the ripening process, is to be avoided, but that it prevents colouring is the reverse of my experience. If, however, the Grapes be constantly syringed, even after they change colour, they will not necessarily be red, but will be devoid of bloom, and like shanked berries in point of flavour.

3. *Deficiency of Heat*.—It is necessary for the ripening of fruit that there be a sufficiency of heat; though this has very little to do with the colouring of Grapes, yet it and dryness of the atmosphere are the essentials for flavour. I have seen Black Hamburgs of the colour of Golden Hamburgs in a vinery with a temperature from 65° to 85° when ripening, but like Sloes in colour in a greenhouse with a night temperature of 50°. Too much heat, inasmuch as it favours rapid ripening, is more frequently the cause of want of colour than less than is necessary to secure flavour, for I find Grapes will colour splendidly in the dark moist autumn months in a temperature of from 50° to 70°. In the case of Vines showing fruit on the laterals, one or two bunches may have been allowed to remain, and were these ever known not to colour though it were October or November before they ripened, although the main crop ripening in July or August was deficient in colour?

4. *Insufficient Ventilation*.—Air is essential alike for colour and flavour in Grapes. They will not colour well without it; but they will not colour sometimes with air day and night. Assuredly insufficient ventilation acts prejudicially as regards the colouring of the fruit, yet I have known Grapes colour well where they had no air whatever in a house not opened during the whole ripening period, the Vines being unpruned, and the bunches not thinned; the doors were left open up to August, and then closed to protect the fruit from depredators. This is not a case for imitation, but it shows that Grapes will colour without air, or with only that entering by the laps of the glass. The house never being wet inside, the blue bloom shone beautifully on the black ground. A dry atmosphere, and ventilation day and night to prevent the deposition of moisture on the berries, secure the bloom of Grapes, which is an unerring test of flavour, though it is by no means uncommon to find the juice of a black-skinned berry sour. Ventilation, so far as it assists in keeping the air in motion, and preventing the condensation of moisture on the berries, is conducive to colour, by preserving the bloom; but that deficient ventilation, or the contrary, will cause Grapes to be red instead of black I do not believe, forasmuch as they may often be seen badly coloured in a well-ventilated and judiciously-managed vinery.

5. *Leaves partially Deprived of their Power of Elaboration in Consequence of the Attacks of Red Spider, Scorching, &c.*—Certain it is that when the leaves are so injured by the attacks of insects, that a certain proportion of their surface is incapable of performing its functions, the fruit must be imperfect, this result very often showing itself in the defective colour and bloom of the Grapes. This is a sure cause of want of colour; but it sometimes happens that the attacks being of short duration, or occurring at the early stages of growth, the berries do not attain their full size, and the leaves have sufficient power to ripen the correspondingly small crop in perfection in respect to colour and bloom. If, on the other hand, the berries attain a good size, and the leaves are then attacked by red spider, or

scorched, the colour of the berries will be bad, and they will be devoid of bloom, or nearly so.

6. *Roots too Deep, or in a Cold, Wet Border, or both combined*.—Grapes have coloured well with me, although no root was nearer the surface than a foot; but the soil was the reverse of wet, and I have also seen them quite red when the roots were deep, and the subsoil heavy and wet. When the roots are deep a late growth is promoted, and this being unfavourable to ripening we have Grapes swelling largely when ripening, but very red. In the case of outside borders it sometimes happens that all will go well up to ripening, then rain may fall daily; and keep the house as dry as we may, the Grapes do not colour, but swell out, and if not, shank. The roots absorb an undue amount of nutriment, it must go somewhere; the old parts cannot appropriate it: hence new parts are made in the form of laterals. It does not matter whether the roots are deep or near the surface, if a continuance of cold rains occur just when the fruit is ripening we may be pretty certain of two results, and very often both—imperfect colouring and shanking. I am convinced that if the border is moist when the Grapes first change colour, it should not be further moistened until they are cut, otherwise they will not colour well, or will do so very rarely, and will not hang long. That a continuance of wet weather (the border being outside) will cause defective colouring, is, I think, proved by the circumstance that the Grapes in the upper part of a house coloured perfectly, the border being dry, and the lower part indifferently from continued wet weather setting in. As further evidence I may add, that with an exposed border a house of Grapes coloured badly, while in another house of which the border was covered with boards, the Grapes coloured well, and hung more than double the time that the others did.

I have now gone over the reasons generally assigned for Grapes not colouring, and stated where I do, and where I do not agree with them. There are cases of want of colour, where none of the above reasons can be assigned, and in which the evil is traceable to want of the requisite appliances and knowledge necessary for Grape-growing; but there are, as I before stated, cases in which Grapes are defective in their colouring under the best management, and with the most approved appliances at command. Everything may be done that means and skill can do, and yet the fruit may be imperfect. I say imperfect, for I am one of those that consider want of colour an imperfection, and to be avoided if possible.

From whence have we disease in plants? From two sources—burdening the leaves with more nutriment than they can elaborate, and on the other hand from a deficiency of nutriment in the soil or atmosphere. For some years no subject was so highly fed as the Vine; and whether it was from the Vine enduring abuse in the shape of strong food without showing any great immediate effects, or from that high feeding causing an immediate increase in the size of bunch and berry, that led some to conclude the Vine was a gross feeder I shall not pause to consider, but will take for granted that in this particular Grape-growers of some twenty or thirty years ago mistook their way. Though dead animals are no longer put in Vine-borders, some growers still employ the bones of animals whole, and in their fresh state. That the oily matter of the bones does not constitute their chief fertilising property is demonstrated by the fact that Vines are quite as vigorous, and more healthy, when the border is composed, in conjunction with other materials, of bones from which the fatty portion has been extracted by boiling, as when fresh bones are employed. The latter I know from experience are positively injurious. What we want from bones in Vine-borders, is the phosphate of lime, and not the gelatine, which is soluble in water, and rapidly becomes putrescent. Putrefaction, whether of animal or vegetable matter in the soil supplies various gases to the roots, and it is from an excess of these that the plants are supplied with more food than the leaves can fully elaborate: hence the rapid extension of the branches and foliage.

It is not uncommon to see in excessively rich borders Vines with leaves like Rhuarb, and making shoots 20 or 30 feet in length in a season. This, we are told, secures strong canes the first year after planting for fruiting the next. Taking this view of the case, we reduce the very long canes, and, there being a very powerful root-action, the buds break strongly and the shoots are very strong; but this season, as we wish for fruit, the shoots, instead of being allowed to run 20 feet, are kept at the length of a foot. With a powerful root-action, and a decreased leaf and branch development, what, I ask, becomes of the sap that the year before circulated in the greater length of rod and leaf? Surely it is impelled into the fruit and leaves

at present existing. The question is, Do the leaves as fully elaborate; and is the appropriation of the sap as complete, as if there were more leaves? We may flatter ourselves that the head controls the root; but if we keep the head close-stopped it is certain we do not diminish the number of roots already existing, and we have large leaves and loose large bunches as a necessary consequence. By the time that the berries are half swelled the vigorous growth and root-action may be so far controlled as to show none of the evils of high feeding that season, but the berries may be actually of less size than was calculated upon, and the crop ripens off small in berry and perfect in colour. Should the berries, however, attain a large size, it is just possible, with root-action now reduced to a minimum, that the colouring may be bad. The root-action being reduced, it does not follow that the decomposition of the materials of which the border is composed will be arrested, but it goes on whether the roots be there to lay hold of its products or not, and the border affords richer food in the following year than in the first or previous one. This state of things continues for a time without any serious evil being experienced as regards the Vines, and would no doubt set itself right; but we, thinking the border must be in need of manure, give a heavy dressing. We have a splendid show of fruit, and take a full crop; for the Vines, from not being fed to excess, show fruit abundantly, and we leave no more bunches than in the preceding year in which they coloured beautifully, but the berries were rather small, which is attributed to the border becoming exhausted. We now have the satisfaction of seeing the Vines stronger, and the berries seem as if they would not leave off swelling. At last they take a turn. "Are they not fine?" says the proprietor to the visitor. But somehow the gardener does not feel quite at ease; he shakes his head, gives extra ventilation, cannot tolerate a plant in the house, and daily becomes more uneasy. The Grapes colour slowly, but he sees a black berry and a beautiful bloom on it. He sighs, and says to himself they will be all right. He never passes the vinery without looking at the Grapes. Three weeks, and not black yet! The sun shines on a bunch, and he sees the seeds in some of the berries—they will not colour. He takes a near view: they have a good bloom, but have a reddish black skin streaked with black, their proper colour. He tries them for flavour, and compares them with others in another house that are black, and vows they are the better-flavoured of the two. Three weeks longer they hang, but grow no better in colour, and he is obliged to own that they are ripe and badly coloured. Another year he will have them black, but for the time being he will affirm that they are better flavoured than highly coloured Grapes. Blindfold a judge, and give him a berry of the imperfect and another of the perfectly coloured, and he will pronounce the imperfectly coloured the better-flavoured; but let him see what he tastes, and he will give the preference to the perfectly coloured, owning, however, that the former are sweeter and firmer in the flesh than the latter, which, though less sweet, are more juicy, brisk, and refreshing.

To what can we attribute defective colouring, when there is nothing wanting in the management and means, but to high feeding? Take what may be an average crop at the time of the fruit showing, and which may safely be calculated to arrive at maturity; if from some over-zeal more food is given in the atmosphere, or at the roots, coupled with extra pains being taken to secure finer fruit than usual, the result is sometimes badly-coloured Grapes, that no one likes to see, much less grow. I may be told that in consequence of the berries attaining a large size from extra feeding, the crop became heavier than was calculated upon, and was, therefore, too great for colouring well. Surely the increased size of the berries was merely the effect, and the primary cause that which gave the increased size to the berries.—G. ABBEY.

#### VENTILATING AND TRAINING IN GROUND VINERIES.

In my opinion a much better mode of effecting the above than the one proposed by your correspondent "F." in No. 229, would be to have a door at the apex of the span at each end. This would give thorough ventilation throughout. These doors could be made to open or shut at pleasure by a mere hinge and button.

Permit me to suggest a few other alterations, I think improvements. Would it not be desirable to fix the case on two tiers of bricks instead of one, the usual practice, and leave the

openings in the upper row? This in some measure would protect fruit from the ravages of mice, slugs, and other vermin.

Again: my practice would be to train the rods on stays—flat pieces of iron lying transversely on the brickwork; this would allow the bunches to hang, thereby swelling and colouring on all sides alike—a desideratum impossible to accomplish when lying on the bare ground, with their upper sides plump and under sides compressed and colourless.—J. N.

#### PROPAGATING AND AFTER-MANAGEMENT OF PELARGONIUMS AND OTHER PLANTS.

(Continued from page 64.)

PELARGONIUMS.—Now is the time to propagate the Pelargonium in order to have good plants for planting out next year. Where large quantities are required pots should be dispensed with altogether; and even where Pelargoniums are grown in small quantities they will be found to do best in boxes, in which way also larger numbers can be kept in a limited space. There are many advantages to be gained by adopting this system, one being that the plants grow better when they are turned out of boxes than they do out of pots. The boxes which I use are made by my own men. Formerly we used to have them made by the carpenters who worked on the estate; but we found the demand much greater than the supply, for the carpenters could not make them without measuring, planing, &c., to a great nicety: the consequence was, we could not obtain more than six or eight boxes a-day from them, so without serving a long apprenticeship to a carpenter I thought I would try my hand at box-making. The first thing I did was to get the sawyers to cut me out a lot of strips of wood about 6 inches wide and half an inch thick. Well-seasoned larch I find as good for this purpose as any wood I can procure. Having obtained a good supply of these, my next proceeding was to cut them up into two-foot lengths. After the boards were all cut up search was made amongst the pieces that had been cut to waste for the ends. Of these all that would measure 10 inches or a foot in length were cut to the desired length; then the whole lot was thrown into a tank for an hour or two to soften the wood a little, as we found after a little experience that the nails refused to go into the sides and ends of the boxes without splitting them, the larch wood when seasoned and very dry being very brittle and as hard as oak. After leaving the pieces in the tank for two or three hours, they were taken out and placed in a pile at one end of the potting-bench, which was cleared for the purpose of box-making.

I and my handy man Brown, commenced the work of nailing the sides together at 6 A.M., and by 12 o'clock we had a large pile ready, which only wanted some narrow strips to be nailed across the bottoms, and the rough edges to be trimmed a little. For the bottoms I use strips of the same kind of wood, about 2 inches wide and 1 inch thick. As they are nailed on, an opening of about half an inch is left between each bar, so that the water may pass away freely. Well, at the end of a not-over-busy day we found we had completed forty-nine of these boxes. Such a quantity we should have been obliged to have waited more than a week for had we depended on the carpenters for them. The next day we had at this sort of work, we found we were becoming pretty expert, and time was gained by hitting the right nail on the head, two blows doing instead of four, so that sixty-three boxes were completed in one day. The way we made them was as follows:—Two ends and two sides were selected to match: the ends were then placed on the bench at the proper distance apart, one of the sides was then placed on the ends and a nail driven in at each end to keep them in their proper place, the ends were then reversed and the other side nailed on; about twenty 2½-inch nails are used for nailing the sides and ends together. I find boxes of this description last quite as long as those made by the skilled carpenter. They are kept in almost constant use from two to three years.

In preparing the boxes for the cuttings, I find the best drainage is charcoal, of which some large lumps are placed over the openings in the bottom of the box, I then put some smaller pieces between, finishing off with some small charcoal or the small siftings from the crock heap. There should be about 1½ inch of drainage in the bottom of the boxes. The remaining space in the box is then filled up with nice sandy soil, and a little silver or clean river sand is sprinkled over the surface. After this the cuttings may be put in, the soil in the boxes having been made moderately firm.

Select good firm cuttings, put about sixty or eighty in each box. See that the cuttings are placed flat on the bottom of the hole made by the dibble. The soil should also be pressed firmly around the sides of the cuttings. After the box is full give it a few taps on the bench to shake the river sand in about the cuttings, and finish the operation by giving a good watering. This will consolidate the sand about the cuttings. As the boxes are filled they are placed side by side in long beds, one or two boxes wide, in the open air. They are then left exposed to all weathers till towards the end of September, when they are placed where they can be sheltered from rain or cold nights. By this time the cuttings will have made roots, and about the end of October they should be stowed away in their winter quarters. The best place for this purpose is shelves as near the glass as possible, and where the air can be kept dry and circulate freely amongst them. The more choice kinds—such as Mrs. Pollock, Sunset, Cloth of Gold, &c., should not be put in quite so closely together as the commoner kinds. The soil for them should also be prepared with more care, and silver sand should be used instead of river sand. They will also require a little more warmth in the dull winter months; but they must not by any means be excited into growth, and no attempt must be made to take cuttings from them till the end of March, when such may be taken off with perfect safety and pricked out under hand-lights on an old spent hotbed. I find the tops of hand-lights the best for this purpose, for placing a lump of brick or stone at intervals for the tops of the lights to rest on will allow the air to circulate freely amongst the cuttings. This is one of the most important points to be attended to in striking the Mrs. Pollock section, for if the air is once allowed to become damp and stagnant for ever so short a period it is fatal to them. I mention this here in connection with their spring propagation, because they cannot be fully exposed in the open air at that early period of the season. In the autumn they are struck just in the same way as the commoner kinds; but I find cuttings of the Mrs. Pollock section, struck in the manner described above, grow much more freely when planted out than those struck in the autumn, the latter having a greater tendency to bloom. As the flower is not much wanted in this section, I should advise the propagation of them to be left till the spring, only putting in a few of the very strongest and best-ripened cuttings in the autumn.

All the kinds of Pelargoniums should have as little water as possible after they are packed away in their winter quarters; but when they are watered, they should be thoroughly well soaked. To do this, they must be watered three or four times over.

*Spring Management.*—About the last week in March, if the weather is pretty mild and open, with sunshine, the plants are all shaken out of their boxes and planted as thickly as they can be, without crowding them too much, in pits and frames, as near the glass as possible. If the soil in the pits is in a nice moist state they should not be watered, but should be syringed every day an hour or two before the sun is off the glass, and shut up; if there is no sun they must not be syringed. For the more delicate section, such as Flower of the Day, Bijon, Mrs. Pollock, &c., if there is a foot or two of leaves put under the soil, it will be all the better, as it will give them a very slight bottom heat, which will insure their immediate root-action.

By the second week in April the plants will have made new leaves, and will be rather crowded; they should then be taken out and put into larger pits, and placed further apart. At this shift the soil must not be pressed firmly about them; the best way is to make little straight cuts with the spade across the frame, stand the cuttings upright against the back of the nick, sprinkle a little fine leaf-soil about their roots, then at the next shift the plants will come out with nice little balls attached to them.

About the 10th of May the plants are moved again into cradle-beds in the open air, trenches are cut across the beds the same as described for the last shift, and a little leaf-soil put in about the roots. They are then gradually exposed to the open air, and in a fortnight from this time are ready for removal to their final quarters.

Many of the craft will say that I am giving myself much unnecessary trouble by removing the young plants so many times, but when the advantages to be gained by this system are taken into consideration, and it is tried, few will grow their plants in pots. The advantages are—1st, There is not one-tenth part of the labour required in watering. When the plants are planted out in the above manner, they only require

watering once or twice a-week, whereas, if they were kept in pots, in very dry days they would want water twice daily. 2nd, Where plants are kept in pots for several months, the soil becomes sour, and many of the roots are decayed; the plant at planting-out time becomes, in most cases, very much pot-bound, and will not readily take to or emit roots into the fresh soil. Plants kept in pots cannot all be in the same state when planted out, for some will be too dry, others too wet; hence it is that one often sees, after a bed has been planted, some plants growing away vigorously, whilst others remain almost dormant, giving the bed a very uneven and unsightly appearance. 3rd, At planting-out time, there is a great confusion, created by empty pots being scattered about in all directions; much labour is required in collecting them, much is also wasted in washing them, and a great number of pots are broken during the operations of collecting, washing, and storing them away. 4th, By removing the plants twice or thrice they receive a slight check; the points of the roots are broken each time the plants are removed, and where one is broken, ten or twenty fibres take its place. Finally, For the varieties that are wanted to produce effect by their flowers, the series of checks to which the plants have been subjected causes them to flower very soon after they are planted in their permanent beds, and they continue flowering in great profusion all through the season. However dry the weather may be when they are planted out, if care is taken in planting, and they have one good watering, they emit roots into the fresh ground almost immediately. This is not the case with plants turned out of pots; should the weather be dry at the time they are planted out, you may water every day for ten days, and at the end of that time, if a plant is taken up, very few fresh roots will be seen.

The Pelargonium-boxes are all washed clean, and are filled with Verbenas, Lobelias, Heliotropes, &c., from the cuttings-pots. These are put into the boxes as thickly as possible, the boxes being then placed in pits and places where there is a gentle bottom heat, and are syringed daily as recommended for Pelargoniums. When they have become established, they are planted out, after hardening them off a little, in the places the Pelargoniums occupied. They are treated precisely in the same way, and are replanted three times before they are placed in their final flowering-beds. Fine plants can be grown on in this way from cuttings put in the last week in April, and I can guarantee from experience that they will make finer plants, and will cover the ground quicker than those that have been propagated in February, and have been kept in pots up to the time of planting out.

VIOLA CORNUTA has proved quite a success, I consider it one of the most beautiful and chaste plants we have for edgings to large beds, and for giving relief to many of our strong and glowing colours. In a future article I shall state the kinds of plants, and the colours that will be relieved by it, and what it harmonises best with. In reply to "Emma," and numerous other correspondents respecting this Violet, I may state here that it may be propagated now or in the spring, and that the Messrs. E. G. Henderson, of the Wellington Nursery, St. John's Wood, London, will be prepared to supply it in any quantity. It also seeds very freely. Seeds sown now will produce good plants for bedding-out next spring.—J. WILLS.

(To be continued.)

## BEDDING PLANTS AFFECTED BY A WET SEASON.

IN seasons like the present, when successive thunder showers at intervals of a very few days, with frequent slighter rains between, dash off or otherwise disfigure the bloom of bedding plants, it is of no small importance to know what plants or rather which flowers endure rain best—not that we ought to disqualify those which do good service in ordinary years, but persons residing in rainy districts ought to know on what varieties they can best rely. The present season has been a more growing one than any we have had for some years, and especially the months of July and August, but the frequent heavy rains, however useful they may have been in increasing the amount of herbage, have certainly not had a similar effect as regards flowers, and in some cases where the latter have been forthcoming they have disappeared in consequence of the deluging rains. A few rough notes of the classes of plants suffering least from this evil as well as those of the contrary description may, therefore, not be out of place; for although

the amount of rain which has fallen in Kent may not have been generally equalled in other parts of the kingdom, yet it may be so in another year.

Commencing in the first place with the plants most capable of enduring rainy weather, it will be generally admitted that *Cuphea strigillosa* stands pre-eminent, its pendant flowers seem to be improved in colour by each shower; *Fuchsias* in like manner do not suffer, and most flowers of a pendant character are protected in a measure from the influence of rain, and consequently escape. The same cannot be said of those growing horizontally, for I know of none that suffer more than *Salvia patens*, in which the footstalks of the flowers seem unable to bear the increased weight of the bloom when loaded with moisture, and it consequently falls off; but it is the flowers presenting their principal front upwards that are in general injured by heavy rains. By these, *Geraniums* of most kinds are injured in the petal, and though the blooms do not fall off like those of the *Salvia*, they hang down in bruised and disfigured masses. All the flowering kinds of the *Zonale* family are liable to this, and blooms that have only been open two or three days fall after heavy rain; even the small-petaled ones of the *Nosegay* class suffer equally with the more improved varieties. I need hardly remark that the variegated section are exempt from this drawback, and, on the contrary, are often improved by rain. Amongst the latter class the variety showing most vigour is the Golden Ivy-leaf, which looks better than in any previous season. Next to *Geraniums*, the *Calceolarias* suffer most, especially those of which the flowers become filled with water. These all fall off when so charged, but the blooms of most of the *Calceolarias* when they become what may be called perfectly ripe are easily shaken off by rain; on the contrary some of the varieties endure the autumn rains unscathed, and the best of these is *C. amplicaulis*. *Verbenas* suffer less from heavy thunder showers than from a prolonged wetting, the latter seems to injure the outer edge of the petal, and it withers and hangs down. *Lobelias* withstand rain well and certainly do better in wet weather than in a continued dry season, while one of the best flowers in this respect, though collecting water, is the *Ageratum*, which does very well in damp weather; and *Petunias* are not by any means the worst. *Gazanias* we all know shut up to escape it, but French and African *Marigolds*, as well as the other members of their family, withstand rain pretty well. *Helichrysums* suffer from it to some extent, but *Asters* and *Stocks* like it better than weather of an opposite kind, and the same may be said of *Dahlias*, the latter, however, growing much taller. *Nierembergias* seem also to like a wet season, but the plant which enjoys rain almost every day is *Aloesoa Warczewiczii*, which in a dry season bears no comparison with what it is in a wet one. Some other plants might be added to the list of sufferers, as *Tropaeolums*, &c.

It must be remarked that although the flowers may either suffer or benefit as described above, the character of the plant is much altered in a wet season. At the present time I have some *Tropaeolums* with the stems touching or lying on the ground, while the upper part of the foliage is 2 feet high, completely concealing the flower. In a dry season, on the contrary, the latter would overtop the other, this is the difference which rain and growing-weather make. *Geraniums*, too, are more productive of leaves and stems than of flowers, and the same remark holds good as to many other plants; *Dahlias* are often fully one-third higher; and in some there is a laxity of bloom, in *Geraniums* especially. *Calceolarias*, on the other hand, produce more bloom by increased growth, so that if that growth can only be effected early enough in the season bloom is sure to follow. *Salvias*, and in fact most plants also become rank, and when so the number of flowers in proportion to the size of the plant is small as compared with what it is under other circumstances; on the other hand, some plants grown for their foliage, as *Perilla* and *Cerastium*, enjoy the moist weather, and bear the cutting and trimming that is necessary all the better of the rain; *Coleus Verschaffeltii* and *Amaranthus*, however, like sunny weather best, and most of annuals in like manner do best under such circumstances. It is hardly necessary to remark that the time when the greatest profusion of bloom may be expected is after a fortnight or so of dull, dry, mild weather, when there has been sufficient rain before the setting in of that period to satisfy the wants of the plant. Persons visiting gardens at such times must not expect the profusion which then presents itself to be permanent, neither must they ascribe the want of it, under contrary circumstances, to unskilful management; for with all our forethought and contrivance Nature will always assert her claim to some dominion

over her subjects, and however we may attempt to overcome her, the results of a wet season will always be different from those of a dry one, and to mitigate the evils of both is what we ought to aim at.—J. ROUSSEAU.

## NEW ROSES.

It was anticipated some time ago that the five seasons of the two or three past years would be productive of great numbers of seedling *Roses*. From the information received from various quarters the anticipation is likely to be fully realised. It is quite natural that the raisers of seedling *Roses* should be desirous of putting forward their productions. It is quite right that their merits should be recognised; but the experience of the past shows that the improvements effected in the "queen of flowers," are gradual, and that out of the great number of varieties annually sent out very few retain a place for a length of time. A word of caution to our *Rose* friends will not be deemed out of place. They will do well to be careful in their selection of new kinds, and not to slight the information that appears in these columns from time to time from various sources.

Among the earliest announcements are those of M. Eugène Verdier, of Paris—a name that has acquired honourable distinction among rosarians. Making a slight allowance for differences of climate and soil, M. Verdier's descriptions have proved truthful as regards the kinds he has hitherto offered, and reliance may be placed upon his selection. It should also be remembered that to M. Verdier we are indebted for Prince Camille de Rohan, undoubtedly the best dark *Rose* yet sent out; also for Madame Charles Wood, Duchesse de Morny, Rushton Radclyffe, Madame Victor Verdier, H. Laurentius, and other fine varieties. He also sent out, but did not raise *Maréchal Niel*, the greatest acquisition to our yellow *Roses* since the appearance of *Celine Forstier*, and promising to surpass all that we yet possess of that colour.

The following are M. Verdier's announcements for the next season. The translation is made from his own circular. The first two are Bourbons, the remainder Hybrid Perpetuals:—

*Julius Cæsar*, very vigorous, with stout dark-green branches; thorns almost straight, strong, and blackish; leaves composed of five broad and thick leaflets, delicate green; flowers large, about 10 centimetres (4 inches) in diameter, in clusters of from three to eight, very full, well formed, beautiful deep rose cerise.

*Madame Charles Ballet*, seedling from Louise Odier, very vigorous, branches robust, distinct green, thorns strong, straight, and reddish; leaves composed of five bright green leaflets; flowers large, about 9 centimetres in diameter (3½ inches), in clusters of from four to six, perfectly imbricated; beautiful fresh delicate rose.

*Alba Mutabilis*, seedling from Jules Margottin, very vigorous, with brownish-green branches; thorns long, straight and blackish; leaves composed of five bright-green leaflets; flowers large, about 9 centimetres in diameter (3½ inches), full, white, tinged with rose, becoming completely shaded with rose in the course of expansion.

*Charles Rouillard*, very vigorous, with straight dark-green branches; thorns few, straight or nearly so, reddish; leaves composed of three to five leaflets, deep green; flowers large, about 10 centimetres in diameter (4 inches), of the most perfect form, full; beautiful delicate rose with brighter centre.

*Fisher Holmes*, very vigorous and free-blooming; branches dull green; thorns short, straight, and yellowish; leaves composed of five dark-green leaflets; flowers large, about 9 centimetres in diameter (3½ inches), full, imbricated like a *Camellia*; magnificent scarlet red; very fragrant.

*John Grier*, very vigorous, with dark-green stout branches; thorns strong, slightly curved, yellowish; leaves composed of five apple-green leaflets; flowers large, from 8 to 9 centimetres in diameter (3½ to 3½ inches), full, well formed, globular, very fragrant; beautiful clear red or dark rose, reverse of petals silvery.

*Jean Lambert*, vigorous, with dark-green branches; thorns numerous, straight, and yellowish; leaves composed of five dark-green leaflets; flowers extra large, about 12 centimetres in diameter (4½ inches); flame colour, shaded fiery red; the buds are often extraordinary, and resemble a pigeon's egg.

*Mlle. Marguerite Dombrain*, seedling of *Rose de la Reine*, very vigorous, with straight bright-green branches; leaves composed of five to seven delicate green leaflets; flowers extra large, from 12 to 14 centimetres in diameter (4½ to 5½ inches),

full, globular, well formed, and very fragrant; beautiful blush rose, very delicate, and very fresh.

*Prince de Porcia*, very vigorous, with dull-green branches; thorns sharp, numerous, yellowish; leaves composed of five deep-green leaflets; flowers large, about 10 centimetres in diameter (4 inches), full, well formed; deep vivid vermilion.

*Professeur Duchartre*, very vigorous with bright-green branches; thorns short, slightly recurved, yellowish; leaves composed of five pale-green leaflets; flowers large, from 9 to 10 centimetres in diameter (3½ to 4 inches), in clusters of four and six, full, globular, well formed, very fragrant; bright red, reverse of petals silvery.

*Souvenir d'Abraham Lincoln*, seedling from Cardinal Patrizzi, vigorous, with reddish branches; thorns sharp and brown; leaves composed of five to seven reddish-green leaflets; flowers medium size, from 7 to 8 centimetres in diameter (2½ to 3½ inches), full, well formed; crimson, tinged with fiery red, purple, and rose.

*William Rollisson*, very vigorous, with bright-green branches; thorns sharp and slightly curved, yellowish-brown; leaves composed of five bright-green leaflets; flowers large, about 9 centimetres in diameter (3½ inches), full, globular; magnificent vivid cherry-red.

The following new Roses were obtained by Messrs. Gautreau and Granger, and rewarded with medals at the exhibition of Brie-Comte-Robert.

*Camille Bernardin* (Gautreau), seedling from Général Jacqueminot, very vigorous, with dark-green branches; leaves composed of five bright-green leaflets; flowers large, about 10 or 11 centimetres in diameter (4 and 4½ inches), full, well-formed; vivid red, edged with white; free blooming and very fragrant.

*Carl Coërs* (Granger), very vigorous; wood and foliage dark green; thorns rather numerous; flowers very large, from 10 to 12 centimetres in diameter (4 to 4½ inches), full; deep purple.

*Exposition de Brie*, very vigorous, with reddish-green branches; thorns short and reddish; leaves composed of five deeply-notched leaflets, apple green; flowers large, about 12 centimetres in diameter (4½ inches), full, well-formed; beautiful dazzling vivid red.

From the foregoing copious, and in some respects superfluous descriptions it is easy to point out one variety likely to prove an acquisition—viz., *Mlle Marguerite Dombain*. That it is the best of M. Verdier's seedlings is evident from the description, and from the fact that he intends to publish an engraving of it. The last three are probably good, and should they turn out so, Carl Coërs will also be an acquisition for the sake of its colour, which is still a desideratum. Nearly all the others are too small for the prevailing taste, although under the high cultivation of the Rose in this country, the actual size of the flowers obtained is greater than in France.—ADOLPHUS H. KENT, *Blechningley, Surrey*.

## NEW FRUITS AT THE SAWBRIDGEWORTH ORCHARD-HOUSES.

PERHAPS one of the greatest treats the lover of fruit culture can find is to visit the orchard-houses of Messrs. Rivers & Son, at Sawbridgeworth, which are now in their most attractive condition. We have already made frequent visits to this establishment, and have never come away without being not only wiser than we went, but deeply impressed with the wonderful field which has yet to be explored in fruit culture. For some years past Mr. Rivers, sen., has addressed himself to the work of originating new varieties of fruits which should supply the deficiencies of those with which our gardeners have been so long familiar. His first attempt was to obtain varieties either very much earlier or very much later than those already in cultivation; and, reasoning from a commercial point of view, in securing a crop of fruit a week or ten days earlier than it is customary for the ordinary varieties to appear in the markets, the fortunate possessor of such gains must necessarily obtain an advantage over all other cultivators. This has been strikingly illustrated by the Early Prolific Plum, which Mr. Rivers raised now many years ago. This is well known to be, if not the earliest, at least one of the earliest, Plums in cultivation. When Mr. Rivers saw what the future must be, he attempted, but very unsuccessfully, to induce large market gardeners and orchardists to plant this Plum on an extensive scale, and thereby secure the supply of the home markets before the foreign importations commenced, and before the old

varieties of home fruit were nearly ready. Mr. Rivers pressed his views in vain, and the large stock of young Early Prolific Plum trees which he expected would have been bought up with avidity was left on his hands, much to his disappointment. Great, however, was his faith in the correctness of the views he had adopted; and seeing the public would not accept the advantage he offered he secured it for himself, and the trees that he could not sell he planted in rows in his own grounds. How many thousands of bushels of fruit these trees have since yielded, and how many hundreds of pounds sterling that fruit has since produced, we are almost afraid to say; but true it is that for some years past the first Plums to be found in the streets of London are Rivers' Early Prolific, and we believe the supply comes mainly from these trees to which we have referred.

This is one illustration of the advantage of procuring varieties of fruit which can be brought to market when the great mass is not in season; and it is to attain this end that Mr. Rivers has devoted so many years to the acquisition of such desiderata, and he has been beyond measure successful in arriving at the desired result. This season has witnessed the realisation of the most sanguine expectations in new varieties of the Peach. For many long years the Red Nutmeg and Early Anne were the earliest and best of which we could boast. Then came the two small but nice varieties, Acton Scot and Springrove, but neither of them was such as ardent fruit-growers could be satisfied with. Then we had from across the Atlantic a new race in the form of the Early York, which Mr. Rivers introduced a few years ago; and from this, manipulated in the most extraordinary way with Nectarines, Clingstone Peaches, and the most heterogeneous and anomalous alliances, Mr. Rivers has succeeded in raising a number of varieties, some of which in earliness and others in excellence of flavour far surpass anything already in cultivation. We have had the opportunity for the last two or three years of watching the development of these; and now, after repeated trials and comparisons, the following have been selected from a large number, all of which are good.

The first is EARLY ALFRED, raised from the seed of Hunt's Tawny Nectarine! Singular fact! It is a Peach of the ordinary size, rather larger than otherwise, and marked with a deep suture that is rather higher on one side than the other. The skin is remarkably tender, pale straw-coloured on the shaded side, and somewhat mottled with bright carmine on the side next the sun. The flesh is white, with the jelly-like transparency of that of a Pine Apple, perfectly melting, richly flavoured and vinous, having an exquisite briskness that excites the salivary glands, and cleans instead of clogging the palate.

This delicious Peach ripens early in August.

THE DAGMAR is another of those exquisitely flavoured Peaches, not quite so large as the Early Alfred. It is the second generation from the Early Albert, another excellent variety raised by Mr. Rivers. The fruit is round, and marked with a shallow suture, which is deepest at the apex. The skin is very tender, more than usually downy, of a pale straw colour, almost entirely covered with minute crimson dots, so dense that they almost form a solid mass of colour; but here and there small patches of the yellow ground colour show through and give the appearance as if the fruit were mottled with yellow. Flesh white, with that gelatinous appearance that the whole of these new sorts possess; it is so tender as to melt entirely away in the mouth, and the flavour is very rich and vinous. This ripens about the 10th of August.

ALEXANDRA NOBLESSE is a noble Peach, and a great gain—a great gain in many ways, for it is of the largest size, and has all the peculiar richness of flavour of the old Noblesse; but, unlike that variety, it has glands on the leaves, and is never subject to mildew. It is a remarkable fact, which we should like to have explained on physiological principles, that almost all the Peaches and Nectarines that have glandless leaves are subject to mildew.

This excellent variety was raised from the old Noblesse, and, as we have already said, is of the largest size, round, and marked with a deep suture. The skin is covered with a rough down, and is quite pale without any trace of colour upon it. The flesh is white, even to the stone, and is very melting, juicy, richly flavoured, and vinous.

A very handsome and excellent Peach, which must take the place of the old Noblesse. It ripens early in August.

DR. HOGG.—This is also a grand early Peach, both for its size and the excellence of its flavour. It differs, however, from all of the preceding in not having that very melting flesh

that they have, but one more firm and solid. In this respect it has a great advantage, as it renders the fruit more portable and not so subject to injury from transmission to a distance. As a Peach, therefore, for all establishments where the fruit is grown for sale, or sent by public conveyance, this will be invaluable; no other variety, that we know, possessing these qualities, combined with such richness of flavour and so early.

The fruit is large and round, with a very distinct suture, which is deeply cleft at the apex. Skin thin but tough, lemon-coloured, dotted with crimson on the shaded side, and with a faint crimson cheek next the sun. Flesh yellowish white, somewhat firm but melting, with a rich full sugary flavour, which adheres to the pitote notwithstanding its fine briskness; it is very deeply stained with red at the stone.

This ripens about the 10th of August, and is the largest early Peach known. As an exhibition variety, it will be in high repute on account of its size and remarkably full flavour; and for market purposes, its earliness, size, and the ease with which it bears carriage, will render it the most valuable Peach in cultivation. The tree is a very strong grower, remarkably vigorous and healthy, and bears immensely. It was raised from a very hardy Peach which Mr. Rivers procured in Brittany, called *Pêche Deniaux*.

### THE CRYSTAL PALACE AUTUMN SHOW. AUGUST 30TH AND 31ST.

THERE was on this occasion a very extensive and excellent show, though from being limited to fruit and the cut flowers of the season, there was not so much variety as at the summer exhibitions. As in previous years, one half of the nave was occupied by fruit, the other by flowers; but the exhibitions did not appear to be so numerous as last year, nor were the tables on the first day so thronged with visitors as usual at the Palace shows.

DAHLIAS constituted the principal feature of the floral display, and several of the stands, especially those of Mr. Keynes, of Salisbury, among nurserymen, and of Mr. C. J. Perry, of Castle Bromwich, among amateurs, were of the highest merit, the blooms being not only large in size but exquisite in form and colour.

For forty-eight blooms Mr. Keynes was first—reading from the left, first-row—seedling Annie Austin, Mrs. Trotter, Lord Shaftesbury, Earl of Pembroke, Lilac Queen, British Triumph, Willie Austin, Ne Plus Ultra, Bird of Passage, Earl Russell, Edward Spary, Juno, Foxhunter, Lady Maude Herbert, seedling Marquis of Winchester; 2nd row—Lord Derby, Charles Turner, Queen of Primroses, Helen Potter, Queen of the Isles, Pauline, John Wyatt, Princess, Lady Palmerston, Donald Beaton, Miss Henshaw, Disraeli, Champion, Miss Herbert, Charlotte Dorling, Chairman; back row—Leah, Baron Taunton, Lord Clyde, Andrew Dodds, Golden Drop, Lord Palmerston, Jenny Austin, Hero, George Wheeler, Peri, Hugh Miller, Mrs. Wyndham, Anna Keynes, Lady Gladys Herbert, and Mrs. Hogg. The second prize was also awarded to Mr. Keynes for a collection consisting, with but a few exceptions, of nearly the same varieties; the third to Mr. Walker, Thame, Oxon, and the fourth to Mr. Wheeler, Warminster. Messrs. Allen, Shacklevell, Wood & Ingram; and Legge, of Edmouton, likewise contributed stands of forty-eight.

For twenty-four blooms Mr. Keynes was again first with Miss Henshaw, Golden Gem, Miss Herbert, Juno, Charles Turner, Bird of Passage, Champion, Annie Austin, Lord Derby, Pauline, Anna Keynes, Disraeli, Golden Drop, Earl of Pembroke, Mrs. Wyndham, Andrew Dodds, Leah, Jenny Austin, Chairman, Baron Taunton, Norfolk Hero, Lady Gladys Herbert, Hugh Miller, and Helen Potter. Mr. G. Wheeler was second; Messrs. Kelway, Laugport, third; Mr. Draycott, Humberstone, fourth; Mr. Walker, fifth; and Mr. Legge, sixth, all having good stands.

To the Amateurs' class for the same number Mr. C. J. Perry took the first position, with excellent blooms of Earl of Pembroke, Deh-cata, Countess of Shelburne, Purity, Model, Empire, Charles Turner, Ne Plus Ultra, George Wheeler, Stella Colas, Miss Roberts, Bob Ridley, Bird of Passage, Chairman, a finely-formed rich maroon seedling, a blush seedling, Leah, Princess, Lord Derby very fine, Hugh Miller, Disraeli, Miss Helen-haw, Lord Palmerston, and Volunteer. Mr. H. Thorneycroft, Floore, Weedon, was second, with an excellent stand, including several of those already named. *Triomphe de Pequ*, Lord Dundreary, Lady Lilian Paulet, Volunteer, and Mrs. Charch, large and fine. Mr. J. T. Hedge, of Reed Hall, Colchester, was third; Mr. Hopkins, Brentford, fourth; Mr. Leslie, St. Peters, Margate, fifth; Mr. Petfield, gardener to G. Thornhill, Esq., Diddington, Hunts, sixth. In Mr. Hedge's stand was a remarkably fine bloom of *Criterion*, measuring not less than 5 inches across, and Madge Wildfire, a very fine scarlet. The class for twelve blooms also comprised several excellent stands, in which figured most of the varieties already enumerated. Mr. Thorneycroft was first; Mr. Petfield, second; Mr. C. J. Perry, third; Mr. T. Dieks, Brockhall, fourth; Mr. Hopkins, fifth; Mr. J. Bennett, gardener to J. C. Thurn, Esq., Champney Hill, sixth. Of Fancies, several very good stands were shown by Messrs. Keynes, Perry, and Thorneycroft, comprising *Queen Mab*, *Striped Perfection*,

*Sam Bartlett*, *Pauline*, *John Salter*, a very fine scarlet-striped buff; *Prospero*, *Joha Baun*, *Mary Lander*, *Formidable*, *Lord Warden*, *Countess of Shelburne*, *Countess of Bective*, *Samoertide*, *Griibaldi*, *Lady Paxton*, *President Lincoln*, and *Stafford's Gem*, a very pretty yellow tipped crimson. Among those from Mr. Perry were *Sturter*, a variety of his own raising, sent out this year, nearly black, and distinctly tipped with white; and *Miss Powell*, purplish crimson, with blackish streaks and light tips. In the nurserymen's class Mr. Keynes was first and third, and Mr. Legge second. In the amateurs' class, Mr. C. J. Perry was first and second, Mr. Thorneycroft third.

Several seedlings were shown, which will be reported on separately. One, *Chung*, was remarkable for its immense size, and another, *Mrs. Savory*, for its peculiarly beautiful colour. Of the latter it is impossible to speak too highly; it will infallibly take a first-class position.

ASTERS, both quilled and tasselled, were exhibited in great perfection and variety. For the former Mr. L. Beslie, East Hendred, was first; Mr. J. Jennings, Shipston-on-Stour, second; Mr. D. Lewis, Hendred, third; Mr. J. T. Hedge, fourth; and in tasselled Mr. J. Ward, gardener to F. G. Wilkins, Esq., Leyton, was first; Mr. Hedge, second; Mr. Wheeler, Warminster, third.

ROSES.—These of course were not in such perfection as at the summer shows; there were, nevertheless, all things considered, some very good stands, particularly those from Messrs. Paul & Son, J. Hollingworth, Esq., and Dr. Cooper. Among the varieties which were seen to most advantage were *Marschal Niel*, *Madame Victor Verdier*, *Pierre Notting*, *Prince Canaille de Rohan*, *Madame Boll*, *Souvenir de la Malmaison*, *Gloire de Dijon*, *Gloire de Santeauy*, *Charles Lefebvre*, *Jules Margottin*, *Senateur Vaisse*, *Madame Bravy*, *Sombreuil*, and *Madame Falcot*. Prizes.—For thirty-six trusses: Messrs. Paul & Son, first; Mr. G. Clarke, Brixton, third. For twenty-four single blooms: Messrs. Paul & Son, Chestnut, first; J. Hollingworth, Esq., Maidstone, second; Mr. G. Clarke, Brixton, third. For eighteen single blooms: Dr. Cooper, Slough, first; Mr. H. Thorneycroft, second; J. Hollingworth, Esq., third; Mr. Hedge, fourth; Mr. W. Smith, gardener to T. Moxon, Esq., Leyton, extra prize.

HOLLYHOCKS were not, generally, in good condition, with the exception of those shown by the Rev. E. Hawke, of Willingham Rectory. Gainsborough, who, besides being a most successful cultivator and raiser of this flower, had the advantage over the growers near London of a later climate. Rev. Joshua Dix, Willingham Deiance, Mrs. Cochrane, Lady Craven, J. Ullett, and Lilac Perfection were a few of the most noticeable. Lord Loughborough and Lord Rokely were also very fine, as shown by Mr. Thompson. Prizes.—For twenty-four:—Rev. E. Hawke, first; Mr. J. Thompson, gardener to H. B. Creswell, Esq., Chatham, second; Mr. B. Porter, gardener to Hon. H. A. Ashby, Epping, third. For twelve: Rev. E. Hawke, first; Mr. J. Thompson, second; Mr. B. Porter, third.

VERBENAS.—The best of these came from Mr. C. J. Perry, and among them were included *Charles Perry*, *Cleopatra*, and *W. Dean*, noticed at page 94, of which the last two received first-class certificates, *Snowball*, the best of the whites, and *Lilac King* very fragrant; as well fine trusses of *Lord Leigh*, *Foxhunter*, and other well-known sorts. Mr. Perry took the first and second prizes; Mr. Vockins, gardener to F. T. Noakes, Esq., Lewisham, the third.

MISCELLANEOUS subjects consisted of cut flowers of stove and greenhouse plants from Mr. Rhodes, and Mr. Frisby, gardener to H. Chaplin, Esq., Sleaford, who received first and second prizes; some good *Zinnias* from Mr. August, Boddington; *Japan Lilies* from Mr. Parker, Lower Norwood; and a pretty silvery variety of *Cupressus Lawsoniana* from Messrs. Water & Goldfrey. From Messrs. Dowrie, Laird, & Laing came a collection of plants suitable for sub-tropical gardens, comprising *Ferdinandia emineus*, *Wigandia caracasana*, *Nicotiana wigandioides*, *Anicra zygomeris*, *Polynnia grandis* with large deeply cut leaves; *Solanum pyracantha* with conspicuous cinnamon spines, and the ribs of the leaves of the same colour; *S. marginatum argenteum*, used in the public gardens at Paris where the silvery margined-leaves have a pretty effect when stirred by the wind; *S. robustum*, a noble kind for bedding; *S. hystrix*, *Baldesi*, and several others of the same family. *Antirrhinum*, *Phlox*, and *Pontstemons* were also shown by the same exhibitors; and *Invincible Sweet Pea* from Mr. S. Brown, of Sudbury, Suffolk, was awarded a first-class certificate. From Messrs. Carter & Co., came tastefully-filled plant-cases, and good examples of Mrs. Pollock *Geranium*.

GLADIOLI AND SEEDLING DAHLIAS.—I had hoped that the alteration in the schedule of the Crystal Palace Autumn Show, by which amateurs were separated from nurserymen in the classes for Gladioli, would have brought together a much larger number of competitors; it did not, and this, coupled with the absence of such growers as Mr. Standish of Ascot, and Messrs. Youell, of Great Yarmouth, tended to make the exhibition of these beautiful autumnal flowers below the usual mark. My friend and neighbour Mr. Sladden, of Ash, near Sandwich, exhibited a fine stand, and there were some excellent spikes in the Messrs. Kelway's collection, although the method of exhibiting them finds no favour in my eyes. I look upon the way in which their second collection was set up with *Yucca* leaves simply as a barbarism which ought not for a moment to be tolerated.

Having adverted in last week's Number to some of Mr. Standish's flowers, I can now add a few notes on some of the French varieties as exhibited by Messrs. Kelway, Mr. Sladden, and Messrs. Paul & Son; some of these are flowers that have been in growth many years, but to

those who are forming or desirous of forming a collection, the notes on them may be of service:—Penelope, an old, very old flower, bluish shaded with carnation, with sulphur and carmine blotch. Belle Gabrielle, rosy lilac, striped with bright rose, large flower. Adonis, an old but good sort, cherry, spotted with carmine. Fulton, one of the new flowers of last year; transparent vermilion, with more of an orange shade than James Veitch, but a well-shaped flower, with good spike. Madame Furtado, another of last year's seedlings, in the style of Standish's Eleanor Norman, but not, to my mind, so good a flower, though my friend Mr. Sladden disagrees with this. James Veitch, a flower of 1863, very brilliant crimson, violet spot, fine spike and very effective. Edalia, a very beautiful flower; under petals white, spotted violet; upper petals marked with white. Le Poussin, clear red on white ground; under petals with large white blotches. Achille, an old, but prettily-coloured flower; currant red, stained with crimson and white. Napoleon III., another old but excellent variety, with good spike; red, with white lines in the centre of the petals. Madame Basseville, cerise rose, with purple spots on a white ground; very good. Bertha Rabourdin, white, beautifully marked with rosy carmine. Madame de Vetry, white shaded, spotted, and blotched with carmine; good. McMahon, glossy satin orange, spotted with red. Marie Dumortier, bluish, violet purple spots on yellowish ground. In Mr. Sladden's stand there were no less than fourteen seedlings of his own raising; amongst them Cato, a curiously shaped one, and a yellow. Miss Sladden, were promising flowers, the latter especially.

Prizes for twenty-four: first and second, Messrs. Kelway & Son, Langport; third, Messrs. Paul & Son. For twenty-four (Amateurs): first, Mr. J. Sladden; second, Mr. W. Ingle.

A large number of seedling Dahlias were sent in. Let me give their names, characters, and awards. Miss Adams, Fancy, poor. Lady Derby, white, tipped. Black Hero, dark. Lilac Perfection, too small. Mr. Gibson, small. Yellow Triumph, bright yellow; second-class certificate; Attraction, Fancy. Sunbeam, scarlet, white-tipped. John Downie, yellow ground, tipped. Lady of the Lake, white, tipped, confused. James Backhouse, lilac; no advance. Jeannie Deans, Chung, yellow striped Fancy, large, somewhat coarse; second-class certificate; will be a useful flower in an amateur's hands: George White; President Lincoln; Sir Greville Smythe; Lottie Atkins, white, beautifully tipped; a splendid flower, first-class certificate. John Bann, cream, fiery-striped; common. Annie Austin, buff; second-class certificate. Marquis of Winchester, dark crimson; fine flower, of excellent build; first-class certificate. Frank Titton, striped Fancy. Majestic, dark purple. Sunlight, buff. Hebe, tipped. Firefly, Princess Alice, Amber Witch, all poor. Master of Arts, bronze satin, lilac back of petals; something in the style of Rawlings' King; second-class certificate. Lillie Franklin, Fair Imogene, Lord Enfield, nothing remarkable. Fanny Start, fine Fancy, scarlet, heavily tipped with white; a first-rate flower, and a great addition.

It will thus be seen that three flowers—Marquis of Winchester, Lottie Atkins, and Fanny Start received first-class certificates; and I can testify to their being decided acquisitions for Dahlia-growers, and especially for exhibition purposes—an opinion in which I am not singular, as some of the best and largest growers in the kingdom expressed the same during the day. Everything passed off well; and the kindly feeling and courtesy that pervades all connected with the Crystal Palace flower shows, marshalled under the guidance of the indefatigable and excellent Superintendent, Mr. Wilkinson, were never more manifested than on this the closing flower show of a very successful season.—D., Deal.

#### FRUIT.

The best collection came from Mr. Miller, gardener to Earl Craven, Combe Abbey, and comprised a good Moscow Queen Pine, Monarch Melon weighing 7½ lbs., splendid bunches of Muscats and Black Hamburgh Grapes, the three bunches of the former weighing 10 lbs., and the latter 10½ lbs., Morello Cherries, Peaches, Nectarines, and Plums. Mr. Bailey, gardener to T. Drake, Esq., Shardeloes, was second with a Queen Pine, Melon, fine bunches of Bowdoin Muscat grown in pots, Figs, Peaches, Nectarines, and Jefferson Plums; and Mr. Donald, gardener to J. G. Barclay, Esq., Leyton, was third. Fruit of the Papaw was exhibited in a collection from Mr. Carr.

PINES were not numerous, but some of them were very good. A splendid Queen from Mr. Barnes, gardener to Lady Rolle, Bieton, was first in the class for that variety. Mr. Miller was second with one of 3½ lbs., and Mr. Higgs, gardener to Mrs. Barchard, Putney Heath, third. In the class for any variety, Smooth-leaved Cayenne, very good, from Mr. Page, gardener to W. Leaf, Esq., was first and third, and Black Jamaica from Mr. R. Smee, gardener to W. Stone, Esq., Dulwich, second. Prickly Cayenne, Moscow Queen, and Black Jamaica were the other kinds shown.

GRAPES were fine, especially the Black Hamburghs from Mr. Meredith, of which the bunches were large, and the berries of extraordinary size, and perfect in colouring; and a fine basket was also shown by the same highly successful grower. Mr. Miller contributed three very fine bunches weighing 11½ lbs., but the berries were not so large; and good well-coloured bunches came from Mr. Osborne, Mr. Sage, Messrs. Lane & Son, and Mr. Ford. Mr. Will's contributed an excellent basket of West's St. Peter's. In White Grapes, good Muscats, but scarcely ripe enough, came from Mr. Osborne, and Golden Hamburgh, from Mr. Miller, was exceedingly fine; the centre bunch weighed

no less than 5 lbs., and the two side ones together 7 lbs. Buckland Sweet-water, and Trebbiano, were also shown in good condition, and Royal Vineyard came from Mr. Williams, of Holloway. The class for the heaviest bunch of any kind was a poor one. Mr. Irving, gardener to the Duke of Hamilton, had Black Hamburgh budly coloured, weighing 5½ lbs., and Mr. Osborne, the same kind, weighing only 3 lbs.

Prizes.—Boxes of 12 lbs. weight: first, Mr. J. Meredith, The Vineyard, Garston; second, Mr. G. Osborne, Kaye's Nursery, Finchley; third, Messrs. Lane & Son, Great Berkhamstead; extra, Mr. W. Cross, gardener to Lady Ashburnton, Romsey. For three bunches of Black: first, Mr. J. Meredith; equal second, Mr. G. Sage, gardener to Earl Brownlow, Ashridge, and Mr. G. Osborne; equal third, Messrs. Lane & Son, and Mr. J. Ford, gardener to Rev. T. D. Hudson, Watton, Herts. For three bunches of White: first, Mr. G. Osborne; second, Mr. W. Miller; third, Mr. T. D. Irving, gardener to the Duke of Hamilton, Wickham Market. For the largest bunch of any kind: first, withheld; second, Mr. T. D. Irving; third, Mr. G. Osborne.

PEACHES and NECTARINES were generally small. Some well-coloured fruits of Royal George, Barrington, and Bellaguard Peaches were shown, and of Violette Hative and Elrge Nectarines.

Prizes.—Peaches: first, Mr. George King, gardener to K. Loader, Esq., Slough; second, Mr. W. Kaile, gardener to Earl of Lovelace, Ripley; third, Mr. C. Evans, gardener to Gen. Cartwright, Weedon; extra, Mr. W. Ingle, gardener to C. G. Round, Esq., Colchester, and Mr. J. Enstone, gardener to Sir J. Duckworth, Wear, near Exeter. Nectarines: first, Mr. George King; second, Mr. W. Tillery, gardener to the Duke of Portland, Welbeck; third, Mr. W. Ingle.

MELONS.—Of these there was an extensive and fine display. Marquis of Ailsa was first in the Green-fleshed class, and Bailey's Gem in the Scarlet-fleshed.

Prizes.—Green-fleshed: first, Mr. T. Godfrey, gardener to A. Bingham, Esq., Ware Park Mill, Herts; second, Mr. T. Crane, gardener to Rev. E. L. Deeds, Hertford; third, Mr. O. Goldsmith, gardener to Sir W. Farquhar, Bart., Dorking. Scarlet-fleshed: first, Mr. C. Smith, gardener to A. Anderson, Esq., Norwood; second, Mr. Bailey, Shardeloes; third, Mr. H. Thorneycroft.

FIGS.—Noticeable among these were good examples of Brown Turkey and Brunswick. Mr. Enstone was first; Mr. Timberley, gardener to Sir C. Goring, second; and Mr. Kaile, third.

CHERRIES were chiefly confined to Morello and Late Dukes, which were very good, but a few Bigarreaux and Flemish were also shown.

Prizes.—Two dishes, distinct kinds, in fifties: first, Mr. G. Sage; second, Mr. Bailey; third, Mr. W. Tillery; extra, Mr. R. Marcham, gardener to E. Oates, Esq., Hailwell.

PUMPS were numerous, and some of them were very fine. The first prize went to Mr. Bailey, for Victoria, Jefferson, and Washington; the second to Mr. Simmonds, gardener to J. Smith, Esq., Dorking, for the last two, and Kirke's; and the third to Mr. Sage, for Kirke's, Washington, and White Magnum Bonum; Mr. J. Wells, gardener to A. Gilbert, Esq., Windsor, and Mr. O. Goldsmith, were equal fourth. Green Gage, Coe's Golden Drop, Goliath, Black Diamond, Pond's Seedling, and some others were well represented.

APPLES, especially the kitchen kinds, were very numerous, but not remarkable as regards size, and many of the dessert kinds had not arrived at their full perfection. Emperor Alexander, New Hawthornden, Lord Suffield, Reimette Blanche de l'Espagne, and Nelson's Glory from Messrs. Gadd & Son, Worthing, were first; and Hoary Morning, Lord Suffield, Blenheim Pippin, Emperor Alexander, Praiseworthy, and Tambour from Messrs. Lane, of St. Mary's Cray, were placed second; Hollandbury and Emperor Alexander from Mr. Webb, of Reuding, who was third, were finely coloured. Mr. Kaile was fourth. In dessert kinds Dr. Cooper, of Slough, who was first, had beautifully coloured examples of Devonshire Quarrenden, Red Astrachan, and Early Red Margaret; and Mr. Sheath, Langley, was second with these three, Cox's Orange Pippin, Ribston Pippin, and White Peach. Mr. G. House, Slough, was third; and Mr. W. Wren, gardener to E. Purser, Esq., Carshalton, and Messrs. Lane, St. Mary's Cray, equal fourth. Collini, Kerry Pippin, Fearn's Pippin, and many others were also well represented.

PEARS were tolerably numerous, but the period of the season only admitted of early sorts being exhibited. The varieties principally shown were Louise Bonne of Jersey, Gansel's Bergamot, Williams' Bon Chretien, and Marie Louise. The heaviest dish was Uvedale's St. Germain, weight 8 lbs. 10 ozs., and a fine dish of Maréchal de la Cour from G. Wilson, Esq., Weybridge, was second. The same gentleman also exhibited a fine dish of Louise Bonne of Jersey.

Prizes.—For three dishes: first, Mr. J. Sheath, Slough; second, Mr. W. Richbell, Epsom; third, Mr. D. Donald. Single dish, for weight: first, Mr. G. W. Gadd, gardener to J. R. Jaffray, Esq., Reigate; second, G. F. Wilson, Esq.; third, Mr. J. Morris, gardener to T. G. White, Esq., Wethersfield. Single dish, for flavour: first, Mr. H. Anstiss, Chiswick; second, Mr. Bailey; third, Mr. J. Fraser, Leyton.

MISCELLANEOUS.—From Messrs. Lane & Son, Great Berkhamstead, and Mr. Geirs, Norwood, came Vines in pots; those from the former being loaded with beautiful bunches. For these first and second prizes were awarded to their respective exhibitors; also, for Peaches in pots from Mr. Vertigan, Clapham, and Mr. Fraser, Leyton. Mr. Sage, sent a collection of the fruit of different kinds of Capsicums and a cluster of Bananas; Mr. Carr, a large cluster of Bananas, the

fruit of the Papaw, and a Granadilla; Mr. Cuthill, of Camberwell, an Australian Melon, weighing 5 lbs.; Mr. Turner, Streatham, good boxes of Peaches and Nectarines; Mr. Sawkins and Mr. Higgs, Curran's; and the Wizard of the North, two Mammoth Gourds of great size.

THE CARSHALTON AND BEDDINGTON SHOW.

On a bright day in last week (August 24th), we made a pilgrimage, and it was a very pleasant one, to the second Show of the Carshalton and Beddington Horticultural Society. This was held by the kind permission of Mr. Aitken in the beautiful park of Carshalton, very near to the house where lived, a century and a half since, the sour-tempered Dr. Radcliffe, the founder of the Radcliffe Library. The site for the Show was happily selected in a fine old park, which is surrounded by the very extensive herb and flower fields for which this district is celebrated. The whole Show, which was a most successful one, did credit to the Committee, and to the horticultural skill of the two small parishes in which all the exhibitors hold their gardens. A very interesting feature of this Show will, on the next occasion, be the specimens of the flowers and herbs cultivated in the little group of parishes of Carshalton, Beddington, and Mitcham, chiefly for their perfumed oils. In Mitcham alone about 750 acres are now employed for this purpose—viz. :—

For the growth of Peppermint, .....	about 224 acres.
" " Lavender .....	" 175 "
" " Roses .....	" 121 "
" " Chamomile .....	" 69 "
" " Liquorice .....	" 39 "
" " Henbane .....	" 25 "

The Lavender and the Peppermint are chiefly distilled for their oils. The yield of the oil of Lavender is now about 10 to 13 lbs. per acre. The plants are changed every three years. The product of oil from the second year is the largest. Of the oil of Peppermint, the product is about 7 to 12 lbs. per acre. About 300 bushels of Roses per acre are produced in good seasons. These are chiefly used for making Rose water. They are gathered before sunrise, and are kept in a drying-house heated by air to about 100° for some time. We do little in our country in the production of the otto of Roses, that comes to us from far more sunny climes. This fine-scented oil, according to Mr. Kimmel, is very largely produced in the districts around Adrianople. It is worth, according to its degree of purity, from 15s. to 30s. per oz. That from the south of France is very fine; the best, however, comes from Tunis, and is worth about £4 per oz. There is also that made at Ghazepore, in the East Indies, worth £12 per oz.! There was imported into England of oil or otto of Roses in—

	1861.	1862.

The oil or otto of Roses is chiefly obtained, according to Dr. Hogg ("Vegetable Kingdom," page 305), from the Damask and Cabbage Roses. At Ghazepore, in India, the Rose gardens occupy about 150 acres of land; each acre contains 2000 Roses, which in a good season, yield in March and April, a lac of flowers, and this weight produces only about 180 grains of the otto. Our Rose water is obtained by distilling off one gallon from 2 lbs. of Roses and two gallons of water. The chief towns of southern France, where the manufacture of scented oils is carried on, are Grasse, Cannes, and Nice. At Grasse, which is the head-quarters of the manufacture, it has been estimated that there are annually used for this purpose, 1,760,000 lbs. of Orange flowers; 550,000 lbs. of Rose flowers; 110,000 lbs. of Jasmine flowers; 66,000 lbs. of Violets; 66,000 lbs. of Cassie; and 33,000 lbs. of Tuberoses. It is hopeless to attempt to cultivate these in our country for perfumery purposes. English flowers, however beautiful in form and colour, do not, it seems, possess sufficient intensity of odour. The only flower which could be had in abundance, would be the Rose; but the scent of even this is faint compared with the southern Rose. The best essence of Orange flower, or *neroli*, is made from the flower of the Bigarrade, or Bitter Orange tree. The other two essential oils, jasmine and cassie, are only distilled in Northern Africa.

We subjoin the list of the prizetakers at the Carshalton Show :—  
 Six Fuchsias.—First, Mr. Shoebridge, gardener to E. C. Goad, Esq., Hackbridge House. Second, Mr. August, gardener to Rev. — Bridges, Beddington. Extra, H. Jackson, Esq., Carshalton.  
 Four Fuchsias.—First, Mr. August. Second, Mr. Holder, gardener to H. Browning, Esq., Wallington.  
 Specimen Fuchsia.—First, Mr. August. Second, Mr. Jarvis.  
 Six Achimenes, distinct varieties, eight-inch pots.—First, Mr. Hubbard, gardener to — Marshall, Esq., Beddington.  
 Six Balsams, distinct double varieties, 11-inch pots, without stakes.—First, Mr. Barnett, gardener to G. Drason, Esq., Beddington. Second, Mr. Hubbard.  
 Six Cockscombs, eight-inch pots.—First, Mr. J. Mortimer, gardener to A. Smee, Esq., Beddington. Second, Mr. Hubbard.  
 Twelve Exotic Ferns.—First, Mr. W. Mortimer, gardener to W. Potts, Esq., Carshalton. Second, Mr. Hubbard.

Twelve British Ferns, rarest and most distinct species.—Prize, J. H. Hay, Esq., Carshalton.  
 Eight Lycopodiums.—First, Mr. Hubbard. Second, Mr. W. Mortimer.  
 Six Zonale Geraniums.—Prize, Mr. Shoebridge, gardener to E. C. Goad, Esq.  
 Five Ornamental-foliaged Plants.—First, Mr. Hubbard. Second, Mr. W. Mortimer. Third (extra), Mr. Whittleton, gardener to L. Charrington, Esq., Beddington.  
 Six Herbaceous Calceolarias.—First, Mr. Harvey, gardener to W. Johnson, Esq., The Limes. Second, Mr. Barnett.  
 Collection of Bedding Geraniums, not less than twelve, six-inch pots.—First, Mr. Harvey, gardener to W. Johnson, Esq. Second, Mr. August.  
 Miscellaneous.—Prize, Mr. Holder, gardener to H. Browning, Esq., for a Cissus; Mr. Mortimer, for a *Coleus Verschaffelti*; Mr. J. Baines, for two seedling Geraniums; Mr. Card, gardener to R. Bethell, Esq., Woodmanstowe. Honourable Mention, Mr. Card, for seedling Geraniums. Prize, Mr. August, for Petunias.

CUT FLOWERS.

Twenty-four Dahlias.—First, Mr. Harvey. Second, Mr. Shoebridge. Twelve Dahlias.—Prize, Mr. Barnett.  
 Twelve Fancy Dahlias.—Prize, Mr. Shoebridge.  
 Extra Prize to Mr. Barnett, for twelve Bouquet Dahlias.  
 Twenty-four Roses.—First, Mr. Barnett. Second, Mr. Wittleton.  
 Twelve Roses.—First, Mr. Wren, gardener to E. Parser, Esq. Second, Mr. Barnett. Third (extra), Mr. Wittleton.  
 Twelve Verbenas, three trusses of each.—First, Mr. Holder and Mr. August (equal), gardeners to H. Browning, Esq., and Rev. — Bridges. Second, Mr. Barnett.  
 Twelve Tasselled Asters.—First, Mr. Holder. Second, Mr. Barnett. Third (extra), Mr. Harvey, gardener to W. Johnson, Esq.  
 Twelve Quilled Asters.—First, Mr. Harvey. Second, Mr. J. Mortimer.  
 Six Hollyhocks, various.—First, Mr. J. Mortimer. Second, Mr. August.  
 A beautiful design for the Table, most tastefully arranged.—Prize, Mr. Shoebridge.

Miscellaneous.—Extra Prize to Mr. August, for thirty-nine Zinnias, distinct varieties.

FRUITS.

Black Grapes, three bunches.—First, Mr. Wren, gardener to E. Parser, Esq. Second, Mr. Rhodes, gardener to L. H. Mackenzie, Esq. Third (extra), Mr. J. Mortimer, gardener to A. Smee, Esq.  
 White Grapes, three bunches.—First, Mr. J. Mortimer. Second, Mr. W. Mortimer, gardener to W. Potts, Esq. Two bunches.—Prize, Mr. Richens.  
 Best Vine in pot.—First, Mr. Holder, gardener to H. Browning, Esq. Second, Mr. Shoebridge, gardener to E. C. Goad, Esq.  
 Best Peach, in pot.—Prize, Mr. J. Mortimer.  
 Best Plum, in pot.—Prize, Mr. J. Mortimer.  
 Pine Apple.—Prize, Mr. Shoebridge.  
 Six Peaches.—First, Mr. J. Mortimer. Second, Mr. Seymour, gardener to Rev. F. N. Ripley. Third (extra).—Mr. Inwood, gardener to J. Aitken, Esq.  
 Six Nectarines.—First, Mr. Holder. Second, Mr. J. Mortimer. Third (extra), Mr. Shoebridge.  
 Apples, dessert, two dishes of eleven each.—First, Mr. Davis, gardener to W. Blackmore, Esq. Second, Mr. Wren. Third (extra), Mr. Shoebridge.  
 Apples, dessert, two dishes of six each.—Prize, Mr. Richards.  
 Apples, kitchen, two dishes of eleven each.—First, Mr. J. Mortimer. Second, Mr. Wren. Third (extra), Mr. Whittington, gardener to G. Brodrick, Esq., Hackbridge.  
 Apples, kitchen, two dishes of six each.—Prize, Mr. Richens.  
 Pears, dessert, two dishes of eleven each.—First, Mr. Davis. Second, Mr. Wren.  
 Pears, kitchen, two dishes of eleven each.—First, Mr. Jarvis, gardener to H. Jackson, Esq. Second, Mr. Davis.  
 Figs.—First, Mr. Jarvis. Second, Mr. Wren.  
 Plums, twelve, light.—First, Mr. Shoebridge. Second, Mr. Davis.  
 Plums, six, light.—First, J. H. Hay, Esq. Second, J. Clark, Esq.  
 Plums, twelve, dark.—First, Mr. Jarvis. Second, Mr. Shoebridge. Third (extra), Mr. Wren.  
 Plums, six, dark.—First, Master Jackson. Second, J. Clark, Esq. Third (extra), Mr. W. Morley.  
 Cherries.—First, Mr. J. Mortimer. Second, Mr. Holder.  
 Gooseberries.—Prize, Mr. W. Mortimer.  
 Red Currants.—First, Mr. Jarvis. Second, Mr. Inwood.  
 White Currants.—First, J. Clark, Esq. Second, Mr. Jarvis.  
 Collection of six dishes Dessert Fruit.—First, Mr. J. Mortimer. Second, Mr. Holder. Third (extra), Mr. Shoebridge.  
 Collection of six dishes of Kitchen Fruit.—First, Mr. Holder. Second, Mr. Shoebridge.  
 Miscellaneous.—First, Mr. Inwood, for Plums and Pears. Second, Mr. Davis, for Melons, Plums, and Filberts.

There was a good collection of Nurserymen's productions, amongst which Mr. Ainsworth's Fuchsias, Gourds, and Marrows deserve notice. Messrs. Dod also showed here some choice Roses, Lilliums, and Caladiums. Specimens of the *Retinospora leptoclada*, in fine and healthy

condition, were amongst the latter. Mr. Morse also showed British Ferns and Dahlias; and Messrs. Cattell, Cucumbers, Peaches, and Plums in pots; *Lilium auratum*, *Clematis Jackmani*, and other plants and flowers.

The Judges were Messrs. Packman, Woodward, and Churchfield.

### PARTITION WALLS IN VINE-BORDERS.

ALTHOUGH much has been said and written upon the construction of Vine-borders, I have neither seen nor heard the least hint of the utility of partitions in them. It is common to see a range of vineries with a long border in front; and when a failure happens, either through some defects of the border, and it is wished to renew a part of it in front of one of the divisions, this cannot be done without the risk of injuring the roots of the Vines in the other houses; whereas, partition walls would keep the Vine roots of each house in the whole range of border within their proper space.

It is somewhat surprising that the great utility of so simple a plan seems to have been overlooked by intelligent gardeners. However, the plan did not occur to myself until lately, when I wished to renew a border in front of the centre house of a range of vineries, and I saw clearly that this could only be done at the risk of cutting off some of the roots of the Vines in the other houses, as already noticed. Partition walls for small borders may be 4 inches thick, of brick laid in cement upon good foundations below the level of the bottom of the borders; but nine-inch ones with tops level with the surface would be best for large borders.

I may observe, that lately a friend asked my advice respecting a Vine-border which he had made inside the house, with a view of keeping the Vine roots from getting out into the cold clay soil, and the sides and bottom of which were cemented. I told him to break the bottom out, and put more rubble, stones, or brickbats below to drain off the water, otherwise his finely-constructed border would soon be like a stagnant tank, neither fit for the growth of Vines, nor of any other plants.—J. WIGTON, *Cossey Park*.

### DESTROYING GOOSEBERRY CATERpillARS.

I HAVE tried an experiment this year in destroying caterpillars on Gooseberry bushes, and I have found it very effectual. I had three boxes made of light material, such as lathwood, large enough to cover good-sized bushes, and with one side open to receive the bush. Wherever I saw the caterpillars making their appearance I smoked with tobacco cloth. I fumigated each bush for six or seven minutes, and as I had the three boxes at work I was not long going over a large plot of bushes, fumigating every alternate one, and the result is that those that were smoked are quite free of caterpillars, and green flies too. On the trees that were not thus treated not a single leaf was left by the 1st of July. I may add that I have tried all the plans recommended in the Journal, but have found nothing equal to fumigation.—WM. MCGREGOR, *Gardener to Hugh McKenzie, Esq., Dundonnell, N.B.*

### BEDDING ANNUALS.

AFTER this long interval we beg to reply to an article that appeared in your impression of the 15th ult., under the above heading. Your correspondent "MONTICOLA" is perfectly right in his remarks on the treatment of the especial subject—*Linum grandiflorum rubrum*, and had we been placed in the same position as himself—that is, having the entire control and arrangement of his own garden, we should, undoubtedly, have treated the plant in the manner he describes as his own. We were not, however, so favoured, and a little explanation of facts may, perhaps, moderate the effect of his deprecating voice, and place our effort, even in "MONTICOLA'S" eyes, on a better footing. In the beginning of April we received from the Council of the Royal Horticultural Society the acceptance of our offer to fill the ante-garden with annuals, the beds in which were to be cleared of Messrs. Henderson's Tulips by the middle of May. The whole of the stock required (some five thousand plants), with a few exceptions, which, however, do not include the *Linum*, were sown in single pots, plunged in the open ground, and treated as hardy annuals, being thinned out eventually to one or two plants in each pot. Under these conditions we calculated that the plants would be in a fit state for turning out by the time specified, and so they were; but delays on the

other side resulted in our accession to the clear beds being postponed until the first or second week in June. The hot and dry weather of the latter part of May was the occasion, to a great extent, of causing the plants to root through the bottoms of their pots, seeking for moisture lower down, which extruding roots were of course torn off on the removal of the plants for transmission to Kensington. The check thus given will, we think, account for the partial absence of success in the want of vigorous growth, and for the "undeservedly shabby" appearance of the *Linum* in contrast to its "gorgeous" display when treated by "MONTICOLA," who sows the seed where the plants are to remain, with the exception of a few thinnings transplanted when quite young. The same remarks will apply likewise to the other subjects introduced in the beds.

With a pertinacity, however, not unlike that which distinguishes the promoters of the Atlantic cable, we are prepared to stand our ground; and though thoroughly conscious that to compare a bed of annuals with a bed of Scarlet Geraniums will, "sure as fate," for brilliancy, give the palm to the latter, yet hearty and colour are not essentially synonymous, and we are persuaded that, by successive sowings, good culture, cutting off all dead blossoms—in fact, bestowing similar care upon them as is devoted to "bedding plants" proper, annuals may be made to produce an effect, of which, perhaps, comparatively few would think them capable, and which would even give many of them a reputation of some distinction as bedders. Let the truly fine display which may be annually witnessed on the grounds of some of our seed-growers, be a perpetual example.—HOOPER & Co.

### HEDGE PLANTS FOR NEW ZEALAND.

In an answer to a New Zealand correspondent in your last Number a wish is expressed that some of your readers would give their experience on the subject of plants suitable for hedges in New Zealand, and now I beg to add my mite.

The Thorn *Acacia* forms in Australia a splendid and almost impenetrable hedge, and close from top to bottom, which can be said of few other plants grown there for that purpose, and where I have seen it, it must have been of rapid growth; but in some instances it is shy enough, particularly under the shade and shelter of a high paling.

Cape Broom grows very rapidly, and forms a nice enclosure if the seed is sown on deeply-dug ground, in two drills, 12 or 18 inches apart; then thin out the plants to a proper distance. Being free of thorns it is not a really good fence, but looks remarkably well. It must be quite common in New Zealand by this time.—W. JACKSON, *Ballyoran*.

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

SUCH ground as is now becoming vacant should be trenched up as roughly as possible, manure being applied if necessary; this should always be done as soon as the crops are off, whether the ground is wanted again immediately or not. *Broccoli*, where a sufficiency has not been planted, large plants may yet be put out with success, they should be laid in with a spade in a slanting direction; earth-up advancing crops. *Cardoons*, earth-up for blanching in favourable weather. *Celery*, continue to earth-up the early crops carefully, the tops of the plants should always be perfectly dry at the time; the crops that have not yet been earthed-up should be kept very moist. *Cucumbers*, those in frames, which it is intended to keep in bearing, should be covered up when the nights are cold, the beds should also be newly lined. *Cabbage*, plant the principal crop for spring use on ground well manured. The East Ham is a good variety for standing over the winter, it is not so apt to run in spring as other sorts. Prick-out into beds, a few inches apart, a large quantity of Cabbage plants, which have just expanded their first two rough leaves; they will be required in spring, for should the Potato disease continue to increase in virulence, the great blank which the loss of an esculent so universally esteemed will occasion must be filled up by extra quantities of other good vegetables, amongst which a fine early Cabbage in April or May meets with general favour. *Endive*, continue to blanch, and plant out from successional sowings. *Lettuce*, another sowing of the various sorts may be made; it is always better to have a superfluity in the spring than otherwise. *Mushrooms*.—Beds may now be made in sheds or

in the open air. *Parsley*, thin the summer sowing while in a young state, the plants will then gain strength to stand the winter. A portion of the spring sowing should be cut down. *Tomatoes*, gather the fruit as it ripens; remove all the shoots that shade it, also some of the leaves.

## FRUIT GARDEN.

Give a final nailing to all wall trees, that there may be nothing to prevent the perfect maturation of the wood. See that *Strawberries* in pots for forcing next season are well cared for, placing them in an open sunny situation where they will have all the light possible, and do not allow them to suffer from want of moisture at the root. Where mulching has been used for Peach and Nectarine trees this should be removed at once, if not already done, for the fruit is seldom well flavoured if the roots are excluded from the action of the sun and air during the period of ripening. It will also be an advantage to have the fruit-tree borders free and unshaded by any crop at this season; the effect of planting *Endive*, *Turnips*, and the like is to keep the border cold and wet, when, in fact, warmth and air are more particularly required. We should be well satisfied to see the width of the borders reduced could even a more limited space be secured exclusively to the wall trees.

## FLOWER GARDEN.

A surplus stock of bedding plants should always be provided against contingencies, the propagation of such as *Heliotropes*, *Verbenas*, and *Pelargoniums* should be proceeded with; as the general utility of these plants for decorative purposes is unquestionable, an ample supply of these is recommended. *Chrysanthemums* out of doors should be carefully staked; if against a wall, where they thrive better, they should be trained while the succulent shoots will bear it; propagate by cuttings for blooming in pots. Budded *Rose-stocks* should be carefully attended to just now, those buds which have started may be encouraged to form a more vigorous growth by stopping the wild branches of the stock. The routine of mowing and rolling must be pursued. Hedges may be clipped. *Auriculas* must be sheltered from bright sunshine, as well as from excessive rain, keeping the pots free from weeds, and occasionally stirring the surface of the soil with a blunt stick. Layers of *Carnations* and *Picotees* where sufficiently rooted may now be taken off the stools and potted. *Pinks* should be planted in their blooming-beds without delay.

## GREENHOUSE AND CONSERVATORY.

Many may hesitate in the work of introducing the house plants while the promise of a late autumn is before them. It is dangerous to trust anything to the weather at this period of the year; therefore, housing tender plants must proceed until the whole stock is reinstated in its winter quarters; but where the opportunity of partial protection exists, many hardwooded plants may, with advantage, be allowed to stand out until the end of the month. Let each plant be carefully examined before housing, and defects in the soil or drainage of the pots remedied. Clear off moss, remove insects, and replace stakes. Climbers will always require attention to keep the shoots in their proper places; take care in training that the part of the trellis or stakes nearest the bottom does not become bare of flowering shoots, as the beauty of the plants depends upon their being clothed with foliage and flowers from the rim of the pot upwards. Pot off small seedling *Calceolarias* into small pots, and keep them close in a frame for a few days. *Luculias*, and other winter-flowering plants growing in the border, must be freely exposed to light and air in order that the growth may be well ripened, and to insure a fine display of bloom.

## STOVE.

Where there is but one house for the accommodation of tropical plants, considerable care and attention are necessary to properly manage them at this season, as some, having completed this season's growth, require to be kept cool and rather dry in order to ripen the wood, while others in free growth require to be encouraged with warmth and moisture. If there is no convenience for removing to a cooler house such plants as have made their growth, these should be placed together at one end of the stove, keeping them sparingly supplied with water at the root, and giving air rather freely, which will generally serve to prevent any attempt at a second growth; and those requiring to be kept warm and moist should also be placed together at the opposite end of the house, where very little air should be given, using every care to keep the atmosphere about them moist. *Allamandas*, *Clerodendrons*, &c., which have done blossoming, may be removed to a vinery where the *Grapes* are ripe or ripening, for as they will require very

little water, they will not do much mischief in the way of causing damp, and their room in the stove will be found useful for other plants. See that everything is free from insects, and keep the foliage of such plants as *Ixoras*, &c., clean by washing with a sponge and soapy water when necessary.

## PITS AND FRAMES.

*Violets* should be potted or planted in a frame, *Mignonette* thinned and sown, *Hyacinths*, *Tulips*, and other bulbs potted and plunged, *Pinks* for forcing encouraged, and *Cinerarias* duly attended to. *Roses* in pots should occupy a fair share of attention. Some frames should now be in readiness for the reception of Alpine plants in pots, especially the more delicate species, to remain for the winter; this should be done as speedily as possible in case a wet season should set in, which would be certain destruction to this humble but interesting class of plants.—W. KEANE.

## DOINGS OF THE LAST WEEK.

A FEW fine days have again come, causing the cut grain so to rattle with the fork, as to lead some of our impatient farmers to regret that they did not use a little patience and wait, instead of carting home the valuable grain in a damp state. In very damp seasons much may be done by building small instead of large stacks, and having inside an open framework in the shape of a cone, so that a draught of air may freely pass through the centre. It was the fashion at one time to talk about Ireland, and its deplorable backwardness in agriculture and everything else. Very probably in our short visit some years ago (and we have yet heaps of notes unused for want of time) we might see only specimens of the best farming, and the most economical management, but in the farms we did see, we do not recollect observing a single stack of valuable grain built on the ground. If nothing more substantial was to be had, stout stakes of wood, some 2 feet above the ground level, were fixed in the ground; on them pieces of zinc, tin, or galvanised iron some 12 or 15 inches square were fastened, and on these, from post to post, the rough wooden framework was placed; neither mouse nor rat could then pass the horizontal out-jutting smooth iron. With such a contrivance, and an open cone in the centre, there could scarcely be danger from damp, mildew, or heating, even in bad seasons. Though anything but timid, we have at times felt a little alarmed at the armies of rats, not to say legions of mice, that retreat from a wheat-stack when it is taken down after being built on the open ground. In many cases, the rats get more than the farmer does for all his labour, and the aroma that is left behind must be anything but in favour of the grain at the market. Huge lumbering barns, whether of brick, stone, or wood, are going out of favour, as the building and keeping them in repair told either upon the profits of the leasehold farmer, or on the rental of the landlord. We have met with cases in which keeping up such and sundry buildings left nothing in the way of a rental. That is no reason why stacks should not be built above the ground, so as to be safe from vermin, or, what in the end would be vastly more economical, be stored in Dutch barns—that is, with solid sides of wood or brick some 2½ feet from the ground, and open thence to the roof, whether that was formed of tiles, slates, or wood and asphalt. The barn would only cost the expense of a few years' thatching, and the expense of thatching would be altogether saved in future. Even for hay, it would form the cheapest plan. If the roof were lofty, in other words if the sides were open for 15, 20, or more feet, the grain would be still more safe than in a stack, and might be thoroughly secured against any wet at the sides, by keeping the ear ends of the sheaves elevated instead of horizontal in building. A strip of zinc or galvanised iron about 15 inches wide along the sides, would effectually keep out all intruders, and any vermin that found their way in would either be taken in with the sheaves, or be forced to run a mine below the building. Fine examples of elevated stacks, and of a Dutch barn, wonderful for its size, may be seen at the farm of Lutou Hoo, the farm buildings and conveniences there being, we believe, as yet unequalled in this or any other country.

## KITCHEN GARDEN.

The change in the weather has led to something like a contest between the lawn and the kitchen garden, the heavy rains having made the former grow wonderfully, so as to be in most places beyond the power of hand machines, whilst small weeds have come up very thickly in the latter wherever there was

room for them to show themselves. As is generally the case, being unable to do all that was necessary, we made a compromise of the matter; and after making all tidy near the mansion we went through with a Dutch hoe the most conspicuous parts of the kitchen garden, and where very prominent, contrary to our usual practice, we ran a rake over the ground, just to remove any weeds above 3 inches in height, and to expose the others more to the sun. In any patches extra thick, the quickest and best way to put them out of sight is just to turn them by a shallow shovelling rather than digging—holding the spade in a nearly horizontal position, or almost parallel with the surface of the ground, and only making it go 3 or 4 inches deep. Even in softish walks this is the quickest plan to clear any very green part. Hoing and raking is of little use in the autumn unless you are sure of some days' sun; and though salt would soon settle the matter by killing all above ground, it will act as a stimulant to future crops; and if the walks are smooth on the surface—that is, very fine and smooth for thin-soled slippers in summer, they will become retentive of moisture, and be apt to be sloppy in muggy weather in winter.

Some of our correspondents have been doing what we hope is rather unusual—reading up some of our old forgotten articles, at least forgotten by ourselves; and this question of *salting walks* is a matter which seems to them deserving of more notice. We shall endeavour to meet their wishes by detailing our present impressions, based on practice and observation.

A wide walk in the kitchen garden, on which not a weed was seen three weeks ago, was becoming all over of a greenish hue, when you looked along it in the morning before the dew was dissipated. There being Box on each side, salt was thrown along, just enough to give it a regular white appearance, on Tuesday morning; it was brushed over on Wednesday forenoon, and now, on Thursday, hardly a trace of the salt is to be seen. The weeds, though small at first, are not quite out of sight yet, but another day's sun will pretty well accomplish that. Some friends salt close up to the Box edging; but we have good reasons for not doing so, and therefore leave a space unsalted of from 9 to 12 inches in width, which is weeded by hand in the usual way.

This is the only walk we have as yet salted, and it is different from most others. In the end of the spring it became a little green; and as we had no time to turn it, even if there had been depth enough, we gave it a deepish hoing with the Dutch hoe when it was damp, and raked it several times when it was dry. The walk had been rather too smooth in winter, and therefore we left the surface rather rough; the gravel left there from the rake consisting chiefly of pieces from the size of Broad Beans to that of Walnuts. Even after several rollings the walk after dry weather would be a little rough to the feet; but from its very roughness it will be better to walk on in winter, as in scarcely any weather will it adhere to the feet, as a smoother walk would be apt to do. The effect of the salt will be to crack and split a number of the stones and pebbles, but we do not think that will be done to such an extent as to render the walk too smooth and moisture-laden for the winter. We can hardly obtain both advantages. The smooth-surfaced walk is the most pleasant in summer; one a little rougher on the surface, but firm withal to prevent the rains sinking in it, is the most serviceable in winter.

We ought here to state, that we have not followed the usual course with our flower-garden walks this season. These walks at first were made very shallow, and were scarcely ever broken on the surface. Every summer, as soon as the bedding was about over, even though few weeds were to be seen, we scattered a little fine salt along them, choosing the sunniest days for the work; then in about a couple of days or so, we threw along them a little fine gravel, or siftings of gravel, just enough to give a fresh appearance, and levelled either with a broom or the back of a rake, and after the first shower whisked over them with a broom and then rolled them down. The salt was partly absorbed by the old and partly by the new surface, and the slight sprinkling prevented anything like softness until the end of the autumn. If any person over-critical happened to be in the way, the slight fresh covering neutralised the white colour of the salt. By such management our walks were generally in good condition all the summer and autumn, and as they were not greatly used in winter, no objection could be taken to them. Last winter, however, they were more used, and after frosts, thaws, and rains, they were more sloppy than we wished to see them. With the exception of the fresh dustings of siftings, they had never had any gravel for more than twenty years, and we have no doubt that the salt had

eaten down into and converted into powdery material all the little stones near the surface. Walks to be used much in winter are, therefore, none the better of being over-smooth on the surface, unless, indeed, the surface should have a thin covering of pure sand, that would be little influenced by frosts and thaws. There is no doubt a great difference in gravels, but good gravel is often very difficult to obtain in some neighbourhoods. The above is about the easiest mode that we have met with of keeping walks nice; but until we had more rough material near the surface we should not like to use much salt for fear of its effect in retaining moisture in winter. With roughish gravel it may be more freely used.

So much have we noticed the effects of salt, soda, &c., in eating into, reducing, and turning the hardest stone into dust, that we would repeat the caution long ago given, not to use salt on gravel near any building or wall of stone, &c. We cannot well pronounce on the distance to be safe; but it would be well not to go nearer at least than from 4 to 6 feet. It is amazing how salt thrown down on gravel, close to the walls of a house, will find its way into these walls, mount upwards, and crumble the stone as it goes. It is safest used on walks bordered by grass edgings. We once saw a fine stone curb for flower-beds shelling off in laminae and crumbling away, and the circumstance was considered unaccountable. We have not a doubt that the salting of the walks did the mischief. We did not require to be told of the salting; the sight of the clear almost crystalline-like gravel was enough. Salt, therefore, even as a weed-destroyer should be used with caution.

Once more as to the mode of applying salt. We prefer the simplest and the most economical. Be the kind of salt rough or smooth, white or discoloured, it is malleted, and made to pass through a fine sieve, and then scattered with the hand or small shovel as thinly and evenly as possible over the gravel, so as to leave salt everywhere. We would sooner go a second time than put on too much, owing to what we have said above as to its moisture-retaining qualities. So much for the mode, now as to the time. That should be in a sunny day, and when our own feelings, as well as the barometer, lead us to expect that the weather will be dry for several days. The longer the salt appears on the surface, the more thoroughly it will act; but even under the above circumstances, the white appearance will not last long. The sunny day is generally followed by dew at night, and the weeds and the gravel absorb the liquefying salt slowly, but more thoroughly, than if more quickly liquefied. Of course, if put on before rains, the salt is carried to the sides of the walk, and into the drains, and if there are Box edgings woe-betide them, unless well elevated. Whilst the salt lies no one should step from the walk to the lawn, or every step will leave a black mark. Ladies and gentlemen generally dislike the white appearance, and, therefore, a time should be chosen when they are not likely to see it. If done along with a fresh surfacing, as detailed above, that objection would be considerably obviated. In our pleasure grounds we should use little this season, but if much green should appear for a few inches at the sides of the walks, we shall use it there in preference to weeding. But for making walks too fine, and too retentive of moisture in winter, there is no plan for keeping them bright and clean in summer that would be equally economical. We prefer for similar reasons of economy using the dry salt at once. We have no objection to urge against those who prefer using the salt melted in either cold or boiling water; but salt for salt, we believe we obtain as much benefit from the dry salt as from an equal quantity either in hot or cold water. Of course, the former acts more quickly, and those who prefer a machine for boiling the water and the salt, may well carry out their own views. The amateur may do all he wants by merely sowing the salt, and keeping his feet from going on grass afterwards.

As soon as possible we shall run the fork through recently-planted Cauliflower, Broccoli, Coleworts, young Spinach, Onions, &c., as the heavy rains have battered the surface, and these crops will be all the better of a little air being let in amongst the roots. About the time this is printed, we shall sow Cauliflower for the first crops next spring. A little rough sand is a good thing to throw over the surface, as slugs and worms dislike it much. Cut Basil, Marjoram, &c., for drying. Will take Onions under cover ere long. If merely kept dry they will not suffer from frost. See what has recently been said of Mushroom, &c. Will turn over, by trenching, part of the Onion ground for Cabbages. Most probably we shall put on a lot of rotten grass, &c., as a manure, but that will be placed some 18 or 24 inches from the surface, so as to tell on the plants

next summer. The plants will stand all the better from the surface soil not being over-rich. Gathered Dwarf Kidney Beans and Runners, rather to insure continued fruitfulness. For those coming into bloom will have some rough covering ready to throw over them in any cold night.

FRUIT GARDEN.

Much the same as in the previous week. All fruit out of doors is much earlier this season than usual. Have gathered lots of Jefferson's Plum from standards for preserving, and late Peaches, &c., are coming in. One great advantage of orchard-houses is, that in a forward season like this you may prolong the season, by keeping the house with abundance of ventilation, so as in fact to make it cooler than the out-door temperature. If ever we should get the chance we would have a cool glass house for such Plums as Reine Claude de Bavay and Coe's Golden Drop, as, in many seasons, we believe they could be thus had beautifully coloured, and rich in flavour up to November. Jefferson on standards are now ripening freely out of doors. Removed a few secondary shoots from dwarf Pear trees, and gathered the riper Apples, as Red Quarrenden, Kerry Pippin, &c. Looked over Vines, as detailed last week. Peaches are better of being gathered before quite ripe, and allowed to lie for a day or two on clean white paper, with, perhaps, a very little clean, sweet, dry hay beneath the paper. They will hardly lie on a hard substance without being blemished; and some kinds, as Noblesse, when nearly ripe, will not stand handling. We have seen well-meaning people fingering such fruit as they went along. It is much of a piece with a gentleman pulling off the blooms from the points of Cucumbers, or a lady going through a viney, and nipping a number of berries out of each bunch to which she had access.

ORNAMENTAL DEPARTMENT.

To put matters right after the rains, we have been obliged to leave cuttings and potting for a little, and go on picking the beds, getting lawns shorn, rolled, &c., and switching and rolling the walks. The few days' sun has done wonders, but last night there was much sheet lightning, and there is a tendency downwards again in the barometer, so that unless there be a fortnight of fine weather, we fear that the great attraction of the flower garden this season will have been past with the end of July.

We remembered some time ago how brilliant a row of the Golden Chain was, but it being on the north side of a ribbon-border that faced south and north, with a ridge in the middle, the rain has punished it very severely, whilst in more open places and with nothing higher above it, it still remains very good. We find, also, that beds in such changeable weather suffer in proportion to the earliness of the time they were a mass of flower. All our first-planted-out beds have suffered most, and though a great many blooms have opened within these two days, it will require a number of days to restore their former brightness. Later-planted beds, and which were just arriving at their best, have suffered less from the wet. The gardens, therefore, that were late in July, are likely to be better in September than those which very good in the beginning of July. It is not easy, irrespective of the seasons, to have them first-rate at both seasons. To have a fine show in the beginning of July or the end of June, presupposes thick planting; but that thick planting without much pruning and disleafing, especially in such a season as this, will be sure to encourage more foliage than is desirable. It is amazing the difference as respects brightness between beds fully exposed and those protected, even on one side, from wind and rain. One annual, with the exception of being double the height it was last season, has given great satisfaction. We suspect it is the same as that designated *Tagetes signata*, by our friend Mr. Robson, at page 164, or something in that way, but which we call *Tagetes tenuifolia pumila*. The *Tagetes tenuifolia* is a free-flowering single Marigold, growing from 24 to 30 inches in height, and with beautifully cut fern-like foliage. The dwarf variety, *pumila*, was a dense mass of orange-mottled flowers last season, and scarcely more than 6 inches in height. This season we have a row of it, but it is fully a foot in height, in some cases quite 14 inches, but in some other cases not more than 9 inches. Many have taken a note of it, as a substitute for *Calceolarias*, &c. Even this annual, however, is influenced greatly by position. Part of the line referred to is pretty well exposed, and especially to the west. Another portion is partly sheltered by the mansion, at the distance of some 50 feet or more. In the first position the plants are higher, from receiving more rain we imagine, and though there is an abundance of flowers, a good

many of the pretty leaves peep through them. In the more sheltered part the plants are lower and are a dense mass of bloom with scarcely a leaf to be seen, except at the sides. It bears the pruning-knife well, and, therefore, is easily kept uniform. The colour is all right enough, but the fastidious must not meddle with it, as it emits, especially when touched, the strong Marigold scent. For beds to be seen a little way off, it may well take the place of the orange-coloured *Calceolarias*.

Just like Clover in some fields, no doubt some gardens are becoming *Calceolaria*-sick. A gardener told us the other day, that though he moved the soil from one bed into another every year, his *Calceolarias* would fail every year. We merely plant in different beds, as we have never yet attempted to change or freshen the soil. Rotation-cropping is the next best. *Calceolarias* on the whole have done well. The time when we had any trouble with ours was in the spring, the roots would not flourish in the cold pit in which the cuttings were inserted in the autumn. We believe it was owing to using old effete soil mixed with some fresh.

*Chrysanthemums* in large plants will want well and frequent watering. Rains must not be depended on, as the showers are thrown by the heads past the pots. Heath and *Eparises*, and the most forward *Camellias*, should now be placed under cover, as excess of wet will injure them for the winter. The more all house plants are gradually hardened in their wood, the better will they pass the winter.—R. F.

PRIZES FOR WINDOW GARDENING.—Mr. Walter H. Bosanquet has agreed to act as Hon. Secretary of the Window-gardening Committee of the Royal Horticultural Society, and to undertake the sole management of the Society's next exhibition of window gardening by the working classes. This involves the collection of the funds required for the prizes, and at least £150 will be needed. Subscriptions in aid of this praiseworthy exhibition will be very acceptable, and may be sent to W. H. Bosanquet, Esq., 22, Austin Friars, London, E.C.

COVENT GARDEN MARKET.—SEPTEMBER 2.

The market is now overstocked with Peaches and Nectarines. The prices of these are consequently lower than they have been for some years.

TRADE CATALOGUES RECEIVED.

William Paul, Waltham Cross.—*Select List of Hyacinths, Early Tulips, Crocuses and other Spring-flowering Plants.*  
 Charles Turner, Royal Nurseries, Slough.—*Catalogue of Bulbous Flower Roots and Tulips.*  
 J. Carter & Co., High Holborn.—*The Gardener's and Farmer's Vade Mecum—Part IV. Dutch and Cape Bulbs.*

### TO CORRESPONDENTS.

\*.\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

**RED SPIDER (An Orchard-house Amateur).**—The only advice we can give you is to gather your fruit as soon as possible after it is ripe, then if you have a large tub or cistern dissolve 5 or 6 lbs. of soft soap in about 10 gallons of water in which 3 lbs. of quassia chips have been previously boiled for ten minutes, then add as much water to this as will enable you to dip your trees in so that the whole of the wood and leaves may become well wetted with this bitter water. If this is repeated two or three times at intervals you will soon get rid of the pest. For the future keep your trees well syringed with a decoction of similar strength whenever the slightest signs of the enemy appear. Syringe your walls with the same mixture as that recommended above, add to it 5 lbs. of sulphur. After this the walls should be well coated over with a thick grouting made of lime cement, using the grounds of the quassia water to mix it with. This grouting should be well worked into the nail-holes &c. in the wall by daubing the brush several times against it.

**YELLOW TROPEOLUM (Clericus).**—We do not know a pure yellow in the way of elegans. If care is taken to remove a few leaves from yellow Tom Thumb, nothing of the colour can be more beautiful.

**LILUM ABRATUM CULTURE (J. B. Boyd).**—Pot it the end of October or immediately it goes to rest in turfy light loam two-thirds, and turfy sandy peat one-third, with a free admixture of silver or sharp sand, chopping up these materials with a spade; well drain the pot, which should be 7 inches in diameter, and on the drainage place the rougher parts of the compost. Half fill the pot with soil, then place the bulb in the centre of the pot, preserving the roots, if any, and spread them out towards the sides. Cover the bulb about half an inch, and give a gentle watering. The potted bulb may then be placed on a cool damp floor where it is not exposed to frost until the shoot pushes above the soil, when it should have a light and airy situation, be watered copiously, and top-dressed to within half an inch of the rim of the pot when the shoot is an inch or two above it.

**POMEGRANATE ON A SOUTH WALL (Idem).**—The reason of your tree not flowering may be its growing so freely and not ripening the wood. We should advise a trench to be dug round the tree at 4 feet from its base, and so deep as to cut through the roots, simply filling in the trench again. This would be best done early in October, and it would check the luxuriant growth. Keeping the shoots thin so that every part of the tree might be fully exposed to light and air would so far ripen the wood as to induce the tree to flower. It is probable that the roots have gone deep down; and, if so, in addition to opening out the trench, so undermine the root as to cut all roots that strike perpendicularly downwards at 18 inches below the surface.

**CHEILANTHES ODORA CULTURE (H. B. N. R.).**—This Fern is most difficult to cultivate. Half fill the pot with corks, and have some nice sandy turfy peat chopped fine, pieces of sandstone broken to the size of a Walnut, and some sweet hazel or yellow loam. Mix them together in the proportion of two parts of the sandstone to one of the peat and loam, and if the very fine particles of the sandstone be sifted out all the better. In this mixture pot the plants rather high in the centre of the pots, and around them place pieces of sandstone, or rather plant so that they may appear growing from between stones, the pot being covered with these, and the loam and peat in the interstices. Give a good watering, and place in an airy and light situation in the greenhouse. This Fern will do best kept near the glass, and near the point of admission of air. If shaded from very bright sun until it becomes established all the better, and, though it will not grow in much shade, it is more free-growing when partially screened from the powerful mid-day sun. It is very impatient of stagnant moisture, and should never be very wet nor dust dry. It is only to be kept in cultivation by very careful culture.

**TRANSPLANTING RHODODENDRONS (Idem).**—The plants cut down last autumn, and which have made fine growth this season, may be moved now, or any time before November, during mild weather, taking them up with a good ball. Do not reduce the ball, but take them up and plant with as much soil as will adhere to the roots. Spring is the best time to plant Rhododendrons, and April the best month; but from the very nature of the root, which always secures their being removed with a good ball, they may be removed at any season, we having planted them from February to November, and in all stages of growth, in flower, making their growth, and when forming their buds, and with the greatest safety. Water well if the weather prove dry after planting.

**SOWING CYPRESS SEED FROM THE EAST (A Subscriber).**—Sow the seed next March in pans well drained and three-parts filled with light sandy loam, level the surface, and scatter the seeds thinly. Cover with light fine soil, and, after watering, place in a frame with a mild bottom heat (75°). When they come up, and before they become drawn, harden off and place in an airy part of the greenhouse, and near the glass. In the autumn, or spring of the second year, pot them off singly in small pots, and give them a shift annually afterwards. The seeds may be sown as above, and placed in a cool airy part of the greenhouse where they will vegetate as surely, though they may be longer about it. It is possible they might also vegetate in a cold frame, but as to whether they will be best in a frame, a greenhouse, or a hotbed, we cannot determine, not knowing either the species or its habitat.

**PROPAGATING GNAPHALIUM LANATUM (P. P.).**—Cuttings taken now and inserted in silver sand with their base at the least possible distance from sandy loam at the bottom of the pan or pot, will strike in a gentle heat. They strike more tardily now than in spring. A better plan is to take up the old plants in autumn, and winter them in a cool airy greenhouse. In February place in heat, and when the shoots are sufficiently long these may be taken off with three or four joints, and treated in the same way as Verbenas, like which they strike freely. They require a light sandy soil.

**SEEDLING PELARGONIUMS NOT FLOWERING (J. B. C.).**—You may expect the seedlings to flower with the general stock next May or June. They do not usually flower in the same year as that in which the seeds are sown, and it is not desirable, for the flowers of Pelargoniums are never so fine in autumn as during the early summer months, and a good flower might be discarded from its not being in character when flowering for the first time in autumn. There will be no difficulty in making them flower another year, but we know of no plan that would force them into flower this year. We would cut the plants down now to three or four eyes, and when broken, and the shoots about an inch long, pot them, as they are now in very small pots, into a size larger, giving them their final shift into six-inch pots in December. In other respects the treatment need not differ from that of named sorts.

**CALIFORNIAN PUMPS.**—If 'WEST CROYDON' send to Mr. Benson, 17, St. Dunstan's Hill, Tower Street, E.C., London, he will send him a list of places where they are in use. We have had one in use here for a month, and, so far, it works very satisfactorily pumping hot liquor. It is a four-inch pump, and we work by an engine, but all the pumps are made to work by hand.—W. N. BAXTER, *Thornton-le-Moors, Northallerton.* "The Californian pump is very simple. It is a common square spout of any length that may be required, about 4 inches by 4 inside with two rollers, one at top and one at bottom, with an endless strap to pass round the rollers. Blocks of wood are screwed on the strap at intervals, and the strap being turned with one or two cranks the water is brought up.—H. FEER, *Builder, Brooke, Norwich.*" [By this it appears that the Californian pump is only a form of the chain pump.]

**OUVIRANDRA FENESTRALIS CULTURE (A Young Subscriber).**—Your treatment is very nearly right, and we shall, perhaps, best meet your wishes by giving the essentials of its culture. Broad glass pans, from the light transmitted through the sides allowing of the structure of the leaves being perfectly seen, are the most suitable. A compost of turfy peat and half the quantity of decayed turf is placed at the bottom of the glass to the depth of 3 inches, and on this from one-half to three-quarters of an inch of river sand. The sand prevents the water from being discoloured when the plant is syringed or fresh water put in, and the leaves from becoming dirty. The plant should be syringed every morning with water of the same temperature as that in which it is growing. This watering with the syringe frees the leaves of any sediment that may adhere to them, and prevents slimy moss forming in the water, in addition to which the sides of the glass vessel should be rubbed occasionally to keep them clean. The soil should all be taken out once a year; March being a good season. When the soil is left in too long the leaves grow smaller and weaker. The plant requires a temperature of from 70° to 75°. The main points are keeping the leaves free from dirt, and all about the plant sweet. These conditions secured, the Ouvirandra grows freely.

**GARDENERS' WAGES, &c. (An Under-Gardener).**—We have already given considerable latitude to all the matters to which you allude. Some strong comments, on the impropriety of making gardeners live in the mansion, and discouraging marrying, and settling down with families, we have reasons for believing did the intended good in many quarters; many gardeners' houses being built where none formerly existed on the demesne. We would wish to see the word "incumbance," as applied to wife and children, banished amongst the deservedly forgotten things of the past. Meantime, gardeners will do well to act with prudence. All our experience leads us to have no faith in strikes, or unions, among either under-gardeners or head-gardeners as a means of improving their condition. So long as young lads are taken into some large establishments, and struck as it were by cuttings, and then sent out in shoals on the labour market, it will be folly to combine for raising wages. Besides, if young gardeners were to strike to-morrow, and refuse to work, common labourers might soon fill their place, and the gardeners would have to find something else to do. That, however, is no reason why better wages should not be given, or why, if shorter hours cannot be made the rule, there should not be an occasional holiday. As to head-gardeners, we have never yet known them to have cohesion enough to agree upon anything, even for their own good. This, no doubt, is partly owing to their isolated and scattered condition. A number of years ago, a gardeners' paper was started, conducted pretty well for nothing, and the whole profits to be given to the aged and afflicted. The paper could only go on by subscriptions being paid in advance; but even that could not be done. Some gentlemen, as Mr. Thomson, of Dalkeith, could tell what may be expected from unity, and its strength among gardeners. The difference to which you allude between mechanics and gardeners as to wages, is often more apparent than real. Suppose in the country an under-gardener has from 15s. to 18s. or more per week, and a mechanic has £1, the gardener has his lodging and constant pay, whilst the mechanic has often lost-time for months, and tools to buy and keep. A head-gardener is generally in a better position than the generality of mechanics. Of course, we are not alluding to wages in London, where lodgings, &c. are expensive. Besides, a mechanic after serving his time, &c. unless he has capital, has little chance of bettering himself, but the young gardener, if he has a few hard-ships, lives in the hope of bettering himself by becoming a head-gardener. On the whole, as we have previously stated, gardening at present offers few inducements for any of the middle classes to engage in it; but for the sons of mechanics, and even of labourers who will patiently work, study, and wait, and submit to some amount of self-denial, it offers a medium for improving their circumstances, and rising in even the social position. Were there fewer professed gardeners, and were these all men of superior attainments to what as a class they are now, an improved social position would follow as a matter of course. We should be only deceiving young men by false hopes, if we did not express our conviction, that the upward progress of the profession even as respects remuneration, will be greatly regulated, just as the conviction gains ground among employers, that an intelligent active gardener may be a much cheaper servant at £100 a year, than an ignorant, careless man, who is content with £50. Nothing surprises us more than gentlemen often parting with a good man when a few pounds more would keep him.

**DOUBLE FUCHSIA (W. Brown).**—Your seedling double Fuchsia is a very fine one; the broad, bright, well reflexed, scarlet sepals are very effective; the dark corolla smooth and full. If the plant is of good habit, has good foliage, and is free flowering, it will be very useful as a decorative Fuchsia.

**PLANTING LILIES OF THE VALLEY (A. R. C.).**—The best time to plant them is immediately after the foliage decays, or from that time, in mild weather, up to the end of March, but the earlier the better. Give them room and a liberally manured soil if a profusion of fine flowers are desired. We cannot tell the name of the plant from the seed vessel sent.

**SEEDLING VERBENA (W. E.).**—It was so withered when it reached us that it was impossible to pass any opinion on its merits.

**SEEDLING GOOSEBERRY (Gooseberry).**—Your seedling Gooseberry has not sufficient merit to recommend it.

**GOLDEN PIPPIN (G. K., Sevenoaks).**—We are in doubt whether the specimens you have sent are the old Golden Pippin or not; they appear very much like the Yellow Ingestrie which was raised from the seed of the old Golden Pippin.

**VIOLA CORNUTA (Emma M.).**—See what Mr. Wills says in another page.

**FLOWER-GARDEN PLANTING (Old Subscriber).**—We do not plant beds, we merely criticise planting, but we will so far deviate as to give the following for your group of nine beds:—1. Centre, Boule de Feu Geranium or Stella, with border of *Centaurea candidissima*, or *Cineraria maritima*. 2. 4. Tom Thumb Calceolaria, or Yellow Prince of Orange as an edging. 3. 5. *Anrea floribunda Calceolaria*, with a good border of *Lobelia speciosa*. 8. 9. Tom Thumb or Brilliant Geranium, with a border mixed with white Variegated Alyssum, and blue *Lobelia*, as conspicuous. 7. 8. *Christine Geranium*, with a border of *Paxtoniana Lobelia*, mixed with *Cerastium tomentosum*. We have no doubt this group would give satisfaction if the bordering were well managed. We would change the planting every year. Our proposed mode would suit either grass or gravel.

**SELECT GLADIOLUSES (Agaricus).**—The lists of "D. Deal," in this and last week's Number, will, we think, answer your purpose.

**WHITE DOUBLE-COROLLAED FUCHSIAS (F.).**—Charles Heineman, Emperor of the Fuchsias, Jean Verschaffel, Madame Cornelissen, Victor Cornelissen, and President Boisduval, are half a dozen fine varieties. The flower enclosed was quite withered when it reached us.

**ACHIMENES FORMING IMBRICATED BUDS ON THE STEMS (A. C. C. H.).**—It is not unusual for Achimenes to form these in the axils of the leaves after flowering. They will fall on the pot when the foliage decays, and may be employed for an increase of the stock, but the best are those that form in the soil; and of them there is generally a sufficient stock without being at the trouble of potting those formed at the axils of the leaves.

**SEEDLING GERANIUMS NOT BLOOMING (Idem).**—Your seedlings, judging from their height and fine foliage, are in too rich compost. They cannot be induced to flower this season. You will, therefore, have to keep them until another year, when, by keeping them under-potted, their vigour would be so far checked as to cause them to flower. Over-potting seedlings gives abundance of foliage, and rich soil contributes to the same result. Keep over the winter, and when the time for planting out arrives, plunge the pots in an open and sunny situation. They will certainly flower next year.

**NAMES OF FRUIT (Tyro).**—Your Apple is Sugar-loaf Pippin. (Quis).—Plums—1, Washington; 2, Kirke's; 3, Coe's Golden Drop; 4 and 5, Jefferson. Apples—1, Emperor Alexander; 2, Surrey Flat-cap; 3, Duchess of Oldenburgh. We do not recognise the Pear; send it again when ripe. (Orontal). Your Grape is undoubtedly Black Hamburgh, suffering from languid root-action. What state is the border in? and is the crop not too heavy? (G. K., Sevenoaks).—The Peach is Barrington, the Nectarino Elrage, and the Plum Fotheringham.

**NAMES OF PLANTS (P. P. P.).**—It is an *Hedychium* and we think the *H. Gardnerianum*, but the flowers were shrivelled up. Some damp moss should have been in the box. (S. R.).—1, *Polypodium vulgare*; 2, *Lastrea Filix-mas*. (J. B.).—1, *Woodwardia caudata*; 2, *Pteris hastata macrophylla*; 3, *Adiantum fulvum* (?). (Kerse, Fothering).—*Momordica charantia*. (D. H.).—*Viola canina*. (G. S. Wittle).—*Spiranthes autumnalis*. (J. B.). 4, *Buddleia Lindleyana*. (Capt. Davies).—*Cotyledon orbicularis*. The spore must have come in by some means—perhaps in watering. (R. C. A.).—*Gypsophila paniculata*, *Erica ventricosa*. (Rap.).—1, *Pittosporum tenuifolium*; 2, *Francoa ramosa*. (Bromley, Kent).—*Polystichum capense*. No. (Old Subscriber).—*Lastrea spinulosa*; *Athyrium Filix-femina*. All depends on the age of the beds; for the first two or three years dwarf-growing vegetables may be cultivated, but afterwards no other crop should be allowed to interfere with the Asparagus on the beds. (G. T. M. Purris).—The Kidney Bean sent was sent out some years ago under the name of the New Zealand Bean, to which country it had been taken from Europe. It is, we believe, identical with the Haricot de Prague jaspé.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

HALIFAX AND CALDER VALE AGRICULTURAL SOCIETY'S POULTRY SHOW.

The above-named Society held their twenty-seventh Annual Exhibition in Clare Hall Park, Halifax, by the kind permission of Joshua Appleyard, Esq., on the 26th of August.

The entries of Poultry and Pigeons numbered 640, and comprised representatives from many of the leading breeders and exhibitors, nearly every class containing specimens of great merit. The whole were shown in open pens belonging to the Society, and the day being exceedingly fine, the success of the Show was insured. The arrangements of the Committee and Honorary Secretary were admirable, and the Meeting was completely successful, financially, as well as in other respects. The Judges commenced their arduous duties at much too late an hour—namely, about 11 o'clock, which, considering that the Exhibition closes at 6 o'clock, and that the public are necessarily excluded from part of the ground until the decisions are given, is an arrangement, we think, only requiring notice to be remedied, and we feel sure Mr. Irvine is too watchful of the interests of the Society not to profit by the hint we give.

*Spanish*, as usual, headed the list. The first prize-pen in adults, we thought, were very considerably indebted to their feather for the position they obtained. *Spanish* chickens were good. *Dorkings* were not numerous, but chickens were better represented, the first-prize pen being very fine. In *Buff Cochins*, Capt. Heaton occupied his accustomed position in a good class; while in chickens the same exhibitor had to succumb to a pen shown by Messrs. Brown & Greenwood, containing a remarkably fine-shaped, good-coloured cockerel, very indifferently accompanied, which changed ownership at £10 10s. In *Cochins*, any other variety, old and young respectively, capital Partridge carried off the principal prizes. *Brahmas* were fair classes. For the best Single Game Cock,

or Cockerel, the Committee offered a silver cup, value five guineas, bringing together twenty-one competitors, which were characterised by the Judges as forming "a very good class." The cup was awarded to a remarkably good Black Red belonging to Mr. T. J. Charlton, of Bradford. Mr. Fletcher was second with a Brown Red; and the third prize went to a Black Red, all old birds, while several pens received notice. Single Game Cockerels were neither numerous nor of especial merit. Single Game Hens were good, the first prize being awarded to a first-class Brown Red, belonging to Mr. E. Aykroyd. The Single Game Pullet class was large, Black Reds taking the lead. In the adult classes of Black Red and Brown Red Game, there was an average competition; but in both classes for chickens the first positions were obtained by birds of remarkable quality, though rather young, and we think both pens will figure to advantage hereafter. Duckwings and Any other Game classes, both old and young, were well filled, the prizes falling to good specimens. *Falcons* formed nice classes, Silvers taking the first prizes both in the adult and chicken classes, good White-crested Black and Golden also winning. *Hamburghs* were both numerous and good. The cup for the best pen, as well as the first prize in their class, was awarded to most excellent Silver-spangled, which have long been successful for their late owner, Mr. Beldon, and now figure to like advantage for their fortunate possessor, Mr. Wood, of Kendal. Each of the other varieties was well represented, the Golden-spangled chickens more especially deserving notice. In "Any other Distinct Breed," adults and chickens, Sulstans were first. Game Bantams were an average collection, Mr. Crosland being at the head of the list. In Laced Bantams, Silvers took the prizes; and in "Any other Variety," Whites had first, and Blacks the other positions.

The Ducks shown under inverted wool skeps, as well as *Geese* and *Turkeys*, were good.

In the Pigeon department the competition was very keen in many classes. The silver cup, for the best pen, was awarded to a very fine Dun Carrier cock, shown by Mr. Colley, of Sheffield. Pouters formed excellent classes, good birds taking the prizes. In Almond Tumblers, Mr. Else had his old position. In this variety there appears to be a

great scarcity of really good true-feathered birds. Mr. Pinto Leite's prize Barbs and Black Mottles were much admired. In Owls, foreign Whites were first, and Blues second. Turbits were largely shown, the first prize being awarded to peaked-crowned Blues, foul in thigh, kite-barred, and coarse. In Jacobins, good Reds won. Fantails were a nice class. Mr. Van Haansbergen had first with small, good-tailed, well-shaped, plain-headed Whites. In Trumpeters, Mr. Briggs was first with Black Mottles. The "Any other Breed" class was large. Frillbacks, were first, and Laced Fantails second. The latter should have been in the Fantail class.

**SPANISH.**—First, J. Newton, Leeds. Second and Third, H. Beldon, Bingley. *Chickens.*—First, J. Marchant, Halifax. Second, A. Heath, Wilts. Third, T. Greenwood, Dewsbury.

**DORKINGS.**—First, J. Ganson, Whitehaven. Second, C. W. Brierley, Middleton. Third, H. Beldon, Bingley. *Chickens.*—First and Commended, Hon. H. W. Fitzwilliam. Second and Third, Mrs. Dale, Scarborough. Commended, H. Savile, Notts.

**COCHIN CHINA (Cinnamon or Buff).**—First and Second, Capt. Heaton, Manchester. Third, C. Jennison, Manchester. Highly Commended, W. Dawson, Mirfield; C. W. Brierley, Middleton. Commended, H. Beldon, Bingley. *Chickens.*—First, Messrs. Bown & Greenwood, Harrogate. Second and Highly Commended, Capt. Heaton, Manchester. Third and Highly Commended, C. Sidgwick, Keighley.

**COCHIN CHINA (Any other variety).**—First and Highly Commended, C. E. Ridsdale, Halifax (Partridge). Second, W. Gamon, Thornton-le-Moors. Third, J. Harrison, Wakefield. *Chickens.*—First and Second, Capt. Heaton, Manchester. Third, Rev. F. Taylor, Kirby Lonsdale.

**BRAHMA POOTRA.**—First, W. Hargreaves, Bacup. Second, H. Lacy, Hebdon Bridge. Third, T. Pomfret, Preston. *Chickens.*—First, H. Lacy, Hebdon Bridge. Second, T. Statler, Manchester. Third, E. Pigeon, Exeter. Highly Commended, W. Hargreaves, Bacup.

**GAME COCK OR COCKEREL.**—Cup, T. J. Charlton, Bradford. Second, J. Fletcher, Manchester. Third, T. Bottomley, Shelf. Highly Commended, C. W. Brierley, Middleton; H. Snowden, Bradford; J. Sunderland, Halifax. Commended, S. Matthews, Stowmarket; J. Firth, Halifax. *Cockerel.*—First, J. Firth, Halifax. Second, H. Wood, Bradford. Third, J. Sunderland, Halifax. *Hens.*—First, E. Akroyd, Bradford. Second, J. Brook, Gomersal. Third, G. Rhodes, Skircoat. *Pullets.*—First, R. Scott, Booth Town. Second, R. Parkinson, Poulton-le-Fyde. Third, J. Wood, Wigan. Highly Commended, J. Firth, Halifax; E. Akroyd, Bradford; T. Dyson, Halifax.

**GAME (Black-breasted Reds).**—First, A. Hodgson, Ilkingsworth. Second, E. Rathide, Halifax. Third, W. Bentley, Cleckheaton. *Chickens.*—First, T. J. Charlton, Bradford. Second, J. Firth, Halifax. Third, B. Consterdine, Littleborough.

**GAME (Brown-breasted and other Reds).**—First, W. Gamon, Thornton-le-Moors. Second, J. Wood, Wigan. Third, J. Sunderland, Halifax. *Chickens.*—First, E. Akroyd, Bradford. Second, H. C. Mason, Leeds. Third, J. Firth, Halifax.

**GAME (Duckwing Grey and Blue).**—First, E. Akroyd, Bradford. Second, H. Snowden, Great Horton. Third, J. Firth, Halifax. *Chickens.*—First, J. Firth, Halifax. Second, G. Hartley, Gomersal. Third, W. Bentley, Cleckheaton.

**GAME (Any other variety).**—First, J. Sunderland, Halifax. Second, H. C. Mason, Leeds. Third, W. Sutcliffe, Mytholmroyd. *Chickens.*—First, H. C. Mason, Leeds. Second, G. Noble, Dewsbury. Third, J. Sunderland, Halifax.

**POLANDS.**—First, C. W. Brierley, Middleton. Second and Highly Commended, J. Smith, Keighley. Third, H. Beldon, Bingley. *Chickens.*—First, H. Gornall, Leeds. Second, J. Smith, Keighley. Third, H. Beldon, Bingley.

**HAMBURGS (Golden-pencilled).**—First, R. Hemingway, Shelf. Second, Messrs. Birch & Boulter, Sheffield. Third and Highly Commended, S. Smith, Northwram. Highly Commended, N. Marlor, Manchester. *Chickens.*—First and Second, S. Smith, Northwram. Third, H. Beldon, Bingley. Highly Commended, T. Dyson, Halifax.

**HAMBURGS (Silver-pencilled).**—First, H. Snowden, Great Horton. Second, J. Dixon, Bradford. Third, H. Beldon, Bingley. Highly Commended, A. K. Wood, Kendal. *Chickens.*—First, T. Briggs, Bingley. Second, H. Beldon, Bingley. Third, J. G. Park, Whitehaven. Highly Commended, H. Smith, Keighley.

**HAMBURGS (Golden-spangled).**—First, H. Beldon, Bingley. Second, N. Marlor, Denton. Third, J. Roe, Manchester. Highly Commended, A. K. Wood, Kendal. *Chickens.*—First, H. Beldon, Bingley. Second, W. Driver, Keighley. Third, J. Dixon, Bradford. Highly Commended, M. H. Broadhead, Holmfirth. Commended, H. Carter, Holmfirth.

**HAMBURGS (Silver-spangled).**—Cup, A. K. Wood, Kendal. Second and Highly Commended, H. Beldon, Bingley. Third, J. G. Park, Whitehaven. Highly Commended, J. Newton, Leeds. *Chickens.*—First, A. Smith, Silsden. Second, H. Beldon, Bingley. Third, J. G. Park, Whitehaven. Commended, J. Dixon, Bradford.

**HAMBURGS (Black, White, or any other variety).**—First, H. Beldon, Bingley. Second, C. Sidgwick, Keighley. Third, C. W. Brierley, Middleton. Highly Commended, S. Briggs, Holywell Green. *Chickens.*—First and Third, C. Sidgwick, Keighley. Second, Messrs. W. & J. Harkers, Bingley.

**ANY OTHER DISTINCT BREED, EXCEPT BANTAMS.**—First, R. Loft Beverley (Sultans). Second and Third, C. Lister, Mirfield (Rumpless and Silkies). *Chickens.*—First, R. Loft (Sultans). Second, W. Chadwick, Halifax. Third, J. Whitterton, Loinore.

**BANTAMS (Game).**—First, J. Crossland, jun., Wakefield. Second, J. W. Morris, Rochdale. Third and Highly Commended, G. Noble, Dewsbury. Highly Commended, D. Ashworth, Halifax.

**BANTAMS (Gold or Silver-laced Sibrigh).**—First, Master C. Hutton, Pudsey. Second, C. W. Brierley, Middleton. Third, J. W. Morris, Rochdale.

**BANTAMS (Any other variety).**—First, C. W. Brierley, Middleton (White). Second, Messrs. J. & A. Briggs, Rawden. Third, Master C. Hutton, Pudsey (Black). Highly Commended, E. Pigeon, Exeter.

**DUCKS (Aylesbury).**—First, H. Beldon, Bingley. Second, G. Thewlis, jun., Holmfirth.

**DUCKS (Rouen).**—First, H. Beldon, Bingley. Second, S. Briggs, Holywell Green. Third, J. Firth, Halifax.

**DUCKS (Any other variety).**—First, C. W. Brierley, Middleton (Mandarins). Second, S. Briggs, Holywell Green. Third, Master C. Hutton, Pudsey (Teal).

**GEESE.**—First, R. Tate, Leeds. Second, O. A. Young, Driffield. Third, W. Gamon, Thornton-le-Moors.

**TURKEYS.**—First, J. Wood, Chorley. Second, C. W. Brierley, Middleton. Third, F. E. Rawson, Thorpe.

**SELLING CLASS (Any breed).**—First, D. Jackson, Liversedge. Second, H. Atkinson, Otley. Third, T. Dyson.

**EXTRA STOCK.**—Medal, F. E. Rawson, Thorpe. Highly Commended, J. Marchant, Halifax; J. Wadsworth, Halifax.

**PIGEONS.—Pouters or Croppers (Cock).**—First, C. Cole, Bradford. Second, A. P. Leite, Manchester. Highly Commended, S. Briggs, Halifax; W. Ashforth, Sheffield. Commended, J. Thackery, York. (Hens).—First and Second, A. P. Leite, Manchester. Highly Commended, H. Snowden, Great Horton. *Carriers (Cocks).*—Cup and Second, T. Colley, Sheffield. Highly Commended, H. Beldon, Bingley; S. Sanday, Notts; A. P. Leite, Manchester. (Hens).—First, A. P. Leite, Manchester. Second, F. Else, Bayswater. Highly Commended, T. Colley, Sheffield. *Almond Tumblers.*—First, F. Else, Bayswater. Second, A. P. Leite, Manchester. Highly Commended, C. Cole, Bowling. *Mottled Tumblers.*—First and Second, A. P. Leite, Manchester. *Balds or Beards.*—First, H. Yardley, Birmingham. Second, W. H. C. Oates, Notts. *Owls.*—First and Second, J. Fielding, jun., Rochdale. Highly Commended, A. P. Leite, Manchester. *Turbits.*—First, J. Thackery, York. Second, S. Wade, Ovenden. Highly Commended, S. Briggs, Halifax. *Jacobins.*—First, C. Cole, Bowling. Second, S. Briggs, Halifax. *Fantails.*—First, W. B. Van Haansbergen, Newcastle-on-Tyne. Second, H. Yardley, Birmingham. *Barbs.*—First, A. P. Leite, Manchester. Second, S. Briggs, Halifax. *Dragons.*—First, J. Percival, Birmingham. Second, S. Briggs, Halifax. Commended, H. Yardley, Birmingham; W. Gaukroger, Halifax. *Trumpeters.*—First and Second, S. Briggs, Halifax. *Maggies.*—First, H. Yardley, Birmingham. Second, J. Harrison, Wakefield. *Any other Breed.*—First, J. Harrison, Wakefield. Second and Highly Commended, A. P. Leite, Manchester. Highly Commended, H. Yardley, Birmingham. Commended, T. Marchant, Halifax.

*Selling Class.*—First, N. Greenwood, Lower Saltonstall. Second, C. Cole, Bowling. *Extra Stock.*—First and Second, J. Fielding, jun., Rochdale. Commended, J. Firth, jun., Dewsbury.

The Judges were—for *Poultry*, Mr. Teebay, Fulwood, Preston; Mr. Hedley, London. For *Pigeons*, Mr. Harrison Weir, London.

## THE DEWSBURY SHOW OF POULTRY AND PIGEONS.

Few, if any, of our local exhibitions of poultry have shown so rapid an improvement as the one held at Dewsbury. Last year the entries of poultry amounted to 129, and of Pigeons to 46 pens, whilst this season the poultry numbered as high as 170 pens, and the Pigeons consisted of 131 pens. Again, the competition itself was of the highest order, showing as great an advance in this all-important respect as it does in point of numbers. The Committee seemed determined to do everything a Committee can do to secure support, and we therefore most heartily congratulate them on the permanent position the Dewsbury Show has now attained. It has been held in connection with a flower and horticultural show for some time past, and the public interest for sensation scenes this year has been much increased, by the introduction into the show-field of the wonderful American trotting horse, called "Kentucky Patcha," that by the kind permission of his owner, Mr. Barnabas Long, of Acton, Spofforth, near Wetherby, was put through his paces almost continuously, from two till six on Wednesday. The amazing trotting powers of this animal may be imagined from the fact, that with perfect ease he distanced horses at full gallop, and that without producing on himself the slightest perspiration. He proved beyond question one of the lions of the day, filling the show-field with gratified visitors; but as our digression has been simply to prove that additional attractions are, pecuniarily, by no means thrown away, though not closely appertaining to the original intentions of a managing poultry committee, we must return to particulars respecting the poultry exhibition alone.

The Poultry and Pigeons were both ranged in the open field, but the day proving as favourable as could possibly be desired, every matter connected with the Show went off most satisfactorily. We noticed among the visitors Sir George Armitage, and others of the nobility, together with most of the resident gentry of the neighbourhood, and promises of additional names to next year's subscription list were numerously volunteered.

All colours in *Cochins* were permitted to compete in one general class; in both the adult and also the chicken classes the Bufts maintained precedence, and the first-prize chickens were some of the best we have seen this year. The White *Cochins* were also very good; but not a single pen of Partridge-coloured ones was entered. In *Spanish*, the chickens were very superior as a class, and exceedingly well shown. The old class, though equally good in character, were out of plumage altogether. The like remarks appertain with equal force to the *Grey Dorkings*. The *Hamburghs* always show to great disadvantage at this season, and, consequently, one or two prizes in these classes were withheld. Most of the *Game* fowls were much out of condition, but were, nevertheless, first-rate specimens. A full month or six weeks will be still requisite to put them in proper order for the show-*pen*. We noticed among the variety classes some exceedingly good *Silks*, *Brahmas*, and purely Black *Rumpless* fowls, the latter (most unusually), having combs single, and as large as those of Spanish fowls. Only one pen of *Sibrighs* was shown, they were Gold-laced, and a rather pretty pen. The Black *Bantams* were equal to the average of

most shows, but the White Bantams were altogether a faulty lot. The Game Bantam class was a great attraction to the numerous visitors; a pen of young Black Reds of great merit, belonging to Mr. John Newsome, of Batley, taking first position, and a pen of Greys belonging to Mr. Tate, of Leeds, being second in order of merit. The *Single Game Cock* class, and also that for *Single Game Hens*, were both good, but the birds, as a whole, being in full moult, detracted greatly from the general interest of this portion of the Show.

The *Ducks*, both Aylesbury and Rouen, were well shown; and a pen of extraordinarily good Grey *Geese* were worthy of especial mention.

The classes for *Rabbits* were not numerously filled, but there were some very good ones exhibited.

The competition throughout the whole of the *Pigeon* classes was unusually severe, and it was deemed necessary, therefore, to give several extra prizes beyond those offered in the printed prize schedule of the Dewsbury Committee. A prize offered by a member of the Committee, Mr. Frith, to the party taking most prizes in the Pigeon classes, to be determined by points, a first prize to count two points, and a second one point, brought about one of the keenest competitions we have witnessed for some years past. In proof we may mention the fact, that four of the most interested competitors came within one or two points of each other.

**COCHIN-CHINA.**—First, H. Beldon, Gortstock, Bingley. Second, W. Dawson, Hopton, Mirfield. *Chickens.*—First, C. Sedgwick, Keighley. Second, W. Dawson. Commended, E. Leech, Rochdale.

**SPANISH.**—First and Second, H. Beldon, Bingley. Commended, E. Brown, Sheffield. *Chickens.*—First, E. Brown. Second, S. Scholefield, Heckmondwike. Highly Commended, T. Greenwood, Dewsbury. Commended, T. Greenwood.

**DORKING.**—First, H. Beldon, Bingley. Second, H. Hemsworth, Wakefield. *Chickens.*—First, S. Pickard, Wakefield. Second, E. Leech, Rochdale. Commended, S. Pickard; H. Hemsworth, Wakefield.

**HAMBURG (Golden-spangled).**—First, H. Beldon, Bingley. Second, R. Tate, Leeds. Highly Commended, H. Carter, Upperthong, Holmfirth. *Chickens.*—First, H. Carter. Second, H. Beldon.

**HAMBURG (Silver-spangled).**—First, H. Beldon. Second, C. Cowburn, Leeds. Commended, H. Beldon. *Chickens.*—Prize, H. Beldon.

**HAMBURG (Golden-pencilled).**—First, H. Beldon. Second, S. Smith, Northwam, Halifax. *Chickens.*—First, H. Beldon. Second, S. Smith.

**HAMBURG (Silver-pencilled).**—First, withheld. Second, H. Beldon. *Chickens.*—First, H. Beldon. Second, W. Laurensen, Yarn.

**HAMBURG (Black).**—First, H. Beldon. Second, R. Tate, Leeds. Commended, C. Sedgwick, Keighley. *Chickens.*—First, C. Sedgwick. Second, R. Tate. Commended, C. Cowburn.

**POLAND (Gold or Silver-spangled).**—First and Second, H. Beldon. *Chickens.*—First, H. Beldon. Second, Mrs. Kell, Wetherby.

**POLAND (Any other variety).**—First and Second, J. Smith, Keighley (White-crested and Black). Commended, H. Carter, Upperthong, Holmfirth (White-crested). *Chickens.*—First and Second, J. Smith. Commended, H. Carter (White-crested).

**GAME (Black-breasted and other Reds).**—First, T. Vickerman, Chickentley. Second, E. Aykroyd, Bradford. *Chickens.*—First, T. Vickerman. Second, J. Ineson, Staincliffe. Commended, T. Greenwood.

**GAME (Duckwings and other Greys and Blues).**—First, E. Aykroyd, Bradford. Second, W. Fell, Adwalton. *Chickens.*—First, R. Tate, Leeds. Second, W. Bentley, Cleckheaton. Commended, J. Ineson, Staincliffe.

**GAME (White and Piles).**—First, H. C. Mason, Drighlington. Second, J. Ineson, Staincliffe. *Chickens.*—First, H. C. Mason. Second, G. Hellewell, Sheffield. Commended, J. Ineson.

**GAME (Black and Brassy-winged, except Greys).**—First, J. D. Newsome, Batley. Second, J. Vickerman, Chickentley. *Chickens.*—First, J. Oldroyd, Dewsbury Moor. Second, J. Ineson. Highly Commended, J. Brook, Gomersal.

**BANTAMS (Gold and Silver-laced).**—Prize, E. Hutton, Pudsey. **BANTAMS (Black).**—First, S. Scholefield, Heckmondwike. Second, H. Beldon.

**BANTAMS (White).**—First, R. Tate, Leeds. Second, T. C. Harrison, Hull.

**BANTAMS (Game).**—First, J. D. Newsome, Batley. Second, R. Tate. Commended, J. Brook, Gomersal; R. Cook, Staveley, Derbyshire.

**ANY BREED NOT MENTIONED IN THE ABOVE CLASSES.**—First and Second, C. Lister, Bracken Hill, Mirfield (Rumpless and Japanese Silk Fowls). Highly Commended, H. Beldon; R. Tate (Brahma Pootra). *Chickens.*—First and Second, H. Lacey, Hehden Bridge (Light-pencilled and Dark-pencilled Brahma Pootra). Highly Commended, E. Leech, Rochdale.

**GAME COCK (Any variety).**—First, W. Whiteley, Liversedge. Second, W. Fell, Adwalton.

**GAME HEN (Any variety).**—First, T. Dyson, Halifax. Second, J. Ineson. Highly Commended, H. C. Mason, Drighlington.

**DUCKS (White).**—First, E. Leech, Rochdale. Second, H. Beldon.

**DUCKS (Rouen).**—First, J. D. Newsome, Batley. Second, H. Beldon. Highly Commended, E. Leech; J. D. Newsome.

**GEESE.**—First and Second, R. Tate, Leeds.

#### RABBITS.

**LOP-EARED.**—*Buck.*—First, E. E. M. Roys, Greenhead, Rochdale. Second, R. Dobson, York. *Doc.*—First, R. Dobson. Second, W. H. Firth, Dewsbury.

**FOUR COLOUR.**—First, T. Hainslaw, Dewsbury. Second, A. Barratt.

#### PIGEONS.

**POWTEES.**—*Cock.*—First and Second, C. Cole, Bowling, near Bradford. Extra Second, J. Thackray, York. Highly Commended, H. Yardley, Birmingham. Commended, E. E. M. Roys, Greenhead, Rochdale; J. Smith, Sheffield; W. Hughes, Leeds. *Hen.*—First and Second, C. Cole. Highly Commended, E. E. M. Roys. Commended, J. Thackray.

**CARRIER.**—*Cock.*—First, H. Beldon. Second, E. E. M. Roys, Extra Second, C. Cole. Highly Commended, W. Massey, Fulford, York; E. Brown, Salford; J. Thackray. *Hen.*—First, J. Thackray. Second, W. Massey, Fulford, York. Highly Commended, C. Cowburn, Leeds.

**TUMBLERS (Almond).**—First, E. Brown, Sheffield. Second, C. Cole. Highly Commended, H. Yardley.

**TUMBLERS (Any other variety).**—First, H. Yardley. Second, J. Smith, Sheffield. Highly Commended, E. E. M. Roys; J. Thackray.

**TURBANS.**—First, H. Yardley. Second, E. E. M. Roys. Highly Commended, C. Cole; D. Canser, Erdington, Birmingham; T. C. Taylor, Middlesborough; H. Yardley. Commended, J. Thackray.

**JACOBS.**—First, J. Thackray. Second, W. Massey. Highly Commended, C. Cole; E. E. M. Roys; T. Metcalf, Southill, near Batley.

**TRUMPETERS.**—First, E. E. M. Roys. Second, J. Thackray. Commended, T. C. Taylor; H. Yardley.

**OWLS.**—First, E. E. M. Roys. Second, H. Yardley. Highly Commended, E. E. M. Roys. Commended, W. Hughes, Leeds.

**BARNS.**—First, H. Yardley. Second, C. Cole. Highly Commended, J. Thackray. Commended, E. E. M. Roys; H. Beldon; C. Cowburn; E. Brown.

**PANTAILS.**—First, J. Thackray. Second, H. Yardley.

**NEWS.**—First, E. E. M. Roys. Second, D. Canser. Highly Commended, J. Thackray.

**COMMON.**—First, M. Spedding, Dewsbury. Second, J. Vickerman, Chickentley. Commended, T. Wallis, Dewsbury; J. Vickerman.

**ANY OTHER VARIETY.**—Prize, H. Yardley. Highly Commended, D. Canser. Commended, C. Cole; E. E. M. Roys.

Edward Hewett, Esq., of Eden Cottage, Sparkbrook, near Birmingham, officiated as Judge.

## COTTINGHAM POULTRY SHOW.

(From a Correspondent.)

The annual Exhibition of the above Society was held on Wednesday the 30th of August, and was a most successful one. The weather was all that could be desired, and some thousands of people from Hull and the neighbouring district thronged the grounds during the afternoon. Some capital specimens were shown in the various classes, and on the whole the awards of the Judges appeared to give satisfaction. In *Pigeons* two special prizes were offered, one for the best pair of Carriers and the other for the best pair of Tumblers. In the latter case it was stipulated that the points to be considered were head, beak, and carriage, and that may account for the seeming anomaly of the special prize being awarded to the second-prize pair. We understand the prize list is to be increased another year, and in that case we anticipate a much larger entry, although upwards of two hundred pens were entered on this occasion.

**SPANISH.**—First, J. Hatfield, jun., Cottingham. Second, W. Charter<sup>d</sup> Driffield. Commended, J. Hodgkinson, Hull. *Chickens.*—First, W. Charter<sup>d</sup> Second, J. Hatfield, jun.

**DORKINGS.**—First, J. Hatfield, jun. Second, W. Watson. Highly Commended, J. Hatfield, jun. *Chickens.*—Prize, O. A. Young, Driffield. Very Highly Commended, W. Holland, Epleworth. Highly Commended, J. Pimley, Leven; W. Holland; J. Hatfield. Commended, R. Robson, Beverley.

**COCHIN-CHINA.**—First, E. Loft, Woodmansey. Second, T. C. Trotter, Sutton. Highly Commended, R. Loft. Commended, H. Taylor, Newland. *Chickens.*—First, H. Merkin, Driffield. Second, H. Taylor.

**GAME.**—First, A. Julian, Hull. Second, D. Pickering, Hull. Highly Commended, J. Hodgkinson. *Chickens.*—First, R. Hardy, Lockington. Second, R. Tate, Leeds. Highly Commended, R. Hardy; O. A. Young.

**GAME.**—First, R. Allinson, Cottingham. Second, R. Robson, Beverley. Highly Commended, R. Robson; W. Charter. Commended, R. Robson. *Chickens.*—First and Second, J. Hodgkinson (Piles).

**POLANDS.**—First, J. Proctor, Hull. Second, G. Holmes, Driffield. Highly Commended, J. R. Jessop, Hull. Commended J. Proctor. *Chickens.*—First and Second, J. Proctor.

**HAMBURG (Golden-spangled).**—First, J. Blanchard, Driffield. Second, G. Holmes. *Chickens.*—First, J. Blanchard. Second, R. Tate.

**HAMBURG (Golden-pencilled).**—First, E. Tate. Second, J. Bilton, Cottingham. Highly Commended, R. Grantham, Cottingham. Commended, Mrs. D. Smith, Kirkella. *Chickens.*—Prize, J. Bilton.

**HAMBURG (Silver-spangled).**—First, G. Holmes. Second, S. Campling, Cottingham. Highly Commended, G. Holmes; R. Voakes, Hull; J. Hall, Willeby. *Chickens.*—Prize, R. Carling, Cottingham.

**HAMBURG (Silver-pencilled).**—First, G. Holmes. Second, J. Bilton. *Chickens.*—Prize, H. Allison.

**BANTAMS (Gold).**—First, J. R. Jessop. Second, W. Charter. Highly Commended, G. Bilton. *Chickens.*—Prize, W. Richardson.

**BANTAMS (Game).**—First, R. Vokes. Second, J. Hodgkinson. Highly Commended, W. T. Entwistle, Otley; R. Robson. Commended, G. Holmes, *Chickens.*—Judges' prize, S. Dielby, Beverley. First, W. T. Entwistle. Second, R. Tate. Commended, R. Robson; R. Voakes; E. Peak, the Park, Hull; J. R. Jessop.

**BANTAMS (Any other variety).**—First, J. R. Jessop (Plack). Second, C. S. Britain, Cottingham (Black). *Chickens.*—First and Second, J. R. Jessop (Black and White).

**ANY DISTINCT VARIETY.**—First and Second, R. Loft. Commended, O. A. Young, Driffield. *Chickens.*—First, R. Loft (Sultans). Second, J. Hodgkinson (Brahmas).

**FARMYARD CROSSES.**—First, R. Loft. Second, T. Coverdale. Highly Commended, W. Charter. Commended, R. Garton, New Village. *Chickens.*—First, G. Robinson, Frodingham. Second, G. Bromby, Pilwoods.

**SELLING CLASS.**—First, M. Robinson, Cottingham. Second, G. Holmes. Highly Commended, T. Webster, Welton; W. Charter.

**GUINEA FOWLS.**—First and Second, O. A. Young.

**TURKEYS.**—First, J. Kyme, Cottingham. Second, W. Dunling, Cottingham.

**GEESE.**—First, O. A. Young. Second, W. Donkin, jun., Cottingham.

**DUCKS (Aylesbury).**—First, T. C. Trotter. Second, W. Lawson, Newland. Highly Commended, O. A. Young.

**DUCKS (Rouen).**—First, O. A. Young. Second, T. C. Trotter.

**DUCKS (Any other variety).**—First, J. R. Jessop (East Indian). Second, O. A. Young (Wild).

**PIGEONS.—CROPPERS.**—First, W. Watson, Beverley. Second, H. Yardley

**Birmingham. Carriers.**—First and Special, H. Yardley. Second, W. Twells, Kirkella. **Turbits.**—First, J. Gawan, Beverley. Second, J. R. Jessop. **Trumpeters.**—First and Second, F. Key, Beverley. **Jacobins.**—First, T. Ellington, Woodmansey. Second, H. Yardley. Highly Commended, J. R. Jessop; T. Ellington. **Fantails.**—First and Second, T. Ellington. Highly Commended, C. Unson, Hull. **Dragons.**—First and Second, W. Watson, Beverley. **Tumblers.**—First, H. Yardley. Second and Special, Head, beak, and carriage alone considered.—Martin, Beverley. Highly Commended, W. Twells; J. R. Jessop; C. Lythe. **Barbs.**—First, J. R. Jessop. Second, H. Yardley. **Nuns.**—First and Second, F. Key. Highly Commended, W. Twells. **Any other variety.**—First and Second, W. Twells, (Swallows and Runts). Highly Commended, H. Yardley.

**RABBITS.**—First, Miss Pease, Hesslewood. Second, O. A. Young. Extra, J. A. Staveley.

**JUDGES.**—F. Ferguson, Esq., Risby Park; and W. W. Boulton, Esq., Beverley.

## PUDSEY POULTRY SHOW.

The second annual show of Poultry and Pigeons was held at Pudsey in connection with the Floral Exhibition on the 29th of August.

In number of entries the show was a decided success, but the great feature was the quality of the specimens shown, scarcely a bad pen of birds appearing for competition; and the encouragement felt by the Committee through the support received from some of the best exhibitors in both sections of the show, will, no doubt, give a decided impulse, which will tend toward the augmentation of the prize schedule for future shows. The silver cup for the best pen in the show was won by Mr. Beldon with a magnificent pen of Spanish, and the silver inkstand, given by Mr. E. Hutton for the best pair of Pigeons in the show, was most satisfactorily given to a splendid pair of Dun Carriers, the property of Mr. Massey, of Fulford, York.

The following is the prize list:—

**SPANISH (Black).**—Cup and First, H. Beldon, Bingley. Second, H. Greenwood, Woodhall Hills. Third, H. Beldon.

**DORKINGS.**—First, J. Hall, Idle. Second, H. Beldon.

**COCHIN-CHINA.**—First, H. Beldon. Second, F. W. Rust, Hastings, Sussex. Third, C. Sedgwick, Keighley.

**BRAHMA POOTRA.**—First, H. Beldon. Second, R. Tate, Leeds. Third, C. Lister, Mirfield.

**GAME (Black or brown-breasted Red).**—First, J. Sunderland, Coley Hall, Second, R. Tate. Third, J. Hodgson, Bowling.

**GAME (Any other variety).**—First, H. C. Mason, Adwalton. Third, J. Hodgson.

**HAMBURGH (Golden-spangled).**—First, H. Beldon. Second, J. Preston, Adwalton. Third, A. K. Wood, Kendal.

**HAMBURGH (Silver-spangled).**—First, H. Beldon. Second, J. Preston, Third, H. Beldon.

**HAMBURGH (Golden-pencilled).**—First, S. Smith, Northowram. Second, W. Harker, Cottingley. Third, H. Beldon.

**HAMBURGH (Silver-pencilled).**—First, A. K. Wood. Second and Third, H. Beldon.

**HAMBURGH (Any other variety).**—First, C. Sedgwick. Second, R. Tate. Third, W. & J. Harker.

**POLANDS (Any variety).**—First and Second, H. Beldon. Third, H. Gerner, Farnely.

**BANTAMS (Game).**—First, T. C. Harrison, Hull. Second and Third, W. F. Entwistle, Otley.

**BANTAMS (Black or White).**—First, S. Schofield, Heckmondwike. Second, H. Beldon. Third, R. Tate.

**BANTAMS (Any other variety).**—First and Second, Master C. H. Hutton, Pudsey.

**DUCKS (Rouen).**—First and Second, H. Beldon. Third, C. Sedgwick.

**DUCKS (Aylesbury or White).**—First, H. Jones, Aylesbury. Second, H. Beldon. Third, J. Leeming, Pudsey.

**DUCKS (Any other variety).**—First, T. C. Harrison, Hull. Second, H. Beldon. Third, C. Lister.

**ANY OTHER VARIETY.**—First, R. Tate. Second and Third, C. Lister.

**PIGEONS.—Pouters.**—First and Second, C. Cole, Bowling. **Carriers.**—

(silver inkstand, given by Mr. E. Hutton for the best pair of Pigeons).—First, W. Massey, York. Second, H. Beldon. **Dragons.**—First, E. E. M. Roysds, Rochdale. Second, H. Yardley. **Antwerps.**—First, H. Yardley.

Second, E. Hutton. **Barbs.**—First, C. Cole. Second, W. Hughes, Leeds. **Owls.**—First, E. E. M. Roysds. Second, C. Cowburn, Leeds. **Turbits.**—

First, J. Thackeray, York. Second, E. E. M. Roysds. **Archangels.**—First, C. Cole. Second, J. R. Jessop, Hull. **Tumblers (Short-faced).**—First, J. Hawley, Burnley. Second, C. Cole. **Tumblers (Long-faced).**—First, C. Cole. Second, H. W. Ilmgworth. **Fantails.**—First, J. Thackeray. Second, W. Hughes. **Largest pair of Pigeons.**—First, H. Beldon. Second, J. Thackeray. **Any other variety of Pigeons, Turbles or other Doves.**—First, C. Cole. Second, J. J. Wilson, Darlington.

The Judges were William Cannan and James Dixon, Esqrs., of Bradford.

## BURNLEY POULTRY SHOW.

This was held on Thursday, August 24th, when the following premiums were awarded:—

**GAME (Black or Brown Reds).**—*Chickens.*—First, N. Grimshaw, Pendle Forest. Second, R. Tate, Leeds. Highly Commended, E. Aykroyd, Bradford, Yorkshire.

**GAME (Any other variety).**—*Chickens.*—First, R. Whittam, Mount Pleasant, near Burnley. Second, J. Turner, Radcliffe.

**SPANISH.—Chickens.**—First, E. Brown, Sheffield. Second, T. Greenwood, Dewsbury. Highly Commended, H. Wilkinson, Earby. Commended, T. Greenwood.

**DORKINGS (Any colour).**—*Chickens.*—First, D. Parsons, Cuerden, near Preston. Second, W. Moorhouse, Read, near Whalley.

**COCHINS (Any colour).**—*Chickens.*—First, C. Sedgwick, Keighley. Second, J. B. Wilkinson, Marsdon Hall, near Burnley. Commended, T. Grimshaw, Bank House, near Burnley.

**HAMBURGHS (Golden-spangled).**—*Chickens.*—First, J. Roe, Hadfield, near Manchester. Second, W. Driver, Keighley.

**HAMBURGHS (Silver-spangled).**—*Chickens.*—First, A. Smith, Silsden. Second, J. G. Park, Whitehaven. Highly Commended, W. Redman, Mount Pleasant, Cliviger.

**HAMBURGHS (Golden-pencilled).**—*Chickens.*—First, S. Smith, Halifax. Second, D. Ashworth, Halifax.

**HAMBURGHS (Silver-pencilled).**—*Chickens.*—First, J. G. Park. Second, A. Nuttall, Newchurch, near Manchester.

**BRAHMA POOTRAS.—Chickens.**—First, H. Lacy, Hebden Bridge. Second, E. Greenwood, Overtown, near Burnley. Highly Commended, W. Gamon, Chester.

**GAME BANTAMS.**—First, D. Parsons. Second, J. Turner. **ANY OTHER VARIETY.—Chickens.**—First, C. Sedgwick. Second, H. Carter, Holmfirth.

**POLANDS (Black).**—Highly Commended, J. Hargreaves, Skipton. **DUCKS (Aylesbury).**—Prize, E. Leech, Rochdale.

**DUCKS (Rouen).**—First, T. Houlker, Blackburn. Second, E. Leech. **DUCKS (Any other variety).**—First, D. Parsons (Call Ducks). Second, J. Hargreaves (East Indian). Highly Commended, T. C. Harrison, Hull (Call Ducks).

**GESE (Any colour).**—First, B. Baxter, Skipton. Second, T. Houlker, Blackburn.

**TURKEYS (Any variety).**—First, E. Leech, Rochdale. Second, C. Sidgwick, Keighley.

**GAME (Cock).**—First, N. Grimshaw, Pendle Forest. Second, W. R. Lane, Birmingham. Highly Commended, R. Whittam, Brierfield, near Burnley.

**COCKEREL.**—First, N. Grimshaw, Pendle Forest. Second, R. Tate, Leeds. **GAME BANTAM COCK.**—First, T. C. Harrison, Hull. Second, Hon. T. W. Fitzwilliam, Rotherham.

**SELLING CLASS (Any variety).**—First, R. Whittam, Burnley. Second, T. Greenwood, Dewsbury. Third, T. Houlker, Blackburn.

Mr. Teebay officiated as Judge.

## WHITWORTH AND ROCIDALE POULTRY SHOW.

This took place on the 23rd of August, when the following awards were made.

**SPANISH.**—First, H. Beldon, Gortstock, Bingley. Second, J. G. Park, High Low Hall, Whitehaven. *Chickens.*—First, E. Brown, Albert House, Sheffield. Second, Messrs. Burch & Boulter, Sbeffield.

**COCHIN-CHINA.**—First, H. Beldon. Second, J. Nelson, Heaton Mersey, Manchester. *Chickens.*—First, C. Sidgwick, Riddlesden Hall, Keighley. Second, A. Bamford, Tong Lane, Middleton.

**COCHIN-CHINA.**—Second, C. W. Brierley, Rhodes House, Middleton. *Chickens.*—Prize, J. Barlow, Leavengrove.

**BRAHMAS.**—First, H. Lacy, Lacy House, near Hebden Bridge. Second, W. Hargreaves, Bacup. *Chickens.*—First, T. Statter, Stand Hill, Whitefield, Manchester. Second, H. Lacy.

**GAME COCK.**—First, C. W. Brierley. Second, T. Statter. **GAME.**—First and Second, C. W. Brierley. *Chickens.*—First, R. Tate, Green Road, Leeds. Second, T. Statter.

**POLANDS.**—First, H. Beldon. Second, C. W. Brierley. *Chickens.*—First, H. Beldon. Second, S. Farrington, Chat Moss, Astley.

**HAMBURGH (Golden-spangled).**—First, R. Tate. Second, H. Beldon. *Chickens.*—Prize, J. Roe, Hadfield, near Manchester.

**HAMBURGH (Silver-spangled).**—First, H. Beldon. Second, A. K. Wood, Burnside, Kendal. *Chickens.*—First, A. Smith, Woodside, Silsden, near Leeds. Second, J. Fielding, Newchurch, Rossendale.

**HAMBURGH (Golden-pencilled).**—First and Second, S. Smith, Northowram, Halifax. *Chickens.*—First, S. Smith. Second, T. Wrigley, jun., Tong Lane, Middleton.

**HAMBURGH (Silver-pencilled).**—First, H. Beldon. Second, A. K. Wood. *Chickens.*—First, H. Beldon. Second, J. G. Park, High Low Hall, Whitehaven.

**HAMBURGH (Black).**—First, H. Beldon. Second, B. Battersby, Heywood. *Chickens.*—First, C. Sidgwick, Riddlesden Hall, Keighley. Second, J. Hargreave, Mill Fields, Skipton.

**DORKING.**—First, E. Smith, Middleton. Second, T. Statter. *Chickens.*—First, J. Stott, Healey, near Rochdale. Second, E. Smith.

**ANY OTHER DISTINCT BREED (Except Bantams).**—First, S. Lord, Bluepits, near Rochdale. Second, N. Rigg, Hamerbottoms, Rochdale.

**BANTAM.**—First, C. W. Brierley. Second, Dr. Morris, Rochdale. **ANY OTHER VARIETY.**—First, C. H. Hutton, Pudsey, near Leeds. Second, C. W. Brierley.

**DUCKS (Aylesbury).**—First, E. Leach, Greave, Rochdale. Second, H. Beldon.

**DUCKS (Rouen).**—First, J. Nelson, Heaton Mersey, near Manchester. Second, D. Howarth, Broadfield, Rochdale.

**ANY OTHER VARIETY.**—First, C. H. Hutton. Second, W. Moorhouse. **GESE.**—Prize, F. Leech.

**TURKEYS.**—First, E. Leech. Second, C. W. Brierley.

**PIGEONS.—Pouters or Croppers.**—First, C. Cole, Bowling, near Bradford. Second, Miss Baron, Bank Cottage, Pendlebury. *Carriers.*—First, Messrs. C. & E. Roysds. Second, W. Massey. *Tumblers (Almond).*—First, J. Fielding, jun. Second, C. Cole, Bowling, near Bradford. *Tumblers (Any other variety).*—First, J. Fielding, jun. Second, J. Thackeray, York. *Balds or Beards.*—First, S. Stott, Clover Cottage, near Rochdale. Second, Messrs. C. & E. Roysds. *Owls.*—First and Second, J. Fielding, jun. *Turbits.*—First, Messrs. C. & E. Roysds. Second, H. Beldon. *Jacobins.*—First, Miss Baron. Second, H. Yardley, Market Hall, Birmingham. *Fantails.*—First, H. Yardley. Second, J. Thackeray. *Barbs.*—First, H. Yardley. Second, F. Bright, Cronkeshaw. *Dragons.*—First, Messrs. C. & E. Roysds. Second, H. Yardley. *Trumpeters.*—First, H. Yardley. Second, F. Key, Beverley, Yorkshire. *Maopies.*—First and Second, Messrs. C. & E. Roysds. *Any other kinds.*—First, J. Thackeray. Second, F. Key. *Selling Class.*—First, J. Hawley, Burnley. Second, F. Key. Third, Messrs. C. & E. Roysds.

**JUDGES.**—Mr. T. Dodds, and Mr. T. Slagg.

## SKIPTON POULTRY SHOW.

(From a Correspondent).

This was held on Friday, August 18th. The quality of the poultry was good, though the pens were not very numerous. *Cochins* were fair, the *chickens* especially. All the *Hamburg* varieties, both old and young, were good. *Polands* were capital.

**DORKING** (Any colour).—First, T. Briden, Earby. Second, H. Beldon, Bingley. *Chickens*.—First, E. Leech, Rochdale. Second, H. Beldon.

**SPANISH** (Black).—First, H. Beldon. Second, J. Newton, Silsden.

*Chickens*.—First and Second, T. Greenwood, Dewsbury.

**GAME**.—First, W. Bently, Cleckheaton. Second, W. Ayrton, Earby.

*Chickens*.—First, W. Ayrton. Second, W. Bentley.

**COCHIN-CHINA**.—First, R. J. Wood, Chorley. Second, W. Dawson, Mirfield.

*Chickens*.—First, C. Sidgwick, Riddlesden Hall. Second, Messrs. Brown & Greenwood, Harrogate.

**HAMBURGH** (Golden-pencilled).—First, S. Smith, Northwram. Second, H. Beldon.

*Chickens*.—First, J. G. Park, Whitehaven. Second, S. Smith, Halifax.

**HAMBURGH** (Silver-pencilled).—First, J. G. Park. Second, H. Beldon.

*Chickens*.—First, J. G. Park. Second, R. Chew, Gishburn.

**HAMBURGH** (Golden-spangled).—First, W. Driver, Keighley. Second, H. Beldon.

*Chickens*.—First, W. Driver. Second, W. Throup, Silsden.

**HAMBURGH** (Silver-spangled).—First, H. Beldon. Second, J. G. Park.

*Chickens*.—First, A. Smith, Silsden. Second, H. Beldon.

**HAMBURGH** (Black).—First, C. Sidgwick, Riddlesden Hall. Second, W. Hird, Bingley.

*Chickens*.—First, J. Hargreaves, Skipton. Second, C. Sidgwick.

**POLANDS**.—First and Second, J. Smith, Keighley. *Chickens*.—First, J. Smith.

Second, H. Bowker, Keighley.

**BANTAMS** (Game).—First, J. D. Newsome, Batley. Second, J. G. Park.

*Chickens*.—First, J. D. Newsome. Second, T. Hartley, Earby.

**BANTAMS** (Any colour).—First, W. H. Briggs, Bradford. Second, H. Beldon.

*Chickens*.—First, H. Beldon. Second, J. Hargreaves.

**ANY OTHER VARIETY**.—Prize, H. Beldon. *Chickens*.—Prize, W. Ayrton, Earby.

**GEESE**.—Prize, S. Swire, Stainton Coates, Hargrave.

**DUCKS** (Aylesbury).—First, J. Newton, Silsden. Second, H. Beldon.

**DUCKS** (Rouen).—First, H. Beldon. Second, J. D. Newsome.

**ANY OTHER VARIETY**.—First, H. Beldon. Second, J. Hargreaves.

**TRERKEYS**.—First, E. Leech, Rochdale. Second, J. B. Beckwith, Winterton.

**PIGEONS**.—*Carriers*.—First, C. Cole, Bowling. Second, H. Smith, Skipton.

*Pouters*.—First and Second, C. Cole. *Almond Tumblers*.—First, C. Cole.

*Ouels*.—First, H. Smith. Second, H. Shuttleworth, Skipton. *Barbs*.—First, H. Smith.

Second, C. Cole. *Jacobins*.—First and Second, C. Cole. *Mottled Tumblers*.

—First, J. Hawley, Burnley. Second, H. Smith. *Baldpates*.—First, J. Collier, Skipton.

Second, W. Scott, Skipton. *Runts*.—First, H. Smith. Second, R. Hebden, Skipton.

*Dragons*.—First, C. Cole. Second, J. Baxendale, Sutton. *Antwerps*.—First, T. Thornton, Skipton. Second, J. Collier, Skipton.

*Any other variety*.—First, C. Cole. Second, J. Thompson, Bingley.

## THE CAUSE OF THE HUMMING NOISE MADE BY BEES.

Does the humming or buzzing of a bee proceed entirely from the wings, or has the mouth anything to do with it? If the former, from whence proceeds the instantaneous answer that is given when the outside of the hive is tapped?—W. A. J.

[The celebrated John Hunter appears to have attributed the humming of bees to the rushing of air through their spiracles, since he found that they can produce a sound independently of their wings; for if these be smeared over with honey so as to stick together, the bee still makes a noise, which is shrill and peevish. He found the same effect from holding the bee by the legs with a pair of pincers, while the wings were perfectly still, and also by immersing the insect in water, though not until it was very much teased.]

## REMOVING BEES FROM AN OLD STRAW HIVE INTO A BOX HIVE.

I THINK you may perhaps be interested in hearing how the above operation was performed, as many people informed me that I must kill my bees to get at the honey. This I greatly objected to; so I applied to a very experienced bee-master to see what he could do. He came up on the 28th ult., early in the morning, and commenced operations by removing the board at the bottom of the hive, and raising the hive with stones, about 2 inches. He then began to beat the sides of the hive, gradually driving all the bees through the small orifice at the top into the cap, or super, on the top of the under hive. He then removed the bottom hive and placed the cap on a stool till the evening. At about 6 o'clock he again came up and placed a three-legged stool upside down on the ground, and inverted upon it an empty straw hive. Upon this he placed the cap, full of bees and honeycomb. Around the two he wrapped cloths, and then beat the sides of the upper hive to drive the entire stock into the lower one. This he successfully

accomplished, and we then took out the comb, which was very pure and good. After turning up the hive full of bees he left them till the following evening, when he again came, and spread a cloth upon the ground about 3 feet square. Upon this he placed three bricks, and put upon them the box hive, full of its old stock. Near it he emptied the straw hive, scattering flour on all the inhabitants, which soon crawled on to the bricks, and thence into the box hive, which must be now tolerably full, though the bees are all quiet in our sunny kitchen garden.

I should add, that our lower straw hive was so old that we feared it would not hold together through the winter if we allowed our bees to remain in it.—P., *Priors Marston, Warwickshire*.

## BEES REFUSING TO HATCH BROOD.

BRING told in THE JOURNAL OF HORTICULTURE that bees will usually hatch out brood placed in a glass over the hive. I have tried it, both last year and this, without success. Finding brood in all stages in a hive of bees driven from the moors, the comb was placed over the hive immediately, without any chill; in fact, young bees were at the time working their way out, and both times the result was the same, the bees clearing the grubs out of the combs instead of hatching them, and carrying them away out of the hive. Being past the honey-gathering season, the cells could not be required for depositing honey; besides, there was space in the hive itself, which, being a weak one, I thought would be strengthened by the brood given. Can you explain this?—F. F.

[This shows how difficult it is to predicate what bees will or will not do under certain circumstances, since ours have always hatched out brood presented to them under precisely similar conditions to those which you describe. It is, however, many years since we placed brood on the top of a hive, as we now always attach it to bars, and insert it within the hive itself.]

## UNFERTILE QUEEN.

The result of microscopic investigation, kindly instituted by Mr. Woodbury and given in THE JOURNAL OF HORTICULTURE of August 1st, fully confirms the observations that have been made relative to the state of the queen. It was doubtful at first whether she was a fertile queen, which had been presented to a queenless stock, and by them cast out, or whether she was a supernumerary from a stock which was raising young queens. That she was the latter the state of both hives subsequently confirms, and the inquirer has since had the satisfaction of having introduced a queen, at first ill-received, by the medium of syrup scented with peppermint, to a stock which would otherwise have perished.—A READER OF "OUR JOURNAL."

## THE LIGURIAN BEE.

It has for many years been known in Europe as a distinct variety of the honey bee. Attempts to import it into this country were made in 1856 by Samuel Wagner, of York, Pa., but unsuccessfully. Other attempts were made, but it was not until May and June, 1860, that these bees were successfully introduced by Parsons of Long Island, and Colvin and Wagner of Baltimore. Since then, other importations have been made from various parts of Europe, including the vicinity of Lake Como, where this bee is said to be found in great perfection. The most distinguished apiarians in our country have devoted much time, labour, and money to importing and raising these bees. For a long time the whole matter was ridiculed by the majority, to whom "a bee is a bee the world over,"—and even now, when these bees are found all over the country in different degrees of purity, many are unwilling to believe them any better than the common bee. What is of interest to every bee-keeper, are the questions whether this bee is adapted to our climate, and if so, how much and why is it superior to the common variety? Many fears were expressed on its introduction that it was not hardy and could not endure our climate. I have found it more hardy than the common bee, wintering well out of doors, working later in the season than the other variety, and venturing abroad in weather when no common bee is seen to leave the hive. Multiplying much faster than the black bee, and if al-

lowed to do so swarming earlier and oftener, they continue also to rear young later in the fall, and are thus prepared to go into winter quarters strong and populous. It was said when introduced that they could not sting, and by some they are now called "the stingless bee." The experience of those who have hitherto brought them into this State has not confirmed these accounts, as they have been found more irritable than the common bee. I think this proves conclusively that few pure Italians have ever been brought here. The cross between the Italian and common bee has always been reported in this country and in Europe to be very irritable, easily provoked, and after once vexed, not to be appeased for a long time. Since I have seen the pure Italians, I am willing to give them the reputation they have always borne for extreme docility, as they never sting unless greatly provoked. No one can open a hive containing these beautiful insects without being struck by the difference between them and the other variety, as they manifest no alarm or irritation. The queen, too, instead of hiding, as a common one always does, remains quietly in her place, and by her red and light colouring can be distinguished at glance.

But, after all that can be said, the main questions with our matter-of-fact people will be, Will it pay? and how much? The only way in which this can be decided, I think, is by comparing them under the same circumstances of season and location. If I tell of 200 lbs. obtained from an Italian colony this season, some one else may bring a report of what has been done by a colony of native bees at some other time or place, and neither statement, as I view the subject, proves anything. What we want, to decide the matter, are accounts of the comparative yield under the same circumstances. My experience on this point has been as follows: In the spring of 1863 I had only two Italian colonies (so called, though they were not pure). They were not strong. Through the season one of them gave me three swarms and stored 100 lbs. in boxes. The other gave me two swarms and stored 26 lbs. in boxes. All of the swarms filled their hives, and all stored some honey in boxes. I had that same summer fifty-nine hives of common bees, from all of which more or less was taken, but not one of them stored a pound of honey in boxes. That season was the poorest honey-producing season I ever knew. Through the summer of 1863 I averaged from nine Italian colonies 119 lbs. each. The best one of these shows this record in my journal: "One full swarm taken from it on the 20th of May; 150 lbs. from it in boxes. The swarm taken from it made 80 lbs. and on the 16th of August threw off a swarm which filled its hive and wintered well." This makes two valuable swarms and 236 lbs. of honey from one colony in a single season.

With this I wish to contrast the fact that from thirty stands of common bees that season I obtained only six swarms and 1,654 lbs. of honey, or an average of 56 lbs. each. The greatest yield from any one was 96 lbs. As these bees were all wintered alike, in the same sort of hives, and were managed in the same way, under the same circumstances of season and location, I claim that this result proves beyond a doubt the great superiority of the Italian bee. I attribute this superiority to their greater industry, their energy, and their more rapid increase of young in the spring, and also their ability to gather honey from the red clover.—(ELLEN S. TUPPER in *Hawk-Eye*.)

### BEE-KEEPING IN CHESHIRE—TREATMENT OF DRIVEN BEES.

I HAVE waited some time to see whether any of our Cheshire bee-keepers would give us any information respecting bee-keeping, and none of them having done so must be my excuse for troubling you. I began bee-keeping in the spring with two common straw hives. No. 1 threw off a swarm on the 7th of June, which I put in one of Messrs. Neighbours' hives, the bottom part of which they had filled by the eighteenth day, when I put on a small super, from which I have since taken 10 lbs. of very nice honey. The old hive swarmed again on the 22nd of June, and on the 28th of July the swarm weighed 14 lbs. nett. Hive No. 2 swarmed on the 21st of June, and on the 28th of July weighed 24 lbs. nett. This shows the difference between a first and a second swarm. I may mention that myself and a neighbour have driven no less than nine hives, and I have the bees of six of the hives in two bar boxes, but of course I have filled the hars of the boxes with brood comb from the driven hives, and have to feed them. I should

like to know whether you think I shall succeed with them.—JAMES HOUGH, *Middlewich, Cheshire*.

[Your driven bees should be promptly and liberally fed, so as to induce them to extend the combs with which their hives have been furnished. If the supply of food be continued until each stock weighs from 15 to 20 lbs. nett, there is every probability of your success.]

### REMOVING TO A SHORT DISTANCE A STOCK HIVE.

THE following method for removing bees in the summer from one part of the garden to another, successfully prevents them from returning to their former stance.

About midday partially drive the stock which it is desired to remove, into an empty hive. Place the empty hive with driven bees on the old site, and the driven stock on the stance intended for it to occupy in future. Then, towards dusk, when the bees are all home and not liable to take wing, carry the empty hive with driven bees to the driven stock, and by a sudden jerk eject the bees on to a newspaper. Hold the newspaper to the entrance of the driven stock, and the bees will hastily march in, and take possession of their old abode. Next morning they will, on taking wing, examine their new quarters, and few, if any of them, will return to their old locality, or if they do, it will be merely to make a flying visit, and return.—R. S.

HOW TO EAT BANANAS.—The fruits of the Banana and Plantain are eaten in a variety of ways. They form alike the savoury and sweet dishes in their native lands, and whichever way they are treated they are always much esteemed. Both raw and stewed they are served up as a dessert fruit; sliced and fried with butter, they are considered a great delicacy. They are also used by the natives for making puddings, the pulp being pounded or beaten up into a paste; simply boiled they are frequently eaten with salt meat. But, whichever way it is taken, the Banana is equally nutritious and wholesome. The experience of M. Boussingault in testing the nutritive qualities of the Banana is very interesting, and we cannot do better than insert it here. He says—"I have reason to believe that the nutritive value of the Banana is superior to that of the Potato. I have given as daily rations to men employed at hard labour about 6½ lbs. of half-ripe Bananas, and 2 ozs. of salt meat." Nor is this fruit valuable alone when freshly gathered; unlike most fruits of a similar succulent nature, it can be manufactured into a highly nutritious and valuable meal. This is effected by depriving the fruit of the outer skin, then cutting it in slices and thoroughly drying it in the sun, after which it is powdered and sifted. The sliced or preserved fruits likewise form an important article of trade in the Society Islands.—*The Englishman's Magazine for August*.)

INCREASED IMPORTATION OF EGGS.—From an official document just issued it appears that in the seven months ended the 31st July last, as many as 233,706,240 eggs were imported against 207,790,320 in the preceding year. In July last, compared with the same month in the preceding year, the increase exceeded 3,000,000.

### OUR LETTER BOX.

DORKING COCK WITH ONE EYE (*J. R.*).—The loss of an eye is not a disqualification in a Dorking cock.

ROUEN DUCK'S WING (*Subscriber*).—The wing you describe is a correct one.

PIGGERY (*J. France*).—Our correspondent would be obliged by being informed where he can see "a first-class piggery, kept on scientific principles." We shall be obliged by an answer being sent to us.

### LONDON MARKETS.—SEPTEMBER 2.

#### POULTRY.

SUPPLY ample and trade dull. The first great supply of Grouse is over. This has had its influence on prices, but the advent of Partridges will be a counterpoise to prevent any great rise.

18	M	Sycamore leaves fall.	66.8	46.8	56.8	17	41	5	7	6	9	1	17	5	28		5	59	261	

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 67.8°, and its night temperature 46.1°. The greatest heat was 86°, on the 12th, 1858; and the lowest cold, 29°, on the 17th, 1840. The greatest fall of rain was 0.90 inch.

PHENOMENA IN RAISING SEEDLING GRAPES.

HAVE forwarded to you a small box containing a few bunches of Grapes for your inspection and opinion. I do not send them on account of any great merit they possess,

but more to illustrate a subject on which I am somewhat sceptical—namely, the crossing of Grapes.

I believe that the majority of Grapes sent out of late years as cross-bred varieties are in reality no crosses at all, but simply sports from seed, that many plants long under cultivation are liable to produce.

No. 1 is a white or golden seedling raised from seeds of Wilmot's or Dutch Hamburgh, without any artificial impregnation by any white variety whatever, or by any chance of such impregnation having taken place by accidental or other circumstances, as no white Grape was in cultivation in this place when the seeds were saved that produced the plants from which these bunches were cut. This variety is a fortnight earlier than its parent, hardy, prolific, and hangs well; the specimens sent are not fair samples of either bunch or berry.

No. 2 is a white seedling from the same source as No. 1. Bunches generally large, loose, and sets very indifferently; a fortnight later than its parent. Seeds saved from the same bunch as No. 1.

A third seedling, raised from the same parent as the above, has proved identical with Busby's Golden Hamburgh, with all its faults and failings most disagreeably conspicuous, convincing me that Busby's is really a seedling from the Black Hamburgh, although at the time of its distribution considerable controversy took place that such was really not the case. For my own part I never once doubted the circumstance. My only doubts are as to its being a cross with the Sweetwater. I am now perfectly convinced that it is not so.

I may here also state that I have produced the Chasselas Musqué true from seeds from the White Frontignan, and it is just possible that Mr. Josling did send out a seedling of his own when he distributed his "Josling's St. Alban's," although it turned out to be identical with Chasselas Musqué. It is a curious fact that out of a number of seedlings saved from the Black Hamburgh I have not been able to obtain one black Grape.

I also enclose you a bunch from a Vine received from a friend in Spain. The fruit I send was perfectly ripe in the first week of May, and has been hanging on the Vine just in the same state as you see it: I think it would hang for months to come. The name sent with it was "De Rey." There is also enclosed another Spanish Grape like the

Ciotat, or Parsley-leaved. The Vine was received here under the name of "Chypre fino." It may be somewhat different from the old Parsley-leaved, but of this I am not certain. The above were all produced in ten-inch pots.—T. M. LINDSAY, Gardener to Robert Napier, Esq., West Shandon Gardens, Helensburgh, N.B.

[These illustrations of Mr. Lindsay's furnish another proof that in the vegetable as in the animal kingdom, when a fixed form has once been broken in upon, there is no end to the vagaries that follow, without any hybridisation whatever, and affording evidence in the opinion held by many, and by ourselves among the number, that the primary agent in breaking in upon the normal form so stamps its impress on the progeny, that at a certain indefinite period its similitude crops up, so to speak, where it would be least expected. From these and other experiments we have seen with Grapes and other fruits, we believe that one of the parents of the Dutch Hamburgh was white, and we would even go as far as to say that one or other of these white seedlings raised by Mr. Lindsay from the Dutch Hamburgh is identical with, or very little removed from, that white parent.

We have lately seen some remarkable examples of this—one at Messrs. Rivers' of Sawbridgeworth, where Mr. Rivers, sen., having raised a very fine melting Peach from the Pitnaston Orange Nectarine, sowed the stones of this Peach, and in return it produced two distinct Nectarines, one with a yellow flesh, and identical in every way, both in fruit, flowers, and leaves with its grand-parent the Pitnaston Orange, and another a white-fleshed fruit, in all probability identical with its next preceding ancestor.

Another instance that we have seen is at the Ascot Nursery, where Mr. Standish has raised his fine new "Royal Black" Grape from Bowood Muscat impregnated by Early Saucer Muscat; and yet this Royal Black possesses no trace of Muscat in its flavour, but is a remarkably early jet-black Grape, as large as the Black Hamburgh, and ripening nearly three weeks or a month earlier. Now, we have not the least doubt but that one or both of those White Muscat Grapes had at some time or another an infusion of the black strain in the parentage.

These are most interesting physiological questions, and give great scope and interest to the present new ideas in modern gardening, and we hope to be furnished with much more evidence, so as to enable us to draw some practical conclusions on the subject.

SEEDLING No. 1 bears considerable resemblance to Golden Hamburgh, but is more firm in the flesh, it being in this respect somewhat similar to the old Black Hamburgh. The skin is perfectly white, and, when dead ripe, of an amber colour: judging from the specimens sent, it is not nearly so good in flavour as the following.

SEEDLING No. 2.—Had there not been other varieties bearing the names of White Hamburgh and Golden Hamburgh, either of these names would have been far more applicable to this variety than to those that bear them. This is in fact a real Golden Hamburgh: in every respect—in size and shape of the berries and flavour of the fruit it is a Hamburgh, and even in the "hammered"

appearance of the berries it closely resembles the Frankenthal, or Victoria Hamburg as it is sometimes called.

DE REY.—This is evidently meant for the Uva de Rey of Spain; but this must be a misnomer, as, according to Clemente, the Uva de Rey is white. The variety sent by Mr. Lindsay is red. It produces a fine large bunch, remarkably well set, and fine round Hamburg-like berries. The skin is thick, and of a uniform dark red, somewhat of the colour of Gros Gromier du Cantal, and adheres closely to the flesh, which is tender, very sweet, and of fine flavour; but the centre is hollow, as in the Dutch Hamburg. The berries adhere very closely to the stalks, and, indeed, show a tenacity in this respect such as we have never met with in any other Grape; it is, doubtless, on this account that the variety is so well adapted for drying; the bunch sent us having the berries, though still plump, in the condition of almost a sweetmeat.

CHYPRE FINO we cannot say much about.

We are much obliged to Mr. Lindsay for his valuable communication.]

### GATHERING AND STORING FRUIT.

THE essentials of a fruit-room are—first, a low and equable temperature; secondly, exclusion of air and light; and thirdly, freedom from frost and damp.

Warmth tends to ripening, causing fruits that are capable of long keeping to be fit for use days and even weeks earlier than they would be if kept in a low temperature; and this early maturity of the fruit is had at the expense of its juiciness and flavour. When the temperature is variable it acts prejudicially on the keeping of the fruit, by at one time tending to ripen and at another to a retarding of that process. A variable temperature is a most prolific source of fruit not keeping, and it is destructive of every good quality of the fruit. The fruit very often decays at the core before it is fully ripe, and sometimes rots, and is seldom melting and delicious, but mealy and flavourless.

The exclusion of air acts as a preservative, for the oxygen of the air is necessary for decay. The presence of air is needed for the elaboration of saccharine matter; but as fruit-rooms are for the preservation of fruit, that which tends to ripening should be carefully excluded, of which air and light are the next in importance to warmth.

Freedom from frost is important in the keeping of fruit, for the cells of the fruit are ruptured by frost, and their juices then speedily pass from fermentation to putrefaction on the fruit thawing.

Damp is no great evil in itself, and does not necessarily lead to decay unless accompanied by warmth and the presence of air. But inasmuch as it tends to and hastens decay, damp should be avoided; but even slight damp is better than dryness with warmth, and the presence of light and atmospheric air, for the presence of these are indispensable for the ripening of fruit, and frequently convert the long-keeping into short, and juicy fruit into shrivelled, sweet, but juiceless, and sometimes mealy instead of buttery.

Now, to secure the essentials above named, nothing answers so well as a dry cellar or room underground. It secures a low and equable temperature, the exclusion as much as is practicable of air and light, and freedom from frost and also damp, especially of that kind resulting from a thaw. The coolness and equable temperature of a cellar is desirable because we wish to keep the fruit without ripening or decay to the longest period, warmth tending to ripen and cold to a retarding of that process; light and the presence of atmospheric air hastening, and their exclusion securing in contact with the fruit the carbonic acid emitted by it in ripening, which is well known to be one of the best preventives of decay. A cool dry cellar, therefore, answers more fully the requirements of a fruit-room than any other description of room.

I am aware that this is directly opposed to the desirabilities of a fruit-room insisted on by many excellent authorities. What is chiefly sought for by them is dryness, but there is such a thing as too dry a room for fruit. So long as there is no deposition of moisture on the fruit the room is not in the least too damp, and when the fruit shrivels the room is certainly too dry, and though it may not lead to decay, it certainly does impair the juiciness, and the firmness and beauty of the fruit are gone.

Extremes of either dryness or moisture are the attendant evils of fruit-rooms on first and second floors. They are at times very dry, especially during the prevalence of windy

frosty weather, when artificial heat may be necessary to keep out frost, and at others they are very damp, rendering fire heat necessary as a means of drying up the moisture that runs down the walls. The employing of fire heat is in itself sufficient to stamp fruit-rooms requiring it as not adapted to their purpose, for we do not want to keep fruit warm but cool, yet we must have a fire during warm damp weather, especially that following a thaw, in order to keep the room sufficiently dry, and we thus make bad worse, for in addition to firing air must be given, and thus we have an excess of damp, warmth, and air, all contingencies promoting decay. I do not hesitate in stating that fruit, especially Apples, would keep much better, more plump, and sound, pitted like Potatoes, than in many fruit-rooms which are really not calculated for keeping fruits, but to hasten their ripening, and cause them to decay long before their customary period. I am not writing upon hypothesis but from experience, which has taught me that a cool room, an equable temperature, darkness, and moderate dryness are necessary for the preservation of fruit. Fruit-rooms on first and second floors are good places for ripening fruit, and it is next to impossible to keep it in them without a large percentage of waste.

The site of the fruit-room should be dry, and if not so naturally it must be made so, and have a north aspect. The best are those with a room underground for the late-keeping, and a room above ground for those fruits that are not long-keeping, and are more or less in a stage of ripening when taken from the trees. In constructing a fruit-room the soil should be taken out 9 feet deep, and 2 feet wider on each side than the required width; 18 feet being a very convenient width, allowing of bins a yard wide all round, and a centre one of 6 feet divided into halves by a partition up the middle, and it may be of any length, and, of course, of whatever dimensions that the quantity of fruit will require. Along the centre a drain should be laid, and one all round the outside of the foundation of the walls and communicating with the centre drain. The flags of which the floor is formed should rest on pillars a foot higher than from whence the soil was taken, and under no consideration be laid on the soil. This foot of space beneath the floor is to be filled with rubble. The walls are to be built hollow, and to insure stability, have throughs every other course. The air we want enters the cellar by drain-pipes with the joints cemented, extended from and communicating with the hollow space in the wall, and thence passing under the floor and opening out through the pathway, a hole being cut in the flags for the purpose, the pipes having a bent end on purpose, their opening or mouth being stopped with a plug. Six of the drain pipes (three on each side), one end communicating with the hollow or cavity in the wall, and the other opening into the cellar at the floor in the pathway, as before mentioned, will be sufficient. The wall is to be carried up hollow for 7 feet, and there the throughs must be mortared so as to divide the hollow part below from that above, and just below this air-holes are to be left in the outer wall corresponding to those left in the inner wall at the base of the building. The wall is then to be built hollow as before for 1 foot, and then throughs again, and mortared as if the wall were solid. There will be openings left in this part both of the interior and exterior walls to allow of any vapour that may arise in the cellar passing out at the upper part, and its place being occupied with colder and fresh air by those openings from the floor, advantage being taken of a dry frosty day. The wall is then built hollow as before for 9 feet above the roof of the cellar, which, of course, will be the first floor, and there is the same means applied to admit air at the floor and to allow the damp and vitiated air to escape at top. The room on the first floor will, of course, have its ceiling, and the tiles or slates will be laid on asphalt. There will be caps for all the openings to admit or let out air, and whilst we have no windows in the cellar, we must have two in that room on the ground floor and furnished with shutters inside. The outside walls are to be coated when dry with boiling coal tar, and have three of such coatings. All round, as there is a two-foot space, rubble is to be placed against the cellar walls and level with the surface, and it is not there to be covered with sods, or turf, or soil, but with coarse gravel. Under present arrangements we shall have no damp but what comes from the interior, of which we will now treat. We have a trough or bin a yard wide all round formed of stone, and 9 inches in depth, excepting where the steps are, and above this, at 2 feet, we have another shelf or bin, and at every 2 feet upwards another, and a fourth 2 feet higher than it. The first is 9 inches in depth, and the second likewise, the next 6, and the

other 3 inches, and each 3 inches less in width progressively upwards. The centre is simply a counterpart of the outside, and is divided by a partition of stone.

So much for the fittings of the cellar. The upper or fruit-room on the first floor should be furnished with wood-shelves, and beech wood is the best. They may be of the same width, but the lowest should not be more than 6 inches, and the upper shelf not less nor more than 3 inches in depth. A four-inch hot-water pipe laid under the pathway, and covered with a grate will complete the arrangements of the room on the first floor. It is scarcely necessary to say the walls should be plastered and well whitewashed, and have effective spouting to carry off the water from the roof.

We have now a fruit-cellar and a fruit-room, and need not care for anything further, unless it be a "ripening-room," which need only be half the size of either the other rooms, and fitted up with birch, beech, or elm shelves, two all round; the first a yard from the floor, and the other 18 inches above it, and 1 foot less in width, with a ledge all round for half an inch of dry silver sand. In the centre should be a table 4 feet wide and 3 feet from the floor, having another 18 inches above it, and half the width, and only extending so far as to leave a space of 12 feet without the upper shelf over the first centre shelf. This part of the shelf is to be covered with green baize, and divided into squares by half-inch strips of birch wood dyed, the first 1 foot from the edge longitudinally, and then cross-wise the entire width; the outer into foot squares, and the central one into two-foot squares. This part is for fruit fit for table, from whence the proprietor can select at will, and to treat and present to friends. This room will require to have a glass roof, and be heated so as to maintain a temperature of 45° to 50° in winter, and provision made for thorough ventilation.

I do not intend to maintain that fruit cannot be kept sound without the appliances I have detailed, but the rooms most resembling these I have found best for keeping fruits. The cellar would take the long-keeping and those desired to be kept a longer period than usual; the fruit-room proper the autumn and early winter fruits; the ripening-room being desirable to bring out more fully the flavour, from the presence of air, light, and warmth being necessary for the elaboration of saccharine matter. When it is not desirable to "keep" fruit (but I am ignorant of when that is), any cool dry room will do for storing Pears, and it does not matter about their being kept in the dark. The fruit in such a room will ripen in due season, the different kinds following each other in the order of ripening. For Apples a room of this kind is not desirable, for the presence of light and air will cause the fruit to shrivel, whereas we wish them to be firm, juicy, and crisp.

Fruit should be gathered before it is fully mature, and so soon as it parts easily from the tree by reversing its position. The fruit is to be gathered on a dry day, and after a continuance of dry weather, and during the mid-day hours chiefly.

The main points in gathering fruit are to avoid bruising, to be sure that it is dry, and nearly mature, but not so much the latter as to fall from the trees when touched or disturbed. To guard against bruising, the gathering-basket should be lined with cloth, and the fruit placed carefully in it, and as carefully taken out one by one and laid on a floor, and if covered with dry sand all the better. It should not only be gathered and handled with the greatest care to prevent bruising, but the nails of the fingers be kept from penetrating through the skin, and that scrubbing and rubbing should be avoided, which some people seem to take a pride in when they get hold of fine handsome fruit. The practice of gathering fruit into a small basket, emptying into a larger, and then tumbling the whole on to a hard floor is pretty nearly obsolete, and where it is still practised should be at once abolished. Small bruises inflicted at the time of gathering and the storing of fruit in the slightest cracked or bruised, or having small holes in them, whether the results of birds pecking at them or wasps digging into them, is certain to lead to decay, not only of the fruit so eaten or bruised but of those which are sound if in contact with the decaying fruit. Injured fruits should be taken from the sound and stored by themselves.

The day after the fruit is gathered it should be stored away, and not left in heaps to heat or sweat. The autumn and early winter fruits should be placed in the fruit-room, commencing with those that keep the shortest time, placing them on the upper shelves, which are best covered with half an inch of dry pit sand. The fruit will rest easily on the sand and not be bruised in the laying, as it may be when laid on

the hard shelf. Each fruit to be laid so that it does not touch that adjoining, and when the first tier is laid they should be covered with dry sand so as to cover the fruit about an inch. The second shelf downwards will take two tiers with half an inch of sand between if the fruit be small, or one if large, with a covering of 2 inches of sand. The third shelf two or three tiers of fruit according to their size, to be covered with 3 inches of sand, and the lower tier in like manner, placing that which will keep but a short time on the upper, and the longest, and so on progressively downwards. Any fruit not keeping beyond a few days need not be stored in this manner, but be placed in a room from 45° to 50°, and with both light and air; and all fruit, especially that for dessert or table use, should be brought from the store fruit-room ten days to a fortnight before using and placed in a room having warmth, air, and light. It will thus be vastly improved in appearance and flavour. A temperature of 40° to 45° is sufficient after November, whilst 45° to 50° will be better previously.

I will now say a word as to placing fruit on the bare shelves. The fruits are bruised by so lying, and being exposed the air plays too freely around, and they are sure to be handled more, whereas fruit cannot be handled too little. Some Apples and Pears keep fairly on shelves, but they may have a turpentine taint if the wood forming the shelves be deal. As for placing fruits on and covering them with straw I can only say it is not objectionable for baking-Apples and stewing-Pears, if it be Rye or Wheat straw and very dry and clean, but even the bare wood is to be preferred for dessert fruit.

The long-keeping fruit is to be housed in the cellar, remembering that the lowest bins are for the very long keeping Pears and Apples, and the Walnuts and Filberts, and if there be a damp place in it that is the place of places for the last two. Two tiers only to be placed in the two lowest bins, no two fruits to touch, and the bin to be filled with sand. For very long keeping one or more bins should be filled with fruit packed in and covered with powdered charcoal, which is undoubtedly the best preservative known. It would add to the keeping if a few stone jars were filled with fruit, packed in either sand or charcoal dust so that no two fruits touched, burying the jar in the sand in the bin, and covering with at least 9 inches of sand.

The fruit being stored away, and none but the really sound stored, it will not be necessary to examine it before its usual season of ripening, when a few fruits being seen to will soon determine whether they will not keep longer. In that case a part of the fruit is to be placed where it will ripen fully. If it will keep longer then a part as before may be taken out to ripen, and the others remain longer until all are removed for ripening. Any that are expressly packed for very late keeping should not be touched until the time arrives they were calculated upon to keep—say, Ribston Pippin Apples until February, Scarlet Nonpareil to March, the Old Nonpareil to May; and of Pears, Glou Moreau to February, Bœurré de Rance to May, and Ne Plus Meuris to May and occasionally June, it being the latest-keeping Pear of which I have experience.

I will now say a few words in regard to the keeping of Brown Bœurré Pears, being those regarding which a correspondent, asked particularly, and whose query prompted me to write these notes. The Brown Bœurré usually is a good keeping variety though its season is early, and not very long. In an ordinary fruit-room it comes into use at the end of October, and continues well nigh through November, and occasionally into December. In a cool, dark room its season is prolonged a fortnight or three weeks. It is needless attempting to keep such Pears as this beyond their season, and I find more Pears rot because they will keep no longer, and people then say they have kept badly. Fruits are no exception to the rule, everything has its season. Pears as they ripen must, therefore, be used, or they will decay. We can only look upon fruit as bad-keeping when it decays before it is fit for table. In that case the fault usually lies in gathering and storing; probably the fruit being over-mature when gathered, or cracked, wounded, or otherwise defective.

But to resume. Fruit stored in an ordinary fruit-room, and, in fact, in any room, will need looking to at the least once a-week, more especially when it is stored so that the fruits are in contact, and then determine how the different kinds come on for ripening, and as far as can be done remove any fruit beginning to decay. It is a bad practice to be continually handling and turning fruit over, and knocking it about. The less of this the better. Once stored there let it remain, for if the

fruit be stored in sound condition it will keep just as well as if every fruit were overhauled daily. This not intermeddling with fruit is not to interfere with that supervision necessary to learn when it ought to be placed in a warmer and lighter room, for fruit does not always keep the same length of time. There is this advantage in having the fruit on shelves, that it is easy to pick out the ripest or most forward; and there is a still greater advantage in placing it on sand—that it will keep longer, and a decaying fruit not contaminate those next to it, for shut out to a great extent from atmospheric changes, there is no fluid exuded.

In addition to examining a fruit-room to ascertain the keeping and maturing of the respective kinds, it should be opened every dry day to dry up damp, if there be any, and to keep the room cool, nothing contributing to this more than a thorough draught. If the room be not damp, then kept closed, and when opened admit no more light than is really unavoidable, and what air it is necessary to give let it be with a dry atmosphere outside, and from 10 A.M. to 4 P.M. During damp weather the room may be so damp that it is really imperative to give air, and to get the air in motion a gentle fire may be lighted, and what heat is given be only during the midday hours, allowing the heated surface to become cool before the room is closed at night. Fire heat applied for the purpose of promoting a circulation of air should not upon any consideration be so great as to raise the temperature. During severe frosty weather a little free heat may be needed to prevent the temperature falling to or below freezing. The nearer the temperature to, and yet above, freezing, the longer and better the fruit will keep. From fire heat the temperature should never exceed 40°. Very few, if any kinds of Apples and Pears, will ripen perfectly in so low a temperature; above 40° they are more or less advancing towards ripening.

For autumn Pears, which do not keep for any length of time, no place answers so well as a cool orchard-house or vinery. The light, the air, and the moderate temperature render the fruit very highly flavoured, and to have them melting they should be taken from the trees before they are so mature as to drop of their own accord. Such maturity renders melting Pears when stored either woody and juiceless, or mealy and insipid, which is the case with *Benréc Superfin* very often from a wall, when gathered quite mature, and an example of the meanness may be found in the *Bon Chrétien*. Of the late Pears, I only know of one instance, and that is the *Easter Benréc*, which from a wall is very often mealy, and from an espalier melting and perfumed, as it always is when in perfection.

It very often happens that the crop of some autumn Pears is so great that it is a question what to do with them, as they all ripen together. Now, by gathering those that are the most mature a fortnight to three weeks earlier than the general crop, or by making two or three gatherings from a tree instead of one, their season will be considerably lengthened; those gathered being placed in a room conducive to their ripening.

Lastly, fruit that is gathered before it is fully mature will be the longest keeping, and by far the best flavoured; but if such fruit be kept in a light, dry room, it will shrivel, and though high flavoured be other than juicy, melting, and refreshing.—G. ABLEY.

#### PLANTING VINES INSIDE OR OUTSIDE.

In replying to "W. B. A." in your Number of the 29th ult., on the subject of planting Vines inside or outside a house, you say, after recommending inside planting, that the roots must not get under the arches or wall plate, so as to reach the outside border. If so, what is the use of an outside border? Having erected a vinery of late with arches in the front wall, the Vines planted inside, and the outside border as carefully made as that inside, I am startled by your observation.—W. F.

[We fear that our answer to "W. B. A." was not explicit enough, and so far as we recollect it is not exactly as we had written it. Alter the part of sentence thus, "but the inside border must be higher than the outside one, and the roots must not descend to get under the arches, in hopes that they will rise into a higher border outside." We said nothing as to the "roots must not go under the arches or wall plate, so as to reach the outside border." If we were crude, you have not quoted correctly. If we had said so, you might well say, "If so, what is the use of an outside border?" Though the above meaning could hardly be drawn from our short note, we are much obliged to you for drawing attention to the want of explicitness. The matter has lately been so often alluded to, that no doubt we

wrote more carelessly than we otherwise would have done. We have few Vines planted inside ourselves, because we would have to disarrange the internal finishings to do so. We have, however, strong reasons for having them all planted inside. Several times we had Vines eaten by rats and mice at the holes where they entered the wall, and this would be less likely to be the case if the stems were all exposed inside. The stems of Vines will not pass some of our winters uninjured without protection, and if we protect with wooden boxes, with sawdust, &c., these boxes, again, give admission to vermin to lodge in them. Even if the border inside is not very wide, but the wider the better, that border is more completely under control as to wetness and dryness, cold and heat, than any border can be that is placed outside, unless there is the trouble and expense of protecting, and that too with waterproof material.

The above are some of the reasons for planting inside. The Vines, also, at all times are more under control. There is no objection whatever, in general circumstances, to having a border likewise outside, and allowing the roots to have free access to that border, by arches or other openings beneath the wall plate, and we like the latter better than arches, because if the border inside is as high as the wall plate, the roots can get out without having to descend much. The term, "must not descend," in the paragraph alluded to, has reference to a fact we have often observed. The front wall was built on arches, leaving, perhaps, some 15 or 18 inches of wall above the arches. The border inside in which the Vines were planted might be little above the crown of the arch, whilst the top of the border outside might be some 15 or 18 inches above the top of the arches. We have had to manage several vineries where the inside border was as much lower than the outside one, and less or more, such circumstances always told against the well-being of the Vines. The mound of earth over the roots outside was rarely penetrated with healthy fibres. It is on such accounts that we advise the inside border to be the higher of the two, and, if there are arches or other openings, that the roots may pass freely into the outside border without being expected to descend much to the arch, and then rise above it outside. Were the choice given us, to have a low border for Vines inside of a house, a high border for the roots outside, and the Vines planted inside, and, on the other hand, a border altogether outside, the roots being where we liked, then we would choose the outside border. But where, however narrow, the inside border is the higher, and the roots have free access outside, and the border, as a whole, slopes from the inside to a lower level at the front of the outside border, then we would decidedly plant all our Vines inside.

#### THE RIPENING OF OUT-DOOR FIGS.

THE explanation of the cause (by "G. S.," page 166), of our obtaining ripe Figs in Jersey some three or four weeks earlier than they can be obtained near London is very satisfactory. I will endeavour to mark some of the autumn-grown Figs here to confirm what I have but little doubt is true.

It has appeared to me, from simple observation, that this fruit thrives best near the sea. In England it may be gathered in perfection in gardens on the Sussex and Hampshire coast, and in the Isle of Wight; the garden at Tarring, near Worthing, perhaps, taking the lead; and who knows but that Thomas à Becket may have walked in the cool arbours formed by these same venerable Fig trees, and have refreshed himself with the fruit thereof? for the ruins of his house are there. But the theory of the Fig's early ripening in Jersey will not, I think, hold good with other fruits and vegetables that ripen here in the open air, and which in England require some forcing. I may instance Melons, Cucumbers, and Tomatoes, all of which ripen in my own garden from seed sown in the open ground; the mildness of our winters would not alone account for this.—A. T., *Noirmont, Jersey*.

[Would not the general mildness of all the seasons in the Channel Islands?—EDS.]

FUCHSIA BLOOMS INJURED BY BEES.—A short time ago you were kind enough to answer an inquiry I made respecting the decay and destruction of my Fuchsia blooms, and you suggested that the effect might be produced through the agency of bees impregnating the blossoms. In compliance with your sugges-

tion I covered the ventilators and windows with fine tiffany, so as to exclude the bees. The result has been most satisfactory. Not a bee has entered the greenhouse, not a single bloom has failed prematurely since the plan was adopted. As you wished to know the result, and as it may be useful to other novices, I communicate it to you as soon as there was no doubt of the fact.—F. L. G.

THE BEST ROSES.

HYBRID PERPETUALS.—Those of which I now give a list have good constitutions, and their other attributes are all good.

- |                               |  |

They are strong growers, hardy, and bloom abundantly. Celine Forestier and Madame Schultz require but little cutting. Here they are all best on Manetti. Even for poles and walls there is no stock so good as Manetti. If the land is strong they will all do well on Briar stocks.—W. F. RADCLIFFE, *Tarrant Rushton*.

MUSHROOM SPAWN—MUSHROOM BRICKS.

To oblige "A Lover of Mushrooms" I will write a few lines on this subject, but have written so much on the same that it will be easier, and perhaps more suitable to your correspondent to write afresh, instead of making many references.

"Made some Mushroom bricks," I said at page 178, is what he wishes to have explained, &c. Now, where only one or two Mushroom-beds are made in the season, on the principle of the division of labour it will generally be the most economical to buy Mushroom spawn at from 5s. per bushel from a nurseryman. Where Mushrooms are wanted all the year through, and even when a few could be had from the pastures they must not be sent to the kitchen—then it may be advisable to have a stock of spawn beside us, whether we go to the market for a portion or use all of home make. Though we have had and seen very poor spawn sent out, so that the carriage cost ten times more than it was worth, I must say that on the whole the most of our nurserymen and seedsmen take a pride in sending out a first-rate article, and I do not consider from 5s. to 6s. too much for a bushel of good material, as, even under the most favourable circumstances, considerable care and watching are required to get it in first-rate condition. I am well aware that the man who makes a thousand or two thousand bushels at a time could do it much more economically than I could make some ten or more bushels. It is very useful to have a nice heap of good stuff beside you, however; and then in these days we ought to know how to do everything, even if we are not called upon from circumstances to engage in doing it.

There are many ways of making Mushroom spawn: I will describe the plan generally adopted by us. We obtain a barrow-load of cowdung, rather stiff than otherwise, and add to that

two barrowloads of horse-droppings, with a few short pieces of straw in it, and about a half-barrowload of rough bits of loam. We work all this well together until it looks like a heap of well-mixed mortar. The less water that is used and the stiffer it is the better. Sometimes the material is rather moist and close, and then we add a bushel or two of cut straw to make it more open; but if all is right, we care about little more than the cowdung and the horsedung. So much for the material.

Then for the bricks, we have a slight frame made with four pieces of half-inch board—but is, two sides and two ends enclosing a space 9 inches long, 4½ inches wide, and 1½ inch deep, just like a mould for bricks, only shallower. We used them exactly of the same depth as bricks, but then they took longer to dry. The mould will answer as well, if not better, if made of thin iron instead of wood. The board-frame, however, answers well enough. Then the next thing is to have a flat clean board and a bucket of water. The frame is placed on the board, filled from the prepared heap, struck level on the top with a clean spade or flat trowel, and the contents, the dung-brick, struck out on a piece of wood, so as to lie flat. To prevent the dung sticking to the mould, the latter is just dipped into the pail of water; the second brick is made the same as the first, and so the process goes on, brick after brick being turned out, and placed on boards or other convenience much faster than I can tell how. From dipping the mould, the sides of the brick will come out smooth and a little damp, but they will soon dry. We like to place the bricks anywhere, so that the rain does not come on them. We shall suppose that they have been on their broadsides for a couple of days, then we go along them, and with our finger, or if rather dainty with a round wooden pin, make two holes in each brick equidistant from each end, and not going quite through the brick. In another couple of days the bricks may be turned on the other side flat, then in a few days set up on one edge, and then again set up on the other edge, and they will soon be firm and dry enough for spawning. Those mentioned at page 178 are just now (September 7th) spawned. This is done by taking some spawn, breaking it into little pieces, so as to go into the two holes of the dung-brick, making it go in pretty tight, and then drawing a little awdung over the place to prevent falling out. When thus saw ned the bricks are built loosely in a heap, and placed on op bed of litter that will just emit a little heat, and surrounded with litter, so as to give a heat to the heap of about 85°, and not more. Of course with such weather as we have now little heat will be required; a slight covering just to prevent over-drying will be sufficient. Overheating will soon spoil the whole. The bricks should be examined, and as soon as the spawn works into the whole brick that brick should be removed to a dry place. Some will not run so freely as others, and, therefore, in a large heap there may be several harvestings. The bricks should be removed as soon as they are permeated by threads finer than the finest silken ringlets. When the spawn appears in threads as coarse as that generally used for sewing, it is a sign that these threads have run rather too much. When harvested in a dry place such spawn will keep good for years. It is well, however, to keep it covered with dry moss or refuse hay to prevent its becoming too dry and hard. There is less trouble in doing all this than in writing about it; but success will consist generally in attending to these matters of detail.

We thus make bricks because it suits our purpose to do so, and because they are easily moved about. We have seen lots of spawn made in a much simpler way, and which, if the weather was dry or there was plenty of shed-room, answered very well. The material was obtained, mixed, beaten, and mingled much as I have stated above. It was then spread out on a hard floor or bottom to a depth of from 1½ to 2 inches, and made firm and smooth on the surface by beating, or by passing a smooth damp roller over it. When it had thus lain a day or two it was cut out into squares, or any other desirable shape, by means of a clear sharp edging-iron, and when dry and cohesive enough was turned, dried, and spawned, just as we have described for the bricks. We should judge, from the size of the cakes, that many makers for the public follow this plan. Where the conveniences exist the first processes are soon got over. We once made a lot on a hard smooth road, and the weather being fine, we had it nicely dried with but little trouble. However done the same minutiae must be attended to to secure a first-rate article. Just as in Mushroom-beds, too much heat will generally make wreck of the whole. When once the spawn begins to run it makes pretty well enough of warmth for itself.—R. F.

## ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 5TH.

**FLORAL COMMITTEE.**—The principal feature of this meeting was the numerous seedling Dahlias, some of which were very good, but not one could be said to be new either in colour or form. The time has arrived when little more can be expected from this flower. The criticisms on the perfection of a Dahlia are quite mysterious, and it requires a most practised eye to form a correct judgment of its merits; and sometimes the fastidious nicety of distinction amounts to an absurdity. This flower still has its devoted admirers, and appears to have many patrons.

Messrs. Downie, Laird, & Laing exhibited a fine collection of Solanums and other fine-foliaged plants. The Solanums formed the chief portion, and were much admired for the various forms of their prickly foliage and stems. A special certificate was awarded to the collection. Mr. J. Coombs, Hackney, sent two seedling variegated Pelargoniums with tricolor foliage—Prism and Eclair. The plants were too young to justify any decision on their merits, and must be seen again. Mr. Bull exhibited a very fine double white-corollaed *Fuchsia* with bright pink sepals. This is by far the best double white variety we have seen. It is very free-flowering, with large flowers. A first-class certificate was awarded it. Messrs. Lee sent a fine specimen of a *Stanhopea grandiflora*, a very handsome Orchid. Mr. Shaw, Manchester, sent three seedling Gladioli with faded spikes; they appeared to be of the striped or mottled section. M. Wailly sent a collection of *Tropaeolum* flowers, many of them pretty, but nothing distinct or new. Mr. J. H. Lock, Herne, Kent, exhibited cut flowers of three seedling Hollyhocks—Annie Mande, a pure white; Thomas Rammell, dark red—the flowers were not near the standard of the present day, being deficient in form and outline. A single flower unnamed attracted attention as a novel colour in Hollyhocks—a very delicate fawn colour. It was remarked that there is no Hollyhook of this peculiar tint of colour. Had it but the necessary qualifications of form and substance, which, like the others, it so manifestly lacked, it would be a valuable flower. Mr. Leach, Clapham Park, sent two single flowers of *Lilium* from Japan. Mr. Wills, Oulton Park, sent another of his hybrid *Verbenas*; also Pelargoniums Beauty of Oulton and Gaiety, which have been previously noticed in this Journal; and a variegated form of *Hydrangea*, marginata, which it was requested should be seen again. Mr. Macintosh, Hammersmith, sent a dwarf seedling *Antirrhinum* of no use. Mr. Veitch sent *Cattleya exoniensis*, one of Mr. Dominy's good hybrids. A special certificate was awarded to it as a fine specimen, it having received a first-class one at a previous meeting. Mr. Perry again sent several seedling *Verbenas*—Champion, a dark maroon, bright eye, large truss and pips, which was awarded a first-class certificate; the others had been exhibited before. Mr. Eckford, High-worth, also exhibited seedling *Verbenas* John Keynes, a bright orange scarlet with conspicuous lemon eye—first-class certificate; Mr. Gladstone, a bright ruby with distinct eye—second-class; Gladiator, Mr. W. Ellice, Isaac Eckford, and Celestial.

Among the seedling Dahlias Mr. Burgess, of Chelsea, exhibited Mrs. Lind, Mrs. Burgess, and Kate. Mr. Pope, Chelsea, exhibited Fancy Dahlia Fanny Start, dull red heavily tipped with white, fine form, medium flower—first-class certificate; and Mr. J. Pope. Messrs. Wood & Ingram sent Dahlia Lord Sandwich. Mr. Bragg, Slough, sent Dahlias Goldbeater; Commander, a fawn colour, which was awarded a second-class certificate; Fair Lady, Commodore, Hon. Mrs. Gerald Wellesley, Belle, and Rival Model. Mr. Turner sent Dahlias Arthur, Amber Witch, Artemus Ward, L'Africaine, Princess Dagmar, Princess Alice, Fair Imogene, Royal Robe, Master of Arts, orange tipped with purple—second-class certificate; and Blushing Fifteen, a rosy lilac—second-class certificate. Mr. Rawlings, Romford, sent Dahlias Majestic, Pirefy, Queen of Autumn, and Aristides. Mr. C. J. Perry sent Dahlias John Powell, Miss Powell, Ne Plus Ultra, and Startler. Mr. Church, Binfield, Berks, sent Dahlias Gladiator and Mr. Savory. Mr. Legge, Edmonton, sent Dahlias Golden Empire, Lilac Perfection, Mr. Gibson, Mr. Braham, Prince of the World, and Eclipse. Mr. J. Keynes sent Dahlias Ultimatum, delicate blush, tipped, a very pretty flower—first-class certificate; President Lincoln, George White, Lady of the Lake, Ellen Potter, Jeannie Deans, Sir Greville Smythe, and Annie Austin. Mr. Allen, Shackwell, sent Dahlias Mr. Tyson, and Crown Jewel, and Mr. Eckford, Dahlia Lady Mary Wilde, a delicate light white and lilac flower—second-class certificate.

**FRUIT COMMITTEE.**—G. F. Wilsou, Esq., F.R.S., in the chair. On this occasion a dish of Walburtou Admirable Peaches was exhibited by Henry Whiting, Esq., of Battersea Rise; these specimens were very good, and well flavoured. Some fine large fruit of the Stanwick Nectarine came from the Chairman, and were quite free from cracking, to which that variety is so liable; they were, however, grown under glass. Royal George Peaches grown on a standard were exhibited by Messrs. J. & C. Lee, of Hammersmith, but they were small, and rather astringent. The same may be said of Peaches, and Elrune Nectarines, also grown on standards, from Mr. Macintosh, nurseryman, Hammersmith. A seedling Peach was exhibited by Jonathan Clarke, Esq., The Mall, Chiswick, gathered from a standard ten or twelve years old, and which bears well every year. The fruit was very large, roundish, tinged with red next the sun; flesh pale, slightly rayed with red at the stone, from which it parts; it was a little astringent, but from its

very large size and ripening on a standard it was recommended to be tried against a wall. The tree has leaves with reniform glands. Another seedling, also grown on a standard, was exhibited by the same gentleman. It was below the medium size, well coloured, but not equal in flavour to sorts in cultivation. A Black Jamaica Pine Apple was sent by Mr. Yates, Manchester, on account of its being affected with decay in spots, but where sound the flavour was excellent. The fruit was submitted to the Rev. Mr. Berkeley, who decided that the diseased spots were caused by the common vinegar mould. Green-fleshed Melons came from Mr. Wills, gardener to Sir Philip Egerton, Bart., Oulton Park; and from Mr. Hudson, gardener to Miss Strut, Chacecliffe, Derby, but neither of these Melons possessed merit. The Garden Castle Egg Plum was exhibited by Messrs. Lee; very good specimens, but scarcely equal in flavour to the Jefferson. The Transparent Gage Plum, however, exhibited by the Chairman was very excellent. It is rather larger than the Green Gage, somewhat later, exceedingly rich, and a most valuable delicious fruit; this variety cannot be too highly recommended. A collection of Figs came from the garden of the Society, and six sorts of Grapes. Among the latter were specimens of the Chasselas Musque de Nantes, with which the Cranford Muscat was compared, and the two were found very similar in appearance and equally rich.

## THE EDINBURGH INTERNATIONAL FRUIT AND FLOWER SHOW.—SEPTEMBER 6TH.

SCOTLAND may well be proud of the great Show held at Edinburgh on Wednesday last; for not only was it great in its extent and in the variety of the products of horticultural skill which were gathered together, but great, too, in the extraordinary excellence by which these productions were characterised. As an eminent English horticulturist most justly remarked, the Show was distinguished not merely by the presence of the good, but also by the absence of the bad. Such a success must have been, and was, most gratifying to all concerned in the Exhibition, to the promoters, to the exhibitors from both sides of the border, and to those who came far and wide to witness the display. In all competitions there must be losers as well as winners, but in this both parties covered themselves with credit; for the winners obtained no cheaply-purchased victory, and the losers departed with the honours of war and a firm determination to renew the fight.

Before proceeding to detail a few words as to the origin of this Show, which was held under the auspices of the Edinburgh Horticultural Society, may not be out of place. The propriety of holding an international horticultural exhibition at Edinburgh was first mooted, about twelve months ago, by Mr. William Thomson, of Dalkeith, and Mr. Young, the Secretary; and the idea having been warmly taken up, the principal horticulturists at home and abroad were communicated with. The result was, that promises of support came freely from all quarters, as well as subscriptions to the amount of £500, setting the Committee at ease on the score of funds. A schedule of a most comprehensive character was framed, containing upwards of a hundred classes, in which liberal prizes were offered to competitors, both British and foreign; and how well this invitation was responded to by gardeners from all parts of the kingdom it is now our pleasing duty to relate.

The Show was held in the spacious Music Hall and Assembly Rooms in George Street, and the Committee having been at work all the preceding night in arranging the multifarious subjects which were brought for exhibition, the tables were ready by six o'clock in the morning for the Judges to proceed to make their awards, and by thus starting early the adjudications were completed and the prizes affixed before the public were admitted. From 9 till 11 A.M. gardeners were allowed the privilege of inspecting the Exhibition for a small admission fee, and afterwards the visitors, who thronged in, were so numerous as to render movement a matter of no little difficulty; and it was evident that if the Society's future shows be as extensive, as attractive, and as numerously attended as this one was, a greatly increased space must be secured to permit of the subjects exhibited being seen with comfort. This was the only drawback to the Show, for in every respect it was admirably conducted, Secretaries, Treasurer, and Committee-men being indefatigable in their labours, and nothing could exceed the attention, the courtesy, and the kindness which they brought to the performance of their arduous tasks. And now to the details of the Exhibition. Fruit was the great feature, and with that, therefore, we shall begin.

## FRUIT.

The display of this was magnificent, fully occupying the whole of the vast Assembly Room; and although the hues of tabling were placed as closely together as it was possible to do without entirely obstructing the circulation of the visitors, there was not an inch of space to spare, indeed some of the fruit had to be set up in an adjoining room. So much of the quantity, now of the quality. Never has it fallen to our lot to see hothouse fruit, and especially Grapes, in greater perfection than the bulk of that exhibited on this occasion. The collections of twenty sorts of fruit were unusually good, especially those from Mr. W. Thomson, gardener to the Duke of Buccleuch, Dalkeith, and Mr. D. Thomson, of Arherfield, and which were pretty evenly balanced in point of merit. Mr. W. Thomson had two excellent smooth-leaved Cayenne Pines, and a handsome Queen, of the extraordinary weight of 6½ lbs.; splendid bunches of Black Hamburgh,

Lady Downe's, Calabrian Raisin, and Muscat Grapes; two well-grown Melons, Crawford's Early and Bellegarde Peaches, Elrage Nectarines, Moorpark Apricots, Jefferson and Victoria Plums, Figs, Morello Cherries, Red and White Currants, Kerry Pippin Apples, and Jargonelle Pears. Mr. D. Thomson had three Smooth Cayenne Pines, two Melons, very fine bunches of Lady Downe's and Black Hamburg Grapes, beautiful Muscats and Calabrian Raisin; very fine Noblesse, Bellegarde and Barrington Peaches, Moorpark Apricots, Kirke's and Victoria Plums, Figs, and Jargonelle Pears, &c. Mr. Tillery, gardener to the Duke of Portland, Welbeck, had also an excellent collection, consisting of Queen and Prickly Cayenne Pines, Normandy Park Green-fleshed and Scarlet Gem Melons, very good Golden Hamburg, Muscat, Black Hamburg, and Gromier du Cantal Grapes; Grosso Mignonne Peaches; three fine dishes of Nectarines; Green Gage, fine Goliath and Magnum Bonum Plums, Moorpark Apricots, Morello Cherries, Hawthorned Apples, and La Panache Pears. Mr. Rose, gardener to the Duke of Roxburgh, Floors Castle, likewise contributed a very meritorious collection.

Awards.—For the best collection of twenty, not more than four sorts of Grapes, two sorts of Pines, and two sorts of Melons: first, Mr. William Thomson; second, Mr. D. Thomson; third, Mr. W. Tillery; fourth, Mr. Rose.

In collections of sixteen sorts, Mr. Melville, gardener to the Earl of Roseberry, Dalmeny Park, had one neatly set up on moss, a star of Grapes forming the centre. It consisted of Canon Hall, Chayovush, Black Hamburg, and Lady Downe's Grapes; Improved Beechwood Melon, Figs, Royal George Peaches, Moorpark Apricots, two kinds of Plums, Williams' Bon Chrétien and Jargonelle Pears, Devonshire Quarrenden Apples, Gooseberries, White Currants, and Morello Cherries. Good collections in the same class came from Mr. Matheson, Thilliallan Castle; Mr. Cook, Holywell Hall, Newcastle; Mr. Lees, gardener to the Earl of Haddington, Tynninghame; and Mr. Temple, Balbrinie. That from Mr. Lees contained Oranges and Guavas.

Awards.—For the best collection of sixteen, exclusive of Pines: first, Mr. Melville, Dalmeny Park; second, Mr. D. Matheson; third, Mr. Cook.

In addition to the above, a prize was offered for the best six varieties of home-grown fruit, consisting of two Pines, two Melons (one Green-fleshed and one Scarlet-fleshed), four bunches of Grapes, twelve Peaches, twelve Nectarines, and twelve any other fruit. This was taken by Mr. D. Thomson, with very fine Smooth Cayenne Pines, Scarlet Gem, and a hybrid Melon, a splendid bunch of the Tynninghame Muscat of Alexandria, Black Hamburg, like jet, a splendid bunch of Calabrian Raisin, Lady Downe's, very fine; five Peaches, Nectarines, and Moorpark Apricots.

Fruiters were likewise invited to compete, and in their case foreign fruit was admitted. The result was two very extensive and meritorious collections from Messrs. Carstairs, of 121, George Street, and Mr. Brown, of Hanover Street, to whom equal first prizes were awarded. From the former came six Pines, twelve kinds of Grapes, fifty of Apples, forty of Pears, and numerous Plums, Peaches, Figs, also Currants of kinds, Raspberries, Blackberries, Oranges, Bananas, and various other fruits. Mr. Brown's collection comprised many fine examples of Apples, both of home and foreign growth, and a portion of them were arranged so as to show the growth attained in different parts of Scotland. There were besides several fine bunches of Grapes, Melons, Plums of various kinds, Peaches, Nectarines, Apricots, Figs, Pears from the continent, Nuts in variety, &c. A Mammoth Gourd, weighing 112 lbs., was also shown by Mr. Brown.

PINES were not numerous. Two handsome Queens came from Mr. Peacock, gardener to R. Scott, Esq., Castle, Dykes Damfries; two excellent Smooth Cayennes from Mr. Thomson, Archerfield; fine Montserrat from Mr. Fowler, gardener to the Earl of Harewood, Harewood House; Cockscorn-crowned Providence from Mr. Gavin, Donibristle. Good fruit of a kind called Bennet Seedling, grown in a 10-inch pot, came from Mr. Henderson, gardener to Lord Manners, Thoresby Park. This received an extra prize. Mr. D. Thomson exhibited in addition, three plants of Smooth Cayenne with very large fruit, which, though not ripe, had an imposing effect. These were awarded, and well deserved, an extra prize.

Awards.—Two best Queens: first, Mr. Peacock; second, Mr. J. Oswald, gardener, Murthly Castle. Two Smooth Cayennes: Mr. D. Thomson, Archerfield. Two of any other sort: first, Mr. Fowler, Harewood House, Yorkshire; second, Mr. John Gavin; third, Mr. John Oswald. Extra prizes, Mr. D. Thomson and Mr. Henderson.

GRAPES constituted the grand feature of the Show, and such an assemblage of magnificent bunches had certainly never before been seen. The whole, almost without an exception, were good, but those exhibited by Mr. Fowler, of Castle Kennedy, Mr. D. Thomson, and Mr. Meredith, were most extraordinary productions as regards size and perfection of ripening. These alone were worth a journey of four hundred miles to see. In eight varieties Mr. Fowler, gardener to the Earl of Stair, Castle Kennedy, was first with splendid bunches of Muscat of Alexandria; Trebbiano, weighing 12 lbs. 9½ ozs.; White Nice, 9 lbs. 6½ ozs.; Black Barbarossa, very fine as regards size; Black Prince, Lady Downe's, with very large berries; Muscat Hamburg and Black Gibraltar, very good. Altogether, this was a most extraordinary collection, such as is rarely witnessed anywhere, and fine though the others were, this stood unquestionably in the first place. Next came Mr. Meredith, of Garston, Liverpool, with an admirably

finished collection, consisting of jet-black Hamburgs; Muscat of Alexandria; Chaptal, 1 foot long and 9 inches across the shoulders; Black Prince, Muscat Hamburg, fine; Black Alicante, with a beautiful dense bloom; Child of Hale, a very large-bunched kind; and Black Barbarossa, very regular and finely coloured. Messrs. Lane and Son, Great Berkhamstead, contributed a good collection, for which a third prize was awarded, and Mr. Rose, Floors Castle, was fourth. In the class for the best four sorts Mr. W. Thomson was first with excellent Black Hamburgs, Lady Downe's, Muscat of Alexandria, and White Tokay; Mr. Cube, Glencarse, Perth, was second; Mr. Millar, Cully Gardens, third; and Mr. R. Greenfield, Painsburn Gardens, Coldstream, fourth. For Black Hamburg, two bunches, Mr. Meredith occupied his accustomed place of first with two beautiful bunches, weighing together 9 lbs. 10 ozs., the berries large, regular, and beautifully coloured; Mr. Richards, Grimston Park, Tadcaster, was second; and Mr. Fowler, third; and several large bunches, but not up to the mark as regards colour, came from some others. For Muscat of Alexandria, two bunches, Mr. Fowler was first with splendid bunches beautifully ripened; and the same may be said of those sent by Mr. Thomson, Archerfield, who was second. Mr. Anderson, of Torwoodlee, Galashiels, was third, with fine bunches, but not so well ripened. Of Red or Grizzly Frontignan, good bunches came from Mr. Meredith, and Mr. Cowie, Calder House, Mid Calder; those from the former being by far the better. Muscat Hamburg, from Mr. Fowler, though a little rubbed, was fine; and good bunches from Messrs. Lane and Mr. Johnston, Torregles, were second and third. Of White Tokay, the best ripened came from Mr. Matheson, Tulliallan Castle; and a compact bunch, but too green, from Mr. Phipps, Ingestrie Hall, was second. In Black Hamburg, single bunches, Mr. Meredith was first with a large and handsome bunch, beautifully coloured; Mr. Richards was second; and good bunches came from other competitors. In the corresponding class for Muscats, Mr. Fowler and Mr. D. Thomson held the same relative positions which they had gained in the class for two bunches, the exhibitions in both cases being very fine and well finished. An extra prize was awarded to Mr. A. Anderson, Torwoodlee, for a large bunch, but not evenly ripened. The whole of this class was good. For Black Alicante, a very large and fine bunch, weighing 4½ lbs., from Mr. Greenshields, gardener to the Marquis of Ailsa, was first; and a beautiful and very regular bunch from Mr. Melville, Glenlee Gardens, New Galloway, was second; an extra prize was given to Mr. Meiklejohn, Dalkeith, for a fine bunch, and an excellent one also came from Mr. Meredith. The class for the heaviest bunch of Black Grapes was quite a remarkable one. Mr. Greenshields was first with Black Barbarossa, weighing 10 lbs. 15 ozs., and measuring nearly 20 inches across and little less in length. Then came Mr. Fowler with a magnificent bunch of the same variety; and Mr. Meredith had a beautiful bunch of Black Hamburg, weighing 4 lbs. 12 ozs., and which everybody regretted should have been pitted against the larger and coarser Barbarossa. The heaviest White Grape was White Nice, of which an enormous bunch, little less than 2 feet long, and weighing 11 lbs., was shown by Mr. Fowler. This variety, however, is stated to have been grown to the weight of 18 lbs. Child of Hale, another gigantic kind, from Mr. Meredith, weighing 8 lbs. 10 ozs., was second. For the finest flavoured White Grape there were fourteen competitors, and equal first prizes were awarded to Mr. Thomson, Dalkeith, and Mr. A. Anderson, Torwoodlee, the former having Duchess of Buccleuch, a richly-flavoured Grape of his own raising, and the latter Muscat of Alexandria. The best flavoured Black grape was Muscat Hamburg, of which Mr. Fowler exhibited a fine bunch, and Mr. Tillery was second with Black Frontignan. For the Black Grape with the finest bloom, the first prize was awarded to Mr. Meiklejohn, Dalkeith, for Black Alicante, the second going to Mr. Wilshe, Cavers Cave, for Black Hamburg.

For collections of Black Hamburg varieties, Mr. Meredith was first with a collection in which the following names occurred—namely, old Black Hamburg, Dutch, Wilmo's, Victoria, Pope's, Mill Hill, Champion, and Richmond Villa. Messrs. Lane were awarded the second prize for a collection in which the names were—Frankenthal, Pope's, Dutch, Mill Hill, and Esperione. Mr. Turner, gardener to Mark Spott, Esq., Riddell, Selkirk, was third. In a corresponding class for Muscats, Mr. Meredith had a first prize for Muscat of Alexandria, Escholac, Troveron, Early Summer Frontignan, Charlesworth Tokay, Canon Hall, Bowood, and Ciotat. For the best bunch of any kind not named in the schedule, equal first prizes were taken by Mr. Fowler and Messrs. Lane, the former having a splendid compact bunch of Lady Downe's, with berries almost as large as those of a well-grown Mill Hill Hamburg, and the latter good Buckland Sweet-water. Black Prince, from Mr. Greenshields, was second. Good bunches of Golden Hamburg and Barbarossa were also shown, as well as Royal Vineyard, by Mr. Williams, of Holloway. A seedling White Grape, named Syrian Muscat, stated to be a cross between the Syrian and Canon Hall, and to be a more certain setter, came from Mr. Melville, Dalmeny Park; also, Champion Frontignan, a seedling between Champion Hamburg and Grizzly Frontignan. This had large reddish berries. Mr. W. Thomson contributed Golden Champion Hamburg. None of the above, however, were adjudicated upon.

MELONS.—About two dozen were shown. The best Green-fleshed was a well-netted fruit of Veitch's Perfection, from Mr. T. Weir; second, Golden Perfection, from Mr. Ross. In Scarlet-fleshed, Gem, from Mr. T. Shannon, Slateford, was first.

Awards.—Greenfleshed: first, Mr. T. Weir, Kerse House; second, Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbry, Berks; third, Mr. J. Johnston, Terregles. Scarlet-fleshed: first, Mr. T. Sharman, Redhall, Slateford; second, Mr. Johnston, Bulgreen; third, Mr. Cooke, Holey Hall.

PEACHES and NECTARINES.—Of the former, Mr. Peacock had excellent examples of Walburton Admirable and Barrington; and Mr. Henderson, of Royal George; Bellegarde, Noblesse, and Violette Hative, were also well represented. Nectarines were not numerous, nor were they remarkable for quality. Elruge and Violette Hative were the best.

Awards.—Twelve Peaches, two sorts: first, Mr. James Peacock, Castledyke; second, Mr. Wemyss, Springwood Park; third, Mr. D. Thomson. For six: first, Mr. Henderson, gardener, Castle Wemyss, Greenock; second, Mr. Cooke, Holey Hall; third, Mr. Jas. Johnston, Terregles. Nectarines, two sorts: first, Mr. John Oswald, Murthly Castle; second, Mr. James Peacock. For six: first, Mr. T. Millar, Cally House; second, Mr. Temple, Balbirnie Gardens, Markinch; third, Mr. J. Gordon, Niddrie House.

APRICOTS chiefly consisted of the Moorpark, of which some good samples were shown.

Awards.—Two sorts: first, Mr. Walter Ellen, Ratho House; second, Mr. Cooke, Holey Hall; third, Mr. David Gloag, Dryland House.

PLUMS consisted of good examples of Green Gage, Jefferson, Imperatrice, Kirke's, Washington, Magnum Bonum, Victoria, and Pond's Seedling.

Awards.—Four sorts: first, Mr. William Melville, Dalmeny Park; second, Mr. T. Millar, Cally House, Gatehouse; third, Mr. R. Ramsay, Mount Stuart, Rothesay.

VINES IN POTS.—A beautiful example of Black Alicante, from Messrs. Lane, loaded with fine bunches, was first in the Black class; Mr. Dickson, Whitehill, being second with Barbarossa. In the White class Messrs Lane were first with Golden Hamburg, and Mr. Gordon, Niddrie House, second.

PEARS comprised some good dishes of Jargonelle from Mr. Combe, Mr. Harrison, and others; and of other kinds the best collection of twelve came from Mr. Scrymgeour, gardener to R. Palmer, Esq., Holme Park, Reading. These, unlike most of the other Pears, were finely coloured, and consisted of Flemish Beauty, Williams' Bon Chrétien, Louise Bonne of Jersey, Duchesse d'Angoulême, Beurré Diel, Marie Louise, Beurré de Rance, King Edward's, Van Mons Léon le Clerc, Beurré Bose, Gansel's Bergamot, and Vicar of Winkfield. The second-prize lot included several of the above, Beurré d'Amanlis, Grosse Calebasse, Knight's Monarch, Brown Beurré, and Winter Crassane. Josephine de Malines, Beurré Sterckmans, and Hacon's Incomparable were among those from Mr. Cramb.

Awards.—Six Jargonelle: first, Mr. J. Combe, gardener, Glencarse, Perth; second, Mr. J. Harrison, nurseryman, Darlington; third, Mr. W. Reid, New Hailes. For six, two sorts, three of each (exclusive of Jargonelle): first, Mr. Scrymgeour; second, Mr. J. Purves, Hermitage Hill, Leith. For twelve, three of each, ripe or unripe: first, Mr. Scrymgeour; second, Mr. J. Stewart, Nuneham Park, Oxford; third, Mr. Cramb, the Gardens, Tortworth Court, Gloucestershire.

APPLES.—In Dessert kinds the chief prizes were taken by Mr. Bradfield, Balingey, Norfolk. His collection of twelve included Blenheim Orange, Ribston Pippin, Golden Nonpareil, Margil, Russet Nonpareil, Golden Russet, Court of Wick, Fearn's Pippin, and Golden Lustre. Mr. Cramb contributed fine specimens of Ribston Pippin, Cox's Orange, Golden Russet, together with Braddick's Nonpareil, Sturmer Pippin, Pearson's Plate, Gooseberry Apple, Cocker Pippin, &c.

In the class for Kitchen Apples, twelve sorts, the best collections were all of English growth. Mr. Cramb, who was first, had good examples of Afriston, Alexander, Dumelow's Seedling, Gloria Mandi, Hanwell Souring, Mère de Menage, Waltham Abbey Seedling, Brabant Bellefleur, Hambleton Deux Ans, and Tower of Glammis. From Mr. Scrymgeour came, among others, Alexander, highly coloured; Blenheim Orange, Kentish Fillbasket, and Murer's Dumpling. In other collections were good fruit of Manks Collin, Northern Greening, Norfolk Beefing, Catshead, Striped Beefing, Rymer, Bess Pool, and some excellent examples of New Hawthornden.

Awards.—Dessert, twelve sorts, three of each, ripe or unripe: first, Mr. Bradfield, Balingey, Norfolk; second, Mr. Cramb, Tortworth Court; third, Mr. Wemyss, Springwood Park. For six, fit for table: first, Mr. Bradfield; second, Mr. Scrymgeour; third, Mr. D. Bain, St. Neot's. Kitchen, twelve sorts, three of each, ripe or unripe: first, Mr. Cramb, Tortworth Court; second, Mr. Scrymgeour, Holme Park; third, Mr. J. Mitchell, Eserick Park, Yorkshire; Extra, Mr. Bradfield, Balingey, Lynn; and Mr. Phillips, Ingestrie Hall.

MISCELLANEOUS.—Some good Warrington Gooseberries and excellent Red Currants were shown; as well as home-grown Oranges by Mr. Wilson, gardener to Mrs. Erskine, Colross. The only collection of foreign fruit came from Mr. Knight, gardener, Château de Portchartrain (Seine et Oise), France, in which were Api Gros, Api Rose, Api Noir and Reimette du Canada Apples; Beurré Diel, Duchesse d'Angoulême, Beurré de Rance, Louise Bonne, Catillae, and some other Pears; Black Hamburg, Tynninghame Muscat of Alexandria, and Chasselas Rose Grapes; also Black Monnikka, a kind which is for the most part seedless. These, however, were unfortunately not in good condition, in consequence of their long journey.

Awards.—Gooseberries: first, Mr. J. Geddes, Bellwood, Perthshire; second, Mr. George Smith, Clermont, Corstorphine; third, Mr. Craw, Jedburgh. Red Currants: first, Mr. James McDonald, gardener, Darn Hall, Pechlesshire; second, Mr. Geddes, Bellwood; third, Mr. R. Ramsey, Mount Stuart, Rothesay. Extra prizes:—for Device of Fruits: Mr. John Fraser, Belmont. For a seedling Pine: Mr. A. Henderson, Thorsby Park. For collection of Pears: Mr. J. Stewart. For an Antigua Queen Pine: Mr. Foulis, Fordel. For Canon Hall, Muscat, and Black Hamburg Grapes: Mr. J. Oswald, Murthly Castle. For Royal Vineyard Grapes: Mr. B. S. Williams, Holloway. For Oranges: Mrs. S. Erskine.

#### VEGETABLES.
