Bean Harvest of spring-sown crops is seldom over in the North before the middle of the month; and when the crop is followed by Wheat, as is generally the case, it is generally cut with the sickle, and stook them on pasture, or Wheat, or Oat stubble adjoining, in order to get the land ploughed and the Wheat sown. The value of steam is incalculable in such cases, as the land can be ploughed and sown with Wheat as fast as the Bean crop is removed. If the land has been saturated with rain to the maximum, it is sometimes difficult to get a proper seed-bed, while the horses' feet do immense harm in drilling and harrowing. To avoid this latter, the seed is sown broadcast by hand, and the

horses walk in the out-casting furrows, hauling the harrows between them, by means of a long pole or draught-bar the breadth of the ridge, the work of sowing keeping close up to the ploughing.

The Autumn Top-dressing of meadows finish, to get the dressing well washed in with the rains of this and the ensuing month, and a greeen sward before the frost sets in. Rich composts are made by saturating peat-earth, scourings of ditches, vegetable mould of any kind, with the liquid from the homestead, or town sewage ; or the earth hills may be mixed with farmyard manure, with lime, if the land requires it, with the refuse of fisheries or gasworks : or a rich compost may be made by mixing 12 or 15 bush. of ashes with 5 or 6 cwt. of artificial manure. Such composts, if properly made, may be applied by a manure distributor, and well harrowed in by a chain-harrow.

Live Stock.—Newly housed live stock require special attention during the change from summer to winter food, as many of the maladies experienced by lambs, calves, and older stock at this season are chiefly due to an oversight of their natural requirements. The familiar old rules, "Only fatten animals that are ripe for the shambles," and "Get rid of an ill-doer at any price," are still in force, as they were prior to the modern theory of early maturity. Much of the complaint that fatting stock do not pay for their keep, arises from the want of due attention being paid to the drafting out of animals that have not attained the ripe age for fatting, for, when the whole herd of the same age is fed up promiscuously, the ripe ones pay but the green ones do not. Stable economy is very diversified. The old rule to keep the bowels right is not more than sufficiently well understood, for a laxative diet to a hard-working horse at this season too often makes "a soft horse softer :" more than a lax diet is needed.

Notices to Correspondents.

BREEDING OF HORSES : *H. T. E.* We do not know of any work which treats specially on the breeding of horses, but all veterinary works have a chapter on the subject. Many papers on breeding are also scattered through the pages of agricultural journals. A pamphlet by Finlay Dun, recently published by Martin Billings, Sons & Co., Livery Street, Birmingham, contains a good deal of valuable information on the breeding of stock.

NOTICE : *A Very Old Subscriber.* Owing to not having your address it has been impossible to write to you at once. We are not learned in the law, but we incline to think that under the circumstances a quarter's notice may be claimed.

SMALL STEAM-ENGINES FOR CHAFFING : *G. D., Hillchurch, Hythe,* writes :—" In your 'Notice to Correspondents' of the 23d inst. 'H. P.' inquires about 2-horse steam-engines. If he writes to me at the above address I can inform him how mine answers (Tuxford), which I purchased 10 years ago."

Markets.

HOPS.

BOROUGH MARKET, Oct. 5.

Messrs. Pattenden & Smith report a steady retail demand for all good healthy samples, prices remaining very firm.

MARK LANE.

MONDAY, Oct. 2.

The supply of English Wheat to this morning's market was very moderate, and was sold at an advance of 1s. to 2s. per qr. There was a good attendance, and a fair demand for Flour, at 2s. per qr. above the prices of this day se'nnight. English malting Barley was 1s. per qr. dearer ; other descriptions unchanged in value. There was no alteration in the value of Beans. Peas brought an improvement of 1s. per qr. For Oats there was a good demand, at an advance of 6d. per qr. In the top price of town-made Flour there was no change, but other sorts were 1s. per sack and barrel dearer.

WEDNESDAY, Oct. 4.

There was a thin attendance of millers here to-day, and the business doing was of a limited character ; prices, however, were well maintained. The supply of English Wheat was moderate, and from abroad the arrivals were good. Trade was slow, but Monday's advanced rates were sustained. Barley was purchased steadily at firm prices. Malt was dull, but not lower. There was a liberal supply of Oats, which sold to a fair extent, at the late improvement. Beans and Peas were in moderate request, at previous quotations. Flour was firm, but not active.

LIVERPOOL, Oct. 3.—To-day's market presented a more subdued appearance after the recent activity, but there was a fair attendance, and sellers were firm, though it was less easy to make progress with sales. Wheat showed an advance of 2d. to 3d. per cental. Flour was 6d. dearer. Indian Corn was again higher, to the extent of 1s. per qr.

METROPOLITAN CATTLE MARKET.

MONDAY, Oct. 2.

The number of Beasts is smaller than on last Monday, yet it is considerable, and the dead markets are well supplied ; consequently, on the average prices are not better. The supply of Sheep is small, especially of English ; trade is, however, slow, and it is difficult to effect a clearance at our quotations. Calves are rather more plentiful, but choicest qualities are not lower. Our foreign supply consists of 3420 Beasts, 11,800 Sheep, and 250 Calves ; from Ireland there are 150 Beasts ; and 1550 from the Midland and Home Counties.

Beasts, 5120 ; Sheep and Lambs, 20,550 ; Calves, 262 ; Pigs, 170.

THURSDAY, Oct. 5.

The number of Beasts is rather larger than last week, and trade is dull ; the average quality is by no means first-rate, choicest descriptions consequently find purchasers at very nearly Monday's quotations. The supply of English Sheep is very short, yet it exceeds the demand ; the number of foreign is also smaller ; a clearance cannot be effected. Choice Calves are in demand. Our foreign supply consists of 450 Beasts, 6500 Sheep, 291 Calves, and 25 Pigs.

METROPOLITAN MEAT MARKET, Oct. 5.

Best Fresh Butter	17s. per dozen lb.
Second do. do.	15s.
Small Pork, 4s. 8d. to 5s. 4d. ; Large Pork, 3s. 6d. to 4s. 0d. per 8 lb.	

ENGLISH WOOL.

The market keeps very firm, but the difficulty found by manufacturers in obtaining an adequate price for manufactured goods causes them to buy very cautiously. Later on, when forward contracts made at low prices have been mostly delivered, buyers will be forced to take goods at a commensurate price to the advance in wools, and we then expect a more active trade, and a further slight upward movement.

HUNT'S superb FANCY WILLM, in 24 varieties, seed or plants, as per former Advertisement.
A. F.'s general Collection, which is the largest in England, will be
The Original Nursery, Reading.

Golden Bronze Pelargoniums.

DOWNIE, LAIRD, and LAING can offer Seed saved from their unrivalled Collection of PRIZE GOLDEN BRONZE PELARGONIUMS, newly harvested, in packets, at 2s., 5s. 6d., and 5s. each. Forwarded free by post. Stamps may be sent in payment. Trade price on application.
Nurseries: Forest Hill, London, and Edinburgh.

Autumn Catalogue.

GEORGE POULTON'S AUTUMN CATALOGUE of PLANTS and CUTTINGS of NEW PELARGONIUMS, FUCHSIAS, VERBENAS, &c., is now ready, and may be had post free upon application.
GEORGE POULTON, Fountain Nursery, Angel Road, Edmonton, Middlesex, N.

Transit Agency for Plants, Seeds, &c.

C. J. BLACKLIN, Cox's and Hammond's Quays, Lower Thames Street, London, S.E.
Forwarders to all parts of the World.

PARIS, SUTTONS' GRASS SEEDS for ALL SOILS. The PREMIER PRIX SILVER MEDAL for GARDEN GRASS, CLOVER, and FIELD SEEDS, was Awarded to
SUTTON AND SONS, Seedsmen, by Special Appointment, to H.M. the Queen, and H.R.H. the Prince of Wales, Reading, Berks.

RAYNBIRD, CALDECOTT, BAWTREE, and BLACKLIN, Seed Merchants (Limited),
CORN, SEED, MANURE, and OILCAKE MERCHANTS.
Address, 21, Seed Market, Mark Lane, E.C.; or Hasingstoke.
Samples and prices of wheat on application. Price Medals, 1851, for Wheat; 1862, for "Excellent Seed Corn and Seeds."

EVERY GARDEN REQUISITE KEPT in STOCK at
CARTER'S New Seed Warehouse, 237 & 238, High Holborn, London.

Thorns and Quick Seeds—1871 Crop.

JOHN SHARPE will on application furnish his LIST, with prices, of the principal SEEDS he is growing this year.
Seed Warehouse, Lincoln.

RICHARD WALKER has to offer the following, for cash:—EAST HAM, ENFIELD MARKET, and DRUMHEAD CABBAGE SEEDS, true to name, 1s. per 100; RED DUTCH PLANTS, 4s. per 1000; WHITE DAISIES, for planting out, 5s. per 100; CARROTS, for planting out, 5s. per 100.
Market Gardens, Biggleswade, Beds.

GENUINE DRUMHEADS, DRUMHEAD SAVOYS, IMPERIAL OXHEARTS, EARLY CABBAGE and BROCCOLI (sorts), well-rooted, from light soil; carefully packed in good crates, and delivered to the Railway Station, at 3s. per 1000.
S. WELLAND, Nursery Gardens, near Godalming, Surrey.

Autumn-sown Cabbage Plants.

W. VIRGO and SON can now supply good strong plants of the undermentioned sorts:—EARLY BATTERSEA, EARLY YORK, ENFIELD MARKET, NONPAREIL, LITTLE PIXIE, and ROBINSON'S CHAMPION DRUMHEAD, at 3s. per 1000; do. RED PICKLING, 5s. per 1000.
The Nurseries, Wonersh, Guildford, Surrey.

CABBAGE PLANTS, Autumn Sown.—Good strong early Battersea, Enfield, and London Market, at 3s. per 1000. Robinson's Champion Ox Cabbage, 2s. 6d. per 1000; also Late Flat Red Pickling Cabbage, at 5s. per 1000; Coleworts, 3s. per 1000. Remittances to accompany all orders.
J. WOODBURY, Nurseryman, Billingshurst, Sussex.

Notice to Correspondents.

RENDLE'S PATENT ORCHARD HOUSES,

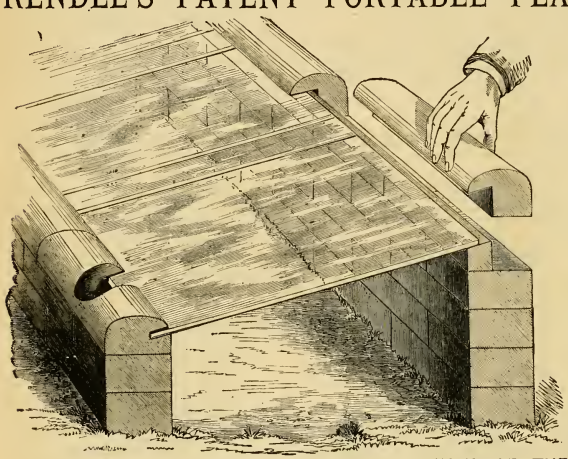
PORTABLE PLANT PROTECTORS, AND GROUND VINERIES.

Secured by Her Majesty's Royal Letters Patent (two separate and distinct Patents, 1869 & 1870).

Under the Distinguished Patronage of—

H.R.H. the PRINCE OF WALES.
HIS ROYAL HIGHNESS PRINCE CHRISTIAN.
HIS HIGHNESS the MAHARAJAH PRINCE DULEEP SINGH.
HIS GRACE THE DUKE OF RUTLAND.
HIS GRACE THE DUKE OF DEVONSHIRE.
HIS GRACE THE DUKE OF SUTHERLAND.
THE MOST NOBLE THE MARCHIONESS OF ANGLESEY.
THE RIGHT HON. THE EARL OF STAMFORD AND WARRINGTON.
THE RIGHT HONOURABLE THE EARL OF PORTSMOUTH.
THE RIGHT HONOURABLE THE EARL OF DARTMOUTH.
THE RIGHT HONOURABLE THE LORD PORTMAN.
THE DOWAGER COUNTESS OF AYLESFORD.
THE RIGHT HONOURABLE LORD ALFRED CHURCHILL.
THE RIGHT HONOURABLE LORD BERKELEY PAGET.
THE RIGHT HONOURABLE LORD BOLTON.
THE RIGHT HONOURABLE LORD DE L'ISLE AND DUDLEY, &c.

RENDLE'S PATENT PORTABLE PLANT PROTECTORS.



This Engraving represents the New Pattern. It will be seen that the top or grooved Brick is formed in two distinct pieces. The Glass rests on the front piece, and the other part can be instantly removed, so that the whole of the glass can be set free from one end of the Protector to the other in a few minutes.

The under Brick is also made with an opening, so that, with the finger, the glass can be removed or shifted at pleasure.

NEW TARIFF AND CARRIAGE-FREE TERMS.

The following Prices are for the Patent Grooved Bricks and the Glass:—

GROUND VINERIES AND PLANT PROTECTORS.		For Delivery in London or Bridgewater.	Carriage Paid to any Railway Station within 100 miles of London or Bridgewater.	Carriage Paid to any Railway Station in England and Wales, or Edinburgh, Dublin, Cork, or Belfast.
Ft. long.	Wide.	£ s. d.	£ s. d.	£ s. d.
10	Glass 9 in.	0 12 0	0 14 6	0 17 0
10	Glass 12 in.	0 14 0	0 17 0	1 0 0
10	Glass 18 in.	0 16 0	1 0 0	1 3 0

100	Glass 9 in.	5 0 0	5 10 0	6 10 0
100	Glass 12 in.	6 0 0	6 10 0	7 10 0
100	Glass 18 in.	7 0 0	7 10 0	8 10 0
100	Glass 24 in.	8 10 0	9 0 0	10 0 0

A reduction of 20s. per 100 feet will be made if 500 feet be taken at one time.

The Patent Grooved Bricks can be placed on ordinary Kiln Bricks set on the Flat. Full Directions for fixing them will be sent with each Invoice.

TESTIMONIALS AND OPINIONS OF THE PRESS.

"*Frogmore House, Windsor, April* 18, 1871.

"Lieut.-Col. Goacher is desired by his Royal Highness Prince Christian to write to Mr Rendle, and tell him that his Royal Highness's Gardener has reported in such high terms of his Plant Protectors he saw to-day, Prince Christian would like one fixed up in his garden."

Copy of Letter from Mr. W. Ingram, *Gardener to* His Grace the Duke of Rutland, *Belvoir Castle Gardens, Grantham, Leicestershire.*

"Belvoir Castle Gardens, near Grantham, Jan. 26, 1870.

"Dear Sir,—I have employed your Plant Protectors for growing Lettuces during the winter, and no plan that I have tried has answered so well.

"The tiles are placed to allow glass 29 inches by 14 inches to slide in the grooves. This gives a space for three rows of Lettuces, and forms a convenient little pit. The protection given is greater than I expected, for although we have had 15 degrees of frost, the growth of the plant does not appear to have been checked.

"The successful application of your plan for securing a supply of Cos Lettuce struck the gentleman (W. R. Ferrand, Esq.) who wrote to you, and led to the order you refer to.—I am, yours truly,

"Mr. W. E. Rendle. "W. Ingram."

Important Testimonial from Mr. Edward Bennett, *Gardener to the* Right Hon. the Earl of Stamford and Warrington, *Enville, near Stourbridge.*

"Enville, August 23, 1871.

"Sir,—The more I see and have to do with your various descriptions of Plant Protectors, Cases, &c., the more I am convinced of their utility: and I would strongly recommend those who have not given them a trial to do so *at once*.

"I remain, Sir, your obedient Servant,

"Mr. W. E. Rendle. "Edward Bennett."

[Mr. Bennett has now in work more than 1000 feet at Enville, and his opinion of their value is of the highest importance.]

From William Grace, Esq., *Witterham, near Ashford.*

"*Sept.* 4, 1871.—Your new patterns are certainly a great improvement on the old. I have some splendid bunches of Grapes in your Ground Vinery, colouring splendidly."

From the Rev. M. Davies, *of Southampton.*

"*June* 9, 1871.—My Strawberries were ripe 14 days before those in the greenhouses."

Extract of a Letter from Mr. D. T. Fish, *Hardwicke, near Bury St. Edmund's.*

"Hardwicke House, Bury St. Edmund's, August 30, 1870.

"I have found the Protector best suited for Early Peas, Potatos, French Beans, Strawberries, Grapes or Ground Vineries, and Winter and Spring Sticking of all sorts. For this purpose they are of the highest cultural value, and can disappoint no one."

And in a *Letter from* Mr. Fish, *dated Sept.* 27, 1871, he says:—

"I have your Protectors in full swing for Lettuce, &c., and find them most useful."

From the Gardeners' Chronicle and Agricultural Gazette (*June*, 1871). *Edited by* Dr. Masters *and* Thomas Moore, Esq.

(*From the Report of the Great Horticultural Exhibition at Nottingham.*)

"The improvements shown by Mr. Rendle in his Plant Protectors bring some of them almost within the category of houses. The old forms are still retained, while new facilities for the removal of the glass are afforded by a movable coping, that is simply laid on the upper edge of the glass. Nothing could be more simple. The Protectors are also shown in more pretentious size and form; Glass Walls and Miniature Houses, in which zinc is used for grooves and wood for sides, instead of bricks and tiles. The Peach Case and Amateur's Plant Case have folding backs of wood, which are let down to tend the Trees or Plants, while the top is also movable. The cordon frame has a hole at the end to admit the Tree, and there can be little doubt of their worth, with the efficient shelter these cordon cases provide. We bear a good character of these Protectors on all hands, and no one can doubt their special adaptation for the purposes intended. As lately remarked in these columns, the great want of modern gardening is more glass, and we hail every attempt to provide it cheaply and in useful forms."

Indian Corn Ripening in the Open Ground during the last Summer.

"*Sept.* 6, 1871.—Notwithstanding the coldness and severity of the last Spring (and be it remembered that the weather was exceedingly cold, even in the last days of June), I have succeeded in ripening Indian Corn or Maize. The seeds were obtained from the Rev. Mr. Brehaut, and sown on April 8, in the Protectors. They were nursed and protected all through April, May, and part of June; the glasses were then taken off, and the cobs of Corn were ripe, thoroughly ripe, by September 1. The plants were transplanted, and grew all through the cold weather without the least check. This will prove the simplicity and excellency of the system more than any other experiment.

"Wm. Edgcumbe Rendle."

From Shirley Hibberd, Esq.

"*Sept.* 5, 1871.—Please send me 80 feet of your Span-roof Protectors, 3 feet wide. I want them for protecting Cauliflowers, Lettuces, &c."

From Edward Barnwell, Esq., *Cresborough House, Haverfordwest.*

"*Sept.* 24, 1871.—I think you will be glad to hear that we have been enjoying some most excellent Black Hamburgh Grapes, grown by Mr. Cooke, with the greatest success, under one of your Patent Vineries."

From Mr. C. Edwards, *Gardener to* Colonel Coryton, *Pentilla Castle, Cornwall.*

"*August*, 1871.—Your Protectors have been most successful. We had more than 25 degrees of frost last winter, and I had two crops of Lettuces in succession. They are most valuable, and I intend working them thoroughly next winter."

From Mr. G. Munn, *Gardener to* Charles Meeking, Esq., *Riching's Park, Slough.*

"*June* 9, 1871.—The Protectors have exceeded my expectations. I covered an Asparagus bed (90 feet long) with the 4-feet Span-roof. The produce was larger and more tender than those grown in the open ground, and it grows much faster, and came several weeks earlier. In the Belvoir Castle patterns we grew Early Cauliflowers and Lettuces. They grew amazingly. The protection is much greater than I expected; in fact, they are invaluable for all kinds of early vegetables for early spring."

From the Rev. W. B. Caparn, *Draycot Vicarage, Weston-super-Mare.*

"The result of my experience in growing Grapes deserves to be known, and I have written to the Editors of the 'Journal of Horticulture' (see 'Journal of Horticulture,' October 6, 1870, as I thought it deserved to be known, and would help in the cultivation of Grapes on a small and inexpensive scale."

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Notice is hereby given, that an ADDITION to the LIST of PENSIONERS will take place in JANUARY NEXT. All Persons desirous of becoming CANDIDATES are required to send their Applications and Testimonials to the Committee on or before SATURDAY, November 11. Preference will be given to those Applicants who have been Subscribers for 15 years. By Order,
EDWARD R. CUTLER, Secretary.

14, Tavistock Row, W.C., October 4.

N.B.—Printed Forms of Application may be obtained of the Secretary.

Noteworthy Horticulturists and Botanists.

NOTICE.—A SERIES of PORTRAITS of NOTEWORTHY HORTICULTURISTS and BOTANISTS is being published in the "GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE." The following have already appeared, and copies may be had on application to the Publisher, viz:—

Dr. HOOKER, C.B., F.R.S.	Professor REICHENBACH, of Hamburgh
W. WILSON SAUNDERS, F.R.S.	Rev. S. REYNOLDS HOLE, M.A.
Rev. M. J. BERKELEY, F.L.S.	R. J. LOWE, F.R.S.
M. DECAISNE	JAMES MCNAB, of Edinburgh.
G. F. WILSON, F.R.S.	ROBERT HOGG, LL.D.
Dr. MOORE, of Glasnevin	

Published by WILLIAM RICHARDS, 41, Wellington Street, Covent Garden, W.C.

The Gardeners' Chronicle

SATURDAY, OCTOBER 14, 1871.

THE season of the year is opportune for inviting the attention of planters to a few HARDY DECIDUOUS TREES and SHRUBS, which are either not well known, or not sufficiently appreciated.

First in our note-book stands Dimorphanthus mandchuricus, a fine Araliaceous tree, which may be compared to the Aralia canescens (so commonly known in the gardens by the erroneous name of Aralia japonica), but is even hardier and handsomer. Its erect Palm-like habit and its noble foliage mark it out as a tree exactly suited to stand in some prominent position, where a dark background would throw out in bold relief its fine bipinnate leaves, which are fuller and better furnished than those of the Aralia just referred to, the leaflets being broadly ovate, and more closely set. In this plant the petiole is furnished with short spines, and the rachis with longer ones, which are needle-shaped. From the examples we have seen it appears to grow freely, and to pass through our winters entirely unscathed, as indeed its native habitat might suggest.

Of another style entirely, but a very beautiful tree, is YOUNG'S new Weeping Birch, a finely pendent variety of Betula alba, exceedingly graceful, the slender branches even in young trees falling downwards almost perpendicularly. There are few more attractive subjects amongst hardy trees than a freely grown Birch with pendent spray, and in this new weeping variety we have the pendulous character developed to the full. The tree, which is of course as hardy as its parent, the common Birch, was discovered in the neighbourhood of Milford, creeping on the ground, and when worked, produces long pendent branches, many of them not thicker than string, and several feet in length, so that they are amenable to the influences of the softest breeze, and altogether the appearance of the tree is most pleasing.

The Sophora japonica pendula, of which we gave a portrait at p. 1195, is another extremely graceful and effective tree, which ought to be met with in every pleasure ground, but is actually seen in but few. The compound leaves of this tree, which are of a full rich green, are also very handsome, and as pendulous as the spray itself. It is perfectly hardy.

In Rhus glabra laciniata we have a dwarfer subject, but one in which the foliage may challenge comparison, for beauty of form and composition, with that of any other deciduous plant in cultivation. It has large spreading leaves of a compound character, and which change to crimson in autumn. The remarkable subdivision of the leaf, together with its richly coloured red stalks, give it a peculiar charm, and few plants can, as low growers, compare with it for prominent isolated positions on the lawn. This, too, is perfectly hardy.

We go back to the pendulous group to introduce the Weeping Turkey Oak, Quercus Cerris pendula, which is a well-marked and distinctly pendent producing stoutish drooping branches, which are clothed with the elegantly cut leaves characteristic of this species. It is less graceful and elegant than the Birch and Sophora already noted, and perhaps also slower of growth than these and some others would be, but where Oaks flourish it would be certain to give ultimate satisfaction, on the score of effective contrast with other trees of ornamental aspect.

Next we single out a rare and little-known tree, quite the opposite of pendulous in its habit of

growth, and known as the Robinia (Pseud-Acacia) pyramidalis. Its close-growing erect branches render it as taper in figure as a Lombardy Poplar; moreover it is perfectly distinct from all other Acacias, and should be introduced, in suitable positions, into all collections of ornamental trees, the erect pyramidal character being thoroughly well developed.

In Robinia Bessoniana we have another remarkably fine tree, very little known, and but seldom planted, though it deserves a place wherever ornamental trees are prized. It is remarkable for its straight vigorous shoots, its large pinnate deep green leaves, and the almost total absence of spines upon its branches; in which latter respect, as well as in aspect, it differs essentially from the common Acacia. The spines, moreover, when occasionally produced, are very short and stout, instead of being long, awl-shaped, and abundant. It is in every way a commendable tree, from an ornamental point of view.

For colour we may include the novel Catalpa syringæfolia aurea, recently sent out from Tunbridge Wells. This is a truly golden leaved-tree, yellow throughout the season, with the hue of a golden-self Pelargonium, not the hue of decadence and death; so that if kept cut down annually it would make a good golden bed or group in any picturesque arrangement of plants in the flower-garden or pleasure ground. What it may do as it gains size we cannot say, as the plants are yet but young, but its colour is constant to the end of the season, so that a good-sized bush of it would most efficiently light up a recess on the lawn where the background was dark, dense, and gloomy. The plant is evidently as free growing as its type, and is said to be as hardy.

One more subject, and we close up for the present. It is the Pterostyrax hispidum of Japan, a Styracaceous plant, so called from its winged drupes. This stands out perfectly well at Tunbridge Wells, and forms a most distinct-looking shrub, of stout, somewhat erect, but well-furnished growth, bearing large ovate acute pale-green leaves, likely to be effective because of its distinctness in the furnishing of shrubbery borders.

On some early occasion we have a note or two to transcribe having reference to the varieties of the common Laurel.

GASWORKS and GARDENS are mutually antagonistic. Shut up a plant in a close room with gas fumes, and it will speedily be stripped of its leafy and floral embellishments, if it be not killed outright. Set up gasworks near a garden, and let them disgorge their clouds of carbon, and belch out their sulphurous fumes over the fair scene, and it either at once becomes a wilderness, or all healthy, prosperous vegetation is at an end. Under such conditions, the leaves of the unhappy plants become choked with a sooty deposit, and nipped by blighting chemical emanations. The culture of delicate flowers is rendered an impossibility, and half—ay, nine-tenths—of the pure fresh healthy enjoyment of a garden is cut off. This is felt as a crying evil, even by the man of position, who may be able by legal measures to procure relief from the tartarean nuisance; but the more humble gardener, who can only look for protection from the outcryings of public opinion, is in an infinitely worse position, inasmuch as the nuisance may not be sufficiently widely felt to procure relief by this means, until it has ruined either him or his garden

From the local papers we find that something of this sort has been going on at Lea Bridge—a spot which has become noted for allotment gardens, something like those of the Nottingham weavers—where many a man of comparatively humble position may be found spending his leisure hours in the profitable or refining occupations of cultivating his vegetable plot, tending his choice flowers, or dressing up his little greenhouse, anon resting himself and contemplating the results of his labours in the adjacent shady bower or summer-house.

One incensed inhabitant of the district writes in disgust of the "abominable amount of sulphurous vapour emitted from the Lea Bridge Gasworks," and finds that "volumes of dense black smoke roll from the gasworks over the gardens, the air becoming speedily charged with sulphur." Another person, who has been an occupier in these gardens for over 15 years, admitting the smoke and fumes to be bad enough, adds, "they poison our water too," by burying the refuse from the works, so that when pumped up it resembles the washings of a tar barrel. Another writes thus:—

"It appears that this new company have quite determined to do just as they please. They make us pay what they like, they sell what sort of gas they like, and they send forth their sulphurous fumes whenever they like. A large gas-house has been erected close to our high road and adjoining the railway. Every one can to his horror witness the filthy fumes rolling out at all hours of the day and night, spreading destruction in their course and dismay around. In a very short time vegetation will wither and dry up, and the inhabitants be compelled to find their homes elsewhere. Then will the authorities of Walthamstow and Leyton see their neglect of duty, in allowing such an abomination to exist upon one of the finest high roads in the country. There is much talk about preserving the forest. Are not those who travel to the forest to be protected? Is not our noble high road to be preserved? Are not our homes and our enjoyment of pure air to be preserved? Are the passers-by and the inhabitants to be subject to this frightful nuisance to please an alien company, who have not the least interest in the locality, other than to make the Lea Bridge gas speculation pay a big dividend?"

The tenants of the Lea Bridge gardens, as we learn on good authority, are men in business in London, who occupy them for the sake of the healthful recreation they afford, and also for the intense gratification they experience in growing their pet flowers to perfection. In doing this, large sums, comparatively, are freely expended, and nearly all the tenants have greenhouses, on which great care is bestowed. They have built themselves commodious summer-houses, or in some cases unique cottages, containing two or three rooms. Seven years since they established a horticultural society, which has, by dint of great perseverance, reached such a point of success that last year it ventured upon a two days' show, and notwithstanding that both days were brought to a continued downpour of rain, which very much diminished the funds, it this year again stood its ground, and was rewarded with great success.

We are told that "the gas-house, so much complained of, was built in the latter part of last year, and was used for a few weeks only in the depth of winter. When complaints began to be made its use was discontinued, until last July, when it was re-opened with a far greater nuisance. Every two hours the sulphurous fumes are sent forth in abundance, and if the company completes, as it threatens to do, the number of retorts to 54, it will be quite unbearable. When the wind blows eastward from any point between north and south, the smoke and fumes are driven over the gardens, and smother them with dirt; and the tenants further complain that the fumes produce nausea and headache. They fully believe, and positively state, that since the opening of the retort-house their flowers have dried up prematurely, and their Roses have turned dry and brown in the bud."

One of the tenants, who has just erected a new greenhouse, finds that "in a day the glass becomes covered with blacks and grit like the fine dust of ashes and coke." All complain most bitterly that now, after spending so much money for their health and comfort, and the means of growing their flowers, their expenditure should be thrown away to put money into the pockets of a gas company, by whom they are overrun—that they are no longer to have the enjoyment they have been used to after the toils and fatigues of the day, and are to suffer in addition a heavy pecuniary loss, for they look forward with fear upon the ultimate effect of these works upon all garden products.

The spirit of recent legislation has been to drive all such companies into a "no man's land," away from buildings and gardens. The Chartered Company was not allowed to go to Victoria Park, nor the Imperial to Old Ford; and, doubtless, if the matter were carried before the judges, they would not suffer that the Lea Bridge Company should, without, as we are told, any Parliamentary powers, come and place itself as a public nuisance close to a railway, close to one of the noblest high roads in the country, and also within 30 yards of these Lea Bridge gardens. If such, indeed, were to be the case, and the asserted right to go where it pleases were established, it would come to this, that in the midst of no one engaged, either in horticulture, floriculture, or market gardening, would be safe from such a vexatious injury. That, surely, cannot be the law of the land.

—— We have received from Mr. CHAMBERS of Beddington a very pretty novelty, in the shape of a greenhouse Fern, which may well bear the name of PTERIS SERRULATA FIMBRIATA. There are now several handsome tasseled varieties of this useful species, all more or less desirable decorative plants. The present appears to be of rather dwarf habit, and the pinnæ terminate in large multifidly-crested apices, the peculiarity of which is that they are split at the extremity into numerous very narrow but irregular divisions, which, from their tenuity and unequal length, give the crests the peculiar fringed appearance which has suggested the name. It will, no doubt, form a very pretty Fern for small cases, and for general decorative use.

—— Among the Pears in the magnificent collection shown at the great Fruit Show at South Kensington last week, by MM. BALTET, of Troyes, the following NEW PEARS are worthy of special notice. For the particulars given we are indebted to M. ERNEST BALTET:—

Beurré Baltet père.—A large fruit, of excellent quality; ripens in November. Raised and sent out by MM. Baltet.

Comte Lelieur.—A delicious fruit, ripening from September 1 to the beginning of October. Raised by MM. Baltet,

Beurré Ladé.—A fine fruit, in form like Bon Chrétien; flesh juicy, finely flavoured; ripens from October to December.

Auguste Mignard.—A large and fine Pear, ripening in November. The two last-mentioned Pears were raised by the eminent Belgian pomologist, M. Grégoire-Nelis, of Jodoigne.

Beurré Van Driessche.—Large and fine; fruit ripening in winter.

Calebasse Oberdieck.—A beautiful elongated Pear, with melting flesh of first-rate quality. It is named in compliment to the celebrated German pomologist.

Incomparable de Beauraing.—Raised by M. Grégoire. A large Pear, having the shape of Beurré Diel.

Souvenir de Leopold ter.—One of the most remarkable Pears raised by M. Grégoire. This was the largest Pear exhibited on this occasion, and is of good quality.

Sucrée de Montlucon.—A large and fine Pear, very productive. A good variety for market purposes.

Fondante Thirriot.—A fine Pear, of French origin, of excellent quality, and produced on a very free-bearing tree.

It remains to be seen how many of these novelties are suitable to our climate and our soils. It is impossible in most cases to lay down any general rule in this matter, as the same Pear which in one garden is of first-rate quality, may yield but indifferent fruit in another neighbouring garden, placed under slightly different conditions. Of older Pears which possess merit we specially noticed in MM. BALTET's collection fine examples of Beurré Clairgeau, Beurré Diel, Beurré Bachelier, Belle Angevine et de Livre (for culinary purposes), de Tongre, Duchesse d'Angoulême, Duchesse Panachée, Doyenné du Comice, Passe Crassane, an excellent winter Pear; Triomphe de Jodoigne, Van Marum, or Calebasse Monstre. Among the Pears were also some singular anomalies, in which apple-shaped fruits had been produced on the same branch with elongate fruit of the ordinary form; a sample of Beurré de Capiaumont was very noticeable in this respect. Among Apples MM. BALTET speak highly of a variety knownas Transparente de Croncels, a fine fruit, produced on a free-growing and very productive tree. This variety was raised by MM. BALTET. We may also notice the beautiful manner in which the fruit were selected and named, and the air of "finish" manifested by the French nurserymen—an appearance probably due to more intense solar light, or heat, or both. When next a fruit show of this magnitude is held, we trust means may be taken to classify the varieties more fully than was done on this occasion. It may sound like heresy to suggest that a long flat table covered with green baize, and laden with hundreds of white plates, is not the most ornamental arrangement that could be adopted, and is a trifle monotonous to the paying public. We believe, did time permit, that a much more effective arrangement could be produced with comparatively little trouble and expense, and one which would allow of the classification, comparison, and exhibition of the several kinds better than the present delightfully simple, but most unintelligent and inartistic system, if we can dignify it by such a name.

—— We have been requested to state, in reference to the EYLES TESTIMONIAL, that the subscription list will be closed very shortly, so that those who desire to join in this expression of esteem and regard, should communicate at once with Mr. JOHN MOORE, Mr. JOHN FRASER; or the secretary, Mr. THOMAS MOORE. We are informed that the amount now in hand is about £95, contributed by 96 subscribers.

—— The article on HYBRIDITY in WILLOWS, from the pen of the Rev. J. E. LEEFE, which appeared in the August number of the "Journal of Botany," and of which we reproduced a portion at p. 1032, has called forth some remarks from Mr. WOOLLS, of Glasnevin, who, in a letter to the author, which appears in this month's issue of the same publication, states that his experience coincides with that of Sir JAMES SMITH, as stated in the quotation from "The English Flora." Dr. MOORE, it appears, has also sent Mr. LEEFE some undoubted seedlings, of one and two years old, of S. phylicifolia = S. tricolor, and also one gathered near to a plant of S. triandra. Mr. LEEFE states that he has "not heard anything of seedlings from any other quarter, and has seen none in his own garden this year. It thus appears that Willows do undoubtedly

spring readily from seed in the Glasnevin Botanic Garden, where the climate appears favourable to their production; and a good opportunity is presented of ascertaining whether, as stated by Sir J. E. SMITH, the seedlings thus springing up are true to their kind." On the same subject, Professor THISELTON DYER writes:—

"I was surprised to come upon a passage in LINNÆUS's 'Amœnitates Academicæ' (vol. i. p. 100), which speaks of the seminal fertility of Willows and Poplars as a thing to be guarded against. 'Ambulacra ex Populo vel Salice frumenta sunto, solos mares assumat; ita enim feminæ terræ mandentur, multiplicantur, ita ut nemus loco ambulacri forment.' The advice, however, might merely be an assumption deduced from the trees being monœcious. It may, perhaps, be a piece of revelation on the other side that DE CANDOLLE ('Physiologie Végétale,' ii. 724) remarks, 'Nous possédons depuis peu les deux sexes du Saule pleureur (voyez SPENNER, Fl. Frib. iii. p. 1061), mais il n'ont pas encore produit de graines.' However, that Willows are hybridisable is proved by the existence of a book, by MAX WICHURA, entirely devoted to the experimental investigation of the subject ('Die Bastardbefruchtung . . . der Weiden,' 1865). Mr. DARWIN, quoting from it, remarks in the 'Origin of Species' (4th ed. p. 315), 'It is known that hybrids raised from very distinct species are sometimes weak and dwarfed, and perish in an early age, of which MAX WICHURA has recently given some striking cases with hybrid Willows.' And in his 'Animals and Plants under Domestication' (vol. ii. 269), he mentions that 'MAX WICHURA united six distinct species of Willows into a single hybrid' (by successive crosses)."

The Hon. J. L. WARREN, moreover, announces having seen, about a month ago, in one of the flower beds which occupy the site of the old reservoir near Grosvenor Gate, Hyde Park, a single seedling plant of Salix exærea, which was then about a foot high.

—— As a proof of the growing taste for FLOWERS and FLORAL DECORATIONS, we may mention that M. JULLIEN'S benefit concert to-night at Covent Garden Theatre is to be made a Floral Festival, and the whole theatre is to be transformed into a luxuriant and beautiful garden—so says the programme. The decorations have been intrusted to Mr. WILLS, of Brompton, who has also, we are informed, to supply 1000 ladies' bouquets, and 3000 gentlemen's button-hole bouquets for presentation to the visitors—one of the largest orders for bouquets, we suppose, that was ever given.

—— The MAXIMUM TEMPERATURES of the AIR during the week ending October 7 ranged from 64°.8 at Blackheath to 51° at Greenock, with a mean for all English stations of 59°.6, and for all Scottish of 53°.9. The MINIMUM TEMPERATURES ranged from 41°.5 at Blackheath to 31° at Perth, the mean for England being 49°, and for Scotland 43°.8. The MEAN TEMPERATURES ranged from 52°.3 at Portsmouth to 44°.2 at Edinburgh. The mean temperature for England was 49°.2, and for Scotland 45°.4. Rain was again recorded as having fallen at all stations, this week the mean rainfall for Scotland (1.32 inch) being slightly in excess of that for England (1.12 inch). The greatest falls in England occurred at Liverpool (2.21 inches), Eccles (2.04 inches), and Manchester (2.23 inches); and in Scotland, 2.09 inches at Aberdeen, and 2.15 inches at Greenock. (See Mr. GLAISHER'S Tables, p. 1330).

—— One of the finest subjects we have seen for the subtropical garden is the PAULOWNIA IMPERIALIS, cut down annually. If protected with mulching in winter the crown and roots remain safe, and in the spring, if the soil be good, it will throw up a shoot of such a robust character as would quite astonish those who have not seen it thus treated. To secure this giant growth a single shoot only should be permitted to grow. We saw it thus treated by Mr. SAGE, in Ashford Park, during the past summer, the surrounding leaves of fabulous proportions, with an aspect quite exotic. Where bold subjects can be introduced, this may be confidently recommended.

—— Dr. F. ARNOUX, of Montpellier, has published a pamphlet of some interest upon the toxicological properties of ANAGYRIS FŒTIDA. The poisoning of two soldiers in 1860 under circumstances which showed the seeds of Anagyris to have been the poisonous cause, directed the author's attention to the subject. Many quotations from ancient authors, classical and medical, are given, all indicating that the deleterious properties of the plant were known at a very early period, though they seem to have ceased to be remembered in modern works. A series of experiments (30 in number) were instituted by the author, from which he concludes that the leaves and seeds, with their extracts, are poisonous, and probably all other parts of the plant, and that animals are killed by their action in a very short time. The first effect which is observed is violent sickness, after which respiration becomes impeded, and at length arrested altogether. Dr. ARNOUX suggests that the active principle of the Anagyris will probably be isolated, and, if alkaloid, should be called Anagyrine.

—— One of the most singular and interesting of plants is the DROSERA BINATA of Australia, frequently met with in gardens under the name of Drosera dichotoma, and having, as the names indicate, the lamina of its leaves divided into a pair of long linear lobes, which are often again once or twice forked. As in other species of the genus these leaves are elegantly fringed by red gland-tipped cilia. We noticed the other day a magnificent specimen of this plant in the nursery of Mr. CRIPPS, of Tunbridge Wells; it was in robust health, throwing up its curious leaves freely, and forming a well-furnished mass of some 2 feet across, and about 1½ foot in height. It was cultivated in an intermediate house.

—— It will be of some interest to our correspondents to know that the NEW POSTAL TARIFF is now in operation. The half-ounce weight disappears, and the half-penny stamp comes into use for letters above an ounce in weight. The lowest letter postage will still be a penny; but the penny stamp will cover all letters not exceeding an ounce; while only an additional halfpenny stamp will be required for every additional half-ounce in weight. At these rates anything may be sent as a closed letter, up to 12 oz. Our correspondents should also remember that the vexatious sample post is now abolished.

—— The Corporation of the borough of Leeds has lately purchased the Roundhay Park estate, which is situated about 2 miles from that town, for a PUBLIC PARK. Altogether, the estate covers 1300 acres, the mansion, park, and lake comprising 700 acres; the price paid was £107,000. Another lot, which will bring the entrance to the park half-a-mile nearer the town, was also bought by the Corporation for £32,000.

—— M. EDWARD PYNAERT, of Ghent, has just introduced some ADHESIVE TICKETS for MARKING FRUIT, which will be found extremely useful in the case of fruit exhibitions. The tickets, of which an example of the natural size is subjoined, are ½ of an inch broad by ⅜ in depth; just large enough to contain a number, the name in legible letters, and a note of the ripening season. Here is a sample:—

No. 69.	No. 70.
NOUVEAU POITEAU.	DOYENNÉ DU COMICE.
Oct. Nov.	*Oct. Nov.*

Two sheets, each containing the names of 50 sorts of Pears, are now ready, and these are to be succeeded by others, including Apples, and perhaps other kinds of fruit, as soon as the demand is sufficient. For those varieties which are already well known and commonly met with, and which necessarily enter into every collection, special sheets have been drawn up, composed of 50 tickets of one variety. These tickets are gummed and perforated like postage-stamps, so that they may be used with facility, and they are recommended especially to exhibitors of fruit for the sake of securing correct nomenclature, for, says M. PYNAERT, "we are all rather disposed to be gastronomists, and we like quite as much to know the real name of a fruit we are tasting, as to know the name of the place from which a wine of a good vintage comes." Those who intend to adopt this system of ticketing are recommended to use the same set of numbers for their trees, which will be found a great convenience. "The general use of our tickets," adds M. PYNAERT, "not only in pomological exhibitions, but in every fruiterer's window, and at every table, will in a little time spread the taste for, and the knowledge of, the best varieties, and will be a powerful aid in diffusing those sorts that are most to be recommended, and consequently in developing the cultivation of fruit trees in general. This the jury at the recent exhibitions of pomology at Ghent understood and at once perfectly understood, and wished to make publicly known by granting us a silver medal."

—— In reference to the ORCHARD HOUSE at SCONE PALACE, it should have been mentioned that the photograph from which our illustration (fig. 288, p. 1293) was prepared, was taken in 1869, when the crop was somewhat light. Both previous to and since that date, the Peach crops in these houses have been so plenteous as to be "nothing accounted of," like the gold in Jerusalem in the days of King Solomon.

PORTRAITS OF GARDEN PLANTS.

AGERATUM LASSEAUXII, *Rev. Hort.* 1870, 90, with tab. A much-branched half-hardy composite plant, requiring greenhouse protection in winter, and suitable for planting out in summer. It is furnished with lanceolate-elliptic leaves, and bears small capitules of rose-coloured flowers, disposed in corymbose heads. It was introduced to the French gardens from Monte Video.

ANTHURIUM ORNATUM, *Bot. Mag.* t. 5848.

This handsome tropical Orontiaceous plant, has smooth green ovate or oblong-cordate leaves on slender terete petioles. The linear-oblong white spathes are 5—6 inches long, on terete green scapes, and enclose cylindrical purplish spadices of about the same length as the spathes, and studded with white points arranged spirally. It is an exceedingly ornamental subject, well worthy of general cultivation in collections of stove plants. It has been exhibited by W. Wilson Saunders, Esq., by whom it was introduced from Venezuela.

CALCHORTUS LEICHTLINII, *Bot. Mag.* t. 5862.

A dwarf herbaceous Liliaceous plant, with ovoid bulbs, narrow glaucous green incurved leaves, and slender scapes, 4—7 inches high, supporting large white flowers, 2½ inches across, whose petals have a single purple blotch above the nectary. It appears to have been introduced from California by M. Leichtlin, after whom it has been named.

CATTLEYA ELDORADO SPLENDENS, *L'Illust. Hort.* ser. 3, t. 7.

One of the most lovely of all the Cattleyas, belonging to the type of C. quadricolor. It has narrow, compressed one-leaved pseudobulbs, and peduncles bearing about two flowers, which in this variety are very large, of a delicate rose, the lip somewhat quadrate at the mouth, and bilobed, deep orange in the throat, surrounded by a zone of white, and of a rich reddish violet at the tip, this deeper colour extending somewhat along the margin, which is elegantly smoothed. M. Linden has imported it from the Rio Negro.

CATTLEYA SUPERBA SPLENDENS, *L'Illust. Hort.* t. 605.

A very beautiful Orchidaceous epiphyte, of dwarfish habit, with fusiform furrowed pseudobulbs, supporting a pair of short ovate-oblong obtuse leaves, and a peduncle bearing two large showy deliciously scented flowers, of a bright rose; the lip with a roundish oblong terminal lobe, deep violet at the tip, the base white, with four or five elevated golden-yellow lines on the disc, and veined with rosy purple. It comes from the Rio Negro, and we have to thank M. Linden for its introduction.

EPIDENDRUM SERIATUM, *Refug. Bot.* t. 90.

A pretty little stove epiphyte, with pyriform pseudobulbs, narrow linear-lanceolate grass-like leaves, and a slender panicle of olive-green brown-spotted flowers, of which the lip is whitish, with violet spots. It is a native of Guatemala.

HELICONIA GLAUCA, *Rev. Hort.* 1869, 112, with tab.

A fine stove herb, of the Musaceous order, with stems a yard high, having lanceolate tern-gron leaves, and supporting a terminal inflorescence, the rachis and pedicels of which are coral-red, the spathes yellowish and the flowers green. It has found its way into the French gardens from South America.

POLYCYCNIS LEPIDA, *L'Illust. Hort.* ser. 3, t. 19.

An elegant stove Orchidaceous epiphyte, with ovate pseudobulbs, broad plaited leaves, and long drooping racemes, the velvety-purple rachis bearing curiously shaped flowers, the narrow sepals and petals of which are of a pale brown or dun colour, while the lip, which has two basal auricles, is coloured, both being dotted with purple. Introduced from New Grenada by M. Linden.

RHODODENDRON LOBBII, *Veitch, Cat.* 1870, 22, with fig.

A brilliant-flowered stove shrub of moderate size, having its oblong elliptic leaves in whorls, and its bright glossy crimson flowers, with a long narrow curved tube, and small spreading limb, in terminal trusses. It was introduced from Borneo by Messrs. Veitch & Sons.

SCUTELLARIA ALBO-ROSEA, *L'Illust. Hort.* t. 584.

A stove shrub, of distinct character, with a tetragonal stem, cordate ovate or oblong undulated leaves, and lengthened terminal racemes of lilac flowers, paler towards the base of the long tube. It is found in woods of the Upper Amazon, and was introduced to Europe by M. Verschaffelt.

TETRANTHERA LHUYSII, *Rev. Hort.* 1869, 368, fig. 78.

A vigorous-growing and very elegantly variegated tree, furnished with entire oblong slightly undulated soft crowded leaves, 6 to 8 inches long, which are glaucous beneath, and above have a broad yellowish-white margin, the rest of the limb being flamed with greenish-yellow, and marked here and there with blotches of deep green. The stalks of the leaves are of a more or less intense red, and the bark is smooth and green. It belongs to the Laurel family, and has been introduced to the French gardens from Japan.

BOX EMBROIDERED PARTERRES.

THE term parterre, I need scarcely say, is borrowed from the French, who have long employed it to designate figures formed on the ground by means of turf, Box, and coloured gravels, with occasional relief in the way of floral tints. In such parterres, therefore, both flowers and shrubs are altogether secondary objects, the main features being the gravel and turf, and the curious scrollwork of Box. Notwithstanding the interest which must always be associated with parterres of this description, when properly placed, they were falling somewhat into disuse until within these last 20 years or so, during which period they have been revived by Mr. Nesfield, who partly employed that style of ornamentation in the decoration of the gardens of the Royal Horticultural Society at South Kensington, as well as in many gardens attached to private establishments in different parts of the country.

Of pieces of scrollwork of this kind one of the most pleasing with which I am acquainted is that represented in the accompanying illustration. It is laid down at Castle Ashby, on one side of the mansion, a glowing flower garden in the way of colour occupying the other. Both suit equally well the places appointed for them, that which is given being visible from the drawing-room, while the dining-room or library windows look out upon the comparatively subdued tracery work represented by our woodcut (fig. 295).

Two more opposite compartments, as regards effect, could not possibly be than those to which I have just alluded; but the mansion coming in between them, so dissociates them, that each stands on its own merit, complete it itself, thus creating a charming variety suitable to different tastes. Those who find the one too gay will hardly have to complain of that fault in the

other, though as much floral beauty as has been considered admissible in such a garden has been infused into it. The initial monograms and heraldry belonging to the Northampton family, sketched in colour on the grass, cannot fail to excite interest, which is sure to be eminently sustained by the bordering, consisting as it does of the Rose, Shamrock and Thistle, also laid down on grass with a freedom and fitness well calculated to elicit admiration. The design for this garden is said to have been furnished by the late Marquis of Northampton himself, a nobleman who was celebrated for artistic taste of a very high order.

its embroidered gardens of long standing. The point is to avoid extremes—neither to have the one too dull, nor the other too gaudy. In both these respects the Box-embroidered parterre at Castle Ashby recommends itself to notice as a model well deserving attentive consideration.

As regards what may be termed colour gardening, though decried by some, I do not see how, in large and fine places, it can well be dispensed with. Does the herbaceous ground at Kew, replete with botanical variety though it be, have admirers equal in number to those which crowd round the beds of gay half-hardy turf or stone, or a raised grass or gravel walk. In certain localities, however, the boundary must not be of too stiff or formal a character. I remember drawing up my bed-room blind one fine summer's morning in the neighbourhood of the Malvern Hills, when behold! an extensive flower-garden decked out in Flora's brightest colours was stretched out before me. For a while I was lost in admiration of its sparkling beauty—its fine specimens of shrubs and ornamental trees, and its magnificent architectural basins and fountains; but, when I began to criticise more minutely, it soon became painfully apparent that

FIG. 295.—BOX EMBROIDERED PARTERRE AT CASTLE ASHBY.

Monogram Letters.—N, N, A, A, Pelargonium Spread Eagle; S, S, S, S, Lobelia Blue King; C, O, T, E, Lobelia seedling, much darker than Speciosa; O, O, D, D, H, Verbena Purple King; I, I, Verbena Russelliana, a bluish grey.
Coronets.—Verbena White Perfection.
Coloured Figures (on the shading principle)—Rose shade: 1, Verbena Brillant de Vaise; 2, ditto, Lord Raglan; 3, ditto, rose-coloured seedling; 4, ditto, Diadem. Lilac and purple shade: 1, Verbena Purple King; 2, ditto, Celestial Blue; 3, ditto, Russelliana; 4, ditto, Amulet.

Rose, Shamrock and Thistle.—A, top part, Lobelia Blue King—lower part, ditto, Speciosa; B, Pelargonium Waltham Seedling; C, selected yellow French Marigold, very dwarf; D, Pelargonium Mangesii; E, ditto, Lord Palmerston; F, Calceolaria, top green, lower part Prince of Wales; G, ditto, Prince of Orange; H, Verbena Russelliana. The other figures are all planted in a similar manner. At each of the four corners of the parterre, which is 120 feet square, stands a pyramidal Portugal Laurel, 9 feet high. The white line outside the Rose, Shamrock and Thistle, is a belt of Box 1 foot thick and 18 foot high; between the Box and the turf is a border of white spar, 4 inches wide, which shows up the pattern very beautifully.

Centuries ago, when garden decoration had not reached the pitch which it has acquired in our day, the mansions of even the most wealthy were associated with but little floral beauty. Parks as magnificent as we have now, surrounded them, and they could boast of massive entrance gates, and often noble approaches; but their clipped Yews and similar quaint arborescent devices scarcely made up for the want of brilliancy such as we have now-a-days. That fine Elizabethan building, Holland House, is none the less interesting because of its bright floral surroundings, nor is Wentworth Castle, in Yorkshire, less attractive because of

plants that fringe the principal walks? I say no. I would, therefore, encourage our now fashionable, brilliant colour-gardens; but, where there is room, I would have Box-embroidered parterres as well; ay, and in suitable situations, too, our old-fashioned mixed borders. The latter, however, must be beyond the limits of the terrace garden, which ought to be separated from the scenery by which it is surrounded by some line of demarcation, such as a low architectural wall, with balustrade, and piers, and vases, a dwarf evergreen hedge, a canal, a ridge of irregular rock or root-work, a sunk fence faced either with its boundary wall, costly though it must have been, was too stiff by far to associate agreeably with the adjoining park scenery. In forming new flower-gardens, therefore, in hilly districts, where the scenery is somewhat undulating and wild, the most skilful consideration must be bestowed as to the kind of boundary by which they are to be surrounded. Some cheap sunk fence, crowned here and there with masses of rock or root-work, among which grow Rhododendrons, Foxgloves, and other showy flowering plants and shrubs, often answers very much better than more expensive architectural erections.

Flower gardens or parterres generally associate best with buildings; but there are exceptional cases in which they may be placed advantageously elsewhere. At Saltburn-by-the-Sea, for instance, just beyond Redcar, in the Cleveland district of Yorkshire, I once laid down what was considered by many to be a very pretty parterre in a natural glen, with a high turf bank on one side, and irregular wood plantations on the other. It was not, strictly speaking, a Box-embroidered garden, although a great deal of Box was employed in it in the formation of chain borders; and when the latter were in full dress, and looked down upon from the neighbouring heights, the effect was all that could be desired. Box-embroidered terrace gardens, somewhat amply relieved by colour, may also be formed advantageously on the side of a valley where the slope is not too abrupt. Let the form be a parallelogram made perfectly level, and as long and wide as required. Owing to the sloping character of the ground the back cutting will be the deepest; let this be faced with stone, raised sufficiently high to form a curb to the next terrace, which should be a grass promenade overlooking the garden, in front of which should also be a dwarf wall, which together with the back should be capped and ornamented, at certain distances apart, with vases. Grass neatly mown should then slope away down to the bottom or valley, in which should sleep a lake with a waterfall at the lower end and a little rivulet at the upper; the opposite bank may be wooded, faced with Rhododendrons, and traversed by walks. Flights of steps may lead on and off the terrace garden, and the back wall should be clothed with choice half hardy climbers or other plants, to which protection may be applied in winter. Where a flower garden must of necessity be made at a distance from the mansion, this is by no means a bad arrangement. There are, however, few places in which expedients, such as have just been recorded, have to be resorted to. *Joseph Nesbon, Oxford Terrace, Hyde Park.*

A NEW SYNOPSIS OF ALL THE KNOWN LILIES.—VIII.

Subgenus 2. LILIUM PROPER.—Bulbs squamose; stigma a thick bead to the style, with three blunt lobes—(*Continued*).

Group 4. MARTAGON (Turk's-cap Lilies).—Perianth loudly bell-shaped, always drooping, its divisions lanceolate, broadest about the middle, not distinctly clawed, reflexed (usually from half or two-thirds of the way down) when fully expanded. Stamens diverging much on all sides from the central axis of the flower—(*Continued*).

Key to the Species.

Leaves verticillate. (Three species described in my last paper, p. 1064).
Leaves scattered.
Leaves linear-lanceolate, reaching half an inch or more broad, 5—7 nerved. } 22. L. MONADELPHUM.
Perianth 2½—3 inches deep, re-flexed only from above the middle. } 22. L. MONADELPHUM.
Perianth 1½—2 inches deep, re-flexed from below the middle.
Leaves thick in texture, distinctly nerved, with very distinct main veins.
Flowers 2½—3 inches deep, with divisions 5—6 lines broad. } 23. L. CARNIOLICUM.
Flowers 1½—1¾ inch deep, with divisions 3—4 lines broad. } 24. L. PONTICUM.
Leaves thin, not ciliated, the main veins fine and indistinct. } 25. L. POLYPHYLLUM.
Leaves linear, ¼—½ inch broad, 3—5 nerved.
Perianth 1½—2 inches deep, with divisions ¼—1 inch broad.
Leaves 20—80 to a stem.
Perianth bright red, not dotted. } 26. L. CHALCEDONICUM.
Perianth bright yellow, dotted. } 27. L. PYRENAICUM.
Leaves few, about 30 to a stem. 28. L. CALLOSUM.
Perianth 2½—3 inches deep, with divisions ½—1 inch broad.
Leaves few, pale, persistently dull nankeen-yellow. } 29. L. TESTACEUM.
Leaves 20—30, perianth bright yellow, scarlet. } 30. L. LEICHTLINII.
Leaves narrow-linear, a line or an eighth of an inch broad, 1-nerved.
Stem 1½—3 feet high, with 80—200 leaves. } 31. L. POMPONIUM.
Stem a feet or less high, with 30—50 leaves. } 32. L. TENUIFOLIUM.

22. *L. monadelphum*, M. Bieb. Fl. Taur. Cauc., vol. i. p. 269; Cent. Pl. Ross., 4; Gawl. Bot. Mag., t. 1405; Kunth, Enum. iv. 260; Spae, Mon., p. 43; Fisch. et Lall. Ind. Sem. Petrop. vi., p. 57; *L. Loddigesianum*, Schultes fil., Syst. Veg. vii. 416; Kunth, Enum. iv. 261; Spae, Mon., p. 43.—Stem stout, erect, 3—6 feet high, glabrous or obscurely downy. Leaves always scattered, 30—50 to a stem, much ascending, linear-lanceolate, the lower ones 3—4 inches long, 6—12 lines broad in the middle, narrowed gradually to the base and an acute point, firm and stout in texture, bright green and glabrous above, distinctly ciliated at the edge, and pubescent all over, especially on the veins beneath, furnished with three veins on each side of the midrib, which are distinctly visible from the base to the apex, the upper leaves growing gradually shorter, and leaving a blank space of 2—3 inches below the inflorescence. Flowers 1—3 in the wild specimens I have seen, but said to reach up to more than 20 in cultivation. Pedicels cernuous, 1½—2 inches long, subtended usually by a pair of lanceolate bracts. Perianth 2½—3½ inches deep, pale bright yellow, tinged round the base with claret-red, the divisions permanently valvate in a funnel-shaped tube in the lower half, spotted down the face up to the top, with a few minute red-brown dots, the divisions only falcate in the outer third in the expanded flower, oblanceolate, rhombic, 6—9 lines broad, narrowed gradually from three-quarters of the way up to the base, glabrous down the groove. Ovary 7—8 lines long; style 16—18 lines, not so much curved as usually in the Martagons; filaments bright yellow, connate towards the base; anthers linear-oblong, 5—6 lines long; pollen yellow. Capsule 18—21 lines long, acutely angled.

Var. *Szovitsianum*: *L. Szovitsianum*, Fisch. et Lall. Ind. Sem. Petr. v. 58; Kunth, Enum. iv. 674; Spae, Mon., p. 42; Flore des Serres, t. 507-9; *L. colchicum*, Stev. Fisch. MSS.—Filaments free to the base. Perianth reflexed from rather lower down, with segments broadest a little above the middle. Pollen said by Fischer and Lallemant to be deeper in colour, and capsule more bluntly angled.

A native of the Georgian slopes of the Caucasus and adjacent regions of Asia Minor. A very fine and very distinct species, approaching the Pomponium in the Martagons, and differing conspicuously from all the other Old World species of the group in the shape of the perianth and the extent to which it is reflexed, in which respect it comes nearest to the typical form of canadense. Like many other Lilies, it has been rather overloaded with names. I cannot see that the plant figured in the "Botanical Magazine" differs in any respect from that of Bieberstein, except that one is taken from a cultivated and the other from a wild specimen, although Schultes founded a new species upon Gawler's plate, which Kunth has also adopted. What is passing about in our gardens and trade lists at the present time as "Szovitsianum" and "colchicum" is, I think, just the same plant, which appears to be no more than a slight variety of monadelphum. Of the two names, "Szovitsianum" is the one which, according to botanical rule, should be adopted.

23. *L. carniolicum*, Bernh. in Mert. et Koch, Deut. Flora, ii. 536; Kunth, Enum. iv. 260; Spae, Mon., p. 33; Reich. Ic. Fl. Germ., t. 999; Parl. Fl. Ital. ii. 404; *L. chalcedonicum*, Linn. Sp. Plant., p. 434, ex parte; Jacq. Fl. Aust. iii. 20.—Bulb ovoid, of a few lanceolate scales an inch deep. Stem 2—3 feet high, stout, erect glabrous. Leaves 30—40, always scattered, much ascending, linear-lanceolate, firm and stout in texture, the lower ones 3—5 inches long, 5—9 lines broad in the middle, quite flat, narrowed gradually to the base and an acute point, the lowermost bluntish, the edge minutely ciliated, the lower surface furnished with 3—4 ciliated veins, which are quite distinct from the base to the apex, the upper leaves shorter, lanceolate, generally leaving a vacant space below the inflorescence. Flowers 1—4 in the wild plant, drooping. Peduncles 2—3 inches long, sometimes bracteolate. Perianth 1½—2 inches deep, bright orange-yellow passing sometimes into scarlet, the divisions oblanceolate, 5—6 lines broad two-thirds of the way up, pubescent at the top, slightly spathulate in the lower half, reflexed from below the way down to the expanded flower, with a few red-brown dots, some of which in the lower part are raised into papillæ; style and ovary each about half an inch long, filaments 8—11 lines; anthers 5—6 lines; pollen fulvous.

A native of Lombardy, Austria, and Turkey, easily distinguishable from chalcedonicum, with which Linnæus and many later authors have confused it, by its much fewer, broader, laxer, distinctly many-nerved leaves. It is a handsome plant, which our English cultivators seem to have passed entirely over, and which has never been figured, although it well deserves it, in any of the gardening journals.

24. *L. ponticum*, C. Koch in Linnæa, xxii. 234; Boiss. in Balan. Plant. Orient. 1866, No. 1531.—Bulb an inch thick, with numerous fleshy lanceolate scales, nearly an inch long. Stems 1½—2 feet high, slender, faintly pubescent. Leaves 20—30, firm in texture, scattered, lanceolate, all scattered, the lower ones 15—16 lines long, 4—5 lines broad at the middle, narrowed gradually to an acute point, rather rounded at the base, thickly pubescent and furnished with several distinct veins on each side of the midrib beneath, the upper ones shorter and narrower, ceasing a space below the inflorescence. Flowers solitary in the three specimens I have seen, but said by Professor Koch to reach up to six, commonly 1—2 lines deep or much reflexed from below the middle when expanded, yellow, the divisions 3—4 lines broad a little above the middle, narrowed gradually to the base; ovary and style each about half an inch long; filaments 8—10 lines; anthers 3—4 lines.

A native of Asia Minor, gathered by Prof. Karl Koch, and lately by Balansa, in the mountainous region of Lazistan. Whether it be more than avariety of carniolicum, I very much doubt, but it is not known in cultivation, and I have only seen three dried specimens of Balansa's plant named and distributed by Boissier. If distinct the characters to separate it from chalcedonicum must be found in the shorter leaves, and the shorter and much narrower divisions of the perianth, which look like those of polyphyllum.

There is also, belonging to the present group, a very little known Albanian Lily, *L. albanicum*, Griseb. Fl. Rumel, ii. 385, of which I have seen no specimens, but which, judging from the description, comes very near to this in the flower, but is said to have leaves that reach 2 inches long, and are glabrous on both sides but ciliate at the edge. Two specimens only of this were gathered by Grisebach on Mount Scardus, in Albania, at a height of 7000 feet, and it is said to have occurred also in Transylvania.

25. *L. polyphyllum*, D. Don, in Royle Ill. Him. p. 388; Kunth, Enum. iv. 677; Spae, Mon. p. 39; Klotzsch, Reise Wald. p. 53.—Stem 2—3 feet high, moderately stout, glabrous, terete. Leaves all scattered, 30—40 to a stem at the flowering time, much ascending, linear-lanceolate, the lower ones 4—5 inches long, 6—8 lines broad above the middle, narrowed gradually to the base and an acute point, similar to those of Martagon, and much thinner than those of carniolicum in texture, the veins fine and anastomosing, both sides glabrous, the edge not at all scabrous or ciliated, the upper ones ceasing several inches below the inflorescence. Flowers 4—6 in wild specimens, in a lax raceme. Peduncles 2—4 inches long, ascending, stiff or flexuose, subtended by a pair of large leafy bracts. Perianth 1½—2 lines deep (colour not known), reflexed from below the middle when expanded, drooping as in the other Martagons, the oblanceolate divisions not more than 2—3 lines broad at the middle, pointed at the tip, narrowed very gradually to the base. Ovary 5—6 lines deep; style 9—10 lines, much curved; filaments 15—18 lines; anthers ⅔ inch; capsule 12—15 lines deep, rather acutely angled, with a distinct neck.

A native of the North-western Himalayas (Cashmere and Kunawar), at an elevation of from 6000 to 8000 feet, gathered by Royle, Jacquemont, and Thomson. It has never been cultivated, and I do not know even the colour of the flowers. It comes very near the form of Martagon with scattered leaves, but the segments of the perianth are much broader, and have more of a claw than in any other species of the Martagon group. From the three preceding, the different texture of the leaves and faint anastomosing venation readily separates it. *J. G. Baker.*

THE AMATEUR GARDENER.

Caterpillars.—A few days ago we heard in our garden the exclamation, "What splendid skeleton leaves!" and, on turning round, we found a lady admiring a bed of Brussels Sprouts, denuded of all its verdure, except its stalks and main leaf-ribs. We confess that our fair friend's taste was anything but gratifying to us, and we muttered something to the effect that it appeared to be true that "what was one man's meat is another man's poison." There was certainly a little of the esthetic about the gaunt remains of what had a month before been the pride of our kitchen garden, but no amount of beauty in the ribs of the leaves of Brussels Sprouts could make up to us for the loss of the delicate and savoury heads we were looking for to accompany our roast beef, &c., in the winter months. And the same remarks would be equally appropriate to the other Brassicas in the season; Cabbages, Sprouting Broccolis, Couve Tronchuda, &c., have all had to undergo the sentimental but unprofitable lot of being turned into collections of "skeleton leaves" for botanical ladies to admire. And this sad fate of "winter greens" appears to be a universal one as far as our knowledge extends, for at a large dinner-table a fortnight back we heard a dire lamentation set up on the subject by two bishops, and a host of aristocrats, clerical and lay.

"Some comfort," was one remark *sotto voce*, "that all your wealth and abundant horticultural appliances cannot avert from you the unhappy lot of a country vicar;" and so the conversation went on in a way which clearly showed that episcopal cares extended even to Cabbages. And our talk upon the point settled down at last into expressions of wonder that science had not taken caterpillars under its cognizance, and devised methods for the avoidance of this almost oriental pest. But after all, when our experiences were duly collated, we felt we had no one to blame but ourselves, for we made the ingenuous confession that we believed neither of us had ever studied the subject. To compass great things with small, this acknowledgment is about as injurious to our common sense as it would be if, having occasional inroads of barbarians in our island, we yet neglected to study their native habitats, their powers, their objects, and the best methods of defeating them.

However, carelessness in the matter of the safety of our winter crops of "greens," had not proceeded in all cases so far as we may seem to have intimated. For ourselves, we had adopted the rather expensive process of hand-picking, and our man declared, without any blushing or other sign of consciousness of crime, that in a fortnight he had gathered not less than 2 pecks of these horrid enemies—dark brown, nearly black, spotted green, light uniform green, and almost white, varying in size from some as large as a little finger to others not more than half an inch long. It is doubtless owing to this process of collection that our plants are less injured than those of our neighbours, and that all our Brussels Sprouts are not reduced to a museum of skeleton leaves. One speaker at the *conversazione* said that his gardener had sent a colony of fowls among his Cabbages, but that on proceeding to look at the result of the experiment, he found that the birds had done no inconsiderable damage to other parts of the garden, but had declined to feast on the caterpillars—a matter of taste in the gallinaceous tribe with which we had become familiar years ago. Another had tried salt, and discovered that the enemy seemed rather to like the dose he gave them than otherwise. At length we came to the root of the evil, the confession of a general

ignorance of the several kinds of caterpillar, of their habits, of the insects from which they come, &c., some of the company not even knowing that every one of them must have come from eggs deposited by a moth or butterfly, and would soon, if let alone, go through the chrysalis or pupa state again to that of a winged insect. Our criminal ignorance will be manifest from the fact that we were doubtful whether some of the grubs, the large dark kind, did not mount up the stems directly from the soil in order to carry on their predatory operations!

To turn the matter into a most serious one, we come to the fact that most of our gardens are suffering from a plague of caterpillars, while we all, masters and men, are ignorant of the resources or the weak points of our enemies. A gardener should know the natural history of every insect that can mutilate his flowers, gnaw into his fruit, or destroy his vegetables, from the red spider and mealy bug up to the locust-like creatures which soon make a pleasant garden a wilderness. If this knowledge were possessed, we could destroy whole colonies of destructive agents in embryo, instead of looking on in stupid amazement at our skeleton leaves. But all our study of insect natural history will not prevent a sudden and unexpected inroads of various tribes, and therefore we should be prepared with effectual methods of destroying them, when they have arrived, in some easy and compendious way. There must be many substances, liquid or in the form of powder, which would check insect ravages without injuring the plants, and we have written this paper partly with the hope that knowledge now confined to individuals may be communicated for the public good to the pages of the *Gardeners' Chronicle*. *H. B.*

FIG. 296.—ZINNIA HAAGEANA FLORE-PLENO (⅓ NAT. SIZE).

ZINNIA HAAGEANA FLORE-PLENO.

WE are indebted to Messrs. Haage & Schmidt, of Erfurt, for the accompanying figures of a new Zinnia (figs. 296, 297), which they regard as the best novelty amongst annuals which the season has produced. The typical form of the species, now generally known as the *Z.* Haageana of Regel, called also *Z. aurea* by Dr. Lindley, in this journal (*Gardeners' Chronicle*, 1861, p. 1114), and further known in gardens under the names of *Z. mexicana* and *Z. Ghiesbreghtii*, is pretty freely cultivated as a neat, low-growing, tufted, yellow-flowered annual, and has long since become a favourite from its usefulness for dried or winter bouquets. The double-flowered variety differs in the form and doubleness of the flower-heads, which are perfectly rosette-shaped, and, moreover, is reported to be constant from seeds. The habit is the same as that of the single-flowered sort, the plant forming densely-branched tufts of about a foot in height, and somewhat more in diameter, and being abundantly furnished with the terminal flower-heads, which, as is usual, are of much longer duration in the double than the single form. The florets are as densely imbricated, and form heads of the same size and outline, as those of the best double Zinnia elegans, than which, however, they are naturally smaller in size. Their colour is a deep orange-yellow, keeping its lustre when dried, and thus rendering this Zinnia an acquisition for bouquet-making. It is likely to be a good bedding plant, blooming continuously till frost sets in. Taking all its points into consideration, this Zinnia appears to be one of the best and most useful of the novelties for the coming season; and to be worth trial as a dwarf orange-yellow bedding plant, especially for late summer flowering. *T. M.*

PLEIONES AS WINTER BLOOMING PLANTS.

THE dull season is upon us, and in most places there is very little flower in either the stove, the greenhouse, or conservatory, so that anything that will enliven the appearance of our houses at this particular season is doubly valuable. It is not for lack of flowering plants that so little bloom is to be found just now in the majority of plant-houses, but because so little care is taken to provide the proper plants. We have the choice of a great quantity of Acanthaceous plants, and others belonging to the Gesneraceæ, which would afford us quite a grand display, but in how few gardens do we find many plants of either of these orders? Then, again, what quantities of good old species of Begonia, which would now be in full bloom, have been turned out of our collections.

My principal object, however, in penning these few lines is to draw the attention of Orchid growers to the gorgeous effect produced at this season by the exquisitely beautiful and chaste flowers of the various species of Pleione. These Indian Crocuses, as they are frequently called, have always been great favourites with me, and I have been always successful in growing and flowering them, but such a sight as that presented by the Pleiones at Manley Hall, the residence of Sam Mendel, Esq., has perhaps rarely been equalled in this country. When I saw them some time ago I remarked to Mr. Petch that their strong growths should flower well, and now there are upwards of 600 blooms upon these plants, their richly marked flowers being almost dazzling to the eye; indeed, such a sight as that presented by these plants is worth travelling from the Land's End to John o'Groat's to see.

Now I would ask, why are so many Orchid growers indifferent to the charms of these plants? They are not difficult to grow, and they are free to bloom, that is, if treated consistently. The great drawback, no doubt, is the fact of their flowers being produced whilst the pseudobulbs are destitute of leaves, which

FIG. 297.—FLOWER-HEAD (NAT. SIZE).

takes from them some of the grace and beauty which they would otherwise possess. This, however, may be remedied to a great extent. I have always neatly arranged the Pleiones when in flower with dwarf Ferns and other graceful-leaved plants, so that their own leaves were very little missed; and I feel sure if Orchid growers would cultivate these gems more, not separating them, as in many instances is done, but allowing them to form good-sized masses, they would soon reckon them amongst the most beautiful plants in their collections.

Pleiones should have a moderate supply of water as soon as the flowers begin to push up; and directly the flowers have faded they should be potted and placed at the warm end of the Cattleya-house, and a liberal supply of water should be given them until the pseudobulbs are mature, when they should be rested until the flowers begin to show themselves. I have some few more notes of winter-flowering plants from the same garden, which I will send you, if agreeable, at a future time. *W. H. G.* [Our readers will, we are sure, appreciate them, the subject being one of much interest. EDS.]

THE ÆSTHETICS OF ROCKERY.

HITHERTO, rockwork has generally been looked upon merely as a means to an end—as the necessary adjunct to a certain class of plants, whose original *habitat* had to be imitated in our gardens in order to ensure their successful cultivation.

There is, however, quite another function appertaining to rockery which no landscape gardener can afford to overlook, and that is its general effect in relation to the surrounding scenery. From this point of view, the rockwork is the main subject of interest; it becomes an important unit in the landscape, and the plants which cover its sides, however delightful in themselves, must be looked on as complementary to it. Here the geologist may have a word to say, and he may possibly help to rectify some of the blunders which are constantly being perpetrated in this respect.

In all cases in which rockwork on a large scale is to adorn well laid out grounds, it may be accepted, as rules never to be departed from—1st, that it should be characteristic of the part of the country in which it stands; 2d, that its form should be that which in Nature is assumed by the particular kind of rock of which it is composed; and, 3d, that in no case should it be constructed in a manner contrary to the broad geological laws to which all rock masses are subject in their natural state.

The first of these three rules, to a certain extent, comprises the two next, and its application must necessarily depend very much in practice on the natural taste of the architect. Still it can be broadly stated, that no rock, foreign to the district in which it is erected, can ever be admitted to a permanent place in a model rockery. In grounds situated on the chalk, miles and miles from any other rock, it would obviously be absurd to construct a ragged mass of granite tors. Again, on the clay and gravel of the Thames valley, where most of the London and suburban gardens stand, any attempt at imitating natural rocks would fail utterly. By this last statement the writer does not intend it to be understood, that in his opinion no rockeries of any kind should, with propriety, be made in such situations—but merely, that as no rock characteristic of the district is obtainable, any attempt at verisimilitude would be unsuccessful. On the other hand, in cases of this kind, honest artificial rockery (such as burnt bricks, slag, &c.), have the best of excuses for being used, so long as it makes no pretence to represent real "live" rock. And, indeed, with the material usually employed for such purposes, attempts of this kind could never be seriously made. It is in cases such as these, where clayey or incoherent matter forms the subsoil, that the notion of rockwork being merely subservient to the culture of some kinds of plants can be admitted, but in no other.

The rule, therefore, must be, that where rock of some sort is to be obtained on the spot, or in the neighbourhood (and here, as throughout this article, the word rock is used not in its more general geological sense, but in its special meaning of stone of a certain degree of hardness), rockeries are to be composed thereof, and of no other. This will ensure an amount of homogeneity and completeness in the landscape which no amount of imported material, however picturesque, could ever attain. For it must be remembered that every feature of the land, every hill and every dell, is, to a great extent, the result, so far as size and shape are concerned, of the nature of the strata or eruptive rocks in which they are sculptured. Thus any departure from the general outline of the country is an æsthetic blunder. If the horticultural engineer raises a crag, let it be where a crag could with probability have existed, not where denudation must have swept it away ages ago. Happy is he who finds natural rocks to work with, native crags to embellish and cliffs to adorn. Such luck is unfortunately the exception, and in its absence attention to the rules laid down here would, it appears to the writer, lead to a more scientific, and at the same time to a more artistic, use being made of the materials available in the various parts of our island.

Of the second rule no more need at present be

observed than this: that every rock-mass exposed to the influences of rain, water, and air, assumes a certain shape and form, according to its composition. A crag of basalt is always distinct in outline from one of grit, and a chalk cliff is very unlike escarpments of harder limestones. It follows, therefore, that in building up a crag, albeit it be made of the same material as that of the natural rocks in the neighbourhood, the greatest care should be taken that its form should be as real as its composition. What these forms are with regard to the principal varieties of rocks to be found in Britain, the writer may perhaps describe in a future paper, as also (in those cases where several lithological varieties occur together), what are in his opinion those most suited for landscape gardening.

To the second rule the third is scarcely more than a corollary, and it has been suggested to the writer several times of late by some curious cases of its neglect which have been brought to his notice, as, for instance, in a large rock-garden in the North, where the blocks of sandstone had been with much trouble and expense made to dip at a high angle to the east—the dip of the strata at that spot, and for miles in every direction being due west, and natural crags with the beds having this direction being visible from the newly formed rockery. Such a blunder, though it must naturally remain undiscovered by the uninitiated, is either ludicrous or puzzling to the geologist, and it gives an air of unreality to the scene, which entirely defeats the object for which a rockery is constructed. Rockwork, in fact, should never assume the appearance of a *lusus naturæ*. Care, therefore, should ever be taken that the position of the rocks used in crag building be that which it would be in a natural crag, not an imitation, but only a skilful reconstruction of the geological survey of England. *G. A. Lebour, F.G.S., F.R.G.S.*

Home Correspondence.

The International Fruit Show.—What were the principles upon which the award for the "most complete" collection of Apples was made at the International Fruit Show, held at the gardens of the Horticultural Society on October 4? My collection consisted of 290 sorts, and the winning one consisted of 171 sorts,—just 119 sorts difference. Now supposing that the 290 sorts were in some respects inferior to the 171, yet I cannot think that they were so much inferior as to be overbalanced by a collection 110 sorts less in number. I do not know the points upon which the judges dwelt; I only know that the schedule stated "the most complete collection." As I and many others understood, this meant the greatest number of sorts first, and where two collections ran one another close then the other points by which Apples should be judged would come into play, viz., size, colour, and quality. So much for myself. Now, as to the collection that took 2d honours, there were in it about 150 sorts. Will the judges say that the 21 extra Apples in the winning stand counterbalanced the 150, which had every other point in their favour? Perhaps not quality,—I could not say; I only saw that, as to other qualifications, they were the best in the show, save in numbers. Now follows the arithmetical problem. If 171 could beat 290, why should not 150 beat 171, seeing that they were much larger and finer-looking fruit? I do not write in spleen or vexation, because I know how ready we all are to think our own productions the best—that is, in a general way; but I do think, when a schedule of prizes is published, that it should distinctly state the conditions upon which the fruit is to be judged, and not leave room for any one to say that he thinks himself unfairly dealt with. There is another thing, that your own columns showed was not understood, viz., how the collections were to be made up—whether they should be the *whole fair* production of the exhibitor, or whether they were to be got together from all or any quarter, as was the case with some of the collections shown. Had I known that we could beg or borrow, I could easily have shown another 100 sorts of fine fruit, as large and handsome as any in the collection. Some showed fruit that were brought for the purpose from the Continent; I could have had from there also at least 100 sorts, finer, or as fine as any that were exhibited. Therefore, when we have another International Fruit Show, let the authorities make it *one and not two* that all fruit shown be the production of the party exhibiting it, and also let them clearly state the points of qualification necessary to win. I was much gratified with the show, and think it will do an immense deal of good to fruit growers generally; and if it only help us to correct our fruit nomenclature, it will have done a great service to cultivators. It also has shown us that our friends over the water are, at least, alive to Pear growing. M. Baltet left us no room to cavil about that. *John Scott, Merriott, Oct. 6.* [Three fruits of each sort were required, whereas our impression is that Mr. Scott showed only one. Eds.]

Passiflora quadrangularis.—I send you fruits of the Passiflora quadrangularis. The plant which bore them is not yet two years old. It bore 50 fruit last year, and about 60 this season, averaging at least ½ lb. each. I find it does not set its fruit freely when there are any fruit upon the plant approaching maturity. We had many flowers on our plant in July, but they all failed, there being at the time an earlier lot of fruit just colouring. As soon, however, as they were cut off, every flower set. Those sent are some of them. *J. Simpson, Wortley Hall.*

Raising Vines from Eyes.—By way of fulfilling a promise, I send you samples of our late crop of Grapes from the Vines that were raised from eyes last year: they are Black Alicante and Barbarossa. With them is a cane of a Black Hamburgh Vine, grown in a 14-inch pot, from an eye inserted in a sod last March; the sod, you will see, still adhering almost entire to the Vine. It is a fair sample of the lot. A writer, some time ago, who had been experimenting on the "pot" and "trift" systems, declared in favour of the old plan, *i. e.*, pottering from one pot to another. I could understand how a good gardener might easily succeed in growing good pot Vines by this plan, but how he could fail to grow them on the turf beats me; for it is apparent, I think, that a Vine eye inserted in a piece of good fibry turf has all the advantages of a pot and none of its drawbacks. The Vines in question carry about six bunches each, and all are beautifully finished. *J. Simpson, Wortley Hall.* [They are capital samples, the canes strong and perfectly ripened, the bunches about 2 lb. weight, and the berries thoroughly well-swelled and well-finished. Eds.]

Wine-making (see p. 1299).—The only utensils required are a small mash-tub, about 20 gallons, and a smaller one to dip into. Add to the Grapes to hand lang till thoroughly ripe, then strip them, and break them down in the mash-tub; allow them to stand four days, occasionally stirring them up; run the juice into the other tub, gather the skins into a cheese-cloth, place a board and weights on them to extract the remainder of the juice. Measure the juice, and to every gallon add 2½ lb. of honey; put it in the cask, leaving the bung out, examine it frequently, and when fermentation ceases bung it up, putting in the whites of two eggs to clarify it. This will require drawing off carefully in about a month, leaving the dregs at the bottom; run the dregs through a double fold of flannel to fine it; wash the barrel, and place the whole in with the addition of one bottle of proof brandy. To every 4 galls. of juice, if not quite fine, add a small quantity of isinglass or white of egg; draw this off about March, and bung down. Bottle off in June or July. As the summer temperature increases, you will (if properly attended to) have a beautiful, rich, fruity, effervescent wine, far superior to much that passes for champagne. Taste must direct as to sweetness. If not sweet enough, add honey. To make a dry wine.—Take 8 galls. of ripe juice, weight about 60 lb. then chop up about 40 lb. of raisins, and put them together in a cask, and stand that in a cool cellar 6 months; draw the wine off, and treat the skins as before mentioned; then add one bottle of proof brandy to 4 galls., and as above mentioned, stand a month, then bottle. You must vary the quantity of raisins according to the richness of the wine you wish to make. My reason for using honey is that it blends better than sugar. If I have not sufficient Grapes I purchase some, the price is generally 2*s.* 6*d.* per 14 lb. quite ripe 2 lbs. per gall. and at this time of year, if you apply to your grocer, the price of year-old raisins is reasonable, the new fruit being in,—my general price is 24*s.* to 30*s.* per cwt. The Malagas are generally used by the London wine maker, but Valencia or Muscatels, &c., will answer. Loaf-sugar will answer if you are unable to procure honey in the villages near you. I have read many recipes for wine-making, all contain more or less water: you will observe I omit it altogether. In Spain, under a more favourable temperature for maturing the Grape, they wish to get rid of the water in their first-class wines. Why should the juice of our fruit require diluting? And considering that the raisins contain all the must or saccharine, the only loss is by evaporation, which you supply by addition of Grape juice. I have produced good wine at 8*d.* per bottle, at the prices specified. I am a grower of Grapes, the outlet is less. If you want to flavour the raisin wine put some sweet almonds in two bottles of brandy for a month, and then add it to the contents of the cask. *Cantab.*

The Rationale of Hot-Water Circulation.—That heat is a mode of motion has passed into an axiom in natural philosophy, and appears to be a matter of everyday experience. We speak and write of caloric as the driving force of the universe. Heat and motion have become well nigh convertible terms. Exhibit the results of heat and you reveal motion; extinguish or lessen it, and the result is rest. Such, at least, is a brief mode of stating the common belief. Nevertheless, it seems but one side of a truth. The springs of motion are not wholly laid in either heat or cold, using these terms in a popular sense. The matter of one uniform temperature, that uniformity would prove the grave of motion. Immobility would be the unalterable condition of a world of one uniform temperature. Rest is the nett product of uniformity; motion everywhere and at all times treads in hot haste on the heels of diversity. The great movements we see around us reveal the force of Nature striving after an impossible equality of heat. In this great contest heat and cold are the racers; they run round circular courses that have no end. It is even difficult at times to know with certainty which takes the initiative. Of more moment is it to be assured that both run on without ceasing. Heat and cold are but opposite sides—the negative and positive poles of the same great force. Certainly both are needed to complete the line of motion, and to knit its parts together in a circle of warming force. And the force and speed of the motion will be as the sum of the extreme difference of temperature between any two points that come within circulating range. The greater the disparity, the more energetic the motion; or, in other words, the more work to be done, the greater the force brought forth to do it. And the worker is not only, nor perhaps chiefly, caloric, but the want of it; or rather—and to write with more exactness—motion comes and is sustained by an endless series of exchanges between more heat and less heat. While these diversities exist motion continues. It is less due possibly to the active agency of caloric than it may seem. It heat gives wings to air or water at one end of the scale, it relatively adds to their weight at the other. For every molecule lifted by caloric, others are pushed forward and onward by gravitation. Caloric does not drag matter along, like some fiery steed with invisible reins, but rather acts sort of collective to clear the way for heavier matters being pushed forward by the force of gravity, or the strivings for uniformity. Nature is provident of force; she never sets caloric, or aught else, to lift, drag, or drop that can find its way to where it is wanted without its aid. In the heating of water she leaves her element to go into the air, or carries them across the surface of the water, at the highest possible levels consistent with her objects. But her returns are placed at the lowest points. By these arrangements gravitation does useful work in the distribution of heat. A vigorous flow of hot air or water once established, the return streams take care of themselves. Elastic fluids, impelled by the force of natural laws, reach the highest points first. From this maximum altitude the descent is simple and easy; it is a mere falling from a higher to a lower point, or rather, like running down. At every step of the journey downwards fresh momentum is gained, and the bite of friction is less felt as a hindrance; and finally, the return stream, parting with its heat all the way, contracting in bulk, and growing in weight, plunges into the boiler or source of heat to be in a more ready state for a second round of distribution. But a point or two of considerable moment ought to be noted here; one is, that the hot water cannot remain in the boiler if we would have it so; the general opinion is, that it is driven out by caloric. But this can hardly be the case, else our tea-pots on our fires suddenly boil dry, but they do not under ordinary heat; they boil without overflowing, but our boilers overflow long before they reach boiling point—in fact, they ought never to boil. The chief reason for this extreme sensitiveness to motion is the great weight of cold water pressing upon the heated and lighter limb of our boilers, if I may so put it. No sooner is the normal strength of the water broken by the levity induced by heat than the strong cold waters rush in, and possibly push so sharply upon the warm water as to help it forward and upwards out of the boilers. There is here a compound action, in which the forces—levity and weight, heat and cold—act simultaneously to induce motion. There is even a third force developed, which is somewhat difficult to describe. It will be understood if I call it the upward bound or rush of heat. Caloric in its hot transit seems to aim at its source—the sun. It hits straights at that mark, and recks not of side issues. Leave several ways open for caloric, and it will always take the highest road. In a current of hot water there are doubtless limits to this law. Beyond a certain height the weight of the water in the return columns would probably check the energy of the ascending force, but within the limits of horticultural heating this rule may be held as absolute, that the higher the flow-pipe the greater the force of the current. By converting the return or lower pipe into a flow-pipe at times this natural help to a vigorous circulation. One other point requires notice. The highest part of the boiler ought to be the hottest, the heating of the water should be cumulative from bottom upwards; if the circulation is rapid, as it ought to be, the boiler kept free of sediment, and the furnace wisely adjusted, the return current will keep the base of the boiler cool. Our chief concern is to keep the crown hot. In our anxiety to save fragments of fuel we often lose sight of this one thing most needful. By multiplying flues on the crowns of boilers we keep its head cool. Better far waste some caloric up chimney than drag a languid stream of black smoke and spent flame to play around the flow-pipe. The fire here should burn its fiercest, and give its last sharp spur to the departing water, telling it in unmistakable terms to be off about its master's business, and not heating the houses. That last fillip at starting not only gives a spurt to the flowing stream, but it creates a vacuum or levity, which the whole weight of the returning column bounds forward to fill up. Hence it follows that unless on very short routes indeed, or under abnormal pressure, the greater the difference of temperature between the flow and return pipes the swifter and the more powerful the circulation. For it must be obvious that were the return-pipe to become as hot as the flow, we should lose the great force of gravity as an

aid to circulation. But the smallest differences tell upon motion, and in all ordinary arrangements it may be accepted as an axiom that the return water reaches the boiler wholly by its own gravity. We have been invited to follow Nature, and I have adverted to certain examples. But in all such cases it is needful to guard against analogies being taken for identities. Nature's actual modes of heating are somewhat different from ours, though her great systems of distribution are the same. Water is heated from above downwards, the air from below upwards. We find it most profitable to heat water as Nature does air—by suspending it over the source of heat; but because in this point we may diverge from Nature, that is no reason why her grand order of heating by hot-water should be set aside or reversed. Having provided the hot-water stream by the best means at our command, we shall get the most heat out of it with the least expenditure of fuel or force by following Nature's mode of distribution. It is utterly impossible to gain aught by making the lowest pipe the flow, unless our pots, teakettles, and boilers can be made hottest at the bottom —and even then we should gain a loss by the change. Since writing the foregoing I have read the Rev. J. M. Taylor's second letter (pp. 775, 776). I am not sure that I understand it; but this much is certain, that any mode of heating horticultural buildings that requires the water to be kept boiling to bring out its merits is impracticable and useless. It cannot be done, if one would, and ought not, if we could. How the arrangement illustrated in the *Gardeners' Chronicle* by Mr. Cannell, which we were assured resulted in keeping the flow and return pipes at nearly equal temperatures, can likewise fulfil the conditions described in this sentence, I cannot divine. Having gained a high level for the water, he prudently keeps it until the water has acquired all the weight by condensation that the cooling process can give it; he then gives it at its final plunge into the bottom of the boiler all the advantage which altitude, perpendicularity, and directness of current can give on it as a motive power! If this were, or is so, then the return-pipe would be almost cold. But, on the contrary, force up the whole mass of cold water by the aid of caloric in opposition to the laws and ways of Nature, the hottest water will still be found at the highest point, that is, at the end of the flow or return-pipe; and instead of being kept there or sent on a circuitous journey to exhaust its heat, it at once returns to the boiler warm, that is assuming, for the nonce, that the circulation flows as the arrow-heads indicate, which, however, I by no means admit. I pass on, then, to present objections. Suppose I raise the flow-pipe at starting above the level of the return, so that it may dip into it; nor the other suggestion to raise flow and return to the same level. The Rev. J. M. Taylor seems to attribute undue importance to the verticality of the return-pipe. But the gravitation is from the highest point, how or wherever placed, and the friction of water in pipes of such bore as is mostly used for heating is but little. As far as I understand this gentleman, I agree with him on the importance of gravitation as an aid to circulation; but I don't see how the arrangements suggested would strengthen its force. On the contrary, they seem to me to neutralise or hinder it. *D. T. Fish.*

Mock Spring.—I do not know what other heading to put when treating of budding and flowering, fruit setting, &c., in these autumn days. It shows that the extremes of temperature to which plants have been subjected these last few years, have such an effect on them that some time must elapse before they can recover themselves. Many spring flowers are out, among them the blue Gentian; a row planted next to Mrs. Pollock Pelargonium is in full flower, and the effect is very telling; Laurel, the old Corchorus, or Kerria as it is now called; Apples, Pears, Currants, full grown fruits, to say nothing of Strawberries, which is a most anomalous occurrence; but what has this year or some places have been taken regularly to table for a week or more. *H. M.*

Picea grandis and Lowii.—I am an amateur collector of Conifers, and am glad to see that the confusion in their names is attracting attention. I first made the acquaintance of Picea grandis in the nursery of Mr. Standish, of Ascot, who has a large and very healthy stock of it, and from whom I bought a specimen. I know it to be the same as Mr. Barron calls by that name, and I have seen it not uncommonly both in nurseries and in private collections, up to about 8 feet in height. There is a fine specimen at Dropmore, where Mr. Frost calls it amabilis, showing a very handsome true amabilis under the name of grandis. At Aldermaston Court, near Reading, there is a large group of it in one of the plantations in the park; the owner could not tell me where he got them, but believed that they were sent from a neighbouring nursery as Douglasii. I ascertained, however, that they did not come from that nursery, and failed to trace their origin. Mr. Standish has also a large and very handsome stock of the long-leaved Californian Picea, which he calls Lowii to which he assigns in his catalogue the synonyms of Parsonii and lasiocarpa. I bought specimens of this from him. About two years since Mr. James Dickson, of Chester, sent me several specimens under the name of grandis, which then seemed to me to be intermediate between the grandis and the Lowii of Mr. Standish. I believe them, however, to be the same as I already possessed as Lowii, but of less vigorous and robust growth. Now, let those who study Conifers, and have an opportunity of going to Kew Gardens, verify for themselves what I am going to state. I have been there to-day, and found, just behind the Museum, in a row of Conifers parallel to it, both the varieties which I have bought as grandis, and both labelled Picea grandis (Loudon), California. It would be treason to doubt the correctness of the naming at Kew, nor can I say that these trees are the two kinds generally known respectively as Picea Lowii, or lasiocarpa, and Picea grandis. In Brown's "Forester," 4th edition, just published, I find only one long-leaved Californian Picea mentioned, which is called Lowii, and the cones of it are said to be hardly distinguishable from those of grandis. I should therefore not be surprised to learn that, distinct as they appear at first sight, they are only varieties of the same tree. We know that great difference of habit and appearance may exist without characteristics sufficient to constitute a distinct species. For instance, I find that at Kew the Austrian Pine is labelled Pinus Laricio var. austriaca, and the Nordmann's Silver Fir, Picea pectinata var. Nordmanniana. With respect to the latter, I have often tried in vain to find a specific distinction when comparing the foliage with that of the common Silver Fir. Do I rightly understand Mr. Barron when I think he says that he possesses the only seedling tree in the kingdom of the so-called true grandis, from which I infer that all the many which are to be found in collections were raised by layers or cuttings from this specimen? If this is so, it need not be thought to lessen their value as ornamental trees. Even many of the species are prejudiced against Conifers raised from cuttings. The handsomest Douglasii at Dropmore, which stands by the drive to the western lodge, was raised by Mr. Frost from a cutting in 1827. It is now about 90 feet high, of beautiful proportions, and the finest specimen I have ever seen. Every admirer of the Fir tribe would like to have its photograph; and it deserves to receive a gold necklace and a guard of honour as a reward for its beauty, like the celebrated Plane tree near Sardis, upon which Xerxes bestowed that distinction. Of the confusion of names which prevails, readers might be tired if I will only mention one more. The British Columbian Hemlock Spruce appears in catalogues under at least four names, viz., Abies Mertensiana (by which it is called at Kew), Albertiana, taxifolia, and Williamsoni. *C. W. Dod, Eton, October 6.*

Recipe for Making Tomato Preserve.—Select firm green fruit, peel as thinly as possible, and to every pound of fruit allow 1 lb. of loaf sugar, 1 oz. of salt for an hour and a half, allow it to cool, tie down, and store away, as with any other preserve. Tomatos treated in this manner form an excellent preserve, and may be likened to ripe Figs, the seeds of the Tomatos bearing out still further the similitude. A doubtless there will remain a quantity of unripe Tomatos this season, perhaps this recipe may be of some use to your readers, which is my excuse for troubling you. *A. S. Kemp.*

Seaside Planting.—I see that your correspondent "S. J. A. S.," in giving a list of plants for seaside planting, has expressed a hope that other correspondents would add to it. Having a good deal of experience in such matters, I would suggest the Sea Buckthorn (Hippophae rhamnoides) as being at least as hardy as any plant mentioned in the list furnished by your correspondent, and far hardier than most of them. From my experience, it would appear to be entirely indifferent to exposure, and to prefer pure sea-sand to any other soil. It is apparently quite hardy, but I do not know if it can be had in any quantity from nurserymen in the neighbourhood of London, but know it can be got in any quantity from nurserymen near Edinburgh. I would also suggest the Whitethorn, Blackthorn, Ash, Birch, and Lime as excellent seaside trees to occupy a place in my knowledge there are Limes in an exposed situation forming dense bushes on their windward side, and thus affording excellent shelter to other trees. I cannot concur with your correspondent as to the hardihood of the common Yew in exposed situations, having found Scotch Fir rather surer; it is true that the latter is liable to be broken, but to my knowledge it grows and flourishes, though as a ragged tree, where the Scotch Fir has died out. *C. C. H. G.*

Leptosiphon roseus.—Your readers will, I hope, be duly grateful to your correspondent, Mr. Skelton, for his praiseworthy anxiety to protect them against my attempted imposition in connection with this annual. That the flowers may gradually lose their freshness of tint is no doubt possible, but I entirely deny that they do so to such a degree as to interfere with their utility as spring flowers, or render them open to the charge of being "dirty" in hue. I hope your correspondent may some day enjoy the vision of tumbling flowers, meanwhile he must, I fear, in common with all of us, be content with something less perfect and enduring. As I object to the fairness of Mr. Skelton's estimate, neither do I wish your readers to take mine unsupported. Here is an extract from a note just received from a veteran horticulturist, Mr. Atkins, of Painswick, who will, I trust, forgive me for publishing his unsolicited opinion without permission rather than lose a week:—"I quite agree with you as to the value of Leptosiphon roseus; it is one of the very best annuals we have had introduced for years. Many who saw mine were quite charmed with it." I could quote other testimonies to the same effect, but I think your readers will consider it needless. Time will show the real value of this annual, and I confidently appeal to that test. *W. Thompson, Ipswich.*

—— Mr. H. Skelton's remarks about the two new annuals, Leptosiphon roseus and Godetia Whitneyi, require no reply; nevertheless, I beg to observe that these two charming novelties have been grown here extensively, and have become general favourites. Both amateurs and connoisseurs consider them to be the finest introductions amongst annuals for several years past. *F. B., Erfurt.*

Twin Vegetable Marrow.—I take the liberty of sending herewith what appears to me to be a perfect specimen of a double (or twin) Vegetable Marrow, which I cut last week, from an ordinary plant growing in the garden at the rear of my house. I have shown it to several of my gardening acquaintances, all of whom agree that it is a novel production. *J. O. Williams.* [The appearance in question is by no means rare. It arises from the juxtaposition and union of two flower-buds, or from the forking of the originally single flower-stalk into two. Eds.]

The Potato Disease.—Mr. Hope in his communication (p. 1294) says he saved all his cattle during the rinderpest on the antiseptic treatment, and hopes to prevent the spread of the Potato disease by the same method. Could Mr. Hope manage to induce the Potato plant to swallow antiseptics like cattle, or to make them imbibe the healing powers of the fumes of sulphur in the circulation of the sap, he might then stand a chance of being successful with his treatment. The disease always appears first on the haulm of the Potato, and descends to the tubers at a certain stage of their growth, and to prevent this with antiseptic treatment seems to me to be impossible. In the experiments I made by potting Potato tubers with sulphur and chlorine gas, the apparently sound ones were mixed with the diseased on the shelves, to see if they would keep sound in the pits when stored. As I mentioned before, the Potato tubers not fumigated showed no greater loss than those operated upon, the ripening-growing varieties mentioned in the spring. After 26 years' studying and experimenting on a cure for the Potato mildew, I have arrived at the belief that planting the early and second early varieties for the main crop is the only chance of saving a sound crop in wet seasons like the present. If Potatos are ripe enough for lifting and storing by the end of July, they will escape any great loss from disease; and this I have experienced this year with some nice samples of Rivers' Royal Ashleaf, Myatt's Prolific, Mona's Pride, and the second early, Taylor's Fortyfold. Wider planting in the rows is likewise to be recommended to the ripening-growing varieties, and the avoiding of rich stimulating manures, especially on strong soils. This year I used for manure the old spent tan from the Pine-pits for all the early varieties of Potatos, and never had better crops, nor the tubers cleaner in the skin. No one will rejoice more than my friend Mr. Hope's being successful by his scientific mode of preventing the Potato disease from spreading, and although rather late in his investigation, he will gain all the more renown if he succeeds. *William Tillery, Wellbeck.*

—— The divergence of opinion respecting the Potato disease is certainly very remarkable, but I think if your correspondents would take the trouble to investigate the matter with the view of arriving at truth, and not jump to conclusions too readily, it would, doubtless, save much valuable time. In your edition of September 23, Mr. W. Hope says he is a thorough believer in the "germ theory," because he observed a Fungus growth upon some affected leaves. Of this I have no doubt, but it does not prove that Fungus occasioned the disease. Will Mr. Hope "be surprised to hear" that the disease has appeared equally bad in Potatos that have tubered under ground, without any appearance of haulm above? Ashleaf Kidneys are very prone to do this. Even when the haulm is apparently healthy, at a certain stage of growth, many diseased tubers will often be found. Mr. Hope goes on to speak of the *enjoyment* of what is known as antiseptic treatment—curing, pickling, salting, smoking,—which he recommends to be tried upon all Potatos after they are dug up, to preserve them from a disease which has already done its work. The *rationale* of all this appears very inconsistent, and is much like locking the stable door after the horse is stolen. All the curing and pickling in the world will not stay the disease before the Potatos are dug up. Your more recent correspondent (Mr. W. Tillery) falls into the same error in stating the disease to be atmospheric. It is well known that no state of the atmosphere has had any effect in preventing the disease, which is universal. The atmosphere cannot be the cause of the disease, though no doubt the destructive character of the disease is greatly influenced by it. Mr. Tillery recommends the raising of fresh seedling varieties as a means of staying the disease, forgetting that this has been done to an enormous extent, as the Potato lists, containing hundreds of names, will testify; and all, after a few seasons' trial, have become more or less diseased. If the real fact is accepted, that the disease cannot be traced to any preventible causes, and if, as I believe,

it is occasioned by "a withering or dying off of the cellular tissue and the vessels, with their contents," it would be much better by good and skilful cultivation to try and ameliorate the disease, rather than to be continually propounding useless remedies for its extinction. The soil in which the Potato is grown will be found to have considerable effect in determining its quality, therefore this should be considered of the very first importance; but, unfortunately, every soil, whether suitable or not, has been called into requisition to produce this ubiquitous esculent, and as a natural consequence a disease has been engendered, which will probably continue so long as such an injurious *modus operandi* is persevered in. *W. H. Rogers, Red Lodge Nursery, Southampton.*

Bedding Plants and Violet Hill Nosegay Pelargoniums.—As some growers find objection to the colour of the above Pelargonium, and a correspondent does not know what it will mix with to make a pretty bed, I give the following arrangement of a large circle planted here this season, which produced a charming effect:—Centre plant, Dracæna australis; next two rows, Centaurea ragusina compacta; then "two" of Iresine Lindeni, one row of Violet Hill Nosegay, two rows of Mrs. Pollock, one row of blue Lobelia, with an edging of Antennaria tomentosa. As a plant of great beauty and good habit to mix with gold and silver Tricolors, I would recommend Heliotrope Beauty of Jersey (a gem), dwarf and compact, most floriferous, of a rich violet-purple shade, Senecio argenteus has done well here, and will be a queen among bedders; also Achillea umbellata and A. ægyptiaca, the latter possessing more grace than the finest Centaureas, and of a like silvery appearance.

Coprosma Baueriana variegata is a charming thing, and will put in the shade Veronica Andersoni variegata. It can be used in the same way. *Wm. Scott, The Kilne Gardens, Falkirk, October 9.*

Water Weeds.—A very good way to remove water weeds from a lake, is to draw through it a piece of rope, or, better still, galvanised strained fencing wire, fastened to the ends of two boats or fishing-punts. Let the boats be about 20 feet, or more, apart, with the wire sunk about 2 feet under water; begin at one end of the lake, row or push the boats parallel with each other across, and after removing to the bank the weeds thus collected, take another drift back to the opposite side. A good many of the weeds will be found to be pulled up by the roots, and all the others broken off a good depth down. Continue crossing and recrossing till the lake is finished. If done about the middle or end of May, or the beginning of June, it would not require doing more than once a year. I think if W. B. tries this method he will find it answer well. With the aid of the swans, and this annual dredging, the surface of the lake will be kept clean, and the weeds, if carted to a spare corner, would ferment and make excellent manure. *Rustic.*

Orchard Cordons.—I notice your correspondent "Malus" says that "Mr. Robinson told us our market gardens would be covered with horizontal cordons trained to iron wires." I never said anything of the sort, but this—"It should be thoroughly understood that I do not recommend this system for orchard culture, or for the production of kinds and qualities of fruits that may be gathered profusely from naturally developed standard trees." A similar misrepresentation was made in a contemporary journal some time ago, also by an anonymous writer. Discussing the question with persons who write in this way is out of the question, but as such statements may mislead many persons who did not look carefully into the matter, I may state that the origin of the discussion in the gardening journals arose from my writing to the *Times* to caution the public against taking the advice of a person who wrote in that journal, advising the cordon system for field and market garden culture, stating that each acre only required 4,000 trees and so. *Wm. Robinson.*

Cool Orchids.—"After a storm, a calm;" so says the proverb. There has been a considerable storm among your correspondents, but as yet the calm seems prospective—very prospective, for the little squalls may again wax into a hurricane. However, according to "Ex-Cantab," "G. H." seems desirous of throwing oil upon the waters. Now, Mr. Editor, these above-named gentlemen have occupied a very considerable portion of your space, and I would now ask any one of your readers what results have been arrived at, what impressions have been left upon their minds? I confess I have been a somewhat inattentive reader—in fact, there always seemed to me to be much to read which was not always quite to the purpose, and I would suggest that tabulated temperatures of the rival Orchid-houses would have been quite as readable, and more easy to refer to. These questions of temperature are wide ones, and "wheedledum and tweedledee" may wrangle over their differences from now to doomsday without very materially narrowing them. It would seem to me that some hardworking botanical penman might well occupy his time in compiling an Encyclopædia of Orchids, giving in a tabulated form after each name the range of the plant, and the ascertained range of temperature, &c., through which each is found growing; a work which, could it be done, would probably show your correspondents how very many shifts they are perforce obliged to make in the matter of temperature. Some time ago I endeavoured to show that a given Orchid may well grow under the various temperatures in dispute, viz., cool and cooler (this appears to be the sum total of the correspondence), and if I do not encroach too much upon your space I will now append a Table of temperatures taken at Darjeeling, where I believe various Orchids are found. These observations have been taken at the Government Cinchona plantations, and are probably pretty correct. It will be seen that the mean temperature varies some 7° between the two altitudes given, and I doubt not that Orchids are found growing equally well under both circumstances. I am not able to append the rainfall, but I have understood that it is very considerable, being something like 130 or more inches at the upper, and 100 inches at the lower, station. I am disposed to think that such Orchids as grow upon rocks in subtropical climates or elevations require more heat than such as grow upon trees; these rocks are often exposed to the full glare of a tropical sun, and are either naturally of a dark colour or are blackened by the weather, they must consequently absorb much heat, which undoubtedly has an effect upon the plants. I have noticed that such plants are often very free flowering, provided they are sufficiently nourished by accumulations of vegetable matter; on the other hand, if they are insufficiently nourished they are scorched to death in dry seasons. I am not aware if it has been attempted to suspend cool Orchids on a wall out-of-doors in summer, it might well be tried.

TEMPERATURES AT DARJEELING.*

Months.	Altitude, 3300 feet.			Altitude, 2550 feet.

* A list of the Orchids growing here would be instructive perhaps they may be found in Dr. Hooker's "Himalayan Journal."
† The temperatures at the lower altitude are not given.

James McPherson.

Dimensions of Conifers.—I think I have seen in one of your late impressions a wish expressed to obtain the dimensions of Conifers in various parts of the kingdom. I therefore send you the measurements which I have taken of some that have been planted here between 1850 and 1860. When planted they were (with the exception of the Taxodium) small plants, from 6 inches to 2 feet in height.

	Height.		Circumference of Stock at base.		Extreme Diameter of Branches.	
	Ft.	In.	Ft.	In.	Ft.	In.
Wellingtonia gigantea* ..	28	4	8	11½	17	6

* Circumference of base has increased 10½ inches during last two years.—† About two or three years younger plant.—‡ Both have repeatedly lost their leaders.—§ Leader killed by early spring frosts for several consecutive years, but for the last three has been untouched.—‖ Seedling from a cone from the Douglas.—A Douglasii taxifolia, about 1853.—¶ Bought as grandis.—** Transplanted about four years since, and suffered much from the dry seasons since.

The latter is intensely blue and perfectly regular and dense in growth. This is by far the finest specimen I have ever seen (a seedling, purchased from Mr. Veitch, planted in 1860). P. grandis—well deserving is name at the Rev. G. T. Markers, Uffeslime, only 2 miles distant—here assumes the ragged character complained of by your correspondent, "C. F. P," from The Grange, Taunton, yet grows rapidly. I have tried, without success, to improve it by transplantation into other soil. Perhaps the fault may be in the health of the individual plant; we know all seedlings are not equally healthy. I have a much larger plant of P. nobilis, but it is a grafted plant, and, as such, I have not thought it worthy of record. I have a broad avenue of Wellingtonias, most of them nearly equal to the two mentioned above; one is certainly a finer plant than either of them in some respects. *J. W. Walrond, Bradfield, Cullompton.*

Veitch's Autumn Giant Cauliflower.—When in Dumfriesshire lately, Mr. Smith, gr. to W. S. Carruthers, Esq., of Dormont, near Lockerbie, showed me a stock of this Cauliflower, with which I was very highly pleased. He cut a head of it for me on Tuesday, October 3, which measured 13 inches in diameter and 34 inches in circumference, and which was in the best possible condition for the table. Like many more, I am often disgusted at the way we are taken in with new things, but I think it right to say that the merits of Veitch's Autumn Giant Cauliflower cannot be too widely known. *Thomas Methven, 15, Princes Street, Edinburgh.*

Notices of Books.

Culture of the Chrysanthemum, *as Practised in the Inner Temple Gardens, &c.* By John Newton, Gardener to the Honourable Society of the Inner Temple.

The culture of the Chrysanthemum in the Temple Gardens has gained well-deserved celebrity, which the author of this little treatise, who succeeds Mr. Broome in the superintendence of those of the Inner Temple, intimates it to be his intention to uphold. He gives us, in brief compass, and in plain language, a very readable account of the flower, its properties, and its culture, under the necessary heads. The instructions given seem to be in all cases trustworthy, and founded on practical knowledge. We notice that here, as sometimes elsewhere, the small-flowered Pompon Chrysanthemum is referred to as "the Pompon," as if that were a substantive name, whereas of course it is used in an adjective form, to indicate a particular group of Chrysanthemums, and refers to the knot-like or tufted character of the small and very double flowerheads of the plants to which it is applied. For the same reason the name of Pompon Rose, meaning a rosette or little Rose, is given to the old and almost forgotten, but very pretty Rose of Provence. At the back of the little Mr. Newton prints the following legend, having reference to the garden over which he watches:—"The Red and White Roses, the badges of the houses of York and Lancaster, are said to have had their origin in the Temple Garden, in the course of an animated conversation, approaching to a brawl, which took place on this spot between the Earls of Somerset, Suffolk, and Warwick; Richard Plantagenet, Vernon, and another lawyer. Plantagenet plucks a white Rose, and Somerset a red one, and Warwick thus prophesies:—

"This brawl to-day,
Grown to this faction in the Temple Garden,
Shall send, between the red Rose and the white,
A thousand souls to death and deadly night."

The Temple Garden was then famous for its Roses, as it is now for its Chrysanthemums."

Taplin's Practical Treatise on the Cultivation of the Onion (Houlston & Sons), is a little brochure, in part reprinted from our columns, explaining the means whereby the writer has attained great success in the culture of this useful bulb, and been frequently enabled to come off victorious at the exhibitions at Banbury, where Onion-growing appears to be made a speciality. Some of Mr. Taplin's points seem to be—to sow the first week in February, to thin with a knife, and to water freely, giving a good soaking of from 8s. to 10s. per week to a bed of 4 feet wide by about 9 yards by 6 yards; this quantity, even in showery weather, being given at least once a week. This is applied after the Onion shows a good strong stem and an indication of bulbing. The tops of the plants are to be kept upright by the use of straight props, about 2 feet long, inserted some distance from the bulbs, but leaning and pressing gently on the foliage, these props being moved as occasion may require. The seed Onions are to be placed on the ground, in a dry, cool room, when they will keep perfectly sound until planting time.

Florists' Flowers.

GLENNY, in his book on the culture of flowers and plants states:—"The RANUNCULUS was once one of the most favourite of florists' flowers, and has been produced nearer perfection than any other subject that we know of;" and yet it has to a great extent dropped from cultivation. There is hope in store for it, notwithstanding. Prizes were offered for it by the Metropolitan Floral Society during the past summer; and, though the competition was not large, there was in it the promise of something better. Even though the prizes were small in amount, it was a gain to get them offered, for the Ranunculus has been unrecognised by compilers of schedules of prizes for many years past.

The flowers produced in competition for the prizes of the Metropolitan Floral Society were wanting in those qualities of size and finish that were imparted to the flowers in times past by those who grew them specially for exhibition purposes in the days of their greatest popularity; still, they were charming and attractive, notwithstanding some deficiencies. It may be asked—Is there any chance of the Ranunculus

becoming as popular as it was wont to be 20 and 30 years ago? There is a chance, though it is at present only as the cloud of the size of a man's hand rising out of the ocean of neglect.

And yet the Ranunculus must be grown to some extent, too, after a certain fashion, if the annual importation of dried roots from Holland affords any criterion by which a conclusion can be reached. That large numbers are sold is an indisputable fact; how they fare would be an item of information of much interest for florists. Many who have attempted the cultivation of the Ranunculus have failed with it, because they did not give the proper attention in one respect or another. That they were struck by the undoubted beauty and symmetrical arrangement of the flowers was not to be wondered at, and this incited them to cultivate it. Its almost perfect form, richness, and great diversity of colours, awakened a desire to possess it, and some roots being obtained, were placed in the garden, without regard to the fitness of the soil or suitableness of position, and it was no wonder they perished, or if they bloomed, were little else than floricultural abortions. Such things as not having the soil properly prepared, planting too late to admit of a vigorous growth and a good head of bloom, planting in a wet and ill-drained situation, and such like—things apparently small in themselves—are important conditions nevertheless, upon the observance of which depends much of the success to be grown and to attain.

About four years ago, one of the prettiest sights to be seen at Kew, just as spring was gliding into summer, was a bed of Ranunculuses. They represented some of the ordinary double and, as they are termed, turban kinds, sold at the seed shops, but could be seen varying in hue from yellow, through crimson to dark; and it was amusing to stand by the bed listening to the comments made on its occupants by some of the folks the fine bright genial Saturday afternoon had brought from London, in order to take a walk about Kew. What Mr. Smith had done with his Ranunculus bed there is no knowing, as of being reproduced elsewhere, without much trouble or expense, and yet how seldom is the Ranunculus to be met with in our gardens.

The soil recommended by Ranunculus cultivators as the best for these favourite flowers, is one composed largely of cow-dung, which should be collected and stored away in a heap to get thoroughly decayed. Planting time varies according to the locality; generally the month of February is the one when cultivators plant their roots. With the Ranunculus, as with many other flowers, a generous treatment is a virtue that always brings its own reward, and so the old florists used to give it a sumptuous feast of fat things. In one of Mr. Carey Tyso's treatises he recommends the following compost:—"Decayed stable and cow dung, in equal quantities, constituting together about one-third, added to two-thirds of loam, will, when mixed thoroughly and incorporated, form a good soil for the main depth of the bed, reserving a portion of loam sufficient to make a top layer of soil, 2 inches deep, to which about half the above stated proportions of well-decomposed manure may be added. It is of importance that the tubers should not be placed in contact with fresh manure, as it engenders disease of the roots, and consequent injury to the plants." The work of preparing the bed was one of some moment with these men. As early in February as it could be done, the soil of the bed was dug out a depth of 18 inches, a foundation made of what was termed a stiff, sandy loam, or the "top spit of a pasture of rather heavy and tenacious but not clayey qualities, with the turf;" this was laid in a ridge, and frequently turned before being used. On the top of this would be a layer of the compost referred to, and the whole was covered with soil till the time arrived for planting the bed. Every advantage would be taken of the first fine weather, and the beds made ready for planting by levelling—a process followed by degrees, so as to allow the soil next to the sides of the beds to be well settled previous to planting. The beds having been levelled, and allowed to remain so for a few days, then planting commenced in favourable weather. Spring planting was the invariable rule, though some, as those in dry warm southern districts, would plant in October, contending that the plants had more time to vegetate and establish themselves. To the many, autumn planting was hazardous, so spring was the time selected. With some of the growers a certain depth at which to plant was as firmly believed in as any one article of their religious belief. One of these wrote as if he was the prime law-maker of the Medes and Persians:—"Keep in mind that it is of the utmost importance, to insure success in the cultivation of this most beautiful flower, that the tubers should be planted exactly 1½ inch below the surface." They observed this admonition as strictly as they did the planting of their Tulip beds on November 9. The same writer (none other than that fine old florist, Mr. Geo. Lightbody, of Falkirk) further stated:—"To insure success I have wood edges inclosing my beds, and to regulate the depth of the drills I use a piece of polished wood, the width of the bed, with notches cut the requisite depth at the ends—this also serves to mark the rows by gently pressing it on the surface. So soon as the row is marked, cut out the soil with a flat garden trowel, as near the required depth as possible, then by pressing the board into the drill till the notches rest on the wood edge, it will at once be seen whether the bottom of the drill is correct. Press the tubers gently into the soil until the crown is about level with the bottom, taking care not to break any of the claws. So soon as the row is planted return the soil and level it. The distance between the rows may be either 5 or 6 inches; and for a bed 4 feet wide, the number of roots in the row may be, of the strong-growing sorts 10 or 12, of the weaker varieties one or two more. When the bed is planted, look over it, and fill up any inequalities with dry soil, and make the surface quite level." If hard frosts set in during March, a few mats were thrown over the beds at night, to save the tubers from injury, but were taken off during the day if the weather was favourable. Worms had to be guarded against. These subterranean borers would occasionally, with a volcano of soil, send up a root, and that had to be planted again, and sometimes lime water was poured into their runs. Later on, as the leaves began to force their way through, the soil was loosened about the plants, and then on all occasions of fine sunny days there would be frequent stirrings of the surface soil to the depth of an inch or so. Then would follow the genial showers of April and May, the time of a florist's heart as a thumping legacy, and in default of showers there would be occasional waterings of the beds, for the Ranunculus relishes a moist soil, and especially while the flowerbeds are forming must there be no lack of moisture at the roots. Then came the period of blooming, the Ranunculus exhibitions, with all their attendant pleasures and pains, gains and losses, hopes and fears, till the bloom failed and the ripening period was reached. With the failing bloom comes the gradual decay of the foliage and the ripening of the roots. Then heavy rains were kept from the beds, and as soon as the foliage began to turn yellow the roots were lifted, as sometimes they would start into a second growth. It was the practice to remove some of the roots daily till all were gradually cleared away. When the roots were lifted, the flower stem was cut off just above the crown, the soil was shaken from around the roots, and then they were put away in a bag or drawer, in a cool airy place, to dry gradually.

In such a manner did the old growers follow out their mode of culture, and now, when an attempt is to be made to bring the Ranunculus once more to the fore, the publication of the details of the mode may be acceptable to many. Where a supply of varieties could be obtained cannot be so readily stated: doubtless lists of these will be forthcoming when a demand for collections arises. *R. D.*

Obituary.

WE have to record, with deep regret, the sudden death from apoplexy, at the age of 49, of Mr. FREDERICK WATERER, the senior partner in the well-known firm of John Waterer & Sons, of Bagshot, whose grand annual display of Rhododendrons has for so many years attracted and delighted the visitors to the garden of the Royal Botanic Society in the Regent's Park. Mr. Waterer, who was a man of robust constitution, retired to rest in his usual health on the evening of the 3d inst., and was found the next morning dead in his bed. He leaves behind him a widow and a large family of young children, by whom especially, as well as by his numerous friends, his loss will be severely felt. Mr. Waterer was an occasional contributor to our columns. We add the following from a correspondent:—

"'In the midst of life we are in death.' These solemn yet beautifully descriptive words must have been listened to with awe-stricken hearts by all those assembled round the grave of Frederick Waterer on Saturday last. On the previous Tuesday he was apparently the same strong man he had always been, and nobody who looked at him on that day would have believed they would never see again that vigorous body impelled by that energetic mind; but so it was. He retired on Tuesday evening, October 3, at his usual hours and seemingly in sound in health as he had ever been, and on Wednesday morning, instead of the robust man, a cold corpse was found. The shock to his family can be better imagined than described, and the manner in which their grief was shared by the whole village of Bagshot showed how well those among whom he had lived and laboured appreciated his many excellent qualities. Frederick Waterer was the eldest son of Mr. John Waterer, who brought the American Nurseries at Bagshot to their present position. He settled down to work early in life, as after a brief course of instruction in the various branches of his profession, by Fancourt at Messrs. Henderson's nursery, whither he had been sent on leaving school, he returned home and threw all his energy into his father's business. His aptitude and skill were quickly seen by his devotion to, and love of, his profession. One instance will suffice to show his extraordinary memory. He has been known to look at a seedling Rhododendron, not his own, and after the interval of three years to recognise it again, having never seen it in the meanwhile. In conjunction with his brothers, Michael and John, he carried on the business after his father's death in 1868, and on the retirement of Michael, Frederick and John shared the business between them. He was born in 1822, and was consequently 49 years old. He married Miss E. Rogers, daughter of the nurseryman of that name in Southampton, by whom he has left ten children, all of whom survive him."

—— We have also with deep regret to announce the death of another well-known nurseryman, Mr. ROBERT TAYLOR PINCE, the highly esteemed proprietor of the Exeter Nurseries, which took place at an early hour on October 9. The deceased gentleman, who was 67 years of age, had been an invalid for more than two years, and succumbed at last to an attack of hereditary gout. He was the son of Captain Pince, R.N., and being originally intended for the law, was articled to an attorney at Liverpool. But in his case Love, which we have poetical authority for saying "rules the camp," ruled, or rather overruled, the law; for during a visit to Devonshire he met the fair niece of the late Mr. Lucombe, the proprietor of the Exeter Nursery, and in due time married her. The young lady is said to have had an invincible dislike to the legal profession, and Mr. Pince in consequence resigned his prospects of distinction in that quarter, and joined his uncle in the pursuit of horticulture and floriculture. He followed his new vocation with all the energy and enthusiasm peculiar to his nature, and soon became an accomplished botanist. He added materially to the variety of the Exeter Nursery's collections by judicious hybridising of well-known species. When in the prime of life he took pride and pleasure in competing with provincial and metropolitan nurserymen for horticultural and floricultural prizes, and was remarkably successful. The Camellias, Rhododendrons, and Orchids of his firm obtained celebrity under his supervision. The Camellia-house in his grounds at Alphington is, perhaps, unrivalled in the kingdom. It is 200 feet long, and the plants in it have been cultivated to the dimensions of trees, producing myriads of blooms, thousands of which find their way annually into London drawing-rooms. During the latter half of his career Mr. Pince devoted his attention to landscape gardening, and in this branch of his pursuit was also eminently successful. He has left the mark of his superior taste and skill upon more than a park and garden in fair Devon. His last work, we believe, of this description, was the laying-out of the grounds at Marley. His labours were not confined to his own special pursuits. He was for many years Chairman of the St. Thomas Local Board, and to the energy which he brought to bear upon the management of the sanitary affairs of that district may be attributed much of the success that has attended the board's operations. Difficulties were to him only objects to be surmounted; and his perseverance and resolution were but intensified by obstacles and resistance. He originated the system for St. Thomas by which the sewage of the district is deodorised and converted into a profitable manure, thus avoiding the cost of a law-suit threatened by the railway company, and the construction of a sewer to Starcross. The plan of deodorisation by means of carbolic acid, adopted at St. Thomas, was also adopted by his advice at Bombay, and from the authorities there he received a cordial vote of thanks for his counsel and guidance. He retired from the St. Thomas Local Board, a year or two ago, with the regret of all the members, and with their hearty thanks for his valuable services. Hundreds can bear testimony to his generosity of disposition, and his numerous acts of kindness. It will be long indeed before his name is forgotten in St. Thomas, and it will never be mentioned without the respect due to a man who did his duty in his day and generation.

THE WEATHER.

STATE OF THE WEATHER AT BLACKHEATH, LONDON,
FOR THE WEEK ENDING WEDNESDAY, OCT. 11, 1871.

Oct. 5.—A fine day, with but few clouds till the afternoon, when the sky became overcast. Rain fell between 3 and 4 P.M.
— 6.—Generally cloudy throughout. A shower of rain fell in the afternoon.
— 7.—Variable in early morning. Overcast from 8 A.M. onwards. Rain fell frequently till noon.
— 8.—A comparatively cloudless day. Very fine.
— 9.—Generally cloudless till noon; variable afterwards. Very fine.
— 10.—Cloudless and fine in early morning; cloudy during the day, and again cloudless at night.
— 11.—Generally overcast till night; then cloudless. A few drops of rain fell occasionally.

JAMES GLAISHER.

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

Hedychiums, which, by the way, flower profusely when planted out into open conservatory borders, will now, where grown in pots, be showing symptoms of ripening, and should therefore be but sparingly supplied with water. As soon as the growths have ripened off, the pots should be removed to a cooler place, where the temperature averages about 53° only. Be very careful in applying water, and as much as possible avoid wetting the floors, stages, or other than the surfaces of the houses, especially during dull sunless weather. *Solanums*, of the scarlet-berried or Capsicastrum type, which have been grown in the open borders, should be immediately potted up and 'placed for a few days in a shady properly protected situation, eventually to be removed into a light warm corner of a cool greenhouse, where the berries formed may have an ample opportunity to ripen into their peculiar deep red tint. Batches of the very beautiful winter flower, *Schizostylis coccinea*, should also be "potted up." To this treatment they readily conform, and progress admirably, not showing the least symptoms of being checked. I may also remark that intermediate and other sorts of *Stocks* potted up now make a good display in the early spring. Be particular to place the several quaint forms of *Lachenalias* upon a light airy shelf during the present and future winter months, as it is only by aiding the leaves at this time, whilst growing up to maturity, that they in their turn are capable of developing the stores which furnish tall fine spikes of flowers. The beautiful *Schizanthus*, potted off into 60-sized pots, should be elevated on light shelves, there to be maintained through the long winter months. Where a sufficiency of glass exists, it will be well now to set a house apart for the flowering plants only. Here a nice, dry, intermediate temperature can be maintained, and the lasting qualities of each sort may thereby be materially developed. As regards bedding-plants, some of the tender kinds will now require to be maintained in this department; it will be necessary to keep the delicate kinds of Tricolor Pelargoniums in an intermediate and moderately dry temperature, especially when potted up late.

FORCING HOUSES.

The heating materials in *Pineries* and *Pine-pits* will now for a few weeks need even more watchfulness than usual, considering that in most instances additions have been made to the tan beds, and that the internal atmosphere is kept somewhat closer, and this with rather more artificial heat. I need not say how quickly roots are sometimes scorched, or how much may follow such an oversight as to permit the injury. The general treatment of *Vines* for the next few weeks must be regulated by the state of the weather. If the sun shines, the external atmosphere being warm and genial, let the heat rise freely (with proper air on) to something like its past maximum; otherwise, however, be particular to maintain the mean temperature by night as nearly as possible about 61°—63°. By so doing you readily neutralise the tendency which fine sunny days may have in inducing an unadvisable amount of growth at this particular season. Those *Vines* which are to be started next year, the pruning of which being completed, should have the stems painted over with a composition consisting of sulphur, soot, cowdung, and lime. Lay it on somewhat thick, so that it may adhere and form a moderate coating upon rods and spurs alike. In using fire-heat in houses containing Grapes which it is desirable to keep as long as possible, be particular not to over-heat the pipes, as to do so at this time is very likely to cause the berries to shrivel earlier than they otherwise would do. As I have before intimated, *Peach* and *Nectarine trees* intended to be started next month, must have all preliminary preparations completed quickly, so that everything may be in readiness to start at the required time. The trees must be started very gently, and therefore no time should be lost. Commence by simply keeping the house moderately close, without the assistance of fire-heat. See at once that the glass in structures where winter *Cucumbers* are grown, as well as all internal surfaces, are made scrupulously clean. Keep up a nice moderate heat only, both top and bottom, and accustom them to as much air as possible, so as to imbue them with all the hardihood possible at this season. Prepare beds in the usual manner for forcing *Asparagus*. Do this by turning the fermenting materials over several times, to insure that there will remain no future tendency to fluctuate.

HARDY FLOWER GARDEN.

Put into a cold frame, so fixed as to be handy for covering over completely with mats and other materials when sharp weather comes, all desirable kinds of *Shrubby Calceolarias*, dibbling them in in rows, and in the soil moderately firm around them. Prepare beds for *Pansies*, elevating them somewhat above the surrounding ground. Finish also planting such bulbs as previously suggested. Also pot up finally any *Piconies*, *Carnations*, superior *Pinks*, &c., which as yet remain still undisturbed; planting any excess which remains on to sheltered borders in sunny situations. Remove the now fading "bedding-plants," at the earliest time possible, and replant the beds or borders with the usual hardy annuals, biennials, &c., which consist of *Silene*, *Myosotis*, *Nemophilas*, *Collinsias*, *Clarkias*, *Antennaria tomentosa*, *Ajuga rubra variegata*, *A. orientalis*, variegated *Arabis*, *Stachys lanata*, *Golden Pyrethrum*, *Festuca glauca*, &c., all of which withstand the inclemency of our winters, and make a fine display in very early spring—especially when planted in combination with such spring bulbous plants as the Grand Duc, Lilac Queen, Scarlet Gem, or Citron Queen, single *Hyacinths*; the Rex Rubrorum, La Candeur, and double Duc Van Thol *Tulips*; with sundry *Crocuses*, Turkish *Ranunculuses*, *Scillas* bifolia and Sibirica, *Anemones*, *Narcissi*, *Snowdrops*, and winter *Aconites*, if you will,—all which tend so greatly to enliven the early garden, and to enhance to the full the charms of springtide.

KITCHEN GARDEN.

Gather up now the leaves of *Cardoons*, twisting a hay band around them, and finish them off by earthing up to their apices. The ground, which grew the *Cardoons*, should have a slope as possible, whereby to ward off the rains. Choose a fine dry period to mould-up *Celery*, according to the various stages it is in, in the matter of growth. As I have said before, this process should be done successionally, we have that the roots rot when maintained during the winter in a wet soil, which dung coverings tend to insure rather than the reverse. Autumn *Cauliflowers* which are "heading in" should now be regularly attended to in regard to "heading-in" the leaves, as a safeguard against frosts. It may be necessary very shortly to take up batches of Walcheren, or early winter *Snow's Broccoli* at a sign of a severe night; otherwise an early autumn frost might blight the best prospects. Where bracken can be had, a rare might be placed alongside, ready to cover them over as they grow, as soon as the first symptoms of frost occur. Make up the prepared materials for *Mushroom-beds* by placing them about 3 feet high, and in width according to the position to be occupied. Let the heap be lightened up, and remain for a day or so to ascertain if more violent heat is possible. Subsequently beat all down as firmly as possible, and spawn in a declining warmth of not more than 80°, otherwise there will be a risk of destroying the spawn before any advance is made. Look to and sort over Onion and Potato crops, both of which possess this season the germs of a latent disease. *W. E.*

Notices to Correspondents.

ALSTRŒMERIAS: *S. G.* These succeed in rich sandy loam, and their tuberous roots require to be planted rather deeply; hence you had better use 8 or 10-inch pots, in which some six or eight tubers may be planted, and as they produce buds from any part of their surface, it matters little how they are placed. The hardier kinds would do better in a deep, warm border of rich, dry, sandy soil, than in pots. If grown in pots, they should, like Lilies, Gloriosas, &c., be planted at once in order that they may come to bloom.

AMERICAN NURSERYMEN: *Inquirer*. You will find a full list in "Hogg's Horticultural Directory."

A TEMPORARY SKATING POND: *G. E.* would be obliged for a few hints respecting the following scheme for making a provision for skating. He says: "The area (about 4 acres) proposed to be acted upon is grass, and nearly level, there being not more than 4 inches of fall in any part. The ground is heavy clay, but well drained. Will one or two nights frost render the ground fit to carry sufficient water to cover the grass, which is short? Or will the temperature of the water from a reservoir, when turned on, thaw the ground, and allow the water to escape?"

BEDDING FUCHSIAS: *C. W. D.* The following varieties have been successfully grown this year in Hyde Park:—Dark: Prince of Orange, Prince Imperial; Light: Lady Heytesbury, Mrs. Marshall; and the following, which are also good sorts for beds:—light: Rose of Castille, Maid of Honour, Snowball, and Madame Cornelissen; dark: Marquis of Bristol, Sir Colin Campbell, Souvenir de Chiswick, and Prince of Orange.

CAMELLIAS: *D. E. C., Aberdeen*. White: Alba-plena, Alba Illustra; blush: Lady Hume's Blush, Jubilee; rose: Duc de Chartres, Henri Favre; pink: Storeyi, Wilderi; crimson: Bealii, Mathotiana; white striped with crimson or pink: Countess of Orkney, Madame Auguste Delaffli; or, crimson striped with white: Jacksoni, Queen of Denmark. The following are very fine, and, in addition to those already named, possess the qualities of form and habit required by our correspondent:—Arnoldiæ Augusta, dark crimson; Cup of Beauty, white, striped carmine; Etoile Polaire, white, striped rose; Grunelli, white; Palmeri, deep rose; Sacco novi, rosy pink.

CUMBERLAND *Subscriber, North*. None better than the true Telegraph (Rollisson's). What do you propose to use the gas-lime for?

CURRANTS: *A. B.* Of course they are "young" trees at the stage you refer to.

DIEFFENBACHIA: *Anxious Inquirer*. Probably the plant is too damp at the root, or is suffering from cold. It needs very little moisture now that it is going to rest, and should not be put in a stove heat.

EPIPHYLLUM: *D. H.* You are surely mistaken as to the "general practice" of grafting this plant on Euphorbia spinosa, and have been no doubt deceived by the mimetic appearance of some of the Cereus and Pereskias, and of the Euphorbias. We must have much better evidence before believing in such an union.

GRAPES: *W. T.* None will suit your purpose better than the Buchanan gooseberry.

MOUNTAIN ASH: *J. D. F.* The jelly prepared from Rowan berries is the proper sweet sauce for venison. The recipe you refer to is as follows:—Put the berries into a stone jar, and place cold water round them; boil to a pulp; strain the juice through a canvas bag. Then to every quart of juice add 2 lb. of sugar, make it boil, and let it boil for ten minutes.

NAMES OF PLANTS: *A. W., Peterkinhaugh*. 1, Lactarius deliciosus, edible; 2, Russula rubra, poisonous; 3, Agaricus rutilans; 4, Boletus badius; 5, Boletus luteus; 6, Agaricus prunulus, edible. The qualities of Agaricus ostreatus are not known to us. *W. G. S.*

NAMES OF PLANTS: *K. and S.* Blechnum cognatum. —*W. B. W.* 1, Asplenium marinum; 2, Adiantum Capillus-Veneris; 3, Asplenium flaccidum; 4, Pteris longifolia; 5, Pteris serrulata; 6, Diplazium lasiopteris. All but the last should thrive in a greenhouse temperature.—*R. M.* Tillandsia dianthoides of Rossi, the Anoplophytum dianthoidum of Lemaire. We should suppose it to be by no means a well-known plant; the only readily accessible botanical work to which we can refer you is "Regel's Gartenflora for 1854," in which a truthful figure occurs (tab. 87).—*A. Comstock, Campbell*. Xyphoncilium lutaceum of Sendtner (Solanum betaceum, Cav.). It is not a native of Madeira, but of Mexico, and not unfrequently fruits in this country, that is to say, in greenhouses. We do not know that is to say, in greenhouses. We do not know that is to say, in greenhouses. We do not know

have attained the length of 3 or 4 inches, and keep every shoot well exposed to the sun's influence. Then you may expect to have good fruit.

VINE PRUNING: *J. B., East Grinstead.* Our correspondent's suggestions on this subject referred only to those Vines which were fully ripened, as a consequence of early forcing. He would not dream of pruning Vines now, with the ground in a cool house.

VINES: *R. S. T.* Plant two Black Hamburgh and one Royal Muscadine; or, if you must have three varieties, let the other be Black Prince. We do not undertake to recommend dealers. Any nurseryman can supply them.

WHITETHORN: *T. Fry.* Transplant at once.

ERRATA.—In 1295 *b*, six lines from the bottom, for "smoked" read "scorched." P. 1295, in report of Royal Horticultural Society's general meeting, for "divided" read "derived;" and for "bran" read "brown." P. 1297, for exhibition of "Fungus" read "Fungi;" and in same par. for Agaricus "jumosus" read "fumosus."

Markets.

COVENT GARDEN.—Oct. 13.

Large arrivals of choice Pears are continually coming in from France, realising moderate rates for the season. New Brazil, Almond, and Barcelona Nuts are now coming forward—the season for them is a good one. Almeira Grapes are not so good this season as usual; fine samples are making about 1*s.* per cask, inferior about 28*s.* to 30*s.* Hothouse produce is now sufficient for the trade, and ordinary Apples and Pears are realising last quotations.

We have also had considerable arrivals of Nuts from Bari, Spain, and Portugal, being the average rate realised. Oporto Onions of choice quality, exceedingly fine, fetch 12*s.* per case, and new fresh Walnuts 5*s.* to 7*s.* per peck.

FRUIT.

	s. d.	*s. d.*
Apples, per ½ sieve	2 0 to 4 0

Coloured Drawings will shortly be ready, for 12 stamps, post free.

Descriptive Priced CATALOGUES free on application.

ORCHIDS. — Gentlemen interested in this class of Plants would do well to inspect our Establishment at Fairfield, and to judge of our mode of growing for themselves. The House we have recently erected, in which the plants are grown, continues to be constant in appearance, without any disadvantage to neatness in appearance, has therefore the admiration of every one, and exerts universal surprise that means so simple should have been so long neglected.

JAMES BROOKE AND CO., 16 and 18, Victoria Street, Manchester. Nurseries: Fairfield, near Manchester.

Winter and Spring Flowering Plants.

F. AND A. SMITH offer the following in strong healthy plants, suitable for decorative purposes :—

IMPORTANT SALE of about 2000 well-established POT ROSES, consisting of the best Tea-Scented and Hybrid Perpetual kinds for Forcing; also a quantity of valuable NURSERY STOCK.
MESSRS. PROTHEROE AND MORRIS will SELL by AUCTION, without reserve, on the Premises, The Hale Farm Nurseries, Tottenham, N. (adjoining the Great Eastern Railway, Cambridge Branch), on MONDAY, October 30, at 11 for 12 o'Clock precisely, by order of Mr. Thomas Ware (who is relinquishing the cultivation of Pot Roses in order to make room for his increasing stock of Perennials and Succulents), about 2000 choice TEA and other ROSES, in 48 to No. 16 pots, consisting principally of Devoniensis, Safrano, Madame Falcot, Mrs. Bosanquet, and the best varieties, strong established plants for Forcing: also a quantity of valuable NURSERY STOCK, comprising 1500 common Laurels, 3 to 5 feet; Euonymus, Green Hollies, Portugal Laurels, Privet, Box, &c.: a large quantity of fine standard and dwarf Roses, embracing the most approved varieties; selected Fruit Trees, a quantity of Stakes, 10 to 16 feet: Acer Negundo variegatum, Thorns, Sycamores, Laburnums, Maples, &c., Standard and Dwarf Roses, and other Stock.
May be viewed any day prior to the Sale. Catalogues may be had on the Premises, and of Protheroe and Morris, Leytonstone, E.
N.B. Frequent trains to South Tottenham from all stations on the Metropolitan Railway.

Sutton, Surrey.
IMPORTANT to NOBLEMEN, GENTLEMEN, NURSERYMEN, MARKET GARDENERS and Others.
MESSRS. PROTHEROE AND MORRIS have received instructions to SELL by AUCTION, on the Premises, The Grange, Sutton, Surrey, three minutes' walk from the Railway Station, on TUESDAY, October 31, at 12 for 12 o'Clock precisely, by order of the Proprietor, a large quantity of valuable and well-grown CONIFERS and EVERGREEN SHRUBS, fine STANDARD ROSES, choice TREES, &c.
Further particulars next week.

Tooting, S.W.
MESSRS. PROTHEROE AND MORRIS have received instructions from Mr. R. Parker to SELL by AUCTION, without reserve, on the Premises, Exotic Nursery, Tooting, near the Priory Station, on WEDNESDAY, November 1 and 2, at 12 o'Clock precisely each day, many thousands of first-class extra NURSERY STOCK.
Further particulars will shortly appear.

To Nurserymen and Others.
EXTENSIVE SALE of PLANTS, GLASS, &c. by CUPAR-FIFE, N.B., on MONDAY, DECEMBER 4, and TWO FOLLOWING DAYS.
TO BE EXPOSED to ROUP, on the above dates, in suitable Lots, the whole of the valuable STOCK in William Taylor's Nursery, Cupar-Fife, consisting of about Seven Acres of Eight Acres, consisting of FRUIT, FOREST, and ORNAMENTAL TREES and SHRUBS, HERBACEOUS PLANTS, &c., and about Six Tons of EARLY POTATOES, of sorts. This stock is particularly worthy of the attention of Nurserymen and Others.
The Sale will take place each day at 10 o'Clock forenoon, commencing on MONDAY with the Ladyloch Nursery, containing the larger and more valuable portion.
Catalogues may be had after November 1, free on application, to W. TAYLOR, Nurseryman, Cupar-Fife, N.B.; or to J. WELCH, Auctioneer, Cupar.—Cupar, October 2, 1871

Waresley Park, near St. Neots, Hunts.
EXTENSIVE SALE of PURE BRED SHORTHORN CATTLE.
MR. JOHN THORNTON will SELL by AUCTION, without reserve, on FRIDAY NEXT, October 20 (6 o'Clock), on the Farm, the whole of the PURE BRED SHORTHORNS, the property of the Hon. Col. Duncombe, M.P. It comprises between 60 and 70 head of Cows and Heifers, and young Bulls, many of which are many representatives of the Fame (Mr. Booth's), Pinella, and Countess tribes, the others descended from fine celebrated Cows, such as Mrs. Mossom's Duchess, Lady Eglé, and Dudding. The Sires have always been very superior bulls of high breeding, including Waresley Premium, Lord Oxford, and Colonel Kingscote's General Wetherby (24,026), and Windsor Lad (27,823), being the latest in use.
Catalogues, with Pedigrees, may be had of Mr. CHANDLER, Waresley Park; of Messrs. J. & J. JOHN THORNTON, 15, Langham Place, Regent Street, London, W.

Cattle.—The SHORTHORN HERD, belonging to R. Reynell, Esq., will be SOLD by Messrs. Sullivan, Kirkham, Co. Westmeath, Ireland, on TUESDAY, October 24, when a number of pure-bred HEREFORD BULLS, about 200 SHEEP, and several SUKSHIRE and other PIGS will also be offered.
Catalogues, with Pedigrees and particulars, may be had of JOHN THORNTON, 15, Langham Place, London, W.

THE BIRMINGHAM CATTLE and POULTRY SHOW, 1871.—The TWENTY-THIRD GREAT ANNUAL EXHIBITION of FAT CATTLE, SHEEP, PIGS, POULTRY, CORN, ROOTS, and IMPLEMENTS, will be held in Bingley Hall, Birmingham, on MONDAY, TUESDAY, WEDNESDAY, and THURSDAY, November 27, 28, 29, and 30, when SIXTY-FIVE PRIZES, amounting to TWELVE HUNDRED POUNDS will be awarded.
PRIZE LISTS, CERTIFICATES of ENTRY, and every information to be obtained from the Secretary.
The ENTRIES CLOSE on SATURDAY, October 28.
B. B. THALL, Secretary.
Offices, 39, New Street, Birmingham.

SMITHFIELD CLUB FAT CATTLE SHOW.—The ANNUAL EXHIBITION of FAT CATTLE, SHEEP, and PIGS, will be held at the AGRICULTURAL HALL, ISLINGTON, on MONDAY and TUESDAY, December 11 and 12, 1871.
Intending Exhibitors are requested to apply for Certificate Forms by the reference letters as under:—

CATTLE.—	For an OX or STEER (in any Class).	
	" B. For a COW or HEIFER (in any Class).	
	" C. For a Pen of THREE OXEN.	
SHEEP.	" D. For a Pen of three WETHERS.	
	" E. For a Pen of three EWES.	[Stock.
	" F. For a SINGLE WETHER SHEEP in Extra	
PIGS.	" G. For a Pen of three PIGS (in any Class).	
	" H. For a SINGLE PIG in Extra Stock.	

ENTRIES for LIVE STOCK CLOSE NOVEMBER 8.
Prize Lists, Certificates of Entry, and all information, may be obtained on application to Mr. DAVID FULLEN, Assistant-Secretary, at the Secretary's Office, Agricultural Hall, corner of Half-Moon Street, Piccadilly, London, W.
N.B. All communications respecting the Show must be addressed to the Assistant-Secretary, as above, and should bear outside the words "Smithfield Club Show."

The Agricultural Gazette.

SATURDAY, OCTOBER 14, 1871.

THE autumnal half of the year's volume of the AGRICULTURAL SOCIETY'S JOURNAL has appeared, with praiseworthy punctuality. The Wolverhampton meeting is reported in it fully. That portion of the report which relates to the implement trial is extremely well done; the remainder, which relates to the live stock show, is also a fair comment on the scanty notes which the judges of the various classes supply. After the report of the annual exhibition, that of the prize farms will probably be read with the most interest. The story is simply told, and the points which must have led the judges to their awards

described in an unpretentious manner. The farms, however, though described, are but little contrasted; and the reader will probably find some difficulty in appreciating the grounds on which the decision of their relative merits has rested.

We shall give the official reports from time to time in our columns, and to-day we also give our own report of the 2d prize farm, which had been written for us by Professor WRIGHTSON immediately after the Wolverhampton show. Both the farms were visited as soon as the decision was known. A short account of Mr. FORESTER's farm appeared indeed in this journal during the week of the meeting, but the second report was written under the express condition that it was not to be published till after the official report had appeared, and we have not been able, therefore, to let it appear till now. The remainder of the volume, though well filled, will hardly command the attention which these, its first and last, articles will receive.

Mr. J. DENT DENT, M.P., contributes a thoughtful review of the condition of the English agricultural labourer, compiled chiefly from the reports of the Commission appointed to inquire into the condition of the employment of women and children in agriculture. There is a very well written report on sewage farming, by Mr. H. J. LITTLE, of Thorpelands, Northampton; and Mr. EVERSHED contributes a good paper on market-gardening, from which it is probable that energetic farmers may learn as much as they can from the official account of the ordinary management which has been followed on the prize farms of the Wolverhampton district. Dr. VOELCKER's account of field experiments, and sundry veterinary contributions, make up the volume, which may be pronounced good, useful, and substantial reading—perhaps less seasoned than usual with that of very lively interest.

There is indeed one piece of almost "sensational" news in its pages, for which we have to thank two such sober-minded men as Mr. CAIRD, C.B., and Mr. NASMYTH, C.E. It is proposed, by the aid of a steam hammer or its equivalent, to waken up the nitrogen of the atmosphere! Any one who should succeed in inducing this mere diluent of the oxygen of the air to enter into such chemical union as to exhibits in ammonia or in the various nitric acid salts, would put into the hand of the farmer an exhaustless source of artificial fertility. It is known that nitric acid exists in the rain-water of a thunder shower, and believing that this may be owing to the influence upon the mixed nitrogen and oxygen of the air of the "violent percussive compression" produced by the passage of the lightning, Mr. NASMYTH thinks it possible by artificial means "to knock into combination the constituent elements of the atmosphere, and so produce a fertilising agent of the most potent efficacy from an inexhaustible source at home." He even contributes a sketch of the machine which may be able to effect this grand result. By its means "*x* tons" are to be lifted "*x* feet," and let fall upon a plug over and within a chamber whose air-contents will be thus violently compressed upon a sufficient quantity of lime to take up the nitric acid which may be formed. When we consider the small weight of air which in all probability is all that can be operated on at once, and the cost of lifting "*x* tons" for the operation it is to undergo, we fear there is not much chance of a profitable result from Mr. NASMYTH's experiment. It is, however, satisfactory to find more than one powerful mind engaged upon matters of agricultural interest, though at present entirely outside the circle of agricultural experience, and their thoughts conveyed to us in a volume, of whose contents it may be generally said that they are—almost to the extent of common-place—decidedly within the circle in question.

—— SOME few sales of English Wheat were made in Mark Lane on Monday, at a decline of 1*s.* per qr., a quantity remaining unsold at a late hour. The condition and quality varied considerably. On Wednesday the supplies were liberal, but prices experienced no further alteration —— At the Metropolitan Cattle Market on Monday trade in beasts was dull, and the prices of the previous Monday were realised with difficulty: for sheep, prices were not much altered, and choice calves were scarce and dear. Thursday's trade in beasts was dull, at Monday's figures.

—— The matter which seemed to engross most of the attention of Irish agriculturists last week was the TRANSFER of the "MARTIN ESTATES" in Connaught, from the Law Life Assurance Company to two enterprising English capitalists. The Irish daily papers are quite joyous over the expected Arcadia that is to be created in the wild district which was once held and maintained in almost regal state by the old Irish family. There can be little doubt that by judicious expenditure the gigantic undertaking may turn out to be one of the most profitable enterprises of modern times. The resources of the district have been completely undeveloped. The new proprietors will be aided by the spirited Midland Railway Company; and they have secured the services of an accomplished agriculturist. The whole of Ireland is in the transition state towards prosperity, so that every part of the present augurs well for success. The *Irish Times* thus describes the estate:—

"There are now on the property above 1600 tenants and a large number of labourers. The estate contains over 200,000 acres of every variety of land. There are the rich alluvial soil, the short, crisp, sheep pasture, the mountain sward, and the peat moss, both black and yellow. To superintend the extensive agricultural and drainage works contemplated, Professor BALDWIN has been engaged, and here he will possess an ample field for the display of that scientific skill and practical ability which rendered his services so extremely valuable to the Government.

"The estate is the largest in the British dominions held by individuals—the purchase money is enormous, the enterprise gigantic. The progress of this effort to improve and open up a magnificent but hitherto companionless wilderness, must be looked for by the subscribing interest. The country abounds with tarns, lakes, and rivers, teeming with salmon and trout. The mountains and heaths are the favourite haunts of game and wild fowl, and shooting lodges will be constructed in suitable places. The scenery is romantic, and the air unsurpassed for purity. The people are most orderly and courteous. We think that no long period will elapse before capitalists and sportsmen from all parts of the empire will seek the wilds and pastures, the lakes and rivers, of the ancient realm of Connemara, and, enjoying the loveliness of the region, become enamoured of the country of which it forms a part."

—— A letter from Mr. BIDDELL, of Lavenham Hall, has been published, in which he strongly recommends the Sugar-Beet industry to the attention of English farmers. After three years' experience, he gives an estimate of the total cost of the crop as amounting to £11 15*s.* per acre. The receipts are—for 15 tons of roots, £15; for tops, 7*s.*; total, £15 7*s.*; leaving a profit of £3 12*s.* per acre over and above the interest of capital. As to the state in which the land is left, he says, "I have grown Sugar-Beet side by side with Beans, and have not at present noticed any appreciable difference in the after crop." He recommends that the crop should take the place of Beans, having a tap-root of the ordinary breadth of roots. "To supersede white straw crops by Sugar-Beet would, I think, be a mistake; for assuming the fertility of the farm to be maintained by grazing, it would be a great inconvenience to diminish the quantity of straw grown. The conclusion to which I have arrived is that, where the farmer is situate within 2 miles of a Sugar-Beet factory, it will answer his purpose to grow from one-eighth to one-fourth of his arable land in Sugar-Beets, if he can obtain £1 per ton for them, and have the pulp back at 12*s.* per ton, which will amount to about 2 tons per acre. The land will be improved, if fed liberally with corn and cake, will in great measure replace the waste caused by removing so much produce from the farm." The effect upon the locality is intimated by the fact that the Beet costs in labour £1 per acre more than the crops which it displaces.

—— The letter of our correspondent, "Kboda Bux," on the TREATMENT OF CATTLE by the RAILWAY COMPANIES, will be read with interest. It can hardly fail of attention from the authorities of the Great Western Company, who are responsible for the experience it describes: and the history of suffering and injury which it relates must, one would think, lead them at once to direct the very obvious improvements and corrections which are at present needed in all that relates to their cattle train service.

OUR LIVE STOCK.

CATTLE.

Two very well bred young bulls have recently been consigned to Messrs. William & Frederick Fanning, of Woooroooolgen, Richmond River, New South Wales, near Sobraon. The first of these animals is WEAL LORD, calved September, 1870, bred by Mr. W. Torr, of Aylesby Manor; sire LORD NAPIER, dam *Weal Royal* by BOOTH ROYAL (15,673), and of the *Waterloo* by WATERLOO (2816) tribe. We have, therefore, in this bull that combination of Booth and Bates families which so often yields first-rate animals. His sire, LORD NAPIER, of the "Mantalini" tribe, was by Mr. Booth's RAVENSPUR (20,628), dam *Alpine* by BRITISH PRINCE (14,197), g.d. *Sylph* by HOPEWELL (10,332), &c. A yearling, daughter of *Alpine*, was sold at the late Mr. James's sale at Westland, August, 1871, for 750 gs. BOOTH ROYAL was by Mr. R. Booth's HOPEWELL, from Mr. J. Booth's *Gertrude*, of the "Bracelet" tribe, and his portrait is given in the 13th volume of Coates' Herd Book. BRITISH PRINCE and CROWN PRINCE were two of Mr. R. Booth's most noted bulls, and were the sires of the well-known Warlaby prize animals for many years. The "W" tribe of Shorthorns, descended from *Waterloo 3d*, bred by Mr. Bates at Kirklevington, has been in Mr. Torr's possession for a great number of years, and his herd at Aylesby Manor is considered the best large herd in Britain. He has hired the best Booth bulls bred at Warlaby, Killerby, and Westland, for more than a quarter of a century. *Weal Royal* is one of the handsomest cows in the Aylesby herd; a yearling heifer from her was sold to go to Canada for 200 gs., and *Warrior's Plume*, a cow of the same tribe, was sold by Mr. Torr two years ago to Mr. Beattie, of Ardoch, who exhibited her at the Shows of the Highland Society of Scotland and the Royal Agricultural Society of England, and at both places she won the 1st prizes. The second bull, NEWBURGH 3D, also a yearling, was bred by Sir G. O. Wombwell, of Newburgh Park, Easingwold, Yorkshire, and is by THE BARD (25,276), and out of *Georgina* by VESUVIUS (21,017). On a proof catalogue with which we are kindly favoured by Mr. Thornton an account of his successes and breeding is given, from which we abridge the following:—NEWBURGH 3D won the 1st prize in his class and silver cup as the best bull of any age at the Easingwold Show, 1871; the 1st prize of £25 as the best yearling bull, beating several noted winners, at the Great Yorkshire Society's meeting at York, in August, 1871, and the first premium at the Ryedale Show. He is full of the blood of the late Mr. Bates' Oxford tribe of Shorthorns, which always commanded high prices, and was used as a cross with the celebrated Duchess family. His sire, THE BARD, bred by Lord Feversham at Duncombe Park, was got by PHOTOGRAPH (20,492), dam *Barefoot* (prize heifer at the Royal Agricultural Society of England's meetings in 1862) by 5TH DUKE OF OXFORD (12,762), and *Snipe* by 5TH DUKE OF OXFORD (12,762), &c. PHOTOGRAPH was by SKYROCKET, a son of 5TH DUKE OF OXFORD, and CHANTICLEER was also by 5TH DUKE OF OXFORD, out of *China*, by Mr. Bates' 4TH DUKE OF YORK. SKYROCKET won the 1st prize at the Royal Agricultural Society's meeting at the Yorkshire Society's Show in 1862. NEWBURGH 3D's dam by VESUVIUS, who was by VICE CHANCELLOR, g.d. (a son of 5TH DUKE OF OXFORD) out of *Valetta* by 5TH DUKE OF OXFORD (12,762), &c. This 5TH DUKE OF OXFORD (by DUKE OF GLOSTER, out of a cow by the 4TH DUKE OF YORK) was bred by Earl Ducie, and sold when five months old for 300 gs. to Lord Feversham. He won the 1st prizes both at the meetings of the Royal Agricultural Society of England and at the Yorkshire Society in 1868.

—— The Waresley Park sale, which we mentioned three weeks since, takes place next Friday, under the direction of Mr. Thornton. The catalogue comprises 71 head, of which 47 are females. The herd contains representatives of several choice and well-known tribes, among which may be named the Fames, Countesses, and Finellas. The "Fame" tribe, bred originally by Mr. Booth, has produced CROWN PRINCE (10,687), HOPEWELL (10,332), HARBINGER (10,297), and many other celebrated animals; also Mr. Fullambe's *Lady's Slipper* and her noted descendants, Mr. Grove (Wood's) "Norman" family. The Countesses, bred on Tyneside, trace to stock in Northumberland, going directly back to Mr. Jobling's TRAVELLER (655), and the Finellas, bred from a cow by Mr. Bates' 3D DUKE OF NORTHUMBERLAND (3964), were originally a noted stock in Nottinghamshire. The other animals are bred from the herds belonging to Mr. Crawley, of Stockwood Park; Mr. Dudding, of Panton; the late Mr. Fawkes, of Farnley; and Mr. Stewart Majoribanks, of Bushey Grove. CLEVELAND LAD 3D (14,283), (son of 2D CLEVELAND LAD (10,569), g.s. GRAND DUKE), was one of the earliest bulls used at SYLVESTER, by a son of DUKE OF GLOUCESTER (11,382), came from Lord Feversham; and VOLUNTEER, bred from the Cobham Park herd, was by MARMADUKE, also a son of the old DUKE OF GLOUCESTER. Sons of these sires, bred from the best cows, have also been used, imparting to the herd a great similarity of character. The sires latest in service, or now in use, are Colonel Kingscote's GENERAL WETHERBY (lot 48), a son of 2D DUKE OF WETHERBY, bred by Captain Gunter from the prize cow *Duchess 7th*, and WINDSOR LAD (lot 49), from a cow by Colonel Towneley's ROYAL BUTTERFLY 5TH, and whose dam was by Mr. Booth's WINDSOR 2D. The animals are spoken of as exceedingly useful, as regular breeders, and good milkers.

—— Mr. Thornton sold the late Mr. Elias Clarke's herd on the 4th inst. The stock, which was of useful character, was brought out in good order. The top price, 50 gs., was given for *Serrate*, a 6-year-old, by Mr. Robarts. Mr. Beattie, of Scotland, also secured several animals of good families at low prices. An average of £26 10*s.* was realised over the 46 head offered for sale.

—— Mr. Angerstein's herd was dispersed by Mr. Thornton on the 3d inst. at Ashby Lodge, Rugby. The stock was principally collected from well-known herds. Thirty-seven head were sold at an average of £31 11*s.* 2*d.* Among the principal transactions were the following:—*Princess Patrick*, eight years old, 37 gs., W. Morley; *Blossom*, six years, 41 gs., A. Ashworth; *Pele*, three years, 41 gs., E. Worley; *Lady of Branches* and calf, 78 gs., Captain Senhouse; *Buxom Maid*, two years, 40 gs., E. Wortley; *Strawberry*, two years, 57 gs., Captain Senhouse; *Duchess*

of Hazlewood, 42 gs., J. Smith; *Princess*, yearling, 40 gs., W. Cropper; *Azalea*, yearling, 41 gs., S. Beattie. The bulls sold at-fair good prices, BRITISH VICTOR went for 32 gs., Mr. Nunneley; UTILITY, 40 gs., J. Riddey; and LORD OF BRANCHES, 43 gs., J. Smith.

LABOURERS' COTTAGES.

THE accompanying illustrations (fig. 298) represent a block of three cottages under one roof, and they have been contributed by Mr. Bailey Denton, jun., as an additional illustration of the advantages that may be obtained from the grouping together of cottages of varying accommodation.

It will doubtless be remembered that a block of three cottages is shown upon a preceding page (p. 1023) of this journal, in which two of the cottages were provided with three bedrooms, while the third had but two bedrooms. In this instance the amount of accommodation is reversed, for while the centre cottage has three bedrooms the cottage on each side of it has only two bedrooms.

That there is advantage in building a certain proportion of cottages with a diminished number of bedrooms, especially on large estates and in districts where cottage accommodation is plentiful, is obvious when we consider that the census returns show that where one family exists with parents and five children, there are two with three children and three with one child only, and a fraction more than two with no children at all. This is a state of things which perhaps is too much overlooked, and which proves that in many cases strict rules with regard to the number of bedrooms may be relaxed, to the benefit not only of our pockets but of the labourer himself.

In the present instance the object has been to reduce the cubical area afforded within the cottages, as far as is consistent with the provision of the requisite breathing space, and thereby to reduce the cost in equal ratio.

That this has been done will be seen by comparing the cubical contents of these cottages with preceding examples; they are as follows:—The centre cottage contains—in the living-room, 1200 ft. cube; in the scullery, 704 feet; in the pantry, 254 feet; in the fuel store, 136 feet; in the first or parents' bedroom, 877 feet; in the second bedroom, 670 feet; in the third bedroom, 630 feet; and in the porch, staircase, and landing, 713 feet cube. The two outside cottages each contain—in the living-rooms, 1186 feet cube; in the sculleries, 448 feet; in the parents' bedrooms, 942 feet; in the second bedrooms, 498 feet; and in the porches, staircases, closets, and landings, 858 feet cube each; making a total of 13,336 cubic feet altogether.

The average cost of the cottages, without any outbuildings, may be said to be about £118 each, or £354 for the block.

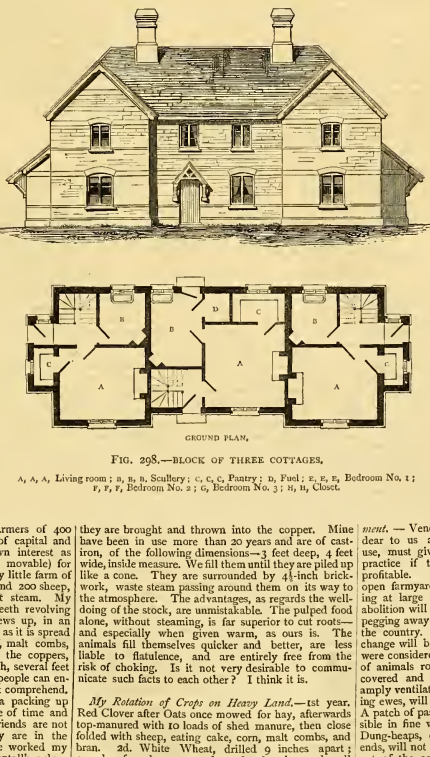

FIG. 298.—BLOCK OF THREE COTTAGES.

A, A, A, Living room; B, B, B, Scullery; C, C, C, Pantry; D, Fuel; E, E, E, Bedroom No. 1; F, F, F, Bedroom No. 2; G, Bedroom No. 3; H, H, Closet.

AGRICULTURAL NOTES.

BY MR. MECHI.

The Steam-driven Pulper, Chaff-cutter, Grinding Mill, &c.—It does astonish me exceedingly that farmers of 400 or 500 acres of land, having plenty of capital and live stock, are so blind to their own interest as to be without steam-power (fixed or movable) for the purposes of stock feeding. On my little farm of 170 acres, with some 20 or 30 bullocks and 200 sheep, I should be completely at sea without steam. My Bentall's pulper, with some 160 steel teeth revolving rapidly on an Archimedean screw, chews up, in an instant, a great Cabbage or Mangel, and as it is spread out, on comes a layer of steamed chaff, malt combs, bran and cake, piping hot, brought from the coppers, so that it ultimately forms a sandwich, several feet high, ready for Sunday's dinner. How people can endure anything slower than steam, I cannot comprehend. Then there is the "millering"—such a packing up and fetching back sacks of corn, waste of time and money, that I really think my farming friends are not half so sharp in these matters as they are in the matters of buying and selling. I have worked my fixed steam-engine for 24 years, and Bentall's pulper for 15 years, so I sent it to have 160 new teeth in. They were all put in mathematically true, and properly wedged up by machinery in about ten minutes. I should estimate the human labour to accomplish this at under *2d.* What a lesson for agriculture! When our teeth are worn down they won't bite properly, and so it is with the teeth of harrows and pulpers. Nothing like keeping everything sharp, including the mental or calculating faculties. Just start the riggers and down come showers of chaff, lots of broken cake, pulped food, water for stock, and all this while the great millstones are filling your sacks with bean meal and ground Oats for your horses and cattle. Even the grindstone is at your service, so your scythe or other tools may be always in proper order. Every young farmer should receive a steam education, if I may so call it, and no doubt he will, as the old folks die out. He will have grown up in a steam age, and not under the old slow-coach *régime* of dear hand and horse power. The cheapest arrangements for steamed food are some great cast-iron pans or coppers, deep and wide enough for a man or boy to stand in and mix up the baskets of chaff, malt combs, bran, and cake as they are brought and thrown into the copper. Mine have been in use more than 20 years and are of cast-iron, of the following dimensions—3 feet deep, 4 feet wide, inside measure. We fill them until they are piled up like a cone. They are surrounded by 4½-inch brick-work, waste steam passing around them on its way to the atmosphere. The advantages, as regards the well-doing of the stock, are unmistakable. The pulped food alone, without steaming, is far superior to cut roots—and especially when given warm, as ours is. The animals fill themselves quicker and better, are less liable to flatulence, and are entirely free from the risk of choking. Is it not very desirable to communicate such facts to each other? I think it is.

My Rotation of Crops on Heavy Land.—1st year. Red Clover after Oats once mowed for hay, afterwards top-manured with 10 loads of shed manure, then close folded with sheep, eating cake, corn, malt combs, and bran. 2d. White Wheat, drilled 9 inches apart; 4 pecks of seed per acre; horse-hoed twice, and well hand-hoed in spring. 3d. Rivett Wheat, same quantity of seed as white Wheat, but manured with 2 cwt. of Peruvian guano, and 1 cwt. of salt. 4th. Mangel; land broadshared after harvest; weeds, &c., harrowed and burned. Twenty-five loads of shed manure spread in October or November. Land trench-ploughed, two horses in front plough, followed in same track by iron plough (breast taken off), drawn by four strong horses. Land lies until early in April, then broadcasted with 3 cwt. of Peruvian guano and 2 cwt. of salt worked in, and Mangel seed drilled in rows at 28 inches from row to row. Time of drilling, April 15 to 20. Seed previously soaked in the wet sand for a few days. 5th. Wheat. Sow in November, with 2 cwt. of guano and 1 cwt. of salt. Land scarified after harvest; weeds and stubble collected and burned. 6th. Beans. Twelve loads of shed manure carted and spread, and land ploughed very deeply, with three horses abreast; drilled at 18-inch intervals,—the pressure put on the drill, so that the coulters should cut through the furrow slice, and deposit the Beans deeply in the solid subsoil. 7th. Wheat, either white or red, drilled in October or November, with 1 cwt. of guano, and 1 cwt. of salt, the Bean stubble having been cleaned, cross-ploughed, and then ploughed into form ready for the Wheat. 8th. Winter Tares. Wheat stubble scarified and cleaned, and 2 bush. of Tares drilled per acre. No manure applied. Tares cut in May and June, passed through the chaff-cutter, and given to horses and cattle; rest made into hay. 8A. Cattle Cabbage same year after Tares. Land heavily manured with 25 loads of shed manure, then deeply ploughed and trench-ploughed, same as for Mangel. Cabbages planted out at intervals of 28 inches, the lines being drawn by the drill. Cabbages consumed in early spring by ewes and lambs, and some pulped for the cattle. All, however, taken off the land. We generally have 2 or 3 acres of Cabbages planted in March, and consumed in September and October. 9th. Oats; 2 bush. per acre, drilled at 6-inch intervals, sown down with red Clover. Manure: 2 cwt. of guano and 1 cwt. salt. The Beans and Wheat, Mangel and Cabbage, are all horse-hoed with Garrett's patent horse-hoe, two or three times, and also hand-hoed. The knives are changed according to the width of drill. A man and pair of horses do 12 acres per day.

My Rotation on Light Land.—1st year. Red Clover mowed for hay and then fed as on the heavy land; sometimes manured after first cutting. 2d. Wheat. 3 cwt. salt sown early in spring. 3d. Barley (sown down with Italian Rye-grass); 2 cwt. guano, 3 cwt. of salt. 4th. Italian Rye-grass, well sewage-irrigated, and cut several times. 5th. Italian Rye-grass, fed and mowed. 6th. White Peas, sown in January, and picked green for London market. The Pea haulm removed to another field for making, and the land cleaned and sown with—6A. White Turnips, fed off, with cake, corn, &c. 7th. Wheat, sown in December, 2 cwt. salt in spring. 8th. Barley, sown with red Clover, and manured with 2 cwt. guano and 6 bush. of salt.

Reform in Live Stock Management. — Venerable agricultural customs, be they as dear to us as they may, by long indulgence and use, must give way to a more modern and different practice if the latter is proved to be the most profitable. I therefore predict that the days of open farmyards, exposed dung-heaps, and the roaming at large of farm animals, are numbered. Their abolition will be a long and big job, but we must keep pegging away for the individual and general good of the country. One of the great advantages of this change will be the removal of those great fences that were considered necessary for the better and safer restraint of animals roaming at large. Our cattle will be in covered and enclosed yards with paved floors, and amply ventilated roofs, and our sheep, including breeding ewes, will be fenced in with iron hurdles on wheels. A patch of pasture or Italian Rye-grass will be permissible in fine weather for our breeding cattle and sows. Dung-heaps, except an occasional one for odds and ends, will not be required, for the manure will be taken out of the covered and paved yards in a fit condition for spreading and ploughing, neither too wet nor too

dry. Cattle will never be without free access to water, and also to rock salt in the mangers. Their food will be composed of a considerable variety, intermixed and prepared, and seasoned with condiments. I use Simpson's Cattle Spice. The same remarks as to water and feeding will apply to sheep in the fold. When cattle are grazing they take much exercise, especially if the land is poor and the food sparse; but in the cattle shed they stand at the manger, fill the first stomach quickly, lie down, and ruminate, thus making the best use of their food. Animals will grow and fatten faster this way, and consume less food, than when roaming at large. They are more healthy, they lie on a warm and dry bed (for straw is a non-conductor of heat), in a well-ventilated shed, and they are free from those atmospheric changes, and dangerous lying on wet grass (damp sheets). They are infinitely less subject to death or disease under cover than roaming at large. This I have proved by 25 years of practical experience. At present we are rather in the dark as to causes of disease, but I have found when I did have any losses it was by animals exposed to atmospheric vicissitudes. The east wind, that blights our hedges with caterpillars, often produces disease in our sheep and cattle. Sheep should never feed off grass or Clover without cake, corn, or other food. The rot, or fluked liver, is prevented by giving to each sheep a pint or less of Barley daily, even when on pastures or meadows known as causing rot. Old short-woolled, broken-mouthed ewes will fatten rapidly in a warm, ventilated shed or stable, if fed on pulped roots, chaffed grass, cake, meal, &c.; but they might ramble a long while on poor pastures, in rainy or winter, without fattening. Old folks like warmth and shelter, and so do young ones in wet or cold weather. Long-woolled sheep can best withstand cold if the weather is dry and the ground not wet. Fatting sheep do well on sparred floors, or on burned clay ashes.

Beware of a Savage Stockman or Groom.—The losses arising from a severe or brutal treatment of animals is considerable, therefore quietly satisfy your mind as to the treatment the stock receive.

Straw for Thatching.—Never, if you can help it, use new, reedy wheat straw for thatching. Thatchers will tell you that new straw will fix very badly between the circular glassy sides of the straw; but old wheat straw is squeezed flat, and often split, by pressure in the stack, so that it forms a compact and safe covering. I always thatch all my straw, and have a handy parcel of old straw for thatching. Many farmers had their stacks unthatched on September 29, after a week's heavy rain, because they had no old straw, and have not yet threshed any corn. Straw stacks are too often left to rot unthatched.

Tiptree Hall Farm (see p. 1209).—Good Mr. Fish, in his zeal, has greatly over-valued both my laud and my exertions. As to honours, all I desire is the honour of having been useful to the agriculture of my country. *J. T. Mechi, October.*

TREATMENT OF CATTLE BY RAILWAY COMPANIES.

When a person has a grievance, the fashion is to write to the *Times*. I prefer writing to you, simply because the *Times* are in some way connected with agriculture, and the grievance I am about to complain of affects them, as it has affected me. My cause of complaint is the treatment of cattle by railway companies. I shall simply state facts, and leave your readers to draw their own conclusions as to whether Mr. Mechi's duty on occasions of this kind is called into requisition in the matter of the treatment of cattle whilst in the hands of the railway companies for the purpose of transit.

Feeling the force of Mr. Mechi's remark, that the more cattle the more meat, and the more meat the more corn, I determined to stock my small farm; and having been recommended to try Bristol market, accompanied by my bailiff, I went there, and purchased, on the 25th of last month, a lot of Irish Shorthorns—about 30, and finer animals never cast eyes on; and although they had, owing to strong head-winds in crossing from Ireland, been 12 or 14 hours longer on the voyage than usual, they were as fresh as could be desired. For these animals I paid in the Bristol market £700. They were driven immediately to the cattle wharf of the Great Western Railway, where they arrived a little after 9 in the morning. On bespeaking trucks for Salisbury, I was told the cattle would be trucked at 7 P.M., and remain in the trucks until 3 A.M. next morning, when they would arrive at Salisbury at 8 the same day.

Whilst standing at the cattle wharf I saw a number of sheep, pigs, and cattle trucked: all of them were said to be for Reading or London. They received dispatch within a reasonable time. The unfortunate purchasers residing on branch lines, like Salisbury, had to leave their cattle in the so-called pens provided by the railway company for the receipt of stock. I do not hesitate to say that the pens are a disgrace to civilisation; a simple strip of ground, the site of an old quarry, up and down, in parts too steep for an animal to stand comfortably, uncovered, undrained, and, when I saw them, 2 or 3 inches deep with sludge. Such is the accommodation afforded by the railway company for cattle to be detained for their convenience a whole day and the best part of the night. Having luckily taken the precaution to leave my bailiff with the cattle, I started on my journey homewards, some 20 miles west of Southampton. At Salisbury I discovered that my unfortunate beasts would be retrucked at Salisbury at 2 P.M. next day, sent on to Southampton, where they would remain a night, and go on to their destination (a few miles east of Southampton) next morning, reaching it about 8 A.M.; the total distance from Bristol being rather less than 90 miles, involving 48 hours from time of delivery to railway. On my arrival at Bishopstoke I was accosted by a salesman, who asked me whether I was the gentleman who had purchased a lot of fine beasts which he saw in the railway pens; my answering in the affirmative, he expressed a hope that I had left some one to take care of them, as he would wager two to one that the animals would never leave Bristol before Saturday morning; that he and others had been served that way at Bristol, and that one of his friends had shortly previously lost a bullock, which from exhaustion had fallen down in the truck and been trodden to death by the others. That the animals were so knocked about with the everlasting shuntings and joltings, by reason of the trucks never being properly screwed up, and fatigued with the day, that for his part he would never send by rail but road by easy stages. Feeling uneasy ater what he told me, in the place of going home I returned next morning to Salisbury, and on arrival there, at 10 A.M., I discovered that my animals had never left Bristol on the Friday morning, and that they would have to stay until the following morning; and as I found that if I sent them *viâ* Southampton I should not get them until Monday morning, I gave instructions by telegraph to my bailiff to truck them only to Romsey, and road them some 16 miles across country to their destination. Personally I make no complaint of a single railway official; they were simply the servants of a vicious system. To cut a long story short, I got my animals home on Monday afternoon, by no means in the state in which I delivered them to the railway; and had not my bailiff found a field a little out of Bristol, into which he put them on Thursday afternoon, and kept them until trucked on the Friday evening, I believe I should have scarcely had one beast alive. Had I left my beasts, as others did, to be forwarded by the rail in the way the railway company forward them in their course of business, my animals would have arrived. The failure to truck them on the Friday morning would have involved their delay from Saturday evening to Monday morning in Southampton, had I "railed" them to the station nearest my home. My bailiff informs me that when he delivered them on the Friday evening into the trucks, the animals were as fresh as he could wish, and that they had quite recovered from the effects of their voyage during the 24 hours they were at grass—that when he saw them at Salisbury he could not believe them to be the same animals. The continual shunting and knocking about had taken all the bloom off them; two heifers had fallen, or laid down; one nearly killed (certainly damaged to the extent of £5); the other much knocked about. On Saturday afternoon my bailiff walked them about three miles out of Romsey, and turned them into a meadow for 24 hours, and then marched them about six miles on the Sunday, when he gave them another rest for the night, and the next day brought them about seven miles home, but in very different condition from what they were when driven out of Bristol market. They are now doing well in a sheltered meadow, but I shall not be surprised if the price we now can buy them at be finally delivered to the Great Western Railway at Bristol. Such are the plain facts. If it should be asked, "Why parade my woes in the columns of your journal; my answer is that what has happened to me may happen to others less able to run the risk I have done, that what has happened to me need not happen if the railway companies performed their duties to the public, as they are morally, if not legally, bound to do. It would pay a railway company well to have proper accommodation for the benefit of cattle at their markets, and to charge a fair price per head for it, for one, and I have no doubt buyers of stock generally, would willingly pay it. They might have sufficient wharfage frontage for trucking at once without those innumerable shuntings, the trucks loosely linked together, jerking the very souls out of the bodies of the poor beasts at least a dozen times before departure, and they might so arrange their trains that animals were not kept nine hours penned in a truck exposed to the weather. Corresponding lines might also manage their times for goods and cattle trucks, so as not to keep animals waiting six or eight hours before they were forwarded. At all events, if they do, they ought to have accommodation for feeding the cattle during such detention. All these things they might reasonably do, and do them they would if they studied their own interests. Such are what railway companies might do.

Nothing, however, can justify a railway company, professing to carry cattle, and knowing the average requirements for each market day at Bristol, not having sufficient cattle-trucks for the day, and not having proper lairs for the reception of animals. If there be on the direction of the Great Western Railway any gentleman who, like myself, feeds a number of beasts, if he would only go to Bristol *incog.* and see what goes on there, I am certain he would never trust a beast of his own to the care of his railway.

As I am a humble follower of Mr. Mechi, and a devout believer in the creed of "More cattle more beef, and more beef more corn," I am compelled to buy my beasts where I can have a pick from a number of those best suited to make meat and manure. I have visited several fairs, and never had so good a choice as I saw in Bristol market. To Bristol market I shall go again, and, provided there be no foot-and-mouth disease, I shall "road" them the whole way by easy stages of 8 or 10 miles a day, leaving them in green fields at least 8 out of the 24 hours. It may cost me more in the first instance, but I shall have the only the satisfaction of knowing that my poor beasts are not tortured, but also of finding them at least £1 a-head in better condition than if sent by rail. One swallow does not make a summer, nor is the withdrawal of the traffic of one animal sufficient to cause the Great Western to relinquish their carriage of cattle. As I have shown, I am by no means the only one who has cause of complaint; possibly the publication of this letter may bring to the front others who have suffered in like manner; under any circumstances it will be a warning to others never to leave their stock until they see them trucked and despatched, and if they have to go over another line on a different gauge, to attend and see them retrucked and dispatched, or they may find their cattle damaged.

The noble-minded Baroness Burdett Coutts has tried to do much for the unfortunate in connection with the tender mercies of railway companies. In some things she has succeeded, but much requires to be done. All attempts to feed in a railway carriage have failed; the animals will not eat. There is nothing, however, to prevent railway companies, if cattle must be detained to carry on the ordinary traffic of the rail, to detain them in sideways in country places, and to have accommodation land close at hand, charging for the same; and in a place like Bristol, with such a large and increasing cattle market, and the improbability of getting sufficient accommodation immediately about the town, common sense would suggest the establishing a station a mile or two out of town, and in the vicinity of green fields. Whether common sense, or even common humanity, will prevail is doubtful, until public opinion is strongly directed against the present system. I send you my name and address and subscribe myself as heretofore, *Woola Bee.*

HEADS.

By Henry Corbett.

"From the cradle to the grave, in all conditions and ages, throughout all nations, from Adam to the last existing man, from the worm we tread on to the most sublime of philosophers, physiognomy is the origin of all we do and suffer."—Lavater.

At a dinner-table one evening at the Farmer's Club, a discussion incidentally arose as to the chief points to be taken into consideration in judging an animal; when there was a very unanimous opinion in favour of heads and shoulders. Narrowing the argument, again, to any one particular point to go by, there was a decided majority amongst the latter or so of us, who joined in the conversation, in favour of heads. The shoulder, no doubt, answers very much for shape and symmetry of frame, but the head answers for everything. If you go for breed, you look above all to the head; if your aim be style or fashion, you must seek it in the head as one time in the first very accomodating phrase known as quality should prove itself by a good head. You get at the very purpose of an animal by a look at his head. The calm placid countenance of a naturally thriving beast; the noble, masculine, well-defined features of a sire of any character; the several uses of the horse, the instincts of the dog, and the mere gluttony of the pig, how safely you may arrive at a conclusion by studying the head. A scale of points for one or two certain breeds has already been drawn out; but, in none of these is sufficient importance, at least as I am bold to think, attached to the head of an animal, for the main index to his purity of blood, strength of constitution, and actual fitness for that service for which he is intended. Who would take to himself a bull with a mean, delicate, "cowy" head? And yet I have seen such distinguished in a Royal show-ring. Who would crave for his own riding the sour-visaged, vicious-eyed hack? Or care to breed, or try to breed from the steery-looking heifer, which has lost the very semblance of her sex, from the misdirected zeal employed in feeding her up for show? A man may save himself a deal of money, trouble and disappointment, by making the head a first principle in establishing a flock or starting a herd.

So strongly have I felt the necessity for more attention being given to this matter, that I have during the last year or so made it my business to collect from some of the best authorities, either as breeders or judges, as it were, a standard series of heads, with the why and the wherefore any one feature should be regarded as an excellence, or another rejected as a drawback. In doing so, it may be as well to observe the herald's order of precedence, and in bringing under review the several breeds or varieties of stock, to begin with that citizen of the world, the Shorthorn. Mr. Booth, of Warlaby, we are told, "attached much importance to the heads of his animals." Conforming, as regards cows, to the

popular opinion that they should be moderately small and tapering, he contended that the bull should not only be broad across the brows, but with a lusty horn, especially stout at the base. Mr. Booth would not use a bull in which these substantial evidences, as he regarded them, of vigorous constitution and procreative power were wanting. And, indeed, sound physiology teaches that the more or less luxurious growth of the horn is the result of constitutional operations. The marked influence of ill-health or castration on the growth of the horn, is sufficient proof of this. That the use of sires exhibiting these indications of a masculine character has no influence on the female progeny prejudicial to their feminine men and character, a glance at the Warlaby cows will show us will suffice. They are remarkable for their lady-like aspect, and graceful well curved waxy horns; those inextinguishable tell-tales of some otherwise unsuspected jump *in* the dark *out of* the dark—inky horns and dingy noses being unknown amongst any of the leading families at Warlaby. The mild, prominent eye is expressive of that equable contented temperament so favourable to the attainment of ripe condition; a tendency further indicated by the double chin-like appendages of pendulous fat beneath the root of the tongue, which, however objected to by some admirers of the horse-like conformation of the head, gives, in the opinion of others, an engaging piquancy of expression, and is always regarded approvingly by the knowing grazier as an earnest of aptitude for kindly feeding. So say the records of Killerby and Warlaby, while this description may be supplemented by something more in detail.

The head of a Shorthorn bull should be broad and moderately lengthy, with a full open countenance, a large prominent eye, and plenty of width between the horns, where there should be a good covering of hair. The horns themselves must be strong and slightly backward with a very gentle inclination of the tips, positively upright horns being the worst of all kinds. From being broad above, the head should taper gradually towards the nose, but not too decisively, as nothing is worse than a bull with an "egg-sacking" frontispiece, as a breeder would say, and the nostrils should be open to be of a clear cream or flesh-colour. Writing, a quarter of a century since, Mr. Wright says of the Shorthorn's head, that "some prefer it to be long and lean, whilst others approve of its being thick and short;" but the long and lean head for a Shorthorn would never do in these days. Mr. Day, speaking to the point of the famous Durham ox, says, "the head was rather long and the muzzle fine, eyes bright and prominent, with the ears long and thin." According to the print the head of the Durham ox, although refined and highbred, is too much and out of date even for a steer, that is, to pass muster in these times.

But the perfection of the improved Shorthorn's head is to be found in the female. The very expression, so calm, so sweet, and so dignified, is of itself a delightful "study;" and when old Homer, in the way of compliment, applied to a countenance of the highest type, ox-eyed, to his matron goddess, he must have drawn upon the future, and have pictured to himself the noble, self-assured, full blown beauty of one of our modern "Duchesses." The tranquil beaming eye, so full, so mild, and yet so prominent, the fairly broad forehead, running down in that graceful line to the muzzle, where we drop the goddess or we shall have Jupiter resuming his masquerade, intent on the conquest of another Europa. The horns of the Shorthorn cow should, then, be slightly curved and spreading, bright and clear in complexion, with a loving, tapering tip; the muzzle wide, with the ears large, and fringed with that fine delicate hair, "only to be found," according to an enthusiast, "on a pure-bred Shorthorn." Still, good though the head may be, this loses nearly all its fascination if it be not properly set on. It should run elegantly into the somewhat full, firm neck, with plenty of play and style in its carriage. Any animal which droops its head in a half-guilty, hang-dog fashion, can never show to thorough advantage, and, of the two, it would be better to have them as the dandy described his partner in the quadrille, "with the head bustled up like a four-in-hand leader." But the naturally, nicely-arched neck is the thing to go for, be it in a woman, a heifer, or a horse. That cute observer Sam Slick felt this when he was fastening the hooks and eyes, "I never see such a neck since I was raised. It sprung right out o' the breast and shoulder, full and round, and then tapered up to the head like a swan's."

There are cerain Shorthorn tribes or herds that have always been known for good heads. Noticeably enough, although fed terribly high for exhibition, the Athelstanford heifers never lost their beautiful expression of countenance, and Rose of something's head was thought to be nearly perfect. I had opportunity of seeing a great deal of these animals for a season or two, occasionally crossing with them as they went the rounds of the national meetings, from England back again to Scotland, or over to Ireland. And there they have demonstrated at Towneley, the Barmpton Roses throw handsome and blood-like heads, and the Hertforth Cherries, as I am assured, were a family renowned for the grandest heads, which came very beautiful and highbred, with a certain whiteness of the eye, very "taking" in its way. Old Cherry was the dam of Gainford, and Gainford was the sire of all Mr. Crofton's best stock. *Bath and West of England, &c., Society's Journal.*

(*To be Continued.*)

THE PRIZE FARMS.

[The following report on the Second Prize Farm was drawn up for this Journal, immediately after the Wolverhampton show, by Professor Wrightson, who was, however, not allowed to publish it till the official report had appeared.]

FOUR-AND-A-HALF miles north of Lichfield, and nine miles west of Burton-on-Trent, lies Alrewas Hays, the property of Lord Lichfield, and in the occupation of Mr. Thomas Winterton—the 2d prize farm in the recent competition between the two counties of Shropshire and Staffordshire. Having seen both the first and second prize farms, we confess to a sense of thankfulness that the decision, as to which was really the best, was not left to us. The exterior in both cases is highly prepossessing, but the judges had opportunities for investigating the results of the two managements, as to profits, which, of course, are not open to ordinary visitors. We may be permitted, however, before giving a short account of the management of the second prize farm, to contrast its appearance and management with that of Mr. Forester's 1st prize farm. Mr. Forester's occupation is smaller, and the soil is of better natural quality. Both are, we should say, easy working farms, although the heavier land will be found at Sherlowe. On both farms, also, the arable land is in better condition, and appears more suited to its purpose, than the grass land. Fences are very neat in both cases, but Mr. Forester has had the advantage of a residence of above 30 years, during which term he has devoted much attention to the department. Mr. Winterton's fences, having been only under his supervision for 16 years, are scarcely so good. So far as root cultivation goes, the 1st prize farm is the best; the Wheat crop is decidedly better on the 2d prize farm, and the Barley is a shade heavier, and is certainly more even down upon the barleys, than upon Alrewas Hays. In live stock we must also give the first place to the first prize farm, for its really good and uniform stock of Hereford cattle and Shropshire sheep. The 2d prize farm cannot boast such a breeding stock, which, of course, even here, the profit might easily lie on the side of the business-like grazier of Alrewas Hays.

We were very kindly received and hospitably entertained by Mr. Winterton, and, although time was limited, we were "all round," and saw and heard as much as we could. Magnificent crops, good fat cattle, fences, clean land, thriving root crops, healthy, lazy cattle, and sheep between nets and hurdles, on Vetches and corn, with salt provided; luxuriant water meadows, which do much for the farm; a perennial flow of water which "makes the farm," and useful buildings;—such are the impressions reflected on the retina in leaving the Alrewas Hays. There was nothing offensive or slovenly, but all bespoke intelligent and continual supervision.

We must, however, enter a little more into detail. Alrewas Hays is 253 acres in extent, of which 145 acres are permanent pasture. It is let from year to year, and has been in the occupation of Mr. Winterton for 16 years. The land is variable in quality, much of it being light, black, and peaty, abounding in round water-worn stones, and apparently, though light, readily worked with inconvenient tenacity. Much of this is underlaid with "Fox-bench," a term which appears to be synonymous with "pan," and relates to a hard concretionary mass of earth and stones at some few inches beneath the surface. Other of the land on this farm is of stronger character, and is cropped in a different manner. The cropping of the farm also varies with the land. On the lighter portion Turnips are followed with Barley, seeded down for two years, and then broken up for Wheat, which is followed with Barley or Oats. On the heavier portion the cropping is as follows:—Swedes and Turnips, Barley or spring Wheat, seeds, seeds, Oats, Wheat.

In glancing briefly at the management of this farm, we shall first make a few remarks on the cultivation of the crops, and afterwards upon the stock, management of labour, &c. In describing the detail of cultivation and management, we propose to treat the crops commencing "roots," of which there are usually 72 acres; 40 or 50 acres are Swedes, 5 to 6 are Mangel, and the remainder white Turnips and Cabbages. The cultivation of roots consists in autumn cultivation with steam or horses, both means being used. The land is left as rough as possible, is cultivated with horses in the spring, say in March; 10 loads per acre of good manure are carted on and ploughed in at the latter end of April. It is also worthy of notice that on both the 1st and 2d prize farms and in the neighbourhood around, it is the custom to sow the artificial manure used for the root crop broadcast, either before ploughing for the last time or before ridging-up, as in the case of Mr. Forester's land. Knowing the importance which is attached in many districts to the drilling of manure with the seed, and thus securing it under the plant, it is interesting to find the habit of broadcasting manures followed by farmers of such undoubted merit. When the above dressing of dung is given, 1½ cwt. of guano and 2 cwt. of Griffin & Morris' manure is applied. The amount of hand manures per acre, however, varies according to circumstances, rising in the case of some poor land lately taken into occupation, to 6 cwt. of bone-dnst or ½-inch bones, and in another case to 2 cwt. of guano and 3 cwt. of superphosphate, with farmyard manure. Salt is also largely used, as much as 25 tons having been this year employed, both for roots and for cereals. It is also noteworthy that salt is considered to be more beneficial on the light than upon the heavy soil. The farmyard manure is partly expended upon the root crops and partly upon the second straw crop (see rotation). A fair crop of Swedes is said to be 20 tons per acre, and Mangel is not extensively grown. The roots are fed upon the land, with plenty of cake and corn, and thus the land is prepared for its somewhat arduous course of cropping. It does not seem out of place here to state that food and manures purchased (including a certain small proportion of corn valued at two-thirds of the market price) amount to 43s. per acre over the entire farm, and that the cake bill alone is equal to from £560 to £600 per annum.

Roots are followed with Barley—a remarkably good crop this year, but inferior to Mr. Forester's crop. We noticed nothing special in the cultivation of Barley, save its goodness, and we pass on to the next, namely, seeds. Never since 1855, when he entered his present occupation, had Mr. Winterton's "seeds" failed till last season. Last year, however, they did fail, and, as a consequence, we saw a considerable breadth of land under Beans and Peas, and about 12 acres of Vetches had been planted upon the fallow land, in order to provide summer food for sheep. This, we were told, was exceptional practice, as usually the sheep are grazed upon seeds. The Beans and Peas just spoken of were very "strawy," one Pea haulm which we took home with us measuring 7 feet 2 inches in length. The Beans were sown in the spring, 13 inches apart, and at the rate of 3 bush. to the acre. This was too thick for such a season, and we fear the crop will suffer in consequence. Seeds are not broken up for Wheat before the beginning of September, and Wheat is planted at the end of October and beginning of November. Mr. Winterton is a strong advocate for seeds being allowed to lie for two years, as both saving labour and bringing the land into order. On the lighter land Wheat is followed with Barley, topdressed with 3 cwt. of superphosphate or 1¼ cwt. of guano, and on the stronger land than upon the upon the broken-up seed-land, and are followed with Wheat. In either case, farmyard manure or the above artificials are employed.

The number of horses varies from 10 to 12. These are at present getting green food without corn. In winter they have 1 bush. of mixed Beans and Oats, and sometimes a little Indian Corn; at other times a little Barley broken in a mill. After Christmas, a small quantity of bran is mixed with their corn and chaff, and the whole mess is moistened with a little water. "Wrack-stuff" is given, and the horses are comfortably honsed. Three or four cows are kept. The remaining cattle were all grazing beasts, mostly nice heifers, two or three years old, and many of them almost "ripe" for the butcher. There are 55 head of cattle now on the farm, and 100 were bought and fatted and sold last winter.

A small ewe flock of 80 is kept just to "clear up," and then all go off fat, and are replaced by others every year. The general sheep management consists in buying in stores as they are wanted, and selling them as they become fat. Eight or nine hundred sheep go off this way in the course of the year.

White Staffordshire pigs are usually kept, and we saw some nice Berkshire sows.

The labour bill amounts to 24s. per acre, and to an average of about £9 per week. An ordinary man will receive 12s. wages, and about 2 quarts of beer per day during winter. Shepherds and waggoners have more. Again, as much as 13s., and 3s. per week as beer money, with a cottage, will represent the summer wages of a good man. When work is let by piece the following prices are paid:—Spreading manure, 1s. 6d. per ton; hoeing Wheat, 5s. to 5s. 6d.; singling and hoeing Turnips, going over the land twice, 9s. to 10s. per acre; tying up and stooking Wheat after the machine, 4s. 9d. to 5s. 3d.; mowing Barley, 2s. to 2s. 6d., with beer; mowing meadows, 3s. 6d., with beer.

After looking over a prize farm one naturally reflects as to whether any lesson has been learnt, anything which may guide us in our own management. Such lessons cannot be numerous on any one farm. It is not indeed for originality but for excellence that one looks, and if we can see one or two points worthy of consideration or new, it is as much as we can reasonably expect. On Alrewas Hays we would submit that the rotation in which two white crops are taken in succession is worthy of the attention of landowners and agents. An antiquated prejudice still exists against this plan of cropping, but any one visiting Mr. Winterton's farm will see that such a course is consistent with heavy crops and clean land. The broadcasting of the Turnip manures is also worthy of attention, and teaches us that on such land the crop can succeed without the aid of superphosphate placed immediately beneath it. The use of salt on the light land is instructive; the high value set upon autumn cultivation *versus* spring cultivation for roots, although generally agreed to, yet in this case has additional support. Lastly, the system of feeding horses with cut food placed in the manger is one which is worthy of being more generally followed than it is. Such are some of the points in the management of the 2d prize farm. It is, however, difficult to

convey an idea of the real excellence of Mr. Winterton's farming by words. The true way to appreciate it is to go and see the farm.

AGRICULTURAL STATISTICS, IRELAND, 1871.

The following is the substance of Mr. Donnelly's report to his Excellency the Lord Lieutenant of Ireland.]

THE collection of the statistics, which commenced on June 1, occupied nearly two months. The enumerators, of whom upwards of 3700 were employed, were selected from the Royal Irish Constabulary and Metropolitan Police, and discharged this duty with their usual efficiency. About 600,000 separate holdings were visited by them, and the names of the various parties from whom they obtained the particulars of tillage and live stock for each holding are stated in the returns.

The abstracts have been compiled from summaries made by the enumerators for their respective districts, and will probably differ in some degree from the revised figures which will be hereafter published; but I do not apprehend that any change of importance will be necessary in the numbers now given.

	Acres.
The total acreage under all crops this year was	5,620,226
The total acreage under all crops in 1870 (revised numbers)	5,641,140
Showing a decrease in the extent under crops in 1871 of	20,914

The crops which increased in extent this year are—

	Increase.	
	Acres.	Acres.
Cereals—		
Beans and Peas		225
Green crops—		
Potatos	14,704	
Mangel and Beetroot	6,505	
Carrots, Parsnips and other green crops ..	2,224	
Vetches and Rape	3,330	
Meadow and Clover		53,882
Total increase on the foregoing crops ..		80,870

The crops which decreased in acreage in 1871 are—

	Decrease.	
	Acres.	Acres.
Cereals—		
Wheat	12,892	
Oats	16,079	
Barley	20,570	49,802
Bere and Rye	261	
Green crops—		
Turnips	11,807	
Cabbage	2,038	13,955
Flax		38,027
Total decrease on the foregoing crops		101,784
Making a nett decrease in the area under all crops of		20,914

It appears from the foregoing summaries that, compared with 1870, Wheat shows a decrease of 12,892 acres, Oats of 16,079 acres, Barley of 20,570 acres, and Bere and Rye of 261 acres. In Beans and Peas there is an increase of 225 acres. In green crops, Potatos show an increase of 14,704 acres; whilst Turnips exhibit a decrease of 11,897 acres. There is an increase in the extent under meadow and Clover of 53,882 acres, and a decrease in Flax of 38,027 acres.

ABSTRACT OF CEREAL CROPS.

	1870.	1871.	Increase in 1871.	Decrease in 1871.
	Acres.	Acres.	Acres.	Acres.
Wheat	330,456	316,564	..	12,892
Oats	1,650,039	1,633,960	..	16,079
Barley	247,283	226,713	..	20,570
Bere and Rye ..	11,797	11,536	..	261
Beans and Peas ..	10,689	10,914	225	..
Total	2,173,656	2,124,079	..	49,577

Decrease in cereal crops in 1871, 49,577 acres.

ABSTRACT OF GREEN CROPS.

	1870.	1871.	Increase in 1871.	Decrease in 1871.

Meadow and Clover	1,658,335	1,692,135	1,670,716	1,773,851	1,827,733

RETURNS OF LIVE STOCK.

It appears from the following Table that the returns of live stock for 1871 when compared with 1870 show an increase in the number of horses of 4976; of cattle, 173,190; and of pigs, 155,539. Sheep exhibit a decrease of 108,163.

THE FOLLOWING ARE THE NUMBERS OF LIVE STOCK FOR EACH YEAR FROM 1861 TO 1871, INCLUSIVE:—

Years.	Number of Horses.	Number of Cattle.	Number of Sheep.	Number of Pigs.
1861 ..	614,232	3,471,688	3,556,050	1,102,042
1862 ..	602,894	3,254,890	3,456,132	1,134,284
1863 ..	579,977	3,144,231	3,308,204	1,067,458
1864 ..	570,158	3,260,094	3,366,044	1,038,480
1865 ..	548,339	3,407,548	3,694,356	1,305,953
1866 ..	535,790	3,746,157	4,274,282	1,457,274
1867 ..	514,180	3,767,603	4,231,249	1,315,791
1868 ..	524,703	3,646,796	4,001,466	869,578
1869 ..	518,201	3,733,675	4,651,355	1,082,204
1870 ..	532,657	3,799,912	4,336,884	1,461,215
1871 ..	537,633	3,973,102	4,228,721	1,616,754

Difference in numbers between 1870 and 1871.

Increase.	Increase.	Decrease.	Increase.
4,976	173,190	108,163	155,539

The total estimated value of horses, cattle, sheep, and pigs this year, is £36,798,763, being an increase of £1,240,988 when compared with 1870, as appears by the following Table:—

ESTIMATED VALUE OF LIVE STOCK IN IRELAND IN EACH YEAR FROM 1861 TO 1871, INCLUSIVE, CALCULATED ACCORDING TO THE RATES ASSUMED BY THE CENSUS COMMISSIONERS OF 1841, VIZ.:— For horses, £8 each; cattle, £6 10s.; sheep, 22s.; and pigs, 45s. each. These rates have been retained since 1841, in order to facilitate a comparison of the value—one year with another. A percentage may be added by any one at pleasure on account of the increased value of live stock since that period.)

Years.	Horses.	Cattle.	Sheep.	Pigs.	Total Value.
	£.	£.	£.	£.	£.
1861 ..	4,913,856	22,565,972	3,911,655	1,377,552	32,769,035
1862 ..	4,823,152	21,136,785	3,801,745	1,442,905	31,224,587
1863 ..	4,639,824	20,437,501	3,639,024	1,334,322	30,050,671

Difference in value between 1870 and 1871.

Increase.	Increase.	Decrease.	Increase.	Increase.
39,808	1,123,735	118,979	194,124	1,240,988

Scutching Mills.—The number of mills for scutching Flax in each province in 1870 was, in Ulster, 1409; Leinster, 39; Munster, 39; Connaught, 31; making in all 1518.

Emigration.—In the first seven months of 1870 the returns of emigrants from the several ports of Ireland show that 53,854 persons left this country. In 1871, the number for the same period was 49,155, being a decrease of 4699 persons in this year.

Weeds.—On several occasions I have called attention to the injury arising from the unchecked growth of weeds which is, unhappily, so apparent throughout almost every part of the country. On this subject that distinguished agriculturist the late Sir John Sinclair has given the following experiments, which prove the great advantage of carefully weeding cereal crops:—

"1. Seven acres of light gravelly land were fallowed, and sown broadcast with Wheat; 2 acre was measured off, and not a weed was pulled out of it; the other six were carefully weeded. The unweeded acre produced 18 bush.; the six weeded acres 133 bush., or 22½ per acre, which is 4½ bush. or one-fourth more produce in favour of weeding. 2. A 6-acre field was sown with Barley, in fine tilth, and well manured. The weeding, owing to a great abundance of Charlock, cost 12s. per acre. The produce of an unweeded acre was only 15 bush.; of the weeded, 28. Difference in favour of weeding, 15 bush. per acre, besides the land being so much cleaner for succeeding crops. 3. Six acres sown with Oats; 1 acre ploughed but once, and unmanured, produced only 17 bush. Another 6 acres ploughed three times, manured, and weeded, produced 37 bush. This experiment proves that Oats require good management, and will pay for it as well as other crops. Ten bushels of the increased produce may be fairly attributed to the weeding, and the other ten to the manure."

Labourers' Dwellings.—It is scarcely possible, both on social and sanitary grounds, to exaggerate the importance of improving the dwellings of the labouring classes; the Legislature has enabled the Treasury to grant loans for this most desirable object through the medium of the Board of Public Works. According to the census of 1861, the number of fourth-class houses in Ireland, each of which had but one room for the entire family of every age and sex, was 89,374,* and in these were living 440,000 persons of pretty.

I have the pleasure of stating that the information from which the abstracts were compiled has been most readily afforded to the enumerators by all ranks and classes in this country; and I here venture to observe to your Excellency, that intelligence, such as is shown in Ireland by the voluntary assistance given to the enumerators, presents an example well deserving of imitation in England and Scotland, where it may be stated—I trust without giving any offence—that agricultural statistics have as yet made but little satisfactory progress, owing, no doubt, to a want of due consideration of the importance of the subject.

I now beg to repeat my respectful acknowledgments to the landed proprietors, tenant-farmers, the clergy of all denominations, and the public press, for a continuance of the generous and valuable assistance which I have for so many years experienced in connection with these statistics. *William Donnelly, Registrar-General, General Registrar Office, Dublin, September* 20, 1871.

THE GARDEN OF THE FARM.—VIII.

HAVING furnished the walls of the farm garden, and occupied all the vacant spaces, and fences, and farm buildings with fruit trees, the next step is to fill the fruit tree borders. Perhaps there is no form of tree so useful for this purpose, so ornamental alike in flower and fruit, and from no other, unless it be the cordon, can so much fruit be gathered from so small an area, as the pyramid.

The trees may be packed closely together, from 3 to 6 feet apart, according to their size, and, properly managed, they are studded with fruits from pointed top to earth-sweeping base. The pillar is but a type of the pyramid. It is kept as near as may be of one uniform size from top to bottom. The weeping pyramid has all the extreme points of its side shoots bent towards the earth, by being tied down to hoops, or weighted with lead or small stones. Some prefer the weeping form for Pears—I do not; while for

* The number of fourth-class houses, according to the Census of 1871, has not yet been compiled.

Apples, Plums, Cherries, nothing can be better than the true cone. A pyramid 9 feet high, with a base 3 or 4 feet through, is a beautiful object at all times. A row of them on a secondary fruit border 4 or 5 feet wide, opposite to the wall-tree border, gives the garden an uncommonly dressy stylish appearance. Even Gooseberries and Currants can be trained in a similar manner, but in their case three leading shoots may be taken up to a stout stake instead of one, to hasten the production of the pillar or pyramid. Planted thus in single file, a yard or four or more feet apart, they have a stately appearance, highly unique, and very favourable to easy gathering. It double file the rows ought to be 5 or 6 feet apart to assume. It is astonishing how much fruit may be gathered off a Gooseberry pillar on good soil and with rich feeding. It seemed needful to make these observations concerning those to most farmers novel forms of fruit trees, but I hasten on now to resume the answers to the query of what to furnish with, by giving the names of some of the best varieties of each class of fruits. These will be arranged in the order of their ripening, beginning with the earliest.

In addition to the Apples already named, all of which would do well as bushes or pyramids, the following may also be grown if space can be found for them :—Red and white Juneating, Kerry Pippin, Red Quarrenden, King of the Pippins, Sam Young, Wyken Pippin, Golden Reinette, Cockle Pippin, Cornish Gilliflower, Winter Peach, Spring Ribston Pippin, Allen's Everlasting.

For *kitchen Apples*, Keswick Codlin, Nonsuch, Gloria Mundi, Manx Codlin, Blenheim Orange, Gravenstein, Warner's King, Bess Pool, Striped Beefing, Bedfordshire Foundling, Greenup's Pippin, Northern Greening, and French Crab—the latter keeping for two years if used bad, and as good, or better, when Apples come again as when gathered.

Dessert Pears.—When Pears are wanted in July and August, one each of Doyenné d'Eté and Citron des Carmes should be grown. The Jargonelle on a wall will succeed the latter. It also does pretty well as a pyramid in sheltered warm gardens. Then, again, is succeeded by Williams' Bon Chrétien, a noble delicious Pear. This carries the Pear season from July to near the end of September. Beyond this a whole host of good Pears prolong the season to the end of March. These early Pears do not keep many days, and consequently a tree, or part of a tree of each, is sufficient. Several trees of the following may be grown without much risk of their rotting before they can be consumed :—Beurré d'Amanlis, Louise Bonne of Jersey, Beurre Superfin, Seckle, Marie Louise, Winter Nelis, Glou Morceau, Josephine de Malines, Beurré de Rance, Huyshe's Princess of Wales, Huyshe's Victoria, Ne Plus Meuris, Easter Beurré.

Stewing Pears.—Most of the best kitchen artistes of late years prefer the best dessert Pears for stewing; but where stewing Pears are in great demand, as they are in many farm households, it may be well to grow a few trees for this purpose. Uvedale's St. Germain, grown on a wall, is undoubtedly the best of all Pears for stewing. It will sometimes reach a weight of 2 lb., and keeps sound till April. It will also grow as a bush or pyramid. The Vicar of Winkfield is a good Pear, as well as a pyramid, and is good either for eating or stewing. Catillac and Bellissime d'Hiver, are handsome free growing sorts, and the Beurré Capiaumont is a small, showy, extraordinarily fertile variety, good for stewing, as well as juicy and agreeable for eating in October.

Plums.—In sheltered positions all those recommended for walls, with the exception of the Impératrice and the Magnum Bonum, will do well as pyramids in the open ground. The following might be added to or substituted for some of those :—July Green Gage, Dennison's Superb, Mullins' Golden Gage, Goliath, and Rivers' Late. Cooking and preserving Plums : Victoria, Prince Engelbert, Diamond, Goliath, Early Orleans, Autumn Compote, and Damson.

Cherries.—To those recommended for walls, the following might be added :—May Duke, Early Purple, Early Frolick, Waterloo, Black Eagle, Bittner's Yellow, Coe's Late Carnation, and Belle Agathe—the three last carrying the Cherry season through September. For cooking and preserving the Belle Magnifique, Kentish, and Morello.

Medlars.—These make a splendid jelly. The Dutch and the Nottingham are the best varieties : they can be grown as bushes.

Mulberries.—These can be kept small by root pruning, and are generally prized ; the black is the only one commonly grown, but there is also a large white-fruited variety.

Quinces.—Where these are valued in pies as flavouring for Apples one or two of them should be grown. The apple and pear-shaped are the best for the kitchen garden. The Portugal is a grosser grower, and its flesh turns red when cooked.

Walnuts.—The meadow or orchard is the place for the common Walnut, but the dwarf prolific variety will fruit at a height of 3 or 4 feet, and is quite admissible into the kitchen or fruit garden of the farm.

Filberts and Nuts.—These are a source of great amusement and pleasure on winter evenings, and no farm garden should be without them. They are best and most prolific grown as small standards with a clear stem of 3 or 4 feet in height. The Cosford is a thin-skinned variety of great excellence ; the Cob-nut every one knows, but several new varieties of it have recently appeared which are great improvements on the original. These are the red and white skinned Prize Exhibition Cob-nuts ; then there are the white, red, and frizzled, and purple leaved, and Prolific Filbert, the latter a prodigious bearer in a small, young state.

Currants.—Black : Naples, this is far superior to the common black. Red : In addition to those named for walls, Knight's Sweet Red, The Grape, Mammoth, and Raby Castle, are good varieties ; the cut-leaved White Dutch is also a very fine fruiter.

Gooseberries.—Several of the best flavoured varieties have already been specified for walls, to these add—Red : Wilmot's, Early Red, Old Rough Red. White : Early White, Snowhill, Whitesmith, Bright Venus. Green : Overall, Keepsake, Model, Green Gascoigne. Yellow : Early Sulphur, Yellow Ball, Leader, Broom Girl. The following are a dozen of the largest Lancashire prize sorts, each berry weighing from ½ oz. to 1¼ oz. :—White : Hero of the Nile, Queen of Trumps, Antagonist. Green : Thumper, General, Telegraph. Yellow : Duckwing, Catherina, Mount Pleasant. Red : London, Wonderful, Conquering Hero.

Raspberries.—Carter's Prolific and Fastolf, red ; and Yellow Antwerp. Autumn Raspberries should be cut right down in winter, or in February ; they then produce strong canes ; about four only should be left to each stool. These fruit from the end of September till the frost finishes them. The October Red and October Yellow are by far the best varieties, much superior to the common double bearing.

Strawberries.—Among the best varieties are the Black Prince, the earliest of all ; Keens' Seedling, British Queen and Sir Charles Napier, Dr. Hogg, President, John Powell, Crimson Queen, The Lady (a good white), Frogmore Late Pine, the latest of all, and a sharply acid, but a refreshing Strawberry after the others are gone. Plant in rows 2 feet or 30 inches apart, and the plants at least 18 inches from each other, on rich deep soil, and top-dress in winter with 4 or 6 inches of strong manure, leaving its bleached surface as a clean bed for the fruit to ripen on in summer.

Grape Vines (for a vinery or greenhouse roof).—As Grapes are grown in several farm gardens, and will very soon be cultivated in all, I give a list of varieties for furnishing a cool vinery. Suppose there is space for eight plants, the following would be a useful selection :—1 Hamburgh, 1 Muscat, 1 Royal Vineline, 1 Frankenthal, or the best variety of Black Hamburgh, 1 Burchardt's Prince, 1 Black Alicante, 1 Lady Downes' —the three last being late good keeping sorts, and the whole easily grown and sure croppers.

To some these lists may seem needlessly full, but room may be found all in good farm gardens. And those who have less space at command may safely dip into them anywhere without risk of drawing a worthless blank. Farmers, as a class, know little of such matters, and it seems desirable to open out pretty freely the treasures of information in their generation gathering. Good varieties take no more space, require no greater attention, than bad or indifferent sorts, but the difference at eating time is immense. The first cost of a fruit tree is a mere fraction of its absolute worth ; the value or worthlessness of its produce measures its worth. Neither is there less necessity to grow the worthless sorts ; the very best are almost equally cheap.

Good maiden trees, that is, untrained plants of all the above varieties, can be purchased at the following prices per plant :—

Prices of Fruit Trees, Bushes, &c., of the best quality.

Gooseberries ,,	0	3	0	6					

Larger fruiting plants of all the foregoing trees, trained into form as pyramids, bushes, cordons, single, double, oblique, vertical, or as fan or horizontal trees for walls, range in price from 1*s.* 6*d.* to 5*s.* or 7*s.* 6*d.* each, according to their size ; strong fruiting canes of Grape Vines, in pots, from 4*s.* to 7*s.* 6*d.*, and very strong 10*s.* 6*d.* each. Excellent standard fruit trees for orchards, a list of which I propose giving in a supplementary chapter on farm orchards, can be purchased at prices ranging from 2*s.* to 3*s.* 6*d.* each, and even less if several dozens are taken. *D. T. Fish.*

FOOT-AND-MOUTH DISEASE.

By Professor Polli, Milan.

THE following article, written by Professor Polli, of Milan, was found among the papers of the late Sir J. Y. Simpson, and furnished to the *Midland Counties Herald*, by Mr. Lawson Tait :—

Directions for employing the sulphites in the foot-and-mouth disease (epizootic aphtha), the carbuncular fever or charbon, the Hungarian pest or cattle plague, by Dr. Giovanni Polli, extracted from the "Bollettino Industriale del Regno d'Italia," published under the auspices of the Ministry of Agriculture.

The pathological principle on which the treatment by the sulphites rests, is the admission of an altered condition of the blood in epizootic diseases as its principal factor or cause, induced by the reception into it, or by the development in it, of a particular morbific ferment. The dyscrasix or faulty condition of the blood, against which both animal functions and nutritive processes are stirred into reaction, originates or sets up the malady. The cure may be said to consist in arresting this decomposition of the blood, of which what we call the prophylaxis is nothing else than the prevention. For this purpose, we avail ourselves of a remedy that is very well borne by the economy, with no inconvenience attaching to it. It has also the property of rendering the organism refractory to the influence of morbigenous ferments, and, moreover, of arresting their operations, and so allowing the animal organism to work itself clear of their effects by customary eliminations. This remedy is no other than the combination of sulphurous acid with alkaline and earthy bases. The sulphite of soda, by its solubility, and also by its low price, is the most convenient of these for curative operations, while the hypo-sulphite is most appropriate for prevention of the disease.

Preventive Treatment.—Whenever a healthy herd of cattle, goats, pigs, or a flock of sheep, have in their neighbourhood an infected animal, stabled, penned or herded with them, where contact with such has been possible, direct or indirect, you may dread the coming of the disease. You will then employ the preservative method, subjecting all animals alike to the following process of treatment :—

For every head at least you make a solution of 3½ oz. (100 grammes) of hypo-sulphite of soda, dissolved in a small quart of water (a litre), and add to it 1 oz. or so (20 to 30 grammes) of common culinary salt, to make the drench more palatable, and also to assist its action. This solution to be taken daily, divided into two doses, one in the early morning, one to be taken in the morning by the animal, and the other half in the evening by way of drench with the horn, or in the same way morning and evening ; the same quantity of the salts may be given with flour mixed up into a paste in ball, taking care to make the animal drink some quart or two of water over and above taking the balls or bolus. From the time the physic is given, no food should be allowed for an hour, and after taking the food the space of two hours should elapse before the salts are administered. This treatment should be perseverd in so long as, from the existence of epizootic disease in the neighbourhood of the animals, there is danger of its diffusion to non-infected stalls.

If the animals so treated by the hypo-sulphites have too much looseness of the bowels, it is best, on alternate days, at least, to give but half the morning dose ; or every you may find it necessary to cut down all doses to one-half, for purging is not desirable—far otherwise, that so the salts should be absorbed and taken up into the system so as to confer upon it the faculty of thorough resistance to all morbific ferments.

For the use of sheep, goats, and swine, the dose that has been mentioned for cattle may be reduced to one-third or thereabouts of the quantity already stated, *i.e.*, rather more than half an ounce (20 grammes), to be given in the morning, and the same again in the evening, or rather more than 10 drachms during the day of hypo-sulphite of soda, and a tablespoonful of salt. The addition of a little common salt may be at any time made, whenever it is thought advantageous to make the animal better savour the lump of paste or solution with the salts. Extreme cleanliness in the stalls, frequent aëration of the shed, a good selection of food, great purity of the water drank, all these should be scrupulously attended to.

Curative Treatment.—When in any herd or stall of cattle—and the same with sheep, goats, and swine—there is present the epizootic disease, to every healthy head of animal you will continue the preservative treatment, that is to say, with the hypo-sulphite of soda, in manner above described. Any animal that is affected with the disease should be subjected to treatment with the sulphite. For cattle, the daily dose of the sulphite should be 3½ to 5 oz. (100 to 500 grammes), dissolved in a quart or somewhat less of water (a litre), with addition of 1½ oz. (50 grammes) of common salt, one-half of this quantity to be given in the morning, and the other half in the evening, either in solution, by means of the horn, or the salt may be mixed into a bolus or ball with flour in paste, in which latter case it is necessary that the animal should imbibe soon after some quart or quarts of water.

Between the taking of the salts and any kind of food one full hour must be suffered to elapse ; so, again, after food has been taken, two hours' interval should be enjoined before the physic may be given.

The utmost cleanliness of the stall, removal of dirt and litter, great freshness of the bed, purity of water drank, ventilation of the premises, are wholly indispensable to success in treatment.

For the epizootic aphtha (the foot-and-mouth disease), the pustules and ulceration that is found about the mouth and lips, on the tongue, and dugs, and cleft of the hoof, should be all well washed and dressed with tow that is well wetted in solution of the sulphite, one part of it to 10 in water, to be made fresh every day. The best preparation and most useful detergent, when the skin displays any raw, is a concentrated solution of the sulphite, one part to six of water.

If from the severity of the complaint, or aggravated condition of the mouth, the animal resists very much the employment of the drench or ball, we must then have recourse to clysters, giving the salt in solution as before, but increasing the sulphite in quantity for the purpose by a quarter or a third, and doubling the quantity of the water. Let it be divided into four equal parts, to be given at regular intervals, so as to be better retained, and purging in that way avoided.

During all employment of the sulphites, it is necessary to refrain absolutely from the use of acid substances, whether internally or externally, such as vinegar, cream of tartar, lemon juice, wine, &c.

The dose of sulphite of soda for the smaller class of animals (sheep, goats, swine, &c.) should be reduced in due proportion, according to the size of the animal, as low as 1 oz. daily, or perhaps a little more (30 or 40 grammes), divided into two doses, and administered with the same set of rules. With these smaller animals we use the clysters just the same as with the cattle.

The droppings of animals that have been under treatment with the sulphites and hyposulphites are apt to give off strong exhalations of sulphuretted hydrogen. This odour is not deleterious, however disagreeable it is, but rather is it depurative and beneficial to the cattle in the stalls, since it permits a part of the sulphurous principles to enter the organism by the channel of the breath, where they give opportunity to the production of the sulphurous acid and the sulphites.

If complained of as inconvenient to those who tend the cattle, it may be mitigated by freer ventilation, or a thorough fumigation with chloride of lime and oil of vitriol in an earthenware pail, once or twice during the day. When this precaution of prophylactic action has lasted for a considerable time, necessitating the use of the hypo-sulphites for some time by way of prevention, there is no cause to fear about the milk, nor yet for the flesh of the animals that have largely partaken of the salts. Both, indeed, are so far improved that they resist the ordinary decomposition. Under equal circumstances and conditions, the milk that is taken from these animals continues fresh for a longer time than is the case with ordinary milk, and it does not pass so rapidly through the customary changes. When such milk is used for making cheese, it requires but a little attention. The flesh of oxen slaughtered after a long use of the hypo-sulphites, will keep sweet and free from taint for a notably longer period than is the case with the flesh of animals that have been treated by the sulphitic medication. The same is true of other flesh, as that of sheep, goats, or swine.

Note.—The foot-and-mouth disease, the carbuncular fever or charbon, the cattle plague, or foreign pest, are three several diseases, having each its specific cause, and consequently are unlike in character or in the amount of alteration produced by them in the economy. But, as the treatment of the sulphites does not do away with that cause (nor could it be hoped that one single thing could destroy such various causes), but rather by a particular action, which is termed catalytical, the ordinary decomposition, under equal circumstances and conditions, the milk that is taken from these animals continues fresh for a longer time than is the case with ordinary milk, and it does not pass so rapidly through the customary changes. When such milk is used for making cheese, it requires but a little attention. The flesh of oxen slaughtered after a long use of the hypo-sulphites, will keep sweet and free from taint for a notably longer period than is the case with the flesh of animals that have been treated by the sulphitic medication. The same is true of other flesh, as that of sheep, goats, or swine.

Note.—The foot-and-mouth disease, the carbuncular fever or charbon, the cattle plague, or foreign pest, are three several diseases, having each its specific cause, and consequently are unlike in character or in the amount of alteration produced by them in the economy. But, as the treatment of the sulphites does not do away with that cause (nor could it be hoped that one single thing could destroy such various causes), but rather by a particular action, which is termed catalytical in the ordinary decomposition.

results: Of six examples of Rape seed, five were referable to B. campestris; one only I take to be B. Napus. The seeds of Brassica campestris are about one-third larger than those of the common Turnip, with a finely reticulated surface, there being also a faint large reticulation. In B. Rapa, Turnip, you have the seeds about one-third smaller than those of the Swede, but with the same markings; while in a sample of spring Rape, from Runia, the seeds are of the same size as those of the Turnip, but with a larger honeycombed reticulation in addition to the fine reticulation of the surface. This reticulation is so large that it can be easily seen with a hand lens. The Rape cultivated in this country seems, therefore, to be Brassica campestris var. oleifera. Of five samples of Rape or Colza examined, two were British, one Italian, one French, and the fifth from Hungary. The Swede is also a variety of B. campestris, the var. Napo-Brassica. Brassica Rapa, var. rapifera, is the Turnip, four samples of which were examined. Brassica Napus var. oleifera is probably the Spring Rape from Runia, only one example of which I have seen. It seems, therefore, that two plants are mixed up, both in this country and abroad, under the name of Rape. *W. R. McNab, M.D., Royal Agricultural College, Cirencester, Oct.* 2, 1871.

SOCIAL SCIENCE CONGRESS.

LEEDS: *Oct.* 8.—*The Sanitary Care of Villages and Cottages.*—In the Health Section, under the presidency of Mr. Godwin, F.R.S., Dr. Acland, of Oxford, stated:—

In any well-ordered modern town the poor have the cleaning and scavenging of the surroundings of their homes done for them. In a village, in an isolated cottage the labourer, often ill fed, always hard worked, either performs this duty himself, or it is left undone. He has to do it before his day's work, after it, or by losing it. What this implies if a man be not strong those who know the people well can alone judge. The effect of this one circumstance is more injurious than can be readily estimated. The condition of the closet accommodation in some villages and cottages is such as is virtually inconsistent with a sense of domestic order, and is productive not seldom of the most injurious effects on the health of the family. The water is poisoned. Fevers are originated, and permanent ill health is engendered through recurring bowel attacks. A generally untidy and miserable state of the surroundings becomes the habit of the family. The children grow up with these associations, having no other home standard of decency. They have known and desire nothing else. I could tell many facts to show the extreme gravity of this matter in our rural districts—grave from its effects on the health of individuals—grave, more grave, from the effect on the moral nature by engendering indifference, and on the intellectual powers of observation and reasoning by producing ignorance and consequent false opinions upon common matters of every-day life. We need not now consider the causes of such things in this age; we have nearly done with that kind of inquiry. We seek now practical remedies for the past and reasonable prevention for the future.

Now, the remedy seems to be this, that, *mutatis mutandis*, the same sanitary care should be bestowed on a cottage in the country as on a house in a town. In the case of a well-ordered town the community provides water for its members, and removes their refuse for them. Not so in a village. The cottages are in many districts that every cottage, or every other cottage, has its well, and, there being of course no sewers, has its own cesspool. The expense and the risk from want of organisation are both multiplied. It may be said that our scattered populations are not worth the care, or that, if worth the care, then the expenditure would in practice be too costly, so that the care of hamlets and villages is either impracticable or visionary. Issue may be joined on both these objections. The rural populations are becoming nurseries for town populations. They cast into the towns either a strong, decent, manly people, or an enfeebled progeny, brought up unwisely. The rural districts contain no less than 9,803,811 persons, having increased in the last ten years by 668,428. They increase in great measure, as is justly remarked by the Registrar-General in the last census, by going into towns, and therefore by carrying their habits, good or bad, with them into the towns, and electing as their administrative officers persons conformable to themselves. The immigration of the rural into the urban population is noticed on the Continent also, and is, in fact, a necessary law of modern civilisation, depending on various causes—some obvious, some recondite. The case of the villages is, therefore, apart from special humanity towards the individuals, truly a national question. As to the executive who are to guide them, the great measure of last session, which undertook to harmonise into a whole all existing powers bearing on the public health, and which has assigned to one minister the duty of consolidating and improving the law, wherever improvement and consolidation are needed, has virtually decided this question. With respect to the purely rural districts, the great powers of the Public Health Acts at present reside with vestries and guardians. In many cases, therefore, they are indirectly in the hands of the very class of persons who require guidance and help. Herein lies a great part of the strength of the Local Government Board. It enlists in the cause of public health, understood in the widest sense, every ratepayer who votes on matters of parish organisation, and the medical men of the poor. Will they act? Will they apprehend their own material interests? We may not doubt that, with the progress of education in self-government, they will. What has to be done in these difficult cases must often, I am convinced, be done by the people, with the aid, but not by the compulsion, of the law.

To revert to the specific proposition from which I started, that the cottages in rural districts should be periodically inspected. Summary relief would be applied. There are two ways in which this can be done. The one, in villages where regular sewers and water supply can be provided and maintained. The other, in isolated cottages, where, from the expense, these methods are practically inapplicable. In Broad Clyst the former has been lately tried. In Stanton Harcourt, in Oxfordshire, the latter plan had been put in operation on the dry-earth system by Colonel Harcourt, the son and successor to the venerable and scientific Canon Harcourt, owner of Nuneham. An inspector, paid by Colonel Harcourt, goes weekly to the cottages on the estate to examine and report on the condition of the closets, and if they are in a bad state he removes the manure as a fine, because then the owners lose it from their gardens. An account of thorough administration of this kind by Baron Rothschild is given in Mr. Disraeli's novel, the Privy Councillor of 1870. The first of these methods cannot pay interest on the outlay, and can only be done by persons who have capital at their command. Neither the parish nor the union can be called on to contribute to a purely local improvement, except on the principle on which a great national work is done, that is, that as the benefit is shared for those who till his land, the outlay being calculated as for the whole of his property; or on that principle which makes the whole country pay some apparently metropolitan charges because they are part of the Imperial expenditure. On the whole, there is no doubt that an arrangement can be made in every rural district, whereby the poor labourer may have the necessary surroundings of his home kept in order for him, like his fellow artisan in the town. It would conduce to his health and energy, and it would be both just and politic, since all who believe in the existence of national, as well as individual morality feel that the agricultural labourers deserve the utmost care of the nation.

Mr. RAWLINSON, C.E., said that the question of providing the best form of human habitations had been neglected, so far as his knowledge went, from the earliest dawnings of history. He knew of no nation that paid attention as it ought to do to the dwellings of the lower class population. He spoke with a full knowledge of the habitations of this country, and he spoke also with some knowledge of the houses of the labouring population in the United States of America and in India; and the sum total of the story was one of utter and gross neglect, which generates a mass of misery, crime, and disease that was indescribable. That being the case, whether Socialism were to come into play, whether the rich were to take something from the wealth of the poor, he did not know, and could not tell, or to speak of the form in which the work should be done. He was simply there to say that there was no safety for any people, there was no security for any Government until the statesman had learnt that lesson from his work, and had worked out the problem as it ought to be solved. Unlike most of the great evils of the construction of dwellings in this country was, first of all, the utter regardlessness of the site, and the subsoil, and the material, and the mode of construction, and then the mode of management subsequently. Now, whether people were going to build cottages for themselves, or cottage or villa residences, or palaces, the first necessity was to have a dry subsoil. If not naturally dry, the soil must be dried by the best means. The second necessity was, that the area upon which the buildings are about to be erected must be isolated from the surface waters by impervious materials, such as to use concrete. The next thing was, that there should be a damp-proof course to prevent the damp rising into the walls. Then, if there was a basement story, it should be isolated from the ground; the earth should not come in contact with the walls. With regard to the arrangement of the rooms, the last speaker had told them briefly and admirably that means must be applied to give ventilation. He spoke in the presence of the chairman, one of the ablest sanitarians that this country had produced, one who had spent his life in studying these questions, and one who probably had tended to do more good than any man that it had been his pleasure to come in contact with, by studying the questions, and teaching, as the editor of the *Builder*, what it was that should be done. In that paper every information could be obtained on the subject. He might first, however, say briefly that domestic houses had two purposes to serve as we use them. They had the domestic purpose for the family—that for the cottager was the entire purpose the house served, as they had few visitors—and the more ornamental purpose. But there was the time when sickness came. People ought to be taught that they could not live healthily within the four walls of their dwelling, whatever the arrangement might be, if they did not open their windows and admit air. Those who visited the dwellings of the poor should see to it that the windows of the bedrooms were opened, and, if they did not open, the landlord should be asked to make the requisite alterations. If the outside air were let in, Nature would do the rest; she would oxidise and purify. If there was a window on a staircase, and there was no other means to procure ventilation, he recommended that the window should be let down some 3 inches from the top and screwed fast, so that none of the servants or any one else could ever close it by day or night. He knew of cases where great benefit had been done by this simple expedient. Then as to closet arrangements. He had had to inspect Windsor Castle, and one would imagine, if ever there was perfection to be found, it would exist where Her Majesty had to reside. In 1821, Parliament voted £500,000 to fit Windsor as a place of residence for George IV. Up to the end of William IV.'s reign he found that £750,000 had been expended upon the Castle. When the Queen had come to occupy the Throne, and in the year 1844, the state of the Castle had become so bad and was so offensive that it was almost impossible to live in it, and it was found upon examination that there were no fewer than 53 cesspools within the basement, all of them full and overflowing. It took some years to remedy the evils that existed, but they had been overcome, and now, probably, Windsor Castle was one of the healthiest places in the world.

PLYMOUTH.

The Lamb Disease.—At a recent meeting, the CHAIRMAN (Sir Massey Lopes, Bart., M.P.) said: There was not a single man or woman in the country who was not in a large degree interested in at all events one question, if not two questions, and that was, as well as other diseases, which he was sorry to say were now raging throughout the country. They had met there to consider more particularly the lamb disease, but he could not help saying just a word or two with reference to two other diseases which were now rapidly spreading. The most serious fact was that the foot-and-mouth disease at this moment existed in no less than 73 British counties, and he had been informed officially that at the present time there were 25,000 cattle suffering from it. This was a very serious matter, and required that the most careful attention should be paid to it. They all knew that pleuro-pneumonia and the foot-and-mouth disease had been imported into this country by foreign cattle, and he strongly felt, as he always had done, that Government had not been sufficiently alive to the injuries and dangers that were continually arising upon this head by these diseases. Furthermore, he was of opinion that every head of cattle imported into this country should be slaughtered at the port of entry, and he looked upon the 12 hours' system of inspection to be a humbug, a delusion, and affording no security whatever. Lamb disease was not, however, a contagious disease. It had existed in the districts throughout Devon and Cornwall, more or less, for many years past. Years ago some Cornish agriculturists subscribed together and gave £30 for the best essay on lamb disease. The prize was taken by Dr. Crisp, whose opinion was that the parasite existed in the lungs, and recommended good and generous diet as a preventive. Mr. Crisp further thought the turning of lambs into Clover or coarse grass when dews were upon it was very likely to bring about the complaint, and that the disease was in some measure owing to the land being overstocked with sheep, to the exclusion of other kinds of cattle.

Mr. TUCKER (Molenick, St. Germans) read a short paper on the disease, in which he said it was not infectious, or indigenous to the land. There was no doubt that the disease had prevailed in the country from time immemorial, appearing in the same fatal form and as at present. With every August came the disease. Greater loss has been sustained in Cornwall from it than from all other diseases combined to which sheep were liable. The highest authorities were agreed that it was a parasitic disease. Through these parasites the lungs were prevented from oxidising the blood; hence great debility, and always diarrhœa before death, this being the effect of debility. He knew of no means of removing these parasites with safety to the life of the animal, but he believed much could be done by preventive means. One great mystery to him was that, while on one farm it was known, on a farm with the same soil it was not known. This was proof that it had its origin in some local cause, and he believed that lambs were annually liable to it when fed on certain pastures, and that a single field or a small portion of land often diseased a large flock. Experience pointed to old and broken land, especially where the pasture was coarse from want of drainage. Here they wanted science to distinguish between healthy and unhealthy pastures, and if such could be done it would be a great boon to the farmers of this country. If they took their lambs entirely off pasture land, he thought they would hear very little of this disease.

Mr. BICKFORD (veterinary surgeon, Totnes) followed with a short paper, agreeing that prevention of the disease should be their first object. But he must confess that the measures just recommended would not at all times avert these calamities; each season seemed

to give birth to its special disease among their domesticated animals; but while foot-and-mouth disease, pneumonia, and cattle plague were eminently infectious, the disease among lambs was neither one nor the other, but a parasitic disease. The effect of the disease was a direct loss of blood, reduction of vital action, and an insufficient conversion of food into blood for the repairs of the body. He was certain that the disease would not be so widespread as it is were it not for the great antipathy farmers exhibited to administer medicine to their flocks. As a rule, sheep were most unsatisfactory patients, due in a great measure to the character of the disease which generally prevailed amongst them, and the resistance they usually offered to its effects; but the prevailing disease among lambs was a parasitic disease, which could be rendered perfectly harmless if treated at the outset by a specific remedy. This he impressed strongly upon them. Parasites were undoubtedly taken in with food. If veterinary surgeons received more encouragement from agriculturists these would not be so much loss of life among our domesticated animals as at present. There was a remedy to this disease.

Mr. PAGE was disappointed with the papers read, because they gave them no specific remedy. His remedy would be to leave the disease to Mother Nature. They must invigorate the system as far as possible, and run a run along with the ewes till August, after weaning. If they did this, he was certain the lambs would be well.

Mr. PRATT thought the disease arose from the absence in the soil of the necessary constituents to keep up a healthy system and healthy constitution in the lamb. Their object should be to supply that deficiency. It was too much the rule to have a disproportionate amount of sheep compared with the horned cattle. They should also plough, use lime freely, and largely admixture grasses, and import a little new blood from the mountains. He knew Dartmoor sheep would not do, but they should be obtained in order to renew the blood. Field Rape would be a most valuable auxiliary in the beginning of August. In allowing sheep to eat a crop after sheep, he believed farmers were doing themselves a great mischief. He proposed a resolution embodying these views.

Mr. HENNEY could not agree with Mr. Tucker that new pasture was the best thing for sheep. He had not lost a lamb in the old pasture.

Mr. SOWDEN had always found his flocks thrive better on new pasture. He frequently changed his sheep. If they had rich lambs they should be careful not to allow them to remain in low ground in foggy weather. While with ewes they should give lambs artificial food, and when they saw anything the matter with them they should apply a remedy at once.

Mr. COULTON (Buckfastleigh) thought the dry season had something to do with it. He believed the lambs were not born in their usual healthy state. To find out the cause of the disease they must look to the breeding animal.

Mr. NEHEMIAH STEPHENS had changed lambs as often as most other men. He had tended them so that no other man could tend them better. He had given them every kind of food, and had introduced the different kinds of grass—had tried Mustard, Rape, white Turnips, everything he thought would be beneficial to the lambs—and yet he had failed either to prevent or cure. By generous diet he had washed them through the disease, but they had so depreciated in value that it was just as ill in a pecuniary point of view if they had died. As regarded overstocking, he would rather overstock with bullocks than sheep. He had imported fresh breeds of sheep, but to no good purpose.

Mr. THOMAS (veterinary surgeon) had found chlorine gas the best remedy.

This, Mr. STEPHENS said, he had tried, but not successfully.

The CHAIRMAN here suggested that the matter should stand adjourned until the next meeting of the Devon Chamber of Agriculture, which was agreed upon.

LONG SUTTON.

LAST week this Society held its 35th anniversary. There is no other merely local association where the programme is so diversified, and where so many really good objects are kept in view. The rewards for labourers and servants and the educational prizes for children are leading characteristics, but that which most draws the company are the poultry, pigeon, and rabbit shows, and the exhibition of live stock. The railway companies this year were liberal in providing excursion trains, and there was a very large attendance of visitors, especially on the first day of the show. Some £400 were given in prizes, besides 35 silver cups, namely, two for farmers' sons, two for roots, and the remainder for poultry, &c. Along the east side of the showyard was stretched a strongly-built wooden structure 30 feet long by 33 feet broad, sufficiently large to hold the poultry, pigeons, rabbits, labourers' vegetables, and flowers, and the amateurs' horticultural show. On the west side boarded stalls and pens were erected for the live stock, and at the north end the sheep and pigs were penned, whilst the south was occupied by the extensive exhibition of agricultural implements. The orchestra for the Grenadier Guards' band was placed in the centre of the field, and Mr. D. Godfrey and his talented corps never had a more appreciative audience than that which surrounded him during the day. The ploughing took place on the Hall Marsh Farm of Mr. John Brown, and being near the town, the work was criticised by large numbers of practised eyes. There were 52 competitors, amongst whom were seven farmers' sons; and it was generally acknowledged that the quality of the work was unusually good. The work of the boys was again admirable. Three double-furrow ploughs were at work, but the land was not in a favourable condition, for indeed the late rains rendered it impossible to clear away the stubbles, as was intended. A Potato drill was also at work in the field, and considerable interest was excited by the working of double-furrow and three-furrow ploughs, shown by Mr. Perkins, of Hitchin, and the preference of the revolving mouldboard-plough. In the live stock classes there were 101 entries, most of them very valuable animals, especially the 2-year-old class, which was altogether a rare one. Hunters were not well represented as regards numbers, there not being more than seven entered for competition; but the animals that were shown were fine specimens of their class, the 1st prize taker being a splendid animal, and executing his leaps with the greatest ease. Twenty-nine beasts were entered, comprising some of considerable merit, but the judges were no doubt affected by the prevailing foot-and-mouth disease. For sheep there was a fine show in every class; those exhibited by Captain Catling, which took the cup, were exceedingly fine animals, and attracted a great deal of notice. The pigs were numerous, and contained some good specimens of the Essex breed; the decision of the judges was in some of the swine classes did not appear to give entire satisfaction. As might be expected from this neighbourhood, the show of Turnips, Mangels, and other roots was unequalled. Specimens of three varieties of Sugar-Beets (varying in weight from 1 lb. to 4 lb.—the 4 lb. roots averaging 18 lb.) were exhibited by Mr. J. Algernon Clarke; and samples of beet-sugar in its different stages of manufacture, and also of beet-root spirit, potash and other products, were shown by Mr. Arnold Baruchson, of Liverpool.

There were 112 different entries of cottagers' garden produce, and 30 women had competed in the plodding and 4700 had been distributed amongst them in prizes. Besides prizes for stacking, prizes to female servants, £350 had been distributed among those who had worked the longest time in service. There was but little given to the cultivated the allotments, yet nothing could tend more to the advantage of the laborer. The amount that could be produced in this way on a rood of land was most remarkable. Then there were the educational prizes, which tended so much to the improvement and advancement of children, and valuable these prizes, which he had not time to particularise. Mr. Swain further remarked that he possessed a curious document which showed the origin of the association; this was a small account book, in which were entered the minutes and subscriptions of the original "Prosperion Society" some 35 years since, from which sprang and grew the present well established Long Sutton Agricultural Association. *Chambers of Agriculture Journal.*

Notices of Books.

The Daily Life of Our Farm. By the Rev. W. Holt Beever, M.A., Oxon. London: Bradbury, Evans & Co., 10, Bouverie Street.

The best way to describe Mr. Beever's book is to take an extract from his introduction to it:—

"It is a twisted, round-about, in-and-out sort of place, our homestead. Such Robinson Crusoe contrivances exhibited in the sheds, stables, storehouses, pens, ponds, and appurtenances thereto. In part we found it so, in part we made it so. It would have been different, in some respects better (pre-eminently as concerns our purse), to have pulled down the old eccentric buildings altogether, and have set them up anew on approved modern principles. But we should not, I am persuaded, have had the enjoyment we have now. It is so much more refreshing to pop in and out of all sorts of unlikely place, by unexpected doors and bridges, and sudden short cuts, than to find, here in the prepared coil of life, in sleek selection of symmetrical Black Diamond porkers, here a wild duck sitting, and there a batch of game fowl: all irregularly intermixed, and mutually helping to produce one charming general effect, as the tinted worsteds of a Turkey carpet do. Personally, beyond a doubt, it doth yield us a far more varied and greater gratification in our daily, nay hourly, rambles of inspection, than if the lines had been ruled severely in accordance with modern improvement. Large spacious barns, stone-tiled and straw-thatched, with lancet slits and iron-stanchioned windows, yards of old-fashioned type, high-walled and wide, suggesting all a period when the owner's wealth was stored upon the premises and banks were yet unknown; when the housewife spun amidst her handmaidens her lord's attire, and all cloth for household use; when the domestics were born and reared, and wrought and died, upon the premises; and he was a travelled man who had been an miles from the scene of his nativity: when the wines and cake were all home-made, and the condiments compounded in the kitchen; when gold was scarce, and subject to be stored, and the yeomen literally lived off his land; when the witch was yet wont to come down, and toss into high air the haycocks, during the makers' mid-day meal; and when there was no bye-road or ruin untenanted by a ghostly inhabitant of some sort."

Like our homestead, "it is a twisted, round-about, in-and-out sort of affair our" book. And, like the visitor to the homestead, the reader of the book has the refreshment of popping in-and-out, and finding in all sorts of unlikely places all sorts of conversations, discussions, descriptions, exclamations, "irregularly intermixed and mutually helping," we very cordially admit, "to produce one charming general effect, as the tinted worsteds of a Turkey carpet do."

Mr. Beever is an agreeable rattle on agricultural subjects—and a sensible man, with a fluent tongue and good-natured disposition, makes a pleasant companion.

Farm Memoranda.

FARM BUILDINGS ON THE ESTATE OF MR. JOHN TOLLEMACHE, M.P.—For many years now, this gentleman has taken the warmest practical interest in the household accommodation of his tenantry; and by a considerable expenditure of capital has replaced the cramped and inconvenient dwellings which served as farmhouses, by large, and in every way commodious, blocks of buildings. Inside one of these fine specimens of the English farmhouse, there is no doubt that the skilled cheese-maker would enter upon a formidable competition with the most costly factory. All that he wants for his business operations he has immediately about him, with ample ventilation and complete protection from the weather. A strong argument of the promoters of the factory system is, that by resorting to it the farming population are relieved from much of the "dairy slavery" they have been subjected to for generations. The reproach is just; but no little share of the laborions work to which this name has been given results from the rule-of-thumb system, which has been tenaciously persevered in, and the ill-contrived habitations in which the manufacture has been carried on. The plan of heating the whey in huge boilers to get "fleetings," for instance, caused a tremendous expenditure of physical strength, and, from the great heat which had to be maintained, incessantly required the health of the women regularly engaged in the work. It is now abandoned, and in most of Mr. Tollemache's new buildings, slate cisterns have been erected capable of holding ample quantities of whey, where the method of cooling efficiently substitutes that of heating to which we have just referred, and by which simple alteration relieves the operators of all the severe exertion attendant upon the other process. The refuse whey is conveyed to the piggeries outside by a pipe running from the bottom of the cistern in the same way as at Tatten-hall. The supplying of water for the various operations, again, used to be a heavy task, as everybody knows how much scrubbing and cleaning has to be done in order to keep a dairy in a proper state. Here, however, a pump has been erected in each yard, connected with which are pipes running to every necessary part of the milk house, so that the men on the farm, by working the pump occasionally, can create sufficient water for daily use inside, the taps only having to be turned on in the same way as when the supply is derived from a water company's main. Ovens for keeping newly-made cheese at a high temperature in order to extract the remaining whey have been constructed with that careful regard to convenience, and the work of moving the cheese in and out is perfectly easy. Further to facilitate this lifting of the cheese after it has taken a solid form—a part of the work which used to be slavish enough—hoists have been put up between the press-room and the store-room, so that by the winding of a small crank, that operation is at once accomplished. We have heard of a stalwart dame who showed her contempt for these machines by invariably carrying the cheese upstairs in her arms, though she had a hoist in the house; her reason being that while she was going up to what the apparatus, do the whole of the operations; but few even of our robust dairymaids have such an uncontrolable love for hard work as that. The store-rooms are, of course, ample in proportions, and sufficiently airy. Let us mention, too, that downstairs, where much of the work used to be performed in the open air a zinc roof has been put up, which excludes the rain and moderates the heat. In every possible way, indeed, the comfort of the workers has been consulted, and the result is the banishment of a great deal of drudgery which used to be the invariable accompaniment of cheesemaking. There has been much ingenuity expended in the rebuilding of these farmhouses, both by Mr. Tollemache and his agent, Mr. Cawley, and they might serve as no mean pattern for landlords equally inclined to do the best for their tenants. That the member for West Cheshire is so, one further illustration

will show. He does not preserve ground game, for the one reason, that he is conscientiously disinclined to encourage the breeding of animals who get their living on his neighbours' produce. Rabbits, of course, are entirely at the mercy of the tenants' guns. There would be an end of the game question very quickly if all landed proprietors were equally considerate. *Chester Chronicle.*

Miscellaneous.

GAMEKEEPER'S TRESPASS.—*Bicester, Sept.* 15.—Thomas Haydon, under-gamekeeper to the Earl of Effingham, Tusmore Park, was charged with doing wilful damage to growing Wheat, the property of Mr. John Sanders, farmer, Kiddington, who occupies the Tusmore Park Farm, on August 30.—Mr. Small said the facts were, that this field of wheat was being cut by machine, and the under-gamekeeper was in the field, and sent his dogs into the Wheat to drive out the game that might be in the corn. Complainant came up and objected to this, but the man, having orders to see that the game was preserved, and thinking that he had a right to do it, held on urging his dogs. The head-gamekeeper believed he had a right to see that the game was hunted out, as the game was frequently killed by the machine; and he considered it his duty to get them out. He did not do his work with malicious motives. Effingham distinctly claimed the right to prevent his game being killed.—Mr. T. Mallan stated that Mr. Sanders had on the Wednesday in question borrowed his neighbour's machine, as his corn was so thoroughly ripe that it was ready to shed. He rode into the field on his pony in the middle of the day, and saw Haydon and a boy with two dogs, which they were hunting into the corn. Mr. Sanders spoke to the boy, telling him to call the dogs out, and the boy did so, but Haydon hunted them in again, and Mr. Sanders went to him and told him that he should not have his corn spoilt in that way. Haydon then made an reply. If he had desisted then there would have been no further action in the matter. As to the lien set up by the defence, that it was the man's duty to protect the game, it might have stood, only it was his own perquisites he was looking after, and not his master's game. What disproves the lien set up is the fact that any pheasants that might have been in the corn would have gone off at the first alarm, and there was no need for the man to hunt his dogs into the corn for three or four hours at that place. The man was warned by the farmer not to do it, yet for the sake of earning himself 3*s.* or 4*s.* by preserving the pheasants that were his own perquisites, and taking to himself any that might have been killed, he remained in the field and did this damage.—[Evidence was given of the facts.]—Mr. Small thought the Bench would at once see that this was no case for a criminal court. The man's express business was the protection of game. He thought they would see that if complainant had suffered damage he had his remedy in a civil court, and had no cause to bring a criminal charge against the man.—Dr. Marsham thought that if he had only once sent the dogs in it might not have been considered wilful damage, but, after he had been warned, to continue the offence aggravated the case.—Mr. Clarke read an extract from the lease, which said "also preserving all game, rabbits, or fish, and liberty for servants or friends to sport over the farm."—Mr. Small contended that though this was not specified, it was for the purpose thereof. The man was ordered to do it in order to protect the game for future sport.—The Bench decided that a conviction must take place, and fined the defendant 5*s.*, costs 11*s.*, damage 50*s.*, and police fees 4*s.*—in all £3 10*s.*

PROPOSED DOOMSDAY BOOK.—We hope Lord Derby's suggestion of the expediency of a new Doomsday Book for England will in the end lead to something. In the present state of the controversy about land, when strong allegations as to the small numbers of landowners are met by flat contradictions, it is obviously expedient to provide some accurate means for getting at the truth. If a complete Doomsday Book is impossible, it should not be very difficult to get a return of the number of owners and the average of their holdings. But there are one or two points in making up such a return which it will be important to attend to, or in the present social state of the country it will be worse than valueless. One is that the return should give of "owners" in the strict legal sense of the word, but of all who have permanent interests of any kind carved out of the soil. It is no doubt important to know what is the number of legal owners, but the bearing of that fact socially is apt to be misunderstood, unless we can ascertain what other people have real interests in the visible property of the country—whether as copyholders, leaseholders (say) for terms of more than 20 years, and even mortgagees, if it were possible to include them. The order for the return will therefore require to be carefully worded. Another important point will be to distinguish above all between house property and unbuilt-upon land. We anticipate that a return of the kind we describe will bring out the fact that an immense number of people have a stake in the country as the owners of houses; but though this is an important fact socially, it would be a misfortune if it should give rise to an erroneous belief as to the ownership of agricultural land. It might give the impression that England is a country of small proprietors as regards land in cultivation as well as houses, which is far from being the case. For ourselves, we should hope to see that the ownership of agricultural land, which is really a difficult business, suitable only for considerable capitals, is neither in a very few hands nor yet very widely diffused. But it will be interesting to see what the distribution really is, and whether it is possible by legislation that would not be worse than the disease to improve it. *The Economist.*

THE REQUIREMENTS OF THE AGE.—The *Aberdeen Free Press* intimates the sort of *régime* we are rapidly coming to. "What the age demands of the possessors of land is that he shall be something more than a mere recipient of its profits, that he shall turn his possessions to the best account for the country by the full development of its resources, or that, if he is unable from want of cash or otherwise to do so himself, he shall make way for some one who will." Upon which we remark, that when "the age" has ordered every useless and injurious tree to be felled, every hedge-row to be kept low, close, and clean, every drainable acre to be drained, and every field to be grazed or cultivated in the best and highest style possible, "the age" will be in a good enough, perhaps, mind not only the necessary money, but the equally indispensable and absent intelligence and resolution for carrying out such an enormous scale of improvement), the agricultural class will take care that all other classes in the community shall "turn their capital to the best account for the country by the full development of their resources." Not a ten-pound note shall be vainly spent, not an hour's opportunity for labour shall be voluntarily lost, not an article shall be fabricated except in the most economical manner. In a word, on the day that "the age" interferes with our due right to manage our farms as we please, "the age" shall also oblige every holder of capital, every possessor of stock-in-trade, every citizen having physical strength, trained skill, or a sound mind, to toil like a slave, or to contrive with ceaseless ingenuity and watchfulness so that "the age" itself did its utmost for the good of the State. *Chambers of Agriculture Journal.*

DEVELOPMENT OF MACHINERY.—The extent to which labour-saving implements have been introduced in agriculture we saw illustrated a day or two ago at Chelmsford. A farmer was seen in one field with gloves on his hands, and with an umbrella over him, and with as much comfort as driving a buggy, he was cutting Oats, the reaper throwing them into regular and convenient sheaves for binding and stacking. We remember the time when, 20 years ago, we were riding above the hurdles, or fences, and let the grain lie where it fell from the scythe. Yet here was a man with a pair of horses, in comparative comfort, doing more in one day than 25 men could have done by hand 20 years ago. *Chicago Tribune.*

LIME AS AN ANTHELMINTIC.—The editor of the *Chelmsford Chronicle* is publishing weekly extracts from former numbers of the same journal 100 years ago; and the following is a letter thus republished from the *Chelmsford Chronicle* of January, 1765:—

"*To the Printer of the 'Chelmsford Chronicle.'*

"The navigation of the river Chelmer, from Maldon to Chelmsford, is a subject which must be of great value to neighbouring lands, greatly interested, and whose thoughts you have promised to encourage, in your paper, by communicating them to the public. I have a remark or two to offer, upon one of its improvements, the utility of which, as appears, upon cold and heavy lands, such as the country west of Chelmsford, chiefly consists of, has been disputed. As a back-carriage, from Maldon, I, some years ago, brought a load of lime, in a gentleman's boat, to Boddings; which, owing to a circumstance not worth reciting, was left upon my hands; and, with some of it, for want of other application, I made the following experiment. I broke down for Oats, before ploughing, as sprinkled it a little with lime, sowed the ground, and harrowed the Oats in. The effect was, that part which I sprinkled with lime produced me a very considerable crop; the remainder, under the same breadth in the same field, was, in a manner, all devoured by the worm; it was a sort of millipedes, but the body of it was red, lank, and long; and, for some years following, when the land was in tillage, I constantly found the carcases of them, in the spot where the lime had been laid. The same year, I sprinkled also a small quantity upon a piece of Barley fallow, which had no advantage, that I was aware of, in point of richness or dryness, from the other part of the field. That part which was limed, went off, as we call it, in May, but soon recovered its colour; that which was not limed, went off also, much about the same time, but never recovered its colour, green, in the Barley, as the other did. And laying the crops apart, measure of ground for measure, that part that had been limed produced me one-third more of corn than the other did. Another year I made use of the principle I had acted upon before, in mind to try what this would do of itself, and carried it upon my fallow for Wheat; but neglecting to check it in the spring, because I durst not venture my sheep upon all the field for fear, except the limed part, it was all over lank and thin, I suffered in the crop, which had too much straw to produce good grain. The lime might not possibly be the only ingredient in the plaster, but it was the principal one; and, if I had mowed it, as they do in Kent, would, I have reason to think, have answered well. The land bore Clover afterwards, and answered in proportion.

"From these experiments, I judge, that lime meliorates and pulverises the soil, destroys grubs, and, by its absorbent qualities, contributes very greatly to the healthfulness and soundness of the grain, even upon cold and wet lands, such as mine, to my great prejudice, are. The virtues of lime upon light land, are, I think, confessed and acknowledged, either for corn or grass; but would be improved, I believe, rather better for grass, as there is no common manure, or compost, to be got in quantities, at any distance from large towns, which will breed, either more, in fineness, or quantity, or continue to promote vegetation so long; but perhaps, if mixed with sludge, or drift out of ponds, or drainings of yards, it would do best of all. This way of using it is much in practice from 10 to 20 miles round London, and, I make no doubt, would be in common use, if fairly and judiciously tried. But the great charge of land-carriage, at present, forbids the mere farmer to go so deep into his purse, to serve one purpose, which must be called upon to answer so many. Pray, sir, inform the public, if it reaches your knowledge, whether, by the aid of the river Chelmer, it could be bought at Chelmsford for 6*d.* a bush.? or what chalk could be landed at there, per ton? That too is not without its great virtues, though not the landsheds in the hundreds experience; and which could not cost much at the pits; the tonnage would be, in a manner, all. If the landlord expects his rent, and the farmer a decent livelihood, it will be necessary, in a few years, to look out for something that may succeed the digging up of doles (so very destructive to fuel and timber) which, it is easily foreseen, cannot long afford a sufficient improvement, with all the ploughing and ditch-earth the farmer can rake and scrape together.

"If these hints may be of any use, to promote the navigation, or instruct my brother farmers, they are at their and your service. *A. Koothinger, Jun.* 2, 1765."

The Week's Work.

OCTOBER 14.—*Mangel Wurzel* is harvested in sundry places about this time, but the work may be deferred to November if the weather is fine and open and the bulbs growing. The crops should, however, be secured before frost sets in, otherwise it is liable to rot where stored. In tailing, remove only the small rootlets and earth, also the branch rootlets of the tap-root, but the tap-root should not be cut, as the exudation of sap is liable to produce rot, &c. From a similar reason, the tops should not be cut so close as to bleed the bulb. Instead twist off the leaves to avoid this, but the process is too dilatory, and if hurriedly and rudely done, twisting is worse than the knife. The bulbs are stored in pits and barns like Potatos and Carrots, though in some cases in narrow lines between hurdles stuffed with straw is preferred. The bulbs in the barns above the hurdles are raised in the form of a roof, and thickly thatched with straw, and the bins are placed alongside each other in a yard, sufficiently close to keep ont frost, but not so close as to prevent the escape of steam from the bulbs. Of course dry settled weather is ideal for harvesting.

Autumn Fallowing and Manuring for spring crops should be proceeded with as speedily as possible.

Manuring for Spring Beans is done either on the flat or in narrow ridges, as for winter Beans, but the land may be left more clodgy, open, and exposed to the winter action. In dry seasons farmyard manure may be carted on to the land with comparatively little harm, and even in wet seasons the harm done is greatly rectified by the winter frosts, especially when the ploughing, smashing, and ridging is done thereon. Whether the land is thus manured on the flat or in drills, it is a better and more forward state to receive the seed in early spring, the fine winter-made mould forming a fine seed-bed either for dibbling or drilling, and staple for the after operations of horse and hand hoeing. The reverse of all this is the case when manuring is deferred to spring, and the work is much more laid over to the horses as compared with autumn.

Parsnips are partial to a dry but rich friable sandy loam, deeply cultivated, and in a high state of fertility. Farmyard manure should be applied at this season, as it requires to be thoroughly incorporated with the land, but it requires to be thoroughly incorporated with the land before the seed is sown. The seed should be sown in a fine seed-bed. The land should be deeply fallowed 18 to 20 inches. For drilling on the flat the manure should be ploughed in 4 to 6 inches deep, and for drilling in ridges it should be finely broken in the open furrows, and in covering the drills should be well ridged up against the winter frost.

Carrots—The land requires to be fallowed and manured for Belgian and common field Carrots as for Parsnips. The Belgian varieties, which are grown on a greater diversity of soil than the common sorts, are proving a more valuable crop, both as to weight per acre and feeding properties, and are therefore fast superseding the other; but the common Carrot is still largely grown on sandy soils.

Potato land is fallowed and manured at this season in the same way as that for Parsnips and Carrots. Opinion is somewhat divided on the manuring of the Potato crop,—some maintaining that the more economical plan is to manure at the time of planting, doctoring farmyard manure with artificial fertilisers, so as to insure its immediate incorporation with the land, as by this plan it yields a more abundant supply of food for young plants. Much may be said in favour of both plans for late spring planting. Autumn manuring with farmyard dung does not do away with the economy of artificial fertilisers at the time of planting. For early Potatos the balance is wholly in favour of autumn manuring; and the fact that autumn manuring obviates

much of the waste farm dung sustains in the strawyard, while it renders the farmer independent of wet and bad weather in spring, is also in favour of autumn manuring.

Mangel Wurzel, Kohl Rabi, and Swede.—The practice is becoming more common of applying farmyard dung at this season to land intended for the growth of these crops next year, artificial manures being applied at the time of sowing by seed and manure drills. The relief which it affords to spring cultivation is greatly in its favour.

Steam Culture.—In the above examples of autumn fallowing and manuring, the ploughing, smashing, ridging, and covering of the manure is best done by steam; and subsoiling, where required, may be done at the same time. So is opening the drills for the manure, the ground or open furrows into which the manure is spread is subsoiled in opening, and in covering the manure by splitting the drills the open furrows left are subsoiled in the same way by a pendent subsoiler under the double-mouldboard plough, thereby with experience a thorough, and their symmetry, beauty, health, and future usefulness be impaired. What they gather in the pastures is no longer fit to support them, and although outdoor exercise is needed, the essentials of the dietary must now be supplied indoors.

Markets.

HOPS.

BOROUGH MARKET, Oct. 11.

Messrs. Pattenden & Smith report an active demand for the best descriptions, and firmness for all others; fully four-fifths of the new crop is already sold. Currency :—Mid and East Kents, £8 to £17 17s. ; Weald Kents, £7 7s. to £11 ; Sussex, £7 to £9 9s. per cwt.

MARK LANE.

MONDAY, Oct. 9.

There was a moderate supply of English Wheat to this morning's market, the condition and quality of which varied considerably ; some few sales were made at a decline of 1s. per qr., and some quantity remained unsold at a late hour ; for foreign the demand was limited, and holders not being disposed to accept lower prices but little business was transacted, except in American ex ship, at a reduction of 1s. per qr. Malting Barley was rather dearer, other descriptions steady. Beans and Peas firm, at last week's quotations. Oats fully as dear. In the value of Flour there was no change.

WEDNESDAY, Oct. 11.

The grain trade to-day ruled quiet. The supplies of both English and foreign Wheat were liberal ; trade was inactive, but prices without further alteration. Fine Barley sold steadily, at full prices. Other descriptions not much inquired for. Malt changed hands slowly on former terms. There were large arrivals of Oats on sale. The demand was not animated, but prices were well maintained. Beans and Peas were steady in sale, with a limited inquiry. Flour experienced a dull sale, at about Monday's quotations.

LIVERPOOL, Oct. 10.—The market was but thinly attended, and the feeling was dull. The demand for Wheat was languid, and the business transacted was to a limited extent, red descriptions being obtainable at a reduction of 1d. per cental. Flour was slow, and previous prices were not maintained. Beans were unchanged. Oats and Oatmeal were quiet. Indian Corn in rather more request, but values showed no material alteration.

SEED MARKET.

The seed trade exhibits but little variation since the date of our last report. A few samples of new German red Clover are to hand, but the high prices asked prevent business. White Clover and Trefoil are both firm. Perennial Rye-grasses meet with a good inquiry, chiefly from abroad, at the recent advance. For Rape and Mustard seed values are steady. Canary seed is dull. Hemp seed is in improved request. New French Italian is exceedingly firm. We have a brisk trade for Blue Peas. Winter Tares experience a slow sale, at the recent decline.

METROPOLITAN CATTLE MARKET.

MONDAY, Oct. 9.

The number of Beasts is not quite so large as last week ; however, trade is dull, and it is difficult to realise last Monday's quotations. The supply of English Sheep is rather shorter, but of foreign larger ; altogether there are more than last week, but choice qualities are by no means plentiful, and prices are not much altered. Choice Calves are scarce and dear, but other kinds are lower. Our foreign supply consists of 3350 Beasts, 14,130 Sheep, 180 Calves, and 20 Pigs ; from Ireland there are 200 Beasts ; and 1470 from the Midland and Home Counties.

Beasts, 5020 ; Sheep and Lambs, 22,070 ; Calves, 208 ; Pigs, 215.

THURSDAY, Oct. 12.

Although the number of Beasts is much smaller than last Thursday, it is quite equal to the demand ; trade is dull, at about Monday's quotations. There are very few English Sheep on offer, and scarcely as many foreign as last week ; prices are rather better for choicest descriptions, but on the whole there is little alteration from Monday. Choice Calves are in demand. Our foreign supply consists of 530 Beasts, 5800 Sheep, 207 Calves, and 10 Pigs.

ENGLISH WOOL.

The rise in the rate of discount has increased the caution displayed by buyers, who are now acting very much on the hand-to-mouth principle, but the wool trade is so intrinsically sound, and stocks so small, that holders are very confident, and in no way inclined to sacrifice their property by trying to force it off in a dull time.

E. A. NEWTON, Actuary and Manager.

Agricultural Land Improvements.

DRAINAGE, SEWAGE IRRIGATION, FARM BUILDINGS, LABOURERS' COTTAGES, &c.

THE GENERAL LAND DRAINAGE and IMPROVEMENT COMPANY.
(Incorporated by Act of Parliament in 1849.)

DIRECTORS.

The Right Hon. Viscount Combermere.	Edward John Hutchins, Esq.
Sir William Lee, K.C.B.	Sir Thomas Phillipps, Bart.

Principal Engineer, Mr. J. BAILEY DENTON.

Agricultural Improvements of every kind are executed by the Company, or the Company discounts regard to Landowners who prefer carrying out the works by their own agents.

Tenant Farmers may, with the Agreement with their Landlords, procure the execution of such Improvements.

The outlay, with all official expenses, may be charged upon the Estate, and repaid by a Rent-charge of about 6 per cent., in 31 years, or at the option of the Landowners in a shorter term.

No investigation of title necessary, and the expenses incurred.

UTILISATION of SEWAGE.

Special arrangements will be made with Boards of Health, Sewer Authorities, and others, for undertaking Works of Sewage Irrigation, together with all Works necessary therefor. The outlay in respect thereof may be repaid either by a sum in gross, or by a terminable yearly payment, discharging in a fixed period the principal amount with interest thereon.

Application to be made to ARTHUR MILMAN, Esq., the Secretary, at the Offices of the Company, 25, Whitehall Place, S.W.

CENTRAL ARGENTINE LAND COMPANY, LIMITED.

Chairman—HENRY WOODS, Esq.

Agent in the Republic—E. HARRY WOODS, Esq., C.E., Buenos Ayres.

Superintendent—WILLIAM PERKINS, Esq., Rosario de Santa Fé.

The Directors offer, on advantageous terms to Settlers, either as Tenants or Purchasers, PLOTS, varying from 80 to 400 ACRES each, of the COMPANY'S LAND, lying on each side of the Central Argentine Railway, from the Port of Rosario to the City of Cordova, the entire length being 261 miles. Towns and Villages are being laid out at various points on the Line, where smaller Plots may be secured for Building Sites.

To secure the best class of Agricultural Settlers and facilitate the Emigration of Families, the Directors are prepared to treat for the Colonisation of Lands within easy reach of the Stations on the Central Argentine Railway, and adapted for immediate cultivation.

Further particulars may be obtained at the Offices of the Company:
London—85, Palmerston Buildings, Bishopsgate Street, E.C.;
Buenos Ayres—Calle Bolivar;
Rosario—Terminus of the Central Argentine Railway;
Where the Plans of the Land (about 400,000 acres), together with the Plans of the Colonies already established, can be inspected.

GEORGE MICHOLLS, Secretary.

85, Palmerston Buildings, Bishopsgate Street, London, E.C.

The Improvement of Landed Estates.

THE LAND LOAN and ENFRANCHISEMENT COMPANY (incorporated by special Act of Parliament) ADVANCES MONEY—

1st.—To the Owners of Settled and other Estates, for the Erection of FARM BUILDINGS and COTTAGES, and for the DRAINAGE, IRRIGATION, ENCLOSING, CLEARING, and general improvement of Landed Property in any part of the United Kingdom.

2d.—For the purchase of Settled Estates in Fee-Simple, and for the REDEMPTION or COMPLETION of MANSIONS, STABLES, and OUT-BUILDINGS.

3d.—To Purchasers generally, to enable them to Subscribe for Shares in Companies for the Construction of RAILWAYS and NAVIGABLE CANALS which will benefit their Property or Estates.

4th.—To Copyholders, for the ENFRANCHISEMENT of COPY-HOLD LANDS.

The amounts borrowed, with the expenses, would be charged on the Estates benefited, and repaid by a Rent-charge terminating in 25 years.

No investigation of the Incumbrances or title is required.

Forms of application, and all further particulars, may be obtained of Messrs. RAWLINSON, HUNTER, and FARRAR, 19, Abingdon Street, Westminster, S.W., and Salisbury; of Messrs. ASHURST, MORRIS, and CRISP, 17, Old Jewry, London, E.C.; of Messrs. WILLIAMS, JEANS, and PATERSON, W.S., 81A, George Street, Edinburgh, Agents for the Company in Scotland; and at the Offices of the Company, 26, Parliament Street.

T. FAIN, Managing Director.
EDWIN CARROD, Secretary.

Land Loan and Enfranchisement Company,
22, Great George Street, Westminster, S.W.

THE LANDS IMPROVEMENT COMPANY.

(Incorporated by Special Acts of Parliament.)

DRAINAGE, RECLAMATION, FARM BUILDINGS, LABOURERS' COTTAGES, TRAMWAYS, RAILWAYS, &c., &c.

DIRECTORS.

John Clutton, Esq.	Granville R. Ryder, Esq.
Frederick J. Halswood, Esq.	Granville R. H. Somerset, Esq., Q.C.
Henry Farquhar, Esq.	Henry W. West, Esq., M.P.
Lord Granville.	Charles Rivers Williams Wynn, Esq., M.P. (Chairman).
John Horatio Lloyd, Esq.	

The Company advances money, authorised under Parliamentary purposes of Agricultural Improvement, including the Erection of Cottages and Farm Buildings, to the Owners of settled and other Estates, and to the Clergy of Glebe Lands in Fee-Simple.

Tenants may, with the consent of their Landlords, execute the necessary Improvements upon the Farms which they occupy, charging them with the cost.

UTILISATION of SEWAGE.—The Company also advances money for the purpose of Works of Sewage Irrigation.

The whole outlay and expenses are liquidated by a rent-charge upon the land, redeeming principle and interest, over 25 years.

No investigation of title is required.

For Forms and further Information, apply to GRANVILLE R. RYDER, Esq., Managing Director, No. 1, Great George Street, Storey's Gate, Westminster, S. W.

ADAMS and FRANCIS INSERT ADVERTISEMENTS in all Parts of the United Kingdom, Colonies, and Foreign Newspapers, Magazines, and Periodicals, WITHOUT EXTRA CHARGE to the Advertiser.

ADAMS and FRANCIS, Advertisement Agents, 59, Fleet Street, E.C.

ONE HUNDRED COLOURED PRINTS, and 44 others.—A pleasing variety of Chromos, Heads of Beauty, &c., for Screens or Scrap-Books, 1s. 3d. per set.

J. REYNOLDS, 174, Strand, W.C.

THE FALL of the LEAF.—At this season, PARR'S LIFE PILLS are used by thousands. They clear from the body all hurtful impurities, restore a healthy action of the liver, bowels, and kidneys, promote the digestion, and thereby create the purest blood, and exhilarate the mind. A small box, price 1s. 1½d., contains 36 Pills, shewing it to be the most economical family medicine.

BILIOUS and LIVER COMPLAINTS, Indigestion, Sick Headache, Loss of Appetite, Drowsiness, Giddiness, Spasms, and all Disorders of the Stomach and Bowels are quickly removed by that well-known remedy, FRAMPTON'S PILL of HEALTH.

They unite the recommendation of a mild operation with the most successful effects; and where an aperient is required nothing can be better adapted.

Sold by all Medicine Vendors, at 1s. 1½d. and 2s. 9d. per box, or obtained through any Chemist.

Adjustable Electric Thermometers.

MESSRS. FRANCIS and CO., Telegraphic Engineers, &c., beg to announce that they are now introducing their new invention, THE ADJUSTABLE ELECTRIC THERMOMETER. It has a double action, giving extreme heat and cold, and may be set at any degree at will. Accuracy warranted. Carriage paid to any Railway Station on receipt of Post Office order for 25s.

Chief Office: 115, New Kent Road, London, S. E.

New Wholesale Depôt, 60, Great Titchfield Street, Oxford Street, W.

Grateful—Comforting.

EPPS'S COCOA.

BREAKFAST.

"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast-tables with a delicately-flavoured beverage which may save us many heavy doctors' bills."—*Civil Service Gazette.*

Made simply with boiling water or milk.

Sold in Packets and Tins only,

JAMES EPPS and CO., Homœopathic Chemists, London.

DINNEFORD'S FLUID MAGNESIA.—

The best remedy for Acidity of the Stomach, Heartburn, Headache, Gout, and Indigestion. It is the safest aperient for delicate constitutions, especially adapted for Ladies, Children, and Infants.

Sold by DINNEFORD and CO., 172, New Bond Street, London; and of all Chemists throughout the World.

COCKLE'S ANTIBILIOUS PILLS.

THE SAFEST FAMILY APERIENT,

In boxes, at 1s. 1½d., 2s. 9d., 4s. 6d., and 11s.

COCKLE'S ANTIBILIOUS PILLS.

These Pills consist of a careful and peculiar admixture of the best known antibilious remedies, with the active principle of the flowers of the Camomile. They will be found a most efficacious remedy for derangement of the digestive organs, and for complaints of the liver, bowels, kidneys, and stomach. Independent of their influence over the secretions, that congestive and unhealthy condition of the system which is the foundation upon their subsequent predisposition to the acknowledged peculiarity of their composition. They are not recommended as a panacea, nor are they adapted to all complaints, but as a mild but searching aperient and tonic in the various forms of indigestion it will not, perhaps, be an exaggeration to state that they have been resorted to under all systems of diet, changes of climate, or atmospheric alternations, with an extraordinary degree of success, for upwards of 70 years. This celebrated Family Aperient may be had throughout the United Kingdom, in boxes, at 1s. 1½d., 2s. 9d., 4s. 6d., and 11s., as well as in India, China, New Zealand, and the Australian Colonies.

COCKLE'S ANTIBILIOUS PILLS.

THE OLDEST PATENT MEDICINE,

In boxes, at 1s. 1½d., 2s. 9d., 4s. 6d., and 11s.

CONTENTS.

THIRSK FLOWER SHOW, September 29.
The following is a LIST of the AWARDS:—

GARDENERS' CLASS.
STOVE and GREENHOUSE PLANTS.
Six Stove and Greenhouse Plants in bloom.—1st, Sir G. O. Wombwell; 2d, Earl Cathcart. Four fine foliage Greenhouse Plants.—1st, Mr. F. Bell; 2d, Sir G. O. Wombwell. Three Stove or Greenhouse Plants in bloom.—1st, J. Walker; 2d, Mrs. Hincks. Six Exotic Ferns.—1st, Sir G. O. Wombwell; 2d, J. Hutton, M.P., Sowerby Hall. Three Lycopodiums.—1st, Mr. F. Bell, Thirsk Hall; 2d, Mr. H. Coore, Scruton Hall. Three Achimenes.—1st, Major Stapylton; 2d, Sir G. O. Wombwell. Four Cape Heaths.—1st, Sir G. O. Wombwell; 2d, Mr. Shenessey, Darlington. Four Fuchsias.—1st, Mrs. Hincks. Two Fuchsias.—1st, Sir G. O. Wombwell; 2d, Mr. Bell. Six Variegated or Zonal Geraniums.—1st, Sir G. O. Wombwell; 2d, Snowdon & Son. Three Tricolor or Variegated Geraniums.—1st, Major Stapylton; 2d, Sir G. O. Wombwell. Three Bronze Geraniums.—1st, Snowdon & Son; 2d, Sir G. O. Wombwell. Two Double Geraniums.—1st, J. Walker, Mount St. John; 2d, Snowdon & Son. Two Petunias.—1st, Snowdon & Son; 2d, Mrs Hincks. Two Lilliums.—1st, Mr. H. Coore; 2d, Mrs. Hincks. Four Coxcombs.—1st, Snowdon & Son; 2d, Mrs. Hincks. Four Balsams.—1st, Snowdon & Son; 2d, Mr. J. Walker. Four Celosias.—1st, Sir G. O. Wombwell; 2d, Snowdon & Son. British Ferns, 10 varieties.—1st, J. Hutton, M.P.; 2d, J. Shenessey.

CUT FLOWERS.
Twenty-four Dahlias, distinct varieties.—1st, H. May, Bedale; 2d, W. Elsworth, Burniston. Twelve Dahlias, distinct varieties.—1st, W. Elsworth; 2d, J. Pratt. Twelve Fancy Dahlias, distinct varieties.—1st, H. May; 2d, J. Walker. Twenty-four Hollyhocks, single blooms.—1st, J. Pratt; 2d, J. Hutton, M.P. Twelve Hollyhocks, single bloom.—1st, J. Harman; 2d, J. Pratt. Twelve Roses, single blooms.—1st, Mrs. Hincks; 2d, Mrs. Coates. Twelve Verbenas, single trusses.—1st, Snowdon & Son; 2d, Major Stapylton. Twelve Geraniums, single trusses.—1st, Snowdon & Son; 2d, Mrs. Barnes. Pansies.—1st, R. Yates, Bradford. Asters.—1st, Snowdon & Son; 2d, Mr. Bean, Clifton, York. French Marigolds.—1st, Snowdon & Son; 2d, R. Yates. African Marigolds.—1st, Mrs. Hincks; 2d, Major Stapylton. Gladioli.—1st, J. Hawman; 2d, Major Stapylton. Stocks.—1st, Mrs. Hincks. Twelve Herbaceous varieties.—1st, Mr. Barnes. Twelve Annuals, varieties.—1st, Snowdon & Son; 2d, Major Stapylton. Six Hand Bouquets.—1st, F. Bell; 2d, Mr. Barnes. Four Hand Bouquets.—1st, J. Walker; 2d, Rev. C. Johnstone. Two Hand Bouquets.—1st, Major Stapylton; 2d, F. Bell. For the best Model of a Flower Garden and Pleasure Grounds.—1st, W. Atkinson; 2d, J. Walker. For the best Device in Cut Flowers.—1st, Sir G. O. Wombwell; 2d, J. Walker.

FRUITS.
Collection of Fruit, 10 varieties.—1st, Mr. Clarke; 2d, Mr. F. Bell, Thirsk Hall. Collection of Fruit, 6 varieties.—1st, Earl Cathcart; 2d, Rev. J. Overton. Two Bunches of Grapes, black.—1st, Mr. Baxter; 2d, Mr. F. Bell. Two Bunches of Grapes, white.—1st, Snowdon & Son; 2d, B. P. Ascough. Peaches.—1st, J. Shenessey; 2d, Rev. J. Overton. Nectarines.—1st, W. Clark; 2d, Major Stapylton. Plums, light.—1st, Mr. Barnes; 2d, Rev. Canon Johnstone. Plums, dark.—1st, Snowdon & Son; 2d, Rev. J. Overton. Apricots.—1st, F. Bell; 2d, Mrs. Newbald. Plums, Green Gages.—1st, Snowdon & Son; 2d, F. Bell. Melons.—1st, Mr. Bean; 2d, J. Walker; 2d, Mrs. Coates. Dessert Apples.—1st, Rev. Canon Johnstone; 2d, F. Bell. Kitchen Apples.—1st, Rev. Canon Johnstone; 2d, T. Barnes. Dessert Pears.—1st, Earl Cathcart; 2d, Rev. Canon Johnstone. Cherries.—1st, Rev. Canon Johnstone. Gooseberries.—1st, Snowdon & Son; 2d, Major Stapylton. Red Currants.—1st, J. Walker; 2d, Snowdon & Son. White Currants.—1st, F. Bell.

VEGETABLES.
Tray of Vegetables.—1st, Snowdon & Son; 2d, Mr. Bean, York; 3d, Mrs. Hincks. Tray of 8 Varieties of Vegetables.—1st, J. Pratt; 2d, Mr. J. Overton. Potatoes.—1st, Snowdon & Son; 2d, Rev. Canon Johnstone. Brace of Prickly Cucumbers.—1st, Snowdon & Son; 2d, J. Walker. Peas.—1st, Snowdon & Son; 2d, J. Walker. Cauliflowers.—1st, Major Stapylton; 2d, Snowdon & Son. White Celery.—1st, Mrs. Coates; 2d, Major Stapylton. Red Celery.—1st, J. Harman; 2d, Mrs. Hincks. Kidney Beans.—1st, Snowdon & Son; 2d, Rev. J. Overton. Cos Lettuce.—1st, Snowdon; 2d, Major Stapylton. Cabbage Lettuce.—1st, Snowdon; 2d, F. Bell. Vegetable Marrow.—1st, J. Pratt; 2d, Snowdon. Beetroots.—1st, Sir G. O. Wombwell; 2d, Mr. Johnson. Jerusalem Spring-sown Onions.—1st, Snowdon & Son; 2d, Mrs. Hincks. Carrots.—1st, Snowdon & Son; 2d, Mr. Bean. Turnips.—1st, Mrs. Hincks; 2d, Sir G. O. Wombwell. Parsnips.—1st, Snowdon & Son; 2d, Major Stapylton. Tomatos.—1st, Snowdon & Son; 2d, Rev. J. Overton. Kidney Potatos.—1st, Snowdon & Son; 2d, J. Walker. Round Potatos.—1st, Snowdon & Son; 2d, J. Walker.

Orchids.

JAMES BROOKE AND CO., Nurseries, Fairfield, near Manchester.—Our recent importations of choice ORCHIDS, especially of the best winter-flowering kinds, having been extensive, and the plants being all in excellent condition, we are enabled to offer them upon terms unusually advantageous. When selections to a fixed value may be sent, if desired, and the choice is left to ourselves, the purchaser pays less than the catalogue prices, and is no loser in regard to merit and variety. We invite attention to our Catalogue and inspection of our stock, especially the contents of our new showhouse.

New English Rose (Hybrid Perpetual Climbing), PRINCESS LOUISE VICTORIA.

WM. KNIGHT, Floral Nursery, Hailsham, Sussex, the raiser of this Rose, will send it out for the first time in November next, good plants at 7s. 6d. each, or three for 20s. Has been awarded Three First-class Certificates. See Report of Floral Committee in *Gardeners' Chronicle*, September 30, 1871.
It will be figured in the "Floral Magazine" for November.
Coloured Drawings will shortly be ready, for 2 stamps, post free.
Descriptive Priced CATALOGUES free on application.

NEW CATALOGUE.

J. WILLS

BEGS TO ANNOUNCE THAT HIS

NEW CATALOGUE of DUTCH FLOWER ROOTS, ROSES, SHRUBS, FRUIT and FOREST TREES, PLANTS suitable for Forcing, &c.,

Is now ready, and will be forwarded Post Free on application. Everything offered is of the best quality, and as cheap as any other house in the Trade. All kinds of Floral Decorations supplied on the shortest notice.
Some idea of the magnitude of J. WILLS' business as an Artistic Floral Decorator and Bouquetist may be obtained from the fact of his having last week received an order for the supply of 2000 handsome Bouquets for Ladies, and 3000 Coat Bouquets for Gentlemen.

ROYAL EXOTIC NURSERY, SUSSEX PLACE, OLD BROMPTON, LONDON, S.W.

The Gardeners' Chronicle
SATURDAY, OCTOBER 21, 1871.

WHAT the ART of seeing is to sure shooting that of THOUGHT is to SUCCESSFUL GARDENING. It keeps us abreast of opportunity, and enables one to hit duty, and overtake work at the right moment and in the most effective place. That fancy is full of deepest meaning, that describes Opportunity with flowing locks in front and bald-pated behind. The thinking man grasps opportunity fearlessly as it approaches, the thoughtless ever runs fruitlessly in its rear. He will bag the richest prizes, either in sport or horticulture, who thinks most wisely and promptly. More evil is wrought, more failures occur for want of thought, than lack of will or knowledge. Knowledge, in fact, apart from nimbleness of thought, the facility of its instantaneous application to each case as it is needed, is of comparatively little use. It is like water in a deep well, a valuable reservoir of refreshment it is true, but incapable of strengthening, gladdening, without the drawbucket to bring it up as we need it. The capacity of thinking is such a draw-bucket. It brings up the wisdom of the past to the level of present duty, providing at once a safe guide and a sure help for our everyday work. It can never be too often repeated that the value of our work depends upon the amount of thought put into it. There are those who attempt to separate thinking from working horticulturists — the first they call theorists, the second practicals. Such distinctions are as untenable as they are mischievous. The best practicals are those who think most—the only true theorists those who have verified all their classified truth by the test of practice, their own, or that of other men. Neither is there anything to hinder one man reading the true lesson taught by another man's practice. On the contrary, there is a strong probability that he may be able more fully to interpret its lessons than the practitioner himself. The careful observer may see further, marshall more correlated facts, weigh truth's meaning with more exactness than the mere worker.

There is a strong tendency amid the working bees in the hive horticultural to be jealous of their natural leaders, that is, those who think more and do better than the average. Each bee intent upon its own work is apt to think its doings the most perfect. But the queen bee alone probably surveys and comprehends the whole structure and complicated use of the

entire hive. To its larger, stronger eye all the cells are marvellously alike. It is very much so with those distinguished by most thought amid the ranks of gardeners. Thinking clears their mental horizon of the mists of conceit, egotism, ignorance; and, looking out upon their craft from the vantage ground of wider truth and broader charity, they learn to esteem the character and work of others as equal to or better than their own, and to measure everything — success, failure, or mediocrity—at its true worth.

Thus the art of thinking, so helpful to our working, becomes the very bond of charity to bind the workers together. All our misunderstandings are born of the mists of ignorance; sweep this clear with a healthy breeze of right strong thought, and the craft would bound up at once to a higher, happier level. Like the cords that fix a balloon to the earth, is the ignorance and weakness begotten of want of thought, and they answer the same purpose, that of keeping horticulturists close to the ground. The first step upwards is to think more and to better purpose. Even genius itself has been defined as an immense capacity for taking thought. Whether this definition is accepted or not, there can be little doubt that thought-taking is the only genius that commands success in horticulture; for what is the art of horticulture from first to last but an incarnation of thought?—life cultured and nourished, utility enlarged and improved, and beauty enhanced, by thought. All the discoveries of man, all the resources of Nature are impressed, by thinking, into the service of production. Science measures the distance and determines the size of the sun; cultivators have to apportion its energy and weigh out its force, to suit the varied capacities of plants. Natural philosophers separate and analyse the constituents of the air—cultivators have to adjust its marvellously exact balances. Geologists classify rocks, earths, salts —cultivators have to mix and use them. Anatomists dissect life—cultivators preserve, nourish, perfect it. Entomologists point out enemies innumerable—cultivators have to attack and subdue them all. In one word, all things that affect life, from the dewdrops that rise to the stardrops that fall, ought to be studied —mastered if possible, by those who would penetrate its mysteries or control its wondrous issues.

Nor is it in these so-called higher walks of horticulture alone, or chiefly, that thought is needed. It is equally or more essential in the every-day operations of common practice. For instance, a tree or plant is transplanted late in the season; the young leaves are soft and tender, and scarcely fully developed; the roots receive a sudden check; the flow of juice to the leaflets is suddenly interrupted. The thoughtful cultivator takes in the whole case; the leaves must be shaded and kept moist, the entire plant developed in a still and moist atmosphere, if possible, and the roots moderately watered. Under such thought-taking conditions the life of the plant is preserved. After a short interregnum it starts afresh, and grows as if nothing had happened to it. But the cultivator with one idea only, would merely water the root, or probably go a step further, and water over the leaves also when the sun shone, but at no other time; and for want of thought, deep and wide, to take in all the facts of the case and all the needs of the plant, it would perish. Here is another case of everyday occurrence among young gardeners. It is early spring. The night has been severe, the sky is bright and cloudless, the cold has done its utmost before the break of day; the temperature of the glass structure is low. The thoughtful young man takes in all the facts; he scans the face of the sky, notes the direction of the wind, registers time, calculates probabilities—a clear day or a cloudy one; and then starts his fires, or damps them accordingly. On the contrary, the thoughtless youth rushes out, notes only two facts—the low temperature outside and inside, makes a rush at the fires, heaps on the coals, draws out the dampers, and in an hour possibly has the inside temperature up to its proper standard; when lo! the sun, which has been gradually rising in strength all the while, comes forth to unite his strength with that of the coal, and the sorely tried plants have to battle for hours with the fierce, exhausting, juice-stealing force of the fire, to their certain exhaustion, and often to their irremediable injury.

We cannot give more illustrations at present, but the everyday practice of horticulture is full of them. And it may safely be accepted as an axiom, that the value of all horticultural work is as the thought put into it. As we sow so shall we reap. The most valuable seeds sown in gardens are thoughts, and nothing yields so full and rich a harvest. The golden age of gardening will date from the time when every worker is also a thinker, and all thinkers sow their best thoughts without stint in the garden.

—— Mr. Tverman, who till recently most efficiently filled the post of Curator of the Liverpool Botanic Garden, has, we learn, resigned that appointment, and is now occupying himself in amateur and experimental gardening, at Penlee, Tregoney, Cornwall, a locality which has been chosen as being well suited for the cultivation of hardy and half-hardy perennials, &c., the climate being mild and moist, and the soil favourable. Long may he enjoy his honourable retirement!

—— For the encouragement of the Saturday half-holiday in London, in connection with the Field Excursions for Natural History Purposes which have sprung out of it, prizes to the amount of 30 guineas are offered by the Duchess of Sutherland, the Countess of Ducie, and the Marquis of Westminster, for competition among members of botanical, microscopical, and geological clubs, and the unprofessional naturalists of London generally. The subjects selected by the prize-givers require from the competitors a knowledge of the Mosses, pond microzoa, and fossils of the London district, obtained by Saturday afternoon excursions during the next twelve months. The prizes are offered through the Early Closing Association.

—— Every fruit-grower, amateur and practical, alike experiences in the autumn months a sore amount of trouble and annoyance, from the havoc committed by Wasps, and many and diversified are the methods adopted for protecting fruit from the ravages of these pernicacious depredators. In the case of Grapes, muslin bags are largely called into requisition, but

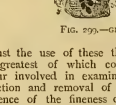

Fig. 299.—Grape bag.

against the use of these there are many objections, the greatest of which consists in the amount of labour involved in examining the bunches for the detection and removal of decayed berries, in consequence of the fineness of the material employed in their construction not admitting such an amount of fresh air as is absolutely necessary to keep the Grapes in a good state of preservation. These drawbacks, however, we are glad to observe, are now in great measure obviated, inasmuch as Messrs. Buck Radclyffe & Co. of Manchester, have introduced, under the title of Vine, Fruit and Grape Bags, an article which will doubtless satisfactorily answer for the purposes intended. These bags are made of several sizes, the material employed is sufficiently strong, and large enough in the mesh to admit of a free circulation of air, without admitting the enemy. The means of fastening them at the neck, by a simple catch of India-rubber, is very efficient. We append an illustration (fig. 299), and recommend them to the notice of our readers.

—— We have lately received from Mr. Fenwick, of Well Head Gardens, Halifax, samples of a very beautiful seedling Diplademia, which we propose to call Diplademia insignis. It is, we are informed, a seedling from D. amabilis, and has flowered for the first time this summer. The plant has now been in flower for several weeks, and thus promises to be of free blooming habit. It is quite distinct from the other fine varieties produced within the last few years—D. amabilis and amœna, and is not only fine in colour, but has more substance in the flowers than any of the other sorts. The colour is a rich, deep, rosy carmine, deeper towards the throat, and as dark on the outer as on the inner surface, the tube having a sharply defined white base. The flowers at this late season, and from a plant in a 7-inch pot, are upwards of 4 inches in diameter. The leaves are smooth, dark-green, oblong, with a cordate base and acuminate apex. It is a very fine thing, and a decided acquisition amongst stove climbers.

—— At a recent meeting of the French Academy of Sciences, M. Dumas, the perpetual Secretary, gave some interesting details of a report written by a committee, of which he is a member, describing the Phylloxera vastatrix, the pest of the Vine. The French Government has offered a substantial prize, to be awarded in 1873, for the discovery of practicable means for its destruction. According to M. Dumas, but two candidates have as yet proposed means which are thought to be good. M. Faucon suggests putting the whole Vine garden under water for two days, which he considers sufficient to suffocate the insects without injuring the plants. In cases where this remedy cannot be applied, M. Blanthou would water the Vines with a liquid composed of 1000 parts water to one part of impure phenic acid. Mr. Dunn's remedy of washing the roots, mentioned in our volume for 1870, at p. 1277, would seem still more likely to be effectual.

—— The *Villa Gardener* says there is a plant of Clematis lanuginosa growing on a garden wall at St. Boswells, having a western exposure, and on which, at the time of a recent visit from the writer, there were 1249 fully expanded flowers. It was one of the grandest sights of its kind the writer had ever witnessed. It must have been grand indeed.

—— The Maximum Temperatures of the Air during the week ending October 14 ranged from 61°.3 at Eccles to 55° at Hull and Dundee, with a mean for the English stations of 58°.2, and for the Scottish of 57°.3. The Minimum Temperatures of the Air ranged from 38° at Portsmouth to 27° at Hull, the mean for the southern country being 32°, and that for the northern 30°.4. The highest Mean Temperature was 48°.1 at Portsmouth, Wolverton, and the lowest, 42°.2, at Glasgow. The mean for all English stations was 44°.9, and for all Scottish 43°.5. Rain fell sparingly over the country during the week, the greatest falls being 0.35 inch at Sheffield, 3.58 inch at Glasgow, and 0.40 inch at Aberdeen. The mean fall for England was 0.21 inch, and for Scotland 0.17 inch. (See Mr. Glaisher's Tables, p. 1362.)

—— The visitor to Woolverstone, as he traverses the drive from the Holbrook road entrance to the pretty church in the park, catches sight of a picturesque block of buildings in the Swiss style of architecture. This is the new Model Dairy. The grounds around this building have been laid out in a very tasteful manner by Mr. Sheppard, the gardener at Woolverstone; and it is pleasant to have occasion to mention, in connection with this fact, that his efforts were so highly appreciated by his employer, John Berners, Esq., that he has presented Mr. Sheppard with a handsome silver tenpot as a token thereof. Such an expression of kindly feeling on an employer's part must always be valued to those who serve, and we are happy to place this instance on record as an example worthy of imitation.

—— We have been trying some experiments with the new insecticide, called Phytosmegma, and have reason to be satisfied with the results. Thrips and red spider, as well as white and brown scale, are all killed readily, if the plants get a thorough dressing through the shower or vaporiser. Mealy-bug is not so easily killed, but we have found that while the first dose clears away much of the mealy matter which protects the insects, a second dressing effectually kills them also. One recommendation of this novel preparation is that it is cleanly, and can be applied, by means of the vaporiser, with great facility, to any part which may be colonised by insects.

—— We understand that the vacancy in the Botanical Department of the British Museum, caused by the promotion of Mr. W. Carruthers, has been filled by the appointment of Mr. James Britten, late assistant in the Royal Herbarium, Kew.

—— The *Athenæum* records the fact that "Dynamite has been most usefully employed in France, in rending the roots of timber trees. In the Forest of Haye (Meurthe-Moselle), where an immense quantity of timber was blown down by storms, the roots remained encumbering the ground. A hole being drilled from 8 inches to 15 inches deep, a dynamite cartridge of 50 grammes (about 800 English grains), provided with a fulminating cap and safety fuse, was placed in it. When the charge was exploded, the root was rended into pieces which were easily removed."

—— M. Dumas has recently reported to the French Academy upon the results obtained by microscopical selection, for curing the silkworm plague known as Pebrine, as suggested by M. Pasteur, and practised by many French breeders of Silkworms. The results were stated to be so far satisfactory, that the plague may be considered as almost entirely suppressed.

—— Mr. Thomas Meehan some time since exhibited to the Academy of Natural Sciences at Philadelphia fruits of an Apple-like Pear, gathered from a Tyson Pear tree growing in the garden of Dr. Lawrence, of Paris, Canada. Dr. Lawrence had a Rhode Island Greening Apple near the Pear tree, and branches of the latter interlaced with it, this interlacing portion alone bearing fruit, though the whole was full of blossoms. The fruit had all the appearance of Apples, and Mr. Meehan, to whom specimens had been sent, regarded them as Apples, but on cutting them open, he found the seeds to be those of the Pear. The granular matter characteristic of the pulp of the Pear was present on the carpels, but none in the pulp, which was wholly fibrous, as in the Apple. The fruit, in fact, had the petiole, carpellary walls, and seeds of the Pear, with the granular Pear pulp wanting, but with the fibrous pulp and epiderm of the Apple. Mr. Meehan suggested that there were two ways to account for these strange productions. They might be produced by a natural evolution of form,

independent of sexual influence, such as plants at times exhibit, or they might arise from cross-fertilisation with the Apple. If the latter, the case would have an important bearing on the question, often mooted, whether cross-fertilisation effects a change immediately in the fruit, or whether change only appears after the germination of the fertilised seeds. In the case of the varieties of Indian Corn, Mr. Meehan observed, we know that the change is immediate, and it is generally believed that some Cucurbitaceous fruits are similarly affected; but he was not aware that it had been observed in other plants, especially in the case of species as distinct as the Apple and the Pear.

—— We may soon expect a new edition of the very useful "Religious Literature of Botanics" of Pritzel, considerable progress having been made in printing the second edition of this catalogue of the books published in all departments of botanical literature.

—— A correspondent of *Nature* thus describes a Great Palm Avenue in the Jardin d'Essai, at Algiers, an establishment which, in 1867, was ceded to the Société Générale Algérienne, and is now under the superintendence of M. Auguste Rivière:—"This avenue was planted in 1847, and is formed of about 80 trees of the Date Palm, nearly as many of the Latania borbonica, and about 150 of the Dragon's Blood tree (Dracæna Draco). The avenue is about 10 yards wide, and runs down every two of the Date Palms there are two of the Dragon's Blood tree and one Latania. It terminates in a clump of Palm trees, which are planted almost to the border of the sea. When it is borne in mind that the Date Palms are from 20 to 30 feet high, the Latanias averaging about 12, and the Dracænas about 8 feet in height, the general effect of this splendid avenue may be imagined. All the trees were, in December last, in full flower or fruit, the golden trusses of the Date Palm contrasting well with the more brightly-coloured clusters of Latania berries. There are other smaller avenues, the most remarkable of which is formed of Bamboo (Bambusa arundinacea), planted in 1863, and forming a mass of foliage, the stems supporting which are from 40 to 50 feet high."

—— The Indian Andromeda Leschenaultii, it appears, yields an essential oil (methyl-salicylic acid) almost identical with the oil of wintergreen, and from which Carbolic Acid can be prepared. Specimens were exhibited at the meeting of the Pharmaceutical Society, which had been prepared by J. Broughton, Esq., the Indian Government Quinologist. The carbolic acid obtained from this source is equal to the purest kind obtained from coal-tar; and though Mr. Broughton thinks it can scarcely be prepared at a cheaper rate than that produced from coal-tar, yet should circumstances render the supply of the English product difficult or uncertain, it may be well to know that a practically inexhaustible source exists in India.

—— Her Majesty's Consul at Messina reports, that the Disease of the Lemon Tree continues its ravages, and nothing has yet been discovered to arrest its progress. Last year both Oranges and Lemons, but especially the latter, were badly tainted, and a large proportion, being unfit for shipment, were converted into juice.

—— Referring again to the Action of Frost on Vegetation, we may call attention to the circumstance that Professor Goeppert has lately published some observations relating to the period when a plant that has entered into the frost dies, and has sought to ascertain whether the process of freezing kills or whether thawing completes the destruction of a plant. According to the theory and practice of many horticulturists, the gradual thawing of a frost-bitten plant is of the utmost importance; hence it follows that frost is less dangerous than a sudden thaw after it, though the direct action of the sun's rays upon the plant. Now we, from our own observations, are inclined to agree with Goeppert in the view that the sun does not exercise the pernicious influence usually attributed to it, and that the damage sustained by vegetation is almost wholly due to the power of the frost. Of course, decisive experiments for or against this position are almost impracticable, on account of the diverse agents and independent circumstances to be considered. A plant will bear a certain degree of cold under certain conditions without sustaining any injury, whereas if that degree be exceeded the plant suffers more or less according to the excess, and nothing can remedy the mischief. Moreover, it is extremely doubtful whether sudden thawing caused by the direct action of the sun's rays increases the injury. The differences in the extent of damage sustained by the same species under different conditions, with the same exposure to the sun's rays, admit of another explanation. If the resisting powers of plants were so narrowly circumscribed we should yearly experience enormous losses, instead of the comparatively exceptional damage that actually does occur. In the numerous experiments instituted by Goeppert, the effects were the same on plants covered with snow after being frozen and allowed to thaw very gradually, and those left exposed. Nevertheless, experiments (Karsten, Sachs, &c.) are not wanting which led to contrary results. These conflicting opinions—for as such they must be regarded—induced Goeppert to seek the means of observing the unfailing signs of death in a frozen plant during the progress of the frost, and after some casting about, he hit upon the plan of watching the chemical changes. Some years ago, Clamor Marquardt detected the presence of indigo in Calanthe veratrifolia and Phajus grandifolia, which, as will be remembered, exists in the living plant as a colourless liquid, and which does not appear as a blue dye until after the death of the plant. If we take the milk-white flower of the former, and crush it between the hands, it will instantaneously assume a blue colour; and, if we allow the flowers to freeze, it is immaterial to what degree—Dr. Goeppert submitted them to —3° to —16° R.—they gradually colour to a dark blue. The labellum and operculum attain the deepest colour, whilst the pollen-masses, and these alone, retain their characteristic yellowish tint, even after thawing. From this it would appear that the pollen-

Fig. 300.—Saxifraga maweana.

masses contain no colouring matter, which is likewise the case in Phajus grandifolia and P. Wallichii. Leaves of these plants exposed to a high degree of frost change at first to a light green, and then to a deep steel blue, and ultimately, when thawed, to a very dark blue; and leaves that had not been frozen, placed between paper to dry at a temperature of +14° R., did not show this deep colour for about the space of eight days, so that the chemical influence of the cold must have been exceedingly intense. Flowers withering naturally exhibit the same peculiarities. Dr. Goeppert accepts this as the most striking proof in support of his argument, that death does not take place before the thaw sets in; and this seems equally applicable as a rule to all parts of a plant.

—— The species of Euphorbia from which the gum-resin, known as Euphorbium, is produced, has long been uncertain. Various species have been mentioned as producing it, especially E. canariensis; but Dr. Cosson, in a paper published in the last number of the "Bulletin de la Société Royale de Botanique de Belgique," identifies with E. resinifera, Berg., a species allied to E. canariensis, and belonging to Boissier's section Diacanthium, as defined in the "Prodromus," in which work, however, it is not noticed. Some fragments found in various samples of Euphorbium enabled Dr. Cosson to identify the species, and he has seen a living specimen in the succulent house at Kew. A full account of the plant is given by Jackson, in his "Empire of Morocco," where it is figured as E. officinarum. Although much used among the ancients, and referred to by Pliny, its gum is now seldom, if ever, used in medicine, on account of its violent action.

New Garden Plants.

Saxifraga (§ dactyloides) Maweana, *Baker.*

Caulibus dense exspitosis copiose ramosis purpureis tenuiter glanduloso-pubescentibus, surculis floriferis e basi decumbente erectis; foliis 6—8 laxe dispositis cordato-reniformibus ultra medium tenuiter palmatipartitis divisionibus 3—5 dentibus oblongis subobtusis instructis; petiolis complanatis dimidio superiore angustealatis limbo saepe 2—3-plo longioribus; gemmis axillaribus robustis copiosis; scapo in corymbum laxum dispositis, pedunculis dense puberulis, calycis dentibus ligulato-lanceolatis subobtusis tubo dense puberulo duplo longioribus; petalis albis obovato-cuneatis pro genere magnis (8—9 lin. longis).

An inhabitant of the Beni-Hosmar range of mountains, near Tetuan, Morocco. This interesting new Saxifrage, of which the characters for horticultural purposes may be best summed up in a single phrase by saying that it is a member of the hypnoides group with flowers as large as granulata, was discovered and brought to England two years ago, by Mr. Geo. Maw, and has been gathered again this spring at the same place by that gentleman, in company with Dr. Hooker and Mr. Ball, during their late expedition. It has been grown at Broseley and Kew since its first discovery, and produces axillary buds so profusely that no doubt it will hold its ground, and become one of our popular favourites for rockwork decoration, for which it is specially adapted from the superiority of its flowers in size to those of all its immediate allies.

General habit of S. hypnoides, the flowering branches ascending in just the same way from an intertangled mass of old stems and barren shoots; new shoots purple in the lower half, finely hairy and glandular. Leaves 6—8 to a shoot, spread over a space of 1½—2 inches, on spreading petioles 6—18 lines long, narrowly winged in the upper half, each with a strong leafy bud in its axil; the blade cordate-reniform, 8—9 lines broad, half an inch deep, with three primary divisions reaching more than half-way down, each primary division furnished with 3—5 broad oblong blunt-ish teeth, the texture rather fleshy and coriaceous. Flowers 4—9 in a lax corymb, the peduncles densely puberulous. Flower-calyx 2—3½ lines long, the ligulate-lanceolate bluntish teeth exceeding the tube. Petals pure white in the upper half, 8—9 lines deep, greenish at the base, distinctly 3-veined, obovate, 4 lines broad, cuneately narrowed in the lower half, the expanded corolla quite three-quarters of an inch across. Flowers in England in the last week in May.

Of the known forms, nearest the Algerine S. oranensis, Munby, Bull. Soc. Bot. France, vi., 284, which differs by its rhomboidal leaves, cuneate in the lower half, cut about half way down into three entire lobes, and more numerous much smaller flowers; and the Spanish S. cuneata, Willd. (S. camposiella, Cav. non Lapeyr.), which has leaves just like those of oranensis, but narrowed gradually into a very short flattened petiole, and flowers not more than half the size of Maweana, arranged in a narrow panicle or simple raceme. The general shape of the leaf recalls that of S. geranioides, but there the divisions are much more numerous, sharper, and irregular, and the profuse axillary gemmæ are absent. *J. G. B.*

ON THE RADIATING ROOT-SWELL AT THE BASE OF A TREE,

And how we may Deal with it, in order to Modify the Course of Vegetation.

There is no part of the whole organisation of a tree more delicately sensitive than the apparently rough and sturdy masses formed by the main root-limbs where they diverge from the central ground axis. This last is indeed the very mid-wife, hand, and interjoining where root, stem, and branches find their union. Life is here most full of vigour, but also highly responsive to every variation of heat, cold, drought, evaporation, nay of light itself. Great command may be acquired over the growth of a tree by a knowledge of the functions of its base, and its leading root-limbs diverging therefrom. And the study of vegetable physiology will quickly enable any intelligent man to master the simple principles with which these functions have been found to harmonise, and to test and try them by his own independent observations.

It happens, not unfrequently, that some fine half-grown tree upon a lawn or foreground, or in the middle of a field, or near a building, or in front of a garden, is threatening to become very soon inconveniently high and large for its place. The owner and his friends are ever admiring it, but yet bewailing the vigour and rapid growth that must soon condemn it to

the axe, amidst general regrets. But far worse—a whole line, or double line of trees, may be felt by every one to be on the point of outgrowing their proper size in reference to surrounding objects.

We cannot practically have recourse to root-pruning in the case of a great half-grown forest tree. It would not only be a costly operation, but exceedingly uncertain in its effects. If done cautiously and tentatively, at a distance from the trunk, equal to that of the extremities of the side branches, it might have but little effect, even though numberless fibres were divided. If performed 2 feet nearer to the centre, and a dry summer supervened, it might prove too violent a remedy. At best it is a rude and harsh operation, such as ought not to be allowable in skilful tree-surgery, if the same end can be attained by milder means.

If, however, we apply a check, not to the extremities of the roots by cutting them, but to the sensitive surface of the main roots, just where they part from the central axis at the bottom of the stem, and admit air and light, heat, cold, and evaporation there, by removing, perhaps, but a single barrowful of turf and soil, we shall soon perceive very remarkable effects. No unsightly weakness of foliage will be visible the following summer, but the terminal shoots will be more or less shortened and arrested, and they will prepare themselves for forming flower-buds to be developed in the next ensuing spring. If we turn our eyes downward to the base of the trunk, and look at the root-space which we laid bare but a few months ago, we shall be struck by its visible enlargement from fresh deposit of bark and woody matter over the exposed surface of the root-limbs, so that they are already bulkier than before. The great plant, whose economy we had disarranged by taking away but a few spadefuls of earth and herbage, has applied itself first and foremost to make good that loss and to guard its most important central organism from the exposition and sudden alternations of temperature, by depositing a fresh layer of bark and alburnum, of more than ordinary thickness, upon the main root-space. To do this, it has transferred its vegetative energies from the upper spray, and bestowed them on more needful work below. Such is the wonderful providence which guides arboreal vegetation.

When summer again comes round, flower and seed will probably be found upon the tree, even if it never bore any before; and, if it formerly bore some, there will henceforward be considerably more, whenever the seasons permit. This free-flowering and seeding will again tend greatly to keep the upper growth under check, and the extension of the head and banches at a minimum.

I do not say that the loss of a single barrow of soil will always produce the full effect desired; but two or three certainly will.

If the site be protected from cattle, and the tree be a Lime or an Elm, ten to one but it puts forth many vigorous sucker-like shoots from the exposed surfaces. If so, let them remain. This, again, is owing to the same great effort to deposit ligneous matter as rapidly as possible upon the denuded parts, and to augment their weight, and bulk, and power to resist evaporation. Every one of those shoots will deposit its contribution of matured descending sap and alburnous matter upon the main root from which it springs; and every one of them will a future time intercept a proportion of the ascending sap from rising towards the head, and will so help to prevent the tree from becoming taller than we wish.

Every one must have observed that where high hedges have been thrown down, but the hedgerow trees have been left standing in a mark or paddock, how bold and majestic and picturesque the development of root-swell in such trees has often become. There are old Ashes and Sycamores of this description in Yorkshire and Northumberland that are worth going miles to examine. The mighty moss-grown knobs upon the aged Sycamores of ponderous base, and the still grander proportions of many of the Ashes with their hoary reticulated bark, clad with countless Lichens, would reward a photographer for all the pains he could bestow in order to represent them worthily. But only an accomplished painter could convey the views of the cryptogamic growths, as seen on a fine day in February. Every one of such trees has had a hard struggle for a time, to replace by deposit of fresh wood the weight and protection of the hedge-bank, which formerly shielded its base from the elements. In time its balance of vegetation was restored, and then it went ahead again at the summit, as of yore.

But when we wish to keep a tree permanently at a minimum of upward growth, we must from time to time repeat the removal of some earth from its base and main root-space. And happily we shall soon perceive that this said root-space is becoming itself a most interesting feature of rugged and unwonted character, with curious interstices, inviting the insertion of Mosses, Golden Saxifrage, and small Ferns. But a whole line of trees may have to be so dealt with, if circumstances compel us either to fell or to arrest the upper growth.

Enough, however, for the present. Many must be well aware that the denudation of root-space would afford new resources to skilful gardeners, when called on to give an opinion in the park or forest. Yet the topic has not been discussed, so far as I have seen, since Matthew wrote his admirable work on the Cultivation of Naval Timber, and counselled the exposure of the main roots of Larch trees in Scotland, to cause them to acquire abnormal proportions, and become fit for knee timber to be used in ship-building. Others will doubtless take up the ball which he then threw down, though it has so long been lost among the grass. And perhaps I may also have a few more words to add and examples to adduce. *R. Carr Ellison.*

CRANBERRIES.

THE Cranberry (Oxycoccus palustris), whether in flower or in fruit, is one of the most elegant of British plants. It is thinly scattered, though widely diffused, throughout Britain, but is rare in the south. The pleasant, but by most persons pleasant, flavour of the fruits has caused them to be largely imported from Russia for domestic purposes; and the gradual extermination of the plant in the places where in this country it was formerly most abundant, favours this importation. Before the draining of the Lincolnshire bogs, Cranberries were brought by cartloads into Norwich market; and Lightfoot states that at Longton, on the borders of Cumberland, £20 or £30 were realised by the sale of them each market day, for five or six weeks together. The Cranberries which we see exposed for sale, are, however, more frequently the produce of the American species (*O. macrocarpus*), which, although native, has only been brought into cultivation during the present century, and until 20 or 25 years since was grown on a very limited scale. A recent report of the Washington Department of Agriculture gives some interesting details of this branch of fruit culture, from which we extract some of the following statistics.

Cranberries grow wild in boggy land throughout the northern provinces of the United States, in the adjacent parts of Canada, both on the marshes of the coast and the glades of the Alleghanies, and as far south as Virginia and North Carolina. They first commenced in culture were in the neighbourhood of Cape Cod, Massachusetts, and the result has been an increased productiveness in the plant. There are now cultivated Cranberry fields in many parts of Massachusetts, as well as in Maine, Connecticut, and New Jersey. In Maine such cultivation is limited, as the country seems to be attended with much risk from frost, except when grown in fields which can be readily flooded, or upon the sea-coast, where the sea-breezes modify the severity of the climate. It is chiefly in New Jersey that Cranberry culture is carried on, that State supplying two-thirds of the whole amount reported, of both wild and cultivated, and over three-fourths of the total of cultivated fruit. In 1869, Maine produced 1000 barrels; Massachusetts, 8000; Connecticut, 2000; and New Jersey, 50,000. Some notion of the rapidity with which the culture is growing may be gathered from the fact that while, in 1868, 3220 barrels were freighted at 19 stations on the La Crosse northern division of the St. Paul and Milwaukee Railroad, 14,585 barrels were freighted from the same stations during the berry season of 1869.

Considerable outlay is necessary in preparing the ground for Cranberry culture, as it has to be cleared and levelled, supplied with sand, drained, and planted, and dams for flooding have to be erected. The cost of preparation is seldom less than 200 dols. per acre, and sometimes very much more; but when a field thus prepared has been set into bearing, the returns for but little further expense incurred except that of securing the annual crop, while the profits are such as attend few other branches of agricultural industry. About a hundred bushels, or 35 barrels, per acre is a fair estimate of production from the time when the "vines" come well into bearing, and the profits per acre are from 100 to 300 dols., sometimes more.

Several varieties are now cultivated, of which three are most in request, known respectively as the Cherry, or round-fruited variety; the Pear, or bell shape; and the Bugle, or oblong. The colour varies from white to dark red, some are mottled red and white. The darker the colour the more valued, as they sell more freely and at higher prices.

The insect enemies of the Cranberry are varied and numerous. The "vine worm" (the larva of Anchylopera vaccineana) is, perhaps, the most serious; it produces two broods a year, and can only be effectually destroyed by flooding. A small beetle, Anthonomus suturalis, has the unpleasant habit of selecting blossoms about to expand, making a hole in them and depositing an egg; and there are other foes, the history of which is imperfectly known. In spite, however, of these drawbacks, Cranberry culture is rapidly on the increase, and bids fair to become a very important branch of agricultural industry.

A TROPICAL FOREST.

[We extract the following graphic account from the Rev. C. Kingsley's "At Last," already noticed at p. 1232.]

IN the primæval forest; looking upon that upon which my teachers and masters, Humboldt, Spix, Martius, Schomburgk, Waterton, Bates, Wallace, Gosse, and the rest had looked already, with far wiser eyes than mine, comprehending somewhat at least of its wonders, while I could only stare in ignorance. There was actually, then, such a sight to be seen on earth: and it was not less, but far more wonderful than they had said.

My first feeling on entering the high woods was helplessness, confusion, awe, all but terror. One is afraid at first to venture in fifty yards. Without a compass or the landmark of some opening to or from which he can look, a man must be lost in the first ten minutes, such a sameness is there in the infinite variety. That sameness and variety make it impossible to give any general sketch of a forest. Once inside, "you cannot see the wood for the trees." You can only wander on as far as you dare, letting each object impress itself on your mind as it may, and carrying away a confused recollection of innumerable perpendicular lines, all straining upwards, in fierce competition, towards the light-level far above; and next of a green cloud, or rather mist, which hovers round your head, and rises, thickening and thickening to an unknown height. The upward lines are of every possible thickness, and of almost every possible hue; what leaves they bear, being for the most part on the tips of the twigs, give a scattered, mistlike appearance to the under-foliage. For the first moment, therefore, the forest seems more open than an English wood. But try to walk through it, and ten steps undeceive you. Around your knees are probably Mamures [Carludovica], with creeping stems and fan-shaped leaves, something like those of a young Cocoa-nut Palm. You try to push through them, and are caught up instantly by a string or a wire belonging to some other plant. You look up and round: and then you find that the air is full of wires—that you are hung up in a network of fine branches belonging to a dozen different sorts of young trees, and intertwined with as many different branches of slender creepers. You thought at your first glance among the tree-stems that you were looking through open air; you find that you are looking through a labyrinth of wire-rigging, and must use the cutlass right and left every few steps. You push on into a bed of strong sedge-like Scleriæ, with cutting edges to their leaves. It is well for you if they are only 3, and not 6 feet high. In the midst of them you run against a horizontal stick, triangular, rounded, smooth, green. You take a glance along it right and left, and see no end to it either way, but gradually rising, as it is the leaf-stalk of a young Cocorite Palm [Maximiliana caribæa]. The leaf is 25 feet long, and springs from a huge ostrich plume, which is sprawling out of the ground and up above your head a few yards off. You cut the leaf-stalk through right and left, and walk on, to be stopped suddenly (for you get so excited by the multitude of objects that you never see anything till you run against it) by a grey Lichen-covered bar, as thick as your ankle. You follow it up with your eye, and find it entwine itself with three or four other bars, and roll away from them in great festoons and loops 20 feet high, and then go up with them into the green cloud over your head, and vanish, as if a giant had thrown a ship's cables into the tree-tops. One of them, so grand that its form strikes even the Negro and the Indian, is a Liantasse [Schnella excisa]. You see that by the form of its stalk—about 6 or 8 inches across in one direction, and 3 or 4 in another, furbelowed all down the middle into regular knots, and looking like a chain cable between two flexible iron bars. At another of the loops, about as thick as your arm, your companion, if you have a forester with you, will splash a machete. With a few cuts the Liantasse he will sever it as high up as he can reach, and again below, some 3 feet down; and, while you are wondering at this seemingly wanton destruction, he lifts the bar on high, throws his head back, and pours down his throat a pint or more of pure cold water. This hidden treasure is as strange as it may seem, the ascending sap, or rather the ascending pure rain-water which has been taken up by the roots, and is hurrying aloft, to be elaborated into sap, the leaf, and flower, and fruit, and fresh tissue for the very stem up which it originally ascended. And before it has that done, the woodman cuts the Water-Vine through first at the top of the piece which he wants, and not at the bottom; for so rapid is the ascent of the sap that if he cut the stem below, the water would have all fled upwards before he could cut it off above. Meanwhile, the old story of Jack and the Bean-stalk comes into your mind. In such a forest was the old dame's hut: and up such a Bean-stalk Jack climbed, to find a giant and a castle high above. Why not? What may not be up there? You look up into the green cloud, and long for a moment to be a monkey. There may be monkeys up there over your head, hurley ree Howley [Mycetes], or tiny peevish Sapajou [Cebus], peering down at you; but you cannot peer up at them. The monkeys, and the parrots, and the humming-birds, and the flowers, and all the beauty, are upstairs—up above the green cloud. You are in "the quarry nave of the cathedral," and "the service is being celebrated aloft in the blazing roof."

We will hope that as you look up, you have not been careless enough to walk on; for if you have you will be tripped up at once: nor to put your hand out incautiously to rest it against a tree, or what not, for fear of sharp thorns, ants, and wasps' nests. If you are all safe, your next steps, probably, as you struggle through the bush between tree-trunks of every possible size, will bring you face to face with huge upright walls of seeming boards, whose rounded edges slope upward

till, as your eye follows them, you find them enter an enormous stem, perhaps round, like one of the Norman pillars of Durham nave, and just as huge; perhaps fluted, like one of William of Wykeham's columns at Winchester. There is the stem; but where is the tree? Above the green cloud. You struggle up to it, between two of the board walls, but find it not so easy to reach. Between you and it, are half-a-dozen tough strings which you had not noticed at first—the eye cannot focus itself rapidly enough in this confusion of distances—which have to be cut through ere you can pass. Some of them are rooted in the ground, straight and tense; some of them dangle and wave in the wind at every height. What are they? Air-roots of wild Pines [Tillandsia], or of Matapalos, or of Figs, or of Seguines [Philodendron, Anthurium, &c.], or of some other parasite? Probably: but you cannot see. All you can see is, as you put your chin close against the trunk of the tree, and look up, as if you were looking up against the side of a great ship set on end, that some 60 or 80 feet up in the green cloud, arms as big as English forest trees branch off; and that out of their forks a whole green garden of vegetation has tumbled down 20 or 30 feet, and half climbed up again. You scramble round the tree to find whence this aerial garden has sprung; you cannot tell. The tree-trunk is smooth and free from climbers; and that mass of verdure may belong possibly to the very cables which you met ascending into the green cloud 20 or 30 yards back, or to the impenetrable tangle, a dozen yards on, which has climbed a small tree, and then a taller one again, and then a taller still, till it has climbed out of sight, and possibly into the lower branches of the big tree. And what are their species? — what are their families? Who knows? Not even the most experienced woodman or botanist can tell you the names of plants of which he only sees the stems. The leaves, the flowers, the fruit, can only be examined by felling the tree; and not even always then, for sometimes the tree when cut refuses to fall, linked as it is by chains of liane to all the trees around. Even that wonderful Water-Vine which we cut through just now may be one of three or even four different plants.*

Soon, you will be struck by the variety of the vegetation; and will recollect what you have often heard, that social plants are rare in the tropic forests. Certainly they are rare in Trinidad; where the only instances of social trees are the Moras (which I have never seen growing wild) and the Moriche Palms. In Europe, a forest is usually made up of one dominant plant — of Firs or of Pines, of Oaks or of Beeches, of Birch or of Heather. Here no two plants seem alike. There are more species on an acre here than in all the New Forest, Savernake, or Sherwood. Stems rough, smooth, prickly, round, fluted, stilted, upright, sloping, branched, arched, jointed, opposite-leaved, alternate-leaved, leafless, or covered with leaves of every conceivable pattern, are jumbled together, till the eye and brain are tired of continually asking "What next?"

The stems are of every colour—copper, pink, grey, green, brown, black as if burnt, marbled with Lichens, many of them silvery white, gleaming afar in the bush, furred with Mosses and delicate creeping film-Ferns, or laced with the air roots of some parasite aloft. Up this stem scrambles a climbing Seguine [Philodendron] with entire leaves; up the next another quite different, with deeply cut leaves; up the next the Cerimen † spreads its huge leaves, latticed and forked again and again. So fast do they grow that they have not time to fill up the spaces between their nerves, and are consequently full of oval holes; and so fast does its spadix of flowers expand, that (as indeed do some other Aroids) an actual genial heat, and fire of passion, which may be tested by the thermometer, or even by the hand, is given off during fructification. Beware of breaking it, or the Seguines. They will probably give off an evil smell, and as probably a blistering milk.

Look on at the next stem. Up it and down again, a climbing Fern [Lygodium] which is often seen in hothouses, has tangled its finely-cut fronds. Up the next, a quite different Fern is crawling, by pressing tightly to the rough bark its creeping root-stalks, furred like a hare's leg. Up the next, the prim little Griffe-chatte [?] plant has walked, by numberless clusters of small cats'-claws, which lay hold of the bark. And what is this delicious scent about the air? Vanille? Of course it is; and up that stem zigzags the green fleshy chain of the Vanille Orchis. The scented pod is far above, out of your reach, but not out of the reach of the next parrot, or monkey, or negro hunter, who winds the treasure. And the stems themselves: to what trees do they belong? It would be absurd for one to try to tell you who cannot tell one-twentieth of them himself.* Suffice it to say, that over your head are perhaps a dozen kinds of admirable timber, which might be turned to a hundred uses in Europe, were it possible to get them thither: your guide (who here will be a second hospitable and cultivated Scot) will point with pride to one column after another, straight as those of a cathedral, and 60 to 80 feet without branch or knob. That, he will say, is Fiddle-wood [Vitex]; that a Carapo [Carapa guianensis]; that a Cedar [Cedrela]; that a Roble [Machærium] (Oak); that, larger than all you have seen yet, a Locust [Hymenæa Courbaril]; that a Poui [Tetoma serratifolia]; that a Guatecare [Lecythis]; that an Olivier [Bucida]; woods which, he will tell you, are all but incorruptible, defying weather and insects. He will show you, as curiosities, the smaller but intensely hard-Letter wood [Brosimum Aubletii], Lignum vitæ [Guaiacum], and Purple-heart [Copaifera]. He will pass by as useless weeds Ceibas [Eriodendron], and Sandbox-trees [Hura crepitans], whose bulk appals you. He will look up, with something like a malediction, at the Matapalos, which every 50 yards have seized on mighty trees and are enjoying, I presume, every different stage of the strangling art, from the baby Matapalo, who, like the one which you saw in the Botanic Garden, has let down his first air-root along his victim's stem, to the old sinner whose dark crown of leaves is supported, 80 feet in air, on innumerable branching columns of every size, cross-

FIG. 301.—ARUM CORSICUM.

clasped to each other by transverse bars. The giant tree on which his seed first fell has rotted away utterly, and he stands in its place, prospering in his wickedness, like certain folk whom David knew too well. Your guide walks on with a sneer. But he stops with a smile of satisfaction as he sees lying on the ground dark green glossy leaves, which are fading into a bright crimson; for overhead somewhere there must be a Balata [Mimusops Balata], the king of the forest, and there close by is his stem—a madder-brown column, whose head may be 150 feet or more aloft. The forester pats the sides of his favourite tree, as a breeder might that of his favourite race-horse. He goes on to evince his affection, in the fashion of West Indians, by giving it a chop with his cutlass; but not to wound, he wishes to show you the hidden virtues of this (in his eyes) noblest of trees—how there issues out swiftly from the wound a flow of thick white milk, which will congeal, in an hour's time, into a gum intermediate in its properties between caoutchouc and gutta-percha. He talks of a time when the English gutta-percha market shall be supplied from the Balatas of the northern hills, which cannot be shipped away as timber. He tells you how the tree is a tree of a generous, virtuous, and elaborate race—"A tree of God, which is full of sap," as one said of old of such — and what could he say better, less or more? For it is a Sapota, cousin to the Sapodilla, and other excellent fruit trees, itself most excellent even in its fruit-bearing power; for every five years it is covered with such a crop of delicious Plums that the lazy negro thinks it worth his while to spend days of hard work, besides incurring the penalty of the law (for the trees are Government property), in cutting it down for the sake of its fruit. But this tree your guide will cut himself. There is no gully between it and the Government station; and he can carry it away; and it is worth his while to do so; for it will square, he thinks, into a log more than 3 feet in diameter, and 80, 90—he hopes almost 100—feet in length, of hard, heavy wood, incorruptible, save in salt water; better than Oak, as good as Teak, and only surpassed in this island by the Poui. He will make a stage round it, some 8 feet high, and cut it above the spurs. It will take his convict gang (for convicts are turned to some real use in Trinidad) several days to get it down, and many more days to square it with the axe. A trace must be made to it through the wood, clearing away vegetation for which an European millionnaire, could he keep it in his park, would gladly pay £100 a year.

The cleared stems, especially those of the Palms, must be cut into rollers, and the dragging of the huge log over them will be a work of weeks, especially in the wet season. But it can be done, and it shall be; so he leaves a significant mark on his new-found treasure, and leads you on through the bush, hewing his way with light strokes right and left, so carelessly that you are inclined to beg him to hold his hand, and not to destroy in a moment things so beautiful, so curious —things which would be invaluable in an English hothouse.

(To be Continued.)

ARUM CORSICUM.

THE Arums form a group of tuberous-rooted herbs, several of which are hardy, and are occasionally seen in gardens. Their foliage is in some cases ornamental; as, for example, in A. italicum, and in the subject of the present notice, A. corsicum (fig. 301); while their singularly-formed and peculiarly-coloured spathes invest them with a degree of interest which renders them worth a place in the herbaceous border. Arum corsicum, also called A. pictum, being a native of Corsica and the Balearic Isles, should, however, be planted in a very sheltered position, or wintered in pots. It is, as the accompanying figure (from Messrs. Haage & Schmidt) shows, a species of curious and by no means inelegant aspect; its leaves are cordiform or hastate, of a deep green colour, marked with veins of a greenish white, and its spathe, which is produced towards autumn, is green, and inflated at the base, and ovate, acuminate, inflexed, and of a dark purple hue above. The whole plant is not more than 4 or 5 inches high.

The Arums, as well as the allied genera, are well

* It may be a true Vine, Vitis caribæa, or Cissus sicyoides (I owe the names of these Water-Vines, as I do numberless facts and courtesies, to my friend, Mr. Preston, of the Botanic Gardens, Port of Spain); or, again, a Cinchonaceous plant, allied to the Quinine trees, Uncaria guianensis; or possibly something else; for the botanic treasures of these forests are yet unexhausted, in spite of the labours of Crueger, Lockhart, Purdie, and De Schach.

† Philodendron laceratum: a noble plant.

‡ Monstera pertusa: a still nobler one; which may be seen, with Philodendrons, in great beauty at Kew.

* To know more of them, the reader should consult Dr. Crueger's list of woods, sent from Trinidad to the Exhibition of 1862; or look at the collection itself (now at Kew), which was made by that excellent forester—if he will allow me to name him —Sylvester Devenish, Esq., Crown Surveyor.

known to be extremely acrid plants; but it is singular that in the case of those producing tuberous roots a wholesome farina should be produced in combination with the acrid juice, and that the latter may be driven off by heat, or removed by washing. In this way the leaves of some of the tropical species are made to form a harmless Spinach, when properly cooked with a change of water; and a kind of Arrowroot, called Portland Arrowroot, is prepared in the Isle of Portland, from the starchy tubers of the common Arum maculatum.

Home Correspondence.

Hot-water Circulation.—There is a time for all things, and the time is surely come when inventors and constructors of hot-water apparatus must not be content to allow the principles which govern the circulation of hot-water to remain a matter of doubt or indifference. This, so far as the expression of opinions from practical men is concerned, is the present position of the matter in the pages of the *Gardeners' Chronicle*, and the results of the experiment near Forest Hill go far to show what confusion may arise in construction and improvement on this account. Men, who give a plain and fair statement of the phenomena which present themselves in such trials as these, render a great service. The immediate result is inquiry, and inquiry properly commences with the consideration of elementary principles, as the question whether, and to what extent, the failure is due, to their violation. The time for inquiry seems to be arrived at, because competition is invited between inventors, and it is most undesirable that invention should have longer to struggle with difficulties arising from doubt as to the nature of the motive powers to be employed; also because the same kind of apparatus seems to give rise to complaint of inefficiency in one place, and to satisfaction in another, and both views are often justifiable by appeal to facts. A good thing may thus get a bad name, while perhaps a trifling alteration, dictated at once by a clear knowledge of first principles, would speedily convert a useless apparatus into one thoroughly efficient. How often may it have already occurred that the fault has been laid to the boiler, costly changes made, new forms invented, when not the boiler but the manner of using it has been at fault! Such, reasons for moving in this direction might be multiplied. Such a stage must commonly attend the history of many appliances which belong to a state of civilisation. The immediate wants of man call upon him to light fires before he invents a chimney. We cannot wait for an accurate knowledge of principles before we begin to move. We must therefore build the chimney, whether or not we understand the principles of draught, however many failures we may experience, however clumsy or inefficient the construction may prove. We must improve chimneys with no other aid to guide us, in the way of theory, perhaps, than an erroneous one; perseverance, with observation and tact, guiding us to a tolerably successful issue, and common sense imitating what has thus been proved to be useful. But leisure arrives in due time for the more accurate investigation of principles. I cannot agree with Mr. Fish that study of apparently elementary points are not matters to be brought forward in the later stages of improvement; on the contrary, it often happens that they are never duly applied until such stages are attained, and are of immense value at that juncture. Agriculture and horticulture bear ample witness to the correctness of this view. True theory, then, enables us to profit by all the past, its errors and failures, as well as by its successes. It directs the present and future, enabling us to arrive at good results without the necessity of costly tentative processes, inspiring confidence in the operator and improver. It enables us to know what has already been attained, and to improve in the most economical and efficient manner that which needs only correction, while a new invention, under the guidance of this indicator, is characterised alike by simplicity, economy, and efficiency. The new circulator, lately tested by Mr. Fish, near Forest Hill, would appear, to my mind, to illustrate by the details of the phenomena presenting themselves going surely to prove that the nature of the motive power has been misunderstood. This system was quoted, I think, not only as an example of the application of the expansive power of hot water, but of that power as producing unusually rapid circulation. An "enlarged edition" of the system first used at Woolwich has resulted, as I apprehended it would, in failure. Mr. Fish's description shows that the action of gravitation has been interfered with in a twofold sense. It also shows that expansive power has been called into operation, and has failed to establish circulation. In a twofold sense, I say, gravitation has been interfered with, for firstly, as a motive power it has been needlessly loaded, and its lifting force so far wasted; and, secondly, the force itself has been diminished by the lessening of the perpendicular height of the boiler. It must be quite clear that if a gallon of boiling water is very much lighter than a gallon of cooled water, it is easier to lift the former than the latter. To insure this, it is necessary to lift it to the full height required while close to the fire, and while yet the fire continues to act upon it; for the moment it ceases to boil it shrinks in bulk, and a column of it containing a larger quantity of water is at once very much increased in weight. To utilise the lifting force to the utmost, then, full advantage must be taken of the light and expanded condition of the water, whatever the power employed to raise it may be. It must not be at a distance from the fire, therefore, that this work must be done, but even while the fire acts upon it: it must be taken by the shortest and most direct route, *i. e.*, vertically. Mr. Cannell raises it by a long and circuitous route, allowing it ample time and means, by contact with the cooling atmosphere of the plant-house, to contract and regain its weight; and the gradual upward inclination of the flow-pipe at the same time insures the reflex pressure of all this increasing weight upon the motive power. If he will raise the water to the highest point at once, when it is in its lightest condition, and let it flow over a circular bend just above the general level of the flow-pipe, it is impossible then that this reflex action upon the motive power can come into operation, for the water will not have regained its weight until that weight becomes of use to the circulation. But this needless loading of the weight is not the only interference with the action of gravitation. Whether it is in itself sufficient to stop the circulation in the Forest Hill case it is difficult to say, but obviously it is only a question of yards, feet, and inches. There is the second point of interference with gravitation to be noticed, which, conjointly with the other, conduces in this case to the failure. When the return-pipes, as Mr. Fish informs us, rest upon the fire-flue, we safely infer that the pipes are sooner or later heated by that contact. We are also actually informed that these pipes with their contents were much hotter than the return of the hot water from the plant-house would account for. Now, gravitation, being heated, the water within them was comparatively lighter (being more expanded) than it would otherwise be. The pressure, therefore, on the contents of the boiler would be less, and the motive power, whatever may be its nature, lessened. Thus the candle is burned at both ends, and we receive an extra load, and a weaker horse to draw it. The work is needlessly increased, and the power to do it diminished. Meantime the very cessation of circulation exposes the water in the boiler to a prolonged action of the fire. Elastic vapour is thus produced in considerable, and elastic force called into action. Yet no uniform circulation ensues; an active power is called into exercise, but it is like that of a restive horse left at liberty to kick and plunge inside a travelling van. Its action threatens the upset of the whole machine, but is perfectly useless as regards imparting any aid to the forward motion of the carriage. So the expansive force produced, not the circulation desired, but a fitful motion, which by the aid of valves can be set going either to or fro at the will of the operator, but which cannot be coaxed into a uniform and established circulation. This fitful motion admits of easy explanation, but the entanglement would needlessly cumber this article. A pseudo temporary circulation may be easily got up by the aid of the valves, but no treatment of it can result in a real and useful one, because an important law of motion is violated in the attempt. It is undoubtedly a law of nature when the gentle heat of a fluid or vapour is employed to produce it, that that expansive force shall be confined and resisted in every direction of its pressure, save in that direction or in those directions in which its force is to be actively employed. Now in a hot-water apparatus we want the force to act in one direction only, in order to establish circulation. In the boiler we provide two orifices connected with two pipes. Let us for the moment call them two, and suppose they are not connected with each other externally. Then the law of motion is violated, for while we intend the elastic force to act as a motive power in one direction, we have another orifice which will at once relieve the pressure and destroy the power. But if we connect the two pipes externally, then we have no opening left for the exercise of motive power, for that circuitous pipe is full of water, and closes up both orifices against the action of circulation as effectually as if they were plugged with iron. The circuit of pipes connected with the opening is a part of the boiler itself. *J. M. Taylor, Seer Green Vicarage, near Beaconsfield.*

Cedrus Deodara Coning.—We have a tree here nicely covered with cones. It is one of the smallest in an avenue of 24 trees, and is, I believe, the first which has produced cones. *J. H. Wallace, Redland Lodge, Bristol.*

On the Culture of Verbenas.—In a place where I once lived I had splendid beds of Verbenas, but when I removed to another neighbourhood about 100 miles off I had a miserable failure. My Verbenas were a disgrace and a disgust to me, from what cause it was impossible to say. However, I determined to turn over a new leaf in Verbena growing—for the better, I hoped. Well, I had a dozen of nice plants from the nursery (I never see such now) of good sorts, but not new, 18*s.* the dozen; and having a one-light frame in famous condition for them, I lost no time in giving them the benefit of it. They seemed to enjoy it much, for they started into rapid growth, and I was not slack in lending a helping hand to things which gave me so much pleasure. Soot and soot-water I knew to be excellent for them, and I strewed a little of the former all round the inside of the frame, and just wetted the plants over-head with the latter ere I closed up for the night. My soot-water resembled the highest coloured ale and the finest wine for clearness, and I could make 100 gallons of it in two hours if I had a receptacle for so large a quantity. My plants became so strong that their leaves in some cases looked like Nettle-leaves, and the branches were fine indeed. Now for a race. Talk of races! Well, a boat-race is a very pretty sight, but my race was with my Verbenas, and fairly I got beaten. They grew more quickly than I could grow them, though I was the winner of the first lot of plants. Let me say I had a frame in nice condition for my cuttings to be placed in, and my cuttings were made thus:—The end of every branch found in a fit state was taken off with about an inch or an inch and a half of stem, but with no joint at the bottom, none being required. These cuttings were struck in pure sand, common building sand passed through a fine sieve and washed clean, the pans to receive it being about 7 inches over and 2 inches deep. I filled these with cuttings, and about nine days were sufficient to allow them to strike, which they did nicely, and they would come away just holding enough soil to cover each little root in a way which nothing that I know of but sand will do. All the pots I could spare were quickly filled with the newly-struck plants, but having some open draining tiles, out of which I had just turned some Peas, I determined to press them into the service for the increasing stock, and I ultimately filled two large lights of a long pit with my young family of Verbenas. By this time many of my first struck plants wanted stopping to make them bushy; both old and young plants seemed perfectly hydra-headed, and here I got fairly beaten. I could not keep up with them, and was obliged to call in help. This I believe to be the key to my success—my sweet dung-heap keeping my plants and cuttings in a vigorous growing state, and (what I learned from dear old Donald Beaton) the manner of taking the cuttings so young and striking them in sand. I never saw any one else plant to it, and I do not remember to have lost a single cutting. I had a fine display at a local show in July from plants struck in the spring, but this must form the subject of another paper. *R. T.*

Hornets.—During the past summer we have been much troubled with hornets? which have attacked several fine Oaks and Elm trees, having eaten large holes in them, causing the sap to flow out in large quantities. We have had trees attacked in the same way before, which have since died. Would the death of these trees be caused by the hornets? and what means could be used to prevent the death of those already attacked, or to prevent the insects from attacking others? Any information under the above circumstances would be thankfully received. *Fred. Lee, Tynford Hall, Brandon.*

Diseases in Tea.—I have been pleased and interested to find that the attention of your pathological authority, Mr. M. J. B., has been directed to the so-called blights in Tea. It is, indeed, difficult to determine the causes of these diseases even on the spot; if, however, you can afford me a little of your space, I should be glad to induce "M. J. B." to give the Indian planters the benefit of a little more of his observation. Now, the Tea plantation soils are usually highly manured, applying vegetable matter, and I should be glad to know if the wood ashes which are mixed with this soil after the burning of the forest, or the application of any artificial manure containing great proportions of potash, would be likely to produce any action in the soil detrimental to the well-being of the Tea-plant. How the brown spots and edges of the Tea-leaves to be accounted for? It may happen that only one plant in a thousand is attacked in dry climates, but this plant is sure to be the seed-bed of various parasitical growths, and as your Hylakandy correspondent remarks, the evil is still more marked in wet climates. Over-run weed, I have heard of losses, amounting to 50,000 lb. of Tea, occurring, which were attributed to these so-called "blights" alone. This is a very serious matter, and if it can be shown that the roots and leaves of the Tea shrub are first decomposed through the agency of any alkali, although I suppose it would be impossible to apply any practical remedy, yet Tea planters would be in possession of a valuable scientific fact, and they would certainly be nearer a solution of the difficulty. My observations agree in the main with those of your correspondent as regards the greater prevalence of the diseases in moist climates, but in addition I have fancied that the brown spots appeared first, and then the leaves speedily became covered on the underside with the mycelium of some Fungus, together with Lichen, &c. I am also certain that these attacks are more prevalent on dirty ill-tended estates than upon such as are better cultivated. In fine, the causes are so indefinite that any articles you can afford for the purpose of elucidating the matter are pretty sure to be largely copied by the Indian papers. I cannot learn from your Indian correspondent's letter if the plants on the eastern side of the plants he alludes to, were attacked by any parasitical growths. *James MacPherson.*

Successful Melon Culture.—Calling on a brother gardener recently in Berkshire, I was astonished at seeing a first-rate crop of Melons (Rowden's Superb) then ripening, which was, as the gardener informed me, the second crop from the one plant. There were on this plant when I saw it 20 fruits, nearly all ripe,

and one had been previously cut, which weighed over 3 lb. The first crop, which was cleared on July 6, I was told, was as fine as the one under notice; but it must be mentioned that the gardener, Mr. Keefe, has every convenience afforded him, his worthy employer, E. H. Morland, Esq., West Iseley, near Newbury, sparing neither trouble nor expense in anything connected with his garden. *H. J.*

Fruiting of Pteris scaberula.—The fruiting of this elegant little half-hardy Fern is of sufficient interest, I think, to be recorded, for I believe that it has very rarely, if ever, borne spores in this country. This is the first that has come under my observation, and I have heard many experienced growers remark that their plants produced no fertile fronds. It is so readily propagated by means of the creeping rhizomes that this circumstance, though noteworthy, is of no particular moment to the gardener. The plant I allude to is in the fine collection at Hassock's Gate, belonging to Mr. Parsons. Probably some of your correspondents may have seen fruiting plants. *H.* [It is very rarely seen in fructification, according to our experience. Eds.]

Orchid Cultivation: Feeding by Precipitation.—Mr. Gosse asks me to explain with more fullness of detail what I intended to convey when I wrote at p. 1229, "In all cases where Orchid cultivation is successful, there must be sufficient means of generating the moisture required without the agency of pipe-heat, and the plants must live upon the food conveyed to them by precipitation." As I fully explained in that letter my reasons for objecting to atmospheric moisture being generated by pipe-heat, I will now confine myself to the two points, "the means of supplying our Orchids with food and water." Upon this subject I wrote you once before, which letter published at p. 203 of this year, and it was in reply to that letter that the Rev. Charles Kingsley used the expression "constant precipitation," which Messrs. J. Brooke & Co. have adopted in their advertisement. Mr. Gosse would do well to refer to that letter at p. 417; it greatly delighted me, as containing views I had long since advocated in your pages, and as often had to regret that the subject was not considered worth the notice of our Orchid cultivators. Mr. Kingsley calls the food conveyed by precipitation in a tropical forest carbonic acid; what the food precipitated by the plan adopted in the house alluded to by Messrs. James Brooke & Co. is, chemically described, I do not know, but I can speak confidently of the result from several years of experience. The house is about 20 feet wide, and is divided by two footpaths, thus forming a centre and two side tables, in the usual way. Under these tables the soil has been taken out to a depth of about 3 feet below the level of the path; the table feet rest upon the walls forming the sides of the path, which are carried up a brick higher than the flags, so that the paths can be made to hold water during the night if required. The space under the tables is filled to put fermenting material in, and the height of the tables above the path added to the depth of the pit below, gives sufficient height for a man to work without disturbing the plants. The material used is spent tan, or refuse bark, some stable manure being added; this material was put in by degrees as required till the pits were full, and it is the best way to prolong the process as much as possible, or, in other words, thoroughly to work out each portion before leaving it to exhaust its fermenting qualities, as the labour of putting such materials in and taking them out is of course important. The means are, turning over and adding nitrogen in the form of manure, or strong manure water, always covering this with a little that has not been so mixed, to prevent the ammonia rising in too rank a form; the atmosphere will dictate when such a change is required, and the saving of labour in damping, &c., will amply compensate for any extra trouble in putting the material in. Now some will say that they have tried putting liquid manure in the evaporating pans, and sprinkling it on the paths, and found that it injures Orchids. I should certainly agree with them in that opinion, for I have found that by such means will kill thrips, therefore why should I doubt its injuring Orchids? Watering plants with strong liquid manure, with a little water added, will kill most plants, but that is no reason why watering them with a good deal of water and no manure should not do them good. I counsel no man to rashly risk a valuable plant, but there are thousands, I was going to say, whose experience in Pine growing will enable them to understand this fully, and no one should try such a plan even upon a Cucumber without he does understand it. I am not explaining a little fancy experiment, but a pushing, business way of making Orchids grow into money, without wasting their time; and Mr. Gosse will remember that he kindly confirmed my opinion, that my Cattleyas were only doing in my house what they do in their own country, where they grow twice each year. Must I also add that this is a treatment for the growing season, and that I am not describing a house for resting Orchids in? By this means the atmosphere can be kept nearer to saturation than by any other plan I know of, certainly than by the two contending forces, pipe-heat and evaporating pans; and as the moisture is thrown up equally regardless of the temperature of the house, it must follow that at night, when the heat is the lowest, the condensed precipitation will be the greatest, thus coming as near as we can to Nature's dew-dropping rain. Mr. Kingsley speaks of the forests being so wet in a morning, that a run among the trees confers all the advantages of a bath. Dr. Hooker and Mr. Holton speak of dripping forests; Mr. Wallace and Mr. Bickmore give a like testimony. Mr. Orton and Mr. Bates, I think, express their surprise that it is possible to be in good health in such humid climates. I need not give you a string of quotations, for it is sufficiently obvious that at the right season we cannot have too much moisture in our houses, even after we have used to the utmost all the means at our disposal. I often hear that Orchids are true weeds; the answer I get is, so is every plant in its own country. But this is not strictly an answer, for what country supplies plants so little susceptible of cultivation as Orchids? The Mistleto is our only example; and though this question is so directly contrary to the traditions of the gentle craft that I hardly expect any gardener to admit it, yet I ask it for the purpose of drawing attention to the important part the atmosphere has to play in their well-doing. *G. H.*

Veitch's Autumn Giant Cauliflower.—I think ample proof has been given in these pages to convince the majority of your numerous readers that this Cauliflower is really what it is represented to be, viz., an invaluable acquisition to our gardens. Nevertheless, by way of corroborating previous remarks, I send a few heads for your inspection, one of which has been in bloom upwards of a month, measuring 17 inches over, and 33 inches in circumference, and comparatively speaking quite white and solid, and fit for table. I sowed a packet of seed in March, also a packet of that of Wheeler, in case of disappointment; planted them out side by side, about 200 of each, and the result has been in favour of the Giant; for out of the 200 plants there were only two intruders, all the rest producing heads in proportion to the samples forwarded, whilst from the Waldheren I have scarcely been able to cut one worth sending to the table. *E. Morgan, Harrow-on-the-Hill.* [A fair sample, Eds.]

Onions.—Having heard a few complaints respecting the lightness of the Onion crop this season, I send you the weight of three out of four varieties which I have grown. I sowed them on March 1, in drills 39 feet in length and 1 foot apart, and had 36 rows—12 of Nuneham Park, 12 of White Spanish, and 12 of James' Long Keeping. They were taken up on September 22, and after allowing them time to dry, I had them cleaned fit for the storing-room, and on weighing them then I found I had of Nuneham Park 21 stones, of White Spanish 24, and of James' Keeping 27 stones. I think I may be satisfied with the crop. *Edward Evans, Gr. to the Rev. Thomas Staniforth, Storrs, Windermere.*

Water Weeds.—There is in this locality a small sheet of water, 4 feet deep, and about an eighth of an acre in extent. It is fed by a small pond, and, when I was, 12 months ago, so densely packed with Anacharis Alsinastrum that it appeared almost possible to walk upon it. At the beginning of this year four Aylesbury ducks were placed on the pond, which was surrounded with wire-netting. They took possession of a small island in the centre, and so frequented the water that, and so thoroughly did they appreciate, their delectable food, that there is not a particle of it to be found at the present time. They are in capital condition, notwithstanding that they have had very little of other food. Is not this an economical method of keeping ducks? and would it not be well to convert our would-be ornamental waters into duckeries of three or four dozen birds to the acre, and thereby save the enormous annual cost expended by many in trying to cleanse them, but in reality making, in many instances, bad only worse? If I have been told that ducks and swans are dreadful enemies to the fisherman; so that I fear there is no alternative but to continue mowing, hoeing, dragging, and forwarding on this Yankee gift to our neighbours below, with a sincere wish that they may get rid of it easier than we; also with a fervent hope that our worthy commissioners may eventually succeed in directing that precious *pabulum* at the bottom of our rivers, in which the Anacharis diabolicum thrives so spendidly, into a more safe and serviceable channel. Then, and not till then can there be any real ground of hope that this vile foreigner will meet a death of exhaustion, of which some few so sanguine. I fear, however, that day is far, very far distant. *Thomas Challis, Wilton.*

The Certificating of New Grapes.—It is said that "burnt bairns dread the fire," but the pith of this proverb seems ignored by the Fruit Committee of the Royal Horticultural Society. Within a few years they have certificated several Grapes of doubtful merit, if not wholly worthless. A few weeks ago one of their certificates was returned, and that most honourably, by the raiser of a new Grape. But, Mr. Rivers says, "Why was it ever given?" We can afford to wait until the merits of new varieties are sufficiently tested, but we cannot afford to be deceived. Just when most of us are smarting under the utter collapse of that splendid deceiver, Golden Champion, we have another new Grape certificated—Dr. Hogg. This is a serious matter. What does the committee know of this new Grape, and how long have they known it? And why does not the Society test such fruits as Grapes in their own garden at Chiswick before certificating them? Hundreds of pounds have been squandered of late years upon new Grapes, not half so good as old ones. And the cry is still, they come. We have heard of A 1 and Emperor of Morocco, and others, *ad libitum*; I myself saw a lot of mostly coarse-looking, unripe, new Grapes at Kensington recently, and believe that one of them was certificated. I cannot conceive of a greater service that the Royal Horticultural Society could render to horticulture than the actual trial of new Grapes in their garden at Chiswick. They can try Peas, Lettuces, bedding plants, and a host of other things; surely for very shame they will not tell us that they cannot devote time and space to the testing of this king of fruits. It requires two seasons at least to establish the true character of seedling bedding plants; and it will need at least three or four possibly to test fully the merits of new Grapes. But, I repeat, we can afford to wait, but not to be deceived. If things go on as they have done, we shall soon look upon the certificate of the Fruit Committee as good and sufficient reason why we should not purchase a new Grape. Does this language seem too strong? Look at the facts. Can any one in his senses doubt that had the Fruit Committee exercised proper caution, they could have found out the spotting, rotting propensities of the Golden Champion Grape? And yet not till hundreds of pounds have been spent, time and space wasted, patience and temper tried to the utmost, will this be the case with those of this Grape been proved by bitter experience. These are strong words, and nothing but a conviction of their truth, and the duty of uttering it fearlessly, would have wrung them from me. A sympathiser deeply with the raiser, who may readily have deceived himself, and with the respectable firm who distributed this Grape; but it is essentially necessary to speak out when we find it written in the "Gardener" of last month that the prospects of this Grape are improving. What, then, could it have been before? I have seen this Grape in many places hung in the hands of good Grape growers, and at each it was either going—going—or utterly gone. The "Gardener" cites Keele Hall as a grand example of success. I have seen it there lately, and probably Mr. Hill will be good enough to inform your readers how many perfect bunches of berries of Golden Champion were safely landed on his employer's table? The Grape is not simply capricious—it is virtually worthless. In some positions it won't grow, while in others it grows freely enough, either grafted or on its own roots. These peculiarities might be condoned, but the vital faults are, that it is sour until it is ripe, and that it cannot be ripened without discoloration and patched spots of absolute decomposition. At times, too, it does not stone. I have met with some fine bunches on strong rods, with never a perfect seed in the entire bunch. But why dwell upon the faults of this specious deceiver? Why, for this—to add that the Fruit Committee of the Royal Horticultural Society had better give up certificating new Grapes, or exercise more skill and caution in determining quality. Most of us were constantly astonished at the views propounded by the pomological director at the Congress of Oxford, when he, in vulgar parlance, put the cart before the horse, by placing size before quality as a test of merit. Possibly this is how the Golden Champion won its spurs. If so, it is the more needful to remind the committee that bigness and worthlessness often go together. Morally I feel I have a claim against the Fruit Committee of the Royal Horticultural Society for damages in the matter of the Golden Champion. Were our courts of law likewise courts of moral equity, I ought to recover the guinea I spent upon it. Possibly such a *finale* would arrest the reckless granting of certificates to unknown and, it may be, utterly worthless new Grapes and other fruit. Since writing the above I have seen "R. D.'s" careful estimate of the comparative merits and demerits of the Mackenzie Court and Golden Champion Grapes. I endorse all he says in favour of the first, and condemn the second more decisively. To every one intending to plant the Golden Champion I would say—don't. *Lynx Eye.*

Helianthus annuus fistulosus.—Lovers of the gigantic and grotesque among flowers, and of the Sunflower in particular, cannot fail to be interested in this fine quilled double form of the common Sunflower. I recently saw a large patch of it growing in the trial grounds of Messrs. Sutton & Sons, at Reading. One would not care to have a big bed of it just outside a drawing-room window, but away along the fringes of shrubbery borders, with a dark background of evergreens to throw it up, it might be introduced among Hollyhocks with excellent effect. The flower-heads consist of a dense symmetrical mass of golden-coloured quilled florets. *K. D.*

Melons, at this season, of any contour or size, are most useful and valuable for the dessert, and especially when Peaches and Plums are getting scarce, and when every week brings additional difficulty in getting up a variety of fruit for a large company. We have just now some dozens of Melons in various stages of ripening, and of various shapes and sorts,

from the small close-netted Lord Peter to the largish Cantaloup Prescot. We have long oval-shaped fruits, as the Cassaba, to a variety between the Trentham Hybrid and the Cantaloup, with the latter's flesh and colour, and the former's flavour and contour,—one of many hybrids I raised in France some years ago. Out of all these Melons, a dozen or more sorts, I could not give the palm to either one or the other; they all get their share of praise, so varied are Melons in flavour, and so varied are palates. As a rule two or three go to the table every day, and are valuable one and all alike. I consider the Melon the best of all fruits for breakfast or lunch, and for this purpose a scarlet and a green-fleshed should be dished together in an oval dish. Green-fleshed Melons on the Continent are not considered so *recherché* as the scarlet, and *vice versâ* in this country, as a rule; yet there are many now-a-days who think as the foreigners, and prefer the scarlet to the green. The truth is, it is all a matter of taste, as with black and white Grapes—all are good, and good's best. I have a notion that too much artificial bottom-heat produces hollow, large, light fruit, and bad keepers. I may here observe that we grow our late Melons in a span-roofed pit in which Potatos are planted in February, the whole being cleared off by the beginning of May, in time for the pit to be prepared for the reception of potted-off bedding stuff, this again being removed by the time our Melons are ready to plant. As I have recommended, 6 feet wide, with one hot-water pipe running round on brackets close under the bottom of the light. It was filled with dry leaves and a layer of soil three years ago, at the time it was built, for Potatos, and has never since received any more additional leaves. A large mound of good loam is placed under the light in the form of a ridge on the pit, forming a cone 2 feet in depth; on the top of this we plant our Melons, and this is all the bottom-heat they get, or it may strictly be called top-heat, as it is derived from the heated air from the pipes, or the sun. When levelled down, these heaps of soil form a grand compost for our second Potato Crop. This pit is 88 feet long, and has a maximum of light, and being at an angle of 45°, or about half a square, is as dry as a bone inside, though drenched with rain outside. Sun-warmth is, I believe, all that is necessary to ensure crops of good late Melons, which, on the whole, we find more valuable than early ones, which appear at a time when Strawberries, Figs, and Peaches in large gardens are in use. I may remark further that Melons grown on mounds in this way and ripened now, will keep better and longer than Melons ripened in a more artificial manner. Some of our fruits will be as good a month hence as now. *H. K.*

Picea lasiocarpa.—Mr. Dod has somewhat misunderstood me; if he refers to my letter (p. 1237) he will find me saying "I have the only plant in England of Picea lasiocarpa of Professor Balfour is in my nursery here," and that I took credit for conserving to the country the only plant of Picea grandis raised from Douglas' seeds. I raised a number from two cuttings, taken from the original tree when about 18 inches high, a good number of which I scattered over the country for the fifth Earl of Harrington, and sold them at two and three guineas each. One was returned from a nurseryman "because it was not the true kind!" I then kept it for myself, after paying for it. I enclose you nine specimens, all taken from plants growing in my nursery—viz. 1, from Douglas' original plant of P. grandis; 2, Picea grandis, from imported seed from Vancouver's Island; 3, P. lasiocarpa, from a cutting off Sir William Craig's original plant raised from Jeffrey's seeds. All these a practical eye will see at a glance are only varieties of the same species, namely, P. grandis; 4 to 9 are from trees varying in hardiness, even to a common observer evidently the same species, viz., Picea Parsonsii. I think you will bear me out, that the specific difference between this and grandis is still evident. *William Barron, Elvaston Nursery, Borrowash.* [1, 2, and 3, are identical, as are Nos. 4 to 9, the two sets being evidently distinct. Eds.]

The Rev. John Fountaine's Vinery at Chiswick.—At this season of the year our pages are often occupied with records of success or otherwise of different individuals in fruit growing by various processes. I wish to be allowed to make a few remarks on my "new method" as carried out in the vinery erected for that purpose at Chiswick. An article upon these gardens appeared in the *Gardeners' Chronicle* a few weeks since (p. 1139), in which your correspondent was kind enough to mention my vinery, with a few cursory remarks upon the system. He says he did not consider "the trees looked in any great degree the better for the appliance," adding, however, that it was "well carried out to the end in view." Like many persons taking only a casual view of the system, he appears to have lost sight of that "end." As regards the appearance of the trees, they could not look much better than those in the large fine orchard-house did, when I saw them in the summer under the superintendence of Mr. Barron, nor could I expect that they should do so, beyond perhaps the foliage being a little darker in colour and stouter to the touch, especially as the fruit, being retarded, had probably not begun to swell when that in the orchard-house was ripe. But "the end in view" is to have a sure crop of fruit, of finer colour and finer flavour than other houses produce, and that from a vinery built and managed to the best advantage for Grapes. Whether this object has been attained, I leave your readers to judge, by giving the answer to my inquiries on the subject of Mr. Barron, the superintendent of the Royal Horticultural Society, who can have no interest whatever in the matter beyond a simple statement of facts. In a letter dated September 22, he writes as follows:—"Peaches we are still gathering off your trucks, and some of them very fine, truly splendid in flavour, better than any others in pots in the orchard-houses." As regards the Grapes, I would refer your readers to an article in your journal, p. 1263, on "The Madresfield Court and Golden Champion Grapes," wherein your correspondent speaks of the former Grape as grown in my cold vinery at Chiswick. "Here" (he says) "the Madresfield Court has the appearance of being a valuable hardy Grape, capable of bearing much exposure as the Black Hamburgh, but very superior in every respect. Here is a robust growth, good bunches, fine berries, a capital bloom, and well flavoured; while the Black Hamburgh, which has borne some very fair Grapes, is comparatively flavourless." This trial will no doubt establish the Madresfield Court (previously considered as only fit for the Muscat-house) as a valuable Grape for cold houses: not that I claim any credit for the discovery—it was entirely Mr. Barron's good judgment which appreciated the fitness of this Grape for the position. I believe I have shown some of the Grapes at the last fruit exhibition. The house is, of course, a cold vinery in the proper acceptation of the term, but any amount of forcing may be applied to ripen the Grapes, or such portion of early Peaches as it may be desirable to bring forward, when the Peach-house and flowers are out in midsummer. I never saw a more beautiful display of mixed fruit than my own house exhibited this year when at the best, but it is unnecessary to expatiate upon it, when the house at Chiswick was erected for the express purpose of demanding a fair trial with other fruit-rate houses. *John Fountaine, Southacre Rectory, Brandon.*

Trees for a Dry Soil.—I should be very glad to know what quick-growing trees answer best on a dry gravelly soil. Beech and Larch planted some years ago have not succeeded; the former die from the tap as soon as they attain to a moderate diameter, and the Larch are but poor specimens. Being in a locality where ornamental trees are desired, I propose clearing a fair and planting entirely afresh. *G. T. E. D.* [We sent your letter to Mr. Barron, Belvoir, who obligingly answers as follows:—"In reply to the inquiry addressed to you by a correspondent, I have to remark that as health, vigour, and rapidity of growth in trees may, according to all appearances, be secured when they are planted in suitable positions in regard to climate, and in soils of ordinary fertility, so the opposite consequences may be expected when trees are placed in poor hungry soils or dry gravel beds, which cannot yield the amount of support essential to a healthy development in proportion to their size. Exposed to such circumstances, trees stunted in growth, and exhibit signs of premature decay, such as your correspondent describes. A dressing of lime might possibly renovate the Larch. I have known that tree to thrive on the oolite limestone formation, where the soil was scarcely a foot in depth. Before planting the ornamental trees, trenching be pursued, trench it, turning in all the surface soil, grass, rubbish, and vegetable *débris*; add, if possible, a dressing of clay, marl, or any good soil obtainable, and add further lime, road-scrapings, and old mortar rubbish. Any dry gravel bed thus treated will become moderately fertile, and may be expected to support trees and assist them to make a rapid growth. The Scotch and Austrian Pines and Pinus Pinaster may be planted; Siberian Elm (a variety grown by Mr. Pearson, of Chilwell, which grows well and rapidly on the gravelly soil of Nottingham Park); Planes, Sycamores, Ailantus, and Spanish Chestnut, might also be tried with a chance of success if the ground is made suitable for their reception, by the addition of any of the materials I have suggested. *W. J.*"]

Abies Douglasii.—There is a slight error to correct in the letter respecting the cutting-plant of Abies Douglasii, by the Rev. C. W. Dod. The tree he alludes to was raised from a cutting in 1833, by myself, and planted in 1835, 18 inches high. I consider the parent tree, which was sown by myself in mid-winter, 1827, and is now more than 100 feet high, with a trunk, 3 feet from the ground, 8 feet 10 inches, to be much the finest tree; but in my estimation, both are magnificent specimens—I should think not surpassed in this country. *Philip Frost, Dropmore.*

Brains and Muscles: Theory and Practice.—The men at the tops of the trees consult the buds and leaves; useful botanists, no doubt, and nurserymen to boot. The men below, as far as they go, look at the roots, as far as the shoots, to know how they grow. The Germans adopt the more expressive terms; they call their nurseries tree schools—"Baumschullen." I am afraid most of us will have to go to school again to learn the proper names. It is to be feared the trees have nursed us, instead of our having nursed the trees; and as youngsters are very apt to forget their nurses, no doubt this may be the reason why we have forgotten the right names. Mr. Dod, with his keen eyes, saw some puzzling things at Kew. Another odd specimen declares that a man with three eyes, not many days since, saw three different collections of trees standing at the Royal Horticultural Society's Gardens at Kensington with wrong names. Can this be true? If so, how sad that the Scientific Committee have not been told of it, and more especially as these trees have been there throughout the summer, in order to teach the Fellows the true names. I, for one, should like to be a Fellow properly taught, and shall not be ashamed to go to school again, if I can only find out where the right schoolmaster lives. *A. B. C.*

Primroses.—A large handful of Primroses was picked on October 17 in a hanging wood above Petersfield. *M. G.*

Foreign Correspondence.

NATAL.—Favourable reports reach us from this colony of the appearance of the Sugar-cane, Coffee, and Cotton crops. The early months of the year were warm, supplied with copious rains, and the prospect of the dry season setting in towards the end of April or the beginning of May was looked upon as most favourable for the sugar and Coffee. The Cotton crop also promised well, a disease which had appeared in a few plantations not having spread. This disease appears to attack the plants very suddenly. A correspondent states that, upon going over his plantation, he "found a considerable number of the best bushes all blasted in the ground, every leaf and flower drooping, and wilted, just as if in the morning the bush had been cut from the root and exposed to the sun all day." These plants were carefully examined; there was abundance of moisture in the soil about the roots. Careful search was made for any worms or grubs, both below and above ground, but none were discovered. The roots were apparently as sound and healthy as those of the unaffected bushes growing next to them, but in cutting into the wood of the stem and branches a discoloration of the lignous part was perceptible.

This kind of disease appears to have been previously quite unknown to Cotton growers, and from observations it appears only to have affected the plants growing in plantations which have been made upon old cattle-kraals, where the manure was in too great excess, and was consequently too stimulating. This theory is borne out by the opinion of a Coffee planter of some experience, who says that Coffee trees grown in plantations similarly situated have been affected in like manner. It is said that in cutting the diseased stem lengthwise a number of rusty-red, irregular, isolated streaks are seen running into one another; in the cross section this reddish discoloration appears to be confined to the soft vascular portion between the medullary rays.

ASCENSION.—A correspondent in this island writes:—"Many of the Indian Pride trees (Melia Azedarach), are larger than I can encircle with my arms. The tree produces an immense quantity of seed, which, in falling, is carried to the lower part of the island, and so is rapidly increasing. The Australian Wattle, too (Acacia sp.) is increasing so fast, that it threatens soon to cover the whole mountain. Of course all these trees bring down the rain; so much so, indeed, that one of the officers who has been here five years says, that even in his time vegetation has extended for a mile further down the side of the mountain, while the "little grass," of which Darwin speaks, has now extended to within 3 miles of the garrison. Last year the Wild Ginger, Briar, and Wattle, grew so fast as to completely block the path to the peak. These facts show how fast introduced plants are spreading. The clinker is rapidly breaking up, and, as in all volcanic places, thus forms good soil. The clinker first becomes heated by the sun, and then when the rain comes, it falls to pieces, or a quantity crumbles off; and when even a thin coating of vegetation is once established on this so as to retain the moisture, almost anything will grow. In the rainy season the grass is as green as any in England. It is, however, twice as long, and so rank that cattle will not eat it."

Societies.

WOOLHOPE CLUB: *Oct.* 10.—The Royal Horticultural Society's exhibition of edible and poisonous Fungi was immediately followed (on Tuesday, Oct. 10) by the annual foray for, and exhibition of, Fungi at Hereford. This congress really commenced on the previous day (Monday), when the members of the Club and many visitors flocked into Hereford. Foremost amongst these were Frederick Currey, Esq., F.R.S., C. Edmund Broome, Esq., of Batheaston, the Rev. W. Allport Leighton, of Shrewsbury, M. C. Cooke, Esq., of London, Edwin Lees, Esq., President of the Malvern Club, and many others too numerous to name, from all parts of the country. On Monday, the day before the great foray, there was a short excursion to Dinedor Camp, near Hereford, preceded by a trial of the comestible qualities of what has been aptly termed the "poor persons' procerus pie." This was a most delicious and appetitious pie, produced, we believe,

under the direction of a lady from London. This pie simply contained two barn-door fowls and 30 specimens of Agaricus procerus, the "Parasol Agaric." There were no two opinions about this culinary triumph; it was pronounced by all who were fortunate enough to get a portion of it, to be at once and in every particular perfect. This substantial embodiment of gastronomic botany disappeared all too soon, leaving, however, an expression of its pleasant recollections stamped on the consumers faces, seldom seen, except, perhaps, in the figures illustrating the cartoon advertisement of "Barry's Nabob Pickles." Returning to the preliminary excursion to the Fir woods of Dinedor Camp, we will simply say that the party consisted of ten persons who met with the success usual on such occasions in procuring an abundance of specimens for the next day's exhibition. Towards dusk one of the party was certainly lost, and had to be searched for by three gentlemen for half an hour or so, amongst the dense growth of Firs, Larches, and underwood; but at last he came to light in an adjoining field, and all the party returned to Hereford with light hearts in a curling fog. By this time hamper after hamper of Fungi had arrived, and one or two devoted gentlemen were busily engaged all the evening (and till late at night) in arranging and naming the specimens by candle-light at the "Green Dragon." Although the writer of this notice retired to bed near midnight, tired almost to death, yet he had to submit to a rude awakening to be told in the dark that there was "a splendid collection of Fungi over at the 'Green Dragon,'" and another awakening long before cockcrow in the morning to be told "to be quick up and help to arrange and name the Fungi over at the 'Green Dragon.'" This was the morning of the "Foray" and "Exhibition," and as this notice may be conveniently divided into two parts, we will take the pleasant "Foray" first, and the somewhat drier "Exhibition" next.

By the 9.20 A.M. train from Hereford, 40 gentlemen and two ladies started for Dinmore Hill. The morning was foggy and fungous, and the excursionists were in the best of spirits, one gentleman even sporting an Agaricus in his button-hole. On arriving at Dinmore the search began in earnest, and here it need hardly be said that the members and guests of this Club by no means confine themselves to the study of the gastronomic qualities of Fungi, but pursue the study of British mycology with such zeal and success that, for instance, Mr. Plowright alone, of King's Lynn, has since the last annual excursion added several excellent new species to the British lists, and detected others new and at present only waiting to be published with figures. Dr. Bull's work in discovering several new things, and Dr. D. M. M'Cullough's, of Abergavenny, in lighting on that noble addition to our Flora, Lactarius controversus, are known to all our readers. The first rarity was met with by Mr. Phillips, of Shrewsbury, in Marasmius fœtidus, a remarkable Agaric, with a disgusting and potent odour of putridity and garlic; Mr. Plowright found the same species next day. Helvella crispa (fig. 302), and H. elastica were soon found, and we were not a little surprised to see a gentleman eating one of the former species raw. Some discussion took place as to the proper mode of preparing this plant for the table, as when not properly cooked it is apt to be tough. A good way is to allow the plants to simmer over a gentle fire for three quarters of an hour, add pieces of ham, or some good beef gravy, and the Fungi will be found both tender and delicious. High on the branches of a noble Beech one of the members espied the lovely Agaricus mucidus (fig. 303), unfortunately out of reach of arms and walking-sticks. Owing, however, to the kindness of a gentleman from Werndûh, who allowed a clergyman to stand upon his shoulders, specimens of this plant were procured for the exhibition. This exquisite Agaric is seldom seen so far north as Hereford, being far more common in the southern counties of England; it is peculiar to the Beech and Beech-mast, and is remarkable not only for its extraordinary beauty, but its very large white spores. Mr. Lees found after this found a good specimen of the rare Polyporus cuticularis. The party during the day crossed the River Lug, to see the unsurpassed lawn, stretching for miles in front of the mansion at Hampton Court. Here, and elsewhere, in grassy places, the Hygrophori claimed special attention. Hygrophorus virgineus, and H. pratensis, were abundant; the former, mixed with H. ceraceus and H. coccineus, looked like so much gold and silver money strewn all over the fields—a regular "Tom Tiddler's ground," where any amount of mycological gold and silver might be picked up. H. conicus, H. niveus, H. puniceus, H. psittacinus, were also seen in abundance, and H. cossus, with its strong odour, exactly like the larva of the goat-moth. Amongst the edible species found were Hydnum repandum, the vegetable oyster; Lactarius deliciosus, the Red-milk Agaric; Agaricus orcella, the vegetable sweet-bread; Boletus edulis, Russula heterophylla, and Agaricus rubescens.

Amongst the most notable poisonous species were Boletus piperatus, Lactarius torminosus, "the slayer," L. turpis, L. blennius, L. vellereus, L. piperatus—and many others, too many to mention. The different species of Cortinarius were everywhere most abundant, a genus which is at present far too little known in this country, and one which it would be well if the Woolhope Club would work up in earnest.

The exhibition of Fungi at the "Green Dragon" hotel was better and more extensive than the one in London. Especially to be mentioned were the collections from Whitfield and that of the Rev. W. Houghton, from the Wrekin, Shropshire. Most attention was, perhaps, paid to the numerous specimens of Agaricus clavipes, the Agaric new to our lists, and Merulius tremellosus, brought by Mr. James Renny from an old Apple tree at Werndûh.

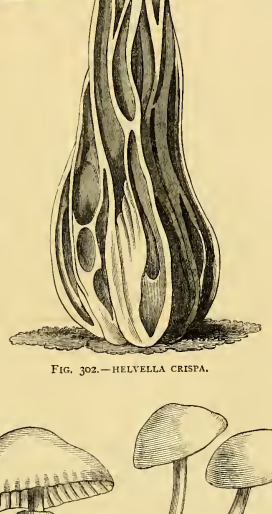

FIG. 302.—HELVELLA CRISPA.

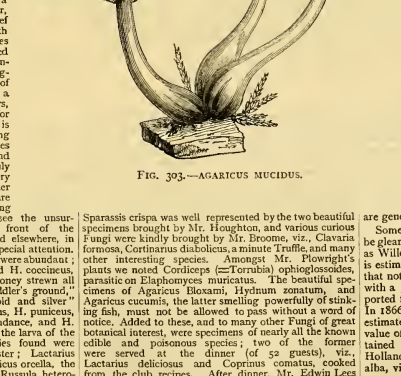

FIG. 303.—AGARICUS MUCIDUS.

Sparassis crispa was well represented by the two beautiful specimens brought by Mr. Houghton, and various curious Fungi were kindly brought by Mr. Broome, viz., Clavaria formosa, Cortinarius diabolicus, a minute Truffle, and many other interesting species. Amongst Mr. Plowright's plants we noted Cordiceps (=Torrubia) ophioglossoides, parasitic on Elaphomyces muricatus. The beautiful specimens of Agaricus Broxami, Hydnum zonatum, and Agaricus cucumis, the latter smelling powerfully of stinking fish, must not be allowed to pass without a word of notice. Added to these, and to many other Fungi of great botanical interest, were specimens of nearly all the known edible and poisonous species; two of the former were served at the dinner (of 52 guests), viz., Lactarius deliciosus and Coprinus comatus, cooked from the club recipes. After dinner, Mr. Edwin Lees read a paper "On the Nomadic Growth of Fungi, with reference to the Germs that are found in Snow and Rain," which subject, though offering a wide field for discussion, was not seriously taken up by any member present. Later in the evening (at the house of Thomas Cam, Esq., the President), an excellent paper was read by Mr. James Renny, of London, "On Saprolegnia and its Alliances," which excited some discussion, and was certainly listened to with the greatest attention by all present. This brought the second day to a very pleasant close. The morning of the third day was devoted to taking notes of, and sketching Fungi by some members, whilst two or three others went again to the Dinedor plantations. Whilst botanising there the party was overtaken by rain, and there was a party of sportsmen shooting, so that what with the rain trickling down, shots flying about, and dogs barking, the party thought it better to return at once, and join the eight or 10 other gentlemen who were going to Haywood Forest, where Strobilomyces had been previously found; here the party met with all sorts of Fungi, notably once more Marasmius fœtidus, Agaricus acerosus and Coprinus picaceus. The Fungi about here, however, though plentiful enough, were of no special interest, they were mostly of the commoner sorts, the genus Cortinarius prevailing. In the evening of this the third day, Mr. Cam, the President, most hospitably entertained at dinner some of the botanists visiting Hereford. On Thursday Mr. Renny acted as guide to a party to Abergavenny, where they were received with the greatest kindness by Dr. D. M. M'Cullough, who conducted them to the celebrated Lactarius controversus rings—this was entirely fresh ground, and in the hilly woods about Abergavenny all sorts of excellent Fungi were found. Mr. Broome returned to Hereford the same evening, Mr. Cooke to London the next day, whilst one or two botanical enthusiasts from London were still there on the following Monday afternoon, making altogether a week's delightful holiday. At Abergavenny three species of Geoglossum were at once found, viz., G. difforme, G. hirsutum, and G. glutinosum; a new set of Hygrophori were met with, viz., the rare Hygrophorus calyptræformis, H. unguinosus, H. murinaceus, H. Colemannianus, and H. leporinus. Agaricus cuneifolius and A. jubatus were also abundant. Polyporus quercinus was met with on an old Oak, and near Llanellen a bank was lighted upon covered with one of the starry Puff-balls, viz., Geaster fimbriatus, mixed with Mr. Berkeley's Agaricus undatus.

Taking all things together, this year's Woolhope meeting must be considered a most successful one. The number of species of Fungi observed was very large—perhaps larger than in any former year; the edible species during the Woolhope week were unusually abundant. As for Agaricus procerus, whole cartloads might have been easily gathered in the open places about woods. During the week, and especially at Abergavenny, the edible kinds have been served with every meal, and always with the happiest results. No one deleterious species has once crept in; and should one ever creep in, why,—*experientia docet*. *W. G. Smith.**

* In the report of the Fungus meeting at Kensington we omitted to mention the extremely rare Rhizina undulata, shown by Mr. Austin, of Reading.

Notices of Books.

The Salix, or Willow; *a Series of Papers*. By William Scaling, ten years Basket-maker to Her Majesty and the Royal Family. London: Simpkin, Marshall & Co. Second Edition.

This little *brochure* deals with the Willow from a cultural point of view, and will be very useful to those who desire information concerning the production of osiers for basket-making. We gather from its pages that, with proper care, Willows will pay the cultivator quite as well as any crop usually grown in this country, and that land of little value for ordinary culture can be made remunerative by this means. It is a mistake, however, that Willows will only grow in wet boggy ground. To grow them successfully there must be an adaptation of the variety to the soil on which it is planted. The soft-wooded kinds of Willow, known in the trade as osiers, will grow in much damper soil than the hard-wooded sorts, which are generally called fine tops.

Some idea of the importance of Willow culture may be gleaned from the fact that the land under cultivation as Willow or osier holts in Great Britain and Ireland is estimated at from 6500 to 7000 acres, or more; and that notwithstanding this, between 4000 and 5000 tons, with a gradually increasing demand, are annually imported from France, Belgium, Holland, and Prussia. In 1866 the quantity imported was 4400 tons, of the estimated value of £48,609, as well as baskets to the value of £45,840. The best basket Willows are obtained from France and Belgium; the worst from Holland, where the rapid growing kinds, such as S. alba, viminalis, and decipiens, are principally grown.

In making a Willow plantation, Mr. Scaling advises that the cutting should be thrust entirely under ground, and he gives very good reasons for so advising, namely, that when so planted they send out straight shoots directly from the ground, and do not grow curved at the base, as they do when they shoot out around exposed and pollarded stools. Besides, when the crop is cut, manure can be more readily got out to the land, which can moreover be ploughed and harrowed, and in this way be kept as clean as an arable field. Such is not the case under other conditions of planting. Willows grown straight are more valuable than when bent or crooked at the butt, and they cannot be grown straight if the stools stand above the ground. The Bitter Willows only must be planted where hares and rabbits abound.

The best and finest qualities of Willows, Mr. Scaling tells us, are grown in Nottinghamshire; these always realise a higher price than any others either of home or foreign growth, not by reason of any superiority of soil or situation, but on account of the sorts or varieties grown, some four or five kinds in particular taking the lead of any grown elsewhere.

The average weight of a crop of the best and hardier kinds of Willow per acre for each state is stated at about 6 tons per acre, and of the soft sorts, or osiers, 7 or 7½ tons; the value of the former, if green (£3 10s. per ton), being £21, or if peeled, £25 nett; and of the latter, £17 10s. green, and £22 nett if peeled. These quantities refer to beds which are properly cultivated, not to those which are weedy and only half planted.

Mr. Scaling specially recommends the Bitter Willows for game coverts and for hedges. Of these he indicates S. monandra as a strong grower, suitable for coverts, but not of much use for basket work; S. Forbyana, equally suited to form thick wiry coverts; S. Kerkii, nearly as vigorous as the others, and more secure against the attacks of game or cattle, and also a really good basket Willow. Mr. Scaling's collection of Willows appears to be one of the finest in this country.

—— Under the title of *The Flowering Plants of Tunbridge Wells*, Dr. Deakin furnishes us with a somewhat novel type of local flora. The speciality consists in the illustration of nearly all the 782 species described with a small woodcut, which, although somewhat roughly executed, is in most cases very characteristic of the plant portrayed. These figures have already appeared in the "Florigraphia Britannica" of the same author. Each species is briefly but satisfactorily described, and notes on habit, use, &c., are added, with the localities; in the latter respect, however, the work is scarcely so complete as might be wished. Critical forms are left unnoticed, or but very briefly referred to, and the scientific names, especially in the index, are singularly ill-spelt. In spite of these drawbacks, however, the work is one which might well be put into the hands of a beginner in botany, who would find in the woodcuts a very useful appendix to the descriptive portion of the work.

—— Messrs. Cassell issue a little book upon *The Uses of Plants*, which appears from the preface to be intended both as "a handbook for teachers," and for "reading lessons for schools." It contains a good deal of information, often well put, and usually correct; but the author has a tendency to "baby talk," which will scarcely be appreciated by those who read the book. Occasionally, and quite at random, the long words are divided for the use of the unlearned, and in many details there is a tendency to descend below the level of a child, whose intelligence would enable it to understand the better portion of the book. We are surprised to learn at present that the "Indian Cress or Nasturtium" belongs to the same family as the Garden Cress and other Cruciferæ; and hope that this and one or two other glaring errors will be corrected in a future edition.

Garden Memoranda.

THE KNOWEFIELD NURSERIES, STANWIX, CARLISLE.—These nursery grounds, which have lately passed out of the hands of Messrs. Little & Ballantyne, occupy 130 acres, and have been most happily chosen for situation, quality, and variety of soils. The site is directly north of the "merry city," on an open and elevated situation. Fewer hedges are seen here than in most nurseries, which is considered a great advantage to hardy trees and shrubs, particularly in reference to late spring frosts. The young wood is also much stiffer and better matured, and is preferred both for home and foreign trade. The grounds are within ten minutes' drive of the central station, and would well repay a visit. The carriage entrance is strikingly beautiful, and the borders, for nearly half a mile in length, are planted near the margin with bedding plants the entire length, on the other side, which is backed up with a mixed evergreen shrubs specially selected for the purpose. We noticed here good specimens of the Gold and Silver Queen Hollies. These are backed up again with fine specimens of weeping and other trees, suitable for immediate effect. The American Weeping Willow is here very fine; also handsome specimens of Weeping Ash and Elm. Altogether, the visitor cannot fail to be interested on once entering the grounds. At the termination of this road we come to the residence of the present spirited proprietors, Messrs. Smith & Watt, where a nicely laid out flower garden meets the eye. Here new bedding plants are tested by the side of older favourites. In the centre of one of these beds is a very handsome specimen of Wellingtonia.

A short distance from this is a newly formed Pinetum, filled with well selected specimens evidently arranged by a master hand. From the Pinetum we turn to the trial ground for garden and farm seeds (not previously sent out), which are conducted with great care. From this part of the grounds about 50 acres of seedling and transplanted forest trees, Thorn Quicks, &c., are seen; this stock is very superior, and well worthy the attention of extensive planters. In close proximity were some ornamental trees for avenue planting, with fine stems and heads, which had been repeatedly transplanted, ranging from 10 to 15 feet in height. They consist chiefly of Limes, Elm, Sycamore, common and purple Beech, Chestnut, &c. We also noticed large tracts of Rhododendrons, hardy Azaleas, Hollies (green and variegated), Yews, Box, Arbor-vitæ, and numerous other dwarf growing deciduous and evergreen shrubs.

We now pass through a portion of the ground which has been set apart for Dahlias and Hollybocks. This portion is well hedged round for shelter. We were too late (October 9) in the season to see these in prime condition, as the frost had already told on the Dahlias. Roses and fruit trees are grown extensively; these collections are most complete and of the healthiest description, the latter occupy about 8 acres. The firm has long been famed for its ability in selecting and sending out fruit trees to suit different soils and situations. The pyramidal and bush trees are not only calculated to furnish a garden at once, but are remarkably well shaped, and if planted early would give a crop the first season.

We now retrace our steps towards the greenhouses, and, by the way, we notice the California Bunch-grass (Elymus condensatus), of which about half an acre will be devoted next season to testing the forage qualities of this new introduction. The glass structures (not in number) are mostly span-roofed, of modern construction, and are well arranged. The first house we enter is 70 feet by 20, and contains a large stock of Camellias well set with flower-buds. In this house we noticed a fine plant of Rhododendron Falconeri furnished with several flower-buds. In the stove, 35 feet by 20, contained a splendid lot of Palms, Ferns, &c. Amongst the latter were good specimens of Todea superba and pellucida, also nice plants of Aphelandra aurantiaca Roezlii. In the centre of this house stood Dracæna australis, conspicuous for its size and beauty. The next house (same size) contains a collection of pot Vines, fruiting from six to eight good bunches each, of fine quality; especially fine were Golden Champion and Mrs. Pince. The show-house, 70 by 15 feet, for flowering plants, &c., was very gay, and contained good specimens of Coleus, Fuchsia, &c., but the most attractive features here were the gold and silver Tricolor Pelargoniums. Achievement, Prince of Wales, Sophia Dumaresque, and Lady Cullum were prominent for colour. One hardy propagating house, and two others of large dimensions for general purposes, were well filled with useful stock.

The seed business is conducted in commodious and convenient premises in English Street, whence many novelties, of their own careful selection, are yearly sent out. Chief amongst those of the coming season will be their Knowefield Purple Swede, which has been exhibited very fine this autumn at local and other shows. This variety is of immense size, thoroughly hardy, of beautiful shape, and likely to become a favourite with the agriculturist for general crop, if not with the gardener for late sowings for winter use. In conclusion, we must remark, that Messrs. Smith & Watt bid fair to follow in the steps of the late much-respected proprietor, Mr. John Little. *T. T.*

Obituary.

We have to announce the death of that veteran horticulturist, Mr. GEORGE MILLS, formerly gardener at Gunnersbury Park, Acton, which took place at his residence at Ealing on September 30, at the ripe age of 84 years. Mr. Mills was a native of Hampshire, and the son of a farmer, and leaving home early in life, owing to his father having married a second time, he came to London, and obtained employment at Roehampton in the gardens attached to the residence of Mr. Goldsmith, with whom about when he served being a Mr. Carter, a Cucumber grower of considerable renown in his day. After remaining here some time, he went into the nurseries of Messrs. Lee & Kennedy at Hammersmith, and eventually became gardener at Cranbrook Park, Ilford, the seat of Mrs. Hall Dare, during her lifetime, and continued to hold the same post under Mr. Hall Dare, M.P. for North Essex. On the death of Mrs. Hall Dare, Mr. Mills became entitled to a pension of £30 per annum for life, left him under the will of that lady. After being about seven years at Cranbrook Park, and on the death of the farm bailiff, Mr. Mills also undertook those duties, and as gardener, and successively farm bailiff and head gamekeeper, remained at Cranbrook Park for something like 22 years. Then came a reduction of salaries on the estate, which induced Mr. Mills to seek a change, and bis advertisement for a gardener's situation being seen by Mr. Copeland, then proprietor of Gunnersbury Park, Mr. Copeland at once drove over to Ilford, saw Mr. Mills, and engaged him as gardener at Gunnersbury. Subsequently the Gunnersbury estate was bought by the Rothschild family, who, when they removed to Gunnersbury, contemplated taking their gardener with them. At that time Mr. Mills had a house of magnificent Muscat of Alexandria Grapes at Gunnersbury, and so much were the purchasers pleased with the appearance of this house that they resolved to continue Mr. Mills in the post of gardener. He was gardener at Gunnersbury Park from 1833 to 1853, as nearly as can be ascertained; and on leaving there went to reside in the Uxbridge Road, Ealing, where he continued to his death, growing cut Roses for market. While at Gunnersbury he wrote his treatises on "An Improved Mode of Cultivating the Cucumber and Melon," and on "The Cultivation of the Pine-apple," both of which were dedicated to the late Baroness de Rothschild. The former passed through three editions. He was buried in the Kensington Cemetery at Hanwell.

—— We have also to announce the decease, after a short illness, of M. JEAN VAN GEERT, of Ghent, which took place on the 14th inst. M. Van Geert was in his 78th year. He was well known as a successful and highly-esteemed nurseryman of long standing, and occupied a prominent position amongst his horticultural *confrères* of that peculiarly horticultural city.

JAMES GLAISHER.

Miscellaneous.

MICHAELMAS DAISIES.

Daisies on the emerald lawn,
Daisies rosy-white for dawn,—
Rosy-white for summer's dawn;
Michaelmas Daisies grey and drear,
Dusk in the dusky close of the year:
Michaelmas Daisies for close of the year.

The year is old, and the weary wind
Withers its glory leaf by leaf;
Gone is the garland that April twined,
Gone June Roses, and August sheaf.
The Apples are gone from the orchard boughs,
Faded the creeper's tangled grace;
The bitter blast from its rest must rouse,
For Winter comes on apace, apace.
The old year yearns for its daisied dawn,
All golden bright and rosy-white:
Dreams of the Daisies, like stars on the lawn,
And makes them again in the dusk of its night.

Daisies on the emerald lawn,
Daisies rosy-white for dawn,—
Rosy-white for summer's dawn;
Michaelmas Daisies grey and drear,
Dusk for the dusky close of the year:
Michaelmas Daisies for close of the year.

M. V., in "Spectator."

THE TOUCAN'S BEAK.—The question has often been asked, "Why has this bird such a remarkable beak?" It seems, says a correspondent, that his method of feeding explains the whole riddle of his long, heavy, serrated mandibles. Like the shovel-nosed tribe, or the digger-like tribe, or the curved-beak tribe, shape, form, size, is everything for their peculiar method of obtaining rations. The Toucans feed on insects which lie deep in the corolla of flowers; it especially delights in tubular corollas, and has a great fondness for the rich, scarlet, Fuchsia-like clusters of the Rose de Monta, of Guayana. These clusters he seizes near the calyx, and by longitudinal movements of his powerful mandibles, aided by their serrated edges, saws them off, and then, by his horny and fimbriated tongue, separates the insect portion from the vegetable, and swallows that of which his palate approves, like any other sensible bird. To see him loop from branch to branch, reach out his long, ponderous nose for his breakfast, saw it off, as one sees a butcher in his stall, to see the parts rejected fall to the ground in petaliferous showers, and he maintain his equipoise, has been one of the most pleasant studies of my ornithological curriculum. I have made frequent autumnal examinations of his injesta, and have always found the shields and remains of insects the most abundant in his craw.

"WILD ANIMALS."—At the last Exeter Assizes there was a case in the calendar which strikingly illustiated the uncertainty attending the legal definition of a wild animal. The prisoner, a fisherman, was charged with stealing a lobster, by abstracting it from the "pot" of a fellow fisherman, the said "pot" being sunk in the English Channel, off the coast of Devon. The counsel for the defence raised the objection that a lobster was a wild animal, and that, therefore, a criminal information could not be maintained. The Judge ruled that a lobster was not a wild animal, but considerable time was wasted in argument before the legal status of the crustacean was fixed. A still more curious instance of the difficulty has arisen in the same county. A swarm of bees alighted in a lane near the residence of a farmer named Pidsley, who straightway hived them. A neighbour named Glenville declared that the bees were his, and shaking the hive out of Mr. Pidsley's hive into his own, carried them away. Pidsley sued in the county court for the recovery of the value of the bees, and the Judge, Mr. Serjeant Petersdorff, after hearing all the evidence, said he must withhold his judgment till next court, "there being a variety of points that suggested themselves to his mind with reference to the ownership of wild animals." The possibility of bees being regarded as wild animals was a new light for the Devonshire bee-masters.

LILIES.—The hardy border Lilies are amongst the most useful garden plants known. They are peculiarly hardy and accommodating, requiring no support from sticks or ties; several of them are perfectly hardy in the winter, and capable of resisting any amount of frost, and, if left alone, they increase rapidly, and become more and more valuable every year. We will say nothing of their beauty, for that is proverbial, but it may be proper to add, that many of the hardy Lilies, that are regarded as only suitable for the greenhouse, and grown with great care under glass, are really as hardy as the old common white Lily, and may be grown with it in the same border. To grow the Liliums well requires a deep, moist, rich loam. A stubborn clay may be improved to them by digging deeply, and incorporating with the staple plenty of rotten manure and leaf-mould. They all thrive in peat, or rotten turf, or indeed in any soil containing an abundance of decomposing vegetable matter. The autumn is the proper time to plant Lilies, but they may be planted at any season, if they can be obtained in a dormant state, or growing in pots. They should be planted deep for their size, say never less than 6 inches. When they have stood some years, they should be taken up and parted, and the borders should be deeply dug and liberally manured before they are planted again. If the stems of Lilies become leafless and unsightly before the flowers are past, it is a sign the roots are too dry, or that the soil is impoverished, and therefore, as soon as the stems die down, they should be lifted and replanted. Lilium auratum, the grandest of all the Lily tribe, is as hardy as our common white Lily, and like it will grow with vigour in good loam, though, in common with the rest, it loves peat. Since it has been cheap, it has been plentifully planted out, and proves to be a remarkably beautiful, and indeed noble border flower; but its distinctness will always ensure it a high degree of favour as a conservatory plant. When grown in a pot, the best soil is sandy peat, but it will flower finely in a rich light mixture, such as Fuchsias require. It is advisable to begin with the smallest size pot in which the bulb can be placed, and then to shift to larger and larger pots as the plant progresses and the flower-buds appear, when, of course, there should be no further shifting. In respect of temperature, this is an accommodating Lily, but as a rule a cool house is better for the plant than one which is unattractive. A high temperature, a free supply of water should be plentiful during the growth and flowering, but should be reduced when the flowering is over. *Suttons' Bulb Catalogue.*

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

To conservatories proper the application of a little fire-heat will now be necessary, if for no other purpose than to aid in dispelling any excess of damp, which if not neutralised in its effects by such artificial means, in combination with a high temperature and the copious supply of water should be plentiful during the growth and flowering, but should be reduced when the flowering is over. *Suttons' Bulb Catalogue

CUCUMBER FOR WINTER FORCING: *E. J. W.* You cannot do better than grow Telegraph, if you can get it true.

ENCEPHALARTOS: *Subscriber, West Gorton.* The scale on your Encephalartos is a common enemy, many of the plants being infested with them when imported. We suspect that you have kept your plants in too cold a house, and that their roots are in a bad condition. Turn them out, and if such be the case, repot them into as small-sized pots as you can get them into, and subsequently plunge in bottom-heat.

GRAPES WITHOUT COLOUR: *X. Y.* Most likely the want of colour is owing to the "good crop." It is either through overcropping, *i.e.*, more fruit than there should be in proportion to the foliage; or through a want of air whilst ripening.

NAME OF FUNGI: *T. S. P.* Polyporus sulfureus, very destructive to Oaks, Yews, &c. We do not know what Fungus the Box. J. G. Wood refers to in "Homes without Hands," not having the book at command.

NAMES OF PLANTS: *An Old Subscriber.* The Caper Spurge (Euphorbia Lathyris). We are well aware that the seeds are much used as a substitute for Capers, but the milky juice contained in all Euphorbias is of a very deleterious character. It is most probable that in this case the saturation in vinegar may correct the acidity of the milky juice. For your better guidance we make the following extract from Syme's "English Botany" (vol. viii. 113):—"The capsules of this species of Spurge have been used as a substitute for Capers, but are extremely acrid, and apt to eat off the lips: they have long been macerated in salt and water, and afterwards in vinegar; indeed, it may be doubted whether they are even then wholesome as a condiment." *Cork.* 1, Quercus Ilex, Scarlet-Subter; 2 and 3, Ilex, the evergreen or Holm Oak; 4, Cucurus tricoccus; 5, Cassinia leptophylla; 6, Pernettya mucronata; 7, Coronilla valentina.—*J. Cocker.* Your Heaths are—5, 6, and 8, Ericas vagans; 4, the red variety (alba), and 8, the white variety (alba); No. 7, the common Ling, Calluna vulgaris.—*A Devonian.* Sedum spectabile.—*A. B.* 1 and 5, Ericas tricta (*alias* E. corsica); 2, Calluna vulgaris alba; 3, Hypericum hircinum; 4, Galium, probably G. linifolium; 6, Sidalcea megana (*alias* Sida malvæiflora).—*E. H.* Apparently a starved example of Athyrium Filix-fœmina crispum.—*Mrs. Clothier and Fungaria.* Sedum dasyphyllum. Not recognised from the leaves alone, possibly an Euonymus or Cornus.—*Old Subscriber.* Prunus Padus.—*T. Smith.* The Pteris is similar to, but not quite identical with, the one we published in Australia. That is more completely and more evenly fringed.—*R. Barron.* 1, Cytomium caryotideum; 2, Platyloma rotundifolium; 3, Litobrochia aurita; 4, Blechnum occidentale; 5, some small variety of Scolopendrium, too imperfect for identification; 6, Onychium japonicum; 7, Aspidium bulbiferum.—*W. E. R.* Pyrus Aria, the white Beam.

PICEA LASIOCARPA: *Working Gardener.* The literal meaning of the name lasiocarpa, is woolly-fruited, from two Greek words, respectively signifying "wool" and "fruit."

ROSES: *Hortus Rosarum* must be more explicit. Does he want Roses to plant against a low south wall, 3 feet high, or to plant in a border in front of the wall? How many? Is it a south or a north aspect which is intended? Generally speaking we cannot say wants too distinctly, as it is often impossible for us to know what is meant by an inquiry, briefly put. Such a question may be plain enough to the writer, who knows all the circumstances, but is an enigma to us if we have to guess at any of them.

TANK HEATING: *Subscriber.* Slates form the best covering for a hot-water tank used for supplying bottom-heat.

TARTS: *J. T.* asks the name of a plant with clear shoots, like those of the Balsam, and which are generally used in winter for tarts. He supposes it to be a trailing plant. Can any reader help him?

VINEGAR PLANT: *T. R. H.* would be obliged to any of our readers if they would inform him how "Grevielle" describes the Vinegar Plant. He has not the opportunity of seeing this work, and all the information he has been able to find is in "Loudon's Chemical and Economical Botany."

CATALOGUES RECEIVED:—F. G. Godwin, Catalogue of Dutch and other Flower Roots.—Godwin & Sons, Abridged Catalogue of the Best Roses in Cultivation.—Louis Van Houtte, Catalogue of Stove and Greenhouse Plants, Conifers, Roses, Rhododendrons, and Fruit Trees.—Charles Turner, Catalogue of Select Fruit Trees, Conifers, Hardy Trees and Shrubs, Climbing Plants, &c.—W. Markets.

COVENT GARDEN.—Oct. 20.

Rather more activity has been observed in the markets the last few days, first quality fruits being in much better demand. The northern towns, too, have been sending orders more freely than usual; prices, however, have but slightly advanced, except in the case of good dessert Apples, which are now making 8*s.* to 12*s.* per bushel. Heavy goods in bulk under the hammer remain at last week's quotations.

FRUIT.

To Gentlemen, Nurserymen, and Others engaged in Planting.

IMPORTANT and EXTENSIVE SALE of NURSERY STOCK.

MR. POYSER will SELL by AUCTION, without reserve, at the Tansley Nurseries, Matlock, Derbyshire, on TUESDAY, October 31, and following days, at 12 for 1 o'Clock each day (Mr. J. Smith, Sen., having decided on clearing off the whole of his extensive Stock), the whole of the NURSERY STOCK of SHRUBS and TREES, suitable for planting: FOREST TREES, consisting of Larch, Spruce, Silver Fir, Scotch, Austrian, and other large quantities; also large quantities of the following.—THORN QUICKS, 2 and 3 feet; BOX EDGING, SPECIMEN, SCOTCH, and Mountain ASH. Upwards of 1000 Lots.

Catalogues may be had ten days prior to Sale, and further information obtained of Mr. SMITH, Sen., or from Mr. POYSER, Auctioneer, Wirksworth, Derbyshire.

To Nurserymen and Others.

EXTENSIVE SALE of NURSERY STOCK, at CUPAR-FIFE, N.B., on MONDAY, DECEMBER 4, and TWO FOLLOWING DAYS.

TO BE EXPOSED to ROUP, on the above dates, in suitable Lots, the whole of the valuable STOCK in HAIRY Taylor's Nurseries, at the West Port of Cupar, extending over Eight Acres, consisting of FRUIT, FOREST, and ORNAMENTAL TREES and SHRUBS, rare CONIFERÆ, &c., and about Six Tons of EARLY POTATOS, of sorts. This stock is particularly worthy of the attention of Foresters, Gardeners, and the Trade.

The Sale will take place each day at 10 o'Clock forenoon, commencing on MONDAY with the Ladyinch Nursery, containing the larger and more valuable Forest Trees.

Catalogues may be had after November 1, free on application, to W. TAYLOR & SON, Auctioneers, Cupar-Fife, N.B.; or from Mr. WELCH, Auctioneer, Cupar.—Cupar, October 2, 1871.

The Nurseries, Mill Hill, Hendon, N.W.

About 4, of a Mile respectively from the Stations on the Great Northern and Midland Railways.

NURSERY STOCK.

MESSRS. HUMBERT AND COX have received instructions from Messrs. Wright to SELL by AUCTION, on the Premises, The Nurseries, Mill Hill, Hendon, on MONDAY and THURSDAY, October 23 and 26, each day at 12 o'Clock precisely, FOUR HUNDRED LOTS of capital NURSERY STOCK, comprising fine specimen Plants, in Tubs, including T. Lobbii, T. canariensis, Thujopsis borealis, Cedrus Deodara, Pinus excelsa, P. austriaca, Cupressus Lawsoniana, Abies Douglasii, Wellingtonia gigantea, Arbor-vitæ, Irish and English Yew; a large quantity of Aucuba japonica, Phillyrea, Alaternus, Laurustina, Arbutus, Portugal and Common Laurel, Tree Box, Spruce and other Fir; Standard and Pyramid FRUIT TREES, Apple, Pear, Plum, Cherry; Standard and Dwarf ROSES; an assortment of FOREST TREES, Limes, Planes, Mountain Ash, Acacia, Chestnuts, &c. &c. Also in excellent condition for moving.

May be viewed two days previous to the Sale. Catalogues may be had at The Nurseries, Mill Hill; Warren's Welsh Harp, Hendon; Red Lion, The Hyde; Candos Arms and Bald-faced Stag, Edgware; Green Man, Whetstone; Crown and Anchor, Finchley; Green Man Street, London Bridge; *Press* Office, Barnet; Peahen and Seven, St. Alban's; Red Lion, Elstree; Anchor, Aldermans, Stanmore; Three Crowns, Bushey Heath; Bell Inn, Bushey; Queen's Head and Railway Hotel, Pinner; King's Head and Railway Inn, Rowe's Chequers, Uxbridge; Swan, Rickmansworth and Hemel Hempstead; Crown, Amersham; George, Chesham; Clarendon Arms, Aston, and Rose and Crown, Watford; and (free by post of Messrs. HUMBERT and COX, Land and Timber Surveyors, Drainage Engineers, Land Agents and Auctioneers, 88, St. James's Street, London, S.W., and Watford, Herts.

THE BIRMINGHAM CATTLE and POULTRY SHOW, 1871.—The TWENTY-THIRD GREAT ANNUAL EXHIBITION of FAT CATTLE, SHEEP, PIGS, ROOTS, ROOT-CROPS, and IMPLEMENTS, will be held in the Bingley Hall, on FRIDAY, MONDAY, TUESDAY, and WEDNESDAY, November 24, 27, 28, 29, and 30, when PRIZES to the amount of TWO THOUSAND TWO HUNDRED POUNDS will be offered.

PRIZE LISTS, CERTIFICATES of ENTRY, and every information may be obtained on application.

The ENTRIES CLOSE on SATURDAY, October 28.

Offices, 39, New Street, Birmingham. B. LYTHALL, Secretary.

SMITHFIELD CLUB FAT CATTLE SHOW.—The ANNUAL SHOW of FAT CATTLE, SHEEP, and PIGS, will be held at the AGRICULTURAL HALL, ISLINGTON, on MONDAY afternoon, December 4, and Four following Days.

Intending Exhibitors may obtain Entry Forms and the Prize Forms by the reference letters as under.

CATTLE.—From A. For an OX or STEER (in any Class).
" B. For a COW or HEIFER (in any Class).
" C. For a SET (in extra Stock).
SHEEP. " D. For a Pen of three WETHERS. [Stock.
" E. For a Pen of three EWES (in extra
" F. For a SINGLE WETHER SHEEP in Extra
PIGS. " G. For a Pen of three PIGS (in any Class).
" H. For a SINGLE PIG (in Extra Stock).

ENTRIES for LIVE STOCK CLOSE NOVEMBER 1.

Prize Lists, Forms of Certificates, and all information, may be obtained of Mr. DAVID PULLEN, Assistant-Secretary, at the office of the Honorary Secretary, corner of Half-Moon Street, Piccadilly, W.

N.B. All communications respecting the Show must be addressed to the Assistant-Secretary, as above, and should bear outside the words "Smithfield Club Show."

The Agricultural Gazette.

SATURDAY, OCTOBER 21, 1871.

IN one of our brief leading paragraphs last week but scant justice was done by Mr. BIDDELL to the prettiness of CROWING. The Beet was saddled with the entire cost of its tillage and manure, and it speaks well for its profitableness to the farmer that it was able to bear the burden and show a nett profit of £3 12s. per acre. Try any other of our green crops in the same way, and most of them would reveal a loss. Hence the common remark that green crops do not pay, and the common practice of charging part of the expenses of manures, &c., to succeeding grain crops. The fact is, those crops perform most of the offices of a bare fallow to the land, and when thoroughly worked and managed, the latter sometimes costs as much as from £8 to £10 per acre. In that case the returns are *nil*. Even the feeding value of Turnip or Mangel does not often exceed £6 or £8 per acre, while the expense of their production is certainly within a pound or two of that of a bare fallow. It is difficult to see how this extra pound of expense is incurred. A shilling or two on the hoeing and the pulling is easily accounted for, but an entire pound extra per acre for labour on the Beet crop is not. Still, taking it so, is there any other green crop, or proper preparation for Wheat, which can show such a profit as the Sugar-Beet?

Now, before discussing the returns from Sugar-Beet, let us remark upon the estimated yield of 15 tons per acre. It is a low yield, and there seems no reason why it should not be increased. We have had a succession of critical seasons since the introduction of sugar-growing at Lavenham — two seasons excessively dry, and this one wet and changeable; yet 24 tons per acre have been grown at Lavenham, and five of the best crops of roots in 1869 weighed 24, 21½, 19, 15, and 14½ respectively. Four tops of the crops were 8, 7, 8, 8¼ tons per acre. With such facts actually accomplished, it is rather discouraging to be tied down to 15 tons per acre. It has never been denied that three or four roots of Sugar-Beet may be grown on the same space occupied by a large Mangel; and as the Sugar-Beet is much more dense, and consequently weighty in proportion to its bulk, than the Mangel, it follows that the yield ought to

equal it. It was found to do so in Ireland, and it was the opinion of the *Norfolk Farmer* that it will also do so in England.

Then, again, in Mr. BIDDELL's return for Sugar-Beet there is an item of 72*s.* put down for the tops. This is the valuation for 6 or 7 tons! The very least that the best growers, according to the returns hitherto published, have been able to grow, is 6 tons per acre. Juicy, crisp, sweet green food, greedily devoured by stock, for 1*s.* a ton! and beef and mutton still 1*s.* a pound. No doubt the difficulty is to use them while they are good; but if we take them at only 4*s.* a ton, then, at 7 tons per acre, another guinea would have to be added to the profits of the Beet crop. Then the matter would stand thus:—

15 tons of Beet	.. ..	.. £15	0 0
7 tons of leaves, at 4*s.*	.. ..	.. 1	8 0
		£16	8 0
Total cost of production, including rent, rates, interest on capital, and allowing no draw-back for unexhausted manures, &c., that go to benefit the Wheat and succeeding crops	.. ..	.. 11	15 0
Profits per acre	.. ..	.. £4	15 0
But raise the produce to 20 tons per acre	.. ..	.. £20	0 0
Same less leaf, say 6 tons	.. .. ..	.. 1	4 0
		£21	4 0
Expenses, as before	.. .. ..	.. 11	15 0
Profits per acre	.. .. ..	.. £9	9 0

And this is by no means the maximum yield of this crop.

By overweighting the crop with the entire cost of production, and underestimating its yield, some seem to think that higher prices may be screwed out of the sugar factors for the roots. It may be so; but it is much more probable that by putting on 20 per cent. on the price of Sugar-Beet, as was suggested at Stowmarket the other day, this new industry will be strangled in its infancy, to the injury of British agriculture and the improvement of the country. A grand project to build a factory, costing £20,000, and to take the produce of 600 acres for five years at £1 per ton, with so much pulp or Beet bread back at 12*s.* per ton, or without pulp £1 1*s.* per ton for the roots, is in abeyance for the present, as the farmers declined to guarantee the roots. It seems worthy of the most serious consideration of agriculturists whether their true interest does not lie rather in increased production than in a higher price for the Sugar-Beet. With the latter ranging from 13*s.* to £1 a ton on the Continent, it does not seem probable that the sugar-maker can afford to pay 25*s.* in England; and with the feeding value of Mangels, Swedes, or Turnips ranging from something like £6 to £12 per acre, surely it must pay better to grow Sugar-Beet, returning from £15 to £25 or £30 per acre; the latter leaving as good a tilth and as large reserve of productive force in the ground for the succeeding crop as the former.

No difference has been found in the Wheat crops after Sugar-Beet, and those after Mangels, or other green crops. It is by no means an exhausting crop, such as Kohl Rabi or Cabbage. Its extra percentage of sugar is manufactured from the atmosphere, and not drawn up out of the ground.

THE experience of so good an observer and so practical a farmer as Mr. EDMONDS, of Southrop, Lechlade, is well worth recording, especially when the circumstances were difficult or unusual. Mr. EDMONDS, like all other English stock-owners, was in difficulties last autumn, owing to the unusual drought of 1870, and the consequent scarcity of cattle food. There was no hay—no aftermath—no Turnips: there was, however, straw of unusually excellent quality. "It soon became evident, not only that the hay must be most sparingly used, but also that the oat and barley straw would be by no means sufficient for fodder through the winter. These also must be largely supplemented by the use of wheat-straw, and the question arose as to how to make the latter most palatable and most digestible. By some, treacle was given, and with good results: 1 lb. or 1½ lb. per day, besides meal, being allowed to each beast. By others, Linseed was used (I was one of those who did so), boiled or steamed, and thrown over the chaff."

Mr. EDMONDS, whom we are quoting, describes in the current number of the Agricultural Society's Journal, his own management, as follows:—

"I do so," he says, "not because I consider that my plan was better than others, but because I can describe it more minutely. I must plead guilty to great indiscreetness in the previous summer, for, finding some of my intended mowing ground too bad a crop to cut, I bought grazing cattle to stock it, disliking to do so with those I already had, and depending upon rain to give a sufficient supply of grass. The consequence was that the former, later in the season, robbed my others of some hay, and those others were obliged to be brought to the yards early in October, none the better for their summer's keep. Nothing daunted, however, by this piece of bad luck or bad management, I ventured—stock being very low in price—to purchase more cattle, tempted the more to do so by having had built some new cattle houses, which I wanted to fill. To find Lent corn straw for them was out of the question. I began to do so, mixing it with a little wheat-straw, but soon found that my sheep would be *minus* cattle if I continued the plan, so determined to feed them upon wheat-straw—some wholly so; for others, mixing it with oat-straw. We had it cut into chaff, and for the yearlings we added 1 lb. of Linseed and 1 lb. of meal

ton; and FAIRFAX by AVON (2393), from Baysham Court: together with two heifers by that grand bull STANWAY, winner of first honours at Oxford, bred by Mr. Rogers, The Rodd. The 1st prize Hereford yearling bull, PEARL DIVER, accompanies this lot, for Mr. Nowlan, West Maitland.

—— Mr. R. W. Reynell's sale, which was some time since indefinitely postponed, is to take place next Tuesday at Killynon, Killucan, Ireland. Mr. Thornton explains that the herd has been bred for 30 years from two tribes of Shorthorns imported by the late Mr. Robert Holmes and Mr. Thomas Barnes, and crossed for a long period with Westland bulls of the Mantalini blood. There will also be offered some good Herefords, bulls of the late Lord Berwick's stock, about 200 well bred ewes, some pure bred Berkshire pigs of the Throckmorton sort, and several thoroughbred fillies.

—— The Shorthorn herd of the late Mr. Stratton, of Burdetop, has been divided between two of his sons, Mr. Richard Stratton, of the Duffryn, Newport, Monmouthshire, and Mr. Joseph Stratton, Alton, Devizes.

—— GRAND DUKE OF KENT 2D by LORD OXFORD 2D (20,215), and from *Grand Duchess 9th*, the property of Mr. W. W. Slye, has been sold to Lord Bective, of Underley Park, Kirby Lonsdale, for 1000 gs.

—— There is something charming in the simple and yet autocratic utterances of the "Kirklevington Philosopher." No qualifying expressions render his teaching indistinct, and dissent from his opinions does not appear to have been contemplated by him as in the least degree possible. "* * No other breed of Shorthorns," he writes, "show a family likeness except my own. Nor has any other breed of Shorthorns the same hair and handling as mine have; nor can it be obtained but through my strain of blood. The rant in the blood, and none now can be found that have the old Hubback blood, and that of his predecessors, and of Mr. James Brown's old Red Bull, and these two bulls were the last remains of those breeds, which had been so long eminent as Shorthorns * * * which was the time when the Shorthorn Colling began breeding." This is speaking with authority; dogmatic teaching more positive than usually falls from human lips. Still there is a relief even in dogmatism, and we cannot doubt that on many points Mr. Bates had a right to hold strong opinions. Hear him explain the origin of his best tribes, and mark the care with which parents were selected for the coming Duchesses, and also the test of merit applied—utility:—

"I should mention here that, previous to Mr. C. Colling's HUBBACK, the prevailing characteristics of the best Shorthorns were high hooks, and the fore-quarters small, and very lightly lyred, as shorthorned cattle so shaped were the very reverse to the objectionable coarse-fleshed variety. But HUBBACK gave a fore-quarter much heavier, and the hooks, though not so high, were wide and pointed forward, making a much longer hook-quarter. This was particularly the character of my cattle, bred between the best Shorthorns and the West Highlander. When I began to use my bull KETTON, the produce from him made both my Shorthorns and myself very much superior to what they were from the *Dairy* bull and STYFORD, the best two bulls I had used before I had KETTON. When KETTON ceased to procreate, I then felt severely the contrast with the Hubback blood had descended from him. I then did not know that any of the Princess blood was left, nor did I know how the Princess tribe was bred, direct from HUBBACK to FAVOURITE. This I obtained till I commenced inquiries to assist old Mr. Coates in preparing the first Herd Book, and I saw no way of restoring the pure Duchess blood but by putting the *3d Duchess* to her mother's own brother, Mr. Coates's bull at the Kelloe Herd Book. This I accomplished in 1820. THE EARL (646), so bred, was calved in November, 1820, and putting him to the Acklam *Red Rose* cow produced my second HUBBACK (1493), June, 1824. This union almost exactly admirably, and gave me a uniformity of character possessing every excellence. I used 2D HUBBACK till I got BELVEDERE, in June, 1831. My best stock are descended from 2D BARMPTON and BELVEDERE, put to THE EARL, a union that answered again most admirably; so that I have combined in my breed of Shorthorns the only three tribes that were all bred direct from HUBBACK to *Favourite*; there are no Shorthorns that have now any pure blood of any of those three tribes, excepting my own herd. It is the union of those three bloods—'Duchess' tribe, Yarborough's dam, and 'Princess' tribe—to which my cattle owe their superior excellence. Having united these three tribes through so large a herd as I and my tenants, the Messrs. Bell, possess, and those who have got the blood through my herd, extending through six tribes in my own hands, and eight of my tenants, we have every means not only of preserving their excellent qualities, but of improving them more and more every fresh cross. We are not dependent on any one bull, as every cross has more or less 'Duchess' blood, with all the excellences which cattle so bred possess. In fact, as *Duchess 34th* proved, by several trials repeatedly made in various years, she consumed less food (hay) per day than my *1st Duchess*, grand-dam of No. 1 in Herd Book. From a quart of milk the yield of butter from *Duchess 34th* was more than from my *1st Duchess*. These are important considerations, when weighed in conjunction with a greater increase of weight in beef, with so much less consumption of food. In fact, this consumption of food and production of meat were nearly equal to the small consumption of the West Highlanders, which are the smallest consumers of any cattle I ever tried on hay alone in winter; and have ever found the consumption of hay correspond with the consumption of Turnips or straw given singly."

—— We quote the following passage from Mr. Jacob Wilson's (senior steward) report of live stock in the current number of the Royal Agricultural Society's Journal, which bearing on a point now attracting some attention:—

"Except in 2-year-old and yearling heifers the show of Shorthorns at Wolverhampton could not be considered up to the standard of former exhibitions. Many reasons may account for this. Since 1868 the Canadians, Americans, and Australians have bought up most of the best yearling and 2-year-old bulls and heifers at good prices for exportation, consequently exhibitors have not those specimens to send forward as fully matured and developed animals. Moreover, the higher bred Shorthorns have in the same period become immensely advanced in value, whilst pure and fashionable pedigrees command such extreme prices that selection is avoided, and the bad with the good are left to grow together, like Tares and Wheat, till an auction is held, which scatters them far and wide; but there can be no doubt that the pure stock of the country, though more rare, is hardly likely to be much improved in symmetry and quality, for there is an apparent coarseness in some of the more fashionable lines of blood."

AGRICULTURAL NOTES.

By MR. MECHI.

Corn Growing or Couch-grass.—Which is it to be? For they can't grow together satisfactorily, seeing that the powerful Couch-grass, Twitch, Squitch, or whatever else it may be called, will be master of the situation. In old-fashioned farming a long fallow was made to get rid of Twitch, and if the ploughing was deep enough and frequent enough, and if the summer was hot and dry, the Twitch went to the wall, but, unfortunately, a moderate summer (for Couch is a lover of moisture), the long fallow failed in its object, and proved to be an unprofitable investment. There is a rare supply of Twitch this season, and as I want to grow good corn crops pretty frequently, I take especial care (cost what it may), to fork it out of the land, shaking it from the soil, and clearing every root from the field to be destroyed. Wherever there has been an old ditch, old fences and trees, which once abounded on my farm, the Twitch will crop up from some deep buried joint of an ancient stock, in spite of 28 years of constant war against it. Still we are, to a certain extent, masters of the situation, but it cannot be done a season as this from 5*s.* to 15*s.* an acre to remove it. When I was once gently doubting the propriety of a pasture of Twitch on a stubble, the farmer exclaimed, "Why, what should I do with my heifers after harvest if I had not this feed for them." I gave up argument at once as a hopeless affair. I remember seeing enormous stacks of it years ago in Lincolnshire, as I passed by rail, intended for making paper, but I believe it was not a success. Most of mine is young Twitch, but where the old ditches were there are some tough old fellows that have got an enormous hold to great depths, and they will show their noses, and seem determined to share the good things with the roots of the future corn plants. I wonder how much Twitch costs the country annually. Would a million sterling pay for it? I think not. It is painfully interesting to see how vigorously Twitch battles with nature, fights their strong, white, devouring snouts. The Suffolk folks call it Spear-grass. I remember raising a considerable storm of indignation at an agricultural dinner not 100 miles from Watford, because I gently doubted the good taste of holding the agricultural show in a field matted with this noxious weed. As my bailiff says, if a farmer allows Twitch to be his master, it is sure to ruin him. It is a very insidious weed, for although on the surface you only see its narrow green leaves, its underground formation is a mass of strong, sharp-pointed skewers or spears, half as thick, and almost as stiff, white, and straight as a tobacco-pipe, forcing their way bodily and rapidly into the soil in every direction where the best plant food is to be found, and carefully avoiding the subsoil where it is poor and undisturbed. None of our "plant foods" have a chance with it, for it occupies the ground, and holds possession by superior strength and tenacity. The only plant that appears to me to have a chance with it is the powerful Bean taproot and side shoots, which resemble it in strength. As one of my men said to-day, when he was forking out the Twitch, "it should, before they eat Beans, have their sides and contents brought to the surface and spread, so as to get out the Twitch, otherwise when merely filled up, the Twitch will retain its vitality and come gradually to the surface, although a yard or more deep." I have a field of 8 acres which grew 7 qr. of Wheat for its last crop some five years ago. I laid it down to grass, and for two years had first-rate crops, but soon the indigenous Twitch took possession of it, and despite of ample manuring and folding the crop has been "no go," so I shall break it up, and it will then, I know, produce me an abundance of other crops. Most of our poor worn-out pastures are mere beds of Twitch, and no doubt it is a great mistake to permit them to remain as permanent pasture. A couple of years in grass is quite enough in such soils. This I have proved by experience on my soil. Of course I something depends upon sowing genuine grass seeds, and taking care that the ground is cleared of Twitch previous to sowing; but herein is the difficulty, for a piece of dirty-looking Twitch, which you think is dead and so pass over, has retained its vitality and only awaits favourable moisture to start it again.

Rats in Corn Stacks.—Nearly all my stacks are on Garrett's patent iron stack frames, 12 of which I have had for 25 years, and now they are as good as new. But I had occasion to place one Wheat stack on the ground, and although my buildings are free, or nearly so, of rats, within a fortnight my corn stack has been populated by them, and I must thresh it out immediately, or I shall, like one of my neighbours, find I have nothing but straw. He left two stacks unthreshed for two years, and on threshing, found no corn in one, and only 5 qr. in the other! As he has passed away, I may now mention it as a warning.

Wet Corn Stacks.—Can any one tell me how much is the total amount of loss, this wet September, caused by unthatched stacks? I know of several instances where the corn has speared or grown from 1 to 2 inches in the straw, and, in fact, the whole is an inseparable mass by the multitude of fibres, and the grain rendered partially or entirely worthless. The excuses for this are various. One had no straw, and no time to thresh; another meant soon to thresh, and so would save the cost of thatching; others had straw, but trusted to the weather, or rather, the expectation of it, forgetting that harvest was later, and that September is a risky month for rain.

The Geological Map of Great Britain hangs in my study, reminding me, by its many coloured patches, how wrong and unreasonable it would be to recommend a uniform agricultural treatment, or one unsuitable to the formation, elevation, aspect, and latitude of the greatly varying soils and districts. Need we be surprised that our eastern and south-eastern counties are cereal, dry and warm in summer, cold and pinching in winter and spring, seeing that we there get the first of the sun and the last of the clouds, which, rising in the Atlantic, are well strained of their heat and moisture by Ireland, and then by the wide intervening space of land between the Irish Sea and the eastern coast. Cornwall and Devonshire, pushed into the Atlantic, meet the warm gulf-stream and luxuriate in its exhalations. An east wind in July and August parches us up in Suffolk and Essex, for it comes over an immense extent of land, while, under the influence of the westerly gale caressing to us over some thousands of miles of the Atlantic, the heat is moderated by moisture to men, plants, and animals alike. This subject might be greatly extended, but enough has been said to show how necessary it is to consider all the conditions before applying any particular agricultural treatment, either as regards soil or crop.

Preserving Root Crops.—We all know that roo crops are costly, and that, having grown them, the question arises how to preserve them from injury or waste, and how to get the best price for them from our stock. I can never believe that it is a profitable plan to leave them in the soil, unprotected by their leaves, and deteriorated by frost. One of the best and most extensive root growers known to me invariably has stored his Swedes very early in November, in small heaps, well covered with earth, ready for feeding in the field in the winter or early spring. The cost of doing this is amply repaid, and, as I am successful in preserving my Mangel, I will state what I believe to be the reasons for my success. I have just finished some very fine ones, almost as fresh and juicy as when stored. A Mangel is never in greater danger of rotting that when it comes up clean and free from earth, for its fibres have then nothing to preserve their vitality. I consider it a bad plan to let them lie on the field in the rain after pulling. Mine are always thrown into the cart as they are lifted from their place, and at once placed in the clamp. As I do not pull them until late in October or early in November, a certain amount of damp or wet earth adheres to their roots. Those with two or three fangs are selected out. Those with only one fine tap-root hold little earth, and consequently rot early; so we use that sort for early consumption. We thatch the clamp with soft Barley straw, which lies close, and keeps out both frost and heat. Hard glassy new Wheat straw won't exclude the frost. A little later we earth them up—that is, plough round the clamp, and enclose them in a thick cover of earth. They keep good until September or October.

A Hint to Coursers.—A farming acquaintance of mine, who had greyhounds, was always lucky in having hares on his farm, although he did not preserve. Hares always make to a gate, where they get taken by the poachers. This farmer caught his own hares, at night, in a gate-net, and gave them a sound whipping with a lady's riding-whip. He then turned them down, and, however sharply driven, they would never attempt a gate again.

Early in the morning, and sometimes late at night, you may, by an occasional look out, see what is neither profitable nor agreeable. A young man who complained of farming was advised by a sagacious friend to go of a summer's morning about daybreak, and drink a glass of water from a spring at the further part of the farm.

The very first morning that he did so, he found a neighbouring person taking out his horse, &c., that had been feeding all night in his fields. I know of an instance where a cunning fellow always turned his horse out at night, and fetched it home before daybreak in the morning. It was often in people's fields, or lost. A farmer wisely offered a shilling to his men every time they could take it to the pound. This settled the matter, and the offender soon sold his horse. A great many things disappear from a farm late and early. Wood, and even coals, sometimes walk off.

Pasture.—Most of our old or permanent pastures, on certain soils, are weedy, exhausted, and unprofitable. If pasture is desired, it is to be laid down for two or three years, but no longer. Hay crops are generally good the first and second year after laying down, but soon become weak and unprofitable. This I know from practical experience. Cultivation is so fertilising and valuable on certain, and indeed on most, soils, that the absence of it for a length of time is decidedly unprofitable. Of course there are exceptions to this rule.

LARGE v. SMALL FARMS.

I HAVE been amused at the discussions which have lately appeared in different periodicals on the relative advantages of large and small holdings, and the consequent advice so freely offered to landlords on the subject, as if they did not know their own business, but required to be taught how to manage their property by outsiders. I am not going to contend that the money return is the only consideration by which they should be guided. I will concede fully that property has its duties, and that a landlord is bound to take care that his lands are well managed, that his cottagers are cared for, and that his little plot is contributing its fair proportion to the national stock. But after all, both owner and occupier must be paid, and by this crucial test of *£ s. d.* must any new system be judged before it can be recommended or adopted. Let us apply this to a farm of 500 acres of fair arable land in an agricultural district some 6 or 7 miles from a market town, and cultivated according to the custom of the country. The rent will be from £600 to £700, the addition of tithes, taxes, and other fixed payments will bring the annual outgoings to £2 an acre, or £1000 per annum. His labour bill will probably be as much, which, with repairs and purchases, exclusive of corn or artificial manures, will bring his annual outlay to £2500 a year. His income, at £7 per acre nett, would be £3500. He must be a bad manager who could not realise thus much, and nobody would grudge him this amount of profit. By this method, too, a fair amount of food, both cereal and animal, is produced, and about 15 labourers and their families kept in the usual style of farm hands.

But suppose our landlord should be persuaded to cut up his farm into small holdings, say from 100 acres to 50 or 20 acres each,—let us see what improvement will result to landlord, tenants, or country at large. The man who has 100 acres will require a decent house built, with stables and outbuildings, which will add £30 or £40 to the rent —say, £235 a-year, including taxes, &c., as before. He and his sons will probably manage the live stock, but he must keep one man and a pair of horses with hired assistance at busy times. This will cost not less than £100 a-year. Add £50 for repairs and replacing losses, £50 for interest on capital (probably borrowed money), £50 for the wages of himself and his family, had they not been employed at home, and a total outlay of £485 will be necessary, without reckoning seed, artificial food, or any of the disasters to which farming is always liable from storms and seasons. To produce this sum he will have to sell the crop of about 25 acres of Wheat, and 20 of Barley—at the outside 180 qr. of bread corn, after deducting the seed—and fetching probably £375 or thereabouts. The remainder of his crops will be consumed by his horses and stock in the manufacture of manure. Should the land be dry, he could probably winter about 60 lambs, making £1 each beyond the cake they eat. Should he have the advantage of a little grass land, he may keep two or three cows and their produce, supply his table and one cow off yearly. This latter would be likely to bring him home; but he or his wife would have to travel twice a-week to market with butter, which would outweigh the extra profit. In either case, and with the sale of a few pigs, they would hardly realise the £100 wanting to balance the yearly outlay of £485. The occupier of any of the 50-acre plots would be in a worse condition. His outgoings for rent, &c., with cottage and buildings, could not be set at less than £120; his own labour with his family at £50, and the necessary labour which he would have to hire at £50 more—bringing his outlay, including seed and tools, &c., to £250, which could only be produced on good stiff land by growing Wheat every other year, with Beans, roots, and Potatos, for pig-feeding. The 20-acre and 10-acre plots would labour under the same adverse circumstances of having to hire labour, which, especially horse labour, will be very expensive, and, at the distance I have supposed from a market town, nearly impossible to procure with any certainty at critical times of the year; both these occupiers, under the supposed circumstances, must on the first unfavourable conjuncture come to grief, after beggaring both the land and themselves.

But if we now reverse this supposition, and place our small tenants within a mile or two of a market town, we shall find the account to present a very different aspect. Our farmer will become a market-gardener—he will get the retail price for his Potatos, Cabbages, and roots, and will procure his dung or town refuse at nearly a nominal cost. He and his household will be able to fill up their time by doing cart-work for hire, or by delivering milk and vegetables. His rent will be considerably increased, to perhaps £5 an acre; but the produce, which was worth only £7 or £8 to the farmer, will now realise from £30 to £40 per acre as sold retail. The same advantage will probably, though in a less degree, to a wheelwright, blacksmith, publican, or other village tradesman, who have some spare time on hand. They can often make 50 acres pay, if industrious, and capable of making the most of their opportunities, where a living from the land only could not be obtained. So a carrier can keep his horses much cheaper by hiring a piece of land than by buying his provender. In all these cases money is made by filling up the odds and ends of spare time, rather than by any process that can be fairly called farming. Moreover the demand for these small holdings must be very limited, for I do not think there is a man out can be found who unites the necessary qualifications for making the most of a bit of land, and a bad tenant is ruinous to the landlord's property.

In making these comparisons of holdings, I have not drawn on my imagination, but could point out instances which are in knowledge of each, thriving and decaying, and the enterprising tradesman flourishing in his place,—of land, left utterly worthless as a farm, becoming highly productive as a market garden; while I know no instance of a labourer in agriculture raising himself to a higher station than a gentleman's bailiff or head man, or cattle dealer, to a wife from the South of England. In the North I am given to understand it is not so; but that from keeping a cow, which is the usual privilege and practice, a labourer can rise to a higher rank and aim at becoming a tenant-farmer. I can only wish it were so here. I have no doubt if there was a demand for very small farms they would be quickly supplied, like any other demand. In the meantime I would caution any landowner, who may be allured by any fanciful descriptions of a rural paradise, where each busy bee is to thrive in his little cell, to pause before he commits himself to such an absurdity; and to ask any doubting neighbour, a little farm to show him what possibility exists of his being able to pay rent and taxes, and earn a livelihood for himself and family. Capital, the application of steam, and the concentration of labour, must in this as in other trades outstrip the little man in the race, and enable the man possessed of these advantages to live and pay a rent, where the other would starve. We have only to look across the Channel at France, Belgium, and Ireland, to see small holders, with the greatest thrift and economy living in penury, which to English eyes is little removed from starvation. *J. B. M.*

HOWARD'S STEAM TACKLE ON THE MOORS.

STEAM, that powerful agent for gladdening the face of Mother Earth, has been doing wonders for the rough wild moor land on the Wass estate, near Thirsk, belonging to Major Stapylton. This moor lies about 700 feet above sea level, and extends over about 30,000 acres, naturally a wild barren waste, producing a few grouse. The portion belonging to Major Stapylton rests upon limestone rock, the soil a peaty, gritty loam, from 4 to 6 inches deep, under which there is an impervious pan from 3 to 7 inches deep, composed of gritty material and rubbly limestone, conglomerated into a hard (impervious to both air and water) crust; from this to the solid limestone rock an open porous bed of rubbly limestone of various thicknesses exists.

When this hard pan is broken through, both air and water pass freely down, washing out the sour sterilising acids. Although limestones are near the surface, they are perfectly inert, and after considerable loss of time and capital it has been found that no manure will do any good until from 4 to 6 tons of lime are applied per acre; limestone being in abundance underneath, kilns are erected in the most suitable situation for economy of cartage.

Upwards of 300 acres are in course of reclamation under the able management of Mr. R. E. Brown, who has gone both cautiously and economically to work; indeed it is seldom that such rare enterprise is guided by so happy a combination of wise economy brought into play for the realisation of the object in view. About three years ago Major Stapylton conceived the idea of reclaiming this brown heath and turning it into green fields and wooded dells, if anything like a fair prospect of a return for the outlay could be established. He commenced the experiment on about 20 acres; the heath was burnt down, and then cultivated by horses. But horse-power proved altogether unequal to the task of breaking up the iron-bound pan that sealed out the fertilising influence of air and water. However, after it had been well fallowed, it was sown with Rape, for which a variety of manures were tried—guano, phospho-guano, dissolved bones, superphosphates, and a portion was limed as an experiment, when it was discovered that lime was indispensable not only as a sweetener of the soil, but to set the manures in action, for until lime was applied they remained dormant; but after its application their fertilising effects were extraordinary; the Rape by its growth showing to an inch how far the lime reached. Where the pan had not been broken, manures were all but inert for want of air and water moving through the soil.

This experiment induced Major Stapylton to turn his attention to steam-power, to obtain the requisite strength of implements and force to break the pan thoroughly, and allow the rains to wash the corrosive acids out of the soil, and the air to permeate through it and decompose the inert organic earth into fertile soil,—a theory the wisdom of which has been thoroughly borne out by the magnificent results obtained when put in practice, and is now making the reclamation of this moor a most profitable undertaking to its spirited owner.

About 18 months ago Major Stapylton obtained a Howard's traction-engine with two winding drums, with all the necessary implements, cultivators, harrows, &c., for working either on the direct or roundabout system. The cost of all was £682.

Having obtained this grand pioneer of agricultural progress in the full development of Mother Earth's generous supplies of sustenance for man, operations were at once systematically commenced by thoroughly breaking up the 20 acres 14 inches deep with the cultivator twice crossing each other, making an excellent preparation for Turnip and Swedes.

Then operations on the wild heath began as follows:—The heath was burnt down at 6*d.* an acre, then twice cultivated with wide shares 6 inches deep, each time crossing the other, at a cost of 15*s.* per acre; then it was left a few weeks to the action of the weather.

Brought forward		£6	15 6
Then well steam harrowed twice, at per acre ..		0	7 6
Burning trasses and roots, &c., and spreading ashes ..		0	7 6
Two cultivatings crossing each other, 14 inches deep ..		1	0 0
4 tons of lime, carted and spread, at 8*s. 9d.*		1	15 0
2 cwt. of phospho-guano, at 122.=24*s.*			
2 cwt. of dissolved bones, at 71.=14*s.*		1	18 0
3 lb. of Rape-seed, 12. 6*d.*; drilling manure and seed, 12. 6*d.*		0	3 0
Rolling, 6*d.*; horse-hoeing, 12. 6*d.*		0	1 0
Weeding		0	1 0
	£6	7	6
Good half crop of Rape kept 120 sheep one week, at 6*d.* each	3	0	0
Outlay left, not repaid	£3	7	6
Two ridgings 27 inches wide, and subsoiling 14 inches deep in bottom	1	0	0
2 cwt. Peruvian guano and 2 cwt. dissolved bones as before	1	18	0
Turnip seed, 2*s.*; drilling manure and seed, 12 6*d.*	0	3	6
Horse-hoeing, 12. 6*d.*; hand-hoeing, 5*s.*	0	6	6
	£6	15	6
One year's interest on this, at 5 per cent.	0	6	9
	£7	2	3
Turnip crop, worth at least	3	0	0
Outlay left not repaid	£4	2	3
Once ploughed with double-furrow plough and two horses	0	6	0
3 bush. Oats, at 28*s.*	0	10	6
Drilling, 12. 6*d.*; harrowing, 12. 6*d.*; rolling, 12.	0	4	0
Weeding, 9*d.*; harvesting and threshing, 20*s.* ..	1	0	9
	£6	3	6
Interest on this at 5 per cent.	0	6	3
Total expense taken down	£6	9	8
5 qr. Oats, at 28*s.*	£7	0	0
30 cwt. of straw, at 2*s.*	3	0	0
	£10	0	0
Expenses brought down	6	9	8
Profit for the four years	£3	10	4

Thus, after all expenses are paid, there is a profit of £3 10*s. 4d.* per acre, and the land in first-rate condition to go on in a four, five, or six-course system of farming, and will readily let at a good rent per acre; thus a comparatively barren, wild waste, is converted into green fields and happy homes of prosperous tenants raising increased supplies of meat for our rapidly increasing population, and contributing a fair share of the riches of this our great and prosperous country, and a rich return to the energetic and enterprising owner, who is creating a grand estate out of that which had scarcely any value.

It is to be hoped that the other owners of this vast valueless waste may regard the signs of the times on the land question, and be induced to follow Major Stapylton's spirited example, and reclaim the whole into farms for the sons of our farmers, who will be glad not only to give fair rents, but protect and produce far more partridges for sport than there are grouse to be found now; thus, in every point of view, there will be a great gain of wealth, stability, power, and pleasure to the country.

Mr. Brown having kept a strict account of all the outlay and work done, the actual expenses are got, and honest data to go by, in calculating the amount of capital required to reclaim such waste lands, and the inevitable results shown. As we witnessed the simple and powerful engine moving about this rough, wild heath, we could not but feel there was a great future for this efficient system of Messrs. Howard, a wonderful advance upon the separate engine and windlass plan.

These waste lands of the kingdom ought surely to be heavily taxed until they are brought into cultivation, and fit for tax-paying profit to live upon.

Expenses and Results.

Total expense of wearing parts, repairs, oil, and grease, as per bills for the 18 months	.. .. ..	£36 8 0
Wire-rope, nearly one-fourth worn	.. .. ..	23 0 0
		£79 8 0
This, on the 968 acres cultivated, gives about 1*s.* 8*d.* per acre for wear, &c., of tackle. To cover interest and depreciation of capital invested, 10 per cent. must be charged on £868 for 18 months	..	102 6 0
This gives about 2*s.* 2*d.* per acre for this item.		
Working Expenses per Day.		
One engineman	.. ..	£0 3 0
Four men (tweaochor, one cultivator, and one porterman), at 2*s.* 6*d.*		0 10 0
One boy, at 1*s.* 6*d.*, and a horse, at 3*s.* 6*d.* ..		0 5 0
6 cwt. of coals, at 8*d.*		0 4 0
968 acres in 176 days at		£1 2 0 = 193 12 0

Thus it is evident that the data here actually given agrees fairly with what we have used in the details in the beginning of this paper, viz., 7*s.* 6*d.* for shallow, and 10*s.* per acre for deep cultivation. The land being very rough, boys are unequal to the management of the porters, therefore Mr. Brown finds it economy to have all men. The fact is, that a popular error exists in the undue stress laid upon the necessity of a man or boy, when the fact is that every £160 sunk in plant represents the equivalent of a man, because the tear, wear, depreciation, and interest on steam tackle is 17½ per cent. per annum, which, on £160, is £28; and a man's wages for the 224 days available for steam cultivation is, at 2*s.* 6*d.* a day, also £28; while in ordinary farming there are not more than 160 days of steam cultivation to be obtained under the most favourable circumstances by any company letting for hire; therefore in ordinary cases £112 worth of tackle represents the equivalent of a man, who, when sick, pays 5*s.* 6*d.* to his club, the tackle when out of sorts has to be taken to the factory for renovation. After seeing what can be done with this apparatus, we came to the conclusion that single-engine tackle like this are the most economical for farmer's own use; while for companies letting out, double-engine tackle perfectly pay the owners best, but the water carting is a great nuisance. Mr. Brown expressed his thorough approval of the engine and implements of Messrs. Howard, which, he says, have gone through this pioneer work and stood the rough usage in a way he could not have believed. *J. P. B.*

TOWN SEWAGE.

DURING the last fortnight there has been even more discussion than usual on the best means of dealing with the sewage of towns, and the general opinion seems to be at present in favour of the water-closet system. That the subject is one of very great importance every one acknowledges, and it is only natural that the authorities in populous towns should watch with attentive interest these discussions, as they may affect future legislation touching their interests.

There are, however, certain objects in view—the doing away with river pollution, the doing away with nuisances in towns, and the saving of manure.

River purification at present occupies the greatest amount of attention, probably because it is the most difficult problem, and requires the most expense in its solution. The nuisances within large towns have secured by no means the same amount of attention, and consequently dry systems of dealing with excrement have been pooh-poohed as not being applicable to them by eminent engineers, who apparently have not given much attention to that branch of the subject, being pre-occupied with the larger scheme.

This must be discouraging to all those who have for some time worked hard with the twofold object of abating the nuisances in towns, and of supplying the farmers with a serviceable and comparatively cheap manure, from Mr. Moule himself to his latest follower.

It seems also surprising that immediately after the searching investigation of, and masterly report on, the earth system, by Dr. Buchanan, in the 12th report of the medical officer of the Privy Council, carrying, as it must do, much weight throughout the country, we should be flippantly told that earth-closets are much more frequently out of order than water-closets, or that they are much more costly, or that if (!) a perfect water-closet could be made, it could be worked at the 20th part of the cost of an earth-closet; and all this, not only without a tittle of evidence, but also directly in opposition to a vast amount of evidence in this country, in America, and elsewhere.

As a reader of your journal I have noticed many conflicting opinions as to sewage irrigation, but chiefly as to the method of carrying it out. Mr. Mechi and others have recognised the difficulty of, in many cases, dealing with the vast quantity of the sewage of large towns on the land which is usually available. If my memory does not fail me, Mr. Mechi stated that a certain proposition was equivalent to feeding 4000 sheep from year's end to year's end on a statute acre of ground.

So far as the health of towns only is concerned, it is scarcely a matter for argument that, if practicable, the decdoration and disinfection of all closet refuse on the spot, and the keeping of it entirely out of the sewers, must be a great benefit. I maintain that this is quite practicable, and am prepared, if space would admit, to prove it.

It must be admitted that sewage irrigation plans have failed, and have been abandoned for others in many instances (Where?), as I believe because there has been too much manure for the available land. The A. B. C. process seems at present to be the favourite, and the most successful wet plan. As a manure manufacturing scheme, its advocates would, of course, wish to have all the excrement, but it leaves, just as sewage irrigation does, the nuisances within towns to be separately dealt with.

I think that any outsider, being neither a professional engineer, nor a farmer, nor wedded to any particular theory, but who lives in a town, and has an eye to its necessities, and reads from time to time the various opinions that are expressed, and studies the evidence that is adduced, must come to the conclusion that it is a mistake to hold up a particular scheme, and think that it will single-handed manage all that is desired.

We want a code of principles such as has been brought forward by the committee appointed to investigate the subject in Birmingham. These principles should bear upon all that is required, whether as to the health of towns, the pollution of rivers, or the nett cost. If such principles were established, it would not be a very perplexing task to carry them out, but it is very perplexing to sanitary engineers if they find one year their labour backed up by official documents, and the next year pooh-poohed by semi-official utterances.

As it has been recently stated or quoted, that earth passed twice through the closet has no more manurial value than common garden mould, I shall be happy to forward to any one who desires it, without charge excepting carriage, and in such parcels as you may judge best, 3 tons of earth passed four times through the closet for trial. I need scarcely add that I am a believer in, and an advocate of Mr. Moule's system, but at the same time I think if his system were generally adopted, enough of manure would be left for sewage irrigation in the slop-water from dwelling-houses, slaughter-houses, and other sources to be met with in large towns. *R. H. A.*

HEADS.

By HENRY CORBETT.

(*Continued from p.* 1337).

LOVELY as are the heads of the females, many bulls of the Bates blood are anything but good in this respect. There is an effeminacy in some of the sort which looks as if perseverance in one particular line had been carried too far, and nothing tells more of any such too close consanguinity than a feeble, weak, "pretty," head. You see it alike in man and beast. And yet you cannot of course, always "breed heads." Wild Eyes, the first bull to push pull with Mr. Walaby, by far the worst "place" about the celebrated prize bull, Commander-in-Chief, was his head, and this was so bad as to mainly account for his ever having been beaten. It was more that of a steer than a bull, plain and common, with an unpardonable horn. On the other hand, Mr. Bates, whatever may have come of it afterwards, evidently attached due importance to this point, as the oft-told story goes of his once buying a bull at a long price, although he had never seen more of the animal than his head.

The chief mark against the head of the Shorthorn, "the damned spot," which, like that on Lady Macbeth's hand, nothing can wash out, is the black or smutty nose, as held to be too sure a sign of bad blood or impurity in a close or more remote degree. But there is no telling how or when you may throw back to a cross, as in the case of Wild Eyes like Wylee, while there were "unsuspected jumps in the dark," that are, nevertheless, very much matters of history. Perhaps no animal of any repute was ever credited with so many black noses as a well-known Northern "Duke," and there are tribes in Ayrshire which throw black noses to this day. There is, however, a difference between a thorough smutty nose, and one which is only dark in patches, of which Mr. Pawlett's prize bull, Baron Walaby, in a very recent example. Many maintain that this was not a smutty nose in the true acceptation of the term, and so one set of judges would pass him, and another bench set him aside. At the Manchester meeting of the Royal Agricultural Society they ordered him out, and at the Oxford meeting they awarded him a prize. According to Mr. Wright—in 1846—"There are many well-bred Shorthorns with dark muzzles. This has been considered by many to be a recent introduction through some inferior cross; but, without denying that, let it not be forgotten that some of the early Shorthorns were not entirely free from it, although not very common, but the sire of Peljambe would not boast of much delicacy there." When, somewhere about the beginning of the present century, Mr. Thomas Booth was showing his Shorthorn herd to a neighbour, the other objected to what he called their raw noses—"in his day the stock was nearly all black-nosed, and he never knew a raw-nosed cow that was not delicate." It must be remembered that this was the word of a Yorkshire farmer, as uttered in the district from which the best Shorthorns have sprung. Early maturity or quick feeding is the chief recommendation of a Shorthorn; and so when we look one in the face we must bear in mind that what we want is, as Mr. Carr puts it, "a placidity and composure of mind, a phlegmatic disposition, suggestive of fattening propensity." In fact, a frisky Shorthorn should be something of an anomaly.

Not so the Devon. I should myself have a fancy for a certain wildness or boldness in the head of a pure North Devon; and when Captain Davy says this should in many points resemble the head of the deer, he seems to me to have very happily illustrated his subject. There is, of course, no surer tell-tale to this beautiful breed of animal than the blood-like head and lively look, as one may often distinguish in this way the little "native" gentleman from his commoner, heavier-countenanced cousin, born and bred on the fat lands of Somerset. With such a description apt to my hand, it would be worse than idle to attempt any other than that I have from Captain Davy:—"The head should be small, with a broad indented forehead, tapering considerably towards the nostrils; the nose of a creamy white; the jaws clean, and free from flesh; the eye bright, lively, and prominent, encircled by a deep orange-coloured ring; the ears thin; the horns of the cow long, spreading, and gracefully turned up, tapering off towards the ends; in fact, the general aspect of the head should in many points resemble that of the deer. At the same time the expression must be gentle and intelligent. The head of the bull are thicker set and more slightly curved, or in some instances standing out nearly square, with only a slight inclination upwards. Fault has been found with the length of the horn of the Devon as being disproportionate, and we have been recommended to get them more like those of the Shorthorn; but I hope, and indeed feel sure, that our breeders will never consent to give up one of the grandest characteristics of their breed."

Here, again, we have the nose, as the old Northern farmer contemptuously called it, and here, too, precisely the same sort of discussion crops up.—"A black, or even a spotted, nose is very much disliked, and a calf so marked is never kept by the best breeders. Now the wild cattle in Chillingham Park are of a creamy white colour, with black muzzles; may not the appearance at rare intervals of these black muzzles, and also of the white of which I have already spoken, be additional proofs, if any be wanting, that the Devons were originally descended from the wild cattle which were natives of these islands. I never heard these marks accounted for. Judging from the rude state of agriculture until, we will say, within the last 200 years, it is just possible that our ancestors were not so fastidious about the colour of the nose as we have since become, and did not object to breed from an animal with a black muzzle."

So says Captain Davy, and his theory is well put; but still it is not so clear why we should be so fastidious in preferring a white nose to a black. The Shorthorn breeders say the smut comes originally from a cross, although this would seem to be something of a hypothesis at best. Can the curse of a black nose be further shown by any accompanying want of style or quality—in a word, does its appearance necessarily imply an inferior animal in other respects? In support of my own theory, I am glad to say that some of the best and most successful Devons I have ever seen have had the handsomest heads, and I need but name Mr. James Davy's Progress family to recall their fine deer-like character, telling as truly of their lineage as the longest pedigree in the Herd Book.

The mottle-faced Hereford is fast going out of fashion. Few people would object to buying a good mottle-faced cow, but no breeder of repute, due to rear a bull that marked, as he might be difficult to sell, for undoubtedly the white faces are now all the fashion. A well-known judge and breeder tells me that, beyond the colour of the face, and the length and straightness of the horn, the good points in a Hereford bull's head cannot differ much from those to be appreciated in other breeds. While, however, the horn of the bull runs straight and level from the poll, those of the cow and ox gradually curve upwards. The eye of the male should be rather lively than otherwise, and that of the cow conveying precisely the same calm, contented, good-tempered look which I have already identified with the Shorthorn. The face should be of a beautiful clean white in colour, backed by a rich red, more especially in the bull; the horn also white or light yellow, occasionally tipped with black, and the nose white; although here, again, we have the evil of black noses, which name, it is said, more frequently in Herefords than in any other breed of cattle. The head should certainly not be small in proportion to the other parts, as, in fact, a head either large or small out of proportion, is simply a deformity in any animal. A really good head must have a certain length and breadth, to which such a phrase as small can never reach. Mr. George Smythies has favoured me with a measurement of the head of Governess, a choice Hereford cow, the property of Mr. Green, of Marlow:—

	Inches.
Length of face	21½
Between eyes	9
Round nose	25
Length of horns	20½
Width of horns from tip to tip	37½

It is said that Professor Owen, if you give him only the thigh-bone of some antediluvian creature, will work up the frame of a perfect monster, and with these

dimensions he could, no doubt, fashion out a model Hereford. Governess, however, was altogether on a larger scale than the animals now exhibited, which are neater and finer, as no doubt but few heads would measure against her. One of the kindest heads I ever saw on a Hereford cow was that of Stately 2d, the property of Mr. Evans, of Swanstone, though she never did quite so well in public as might have been expected; but—

"If to her share some trifling errors fall,
Look in her face and you'll forget them all."

The champion Hereford bull of his day, on the contrary, begins with a somewhat mean, small head; whereas there should be something very noble in the head of a white face, when seen at his best.

There is no animal which tells more of high breeding than an Alderney, or rather, a Jersey-born cow. There is a refined air and carriage, a certainly comely "presence," which would forbid all thoughts of the butcher, and never carry one's appetite beyond a syllabub on thin bread-and-butter. A Shorthorn bears "beefsteaks" on his very visage, whereas we shudder at the notion of cutting prime pieces out of old Daffodil, or of putting a round of Nora Creina in salt. It would be worse than killing and eating the pet lamb, let alone the question of Daffodil's possessing any prime beef; while Nora, more palpably, being all angles can have no rounds. No—the head and beaming eye of the Alderney speak again of her purpose, of rich cream and yellow butter; but the charm here is all on the cow's side. Beyond a peculiar, wild, wicked eye there is not much to admire in the head of an Alderney bull, and even the cows lose much of their graceful character when bred away from their native isle. In the Jersey scale of 36 points for a perfect cow or heifer, one each is allowed for the following excellencies:—"Head, small, fine, and tapering; cheek small; throat clean; muzzle fine, and coloured by a light colour; nostrils high and open; horns smooth, crumpled, not too thick at base, and tapering; ears small and thin (one point), of a deep orange colour within (one point); eye full and placid." The eye of the bull must be lively and his horn tipped with black, but beyond these points as much the same as Mr. Dumbrell, of Ditchling, who has the largest herd of Alderneys in the kingdom, has thus sketched the head for me:—"The horns should be fine, tapering, and crumpled, coming level from the head, and not turned up. The ears large, plentifully fringed with fine silky hair, with the inside also of the ear of a deep rich orange colour, and the hair between the horns fine. The eyes, placed wide apart, should be large, prominent, bright, and intelligent; the forehead wide, and depressed in the centre; the cheek fine, and very tapering to the nostrils, which should be large, and the muzzle black, edged with tan. The head itself should be distinguished by a certain unmistakable evidence of good breeding, which is readily recognisable, but not so easily put upon paper." The Jersey society goes on to distribute the other points over the back, the barrel, legs, and so forth; but if we put down 15 points for the head, and 10 for the udder, leaving the other 11 for general appearance, we should arrive at a tolerably accurate, if not so elaborate, an estimate of an Alderney, which, after all, you must judge mainly fore and aft. I cannot believe in any man writing a note with a pencil in his hand and carefully entering one point for this, and another for that, until he had proved a very pretty little sum in simple addition. He would surely "bother" himself during that somewhat tedious process.*

Mr. M'Combie, again, speaking of course of his much-doted Blackfolds, says:—"A perfect breeding or feeding animal should have a fine expression of countenance; I could point it out, but it is difficult to describe upon paper. It should be mild, serene, and expressive. He should have a small, well put-on head, prominent eye, with a clean muzzle. Thick legs, thick tails, small bones, thick necks, small head, thick skin and bristly hair, always point to sluggish feeders." Some years since I was at a meeting of the Highland Society at Aberdeen, when rather a good story got about as to the heads of these famous Polls. Some philanthropists from Paris were present, and so struck were they with the Aberdeen-Angus cattle, that they offered, on the part of some French humane society, an extra medal for the best bull, the impression being that an animal without horns could do little injury either to the herd or the herdsman. "Whereas the Poll has, in 'fancy' parlance, only a "fighting mug of his own," as often enough, like bulls of other breeds, a bit of temper, and with that hard bullet-head of his he will at times butt away like a nigger. However, the medal was duly awarded, and the French embassy returned, no doubt able to report that it had discovered a breed of cattle which must have flourished in Arcadia in the Golden Age—so gentle, so mild, and so harmless.

Let us look to another kind of Scotch cattle, and what would the West Highlander be without his head? The butcher will say in answer—"the very best beef"—but with his head all his character is gone. There is a wild grandeur, I had almost said majesty, about the head of the Highlander, that should count up very fast in any scale of his points, as perhaps no other animal shows in this respect such insignia of Nature's nobility. You may read of his Highland home in his clear bright eye, his magnificent horn, and his rough, but right royal coat. And the Southron would seem to have a deal still to learn in this way, for at the Smithfield Club Show of 1869, the judges selected as the best Highland ox an animal with an ugly "cowy" half-Ayrshire head, that was, no doubt, a mongrel; and a new class had straightway to be instituted, in order to avoid such awkward "findings" for the future. *Bath and West of England Society's Journal.*

(*To be Continued.*)

STRAW-CHAFF FOR CATTLE FEEDING.

By Dr. Voelcker.

In the current number of the Journal of the Royal Agricultural Society of England, Dr. Voelcker has an article upon the method of preparing straw-chaff adopted by the late Mr. Jonas, of Chrishall Grange, Saffron Walden. Dr. Voelcker says, the peculiarity of the plan of Mr. Jonas consists in the use of a small quantity of green Rye, or green Tares, as a fermenting agent.

Mr. Jonas, who for many years has been a great advocate for the consumption of a large portion of straw-chaff for feeding purposes, uses a 12-horse power engine for threshing, dressing, and bagging the corn ready for market, and cutting the straw into chaff, at the same time. With 1 ton of straw-chaff he uses about 1 cwt. of Rye or Tares, cut green into chaff, and 1 bush. of common salt. This is done in spring and summer; the chaff is not used until October or the winter months. The addition of the green stuff causes the straw-chaff mixture to heat; the volatile and odoriferous principles produced by the fermentation are retained by the straw-chaff, itself undergoing a kind of slow cooking process, and they impregnate the whole mass with an extremely pleasant flavour, scarcely inferior to that which characterises well-made meadow hay. It appeared to me interesting, if not useful, to compare the nutritive properties of straw-chaff prepared according to Mr. Jonas' plan, with ordinary wheat-straw, and I therefore made a careful analysis of a sample of chaff taken from the bulk at Chrishall Grange, supplied to me by Mr. Jonas.

Analysis of the Straw-chaff.—The following results were obtained in the analysis of this straw-chaff:—

Moisture	7.76
Oil and fatty matter	1.60
*Albuminous compounds (flesh forming matters) ..	4.12
Sugar, gum, and other organic compounds soluble in water	10.16
Digestible fibre	35.74
Woody fibre (cellulose)	34.54
Insoluble mineral matter (chiefly silica) ..	3.20
Saline mineral matters (chiefly common salt)	2.81
	100.00
*Containing nitrogen	.67

The term woody fibre (cellulose) in the preceding analysis applies to that portion of the straw-chaff which remains behind after successively treating the material with water, dilute sulphuric acid, and dilute caustic potash solution, and exhausting the residual dried substance with alcohol and ether. There can be no doubt that the different alkaline and acid secretions in the animal organism exercise similar, probably even more powerful effects upon the food than these successive exhaustions with various chemical agents in the laboratory. The treatment with dilute acid and alkali, therefore, affords a better insight into the digestibility of the bulk of straw than the mere exhaustion with water. Let us now compare the preceding analysis with the composition of ordinary wheat-chaff. The following is the composition of a sample of well-harvested wheat-straw, which was neither under nor over-ripe:—

Moisture	13.33
Oil and fatty matter	1.71
*Albuminous compounds (flesh-forming matters) ..	2.93
Sugar, gum, and other organic compounds (soluble in water)	4.26
Digestible fibre	19.40
Woody fibre (cellulose)	54.13
Insoluble mineral matter (chiefly silica) ..	3.01
Saline soluble mineral substances	1.13
	100.00
* Containing nitrogen	.47

Wheat-straw and Straw-chaff Compared, to the Advantage of the Latter.—A comparison of the composition of ordinary good wheat-straw with that of straw-chaff prepared by the system pursued by Mr. Jonas brings out several points of interest, on which a few observations deserve to be made. 1. In the first place it may be remarked, that both kinds of straw-chaff contain about the same proportion of oil. The oil exhausted from straw by means of ether has a bright yellow colour, is sweet to the taste, and renders straw more palatable and more nutritious than it would be without this constituent. It is appreciable in quantity, for according to the preceding data, 1 ton of straw-chaff contains about 39 lb. of oil. 2. It will be seen that fermented straw-chaff contains rather more than 4 per cent. of albuminous, or flesh-forming compounds; whereas ordinary wheat-straw contains, in round numbers, only 3 per cent. The prepared wheat-chaff, therefore, is one-fourth richer in materials which produce the substance of the lean fibre of meat, or the muscle. 3. Common wheat-straw, of good quality, contains about 44 per cent. of sugar, gum, and similar soluble organic compounds. In over-ripe straw the amount of these soluble matters is less. On the other hand, in the sample of fermented straw-chaff analysed by me, the percentage of sugar, gum, &c., amounted to 10.16, or to nearly two-and-a-half times the amount which occurs in good unprepared wheat-straw. The much larger proportion of sugar and other soluble matters in the fermented straw, no doubt, is due to the green-stuff employed in its preparation; but, at the same time, the process of heating the mixture, it is quite probable, may have had the effect of rendering the chaff more soluble in water. Bearing in mind that the chaff prepared by Mr. Jonas contains so large a proportion of succulent matter, it is no wonder that cattle and sheep are fond of it, and thrive upon it in a much higher degree than upon ordinary wheat-straw. 4. A comparison of the relative proportions of digestible and of woody fibre in fermented wheat-chaff, with their proportions in common wheat-straw, exhibits striking differences, which cannot fail to come to the notice of stock-feeders. Taking together digestible and woody fibre, we have in the fermented straw-chaff 70.38 per cent., and in ordinary wheat-straw 73.53 per cent., showing a slight difference in favour of the fermented chaff, which, being richer in sugar and other matters soluble in water, contains about 3 per cent. less vegetable fibre than common wheat-straw. When the vegetable fibre of each kind of straw-chaff, or the material insoluble in cold and boiling water, is treated with dilute acid and alkalies of the same strength, for the same length of time, and under all conditions precisely alike, a certain proportion of the vegetable fibre is rendered soluble. This soluble portion figures in the preceding analysis as digestible fibre, whilst the matters insoluble after treatment with the various chemical agents is termed indigestible or woody fibre (cellulose). Although it is not necessary to convey by this expression the idea that animals have the power of resolving crude vegetable fibre into digestible and into woody fibre, in precisely the same ratio in which we can separate them in the laboratory, a tolerably good opinion may be formed of the relative digestibility of various foods, consisting principally of vegetable fibre, by submitting them to the process usually employed in laboratories for the determination of woody fibre. In the cases before us, it will be seen that of the total amount of vegetable fibre present in the fermented wheat-chaff, 45¾ per cent. were rendered soluble by the treatment described, and 54¼ per cent. were consequently left behind as indigestible woody fibre, whilst the 73¼ per cent. of vegetable fibre present in common wheat-straw chaff were resolved, by treatment with dilute acid and alkaline liquid, into 19¾ per cent. only of digestible, and into 54 per cent. of indigestible woody fibre. In other words, the same treatment rendered soluble 50.85 per cent. of the vegetable fibre of the fermented prepared chaff, and only 26.38 per cent. of the fibre of common wheat-straw. These differences are very marked, and well calculated to explain, in a great measure, the great superiority of the fermented chaff as feeding material, over common straw-chaff.

Fermentation: the Cause.—The fermentation to which the straw is submitted in Mr. Jonas' plan thus has the effect of rendering the hard and woody matter which constitutes the bulk of straw, more soluble and digestible than it is in its natural condition. But useful as the effect of the slow and moist heat, developed in the mixture of straw-chaff with green Rye or cut Tares, no doubt is in rendering the fibre of the chaff more digestible, this is not the only recommendation of Mr. Jonas' admirable plan of preparing a really very nutritive and important food for stock. Another recommendation is the extremely delicate flavour and the palatable condition which is conferred upon the straw, in the process of fermentation. The prepared straw-chaff, kindly sent to me by Mr. Jonas, has the agreeable smell which characterises good green meadow hay, and a hot infusion with water produced a liquid which could hardly be distinguished from hay-tea. Although fermented chaff resembles hay so much in taste and smell, it need hardly be stated that the latter is more valuable for feeding purposes. However, the differences in the nutritive properties of meadow hay and straw-chaff made from rather under-ripe wheat-straw, prepared and fermented in accordance with Mr. Jonas' directions, is not so great as might be imagined by some. A little cake ground into meal, and sprinkled over the chaff, would go far to obliterate the difference in the feeding quality of the two kinds of chaff. I would particularly recommend for that purpose, a cake rich in albuminous compounds. Green German rape cake, or decorticated cotton cake, added to the straw-chaff in but small quantities, will bring up the percentage of albuminous compound to what it is in good meadow hay. Best decorticated cotton cake contains about 40 per cent.; green rape cake about 33 per cent.; and the finest linseed cake, from 30 to 32 per

* Since writing this, I have heard an amusing story in point. A scale had been settled for certain breeds of sporting dogs, and at one of the shows the judges, after having awarded the premiums in a class, went on to prove their decisions by the new system. They accordingly noted down so many points for the head of the first prize dog, so many for his tail, so many for style, and so forth; and they proceeded to appraise the second and third prizes after the same fashion. The several totals were then carefully counted up, when it was found that each of these three dogs had precisely the same number of points in his favour!

cent. of albuminous compounds. About 2 cwt. of decorticated cotton cake, ground into meal, and added to 1 ton of fermented straw-chaff, presuming it to have always the same composition as the sample analysed by me, I find, constitutes a mixture which agrees closely in composition with good meadow hay. Chaff, especipally if it be made from over-ripe straw, is not readily taken to by cattle, on account of its insipid taste and harshness; and considerable difficulty is experienced to induce stock to consume straw-chaff in as large quantity as is desirable. To meet this difficulty, several stock-feeders with whom I am acquainted have found it useful, in practice, to use straw-chaff with some treacle previously diluted with sufficient water to impregnate uniformly the chaff with the sweet liquid. The only fault I have to find with this otherwise good plan of rendering chaff more palatable is, that the farmer has to pay from £13 to £14 per ton for the treacle, and obtains in that material only about 54 to 60 per cent. of sugar, the rest being water and impurities of no feeding value. By Mr. Jonas' plan, straw-chaff is not merely made more palatable, but, as it is mixed with a little green food, it undergoes a slow cooking process, and becomes more digestible, and permeated by a delicate hay flavour. Thus the most is made both of the green stuff and the straw, and an excellent food is produced at a trifling expense, greatly superior in feeding properties to treacled ordinary straw-chaff, which costs more money. The great simplicity of preparing and storing straw-chaff, and the inexpensiveness of Mr. Jonas' plan, are further advantages, which all who consume much straw may secure to themselves.

Home Correspondence.

Waste Brings Want, and this is as true of a nation as of an individual. At the present rate of waste of the constituents of our food after we have consumed it, the nation must become *pro tanto* poorer and more dependent on other nations for its supply of food. London alone sends into its Thames, in seven years, the whole of a year's produce of the United Kingdom, or its equivalent, which costs about £150,000,000 sterling; and as our town populations are estimated at 15,000,000, the waste in seven years is that from food which has cost £1,000,000,000, or much more than the total amount of our national debt. These are not imaginary figures, as I shall now prove. Our population is 32,000,000, our farmed area is only 46,000,000 of acres; having, at £4 an acre, an annual produce worth £184,000,000; so that 1½ acre of British soil is not near enough to feed each individual, and we therefore have to draw upon foreign countries for the remainder. As their production of food per acre is less than half that of our own (in some cases not a third), another 20,000,000 of acres are probably required to supply us. I speak of bread, meat, Potatos, butter, and cheese, and leave out of consideration the vast area of land required for tea, coffee, sugar, wine, spices, &c. Well, then, we require 2 acres each to feed ourselves and our dependents. I mean the available produce of 2 acres, because the farmers have a million of farm horses which consume, probably, the produce of 4,000,000 to 5,000,000 of acres. Licensed, or taxed horses, non-agricultural, number 1,500,000, and they eat (I assume the produce of some 3,000,000 or 6,000,000 of acres. If I add to this of our own production all the tea, sugar, coffee, wine, &c., received from foreign countries, and consumed in London, and all the products of our fisheries, the amount I have named will be vastly increased. It probably takes the available produce of 50,000 acres to feed Londoners for one day, and 20,000 acres to feed their horses for a week. To what extent, in manurial money value, do we Londoners thus withhold from the land? Mr. Lawes, and our other chemical authorities estimate the manurial results of its consumption of food at percentages, according to its constituents, varying from 10 to 40 per cent. of cost. We may, therefore, safely value the voidances at one-tenth of the value of the food consumed. At this rate the loss to London might be put at £2,000,000 sterling annually, or for all the towns at £10,000,000 sterling annually. There is an unerring way of testing this question—a crop grown on 1 acre, if consumed on that acre, will fertilise it, but if the crops of 2 acres are consumed on 1 acre, the fertilisation is amply sufficient to produce a great crop. Therefore, if each individual on an average consumes the produce of 2 acres, the voidances resulting from it, if all economised, ought to fertilise 1 acre. On this principle or calculation the population of London and their horses should fertilise 3,000,000 of acres annually. Of course there can be no reasonable hope of this taking place, but it illustrates the folly and waste of applying the annual voidances of 50 people to a single acre of land, and continuing to do this year after year. Even at this rate, 60,000 acres would be required to utilise the sewage of the 3,000,000 population of London. This question is of such vital importance naturally, that our Legislature and Government should, in my opinion, take initiative action upon it, by the purchase of a sufficient area in various directions, and a resale when properly completed. The city of Glasgow, by a single pipe of 4 feet diameter and a fall of 5 feet per mile, has, at a cost of a million sterling, obtained from Loch Katrine, 40 miles distant, 22½ million gallons of pure water daily. Steam power would, at a cost of 8*s.* 6*d.* per 1000 tons of sewage, raise it 200 feet high, which, at a fall of 5 feet per mile, would convey it 40 miles away from London. But then the sewaged land must be drained, naturally or artificially; so it is a "big job," which will ultimately force its way to a solution. Still, as compared with our railways it is, for engineers, a very little job. It is estimated that we shall this year require 13,000,000 qr. of foreign Wheat independent of our enormous imports of other kinds of grain, meat, butter, cheese, and a million of foreign eggs daily. *F. J. Mechi, Tiptree.*

Landowners and Labourers.—Your correspondent, E. Minshall, writing from an estate office, makes some suggestions by way of improving the agricultural labourer. I fear his reasoning will not improve matters. His first suggestion is that "all landlords and agents should use every endeavour to retain upon the estate the labourers' sons." He says, "three of every five find their way to the towns and cities," and this would be avoided if "good cottage accommodation was to be obtained in the country." May be it has not occurred to him that families will outrun the requirements of an estate, excepting where certain portions of J. S. Mill's "Political Economy" has been studied and acted upon—namely, the natural law of supply and demand seems to be unknown to him. Secondly, that "every cottager should hold direct from the landlord, and not under his master. In most cases, cottages are leased to the farmers, who sublet them to their workmen as weekly tenants. This arrangement is bad, for in many cases under it the labourer feels himself a sort of slave to his own master." The farmers in and around Aston, Preston Brook, indeed as far as the dictum of this estate office reaches, must be, to say the least, a queer lot; they will pardon me, but Mr. E. Minshall would make it appear there is not a "man of any honour" among them. His "man of any honour" (the labourer) feels it a sort of slight to take his cottage from his master, and not from the owner; at the same time, he (Mr. Minshall) says, "Now, if every cottage was let direct to the labourer, under a tenancy subject to the farmer to nominate the tenant, subject to the approval of the agent, an improvement would be made. The cottager would feel himself independent," &c. He would release the labourer from what he terms the slavery of his master, but the farmer is to be subjected to the tyranny of the agent. Would it be the fact of the farmer being compelled to ask the agent's permission to remove a tenant from a cottage on his farm, be sufficient to give rise to those "vast number of squabbles" which have sprung up, Mushroom-like, in his imagination? Now, let Mr. E. Minshall say had these "three out of the five" lads, who have sought for work elsewhere, remained on the estate, would they, and the labourers now located on the estate, be dealt with more honestly by him than the farmers? Is the breast of Mr. E. Minshall the only soil congenial to the growth and nurture of that noble virtue, "common honesty?" *A Farmer.*

Cottages.—The remarks which I made upon the former set of three cottages, apply nearly equally to those which you publish at p. 1335. It will at once be seen that the middle one of the three is a very imperfect form of cottage, and it is very difficult, if not impossible, to make it otherwise. As I said before, it is a far better plan, in general, to build two-roomed cottages for single, and three-rooms ones for married, and not to mix them up together. The two end cottages in Mr. Denton's plan would make a pretty good pair of two-roomed cottages. Of course it is a defect in them the pantry opening out of the living room, but there is no reason why it should not open out of the porch in these plans, which would be much better. Even with this alteration the plan is not so good or so cheap as plan No. 9 in my book on cottages. Cottages on that plan can be built for less than £200 the pair in most parts of England, with more accommodation in them at the end than those in 1335 plan, and I am not aware of any serious defect in the arrangement of that plan. *C. W. Strickland,* 30, *George Street, Hanover Square, October* 16.

Flowering Stems.—Like "Observer," I have been much struck this year with the disposition of biennial plants to run to seed in their first year's growth. The early Cabbages exhibited this tendency more than they usually do, and Mangels have largely run to seed. Many of my spring-sown Onions threw up flower-stems. I, too, like "Observer," have found some patches of Dodder in my Clover sown with the Barley this spring, in a field where Clover has not been grown for 16 years; the seed could hardly have been dormant so long in the soil. The Swedes are much injured in this neighbourhood by the insect "Observer" speaks of, destroying the crowns of the young plants; this is a common occurrence in Norfolk just about the time the Swedes are singled, and they generally recover from the attack without material damage. This year in many fields 90 per cent. of the Swedes suffered in this way, and, contrary to my experience in former years, the fresh crowns formed after the original injury have been destroyed in the same way, so much so that large numbers of the Swedes even now have no leading shoots. Cabbages, Couve Tronchuda, and Broccoli have been attacked more or less by this insect, though not to so large an extent. White Turnips are uninjured. I fear any protection against damage in future is not to be expected. Can any of your correspondents say what the insect is which deposits its eggs in the crowns of young Swedes? *J. G. Nelson, Addorough Rectory.*

Tanks in Rural Districts.—My friend Mr. Mechi states in last week's *Agricultural Gazette* that underground tanks should be of brick, well cemented. If the ground is firm, bricks need not be used except for the dome. Two-thirds of the tanks in this district are cemented upon the solid, and stand better than if bricked, the latter being very liable to cause a leakage from settling and cracking. A tank of this kind sufficient for two cottages to be completed for £6, exclusive of a pump. Farm tanks cost from £12 to £15. *William Brown, Land Agent, Tring.*

Societies.

DOCKING.

The Harvest.—At the late meeting of this Society the Earl of LEICESTER said:—I must congratulate you upon meeting after your farming prospects have been so successful. You have grown good crops, and you have harvested them well. It has been a year that has been peculiarly favourable to the soils that we cultivate; in fact, the light land has at last had a turn. And I will ask you whether we have on this description of soil, and in a favourable season, grown all that it is possible to grow with profit? whether we have retained the greatest possible return at the least possible cost? and whether our grain crop and our root crop are all that could be desired? I fear that those questions can hardly be answered in the affirmative, and as long as we are so cautious in deviating from the beaten track, and so slow in adopting the knowledge that is extending itself throughout the country, we shall be more dependent upon the seasons than we ought to be, and we shall not obtain that success for our efforts which we otherwise should do. Since I last met you, I have travelled much through England and through parts of Scotland; and, taking into consideration the whole of the land that I have seen under cultivation, I think I may safely state that the produce of the land might be nearly doubled under a perfect system of agriculture. I have observed a want of capital and skill on the part of the occupier, and an apparent want of assistance and encouragement on the part of the owner. The buildings were bad and inconvenient, the fields too small and ill-arranged, and too often covered with useless timber. But the two greatest evils that, in my opinion, prevented the growth of larger crops were inferior drainage and shallow cultivation. Now, the soils that we cultivate have a natural drainage, but I am now convinced that on the lightest of our Norfolk lands deeper cultivation than we are in the habit of adopting would be remunerative. I have not had an opportunity yet of inspecting the root crops of my neighbours, but I fear that they are not altogether satisfactory. I last year, however, grew a mangel for my root crop 12 inches deep by the aid of steam, and much of this land was, I am happy to say, lighter than that which is generally to be found on my estate; and I would ask those gentlemen who are sceptical as to deep cultivation for the root crop on such soils as ours to examine my root crop before they judge for themselves. I do not assert that deep cultivation will secure the root crop in such droughts as we sometimes experience in this county; but it will have this effect, that the drought will not injure the roots on the deep ploughed land until two or three weeks after those on the shallower soil are destroyed; and in those two or three weeks rain may come, and the root crop may be saved. This was my case last year; it has also been so this year.

A doubt had been expressed as to the result of deep cultivation upon the succeeding corn crops. I did not entertain this doubt, because I believed that a heavy root crop was, on our soils, the best preparation for the succeeding corn crops, if a due proportion of that root crop was fed off on the ground. This, as far as my experience goes, has been the case. I have lately threshed some Barley on land which was ploughed 12 inches deep for the root crop, to test an experiment that I had made of sowing Barley 12 inches from drill to drill; and as it is important, gentlemen, where figures are stated to be accurate, I will, with your permission, read the result of that experiment. The experiment was on two pieces of land adjoining each other, each containing 1 a. 3 r. 28 p. Two-thirds of the previous Turnip crop fed off with fat sheep, eating 1 lb. of linseed-cake per day." I ought to state with this exception, all my Barley on the Park Farm is drilled 9 inches from drill to drill. "One piece drilled at 9 inches apart with 2 bush. of seed per acre, produced, best corn, 20 coombs; best tail, 2 coombs; inferior tail, 3 coombs; total, 25 coombs, or 13 coombs per acre. One piece drilled at 12 inches apart, with 1½ bush. of seed per acre, produced, best corn, 20 coombs; best tail, 2 coombs 1 bush.; inferior tail, 2 coombs; total, 24 coombs 1 bush., or 12 coombs 2 bush. 1 peck per acre." The conclusion I have come to from that experiment is this, that considering that the seed corn was the same in both cases, air and light are necessary to protect all crops, and also that wider

distances and less seed might be used than is generally the custom; and I think that as 12½ coombs was the produce of 43 acres of land of 9 inches from drill to drill, the beneficial effect was the result of deep cultivation for the root crop. And I find also that after deep cultivation Clover seems to be kinder and more likely to stand on that land which has a certain admixture of the subsoil than where such an admixture has not taken place. I do not recommend the 12 inches from drill to drill. I believe that is too wide on our description of soil, as the 6 or 7 inches is too narrow. On my Marsh Farm of strong land, I find I never sow nearer than 12 inches either for Wheat or Barley; and I find that 3 pecks of Wheat and a little more than 3 pecks of Barley is ample seeding. Before I sit down I will say one word to my brother landlords. I do not believe that agriculture will ever attract that capital, that skill, and that energy that is required to bring it to perfection until ample security is given in the form of a lease to the occupier of the farm, and from that lease many unnecessary restrictions which exist in 99 leases out of a 100 are omitted. I found that in the lease in use on my estate there were many restrictions—such restrictions as I should not like to be bound by were I a tenant of a farm. I have, therefore, with the assistance of my agent and my tenants, devised a form of agreement or track, and endeavoured to frame a lease more in accordance with the spirit of the age, avoiding all interference with the capital of the tenant, removing all clauses that dictate as to the cropping of the soil or as to the sale of the produce, and, as far as I can, giving security for the capital invested. I have endeavoured to place my tenants in that position which I should like to hold as an occupier of land; and in doing so I am satisfied I have studied my own interest as well. That lease will be printed, and with as few legal phrases as is practicable; and I shall be happy to submit a copy of it to any of my friends who may like to see it, because I believe, with certain modifications, it may be adapted to many estates of this country, both for the advantage of the landlord and the tenant.

Mr. H. E. Blyth remarked, that Mr. Simpkinson was not altogether acquainted with the details of agriculture, or he would have been aware that one of the great objects in view during the last few years in cultivating the soil by the aid of machinery was to endeavour to make the labour bill less in amount. Whether or not that was right in principle he would not argue; but there was no question that the introduction of most expensive and powerful machinery to many operations on land not so many hands were required to cultivate it as 10 years ago. He could fully bear out what the noble lord had said with respect to the advantage of deep cultivation, especially in the growth of the root crops; for he had long noticed that where they double furrowed, or used something to grub the soil up to a greater pitch without turning over the subsoil, that the drought did not there affect the root crop so soon by two or three weeks as where the ground was only cultivated in the common manner. He had also frequently noticed the effect of deep cultivation for root crops upon the succeeding crops of corn, but whether the effect described would always be produced, he could not say. Speaking of the Association, Mr Blyth said that its funds continued in an equable position, the subscriptions being liberally maintained, while there was between £100 and £110 at the bank. Premiums were awarded by the Association to young servants retaining their situations for a certain number of years. But servants now-a-days were not fond of remaining for years together in the same service. There was no doubt, in consequence of the facilities there were for young people getting about, and partly because of the temptations of which they could avail themselves, and which made them rather unsettled. Though the Association might not have been successful in securing their object in that class, it most assuredly had produced satisfactory results in the class of skilled work, such as ploughing, stacking, sheep shearing and thatching. But he was afraid that in some of these they might be getting out of the right track. For instance, the premiums for ploughing were given to the man who drew the straightest and worked the best furrow on a given piece of land in the course of so many hours. The noble lord, not directly, but practically, said that ploughmen were to be superseded by steam-engines; while the intelligent farmers of the neighbourhood set their men to plough in a round O and not a straight furrow at all. There might be what were known as "hogs backs" and "slips" which were soon covered up with a harrow without being detected by a master. If clean ploughing was good, then circular ploughing had certain great disadvantages. Then the ploughmakers had excelled in producing implements of first-rate character. And what did the ploughman do? So perfect and so good were the ploughs that a man would get on the tail and ride from one end of the field to the other; and if that were not enough let them set two ploughs into a field, and then one man at one end and the other at the other would move the horses backwards and forwards and not go near the plough. If these things prevailed on farms it was no use the Association giving prizes for straight ploughing. These were some of the anomalies which had crept in, and which were telling them that as the times had changed it was necessary that they should make some alteration in their programme before long.

Sir W. Jones proposed "The Judges of Summer Work," in doing which he referred to the problem he put before the Norfolk Agricultural Association for solution, namely, "What will give a good crop of hay, and not grow Sainfoin. And a good crop it has. The gentlemen had informed him that Sainfoin was the solution of the problem. He differed from them, for Sainfoin would not grow on all soils; indeed, there was a large proportion of land in this country which would not grow Sainfoin. Many and many a good field which might have grown Trefoil or Clover had he seen thrown away because it was given up to Sainfoin in the hope that it could be grown. He had attempted it, and with very poor success, on good land. It would grow on light and thin-skinned land. Those gentlemen who had tried to set him right had uniformly been West Norfolk men, who judged by their own experience; but, take a farm on the light lands of East Norfolk, and it would be found that Sainfoin was not the solution to the problem. He only wished some one could find the answer. With respect to what had fallen from Mr. Simpkins on the subject of the census, he would suggest whether it was not possible that the exodus of labourers from Norfolk to the North of England might not be more owing to the attraction of the North than to the repulsion of Norfolk. In the North there was an immense scope for labour. The gigantic development made year by year in the factories and coalfields called for a large increase of labour. Naturally enough, the increase there was only about the same as it was in Norfolk, but the deficiency was made up by the North attracting by higher wages the surplus of the agricultural population. He was therefore inclined to believe that if we could found that it was not so much the repulsion exercised by the agriculturists as the attraction of, and the deficiency of, labour in the North. Wherever there was a depression, fluid would flow in and bring it up to a level. This was a law of physics, and there was a similar law in political economy, for where there was a deficiency of labour, labour would flow in and fill up the void. The increase of labour produced in the North was never sufficient to meet the demand for it created by the erection of new mills and the opening of new mines; consequently the surplus labour from this district flowed there constantly as water flowed to a hollow. What had been noticed was not so much a fault on their part as the result of the immutable laws of labour.

Mr. T. Everitt thought that farmers would find on referring to their books, that it cost them as much for labour now as it did 10 or 20 years ago, *plus* the cost of many expensive machines. Farmers were now rather short of labour, and some would employ more hands if they could get them.

The Chairman said that Mr. Simpkinson, in his address to the labourers, put the question of labour as one of profit to the farmer—that it was not the farmer's business to pay more for it than would make a profitable return. He believed that they could not to employ more labour on their farms than would make a profitable return. It was a question of profit and loss in the employment of labour. They ought to employ as little labour as they could, in reference to the return they got for it. As far as the migration of the labourers from Norfolk was concerned, he agreed with Sir W. Jones that the attraction in the North was at present very great. But he believed that this would soon rectify itself, for though the wages of the labourer in the North greatly exceeded the wages of the labourer in agricultural districts, the amount left to him, after making all deductions, was in the agricultural districts equal to, if not greater than it was in the northern counties of England. If this were so, the matter would soon rectify itself, and labour, like capital, would be transported to where it was wanted. He believed that agricultural labourers were more or less well off as they are now. They might be better off in having good habitations, for a good habitation was the first thing for a labourer to possess, and until they had good houses their position could not be improved. An improvement had, he believed, been made in this country greatly in favour of the agricultural labourer, in the improvement of the cottage accommodation. With this, and increased pay which he would receive from having more education, which would make him more valuable to his employer, they would find that the migration that had been going on to the North would soon come to an end.

The Rev. A. Napier, in giving "The Agricultural Labourer," said that what Mr. Simpkinson had uttered was an excellent, and a sound doctrine of political economy. There was only one point on which he differed from him. He seemed to infer that the exodus of labour from the agricultural counties, and especially from Norfolk, was an evil. Without entering very deeply into that question, he (Mr. Napier) was inclined to doubt whether it was a benefit or an evil. He ventured to assure them of the absolute certainty that the exodus had begun, and that it would continue. It appeared to him that the exodus was not an evil, for those who were left behind would be more thought of and better paid. He believed that the scarcity of agricultural labour would be followed by an enormous increase of employment of machinery, and he apprehended that the employment of machinery would not hurt but greatly benefit the farmer, and at the same time be a great benefit to the labouring man. He had watched the men who went up to receive the various prizes. A great number of them were excellent specimens of the agricultural labourer—sturdy, vigorous, hardy fellows. When he heard that those who attended to engines were about to go up for their prizes, he determined to watch the men. Four were called up, and four received prizes. More intellectual looking men than those he had not seen for a long time. So much was he taken with the aspect of one man that he edged his way through the crowd and drew up to him, when he was struck with the cast of his head. That man had a head upon his shoulders. A man like him for machinery was worth six common labourers. Furthermore, it would be found that the great Act of last session just came in to help the farmer and the whole social system. Mr. Foster's great Bill, sy, his large Liberal Bill, would prove, he thought, the greatest source of benefit to the agricultural labourer and to the whole community.

RODING LABOURERS' FRIEND SOCIETY.

At the late annual meeting of this Society, Mr. Glyn, who presided, gave the toast of the evening. He said:—

We are members of a society whose object it is to benefit the labourer, and if there be a body of men in England who deserve our sympathy and our care that body is composed of the agricultural labourers. I think that to-day the gathering showed that the labourers themselves in this district are alive to the benefits of this Society, and also that the Society itself is really doing a good work among them. The objects of this institution seem to be three-fold—to encourage skill in the field; to promote good gardening; and to reward industry at home. But I think, seeing that we are a body of men who come together in the interest of the labourer, there are other topics connected with his welfare that it is well for us occasionally to speak about, and, if possible, to act upon. It is our universal opinion, for instance, I think, that the labourer generally, for moral effects, is not well lodged. That matter we cannot do much in, beyond expressing our opinion, because it is a question for the landlord and the man who has got money, but the labourer with regard to his life externally is quite another matter. We know that what is everybody's business is nobody's business—that is a very great trouble in the world—and if there is any work to be done nobody ought to do it is to take care that the labourers' cottages are healthy —that their drainage and water supply are in proper order. The law of sanitary affairs is a little difficult, but I have looked into it, and I believe that now the vestry of every parish in England is the sanitary authority in regard to drainage, and it is the business of every vestry to appoint a committee who shall make an investigation of every cottage. We have done that in our parish, and I hope that in the course of a year or two we shall have drainage and cesspools as perfect as we can well make them. With regard to water, I regret immensely that there is no power given to us by Act of Parliament enabling us to forbid anybody from building a cottage that is not well supplied. I saw cottages building as I came here, and I wondered whether there was a well or anything better than a stinking ditch to supply them with water. These are matters that ought to be relegated to the vestries with absolute power to say, "Here is a bad drain or a stinking well; Mr. Landlord, make it right." Then there is the question of labourers' clubs. The other day a most excellent and well-conducted man in our village came to me, bringing a long document, which he had no money to pay. I said how about your club? "Club!" he replied, "I belonged to one 43 years, and it broke; I belonged to another, and it broke also." Can there be a greater blow to a labourer, after subscribing to a fund for years, than to find, when he has need of it, that he has been relying upon a rotten reed which breaks in his hand! The clubs about me are most of them public-house clubs, and one of them has a rule to the effect that on club nights as many quarts of beer shall come in as there are members, so that with 100 members and 200 present at the meeting, I suppose that 100 quarts of beer have to go somewhere. Suggesting that this subject also ought to be dealt with by Act of Parliament, the Chairman proceeded to say that he was told there were admirable clubs at Dunmow and Bishop Stortford, and to urge upon those present to get the labourers to join well-established and properly conducted clubs instead of those held at public-houses.

Mr. Shepherd responded. He believed the Society had done great service to the neighbourhood. When it first started the question of cottages, as a question of the employer of labour, attracted its attention, and for many years prizes were given in order to induce the labourers to take more care of their houses, which, alas, were sometimes little better than pig-styes. But, although they were so bad, generally the old cottages took the prizes from the new ones. An old cottage, well kept, was really a very warm abode for the labourer and his family. In fact, most of the cottages then about were old farmhouses, and he thought,

taking all together, that there was no agricultural district with better cottages. There had been some built in his own parish during the last few years, very comfortable houses, with three bed-rooms, and for which not a high, but a remunerative rent was obtained. Still, he thought those old cottages, with their thatched roofs, and the Ivy climbing round them, and the Honeysuckle too, were to be preferred for their warmth in winter and their coolness in summer to those built of brick, which were generally broiling in summer and cold in winter. Alluding in passing to the changes which the programme of the Society had of late undergone, in dropping the "moral" prizes and so forth, Mr. Shepherd dwelt on the new prize of £5 for the best ploughman, open to all England, took some credit to the immediate neighbourhood, because it had once more been able to hold its own against ploughmen from Canfield, Bardfield, and other places; and, in conclusion, he expressed the warm desire of himself and Mr. Reeves for the Society's continued prosperity, and, in order to that end, asked for the continued support of its members.

GREAT BRAXTED.

Colonel Brise, M.P., proposed the toast "Success to Agriculture, coupled with the name of Mr. Mechi." If he had had the drinking of this toast, he should have put it "Mr. Mechi and Agricultural Reform." Mr. Mechi had nobly and gallantly earned the name and title of an agricultural reformer. It was his (Colonel Brise's) lot, or it might be his stupidity, that he had not always followed in Mr. Mechi's line, but he nevertheless said that the country generally was greatly indebted to that gentleman, that his earnestness and heartiness and good-tempered arguments, and his unintelligible statistics, at times greatly tended to puzzle them all, and to lead them to look upon him as one of the greatest lights of the day. With these few remarks he would propose "Success to Agriculture, coupled with the name of Mr. Mechi."

Mr. Mechi was warmly applauded, and returned thanks. He was much interested and delighted at the success of their meeting that day, and particularly at the remarks made by the Chairman in addressing the labourers from the waggon in the afternoon. They could not do better, socially and politically, than look after the welfare of those below them, and encourage them in every possible way. The subject of agriculture was a very large one, and must necessarily provoke in its discussion a great variety of feelings. There was a very harmonious meeting—he had turned it over in his mind for a long time—he thought it was undesirable to disturb that harmony; and therefore, however reluctant he might be, he had made up his mind not to enter into a discussion upon agricultural points. He wished for the success of the Society, and was always glad to come to their annual meeting.

The Rev. C. B. Leigh, in proposing the "health of the Chairman," of whom he spoke in highly complimentary terms, took occasion to congratulate the agriculturists of the Braxted district on having hitherto escaped the infliction upon them of the Highway Board system. Mr. Mechi had lately issued a luminous manifesto, and he (Mr. Leigh) was in hopes that he would have explained it that evening and made it intelligible to their minds like his. He knew labour was dear, and hay had been selling at an almost ruinous price, and when stock was almost at famine price, how Mr. Mechi could recommend that the grass lands of this country should be ploughed up was past the conception of his simple mind.

The Chairman, in returning thanks, congratulated them upon the harmony of the meeting, and contrasting it with the rows on some former occasions, when Mr. Mechi had been attacked in an unfair manner, which he deprecated as being discreditable to the Society, reminded them that abuse was not the proper weapon with which to meet argument. He regretted that Mr. Mechi had withheld his speech that evening, for, as their chairman, he had hopod to have derived some information from it, and if Mr. Mechi had advanced opinions contrary to what he (the chairman) believed to be right, he should have liked to argue the point a little, and have it out with him. His notion was, that Mr. Mechi was sometimes very quick in finding a hare, but not always so successful in killing her, and on this occasion he thought that he had met his match, for the answers that had appeared in the newspaper in reply to his letter, headed "Agricultural Reform," must have told him that he was starting a wrong measure of reform, and that it would not go down. With regard to the question of pasture, he did not mean to say that there were not some pastures in the kingdom which were beyond restoration, but he maintained that, as a general rule, the tree must be dug about, and dunged, and cultivated, and it was just the same with pasture. (Mr. Mechi: Hear, hear.) Many farmers had asked him to let them plough up their pasture, and he had told them he would give his permission, if after they had treated it properly, it was not worth their keeping as pasture. In those cases, the land still remained pasture, and he advanced it as a strong opinion of his own, that a farm, with 20 acres pasture out of 100 acres, properly cultivated, would grow as much——

Mr. Mechi: Properly cultivated?

The Chairman: Properly cultivated, Mr. Mechi. Why, in some cases pasture was so much more cultivated than arable land, that many leases provided that all the manure should be put on to the pasture and none on to the arable land.

Mr. Mechi: I was not aware of that.

The Chairman: I am glad that I for once stand here and say that I have given Mr. Mechi some information.

The Rev. F. Watson proposed "The Health of the Judges," coupled with the name of Mr. C. Hall.

The Chairman congratulated Mr. Hall on this having won the silver cup given for the best Mangel.

The Rev. F. Watson said he should like to hear from Mr. Hall whether the Mangel which he had exhibited that day were grown on drained or undrained land.

Mr. Hall acknowledged the toast of "The Judges," and said he had acted as one of that number almost from the formation of the Society. As to the character of the work that day, he might state that the drilling was very much improved since the Society was first established, and the work on Mr. Wakelin's farm was done particularly well. The stacking on large farms was also much improved, but he was sorry to say this was not the case on the small farms under 200 acres, for which he had almost decided to withhold the prize. The ploughing had been bad for the class. It was done well considering the character of the land, and the ploughmen had very much improved since he first acted as judge; but he would suggest to the committee that another year they should select a clover-lea for the ploughing. The best ploughmen could not show off their work on soil like land, and the boys could do it almost as well as the men, for there was then no skill in it. As to his Mangel, he might state that he had been an exhibitor for many years, and was never beaten until last year, when he took only second prize.

Colonel Brise: Were they grown on undrained land?

Mr. Hall: The land on which I grow my Mangel is not drained. I never have grown them on drained land.

Mr. Potter: Your land does not require it.

Mr. Hall: I am prepared to grow Mangel with Mr. Mechi on undrained land.

Farmers' Clubs.

IXWORTH.

Harvest Work.—At the first meeting of this Club for the present season, the subject for discussion was the best means of harvesting corn.

Mr. Peto said—When he lived near London, some 18 years ago, it was then the custom in Middlesex to fag the corn, to chop it in against the standing corn, and then gather it in. Good workmen would thus make very clean work, leaving hardly an ear on the land; consequently, no raking being wanted, this would be done at a cost varying from 10*s.* to 20*s.* per acre. They next came to the Suffolk and Norfolk style of harvesting. As far as his own experience went, he knew of no better or cheaper plan than the usual custom of mowing the crops and putting so many acres to each man to complete. The reaper was costly, and if they took into consideration the horse labour (no small item), and made a valuation of the horses before and after harvest, a considerable loss would be found in the condition of the animal. He had put down the cost of each, and he found it to be as follows for the Suffolk mode of harvesting—17 acres per man for £7, averages 8*s.* 3*d.*; horse drivers, leaders, and rakers, and what extra help might be given, 9*d.*; his stacks would average 10 acres per stack, Wheat and Barley, containing 10 squares, all pegging at 1*l.* per square, 1*l.*; so that the whole could be performed in this manner for 10*s.* per acre. With a reaper the items were as follows. Horse labour, 2*s.*; tying, 3*s.* 6*d.*; carting and stacking, 3*s.*; tying and carting rakings, 1*s.*; thatching, 1*s.*; oil and wear and tear of machine, 1*s.*; thus making a total cost of 11*s.* 6*d.* per acre. It appeared to him that if they used the reaper, they ought to cut the whole of the corn by it, putting it out to tie, cart, and stack, at about 8*s.* per acre. By using the reaper they wanted to reduce their men, say a fourth; but by lessening the quantity of men they could only work with three forks in carting instead of four, and the operation would be very tedious. He had a machine, but did not put it in the harvest, because he was of opinion that it was of little assistance on account of the men taking advantage of the help given, and not working as hard as formerly. In neighbourhoods where there was sufficient labour, he should prefer the old system to the present mode of using the reaper. He had completed his harvest, 17 acres per man for £7 each, without the necessity of a disagreeable word, in three weeks and four days, all pegging at 1*l.* per square. In manner, as he believed, if spared for another year, that his men would take the harvest on the same conditions. He had noticed that those farmers who used the reaper were generally behind, but as the harvest was only just completed, he hoped the subject would be thoroughly discussed, and he should be happy to answer any questions that might be put to him.

The Vice-Chairman (Mr. Fison) gave them his harvest expenses. His harvest consisted of 151 acres, 70 of which were Wheat, 70 Barley, 5 Beans, and 6 Sainfoin. He engaged 12 men, being 10 harvest-men, one horseman, and one thatcher, and he paid them each £7 8*s.*, including the shilling hiring money. One old man had £3, a man to attend the thatcher had £3 5*s.*, and seven boys £10 10*s.*, making his harvest expenses altogether, with £2 for horkey, £109 5*s.* This was a little over 14*s.* 6*d.* per acre. If they deducted the help, which in some cases they did not talk much about, deducting the horseman, thatcher, and the one man to help, it reduced the amount to £89 4*s.*, or 11*s.* 9*d.* per acre. In reference to reapers, he might say he had had one for the last four years. What use it would be in a wet harvest he must leave, as during the time he had had it the harvests had been dry ones; but during the last four years he had been quite as early as his neighbours, and he was disappointed that he had not finished earlier. His men said it was due to the fact that his crops were more bulky. The one he used was Samuelson's 2-horse Eclipse, and its expenses since he had bought it had been a mere bagatelle. He had it the first year just before harvest, and several of the bolts broke. This was a general evil, from the machines not being sent out sufficiently strong. He had duplicates made of the parts likely to break, and since then he should suppose it had not cost him 30*s.* Its present state was very satisfactory, but he had, nevertheless, sent it to his mechanic to have all the bearings and things of that kind thoroughly looked to. Therefore, the interest on the outlay was not a very great deal, not more than about 5 per cent. That was not allowing for wear and tear. But when a man laid down money in that way, whatever that amount might be, he ought to have something for it—he ought to be able to reduce his expenses by some amount, by way of interest on the outlay, and in the case of the reapers he could not see that they did that. His men finished harvest in three weeks and two days.

Mr. Elvin (Mr. Fison's bailiff) said the machine cut about 60 acres of wheat, and 20 or 25 of Barley, allowing for cutting into and around the fields.

Mr. Peto said that observation just touched the point. On heavy land there was so much preparation to be made before the reaper could get to work, that he believed if some good men were put to work in the field they would cut the corn as quickly. If a reaper were employed at all, it should be on the mixed soil land, where there were large fields. Then, again, they all knew as practical men that they very often had a day, in the harvest of the finest weather, when they could not cart their Wheat, and if they employed 20 men, or whatever the number might be—he that year had employed 19—they would cut 40 acres in a day with the greatest ease, and a practical man would not give a thank-you for more. Again, as to Barley, four days out of five they could not commence carting till 9 or 10 o'clock in the morning, and if their men were industrious, commencing cutting at 5, they would keep themselves going without wanting a reaper at all. Therefore, in the Barley harvest, he contended, a reaper would be of little use at all, if the men would only go to work in a proper style.

Mr. Fison said his experience was that, except after heavy rains, the machine would cut from the earliest dawn.

Mr. Goldsmith said the great advantage of the reaper was that it laid the corn lighter, and consequently it could be carted two days sooner. He tried the experiment himself the first year he used it.

Mr. Peto said he was quite of a contrary opinion.

Mr. Goldsmith said he cut half a field with the reaper and half with a sythe to compare, to try it. A little rain came, and they got up that cut by the machine two days before that cut by the scythe. The scythe "roped" the corn up. He believed, also, their Barley in a wet season would grow sooner when cut by the scythe than by the other way.

The Vice-Chairman said his men objected to the reaper for that reason. The corn did not get bound together. It was, as they said, "fuzzy."

Mr. Day said the reaper did not cut so closely as the scythe, because it went more on the level.

In answer to a question from the Chairman, Mr. Goldsmith said he believed layers ripened more quickly when cut by the reaper, as the sun could penetrate.

Mr. Manfield said, after all, the old system of reaping was not the most expensive plan, but it had gone out, and rightly, because it left so much work to do afterwards. The haulm was left on the land, and that had to be cleared away before they could get at the stubble, while under the present system they could get at it at once to break it up. Since that time, within the last few years, reaping-machines had become the fashion, and they ought to have been of a very great advantage to them as farmers. The corn was certainly cut in a most workmanlike manner, and not only that, but it was laid in sheaves, and so it was very easy to tie, but somehow it was not the advantage to them that it ought to be. Even in the wetting of their corn, somehow or other their men took just about as long now to the corn after the reaper as they used to cut and tie it. He believed many who had reaping-machines would bear him out in that respect. Mr. Peto had given them his figures in a straightforward way, and he certainly must congratulate him on getting his harvest done in so quick a manner. As he understood him he had little or nothing done with the reaping-machine, and the price he had quoted included the thatching. Now he (Mr.

Marnfield) must tell a very different tale about his harvest. He had not so many acres per man; he gave his men the use of a reaper, and they were five weeks and one day in completing their harvest. Mr. Manfield went on to say that he did not quite agree with Mr. Peto's estimates as to the expense of cutting with a reaper. He thought 2*s.* per acre for horse labour was fair enough, but tying certainly ought not to cost 2*s.* 6*d.* per acre. He was speaking of what it ought to be, not what it was. He contended a man ought to be able to tie up and shock 2 acres a day. He should put tying at 2*s.* 6*d.* per acre, and carting at the same sum. For carting rakings he should think 1*s.* a fair price, and he quite agreed with Mr. Peto and disagreed with Mr. Fison as to the wear and tear of the machine. He thought the wear and tear would not be less than 1*s.* per acre.

The Vice-Chairman: I don't think that my machine has cost me that the whole time I have had it.

Mr. Elvin: Nor, nor one-half of it.

Mr. Manfield said his was Hornsby's. It had cut 175 acres of corn every year for five years, and it was now nearly worn out, besides costing a good deal for sections, knives, &c.

The Vice-Chairman said his machine at the present time was as good as new, and never cost a penny for knives. He had supplemental knives, and he hoped it would last his lifetime.

Mr. Manfield went on to observe that he did not think there was so much saving in a reaper as was imagined. He wanted three men to accompany it, one to drive, another to cut the corners, &c., and almost another to sharpen the knives. With regard to Barley he thought there was some saving in labour, but he differed with the opinion expressed, that there was any advantage in carting. Some wet got on his Barley, and that which was cut by the scythe was ready for carting first; but then he must admit that his reaper was one which laid the corn as though it were to be tied. It would have been better for carting, but as it was the layer held the wet. His harvest cost him from 11*s.* to 12*s.* per acre.

The Vice-Chairman said his thatching cost him £12 13*s.*

The Chairman said then that was more than Mr. Peto's cost.

The Vice-Chairman said he hoped his crops were the heaviest. He should average 7 acres to a stack, while Mr. Peto's averaged 11. At a later period of the discussion it appeared, however, that Mr. Peto's stacks were the larger, being 12 by 5½, while Mr. Fison's were only 10 by 5.

Mr. Goldsmith said he had been looking over his books that had last year, and he found that he never got his harvest done under 10*s.* per acre, while this year it would be, including everything, about 12*s.* 6*d.* He had 10 men with 15 acres each, and he gave them £5 10*s.* in money and £1 in malt and hops, and finding that they were very much fagged, and that the beer they were drinking was not very good, he gave them some beer, using up six half-barrels.

Mr. Day said there was no cheaper way of doing harvest, especially on light land, than by using the scythe, and sticking to it. He was quite persuaded the more the reaper was used the less the men did. He had had one for seven years, and it was his experience, and he thought his men were inclined to agree with him, that it was much better to do without the reaper. They were very expensive, and on heavy land could not be moved if they got a quantity of wet. He gave 10*s.* per acre, and found drivers and horse-rakers, the men finding hand-rakers. A little farm he had down at Newton cost him 12*s.* per acre. He worked 14 acres per man, which was £7 each, and about the average price. He was nearly five weeks about his harvest, and that was what he objected to in the men, that they would not work.

The Chairman, in summing up the discussion, said he should be very sorry to see the Club take a retrograde step, and no man felt the value of machinery more than he did; but he was sure they would all agree that its relative value was far greater in some counties than in others. He pointed out, by reference to the prices paid per acre mentioned that evening, that the sum varied according to the character of the land, and so did the amount a man would do. What they wanted to do was to encourage the men to earn as much money as they could, because that was the good period of their lifetime, by means of which they could their rent and any little back score they had got. Although unwilling to take a retrograde step, he did find when the men had the machine—whether they stopped to look at it or not he did not know, but they did not do so much work. Still, if he were going into an occupation again, he would not be without a machine, for a time might come when it would be useful; and he believed in that part of the country, where their labour was not drawn away by adjoining manufacturing districts, they could do their work better, on the whole, by putting it out than by the aid of the machine. Still, no two harvests were alike. In some years they would hardly be able to get the machine to work, while in another year they would be very glad of it. He must confess he thought by leaving the matter very much to the labourer they gave him more zest and will in finishing the harvest; but the whole labour question was one which required a great amount of consideration, and was included in the matter they were discussing.

Mr. Greene pointed out that the position of the labourer in the agricultural districts was different from that of one in the manufacturing part of the country, because at times the farmer wanted him very much, and at others could find scarcely anything for him to do. They could not look at this question from the mere supply and demand point of view. If they discharged their labourers they could not expect them to wait doing nothing till harvest came round, and they were wanted. He knew it was the fashion for people to talk publicly about the bad way in which the agricultural labourer was treated, and what ought to be done, but they did not know the difficulties with which a farmer had to contend. He knew that many a farmer found his labourers work at a period when he had nothing really for them to do, rather than throw them off. He believed by giving their labourers the opportunity of earning money in harvest-time they could do very much without machinery, and his practical experience was, that by this means harvest could be well done, and at an economical price. As to his friend Mr. Fison, they all knew he drew from some other purse besides the farming one, yet he had always been very cautious in his labour, because he grew very large crops, both of straw and corn; and he thought Mr. Peto would be very glad to pay his expenses and change crops.

The Vice-Chairman expressed his agreement with the Chairman's views. He thought a farmer ought always to keep his staff of workmen about him, and have as little extraneous help as possible. He proposed a vote of thanks to Mr. Peto for his paper, observing that he had set a very good example, one which he hoped would be followed, in cutting his paper short. What they wanted was a discussion, and not a lengthy paper.

Notices of Books.

Model Lodging Houses for the Industrial Classes. By Banister Fletcher. Longmans.

This is a book rather for those interested in towns and townsmen, than for country people. Mr. Fletcher discourses of dwelling-houses for letting in flats, of courts and alleys, and how to improve them; and the examples by which he illustrates his propositions are those of streets and towns—places where "land can be obtained at building lease at a price of 10*s.* per foot frontage." We direct the attention of our readers to it, nevertheless, as containing much in the way of suggestion and ingenious contrivance which may be serviceable anywhere.

A Treatise on Horse-shoeing and Lameness. By Joseph Gamgee, Veterinary Surgeon, formerly Lecturer on the Principles and Practice of Farriery in the New Veterinary College, Edinburgh. Longmans, Green & Co.

A well-written and well-illustrated book, by an experienced man. We take an extract from the very interesting historical chapter by which it is introduced:—

"The English public has been so unaccustomed to look for anything rational and intelligible about horse-shoeing, that the idea of associating the reasoning faculties with physical power in the process of shoeing horses is scarcely entertained. When one reads *farrier*, unless the term is qualified by reference to shoeing, nobody can understand what is meant. Even after reading through part of De Gray's "Expert Ferrier," and finding nothing about horse-shoeing in the first 30 pages of the book, I began to suspect what the author meant by *farrier*, when, on arriving at the 35th page, I found the explanation as follows:—

"'Of what points consisteth the office of ferrier?—Handful and handywise. What is the ferrier's art? It principally consists of four things—to wit: science, experience, knowledge, and handywork.

"'Handywork is to heat the iron well, to sodder well, to forge well, to trim the shoe well, to make and point a nail well, to pare the hoof well, to cauterise well, to let blood well, to be light and well-handed, bold and handy in dressing a horse well, of such accidents as may happen unto him.'

"This extract is from the work of one of the three or four chief English writers on farriery of the 17th century, and De Gray was in the service of Charles II. We here find the whole art of shoeing horses, which was also practitioner in general for the treatment of diseases.

"The old English writers are commonly mentioned as not worthy of being consulted now; but at least references to them as authorities, since they are all we have, besides oral traditions, as a set-off against Solleysel and others in France, of the same period, and to compare with Ruini and his fellow-country writers in Italy a century and more earlier.

"No nation could produce abler men than our own as mechanics for working iron; but Englishmen did not to any great extent display their usual talents in the development of horse-shoeing.

"Our country, with its all-the-year-round moderate temperature and well-adapted soil, produces the most powerful horses of any in the Old World; and the want of economy in their management has been equal to the bounteous natural endowments conferred upon us.

"Is horse-shoeing an art that can be learned and followed as a distinct calling, with credit and remuneration to those depending on it for their livelihood, and to the satisfaction of the horse-owning public? I believe not; and I have neither arrived at this conclusion incon siderately, nor without ample data for it. Horse-shoeing never has stood alone in Europe, so far as its history shows; it may sometimes seem to be followed independently; but, on careful inquiry, it is always found otherwise.

"I deem it expedient to express myself plainly on this point, because on a clear understanding of it very much depends the possibility of carrying out any adequate reformation in farriery.

"At the end of the last century and beginning of the present one the farrier was in England a general practitioner; sometimes his field of occupation was among horses and cattle, and not in horse-shoeing; but we never find a shoer who was not more or less a dealer in drugs, or else a general smith."

Poultry for Prizes and Profit. By James Long. Exchange and Mart Office, 32, Wellington Street, Strand, W.C.

This pamphlet is Part I., and relates to poultry for prizes. We presume, therefore, Part II. will appear hereafter and enlighten us on certainly the more important subject of poultry for profit. The present division is well illustrated, and contains much that is accurately descriptive of the different breeds, with instructions for breeding. Take the following as an example, in which the art of breeding pure Spanish poultry is referred to:—

"In selecting stock it is well to put a 2-year-old cock to not more than three 2-year-old hens, each weighing about 6 lb.—the cock weighing from 7 to 8 lb. It is highly important the cock's comb should be perfectly strong, stiff, and erect, thick at the base, and tapering delicately to the points. The hen's comb, though falling well over the eye, should be also thick at the base, and perfectly stiff throughout—a flabby-combed hen usually throwing falling combs in the cockerels, a most fatal point. As regards breeding for face, we strongly advise the greatest caution in purchasing stock. Inquire strictly as to the pedigree of the birds, for an ill-shaped cross will destroy the strain, and throw faces so red that it cannot be bred out. Although in the very best yards the chickens differ much in quality of face, birds are always obtained that do credit to the breeders; yet a bad cock will fail to throw a single good chicken. Let the stock be very white, and perfectly smooth and large in face, and of a strain that can be depended upon. The minor points, such as legs, shape, plumage, and size, must of course be correct.

"The chicken should not be hatched earlier than the end of April; early broods are always delicate, and die off mysteriously when the legs begin to show, pick out and discard those showing a decided red tinge—they will only blush the more the longer they live; but the bluish faces should be well cared for, as they generally make the best birds. Good Spanish cocks will sometimes blush a little; when this happens they should be shut in the dark, away from the hens, and their faces gently washed twice a day with milk. Sometimes the sun will discolour the face, and at other times it gets spoiled by a discharge from the eye—"

and so on. We doubt if anything in poultry literature will beat this for detail. The circumstances of other breeds are described with equal care.

Farm Memoranda.

A Visit to Woolston.—We had read of this place, and often wished to see the spot; so, being in Bucks a fortnight since, we, in company with three friends, made bold to call upon the chronicler of steam ploughing at Woolston. It was a dull, quiet September morning, and our road lay through a flat, well-wooded district, bordering on the Ouse. Passing through the town of Newport Pagnel, we came upon broad, rich meadows, with here and there a homestead, and near it a few fields of useful-looking heavy land; undulations occurred as we progressed, and at Woolston we found a small village on the flat, with high ground on the north-west side. We had heard so much of the stiff poor clays in this locality, and of the wonderful change wrought in them through the agency of steam, that we went with more than ordinary care upon every feature of the district for a close resemblance to the clayey neighbourhood with which we are more especially concerned. In this respect we were disappointed; for neither in Woolston nor around it did the land appear of that low class we are accustomed to meet about. The Woolston Farm is some 300 acres in extent, 160 or thereabout being arable. The land nearest to the house appears to be a heavy loam resting on clay, beneath which, we were informed, at a depth of 2 feet, is a stratum of sand, into which the drains are sunk, the water from them finding an outlet in a stream of considerable size, which bounds the farm on the south. The fields are large, level, and fairly square, and well adapted for operations by steam. For 16 years this part of the farm has been stirred and worked by the ridge plough and cultivator, invented and patented by Mr. William Smith, of world-wide celebrity. Adopting a 6-field system, and manuring the root and Bean land with 12 tons of farmyard-dung per acre, he has successfully raised a more than average bulk of produce annually, at a marvellously small cost for cultivation. Autumn tillages are thoroughly believed in. The land, steam cultivated at this season, is harrowed down in the spring; that coming in for Beans or roots is manured and ridge-ploughed by the same agency. One field in

particular was pointed out to us as having grown Barley in succession since the year 1868. We saw samples of grain for the several years, and the produce of 1871 far surpassed in quality any of the growth of previous years, and the quantity promised to reach that of former season's weight, 57 bush. per acre. We should mention that this field was originally pasture, which will account for its productiveness. A piece of luxuriant strong grown roots bore testimony to the Woolston management. This ground received 20 tons of manure each September, 1870, which the ridge-plough covered in. The roots are drilled on the ridges at intervals of 36 inches. The excellence of the cultivation and cleanliness of the surface of this field was most striking, as was indeed that of all the fields we visited.

Hitherto we had seen nothing resembling the poor stiff clay associated with the history of Woolston; remarking as much to the wealthy proprietor, we are promised a sight of it on the other side of the canal bank. We pass over a few poor pastures, which, in their present condition, do not look highly remunerative, nor do we imagine that they will ever become very profitable until a deeper system of drainage is carried out, for, with all deference, we object to a depth of but 2 feet for drains. The weak part of the farm is now reached, and we at once notice the cracks under the influence of each step, and portions of oolite rock and pebbles on the surface fail to convey the notion of a poor stiff clay soil. No, Mr. Smith (fortunately for him) is not the cultivator of really poor unkind clays; on the contrary, he is dealing with a soil full of substance and stamina, which needs but drainage, his energy, and his steam-cultivating system to redeem it; and he is just the very person to do it, and many would do well to follow in his path. He has succeeded in picking the lock of the strong box, and now that we have seen his farm, we understand that his management is right. The grand starting point is drainage on the arable land at 8 or 10 yards' intervals, at a depth of 4 feet. Why a less depth is preferred on the grass land, we do not understand. Then follows deep autumnal steam cultivation, or the ridges which cover in 12 loads of manure per acre at that season as a preparation for Beans, or other crop. Men with forks go over the land thus operated upon once or twice during the winter, to remove any Couch on the ridges. When Barley or other white crop succeeds Wheat, a dressing of 5 cwt. of superphosphate is applied to the land in the spring. A large proportion of straw is sold to the London market at 50s. per ton, in exchange for London horse manure, delivered by barges on the farm at 6s. 6d. per ton.

Mr. Smith's mode of dealing with his land is admirably successful. He has continued to take grain crop after grain crop in succession for a series of 16 years, and the soil is apparently still full of life and vigour, and it is certainly more free from weeds and Twitch than any similar area with which we are acquainted.

Although the Woolston system of steam cultivation has not gained the blue riband of the Royal Agricultural Society, it is justly entitled to be considered the true method of working land, and the carefully recorded operations by it (priced as we thought very fairly) show that there is no more economical mode of cultivating. We could not but compare the energy and intelligence which reigns on Mr. Smith's farm, with the sluggishness and indifference of many occupiers of similar land in other directions; and we would strongly advise all who are interested in raising the productiveness of their poor clays to visit Woolston and copy the system pursued there. In taking leave of our friend Mr. Smith, we cannot but congratulate him upon the perfect success of his mode of culture, and to express our hope that he may long continue to publish his annual reports of the Woolston management. If his apparatus does not possess the newest and most perfect features of modern machinery, it exhibits the purest and the most economical mode of cultivation yet practised. *J. L. F., Clipstow.*

MERSE OF BERWICKSHIRE: *October* 16.—We have at last got through one of the most tedious harvests. Five weeks had secured most of our white crops, and our hill neighbours had scarce anything secured, when the weather fairly broke three weeks ago, and there was nothing for it but to wait. When everything was soaking for a fortnight, even the penny papers couldn't keep it from serious damage, and such weather was equally bad for much that had been unduly hurried to the stack.

We may class this harvest with the disastrous years 1856 and 1857, and the scarcity of good corn is already felt in the markets. Barley will be "the crop of the year," as the maltsters will find to their cost if they haven't plenty in the South. The quality is not to be compared with past years, nor will the quantity be satisfactory. Wheat always was a shabby crop. Oo rubbing out heads, one-half of the grains are found to be light and defective. Potatos are being lifted, not more diseased than might have been expected. Turnips are no such great crop after all the cry, having got a check in the end of August. The exorbitant prices of live stock are beginning to slacken. *J. L.*

Obituary.

MR. G. JACKSON, of Tattenhall Hall, expired suddenly, of heart disease, at his residence near Chester early on Tuesday of last week. He had been working hard at the harvest, and after his days' labours were over, had been busily engaged writing a report on farms for the next Journal of the Royal Agricultural Society, he having been appointed by the Society one of its farm inspectors for the year. Whether the exhaustion consequent upon this unusually close application induced the malady is not stated, but it proved fatal. Mr. Jackson had been an extensive and successful farmer, and had done much to advance agricultural knowledge. In his capacity of inspector of farms for the present year, he had twice visited some 28 farms, the report upon which he lived just long enough to complete. To him belongs the merit of establishing the first cheese factory in this country, the factory at Tattenhall taking priority in point of time of those at Derby and Longford; and this he did entirely from his own private resources, except so far as facilities were given him in connection with the building by his landlord, Mr. Barbour. The deceased only a few years ago, assisted by a few friends, established a British school in the village, which has been prosperous from the day it was opened; and this has been followed by a still heavier undertaking, the building of a large chapel.

Miscellaneous.

VOLUNTARY RETENTION OF MILK.—Almost every rustic who has either followed his mother or the maid to the dairy must be familiar with the ancient saying, the cow keeps or refuses to give her milk, and chiefly to be observed when a strange person performs the operation of drawing away the lactiferous fluid; but the rustic, it must be, makes a study of the veterinary profession, and in due course makes himself acquainted with the anatomy and physiology of the mammary glands of the cow, when perchance the thought turns uppermost in his mind, how can the cow retain her milk, seeing no muscular tissue enters into the udder whereby the flow of liquid from the teats can be checked? Bosh! it is, after all, old wife's talk—it can't be. Well, I must confess I was rather dubious about the fact that a cow does, or can, retain her milk, and all simply because the *modus operandi* did not reveal itself to me; for like many others in quest of knowledge, I travelled too far and grazed too high to find it out; it was not till I purchased my wild, passionate little Kerry I found it out. Well, the mind of the cow (for my readers may be assured she has one, the same in kind with their own, differing from it only in degree) when disturbed in the humble, generous animal, or when passion is roused, has the effect of arresting the secretion of milk. Such is the mysterious and close union the mind has with certain actions of physiological systems. We see it in a cow or animal suffering from parturient fever. When due to parturient excitement, which system surcharges the blood, and a passive, non-secreting state of the udder in many cases in the early stage, all the morbid phenomena present are dispelled as by magic by allowing her calf to suck her—sending with the bridge of its nose, as it were, an electrifying, but genial, health-giving shock. I might give many analogies from the lower animals, but here shall not trespass, but stick to my own class of patients. We have a proof that the milk is a fluid quickly made and secreted, in activity resembling that of the secretion of saliva; that the cow is an animal grateful for kindness and love to others, when a good supply of milk, in addition to good feeding, it is necessary to keep them quiet, and free from all excitement. The same cause of reasoning will also elucidate many things peculiar in the milking qualities of different individuals and breeds of animals. Lastly, be kind to the cow, for there is for the violation of this law an unfailing lordly power will surely, in this case, be visited with moral punishment. *A Veterinary Correspondent of the "Dublin Farmers' Gazette."*

AGRICULTURAL STATISTICS.—We have received the following good-natured query from a correspondent, who, in forwarding to us the special schedule we desired him to fill up, writes:—"General report says the Wheat yields badly, all other crops above an average; root and forage crops much above an average." For this general report we thank him, but with it he had been unbiassed by individual opinion, and expressed in figures under the headings of our schedule, but to this form "T. A." objects, as follows:—

"Sir,—I think your inquiries too inquisitive when you ask us to give our private estimates of our crops, which, no doubt, most of us make, and act accordingly for our own interest; but it is too much to ask us for them for publication, so that the trade may benefit, under the pretence of benefiting the country. Can you tell me producers who are so philanthropic?"

It is to answer this very old objection that we notice it. "Do any other producers inform the public of their stocks, &c.?" Yes, the Cotton Statistics Act requires regular periodical reports of the stocks and sales, and most manufacturing and commercial interests reveal their position from time to time; banks, mines, ships, public companies generally, undoubtedly expose their business to public criticism, which, like healthy air, should pervade and invigorate all sound speculation. With respect to agriculture, its position is so far singular, that as its shop or manufactory is the wide open country, where cultivation, production, and marketing, must be performed under universal inspection, concealment is impossible. Farmers work like bees under a glass hive, not like chemists, and a few other producers, in secret laboratories. Concealment is therefore impossible, if it were desirable. Such being the case, it is much better that judgment should be true, rather than inaccurate—it is the farmers' interest, quite as much as it is the interest of the public, that the national verdict as to the corn crops should be correct; and who better than the farmer can tell the truth of his own particular field? That truth being known, the nation, with real English love of fair play, pays cheerfully full value for the produce of agriculture; did so last year, it will do so this, in any season. England, like an economical yet liberal housekeeper, reckons up her Wheat stores, home and foreign, and pays for them ungrudgingly, at the fair market price. Now, the real issue implied in "T. A.'s" objection is that the season's market price may be enhanced by concealment. Is this likely? Would not the buyer probably fancy the stores were larger than represented by the seller? In fact, the difference in opinion (even after every farmer and dealer should give his estimate) would still be very great; and these fluctuations in demand would always agitate the surface of the grain trade. But then panic would never heighten or depress value to a ruinous extent, as prices must keep nearly to that natural level which the season had established. To sum up the whole argument, knowledge of agricultural produce fixes a real value to the farmer's crops, whilst uncertainty arising from imperfect information attaches a fictitious value, which may either be too high or too low, and therefore unjust; and, as a result, when the value of produce is left to chance, the scale would turn towards the public, simply because the public as the buyer always must have the buyer's privilege. Let, then, the farmer, to use a metaphor, throw open his barn door, count his ricks, number his flocks and herds, and he will find agricultural statistics will be the best salesman of agricultural produce that he can employ. *H. Kains-Jackson's Harvest Journal.*

The Week's Work.

OCTOBER 21.—*Turnip Fallow* extend over a very large area of the cultivated land of the kingdom. Over the whole of Scotland, and a great part of the north of England, with most of the sister country, for example, about a fifth part of the arable land is under Turnips. Such an extent of land shows the importance of the crop, and all who have any successful experience in its growth are familiar with the advantage of a thorough deep tillage at this season, subsoiling when the bottom is unsound, so as to increase the depth of the staple when the noxious matter is either neutralised or washed out by drainage.

Draining should commence immediately after harvest, and be prosecuted with vigour so long as there is a wet furrow of land on the farm. It is generally advisable to do so much yearly, and the break under fallow or lea is the portion usually set apart for drainage, the ploughing after being followed by subsoiling, which greatly promotes the work of drainage and aeration.

Top-dressing leas for cropping may be done as late as the beginning of November, the ploughing being deferred until the top-dressing has produced the desired effect on vegetation and to dilute organic matter on the surface, which is known by the green sward produced,—in other words, the top-dressing should be well worked into the roots of the grass with a chain-harrow; and as soon as the more soluble and fertilising portion is washed into the land, and the grass up, or the land is in a workable state, the surface falling to the bottom of the furrow when the land is ploughed, the ploughing may be done. In examples where the land lies two years in grass — the first year hay and the second pasture—some prefer top-dressing after the hay crop, the compost being applied as soon as the cattle are housed, or when the stock can be removed to other pastures, or soiled indoors. Clay may also be applied to the hay stubble in frosty weather; but of this more afterwards, when the frosty weather comes; so may chalk to a different class of soils, but lime compost may be applied in autumn.

Lea Ploughing for Oats or spring Wheat usually followed the ploughing of Wheat and Oat stubble for Turnips, according to the old practice; but steam culture is turning topsy-turvy many old tillage rules, for those who smash only plough their leas with their teams while they are smashing up their stubbles by steam, so that where the latter has to be hired the former may take precedence as to time; but the more advanced plan is to do both the smashing and ploughing by steam, the advantage on the one being as great as on the other.

Threshing proceeds the moment cattle are housed for the winter, a regular supply of straw for provender and litter being daily required. Straw may be cut into chaff and salted in bins, but the more newly-threshed it is the more valuable for cattle food, for the small allowance of salt is insufficient to preserve it from waste, more especially when the straw has suffered deterioration either from lodging, bad harvest weather,

or dampness in stacking. Any coarse straw of inferior quality may be threshed out and stacked for litter.

Highland Sheepwalks present a very different practice from those of the southern counties of England at this season. From the more elevated and exposed districts the flocks are removed to the lowlands; on the more sheltered, shepherds have to contend with the heavy snowfalls which now become common. Rams are put into condition for being turned to the ewes about the middle of November. Towards the close of October sheep-bathing commences. Various baths are used, as "the turpentine bath," or the more common one—a decoction of tobacco, to which is added spirit of tar and soap. To cure scab some add "sulphur-vivum," but bad cases of scab require sheep-ointments, as preparations of carbolic acid and mercury; others smear with a compound of tar and butter—a gallon of tar poured into from 6 to 8 lb. of melted butter, being a common salve calculated to smear a score of blackfaced or Cheviot wethers. Smearing kills tick and defends the skin from cold and rain, but it less or more injures the wool. Old wedders are sold for fattening in the lowlands on Turnips, and draft ewes not sold last month are disposed of as early in this as sales can be effected, and served with Leicester rams as soon as they arrive at their new quarters.

Milch Cows should now be "taken" with their winter dietary.

The Dairy now requires artificial heat to keep it dry, thoroughly ventilated, and at the proper temperature (60°); and if this is done, and the cows properly attended to as above, a rich supply of butter may be made for market; good cheese may also be made, but at more expense for fire.

Swine.—Dairy porkers and bacon hogs now thrive amazingly. Full-grown hogs can be forced forward very fat on steamed Potatos mashed with barley meal or Indian Corn meal, seasoned with a handful of acorn meal, and a little sour wash to swill it down with.

Notices to Correspondents.

BOOKS: *A Constant Reader.* Probably "Our Farm of Four Acres" (Chapman & Hall), would suit you. If you want elaborate works on agriculture, Stephen's "Book of the Farm" (Blackwood), "The Farm Calendar" (Warne & Co.), "Cyclopedia of Agriculture" (Blackie).

FARM ACCOUNTS: *Agricola.* Apply to Mr. Alexander Jemmett, Murrell Hill Farm, Binfield, Reading.

GREEN-COATED TURNIP: *The Earl of Essex* would be glad if any of our correspondents who have pitted Green Rounds, or other soft-fleshed Turnips, would tell him their experience as to whether they have kept well, and till when.

MERINO SHEEP: *Inquirer.* We know of no history of the Merino sheep in any separate publication.

STORING DRUMHEAD CABBAGES: *Anglo-Saxon* writes to ask if any one has practised storing Cabbages, and if so, with what success. Kohl Rabi will stand the winter out.

Markets.

HOPS.

BOROUGH MARKET, Oct. 19.

Messrs. Pattenden & Smith report a steady inquiry for all descriptions, more especially the better sorts of East and Mid Kents, the tendency being towards higher prices, owing to the great scarcity of choice samples.

MARK LANE.

MONDAY, Oct. 16.

There was a fair supply of English Wheat to this morning's market, a portion of which only was disposed of at the extreme prices of this day se'nnight. The attendance was good, and a moderate amount of business transacted in foreign on the same terms. Barley and Beans were fully as dear. White Peas sold at an advance of 1s. per qr. Oat trade was firm, and fine Russians brought rather more money. Flour was fully as dear.

WEDNESDAY, Oct. 18.

The Corn Exchange to-day was thinly attended by millers, and the business transacted was on a limited scale. There was a small supply of English Wheat on sale, but the receipts from abroad were good. For all qualities a slow demand prevailed, at the rates current on Monday last. Fine Barley was purchased steadily, but other descriptions were quiet. Malt sold cautiously on former terms. Oats, the show of which was large, met with a limited inquiry, at previous quotations. Maize was firm in value, with a moderate demand. Beans and Peas were in fair request, at about late rates. Sales in Flour were effected slowly, at Monday's currencies.

SEED MARKET.

The agricultural seed trade maintains the same firm but quiet position noted in our last. Clover seed excites as yet but little attention. Perennial Rye-grasses continue to advance in price. New French Italian is in improved request, and realises more money. Winter Tares, although not very cheap, meet with a slow sale. Rape and Mustard show no alteration in value. Blue Peas are in brisk demand, at increased rates. Bird seeds move off in retail at last week's currencies. There is a good business still doing in seed Wheats for France.

METROPOLITAN CATTLE MARKET.

MONDAY, Oct. 16.

The number of Beasts is much smaller, and choice qualities in good demand at higher rates; a fair clearance is effected of all kinds. The supply of English Sheep is unusually small, of foreign plentiful. Trade is not very brisk, but higher prices are realised for choicest qualities. Choice Calves are likewise dearer. Our foreign supply consists of 3230 Beasts, 15,350 Sheep, 1333 Calves, and 70 Pigs; from Ireland 200 Beasts, Scotland 233; and 1347 from the Midland and Home Counties.

Beasts, 4800; Sheep and Lambs, 20,550; Calves, 148; Pigs, 165.

THURSDAY, Oct. 19.

Our supply of Beasts is small, but quite equal to the demand; we have a very slow trade, and at lower prices. The number of Sheep is also smaller, and the demand has also decreased; the few on offer are nearly all disposed of, but at lower rates. There are scarcely any choice Calves on offer, the quotation for them is con-equently almost nominal. Trade on the whole is dull. Our foreign supply consists of 220 Beasts, 3420 Sheep, and 151 Calves.

ORCHIDS. — Gentlemen interested in this class of Plants would do well to inspect our Establishment at Fairfield, and to judge of our mode of growing for themselves. The House we have recently erected, in which the plan of supplying moisture by continued precipitation, without the aid of flues, is nearness in appearance, has been the admiration of every visitor, and excites universal surprise that means so simple should prove so long neglected.
JAMES BROOKE AND CO., 16 and 18, Victoria Street, Manchester.
Nurseries: Fairfield, near Manchester.

RHODODENDRON HYBRIDUM, from seed, 2-yr. and 3-yr. transplanted, 20s. per 100; 4 to 6 inches, 30s.; 6 to 7, 40s.; 8 to 12, 50s. per 100; 12 to 15, 15s.; 12 to 18, 20s.; 18 to 24, 30s.; 2 to 3, 40s.; Stocks, 12s.; Splendidum (white), Maidi, Blush, 7 to 15, 30s.; Jacksonii, Yellow, 12 to 18 in., 5s. per doz.; Woolneri, 12 to 15, 12s.; Caucasicum pictum, 12 to 15, 20s. to 25s.; all bushy, healthy plants. EVERGREEN PRIVET, 18 to 24, 10s. per 1000; 24 to 30, 20s. BERBERIS AQUIFOLIA, 15 to 20, 50s. AUSTRIAN PINES, 18 to 24, 50s. ENGLISH OAK, 18 to 24, 20s. WYCH ELM, 3 to 6, 20s.; 6 to 8, 30s.
ISAAC MATTHEWS, Nursery-man, Milton, Stoke-on-Trent.

TO WILLOW GROWERS.—The Planting Season having commenced, WILLIAM SCOTT, WILLOW MERCHANT, *Hanford, Notts*, is now ready to execute orders for
WILLOW PLANTS and CUTTINGS for Timber Trees and Coppice Wood.
WILLOW PLANTS and CUTTINGS for Ornamental Trees and Shrubs.
WILLOW CUTTINGS for Basket Makers' purposes.
BITTER WILLOW PLANTS and CUTTINGS for Hedges and Game Coverts.
WILLOW STOCKS for Budding and Grafting.
Descriptive CATALOGUES free upon application as above.
"The Salix, or Willow Tribe," second edition, post free, 1*s.*; or of SIMPKIN, MARSHALL AND CO., London.

JAMES, PLANES, 10, 12, and 15 feet high, stout, straight, and splendidly rooted, by the dozen or hundred.
HOLLIES, green, 2, 3, 4, 5, 6, 7, 8, 9, and 10 feet.
Variegated
Growers may select from many thousands of these Hollies, which are finely grown plants, and will be guaranteed
GOLDEN QUEEN, SILVER QUEEN, and WATERER'S HOLLIES.—Hundreds of handsome specimens, 4, 5, 6, 7, and 8 feet high, guaranteed.
HODGINS'S VARIEGATED-BERRIED, LAURIFOLIA, MYRTIFOLIA, and other varieties of Green Hollies, 5, 6, 7, 8, and 10 feet high, have numbers of splendid plants, grown for 24 stamps.
YEWS, Common, many thousands, 3, 4, 5, 6, 7, 8, 10, and 15 feet high, guaranteed.
YEWS, GOLDEN and ELEGANTISSIMA, as globes, standards, and pyramids, up to 8 and 10 feet high.
ANTHONY WATEREK'S CATALOGUE of AMERICAN PLANTS, ORNAMENTAL TREES, &c., Priced and Descriptive, and containing illustrations from photographs of Weeping and Golden Queen Hollies, as standards and pyramids; the Weeping Sophora, the Weeping Deciduous Cypress, Golden Irish Yew, Standard Rhododendron, and Cupressus Lawsoniana erecta viridis; will be forwarded on receipt in return for 24 stamps, or the whole Catalogue without the illustrations for 6 stamps. With reference to this Catalogue A. W. has the satisfaction to state, that he has received at least a hundred unsolicited testimonials of a highly complimentary character, amongst others Mr. H. C. Bolin, whose knowledge of such matters gives authority to his opinions, writes as follows:—"I am delighted with your new Catalogue; it is a great advance upon all that has been done before." The *Gardeners' Chronicle* and other gardening publications have also made frequent allusion to it, as one of the best Catalogues ever issued. The illustrations have been freely copied, both in this country and America.
ANTHONY WATEREK, Knap Hill Nursery, near Woking, Surrey.

Choice Seeds, for Present Sowing.

B. S. WILLIAMS begs to announce that he has just harvested NEW SEED of the following:—Williams' superb strain of PRIMULA, red, white, and mixed; Neill's choice strain of CALCEOLARIA; Weatherill's choice strain of CINERARIA; and Wiggins' prize strain of CYCLAMEN. All the above at 2*s.* 6*d.* 3*s.* 6*d.*, 5*s.* 6*d.*, and 10*s.* 6*d.* per packet, post free.
Victoria and Paradise Nurseries, Upper Holloway, London, N.

Phalænopsis grandiflora.

MESSRS. JAMES VEITCH AND SONS, having received an importation of the above, in the FINEST POSSIBLE CONDITION, beg to offer them at the following low prices; all the plants are established in pots.

Smallest size, healthy young plants,	25*s.* each,	£12 12*s.* per dozen.
Second size,	42*s.* each,	£22 per dozen.
Strongest size	63*s.* each,	£36 per dozen.

Royal Exotic Nursery, Chelsea, S.W.—October 28.

Notice.

H. LANE AND SON'S Descriptive CATALOGUE of ROSES, FRUIT TREES, VINES, CONIFERS, DECIDUOUS and EVERGREEN TREES and SHRUBS, HERBACEOUS PLANTS, AZALEAS (Indian), CAMELLIAS, &c., may now be had free on application. The prices will be found moderate, combined with quality. An inspection of the growing stock is earnestly solicited.
The Nurseries, Great Berkhamsted, Herts.

HOCK AND CO. beg to intimate that they can now supply fine and healthful CORMS of the following Collection of CANNAS, containing the newest and the best older varieties.
New CANNAS.—12 for 4*s.* 100, 32*s.* each 2*s.*; Adolph Weick (Dark), Admiral Dumont (Sidley), Augustin Fèvre (Sidley), Auguste Joigneau (Chatè), Dr. Grosnier (Nardy), Gloire de Toulouse, Jacques Flusrer (Nardy), Jean Vaneeck, Meme Developpement Robichon, Mulle. Schmit (Nardy), Prince Impérial, Sénateur Cheveau.
Best varieties, of former years—12 varieties for 10*s.* 6*d.* each 12 of one variety, 4*s.*; 25 of one variety, 7*s.* 6*d.*
The whole Collection of newest and best varieties f ormer ye ars, altogether 24 for 4*s.*
HOCK & Co. beg also to offer strong plants of DAHLIA ARBOREA in 48 sorts, as well as in varieties of new PHLOX DECUSSATA for 5*s.*—HOCK AND CO., The Khine Nursery, Castel, opposite Mayence.

HOWCROFT AND WATKINS, SEEDSMEN (Successors to CHARLWOOD & CUMMINS) keep a choice assortment of EVERLASTING and DRIED NATURAL FLOWERS and GRASSES, Coloured Grasses, Wheats, Bouquets, &c. ; FRENCH IMMORTELLE WREATHS and CROSSES, for Funeral Decoration.

HOWCROFT AND WATKINS, SEEDSMEN (Successors to CHARLWOOD & CUMMINS) keep a large Stock of various articles in PLAIN, ENAMELLED, and ETRUSCAN FERN-CASES, Ornamental Seed Vases, Garden Seats, Window Boxes, Fern-Stands, Flower-Pots, &c.
14, Tavistock Row, Covent Garden, London, W.C.

WHEATH has to offer, at a cheap rate, fine GREENHOUSE and BEDDING PLANTS:—ALTERNANTHERAS, ALOCASIAS, CROTONS, FERNS, IXORAS, PALMS, PANDANUS; also a few GREENHOUSE PLANTS, EXOTIC FERNS, by the dozen or hundred. The whole of the above are in the finest condition. He will be happy to forward a printed priced LIST with dimensions on application.
Exotic Nursery, Cheltenham.

JAMES DICKSON AND SONS beg to draw attention to, and to solicit an inspection of, their almost unlimited stock of FOREST, FRUIT, and ORNAMENTAL TREES, SHRUBS, ROSES, and all other NURSERY STOCK.
The "Newton" Nurseries can now be reached on foot in 8 minutes from the Chester Passenger Station.
Priced LISTS post free.
JAMES DICKSON AND SONS, "Newton" Nurseries, Chester.

CONIFERS for SALE.—A large quantity to be Sold, in Lots to suit Purchasers.
THUJA WARREANA, 3 feet.
CEDRUS ATLANTICA, 3 feet.
CUPRESSUS LAWSONIANA, 3 feet.
The above have been three times Transplanted.
Mr. ALEX. ROBERTSON, Powerscourt, Enniskerry, Ireland.

Versailles Nursery, William Street, Hammersmith.

THE Nursery Stock of the late Mr. SALTER'S noted collection of CHRYSANTHEMUMS, Double PYRETHRUMS, DAHLIAS, PHLOXES, GERMAN IRIS, PHLOX DECUSSATA, &c., is now being SOLD at reduced prices. Several GREENHOUSES are also for sale.
Apply to Mr. STONE, at the Nursery; or to Mr. CHANDLER, Horticultural Agent and Valuer, Underhill Road, Dulwich, S.

Northampton Nurseries.

JOHN PERKINS, SEN., begs to call the attention of Noblemen, Gentlemen, and others engaged in Planting, to his extensive STOCK of the following, the whole of which will be offered at very low prices:—

Whitethorn or Quick, extra fine, 2 years
Spruce Firs, 2½ to 4 feet
Scotch Firs, 2 to 3 feet
Larch Firs, 1½ to 2, 2½ to 3, and 3 to 4 feet
Pinus austriaca, 1½ to 2, 2 to 3, and 3 to 4 feet
Hazel, 2 to 3 feet
Hornbeam, 2 to 3 feet
Evergreen Privet, 1½ to 2, 2 to 3, and 3 to 4 feet
Berberis aquifolia, 1 to 1½ feet
Furze, 1½ to 2, 2 to 3, and 2 to 3 feet
Portugal Laurel, 1½ to 2, and 2 to 3 feet
Common Laurel, 1½ to 2, and 2 to 3 feet
Black Italian Poplar, 4 to 6 feet
Blackthorn, 1½ to 2, and 2 to 3 feet
Roses, &c., &c.

J. P.'s stock of all kinds of FRUIT, FOREST, ORNAMENTAL TREES, &c., is very extensive, and in the best possible condition for planting, having been frequently transplanted. Descriptive priced CATALOGUES free by post, or on application.
59, Market Square, opposite the Corn Exchange, Northampton.

OFFICINAL AND MEDICINAL PLANTS, TROPICAL FRUITS, &c.

MR. WILLIAM BULL

BEGS to offer the following from his collection of living economic Plants, which contains specimens of nearly all the species and conditions in domestic use, many of the most highly esteemed tropical esculent fruits, also of those from which furniture and other woods are obtained, the principal gums and medicinal products, the poison trees from Brazil and Madagascar, at one time only heard of in tales of fiction, plants which supply our daily beverages and food, as well as many of historical interest.

African Mangosteen	Garcinia Livingstoni	*Africa.*
Alligator Pear	Persea gratissima	*West Indies.*
Allspice	Eugenia Pimenta	*West Indies.*
Arootoo Dye Plant	Bixa Orellana	*Trop. America.*
Arrowroot	Maranta arundinacea	*West Indies.*
Australian Banyan	Ficus macrophylla	*Australia.*
Balsam of Peru	Myroxylon Pereira	*Peru.*
Betel Nut Palm	Areca Catechu	*East Indies.*
Betle Pepper	Piper Betle	*East Indies.*
Bitter Aloe	Aloe socotrina	*Socotra.*
Black Pepper	Piper nigrum	*East Indies.*
Black Tea	Thea Bohea	*China.*
Bread-fruit Tree	Artocarpus incisa	*Otaheite.*
Calabar Palm	Elaeiper guineense	*Brazil.*
Camphor	Camphora officinalis	*Japan.*
Candle Tree	Parmentiera cereifera	*Panama.*
Cardamom	Amomum Cardamomum	*East Indies.*
Cherimoyer	Anona Cherimolia	*South America.*
Chinese Plantain Tree	Musa Cavendishi	*China.*
Cinnamon Tree	Cinnamomum verum	*Ceylon.*
Clove Tree	Caryophyllus aromaticus	*Moluccas.*
Cocoa	Theobroma Cacao	*Trop. America.*
Coffee	Coffea arabica	*Yemen.*
Contrayerva Root	Dorstenia Contrayerva	*South America.*
Cotton Tree	Gossypium herbaceum	*East Indies.*
Croton Oil Plant	Croton Tiglium	*East Indies.*
Cuba Bast	Paritium elatum	*West Indies.*
Cubeb	Piper Cubeba	*Java.*
Date	Phœnix dactylifera	*Levant.*
Divi Divi	Cæsalpinia coriaria	*West Indies.*
Edible Fruited Passion Flower	Passiflora edulis	*Brazil.*
Edible Vangueria	Vanguieria edulis	*Madagascar.*
Fiddle Wood	Citharoxylon quadrangulare	*Jamaica.*
Fragrant Cedar	Cedrela odorata	*West Indies.*
Gumboge	Xanthochymus pictorius	*East Indies.*
Gigantic Granadilla	Passiflora macrocarpa	*Brazil.*
Ginger	Zingiber officinale	*East Indies.*
Grandilla	Passiflora quadrangularis	*West Indies.*
Green Tea	Thea viridis	*China.*
Grenadilla	Passiflora laurifolia	*Brazil.*
Japanese Pepper	Piper Futokadzura	*Japan.*
Latanier Palm	Latania borbonica	*Madagascar.*
Lemon Grass	Cymbopogon Schœnanthus	*East Indies.*
Loquat	Eriobotrya japonica	*Japan.*
Mangosteen Tree	Garcinia Mahobyra	*East Indies.*
Malay Apple	Jambosa malaccensis	*East Indies.*
Mammee Tree	Mammea americana	*South America.*
Mango	Mangifera indica	*East Indies.*
Mangosteen	Garcinia Mangostana	*Java.*
Matico	Artanthe elongata	*Peru.*
Mustard Tree of Scripture	Salvadora persica	*Persia.*
Nasberry Tree	Achras Sapota	*South America.*
Nutmeg Tree	Myristica fragrans	*Sumatra.*
Oil Palm	Elais guineensis	*Guinea.*
Orange Tree	Citrus vulgaris	*Columbia.*
Otaheite Apple	Poupartia dulcis	*Society Island.*
Patchouli Scent Plant	Pogostemon Patchouli	*East Indies.*
Physic Nut	Jatropha Curcas	*Africa.*
Pimento Tree	Eugenia pimenta	*Jamaica.*
Red Bark	Cinchona succirubra	*Trop. America.*
Rice Paper Plant	Aralia papyrifera	*China.*
Sandal-wood	Santalum album	*East Indies.*
Shaving Brush Custard Apple	Anona palustris	*Jamaica.*
Sarsaparilla	Smilax Sarsaparilla	*North America.*
Silk Cotton Tree	Bombax malabaricum	*Malabar.*
Sour Sop	Anona muricata	*West Indies.*
Strychnine	Strychnos Nux-vomica	*East Indies.*
Sugar Cane	Saccharum officinarum	*India.*
Sugar Palm	Arenga saccharifera	*East Indies.*
Sweet Sop	Anona squamosa	*Trop. America.*
Sycamore of Scripture	Ficus Sycomorus	*Persia.*
Tamarind Tree	Tamarindus indica	*East Indies.*
Tonquin Bean	Dipteris odorata	*Guiana.*
Traveller's Tree	Ravenala madagascariensis	*Madagascar.*
Turmeric	Curcuma longa	*East Indies.*
Turpentine Tree	Pistachia Terebinthus	*South Europe.*

AND MANY OTHERS.

Collections, Large or Small, of Living Plants, of Officinal and Medicinal Plants, Tropical Fruits, &c., can be made from the preceding List, at any prices from

3 to 15 Guineas.

The difference in Price of the Collections principally depends upon the number of plants included, their size, and the rarity of the species.

ESTABLISHMENT FOR
NEW AND RARE PLANTS,
KING'S ROAD, CHELSEA, S.W.

RHODODENDRONS, FINEST NAMED VARIETIES, BEAUTIFULLY SET WITH FLOWER BUDS.

MESSRS. VEITCH & SONS

BEG TO ANNOUNCE THAT THEY HAVE

A SPLENDID STOCK OF THE ABOVE,

WELL SET WITH FLOWER BUDS, AND ARE ENABLED TO OFFER BEAUTIFUL PLANTS, SUITABLE FOR FORCING OR PLANTING IN BEDS, AT

30s. to 42s. per dozen.

MESSRS. VEITCH AND SONS have a large stock of named sorts in other sizes, and also of HYBRIDS and PONTICUM RHODODENDRONS, and will be happy to send samples and quote Sizes and Prices by the Hundred or Thousand.

ROYAL EXOTIC NURSERIES, CHELSEA; and COOMBE WOOD, KINGSTON, S.W.

New Plant.

ALLAMANDA CHELSONI.—This attractive novelty has been imported from the West Coast of Africa. The peculiar character of its flowering growth (which is often elongated a foot or two), and its continuous blooming property, somewhat similar in this respect to A. Hendersoni, make it one of the most desirable of its family. The flowers are about the size of those of A. Aubletii, intermediate in colour between that species and A. cathartica, of great substance, and free from the objectionable habit of reflexing which exists in the flowers of A. Aubletii. Price 5s. 6d. each.

Mr. WILLIAM BULL, Establishment for New and Rare Plants, King's Road, Chelsea, London, S.W.

Noteworthy Horticulturists and Botanists.

NOTICE.—A SERIES of PORTRAITS of NOTEWORTHY HORTICULTURISTS and BOTANISTS is being published in the "GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE." The following have already appeared, and copies may be had on application to the Publisher, viz.:—

Dr. HOOKER, C.B., F.R.S.
W. WILSON SAUNDERS, F.R.S.
Rev. M. J. BERKELEY, F.L.S.
M. DECAISNE.
G. F. WILSON, F.R.S.
Dr. MOORE, of Glasnevin
Professor REICHENBACH, of Hamburgh
Rev. S. R. HOLE, M.A.
F. J. LOWE, F.R.S.
JAMES MCNAB, of Edinburgh.
ROBERT HOGG, LL.D.

Published by WILLIAM RICHARDS, 41, Wellington Street, Covent Garden, W.C.

SATURDAY, OCTOBER 28, 1871.

MEETING FOR THE ENSUING WEEK.

WEDNESDAY, Nov. 1	Royal Horticultural (Fruit and Floral Committees), at S. Kensington	..	11 A.M.
	Ditto (Scientific Committee)...	..	1 P.M.
	Ditto (General Meeting)	..	3 P.M.
THURSDAY, —	2—Linnean	..	8 P.M.

WE recently transcribed some seasonable notes respecting a few rare deciduous ornamental hardy trees, which we are glad to find have been appreciated. Now we have to introduce, in a similar way, one of the best and most useful of evergreens, namely, the CHERRY LAUREL, and to note some of the peculiarities of the most remarkable varieties to be met with in cultivation.

We will refer first to the forms most nearly related to the common Cherry Laurel (Cerasus Laurocerasus)—itself too well known to need more than a passing reference. Of these the most prominent is the Versailles Laurel (latifolia), a very large-leaved kind, differing only in size from the common sort. When first introduced at the meetings of the Floral Committee a year or two since, a very proper doubt was entertained as to whether or not this extra size might be merely the result of special culture, but we have since seen it at the Tunbridge Wells Nurseries growing freely by the side of the common Laurel, and maintaining a decided difference, both as to robustness of habit and boldness of foliage. Whether it is more or less tender than the type, which, we all know to our regret, sometimes gets severely touched by frost, we are not aware.

Another variety, also closely related to the common Laurel, is the round-leaved Laurel (rotundifolia), which has been exhibited by Mr. W. PAUL, and which we have noticed growing in his nursery at Loughton, in a situation where its hardiness was thoroughly tested. The habit of this sort is very dense; the leaves, though not exactly round, are particularly broad and short, and are serrated at the edge, and the whole plant appears to us to have an aspect recalling that of a Bay Laurel rather than a Cherry Laurel. We look upon this as one of the best of the forms belonging to the same race as the common Laurel, while a narrow-leaved form, occasionally seen, is one of the worst from an ornamental point of view.

Of a distinct and hardier type is what is known as the Colchican Laurel (colchica). One of its peculiarities is its remarkably spreading habit of growth, without much tendency to get upwards, a quality which seems to adapt it specially for planting as undergrowth or cover. Another of its peculiarities is the pale hue of the back of the leaf, which somewhat detracts from its beauty as an evergreen. The leaves are rather lengthened out, conspicuously pointed, and glossy, and have a sort of refined character, which no doubt would command the approval of most persons of taste in these matters. It is, undoubtedly, a better evergreen than the common Laurel.

The Caucasian Laurel (caucasica) is again of another distinct type, and, so far as we have been able to observe, is the most valuable of all the Cherry Laurels we have in cultivation. It has a

bolder and more vigorous style of growth than the common Laurel, is naturally much more inclined to assume an erect habit of growth than colchica, and is, at the same time, dense and well furnished, thickly clothed with fine, broad, dark-green glossy foliage. What is, however, of still more importance, in regard to an estimate of its merits, is the fact that it is hardier than any of the other varieties.

The Cherry Laurel is so often and so much in request as a shrubbery plant, that we trust our readers will find these brief memoranda of the peculiarities of the different kinds to be useful to them in making their selections, now that the planting season has again come round.

—— At the meeting of the Fruit Committee of the Royal Horticultural Society on September 20 last, Mr. J. May, Westfield Gardens, Hayling Island, exhibited a dozen remarkably fine SHALLOTS GROWN FROM SEED, since which time it appears Mr. MAY has been inundated with letters requesting him to inform the writers how he obtained such satisfactory results. As to give full details of his treatment to each of his applicants would entail upon him an unnecessary amount of labour, Mr. MAY requests us to afford him space to answer them, once for all, through the medium of our columns, which we have much pleasure in allowing him to do in his own words:—

"Nothing can be more simple than the treatment which these Shallots receive at my hands. The first and primary point is to obtain good, well-ripened seed, which I have done for some time by selecting the best roots from year to year and planting them in good soil, in some warm sheltered place, where they get the full benefit of the sun. I plant as early I get, perhaps, two in ten to run to seed, and from these (if the autumn is fine) I get my seed for the next year's supply. The seed must be thoroughly matured, otherwise the produce is uncertain. On March 20, this year, I sowed my Shallot seed alongside that of my Onions, on ground which had, during the winter, been trenched 2 feet deep, with manure under both spits, and left rough to get thoroughly pulverised by frost, &c. I raked down and trod and raked hard at the time of sowing, just in the same way as the ground is usually treated for Onions. As soon as the seedlings are large enough to thin they are drawn out, and left about 12 inches from plant to plant. After that is required after that is to keep the Dutch hoe occasionally run between the rows, to keep down weeds, and to prevent rapid evaporation after rain. The 12 exhibited on the 20th weighed 4 lb., and were a fair sample of the whole, but I hope to be able by careful selection to produce much better roots than these. Where, as in many large families, a quantity of this root is required, those grown from selected seed will soon supersede those obtained by the old method of planting roots for the current year's supply."

Another correspondent at Hayling also grows his Shallots in the manner above described, as will be seen on reference to p. 1254 of our volume for 1869.

—— The basement of the Town Hall, Birmingham, was recently fitted up by Mr. VERTEGANS, of the Chad Valley Nurseries, as a refreshment *salon* during the Mayor's *conversazione*. It appears that the walls and pillars were carefully whitewashed; and the latter, with a tasteful edging of red, and the motto of the borough, "Forward!" in the same colour on each, were further ornamented with evergreens and Holly berries. The walls were also latticed with these latter decorations, and the centres afforded the glowing green and scarlet, with the white background, was effective. The greatest attraction of all was a fountain and cascade at the end, adjacent to the front of the hall, and which formed a charming spectacle. A semicircular space, lined with Ferns, ornamental foliage plants, and flowers, arranged with artistic skill, formed a natural grotto, from the far extremity of which a cascade of sparkling water flowed down among the plants, while a small fountain, with a convolvulus jet, found place in the centre of the retreat.

—— We are glad to see that the breeding of HYBRID CAPE PELARGONIUMS is engaging the attention of cultivators, not so much perhaps for the sake of the gains already acquired, as for those which we may reasonably expect to reward the persevering experimentalist whose efforts may be turned in this direction. There is no apparent reason why we should not as greatly improve other distinct races of Pelargoniums as those which constitute our modern show and zonal varieties. Mr. WILSON SAUNDERS and Major TREVOR CLARKE may be cited as workers in this field, and now we may quote from the practical ranks, Mr. SAMPSON, of Yeovil, who is just sending out some new Oak-leaved sorts, reminding one of that old favourite, the Fair Helen of our youthful days, but differing in colour. They are said to be the result of a cross between the Cape and the Nosegay sections, and to have flowers of a finer and stouter build than anything that have preceded them; while being free of bloom, it is believed that they will prove valuable both for winter or summer decoration, as well as useful for cutting from, as they yield a continuous supply of flowers. The plate Mr. SAMPSON has issued represents them as being of different shades of rosy-purple, spotted after the style of the variety already named. The trusses are shown as being full and compact, one is of a violet-purple, dashed with rose, another deep rosy-magenta, and a third rosy-violet, shaded with carmine, all of them with dark crimson spots and stripes most prominently marked on the upper petals. We trust Mr. SAMPSON, or some one else, will go on seeding and selecting till we get these Oak-leaved Pelargoniums as fine and as varied as their hitherto more favoured relatives.

—— Mr. CHAPMAN, whose useful aids to GRAPE THINNING we described at p. 1193, reminds us that we have omitted to mention his pruning scissors, without which the other contrivances are incomplete. "The same pair of scissors which I use for thinning the Grapes, I also use for cutting the wire into the lengths required for suspending the shoulders of the bunches, which prevents the necessity of using a pair of cutting pliers." What Mr. CHAPMAN does in this case, is to make a small semi-circular notch—which any grinder can do—in one of the blades of the scissors, this simple notch being sufficient to hold the wire firmly, so that it may be severed by the other blade. It is a manifest convenience to be able to cut the wires as required, without the necessity of carrying and handling a second instrument for the purpose.

—— The publication at an early date of a new gardening journal, to be called "THE GARDEN," is announced. The new-comer is, we learn, projected by Mr. W. ROBINSON, F.L.S., and will be edited by that gentleman.

—— The success which has attended the introduction into this country of the form of blind for windows generally seen in use on the Continent, has led Messrs. DICK RADCLYFFE & CO. to introduce a more substantial and rougher article for outside use, and especially for GREENHOUSE SHADING, samples of which are before us. The annexed illustration (fig. 304) will give an excellent idea as to the use for which they are intended, and for which few materials are so well adapted. The price, we are informed, is very moderate,

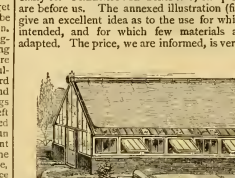

FIG. 304.—SHADING FOR GREENHOUSES.

so that there is no reason why this elegant article should not be universally employed. Some of the forms laid before us would, if cut to the proper size, make excellent "ventilators" for drying plants for the herbarium, being much lighter, and more portable, than those generally used.

—— Instances of so-called PARASITIC TREES are not very uncommon, but the following is somewhat remarkable. On the bank of a side stream of the Cherwell, at Oxford, there stood a few years ago (and probably does still), a pollard Willow, on the top of which a Sycamore had grown. The root of the Sycamore had run down the hollow trunk of the Willow, and seemed to be gradually becoming converted into a trunk itself, for the old Willow's natural tendency to split was being increased by the strong growth of the Sycamore. It would be curious if, as seemed likely to occur, the Sycamore were eventually to stand rooted in the ground, after the decay of the Willow, with some 5 feet of original root transformed into trunk.

—— On the last plate of CURTIS' "British Entomology" is the following curious notice:—"I consider myself fortunate in being able to introduce into my plate (of the honey bee) the HIVE of some HIVE BEES which was discovered by Lord MALMESBURY in his plantations near the river Avon, not far from Sopley. I had the gratification of seeing it before it was removed in October, 1838; it was attached to the arm of a tree, and hung down as represented in the plate about 2 feet from the ground; a considerable number of the bees had died with their heads in the cells. Combs have been rarely formed in hollow trees in this country, but one formed on the outside is, I believe, without a parallel in the history of bees." Curious as this account is, a very similar case was pointed out to us a few years since by Lord MESTEYNE in his park at Casewick, in Lincolnshire. An Ash tree partially hollow was occupied at the base by some specimens of Polyporus fomentarius, while half way up on the trunk was a specimen of Polyporus hispidus, below which was a strong hornets nest. About 5 feet above this some bees had formed on the outside of the trunk five perfect combs, four of a considerable size, parallel to each other, exactly as in CURTIS' plate. When we saw them only a few bees were about the combs, which were so loosely fixed that every puff of wind moved them. The hornets, however, did not molest the bees, though very probably in an earlier stage they may have robbed the honey. The hornets were so abundant that it was not possible without some risk to examine the comb very closely, so that we were contented to get the best sight we could with a telescope. Ultimately the combs fell, but we have no further information. It is not certain whether the bees in the first instance had chosen too narrow a hole, or whether they had been driven upwards by the hornets. While speaking of entomological subjects it may be interesting to some of our readers to know that a fine specimen of Deiopea pulchra was found in a stubble field at Marston Trupil, Northamptonshire, by the Rev. W. LAW, but not near the sea, as has been the case more frequently where this rare and beautiful moth has been found. *M. T. B.*

—— The highest MAXIMUM TEMPERATURES of the AIR during the week ending October 21, ranged from 68°.4 at Blackheath to 57° at Dundee, with a mean for the English stations of 65°.3, and for the Scottish of 59°.9. The MINIMUM TEMPERATURES of the air ranged from 42°.5 at Bradford to 33° at Perth; the mean for England amounted to 37°.7, and for Scotland to 37°.3. The highest MEAN TEMPERATURE (54°.6) occurred at the most southern station, viz., Portsmouth, and the lowest (48°.2) at Dundee. A value of 48°.4 was also recorded at Aberdeen. The mean for all England was 52°.9, and for Scotland 50°.1. The RAINFALL for the week was large at some stations; the highest, Greenock, as much as 2.08 inches fell, and at Newcastle-on-Tyne and Perth the amount exceeded 1 inch. The mean fall for England was 0.67 inch, and for Scotland 0.79 inch. (See Mr. GLAISHER's Tables, p. 1394.)

—— We have found FRETTINGHAM'S LIQUID COMPOUND a very efficient agent in the destruction of insects upon plants. Applied by means of the Horticultural Vaporiser, to which we referred at p. 876, it effectually kills both thrips and red spider, and, with care in the application, white and brown scale also. The mealy-bug is killed when the liquid fairly reaches them, but it requires a double application through the vaporiser to make sure of this. Probably this pest would be more effectually got at by means of a sponge or brush. The compound does not in any way injure the plants.

—— Mr. J. R. GORDON records in the *Scientific American* a somewhat novel use for the stem of AGAVE AMERICANA. He says:—

"One Sabbath evening—the sailor's vacation—I watched a number of men who had provided themselves with axes, making an attempt to secure one of these plants, which they could not accomplish without cutting its surrounding leaves; and, as I was desirous of knowing what use they would make of it, I approached and questioned them. One of the men informed me that they made razor-strops of the stalk, and that it furnished tolerably good ones too. It was cut into lengths of 3 feet, in order to be portable, and at leisure it would be cut into the desired form of razor-strops."

—— There is, says *Nature*, in the Museum at Cassel, a curious collection illustrating EUROPEAN and OTHER TREES. It is in the form of a library, in which the back of each volume is a flat trunk of some particular tree, the sides are made of perfect wood, the top of young wood and the bottom of old. When opened, the book is found to be a box containing either wax models or actual specimens of the flower, fruit, and leaves of the tree.

—— One of the most conspicuous plants of Yucatan is a showy species of BROMELIA, allied to *B. bracteata*, if not actually that species. It grows parasitically in the forks of the forest trees, and greatly enhances the scenery with its long bright scarlet bracts. The Indians even now have great admiration for this plant and its congeners, which played an important part in the sacred rites of their ancestors. It was from the axils of the leaves that the pure water of heaven was collected to be used for the baptism of children. On such and other equally solemn occasions it was essential that water should be used which had come direct from heaven, and never touched ground; hence the value of this and similar plants which collected the rain in a manner akin to that of our common Teasel.

—— At one time only recognised among us in connection with sauce, the TOMATO is yearly becoming more popular as a vegetable. Mr. ROBINSON gives a graphic account of its use in America. He says:—"From the hot States round the Gulf, and from sunny and genial California, where it grows as freely as Groundsel does in England, to the Canadas and the Northern States, where they must first be raised in heat, as with us, the Tomato is a blessing to this country. No other product is so popular with all classes, high and low, and probably none so wholesome among the many things here used. For months in summer and autumn it may be gathered fresh. It shares the fate of Peaches, Pears, and Oysters, and is preserved in tins for winter use, so that practically it is obtainable all the year round. Stewed, baked, as sauce, or in soup, eaten raw as a salad, or with sugar, in all these ways it is good; but during the heat of summer in no way is the Tomato more agreeable to those who know

its merits than when eaten 'from the bush.' The process is simple. Select a good ripe fruit, place the lips against its glossy sides, bite a piece clean off without fear, and then suck with all your might. At first certain succulent leathery coats may offer some resistance, but soon the red heart's juice, kept cool in the hotter days by the outer coats, will begin to flow, and victory will be yours. In every country enjoying a higher temperature than that of England, the Tomato should be grown abundantly as a common garden or field crop; and even where, as in Northern England, you cannot even ripen them against walls, they may be easily grown in empty frames, &c., unused in summer; and, once plentiful, every child would learn to relish a food so wholesome and so excellent."

VINE GRAFTING.

SOME 28 years ago Mr. Douglas, of Babworth, East Retford, successfully inarched a Black Hamburgh upon an old Syrian Vine, and which up to the present time has answered every purpose, still producing wonderful bunches of good-sized Grapes.

A few years later on, when the Barbarossa [Gros Guillaume] was first introduced, Mr. Douglas was fortunate enough to obtain a single eye of it, and being, naturally enough, anxious to see its fruit as soon as possible, he bit upon the following plan for getting a strong shoot, and in carrying it out was not disappointed. He simply bored a hole in the cane of the same Syrian Vine, shaped his bit of wood of the Barbarossa peg fashion, and drove it firmly into the stock; the result being the production of a cane quite to his satisfaction, and which in due time bore fruit. I lately visited Mr. Douglas, and saw such bunches of Grapes of both sorts on the old Syrian Vine as most gardeners would not be ashamed of.

He also drew my attention to his new method of grafting the green wood upon green wood, and there they were, eight grafts in all, worked at various times since he first successfully carried it out. The system of grafting which he follows is understood as whip or tongue grafting, the grafts being tied on with nothing more than some nice matting. The reason which induced him to try this plan was the want of Vines in pots to inarch with. I must confess that to all appearance Mr. Douglas' new method has answered admirably, and will prove an immense boon to gardeners, more especially as under the new postal arrangements green grafts may be conveyed almost at the shortest notice from the Land's End to John o'Groat's in a few hours, and be grafted with every chance of success. I enclose two pieces cut from two of the Vines for your inspection. No. 1 was grafted upon March 11, and the piece sent was taken 20 feet from the graft; No. 2 was grafted on March 17, and taken 12 feet from the graft after being twice stopped; and I confess to having seen Vines take two years on their own roots to make such rods. Four other rods which I saw (grafted on June 18) were smaller than those from which I have sent you samples, but were growing fast. Two of these four were taken from a pot Vine that had been forced, and turned out-of-doors over a month, and notwithstanding the difference in the ages of the scion and the stock they were doing well.

I have only to say in conclusion that the whole of the grafts put on as above stated, are going on very satisfactorily, and that this system is, in my opinion, the most simple for grafting the Vine yet adopted. Without at all flattering Mr. Douglas I must mention that he appears to be quite at home with the Vine, and exhibits as well very superior skill in the management of the fruit, flower, and kitchen garden departments at Babworth Hall, over which he has presided for upwards of 30 years. *J. Miller, Worksop Manor.* [As was to be expected, the wood received was not particularly stout, but was well ripened, and showed good eyes. This system would seem to be a good one to fall back upon where Vine budding has failed. EDS.]

BOMAREA CHONTALENSIS.

IN a previous number (1871, p. 479), Dr. Seemann described this handsome stove climber, of which we now give an illustration (fig. 305), from a plant that flowered in Mr. Bull's nursery at Chelsea in August last. We need only refer to the description above cited, and add what Dr. Hooker in the "Botanical Magazine," tab. 5927, says as to the flowers:—Flowers 1¾ inch long, sub-campanulate, obtusely trigonous; outer segments thick, fleshy, waxy, rose-red, with a few brown spots round the margin at the tip, obovate obtuse, very convex, obscurely keeled at the back, with a thick rib towards the tip; inner segments a little shorter and much narrower, spathulate obtuse, apiculate, quite entire, pale yellow blotched with brown, claw concave at the base in front. Anthers dark purple, style columnar; stigmas three, short, spreading. Ovary turbinate, trigonous, with three thick ribs. Dr. Hooker further adds, that it is closely allied to B. edulis, a native of San Domingo, the tubers at the end of the root fibres of which are boiled and eaten as Potatos under the name of Topinambours blancs. The present plant is also tuberous, and easily cultivated. It is one of the most elegant of Mr. Bull's introductions.

FIG. 305.—BOMAREA CHONTALENSIS.

A TROPICAL FOREST.

(Concluded from p. 1359.)

AND where are the famous Orchids? They perch on every bough and stem; but they are not, with three or four exceptions, in flower in the winter; and if they were, I know nothing about them—at least, I know enough to know how little I know. Whoever has read Darwin's "Fertilisation of Orchids," and finds in his own reason that the book is true, had best say nothing about the beautiful monsters till he has seen with his own eyes more than his master.

And yet even the three or four that are in flower are worth going many a mile to see. In the hothouse, they seem almost artificial from their strangeness; but to see them "naturel," on natural boughs, gives a sense of their reality which no unnatural situation can give. Even to look up at them perched on bough and stem, as one rides by, and to guess what exquisite and fantastic form may issue, in a few months or weeks, out of those fleshy, often unsightly leaves, is a strange pleasure; a spur to the fancy which is surely wholesome, if we will but believe that all these things were invented by A Fancy, which desires to call out in us, by contemplating them, such small fancy as we possess; and to make us poets, each according to his power, by showing a world in which, if rightly looked at, all is poetry.

Another fact will soon force itself on your attention, unless you wish to tumble down and get wet up to your knees. The soil is furrowed everywhere by holes; by graves, some 2 or 3 feet wide and deep, and of uncertain length and shape, often wandering about for 30 or 40 feet, and running confusedly into each other. They are not the work of man, nor of an animal; for no earth seems to have been thrown out of them. In the bottom of the dry graves you sometimes see a decaying root: but most of them just now are full of water, and of tiny fish also, who burrow in the mud and sleep during the dry season, to come out and swim during the wet. These graves are, some of them, plainly quite new. Some, again, are very old; for trees of all sizes are growing in them and over them.

What makes them? A question not easily answered.

But the shrewdest foresters say that they have held the roots of trees now dead. Either the tree has fallen and torn its roots out of the ground, or the roots and stumps have rotted in their place, and the soil above them has fallen in.

But they must decay very quickly, these roots, to leave their quite fresh graves thus empty; and—now one thinks of it—how few fallen trees, or even dead sticks, there are about. An English wood, if left to itself, would be cumbered with fallen timber; and one has heard of forests in North America, through which it is all but impossible to make way, so high are piled up, among the still-growing trees, dead logs in every stage of decay. Such a sight may be seen in Europe, among the high Silver Fir forests of the Pyrenees. How is it not so here? How indeed? And how comes it—if you will look again—that there are few or no fallen leaves, and actually no leaf-mould? In an English wood there would be 1 foot—perhaps 2 feet—of black soil, renewed by every autumn leaf-fall. Two feet? One has heard often enough of bison-hunting in Himalyan forests among Deodaras 150 feet high, and scarlet Rhododendrons 30 feet high, growing in 15 or 20 feet of leaf-and-timber-mould. And here in a forest equally ancient, every plant is growing out of the bare yellow loam, as it might in a well-hoed garden bed. Is it not strange

Most strange; till you remember where you are—in one of Nature's hottest and dampest laboratories. Nearly 80 inches of nearly rain, and more than 80° of perpetual heat, make swift work with vegetable fibre, which in our cold and sluggard clime would curdle into leaf-mould, perhaps into peat. Far to the north, in poor old Ireland, and far to the south, in Patagonia, begin the zones of peat, where dead vegetable fibre, its treasures of light and heat locked up, lies all but useless age after age. But this is the zone of illimitable sun force, which destroys as swiftly as it generates, and generates again as swiftly as it destroys. Here, when the forest giant falls, as soon tell me that they have heard him fall, on silent nights, when the cracking of the roots below and the lianes aloft, rattles like musketry through the woods, till the great trunk comes down, with a boom as of a heavy gun, re-echoing on from mountain-side to mountain-side; then—

> "Nothing in him that doth fade,
> But doth suffer an *exchange*
> Into something rich and strange."

Under the genial rain and genial heat, the timber tree itself, all its tangled ruin of lianes and parasites, and the boughs and leaves snapped off not only by the blow, but by the very wind, of the falling tree—all melt away swiftly and peaceably in a few months—say almost a few days—into the water, and carbonic acid, and sunlight, out of which they were created at first, to be absorbed instantly by the green leaves around, and, transmuted into fresh forms of beauty, leave not a wrack behind. Explained thus—and this

I believe to be the true explanation—the absence of leaf-mould is one of the grandest, as it is one of the most startling, phenomena of the forest.

Look here at a fresh wonder. Away in front of us a smooth grey pillar glistens on high. You can see neither the top nor bottom of it. But its colour, and its perfectly cylindrical shape, tell you what it is—a glorious Palmiste: one of those queens of the forest which you saw standing in the fields; with its capital buried in the green cloud, and its base buried in that bank of green velvet plumes, which you must skirt carefully round, for they are a prickly Dwarf Palm, called here Black Roseau [Bactris]. Close to it rises another pillar, as straight and smooth, but one-fourth of the diameter—a giant walking cane. Its head, too, is in the green cloud. But near are two or three younger ones only 40 or 50 feet high, and you see their delicate feather heads, and are told that they are Manacques [Euterpe oleracea]; the slender nymphs which attend upon the forest queen, as beautiful, though not as grand as she.

The land slopes down fast now. You are tramping through stiff mud, and those Roseaux are a sign of water. There is a stream or gully near: and now for the first time you can see clear sunshine through the stems; and see, too, something of the bank of foliage on the other side of the brook. Not much sight, it may be, of the head of a tree aloft, blazing with golden trumpet-flowers, which is a Poui; and of another lower one covered with hoar frost, perhaps a Croton [Croton gossypifolium]; and of another, a giant covered with purple tassels. That is an Angelim. Another giant encroaches even him. His dark glossy leaves look off sheets of silver light as they flicker in the breeze; for it blows hard aloft outside while you are in stifling calm. That is Balata. And what is that on high?—twenty or thirty square yards of rich crimson a hundred feet above the ground. The flowers may belong to the tree itself. It may be a Mountain Mangrove [Mononobea coccinea], which I have never seen in flower: but take the glasses and decide. No. The flowers belong to a liane. The "wonderful" Prince of Wales' feather [Norantea] has taken possession of the head of a huge Momibin [Spondias lutea (Hog plum)], and all over with crimson combs, which crawl out to the ends of the branches, and dangle 20 or 30 feet down, waving and leaping in the breeze. And over all blazes the cloudless blue.

You gaze astounded. Ten steps downward, and the vision is gone. The green cloud has closed again over your head, and you are stumbling in the darkness of the bush, half-blinded by the sudden change from the blaze to the shade. Beware. "Take care of the Croc-chien!" shouts your companion: and you are aware of, not a foot from your face, a long, green, curved whip, armed with pairs of barbs some 4 inches apart; and are aware, also, at the same moment, that another has seized you by the arm, another by the knees, and that you must back out, unless you are willing to part with your clothes first, and your flesh afterwards. You back out and find that you have walked into the tip—luckily only into the tips—of the fern-like fronds of a trailing and climbing Palm such as you see in the Botanic Gardens. That came from the East, and furnishes the rattan canes. This [Desmoncus] furnishes the Gri-gri canes, and is rather worse to meet, if possible, than the rattan. Your companion, while he helps you to unpick the barbs out, calls the Palm laughingly by another name, "Suelta-mi-Ingles;" and tells you the old story of the Spanish soldier at San Josef. You are near the water now; for here is a thicket of Balisiers [Heliconia]. Push through, under their great Plantain-like leaves. Slip down the muddy bank to that patch of gravel. See first, though, that it is not tenanted already by a deadly Mapepire, or rattlesnake, which has not the grace, as his cousin in North America has, to use his rattle.

The brooklet, muddy with last night's rain, is dammed and bridged by winding roots, in shape like the jointed wooden snakes which we used to play with as children. They belong, probably, to a Fig, whose trunk is somewhere up in the green cloud. Sit down on one, and look, around and aloft. From the soil to the sky, what peeps through here and there is packed with green leaves of every imaginable hue and shape. Around our feet are Arums [Spathiphyllum cannæfolium], with snow-white spadixes and hoods, one instance among many here of brilliant colour developing itself in deep shade. But is the darkness of the forest actually so great as it seems? Or are our eyes, accustomed to the blaze outside, unable to expand rapidly enough, and so liable to mistake for darkness air really full of light reflected downward, again and again, at every angle, from the glossy surfaces of a million of leaves? At least we may be excused; for a hat has made the same mistake, and flits past us at noonday. And there is another—No; as it turns, a blaze of metallic azure off the upper side of the wings proves this one to be no bat, but a Morpho—a moth as big as a bat. And what was that second larger flash of golden green, which dashed at the moth, and back to yonder branch not 10 feet off? A Jacamar [Galbula]—kingfisher, as they miscall her here, sitting, fearless of man, with the moth in her long beak. Her throat is snowy white, her under-parts rich red brown. Her breast, and all her upper plumage and long tail, glitter with golden green. There is light enough in this darkness, it seems. But now a look again at the plants. Among the white-flowered Arums are other Arums, stalked and spotted, of which beware; for there the poisonous Seguine diable,* the dumb-cane, of which evil tales were told in the days of slavery. A few drops of its juice, put into the mouth of a refractory slave, or again into the food of a cruel master, could cause swelling, choking, and burning agony for many hours.

Over our heads bend the great arrow leaves and purple leaf-stalks of the Tanias [Xanthosoma]; and mingled with them, leaves often larger still: oval, glossy, bright, ribbed, reflecting from their underside a silver light. They belong to Arumas [Calathea]; and from their ribs are woven the Indian baskets and packs. Above these, again, the Balisiers bend their long leaves, 8 or 10 feet long a-piece; and nuder the shade of the leaves their gay flower-spikes, like double rows of orange and black birds' beaks upside down. Above them, and among them, rise stiff upright shrubs, with pairs of pointed leaves, a foot long some of them, pale green above and yellow or fawn-coloured beneath. You may see, by the three longitudinal nerves in each leaf, that they are Melastomas of different kinds—a sure token they that you are in the tropics—a probable token that you are in tropical America.

And over them, and among them, what a strange variety of wings! Look at the contrast between the Balisiers and that branch which has thrust itself among them, which you take for a dark copper-coloured Fern, so finely divided are its glossy leaves. It is really a Mimosa—Bois Mulâtre [Pentaclethra filamentosa] as they call it here. What a contrast again, the huge grassy fronds of the Cocorite Palm, which stretch right away hither over our heads, 20 and 30 feet in length. And what is that spot of crimson flame hanging in the darkest spot of all from an under-bough of that low weeping tree? A flower-head of the Rosa del Monte [Browne]. And what that bright yellow-coloured fox's brush above it, with a brown hood like that of an Arum, brush and hood nigh 3 feet long each? Look—for you require to look more than once, sometimes more than twice—here, up the stem of that Cocorite, or as much of it as you can see in the thicket. It is all jagged with the stumps of its old fallen leaves; and among the butts perch broad-leaved Ferns, and fleshy Orchids, and above them, just below the plume of mighty fronds, the yellow fox's brush, which is its spathe of flower.

What next? Above the Cocorites dangle, amid a dozen different kinds of leaves, festoons of a liane, or of a Vine, which is neither Vine nor liane, but one of Bignonias, Bauhinias—what not? And through them a Carat [Sabal] Palm has thrust its thin bending stem, and spread out its flat head of fan-shaped leaves 20 feet long each: while over it, I verily believe, hangs, 80 feet aloft, the head of the very tree upon whose roots we are sitting. For amid the green cloud you may see sprigs of leaf somewhat like that of a Weeping Willow [Ficus salicifolia?]; and there, probably, is the trunk to which they belong, or rather what will be a trunk at last. At present it is like a number of round-edged boards of every size, set on end, and closely packed at their edges. There is a slit down the middle of the trunk, 20 or 30 feet long. You may see the green light of the forest shining through it. Yes. That is probably the Fig; or, if not, then something else. For who am I, that I should know the hundredth part of the trees which we look at?

And above all you catch a glimpse of that crimson mass of Norantea which we admired just now; and, black as Yew against the blue sky and white cloud, the plumes of one Palmiste, who has climbed toward the light, it may be for centuries, through the green cloud; and now, weary yet triumphant, rests her dark head among the light foliage of a Ceiba, and feeds unhindered on the sun.

There, take your tired eyes down again; and turn them right, or left, or where you will, to see the same scene, and yet never the same. New forms, new combinations; a wealth of creative Genius—let us use the word with all its true sense—quite possible to us, for the human intellect or the human eye, even as He is who makes it all, whose garment, or rather whose speech, it is. The eye is not filled with seeing, or the ear with hearing; and never would be, did you roam these forests for a hundred years. How many years would you need merely to examine and discriminate the different species? And when you had done that, how many more to learn their action and reaction on each other? How many more to learn their virtues, properties, uses? How many more to answer the perhaps ever unanswerable question—How they exist and grow at all? By what miracle they are compacted out of light, air, and water, each after its kind? How, again, those kinds began to be, and what they were like at first? Whether those crowded, struggling, competing shapes are stable or variable? Whether or not they are varying still? Whether, even now, as we sit here, the great God may not be creating, slowly but surely, new forms of beauty round us? Why not? If He chose to do it, could He not do it? And even had you answered that question, which would require whole centuries of observation as patient and accurate as that which Mr. Darwin employed on Orchids and climbing plants, how much nearer would you be to the deepest question of all—Do these things exist, or only appear? Are they solid realities, or a mere phantasmagoria, orderly indeed, and law-ruled, but a phantasmagoria still; a picture-book, by which God speaks to rational essences, created in His own likeness? And even had you solved that old problem, and decided for Berkeley or against him, you would still have to learn from these forests a knowledge which enters into man not through the head, but through the heart; which (let some modern philosophers say what they will) defies all analysis, and can be no more defined or explained by words, than a mother's love. I mean the causes and the effects of their beauty; that "Æsthetic of plants," of which Schleiden has spoken so well in that charming books of his, "The Plant," which all should read who wish to know somewhat of "The Open Secret."

But when they read it, let them read with open hearts. For that same "Open Secret" is, I suspect, one of those which God may hide from the wise and prudent, and yet reveal to babes.

At least, so it seemed to me, the first day that I went, awe-struck, into the high woods; and so it seemed to me, the last day that I came, even more awe-struck, out of them. *Kingsley's "At Last."*

* Dieffenbachia, of which varieties are not now uncommon in hothouses.

THE AMATEUR GARDENER.

Carnations and Picotees.—Floral tastes, like all others, change as time rolls on, and the amateur gardener who has reached the grand climacteric is rarely found to patronise the favourites of his youth. Not only our fashions in flowers, but even our art science, and research combine to introduce so many new species and varieties, that the exclusive culture of a few favourites is now more rare than it was a generation back. We do not now so often see a stand of perfect Auriculas, nor a collection of Carnations and Picotees grown in pots, and tended day by day with almost parental care. Even the smaller gardens of our day are so occupied with "bedding plants," that comparatively little time and space remain for the exclusive culture of those plants which used to be under the daily supervision of those technically called "florists." Our memory goes back for 40 years, when Mr. Henry Groom held a fine piece of nursery ground at Walworth, the freehold of which belonged to the Dean and Chapter of Canterbury, and which is now covered with houses, the special site of the garden being now designated Lorimer Square. We quote Gray feelingly, in reference to the Mourning Fields, when the numerous rich meadows and market gardens which extended as far as the eye could reach, towards Kennington and Clapham, but have now no available space for flying a kite, or dabbling in a pond:—

> "Ah, happy hills! ah, pleasing shades!
> Ah, fields beloved in vain!
> Where once my careless childhood stray'd,
> A stranger yet to pain."

And we do not doubt that many readers of the *Gardeners' Chronicle*, should they read this paper, sympathise with us in regretting the entire vanishing away in the neighbourhood of London of the numerous places once dedicated to Flora.

Both at Walworth, and, when forced by bricks and mortar to migrate to Clapham, Mr. Groom drew admiring crowds every year to his celebrated collection of Tulips; but it was as a grower of Carnations and Picotees that we first knew him at the former residence. We speculated, as well remember, in twelve pairs, and having a special predilection for "flakes" and "bizarres," our purchase only included two pairs of Picotees. We bought in the autumn, as every grower should who wishes for as fine a growth as possible the next year, though, to counterbalance this advantage, he must encounter the perils of winter, when we duly planted in twelve enormous pots, one pair in each, in a compost which then was in vogue, but which we believe a more scientific treatment has since exploded, in which pigeon's dung and the scum of sugar-bakers' pans performed a part, and which had been boiled, to guard against the possible existence of a lurking wireworm or other insect fatal to the florist's prospects. Woe be to him who, neglecting all due precautions, finds the stem of his best Carnation gnawed through by one of these pests! But there are other enemies besides insects, and by the time the spring arrived we were *minus* a few of our plants from inherent disease, or from being insufficiently rooted, or some occult cause, baffling all floricultural care and skill. At length our little stock began to "spindle," and then began the mysterious operations of manure-watering, applying suitable sticks, and, somewhat later, the tying up the blooms to prevent their splitting, and spreading out the petals on a card carefully fitted to the advancing bud All this was very interesting to us then, and so was the providing a canvas shade to protect the flowers from sun and rain and to prolong their blooming, and last we were repaid by the visits of all our friends to admire the collection and praise our taste and perseverance.

But in looking back on this long and painstaking process, we confess to feeling that we should not like all this laborious culture to come over again. The flowers were certainly many of them beautiful, but even at the time we felt that the "trussing" process was too artificial, and that the flower spread out on a card

wanted the charm of naturalness to a great degree. Afterwards we took to growing commoner kinds of Carnation and Picotee, such as would develope themselves into large groups of flowers, and allow us to present a friend with a handful, or make a bouquet of them for the drawing-room. But it is only rarely that such a bed can be secured, and when possessed the plants will not produce fine flowers unless often renewed. This reminds us of the process of propagating, and of the fact, so worrying at the time, that some of our plants produced no "grass," that is, no shoots suitable for "layering," when a small sprout would be taken off, to be "piped" with very doubtful success under a hand-glass.

Well, this method of cultivating Carnations and Picotees still goes on, as our readers may see by the advertisements of the plants at so much "the dozen pairs" in the columns of this paper. But the old culture has a formidable rival of modern growth in the practice of raising these flowers from seeds, now so common, and so amply rewarding the cultivator. It appears that the science which has enabled double Carnations to be grown easily from seeds was developed first in Italy, and the finest collections come from that country. We have grown some splendid double flowers from seeds purchased in England, and we advise our readers to try the experiment. It is too late to sow the seed now, August being the best month, or March will do as well, though in that case the plants will not bloom till the year following. Sow in pans, in light rich soil, and transplant as soon as the seedlings are strong enough to be handled. *H. B.*

NEW INVENTIONS FOR PLANT AND FRUIT PROTECTION.

It is only a few years since that Mr. Rendle introduced his protectors to the public. Very simple and unpretending things they were. One of their early tidies, if I remember rightly, was "A New Trap for Sunbeams," and their chief merit consisted in this, that the sunbeams they caught they kept. Their brick sides absorb much heat by day, and let it go forth to fight the cold with at night. Thus it came to pass that these protectors, though so simple, were found efficient. Experience, that surest of all tests, has proved that they keep out more cold and let in more warmth than either *cloches* or handlights — hence their deserved success.

Founded on true principles, adapted to general wants, the protectors have grown marvellously, alike in height and breadth and number. The central ideas, warmth, virtual imperishability, and portability to the utmost, were sown; and like all true thoughts they have fructified and grown. And the growth in this instance has been most rapid. And if they grow as fast in the future as they have done in the past, they must speedily cover the greater part of the field of horticultural enterprise, wide as it is. Starting humbly, a few inches from the ground, they have risen to the stature of ordinary span and lean-to houses, with glass ends and doors. Recommended at first chiefly for dwarf crops, such as Lettuces, young Cauliflowers, early Carrots, Radishes, Strawberries, bulbs, and other flowers; now they have risen to the stature of lawn conservatories, orchard-houses, vineries, glass screens for walls of any height, &c. Neither has the development of an idea been, as is too often the case, a series of supercessions, but a course of regular and upward progress. No old ground has been relinquished in the occupation of so much new. With the exception of some structural improvements, to be presently described, the old protectors are as well fitted for their work as at the first. The new types by no means supersede the old, they only enter into fresh fields of usefulness.

We often hear of enthusiasts riding their hobbies to death: Mr. Rendle has succeeded in riding his into newer, higher, wider spheres of life. I believe I was among the first to recognise and testify to the merits of this invention; and many were the sly hits and cynical sneers hurled at me in consequence. It is, consequently, a self-gratifying to find that merit now acknowledged, and those early favourable impressions confirmed by a great cloud of witnesses, many of them carrying such weight in the horticultural world that it is an honour to think with them.

Therefore, leaving these and others to testify to the usefulness of Rendle's protectors, I will proceed further to illustrate the expansion of an idea by briefly describing one of the newer forms that have recently appeared. Before doing so, however, it may be well to refer to the chief structural improvements that have been effected. This consists in making one half of the grooved bricks in two pieces, to facilitate the removal of the glass. With ordinary care, I never found any difficulty in working the old forms; but complaint was made by some of a difficulty in quickly and safely removing the glass. The new pattern renders such difficulties impossible. The glass lies on, or in, the lower portion of the grooved brick, the upper half is then laid on, and keeps the glass firmly in position, and forms a coping over it. Fig. 306 shows a section of both parts of the Belvoir Castle pattern. It must be obvious at a glance that when the upper portion is removed the square of glass can be instantly taken out. The front coping brick continues of the old pattern, and is pierced with holes at intervals for the discharge of the rain-water.

For span-roofed protectors, the covering tile assumes the form of a fat, dumpy T, as shown in fig. 308.

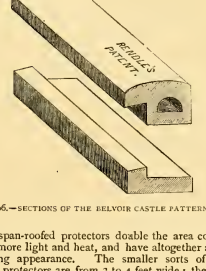

Fig. 306.—SECTIONS OF THE BELVOIR CASTLE PATTERN TILE.

These span-roofed protectors double the area covered, admit more light and heat, and have altogether a more imposing appearance. The smaller sorts of span-roofed protectors are from 3 to 4 feet wide; the larger ones with central platform of wood, and intermediate

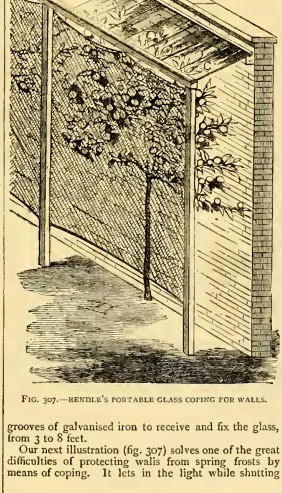

Fig. 307.—RENDLE'S PORTABLE GLASS COPING FOR WALLS.

grooves of galvanised iron to receive and fix the glass, from 3 to 8 feet.

Our next illustration (fig. 307) solves one of the great difficulties of protecting walls from spring frosts by means of coping. It lets in the light while shutting

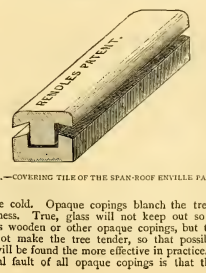

Fig. 308.—COVERING TILE OF THE SPAN-ROOF ENVILLE PATTERN.

out the cold. Opaque copings blanch the tree into tenderness. True, glass will not keep out so much cold as wooden or other opaque copings, but then it does not make the tree tender, so that possibly the glass will be found the more effective in practice. The cardinal fault of all opaque copings is that they so coddle the trees that a lesser amount of cold injures them as much or more as a greater without covering. This is like keeping out the cold with one hand and letting it in with the other. Practically it matters little in the end whether a crop is ruined by more cold without protection or less cold with it. To shelter without weakening should ever be our object; glass copings furnish us with the means of doing so, and therefore they are likely to prove most useful. Besides, the efficiency of most protecting expedients is largely dependent on their ability to keep the trees dry. Scarcely any material can compete with glass in this respect. It is not only impervious to water, but, offering no obstruction to light and heat, the trees are almost sure to be dry under it, and hence the night frosts would find them prepared to resist its power to the uttermost. These copings are warranted by the inventor to stand the strongest winds, and are likely to be extensively used as shelters from heavy rains, protectors from spring frosts, and aids to the maturation of late autumn fruits. *F.*

THE RATIONALE OF HOT-WATER CIRCULATION.

"Caloric," Mr. Fish says, "is the driving force of the universe." The import of these words is that caloric is pre-eminently above all other forces, or even exclusively of all others, the driving force. Such is the grammatical value of the definite article—such the ordinary meaning attaching to the expression. The reader who, from respect to this gentleman's opinions, might be ready to accept this statement in all its force must not lose sight of the fact that the writer himself at once abandons one-half of its value. "For every molecule," he says, "lifted by caloric, others are pushed forward and onward by gravitation." On the first part of this sentence I beg to refer the reader to the concluding passage in this letter. The second part of the quotation is that which immediately concerns us. It ascribes to gravitation a driving force fully equal in extent and power to that of caloric. I object, therefore, to this undue prominence given to the driving power of caloric, as tending to mislead, and prepossess the mind of the reader with the idea that it is chiefly, if not exclusively, to this power that the circulation of hot-water is due.

The action of caloric on fluids and gaseous and other bodies as a motive power is confined, I believe, to its property of causing expansion or contraction on those bodies. But though, under certain conditions, immense motive power is directly produced by its agency; yet, in a multitude of cases, effects follow expansion, which are not referable to caloric, but to forces quite independent of it. Thus while, on the one hand, the expansion being resisted, elastic force is generated, as in the gun and steam-engine, caloric, by this production of expansive power, is the cause of all the tremendous results so familiar to us. But when, on the other hand, the expansion is unresisted, the effect of caloric is limited to the production of relative proportions of bulk and weight in the body acted upon, bulk being increased or diminished while weight remains the same.

Motion constantly ensues upon such changes, which are certainly not traceable to any lifting power of caloric; for such motions ensue where caloric is not present, or being present is passive. Any body which barely floats in water, will at once rise in it from the bottom to the surface on the least increase of bulk, whether caloric or any mechanical cause give rise to that expansion. The same thing is seen in the atmosphere, and in all other liquids. A slight decrease in bulk, on the other hand, will leave a predominant force to gravity, and the shrunken body will fall to the bottom. The balloon falls or rises by very slight alterations between the relations of bulk and gravity. Caloric being most active in the expansion and contraction of bodies, is thus an accompanying and active agent of other forces, presenting bodies to the action of these lifting and depressing powers, but not itself producing these motions.

Deposing caloric from the high position assigned to it by the writer, I must further strongly object to another statement, as misleading. "It is difficult," he says, "to know which," viz., heat or cold, "takes the initiative. Of more moment is it to be assured that both run on without ceasing." Doubtless it is of more moment to an ordinary gardener to know that he has a heating current which runs on without ceasing, than to know why it does so; but how with the constructor of such apparatus? Is the difficulty of discerning between cause and effect to turn him away from these important points, and is he to trust to the chapter of accidents to further him in any attempt at improvement? Moreover, if he does not acquaint himself with the real cause of motion, he will probably hold wrong notions, and act upon them, and be misdirected by them; and, if I am not very much mistaken, such a case of misdirection will be found in Mr. Fish's own letter. The attendant is there directed (and by implication the engineer or constructor) to give his chief attention to the extra heating of the crown of the boiler, the bottom being left to the cooling effect of the return current. Now, if gravitation be the motive power, no instruction, with respect to the lower part of the boiler, could be more misleading. "The greater the disparity," as Mr. Fish well states it, between the hot and the cold,

"the more energetic the motion." Now, to allow any portion of the lower part of the ascending column of hot water to be occupied with cool water, is to do away with some of this disparity. If 6 inches or 12 inches of the column of water in the boiler at the base be cool, that cool water will be an equipoise to the cool water in the base of the descending column. It will be just equivalent to cutting off so many inches from the altitude of the fall and weight of the descending force. Nay, if this direction of the writer were correct, the boilers might be at once lifted out of their stokeholes, and the fires placed nearly on a level with the flow-pipes. What would practical men say to this question? Yet it would be correct if the principle on this instruction be true, that the base of the boilers may be left cool, so that the crown be hot. These men virtually acknowledge the opposite principle, so far as relates to the base of the boiler. They set the boiler as low as they conveniently can; the import of which is that a column of water in the boiler on the same level with that of the return column, but consisting of cool water at the bottom, warmer water in the middle, and hot water at the top, will not effect their object. They get their cooled water down below the whole level of the system, where it can do no harm. Thus they get that at a comparatively low elevation, and find the advantage of doing so.

The constructor who shall thoroughly carry out the gravitation principle, extending the heating surface of his boiler horizontally at the lowest part, and so make the whole contents of his boiler thoroughly hot from the base to the crown, will not only do much towards clearing up the doubt which overclouds this important subject, but will be able to dispense with that depth of stokehole which is complained of as so inconvenient. To carry out the principle of gravitation thoroughly, the running current should not be allowed to receive from the summit level till it has attained its maximum of coolness, and the ascending current should not be allowed to leave the base level till it has attained its maximum of heat; for "the greater the disparity between the hot and the cold the more energetic the motion," that is, do not lose sight of the special degree of heat in the terms maximum of coolness and maximum of heat. The great principle is diversity between these two things.

When looking on, even as spectators, at the Creator's works, the interest we feel in them, and the instruction we derive, depend much upon our recognition of the fact, that in the midst of seeming disorder there is a most accurate adjustment of cause and effect; and this implies some slight acquaintance with the powers at work and the laws of motion. How much more, then, when no longer as spectators but as constructors we endeavour to set *our* currents in motion and make them run round without ceasing. If our commencements are feeble, that feebleness is in great measure due to our ignorance or imperfect knowledge of the nature and modes of operation of the forces we are about to deal with. Hence, though we cannot stop for perfect knowledge, there can be no question as to the intense importance of it. Total failures, clumsy and badly working productions, and perplexing phenomena, are regular attendants on those stages of constructive effort wherein the guide chiefly relied on is the chapter of accidents. Even loss of life, as in disastrous explosions of steam machinery, has resulted from ignorance of the nature of powers called into operation. The least, therefore, that can be said in reply to this rule of Mr. Fish is, that the course of improvement demands the closest possible acquaintance with the nature of the powers employed and the laws of motion.

It may appear over critical thus to challenge a sentence. I do so because it appears to me not to be isolated, but indicative of and in accordance with the reasonings which follow, and to characterise them. Thus in one place strong motive-power is yet ascribed to the returning cold water, while yet the limb of the boiler which conducts it is called the negative limb. They are called strong cold waters, described as pushing sharply upon the warm water in the boiler, as encountering there levity in contrast with their own weight, as opposing, in other words, of weak resistance to the strength and weight and rushing impetus of the invading current; and after all this what follows as the result? Nothing more than "help" in lifting the hot water, and that help only "possible." A most lame and impotent conclusion certainly. The writer fairly describes and accompanies the force described in strong terms, and yet turns back at the very point of its contact with, or impact upon, the hot water. He interposes between the inrushing power and the reality of its impact and consequent propulsion of the hot water. These strong cold waters, he says, by their weight and impulse are "the chief cause" of the sensitiveness to motion found in the hot water; yet, in other words, he speaks of their "bounding forward" as only "to fill up a vacuum." In this last expression the impact of the descending cold water on the hot water is virtually denied. It does not attack a retreating foe in the rear, but simply occupies a vacated position. Uncertainty of sound is then a most conspicuous feature in this description of the gravitation of the cooled water. The same uncertainty characterises the description of the effect of caloric. It is, he says, the driving power of the universe. Again, he says, it can "hardly be" caloric which lifts the hot water. Now from this language about gravitation and caloric, we might conclude that he had given them both up as constituting motive powers in hot-water circulation. Yet he does not, for he adds:—"There is thus a compound action, dual forces acting simultaneously to induce motion." And though one "can hardly be" the lifting force, and the other only "possibly helps," yet finally they are claimed as motive powers.

The writer then calls in to his aid a third force. No wonder, being so little satisfied with those already dealt with. This third force he defines to be the upward bound or rush of hot water, and appears to account for this action on the principle that caloric "ever aims at its source—the sun." This force, imaginative as its conception is, evidently is not brought to avail even were it existent. The rotation of the earth effectually shuts out the idea that upward motion in the direction of a boiler can be towards the sun. That motion is upward at sunset and at sunrise; and even at midnight, when it is more nearly opposite to the sun's position than towards it. If caloric "ever hits straight at that mark," viz., at the sun, its direction in a boiler, with respect to the sun's position, would vary as the spokes of a wheel or the hands of a clock.

I can hardly conceive a break down to a theory so thorough as is exhibited in this instance. It falls to pieces in the hands of its best supporters. Any attempt to explain and illustrate the caloric theory as that to which the circulation of hot-water is due, brings nothing but confusion of ideas and self-contradiction. When attempted in the guise of "expansive force," it immediately comes into collision with the laws of motion. He who undertakes it undertakes a hard task. How simple, on the other hand, the statement, the explanation, and illustration of the gravitation theory. In reply to Mr. Fish's remark on my use of the term "boiling water," I can only say that such a temperature is the necessary condition of the principle for which I contend. When he says that I attribute too much to verticality in the return pipe, he must remember that I use the word in a sense which admits of modification without in any way affecting the soundness of the reasoning. The descent of the return-pipe may be measured by feet rather than by hundreds of feet. It should be direct rather than by gradations at long intervals.

"The gravitation is from the highest point," as Mr. Fish justly observes, "how or wherever placed;" but the advantage gained to gravitation by the directness and short distance of the descent I contend for is, that it does not take place until weight is restored to the water by condensation. Its descent commences, as in the common arrangement, long before the final approach to the boiler; it does so, therefore, while very little of the force of the term Mr. Fish himself applies to it in that condition is "levity." If it descends in this condition it will not answer to his description as that which characterises his descending columns, viz., "strong cold waters:" such are his words. We want that strength from the highest point of the fall, because the higher the fall the greater the power. My principle in developing the action of gravitation is very simple, and may be readily proved to be in full accordance with many of Mr. Fish's own remarks when tracing the operations of gravitation. I think, therefore, that I have left him little room for saying that the upward-bound arrangement of pipes would seem to him to neutralise circulation.

Mr. Fish has rendered good service to the cause of truth in this matter by his fearless admission of points without regard to their effect on his own theory. I shall hope to see his able pen assisted on the simpler and more useful side of this question. I hope I have not said a word in this paper which may make the discussion between us anything else than a perfectly friendly one. I shall be happy to contribute a few short papers on the principles which govern the movements of fluid bodies irrespective of them, and their bearing on the construction of chimneys and flues, as well as on hot-water apparatus, if the Editors approve. *J. M. Taylor, Seer Green Vicarage, Beaconsfield.* [We quite approve. Eds.]

Home Correspondence.

Covent Garden in Darkness.—Can any of your readers tell the reason of Covent Garden being left in utter darkness at this season of the year? Is it intended to give the swell mob an opportunity to walk off with our goods while they are being unloaded in the dark? for it is almost an impossibility to prevent them. We commence unloading our goods about 3 o'clock, and have to grope about in the dark until daylight (about half-past 6), by which time many of the greengrocers have finished their buying. Since the lamps fell back upon the old, discarded naphtha lamps?—if so, we shall indeed be going back to the dark ages. *M. C.*

Miltonia Warscewiczii.—"C. J. W." wishes to know if more than 15 flowers have been produced on one spike of the above plant. Allow me to inform him that we have now in bloom a spike on which are 16 flowers, each measuring 1¼ inch across the lip. This is also the best coloured variety that I have yet seen. The pseudobulb which produces it is 7½ inches in height, and 4 inches in circumference, which is larger than any of the old imported bulbs I have seen. I may also state that this plant, and several others of the same kind, have flowered with us twice this season, and I believe they will do so regularly when fairly established. *E. Mitchell, Cliff Point, Broughton, Manchester.*

Hybernation of Plants.—At p. 1070 "G. H." gives a quotation from a lecture by Prof. Dyer, and at p. 1229 brings it to my notice again in a very prominent way, giving as a reason for so doing the assertion that it is so contrary to my theory of resting Orchids. I have read the quotation very attentively, and I cannot understand how your correspondent could arrive at this conclusion, except upon the supposition that he intends to make comparisons between plants that have no resemblance to each other. Let us first examine those sentences which refer to hardy plants: "There is no inherent disposition common to all plants to hybernate during the winter." Whoever said there was?—not "Ex-Cantab" most certainly. "Hybernation is forced upon them by deficiency in one of the conditions necessary to their growth, viz., warmth," so that in a mild winter trees retain their leaves and continue to grow. Quite true in many cases, but I am quite sure that Professor never intended that to apply to all hardy plants, but to certain kinds of trees, shrubs, and herbaceous plants. But, with all deference to "G. H.," I do not intend to compare a Cattleya with a Spruce Fir, an Oncidium with a Laurel, or an Odontoglossum with a Periwinkle. There is no resemblance to each other in these plants, but there is a large class of hardy plants, the Monocotyledons, many of which do somewhat resemble Orchids, both in their mode of growth and resting. The pseudobulb of an Orchid is a reservoir of nutriment for the future use of the plant, and to retain its vitality and nourish the young growth. Many herbaceous plants have reservoirs for the same purpose, but in different forms. Nearly all these plants have a most decided disposition to hybernate, and many of them do not do so for want of either heat or moisture. Many examples of this may be found in the following genera:—Crocus, Leucojum, Corbularia, Ajax, Queltia (in fact, nearly all the Narcissus group), Scilla, Hyacinthus, Muscari, Fritillaria, and several others. Now, it is perfectly well known that the foliage of these plants ripens off very early, and the plants, like some of the Orchids, are resting in our hottest season. Thus the only section of hardy plants that can reasonably be compared with Orchids confirms my resting theory in a very forcible manner. When speaking of hot climates, the Professor says that the absence of moisture produces an enforced season of rest in vegetation, but at the hottest time of the year; and adds that the habit of flower-producing needs a special season of rest; thus, as I understand it, the plant needs the rest, and Nature provides a season for it—again confirming my theory; and I am very much indebted to "G. H." for bringing this quotation forward in such a prominent way. I had promised to make a few remarks upon this subject, but this quotation has confirmed my theory to such an extent, that any further notice from me is quite unnecessary. "G. H." thinks Professor Dyer is right, and, for once, I quite agree with him. *Ex-Cantab.*

Lifting Fruit Trees in Nurseries.—In visiting a nursery a short time since I was astonished to see a newly packed bundle of Apple trees with all the leaves still adhering to the branches. On examining the wood with the principal, it was found to be shrivelling. The reason is obvious. I don't think this is a common occurrence in nurseries, yet withal I would advise those who don't know better, when orders have to be executed early, to strip all the leaves off ere a root is disturbed with the spade. It is easily done when the tree is in the ground, and while the sap is not checked; but let the tree be lifted, and the leaves allowed to remain on for a day, they are difficult to remove, and the wood, moreover, suffers materially. At this season, when Apple trees in general are green longer than usual, a timely word like this may be the means of saving a good many trees, not only Apple, but others, from injury. *H. K.*

Trees for the Yorkshire Coast.—Having a piece of ground in Yorkshire, containing about 4 acres, abutting, with a north-east aspect, on the sea, which I am wishful to convert into pleasure ground, I would feel greatly obliged if any of your numerous readers would kindly inform me, through your columns, the kinds of evergreen trees and shrubs best adapted for growing and flourishing in this exposed situation. Also the age or size they would recommend them to be planted, and the time most suitable for performing the operation. *Arbor.* [See pp. 1295, 1328. Eds.]

The Certificating New Grapes.—Your correspondent "Lynx Eye" (p. 1359) deserves the thanks of the gardening community for his remarks on the certificating new Grapes by the Fruit Committee of the Royal Horticultural Society. There is no fruit so easily raised as the Grape, and as they can be fruited in two or three years from the seed, we can afford to wait until a really good variety is proved before it is sent out. How much more would it have put into the pockets of Messrs. Lee had they kept in their really good variety, the Madresfield Court, for a year or two's longer trial before they sent it out? I have now three varieties of seedling Grapes raised from the Frontignan section,

and all, as regards flavour and size, equal to the White or Grizzly Frontignan, but I should not think of distributing them till thoroughly proved. The so-called Strawberry Grape named Ferdinand de Lesseps, and certificated by the Fruit Committee, is only a curiosity as regards flavour, and as such will remain in the limbo of obscurity. Another newly certificated Grape named Dr. Hogg may turn out to be a first-rate sort, but the Fruit Committee can know nothing as yet of its habits or permanent excellency. The Doctor can afford to wait, for you have lately, in your columns, given him a first-class certificate (his portrait). I mean new Grape should be worthy of him before it is sent out. If the Royal Horticultural Society is to fulfil its mission worthily, it should be the testing institution, to grow and try all kinds of new seedling fruits before they are sent out. There is no one better qualified to report on new fruits than Mr. Barron, the Society's superintendent at Chiswick, for he can both grow them well and give an unbiassed opinion as regards their merits. The raisers would then find the advantages of these trials, for really first-rate varieties would find a larger sale, as the public would buy them with confidence. *Vitis.*

Apple Stocks.—At p. 1264 you kindly inserted some observations of mine about the Pommier de Paradis Apple. You there make me say, "examples of this stock I have seen." I think I said, or, at least, I meant to have said, "this tree," to show how hardy it has proved amidst the almost general wreck of other kinds, meaning that it, as an Apple tree, not as a stock, did not suffer like most other Apple trees in this neighbourhood, many of which have been killed, and many more seriously damaged. I think that the error will explain what I meant. I went on to say that "the extreme hardiness of this as a stock, I should think, would tend to the healthy development of more tender kinds." I merely put this hypothetically, and I further added that "our young trees worked upon this stock this season have made uniformly good wood (I send you half a dozen sorts, to show you that what I have stated is the truth), and that I now feel satisfied that no other stock can equal it in hardihood, let the summers be what they may." This was, perhaps, too much to assert in regard to capabilities, but as regards this it is perfectly true. I have got Paradise stocks and Doucin stocks from every quarter I could obtain them, and I honestly affirm that none of them grow here with anything like a healthy growth. I have five sorts from France, and I have what they called Paradise stocks from Belgium, but I have yet to see a single Paradise stocks, otherwise the broad and narrow leaved Nonsuch, and I must say that I cannot grow them here; they are immeasurably behind what I, for want of a more distinctive name, call Scott's Paradise stock. Such is the fact, and any one who chooses it can come here and see all the sorts growing upon the same soil together. To the Editors' remarks, "We are not sensible of any general wreck amongst the Apple stocks," &c., I reply, neither am I; mine never were finer, nor the young trees worked upon them more healthy. I have now to call attention to the remarks of "Malus," at p. 1295: he asks what "I mean by the general wreck of Apple stocks?" He will see, by what I have said above, that it was not Apple stocks that I meant, but trees in gardens and orchards. "Malus" seems to think that the general wreck of Apple trees was confined to Somersetshire and Devon; if he has carefully read the columns of the *Gardeners' Chronicle*, he has no doubt found that these two counties were not the only two unfortunates. Let "Malus" turn to p. 1038, and read down the second column, headed Apples, and let him dwell upon what is there said about Hereford and Gloucester, then read all that has been said by your intelligent correspondents, p. 1039, and onwards, I then think that he will doubt his own assertions about the shining bark and grand foliage. The shining bark he can see in hundreds of orchards here, but "Where, and oh, where does the fine, grand foliage dwell?"—in very few places that I have seen this season. The only grand foliage I have seen—is upon newly-grafted trees, and young trees in sheltered places; I do not know if I am right in saying that I think I see a little *mutter purpose* in his remarks about the "poor damped mossy trees of Somerset looking as if they were tasting of death." This is such a palpably wrong assertion, that I will leave others to refute it; I only say that "Malus" might shave himself by using the bark of the trees hereabouts as a mirror. Sweeping, wholesale assertions made by unknown writers are not worth refuting, they refute themselves. "Malus" further says, that "An Apple tree on the French Paradise, at three years old, is 2 feet, and on the English Paradise 3 to 3½ feet—three years to grow 3 to 3½ feet! Why, worked on my Paradise stock, it grows over 4 feet in six months, as you will see by the specimens sent, which were budded August, 1870, or grafted this year in April. I need not dwell longer upon the observations of "Malus," excepting to say that I am no advocate for half-starved dwarfings, upon whatever kind of stock they may be worked. Give me a healthy, well-developed tree, on a stock that will grow it, and at the same time throw it into bearing; let me have a tree that gives at the same time a good growth, healthy leaves, and handsome, well flavoured fruit. These you can never get from over-dwarfed and over-pinched trees—they may serve for amateurs and children to amuse themselves with. So I may say about the cordons; neither of them will ever do much to fill Covent Garden or the Borough Markets. *J. Scott.*

Veitch's Autumn Giant Cauliflower.—I have every reason to believe that the majority of your readers are fully alive to the excellence of this Cauliflower, nevertheless I cannot see our old and trusty friend, the Walcheren, who has served us well for so many years, condemned without entering a protest. You correspondent, Mr. Morgan, must have got the very worst stock in the trade. For my part, I have been cutting the latter variety for two months, and such heads, too; I have never seen better. Allow me to tell Mr. Morgan that, for the family table, large Cauliflowers are, in my opinion, not desirable. Nice little compact heads, three to a dish, are much better for these reasons. Large Cauliflowers have often a strong and very unpleasant taste to pure palates, and small, perfectly white heads, fringed with their green foliage, look far more artistic—a point almost as much thought of as quality at the present day. *R. Gilbert, Burghley.* [Our correspondent sent samples to confirm his statements, in which we quite agree. EDS.]

Ground Vineries.—I wish to bear testimony to the continued success that results from the cultivation of Grapes under Rivett's ground vineries. Bunches of Black Hamburgh have been grown by me under them this season—by no means a favourable one—up to 2 lb. 6 oz., and Black Prince up to 1¼ lb. They were perfectly finished in every respect, the Black Hamburghs by the middle of the second week, and the Black Prince by the middle of the first week of October, being later than usual. *A. Boyle, South Wales.*

The Potato Disease.—As a means of preventing the spread of the disease amongst Potatos after they are raised, I was advised to have recourse to a remedy which I, as an unlearned, practical gardener in America, the plan being to strew some slaked white lime amongst them as they are deposited in the cellar or storeroom; and having acted upon the advice, I am pleased to say that up to the present time the experiment appears to have succeeded. I was told by some one to whom I mentioned this, that lime would be likely to impart to the root a nauseous flavour, but it seems to me that, on the contrary, the flavour is improved if anything by it. The Potatos are apparently rendered by it more "mealy," or "floury," than was the case previously to the sprinkling of the lime with them. I am informed that if a Potato which is but partially diseased be placed in slaked lime the disease will not extend itself further in it. *R. Bond, Tredegar.*

Onions.—Some years ago I was residing a short distance from Aldermaston, and I had, attached to a large garden attached to the house, I set myself the task of cultivating it without assistance, and it so happened that during this time the Potato disease was prevalent more or less; and entering fully into my occupation, I endeavoured to find a remedy for this mysterious disease. I was thought that the cause arose from a deficiency of its proper aliment in the soil, and with this idea I considered that I might remedy it by planting the Potato in soil in which nothing had ever grown before; at all events, I resolved to try the experiment. The garden being a gravelly soil, I had recourse to the following: working the entire surface, about two spades' depth, there was a thick layer of an intermediate soil on the top of the gravel, and which was too far below the surface ever to have been used or turned up in cultivation, I got out a quantity of this, and it being very much like a riddled lime, when planting the Potatos by trench, I applied sufficient of this soil to cover the sets, and the result far exceeded my expectations; the tubers were not only entirely free from disease, but very clear and delicate, and also of improved flavour in eating, whilst others planted in the ordinary way were diseased. I pursued this plan for several years, with always the same results. The soil at my present residence being a clay, does not afford the means of continuing the experiment, and the disease not having appeared for some years rendered it unnecessary. *W. F., Kidderminster.*

Ablaqueation.—It is to me most interesting to see this favourite operation of John Evelyn, one which he practised 200 years ago, alluded to by Mr. Ellison (see p. 1355). I remember, when I was young, stumbling at the term—thinking it was a technical and not a dictionary word. The term is often employed by Evelyn in his "Kalendarium Hortense." Webster renders it "a laying bare the roots of trees, to expose them to the air and water." Evelyn, in his "Kalendarium" for October (mine is the 6th edition, 1676), says "Now is the time for ablaqueation, and laying bare the roots of old and unthriving, or even hasty blooming trees." This seems the opposite of the practice Mr. Ellison advises, for Evelyn seems to wish to give vigour to unthriving trees, or those even hasty in blooming, which, I presume, means trees that are inclined to blossom prematurely. I have read most of Evelyn's works, but have never come across any passage in which he describes the effect of ablaqueation. It seems not to have been practised by our gardeners—perhaps for a very good reason; still it would be interesting to know what the operation, like root-pruning, will bring on fruitfulness in trees. The "Kalendarium" for January says, "Uncover as yet roots of trees where ablaqueation is requisite," so that it seems to have been practised all through the winter. The time to cover them up he gives under March, in which he says, "Cover such tree roots as you laid bare in autumn;" but he does not mention the effect of uncovering the roots during the winter. This will be a question to put to rest by some of your contributors. Mr. Ellison says the base of the roots only should be laid bare, and it seems for a length of time. In my experience I have found that uncovered roots for a season or two form buds and shoots, and this with a grafted tree would prove injurious to the graft. But I confess to never having tried a winter's ablaqueation, which could not do much harm, and the experiment may at once be tried by fruit tree cultivators. It is curious to observe the dearth of good Pears 200 years ago. The Pears for November are few as compared with the hundreds of Pears now "in prime and yet lasting." Evelyn's list is as follows:—"Massive Pears: Long Bergamot, Warden (or Saline), Rennet Cot, Sugar Pear (I suppose Sucre Vert), Tardy Pear, Ice Pear, Dina Pear, Deadman's Pear (said in December to be 'excellent'), Winter Bergamot (I suppose Bergamotte de Paques), and Bell Pear." Most of these Pears would, I think, require iron teeth and a leather stomach. *Thos. Rivers.*

Tomato Preserve.—Having a quantity of Tomatos, which have no chance of ripening, I have tried your correspondent's recipe (p. 1328), and so far as my taste goes, I can speak well of it, and decidedly agree with making the preserve in preference to leaving the Tomatos to the mercy of "Jack Frost." I find that the Trophy Tomato is rather a late variety, large, and very smooth, consequently it makes an excellent variety for the purpose, as no difficulty is experienced in peeling them, as there is with other varieties. *E. Morgan, Harrow-on-the-Hill.*

Orchids.—A letter at p. 1329, from your excellent correspondent, Mr. MacPherson, suggests that some "hard-working botanical gleaner" should address himself to the task of collecting and tabulating particulars as to the elevation at which Orchids grow in their native countries; also as to the temperature and the rainfall of the respective districts—this with a view to supplying cultivators with the means of gaining clearer ideas, or at all events more uniform and definite opinions, as to the best modes of growing their plants, than they appear to possess at present. I shall be glad to do my best towards carrying out this capital suggestion, and to put myself in correspondence with any gentleman who may be disposed to co-operate; and, as I am probably unknown to many of the Orchidologists among your readers, allow me to say that I have for many years given attention to Orchids, and that I am now engaged upon a little volume treating of these plants. Whether to me that work is to be may in England, comparatively little can be done without aid from collectors abroad, and from gentlemen residing in Orchid countries. Could not some kind of official circular be addressed to those who are known to be interested in Orchids, and especially to Curators of Botanic Gardens in the East and West Indies, &c.? Perhaps it might not be thought wide of the functions of the heads of our botanic gardens so to communicate with foreign curators and others. Surely all would be willing to assist in an inquiry so valuable, not only from a purely to physical science. The *Gardeners' Chronicle* might be disposed to invite the attention of its foreign readers to the value of the services which they may thus be able to render, and serve as a medium for their communications. *Leo Grindon,* 71, *Rumford Street, Manchester.*

Blackbirds and Thrushes.—I am afraid that it is not generally known by those who destroy these sweet warblers and their nests that these birds do a great deal of good—I have found them particularly useful the past season in carefully keeping clear our pleasure-grounds from worms by their constant feeding on them; so, with the aid of our little friends and Green's mowing machines, our lawns, which are several acres in extent, have been the admiration of all who have seen them. *F. J.*

The Seaham Hall Trial of Peas.—The criticising remarks of "A. D." at p. 1294 on the trial of Peas at Seaham Hall are not devoid of interest, though some of his comments are not flattering to the conductor of the experiments, as he seems to doubt the accuracy of dates and figures. In answer to such an assertion, I beg to say that the experiments were conducted with great care and attention, all particulars of each variety being daily noted. The following statement may be of interest to show the way in which the trial was conducted. Each sort was sown in rings 3 feet in diameter and 3 feet apart. As soon as the first 24 flowers appeared on any variety it was marked as in flower, it being my object to have a fixed period of their flowering. I considered an early stage of flowering a good period to note. As soon as the Peas attained the size of Barley, or so, they were marked as ready; after that time of growth every particular of their character was noted daily. I cannot see how the trial has been robbed of its value in consequence of the dates and figures. I think it is of more interest, as it reveals to "A. D." the character of each

variety in a wet season. The advice which "A. D." gives, as to how to test the value of Peas, no doubt would be of much interest if he would publish his trials in the southern climate. It is remarkable that "A. D." from his close scrutiny, should not have found out that periods of blooming in Peas afford no real guide as to periods of cropping. It is well known that different varieties are not of the same growth and constitution, therefore different periods from flowering to being ready might naturally be supposed to exist. The remarkable diversity, as "A. D." finds with Peabody, is not like cases; as I find from my note-book that the time of flowering is July 1, instead of June 1, a mistake either of my copy or of the printers. The reason why my remarks of commendation are general and superlative are because I find only two kinds that I consider inferior. The tall kinds are good to those that have plenty of time, stakes and ground to spare. Those that I consider too tall are kinds that have grown with me from 4 to 5 feet before they begin to pod. Therefore I cannot recommend them. I find that "A. D." agrees with me in stating that dwarf Peas are the best, but I doubt if ever we shall find Multum-in-Parvo to beat Little Gem, as the former requires stakes. Experiments of this kind, whether conducted at Chiswick or in the North, will always be of interest, and private trials will always carry their weight, and no doubt are safe and reliable.—Mr. Eastes writes to know from what firm I obtained the Carter's Invicta Pea. I beg to say that the so-called Carter's Invicta Pea was given to me by a private grower, and he writes to me to say that the Pea was supplied by Messrs. Carter & Co., but that the addition of "Carter's" to the name was by some means an error on his part. *Robert Draper, Seaham Hall, Sunderland.*

Rock Plants for the Sea-coast.—Nobody having given the information sought by Mr. Miller, I therewith append the names of a few plants suitable for the situation indicated by your correspondent:—Cotoneaster thymifolia and *C. microphylla, Euonymus radicans foliis variegatis, *Coronilla varia, Berberis empetrifolia, Eryngium sp., Cistus, dwarf species, Helianthemums, Armeria vulgaris, Iberis, various species, Sedums, Sempervivums, Silene maritima, Stocks, Wallflowers, Koniga maritima variegata, *Lavatera arborea, *Saponaria officinalis, Lathyrus latifolius and L. sylvestris. This list might be extended almost indefinitely by persons of longer experience in plant-growing by the sea. Those preceded by an asterisk require considerable space. *H.*

Mixed Bedding Plants.—I can fully endorse your correspondent's statement (p. 1295) respecting Viola Perfection as a "mixed bedding" plant. As such it is indeed a gem, but we must not confine its usefulness to mixing only. It is suitable either for mixing, massing, bordering, or ribboning, in almost any position, or in almost any soil. If Mr. Gardiner or "A. D." when at Hatfield Place had spent a few miles further south to Rotherfield Park, the very place where the plant in question was raised, and where its raiser exhibits so much taste and skill in its display, they would have had ocular demonstration, not only of its usefulness as a mixed bedding plant, but of its exquisite grouping in every form above described. It contrasts well with anything, and will no doubt be extensively used when better known. I believe at the present time the true stock is not generally known, there being so many counterfeit varieties in circulation, which cause great disappointment. Viola Queen, which is an account of a new Viola called Lavender Queen, raised by Mr. Speed of Chatsworth, and of which your correspondent, Mr. Read, speaks in flattering terms. Should it prove to be what he describes it, it will, I am sure, be eagerly sought. This induces me to direct your attention to another seedling Viola, which I saw when on a visit to Rotherfield Park. It was raised by the successful introducer of Viola Perfection, and if my memory serves me right, he has rightly named it Viola Enchantress. It is of a rich dark velvety purple colour (as near as I can describe it), of extraordinary substance, with stout flowers and foliage, and moreover, beautifully scented. It eclipses anything I have hitherto seen; and, from the description given of Mr. Speed's Lavender Queen, I am of opinion that the two would make an excellent combination,—a fact which, however, can only be proved when they are before the public. *E. Morgan, The Butts, Harrow-on-the-Hill.*

Agaves as Decorative Plants.—How is it that the nobler forms of these plants are not more used for subtropical work in the parks? I have often been surprised to see such tender subjects as Musas put out for the winds to sport with, making them look about as happy as the tropical birds in the Zoological Gardens on a winter's day, while the many hardy and fine plants to be found amongst the Agaves are almost neglected, though they can be wintered better, and will stand all the cold and rain we get from May to October. A. americana, and its varieties, variegata and striata, A. Jacquiniana, Salmiana, pottatorum, and Fourcroyoides, are the best for positions where large plants are required. There are many dwarfer growers that can be used with advantage, either in vases or in the open ground; many beautiful varieties of A. Verschaffeltii, also A. Seemanni, A. univittata and A. coerulescens may also be used to give variety, as they look well in all weathers. The best for vases are A. filifera, A. geminiflora (known under the name of Bonapartea juncea) and A. striata. Until lately the number of Agaves was thought by many gardeners to consist of about a dozen species, for although a few collections have existed in this country for some time, until lately the number of species and varieties has been small in comparison to what they are now, amounting to about 170. Many of these are quite new, and amongst them are some imported seedling varieties. There is a great diversity of form in the seedlings, in those of A. Verschaffeltii especially, and which seem to vary more as they get older, both in shape of leaf and spine, and in the tint of foliage, some being almost white and others green, the spines in some being black, in others almost yellow, while the margin of leaf in some is set with small spines, others have deep indentations, and are furnished with desperate teeth. From New Grenada has come a set that have been named horrida and Roezlii, but out of 50 plants one cannot find two alike. Another beautiful species is A. Bessereriana, the plant being almost white, with black spines, growing about 2 feet through, and 1 foot 6 inches high, with the same tendency to vary. The leaves of full-grown plants differ so much in length and shape that one might be excused if he called these distinct species. We now know examples of the mutation of species—deserving even of Mr. Darwin's attention. If we get seedlings of the older species they invariably come true. The same tendency to sport may be seen in seedlings of Mammillaria spinosissima, though other species come true; and in Echeveria and Sempervivum we may lean for lot of seed, you get five or six varieties. This tendency to sport in some species has caused botanists to give two or or three names to the same plant, and if nurserymen fall into the same error, we must not complain; but it would much aid us if more caution were observed, though caution should not lead into the other extreme, by saying, because one species varies, all do, for though Mesembryanthemums seem very near in habit, yet I have never seen a sport, though I have raised thousands from seed. *J. Croucher, Gr. to J. T. Peacock, Esq., Sudbury House, Hammersmith.*

Coning of Cedrus Deodara.—I have seen several young trees this season, from 6 to 8 feet high, bearing cones, and I have also observed the same thing in young specimens of Wellingtonia gigantea. *H.*

The Premature Bolting of Green Crops.—Mr. Earley has done good service by calling attention to this matter. There can be no question about the fact. From the early days of spring, when the winter Cabbages bolted, in many cases in whole battalions, down to the touring rains of one of the wettest summers we have had for years, this tendency to bolt has been constant and well-nigh universal. Perhaps no crops have suffered so much as Cauliflowers, they seemed to bolt, to use an Hibernianism, before they were formed; in very many instances the flower never left form and size, and even in the case of small patches, instead of turning in or setting together closely, as a good Cauliflower ought to do. With the exception of the spring Cauliflowers wintered under glass or raised in the spring, I have seen but few perfect heads this summer. I have lately seen some fine looking lots of Veitch's and Sutton's varieties, but whether they will keep close or sprawl it is yet too early to say. Most of us are familiar enough with the bolting of Cabbages, Cauliflowers, &c., but generally the heads close in first, and open and bolt afterwards. This season they have sprawled and bolted from the beginning—a very important difference, and one also that makes the malady of this season more difficult to cure, and its cause more mysterious to unravel. This also strengthens my belief, to use the words of Mr. Earley, "that there is in Nature something which influences the aftergrowth of plants before the set time arrives for the secret to be unfolded" (see p. 1231, col. *a*). What that something is seems difficult to discover. Mr. Earley almost says it is the most felicitous condition of growth. But he concludes with querying why plants should assume this remarkable habit then, when surrounded with those suitable conditions? Greater force may be added to this query if we put it thus—Why should plants surrounded with the most felicitous conditions of growth run to seed prematurely? For it is a fact that the majority of the plants that bolt are undersized. Had they reached maturity and a maximum size, fostered with felicitous conditions, one could easily have understood their rushing into seed; but they throw their vitality into seed-bearing before they are half grown. This fact seems to point to a check, not a stimulus, as the cause of premature bolting, such as we have had this season. Have we had any such checks? We have, all through the season. The changes this season have been less from drought to an excess of water, than from moderate heat to excessive cold. We have scarcely been a month throughout the season without frost, and the loss of heat from evaporation has been tremendous. I believe these changes of temperature have checked growth, and forced the plants to bolt. Possibly this theory will be confirmed by noting the crops that have bolted most freely—Carrots, Cauliflowers, Sugar-Beet, Mangels. As far as observation has gone, Parsnips, Swedes, Turnips, Onions, Borecole, and Broccolis have not run so freely. What then? Only this, that possibly they were not so susceptible to atmospheric changes. I admit, however, that it is rather premature to write positively of the new crops of Broccoli. Only looking over them, the stems of many near the base of the leaves look rather too fat and lumpy, as if they were gathering up their energy for a bolt. I hope this may not prove to be the case; but if it should, I think a frost-bite in their seed-bed, which all of them had, is much more likely to induce premature bolting than the most felicitous conditions of growth. *D. T. Fish.*

Skinned Fruit Trees.—Your advice to a correspondent respecting the skinning of fruit trees by rabbits, at p. 1267, has recalled to my mind an experiment which I tried last spring on two Apple trees. These were selected as the two worst, out of an orchard which had been attacked by rabbits. They had all the skin peeled off, and had the appearance of being scraped to the extent of from a foot to 15 inches all round. I cut some thin turf and tied around these parts, placing the earth side next the tree, and kept the turf moist in dry weather. To-day I examined them, and I find a layer of bark has formed all round, though very uneven, as if inclined to form roots, which shows perhaps that I ought to have taken off the bandage before. The trees meanwhile have made wood, and have buds formed for a good show of bloom. *H. M.*

The Hybridity of Willows.—Expecting to find that many planters would be able and ready to reply to the Rev. J. E. Leefe on this subject, I allowed it to pass by without comment, the more especially as the matter would have received notice in my book on the "Salix or Willow," now in course of publication. I was aware that the question was a disputed one, and also that few botanists seemed very clear about it; but the same may be said of everything connected with the genus Salix. There are seedlings innumerable now growing in my nursery at Hadzor Hall, and have great pleasure in sending the Rev. J. E. Leefe a few in different stages of growth for his satisfaction, should he desire it. I have them from many species of Willows, and some have been crossed and recrossed, and are now grown for regular trade purposes. I would suggest that the Rev. gentleman and friend at his friend have not succeeded in producing them has been chiefly from the want of shade and moisture. I have not succeeded in obtaining them from Willows of greatly dissimilar character, although by recrossing I have now intermediate varieties between several species, as between the purpureas and the viminalis, S. fragilis and S. viminalis, S. lacustris and S. rivularis, S. triandra and S. amygdalina—in fact, I am driven to the conclusion that the species of Willows are comparatively few, but the number of varieties innumerable, and that many of the now called species are only varieties. *William Scaling, Basford, Notts.*

Hornets.—Your correspondent, at p. 1358, asks for any information respecting the hornet. It is well-known that the hornet builds its nest in any hole in a tree, house, or other structure, provided it is dry and there is a cavity below or outlet from the bottom of the position where the nest is placed or suspended. This seems to be necessary for keeping the nest dry, or, as Mr. Lee remarks, the sap flows out in large quantities from the tree. This moisture is not water, but the tree, it is the excrements which are passed from the body of the insects. If you could see a hornets' nest, suspended by the insect itself, there would be a large opening at the bottom of the nest; and, as the insects need, they come down to this open part of the nest for the purpose of passing the moisture above referred to. I, only a few days since, found a hornets' nest in an attic, suspended like a small balloon, with the opening in the bottom, from which I carefully watched the hornets. The moisture from the nest was so great that it penetrated the first floor and continually dropped down on the second floor. What this moisture contains, chemically, or whether it would be injurious to any living tree and likely to cause its death, I do not know. If your correspondent would dip some tow in spirits of turpentine and place it in the hole as close to the nest as possible, and stop up the hole so that no moisture could ooze, I have no doubt the hornets would be destroyed, and the tree would certainly not be hurt by the turpentine. *P. Fry, Addington.*

The Champion of Scotland Pea.—No one can doubt the usefulness of both trials of plants and vegetables, and particularly Peas, as unfortunately very few gardeners have the opportunity of trying so many sorts as Mr. Draper has done. His remarks on the qualities of some of them show a great difference from what they are in the neighbourhood of Manchester, and particularly so the Champion of Scotland, which Mr. Draper characterises as bad in flavour, and cannot be recommended. This Pea was sent out, if I remember right, by Messrs. Lawson & Sons, of Edinburgh, about 10 or 12 years ago, at which time I ordered 1 quart, and sowed them and the Champion of England both the same day, and side by side. The difference between them in being ready for gathering was very slight, the English Champion being a little earlier and rather lower in growth, but the Scotch Champion commenced podding much nearer the ground, with larger pods, well filled, and more in

number. When we sent it to the kitchen my master, whose favourite vegetable was the Pea, considered it the finest and best flavoured he ever tasted, and wished me to grow a good quantity of it another year; ever since then the best half of my order for Peas has been the Champion of Scotland. When the Royal Horticultural Society held its show at Manchester I exhibited in three classes of vegetables, viz., in the classes for 12, 8, and 6 dishes, and was awarded the 2d prize in each of them. I had a good dish of the Champion of Scotland Pea in each class, and on the night of the second day of the show I met Mr. Baines, then a neighbour of mine, but now at Southgate, who said, "I don't think they have left you a single Pea among all the three dishes; there were the empty pods, but those splendid Peas in the 1st prize collections, called Snowden's Nonsuch, are scarcely touched." Some pods were opened, but the Peas not taken out, as was the case with many other good dishes of Peas shown. The Scotch Champion had been tried in flavour I think he would not have received so much favour from the public. Therefore I conclude Mr. Draper could not have had the true article, as there are few Peas, under good cultivation, that will give the grower greater satisfaction in every point than the Champion of Scotland. *James Smith, Gr. to Wm. Blinkhorn, Esq., Waterdale, Sutton, Lancashirer.*

Madresfield Court and Golden Champion Grapes.—How widely the report of your correspondent "R. D.," on the merits of these two Grapes, differs from my experience. First, I would refer to the Madresfield Court, which we have growing in a late vinery, budded on a Vine of West's St. Peter's, a young plant headed down specially for its accommodation. So far as vigour is concerned, no stock can be more desirable. We have had it in a bearing state for two years past, and each season, contrary to anticipation, it has completely deceived me. The bunches and berries are large; nothing whatever appears to be amiss till just before the ripening process is completed, when atrophy overtakes every berry, the skin begins to shrivel, and so continues to collapse till the flesh is consumed, leaving behind nothing but withered husks. Let it not be imagined that such a defect is brought about by either an excess or a deficiency of water, as nothing of the kind has occurred. The roots are confined exclusively to an inside border, and hence completely under control. In the same house, and treated exactly alike, we have West's St. Peter's, Black Lady Downe's Seedling, White Tokay, and the Mrs. Pince, budded on the Black Hamburgh, producing fruit in every way satisfactory. Now, what question can be asked, if there is no constitutional defect in the Madresfield Court, why should these other varieties do so well? In a midsummer vinery, where the crop ripens about the middle of July, we have this kind budded on the Black Hamburgh stock, and find the result to be exactly the same as in the preceding case. Here we had no difficulty whatever in growing excellent White Muscats, and several other varieties requiring a considerable advance of temperature above our late vinery; so we are, I think, not justified in attributing any defect in the Madresfield Court, to an insufficiency of heat. Most gardeners of experience will admit that, quite independent of cultural ability, some of our Grapes succeed well on a particular kind of soil, but remove them to that of a different character, whether physical or chemical, and the quality of the fruit will just be in proportion to the change of circumstances. Such being the case, I do not for one moment question the accuracy of "R. D.'s" report; but this I may say, that a Vine of a fastidious habit, however excellent the quality of its fruit may be, can never benefit the country at large. We have as yet no certain knowledge of the influence exercised by the stock over some varieties of the Grape Vine; that there does exist an active power of some kind is beyond doubt. Some years ago I had the Alicante worked on the Black Hamburgh, but instead of deriving any advantage from the union, as I had expected, the very reverse happened. Vitality was much reduced, and the berries exceedingly small for that kind when nourished by its own roots. I made another experiment by having the White Tokay grafted on the Black Hamburgh, the Vine abated none of its vigour; but instead of the berries being oval, which is their true character, they were round, more crisp in the flesh, and smaller in size. Did time and space permit, I could bring forward numerous cases, selected from our hardy fruit trees, where the grafting of one kind of Pear or Apple upon another variety not only hastens or retards maturation, and sometimes produces barrenness. [Pray do.] My first introduction to the Golden Champion was at the Manchester meeting of the Royal Horticultural Society, and certainly the sample exhibited was not by any means calculated to engage the attention of purchasers. But in opposition to appearance I ordered a plant, and had it budded on the Black Hamburgh. The first year's produce was by no means encouraging, several of the berries were spotted, and consequently decayed, so I began to believe that the adverse opinions in circulation against it were quite true. This season circumstances have changed very much. We have hardly had a faulty berry; certainly not more than is usually to be met with. Some of the bunches exceed 3 lb. in weight, the berries exceeding 4 inches in circumference. True to its name, the colour was excellent and the flavour good. So much has this Grape improved in my estimation, that I propose to increase our stock, destroy the Madresfield Court, and substitute the Mrs. Pince, which, whatever may be said to the contrary, is an excellent Grape. The Golden Champion, like the Golden Hamburgh, for the production of large bunches, requires to be treated on the long spur or long rod system of pruning, and to finish off the fruit well should have a strong heat equal to that given to the Muscat. *Alexander Cramb, Tortworth.*

Foreign Correspondence.

GHENT: *September.*—This with its 200 horticultural establishments, must be the very paradise of nurserymen, and yet it does not seem by any means to have any exceptional advantages. What can have induced so many to prefer their establishments here than at Antwerp or Brussels? Yet so it is, and with a light and sandy soil, with a climate which must be cold and damp in winter, the Ghent nurserymen have managed to gain for themselves a reputation which is world wide, and a success in some special forms of culture in which they are wellnigh unapproachable. Where, for instance, are Camellias done as they are here? I have seen, doubtless, as fine plants elsewhere, but for quantity, for neatness, for vigour of growth, especially in small plants, we in vain look elsewhere for a parallel. It is from hence that the enormous numbers of small plants that fill our London nurseries and Covent Garden in the season, come—"innocents," too often, not indeed "born to bloom unseen, and waste their sweetness on the desert air," but doomed to the gaze of the company in crowded gas-lighted drawing-rooms, and then to perish,—for hardy as the Camellia is, it will not bear all this; and then in Palms, in Cycads, in Agaves, where can we find anything like the amount or success of cultivation that we can in the Ghent establishments.

Amongst the many "Vans" and "Vers," the Van Houttes, Van Geerts, Vervenne, Vandercruyssens, &c., who knows not the Van Geerts of Ghent? Where, for quantity of Verschaffelt has long been honourably distinguished; the establishment of M. Ambroise Verschaffelt, which has now passed into the hands of M. Linden, and that of M. Jean Verschaffelt, of which I now write, are amongst the foremost of their class, and both in the great International Exhibition of 1866, and during the present season, the latter has shown the capabilities and resources of his establishment to the frequenters of the London shows, while the genial character of its proprietor has won for him many friends when he has come among us. The establishments, while not on so extensive a scale as Van Houtte's or his consin's, is yet one of considerable magnitude, and the cultures to which he especially devotes himself are carried on with great care and energy, and he is continually importing from Mexico, Brazil, and other countries large specimens of many of them. Orchids are not much cultivated in Belgium, excepting at M. Linden's—whose collection of 1200 species is perhaps unrivalled—to the same extent as in England. There are not so many amateurs, and the plants are, generally speaking, smaller. Many of the finest in vain look for such Orchid-houses as Veitch's, Williams', Bull's, or Rollisson's; but M. Verschaffelt grows his at a moderate temperature, so that plants from here are the more likely to thrive than when grown in a higher temperature; but in his Orchid-house I noticed a few remarkable things. There was, for instance, a new plant from Guiana, somewhat in appearance like an Alocasia, but with leaves of such a substance that they might be very easily taken for leather, while the leaf-stalks were like those leathery stalks of seaweed so common on our coast; the species was, however, rare even as yet to be known. Here also were quantities of the curious Tillandsia argentea; some placed on the dead trunks of Tree Ferns looked remarkably well—in fact it seems most accommodating, for M. Verschaffelt assured me he had grown it in all sorts of ways, but preferred it on the dead trunks of the Tree Ferns, and never lost a plant, while he has got a large number of young plants; so that, rootless though they be, they multiply freely. Here also were good plants of Plumieria bicolor, an Apocynaceous plant, white with yellow centre, very free flowering, and likely to be very useful as an ornamental plant. In another house I noticed some magnificent plants of the fine Crinum amabile, one of those fine old plants which novelties have elbowed out of the way; also a very remarkable Hemerocallis, with variegated foliage, one half of the leaf white, the other green, and which so curiously formed a growth, that looking at the back of the plant it seemed to be all white, and in the front all green. There were also some grand plants of Musa Ensete, a plant so valuable for subtropical gardening from its showy appearance and rapidity of growth.

But the greater portion of the houses here are devoted to the growth of Palms, Cycads, Tree Ferns, and similar ornamental foliage plants, which are so much more valued on the Continent than with us—and magnificent indeed are some of the plants; while Palms for the million is no idle word, for here we see pots of Chamærops excelsa with 50 seedling plants for sale at 40 fr.; Phœnix dactylifera, the same; while Latania borbonica, Corypha australis, Chamærops Fortunei, were to be had by the thousand. Of Zamias there were some magnificent specimens, both home-grown and imported specimens; amongst the most remarkable were Altensteini, cycadefolia, horrida, and the very striking Lehmanni. I do not wonder at the admiration which these plants excite amongst the Continental horticulturists, and do very much wonder that those who have large conservatories with us do not grow them more than they do. Of Tree Ferns there were some fine specimens of Cibotium princeps, Dicksonia antarctica, Cyathea dealbata, and dealbata excelsa, although some of the large plants had just been sent away. The collection of Agaves is wonderful. M. Verschaffelt cultivates upwards of 100 species, and they are to be seen in all sizes, from the tiny seedling plant to large specimens. Of the latter he has some, such as dentata, for which he asks £40; of horrida (well named) an unique example; Kerchovei and Kerchovei macrodonta, very large; dealbata nana, very remarkable; laticincta, a dwarf species, a bright lustrous green, largely variegated with white; Nissoni, with a large, deep, golden-yellow line in the centre of the leaves; Verschaffeltii, of which there is a large quantity of imported plants, and one with golden-yellow bands on the leaves; while pulverulenta, filifera, univittata, marginata, and other fine varieties, were to be seen in all sizes. Amongst them was a plant which had all the appearance at first of an Agave, but which was in truth Echeveria agavoides—one that is destined, if subtropical gardening holds its own with us, to be brought into extensive use. There are a couple of plants of it at Kew, and at another place on the Continent, but otherwise it is confined to this establishment. It was found impossible to propagate it in any way, but M. Verschaffelt received a quantity of seed from Mexico, and he has been enabled to raise a considerable quantity of young plants; out-doors it crops a little beautiful rose margin, and I cannot but think that it will be a very interesting addition to our succulents for summer gardening.

Passing to the out-of-door department, I saw a large quantity of those beautiful standard and pyramidal Bays, Portugal Laurels, and others for which the Ghent nurserymen are so famous, and which they do so well. Some plants here are worth 600f. the pair, and for terraces, for public places, where a regular form is desirable, they are admirably adapted. The standard Orange trees many saw at Kensington not long ago, and although much admired, they did not find, as the Agaves did, purchasers. There were immense quantities of Dracæna indivisa, Camellias of all sizes, and the other cultures of a Belgian nursery. There were also some very beautiful varieties of the variegated form of Phormium tenax; two were especially noticeable—Cookii, dwarf, very pretty, and distinctly margined with brown; and one unnamed variety, with a splendid band of a rosy-yellow hue. There was also a variegated variety of Gnaphalium lanatum, which will be useful as a bedding plant; it is very free and very pretty. While speaking of the outdoor department, I should say that M. Verschaffelt speaks in very warm terms of Delphinium nudicaule, introduced by Mr. Thompson, of Ipswich, considering it to be one of the best introductions of late years for the herbaceous border.

I have thus endeavoured to indicate some of the more remarkable features of this establishment, feeling, of course, that it is impossible in such a sketch to do anything like justice to its resources and the value of its cultures, but at the same time desirous of informing those who have not visited Ghent of some of those special cultures for which it has become famous. *D., Deal.*

Notices of Books.

The Lichen Flora of Great Britain, Ireland, and the Channel Islands. By the Rev. W. A. Leighton, Shrewsbury: printed for the author, 1871. 8vo, pp. 470.

This is a book which will find its way directly, as a matter of course, into the hands of every one who is interested in the very difficult class of plants of which it treats. The author is a veteran worker in the field, and well-known as a thorough master of his subject. His monograph of the British Arcaspros Lichens, published by the Ray Society in 1851, with full dissections and drawings of the spores of all the species, marks an era in its literature. He was one of the very first to bring to bear upon Lichens the full resources of the most advanced microscopes, and to recommend that careful and systematic study of the spores which, during the last generation, has completely revolutionised their species limitation. Since his first work he has published an extensive fasciculus of specimens of the British species, and many detached papers in the "Annals of Natural History" and Transactions of the Linnean Society. It was quite expected that he would undertake many years ago a general handbook of the British species, but he has delayed to do this till the present year, and in 1861 a Manual was published by Mr. Mudd, now curator of the Cambridge Botanic Garden, in which all the species then known in the island were excellently marshalled and described. From the recondite nature of the subject and the delicate manipulation required to see the spores, there are probably fewer students of Lichens than any other class of Crypto-

gamic plants. Perhaps in the whole country there are not more than from half-a-dozen to a dozen collectors now living actively engaged in studying them, but the zeal and energy with which they have worked may be gathered from the fact, that since Mr. Mudd's book appeared the number of species known in the country has been increased more than 50 per cent., what was 500 in round numbers in 1860 having been augmented to nearly 800 in the present work.

The state of the classification of Lichens much resembles that of Ferns. There are two schools of classifiers, both agreed substantially as to the circumscription and definition of groups higher than genera, but differing materially in the number of genera they make and the kind of characters on which they found them. Mudd, like Hoerber and Massolongo on the Continent, was a "splitter" of genera, not keeping together in the same genus species with asci and spores decidedly dissimilar in character, and in consequence using new names copiously. Leighton follows Nylander almost implicitly, making much fewer genera, retaining, for instance, Lecidea, with 233 British species intact, and not deviating conspicuously in this respect from the path chalked out by Acharius and Fries, except that, of course, the genera of the older writers, which are now to be subdivided, like Lepraria, are rejected. In Lichens, fortunately, the two schools do not differ materially in the number of species they admit, both being willing freely to characterise and name a host of forms which exist with a comparatively less clearly marked individuality under the heading of varieties. If these are counted the number of forms now known in Britain does not fall far short of a thousand. But besides the difference caused by the added species and a different plan of genus-limitation, there is another important innovation in the work of 1871 as compared with that of 1860, as Leighton, here again following Nylander, brings chemistry into requisition, using largely as characteristic the results obtained by treating the thallus with hydrate of potash and hypochlorite of lime. It is very rarely that he makes species founded solely on chemical grounds, but he considers that chemical character will furnish a great help in their discrimination, and in some cases, as in Parmelia, founds his sub-genera entirely upon them.

The geographical distribution of the species is worked out very carefully. The author traces each of them through Britain by means of the botanical provinces used in Moore and More's "Cybele Britannica," and through Ireland by means of the similar divisions used in Moore and More's "Cybele Hibernica." He gives special stations copiously, with the names of the authorities on which they rest, and devotes a line to an account of the general world distribution of each species. So that although we know really far less about the dispersion within our island of Lichens than of Mosses, we have now that of the former much more thoroughly worked out, and the blanks with what filling up for each species, clearly shown. The parts of the island which the author mentions as still almost unexplored, are the whole of the north and north-western counties of Scotland, including the Hebrides, Orkneys, and Shetland isles; nearly the whole of the north, north-west, and midland counties of Ireland; in England the counties of Cheshire, Lancashire, Derby, Nottingham, Lincoln, Stafford, Hereford, Monmouth, Gloucester, Warwick, and Northampton; the whole of South Wales, and large districts in North Wales. He intimates that he will gladly receive Lichens from any of these tracts, and that he intends to prepare a census of all the Lichens hitherto discovered throughout the world, and that he proposes to issue shortly new sets of specimens, containing from 150 to 200 species, to illustrate the principal genera, and that for both of these two last named publications he is ready to receive the names of subscribers.

The point which strikes us in glancing over the book as most open to criticism, is the little pains that have been taken to adapt it to the requirements of beginners. When we get down to species the descriptions are by no means unnecessarily curtailed, but many terms are used which are entirely peculiar to modern Lichenology, and there is no glossary or general explanation of organography, and the range of structure in the different parts of the plant, such as is carefully given both by Nylander and Mudd. The introductory key to the tribes and genera, which is most important in such a book like this, is so drawn up that it is often quite impossible to understand their essential characters by using it alone. Take for instance the six series of Lichenacei, the family including more than seven-eighths of the species, which stand as follows :—

Series 1. *Epiconiodei*.—Spores pulverulent on surface of fructification.

Series 2. *Cladodei* (no doubt a misprint for Cladeniodei).—Thallus foliolose; apothecia terminal on podetia, bratorine.

Series 3. *Ramalodei*.—Thallus efoliolose, puticulose, or filamentose; apothecia lecanorine.

Series 4. *Phyllodei*.—Thallus foliaceus, depressed, lobed.

Series 5. *Placodei*.—Thallus crustaceous, squamose, radiate, granulose, powdery, or evanescent.

Series 6. *Pyrenodei*.—Fructification in closed receptacles.

Who would gather from this that is intended in the first instance to establish a contrast between the open disciform receptacle of series 1 to 5, and to contrast it with that of series 6; that next, attention has to be directed to the difference between Lichens with exposed spores, and Lichens in which the spores are permanently contained in asci, and embedded inside the disc of apothecia, as in series 2 to 4, and that series 2 to 4 agree with one another essentially in the nature of the fructification, but differ mainly in the habit of the thallus? These are points that should be clearly brought out in the key, for they are the very first things which a student of Lichens needs to be taught, and which, when he gets a book of this kind, he expects to have clearly explained to him. No doubt it is better able to unfold these connecting points than the writer of this handbook; and we trust that, when a new edition is called for, he will both give a structural introduction, and recast and amplify his general clavis, so that a student possessing no other book on the subject may be able to use this as a guide in his practical daily work, and that he will entirely strike out all such definitions as "Tribe 14. Lecanora. —Apothecia lecanorine," and "Tribe 18. Pyrenocarpa. —Apothecia pyrenodine," which give no more information to a student than the mere occurrence of the name of the genus by itself, standing alone in a catalogue. The entire want of an index of species will involve a great loss of time upon those who use the book. Verrucaria has 113 species, and Lecidea 233; and, as the matter stands, the only way to find one of the latter is to search for it over the 60 pages in which they are grouped with the sparing citation of synonyms, will puzzle all but the few thoroughly-experienced special Lichenologists exceedingly. To take an instance, some half-dozen Lichens are thoroughly familiar to British collectors under the generic name Borrera, under which every one will look for them, and which is given for a whole generation. Let us suppose a student trying to find these here. He will look first for the generic name in the index, and not find it; then perhaps turn over the pages in search of it, still without success, for it does not appear to occur at all. If he be easily daunted, or has time to spare, he will let the book fall in despair. If he be very energetic and persevering, he will search on and find plants with the same specific names placed, one under Evernia, and the others under Physcia. These are really the plants he requires, but a beginner will not get much help towards knowing it in the only reference that we have given, and before he can be sure, will need to compare his specimens with the generic and specific diagnoses in detail.

Garden Memoranda.

NEW WINTER GARDEN IN EDINBURGH.—That the love of floriculture and the pursuit of botany as a pleasant and useful study are making rapid progress among all classes of the people is abundantly evident from the numberless gardens which are springing up around the city, the care which is bestowed on the cultivation of villa plots, and the large attendance of students of both sexes at lectures given by Professor Balfour at the Botanical Gardens. It must, therefore, be matter of general interest to hear of a new place of public resort having been formed of plants may be studied, and the love of beautiful flowers gratified. Although the houses at the Botanical Gardens are open to the public, yet they are not always available to the amateur florist or botanist. It is only on certain days of the week that admission can be obtained, and, moreover, for a large mass of persons, the distance of the gardens from the city practically bars the way to enjoyment and improvement. The opening of the new winter garden which has been erected at Haymarket by Messrs Downie, Laird & Laing, nurserymen, may therefore be looked forward to with considerable interest, more especially by residents in the West End, to whom its benefits will be most accessible. About eighteen months ago, Messrs. Downie, Laird & Laing obtained from the governors of George Heriot's Hospital a feu of an acre and three-quarters of the ground lying east of Haymarket Railway Station, which was then occupied by them as a nursery. The remainder of the ground was feued off for the streets now known as Magdala Crescent and Coates Gardens, and the portion now in question lies between these two handsome ranges of dwelling-houses. On this feu, Messrs. Downie, Laird & Laing agreed with the superiors to erect a winter garden, and Mr. Downie, accordingly, after visiting many of the largest conservatories in the country, designed the elegant structure which has now been completed. The conservatory, from its extent and beauty, enhances considerably the amenity of the district, and, when it is thrown open to the public, it cannot fail to prove attractive to all sections of the community. It has two fronts—the façade facing the Glasgow Road and a side elevation abutting upon Coates Gardens. The main front is, of course, the most ornate, and viewed from the Glasgow Road, it has a handsome proportion at once strikes the visitor. The principal house is 130 feet long—the end gables and the first course being of polished freestone, while a glass superstructure rises in three stages—the first of plain, the second of ground, and the third of figured glass. Each stage is marked off with ornamental iron fretwork extending the whole length of the building. The main entrance is in the centre block, which is 50 feet wide and 30 long, and is surmounted by a handsome dome 65 feet high. East and west of this central hall extend wings 30 feet wide and 26 feet high, surmounted at the ends by lanterned pinnacles with ornamental finials. The roof of the building is constructed in graceful curves, and is supported by light iron pillars. At right angles to the main building and running in a northerly direction, is an *annexe* 50 feet in length by 28 in breadth. In each wing are retiring and waiting-rooms, and these are surmounted externally by the royal arms in carved work, and by ornamental vases containing variegated Aloes. The interior of the large house has not yet been completely finished; but enough has been done to give a general idea of its effect when furnished with plants and flowers. The floor is laid with mosaic tiles, and the walls are painted a delicate stone colour, the panels being relieved with stripes of red and blue and gilt beadings. At each end large mirrors are let into the walls, by which the long rows of plants and flowers will be reproduced *ad infinitum*. In the centre of the house are to be planted Camellias, Azaleas, Aloes, and an immense variety of hothouse plants; while ranged along the sides are placed iron perforated tables for pot-plants and ornamental foliaged plants. In heating the main building no fewer than 1650 feet of hot-water piping are employed; and ordinary water pipes have been laid all round the house, to afford facilities in watering the plants. Beneath the dome a large terra-cotta fountain has been erected, and the pleasant music of the rippling water will enhance the other attractions of the place. Leaving the main building, a covered way conducts the visitor to the Fern-house, which is 37 feet long by 20 feet broad, and from which an ornamental spiral staircase leads to the long range of houses forming the east of Coates Gardens front. The houses, which are 188 feet long by 17 broad, and are heated with 930 feet of piping, stand on a terrace which slopes up from the street—the slope being tastefully laid out in flower beds. Seen from Coates Gardens, this range, although not so ornate as the main front, has a very chaste effect—the centre block having a lantern roof capped with ornamental iron fretwork. Within the grounds, and running parallel with the main building, but not visible from the street, are a series of new stove, green, and propagating houses, extending to 408 feet by 16 feet broad, and heated by means of 2300 feet of piping. The heating power is supplied from a large boiler placed in the potting-sheds beneath the terrace houses, and the smoke is carried away through two flues carried up the gable of the dwelling-house erected to the north of the winter gardens. The whole of the houses are thoroughly aired by means of new patent lever ventilators. A considerable amount of work has yet to be done in the way of painting, tile-laying, &c., before the whole of the houses can be furnished with plants and flowers; but it is expected that the winter garden will be opened about the New Year, when a good display of blossoming plants will be most acceptable. It may be mentioned that the large building was erected by Messrs. Alex. Cruikshanks & Sons, horticultural builders, Arbroath, and the houses on the terrace by Mr. David Lowe, Gilmore Park. *The Scotsman.*

THE WEATHER.

STATE OF THE WEATHER AT BLACKHEATH, LONDON,

JAMES GLAISHER.

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

Chrysanthemums will shortly assert their claim to be considered the most popular of our early winter decorative plants, and though I do not think the firm growth latterly made will be capable of standing much frost out-of-doors, a couple of nights' display in all instances where protection from frost is afforded. It will no doubt have been observed that I have almost invariably refrained from making any suggestions as to affording liquid manure to growing plants, because I hold the opinion that better flower-producing growths are made without supplying so stimulating an aid. Now, however, that the flowers are actually expanding, good manure water should be afforded abundantly, and the result will show itself in the production of blooms of extreme beauty. Those plants which are placed under cover, and the pots of which are not plunged, will be found to get dry very quickly, and will therefore require to be frequently watered, notwithstanding the dulness of the season. To neglect them in this matter will assuredly be ruinous to the blooms, as well as cause the plants unnecessarily to shed many of their leaves, a contingency by all means to be guarded against. Where temporary protection only is afforded, and consequently the necessities of other plants have not to be considered, it would be of great benefit to the plants to occasionally syringe them overhead. See to the potting up of any plants that are intended for late flowering, and bring the necessary operation of tying-up of such plants as need it to a close. Finish thinning out *Pot Mignonette* for late display, subsequently making the soil firm around the base of each plant; after which the pots should be placed upon light, airy shelves, or in some similar position. Give to *Tree Violets*, now about to flower in pots, occasional moderate applications of liquid manure. *Camellias* will now require constant attention in the matter of affording an uniform supply of root moisture, otherwise there will be some risk of their shedding their blooms. On the other hand, an over-supply is quite as likely to end in a like injurious tendency; hence the need of such an amount of care as I have suggested. The surfaces of the pots of these, and other similar plants, will often, and especially if the soil is at all retentive of moisture, become unclean, or green around their outer sides, which also is liable to increase the above evil. These should, therefore, whenever such is the case, be thoroughly well scrubbed over, at the same time the drainage should be seen to, and, if necessary, the pots raised in such a manner that the air can act more freely upon each, and so exert to the full its drying influence. The night temperature in stoves proper should not by any means exceed 60° at this date, and onward for some time to come. Continue to pot off successionally *Herbaceous Calceolaria* seedlings as they attain to a size befitting the operation, and give a slight shift to any old plants which have made good progress since they were last potted. The coolest and dampest end of any structure should be reserved for them, direct heat from any kind of actual heating mediums being antagonistic to their well-being, whilst they are materially benefited by too close proximity thereto. Let any old plants of *Cape Pelargoniums* which have advanced materially in the matter of autumn growth, and the roots of which moderately fill their pots—the latter being of such a size as to obviate the necessity of shifting again at this dull season—be now forced gently into a state of semi-rest by partially withholding water from them and by affording air freely. Do not under any circumstances maintain climbing plants too densely above those which may be of value underneath them. Where there is a demand for early forced flowers, it will be necessary now to introduce a plant or two of *Camellias*, the buds upon which are prominent, into moderate heat. The earliest *Hyacinths* and *Tulips*, with *Narcissi*, should also be introduced into the forcing pit, as well as such subjects as *Salvias*, the Lily of the Nile (*Richardia æthiopica*), various *Amaryllis*, such as *A. formosissima*, *A. crocata* and *A. sarniensis*, *Freesias*, *Primula sinensis*, *Thunbergia laurifolia*, Solomon's Seal (*Polygonatum*), *Genistas*, *Hoteia japonica*, *Cannas* of the indica type, whose natural season of blooming is December; Tree or perpetual *Pinks*, *Picotees* or *Carnations*, *Roses*, and *Cyclamens*. Seedling *Nemophilas* sown a month ago to flower on shelves in the early spring should be now potted singly into 60-sized pots.

FORCING HOUSES.

Much difficulty will the Pine grower experience now who has to deal with the main stock and actual fruiters, some of which, it may be, are ripening, and all in the same house. Those swelling their fruit require a close, snug, warm position, whilst fruits that have finished swelling should be maintained as near to the pipes or flue as possible, all felicitous surroundings being made the most of. Berries often decay in large bunches of Grapes in an incredibly short time at this period of the year; hence an almost incessant dab with the sponge is kept on all, in connection with the performance of a dry atmosphere with gentle artificial warmth. Delay not in procuring the necessary protecting materials, whether fermenting or otherwise, for the protection of out-door *Vine borders* attached to those *Vineries* which are to be forced early. I have suggested previously how desirable it is in the early autumn to place a good thick covering of dry material over them to avert the loss of natural and latent heat which otherwise has taken place. It is better far to economise such warmth as the ground naturally possesses, than to allow the heat to fly away and be obliged to resort to such a poor substitute when a little warmth is required. I need add little at this time to my former suggestions regarding the early pruning, cleansing, and preparing of successional houses, which come under this heading.

HARDY FRUIT GARDEN.

Red, white, and black *Currants* may now be planted; in doing so it is of the utmost importance that the best varieties only be planted, as the labour is the same to produce of good and bad cannot be well estimated in an imaginary manner. Raby Castle, La Fertile, and a variety I have heard called the Marseilles, are the best reds, the former being a good hanging variety. Of *White Currants* there is but one, White Dutch, with its half-dozen synonyms, to choose from. *Black Currants* have long been represented in Black Naples and Ogden's Black, though these are exceeded, in the matter of increased fertility and a better hanging capacity, by Lee's Prolific Black. This is also a good time to plant *Gooseberry canes*. Of the latter varieties, Carter's Prolific and Fastolf are the best, generally speaking. Prince of Wales (Cuthbush's) is a remarkable grower: Autumn Black, October Red, and October White being equal to any of their respective colours. To economise space and maintain an ultimate outlay for canes and labour, it is advisable to plant these in rows of not less than 4 feet apart, and to place thereto a permanent wire fence. This need not be higher than 3 feet, and with two wires only, as much vigour is lost by pruning Raspberry canes too little, leaving the top buds to carry the crop at a height of many feet, whilst the lower and riper eyes remain dormant.

KITCHEN GARDEN.

Any *Capsicums*, *Chilies*, or *Tomatos*, which are still unripe, should be gathered and removed into a warm, dry atmosphere, to ripen off better. Remove from the open ground all *Endive*, tied or not, intended for winter use as early as the weeks fit hence, as a frost would destroy much of them. The same remarks also apply to all good usable *Lettuces*. Those who possess *cloches*, or any of Rendle's protecting tiles, &c., should use them for such purposes with all despatch, as a sharp frost may visit us at any time now. Those who have permanent frames should prepare straw hurdles, or any other kind of temporary protection, to be ready for the advent of King Frost. At this period, *Walks* may be turned, or gravelled, *Box edgings* planted, and suchlike operations entered upon when time sufficient is to be had to remove. *Scorzel*, *Runner Beans* and well trench the ground subsequently. Make a sowing of *Broad Beans* to stand through the winter for the earliest spring crop. Turn up a dry piece of ground, and let the surface become mellowed over with the action of the air, preparatory to sowing the first crop of *Peas* at an early date. As for the rest, though little can be suggested in a Calendar at this dull season, abundance of work will exist in the necessary cleaning up of dead leaves and other litter which accumulates so quickly now. *W. E.*

TOWN GARDENING.

Grass Plots and Verges should now be well rolled, and mowed for the last time this season. The edgings should also be trimmed with the edging iron, and the gravel-walks be cleared of weeds, swept, or turned, and rolled once or twice a-week, which will give a neat and agreeable appearance to the garden for the autumn. The altering and making of gravel walks should now be proceeded with, as well as the laying of turf, as quickly as possible, before severe weather sets in. *Dahlias* and *Marvel of Peru* should now be cut down within 3 inches of the ground, be taken up, and placed to dry for a day or two, when they should be put away out of the reach of frost for the winter. The *Iris germanica*, a most useful plant for town, including its many beautiful varieties, should now be propagated by dividing the roots, and planting them where they are intended to flower. The following *Bulbs* should be at once planted to insure success:—*Tulips:* plant 3 inches deep from the upper side of the root; each hole should be made with a trowel, and a little silver sand put in and around the root. *Hyacinths* treat in the same manner, but *Crocuses* must only be put in 2 inches deep. To flower the Hyacinths in perfection, they should be planted in pots, which can be hooped over, so as to protect them from excessive rains and frost. Plant *Deciduous Trees* and *Shrubs*, stake them to protect them from rocking about, and cover the roots with rotten dung. Defer planting *Evergreens* till spring; for, if planted now, they get choked with soot and dirt, and do not start so freely as in spring. *J. D.*

Notices to Correspondents.

*** Carriage of Parcels.—We are at all times willing to render assistance in the matter of naming plants, fruits, Fungi, &c., but our correspondents should remember that this entails, on our part, a very considerable expenditure of time, labour, and expense, and the least they can do is to pay the carriage of their parcels. In cases where this is not done, we shall rigidly adhere to our rule of not receiving such communications.

Article for Insertion: *Messrs. S.* The writer had no authority for making any such assertion.

Double White Bramble: *E. Y. W.* The double White Bramble is seldom met with. The Messrs. Osborn & Sons have informed us that they possessed the plant for many years, but have found it difficult to increase, and it rarely flowers with them.

Double Apples: *R. M., Norton*, sends us a good example of the union of two Apples, forming a V-shaped fruit. Such instances are not uncommon.

Fungi: *T. S. P., Moorhill, Sheffield.* 1, 2, Agaricus squarrosus; 3, Coprinus picatilis.—*T. A., Heathfield Gardens.* The Fungus is Agaricus arvensis, the Horse-Mushroom, not quite so good as the true Mushroom, but edible. *W. G. S.—J. C., Luton Hoo.* Your Puff-balls are not the edible species (Lycoperdon giganteum), but L. celatum, which is probably not good for food. For books on the subject of Fungi,—"Mushrooms and Toadstools" (Hardwicke, 192, Piccadilly, 6s.); Berkeley's "Outlines" (Lovell Reeve); and Cooke's "Handbook" (Macmillan, £1 4s.). *W. G. S.*

Grapes and Pine-apples: *A. B.* These cannot be grown satisfactorily together. The Pines do not like to be under the shade of Vines, and the latter, especially when the fruit and wood is ripening, are seriously injured by the close humid atmosphere necessary for the well-doing of the Pines.

Growth of Oak: *W. W.* Your letter was unfortunately mislaid, so that we cannot be quite sure to what you refer. We believe, however, that what you sent was a specimen of the Artichoke Gall described at p. 1162. We will endeavour to supply the requisite information as to the Hawthorn in an early number.

Japanese Copying Paper: *W. T.* A beautiful, thin, soft, yet strong paper, well adapted for copying, for packing, or even for correspondence. We do not know the substance of which it is made, but believe it is the fibrous bark of a species of Daphne, or perhaps Broussonetia Bœhmeria. Messrs. Straker, the importers, might be able to supply the desired information. See an article on the subject in the Journal of the Society of Arts of October 13.

Lace: *E. M. O.* The sample enclosed is made from the fibre of the Banana or Plaintain, much used in the West Indies for fishing-nets.

Malformed Pear: *J. B.* and *R. P.* An instance of prolification. Many such have been figured in our columns at various times.

Mowing: *C. F. P.* A suitable horse and full-sized, first-class horse machine and two men should be able to mow 4 acres of lawn a day, cutting it twice over, supposing there are the average obstructions to contend with in the way of trees, &c. A machine of the second order it is not hard work for a suitable horse to work it.

Names of Fruits: *A. B. Apples:* 1, Adams' Pearmain; 2, probably Reinette du Canada; 3, Northern Greening; 4, large Hautbois; 5, Lemon Pippin; 6, resembles Rymer; 7, Red Winter Reinette.—*F. H. Pears:* 1, Beurré de Rais; 2 and 3, Glout Morceau; 4, St. Germain. *Apples:* 1, Ribston Pippin; 2, not certain.—*John Bennett.* We cannot name any of your northern Apples with certainty.

Names of Plants: *Old Sub., Oxfordshire.* No. 1, Juniperus recurva; 2, Cupressus, sp. Materials insufficient.—*J. T.* Passiflora quadrangularis var. Buonaparte.—*J. S.* Lithospermum prostratum, Loisel—native of the south of France. Usually wrongly named in gardens.—*W. J. G.* Veronica decussata. Native of the Falkland Islands and Patagonia. A very old denizen of our greenhouses, having, so we learn from the "Botanical Magazine," been introduced as long ago as 1776.—*H. J. V.* Cissus orientalis; the C. glabra. Native of South Africa.—*F. W. C. 1,* Cystopteris sempervirens; 2 and 3, C. fragilis; 4, Polystichum angulare, irregular variety; 5, Scolopendrium vulgare submarginatum; 6, S. v. lobatum.—*J. L. N.* Omphalodes verna.—*Mrs. Parr.* 1, Euonymus europæus, Spindle Tree; 2, Cornus sanguinea, Cornel

Tree.—*F. S.* 1, Zygopetalum Mackai; 2, leaf only, Chamæpeuce diacantha (?); 3, Coccoloba platycladon; 4, Ceratopetalum gummiferum; 5, probably some Hakea or Grevillea—can't tell from such a scrap; 6, Sisyrhinchium sp.

PEACHES FOR A COOL HOUSE: *T. G.* We would recommend Early York, Grosse Mignonne, Royal George, Bellegarde, Barrington, and Walburton Admirable.

PLAN OF FLOWER-BED: *A Subscriber* writes that he applied, enclosing a fee, to a well-known nurseryman, in August last, for advice on the subject of his flower-beds. The information was promised, but has never been forthcoming, and now it is declined to be given in the score of want of time; meantime the fee has not been returned. Our correspondent has been badly treated, but we can only recommend him to apply for his money, which, of course, he will have refunded.

PORTRAITS: *G.* We feel flattered at your suggestion, which, however, our modesty forbids our acting on. The portraits already issued are all of them those of "counsellors," and more will be issued subsequently.

PREVENTION OF THE POTATO DISEASE: *J. J.*, who has, he says, an infallible method of prevention, should tell the public what it is.

RABBIT-PROOF FENCE: *An Old Subscriber* asks us to publish a list of plants and shrubs which rabbits will not destroy, he being over-run with these nibbling little animals. As a commencement, we may mention Pinus Laricio, Rhododendron ponticum, and Berberis aristacantha. Perhaps some of our readers who can reply from experience will kindly extend the list.

SPOILED GRAPES: *J. J. M.* The examples you have sent are decidedly the dirtiest Black Hamburghs we have ever seen. They have been shockingly mismanaged somehow. They bear traces, however, of having started well in spring, though the bunches were properly developed. It appears as to that upon the result of keeping the house too close and moist during the colouring period. Next season we would recommend you, as soon as the berries have finished stoning, to nail the lights of your house open. Air they cannot not be closed day nor night. It is air that is wanted.

VINE ROOTS: *J. A. L.* We see nothing whatever the matter with them. They seem to be perfectly healthy.

CATALOGUES RECEIVED.—Kelway & Son, Twenty-first Annual Catalogue of Gladioli.—Hogg & Wood, List of Flowering Bulbs, &c.—Von Hoek & Co. (Castel, opposite Mainz), Herbst-Garten- und Samen- und Pflanzen-Handlung—Emil Liebig (Blasewitzer Strasse, No. 15, Dresden), Price List of General Nursery Stock.—Ballet Frères (Troyes), Catalogue of Fruit Trees, Roses, Shrubs, &c.

ERRATUM.—The word "not" should have been omitted in the third line from the bottom of the article from Geoppert, on the Action of Frost, p. 1355, col. *b*, p. 1353, col. *c*, for "seeing" read "swing."

COMMUNICATIONS RECEIVED.—C. L.—J. J.—D. T.—A. B.—R. H.—M. A. B.—S.—H. M. (with thanks).—H. D.—J. H. M.—A. C.—A. W. F.—M. S.—C. J. R.—H. H.—J. G.—J. M.—T. G.—H. J. M.—M. B.—J. J.—Dhune Ehuah.—A. B.—R. H.—B.—J. C.—R. F.—Florist.—J. H. V.

Markets.

COVENT GARDEN.—Oct. 27.

A very steady business is maintained, and prices are rather in favour of sellers. Roughly vegetables are abundant and good. Foreign produce ample, and large quantities are offered from ports of shipment, comprising Pears, Apples, Lemons, Nuts, Grapes, and Pomegranates, which realise fair prices under the hammer. The principal flowers on sale are Heaths, Chrysanthemums, Asters, and Fuchsias.

FRUIT.

IMPORTANT SALE of VALUABLE NURSERY STOCK.

MESSRS. PROTHEROE AND MORRIS will SELL by AUCTION, on the Premises, the Gravesend Nurseries, Gravesend, E., on WEDNESDAY and THURSDAY, Nov. 1 and 2, precisely, by order of Mr. Thos. Eves, successor to the late Mr. Englefield, who is relinquishing the cultivation owing to the sale of the Nurseries being required immediately for Building purposes, a large quantity of VALUABLE NURSERY STOCK, including 2500 Green and Variegated Box, 2 to 4 feet; 2000 Laurustinus, 18 inches to 3 feet; 500 Berberis aquifolia, 2½ to 4 feet; 700 Chinese and Siberian Arbor-vitæ, 2 to 4 feet; 1000 Irish Yews, 3 to 5 feet; 3000 3½ feet; 3000 bushy Laurels; 2500 fine Spruce Firs, 4 to 9 feet; a quantity of Ornamental Conifers, Cedrus Deodara, 3 to 5 feet; 2000 Portugal Laurels, Lilacs, &c.; clean grown FRUIT TREES, consisting of 1000 Standard Apples, Pears, Plums, Cherries, 7-yr. Pears, 250 2-yr. Lord Suffield Apples; 3000 fine STANDARD BANANA TREES, 6 to 8 feet, consisting of Cavendishii, Sinensis, Chestnuts, Laburnums, Elms, Sycamores, Limes, Planes; 600 fine Irish Yews, in pots, 7 feet; 150 strong Pampas Grass, &c.
May be viewed any day prior to the Sale. Catalogues may be had on the Premises, and of the Auctioneers and Valuers, Leytonstone, E.

Auction Mart, Tokenhouse Yard, E.C.

MESSRS. PROTHEROE AND MORRIS will SELL by AUCTION, without reserve, at the Mart, Tokenhouse Yard, E.C., on TUESDAY, November 7, at 12 for 1 o'Clock precisely, a fine-class COLLECTION of DUTCH BULBS, a choice assortment of 300 fine Standard and Dwarf ROSES, selected HARDY AMERICAN PLANTS, &c.
On view the morning of Sale. Catalogues may be had at the Mart, as above; and of the Auctioneers, Leytonstone, E.

Notice of an Important and Extensive Sale of NURSERY STOCK.

Brox Nurseries, Chertsey, Surrey: within 1½ mile of the Chertsey, Weybridge, and Addlestone Stations on the London and South-Western Railway.

J. WATERER AND SONS have been instructed by Messrs. Gray & Son, in consequence of the Dissolution of Partnership, to SELL by AUCTION, on TUESDAY and WEDNESDAY, October 30, and following days, at 12 o'Clock precisely each day, the whole of the very valuable NURSERY STOCK, on 16 acres of Land, consisting of 400 dozen fine Standard and Dwarf Roses, comprising all the most approved varieties, fitted to suit private Buyers and the Trade; upwards of 70,000 choice Conifers, from 6 inches to 5 feet, including Cedrus Deodara, Pinus excelsa, Pinus Lambertiana, Cedrus atlantica, Cupressus Lawsoniana, Pinus Nordmanniana, Picea nobilis, Wellingtonia gigantea, Pinus austriaca, Abies pectinata, Thujas; 7000 Acer Negundo, 2 to 6 feet; 5000 Silver American, Chinese, and Siberian Arbor-vitæ, from 1 to 6 feet; 1000 Portugal Laurels, 4 to 6 feet; 1000 Irish Yews, 2 to 3 feet; 1000 Laurustinus, 5 feet to 7 feet; 1000 Aucubas, from 3 feet to 5 feet; 50,000 Quick of sizes; 10,000 Common Laurels; 10,000 Portugal dittto; 25,000 Rhododendrons, from 2 feet to 7 feet; 10,000 Standard and Dwarf Ornamental Trees, trained and Maiden Fruit Trees, consisting of Apples, Pears, Peaches, Nectarines, Cherries, and Plums, the most approved sorts, and in which are true to name; about 150 lots of very choice mixed Shrubs fit for immediate Ornamental Planting, and a great variety of other Stock. The Auctioneers beg to call the special attention of Gentlemen, Nurserymen, and others, to this Stock, the whole being in a most perfect and safe condition for removal.
May be viewed ten days previous to the Sale, and Catalogues had on the Premises, at the principal Inns in the neighbourhood, and of Messrs. WATERER AND SONS, Auctioneers and Valuers, Chertsey, who will forward them on application.
N.B. There is direct railway communication for goods from Chertsey Station to all parts of the United Kingdom.

Re Mr. R. Glendinning, Deceased.

IMPORTANT NOTICE of NINE DAYS' ABSOLUTE CLEARANCE SALE of the entire and very extensive Nursery Stock, Conservatories, Greenhouses, Tools, Trade Effects, valuable Horse, Market Cart, and Complete Plant, on the Premises, Chiswick Nurseries, Hay's Road, Turnham Green, and Chiswick Lane.

MR. J. SMITH is instructed by the Executrix to SELL by AUCTION, on the Premises, near the Southern Stations, and Toll Gate, Turnham Green, on MONDAY and TUESDAY, October 30 and 31; WEDNESDAY, THURSDAY and FRIDAY, November 1, 2, and 3, and commencing on November 6, 7, 8 and 9, commencing each day at 11 for 12 o'Clock punctually, the entire and beautifully select NURSERY STOCK, in fine condition for effective planting after removal, including many prize specimens. The Catalogue will comprise 1. The Trade Fittings and Effects, Tools, Implements, &c. 2. The Collection of Forest Trees, 2000 Standard and Dwarf Perpetual and other Roses, 7000 Stove and Greenhouse Plant Specimens, and 20,000 Fruit Trees, 600 Vines, &c., &c., as described in Catalogue.
May be viewed by Catalogue on Saturday prior. Catalogues, showing the arrangement of each day's Sale, to be had at the places of Sale, and of the Auctioneer, 58, King Street, Hammersmith, W.
THE LEASE of CHISWICK LANE NURSERY to be SOLD by PRIVATE TREATY, 42 years unexpired.

Continuation of Great Nursery Sale.

MR. HENRY WALTERS will CONTINUE the SALE of choice NURSERY STOCK, at the Wetley Rocks Nurseries, on TUESDAY, November 7, and NOVEMBER 8 and 9, when upwards of 50,000 Rhododendrons in variety, a large quantity of Hollies in variety, Azaleas and other American Plants, Yews, and almost every kind of Evergreen; with a choice selection of FRUIT TREES, will be Sold, without reserve, as the owner is declining business.
Catalogues may be had from the Proprietor, Mr. A. B. FOX, The Nurseries, Wetley Rocks, near Leek, on and after the 25th inst.

To Gentlemen, Nurserymen, and Others engaged in PLANTING.

IMPORTANT and EXTENSIVE SALE of NURSERY STOCK.

MR. POYSER will SELL by AUCTION, without reserve, at the Tansley Nurseries, Matlock, Derbyshire, on TUESDAY, November 7, and three following days, at 10 for 11 o'Clock each day (Mr. J. Smith, Sen., having decided on clearing off the portion of Nursery Stock), the whole of the FOREST TREES, SHRUBS and TREES, suitable for planting: FOREST TREES, RHODODENDRONS, EVERGREEN TREES and SHRUBS, in large quantities; also large quantities of the following,—THORN QUICKS, SCOTCH FIR, LARCH, SPRUCE, OAK, ASH, and Mountain Ash, Transplanted.
Catalogues may be had 10 days prior to Sale, and further information obtained, from Mr. SMITH, Sen.; or from Mr. POYSER, Auctioneer, Wirksworth, Derbyshire.

To Nurserymen and Others.

EXTENSIVE SALE of NURSERY STOCK at CUPAR-FIFE, N.B., on MONDAY, DECEMBER 4, and TWO FOLLOWING DAYS.

TO BE EXPOSED to ROUP, on the above dates, in suitable Lots, the whole of the valuable STOCK in William Taylor's Nurseries, at the West Port of Cupar, extending over Eight Acres, consisting of FRUIT TREES, and ORNAMENTAL TREES and SHRUBS, rare CONIFERÆ, &c., and about Six Tons of EARLY POTATOES, which stock is particularly worthy of the attention of Foresters, Gardeners, and the Trade.
The Roup will commence at 10 o'Clock forenoon, commencing on MONDAY with the Landynch Nursery, containing the larger lots of Ornamental Trees and Shrubs.
Catalogues may be had after November 1, free on application, to W. TAYLOR, 14, Crossgate, Cupar-Fife, N.B.; or from Mr. WELCH, Auctioneer, Cupar.—Cupar, October 2, 1871.

THE TWENTY-SECOND ROYAL BERKSHIRE ROOT SHOW will be held in Messrs. SUTTONS' NEW LARGE WAREHOUSE, READING, on SATURDAY, the 4th November 18, when PRIZES amounting to upwards of SIXTY POUNDS will be awarded for the best collections of Mangel Wurtzels, Kohl Rabi, Potatoes, &c., including a 60 GUINEA SILVER CUP for the best 24 Specimens of SUTTONS' CHAMPION SWEDES, with £5 and £3 for the next best collections, and the SILVER CUP offered by Messrs. Griffin, Wolverhampton, for the Best Collection of Roots.
For complete Particulars, and Form of Entry, apply to SUTTON AND SONS, Seedsmen, Reading.

THE BIRMINGHAM CATTLE and POULTRY SHOW, 1871.—The TWENTY-THIRD GREAT ANNUAL EXHIBITION of CATTLE, SHEEP, PIGS, DOMESTIC POULTRY, CORN, ROOTS, and IMPLEMENTS, will be held in Bingley Hall, on SATURDAY, NOVEMBER 25, and MONDAY and TUESDAY, November 25, 27, 28, 29, and 30, when PRIZES to the amount of TWO THOUSAND TWO HUNDRED POUNDS will be offered.
PRIZE LISTS, CERTIFICATES of ENTRY, and every information may be obtained on application to
The ENTRIES CLOSE on SATURDAY, October 28.
R. E. LYTHALL, Secretary.
Offices, 39, New Street, Birmingham.

SMITHFIELD CLUB FAT CATTLE SHOW.—The ANNUAL SHOW of FAT CATTLE, SHEEP, and PIGS, will be held at the AGRICULTURAL HALL, ISLINGTON, on MONDAY afternoon, December 4, and four following Days.
Intending Exhibitors are requested to apply for Entry Forms by the reference letters as under.

CATTLE.—Form A, for an OX or STEER (in any Class).
" B. For a COW or HEIFER (in any Class).
" C. For a PAIR of OXEN.
SHEEP. " D. For a Pen of three WETHERS. [Stock.
" E. For a Pen of three SHEARLINGS (Pure Bred
" F. For a SINGLE WETHER SHEEP in Extra
PIGS. " G. For a Pen of three PIGS (in any Class).
" H. For a SINGLE PIG (in any Class).

ENTRIES for LIVE STOCK CLOSE NOVEMBER 1.
Prize Lists, Forms of certificate, and all information may be obtained on application to Mr. DAVID PULLEN, Assistant-Secretary, at the Office of the Honorary Secretary, corner of Half-Moon Street, Piccadilly, W.
N.B. All communications respecting the Show must be addressed to the Assistant-Secretary, as above, and should bear on the outside "Smithfield Club Show."

The Agricultural Gazette.

SATURDAY, OCTOBER 28, 1871.

FORTHCOMING MEETINGS.

WEDNESDAY, Nov. 1.—Royal Agricultural Society of England.—Noon.
MONDAY, " 6 { London Farmers' Club (Mr. C. S. Read, M.P., in the Chair), at the Salisbury Hotel—6 P.M.

THE guides and mentors of Agricultural Society—whether self-appointed or otherwise have a puzzling task before them. Not one of them can speak but he is straightway contradicted by another. And it is probably a happy thing that our progress is the result, not of attention to the remonstrances or exhortations of these outside spectators of the general body, but

of the conduct individually of each member of the rank and file, who is obedient not to any general officer over all, but to his own perception of what, in his individual interest, it may be best for him to do. We would rather have the car of progress harnessed to what is probably the imperfect knowledge of the man whose insight is thus quickened, than to the wider and perhaps more perfect view of the mere philosopher, who may be only a spectator with no personal interest in the result.

Mr. MECHI's recommendation to break up our grass lands, and the immediate protest of Mr. JAMES HOWARD and others, are thus happily both of them of little influence or use. The relative profitableness of the two recommendations has to be determined on separate estates and fields by each man for himself, and the resolution of the owner and the tenant rests on something altogether independent of the general view of the national interest which Mr. MECHI takes. Some of the best grass lands in the country are now being broken up, or have been already converted, and have yielded for many years double the rent which the landlord formerly received; much inferior grass land has also been broken up, and much very difficult and laborious clay land has been laid down—simply because the course determined on was the most likely to be profitable in the several instances concerned. Probably those of the many controversial pens, which were set to work by Mr. MECHI's recent letter on agricultural reform, most nearly told the truth, which took occasion, not so much to protest against any particular recommendation as to declare that any recommendation at all is futile, impotent, impertinent.

That on which the efforts of the mere outsider, as it seems to us, can alone be usefully exerted, is to urge upon all alike the safety and advantage of liberty for the full exercise of this power of individual choice, on which agricultural progress after all depends. The folly of the owner who restricts the efforts of the tenant to extract a profit, is just as great as that of the tenant who would hide the increased fertility which he has created or extracted. Certainly, if it be true that "all men speak well of thee when thou doest well unto thyself," it should be especially true of the landlords as a body, in reference to the well-to-do land-tenant. The prosperity of the latter, based as that is on the increasing fertility, and therefore the increasing value, of the property of the former, is a thing of interest to both alike. And that system of land letting which gives the greatest confidence to the tenant — the greatest liberty to his intelligence, inventiveness, and enterprise, and the largest scope for the investment of his capital, is on both sides to be preferred. The object of the landowner ought to be to enlist the self-interest of his tenant in the maintenance and increase of fertility; and it will be best attained by making him sure of reaping the fruits of his industry and outlay. It will be attained, in the case of a carefully chosen tenant, by giving him the land for a term of years, to do with it, in fact, whatever a farmer or a gardener may think desirable.

We have not yet seen the form of lease to which Lord LEICESTER referred in the capital speech reported in our columns last week, but it drawn in the spirit of the remarks by which his lordship introduced it to his audience at Docking the other day, we will back it for promoting energetic agriculture against all the systems of elaborately calculated tenant-right that ever were devised.

We go entirely with Lord LEICESTER, when he says :—

> "I do not believe that agriculture will ever attract that capital, that skill, and that energy which are required to bring it to perfection until ample security is given in the form of a lease to the occupiers of the farms, and from that lease many unnecessary restrictions which exist in 99 leases out of 100 are omitted. I found that in the lease in use on my estate there were many restrictions—such restrictions as I should not like to be bound by were I a tenant of a farm. I have, therefore, with the assistance of my agent, and my friends, deviated from the beaten track, and endeavoured to frame a lease more in accordance with the spirit of the age, avoiding all interference with the capital of the tenant, removing all clauses that dictate as to the cropping of the soil or as to the sale of the produce, and, as far as I can, giving him security for the capital invested. I have endeavoured to place my tenants in that position which I should like to hold as an occupier of land; and in doing so I am satisfied I have studied my own interest as well."

We shall be delighted to publish Lord LEICESTER'S lease as soon as it is offered to the public, certain that if drawn in the spirit in which it has obviously been conceived it must define the relationship of landlord and tenant, so as to make it a source of profit to both. And then we may be sure that even Mr. MECHI need not be anxious about the national interests. They are best attended to by being left in the separate unfettered hands of the millions of individuals of whom the nation consists.

THE Journal of the Agricultural Society of New South Wales loses no opportunity of advocating the system of JUDGING BY POINTS. Its leading argument, that thereby the judges are forced to make a detailed examination and estimate of quality—which, however, they can hardly fail to make if they do their duty—is no doubt of some weight; and, if the relative shares of the several points to be considered could always be accurately defined, and are always the same in the different examples under examination, no doubt "judging by points" would be unquestionably the best method. In the case of manufactured articles, and even in that of dead produce—in the case, for example, of wines, dairy produce, vegetables, and wool—it would be a great help towards accurate judgment if the judges were beforehand told that a certain number should be allowed for perfection under each of half a dozen different heads, and that the place of any one competing "entry" on the final list should be determined by simply adding up its several merits thus individually ascertained. But we doubt the applicability of any artificial scale to a breeding animal, whose value depends upon its life, and health, and vigour, and its power of begetting offspring of similar merit with its own. And we can easily understand a set of conscientious judges adding up the particular valuations at which they had arrived, and then—knowing by general inspection the order of merit in which the animals ought to be placed—standing aghast at the results of their arithmetic. Nevertheless, we quote the remarks of our contemporary, first upon the fitness of the system to the estimation of quality in the case of wines, and next upon its equal fitness to the judging of live stock :—

> "The awards of the wine judges contained in the present issue of this journal fully confirm the value of the point system, and the wisdom of adhering to it. The judges have carried out the desires of the Council to the letter. No alteration has been made in the form of the award paper, and the points have been distributed to each sample under each head. The judging was conducted with such deliberation as to admit of the greatest particularity in this matter, and the consequence is that the document countersigned by the wine stewards is about the most perfect example of point judging we have to refer to. If the stewards in all the several sections of the great meeting next month are so fortunate as to find judges in the several juries as competent as fully filled up as the one now under review—which is scarcely to be expected in all cases—the Society may regard the result as highly satisfactory. The system of judging by points must then be looked upon as pretty firmly established.
>
> "It seems to be supposed by some persons that the point system is introduced only because it is something new. But this is not the case. Much consideration is sought under the conviction that it will introduce more care in the examination and comparison made by the judges. It is introduced in the favour of the exhibitors, who, before competing, must be prepared for these strifes, should not have reason to complain of the incompetency of the tribunals to which their exhibits are submitted. If a society of this sort is to succeed, and its success is to be based upon the public confidence, too much care cannot be taken to establish the competency of the tribunal before which the competitors are to display their several claims to priority. The impression that prevails amongst the Council is, that the point system of judging tends to insure competence and care and impartiality in the jury, and for that reason it is now being tried.
>
> "It cannot be denied that this mode of judging is more applicable in some of the sections than in others; but any inapplicability observed in it is more evident in the minor than in the major sections. At all events, in horses, cattle, and pigs the judges of last year spoke out boldly in favour of it, as directing them to a nicer comparison of the various animals than they would have otherwise entered into. The award papers were then hastily drawn up, and, in some respects, defective. Since that period the subject has occupied the attention of the stewards and the Council, and a set of qualities has been determined upon, with their relative values attached."

THE rates of the previous Monday held good at Mark Lane on Monday last, for dry and good samples of English Wheat—inferior being difficult of sale. Wednesday's trade was much the same in instances prices were somewhat easier.——At the Metropolitan Cattle Market on Monday, prices for beasts were rather better than in the previous week, and a good clearance was effected. Trade in sheep was brisk, at fully the prices of the Monday previous. Beasts on Thursday's market brought rather more money, and sheep maintained their prices; choice calves also realised high rates.——The Seed Market is quiet, but prices are firm.

—— This is the last day on which ENTRIES of LIVE STOCK, to be exhibited at the MIDLAND COUNTIES SHOW in Birmingham, can be received by the secretary, Mr. Arthur Smithfield Club Show, at Islington, November 1 is the last day on which entries can be made.

—— The following note has been addressed to Mr. BAILEY DENTON by Mr. CLUTTERBUCK, of Hinxworth. It will be seen that it bears most satisfactory testimony to the thorough efficiency of those measures of AGRICULTURAL REFORM which were some years ago carried out on that estate under Mr. BAILEY DENTON'S direction. Hinxworth is a capital example of the advantages which have been derived from the drainage and deep cultivation of clay land :—

> "I have just returned from Hinxworth, and after a pretty close investigation, I think you will like to hear the results.
>
> "The crops on my old farm have perfectly astonished me, and our hopes of ultimate success have been realised. The cold (so called), undrainable land, has produced crops both in quality no less than quantity equal, possibly in some instances superior, to those grown upon the free open soils on the estate. I assure you I was delighted with what I saw. Mr. NEWTON, who occupies the farm, is an intelligent person, and now that he has adopted steam ploughing, is perfectly satisfied with his future prospects. I found a double-engine Fowler's plough at work on No. 21 (the Ridgway field), a very clean Bean stubble. Mr. NEWTON very much prefers the direct traction to the roundabout system. On the other farms the tenants also adopt steam ploughing; in fact, an agricultural revolution has been effected in the parish. On every side I heard those principles which we—you not the least—first inculcate, admitted to be correct and practicable. Hedges are cut close after harvest, and channels and outfalls are now cleared out as a matter of course.—in fact, you would hardly recognise the place.
>
> "When next you have an opportunity, will you mention these facts to JOHN SCOTT, if he be in the employment of your Company. You may add that I look to his energy and zeal in my service as having done much towards making some of the natives think who never thought before. I hope he is well.
>
> "These facts will, I feel sure, give satisfaction to you, and may add one item to the now, no doubt, very numerous instances in which your Company has effected much real good.
>
> "In such a district as that of the low lands of Hinxworth your burnt-clay roads have proved most useful; indeed you may remember that I have often called them the key of the position. How could steam-engines march to their work without the roads? I was surprised to see that the heavy engines had travelled so well."

—— Mr. W. H. SPURGIN thus writes in the *Times* on the so-called "CHARLIER" SYSTEM of HORSE-SHOEING:—

> "I have often noticed in Cheapside, when the asphalte is at all greasy, that scarcely any of the horses trotting over it are able to retain their foothold, and therefore get lamed or strained. I would suggest that all horses should be shod upon the "Charlier" system, as I believe the omnibus horses are in Paris—and they do not slip upon the asphalte.
>
> "The Charlier shoe is much lighter than the ordinary one, being about three-quarters the length and half the width of the latter; it is fixed to the horse's feet into a groove in the hoof made by means of the Charlier knife. The horse's frog and bars are allowed to grow, so, consequently, the horse has almost the entire foot to support it, instead of only that on the tips of the ordinary shoe, and sometimes only the toe and heel. The frog acts as a sort of skid, and prevents slipping. I have often heard the remark, 'Well, but the frog becomes sensitive, the horse will go lame;' but it is not so, as the frog soon becomes as hard as gutta percha, and gives slightly, but causes no pain, and concussion is almost prevented. These shoes last over two months, as my horses have not yet quite shed

has been established, in which ploughs, scythes, and other tools are made by native labour for native use. The poor Ryot cannot afford as yet to buy English-made implements, neither are English implements suited to their primitive ways. Seeds are imported from other countries, and after use are distributed gratuitously to the Ryots. Mr. ROBERTSON is evidently growing in influence and usefulness, having the general direction of agricultural matters in the Presidency, and winning high official approval, the Governor in Council having recently spoken in eulogistic terms of the success that had attended his endeavours.

—— Here is a piece of news!—The tenants upon the Sarsden Estate (Oxfordshire) have presented a magnificent timepiece to GEORGE BUSHROD, game-keeper, on his leaving his post there to fill the same situation on the Gloucester and Tortworth property. Such a present is of rare occurrence, but they felt some token of respect should be shown to a man who, after 20 years' residence at Sarsden, had done all in his power not only to preserve the winged game, but to enable the tenants to enjoy their privilege of coursing the hares, and of destroying the rabbits. He was courteous and ever ready to oblige, and he carries with him the good wishes of the subscribers for success in his new home. The timepiece was supplied by Mr. SIMMS of Chipping Norton, and bears the following inscription on a neat silver plate:—"Presented to GEORGE BUSHROD by the tenants of the Sarsden estate, for his straightforward conduct as game-keeper to the Right Hon. Earl DUCIE. Sarsden, September 1, 1871."

OUR LIVE STOCK.

CATTLE.

THE sale of Colonel Duncombe's Shorthorns took place on Friday, the 20th inst., at Waresley Park. We have already, in our impression of the 14th inst., explained the breeding of the animals composing this herd. The stock was brought out in nice condition, full of hair and quality, not large, but uniform and good. The company was numerous, and the bidding spirited. Forty-eight cows made £40 3s. 3d. each, 23 bulls £32 each, and the 72 animals disposed of realised an average of £37 10s. 4d., and a total of £2663 17s. The highest price was given for *Sugar Loaf* by CANTAB (23,597), and of the "Countess" tribe —a splendid 2-year-old heifer, with a sweet head, fine quality, and good looks. She was purchased by Mr. W. Dangar, for Australia, at 80 gs. Among the principal purchasers were the following:—*Mulberry*, by VOLUNTEER (19,087), 41 gs., Capt. Reed; *Windsor Lass*, by ROYAL BUTTERFLY 5th (18,756), 43 gs., H. B. Wright; *Satin*, by VOLUNTEER (19,087), 40 gs., H. B. Wright; *Lavender*, by CONFEDERATE (19,493), 40 gs., W. Trethewy; *Queen of the Mist*, by VOLUNTEER (19,087), 42 gs., W. Ladds; *Girl of the Mist*, by HOVCRITE (19,996), 63 gs., H. Grant, Australia; *Patty* 3d, by HOVCRITE (19,996), a very sweet-looking animal, 55 gs., Major Fanning; *Windsor Queen*, by SAILOR BOY (22,825), 40 gs., Captain Reed; *Mirabel*, by SAILOR BOY (22,825), 45 gs., Messrs. Dudding; *Spray*, by SAILOR BOY (22,825), 49 gs., H. B. Wright; *Sarsnet*, by SAILOR BOY (22,825), 40 gs., Earl of Cawdor; *Soft Soap*, by SAILOR BOY (22,825), 47 gs., T. Topham; *Countess of Windsor*, by CANTAB (23,507), 42 gs., Mr. Banks, butcher; *Queen Mab*, by CANTAB (23,507), 51 gs., T. Rose; *Sylph*, by CANTAB (23,507), 40 gs., W. Ladds; *Lily of the Valley*, by CANTAB (23,507), 40 gs., G. Brown; *Mountain Dew*, by CANTAB (23,507), 50 gs., T. Rose: *Sugar Loaf*, by CANTAB (23,507), 80 gs., W. Dangar, Australia; *Sunflower*, by GENERAL WETHERBY (24,026), 41 gs., J. Parker, *Wetherby*; by GEN. WETHERBY (24,026), 40 gs., S. Beattie, Canada; *Duchess Wetherby* 3d, by GEN. WETHERBY (24,026),40 gs., Earl of Cawdor; *Maid of the Mist*, 61 gs., T. Rose; GENERAL WETHERBY (24,026), by 2D DUKE OF WETHERBY (21,618), 46 gs., Earl of Cawdor; WINDSOR LAD (27,823), by SAILOR BOY (22,825), 46 gs., G. Armstrong; DUKE OF WETHERBY 3D, by GENERAL WETHERBY (24,026), 47 gs., W. Trethewy; WINDSOR BOY, by GENERAL WETHERBY (24,026), 47 gs., Mr. Hartley; SPLENDOUR, by GENERAL WETHERBY (24,026), 50 gs., G. Hodgkinson, M.P.; FRANCIS 1ST, by GENERAL WETHERBY (24,026), 45 gs., D. M. Brown.

SHEEP.

MR. CORBETT'S descriptions of the heads of Leicester and Lincoln sheep in the Journal of the Bath and West of England Society are puzzling. He tells us that "the Leicester head should be especially bare and free from wool of any strength;" and, "of the other breeds, the improved Lincoln now looks to take after the Leicester head." Previously (p. 115) we are informed that "the Leicester head should be covered with beautiful silky wool;" but, as the ears are included in this statement, and we are also told "there must be a peculiarly delicate tint of *blue* visible just beneath the wool on the head," we assume that in this passage the "wool" really means hair. This information is not only indefinite, but, so far as it conveys any meaning at all, incorrect.

Lincoln and Leicester sheep both possess a natural top-knot, of which, however, it is unfortunately the custom to deprive them when they are trimmed for show. The Lincoln sheep exhibited among the wool-bearing animals at the recent International Exhibition had well developed top-knots, and we have noticed the same feature repeatedly when examining flocks in their native county. The Leicester does not show so definite a top-knot, and occasionally little or none. That he "should be separated bare and free from wool" is, however, a statement from which we entirely dissent. Not only is this untrue with regard to many of our best Leicester flocks, whose "character" should not be ignored, but there are disadvantages connected with such bareness of head, namely, liability to annoyance from flies, and a corresponding tendency to bareness on the "purse" and belly. Has Mr. Corbett taken his types of Lincoln and Leicester heads from the well trimmed and shaven countenances of our Royal and other agricultural meetings then?

INDIAN CORN.

I HAVE received the following interesting communication from Miss S. Cobbett, a daughter of the late Mr. William Cobbett. It is the translation of a note from a German periodical, and, as I have seen the perfect ripening of the corn in this country (specimens of which, sent to me by Mr. William Cobbett, ex-M.P., were exhibited on Messrs. Sutton's stand at the last Christmas Cattle Show), I think that the time has arrived when we should entertain and discuss the propriety, or rather profit, of growing it. In September, 1870, when I visited Mr. Hope's sewage farm, at Hornchurch, near Romford, I was particularly struck with the growth of a splendid crop of Indian Corn, 8 feet high, the stems nearly as stout as a mopstick, and magnificent well-developed heads of corn. It struck me as being especially advantageous as a gigantic appropriator and utiliser of an immense supply of sewage. Of course the means for drying and properly securing the crop would be readily found, should it promise a remunerative one.

Seeing how greedily a cow devoured a considerable portion of the stalk, I thought it likely that, like the hard and once neglected Bean-stalk, it might, by hot-water softening, be a valuable addition to cattle food. As a green crop, Mr. Hope put its value at a large sum that I write from memory. It appeared to me that the heads I brought home that it was then almost matured and fit for drying; but Mr. Hope will, no doubt, enlighten us on this point. I do not see why it should not suit our climate as well as northern Germany. We should remember that once thought that our climate unsuited for Sugar-Beet; but now chemical analysis has shown to us that our Sugar-Beet contains quite as much saccharine matter as most of the Continental growth.

It will be rather singular, and not very creditable to our sagacity as agriculturists, if the late Mr. Cobbett's persevering conviction about the growth of Indian Corn in this country should prove a correct one.

If we are to utilise very large quantities of sewage on very limited areas, the Maize appears to me to be the very plant to accomplish this object.

The price of Maize here is nearly that of ordinary Barley, and there is an ample market for it always available; and we shall have, as we have in Wheat, a natural protection of nearly 20*s.* per qr. in our favour, arising from the distant places of its growth and the heavy costs of transit. There is also this advantage over our Barley crop, that the spaces (4 feet) between the rows permit of its being made a fallow or clearing crop.

In my early days, when I knew the late Mr. Cobbett, Indian Corn was only known as a sort of curiosity in a botanical greenhouse. Subsequently it was grown in Potato famine, corn-flour and Indian Corn have become "the order of the day," both for feeding men and animals. *J. Y. Mechi, Tiptree, October.*

TRANSLATION.

The Maize, like many other of the most valuable productions of Nature, was long in establishing itself as a crop for general field cultivation in Europe; for, being too highly valued by a few, and undervalued by the many, who were not acquainted with its useful properties, it was full a hundred years before people in general became convinced of its worth. Whether the Indian Corn is really a native production of America or not, is matter of doubt; but it is certain that the Europeans found it there upon the discovery of that part of the world, and that it had been already long cultivated, although it had never been seen in Europe, nor even mentioned by any European author.

The Spaniards being the first who brought it to this hemisphere, it is only first cultivated in Spain, where Oviedo, who published a description of it in 1525, states that he has seen fields of it in Andalusia; but although the Spanish discoverers must have seen it growing in the Mexican crop in Anahuac, it does not seem to have made great way even in Spain for many years, since up to the end of the reign of Philip II., in 1598, the cultivation of it appears to have been confined to a few places, and to have been very sparingly carried on. It is said to have been brought from Sicily in the year 1560, to the south of Spain, by some Spaniards, and in that way to have obtained the various names of Spanish, Sicilian, and Turkish corn. In Italy it was but little cultivated until the end of the 16th or the beginning of the 17th century; but it is probable that it was introduced into France at the time of its discovery, since it was already known there during the reign of Henry II., from 1547 to 1559, although it did not obtain any great degree of estimation till the end of the 16th century, after which time it came into cultivation all over the south of France, and reached as far north as Luneville and Ruffec. It was introduced into Germany during the first half of the 16th century, and, according to Leonard Fuchs, who published an account of it in 1545, it came there from Greece and Asia under the name of Turkish frumentum, but was only cultivated in gardens. The general cultivation of it in the Tyrol followed in the first half of the 18th century, and at present it is the principal crop in the level lands of the Upper and the Lower Inn, as well as in South Tyrol.

There are accounts of this corn in Hungary as early as the first half of the 16th century, and it is possible that from there it went into Turkey, as it is quite certain that the name from Hungary into the south of Russia and into Styria in the 17th century. Carinthia received it early from Italy, but it was later before it became known in Georgia, in Istria, and in Austria, below the Ens. In the milder parts of Franconia, in the middle and lower districts of the Neckar, and in the valleys of the tributaries of that river, it has long been cultivated and greatly esteemed; but that which grows in Baden, in the valleys of the Rhine, Murg, and Grand Duchy of Lower Hesse (with the exception of the province of Starkenburg), in the Electorate of Hesse, in Westphalia, and in Rhenish Prussia, is not so much thought of. In the kingdom, and in the province of Saxony, in many parts of the middle mark of Prussia, and even in Pomerania, the cultivation of Maize has succeeded perfectly, and has been permanently established. In Belgium, also, it is cultivated with great facility. It was brought into England as early as 1562 or 1595, but not until of late years has its cultivation been attempted as a field crop.

The Maize belongs to the family of the grasses, and has two kinds of blossoms, namely, such as has only anthers, and such as has only pistils, and which have, therefore, no androgynous blossoms, but only either male or female blossoms. The plant has an upright, stout stalk, scored and smooth, and grows 3 to 6 ells, or 18 feet high. Strong, broad, lancet-formed leaves, at the bottom of which the female spadix come forth, which are covered by a close covering of leaves, out of which the long styles of the pistils project and hang down like a large bunch of silk. The male blossoms form at the end of the stalk, a bunch of many blossomed and separated panicles, and have two chalice valvules, which enclose two blossoms, out of which hang coroll valvules, while the female chalice encloses only one blossom, which also has two corolla valvules. The fruit or grain is arched on the outside, yellow, and smooth, and is wedge-shaped towards the inside, where it is attached to the cob.

There is only one species of Maize, but this has undergone many alterations in the course of time with regard to form and size and length of time in ripening, so that at present seven varieties are known, which are generally ranked under two principal heads, namely, the American (Zea altissima s. hirsuta), and the European Maize (Zea Mais et praecox, Lin.). The former grows to the height of from 12 to 15 feet high, the latter to only about from 4 to 8 feet.

The warmer the climate the better it suits the Maize, which ripens, nevertheless, and comes to perfection, in countries of a colder north, provided the climate is not cold from being too high, too mountainous, or damp, or one which offers hindrance to the influence of the sun. It is said by Professor Lengerke that on the Mecklenburg coasts of the Baltic it will come to perfection for many years in succession; that in favourable seasons it will ripen on the highest points of the Eifel; and that in Carinthia the common tall Maize ripens at a height of 3300 feet above the Adriatic sea; and in the valley of the Rhine, at Trons, even at the height of 5650 feet above it. It is a plant which requires protection, but which does not do well in the shade. The situation which suits it best is one which lies to the south and is protected from the north. As to soil, it succeeds in any that has strength enough, or that will bear manuring. But a sticky, clayey, or damp soil is not suited to it, and a light soil is preferred to it than a heavy one. It thrives well, nevertheless, in rich, deep and mellow land, and grows with the greatest luxuriance in places where the soil is somewhat sandy and with vegetable matter as to be too rich for the culture of other plants. At certain times the banks of a river which has overflowed, or the beds of dried up lakes or ponds, are complete hotbeds for the Indian Corn.

Fields which the preceding crop was Clover, Tobacco, Beans, Hemp, or spring Wheat, are those which are most favourable to the Maize. In some districts it is usual to sow it after spring Wheat in the more northern and colder climates, but in the more southern and warmer districts it is sown in land which has lain fallow; and land which is intended to bear this crop should be ploughed in autumn or winter as deep as possible, and left to lie all through the winter in rough, uneven furrows, in order that the earth may become more mellow and loose, and that the vermin may be destroyed.

In choosing the seed for sowing the roundest and most glossy grains should be taken. They should be separated from the cob by the hand in the spring, taking those which are in the middle of the ear and rejecting those of the ends as being the worst. Care should also be taken to reject all those which may have a black spot at the germ. In the cultivation of the Maize it is of great importance to select good seed, because, as the plant is a large one, a bad grain cannot be sowed very thick, and the failure would therefore be great if many of the seeds failed.

The time for sowing is earlier or later in May, according as the situation is northern or southern, for the earth ought already to have been pretty well warmed, and there should be no longer any danger of night frosts. In the south of Germany it may even be sown by the middle of April. If cultivated merely for the stalk itself, to be used as fodder, it may be sown as late as the middle of June; and as a green crop till the end of July.

In Italy, Franch-comté, Burgundy, Hungary, and Styria, it is the custom to sow the Indian Corn broadcast, but in the north of Germany it is sown in rows, which is the preferable way, whether cultivated for green fodder or for the grain. When the corn is up the earth must be repeatedly loosened round it, and each plant must be hilled-up, taking care at the same time to destroy all weeds. The first loosening of the earth takes place when the plants are about a foot high. It is usually performed with a hoe, but it is also sometimes done with a harrow, in which case the earth is left in rough furrows at the time of sowing. Later, when the plants are about a foot high, a second hilling-up is performed with a shovel-plough. This second hilling-up is very necessary, for the Maize has very large roots, and at the top of these bears other roots which are called the crown roots, and which, if well covered with earth, are capable of conveying a great deal of nourishment to the stalk, as well as of affording it great support, and thereby enabling it to resist strong winds.

During growth Maize suffers less than other crops from frequent changes of weather. Continued wet, provided that the water does not actually remain lying in the field, does not damage it, even during flowering time; and as little does it harm from occasional drought. The thing which is most prejudicial is continued cold, and great harm is often done in a field of Maize by a heavy storm of wind. If the plants stand too close together they grow tall and slender, are easily beaten down in raising, and broken by a moderate storm of wind and rain, in which case no attempt must be made to raise them till the leaves are dry, but then there should be no delay. It must be done with the hand, carefully separating the plants from each other, and then, when stood upright, and still holding with the hand, the earth should be pressed tightly to the loosened roots with the foot. Those which may have been broken off by the wind, and which get broken in the raising, are used as fodder, as well as the shoots which come out from the stalk, and which must be pulled off. After fructification the plant should be topped—that is, the male blossom should be cut off; and then, also, should be removed the superfluous ears of corn, it not being advisable to leave more than three upon each plant. These toppings, and the ears which have been pulled off, are used as fodder.

Maize is subject to a disease which produces what are called blight boils. These show themselves mostly on some part of the cob, in the form of a swelling, covered with a delicate white skin, which, when cut, is filled with a watery substance, which changes by degrees to a black powder. This disease is said, however, not to be at all detrimental to the corn. Sometimes, also, a kind of blight, known as the "spessen," appears, by which the ear, or part of it, is destroyed. At other times a maggot is found inside the ear, which attacks both spindle and corn. The birds are as troublesome when the corn is ripening as they are at sowing time, and every means must be used to frighten them away. One effectual means of doing this is to drive stakes into the ground, and from one to another of these to draw threads, with here and there feathers attached to them. Rats and mice, as well as various insects, such as the mole cricket, or churn-worm, are very destructive to the seeds, and these are best destroyed by frequent ploughing or harrowing, by which means the earth is rendered more productive, and the harvest more abundant.

The uses to which Indian Corn is put are numerous, being thought so much of in America that it is much preferred to wheat, particularly in the United States, where its yearly produce is double that of all the other kinds of corn. It forms in that quarter of the globe a very important part of the sustenance of man and beast, being used for bread, cakes, puddings, pastry, and an infinite number of other dishes, besides being a principal part of the food of oxen, pigs, sheep, poultry, and even horses. When used for bread it requires to be mixed with a portion of Wheat or Rye flour, as it would be too heavy alone, and would not possess sufficient consistency. In Italy it is universally used for polenta, whilst in England very excellent bread, mixed with Wheat flour, has been made of it, as well as puddings, light cakes, pancakes, and an infinite number of other dishes, besides being a principal part of the food of oxen, pigs, sheep, poultry, and even horses. In some countries grits are made of the grain, which is also used for brewing beer and distilling brandy; indeed, the art of making from it a most intoxicating liquor was already known to the Americans at the time of the discovery of Arterica by the Spaniards. Besides all that has already been enumerated of the valuable properties of the corn, it may be added that the ears, whilst the grain is still green, are extremely good to eat, either roasted or boiled, with a little butter and salt rubbed over them. The plant itself has so much sweetness in it that syrup and sugar can be made from the knobs.

Maize is a plant which serves for many things besides food. The stalks, and the cobs when stripped of the grain, are used as firing in places where fuel is scarce. If it is meant as green food, then it should be cut low, and young nor too old. The most appropriate time for cutting it is from the beginning of blossoming time to that at which the grain is set.

In southern Germany the harvest time of the ripe Maize often falls in August, but oftener in September; in the northern districts it falls at the end of September or the beginning of October. The plucking of the ears from the stalk, which is the first harvesting, and which is done whilst the plant is standing, can be done by women and children, as can also what is called the stripping. This latter must by no means be delayed after the ears are gathered in, especially if they lie longer than a few hours together they heat, a consequence of which is that the leaves become rotten, and the corn has a bad taste. What is termed stripping is taking the husk off the ear, the husk being a set of thin leaves which are tightly wrapped round it. These leaves make excellent beds, if put loosely into a case.

If the Indian Corn is dried in drying-houses, in an airy corn-loft, or in an oven, then all the leaves are pulled off, and the stump of the cob is also broken away; the ears must not, however, lie more than half a foot thick, and must be constantly turned with a rake. If the ears are to be dried by hanging them up, then the three or four innermost leaves of the husk must be left on the ear, that they may be pulled back, and gathered up together, and by that means several ears tied into a bunch, and then hung up on ropes or on poles to dry.

The grain being perfectly dry it may be shelled, or separated from the cob, the usual time for this being when the hard frosts set in, or in the spring. In districts where the Maize grows in no great abundance, the common way of doing this is to rub the ear of corn upon the back part of an old scythe, or sickle. In the Tyrol they use a kind of large wooden curved shovel, which is made fast upon a bench, which projects beyond the funnel on both sides. The corn falls through the funnel into a measure placed beneath. The flail is sometimes used for removing the corn from the cob by threshing, but if done in this way the ears must be heaped up into high heaps that the stroke of the flail may be more rebounding, and may not injure the grains.

The most approved way, however, of separating the corn from the cob is by means of Mariot's machine, which consists of a notched iron plate, which is moved forwards in a vertical direction by means of two dented wheels and a winch, the ears of corn being pressed against this iron plate by a board running parallel to it. For this board Gardeer has substituted a kind of herculean wedge with teeth, which revolves on its axis whilst the ears of corn are cast into the space between it and the iron plate, through a tin tube, into which they are thrown.

TOWN SEWAGE AND THE ENGINEER.

NOTWITHSTANDING the accomplishment of wonders by Chambers of Agriculture and Farmers' Clubs all over the country, in the way of practical papers and discussions thereupon, that energetic secretaries and members are ever discovering or suggesting, there remains one subject not yet thoroughly laid hold of by either, and that is, the really universal application of sewage to the land in economical way. Thus, a great deal has been written and said on the subject of sewage irrigation, and much has been done, and is being done, in the way of experiment—thoroughly successful experiment; but united action is required, so as to keep abreast of the investigations of Her Majesty's Rivers Commission, and that there is universal conviction that the sewage of towns must be returned to the land—that, at any rate, it must not be floated into the rivers; and as its natural place of lodgment is the land—its original source, so to put it—that the sooner it is returned to it, in the most economical way, the better for the land, and most especially so for all who live upon it, or on its fruits—and that means every living soul. With few exceptions, thinking men are agreed on this; crotchetty people we leave out of consideration, they have had their innings, and have not shouldered their bats out of the field complained. Some vacillators may have hesitated over the "Système Liernur," but we who believe in cheap water carriage, and have at hand that means of transport, can afford to pass with a "blink" the blandishments thereof, and, though not abstainers, declare our determination to stick to water.

Towns generally, we believe, will gladly hand over their sewage to the land at a very low figure, looking for profits to the cheapened vegetable products brought in return to the inhabitants thereof. Then how is this sewage to be got to the land? What description of land is to be made the recipient thereof? And who is to pay for it? Especially the *piper* who has the unjust suspicion of perpetrating a pun! These are the questions for the various agricultural associations to settle, and to enable them to arrive at a settlement we have a suggestion or two to make.

There is extant a splendid Geological Map of the country, and a most valuable Survey Map. Every physical condition of every county is in them beautifully portrayed, and so in part is that of every social beehive. Now, always remembering that the sewage must and ought to be returned to the land, how is it possible, with the aid of these maps, to settle where to take it, and how to do the work most efficiently? Chambers and Clubs have advising chemists—at least, some of them have, and all ought—what is to hinder them from calling in the consulting engineer? Really, nothing. But then owners as well as tenants are interested in this "disposal of sewage" question, and to their councils agricultural associations must invite every landlord. No right-thinking owner of land can possibly refuse to lend an ear, and help; hence we consider that no difficulty whatever will be experienced in getting the aid of the ear and tongue, ay, and pocket also, of every intelligent landowner in the country.

Now for the discussion. We will suppose the Chamber or Club to have settled the preliminaries; then let the county—the owners and tenant-farmers representing it—appoint a deputation to meet the Council of the county town; in joint conclave let them appoint an engineer to report on a plan for the disposal of the sewage, with the assistance of the geological and survey maps,—this official will not require to leave his office to do the preliminary rough work,—and let him report in "so many" months to the united body. But all counties should simultaneously enter on the work, it being understood at starting that all towns in each county would be ready, even if compelled by Act of Parliament, by a certain time, to open their sewage sluices for the benefit of the country; and we sincerely believe that in less than 12 months there would be presented to the general public—to a universally interested world (including speculators)—a plan for disposing of British sewage, the sale of which (that is, the plan in book form) would repay first cost, and leave something over. Whether the charge (first cost) could be made a county one or not—put on the rates—we know not, we think it might; certainly the outlay would prove a profitable one for both owners and occupiers, whether of farms or town dwellings.

Here, maybe, the "careful" reader will inquire, What would the consulting engineer be actually asked to report on? Well, supposing the towns ready to discharge their sewage into the country, casually conning his maps the engineer would study the levels of supply and demand, the distance between the different points of output and intake, and the cost of uniting them per pipe and distributing engine, &c.; he would divide this cost by the acreage to be supplied, and render his first rough estimate accordingly. Compared with railway engineering, that of sewage transport is as 0:1—out of consideration. The main lines of supply being completed, there is little doubt but that many subsidiary streams would soon thereafter have to be sent flowing into the mains, and owners, occupiers, and every scrap of sewage might be utilised, giving a handsome return to both town and country, and uniting both more firmly in the bonds of profit and expediency, —to take a low standard of unity.

At this point a "bill" might be sounded by the economical Hibernian, and with every possible show of reason. If, then, with say, the benefits contemplated are to be national, should not the nation pay the preliminary expenses, and save all "local" purses? Well, this is only another phase of the question, the result would, in the end, be the same. But perhaps a Government Commission, consisting of two engineers, a landowner, and a thorough agriculturist, with a reporter, could accomplish the work in the same time as, and at less expense than, a multitude of county counsellors. It is for agricultural associations to take this view into consideration, and to get the Board of Trade or Commerce as well as the Councils, in order to get up an agitation which a not unwilling Government would listen to. But action must be taken; the land and the people cry out for cheap food; and the result of well-directed and continued action in most cases in ordinary life is wealth.

Science and common sense have done wonders for commerce and ordinary social life, and they are ready to set to work to accomplish even greater wonders—in making the earth to yield its utmost service in the production of food, fruit, and flowers. And here it may be noted that these suggestions and remarks are thrown together by one who for 20 years has taken a great interest in all relating to the question of sewage utilisation, and who hopes that he may be spared to see every railway in the land made to do extra duty as a road along which will be carried the "waste" of every town, to the embankment of every field in the occupation of British farmers. *E. C.*

POULTRY KEEPING.

BY W. B. TEGETMEIER.

A GREAT amount of paper and print has been expended on the question as to the profitable or unprofitable character of poultry as farming stock. On the one hand it is maintained that fowls do not pay the farmer under any circumstances, and on the other that they yield a very handsome profit. Mr. Mechi, one of their latest advocates, states that they cost no more to produce than a corresponding weight of beef or mutton, and that they sell for double the price per stone. As usual in similar cases, I believe the truth lies between the two extremes. Poultry certainly can be made to pay, and yield the farmer a very satisfactory return. On the other hand, they cannot be reared in very large numbers, and certainly cost more per stone to produce than butcher's meat. The profitable production of poultry may be best considered under four distinct heads, namely, fowls, ducks, geese, and turkeys, as the conditions under which they may be reared advantageously vary considerably, and those birds which are most profitable in one locality may be the least so in another.

Fowls.—In the following remarks I shall not enter into the consideration of fancy stock, but regard the birds solely as meat-producers. For market purposes a large-sized, hardy breed is required—one that will yield, without trouble or coddling, a good supply of large early chickens. If, on the other hand, eggs are more remunerative than chickens, the size of the fowl is not so great an object. For market-fowls the breed most available in this country is the grey or coloured Dorking; the chickens, however, have the disadvantage of being delicate, and consequently difficult to rear. The large Asiatic breeds, on the contrary, are very hardy, but they are not good as market-fowls, as the skin and fat are apt to be yellow, and the breast not well covered with flesh. By crossing these races a large, useful, hardy fowl may be produced. I do not maintain that half-bred Brahma and Dorking chickens will be equal as first-class market-fowls to pure-bred Sussex or Dorking; but from the larger number that can be reared on an ordinary farmyard, where no very especial care is given to them, they will be found much more profitable. Nothing is easier than to establish such a

breed: half-a-dozen Brahma hens, either of the dark or light variety, large and short-legged, may be run with a good short-legged Dorking cock: the chickens will be found exceedingly hardy, and if well fed will grow rapidly. In supplying the market, all the cocks should be killed off, and of the pullets, those kept for stock should be such as have short white legs and plump bodies. These the next season should run with a fresh Dorking cock, not even related to the first, or, if a further cross is thought desirable, with a good Houdan cock. If eggs and chickens are desired for market purposes, the Houdan breed will be found very valuable. The chickens are not so large as those of the cross just recommended, but they are good in quality, mature early, and fatten rapidly, and the hens are very free layers; but, as they rarely sit, a few Brahma hens may be kept to hatch their eggs. It will be found more advantageous to use Brahma or Cochin hens for this purpose, inasmuch as their buff-coloured eggs are easily distinguished from those of the Houdans. The Crèvecœur or black-crested French fowl offers a good cross with either Dorking or Brahma; but their black legs tell somewhat against them in English markets, as there is a prejudice against dark colour in the meat of many purchasers. The great drawback against most of the farmyard poultry is the want of size. This may be remedied by keeping better breeds, provided the chickens are well fed from the very first. It cannot be too strongly impressed upon the rearers of market-poultry that "penny-farmed" birds cannot be hoped for if the chickens are not well fed from the very first day they leave the nest. It is not enough to put the hen and newly-hatched brood under a coop, and throw them some tail Wheat two or three times a-day; such treatment will never make large birds. During the hatching the hen should be left undisturbed; the young chickens should not be removed from under her as they are hatched—but when all are out and quite dry and strong, the hen may be cooped in a dry, sunny spot, and a good feed of corn and soft food given to her. The chickens want no food for many hours after they are hatched, as are then digesting the yolk of the egg, which constitutes their first food, and acquiring strength to run about. When they begin to peck, they should be fed with soft food and very small grain. Unquestionably, the best soft food is an egg beaten up with a little bread, milk, and bran, and baked in oven, or by the side of the fire, until it sets into a soft custard. Chickens fed or partially fed on this make wonderful progress. Another point often overlooked is the time at which the young chicks are fed. If they are to make large fowls, they must be fed soon after daylight; if, as is too often the case, they are left hungry for three hours early in the morning, they are always stunted in their growth. They must be fed the first thing, and whilst they are young, every two or three hours during the day. A large lump of soft food, such as oat or barley meal, mixed with milk or water, is better than put into the hen's coop, and it is thought that it will suffice for the day; in a short time it becomes trodden on and defiled, and it is then no longer wholesome food. The right plan is to give no more soft food than the chickens can eat at once. Over-night, a supply of grits, ground Oats, or small Barley, should be put down for them, as the first meal in the morning. Many poultry-keepers are partial to keeping the hens with chickens under coops for some weeks. I am decidedly opposed to the plan. By so doing, the natural insect-food that the hen acquires by scratching—the worms, grubs, small seeds, small flies, &c.—are denied to the chicken, and no artificial diet will compensate for the loss. Nor can the hen dust to free herself from vermin, that feed sumptuously on the young chicks at night. It is said that the hen if not cooped will draggle the chickens through the wet grass, and tire them out. A half-starved hen may possibly do so; but, if she is well fed with corn, there is no danger of her so doing. If preferred, she can be shut up until the dew is off the grass; but the finest and heaviest chickens I have ever bred have been those that have been with hens that were never shut up in houses or coops, but range under open sheds, could go out at all hours. If the hens are allowed to scratch for the chicken, the chopped meat and meat-broth which are requisite for them when closely confined, is altogether unnecessary. It is the custom of some game-rearers to hang up in the woods any dead waste animal, to supply maggots for the young pheasants. This is not desirable near a homestead; but any refuse animal remains may be utilised without offence, by allowing them to become thoroughly fly-blown, and then burying them in the fowl-run; the maggots attain their full size underground, and previous to turning into flies work their way instinctively to the surface, furnishing an abundant supply to the young chickens.

There are a few other points in the management of fowls, about which it may be desirable to say a few words. In the first place, let me caution all agriculturists against attempting to employ any artificial incubators: despite of all the care and attention that has been devoted to their construction, not one has been found a success in actual practice, nor do I know of any person who continues to employ them except experimentally. There is no great difficulty in hatching a certain number of the eggs in incubators, but rearing the chickens in any number without hens is hopeless. Whatever may be the case in the warmer climate of Egypt, in the colder latitude of England artificial incubation is a delusion. The keeping of fowls in very large numbers by the establishment of what have been called poultry-farms, has attracted considerable attention of late. It has been argued that if a moderate number of fowls around a homestead can be made, as they unquestionably can, to yield a fair profit, it is only necessary to multiply the number by 10, 20, or 100 to secure a proportionate return. No argument can be more fallacious. Whenever a very large number of fowls is collected together in one place, the ground becomes tainted, and disease invariably breaks out amongst them. Poultry-farms have been tried under almost every possible condition, and have invariably proved failures. If a very large space of enough useless ground can be devoted to them, a considerable number may be kept; but such ground is rare near the farm-houses in England. The reason of the greater number of fowls being reared in France (from whence before the war we were in the habit of importing considerably more than one million of eggs per day) is that, in the place of large farms, the country is divided into very numerous small holdings, and that at each of these a good stock of fowls is maintained. The profit to be made by poultry depends so much on the management and on the demand for fowls in the locality that it cannot be accurately stated. Mr. Mechi, who allows his fowls free range of his cornfields, and regards them as his best friends in the destruction of noxious insects, maintains that they cost no more to rear than a corresponding weight of beef or pork, although they produce double those meats in the same space. But when it is remembered that, during the whole of their lives, corn, in some form or other, forms the main food of poultry, and that, whilst they are young chickens and during the time they are fattening, their food is of an expensive character, whereas beef and mutton are grown upon grass, it is clear that the former cannot be other that one costs much more to produce than the other. Moreover, if the growth of poultry be quite as profitable as Mr. Mechi would maintain, how is it that almost every cottager in the kingdom does not follow the more remunerative pursuit? The poultry, properly tended, will yield a good profit I am fully aware; but that fowls can be reared at the same cost as beef and mutton I must have some very definite accounts to prove.

Turkeys.—In many parts of the kingdom the rearing of turkeys is followed with great advantage, whereas in other localities a turkey in a farmyard is a rarity. There is no doubt that turkeys, properly managed, are amongst the most profitable of live stock, and it is difficult to account for their absence from many places where they could be advantageously reared. Turkeys consume a much larger proportion of green food than fowls, and grow into size almost without cost; when fattened, they realise a high price in the market, and, as they are chiefly in demand in cold weather, can be sent to market in distant places, as Scotland. Many farmers and farmers' wives, however, dread engaging in the rearing of turkeys, believing them to be exceedingly delicate when young. I believe properly-managed turkeys are not more difficult to rear than common fowls, and I am quite certain they can be raised to much greater profit. The first point to be observed is to follow Nature as far as possible. I make my turkey nests on the ground; or if in a paved house, in large shallow boxes, half-filled with mould that can be damped at intervals. The hens, unless they come off regularly, are fed off to feed, and then supplied with grain with a liberal hand. When the young ones are hatched, they are left undisturbed under the hen until the next day. No attempt is made to cram them—an absurd practice, which interferes most injuriously with the due digestion of the yolk that is absorbed into the intestines at birth, and constitutes the food required for 24 or 30 hours after hatching. The first food given them is egg beaten up with an equal bulk of milk, and baked into a soft custard; this is alternated with crumbled bread mixed with milk, to which oatmeal is added in a gradually increasing proportion. Ants' eggs are given, if I can get them; and this food should be continued for a fortnight or three weeks. Quite as important as any other part of the dietary of young turkeys is the supply of green food, and many persons chop up Nettles, Onions, &c., with the meal; but if young turkeys are watched when grazing, it will be observed that they prefer eating bitter herbs belonging to the natural family Composite, or compound flowered plants, such as the Dandelion, &c. The common Lettuce belongs to the same tribe, and I have this year fed largely upon it. The greediness with which young turkeys devour this plant is remarkable. At three weeks old a dozen turkey chicks will eat four or five large Lettuces in a day, and they even seem to prefer them when running to seed, at which time there is abundance of milky juice in the plants. At the age of a month, they will begin to peck a few grains of Wheat or Barley: but bread-and-milk and meal should form the staple of their food for the first two or three months of their lives. Most persons say that young turkeys are particularly delicate when they are "shooting the red." This is not to be wondered at, when it is remembered that they are generally put on whole grain, without milk, long before they arrive at that age, and suffer accordingly. Another point of the highest importance in feeding turkeys, or young birds of any kind, is the hour at which they get their first repast. In summer it is daylight at 4 o'clock in the morning. If the birds have their first meal deferred until 6 or 7 o'clock, they have been hungry for two or three hours, and suffer very much. To be successful in rearing these, and any other young birds, they must either be supplied over-night with their first meal, or the poultry maid must be up with the lark. There is no better plan than putting the hen and chicks, for the first month or two, in a closely-wired aviary at night, which is open to the early sun; and Lettuce and a good supply of soft food can be put under a coop, so that the hen cannot eat it, and there will be found but little left an hour after daybreak. If the young turkeys are well fed from the first, they can be fattened by shutting them up for a fortnight or three weeks in any small sheltered court, and feeding them on meal and milk: and they ought to produce from 10*d.* to 1*s.* per lb., live weight, at Christmas. Selling them direct to the consumer, if possible, will be found a far more profitable proceeding than consigning them to a salesman, against whom the producer has not the slightest check.

Ducks are, under certain conditions, amongst the most profitable of farm stock. Aylesbury and its immediate neighbourhood is said to receive upwards of £20,000 yearly in ducklings sent to the London market. The usual mode of managing ducks in country districts is as erroneous as it is possible to conceive. The breed of ducks is usually bad, and the broods are not killed until they are six or seven months old. For market purposes there is no breed so profitable as the large white Aylesbury variety. These, if well-fed, begin to lay about Christmas, and the eggs should at once be placed under hens; for this purpose Cochins or Brahmas are admirable. It need not be insisted on that abundance of food must be supplied to produce eggs in winter. The only mode of feeding ducks satisfactorily is to put the corn in water; a shallow feeding-trough or other vessel should be provided, and the Oats to be placed in enough water to cover them. This mode of feeding avoids all waste, as every grain is taken out of the water by the birds, and none is trampled under foot. As ducks usually lay at night, the brood stock should be shut up till morning, and the eggs at once removed, and, as soon as practicable, placed under hens. The young birds are fed the next day, when they should, if the weather is at all cold, be placed in a warm shed with the hen, or, if several broods are hatched at the same time, and the shed is a warm one, they may all be given to one hen. At first they should be fed on oatmeal and milk; afterwards Oats may be given them in water; but if required to fatten and mature rapidly, the Aylesbury rearers feed them almost entirely on meal, boiled with a small proportion of greaves; but the flavour is not as delicate as that of corn-fed birds. If duly cared for, young ducklings should be perfectly feathered, fat, and quite fit for the market in less than two months, and the spring birds often produce 6*s.* or 7*s.* each in the London markets. The ducklings so forced are never allowed access to water, but are kept caring and growing during the whole of their short lives. After one or 12 weeks a duckling is only kept to waste, as it then begins to moult its first feathers, becomes poor, and does not gain in weight. Of course the profit on ducks is to be made only by sending them to market at the proper time—namely, when 8 to 10 weeks old. If they are kept till they are six or eight months old, they are inferior for table purposes, cost more to produce, and yield less to the producer. It is no wonder that, under these circumstances, people say "ducks don't pay."

Geese can only be profitably kept where there is abundance of grazing ground, as they derive the greater part of their nourishment from grass. Under suitable conditions no birds can be more profitable, but under unfavourable circumstances they are remarkably so. Of the three varieties, namely, the pure white or Embden, the grey or Toulouse, and the common saddle-back, the former are to be preferred, as the birds pluck much better and clearer than the common parti-coloured breed. The management of geese in suitable localities is attended with very little trouble. In the early part of the year the old geese should be well fed with Oats thrown into water, so as to stimulate them to early laying in February, if possible. When she has laid from eight to 15 eggs, the goose remains on the nest and her eggs may then be given to her. When hatched, the goslings require grass, meal slaked with water, or porridge made with oatmeal. After a few days, Oats, in water, may be given, and with the food they find by grazing the young will do well until fattening time, when they should be fed on Oats, in water. In many parts the geese are partially plucked two or three times a year for the sake of the feathers. Nothing can be more injurious than the practice; the small sum obtained for the plumage is much less than the deterioration in the value of the bird. In concluding these remarks upon poultry as farm stock, I would impress on the agriculturist the necessity of commencing with really good stock. On many a farm where nothing is to be seen but the most improved varieties of cattle, sheep, and pigs, there may be observed a number of the most wretched fowls and small worthless ducks and geese, that are hardly worth the food they have consumed. Nothing can be done in the way of profit with such stock. Really good large breeds must be procured, but it must also be remembered that this alone will not do; they must be well fed and well housed, and even these two condi-

tions will be of no avail unless the birds are well tended, and the young stock more especially never allowed to be checked in their growth by hunger. Good breed, good feeding, and good attendance, are the three golden requisites to profitable poultry keeping. *The Bath and West of England Society's Journal.*

HEADS.

By Henry Corbett.

(Continued from p. 1390).

The beauty of the horse, and of the head of the horse, have been sung in all ages. Job says, "the glory of his nostril is terrible," and that "he smelleth the battle afar off;" while Virgil repeats the image:—

"Micat auribus, et tremit artus ;
Collectumque premens volvit sub naribus ignem."

And this notion of "nostril fire" has been pronounced "the noblest line that ever was written without inspiration." Again, Homer and Shakespeare are never weary of taking the horse as an illustration of courage, vigour, and intelligence. I am inclined to doubt, though, whether the ancients could really have had any correct idea of what a horse's head should be, from the very name which Alexander the Great gave his almost equally renowned charger—Bucephalus, a composition of two Greek words, *bous* and *kephalos*, that is, the head of a bull ; just about the worst kind of head a horse could have. We see this repeated, however, at a later period in the animal on which the Knights of the Tourney were mounted, where the same thick, broad bull's head is very commonly the type. But a man in armour was, of course, a great weight, and his war steed probably more of a heavy draught-horse than the stamp upon which we now see a dragoon officer. In fact, the modern charger, the hack, and the hunter, must all show breed ; and let me thus endeavour to sketch the head of the well-bred horses, as it should be. The size of this must be in just proportion to the Body, as certainly not noticeably small, but of a happy medium in length and breadth. Indeed, a horse's frame should "prove" by his head. The ears should be long, somewhat thin and moderately open, and not set too wide apart, nor pricked up, but the rather with a gentle inclination at the points towards each other. Our cropping forefathers, when they went so much for short pricked ears, could have had but a poor notion of the actual beauty in this feature of the horse, nevertheless, there are writers who go with them ; Youatt, amongst others, who says, "the ear should be small and erect." And I cannot agree with him, no do I think that he was any great authority on the horse. In the short, stiff ear you lose that beautiful significant "play," almost as true a reflex of a horse's "thoughts" as the eye itself. There is scarcely a movement of the ears but which has its meaning, and on this our barbarian ancestors improved by cutting them off! A lop-ear is assumed to indicate coarseness of breeding and sourness of temper, but this is not invariably the case. I have seen some thorough-bred horses with lop-ears ; and Oulston, who carries his very drooping is, in other respects, a horse of peculiar delicate appearance. Nor does the lop always answer for sluggish or bad disposition, as it is more "the look of the thing" after all, and I knew a really good judge who rather fancied a hack with one lop-ear. Beginning, then, with the lengthy, flexible ear, the horse's forehead should be broad, bold, and gradually expanding in width from the pole to between the eyes, which should be set in the head a third of its entire length from the pole. Nothing has a worse effect than the eye of the horse being set up too high in his head. And the eye of the horse is, of course, one of his great beauties, and the chief tests of his character. Dark, bright, and lively, it should be a combination of spirit, sagacity, and gentleness, as, in fact, the eye of a gentleman. Especially to be avoided is the small, sunken pig's eye, which tells of everything that is bad.

To proceed, the face from the forehead should be rather round—not exactly bulging like the Johannas—gradually reaching to a slight dip between the eyes and the nostrils, and then rising and falling again before coming to the nose. This dishing in the face of the high-bred horse is deservedly prized, as the great eminent Roman nose or "Blackbird's bend" is to be equally avoided. How capitally Leech has transferred all its native ugliness to Jorrocks' Arter-Xerxes ! The nostrils should be square and open, with a sharp angular look about them that gives a certain peculiar grandness and force to the face. The saying that "a horse should be able to put his nose into a pint pot" is something very like nonsense ; as, indeed, I scarcely ever knew a horse with what a woman would call a sweet, pretty head, to be good for much. It is the expression of the horse's countenance which constituted his chief charms, and here are many sober-headed horses who, without being handsome, show this all but speaking intelligence in a very remarkable degree. The jowl should have a sweep from the root of the ear, with a good depth and a width of channel, tapering gradually to the muzzle. Plenty of room for the windpipe to play in is a great point, and the best judge of a yearling we have, or certainly a gentleman who generally does the best by his purchases in this way, makes this width of jowl a cardinal point. The lip, another sure sign of blood, should be thin, firm, and of moderate length, as the pendulous thick lip is unsightly in itself, and a tell-tale of bad breeding. A fat or fleshy head cannot, of course, be ornamental either to man or beast, and, as every one has his own fancy, mine is for a lengish, lean head on a horse ; how many good nags have I known with that serious, almost judicial cast of countenance !

The horse's head must, above that of all other animals, be well set on. The effect of the best head is ruined if the ran "throaty" into the throat, while a certain inclination is everything, either in the way of elegance of appearance or comfort in going. I have seen some good race horses with ewe-necks, but that of the hunter or the hack must give nicely in the right direction, if the horse is to be ridden with anything like satisfaction. I have said that the shoulder should answer for action, but I do not know but that you may often get at a key to this from the head. When you see a dull, drowsy-eyed, melancholy-visaged beast, drooping his head in his stall, cannot you tell before you have him out what a slouching, slovenly goer he will prove, ever waiting for a dig of the spur or a crack of the whip? whereas the bright, cheerful-looking horse points his ears, and steps away at once. The head of the heavy draught horse is not so important a point as that of the better bred one. It lacks much of the sensibility of the other, does not taper nor dish so much in front, and, in fact, must necessarily with the character of a mere beast of burden. Still great improvement is observable in the heads of our cart-horses, from the time when our old black breed was in the ascendant, and in none more so than amongst the Suffolks. At the time I first met with these, while in their native county, I was assured that the small, mean pig-eye was "the proper thing ;" but since then this has gone very much out of fashion, and the heads of some of the more modern Punches are now handsome enough,—in fact, as some good old Conservatives will have it, a vast deal too pretty for the hard-working.

I cannot, however, but rank myself amongst the stanch admirers of the Arabian ; but in General Dumas' book on the horses of the Sahara, edited by Abd-el-Kader, there is a high-flown description of the head of the Arab, too amusing not to be given :—"The eye of a horse should be turned as if trying to look, at its nose, like the eye of a man who squints. Like a beautiful coquette who leers through her veil, his glance towards the corner of the eye pierces through the hair of the forelock, which covers his forehead as with a veil. The ears resemble those of an antelope, startled in the midst of her herd. The forelock is abundant. In the hour of pain mount a slender mare, whose forehead is covered by silky and flowing hair. The nostrils are wide : each of his nostrils resembles the den of a lion ; the wind rushes out of it when he is panting." *Bath and West of England Society's Journal.*

(To be Continued.)

WATER.

The farmer has no element to deal with so essential to his success in business as water, for its character and action largely depend upon quantity. The tissues of plants under the microscope seem sacks of water, and we are told that man and beast are made up of a very small portion indeed of dry goods, and the rest water. Irrigation, draining, and warping are all but verses taken from the general chapter of the deeds done by the agency of water. Water is a dissolvent of earths by itself, like something having life ; no other heavy body moves so lightly over the ground and from place to place as water ; and from the numerous wells that have been dug, as well as from the springs that rise to the surface of their own accord, it is evident that the supply of water underground is nearly as general as that of the air we breathe.

In this country the usual rainfall is about 30 inches in the best cultivated districts, and this amount of rainwater would supply all our wants liberally if we could only prevent it from running to waste. A great weight of water falling from the clouds carries off a great deal of the filth of towns, and indeed of country dwellings as well, and thereby proves itself by far the most powerful scavenger that we possess ; but the farmer sees with dismay the pitiless pelting of a stormy day washing the manure out of his farmyard, and carrying it out to the open sea. This text has furnished a never-failing theme in the hands of our great agricultural instructor, Mr. Mechi, at the gatherings of the experts in farming, where the note of warning, slightly varied, runs thus :—"Put your trust in Providence, and keep your *dungpills* dry."

The old school of gardeners, who grew early Melons and Cucumbers on heaps of stable-dung, before the system of heating by hot water was invented, thoroughly understood the various processes through which the dung had to pass before it was worth a shred of vegetable matter, as would first turn of a blue colour and then burn black, and in this way get to be utterly useless either as a fermenting material or for manure ; and the great bulk of London dung when it leaves the stables is seldom fit for manure, and the bulky load that a single horse can draw tells clearly that it is only dry litter. A covered manure-heap is certainly not the place for such an article, and many fields near London are marked with manure of this kind.

One of the best designed farm steadings that I have seen was built for Charles Fraser, Esq., of Williamston, in Aberdeenshire, and the manure pit occupied an important place in the design. The architect reckoned the annual rainfall to be about 3 feet, and planned the clearing for the reception of the dung from the stables, byres, and sties accordingly, so that all the manure had simply to be kept level, and thus the whole mass being always too wet to ferment suffered no waste, but, on the contrary, got improved, so that I have seen the silver ease of the carter's watch quite black with the atmosphere of the manure-pit, and the excellent crops of Turnips told plainly that the manure-pit had been well managed ; and if any zealous improver had offered to erect a shed over the manure-pit at his own cost, the proprietor would have laughed at the idea, for his was not a dungheap by chance, but a manure-pit by design. Brewers' grains or draff is kept sweet in tanks or cisterns under ground for the milk cows of the London cowkeepers, and the dry barley-meal that is usually mixed with it absorbs the water that was added to keep it from souring or fermenting. A tanner's bark pit is quite a case in point, for as long as the bark remains in the tank it is cold enough, because it is saturated, but get it half dry into a pit in the Pine stove, and it will heat violently and decompose, and finally get to fine black dust of no value as a manure, notwithstanding its vegetable origin. The mystery entirely disappears when come to actual facts and consult the rain gauge ; why, then, should any one attempt to complicate a thing that has already attained all the perfection it is capable of receiving, and that by the cheapest and simplest means? for there is seldom any lack of room downwards to hinder from getting a pit 3 feet deep, with an inclined plane for the carts to get in and out. I speak here only of the general practice of storing manure, and do not enter upon the specialities of manure tanks or manure sheds, where sheep are fattened on boards and their droppings occupy the ground floor of the apartments, and where cinders are added to sweeten the air and improve the manure. These are laboratories, and have their accessories in high-priced steam-engines, cast-iron pipes, sulphuric acid, and the like ; but I maintain that a wet dung-pit, well managed, will be found the substitute of the ordinary manure. From the earliest records of our race we learn that the planter always watered, until, in the days of the Apostles, it had become an idiom in the language, "Paul may plant, and Apollos may water," &c. ; yet after all that has been done and said, and having all the experience of horticulturists before my eyes, where should we look for a farmer that would think of watering?—and if I had been silly enough to hint that if it pays a man to water his garden it would do so to water his field, I should have been looked upon as a visionary ; but the sewage farms have done this problem practically, for in reality a supply of dirty water differ from the supply of plenty of dung and plenty of clean water to plants, whether in garden or field, by the perch or by the acre? In short, we are only on the verge of a magnificent landscape, where the root crops will get justice them in dry weather by means of watering, so that if the farmer gets enough of sunshine, the crop will be pretty nearly under his control—for tilling, manuring, timely sowing, and the like, are all of the usual kind that he is accustomed to grapple with, and the root crop secured leads to prosperity with the crops that are to come after.

The splendid sheet of water at Blenheim was made by a single dam dyke across the valley by the skill of the eminent landscape gardener, Mr. Brown, better known as "Capability Brown."

I have seen a large tract of land, high and dry, fit for nothing but sheepwalk, but when a few acres had been converted into a lodge for rainwater, it was no longer the dry farm as formerly, for the threshing-machine was driven by water supplied by the sloping sides of the hill ground ; and if Divine Providence sends an annual supply of like essential elsewhere but to a tank 3 feet deep all over the farm, there need be no want of water when it is needed, and there need be no more difficulty in watering Turnip drills than there was in making them. It is enough for my purpose that the sound practice of watering for root crops has got from the garden into the field, and it would be an easy matter to settle what portion of the success attending the crops on sewage farms was due to simple watering, and what to the manure conveyed by water during the trying time of the summer of 1870. The constant watering of all the indoor garden plants with clean water, and the state of perfection they attain to, leaves no doubt on the minds of the best cultivators that they have to supply water as freely as they supply air and light during the growing season to their plants. The ornamental water in most gardens is useful as a reservoir to supply the wants of the flower garden, and if I could only induce one farmer to build a dam dyke and store a good supply of water, to be used at discretion, as the need arises, I shall not have written in vain. There is no difficulty in convincing a man of the great service that draining is to wet land, but when it is proposed to husband the great blessing of a column of rain-water, 2 or 3 feet deep, which a kind Providence conveys to every field annually, however high or dry the field may be, nobody thinks of tampering with such a task, but if a person has had a little experience of the value of a water-store

on high ground, he would not willingly part with such a privilege. We had acres of water above the level of the garden at Alton Towers, and used a hose for watering, and one man and a boy were sufficient to conduct the operation, pouring a continuous stream of water all the day where watering was wanted; and in the worst of cases, where recourse is had to the water-cart, much may be done at lessening the labour. Sir Simon Clarke's water-cart had a valve in the bottom, and was all below the level of the axle-tree, so that when the horse walked into the pond the cart filled in a few minutes without any labour, and I am advocating a system that does not require any fatigue to raise water. The "wheel at the cistern" and "the iron-bound bucket that hung in the well," are not to be named against a mill-dam filled with arched snow, or the rains of a "fill-ditch February," for the water God sends us will be found not only the cheapest but the best. *Alex. Forsyth, 9, Islington Square, Salford, Manchester.*

Home Correspondence.

I am an Agricultural Sinner.—Such, at least, is the opinion of a great many farmers, and some landlords, especially of a certain class, who say or think, "Confound that Mr. Mechi—I wish he was comfortably under the turf, for he is always creating an agricultural disturbance, and won't let agriculture alone. Besides, he is letting people into the secrets of our calling, and we shall have the landowners' eyes opened, and our rents raised." Now, I don't complain of this, because it is a natural feeling; we most of us dislike change (even if it be improvement), and the trouble attending it. How loth we towns-people were to part with our old stage coaches, and did we not protest against the horrible smoke, noise, and nuisance of the locomotive engine? and did we not so oppose the introduction of railways to our towns that they had to be constructed far away? and then, when too late, we repented of our folly, and had, in many cases, to make branch railways to reach the main line. So it will be in agriculture: when the farmer is more free in action, by means of a lease, or better still, a valuation for unexhausted improvements, he will not be afraid to say that he is making a living by his business, and will not be, as is too often the case now, hypocritically croaking about farming being a bad trade, and one to lose money by. I remember in my early days, when my employer (a merchant) had bought an estate in Kent, his principal tenant (a most respectable gentleman), always when he came to pay his rent brought a balance-sheet, showing what loss he was sustaining. Of course the landlord, a sharp-witted man, smiled at the innocent deceit and forgave it, but did not believe that any man would be so foolish as to continue a business by which he was always losing money. My agricultural friends ought really not to be angry with me, but the very contrary, for I have laboured long and hard to try to convince landowners that it is to their interest as well as to the tenants' that there should be more freedom of action and more security of tenure for the tenants, and that their land should be drained, their fields open and free from timber, and that there should be good cottages well suited for the times, and roads, and the costly but necessary implements of machinery of modern and improved agriculture. No doubt we are just emerging from a primitive and pastoral and almost feudal age, but mighty steam, which has severed so many attachments, will break up the new and improved agricultural methods (both as landowners and tenants), and we shall soon look back with shame to the present time, when our annual agricultural available produce is less than £4 per acre, and we shall then, no doubt, consider it as unprofitable and degrading to the foreigners for corn, meat, and bread, meat, butter, cheese, and eggs, as it would be to rely upon foreign supplies of cotton and woollen manufactures when we have ample means to produce them properly at home, and thus afford increased and ample employment for our industrious millions. Time is getting short with me, but so convinced am I that I am doing useful service to my country, that I shall, even at the risk of offending prejudices in favour of old customs, continue my exertions for improved agriculture and increased food, profit, and employment for our people. *T. Y. Mechi, Tiptree, October.*

Summer and Winter Wheat.—My attention has been called to a paragraph in the *Mark Lane Express* of September 10, about the failure of nursery Wheat (a winter variety) sown in France in the spring of the present year, and, in consequence threatened litigation for disappointment and loss. This state of matters has, in all probability, arisen from not knowing the distinction between summer and winter kinds of this cereal. Linnæus ranks these wheats as distinct species, and contrary to the jaundiced but great botanist's classification. When in Canada West in 1833, I was shown a piece of ground which had been seeded in spring partly with the summer Wheat of Canada East and partly with winter Wheat from Scotland. On July 7 I found the crop of summer Wheat very promising and coming into ear, while the crop of winter Wheat was only 4 or 5 inches high and without an indication of earing. Since that time I have seen similar effects in different parts of England, where winter Wheat had been sown late in spring. Upon one occasion, by way of experiment, I sowed in this locality both kinds of Wheat on March 15, April 15, and May 15. The March seeding eared in the usual way with both Wheats. In the case of the April seeding the summer Wheat eared well, while only two abortive stalks and ears came forth from the winter Wheat—the rest of the plants being leaves. With the May seeding the summer Wheat eared and ripened, but the winter Wheat continued tufts of grass. On July 18, 1870, I sowed here a variety of Barley, which ripens a week sooner than the Chevalier, contiguous to a variety of summer Wheat named red Tuscany. Both of the cereals blossomed before being cut down by frost, and throughout their growth the Wheat appeared to be more robust and earlier than the Barley. The non-earing of winter Wheat, when sown late in spring, is a property inherent to the species, and is displayed in the climates of Canada West, Britain and France, and of which Wheat growers ought to be aware. *Patrick Shirreff, Haddington, Oct.* 18.

"Water" on the Brain.—In the *Times*, within the last few days, there has been an attempt to enlighten the public mind on the sewage difficulties. It is now proposed to bring together a wrong course has been followed; and, as the expressions we have also pointed, I shall quote them in the few remarks I am about to offer. It is stated that "we have been floundering in the mud, and getting out of one stupidity into another; " that "we played the Hercules, and transformed every town—of course at the cost of the Thames or some other stream." These are very humiliating confessions, but they are appropriate; and it is not necessary to quote more from the article in reference to the waters of the rivers being polluted by the course adopted; but the more immediate attention of the public is directed towards the writer on the subject taken by Mr. J. Bailey Denton, that there may be no more "floundering in the mud." Mr. Denton objects to all that has been done—such as passing the sewage "over the surface of the land by the alternation of water and furrow"—that it "remains sewage still;" "it does not do its duty, but pollutes the stream into which it is discharged." "On the other hand, the artificial stagnation of sewage water is a most offensive nuisance," and it is "contrary to the order observed by Nature in the growth of plants." "Stagnation," he says in Hyperesis, stiffles, and kills vegetation;" "it drowns the surface, and by consequent evaporation it chills the air;" "a wet surface is a cold surface," and it also prevents that aëration of the soil which is so essentially necessary to successful cultivation. These observations and deductions are so obvious, I presume no one will dispute them. But nevertheless these are the results of the course which still is advocated by writers for the Press, and by many who are called engineers. However, there is said to be a new ray of hope in a scheme proposed by Mr. Denton for meeting all the difficulties alluded to. He would construct a filtering bed, of a friable and permeable soil, with drains 5 or 6 feet beneath the surface. The water, it is stated, "will re-appear at the aperture of the drain as fit for drinking as the Thames above the lock"—indeed, "fitter," Mr. Denton says. Only 223 acres, properly laid out and converted into a vast filter, will be sufficient for the sewage of a town with 10,000 inhabitants." As all other plans of utilising sewage by concentration, precipitation, evaporation, &c., are reported to be failures, it will be necessary to make a few observations and to employ a few figures, so that some idea may be formed of the difficulties alluded to. He would construct a filtering bed, of a friable and permeable soil, with drains 5 or 6 feet beneath the surface. The water, it is stated, "will re-appear at the aperture of the drain as fit for drinking as the Thames above the lock"—indeed, "fitter," Mr. Denton says. Only 223 acres, properly laid out and converted into a vast filter, will be sufficient for the sewage of a town with 10,000 inhabitants." As all other plans of utilising sewage by concentration, precipitation, evaporation, &c., are reported to be failures, it will be necessary to make a few observations and to employ a few figures, so that some idea may be formed of the difficulties which may be expected from Mr. Denton's remedy for the difficulty, which is so prominently brought before the public; especially as the data are given—population and the area of the filter. The ordinary water supply of a town is 30 gallons per head from which sewage for each person per day. Say, 25 galls. for 10,000 persons will amount to 250,000 galls., which, divided by 224, will express the quantity—1116 tons—as the weight of sewage to be filtered through 5 acres of permeable soil, or 223 tons per acre every day, which is equal in quantity to about 2½ inches of rain per day. The writer in the *Times* further says:—"It is encouraging to learn that 600 or 700 acres will do for the whole metropolis for a long time to come;" but he alludes to the possible necessity of requiring many more acres. However, the estimate is a fallacy, based on a gross arithmetical blunder. As to the possibility of such a quantity as 223 tons daily soaking through an acre of soil, it must be well known by the most careless observer that during heavy rains a very large portion of it passes off the surface into the gutters, brooks, &c., to the rivers—hence a flood occurs; and this, too, with much less than 2 inches of rainfall in a day. The quantity of water used in towns varies considerably; in some it is less than 25 galls. average per person, in others there is a supply of 50 galls. each. The effects of the flow of sewage from what were originally brooks or rivulets in many towns, may furnish matter for a very highly wrought water-colour illustration. In the meantime it may not be amiss to allude to the fact that an inch of rain on an acre amounts to rather more than 100 tons, and consequently the figures which are used in the published records of the rainfall as decimal fractions, may be read as representing the quantity in tons on the acre: for example, .55 would represent 55 tons; .07 would be 7 tons. This reading I communicated to the Registrar-General some years since, in the expectation that if generally known it would enable persons readily to appreciate statements as to the effects of rainfall on a district. It is presumed sufficient has been said from time to time to show that the difficulties in the way of a satisfactory solution of this question are not yet got rid of. But there are deep-rooted errors in the way: for instance, the water is frequently called the carrier of the manure to the point where it is wanted; it is rather the inseparable bulky companion which is carried along with the manure to its destination, and when there, it is in the way, and is the real cause of all the difficulties complained of. It is, however, an important step towards a cure when the knowledge of the cause of a disease is arrived at. Is it in this case water on the public brain? *Henry Phillips, Albion Place, Heavitree, Exeter, October* 11.

Landowners and Agricultural Labourers.—Your correspondent, "A Farmer," judging from the tone of his remarks, must surely imagine that the intention of my former letter on this subject was chiefly to inform the readers of the *Agricultural Gazette* that there was not a man of any honour amongst the farming community. I was not aware that my remarks could convey that impression, and certainly I never for a moment thought so. A word or two of explanation, therefore, may be necessary. First, as to retaining the labourers' sons on an estate. Possibly in some cases the supply would exceed the demand, but they would be very few, I am inclined to believe. It must be borne in mind that whatever might be done to keep these lads in the country, and train them as labourers, it is hardly likely that they would all turn out good workmen, and some would, therefore, go into the towns and cities to seek for employment more suited to their tastes. And, again, when these lads have grown up, have learned their business rightly, it is probable that they would take the place of those who are not so well up to their work. Just for the time, of course, the supply would exceed the demand, but it is probable that things would soon right themselves, by the men themselves finding employment elsewhere. In these places, where the workmen are natives, and where there are plenty of them, of course nothing more can be done; but where the labourers are principally foreigners, it would be for the benefit of the farmer if the labourers' sons could be retained, as to the workmen taking the cottage from the owner, instead of from his master. Most farmers object to it, because, as they candidly admit, they have not so much authority over them unless they are their tenants as well as their servants. I am quite willing to acknowledge, that by the majority of farmers this power would be rightly used; but, on the other hand, there are many who make use of it to gain their own ends, and as it would be unfair to make "fish of one and flesh of another" to remedy the evil it is necessary to take the cottage from all and let them to their masters direct. But a higher and better reason for the proposal is, that if it was carried out the labourerer would be in a better social position; he would feel himself more independent, and I believe the result would be, that he would become a better workman. Anything that can be done to raise the condition of the agricultural labourer will, I am firmly convinced, bring forth good fruits, which will not only benefit the labourer, but also his master, the tenant-farmer. Certainly the suggestions contained in my former letter were made with a view to improve the labourer's condition, rather than of showing up the injustice of some tenant-farmers, although as an additional argument, I was obliged to refer to some instances of the latter, which I have either known or heard of. *E. Minshall, Estate Office, Aston, Preston Brook.*

Steam Cultivation: Mr. Smith on the Contract System.—Farmers who fritter their money away in having a few acres done yearly by the contractor, are like children in a fair, scattering their money for the showman to pick up; and as they have done before they will again show to the contractor the necessity as a badge against their high prices charged for the work done. Mr. Robinson (a contractor) gave, in a paper read last autumn before the Wisbech Chamber of Agriculture, some good and sufficient reasons why contractors must charge a high price for the work done. I can now give some evidence in support of his reasons. He told the farmers plainly that they must look to an increased produce for their means of payment. My heavy land produces yearly full 12 bush. of corn per acre more than it did under horse culture, and the dead fallow system. To get this I am obliged to get all my work (that is, steam-power work) done in the autumn, and so must every farmer in England, if England's 800,000 acres of dead fallow are to be made to grow corn yearly. To give all the work in the autumn, the contractor's season must be a short one. This year we had a late harvest. October 10 was the earliest moment I could start my steam tackle. It is possible that a contractor might have found work a little earlier; but we must remember that if the land is to be all in crop, these crops must be harvested. It will never do to keep land idle for the fun of finding the contractor land to practise upon. If I fix the middle of August as the contractor's entering point on an average of years, he will get 16 days in

August, 30 in September, and 31 in October, and that will end his season, for the dirty dark days in November will never do for him. In this way he gets 77 days. From this must be deducted 11 Sundays. This fixes him at 66 working days. What is his average daily earnings? is the next question. Here is some evidence upon the point. On September 20, when on my field, at about 10 A.M., I heard, I thought, an engine on the canal in distress. Half an hour later I heard it again, and from its heavy beat I thought it was in great distress: therefore I jumped to the conclusion that it had got stuck deeply in the mud; so I looked out to see what was up, when I found under the canal hedge a double engine set of Fowler's big tackle just starting on a 17-acre field Bean stubble. This field, although in another parish, joined my own land; so I jumped over the hedge to see the big things that had come to pay me a visit. Yes, and I took stock of them. The implement was a thoroughbred "Smith," not only in turning at land's-end, but in construction upon all points; even the means of guiding was copied from the Woolston man's combined machine. I had a ride upon it as ploughman, so I know all about it. The engines have 8-horse power nominal, but when starting the implement on a run of 250 yards the pressure gauge showed at 110 lb.; yet, after the run it stood at 80 lb.; therefore a run of 250 yards took 30 lb. of steam pressure out of the engine, and this in the face of a thundering fire in a big fire-box. This not only proves that 8-nominal is 16-real, but that it takes to work one big implement—the one to do the work while the other takes wind, or rather steam—but it also proves to my Lord Dunmore and others who advocate "road steamers" working upon the land, that a single engine cannot work a big implement even without having to take its own dead weight over the land. This engine when standing still worked all its working power away while pulling a big implement 250 yards. Now let us look to the work done by these two big engines. They, working all their time (meal time for men included), when the corn mill was at work and this set, to allow of a change of men to take their meals in turn), finished the 17 acres once over at 9 A.M. on Sept. 21, and then shifted to another field on the same farm, 9 acres, and did it twice over by dusk that evening, and then set themselves ready to start on to another job the next morning. Well, 41 acres done in the week by done twice over, and 14½ an acre for the work done once over. In this way we get a total earning for two days' work of £20 18s., or an average of £10 9s. per day. Multiply the contractor's 66 days for his season by this, and we fix his total earnings at £693. From this we must deduct 15 per cent. for wet days and breakages (the set, a new one, that I am remarking upon has lost all this in time already this season), which brings the total down to £554 8s. The four men must have £1 per day between them for 66 days. The cost of tackle is £1800; upon this we must allow 20 per cent. for interest of money, wear and tear, and depreciation, £360. These, together, make a total of £426 to be deducted from the £554 8s., which leaves a balance of £128 to keep and pay the contractor for hunting about the country to keep his £1800 from slipping through his fingers. This is capital evidence in support of Mr. Robinson's, shows that the farmer must pay a high price for contract work. Taking the above as our guide, what will be the price of the work to the farmer? My neighbour's cost, £20 18s. for 26 acres, gives an average of 16s. 1d. per acre. To this must be added 2s. per acre for carting: a man with a horse and cart, drawing coal from engine to engine, 4d. an acre, and water carting will cost 4d. an acre; therefore the total cost stands at 18s. 9d. My 4s. 7½d. an acre contrasts strongly against this; yet the contractor's balance of £128 a-year shows that the farmer has no chance in using it given against the contractors' prices. Mr. Robinson is right; the contractor must have a high price per acre. England never will be farmed upon the contract plan, let the bigwigs try it on as they may. *William Smith, Woolston, Bletchley Station, Bucks, Oct.* 19.

Imperfect Tillage—Worn-down Implements—False Economy—Does it Pay?—Certainly not, especially on our tenacious, adhesive, tile-earth clays, where small horses are of little use, and where big ones answer all the better for having well-conditioned implements. If we expect to have, on such soils, friable moulds and well deposited seed, the drill coulter and harrow teeth must be sharp. We are now drilling winter Beans on a Wheat stubble, which has been well scarified or broadshared, the weeds and rubbish harrowed together and burned, manure carefully spread, and the land deeply ploughed with a pair of large strong horses. We had some doubt whether the furrow-slices could be sufficiently divided or crumbled, but our sharp steel harrows, used two or three times before and after drilling, have made a good job of it, and the drill coulters, being new and sharp, have cut through the furrow-slice, and thus deposited deeply, which I consider most important for Beans; they, like the Couch-grass, or Twitch, are sure to push their way to the surface, and send down their hard powerful tap-root into the dense subsoil. The roots of winter Beans should be thus well protected against the severity of winter. I expect that a good deal of land will next year be in a mess as to weeds, for in many cases there is no broadsharing, harrowing, and cleaning, but the whole is ploughed in to take its chance—a rather poor one for the delicate Wheat fibres on a dirty Bean stubble. Want of drainage on stiff clays will be felt this winter, for the heavy rainfall of September (5 inches, or 500 tons per acre) has well soddened the subsoil. There are many matters on our farms that are neglected because they are less obviously pressing than certain other things that dare not be omitted. Roads, fences, and implements, are too commonly neglected, and the "stitch in time" not having been taken, the nine stitches have not been saved. Dilapidations, in the matter of fences, roads, implements, and buildings, are much too common and unprofitable; and, unless a special duty is imposed on some individual, what is everybody's business becomes nobody's. Landowners, at the termination of a 14 years' lease, know something of these matters, and so do incoming tenants. It is no uncommon event to see implements half buried in mud, or eaten by rust, lying exposed, or grown over with grass or other vegetation. Landowners should consider that costly modern implements and machines require sufficient shelter, and the tenant should not object to such a reasonable wish: the accommodation thus afforded. *J. T. Mechi, Oct.* 19.

Reclamation of Waste Lands.—In no part of the United Kingdom is there more scope for adding to the agricultural resources of the country than in that of North Lancashire; and it is my purpose, I think, be more need for it, as I purpose shortly to show. With our vast national increase of population, the question of how to provide for this increase must at no distant date form a difficult problem for the Legislature to deal with, and it would be well to take "time by the forelock," ere the wants of the population become too pressing for instant action to supply. During the past 20 years the borough of Barrow-in-Furness has risen from an isolated fishing village of some 200 inhabitants to a thriving shipping port and manufacturing town, numbering 30,000 inhabitants; and there are now works in process of erection which it is computed will, on completion, add another 10,000 persons in the course of the year 1872. Added to this, several small villages in the immediate neighbourhood have, by the introduction of blast furnaces, steel works, iron mines, &c., increased their numbers, and swelled their populations. At an ordinary computation, I should say that the past 10 years has added not less than 25,000 persons to the population of that once obscure part of England, known as North Lonsdale. The primary cause of this access of manufacturing industry to the district, I believe, was due to the late Duke of Devonshire, assisted by the mayor of Barrow, James Ramsden, Esq., by whom all the details of this great work have been planned and carried out. The question—a vital one—arises, How are the wants of this large accession of mouths to feed to be met? Twenty years ago, the district population was some 10,000 or 12,000 souls. The year 1872 will probably see it from 50,000 to 60,000. Already the pressure is much felt, and farm produce is at an exorbitant price. What must it soon become? It seems scarcely possible of belief that whilst our local rulers are straining every nerve to meet the gigantic wants—some of which employ their thousands of men each—thousands upon thousands of acres of land are lying in close proximity to us totally unproductive,—useless, in every sense of the term. First, let us begin with the estuary of the Duddon Sands. Mr. Wakefield Rawlinson, Kirkstone, resident at Foxfield, and some thousands of acres above the viaduct might be reclaimed at a trifling cost. A few years ago the company applied to Parliament, and obtained powers to cross the estuary of the Duddon a few miles lower down, but have since abandoned the idea. This would have given an immense impetus to agricultural interest. We next come to Morecambe Bay. By a great triumph of engineering skill, the late John Brogden, Esq. (father of the present member for Wednesbury), constructed a viaduct across it a little to the eastward of Ulverston. Here, again, are thousands of acres lying waste, and requiring but a moderate sum for the river Leven to transform this waste of sands into smiling farms on its banks. Farther to the eastward again, is another portion of Morecambe Bay, which the Ulverston and Lancaster Railway intersects, known as the Leven Sands. Here Mr. Brogden, M.P., has reclaimed a portion of the sands, with excellent results; but there is yet much more to be reclaimed. Lastly, I come to a gigantic project, the success of which was never doubted by the late Mr. Brogden; but its renunciation by him made many wiseacres shake their sage heads, as they did also when he propounded the feasibility of crossing Morecambe Bay at its present point, a distance of half a mile, on iron girders. The work was pronounced the chimera of a disordered brain, yet it has stood intact the storms and tides of 14 years. Mr. Brogden, foreseeing the influx of population which was, in consequence of rich mineral ore, erection of iron works in the district would bring, wished to carry the railway from Piel Island to Morecambe, about 10 miles lower down the bay than the course of the present railway, and was fully impressed with its practicability; and also that the miles and miles of sand which might thus have been brought into culture would have returned a princely outlay for the work. There is yet ample scope for it, and the queries how to provide for our wants cannot much longer be burked. Surely this is a question which might be made a national one, and which our rulers would do well to inquire into, seeing that the outlay required might be made so productive. *J. R. R.*

Societies.

SOCIAL SCIENCE CONGRESS, LEEDS.

The Utilisation of Sewage.—Mr. C. Rawson, of the Native Guano Company, read a paper on the "A B C" process. He said that in consequence of the unsuitable works in which their experiments had been carried on at Leamington, and from other unfavourable causes, he was quite prepared to admit that many of the objections which had been made to the process had some foundation in fact, although he must deny many of the theories or hypotheses that had been drawn from them. Only three schemes had been proposed for dealing with the sewage of towns—irrigation, filtration, and precipitation by chemical means, and circumstances might occur in which either would be preferred in practice, while in some instances their combination might be more effective, and lead to improvements in agriculture hitherto ignored. He claimed that by the "A B C" process all the suspended and from 60 to 75 per cent. of the soluble matter can be removed from the sewage, even by the ordinary working of the system. Still greater results might be obtained by further treatment, but even if some portions of the manure did remain in the effluent water, he believed these might be utilised by putting it over the land, and thus all waste must be avoided. With regard to irrigation, he might be allowed to point out certain difficulties that must necessarily occur, and were inseparable from the adoption of that system. At least one acre of land was required to utilise the sewage of 100 adults annually—according to many eminent authorities; but scores of towns could not secure that amount of land for irrigation. Again, neither landlords nor farmers had shown any very strong desire to receive this sewage on their lands; and land must generally be acquired by town authorities by means of Acts of Parliament. His object, however, was not to attack irrigation or any other process, but merely to explain their own; but he could not pass on without remarking the probable injury to the adjacent land by its propinquity to a sewage farm; and if the feeling of the richer class of the community was against such a course, what right had we to force on our poorer brethren a process which must injure the land on which their families from the typhoid and other forms of disease from miasmatic exhalations? Not only, however, did he admit, but he proudly acknowledged, that magnificent crops had been obtained by a judicious use of sewage through irrigation. The constituents of sewage contained the finest known manure substances, and on this fact rested the success of the "A B C" process. These were the elements they claimed to retain in the native guano; and their only difference with the most enthusiastic irrigationist was how to give the land the benefit of these valuable constituents in the most economic and least objectionable way. The irrigationist would pour it on the land in what he thought a wasteful quantity, whilst the "A B C" process would convert the same sewage into a dry, portable, and effective manure. The name of the "A B C" process has been derived from the initials of the chief ingredients used: Alumina, Blood, Clay, and Charcoal. We have for a considerable time substituted for the expensive ammonia-alum, formerly used, a crude sulphate of alumina, which is just as effective, and much more economical. The proportions in which these materials are employed are adapted carefully to the nature of the sewage under treatment, both as regards quality and quantity; the latter conditions not only vary in comparing the sewage of one town with that of another, but also in respect of the changes which hourly occur during the day, owing to local causes, also equally varying. Thus, in the manufacturing districts, the condition of the sewage is subject to sudden and violent fluctuations, arising from the waste liquors of all kinds of processes, while in towns where few manufactures are carried on, domestic causes operate similarly, though in a less degree. It will be apparent, therefore, that the treatment of sewage by chemical precipitation demands a very careful study of all such circumstances. Experience is required to secure complete success; but as these changes in the sewage are exceedingly regular, both as to time and condition, it is not difficult, by a little attention and forethought, to be fully prepared to meet them with success. Our process has encountered much opposition, and I shall therefore conclude my remarks by giving some particulars as to results. The manure has been submitted to two tests—that of chemical analysis, and that of actual use by the agriculturists. From the former it meets with little favour, while I have scores of letters from the latter giving unqualified approbation of the native guano used in the garden, the field, and the orchard. Our second season (last spring) was a safe indication as to what our future course will be. The demand by those alone who had previously used our guano far exceeded all our powers of supply, and our agents did not solicit new orders, simply because we could not meet those of our former customers.

The price of our native guano has been, and still is, £3 10s. per ton at the works, and we have already disposed of upwards of 30,000 bags at that price, with this result—that in almost every case farmers who have made a trial of it in small quantities have eagerly sought for larger supplies. From the unfortunate defects of the Leamington works, I am not surprised at some of the unfavourable conclusions drawn by the Rivers Pollution Commissioners during their two visits to Leamington; nor that they, from circumstances with which they were unacquainted, should have felt suspicious of what they saw there. I maintain, in publishing such an attack on this company without more thorough and patient investigation. Their strictures, however, were not thrown away; and I hope their future inquiries into our process will be conducted in a more considerate spirit, and without reference to the past. I would particularly mention that, in suitable works, not the slightest nuisance arises from the process. Another important feature in the process is, that in the "A B C" works the excreta collected from such receptacles as Moule's, Goux's, or other similar system, may be turned into native guano by the same means deposited mud, with probably but a slight addition of "A B C" mixture. The contents are at once deodorised, and can be dried without nuisance. It is the intention of the company to establish in some central town, in the neighbourhood of which the raw materials so require can be cheaply obtained, and where there is an abundance of suitable clay, a manufactory of dry "A B C" mixture. This will relieve towns from the necessity of having a chemical staff. Another important consideration connected with our "A B C" process is its economy. Cheapness at which our works can be erected. Heavy expenses must naturally be incurred in preparing land for irrigation. I my mention, as a comparison, that Birmingham would have to incur an outlay of £1,200,000, whilst our "A B C" works would not cost above £50,000. Blackburn is spending £185,000 on her irrigation farm, while we would have treated her sewage at an expense of £15,000. I might adduce other instances, but think I have said enough to show that, in this respect also, our process has great advantages over other systems. The last point I have to advance in favour of the "A B C" process is certainly not the least conclusive one. It is successful in a commercial point of view, and pays! Even in the south of England, where coals and chemicals are far more expensive than in the north, our native guano costs us only 30s. 35s. per ton, leaving a profit of £2 per ton. Now, in Leeds, for instance the case of one city, to show what a profit of £2 per ton really means. The metropolis daily pours into the Thames 100 millions of gallons, or 448,740 tons of sewage. From experiments we have made with this sewage, we estimate that the "A B C" process would convert this into over 1000 tons of dry manure, worth, annually, at £3 10s. per ton, the enormous sum, for the metropolis alone, of £1,282,500. I cannot conclude this paper without mentioning to the section that the authorities of Leeds resolved some months ago to make an experimental trial of the "A B C" process. Their works are hardly yet completed, and certainly not yet in such neat condition as we hope shortly to see them; still, they will afford any gentleman interested in the solution of the great sewage question an opportunity of seeing our process in actual operation. We shall welcome any such visitor, and give fuller explanations than are possible here. I trust that these trial works will be found such a success by the Town Council that all their daily 11,000,000 gallons of sewage may shortly be treated by "A B C" to their profit and honour. The works are situated at Knostrop, to the south-east of the town, and adjacent to the river Aire. On the left of the entrance is a chimney, 90 feet high, which takes the products of combustion of two boilers having a nominal power of thirty horses each, and the heat and gases from a range of drying sheds. Each of these sheds has an area of about 1000 square feet; they are heated by steam, which passes below into floors, the mud being placed on these in a thick liquid state. Over the surface of these floors a current of hot air is drawn from the boiler flues, escaping at the further end of each shed by flues leading to the chimney. It will hence be seen that the principle of drying involves the double mode of applying heat both above and below the mud. For the purpose of increasing this upper drying, a cover is placed at a small height from the mud, removable when it is dry, and replaced when fresh mud has been spread on the floor. The effect of the cover is to increase the draught, and, at the same time it prevents waste of heat. The remainder of the arrangements in regard to machinery, "A B C" pits, and the agitating or centre pit, &c., are precisely similar to the general plans I have already described. The settling-tank, which is at the south-east of the works, has a length of 170 feet, is 24 feet in width, and about 12 feet in depth; but till we have had some experience in working the Leeds sewage, it is impossible to say the exact number of gallons of sewage we shall be able to treat in the twenty-four hours. In conclusion, I claim that our "A B C" process is pre-eminently suited for treating and utilising the sewage of large towns. The effluent water can be made clear, inodorous, and almost chemically pure; the process can be carried on free from nuisance, and the profits are large and certain. I feel confident that these will be admitted facts as soon as the works of Leeds, Bolton, and Crossness are in working order.

DISCUSSION.

Dr. HARDWICKE read a paper by Dr. Robert Elliott, Carlisle, upon "What are the best means of utilising sewage?"—The only practical system seemed to be an elaborate and extensive carrying out of the plan of Mr. Alex. Macdougall, Penrith, which had now been in operation for upwards of 12 years at Carlisle—viz., of immediately carrying off all excreta by an underground system of drainage, with arrangements for ventilation into furnace chimneys, and which at some suitable place or places has its liquid sewage, free from putrefaction, pumped up by steam power, and suitably mingled with carbolic acid, applied in rotation through a system of long movable channels or troughs to the adjacent fields, in which instance the irrigation has proved highly successful.

Mr. SYMINGTON read a paper descriptive of the method of dealing with sewage proposed by Mr. Semmng, of Glasgow. As an example of the working of this method, excreta would be intercepted from the soil-pipe of each house or block of houses by the patent sewage filter, which forms the essential and distinguishing feature of Mr. Strang's scheme.

Mr. W. T. M'GOWEN, town clerk of Bradford, read a paper holding the irrigation system to be impracticable for large manufacturing towns, if they are to undertake the whole operation themselves.

Dr. F. J. MOCATT said he had spent 30 years of his life in India, and approved of the dry-earth system, known as the "Moule."

Mr. W. H. MICHAEL, London, said that the gentleman who read the first paper had said that a sewage irrigation farm was a bog. He could never have been at a good sewage irrigation farm. The same gentleman had said it would be detrimental to health. There, again, he had never been at a sewage irrigation farm properly conducted. The solid constituents of manure which one gentleman proposed to treat by chemicals constituted the worthless part of it, and the first thing in dealing with irrigation was to separate the whole of the solid constituents. Any process which might be proposed that treated only with regard to the solid constituents of sewage must be put aside as utterly worthless. The whole value of the manure lay in the fluid portion. Having been engaged for many years in seeing irrigation at work, he thought it the purpose not only to remove what sort of nuisance, but to be extremely beneficial in producing food —because to talk only of Rye-grass being produced was another stupid absurdity.

Mr. C. O. HALL described a plan for dealing with refuse invented by himself, and undertook to fix closets in the town and remove the refuse for nothing.

Mr. R. RAWLINSON, C.B., said that for modern communities, which were vegetarian, there were several things that had to be done to secure the public health. The question had to be discussed, for instance, how they were to remove the slops from the houses. Sewers and drains were supposed to pass along the drains corrupted the atmosphere of the houses, but if that were so, the drains did so very unnecessarily. No drain ought to communicate directly with any house; it ought to have at the most a ventilating shaft running up to the fresh air, so that any gas generated should not pass into the dwelling-house. The dry earth system might do for detached dwellings, and for large establishments, for goals, for barracks, for any place where persons were entirely under command, where there was no objection to bear the expense of the separate manipulation, and where the gardeners could be found. He took it for granted that the excreta must be removed either in the first state or in the wet state. If in the dry state, it was removed necessarily by mechanical means, or by human agency. If in the wet state, having made sewers and other arrangements whereby they could be ventilated, the excreta removed itself to any point that was desirable, and, where necessary, they might call steam-power into use under such a system. With regard to irrigation, he would not discuss the question further than to say that sewage might be applied to land with perfect success without causing the smallest nuisance, and that probably, according to circumstances, there would be a great profit upon the application of it. The conclusions they had to were these—that no human means, so far as we at present know, of treating sewage by chemicals did more than remove one-eighth of the salts of sewage from the effluent water; and that the brightest and best clarified sewage, nearly as bright as the water in the bottle before him, was then in the very best possible condition to be put upon the land for the purposes of irrigation. Mr. Blackburn, who had spent £185,000 in order to irrigate 1000 acre of ground for any of those patent manure manufacturers, and he would give them his sewage to manipulate —and it was the richest that could be got, there being 16 instead of 8 grains of ammonia to the gallon—and what was returned to him when they had done with it. He could only say, that if such manufacturers by the "A B C" process could make the manure worth £3 to £4, or £4 per ton higher value per ton, they would do what all the chemists he had been in contact with tell him that it was impossible to be done. However, these gentlemen said they got that price for it, and there he must leave the question.

Councillor MATAERS said that water had been more recommended than any other system, but the time had not arrived yet when any gentleman could take upon himself to say that this or that was the best scheme, because, dependent upon the position of towns would be the system to be applied. He thought the "A B C" system the best hitherto. The company certainly dealt with the sewage better than by any other system that had been made known to the Town Council of Leeds, and the manure, he reported, to have turned out well in the hands of several farmers.

Mr. W. HOPE, V.C., gave interesting details as to the system of irrigation pursued on his farm of 120 acres at Romford, maintaining that his experience demonstrated irrigation to be a most successful method of utilising sewage. The quantity of sewage coming from a town with 8000 inhabitants was too great for use, and a portion was merely purified. In order to use sewage he should like an acre for every 20 persons, but to purify it a very much smaller area was necessary.

Mr. WEBSTER, Q.C., held that there could be no question that the removal of sewage by the water system was the most economical; but there were, no doubt, places, such as Birmingham and Leeds, where the irrigation system involved enormous difficulties as to the extent and distance of land, and therefore such places must consider whether there was any other practical mode of dealing with sewage. He recommended those who were anxious upon the question of public health not to indulge in extreme opinions. There could be no question that the water system was the best for removal, and that the irrigation system succeeded most completely, but surely some chemical system might be found. As a matter of pure science, he thought it discreditable that some means could not be found of restoring what had been put into a fluid state.

Mr. RAWSON, in his reply, said that the manure produced by the company cost from 30s. to 35s. per ton making, and they had no difficulty in selling at £3 10s. per ton of their manure on hand.

The PRESIDENT (Geo. Godwin, Esq.), in closing the discussion, said he did not wish, in the interest of the community at large, to urge that irrigation should be employed extensively, and in those places where it could possibly be adopted, and he asserted, moreover, that he had the strongest ground for doing so. What was the use of a Royal Commission, of the labours of the British Association, and of the Rivers Pollution Commissioners, in all cases coming to a conclusion in favour of irrigation, if they, who could not possibly go into the subject minutely to the same extent, were not to attend to the recommendations? He could say that irrigation was, under the greater number of circumstances, the best mode to adopt. And he maintained that the evidence from these farms, from Mr. Blackburn's farm at Aldershot —of which he knew something—and a number of others, as at Croydon, and Mr. Hope's valuable farm at Romford, ought to induce them to say that irrigation was the best means to employ. With regard to the "A B C" process he was very anxious, knowing that it was a great interest, not to say anything unfair; but really he was compelled to say that these gentlemen said more than they could possibly prove. They said they got £3 10s. per ton for the manure. But would they prove that it was worth £3 10s. per ton? Such chemists as he had spoken to said it was not worth that. The expensive process which they were themselves not prepared to guarantee a manure at such a price as that manure was worth. It was all very well to say that they had sold so many thousand tons, but they had not yet proved the value of it, or that the farmers would continue to use. Then, with regard to the effluent water, which they said they were quite willing the irrigators should have. That did not answer the question at all. Was it true that this effluent water was sufficiently purified? Did it sufficiently purify it? He, however, feared to pursue the subject, seeing that the process was now a great commercial speculation, but nothing that the "A B C" advocates had said or done had affected his mind on the subject of irrigation. They had, it seems, seen that they must get rid of sewage immediately, that water was the readiest means of transporting it, and that when properly disposed of on land it really did no damage whatever to the atmosphere. Irrigation, for example, a country that had had irrigation generally at work for 1000 years, and a great deal longer period by their own records; and all the evidence was, he thought, in favour of irrigation. He hoped the people of Leeds would look into it. They must no longer delay, with a thousand middens—the death-rate told them of the work that had to be done—and of the "A B C" process they must satisfy themselves either as to its goodness or its badness. If good, let them adopt it entirely; but if bad, then at once they must set to work to get rid of the sewage, and put it on the land around.

Farmers' Clubs.

NEWBURY.

The Chalking and Liming of Land.—Mr. F. EVERETT lately read a paper on the above subject before this Club. He said:—

The inorganic or manual substances in the soil are silica, alumina, lime, oxide of iron, magnesia, potash, sulphur, phosphorus, chlorine, and fluorine. Among these, lime is one of the most important, and enters more largely into the composition of plants than any other. Without its presence in the soil, nearly all our cultivated plants refuse to flourish; notably among farm crops—Turnips, Barley, and grass seeds. The importance of a good root crop preparatory to Barley, and a good Clover stub in preparation for Wheat, cannot be over-estimated, and if by the application of chalk or lime we may reckon, with tolerable certainty, upon a good crop of roots and Clover, we secure a good yield throughout the four-course rotation. I think the most practical men will allow that no amount of farmyard manure is an efficient substitute for chalk where land requires it. So thoroughly convinced am I of the importance of supplying lime in one of its various forms of combination when its application to the soil can be proved to be necessary, that I have made the subject a special study and inquiry for eight or nine years since I had the soil of my own farm analysed by Dr,

Voelcker, believing it to be deficient in lime. I have since proved the opinion then expressed by him to be entirely correct. "It will be useless," he said, "to go to any great expense in the purchase of manures till your land has been either limed or chalked." It is very remarkable, in my own case, how fully experience has proved to me the correctness of the above statement. "A dressing of chalk," remarked an old farmer to my men last year, when busy chalking, "will do this land more good than all the dung in Newbury." Here, at any rate, there appears to be no antagonism between what is called theory and practice. Dr. Voelcker and my practical friend being of the same mind. Before proceeding further, let me bring to bear the testimony of Johnson, who, in his work on "Use of Lime in Agriculture," has placed within the reach of agriculturists the richest possible store of information with respect to the subject we are discussing. At p. 124 of his work will be found the following remarks:—"On examining the chemical nature of the ash of plants, it is found that lime in all cases forms a considerable proportion of its whole weight. Hence the reason why lime is regarded as a necessary food of plants, and hence also its beneficial influence in general agricultural practice. The quantity of pure lime contained in the crops produced upon one acre during the four years' rotation, amounts, on an average, to about 200 lb., equal to 360 lb. (say 3¼ per cwt.) of carbonate of lime in the state of mud, shell-sand, or lime-stone gravel. It is obvious, therefore, that one of the most intelligible purposes served by lime as a chemical constituent of the soil, is to supply this comparatively large quantity of lime, which, in some form or other, must enter into the roots of plants. But the different crops which we grow contain lime in unlike proportions. Thus the average produce of an acre of land under the following crops contains of lime:—

	Per Acre.	Grain.	Straw or Roots.	Total.
				lb.
Wheat	25 bush.	1	12	13
Barley	40 bush.	1½	15½	17
Oats	50 bush.	3	19	22
Rye	26 bush.	1½	15½	17
Beans	25 bush.	23	34	56
Turnips	20 tons	46	72	118
Potatos	8 tons	8	31	39
Red Clover	2 tons	77		77
Rye-grass..	2 tons		30	30

These figures speak for themselves, and in passing, I will only draw attention to the large proportion of lime contained in the Turnip and Red Clover crops, which I have previously pointed out as crops especially benefited by the application of chalk or lime. Here, I think, may be aptly quoted Liebig's minimum law, which though for the present it may be scorned by practical men, is destined ere long to be acknowledged as lying at the root of all sound practice, and is a safe guide to all who are not unwilling to confess that the researches of scientific men materially assist us in working out our every-day practice. "Every field," says Liebig, "contains a maximum of one or several, and a minimum of one or several, nutritive substances. It is by the minimum that the crops are governed, be it lime, potash, nitrogen, phosphoric acid, magnesia, or any other mineral constituent: it regulates and determines the amount of continuance of the crops. Where lime or magnesia, for instance, is the minimum constituent, the produce of corn and straw, Turnips, Potatos, Clover, will not be increased by supply of even a hundred times the actual store of potash, phosphoric acid, silicic acid, &c., in the ground. But a simple dressing of lime will increase the crops on a field of the kind, and a much larger produce of cereals, Turnips, and Clover will be obtained by the use of this agent than as the case of wood ash (on a field deficient in potash) than by the most liberal use of farmyard manure." It becomes, then, a matter of primary importance to ascertain whether or not our land requires chalk. It is generally taken for granted that where roots "club," lime in some form must be applied. To counteract this evil, my own four years' experience has proved the soundness of such a conclusion. But I venture to think that there is a large area of land that would be greatly benefited by the application of chalk where the above direct proof of the necessity of applying it might be wanting, and where we must seek further for more subtle indications of the deficiency of lime in the soil. Many practical men may be able to call to mind cases in which they have not been satisfied with the general yield of their crops—though great pains may have been taken in their cultivation, and large outlay may have been made in the hope of profitable returns. I think that I could mention land and certain fields on some farms of this district, where, although the roots may not actually "club," yet there are indications that something is amiss—there is a short Clover crop, perhaps—a profuse quantity of weeds, or an unkindly mechanical condition of the soil. Something is wrong, and yet we hardly know what. In such instances, I would suggest that it might be well to have the soil analysed, and carefully to note the character of the weeds growing upon it. There are certain weeds which are almost a sure indication of a deficiency of lime; many of them flourish upon my own farm, and those farming land requiring chalk will, I feel sure, bear testimony that they are indicative of the absence of lime. Many must be able to call to mind instances where an application of chalk has entirely changed the unkind nature of the soil, and rendered land productive which previously was incapable of producing remunerative crops. I am disposed to think that "Clover sickness," one of our stock grievances, is often owing to an insufficient quantity of lime in the soil, and it is stated by Sibson that the application of lime has, in some instances, proved a remedy for this disease. Another matter for practical consideration is the best mode of applying chalk, and the season of the year at which it is best to supply it. In connection with chalking, I think there is one point which, though worthy of careful consideration, often is disregarded. I refer to the different quality and value of various kinds of chalk. It will often be found that chalk dug from different pits, though on the same farm, will vary considerably in chemical composition and mechanical structure. Such is the case on my own farm. Suspecting it was so, I sent a sample from each of the pits I am working to be analysed by Sibson. The analysis of the two samples shows the following results:—

	No. 1.	No. 2.
Moisture	1.49	.38
Carbonate of iron	93.42	98.33
Oxide of iron, and alumina, with traces of phosphate of lime	1.72	.62
Phosphate of lime	..	.18
Silica	3.46	.67
	100.00	100.00

"No. 2," Sibson remarks, "is much richer in pure carbonate of lime than No. 1, and has also a notable quantity of phosphoric acid, which enhances much its value for use on the land. The fact of its disintegrating better is much in its favour, and it is evident that this description of chalk should be used in all cases where obtainable. A less quantity of this would also suffice, and might be used in more moderate quantities than is customary in the district." I was anxious at the same time to ascertain whether chalk containing phosphoric acid might be considered in any way a substitute for superphosphate in the cultivation of roots. Sibson replied as follows:—"A chalk containing phosphate would take the place in part of superphosphate, although it could hardly be taken as a substitute." It only remains for me to remark that I have purposely connected the operations of chalking and liming, because what we endeavour to effect in this neighbourhood by the use of chalk, others in different districts have accomplished by the use of lime—that is to say, chalk or other limestone passed through a kiln, and deprived of its carbonic acid, in which form lime is more potent, but still in many respects performs in the soil the same offices as chalk. Pure lime is largely used in Scotland, and there farmers are especially careful to keep their land sufficiently supplied with it. Liming also is systematically carried out in south Durham and Worcester.

	Bush.	Years.	Bush. in a Year.	When applied.
Roxburgh ..	200	every 19 or 10½		To the fallows.
Ayr Kyle ..	40	,, 8 ,,	8	To the lay.
Carse of Stirling ..	90	,, 12 ,,	9	,,
South Durham ..	90	,, 12 ,,	8½	,,
Worcester	70	,, 6 or 8 ,,	10	Before grasses or Tares.

I am aware there is a prejudice entertained by some owners of land against the use of lime in a caustic or pure state, but it is a prejudice which, it may be hoped, will vanish under the light of more extended knowledge.

Notices of Books.

The Mechanics of Agriculture: *A Paper read at the Turriff Agricultural Association's Dinner, August 9, 1870.* By Alexander Leslie, Turriff. J. Murray, 28, St. Nicholas Street, Aberdeen.

We do not remember to have seen this lecture before, and are glad, as many of our readers will be, to see it in the form of an independent publication. It is a very fair and comprehensive review of the several classes of machines employed in the cultivation of the soil, the sowing and harvesting of crops, and the preparation of produce for the market. It is interesting also for the obvious desire of the author to award personal credit wherever it is due; and for the dexterity with which apt quotations from other writers are used to enforce the argument. Two of these extracts we shall re-quote here:—

(1). "'Man,' it has been said, 'is a tool-using animal. Weak in himself and of small stature, he stands on a basis, at most, for the flattest soled, of some half square foot, insecurely enough; has to straddle out his legs lest the very wind supplant him. Three quintals are a crushing load to him. The steer of the meadow tosses him aloft like a waste rag. Nevertheless, he can make tools, can devise tools. With these the granite mountain melts into fruitful valley: he heads the glowing iron as if it were soft paste; seas are his smooth highways; winds and fire are his unwearying steeds. Nowhere do you find him without tools: without tools he is nothing, with tools he is all.'"

(2). "In concluding this survey, we may observe that we have found sufficient corroboration of the remark of a great living practical philosopher, Mr. Edwin Chadwick, that the number of improved agricultural implements and machines that might be profitably used and are not is greater than the number of those that are used."

The lecture occupies ten readable pages, and will repay perusal.

Wall's Manual of Agriculture for the Southern United States. By Major E. G. Wall, of Mississippi. Trubner & Co., 80, Paternoster Row, London.

Besides the above words this little book bears upon its title-page the statement that it is for every cultivator of the soils adapted to the "great staples"—by which, after consideration, it appears to be meant that it is especially adapted for Cotton, Sugar, and Tobacco growers. For them also it is illustrated, the coloured plates representing rot in Cotton and the ravages of the Cotton caterpillar. There are, nevertheless, notes also on the general chemistry of soils and manures, on the cultivation of Wheat, Potatos, grass, and other crops of temperate climates, and a few pages on stock feeding. It is a very crude and undigested collection of memoranda, and excepting a short and simple passage, it is not likely to be of much service to English readers. It is, indeed, beyond the power of any man, even of one who unites in his own person all the advantages of civil, military, and agricultural education, to write a complete manual of agriculture in 250 small pages. The following are the contents of three of them on the subject of cattle feeding, which is just now of the greatest agricultural importance:—

"There are some important points involved in the preparation of food which demand the farmer's attention. Economy in feeding requires not only the right kind of food, but also proper preparation as will give the food its greatest value. It must be in such condition that the animals to be fed will relish it; that they will consume it entirely without waste, and that it shall all be digested, and thus fitted for the purposes it is intended to serve.

"We often see provender rejected by cattle because its condition is that of coarse, dry, hard stalks, or straw, difficult to masticate, and often insipid, when eaten alone. Again, the same choice portions of hay may be picked out by horses, and the remainder pulled down and trodden under foot. Then we often find whole grains passed through animals, as may be seen in the droppings of cattle when fed on unground corn, or of horses when fed on unground oats. To avoid such waste, we must pay attention to the most economical means of reducing provender to the best and most palatable condition.

"The means best adapted to the preparation of food are cutting, grinding, mixing, and boiling, or steaming. Cutting aids both mastication and digestion. The question here arises, 'Will it pay?' This must be decided by the circumstances of the case. If the farmer has a great deal more straw and fodder than his stock will consume, and wishes to use the excess as litter to absorb liquid manure, he may not find any economy in cutting the food. And even in the case of feeding hay, if the supply is abundant and the latter low, as is frequently the case in grass-growing regions, it may be more economical to feed it whole, even with considerable waste, than to expend upon it the necessary labour to cut it up. In sections of country where such economy prevails, or where there is a sufficient demand for it, to keep up the price, good 'cutters' will be among the most economical implements on the farm. And they are no less so in towns and cities when horses and cows are fed at considerable cost.

"Grinding sustains very much the same relation to grain that cutting does to long forage; but, as grain is more readily transported than other products of the farm, economy in its use becomes more highly important. Grinding is thought by many experienced farmers to add from 20 to 30 per cent. to the nutritive value of grain when fed to hogs or horses, and from 40 to 50 per cent. when fed to cows. The cow masticates grain much less completely than either the hog or the horse. In autumn, before corn has become hard, there is but little advantage in grinding it for hogs. Making ready to eat, cooking and grinding with marked advantage. When horses or cattle are fed on any kind of long forage (hay, straw, fodder, or shucks), together with meal or bran, the former should be first moistened, and the latter mixed with water enough being added to make the meal or bran adhere. There will then a double advantage arise; first, of having the whole completely eaten up without waste; and, secondly, more perfectly manifested digestion. A similar advantage arises from cutting Beets, Turnips, Carrots, Pumpkins, &c., and mixing them with meal.

"In localities remote from the sea-shore, where vegetation affords too little of the salts of soda to supply the demands of the animal fluids, common salt should be mixed with the food, or else a supply kept in a sheltered place, so that stock may get it when they want it. From four to five pounds to the ton is a ton of hay or fodder, when stored away, will greatly improve its quality and aid in its preservation. A small quantity of salt is beneficial to hogs, if given regularly, but large doses are very poisonous.

"Boiling and steaming render substances more soluble, and in that way promote digestion. Steaming may be profitably applied to hay when fed to young animals, and to sheep, whether old or young. Green grass is more valuable than hay made from it. In making hay there are changes produced in the stalk and blades, partly physical and partly chemical. Among these changes is the greater solubility of the fibre. This makes it indigestible. Steaming reduces it back to a condition somewhat similar to that of green grass.

"Boiling may be applied to grain, either whole or ground. It renders the starch more soluble; and if in the case of meal, a slight fermentation is produced before boiling, a large portion of the starch will be changed to dextrine. This is one of the steps in the progress of digestion already made. Roots should generally be boiled or steamed.

"If our object is to make food perform its office as rapidly as possible, that is, if we wish it to cause rapid growth and rapid fattening, the most digestible condition is the best. In such cases the animals should be kept comfortable and quiet, and there will be but little waste of food. Boiling is especially adapted to hogs, and almost indispensable to the thrifty growth of young pigs.

"For horses and oxen, the boiling of meal is a disadvantage. The digestion then goes on too rapidly. If the grain is ground and mixed with cut hay or straw, the digestion is made complete, and goes on more slowly. In this way the digestive organs are not so quickly left inactive, and the sensation of hunger is not so soon produced."

Farm Memoranda.

WHITTLESEA MERE.—A paper was written in the 21st volume of the Royal Agricultural Society's Journal on the drainage of Whittlesea Mere, and in it, besides other matter, a short account was given of the process of spreading, upon a part of the surrounding tract of peat-bog, a coating of soil, of an average thickness of 5 inches, taken from the bed of the Mere. From the point whence the soil was taken, to the farthest point of delivery, the distance was nearly 2 miles, and the expense of the operation very great. The cost, indeed, has so far exceeded the estimate given in the paper alluded to, that this opportunity should be taken of giving the actual result, now that the work is finished, the plant sold off, and the account closed. The closest calculation, then, which it has been found possible to make, gives for the cost of claying to the depth of 6 inches from £18 to £19, and for a depth of 4 inches between £15 and £16.

The land thus clayed lets readily for 50s. an acre, so that, even at the increased cost, it has proved a remunerative operation, especially when it is borne in mind that the land was previously in the state of rough bog, producing no rent whatever.

At a distance of 2 miles from the Mere, and near the village of Holme, a corner of the peaty tract runs up to the higher land of the surrounding country, and about 230 acres of this has been taken into a home farm, nearly 200 acres having been first covered with clay to an average depth of 3¼ inches. The cost of claying this piece of bog-land has been small in comparison with that just referred to. Here the average distance to which the clay was carried did not exceed half a mile; the excavation was easier, and after a short time, steam-power was called in; and an engine, traction-rope, and portable rails, were substituted for horses, the cost, on the completion of the work, being found to have been little over £9 per acre.

It has been suggested that, as the operation was finished in the spring of 1866, sufficient time has elapsed to make it a matter of interest to record what the experience of nearly four years has shown to be advantageous or otherwise in the management of bog-land, recently reclaimed and clayed.

Of the 230 acres taken into the farm, although a small proportion had been more or less under cultivation, some for two or three years, and some for a longer period, by far the larger part consisted of the roughest kind of bog. Of the whole, about 190 acres have been drained, 40 remain undrained. Of these 40 acres, about 15 had been for several years under cultivation, and 25 only for one or two years.

It would have been far better, doubtless, if, in anticipation of the claying, the rougher part could have been prepared, and brought into a state of semi-cultivation a few years previously, so that something like a top soil should have been forming, with which the clay, when deposited on it, would have readily amalgamated in the course of the usual farming operations. As it was, however, circumstances made it necessary that the whole part should be taken in hand at once, and the clay being spread, on an average, at the rate of half an acre a day, the whole 190 acres were covered within a very limited time.

The surface of the rough bog, though levelled and prepared for its coating of soil as well as was possible, consisted mainly of lumps of fibrous, and nearly wholly vegetable, peat, having no sand in it, and looking much like masses of dark-coloured tow or oakum. Beneath this upper covering of a loose dry growth of vegetable matter there exists, at a depth of a foot or so, a stratum of a hard dry, red "moor," or peat in another form. This seam is from 10 to 18 inches in thickness, and is of such a nature that the roots of no plants appear able to penetrate it. Immediately below this obdurate band the character of the peat changes. It becomes soft, dark, and greasy, and, when reached in process of cultivation, is found to be very fairly fertile.

In that part of the farm which has not been clayed it is sought to get rid of this sterile seam of "moory" peat by very deep subsoil ploughing. This process, repeated at intervals, brings more and more of the objectionable substance to the surface, where it is raked into heaps and burned, until a sufficient land is broken up, and the roots of the various crops are enabled to pierce into the softer and richer soil beneath.

Where the land has been clayed the breaking up of the land will require considerable time, and can only be done very gradually; any extra deep ploughing being avoided for fear of the clay being lost. Implements, however, which, without subverting the top soil, will cut deeply into and so break up the hard stratum below would be useful.

Even after the 4 inches of clay had been spread on it there was no inconsiderable portion of the newly reclaimed land on which horses could not work without constant danger of being bogged, and having to be drawn out with ropes; and attention was consequently directed to cultivation by steam, which system has now been adopted over the whole farm. So perfectly satisfactory has been the result of its adoption, that, although the better drainage and better surface which now exists would enable horses to work anywhere, it is demonstrable that a return to horse cultivation would be an unremunerative and retrograde movement. To the steam-engine, windlass, and wire-rope, which were used in the claying operations, there have now been added a Fowler's four-furrow plough, with wheels 12 inches wide, a Coleman's cultivator, covering 8 feet 4 inches of work, and a roller 8 feet in width; the last two implements being adapted to steam purposes with a drawage apparatus—the joint contrivance of Messrs. Amies & Barford, and the bailiff, Mr. Crosbie—enabling them to turn with the utmost facility on their own ground on arriving at the headlands.

The management of that part of the peaty tract of land which, from its nature, requires further cultivation, needs little remark here. The 3 inches of clay bestowed upon it has produced excellent effects, and, readily amalgamating with the existing top-soil, has formed a rich and fertile mould.

The treatment of the rough bog, which had only just been levelled and prepared to receive the clay, has been, to a great degree, exceptional and experimental. It is unadvisable to attempt to bring land in this raw condition too quickly under the system of rotation of crops adopted in the case of land which has long been under tillage.

The first to the thorough drainage of the land, the complete amalgamation of the peat with the clay being all-important, it has been found that, to this end, it was a mistake to sow, as was largely done for a first crop, either Rye-grass and Clover or mixed grasses. It was proved to be a better plan, after giving the newly levelled land as much cultivation as could be fairly bestowed upon it previously, to sow Coleseed, if possible, early in July; and, there being no sufficiency of straw as yet on the farm to make manure of, to feed it off with sheep requiring oilcake, that is to say, both fattening sheep or lambs, rather than ewes; to plough, as the weather might permit, in the winter, and in the spring to sow Oats. These should not, however, be sown early, as experience proves that such lands, being generally low, are peculiarly liable to suffer from spring frosts. In May or June, red and white Clover, Timothy, Parsley, Trifolium, Pacey, and Italian Rye-grass, should be sown and hoed in. These seeds should remain only one year down. It is bad economy, with the land in such a crude condition, to keep them even a second year, for not only do they deteriorate quickly themselves, but a year of cultivation and mixing of the soil is lost.

In the former of the two cases mentioned, where grass was sown as a first crop, Wheat, to a limited extent, was tried after the second, and even third, year of the seeds being down; but, as might have been expected, with very poor results.

In the latter case, where the cropping has begun with Coleseed, followed by Oats and seeds, it has yet to be proved what the Wheat crop sown this autumn will be. The plant looks well at present, and the extra cultivation which the soil under this plan has received will be very favourable to the Wheat crop.

Speaking generally of the assistance to be derived from artificial manures for land of this quality and in this condition, it has been found that superphosphate of lime is by far the best to use, although phospho-guano, obtained from Messrs. Anderson, Edinburgh, is not unsatisfactory as a second result. Peruvian guano has almost wholly failed, alike on the clayed and unclayed land. The phospho-guano is as nearly as possible double the price of the superphosphate used, the cost being 11s. 6d., and 6l. per cwt. respectively; and, an equal money value of each having been repeatedly tried, the results have been found in almost every case to be as nearly as may be similar. It is doubtful whether in the case of a rough bog just reclaimed and clayed, it is remunerative to go to much expense in artificial manures for the first year or two, and until the clay has become incorporated with the peat. Dr. Voelcker was consulted as to this, and in his reply he says,—"I fear you will not reap the full benefit from the artificials named in your note by applying them on peaty land recently clayed. When the clay has become more mellowed, these artificial manures would, no doubt, give you a much better crop than they are likely to produce on the land in its present condition." This opinion has been amply confirmed. On the more advanced land the benefit of the artificials named has been all that could be expected, while on the more backward portion of the land no results proportionate to the outlay have been realised.

Last year, on the unclayed peat land, the difference in the yield of two fields of Oats, one of which had 3 cwt. and the other 4 cwt. of superphosphate, was estimated at 12 bush. per acre. The fields lie near each other, are of precisely the same character, and their previous treatment had been nearly identical.

Less than 4 cwt. of superphosphate, or its equivalent in phospho-guano, has been found inadequate, whether for the corn, Coleseed, roots, and Potatoes given on the more matured land, or for the first two of these crops, which alone, as yet, it is thought prudent to grow on the more recently reclaimed bog.

An acre or two of the more backward of the clayed land was tried last season with Kohl Rabi, and with such good results that more will be sown with the same useful kind of root this year. In another year or two it is to be hoped that Potatos may be ventured on, seeing that already, in the somewhat more advanced clay land, very good crops have been produced; that of last season was at the rate of 8 tons per acre, the seed having been procured direct from Scotland, and sown with 4 cwt. of superphosphate to the acre.

A strong recommendation by Dr. Voelcker, to use burnt clay largely for mixing with the peat and raw clay, has not as yet been carried out on a scale large enough to make it worth recording the results; but, judging from the little that has been done, it seems probable that the advice "by all means burn the stiff clay extensively, for you cannot possibly get a better material in quantities for improving your peat land" will be found, subject to the cost of the operation, to be worthy of being acted upon.

The 40 acres of unclayed peat land, forming part of the farm, and lying side by side with the portion that has been clayed, afford excellent opportunities of comparing their respective values, and give abundant evidence of the superiority of the latter. The corn crops on the clayed land—speaking again of that part of it which is in a more matured state—are far better in quality; and, with the exception of one Oat crop in a peculiar season, in quantity. The straw is better, especially for feeding purposes, the difference in value having been sometimes estimated at 5s. per acre. The liability to damage by spring frosts is very greatly lessened, and an earlier ripening of the crop is insured. In the case of Potatos, the yield under circumstances other than that of clay or no clay precisely similar, has been found to be not far from double; while in the case of Coleseed and root crops—perhaps rather more in that of Kohl Rabi than of Mangels—the great advantage in the admixture of the clay is conspicuously apparent in the increased produce.

These are, perhaps, the points most worth recording in the treatment and farming of a tract of bog-land recently reclaimed and clayed; but, in considering them, the nature of the bog or peat itself must not be forgotten. The almost total absence of sand distinguishes it in a marked manner from peaty districts like that around Bagshot, and in a less degree from the bogs of Ireland; for the improvement of which considerable modifications in the above methods of cultivation, and manures employed, would have to be adopted. *W. Wells, M.P., in the Bath and West of England Society's Journal.*

Miscellaneous.

FOOT-AND-MOUTH DISEASE.—The following letter appeared in Thursday's *Times*:—

"The present complaint among cattle has assumed such terrible proportions, and its consequences are of such serious moment, not only to agriculturists, but, as regards our supply of meat, to the whole community, that though not a grazier I trust I shall be indulged to offer an opinion on the subject, and the means by which it may be lessened, if not entirely removed. I am old enough to remember the introduction of this foot-and-mouth disease, and, having been born and brought up in one of the most important farming districts, was early made aware of its mischievous effects. It came in with the great extension of the railway system some 20 years ago, and has increased as railways have spread more into outlying agricultural districts of England, Wales, Ireland, and the cattle-supplying countries of the Continent. Like all affections of the kind, certain seasons—especially cold and wet ones—are more favourable to its increase than others, but it has never been entirely absent during any part of the period I have named. No one who has any knowledge of human or animal pathology, and has witnessed the treatment cattle are subjected to in their transit from the agricultural parts of Ireland to those of England, will be surprised that it results in serious illness. Driven—perhaps some miles—from the pasturage on a fair to the railway there to wait for hours the greatest mental and bodily irritation and distress; immediately afterwards, without either food or rest, they are packed into open railway trucks as close as they can stand, and, entirely unable to change their positions, travel in all kinds of weather hundreds of miles to a fair in England, sometimes left stewing in a siding, sometimes in the draught produced by passing through the air at the rate of 40 miles an hour, and only the disagreeable and not very salutary interlude of a six or seven hours' sojourn on the deck or in the hold of a steamer. On arriving at the second fair they go through another day's ordeal such as they suffered at the commencement of their journey; and, even if fortunate enough to meet with a purchaser at once, must again travel a longer or shorter distance by rail or road before they reach their ultimate destination, the farm, where, with their nervous systems exhausted and their circulation deranged, they are turned into a damp straw-yard or a colder and damper field, to feed upon green grass or dry straw or hay,

probably of not first-rate quality. The natural effect of all this unnatural treatment is to produce fever of a low typhoid character, accompanied by inflammation of the vessels of the lower extremities and irritative congestion of the mucous membranes, more or less extensive and severe in proportion to the amount and long continuance of the exhaustion and irritation and the constitutional power of resistance of the animal. How this affection is communicated from the sick, travelled beast to the sound, home-bred one will be easily understood by remembering the various uses to which the nose and tongue are applied by quadrupeds, and the tendency in the secretions from inflamed mucous membranes to set up similar morbid action in sound ones when brought into contact with them. Such I believe to be the source, and such the pathological character of this disease. The remedy to be taken for its relief I will class under two heads,—preventive and curative. The first are simply questions of expense, and may be summed up as follows:—A proper time allowed to the cattle for rest and refreshment, after undergoing the excitement and fatigue of the first fair, before they are put on to the railway; much more roomy and sheltered accommodation while travelling by rail and steamboat, with proper provision of food and water; a warm, dry, but airy fair, with light, nutritious, and moist food for a few days after their journey; and last, but not least, more considerate treatment while standing in the fair or market for sale. The curative treatment is directed by the nature of the disease. The sick animals should be placed in a warm, dry, sheltered, but not shut-up building, as thinly as possible, with plenty of dry litter under them; the food, soft and nutritious, as boiled linseed-cake gruel, bran mashes, and a little steamed hay, but no dry hay or straw, nor green grass or roots—the medicines cordial and sedative, such as camphor and ammonia, with small doses of opium. The measures I propose will doubtless involve some expense and trouble, but I will ask my agricultural friends whether it is not better to pay a little more at first for the carriage of their cattle to the farm than to graze them through a summer, and, perhaps, sell them at the end of it for less than they cost when bought in; and whether the trouble and annoyance of inspection, examination, obtaining orders for moving, &c.—in fact, the various measures of repression I remember being enforced during the outbreak of the rinderpest, and which are now being called for on all sides—will not be greater than to give the care and attention I have suggested to the poor creatures themselves; especially as I am convinced no means of repression, no attempts to stamp it out, will be of any avail while the primary source of the mischief is constantly in action. *M.R.C.S.E., Portmadoc, Oct. 23.*"

SMALL FARMS.—Excellent, sound, and practical as is Lord Derby's judgment on most subjects he handles, yet most will agree with the writer of the letter which I beg to call the attention of your readers, as it appeared in the *Times* of September 8, and more particularly to the last paragraph :—

"SMALL FARMS.

"To the Editor of the 'Times'.

"SIR,—I see that Lord Derby, in his speech at Liverpool, has said 'That the peasant cultivator has just as much chance of holding his own against the combination of capital and science as bows and arrows have of superseding breech-loading rifles, or handloom weaving of driving the powerloom out of the field.'

"This appears to me far too broadly stated. The civilisation of the present day needs both the large and small farm. An industrious man, occupier of a small holding, with a large family, can turn labour on his own children to a more profitable account than can be done on large holdings, where the boys and girls are bred up too gentrelly to work hard. On large tracts of poor or medium land, where little grain can be got out of a few acres, the application of capital and enterprise is needful; but where the soil is naturally rich, and in the neighbourhood of towns, it will be found that the small holder or peasant cultivator will pay higher rent and produce more per acre than the great capitalist.

"In our large cities the demand for fruit, vegetables, and poultry (the last a branch of food supply too much neglected) is quite unlimited. These things are most important in a sanitary point of view, and are produced in greatest abundance in small plots, where manure is abundant and land rich.

"The small but wealthy vegetable growers in France, in Belgium, or in the county in which I reside—Kent—will testify to this. The population, too, of Ireland, and the high rents which are obtained there, testify to the same class of facts.

"I believe that a healthy state of agriculture is best reached by a wise mixture of small and large farms, as I live in a rich district of Kent where I see much of the mixed system and its beneficial results.

"I remain, Sir, your obedient servant,

"WALTER C. JAMES.

"Bettershanger, Sandwich, Sept. 7."

The question raised by Lord Derby is not "Small and Large Farms," but whether the cultivation of the soil shall be carried on only by capitalists, to the exclusion of the working peasantry. I will not enter into the details of this question, which have been so frequently brought forward with the *pros* and *cons*; my object being only still farther and again to call the attention of landowners and agriculturists to a broader consideration of the subject. The tendency of the age ("to commerce long a prey") to the accumulation of capital and monster establishments, is to shut out and overwhelm an industrious worker with moderate means, which, in the case of land, amounts to a monopoly. The landowner lets his farms of 800 or 1000 acres at their proper value, and with the best intentions, the belief being that a larger produce can be created at a less proportionate cost than in small farms or holdings. It is not my purpose to enter on this question comparatively, nor to oppose the creation of large farms, but to suggest the question whether the smallest capitalist or a successful and industrious peasant should have an opportunity of cultivating his native soil or be practically excluded. Many thinking and observant men have thought that for the last two or three generations the British race has physically degenerated, and this belief is now more generally entertained. The vigour and stamina of our race depend on the health and well-doing of the bodily hard-working man, the mechanic, and above all the worker in our fields; the employment in various workshops and crowded factories under cover, although tending to an apparently precocious intelligence, tends also to delicacy of habit, want of robustness, and in a generation or two to a degeneration of the species. From different causes our race of agricultural labourers has fallen off; the introduction of machinery and other circumstances have made work scarce and fitful, so that, independently of weather, many of our so-called labourers necessarily become idlers, and many of our best and most intelligent and energetic have emigrated. At the present season, for want of hands, much of our cereal crop is being seriously damaged, and if a strict calculation were made, it seems probable that it would have answered to farmers to have kept more labourers, even at half-work, during the winter. The damage created by want of hands to gather our crops "when the sun shines" will be a counterbalance to the skill which boasts of making "two blades of grass grow where one grew before." Already agitation has commenced on the subject of labour-wage, which from the state of the times will probably spread; and although it is to be hoped that there will never be any legislation, it is obvious that there will be ere long some legislative enactments regulating its use and distribution. I am aware not only that much remains to be said on the above subject and its obvious ramifications; "lengthy" as this communication may appear to many, my object has been to call the attention of a most important subject already somewhat pressing and shortly to become urgent; and I do not enter on it now merely on account of the present state, but, if I may use so hard a word, ethnologically as regards the future. The very best and pick of our working men and women are invited and courted where our work-with wage is spoken; let us keep and cherish them, and hold out every chance and help for honest men to obtain recompense and comfort by their own self-reliant exertions; let us lead them to respect themselves and their employers, and to love their native soil. *Thomas Warner, in the "Wilts and Gloucestershire Standard."*

The Week's Work.

OCTOBER 20.—*Wheat Sowing* is now in full swing. It should be concluded without delay on fallows, Clover and Bean stubbles, and also after root crops, as soon as they are removed from the ground.

Mangel Wurzel.—Finish harvesting as soon as possible, however promising the weather may be for the ensuing few weeks, for a frost has yet to come ere they are stored, so as in the slightest degree to affect the bulbs, and if a frosty night is followed by a change, it is generally advisable to give them a day or two of fresh weather to recover, provided the risk is not greater than the advantage likely to be gained. Sudden changes have the effect of making the characteristics of the season in some places, and if there is any prospect of a return of frost, pull and store in small pits. If, in very bad cases, a deep outcasting is made with a plough, and three or four drills on each side thrown in and covered with the fresh earth, mixing, if at the same time, with the bulbs, will recover, and be fit for storing in a week or so. Pits should be examined before they are finally earthed up for the winter, whether the bulbs were touched with frost or not. Small pits may be made sufficiently close to each other, that in turning two or three may be stored in one, and this is the safest plan when there exists any suspicion of frost-bitten Mangels. The expense, compared with the safety of so valuable a crop, is comparatively nothing. Select a fine drying day for turning, and throw aside all bulbs in the slightest degree affected. By cutting off the frost-bitten portion, most remain which may be given to store cattle, so that the loss actually sustained may be trifling.

Turnips, Hybrid and Yellow, may be stored as Swedes. If intended to be consumed on the land by sheep, it is better to store in long narrow pits than to collect in large ones together. Ten to 20 drills may be stored in a deep plough outcasting, and covered with the plough; or if to be used immediately they may be covered with the tops. And when stored this way the shepherd folds close up to the outcasting, and when bulbs stored in one outcasting are finished he brings up his fold or nets to another, until the whole field is folded. Sometimes part of the crop is stored at the homestead, and the remainder in the field for folding; but the only difference which this involves in the storing is a greater distance between the pits or outcastings in which the baths are stored. Turnips are sometimes "clamped," *i.e.*, pulled and carted to some spare ground, where they are set close two rows in depth, with the tops and tails on, and lightly covered with straw or horse-dung to defend them from frost.

Early Lambs force forward for Christmas; and in doing so it should be borne in mind that fineness of quality as also weight depends much more upon the quality of the food of the ewes than on what the lambs themselves eat exclusive of milk, and that rich milk is the natural and best food for making fine rich lamb—that which will fetch the top price in the shambles; and it should farther be borne in mind that quantity of milk in fattening lambs will not make up for quality. In point of fact, a large bellyful of thin milk, or washy food of any kind, is injurious to both growth and shape; so that when put upon succulent green food of any kind the ewes should have an extra allowance of ground corn and Clover hay. Moreover, in cold or wet weather at this season, succulent, washy food is more objectionable than in the warm dry weather of summer. Corn is better for making rich milk than cake, Clover hay than meadow hay, other things being equal. Cabbages are better than Turnips, and the yellow-fleshed varieties of Turnips are to be preferred to the white-fleshed. But of all our root crops grown the Belgian Carrot is perhaps the best for milch ewes at this season. Sheltered pastures are essential for ewes and lambs, for nothing reduces the quantity and quality of milk more than exposure to cold wet weather. As a rule, the skins of ewes and lambs should be kept dry and comparatively warm, and if this cannot be done out-of-doors, house the flock at once in roomy pens, and feed wholly on artificial food; and this applies to ewes that are lambing, or whose time is nearly up. In-lamb ewes for lambing in January and February should also have shelter, and where this cannot be had naturally, stuffed hurdles or straw webbing should be used, one row standing above the other, so as to form a semi-roof for the ewes to go under in bad weather.

Notices to Correspondents.

COMBINED THRESHING-MACHINE: *W. T.* desires to ask, through the *Agricultural Gazette*, some of our correspondents to inform him where is the best portable combined corn threshing, dressing, and straw shaking and elevating machines? Also whose is the best portable chaff-cutting machine? His engine is 12-horse power.

FARMERS' CO-OPERATIVE ASSOCIATION: *A. B.* There is one in operation in Essex, under capital management; and for particulars you may consult our advertising columns. The address is—"The Farmers' Supply Association, 69, King William Street, E.C."

FRUIT TREES: *An Anonymous Correspondent* asks:—"Where can fruit trees be obtained at the prices named by D. T. Fish in his article on Fewer Gardens?" To this we reply:—Any respectable nurseryman can supply them.

SWEDE TURNIP: *Inquirer.* Top and tail them, and throw them into heaps on the land, and cover them with the tops, and then with earth. Let each heap contain the roots on one fold, or two folds, so as to suit the work of the Turnip-cutter.

THE WOOLSTON IMPLEMENTS: *Inquirer.* The best description of Mr. Smith's implements and mode of working, written by himself, is to be found at p. 84, 1870, of the *Agricultural Gazette.*

Markets.

HOPS.

BOROUGH MARKET, Oct. 26.

Messrs. Pattenden & Smith report a good demand for consumption, prices for all descriptions being fully maintained. Stocks are greatly reduced, the quantity of new Hops offering being surprisingly small for the time of year.

MARK LANE.

MONDAY, Oct. 23.

The supply of English Wheat to this morning's market was small. Good dry samples brought last week's quotations, but inferior were very difficult to sell. For foreign the demand was limited in extent; prices were unaltered. Barley was a slow sale at late rates. White Peas rather dearer. The Oat trade was quiet. For Maize there was little inquiry. Flour unchanged in value.

WEDNESDAY, Oct. 25.

The Corn Exchange presented a quiet appearance There were fair supplies of English Wheat on offer, and the arrivals from abroad were on an extensive scale; trade was inactive, and prices in some instances were slightly easier. Fine Barley was steady, but inferior qualities were quiet. Malt changed hands slowly, on

former terms. Oats were in liberal supply. The demand was slow, but for sound corn prices were well sustained. Beans and Peas were quite as dear. Flour was dull, and prices favoured buyers.

METROPOLITAN CATTLE MARKET.

MONDAY, Oct. 23.

The number of Beasts is smaller than last Monday, and trade is active; on the average prices are rather better, and a good clearance is effected. The supply of English Sheep is larger and of foreign smaller than last week, the total number being rather large. Trade is brisk, at fully last Monday's quotations. Choice Calves are readily disposed of at our quotations. The foreign supply consists of 3100 Beasts, 11,000 Sheep, 246 Calves, and 30 Pigs; from Scotland, there are 5 Beasts; from Ireland, 350; and from Holland and Rhine Countries.

	s. d. s. d.		*s. d. s. d.*

		Calves	3 8—6 0
		Pigs	3 4—5 0

Beasts, 4630; Sheep and Lambs, 18,220; Calves, 276; Pigs, 125.

THURSDAY, Oct. 26.

We have a few more Beasts than last Thursday, the excess, however, is in foreign, trade is good, and choicest qualities are rather dearer. The number of Sheep is also rather larger, still the supply is limited, and there is a fair demand at Monday's quotations. Choice Calves are scarce, and realise high rates. Our foreign supply consists of 480 Beasts, 4480 Sheep, and 165 Calves.

THE SALIX, or WILLOW. By W. SCALING, Willow Nurseryman, Basford, Notts. A revised and enlarged edition, containing Instructions for its Planting, Culture, &c., with Observations upon its Value and Adaptability for the Formation of Hedges and Game Covers.

Post free 12 ; or of SIMPKIN, MARSHALL, and CO., London.

Notice.

NEW GARDENING JOURNAL. On November 25 will be published the First Number of THE GARDEN, a Weekly Illustrated Journal, devoted solely to Horticultural Interests.

THE GARDEN is projected by, and will be under the editorship of, WILLIAM ROBINSON, F.L.S., Author of "Alpine Flowers for Gardens," the "Parks, Promenades, and Gardens of Paris," &c., &c.; and the best writers in every department of Gardening will be contributors to its pages.

Advertisements, to insure insertion in the First Number, should be forwarded without delay to the office.

THE GARDEN may be obtained through all Newsagents and at all Railway Bookstalls, at 4d. per copy. It may also be had direct from the Office at 5s. for a Quarter, 9s. 9d. for a Half-year, and 19s. 6d. for a Year, payable in advance. Single Copies (post free), 4½d.

The Office of THE GARDEN will be at 37, Southampton Street, Strand (next door to the *Saturday Review* Office), where all Communications should be sent.

A. C. VAN EEDEN and CO., FLORISTS and BULB-GROWERS, Wiggewieg, No. 91, Haarlem, Holland, have the pleasure to inform the Trade and Amateurs that the Proof Number of the "ALBUM VAN EEDEN," Floris of Haarlem, Coloured Plates of Flower Roots, is just published, and will be sent free on application. The "Album van Eeden" will consist every year of 12 large and beautifully Coloured Plates, and will cost, free by post, payable in advance, will be 12s. per annum. Appended are a few

TESTIMONIALS.

" Edinburgh.

" We have perused the proof-number of the 'Album van Eeden,' and consider that the illustration is remarkably well done, and that the work will become popular in this country.

" PETER LAWSON & SON."

" London.

" We have inspected the proof-number of your 'Album,' and think it is very nicely got up.

" JAMES CARTER, DUNNETT & BEALE."

" London.

" We consider it a great idea, and has long been wanted by English gardeners.

" DICK RADCLYFFE & CO."

" Liverpool.

" I must congratulate you on the enterprise and spirit with which you have commenced a work so much needed by all in the trade, and so likely to prove a great value to both the amateur and business man.

" R. WILSON KER.

" Hon. Secretary to the Horticultural Society of Liverpool."

" London.

" We have every reason to believe that your new work will be a great boon and blessing to the amateur cultivator of bulbs as well as the trade.

" W. CUTBUSH & SON."

PEAT or LOAM supplied at lowest rates in any quantities.

Apply to the Manager, Hampstead Heath.

N.B. Orders promptly executed by Rail or to Wharves.

A liberal discount to the Trade.

The Gardeners' Chronicle

SATURDAY, NOVEMBER 4, 1871.

IT is very amusing, and often highly instructive, to listen to the comments of travellers on the plants grown in this country in our Palm-houses, Orchid-houses, and the like. "Oh! this is all very well, but you should see them as I have along the banks of the Amazon," or "What magnificent flowers! In the tropics we don't get such bloom as that." We are all of us accustomed to hear such expressions as these—referring to WILD and CULTIVATED PLANTS respectively, and the contradictions they involve are often more apparent than real. In the first place, it must always be remembered that plants in a state of Nature grow, not necessarily in the localities best suited for them, but where they can. The home gardener is very often enabled to place his charges under more favourable conditions than they enjoy in their own homes. The very absence of competing plants is in itself an enormous gain, and one which the gardener, with his wits about him, and moderate appliances at command, can in most instances secure. On the other hand, there are other circumstances, such as the intensity of light in tropical countries, which favour some phases of vegetation to a degree not realisable, in our more clouded atmosphere, by any art of the gardener. It follows from this, that the best gardener is not he who exerts all his efforts in the attempt to imitate the conditions under which any particular plant may happen to grow in its native country, but he who uses his skill in the endeavour to grow the plant to the best advantage under the conditions at his disposal. To endeavour to imitate in our stoves all the conditions of a tropical climate is to strive after the unattainable; to avail oneself to the fullest extent practicable of the circumstances and conditions under which plants will grow in this country is to deserve success, and to a large extent, it may be added, to command it. Moreover, we must never lose sight of the requirements of the plant as growing in its own country, and the requirements of the gardener who holds it in subjection here. In the one case leafage to utilise every sunbeam and drink in every breath of vapour or of gas; in the other only so much foliage as shall ensure the production of brilliant flowers and well ripened fruit.

The gardener must have a thorough knowledge of general principles to begin with, and then he must have sagacity and tact enough to know how to apply them to varying conditions and requirements. He can get his knowledge of general principles from books or lectures, but his practical sagacity must be developed by experience. Books, or the lessons of men of science, will supply him with the ingots, but it is he himself who must mint those ingots into serviceable coin.

These remarks have been suggested to us by the perusal of an excellent paper on the culture of Orchids in Bengal, by Mr. SCOTT, of the Royal Botanic Gardens, Calcutta, a copy of which is before us.

Lower Bengal has but a small number of indigenous Orchids, and the climatal conditions were deemed so unfavourable, that but little attempt was made till recently to cultivate them in that province. In 1866, however, the late director of the Garden, Dr. THOMAS ANDERSON, whose recent death all botanists lament, suggested that the Orchids should be grown in those thinly thatched structures used by the natives for their Betel (Piper Betel). These structures have flat roofs, consisting of a light framework of Bamboo resting on Teak rafters, on which latter a thin layer of dried grass is fixed. The sides are formed in a similar manner, so that while the direct solar rays are cut off, there is still plenty of diffused light. These buildings, writes Mr. SCOTT, modify very effectively the ungeniality of the climate, screening the plants in the cold season, and checking the intense nocturnal radiation which then prevails, while in the hot season they admit a light diffused as that of their native forests, and thus the plants require little besides a free supply of water to supply their wants during the growing season. "Tropical Orchids," further writes Mr. SCOTT, "with few exceptions, delight in an abundance of light and heat, but in their season of growth they none the less require a highly humid atmosphere; and thus, in the construction of our Orchid-houses, it should be our aim to afford screens, which, while securing the latter, also admit an abundance of sun-light and heat." In the resting season the Orchids, in the Calcutta Garden, require little or no water, but in the hot season, which begins about the end of February, when the majority of Indian Orchids begin to bloom, watering becomes necessary, care being taken not to water overhead when the plants are in flower. During the rainy season, from the middle of June to the middle of October, artificial watering is had recourse to when necessary, till the onset of the resting period, when it is comparatively discontinued. In this way nearly all the tropical Indian Orchids, as well as representatives of many of the South American genera, have grown well and flowered freely in the Calcutta garden. These results have been attained by the use of airy, light-diffusing screens of dry grass, and by affording water when required, as just indicated. Mr. SCOTT very properly insists on the careful study of the hygrometer, and gives Tables, showing the weekly means of the wet and dry bulb thermometers in the garden at Calcutta, which we commend to the notice of our Orchid cultivators as worthy of their inspection.

Many other suggestive hints are scattered through Mr. SCOTT'S paper; amongst others, the circumstance that many of the Indian Orchids, which are deciduous in their native habitats, retain their leaves in the stoves of this country. Dendrobium Falconeri is cited as an illustration of this; moreover, says Mr. SCOTT, the flowers of this species in India are superior to those produced in this country, each shade of colour being distinct and well defined. Altogether Mr.

Scott's paper, though of course written for Indian use, is one which may be perused with profit by our home growers.

As there seemed to be a great want of information regarding the observations which have long since been established respecting the Potato Disease, it was thought advisable, on the occasion of the exhibition of Fungi, at the Royal Horticultural Society's rooms, on October 4, to make a short statement on the subject, accompanied by figures, some of which are reproduced here. It is so generally recognised by the best scientific observers that the disease is actually produced by a parasitic Fungus, that it was not thought necessary to touch at length on mere speculations, which really arise in the first instance from a notion that no Fungus will grow except on organisms previously diseased. This notion has, however, been so often refuted, that it would be mere waste of time and paper to dwell upon it, though it was once so prevalent that Dr. Montagne, who advanced further than any one when the disease first became prevalent in Europe, and whose observations, in conjunction with those of Mr. Berkeley, were published in the first volume of the octavo Journal of the Horticultural Society in 1846, gave up for a time his well founded opinion, returning to it, however, at a later period.

The first appearance of the Potato disease is indicated by the presence of brown spots on the upper surface of the leaves. If the reverse of these spots be examined, it will be found that the brown colour has been produced by the action of a parasitic mould, which gradually extends in the circumference of the spots, destroying the tissues as it proceeds, and ultimately gaining extensive possession of other portions of the plant.

The mould in question belongs to the genus Peronospora, of which some 40 species are known, all of which are parasitic on living plants. This mould had not been observed previous to 1844. It was not contained, either in the collections of De Candolle or Sowerby, and a notion once prevailed that it was some species which had acquired a somewhat different character, from migrating to a plant of exotic origin. The distinctive character, however, of the swellings on the threads is so different from anything which has been observed in other species, that it is impossible to acquiesce in that opinion, and as the disease is known in the native country of the Potato, though the parasite has not been detected there, it is more natural to suppose that it was imported, unless we have recourse to the theory of spontaneous generation, which at present is a mere matter of speculation. The mould, Peronospora infestans (fig. 309, 1), bears abundance of spores on the tips of the branches, the mycelium, or spawn, burrowing amongst the cellular tissue of the leaf (fig. 2), and causing rapid decomposition, while the vertical threads, which branch and bear the spores, find their way through the stomates, or leaf pores. The spores themselves falling on different parts of the plant germinate (fig. 3), and penetrating the tissues (fig. 4), produce a brown tint not only in the cells with which they are in immediate contact, but in the adjacent cells.

It is, however, curious that some of the spores in which no perceptible difference can be found at first, undergo a peculiar process. The contents become differentiated, as first observed by Dr. Montagne, though more perfectly by De Bary, and are divided into a number of nucleated cells, which ultimately produce a multitude of zoospores*, that is to say, moving spores, which are exceedingly active so long as they have sufficient moisture in which to exercise the two thread-like processes by which they change their position (fig. 6). These bodies, like the ordinary spores, germinate (fig. 7), and penetrate the tissues (fig. 8), producing the same brown tint, and in the same way as in the former case.

In many species of the genus another more perfect form of fructification has been observed, in which there is clearly the action of a male element. In Peronospora alsinearum, for example (fig. 309, 11), there are distinct antheridia, or male organs, which come in contact with peculiar cells originating within or amongst the tissues of the leaves, and in consequence of this contact and interchange of the contents of the cells in question a resting spore is formed as in Peronospora viciæ (fig. 12), which is dormant through the winter, but can propagate the plant at a later period.

* Dr. Montagne observed the production of a multitude of sporidia in the spores, but did not ascertain the fact that they were zoospores. See figure in Journal of Horticultural Society.

It is not quite certain whether this perfect form of fructification has been observed in the Potato mould. Dr. Montagne, however, figured in the memoir above quoted (figs. 9, 10) a genus discovered in spent Potatos by Dr. Payen, to which he gave the name of Artotrogus, which there is reason to believe is the resting spore of Peronospora infestans. Resting spores, moreover, have not yet been observed in the Onion

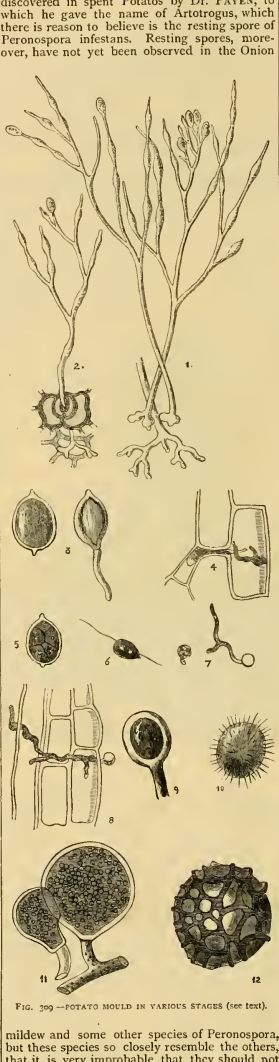

Fig. 309.—Potato mould in various stages (see text).

mildew and some other species of Peronospora, but these species so closely resemble the others, that it is very improbable that they should not have resting spores, though they may be produced more rarely.

Such is the character of the Potato mould, and we see at once that it is capable of producing the brown chemical change in the cellulose which is so characteristic of the Potato murrain; that it is far more easily propagated in wet than in dry weather; and that from its habit of infesting the intimate tissues of the plant it is exceedingly difficult to apply any remedy, the sulphur which is a specific in the Hop and Vine mildew because the Fungi to which these diseases are due are superficial, having little effect on the Potato mould.

The annexed illustration (fig. 309) represents, under various powers of the microscope:—

1. Peronospora infestans.
2. The same, burrowing amongst the tissues of the leaves, and making its way through the stomates.
3. Spores, or more properly speaking, conidia, germinating.
4. The same, sown artificially, and penetrating the tissues after 18 hours.
5. Spores with contents differentiated.
6. Zoospores.
7. Zoospores germinating.
8. Zoospores sown artificially in the stem, and, after 24 hours, penetrating the tissues and entering the intercellular spaces.
9. Young Artotrogus still in mother cell.
10. Young Artotrogus free.
11. Peronospora alsinearum, with an antheridium and mother cell.
12. Resting spore of Peronospora viciæ.

Peronospora infestans is frequently developed on other Solanaceæ, and is very common in the fruit of the Tomato.

It seems quite absurd, when the whole *rationale* of the Potato disease has been so amply explained, to look for an explanation in mere climatic conditions, exhaustion, weakness of constitution, or any of the empirical causes which are so often brought forward, and mostly by persons entirely ignorant of what has been observed by men of science. *M. J. B.*

—— Some few years since, M. Alph. de Candolle drew attention to the arrangement of the Veins of the Leaf in some species of Beech (Fagus), in which he pointed out that the lateral veins, instead of running up into the crest of the little lobes or teeth of the margin of the leaf, as is usually the case, terminated in the sinus or notch between them. Although in some cases both forms of nervation exist in the same leaf (a caution to fossil botanists), yet in other cases it appeared to M. de Candolle to be sufficiently constant to be used as a specific character. In this manner, for instance, M. de Candolle distinguishes our European Beech, in which the tendency is for the veins to run into the shallow notches of the leaf, from the American form, where the veins run into the teeth or lobes. M. de Candolle also cites as illustration of this unusual direction of the nerves, Coldenia procumbens, Crataegus Oxyacantha, the Hawthorn, and Rhinanthus. To this list, no doubt, many additions could be made; one is before us as we write, in the leaves of Ceratopetalum gummiferum. We have also seen a similar arrangement in the linear leaves of some Dryandra or allied Proteaceous plant; in some Saxifrages, *e.g.*, S. Geum, in Betonica officinalis, and obscurely in Hieracium murorum, Teucrium Chamædrys, and Tussilago fragrans. The point is one of some importance in structural botany, not only with reference to fossil leaves and their appropriate discrimination, but also to such cases as the venation of the flowers of Composites, and of the so-called gamopetalous corollas in general.

—— We hear that Dr. Hooker has placed the Lichens which he collected during his Morocco expedition in the hands of Rev. W. A. Leighton, of Shrewsbury, for examination and determination.

—— It appears that Virgin Forests are still to be found in central Europe, that is, in Bohemia and Moravia. The forests consist of Silver Fir, Picea pectinata, Spruce, Pinus Abies and Beech. Some of the Firs measure 7 feet in diameter, and have a height of 160—170 feet, one even is registered to have measured 200 feet in height, with a diameter of 6 to 8 feet, though the majority of the trees do not attain such dimensions. Owing to the paucity of species the general aspect of the woods is monotonous. The trunks run up to a great height before branching into the head, and thus allow of the growth of underwood.

—— Not long since we had occasion to record the occurrence of Male and Female Flowers on the same Tree in Araucaria imbricata as grown at Bicton. It now appears that a similar circumstance has lately been observed by M. A. Rivière in the Experimental Garden of Hamma, near Algiers. The occurrence of so many cases of a similar kind in other ordinarily unisexual plants leads us to believe that, under suitable conditions, any plant can change its condition. But what are the suitable conditions? What are the conditions, for instance, which have led to the production during the same season of the monœcious state in an Araucaria at such very different places as Algiers and Bicton?

—— The Maximum Temperatures of the Air during the week ending October 28, ranged from 68°.8 at Portsmouth to 54°.8 at Aberdeen, with a mean for the several stations in England of 60°.2, and for those in Scotland of 57°. The Minimum Temperatures of the air ranged from 42°.1 at Liverpool to 32° at Wolverhampton and Hull, with a mean for English stations of 35°.8, and for Scottish of 36°.5. The Mean Temperatures were generally

uniform. The highest, 50°.6, was recorded at Liverpool, and the lowest, 46°.4, at Norwich. Five out of the seven Scottish stations registered mean temperatures exceeding 48°, and the mean for the whole was 48°.3. The mean for the English stations only exceeded this by 0°.3. The RAINFALL at the various stations in England was generally small, the exceptions being Manchester, 0.92 inch, and Eccles, 1.08 inch; the mean being but 0.35 inch. In Scotland, Edinburgh recorded a fall of 0.70 inch, Glasgow 1.02 inch, Dundee 0.75, and Greenock 1.53 inch; the mean for the several places in that country being 0.78 inch. (See Mr. GLAISHER'S Tables, p. 1427.)

—— FRIES states in his "Epicrisis" that the three varieties of AGARICUS COLUMBETTA occasionally occur severally with red, brown, or violet spots. Some specimens of varieties were found by Mr. BROOME in Denbighshire, which were marked both on the stem and pileus with bright violet spots. Remembering that coloured specks occur now and then on Fungi, as figured by BULLIARD under Agaricus ulmarius, which in one case at least has been ascertained to be an early stage of Epicoccum, while the structure is that of the celebrated blood-rain of Dr. MONTAGNE (Fulmella prodigiosa), it occurred to us that these violet spots might be something analogous. On examination under the microscope, it was found that they consisted of myriads of very minute granules, which rather confirmed our notion, but it was thought advisable to test the matter by sowing some of the substance on stiff paste. This accordingly was done, and now, after a few days, the surface is covered with the most brilliant violet coat. At present it is quite uncertain what the ultimate development of this substance may be, but the circumstance is worthy of record, as it belongs to a set of organisms which probably act a very important part in the diffusion of disease, and especially of hospital gangrene. The blood-rain was propagated with great ease and rapidity, and as, on experiment, it made a permanent dye, it was at one time thought that it might be of economical interest. It is very probable that this substance may have the same property, but the brilliant aniline dyes entirely put such minor succedanea out of the question. *M. J. B.*

—— Some few months since we mentioned a LATE-FLOWERING LILY of the VALLEY, shown by Mr. STANDISH, as an apparently distinct variety; and subsequently it was observed by a correspondent, that late flowers accompanied by similar appearances were the result of very early forcing, under which treatment many plants would go blind, and develope only late blossoms. The exhibition of Mr. STANDISH'S plants again at this season shows our first impression to be correct. The foliage is in full vigour now, while that of ordinary potted Lilies has died down, and it is moreover totally different in form, being broadly ovate, as broad as long, instead of the usual elliptic-oblong figure. The variety, whatever it is, appears to be entirely unknown both in this country and on the Continent.

—— The new GLADIOLUS CRUENTUS, described at p. 105, 1870, has, as was anticipated, given rise to an entirely new form amongst these popular flowers. In a variety, which has been named Alice Wilson, raised, with many others, between cruentus and brenchleyensis, the regular form of the first-named parent has had the effect of producing a flower which, having its segments recurved, have much more the aspect of a Lily than of a Corn-flag. The segments are all white, tipped with a rich carmine-rose, the three sepaline ones, which are slightly the larger, having also rather more of this colouring than the three inner ones; but each set—the petaline and sepaline—being similar in form, and equally recurved, a beautiful flower, of an entirely novel character, has been obtained. Messrs. STANDISH & Co. are the fortunate possessors.

New Garden Plants.

MASDEVALLIA HARRYANA, *n. sp.*

Folio elongato oblongo spathulato obtuso basin versus late ac sensim attenuato; sepalis lateralibus lato semiovatis apiculatis, sepalo dorsali lineari porrecto.

There is a good deal to say about the purplish, violet,

FIG. 310.—A, MASDEVALLIA VEITCHIANA. B, M. TOVARENSIS.

and crimson Masdevallias. After a long study and some correspondence and personal intercourse with A. van Brantegheim, Esq., of Brussels, who grows Masdevallias and all cool Orchids like weeds, I have now some decided views about these curious plants; and I will soon give a general sketch of these plants in the *Gardeners' Chronicle*, but for the moment I must confine myself to the publication of a remarkable plant which has recently flowered in the wonderful collection of the Messrs. Veitch. The flower is a very dangerous, if not a victorious, rival of the Masdevallia that has been called M. Lindeni by Monsieur André. The large broad shining leaves may form a great attraction to Masdevallophilists, but the blossom itself must move the admiration of every one who appreciates a wonderful flower. It has just flowered, I hear, for the first time in England. The flower reached me September 11. I feel a great pleasure in dedicating it to my excellent friend, Harry Veitch, Esq. *H. G. Reichb. fil.*

MASDEVALLIAS.

WE have here a charming genus of little plants—gems of the first water, one might say, seeing that they are most of them so chastely beautiful, and comparatively rare—a fact that detracts nothing from their value, as purchasers already know by experience. The fact of their rarity may be accounted for satisfactorily, if we remember that most of the species of this genus, not all, are found growing at exceedingly high altitudes, and doubtless many get their death-blow by being torn from their fresh and cool habitats on the Peruvian or New Grenadian ranges, and then subjected to the intense heat of the lowland plains below previous to their being dispatched hither to enrich our collections.

In 1864 we find that veteran orchidophilist, J. Bateman, Esq., F.R.S., writing as follows with regard to these plants:—"The range of this remarkable genus is higher than that of any in the entire family of Orchids. Its species are chiefly confined to the Andes of New Grenada and Peru, where they reach an elevation of more than 10,000 feet. They are of humble growth, resembling Pleurothallis, but with flowers of good size, great beauty, and presenting the utmost variety of colour and form. About 50 are known to botanists, but being of very difficult importation, scarcely more than half-a-dozen are yet to be found alive in Europe. They should be planted in small pots placed near the glass, but always shaded from the sun's rays, and kept in a cool and moist situation. A north house will probably be found indispensable. They grow freely, but are very impatient of the knife; hence it is difficult to increase them. M. coccinea is perhaps the finest species, but it has not yet flowered." In M. Linden's catalogue for the present year we find half a score species enumerated, with prices varying from 12*s.* to nearly as many pounds, while in 1865 Messrs. J. Backhouse & Son offered a species of this genus, imported from New Grenada, bearing "solitary, purplish rose-coloured flowers," for the extremely low sum of 10*s.* 6*d.*

On glancing over the catalogues of our own and foreign growers, I find about 20 species mentioned, viz.:—

Masdevallia amanda
" Amoni
" candida
" caudata
" civilis
" coccinea
" cuprea
" elephanticeps]
" fenestrata
" hians
" infracta
" Lindeni
" maculata
" ochracea
" octodes
" picturata
" rio grandensis
" tovarensis
" venusta
" Veitchiana

Unfortunately I have no means of ascertaining whether any of these so-called species are synonymous; but even supposing this not to be the case, it shows that there are some 30 or 40 species yet to introduce to our collections, which we possess at present only in our books or herbaria.

One of the most beautiful species in general cultivation is the Peruvian, M. Veitchiana (see fig. 310, A.) The gorgeous flowers of this novelty are solitary on long scapes, and are of the most brilliant orange-scarlet, set with short purple hairs, which latter give an indescribably rich appearance to the elegant long-tailed sepals.

M. tovarensis (see fig. 310, B) is from Tovar (Columbia), as its specific name implies, and must be considered as one of the best. Its curious shaped flowers are borne in pairs on the apex of a triquetrous scape, about 6 inches long. More rarely this plant produces three flowers on a scape. The flowers themselves are of the purest white, and remain perfect for weeks in a cool, moist atmosphere.

M. maculata is another choice species from Columbia, bearing yellowish flowers spotted with rose and purple,

the sepals being also much elongated. This species flowered in the collection of the late Consul Schiller at Hamburg.

M. coccinea was introduced to our gardens from Pamplona, in New Grenada, and is a perfect little gem. Lindley described it as "a charming thing, with flowers as red as a soldier's coat."

M. infracta is another attractive form of the genus, with purplish-lilac flowers, and beautiful glossy foliage.

M. civilis is an extremely curious green flowered species, which I saw in flower in the old cool Orchid-house at Kew in 1868. Its flowers are borne solitary on short scapes, and are semi-tubular, with reflexed, long-tailed sepals, of a green colour spotted with brown within.

One of the finest of the recently introduced species is M. Lindeni, which was noticed in the *Gardeners' Chronicle* for June 25, 1870, as flowering in the collection of M. Linden at Brussels, its flowers being described as of "a puce or crimson colour."

Masdevallias, taken generally, may be characterised as being the "coolest" of Orchids, if we except the glorious South African Disa grandiflora, which Dr. Moore, of Glasnevin, has recently treated as a "subtropical," and bloomed it out-of-doors, planted in an artificial bog.

Masdevallias grow well in shallow pots, or small pans, in a compost composed of fresh, fibrous peat, with crocks, charcoal, and coarse smashed road-sand, intermixed. The surface of the compost may be covered with fresh living Sphagnum, which not only adds to the neat appearance of the plants themselves, but also assists in preserving an equable moisture round their roots. They require an abundant supply of moisture while growing, both at their roots and in the atmosphere, and care must be taken to keep them as cool as possible during the hot summer months, as also to protect them from scorching. When well grown they bloom profusely, and are justly reckoned as being amongst the choicest "pets" of the cool Orchid-house. Who knows but that in a year or two's time we shall find some of them capable of enduring our winters when planted in sheltered localities out-of-doors? *F. W. B.* [It will be seen from the preceding article that Professor Reichenbach has described a new species, and further intends to give a general sketch of these plants, an announcement which will be received with great satisfaction by Orchid lovers. Eds.]

A NEW SYNOPSIS OF ALL THE KNOWN LILIES.—IX.

Subgenus 2. LILIUM PROPER.—Bulbs squamose: stigma a thick head to the style, with three blunt lobes—(*Continued*).

Group 4: MARTAGON (Turk's-cap Lilies).—Perianth broadly bell-shaped, always drooping, its divisions lanceolate, broadest about the middle, not distinctly clawed, reflexed (usually from half or two-thirds of the way down) when fully expanded. Stamens diverging much on all sides from the central axis of the flower—(*Continued*).

Key to the Species.

Leaves verticillate. (Three species already noticed.)	
Leaves scattered.	
Leaves linear-lanceolate, half an inch or more broad, 5–7 nerved. (Four species already noticed.	
Leaves linear, $\frac{1}{4}$–$\frac{1}{2}$ inch broad, 3–5 nerved.	28. L. CALLOSUM.
Perianth $2\frac{1}{2}$–2 inches deep, with divisions $\frac{1}{2}$–$\frac{1}{3}$ inch broad.	
Leaves close, 50–80 to a stem.	
Perianth bright red, not dotted.	26. L. CHALCEDONICUM.
Perianth bright yellow, dotted.	27. L. PYRENAICUM.
Leaves lax, about 30 to a stem.	28. L. CALLOSUM.
Perianth $2\frac{1}{2}$–3 inches deep, with divisions $\frac{3}{4}$–1 inch broad.	
Leaves linear, pubescent; perianth dull nankeen-yellow.	29. L. TESTACEUM.
Leaves 70–80, perianth bright yellow or scarlet.	30. L. LEICHTLINII.
Leaves narrow-linear, 1–$1\frac{1}{2}$ line broad, 1-nerved.	
Stem $1\frac{1}{2}$–3 feet high, with 80–100 leaves.	31. L. POMPONIUM.
Stem a foot or less high, with 30–50 leaves.	32. L. TENUIFOLIUM.

26. *L. chalcedonicum*, Linn. Sp. Plant. p. 434, *ex parte*; Bot. Mag. t. 30; Redouté, Lil. t. 276; Kunth, Enum. iv. 262 (excluding localities); Spae, Mon. p. 32; but not of Jacquin and many authors of local European Floras; *L. byzantinum miniotum*, Bauhin, Pin. 78.—Stem stiff, erect, 2–3 feet high, striated, glabrous, or obscurely pubescent. Leaves at the flowering time 50–80; lower sub-patent, upper ascending, all scattered, linear, the lower 2–3 inches long, 2–3 lines broad at the middle, narrowed gradually to the point and the base, firm in texture, finely pubescent at the edge and beneath, distinctly 3–5 nerved, the upper reaching up to the base of the inflorescence. Flowers 1–6, subcorymbose, pendulous. Peduncles 2–4 inches long, sometimes bracteolate. Perianth 1½–2 lines deep, bright scarlet, rarely yellowish, the divisions reflexed from below the middle when expanded, lanceolate, 5–6 lines broad at the middle, papillose in the lower half, not at all pubescent down the borders of the groove. Ovary 4–5 lines long. Style 6–8 lines, much curved; filaments about an inch; anthers linear-oblong, 3–4 lines; pollen red.

A native certainly of Greece and the Ionian Islands, and according to authors also of Asia Minor and Persia, but these last statements appear to rest only upon vague horticultural tradition. It is an old well-known favourite of our gardens, and was brought into cultivation in Western Europe as long ago as the middle of the sixteenth century. We have in L. chalcedonicum, pomponium, and pyrenaicum a parallel case to that of the Lebanon, Atlantic, and Deodar Cedars, three plants from different geographical areas extremely close to one another in character, so near that when they are cultivated it is often not possible to say to which of the three individual specimens they belong. It would, no doubt, be better to place them as subspecies only.

27. *L. pyrenaicum*, Gouan, Ill. 25; Redouté, Lil., t. 145; Kunth, Enum. iv. 262; Spae, Mon. p. 31; Reichb. Icones Fl. Germ. t. 992; *L. flavum*, Lam. Gall. ili. 283.—Stem 2–4 feet high, strong, stiff, erect, finely furrowed, subglabrous. Leaves always scattered, very numerous, as many as 100 to a stem, erecto-patent, firm in texture, the lower 3–5 inches long, 2–3 lines broad at the middle, narrowed gradually to the base, and an acute point, usually distinctly 3-nerved, the edge slightly inrolled, minutely minutely ciliated, the upper ones extending usually up to the base of the inflorescence. Flowers 1–50 in wild specimens, up to a dozen in cultivation, not forming so regular or elongated a raceme as in pomponium. Lower peduncles 2–3 inches long, sometimes bracteolate. Perianth pendulous, 1½–2 inches deep, bright yellow, the divisions reflexed from below the middle when expanded, lanceolate, 3–4 lines broad, dotted more copiously down the inwardly green-purplish-black, the upper ones pubescent. Genitalia like those of pomponium, but the style rather thicker.

Confined to the Pyrenees, where it is tolerably frequent in woods, both upon the French and Spanish sides. It is very near L. pomponium, from which it differs principally by its broader usually distinctly 3-nerved leaves less inrolled at the border, and by its yellow flowers.

28. *L. callosum*, Sieb. et Zucc. Fl. Jap., fasc. ix., p. 86, t. 41; Kunth, Enum. iv. 262; Spae, Mon. p. 34; Miquel, Ann. Mus. Lug. Bat. iii., p. 156; *L. pomponium*, Thunb. Fl. Jap. p. 134, non Linn.—Stem 2–3 feet high, moderately slender, glabrous, subterete. Leaves scattered, much laxer than in its neighbours, not more than about 30 to a stem at the flowering time, the lower ones 4–5 inches long, scarcely over ½ inch broad at the middle, narrowed gradually to the base and with a long acute point, the edge slightly recurved, not perceptibly denticulate, the midrib with 1–2 distinct nerves on each side, the upper leaves growing gradually shorter, ceasing 2–3 inches below the base of the inflorescence. Flowers up to a dozen in a narrow regular thyrsoid raceme, all drooping till the capsule appears. Peduncles not more than 1–1½ inch long, subtended by a pair of small bracts, which are ovate, indurated and hook-shaped at the tip. Perianth bright scarlet, 1½–1½ inch deep, the divisions reflexed from about half way down when expanded, oblanceolate-spathulate, 2½–3 lines broad at the middle, the upper ones the largest, the lowest flown in the face in any of the specimens I have seen. Ovary and style each about half an inch long; filaments about an inch; anthers 3–4 lines; pollen bright red. Capsule 1½–1¾ inch deep, with a distinct sharp angle.

A native of Japan and the Loo-choo group, noticed long ago by Kämpfer and Thunberg. It was confused by the latter with the European L. pomponium, from which it differs widely in both leaves and flower. The very narrow divisions, turning back from only about half down, are very different from those of any other species. It was introduced into cultivation by Siebold about 1840, and carefully described and figured by Zuccarini. The name refers to the bracts, which are very different from those of any other Lily.

29. *L. testaceum*, Lindl. Bot. Reg. 1842, Misc. p. 51, 1843, t. 11; Paxt. Mag. Bot. 1843, p. 221, *cum icone*: Kunth, Enum. iv. p. 673; Spae, Mon. p. 40; Flore des Serres, t. 907; Regel, Gartenfl. 1865, p. 349; *L. nankeenense*, Hort., Walp. Ann. vi., p. 110; *L. sabellinum*, Kunze in Mohl et Schlecht. Bot. Zeit. i., p. 609; Linnæa, xvii., p. 570.—Stem reaching 5–6 feet in height, comparatively slender, nearly smooth, finely striated, subglabrous. Leaves always scattered, very close, 60–100 to a stem at the flowering time, erecto-patent, firm in texture, linear, the lower ones 3–4 inches long, 3–4 lines broad at the middle, narrowed gradually to the base and point, 3–5 nerved, the edge and midrib beneath distinctly ciliated, the upper ones growing gradually shorter, leaving a blank space of 3–4 inches below the inflorescence. Flowers usually 1–6, but sometimes up to a dozen, in a rather regular thyrsoid raceme. Lower peduncles reaching 5–6 inches in length, cernuous at the apex, after the ordinary Martagon fashion. Perianth bright nankeen-yellow, rather variable in intensity of the paler tint, the divisions above this strongly reflexed, a peculiar ("nankeen") not very bright shade of yellow with a tinge of dull red in it, reaching 1–2 inch broad a little below the middle, broader than usual up to the point, deeper in colour, and slightly papillose towards the throat, with a few orange-red spots. Ovary 6–9 lines long; style 12–15 lines; filaments 15–18 lines, the same colour as the petals; anthers half an inch; pollen orange-red.

A very distinct-looking plant, now and widely diffused. It is vaguely reported as Japanese (see Miquel, Ann. Mus Lug. Bat. vol. iii., p. 155), but has never been satisfactorily matched with wild specimens. If it be a garden hybrid, candidum would seem most likely to be its parent on one side, and pyrenaicum on the other. The general habit of the plant is very like that of candidum, but the shape of the perianth is of the typical Martagon type, and the colours are quite peculiar.

30. *L. Leichtlinii*, Hook. fil. Bot. Mag. t. 5673; Ill. Hort. t. 540; Flore des Serres, t. 1736; Belg. Hort. 1869, t. 11; Floral Mag. t. 509.—Stem 2–3 feet high, moderately slender, obscurely puberulous; leaves all scattered, lax as compared with its neighbours except callosum, erecto-patent, moderately firm in texture, the lower ones 3–4 inches long, ½–¾ inch broad below the middle, narrowed gradually to the base and with a long acute point, distinctly 3-nerved, the midrib prominent, the edge and under surface obscurely puberulous, the upper ones ceasing 3–4 inches below the base of the inflorescence. Flowers 1–2 in all the specimens I have seen; pedicels erecto-patent, 3–4 inches long, deep, bright yellow, the divisions rolling back from near the base when fully expanded, so that the flower reaches 3½–4 inches broad, lanceolate, ½–¾ inch broad at the middle, spotted copiously down the face with large purplish-brown spots, the base broad with the groove bordered with hairy lines. Ovary half an inch deep; style 1½–2 inches; filaments 2½–3 inches; anthers 6–8 lines; pollen reddish.

Var. *Maximowiczii*: *L. Maximowiczii*, Regel, Ind. Sem. Hort. Petrop. 1866, p. 26; Gartenfl. 1868, p. 322, t. 596; *L. pseudo-tigrinum*, Carrière, Rev. Hort. 1867, p. 410, with a coloured plate; Regel, Gartenfl. t. 664.—Stem thinly puberulous. Leaves 70–80 to a stem, lax as in the type. Flowers 3–4, the groundwork of colour bright scarlet; style and filaments shorter.

The typical L. Leichtlinii of the Botanical Magazine came up amongst a bed of *L. auratum*, at Messrs. Veitch's, in 1867. Whether it be a wild Japanese species or a garden hybrid is not known, but it has never been matched yet with wild specimens. Whether L. Maximowiczii be a distinct species or a variety, or a hybrid with one of the parents different, I do not know enough to say with any confidence; but it clearly comes exceedingly near to Leichtlinii, both in its habit and flower. By their broad divisions, spreading from very low down, these two plants come nearer to the Archelirions than do any other of the Martagons, but the outer divisions, especially, are much more narrowed in the base, and the flowers droop in typical Martagon fashion. Miquel has omitted them from his enumeration of the Japanese Lilies, in the third volume of the "Annals of the Leyden Museum."

31. *L. pomponium*, Linn. Sp. Plant. p. 434; Bot. Mag t. 971; Kunth, Enum. iv. 266; Spae, Mon. p. 30; Gren. Fl. France, iii., p. 181; Reich. Ic. Fl. Germ. t. 991; *L. angustifolium*, Bulb. Dict., No. 6; *L. rubrum*, Lam. Gall. iii., p. 283.—Stem 1½–3 feet high, strong, stiff, erect, finely furrowed, inconspicuously pubescent. Leaves always scattered, very numerous, as many as 100 to a stem, ascending, firm in texture, the lower 2–3 inches long, 1½–2 lines broad at the middle, narrowed gradually to the point and the base, the edges inrolled, distinctly ciliated, the midrib only prominent, the upper leaves diminishing to 1 inch long, the uppermost of all leaving generally a space of 1–2 inches vacant beneath the inflorescence. Flowers 1–8 in wild specimens, up to 20 in cultivation, arranged in a broad rather regular thyrsoid raceme. Peduncles 2–3 inches long, strong and broad. Lower pedicels 3–4 inches long, sometimes bracteolate. Perianth 1½–2 inches deep, bright red or tinged with orange, the divisions lanceolate, reflexed from below the middle, when expanded, 5–6 lines broad, pubescent at the tip, narrowed gradually to the base, with few or many minute black dots, and papillæ down the face, the groove glabrous. Ovary 5–6 lines long; style 7–9 lines, much curved; filaments 12–14 lines; anthers ¾ inch; pollen bright red.

An old well-known garden favourite, indigenous in Lombardy, Savoy, Dauphiné, and Provence. For remarks on its affinities, see what is said under chalcedonicum and pyrenaicum.

32. *L. tenuifolium*, Fisch. Ind. Hort. Gorenk. 1812, p. 8; Schultes fil. Syst. Veg. vii. p. 409; Kunth, Enum. iv., p. 263; Spae, Mon. p. 33; *L. pumilum*, Redouté, Lil. t. 378; Schultes fil. Syst. Veg. vii. p. 410; Kunth, Enum. iv. p. 263; *L. linifolium*, Hornem. Hort. Hafn. i., p. 226.—Stem 1–1½ foot high, very slender, glabrous. Leaves closely placed, much ascending, 30—50 to a stem at the flowering time, linear-subulate, one-nerved, ½—2 inches long, not more than a line broad, the edge enrolled and minutely denticulate, the upper ones ceasing 1–2 inches below the inflorescence. Flowers usually solitary in wild specimens, rarely two, drooping or suberect. Perianth 1½ inch deep, bright scarlet, the divisions oblanceolate-spathulate, 3–4 lines broad at the middle, spreading from a little above the base when expanded, usually unspotted, rarely with a few minute nearly black dots in the throat, with more of a claw than is usual in the Martagons, with a distinct glabrous groove. Ovary 3–4 lines long; style 5–6 lines; filaments 8–9 lines; anthers ¼ inch; pollen bright red.

Stretches through Siberia from the Altai to the north of China. A very distinct species, which was brought into cultivation about 1810, and widely dispersed, and named almost simultaneously by three different authors in Russia, France, and Denmark. It comes nearest to pomponium, but differs abundantly in stature and the shape of the perianth, and is very much the slenderest and slimmest in habit of all the species of the genus. *J. G. Baker.*

ARTICHOKE GALLS.

ONE of your scientific correspondents, who from his initials ("Alb. M.") I may without conjuring assume to be my friend, Mr. Albert Müller, lately gave in your pages (p. 1162) a short but interesting account of the origin of Artichoke galls, in which certain points are taken for granted which seem to me to be either attended with doubt or erroneous. I should therefore

like him to reconsider them, and as they involve some considerations which may be interesting to others of your readers as well as him, I shall take the liberty of stating my doubts in your pages.

He tells us that the Artichoke gall is caused by the puncture (meaning, of course, also the oviposition and its consequences) of a female Cynipidæous fly called Aphilothrix gemmæ (better known as Cynips gemmæ). He does not say where the puncture is made, but from the context it is plain that he considers that the puncture is made in the bud of the future acorn, and that it is confined to the acorn; and he has, apparently, good grounds for saying so, for, as he points out, if we take an Artichoke gall, and remove the cone-like foliaceous covering, a small stunted acorn will be found within. Moreover, the foliaceous covering in question has all the appearance of the cup of the acorn with the bracts composing it run wild. This, I believe, is always the case. I have opened many, and I never opened one in which the acorn was not detectable. [We opened one a few days since, and found no trace of acorn, but only the leafy cup. Eds.] This may seem proof positive that the puncture is made and the egg laid and the grub developed invariably in the ovary of the young acorn.

But there is another side to the question. If you look at the Artichoke galls growing, you will see that they are not in the position where the acorns are usually found, but rather, oftener in the position where leaf-buds would have grown [Yes.]; and they do not occur so frequently or in such numbers on the old bearing Oak as on young shoots, where an acorn is by no chance ever seen. I plucked them a few weeks ago on young suckers, only a couple of feet in length. I think the explanation of this apparent inconsistency is that the insect deposits its eggs indiscriminately in any bud, whether flower-bud or leaf-bud; and, when deposited in a leaf-bud, that the irritation caused by the grub at the outset stimulates the bud to develope into a flower-bud, although its continuance ends by destroying the formative action of the fly first set up. We know that, by treatment or change of condition, the leaf-buds can be developed into flower-buds, and I imagine that this is what takes place here. To suppose that the attack is confined to the female flower-bud is to endow the insects with a greater knowledge of the future of the bud than the tree has itself; and although it is true that different species of Cynips are assigned to different parts of the Oak, as to the leaf, the bark, the bud, the root, the difference in the secretions which we know to exist in each of these is a sufficient direction for their instinct, but no such direction exists by which they can be enabled to distinguish between a leaf-bud and a flower-bud in their early stage.

One additional argument, from authority (although it is little that I care to bow to authority), may be worth mentioning, as showing that Linnæus at least, who gave the insect its name, did not look upon it as a denizen of the acorn, but of the bud. He called it Cynips gemmæ, not Cynips glandis—the gall-fly of the bud, not the gall-fly of the acorn.

As my pen is in my hand I may note that I find that a remedy of Mr. Müller's, which one would think sufficiently free from ambiguity, has been misunderstood, viz., that owing to the abundance of this gall this year, the idea of harvesting acorns must be abandoned wherever the fly has got a firm foothold. That must only be understood to mean that the idea must be abandoned *because* there are no acorns to harvest. It is not that acorns apparently good are to be rejected as in reality bad, but that the gall has been so destructive as to destroy all the acorns. From the view that I take of these galls I cannot refer any scarcity of acorns to their having been, and I scarcely think they can do so by affecting the health of the tree. That will be the cause what it may, wherever any one has acorns he may use them with confidence. It is only Artichoke galls that are not to be harvested, and no one is likely to think of making a crop of them. And here I may say, *apropos* to the word harvesting as applied to acorns, that I think it rather leads to an erroneous impression on a point of practice. Some authorities tell us that the proper mode of raising acorns is to spread them on barn floors, for the purpose of drying them, but practical men will bear me out in stating that the true secret of growing acorns is to put them into the ground with all speed. Harvesting must therefore not be taken to be a recommendation of storing.

There is another portion of Mr. Müller's remarks which I do not like to pass without comment, viz., the extent to which he ascribes the present abundance of the Artichoke gall. He attributes it "to the reckless way in which our Oaks are often managed. Everywhere the fine timber is felled, giving place to unhealthy under growth or upshots from the ancient roots. Such copses are surveying, in which these swarms of these flies annually, whose oviposition in the buds of full-grown bearing Oaks destroys all hope of a harvest of acorns. We must give up 'saving our bacon' so long as we encourage the wholesale felling of mature Oak timber without taking care that its place is filled by properly planted healthy young trees." I am at issue with him on almost every one of the premises on which he comes to the above conclusion. I am at issue with him as to our Oaks being often managed in a reckless way. I maintain that generally throughout Britain the Oak forests and plantations are managed with consummate skill. Where there is so much properly held by private individuals there will always be cases where the owners are careless and ignorant, and their property mismanaged, but I maintain, without fear of contradiction from any one well acquainted with the subject, that the good management and cultivation of the plantations and forests in Britain, and particularly of Oak forests, bears as high proportion to the general average as does that of agriculture or horticulture. As the proportion of bad farming is to good farming, so is that of bad forestry to good forestry. Next I am at issue with him as to the fine timber being "everywhere felled, and in its giving place to unhealthy undergrowth. I do not know whether this is a periphrasis condemnatory of the practice of growing copsewood — (that is a wide question, which I cannot touch on here), but the natural interpretation of the words are that fine old timber is recklessly cut, and that it is from its roots that unhealthy shoots spring. Why my friend considers them unhealthy, he does not say, but I dispute that they are so. It can hardly be copsewood that is meant, for the mode of making copse is not by cutting down fine old trees, but by cutting down those of no great size on regular rotation. I am not at issue with him as to the young copsewood being a nursery of gall-flies, but I am at issue with him as to the copsewood being any more the nursery of gall-flies than plantations of young timber, or indeed healthy young trees. Wherever the fodder is, there will the forager be; and whether the young fodder is copse or plantation will, in my view, not make the slightest difference. The season suiting, they will thrive in both, and in that sense the young Oaks will be nurseries of gall-flies; and if the Artichoke gall-fly really makes the pests of its young in the buds generally, and not solely in the acorns, there is then a very good reason why they should be in greater abundance in young plantations than about old Oak trees. The young shoots are healthier, more vigorous, and make more succulent buds, which are more to the mind for the fly than those on the drier old Oak tree. That the greater abundance of the fly this year than in former seasons cannot be due to any such cause as Mr. Müller assumes must, I think, be apparent from the fact that there has been no progressive change in the management of the woods throughout the country; and we know that the increase and decrease of other insect pests are sudden and mysterious without any corresponding change in circumstances to which they might be referred. The most general cause assigned in such cases has been some peculiarity in the season or in the preceding season, and to that I should in like manner be rather inclined to refer the increase noticed by Mr. Müller. My own observations this year, which have been tolerably widespread, confirm his to the extent that the gall has been very abundant, but I cannot say that I observed any corresponding deficiency in the acorn crop. *Andrew Murray.*

Home Correspondence.

Coniferous Nomenclature.—In my letter in the *Gardeners' Chronicle* of Sept. 30, I made a severe remark, touching the integrity of the late Mr. Jeffrey's character, viz.: "In Jeffrey's second (Oregon) expedition he plucked our Scotch friends and others of their cash, and then cut off to the diggings and left them in the lurch." At the time I penned the above paragraph I was not aware that Mr. Jeffrey was no more. My motive for writing it was that it might meet his eye in some distant part of the world. Shortly after it was published, Professor Balfour, of Edinburgh, wrote me a letter in which he said Mr. Jeffrey's integrity. I answered the doctor, to the effect that a Scotch gentleman, personally connected with the Oregon expedition, of which the late Mr. Jeffrey was appointed botanical collector, had told me that "Mr. J. had much overdrawn his account, and that after the last sum (a considerable one) was sent out to him, he never afterwards sent either a letter, seed, or plant." This morning, just as I was about to start for town, I received a second letter from Dr. Balfour, enclosing one from Mr. Henry, the then secretary for the Oregon expedition; which letter I hope you will publish, with Dr. Balfour's opinion of Mr. Jeffrey and his fate. It is with pleasure that I have this opportunity afforded me of doing justice to the memory of the lamented collector, over whose death, both as to time and place, there is still the veil of mystery overspread. *Wm. Barron.* [From Mr. Anderson-Henry's letter we make the following extracts relating to the subject at issue:—

"I beg to say, in reply, that I have re-perused Mr. Barron's remarks on Jeffrey's second expedition at p. 1257 of the *Gardeners' Chronicle*, in connection with his letter of the 21st inst. I have very distinct recollection of all the circumstances attending its failure. We had all of us our surmises, some of them far from charitable. But of this I am certain, we never heard of his having 'cut off to the diggings and left us in the lurch.' Neither was there any tangible ground for believing another vague rumour, to which Mr. Barron perhaps alludes, of his having made over the collection he had made for us to other parties. You will remember he was singularly and blameably remiss in writing, and we of the committee consequently judged hastily, and, of course, harshly of him. But all his antecedents were in his favour, and from some accounts we got long afterwards, there was little room left to doubt that he perished in some of these little-traversed deserts into which he had wandered."

Dr. Balfour says:—

"Jeffrey I look upon as having been an honest man, although a bad correspondent. He fell a sacrifice to his zeal for collecting."

Botanical collectors do so much service, and incur such frightful risks in doing it, that the greatest caution should be exercised in making uncharitable statements. Eds.]

Covent Garden: Lighted, but not Covered.—A public meeting, convened by the Market Gardeners', Nurserymen's, and Farmers' Association, to which were invited the salesmen, shopkeepers, and all persons renting premises or stands in Covent Garden, was held at the "Bedford Head," Maiden Lane, on Tuesday, October 31, for the purpose of discussing what further steps should be taken to endeavour to obtain the much-needed covering for the open parts of the market. The meeting was informed of the result of the deputation, which waited upon Mr. Davison in reply to his letter, printed in the *Times* some few weeks back, which was to the effect that the Bedford authorities had no objection to grant the request for the covering of the market, "if" they could get the present occupiers of the Grand Row and the other covered portions to agree to it. I think the uncovered frequenters of Covent Garden have in a great measure to thank the *Gardeners' Chronicle* and other insertions in the daily press for this so far satisfactory reply, for the "if" is so insignificant and unreasonable that it cannot long stand against the universal protest that must be raised against it; for one would almost think we were asking the Duke of Bedford to take the covering off them and put it over us, to say—Yes, I have no objection to cover you, if you get their consent. I do not see what we, *i. e.*, the uncovered ones, have to do with the Grand Row or the other covered portions, we simply ask for a protection from the weather, and we do not wish to interfere in the slightest with their position, although, as I have often asserted, if all united in one grand effort, Covent Garden might possess a Grand Row worthy of the name, the occupiers of which would soon have cause to thank the Market Gardeners' Association for originating such a general benefit. But to return to the meeting. After some little discussion it was resolved that a memorial should be prepared, signed, if possible, by every frequenter of Covent Garden; and it is to be hoped that no one will lose this opportunity of signing their names for such a universal want. *M. C.*

Glass Copings.—If your correspondent "F." will refer to the *Gardeners' Chronicle*, of July 16, 1870, p. 958, fig. 178, he will see my article on these structures, which I have used with good effect for the last two years. Soon after I sent that communication to you I carried out the plan to a greater extent, and, indeed, realised the conditions which you seem to think so essential in order to protect fruit trees, alluded to by you in p. 770 of the present year. I enclose you a sketch, from which you will see that no putty is required, and everything about it is easily managed by a gardener, if he can cut the glass for repairs, &c. I have grown very fair Melons under these frames when removed from the east wall. The advantage of using iron uprights is that they cast so little shade on the trees. *Edward Webb, Greenfield, London Street, Faversham.* [We will be glad to receive, that Mr. Rendle's arrangement is almost identical with that of Mr. Webb, published about twelve months previously. Eds.]

Evergreen Fir Trees at Zurich.—Can any of your readers who have been in Zurich, in the gardens of the Pension Baur au Lac, and seen the pair of fine evergreen Fir trees in the garden near the lake, inform me what the name of that variety of Fir is? They are simply superb, being perfect pyramids of dark green foliage, 35 or 40 feet high, whose branches sweeping the grass—lying on it, in fact—are as thickly clothed with leaves, and as green, as any of those above them, with trunks, as well as I recollect, about 18 inches through. Now, as evergreen Firs of that size generally lose their lower branches before that time, and the symmetry of the tree is thereby destroyed, a pair like at once seen that the above peculiarity is a valuable one. I should therefore be glad to know, either from some one who has seen these trees what they are, or to hear from any one else what variety of Fir answers my description. *A. Boyle, Whitland.*

Vines and their Water Supply.—All honour to Mr. Lane, of Berkhampstead, for the very excellent display of Grapes which he made at the recent International Fruit Show. His productions warmed up the old recollections of veteran Grape growers, and, as I saw in several instances, caused them to press the hand of the successful exhibitor in sheer enthusiasm and for dear "auld lang syne." The number of varieties (21, I believe), the uniform size of the berries, and the finish of the whole, were prominent—most prominent traits. The premier bunches of Mr. Bannerman were also excellent, and did him much credit. You, Messrs. Editors, have informed us that a stream of water flows by at the very toes of Mr. Lane's Vines, and would have us draw some very useful lessons therefrom. We are all agreed that Vines are a very gluttonous race of

plants, feeding far or near, wherever their roots happen to be, upon almost every conceivable kind of vegetable or animal waste or refuse. Now many earnest and very able practioners still believe and persistently aver that an excess of cold moisture at the roots is the main cause of shanking. Mr. Lane's Grapes, however, grown beside this stream [Not stagnant, but perpetually flowing from an adjacent spring. Eds.] during such a cold wet season as the present one, give no room to afford a practical denial to this presumption. And really, when we look the facts fully in the face, there seems to be here a truthful sign-post planted upon an incontrovertible base, and indicating that the real enemy is dearth of supply at the roots, or semi-starvation, in a not over-feeding way. Vine-Vines for instance—and I have in my mind's-eye the grand examples grown annually by the late gardener at Hatfield House, Mr. Burton—maintained in an atmosphere highly charged with humidity, and dosed with the rank ammoniacal waterings which all successfully grown pot-Vines receive daily, and the facts are startling. Why, the roots are capable of subsisting under an almost aquatic regimen; and, moreover, do they not often have pans of pungent ammoniacal liquid set beneath their pots? Now, I say, in support of your hypothesis, that in the case of pot-Vines the above waterings are upheld for a longer time than is really necessary, not half the ill-effects will attend the crop as when a too limited supply is afforded throughout their earlier stages of growth. The roots subsist amidst their most relished food, which does not become absolutely injurious even when the system is overcharged upon it, the whole superstructure of the plant is based on the principle of the food supply being ready waiting, even it may be superabundant, ready against the moment when the young buds first call for support; and if just at this nick of time and onward the food could be withheld, even as pot-Vines are glutted, I believe that good and not harm would follow. Outdoor Vines shank not; their roots spread far and wide, and are ever on the alert and ready for the demand. And mark the fact, that they often commence to ripen just as the rains, heavy rains, and coldness clearly appear to overtake the oldest Vines produce crops uniformly large and good, and seldom shank. It is the distance the roots ramble —the ready supply, without the need to say "hold, enough," which gives them such reliability. Mr. Lane's Vines, it may be, quaff rude health to the full from the volume of the passing stream—the full and free-flow. Let me give another case in point. Lift an old Vine—one, say, 40 years of age; place it upon a bed of good soil, and surround it with the most unctuous food, leaving it to the indecision which marks our practice with most outdoor Vine borders, and the chances are that it will answer our expectations by renewing its lease of life; but deluge the border and the roots with fresh water or diluted manure, and the chances are that a crop of fruit will be afforded such as will set the grower thinking and wondering for the rest of the season. Here is a proof that roots are in entire subservience to the branches. Even if every rootlet be destroyed, and you place the old roots rightly, and afford them a proper supply, their part of the contract will be duly performed. Mr. Lane's exceptional success upon the water side revives the memory of what are the most favoured conditions under the Vine of the tribes, where it may be said to be indigenous and at home. Commencing with Noah, who "planted a vineyard," we are bound to surmise that if he did not find his Vines in the vicinity of a river he planted them there. Pallas tells us that the Vine grows naturally near the Black and Caspian seas. The colonies Rehmidi variety hugs closely, no doubt, the Persian Gulf. On the northern shores of the Arabian Sea it is met with. All this tends to show that the Vine thrives best at the base of mountainous districts, and in positions where deep and, if anywhere, moist fatty unctuous soils subsist, either alluvial, or where the detritings of ages are deposited. Its habit of growing in the vicinity of the sea shows a liking for sudden deluges of rain. In a word, taking pot-Vines as an example, we find that, first and last, the roots must have a superabundant supply, and what they don't want (and they will reject [or could absorb]. The rational inference is, that a too limited supply of root nourishment must be the precursor of evil. *William Earley, Valentines.*

Hornets.—At p. 1358 of your number for October 21 is an inquiry as to the means to be used to prevent the attacks of hornets on Oaks and Elms, the insects being mentioned as having eaten such holes in them as to cause the sap to flow out in large quantities. In cases where the hornets can be observed at work, as occasionally I have seen them myself on Ash saplings, a little tar smeared over the place will preserve them perfectly from their attacks. Moreover, hornets being large insects can be readily traced in their flight, by a little watching, so that the nest they come from may often be found and destroyed. From your correspondent's description of the "large holes" in "fine Oaks and Elm trees," I should, however, guess there was a second cause of mischief. The hornets frequent the holes caused by the goat moth or leopard moth caterpillar, which often exude much moisture; and the death of the tree seems rather to point to the internal injury of these most destructive grubs than to the superficial injury caused by the hornets. By carefully probing down the holes with a stout wire, hooked at the end if possible, or even cutting down on the larger grubs with a chisel, the creatures may often be destroyed, and the tree saved. It is best where feasible to draw the grub out with the hooked wire. *E. A. O.*

—— Were not the holes in the Oak and Elm trees complained of by Mr. Lee, of Brandon, caused by the larvæ of Cossus ligniperda, the goat moth, rather than by hornets? The sap, exading from the ravages of the larvæ within, proves exceedingly attractive to wasps and hornets: hence the probable error. *Dhune Thuach.*

Onions.—I was greatly surprised to hear from your correspondent, Mr. Evans, at p. 1359, that complaints have been made respecting the lightness of the Onion crop this season, as from observations in this neighbourhood I supposed they were unusually abundant. A piece of ground here, measuring 41 perches, produced 20 bush., the kinds being James' Keeping, White Spanish, and Giant Madeira. I find that a bushel weighs about 50 lb., so that our total weight will be over 71 stones. Now Mr. Evans' ground, being 30 feet by 30, contains a little over 3 perches, and his total is only 72 stones, his crop, though good, is not extraordinary. I may add that Onions are grown extensively in this locality for market, and the price at storing time was 2*s.* per bush., which certainly does not look like scarcity. *A. Bridgeman, Betteshanger, Sandwich.*

The Vintage in Germany, &c.—What pleasant ideas one always has of the vintage: a sunny hillside, gay colours, and merry voices. Now for reality: a bitterly cold morning, hard frost still on the ground, no sun, and people shivering over the half-ripe Grapes. This is what I saw a fortnight ago at Ems, close to where the dearest Rhine wine is made. Can you tell me how the large black slug, which is sometimes brown, can be the same being as the awful looking red one to be met everywhere about Ems? it is red as red-lead, redder than ochre. *Somerset.*

Propagation of the Garden Varieties of the Bramble.—If your correspondent, "E. J. W.," experiences difficulty in increasing his stock of these plants, it may be removed by a stroll into a shaded wood where Brambles and decaying leaves abound. In the autumn they will send the long shoots of the year bury their extreme ends amongst the leaves, and there form a semi-bulbous knob, which during the winter months throws out roots in all directions, and in the spring develops a strong shoot, capable of a separate existence if removed. I imitate this process by placing the double ending in a shaded place, and about August bury the ends of the long fresh shoots an inch below the surface of the ground, covering it lightly, and transplant the young plant at the end of the year. By thinning out the old wood each year, in fact treating them like Raspberry bushes, I have no difficulty in flowering them. *T. B.*

The Seaham Hall Trial of Peas.—I thank Mr. Draper for his candid reply to my criticisms of his report on Peas, a few weeks since, but must take exception to his assumption that I considered the periods of blooming in Peas to be indicative of periods of podding. I rather pointed out that, according to Mr. Draper's figures, it was altogether unreliable, and therefore a fact of but little moment. I am surprised to hear from him that Multum in Parvo needs the support of sticks, as with me it has never exceeded from 16 inches to 18 inches in height, and crops most abundantly. *A. D.*

Tar for Tree Wounds.—As "tar" has often been recommended of late, as useful for healing wounds upon trees, I would suggest that the term should not be taken in its common or general signification. The only tar that can be used with success is the Stockholm tar—certainly not gas tar, in any form. *W. Earley.* [A fitting caution. Eds.]

Araucaria imbricata Gumming.—There are growing here three good-sized specimens of the above-named tree, but I am sorry to say one of them is suffering very much from this cause, or what I think it is, and is generally termed gumming. This tree stands in a part of the pleasure grounds, and is very much exposed to the west winds, which at different times blow it about very much, so much so that about four years ago the roots seemed to give way to the pressure that many upon it, from time to time, and consequently the tree was growing crooked. At that time I had a trench cut all round about 4 feet from the main stem; then the earth was carefully worked away from the roots with our garden forks, until we had the tree, as it were, undermined. After we got it upright the space was filled in with a mixture of turfy loam, leaf-mould, and a little well decomposed manure, finishing the operation by chaining the tree to prevent its being blown about. I was in hope that when the roots made a good start in the new compost the tree would soon recover from the disease, but as yet see no signs of improvement. It has now lost several of its lower branches, and others are looking very sickly, and undoubtedly will in course of time go like the former. This tree, I am told, is from 25 to 30 years old, and now stands from 18 to 20 feet high. The other two alluded to are much about the same height, and from what I can learn were planted about the same time. One of them is looking remarkably healthy now. As to the probable cause of the disease, it is my opinion that the tree was injured in some way or other when in a young state. Have any of your correspondents met with a similar case amongst trees of this Araucaria? If so, I hope they will have the kindness to make it known through the medium of your columns, and give their opinion as regards the cause of the disease, &c. *M. Stalker, Hoosted Park.*

The Ranunculus.—I was glad to see "R. D.'s" appreciative article on this lovely flower; to me it has ever been one of deep interest, for it was the sight of some beds of it when I was a boy that made me a florist, and I have always had a great love for it, and yet how rarely one sees it in perfection: it requires, we know, a great deal of care, more than in these days of "grand effects" and rapid results is likely to be bestowed on growing a collection of it, and it is one sign of its neglect, that I know of but one real grower of it for sale, viz., Mr. Carey Tyso, of Wallingford. I quite agree with what "R. D." said about those exhibited at the Crystal Palace: they were not (although mine won the 1st prizes) what they ought to have been, and what I hope they will be in future, not the fault of the sorts, for I think I may say I have the finest collection of them in the South of England, having, with my brother, become the possessor of Mr. George Lightbody's splendid stock, but as unfortunately he could not superintend their planting last year, the results were small. They have increased in size this year; and if the season be favourable, I hope to show them well. Why does the Royal Horticultural Society not include them in their schedule? They are surely as worthy of prizes as Lachenalias or Mignonette. *D., Deal.*

On Storing Vegetables.—As much, if not more, depends upon how a thing is stored, as it does upon how it is grown, to keep up a supply through those months of the year when the great enemy of vegetation silently and every hole and corner of which is not contented with laying bare the outer world, it seeks to destroy the remembrance of the joyous summer hours, when all things seem hopeful and satisfying, by spoiling first one thing and then another which was thought out of his way. Providing the garden or farm with convenient and efficient storehouses is one of those things which never ought to be overlooked, as, although it is one which is not thought of as it should be, it is beyond dispute a paying one. How many tons of Potatos are spoiled yearly in the United Kingdom for the want of such storage accommodation, is a question which is just now worthy the attention of the leading men of all grades of society. Some of your correspondents have already given excellent advice on storing the Potato, but the great want still is more room. It is a fact now generally admitted by the leading growers, and one which I think will take hold on the people at large—that to have good crops, and these free from the disease, early varieties only should be planted. Now, to have good sets for planting, the old practice of storing them in heaps, and picking the tubers over every now and then, must be abandoned. Potatos for "seed" should never be stored in a heap nor be picked over. It is necessary, if you wish to have strong, early, Potato-yielding shoots, that the first shoot should be attached to the Potato when planted; but how is this to be done without convenient storehouses? I have now a fairly large house, where I have been accustomed to pile up from 10 to 20 tons or more of Potatos for use, I would say, have two or more false floors put up. By false floors I mean movable planks, which can be supported at the ends by other strong planks fastened against the wall. Some of the planks should be left out at the ends or in the middle, for the convenience of looking them over at intervals. This method would divide the bulk of the Potatos, and prevent that heating and spoiling which occurs in heaps of several tons, and which is commonly seen. A similar arrangement should be provided for the "seed" to be spread there, so that one shall not rest on another; and those who provide the same means will be more than repaid in the crop of Potatos that "seed" kept in such a manner will produce. I have been digging Potatos for use from seed thus treated, when a friend of mine who planted before me said that his were only breaking through the soil. The reason was, his had to make up for the lost shoots which had been rathlessly pulled off, while mine started at once with vigorous shoots, which had been waiting, as it were, for the soil. It is quite evident that an increase of store room is the next move in the Potato question. Other things must not suffer much, however we are straitened already in this matter of store room. Onions keep best spread out thinly over a floor; and can we do without Onions? Tell the cook you have a poor crop of Onions, and the immediate demand will at once give you an estimate of the supply required. The first aim of the gardener is to get the best keeping variety. The rage for getting large ones is a mistake. Extreme growth, whether in vegetables or fruit, has many disadvantages; large samples, for instance, having rarely the proportion of flavour found in smaller ones. The practice of "forcing size" has, in my opinion, been two much encouraged. If flavour is the requirement,

why aim at diffusing it through a larger body of matter when it can be had in a smaller compass? Shape even has something to do in the keeping of the Onion. I like an oval Onion. These, from their shape, never rest on the side where roots are emitted, lessening thereby the chances of growth, which often occurs when that part rests on the floor. A flat Onion is the very worst to keep, small Onions should be set apart for late keeping. I have never found "roping" or tying up Onions preserve them so well as spreading them over a floor. A great deal depends on the treatment they receive before housing. After they are pulled up they should be spread on a hard walk exposed to all weathers and frequently turned, and every time pulling off all the decomposed parts of the stem until nothing remain but the bulb itself, then when a dry day comes put them into the store-room. By observing these rules I never have occasion to scar the roots with hot iron or wish the Tripolis come. Carrots, Beet, Salsafy, &c., also want room. The heaps are too big, half of them rot or grow to be useless. All cry out "Room, more room!" *H. Mills.*

Grapes, New and Old.—While the merits of Grapes are being discussed in your columns allow me to give my experience of several varieties grown here. Mrs. Pince's Black Muscat I tasted the first time it was shown in London, now some 12 years ago, and I then pronounced it to be first-class, and after growing it myself I have no reason to alter my opinion; it sets freely, and keeps well. Muscat Hamburgh, raised by James Lane, many years gardener to Horsley Palmer, Esq., Hurlingham House, Fulham, is a delicate Grape, of good flavour; it does best grafted on the Black Hamburgh. I have, however, dug it up, Mrs. Pince's Muscat being a better sort. Golden Champion with me is a delicate Grape. White Lady Downe's is, in my opinion, a useful variety, growing in the same house, and setting as freely as the Black variety, and I believe it will keep well. Royal Vineyard has disappointed me; like its parent, the Syrian, it grows very strong, but with me does not set well. Madresfield Court I have not fruited, but hear it well spoken of. Gros Colman is a fine, large, black late Grape, which sets well, keeps well, and produces fine bunches. The Alicante, when true, is another fine black Grape. Of West's St. Peter's I would say, let not those who possess this old variety be in a hurry to discard it, for when well done it is a good late Grape. *T. Rust, Eridge Castle.*

The Effect of Snow on the Douglas Fir.—Would any of your readers kindly inform me whether the snow, if it falls in heavy quantities, is at all likely to break the branches of the Douglas Fir in the way that it does those of the Cedar of Lebanon and even the Spruce? Also, is not 7 feet 10 inches, which is I think the girth of the trunk of the large Douglasii at Dropmore, a very small measurement of trunk for a tree 100 feet high? *G. F. M.* [A heavy fall of snow is assuredly likely to break the branches of the Douglas Fir; to what extent, depends on the weight of snow and the toughness of the wood. Eps.]

FIG. 311—SHOWS THE EFFECT OF THE GROWTH OF A PARASITE ON A BRANCH.

Societies.

ROYAL HORTICULTURAL: *November 1.*—J. Russell Reeves, Esq., in the chair. The usual preliminary business, which included the election of five new Fellows, being concluded, the Rev. M. J. Berkeley proceeded to address the meeting, first directing attention to a specimen of Polystichum angulare var. proliferum, which he recommended to the notice of artificial flower makers, as furnishing one of the most elegant designs for a wreath with which he was acquainted, and then stating that some doubt had been expressed as to whether the late-flowering Lily of the Valley exhibited by Messrs. Standish & Co. was a distinct variety or not, some writers in this journal having observed that the late flowering could be brought about by drying it or otherwise starving the roots. Plants of the old Convallaria majalis and of the one under notice had, however, been seen growing side by side in the nursery at Ascot during the past summer, by members of the Council and of the Floral Committee, as well as by several distinguished foreign horticulturists, all of whom, as well as Mr. Berkeley himself, had come to the conclusion that it was undoubtedly in every way a distinct variety, and a valuable acquisition. A letter was then read from A. Trollope, Esq., confirming the testimony already given as to the productiveness of the Royal Ascot Grape, and stating that the writer had had two crops on the Vine at the same time this season, and this on a cane grown in an ordinary ground vinery. Some doubt, said Mr. Berkeley, had also been expressed as to whether the common edging Box bears seed, but Major Trevor Clarke had brought a seedling plant for exhibition, which he thought on examination would turn out to be a new variety. Major Clarke also brought up a good specimen of the fruit of what was generally called the Bush Squash, and which was also known under the name of the Custard Apple, the common name for Anona. The great inconvenience of the common Marrow, said Mr. Berkeley, was, that it grew to such a length, whereas the growth of the former was of quite the opposite character, and the fruits were equally good. Alluding then to a collection of autumn fruit from the gardens of W. E. Hubbard, Esq., the speaker stated that amongst the exhibits were cones of Pinus Webbiana, a plant which was not common in gardens, and the fruit of which was rarely seen in England. Mr. Berkeley then alluded to a very interesting subject, respecting colour in Fungi, which will be found mentioned at p. 1291, and concluded by reading the following communication from Mr. W. Jones, Kilboy:—

"Sir,—I have taken the liberty to send to the Royal Horticultural Society's gardens a small specimen of Spanish Chestnut, to illustrate the evil effects of close pruning, and also to confirm the theory that a wound in timber (native) never heals. The bit of timber in question shows the effect of sawing off a small branch, not thicker than one's thumb, and over this very small wound 200 (and upwards) of annual rings of growth have been formed, and still the wound is just the same as when the saw did its work, even the saw-marks give evidence that the saw that pruned the timber was in bad order. It may be seen that the bark healed over the small wound (perhaps in one season, as all is sound), but still, owing to the small flaw, all the valuable timber in its neighbourhood is quite worthless as timber for furniture, or, indeed, for any useful purpose whatever. Consequently, the sooner a reformation in forest pruning (in the British Isles) sets in the better, perhaps.

"Now, it is a very generally received opinion that the vegetable and animal kingdoms in many cases approximate very closely to each other, but in the case of wounds the parallel ceases, inasmuch as the wounds in animals heal, and wounds in the vegetable kingdom only close over, but never heal; and, at the risk of being considered tedious, I will give you a very practical illustration. About six years ago my left hand was shot clean off, and the shattered bone was sawn off 3 inches above the wrist joint; now, not only have the cuticle and muscle healed over, but the bone has rounded and lengthened out, I think, 2 inches (?), and the circulation is restored nearly as perfect as ever."

Scientific Committee.—A. Murray, Esq., in the chair.

Mr. Berkeley exhibited a branch of an Apple tree perforated by the larva of an insect; also a fasciated shoot of Myrica cerifera. He also read a communication from Mr. Bard, of the Wellington Nursery, St. John's Wood, relating to a disease on the leaves of Wigandia, analogous, in Mr. Berkeley's opinion, to that of the Verbena, and for the cure of which Mr. Bard had applied slaked lime; he also to some Bouvardias. Mr. Bard had been induced to adopt this plan from his previous success with diseased Potatos. Certainly most of the Wigandias exhibited presented no trace of the disease alluded to.

Messrs. E. G. Henderson also exhibited a series of specimens showing various sports in different varieties of Coleus.

1. Coleus Telfordii aurea.

2. A sport from No. 1, showing two distinct forms of growth.

3. Coleus Emperor Napoleon, a hybrid plant, the production of a cross between Coleus Berkeleyi and Plectranthus fruticosus, a well-known shrub, often seen in cottage windows, the object of which experiment was to obtain a hardier and more suffruticose habit of growth, adapted for garden decoration generally, which is found in the more robust character of the present plant.

4. Plants of Coleus Emperor Napoleon, selected from a large batch, showing a partial return to both parent types.

Mr. Munby exhibited a seedling Pelargonium, in which the thalamus of the flower was prolonged, and bore a number of scales and petal-like bodies, quite altering the character of the plant.

Mr. Murray exhibited specimens of an insect, Atropos divinatoria, which had been found destructive to Tea imported from Assam. A brisk discussion ensued among the entomologists, and the general opinion seemed to be that the insect in the first instance had taken up its quarters in the ship in which the Tea was brought.

A beetle, collected in Angola by Dr. Welwitsch, was exhibited, showing a curious parasitic growth, of a bright crimson colour, from the under surface, but whether of animal or vegetable origin seemed uncertain. Dr. Welwitsch himself believed that they were the eggs of some Crustacean.

Mr. Murray also showed a specimen of a woolly gall, of a pretty pink colour, growing on a spray of an Oak in Guatemala.

A series of specimens of canker in Ash trees was also exhibited by the same gentleman, as also specimens of Firs, distorted apparently in consequence of the roots coming in contact with some impervious material. Mr. Murray also showed a branch of a tree growing in Guatemala, and curiously deformed, apparently from the growth of some Loranth. A similar form, imported by Mr. Skinner, was figured in our columns many years since (fig. 312).

Dr. Masters showed male and female cones of the Deodar, which seem frequent this season.

Floral Committee.—W. Marshall, Esq., in the chair. At this meeting prizes were offered for specimen plants and cut blooms of Chrysanthemums, but, unfortunately, the date was too early to have this plant in perfection, and consequently the show was of a very poor description. In the amateur's class for 6 cut blooms, distinct, there was only one exhibitor—Mr. Rowe, gr. to Mrs. Lewis, The Rookery, Rochampton, who was also the only one who put in an appearance in the open class for 24. In both cases the 1st prize was awarded, though but few good flowers were staged. The best were of Lord Derby, dark purple, incurved; Empress of India, white; Mr. Brunlees, indian red, tipped with gold; Aurea multiflora, yellow; Mrs. G. Rundle, white; Prince Alfred, rose-crimson; Beverley, white; Golden Beverley, Guernsey Nugget, primrose-yellow; Novelty, bush white; and Cherub, golden amber. Mr. Adam Forsyth, Brunswick Nursery, Stoke Newington, also sent a dozen flowers of fair quality. Mr. Rowe also took the 1st prize for 6 large-flowered Chrysanthemums, distinct, Mr. Goddard, gr. to H. Little, Esq., Cambridge Villa, Twickenham, being 2d. The one order of merit was also observed in the class for 6 distinct Pompon Chrysanthemums. Mr. Rowe's plants in the first-named collection were severely cut to the conical bush form, and the flowers not half opened, whilst those from Mr. Goddard were grown in the more natural way of trees, from 4 to 5 feet in height, on clean stems, and for the most part well-flowered, especially a plant of aurea multiflora. The Pompon varieties were so backward as to require no further comments. In the class for 9 decorative berried plants, in pots, distinct, there was a poor display, the principal things shown being Cotoneasters, Solanums, and Ardisias, whilst one exhibitor staged a dwarf Orange tree, on which were two fruit!—a beautiful berried plant, certainly. First-class Certificates were awarded to Messrs. E. G. Henderson & Son for Sedum acre elegans, a dwarf, vigorous-growing, greenish white variety, that will be very useful as an edging plant, and an acquisition for covering the prominent points of rockwork; and to Mr. Green, gr. to W. W. Saunders, Esq., for Lomatophyllum Sandersii, a green leaved species, margined with reddish spines; and Billbergia chlorostieta, a beautifully marked species from Brazil, the true botany blue, spotted and mottled with green. Special Certificates were voted to Mr. Chaff, gr. to A. Smee, Esq., Carshalton, for a very fine specimen of Pteris scaberula, about 4 feet 6 inches through, which was planted in a hardy fernery in June last, and was sent to show the fine growth it has made in the open air; to Messrs. Standish & Co., for a collection of seedling Gladiolus, most of which were the result of crossing with G. cruentus. Several of them were of the most brilliant colours, and if not quite up to the florist's standard, they will be much in demand for late conservatory decoration. One of the varieties, named

Alice Wilson, is wonderfully distinct in shape, the individual flowers more resembling those of a Lily than a Gladiolus, and very rich in colour. A similar award was made to Messrs. E. G. Henderson & Son for a nice collection of alpine plants, including a great variety of Saxifrages. The same exhibitors also sent flowering specimens, in cutting pots, of Bonvardia Davisoni, a valuable new hybrid, having the white flowers of *B. longiflora*, with the vigorous growth and large masses of *B. Hogarthii*. It will be a fine variety for cutting for bouquets and for decoration in winter. Mr. Kemmery, gr. to E. G. Wrigley, Esq., Bury, Lancashire, sent some fine cut flowers of Cattleyas, Lælias, Miltonias, &c.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair.—This was a very interesting meeting, greatly enhanced by the excellent competitions for dessert Pears and Potatos, very fine examples of which were exhibited. From Mr. C. Lidgard, Albion Road, Hammersmith, came a very fine and well-grown collection of Celery, including Williams' Matchless Red, Hooley's Conqueror, Williams' Matchless White, Manchester Solid Red, and Knight's New White Grove, and to which a Special Certificate was voted. A similar award was also made to Mr. G. Ward, gr. to W. Hubbard, Esq., Leonard Lee, Horsham, for a collection of autumn fruit, which included cones of Pinus Webbiana, the fruit of Cydonia japonica, Siberian Crabs, and the pretty little yellow Wax Apple; to Mr. J. Gavell, Daventry, for a splendid single fruit of the Gloria Mundi Apple, grown on a tree three years old, in California; to Mr. Chaff for a dozen dishes of well grown and nicely coloured Apples; to Mr. Wells, Southlawn, for good examples of Blenheim Orange and Snow's Muscat Hamburgh Grapes, grown in ground vineries, the latter especially being very good; to Mr. Rose, The Royal Gardens, Frogmore, for three magnificent specimens of the single-fruited Queen Pine, which weighed in the aggregate 22 lb., and which were cut from plants grown from rootless suckers planted September 20, 1870, thus confirming a statement made to us by that excellent Pine grower, Mr. Rose, to Lord Carrington, to the effect that the best Pines he cut were from plants not exceeding 15 months old; to Mr. Jacques, gr. to J. C. P. Cunliff, Esq., Hooley House, Coulsdon, for a fine single dish of Jargonelle Pears, and from a plant on which 62 of a like size were grown; to Mr. Sage, gr. to Earl Brownlow, Ashridge, for a very fine fruit of Musa Cavendishii, weighing 46 lb., which, however, was not fully matured; to Mr. Johnstone, gr. to Lord Airlie of Strathmore, Glamis Castle, Forfarshire, for three exceedingly well-finished bunches of Muscat of Alexandria Grapes, weighing 10 lb. 6 oz., of which it was said there were 800 bunches of a like quality in the same house. The specimens shown were even in size, regular in shape of bunch, with well-proportioned shoulders, fine in berry, and capitally coloured. The house from which they were cut must be a grand sight, and a monument to all that is successful grower. From Mr. J. Powell, Frogmore, came a seedling Pear, named Premier, raised by him, and which is, we believe, in the hands of Mr. Turner for distribution. The fruit sent were grown on a young standard, and stated to be smaller than usual; it was also said to keep in good condition for several weeks when ripe. The Committee considered it "very promising," but as it was rather past its best, requested to see it again another year. Mr. Gilbert, gr. to the Marquis of Exeter, sent nice examples of Telegraph Cucumber, and of a variety called Major Clarke's Seedling, which so nearly resembles the former as to be undistinguishable, but a fine type of a winter Cucumber for all that. Mr. Frisby, gr. to H. Chaplin, Esq., M.P., Blankney, Lincolnshire, sent specimens of a good type of garnishing Kale; and Mr. Cowley, Chalfey Lodge, sent a pure double-curled variegated Parsley. Messrs. E. G. Henderson & Son had examples of Xylaria polymorpha, a very curious, but not very rare, Fungus; and Mr. J. Cross, gr. to Sir H. Goldsmid, Bart., Knightsbridge, Chiswick, had specimens of Walcheren and Veitch's Giant Cauliflower. Mr. C. Brown, gr. to D. P. Grenfel, Esq., Springfield House, Taplow, exhibited eight dishes of Apples, grown on horizontal cordons, planted in November, 1869. Mr. C. Ross, gr. to C. Eyre, Esq., Welford, Newbury, had a good and well-kept dish of Reine Claude de Bavey Plum, and good examples of Guthrie's Late Green, Impératrice Eléne, and Reine Victoria Plums. From Mr. J. Gardiner, gr. to Col. Astley, Elsham Hall, Lincolnshire, Mr. Earley, gr. to C. M. Ingleby, Esq., Valentines, Ilford, exhibited specimens of Earley's Defiance Tomato, a seedling of considerable merit, raised by him. It is round in shape, of a deep crimson colour, and a very heavy cropper. Mr. Earley had during the summer months a row of single plants in 9-inch pots stood out on an open border. When transferred to a shelf in the house to help on the ripening process, the shoots presented the appearance more of ropes of Onions than of Tomatos. The produce of one of these plants was cut, and weighed no less than 42 lb., which fact speaks for itself of its productive character. The Committee considered it of very high promise, but adhered to their rule of not granting a certificate until it has been tried at Chiswick. As before mentioned, the prizes offered for a collection of dessert Pears brought out a very good competition, which showed that in point of quality the English grower is nothing behind his foreign compeer. The 1st prize was taken by Mr. Fowle, gr. to Sir Sydney Dimsay, Bart., Cobham, Kent, Hants, with remarkably fine specimens of Beurré Clairgeau, Conseiller à la Cour, Duchesse d'Angoulême, William's Emmaüs, Duchesse d'Angoulême (?), Hacon's Incomparable, and Flemish Beauty. The Pears exhibited were gathered from bush trees on the Quince stock, and the latter ones from wall trees on the Pear stock. They were truly beautiful examples, fine in size, nicely coloured, and A 1 in flavour. The dish of Flemish Beauty attracted much attention on account of their fine size and high colour, indeed, in the latter respect we never saw better. The 2d prize was won by Mr. Gurland, gr. to Sir T. Dyke-Acland, Bart., whose fruit nearly always stand high in the prize list. On this occasion he had Beurré Clairgeau, gathered from a pyramid, and weighing in the aggregate 5 lb. 2 oz., and good in flavour; Beurré Bachelier, from a pyramid, weight 6 lb. 3 oz., and of splendid flavour; Doyenné du Comice, from a pyramid, weight 4 lb. 3 oz., flavour very good, but not so high as we have tasted in specimens from Killerton; Maréchal de la Cour, from a pyramid, weight 4 lb. 3 oz., very fine; Gansell's Bergamot, from a pyramid, weight 3 lb. 10 oz., and very fine and excellent in flavour; and Van Mons Léon le Clerc, from a wall, weight 3 lb. 15 oz., and excellent in flavour. Mr. Stephenson, gr. to F. C. Barker, Esq., Leigh Hill, Essex, was 3d, with medium-sized but well-flavoured examples of Urbaniste, Grand Soleil, Hampden's Vicomte, Marie Louise, Beurré Diel and Glou Morceau. Capital examples were also contributed by Mr. Sage, Ashbridge, Mr. Miles, Wycombe Abbey, Mr. Lumsden, Elvaston Hall, Mr. Frisby, Blankney, Mr. Daft, Mr. G. Goldsmith, Mr. G. Craddock, Mr. T. W. Gardiner, and W. Thompson, Esq., Clements, near Ilford. For the prizes offered by the Rev. G. Kemp, a member of the Committee, for 6 bunches of Grapes, grown in the open air without any protection, the competition was not so interesting as last year, though the examples shown were by no means inferior in quality. The best came from Mr. J. Norris, Francis Court, Broadclyst, Devon, nice bunches of White Sweetwater, and very well ripened. Mr. J. Tranter, Upper Assenden, Henley-on-Thames, was 2d, with nice examples of the same variety. Well ripened samples of the same kind were also shown by Mr. Garland, Mr. J. Hepper, The Elms, Acton, and Mr. T. Bellworthy, a garden labourer at Killerton.

The principal feature amongst the Potatos was the competition for the prizes offered by Messrs. James Carter & Co., which was for the best dish of Carter's Main Crop, and for the three best collections, to include Carter's Ashtop Fluke, Cambridgeshire Kidney, Redskinned Flourball, and Victoria. The best collection and dish of the first-named was contributed by Mr. C. Frisby. It is a red pebble-shaped tuber, possessing much quality, and said to have been raised from seed in the neighbourhood of Birkenhead. In outline and smoothness of skin it possesses a fair merit, but the apparent dryness, and its easily recognisable by the white spots which are evenly distributed over its surface. When cooked in a steamer, with its "jacket" on (as all Potatos should be), it turned out white and mealy, fine in texture, and of very good flavour. The best collection was contributed by Mr. Lumsden, who staged very good samples of 51 varieties, including those above named, a number of the Regent kinds, and a nice dish of Early Rose Wonder, a pebble-shaped round, smooth in outline, good in quality, and one of the earliest with Mr. Lumsden. The 2d prize was taken by Mr. C. Ross, with 29 dishes of very fine samples, though many of the varieties were of the roughest description. The next best collection came from Mr. Frisby, which included 42 varieties. For the prizes offered by the Society, Mr. Dean, seedsman, Ealing, came 1st, with a collection of 36 varieties, clean and well grown, and including most of the improved kinds raised by Mr. Fenn. Mr. Lumsden came in 2d with a collection in every respect similar to the one above mentioned, and Mr. C. Ross was 3d. The very creditable collections were also shown by Mr. Garland and an exhibitor whose name was not given. Messrs. Carter & Co. also exhibited a large collection of vegetables, which included a fine series of the Large Surrey Onion, Carter's Short-top Six-weeks Turnip, and a good sample of their improved Brussels Sprouts, which have the merit of hearting-in firmly whilst others are growing into leaf, as is the case, to a great extent this season. With them were also some good specimens of their Drumhead Savoy, very large and hearted-in very solidly; several varieties of Beet, 58 varieties of Potatos, including most of the new American varieties; and a very fine assortment of Onions. A Special Certificate was awarded.

Notices of Books.

L'Art de Greffer, &c. Par Charles Baltet. (The Art of Grafting, &c.) Paris: Masson. Pp. 320, fig. 112.

This is a plain and practical treatise on the various methods of grafting, with numerous illustrations. Little is said, either as to the history of the process—a well-worn subject—or as to the physiological questions involved. Very numerous methods are alluded to, and many more, we have no doubt, might be added. Some of these seem to us merely matters of fancy, and to possess no special advantages of their own, though this is a matter on which we would gladly have had the benefit of M. Baltet's experience in somewhat greater detail. It is difficult to understand, for instance, that any notable advantage can be derived from grafting a cutting of an Aucuba on another cutting, and letting the processes of adhesion and root making go on in both cuttings at the same time. The sympathies and antipathies of plants in the matter of grafting is a subject requiring much more extensive investigation than it has yet had; and, as the physiological information sought by this means could not be obtained without much valuable practical information being obtained at the same time, we earnestly hope some of our readers with the requisite means and leisure will take up the subject. The discovery of suitable stocks for fruit trees, &c., is one of the most important things an experimenter could turn his attention to, as it would often enable him even to set climatal rigours at defiance. M. Baltet's little book is most serviceable for practical purposes, and more especially for the eighth section, wherein he gives a list of trees and shrubs adapted for this mode of propagation, the best known stocks, the most suitable method to employ, the season, and other details which we know not where to find so readily in any other easily accessible work. The style is agreeable, clear, concise, and as free from useless verbiage as the veriest stickler could desire. We heartily commend the book to all young gardeners or amateurs conversant with the French language.

Florists' Flowers.

THE relative value of the new LARGE-FLOWERED or SHOW PELARGONIUMS of the present year may be summed up in a few words—they are among the most successful of the floral products of the season. They rank high up in the list of new flowers of the year, and so fine in character and grand in development were some of them, that—were not the florist's art one of illimitable achievements—it might be supposed the *ne plus ultra* of perfection had been reached. But it is not so. The moving finger writes its lines of fresh beauty, and having written, moves on again, now resting, and always producing inconceivable pictures of luminous splendour.

It is to Mr. Foster that the chief honours of the year must be awarded. That ten First-class Certificates should be given to flowers of his own raising in one year, is something almost unprecedented. The pleasure derived from watching the gradual unfolding of these beautiful flowers—and who can conceive what pains have gone into the rearing of any one of them?—far outweighs their commercial value multiplied many times.

Arranged alphabetically, Mr. Foster's flowers come in the following order:—Achievement, lilac-rose lower petals, with bold maroon spot on the upper petals, and edged with lilac, and having a large white centre; a fine flower, of splendid quality and extra form. Blue Bell, a strikingly novel flower, lower petals pale bluish purple a glossy black spot in the petals margined with purplish-rose, and clear white throat. Cæsar, a bright looking painted flower of fine form; lower petals crimson, stained with dark maroon, dark maroon top petals, and margin of crimson, Charlemagne, soft salmon-peach lower petals, with small maroon spot on the upper petals, and broad margin of bright rosy pink; large white centre; stout, large, and of fine form. Chieftain, clear rose lower petals, dark maroon top petals, and margin of shaded rose; bold white throat, fine form, and splendid truss. Conquest, rosy scarlet lower petals, with small maroon spots on the upper petals, and broad edge of purple; a bright and showy flower of fine quality. Pompey, warm orange lower petals, maroon top petals margined with fiery orange, clear white throat: a large, rich-looking flower, of the finest form. Prelate, lower petals shaded purplish maroon, glossy black top petals, with narrow purple margin and white thread; a handsome and bold flower. Royal Bride, delicate soft salmon-pink lower petals, and large white throat; maroon spot on top petals, margined with lively violet-rose; a fine and attractive variety. Lastly, Rubens, rosy purple lower petals, and clear white throat; maroon spot on top petals; a medium-sized and attractive flower. Mr. Hoyle received a First-class Certificate for Zephyr, having heavily painted crimson lower petals, and black top petals, narrowly margined with a thin edge of crimson: fine form and substance. Mr. Foster's Black Prince is a rich dark flower, having narrow lower petals, and glossy black top petals, with a thin regular edge of crimson. Ada (Beck) also received a First-class Certificate. The flower has deep pink lower petals, and bold white throat, dark top petals, irregularly margined with bright rose, finely formed, and of good substance. Forcing Pelargonium Enterprise was exhibited by Messrs. E. G. Henderson & Co., and received a Second-class Certificate; this has white petals, much fringed on the edges, with a very dark blotch on each; good habit, and very free. Messrs. Foster & Hoyle's flowers will as usual be distributed by Mr. Turner, of Slough.

No new fancy Pelargonium has come to the fore during the same period. All the other sections are constantly receiving additions, more or less valuable, but the fancy varieties are augmented very slowly in comparison. There is no doubt a reason for this, and ere long we hope Ladies' Pelargonium Society will be forthcoming, for past experience proves there can be no standing still in the march of improvement. *R. D.*

Obituary.

ON the night of the 1st instant died, full of years, WILLIAM BAXTER, formerly Curator of the Botanic Garden, Oxford. Better known to a former generation than to the present, Mr. Baxter's reputation as a gardener and a botanist has been to the present race a tradition of the past rather than a fact of the present. Mr. Baxter was appointed to the Botanic Garden as long ago as 1813, and retired in favour of his son, Mr. W. H. Baxter, the present holder of the office, some 20 years since. In 1817 he was admitted as an Associate of the Linnean Society, and in the present month he sank to his rest in his 84th year. If to this we add that he was the author of an illustrated work on British botany, and that he distributed, many years ago, specimens of leaf Fungi, we shall probably be saying as much as is known to the great majority of our readers of Mr. Baxter's career. Those few, however, who were privileged to know him, even in his declining years, would feel with us that to let such a man pass to his grave with but the bare record of the

fact would be to commit a great injustice to the memory of one whom modesty and diffidence kept in the background, in spite of his great talent as an observer.

When Mr. Baxter was first appointed to the Botanic Garden, Oxford, Botany had sunk to its lowest level; Sherard, Dillenius, and Sibthorp had stooped to the past. Dr. Williams, who held the chair in the early part of Baxter's curatorship, was an elegant scholar, and an amiable man, but added nothing to botanical science; and for practical instruction in botany the undergraduates of that day had recourse to the teachings of Mr. Baxter. Among his pupils were many men who subsequently distinguished themselves in various ways, and some of whom, such as the present Bishop of Chichester, kept up their acquaintance with their instructor up to recent times. It was at this period the noble herbarium of Mr. Baxter called it, "British Botany," at the work in several volumes, devoted to the description and illustration of British plants. The illustrations are of unequal merit, but the amount of information accumulated is extremely large, and bears witness, not only to great shrewdness of perception and accuracy of observation, but to indefatigable zeal and labour. But it was in Cryptogamic botany that Mr. Baxter specially excelled; in this proving himself a worthy compeer of his fellow labourers—Dawson-Turner, Borrer, Purton, and others. Even to comparatively late years, Mr. Baxter continued, in a remarkable degree, his knowledge of Mosses and Epiphyllous Fungi, gained at a time when the number of students in those departments of botany in this country might be counted on the fingers of one hand, and acquired before the compound microscope had become the valuable instrument it now is. But Mr. Baxter did not allow his botanical pursuits to interfere with his practical duties. It is on record that he made great changes for the better in the garden, raised its level so that it was no longer flooded, and stored it with rare plants to an extent that rendered the Oxford Botanic Garden one of the most remarkable of its time. The number of hardy herbaceous plants and of British plants under cultivation under Mr. Baxter's management was, considering the restricted space at his command, greater than that in almost any other establishment in the kingdom; and the reason is obvious—he knew plants, and loved them.

On the death of Dr. Williams, in 1834, Dr. Daubeny was elected to the professorship, and immediately proceeded still further to improve, and, indeed, remodel the garden. So eager was the Professor to commence operations, and so anxious was the Curator to carry out his views, that, as we have heard, on the very first night of his appointment, the Professor and Curator, lanthorn in hand, proceeded to the garden, and then and there projected much of the alterations that were subsequently carried into effect, and which, with modifications introduced by the present Curator, have rendered the Oxford garden, for its limited size, so complete an establishment. It is not improbable that unduly protracted labours induced those aggravated attacks of mental depression under which at various times Mr. Baxter suffered, but from which he had of late years completely recovered.

Mr. Baxter was, we believe, in the receipt of a trifling pension from the University—in amount, unless we are mistaken, quite inadequate to the merits of the recipient, and unworthy the liberality of a rich university. In this particular it is possible that Mr. Baxter's retiring habit acted prejudicially to his interest. Be this as it may, no one ever came in contact with him without being impressed by his amiable disposition, his great knowledge, extraordinary memory, and his willingness to oblige. Mr. Baxter has accumulated an extensive library of botanical works, which we presume will now be dispersed.

Oct. 26.—Generally cloudy till night; then variable. Slight fog.
" 27.—Generally overcast. A little rain fell in the afternoon.
" 28.—Very fine and nearly cloudless in the early morning. Cloudy after 9 A.M. A little rain fell between 8 and 9 P.M.
" 29.—Light clouds prevalent throughout. A very fine day. Lunar corona and halo at night.
" 30.—Generally overcast. Rain fell from 11.30 A.M. to 2.20 P.M.
" 31.—Rain fell between 3 and 4 A.M., and occasionally in the afternoon. Overcast till night; then very variable.
Nov. 1.—Variable amounts of cloud prevalent. A fine day.

JAMES GLAISHER.

Garden Operations,

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

Orchidaceous plants in general should now be induced by the gentlest means possible to settle down to rest. In instances where young growths are being made, the pseudobulbs are not freely swollen out, they should be encouraged to the utmost extent, if they are of primary importance to the plant, but not otherwise. No plant should be kept at this season in a state of excitement of any activity, unless it is absolutely necessary. Attend particularly to any symptoms of drip that may occur, as it often does at this time, through the condensation of moisture upon the glass. The least drip, as is well known, which falls upon the delicate leaves of some Orchids, such, for instance, as *Phalænopsids*, is certain to cause them much injury. The temperature in the *Acrides-house*, or what is sometimes called the Indian-house, should not exceed 58° by night or 68° by day. In the cool Orchid, or Mexican-house, 48° will now be ample by night, whilst an increase to 58° will meet all their requirements by day. The later distribution of the plants in both houses it will be necessary to bear in mind that those plants which are decidedly at rest should occupy positions in the driest part of either structure; and that where a distinction can be made between evergreen and deciduous *Orchids*, it should be done, so that those truly deciduous ones may not only be kept apart from their associates, but be forced, even by somewhat harsh means, to divest themselves of their leaves. The only secret, in regard to blooming deciduous Orchids efficiently, is to thoroughly ripen off the young pseudobulbs, and to cause them to perform their natural functions without let or hindrance. The successful cultivator knows too well what a mistaken kindness it is to maintain upon such plants the young leaves of the current season's formation beyond the natural period, that is, away into the winter months. Even by withholding water from the roots altogether for a time will scarcely go to rest, in consequence of the somewhat close humid atmosphere to a certain extent maintaining them. Hence the need to resort to a somewhat extreme cold temperature. Take *Dendrobiums* as examples, and notably *D. nobile*, which seldom blooms more profusely, or produces finer flowers, than when wintered in a dry corner of an ordinary cool greenhouse. In my remarks upon *Chrysanthemums* last week a letter was transposed, and materially altered the meaning I wished to convey. I said that owing to the "firm" (which in gardening phraseology is a synonym for flourishing) growth these plants had made, they could not be anticipated to stand much severe weather, and so should be protected—not that they had made a "firm" growth, as such a growth would withstand many vicissitudes of weather. The cultivator of plants should now bear in mind that his greatest advancing enemy is damp, and that its most natural antidote is fresh air, which should be given with all possible abundance, at every opportunity that occurs. When a miscellaneous collection of greenhouse plants has to be wintered in one house, such for instance as *Heaths* and *Calceolarias*, *Cinerarias*, &c., each requiring different and very distinct treatment, it will be advisable always to separate them from each other as much as possible by placing the hard-wooded subjects at the driest, and the soft-wooded ones at the coolest and dampest end of each house, where the necessary amount of moisture can be allotted them with perfect immunity from direct injurious consequences to the others. A few of the finest plants of *Primulas*, double and single, which may not be showing flower prominently, would be benefited by a moderate shift into a light porous soil. In potting them at this time press the soil more firmly around the roots than previously, which will be beneficial in more ways than one. It is very important in all efforts at successful plant growing to take care that too much artificial heat be not used for the next few weeks.

FORCING HOUSES.

In regard to the protection of *Pine-pits* during only moderately cold periods and onward through the more severe winter weather, always have resort to external coverings of mats or other similar materials. By rolling these over the lights at dusk, and removing them early in the morning, we not only retain the latent heat of each day, but maintain besides a moderate amount of warmth throughout the night, at the same time obviating a great outlay of fuel. I scarcely need add that two thicknesses of mats are better than one, and that the use of them does not entail nearly so much expenditure as the fuel so saved would have amounted to, if employed as the alternative. For forward successionals or spring-fruiting plants, though no check should be allowed, must now have the temperature brought down with a firm hand to a mean as near to 63° as possible. Actual fruiters, on the contrary, may enjoy a mean of from 65° to 75°, according to their previous treatment and the time when the fruit are required ripe. Push forward by all legitimate means the final ripening of late Grapes before the worst season for so doing arrives. *Pot Vines* for successional forcing should have the pots now placed in a position where no injury can accrue from frost. It will be as well also to so place them that they do not become too wet at the roots. Continue the removal of all leaves from vineries going to rest at the earliest moment possible, and so by maintaining a pure wholesome atmosphere help forward the final ripening process. I have repeatedly urged the great importance of early pruning, yet would again suggest that this process be undertaken in regard to all such as the above, which are intended for forcing as early as possible, the wood being properly ripened and the sap moderately at rest.

HARDY FRUIT GARDEN.

Remove immediately all dead or decaying leaves from *Vines* against walls, *Fig trees*, &c., and brush over all *Peach*, *Nectarine*, and *Apricot* trees to which the foliage still adheres too tenaciously. Just "wisp" the branches upward with a neat broom, and in such a manner as to cause the leaves to become detached without using such an amount of violence as is likely to injure the buds. Let all fruit be gathered without further delay, and endeavour to keep the *Fruit-room* as dry as possible, by an admission of fresh air periodically, closing the windows or other means of ventilation by night and during foggy periods when the air is greatly charged with moisture. Go on to the mulching of all young trees planted during the past spring and autumn, and restake standards of any kind before the winter winds with heavy snow and rain arrives. Make every preparation for planting young trees, by trenching and manuring the necessary space around the centre, wherever they are to be planted, taking care to elevate the exact position sufficiently to insure the trees being set slightly above the surrounding ground when the soil has settled down permanently. It is customary to manure *Strawberry plants* at this time, but being a convert to spring mulching for such plantings, say—don't.

HARDY FLOWER GARDEN.

It will be greatly to the advantage of all autumn-planted spring-flowering plants to hoe carefully amongst them at this time, choosing a fine drying day for the operation. Especially would I recommend that out-door *Alpine Auriculas* be so treated, after being first divested of any decayed foliage that may adhere to them. Remove such plants which continue to form from frame Neapolitan and other *Violets*, and break up the surface soil a little amongst them. Any of these latter which may show flower-buds freely should also on a fine day have a good watering with liquid manure. Every kind of semi-hardy plants maintained under the protection of ordinary cold frames should have the freest possible supply of air. Take up any choice stools of *Hollyhocks*, and pot them for sheltering in a cool frame. Cut down *Dahlias* and all herbaceous plants which have ceased to be ornamental, and by repeated use of the rake and broom lighten the ground of the falling leaves to forward the final efforts at collecting them.

KITCHEN GARDEN.

Broccoli, which is growing very strongly, will be far better taken up and laid with the heads to the north, placing soil nearly up to the collar of the plants. Take up roots of *Seakale*, the foliage on which is ripened, and put them in the Mushroom-house or some warm place away from the light. *Asparagus* plants should also be taken up and planted on the hotbeds already prepared,

as lately suggested, taking care not to have too violent a heat at the outset, as it oft-times causes the supporting roots to rot away. *W. E.*

Notices to Correspondents.

BOOKS: *Old Subscriber, Inverness.* Kemp's "How to Lay Out a Garden."

CARROT GRUB: *Subscriber.* The refuse lime from gas-works is considered to be an efficacious application to ground affected with this grub. Soot, either alone or mixed with salt, may also be beneficially employed.

COCKCHAFERS. *Aspley* asks: "How shall I destroy the grubs of the cockchafer, which are making great havoc of the grass root s of my lawn?"

FUNGI: *A. W. E., Woodhall Spa.* We presume you are a new subscriber, and do not know our rule,—to name six sorts at a time only. Please remember this in future. 1, Lactarius uvidus, poisonous; 2, Russula fœtuta, poisonous; 3, Agaricus phalloides, poisonous: 4, A. rubescens, edible; 5, A. muscarius, poisonous; 6, Lactarius blennius, poisonous; 7, L. turpis, poisonous; 8, L. torminosus, poisonous; 9, Agaricus fasciatus, poisonous; 10, A. rutilans (small); 11, A. fascicularis; 12, A. muscarius; 13, A. psittacinus; 14, Hygrophorus psittacinus; 15, Agaricus subluteritius; 16, A. æruginosus, poisonous; 17, Hygrophorus virgineus, edible; 28, Boletus edulis, edible; 19, Polyporus chioneus; 20, Lactarius spilotus; 21, Agaricus butyraceus; 22, A. infundibuliformis, var.; 23, A. mutabilis; 24, A. procerus, edible; 25, A. rutilans (large). *W. G. S.*

FUNGUS ON PEAR LEAVES: *G. W., Trumpington.* Roestelia cancellata: burn all the leaves immediately. *M. J. B.*

FUNGUS ON PEAR ROOTS: *J. A. P.* The affection of your pear roots is very curious. The Fungus on them appears to be quite new. A further report will be given when there has been time to study it. *M. J. B.*

GALL ON HAWTHORN: *W. W.* The specimens sent are the leaf-roses induced by the larva of *Cecidomyia crataegi*. Have you any hedge infested with them?—if so, when you shear it, be careful to burn the clippings; the fly is difficult to get rid of, when once it is firmly established. *M. J. B.*

GESNERA EXONIENSIS: *Florist.* The particulars which you give are so meagre that we can only surmise your non-success in the culture of this beautiful plant to be due either to the want of a suitable amount of heat during their growing, or that you have had to have afforded a proper season of rest. Start the plants into growth as early as convenient in February, and as soon as they commence growing actively, push them along vigorously in a temperature of not less than from 70° to 75°, though from 5° to 10° more would be better. Do not syringe them overhead whilst growing, but rely upon a good supply of atmospheric humidity to furnish the requisite moisture required. When ripening off, plants show a tendency to ripen off, commence to limit the supply of water to the roots, and so decrease it that when the foliage actually dies down, a little latent moisture only will remain in the soil. *W. E.*

GLASS FOR VINERIES: *Thomas Green.* We have had no experience of the use of coloured glass for vineries, so cannot pretend to speak with any authority on the subject; we should be inclined, however, to prefer plain, inasmuch as all coloured substances tend to subdue the light. This has been thoroughly proved in the case of green glass in the Royal Gardens, Kew. And Vines, above all other plants, seem to enjoy the full and direct influence of the sun or light on them.

LAYING TILES: *Tyro.* The plan recommended by Messrs. Maw is to lay as evenly as possible a bed of concrete composed of one part of finely rubbed quicklime and three of gravel, or an even layer of bricks or flag-stones will serve as a foundation. We cannot recommend you to be content with merely levelling the soil.

NAMES OF FRUITS: *Alexander Crumb.* Your Pear is Brown Beurré—an exceedingly fine sample.—*George Frost. Pears:* 2, Louise Bonne of Jersey; 3, Passe Colmar; 4, Beurré Diel; 5, Beurré Diel; 8, Duchesse d'Angoulême; 10, Old Crassane.—*T. H. V.* 1, Winter Chaumontel; 2, Hacon's Incomparable; 3, Colmar d'Aremberg; 4, White Doyenné; 5, Autumn Colmar; 6, Beurré Diel.—*T. H. Appleby.* Golden Noble.—*James Cocker. Pear:* Not known—very bad variety.—*M. J. Pears:* 1, Beurré Diel; 2, 4, 6, Marie Louise; 3, Urbaniste; 5, Louise Bonne of Jersey; 7, Beurré Bosc; 8, Vicar of Winkfield; 9, Monsieur; 10, Beurré de Capiaumont.—*H. H. Pears:* 1, 12, Beurré Bosc; 2, Beurré Rance; 3, Beurré Bosc; 4, Knight's Monarch; 5, Beurré de Capiaumont; 6, 11, Easter Beurré; 7, White Doyenné; 10, Marquise; 13, Glou Morceau.—*Apple:* Yellow Bellefleur. *Pears:* 1, Easter Beurré; 3, Marie Louise; 4, Beurré Rance; 5, Triomphe de Jodoigne; 6, quite rotten; 7, Beurré d'Amanlis.—*A. F. B., Somerset.* Send us 50 (fifty) specimens of Pear to name! We propose to distribute them among our friends, for the benefit of their youngsters, as it must be obvious to any one but "A. F. B." that it is perfectly unreasonable to suppose that we can, with our multifarious duties to other subscribers, give the requisite time and attention to name so many varieties. Our rule for years has been to name six varieties at a time. Next time, perhaps, "A. F. B." will forward a handsome fee with his 50 Pears.

NAMES OF PLANTS: *Y. M.* Polystichum aculeatum lobatum.—*J. Buddington.* The common Pteris aquilina, or Bracken, developed from the spores.—*C. L.* 1, Oncidium tigrinum, otherwise known as *O. Barkeri*; 2, Oncidium ensatum; 3, Cymbidium pendulum; 4, Phalænopsis Parishii.—*M. D.* Your Fuchsia is F. magellanica, of Lamarck, a plant also known by the names of F. gracilis, Lindley; and F. macrostemma, Ruiz and Pavon. It has long been cultivated in gardens, usually, however, under the erroneous name of F. coccinea, which is a distinct thing entirely.—*T. Cocker.* 2, Calluna vulgaris, and r, its var. alba; 3, Erica stricta (E. corsica); 4, E. cinerea.—*H. Doubleday (Epping).* Cosmos diversifolius, Otto, and, we suppose, the variety atrosanguineus, as figured in "Botanical Magazine," t. 5227 a plant introduced some few years ago by Mr. Thomson, of Ipswich, from Mexico.—*A Reader.* Dendrobium chrysanthum.—*W. S., Perth.* The plant you send is Matricaria inodora, of which we have previously, on rare occasions, seen double flowers.

SOOT-WATER. *S.* would feel obliged to "R. T." (p. 1358) if he would be so good as to say how he makes soot-water. Soot-water in so short a time, that will not stain the leaves of plants.

ZAMIA PLUMOSA, &c.: *F. H.* We cannot tell you. It is a question for our advertising columns.

CATALOGUES RECEIVED.—F. & A. Dickson & Sons, Descriptive Catalogue of Roses and Hollyhocks.—Wm. Drummond & Sons, Catalogue of Forest, Ornamental, and Fruit-bearing Trees, Shrubs, Conifers, &c.—William Urquhart & Sons, Catalogue of Forest and Ornamental Trees, Shrubs, and Evergreens, Ferns, Roses, Fruit Trees, &c.

COMMUNICATIONS RECEIVED.—R. G.—A. Z.—A. B.—J. C. B. Co.—D. G.—R. S.—T. C.—H. S.—T. W.—S. C. H.—J. McD.—H. & S.—W. C.—T. H.—J. M.—Amateur.—D. T. F.—G. S.—J. T.—Rosarum Hortus.—E. M.—J. T. B.—H. K.—W. R.—C. D.—T. C.—M. M.—Vitis.

Markets.

COVENT GARDEN.—Nov. 3.

We have but little alteration to report here. General rates have been maintained, and a fair amount of business for the season is being transacted. Foreign goods are in request, especially of best qualities. A few samples of Newtown Pippins have been offered, but are not worth much attention.

FRUIT.	s. d.	s. d.
Apples, per 3 sieve	0 10	5 0

WANT PLACES.—Letters to be Post Paid.

EXPERIENCED GARDENERS (or as GARDENER and BAILIFF), of various qualifications, recommended to Gentlemen.—Further particulars given on application to Messrs. E. G. HENDERSON AND SON, Wellington Nursery, St. John's Wood, N.W.

GARDENERS.—THOMAS KENNEDY & Co., Seedsmen, Dumfries, can recommend a few good MEN in WANT of SITUATIONS, and will be glad to answer any inquiries respecting them. No charge.

GARDENER (Head).—Age 37, no children; thorough practical knowledge of the profession generally. Good character.—T., Pine-apple Nursery, Maida Vale, W.

GARDENER (Head).—A successful Cultivator of all kinds of Fruit, Flowers, and Vegetables. Wife a good Laundress. Good character.—GARDENER, 5, Cemetery Street, Biggleswade.

GARDENER (Head).—Age 45, married; thoroughly acquainted with the Management of Stove and Greenhouse Plants. Can be warmly recommended by his late employer.—E. T. D., 2, Moorgate Street Buildings, E.C.

GARDENER (Head), age 45, married, family.—Has the Advantage of being energetic, and is now desirous of his services to any Nobleman or Gentleman in want of a thorough practical Gardener. Would be glad to meet with a Place where he could have the strictest investigation.—J. E., 32, Lockington Road, Battersea Park.

GARDENER (Head).—Age 40; possesses a very superior knowledge of Fines, Grapes, Melons, Cucumbers, Mushrooms, Pines, Orchids, Stove and Greenhouse Plants, and Flower Garden; a first-class Kitchen Gardener. Can have Plans and Estimates for Glass-structure particulars to T. J. G., Post Office, Upper Tooting, Surrey, S.W.

GARDENER (Head).—Age 30, married; thorough practical knowledge of Gardening in all its branches, including Fines, Grapes, Melons, Cucumbers, Mushrooms, and Stove and Greenhouse Plants. Also an excellent Flower and Kitchen Gardener. Good references. Total abstainer.—A. M., Post Office, Celyn-bedd, near Wrexham, Denbighshire, South Wales.

GARDENER (Head).—Middle-aged, married, no family. Thoroughly understands Gardening in all its branches, having had great experience; can undertake the Management of Stock. Wife a good Dairy and Poultry Woman, and used to the Care of Mansion. Can be highly recommended by the present and late Gentleman they have just left.—J. W., 1, Clyde Terrace, Forest Hill, S.E.

GARDENER (Head).—Mr. ROBERTS, Gardener, Park Gate, Cheltenham, Gloucestershire, is happy to recommend his foreman, WILLIAM MINDENHALL, to the notice of any Lady or Gentleman requiring a good Gardener. W. M. is practically acquainted with the Management of extensive Gardens; has had considerable experience in good establishments in England, and has been over four years in present situation. Good testimonials to character and ability.—For further particulars, address as above.

GARDENER (Head, Working).—Age 42, married, no family; thoroughly understands Gardening in all its branches, and is well up in Grape, Melon, and Cucumber Growing; also Orchard-house Fruits, Stove, Greenhouse, and Conservatory Plants; Flower Garden, Park, Meadow Land and Stock. If required, Wife could attend to Poultry and Kitchen. Many years' good reference.—A. B., Mr. Cattell's Nursery, Westerham, Kent.

GARDENER (Head), where two or more Men are kept.—A Gentleman wishes to recommend a young Man, single, who has had experience in all the Forcing Departments, &c.—A. P., Post Office, Scole, Norfolk.

FOREMAN (or HEAD, in a small place).—Married; can be highly recommended. Thoroughly understands the Culture of Fines. Five years' experience. Excellent character.—G. A., Greenlands, Henley-on-Thames.

FOREMAN.—Age 26, thoroughly practical; understands Early and Late Forcing in all its branches, including Stove and Greenhouse Plants. First-class character from present and late employers.—A. T., Gardens, Stackpoole, Pembroke.

FOREMAN.—Age 24; has had much experience in Gardening, in a private establishment, where Forcing, &c., is carried on. Can have first-class references.—A. B., 16, Royal Nurseries, Slough.

ESTATE AGENT, or STEWARD and GARDENER.—Age 42; has Managed with success a Home Farm of 500 Acres, large Gardens, Timber and Plantations, and the general Repairs of the Estate. First-class character from present and late employers.—A. T., Gardens, Stackpoole, Pembroke.

FOREMAN.—Age 24; has had much experience in Gardening, in a private establishment, where Forcing, &c., is carried on. Can have first-class references.—A. B., 16, Royal Nurseries, Slough.

ESTATE AGENT, or STEWARD and GARDENER.—Age 42; has Managed with success a Home Farm of 500 Acres, large Gardens, Timber and Plantations, and the general Repairs of the Estate. First-class character from present and late employers.—A. T., Gardens, Stackpoole, Pembroke.

ESTATE BAILIFF, or ESTATE BAILIFF and GARDENER.—Age 30, married; understands all kinds of Estate Business, including Fencing, Road-making, Timber and Plantations, and General Repairs; can Prepare Plans and Specifications for Farm Buildings, &c. Also a good practical Gardener; has had a good deal of experience in Laying-out and Planting New Gardens and Pleasure Grounds. References from present and previous employers. —A. B., Post Office, Devizes, Wilts.

STEWARD or BAILIFF.—Married; thoroughly experienced, and well up in the Management of Land and Stock, Draining, Fencing, Embanking, Land and Timber Valuing, and to Ireland. Good testimonials and references.—A. B., Sudbury Siding, Harrow, N.W.

To the Seed Trade.

TRAVELLER.—Age 37; highest references.—J. P., *Gardeners' Chronicle* Office.

Seed Trade.

TRAVELLER and SHOPMAN.—Thoroughly acquainted with the Road and Home for upwards of 16 years. First-class references.—J. E., 3, Regent Road, Ellis, Liverpool.

Seed Trade.

SHOPMAN.—Age 28, single; 11 years' experience in all the branches; knowledge of Accounts. No objection to go abroad.—SEEDSMAN, Post Office, Newcastle-on-Tyne.

Seed Trade.

SHOPMAN, or otherwise.—Age 32; five years in one of the largest London Wholesale Houses.—C. C., 3, Albert Cottages, Avenue Road, Hackney Downs, N.

To Seedsmen.

WAREHOUSEMAN, in Writing and Executing Orders.—Age 26, married; desires a permanent re-engagement. London preferred. Eight years' character.—J. R., 32, King Street, Portman Square, W.

MR. R. GAINSFORD, AUCTIONEER, AGRICULTURAL and GENERAL VALUER, after many years' practical experience in Nursery, Market Gardening, and Agriculture, begs to offer his services to his Friends and the Public in general, and hopes, by strict attention, to merit their support.—Park Farm, Hanwell.

MR. JAMES FRASER, HORTICULTURAL and AGRICULTURAL VALUER and AUCTIONEER, Mayland's Farm, Romford, Essex; late of the firm of J. & J. Fraser, Lea Bridge Road.

JOHN MARTIN, DRAINAGE and SEWAGE ENGINEER, undertakes the OVER and UNDERGROUND APPLIANCES for the UTILISATION (Wet or Dry) of the SEWAGE of TOWNS, MANSIONS, &c.; and the IRRIGATION of ESTATES, GARDENS, FARMS, &c. (single or in combination).
J. MARTIN, Kincardine-on-Forth, Scotland.

MR. LEWIS S. WOODTHORPE, HORTICULTURAL AUCTIONEER and VALUER, Manor Nursery, Sible Hedingham, Essex.

TO BE LET, The VINEYARD NURSERIES, Neithrop, Banbury, Oxon, containing Four Acres of Land, Dwelling-house, Vineries, Greenhouses, &c. For particulars apply to Mr. LAKIN, 59, West Street, Warwick.

Tredegar Nursery, Bow, E.

TO BE LET, with Immediate Possession, the above, comprising NINE GREENHOUSES, FITS, and also 150,000 PLANTS, adapted for the London Markets.
For particulars, apply to PROTHEROE and MORRIS, American Nurserymen, Leytonstone, E.

To Nurserymen, Florists, and Others.

TO BE DISPOSED OF, by Private Treaty, the old-established and well-known NURSERIES, situate about six miles south-west of the city of Manchester, so long and successfully carried on, comprising Six Greenhouses, Five Ranges of Fits, with Hot and Cold Water, with the whole of the HERBACEOUS STOCK, &c. These Nurseries are over 20 Acres, and are well stocked with choice EVERGREEN and FOREST FULL TREES, such as are rarely met with. None but principals need apply.
For further particulars, apply to J. HOCKENHULL, Nurseries, Sale, near Manchester.

SALES BY AUCTION.

SALE THIS DAY, at HALF-PAST TWELVE O'CLOCK.

Dutch Plants and Bulbs.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on SATURDAY, November 4, at half-past 12 o'Clock precisely, a consignment of choice FRUIT TREES and SHRUBS from Flushing, consisting of FRUIT TREES, RHODODENDRONS, HOLLIES, Standard and Dwarf ROSES, Clematises, Plums, Pears, Deciduous TREES and SHRUBS; also an importation of choice Double and Single TULIPS, CROCUSES, NARCISSUS, HYACINTHS, IRIS, IXIAS, LILIUMS, GLADIOLI, and other Bulbs, just arrived from several well-known Dutch Farms.

CENTRAL CHAMBER of AGRICULTURE.—A MEETING of the CENTRAL COUNCIL will be held at the SALISBURY HOTEL, Fleet Street, on THURSDAY, November 7 (Time, 11 o'Clock in the Forenoon), when Deputed Members from Provincial Chambers and other Bodies are requested to attend.
Members of the Legislature who may be interested in the subjects for consideration are also invited to be present, and Members of the Central or of Provincial Chambers, who are not deputed or on the Council, are welcome to attend though not privileged to vote.

AGENDA.

To transact General Business.
To consider and resolve upon the Report of the Committee upon the Constitution and Rules of Association of the Central Chamber. (*Discussion adjourned from May 3.*)
To receive the Report of the Local Taxation Committee.
To receive communications with reference to the policy of Appropriating for Secondary or Middle-class Education Endowments left for Provincial Education of the Poor.
To consider what steps shall be taken by the Council toward securing the Assistance and Co-operation of Chambers in Imported and Contagious Diseases of Live Stock.

JOHN ALGERNON CLARKE, Secretary.
The Salisbury Hotel, Fleet Street, E.C.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

CARDIFF MEETING.

A SILVER CUP, value £100, offered by Sir WATKIN WILLIAMS WYNN, Bart., for the Principal Prize at the Society's 32nd and SECOND PRIZE of FIFTY POUNDS, offered by the SOCIETY, will be awarded to the Occupiers of the Two Best Managed Farms entered for the Society's Prize Establishment, which are not less than 200 Acres in extent, at least one-fourth of the land (not Sheep walk) being under tillage. Competing Farms must be occupied by a tenant farmer paying a *bona fide* rent for three-fourths of the land in his occupation, or by a Landowner occupying his own Farm, the total extent of whose property in agricultural Land (exclusive of Sheep-walk) does not exceed 600 Acres, and whose business is Farming. Forms of Entry may be forwarded on application to

H. M. JENKINS, Secretary.
12, Hanover Square, W.
N.B.—The LAST DAY of ENTRY is DECEMBER 1, 1871.

The Agricultural Gazette.

SATURDAY, NOVEMBER 4, 1871.

MEETING FOR THE ENSUING WEEK.

MONDAY, Nov. 6 { London Farmers' Club (Mr. C. S. Read, M.P., on The Agricultural Labourer), at the Salisbury Hotel—6 P.M.

PUBLIC opinion on the subject of TOWN SEWAGE appears to be still in a very unsettled plight. The belief of the so-called "A B C" or Native Guano Company, that they have the power of precipitating a valuable manure from it, seems to be shared by a large number of people. A Royal Commission, whose business it has been to investigate all possible methods of purifying the rivers, has however investigated this plan of dealing with the filthy drainage water of towns; and after careful examination, on more than one occasion, of a scheme which they would have welcomed as a short and easy remedy for one class of the difficulties which beset them, they were forced to the conclusion that the process neither purifies the water nor manufactures a valuable manure. It does not precipitate the dissolved organic matters from the filthy stream in which, in town sewage, they are so diluted; and the flocculent suspended matters which that stream carries along with it are of small value as manure. Walking last Monday across the Aldershot irrigation farm, where Mr. BLACKBURN deals with the sewage of the camp, we came upon subsidence ponds, where the dirty stream is supposed to leave the greater portion of its suspended matter behind it. Here, indeed, the tanks were full, and stank abominably; but the foreman said the material was of very little use. It had been well washed on its way there, and all that was good lay in the water which had left it. But this material, further diluted with the clay employed in the process, is virtually the substance of the "A B C" manure: or, if the so-called native guano contains the finer flocculent matters, which a rough subsidence of this kind would collect, the finer particles are really better washed than the larger masses, and are of even smaller value. Every 10 cwt. of this solid excrementitious matter in the sewers of a town driven and tumbled along in 100 tons of water, and ere it reaches the sewer mouth it must have given up whatever soluble fertilising matter it contained. The water which carries these dissolved matters also carries the more worthless skeleton with which it is soluble. In the so-called "A B C" process the sewage is subjected to the cleansing influence of "alum, blood, and clay," under which all these suspended matters are thrown down, and at some expense collected and offered for sale at, we believe, £3 10s. per ton. The clarified water then leaves the works, apparently cleaned, but really containing almost all the putrescible and almost all the fertilising matter it had originally contained. It will still make the river which receives it filthy, and it will still make the field over which it may be poured fertile. Considering the plague inflicted on the sewage farmer by the suspended matters with which he has to deal, it is even better sewage for his purpose than it was before, and the worthless matter which is thus lost out of it he is very glad to lose. It is thus comparatively worthless matter, nevertheless, which is offered for sale under the name of native guano. Hitherto the agricultural evidence of its character has been very slight. There has not been much chance as yet of determining its value in the field. Such results of its trial this year as we are now, however, learning, entirely bear out the conclusions of the chemist. Thus the *North British Agriculturist* refers, as follows, to an experience of the past year in the North:—

> "Since the discussion of this question at the Social Science Congress, Leeds, we have had an opportunity of inspecting the turnips grown on land to which 'native guano' had been applied. The first field examined was Swedes—soil light loam, naturally fertile, situation between 200 and 300 feet above the level of the sea, by which it is bounded on the east. Farmyard manure had been applied to the whole of the field, and auxiliary manures used in addition. To 5 acres on one side of the field about 5 cwt. per acre of 'native guano' was applied. The other portion was manured with a mixture of guano and superphosphate of lime, applied also at the rate of 5 cwt. The weight of bulbs on the latter portion would be about 18 tons per acre; while on the portion where the 'native guano' was applied the weight of bulbs would not at the present time exceed 8 tons per acre. As the Turnips will not be stored for a month or two, the bulbs will doubtless increase. As they stand, the whole crop are healthy and luxuriant. We next proceeded to examine a field of Green-top Yellow—land a light loam, and gravelly subsoil, elevation about 300 feet. The difference in the appearance of the crop, seen at a considerable distance, where the 'native guano' had been applied, was very marked, and when closely inspected the weight of bulbs might be about 9 or 4 tons per acre—the leaves partly decayed. Where farmyard manure had alone been applied the weight of bulbs would be about 20 tons. We estimated the crop to be worth about £7 an acre, and the Turnips where the 'A B C' manure had been applied between 50s. and 60s. per acre less. The inspector of this farm considered that the 'A B C' manure had injured the crop, but as no portion of the field was left unmanured, there were no means of judging as to the correctness of his opinion. We learned that no other four farms in the county (Kincardine) experiments of a similar character had been undertaken, and the results were equally unfavourable for the 'A B C' manure. The experiments on the two farms we examined convinced us that it was unnecessary to proceed further for the purpose of inspecting Turnips grown by the 'native guano.'"

The fact cannot be too strongly insisted on, that it is the soluble part of the contents of sewage on which its agricultural value depends.

This is present in the mass of water which contains it so dilute a form that to separate it by precipitation is impossible. On the other hand, there are plants capable of dealing with large quantities of water; and to these it may be applied, and they will extract the manure which it contains and feed upon it with a resultant fertility which is quite unexampled otherwise. Cabbage, Broccoli, Mangel Wurzel, Italian Ryegrass, Celery, Rhubarb, yield enormous crops under sewage. The soil, the air with which the soil is mixed, the plants which fill the soil with their roots, are together a perfectly successful agency, not only for utilising it but for cleansing it. And if the highest scientific authority be desired we may quote VOELCKER, LAWES, and GILBERT, FRANKLAND, ODLING, and WAY as being unanimously of opinion that thus alone can sewage be at once cleansed and utilised; and they are also unanimously of opinion that in this way it can be cleansed and utilised without the creation of a nuisance to the neighbours; which is more than can be said of any of the plans for precipitating its filth which have been tried one after another, and found to fail.

—— Only best samples of English Wheat brought the previous Monday's prices at Mark Lane on Monday. Welsh steady; Irish rattling, at 1s. per quarter previous rates. ——The prices for beasts were very little altered from those of last week at the Metropolitan Cattle Market on Monday. On Thursday choice beasts were not plentiful, therefore but little reduction in price; and there was scarcely any alteration in the price of sheep, but choice calves found a ready market, at higher rates.

—— Talking lately to a man who had been more than 40 years the tenant of a capital farm in Bedfordshire, we were delighted to hear him express a confident opinion of the great improvement in both Masters and Labourers, and in the relationship subsisting between them, since he had been in business. The labourers are better servants and worthier men, the farmers are better and worthier masters, according to his belief, and he illustrated it by reference to opinions and to facts. Hear now Mr. Clift, of Whimple, Devonshire, who thus replied to the toast of the evening at the recent ploughing match dinner. He said Whimple was improving very much, and the farmers in the neighbourhood would compare favourably with any men of their class in the country. The reason of this was that they did not keep their money in their pockets, but spent it liberally on their farms. He had been in the parish 60 years, and could bear testimony to the progress which had been going on during that time. They had now got a railway and a new schoolhouse, both great improvements.—So much for fact, and there can be no better witness than a resident for so many years in the locality we describe. But now Mr. Clift proceeds to give us reasons for the state of things, and here his judgment of course can be only speculative:—With regard to education, the effect of it was to make the labourer too independent, and the labourer's children did not care for farm work—one would be a dressmaker, another a policeman, and so on, and by-and-by there would not be able to get any one to do farm work. I hope no offence (he said), but that is my humble opinion, and I cannot be convinced it will be different. I am willing every child should have a certain amount of education, but they are going to have a better education than the farmers' children if they are willing to do; the farmers' sons in this parish will have to go to work younger than the farm labourer. I was bound to go out to work and earn my own living at five years of age; now the labourers' children went go to 13 before they go out: but who's to pay for it? Our worthy member, the cause of the honourableest men in the county of Devon, says every labourer shall keep a cow. Let him do it, and he will be that independent of his farmer, his master; he will be home, and we shan't get him half his time. Mr. Clift concluded his speech, which seemed to be in accord with the feelings of a good many farmers in the room, by repeating his disapproval of the suggestion thrown out by Sir Thomas Acland, and approved of by Sir Lawrence Palk, that farm labourers should be allowed to have "cow leases."

—— Mr. Edward Wilson, who writes from the Reform Club, and says that he is a farmer in England with some hundreds of sheep and cattle, but with neither horn nor hoof in Australia, nor shares in any meat-preserving company, thus describes an experiment for the determination of the quantity of *feed* there is in a leg of mutton. A comparison between the cost of butchers' meat purchased at the shops and preserved meat imported from Australia, had quoted the difference at about a third of the English price. He says:—

"My little experiment seemed to show that the difference was more nearly twice that amount. Wishing to know exactly what was the loss in cooking and what the proportion of bone in an ordinary joint, I had a leg of mutton weighed as it came from the butcher's, weighed again when roasted fit for the table, and I then had the meat accurately pared off, and it and the bone weighed separately with the following results:—Leg of mutton before roasting, 9 lb. 10 oz.; ditto after roasting, 6 lb. 12 oz.; weight of cooked meat, 4 lb. 13 oz.; bones, 1 lb. 15 oz.; gravy, 10 oz. By this calculation we find, what probably our thrifty housekeepers know, but very many of us do not know, that if we pay the butcher 9*d.* per lb. for a leg of mutton, the cooked slice of mutton on our plate costs us about 19*d.* per lb.; and that we must compare English meat in that state with Australian meat cooked and without bone, at 16*d.* or 17*d.*, to judge justly between them."

—— We take the substance of the following account of the Adventures of a Road Steamer from the *Pall Mall Gazette*, which quotes from the *Scotsman* its account of a feat without parallel hitherto performed by a large road steamer—namely, running from Ipswich to Edinburgh by road, a distance of 450 miles, in 77 hours' travelling time. The engine, which is one of four now being built by Messrs. Ransome, Sims & Head for the Indian Government, under Thomson's patent, with india-rubber tires, is of 14 nominal horse-power, but has several times been worked up to 60 indicated horse-power; her weight is about 13½ tons; length, 15 feet; breadth, 8 feet 8 inches; height to top of chimney, 15 feet. The omnibus weighs about 3½ tons, and is seated for 21 people inside and 44 outside—total, 65. The start from Ipswich on Friday morning, September 15, under charge of Lieutenant Cloughton, and the early town reached was Stowmarket, where the road for miles was overshadowed by trees, and it was necessary to keep men on the roof with saws and axes to cut a passage for the chimney. She arrived at Bury St. Edmund's in time for breakfast, having run the first 25 miles in four and a half hours, including all stoppages. On arriving at Newmarket a difficulty also arose with the police, who directed the engine to "move on." It continued its journey in peace, reaching Ely at 6 P.M. Here, after coaling and getting direction, the drivers engaged a guide to pilot them across the Fens to Peterborough; he commenced his task by losing his way about 10 miles from Ely, and finished by directing the engine along the brink of the 40-foot river. As the engine went on, the road got narrower and narrower, until it was only a few inches of gravel between the wheels and the sloped down steeply on one side to the river, on the other to the hedge, and for the utmost care taken by the steersman to keep the engine exactly central on what there was of road, the wheels would have cut away the rotten, boggy bank, and the engine would have gone into the river. Here, at the foot of a number of this nervous work a tube burst, which delayed the travellers several hours, and gave them an opportunity of resting in the omnibus, thus ending the first day's journey of 70 miles. The second day's journey was a short one, as, being Saturday, it was necessary to find a good place to lay up the train over Sunday. On Saturday morning, at 6 A.M., the train started and made a splendid run from Wansford to Doncaster, 83½ miles in 10½ hours, including unavoidable stoppages for water, coals, &c. Most of the miles on this days' journey were actually done in 30 minutes, some of them in 25, or at the rate of 48 to 50 miles an hour. The following days' run was from Doncaster to Ripon, and thence to Darlington and Wooler. The road became very bad after leaving Morpeth, and as the travellers approached Wooler it was more like the channel of a grass-grown burn than anything else. Outside this place a toll-gate man absolutely refused passage, and a small power of steam had to be applied before the party could proceed. He came on to Wooler to give the engine in charge to the police, but the "force" was extremely civil and obliging. Next day, after loading, the train proceeded to Coldstream, and, by dint of running all night, crossed the Lammermoor ridge early in the morning, arriving at Edinburgh on the 5th. She came in by the Dalkeith road and the bridges, and swung round into Prince's Street in grand style. Although there were tramway obstructions in that street, she threaded her way through them all and distanced all the traffic, turning up into George Street, and so on to a coach-builder's yard in the West End, where she was laid up. Since that time she has made several trips of an experimental nature, in one of which she took 40 tons of gross load up Soutra Hill, which is an incline of 1 in 17, of upwards of a mile in length. After a return journey to Ipswich she will be shipped off to India. The chief difficulties encountered by the engine on her journey appear to have arisen from foraging for water and coal. She also had minor difficulties to encounter with the toll-gate people, who could with difficulty be persuaded that, being the property of Government, she did not pay toll.

OUR LIVE STOCK.

CATTLE.

Mr. R. W. Reynell's sale, which was unavoidably postponed some weeks since, took place on the 24th inst. at Killynon, Killucan, Co. Westmeath, under the management of Mr. John Thornton. The cattle were well brought out before a capital company, and bidding was spirited. The general average of £32 2*s.* over 28 animals was obtained, and a total of £898 16*s.* Twenty-one cows made £35 7*s.*, and seven bulls £22 7*s.* each, and the highest price was obtained for *Molly Connor* by Lord Spencer (26,708), and descended through *Molly Asthore* by Emperor (12,835), from *Fairy Queen* by Coriander (6895). This animal, really a splendid heifer, "nearly perfection, and with a coat of fine hair 3 inches long," to quote from an admirer and eye-witness, was sold to Mr. W. S. Garnett for 80 gs. The following is a list of the principal prices and purchasers:—*Lady Rose* by Duke of Leinster (17,724), 50 gs., R. Cox, Australia; *Arrah-na-Pogue* by Royal Prince (27,384), 53 gs., Mr. W. Barnes; *Ophelia* by Royal Prince (27,384), 45 gs., Mr. W. S. Garnett; *Ketchup* by Duke of Leinster (17,724), 40 gs., Mr. W. S. Garnett; *Molly Connor* by Lord Spencer (26,738), 80 gs., W. S. Garnett; *Princess* by Lord Spencer (26,738), 40 gs., Mr. W. S. Garnett. The bulls sold at prices varying from 15 to 32 gs., the latter price being given by Mr. W. Barnes for Prince Arthur Patrick by Royal Prince (27,384), and a descendant of *Pauline* by Prince of Northland (4826). We also append a list of prices given for Hereford bulls at the same sale, which averaged £15 17*s.* 4*d.* each. Eton Montem by Sir Harry (2767), 20 gs., J. Featherstonehaugh; White Hart, by a bull of Lord Berwick's, 22 gs., R. W. Reynell; White Nob, by Mr. Scally's Bull, 13 gs., Major Gayston: Sir John, by Mr. Scally's Bull, 11½ gs., Mr. S. Winter; Sir David by Mr. Scally's bull, 13½ gs., Mr. S. Winter; Wellington, 9 gs., R. Featherstonehaugh; Master Dick, 9 gs., O. Byrne; Master James, 22 gs., R. W. Reynell; Master William, 16 gs., R. W. Reynell. The sheep, from Leicester, Border Leicester, and Lincoln stocks, sold at prices varying from 55*s.* to 58*s.* 6*d.* for hoggets, and 58 gs. to 60*s.* for ewes. Some Berkshire pigs of a week old, bred from Sir Wm. Throckmorton's stock, were sold for as high as 70*s.* and as low as 27*s.* each.

—— Mr. R. P. Davies (late of Ridgeway) has published a private catalogue of his herd of Shorthorns now flourishing at Chipping Sodbury, Gloucestershire. The herd comprises 54 animals, 47 of which are females. All are well descended and belong to highly fashionable strains kept up by the use of first-rate bulls. The most striking feature of the catalogue is the large collection of Kirklevington, six bulls and 15 females, all direct descendants of *Kirklevington 7th* by Earl of Dalhousie (1,177), and the results of crosses with General Canrobert (12,926), 4th Duke of Oxford (11,387), Delhi (15,856), 3d Lord Oxford (22,200), 7th Duke of York (17,754), 2d Duke of Clako (21,576), and other equally well bred bulls. The Kirklevingtons are succeeded, in the order of their pedigrees, by *Lord Oxford* by 13th Duke of Oxford (21,604), and tracing back through *Filbert* by *2d* Cleveland Lad to *Fletcher* by Son of Young Wynyard (2859); next follow four Darlingtons, after which are half-a-dozen Wild Eyes, three Seraphinas, two Charmers, two descendants of *London Pride* by Janizary, four representatives of *Rhoda* by Harry of Gloster (14,674), three Honeys, descended from *Helen* by Oregon (8371), and six representatives of *Amity* by Chaffcutter (12,572). The bulls comprise 2d Duke of Gloucester by 7th Duke of Oxford (21,605), *Duchess* extinction on the female side through his mother, *11th Duchess of Geneva*, and six young Kirklevington bulls.

—— At Sir William Stirling Maxwell's sale of Shorthorns, at Keir, on the 26th ult., an average of £37 6*s.* 9*d.* was obtained over 16 animals sold. The following is a list of the prices and purchasers:—Red Rover by Mr. Booth's Banner Bearer, £52 10*s.*, Mr. Hope, Fenton Barns; Standard Bearer by Mr. Booth's Banner Bearer, £29 8*s.*, Mr. Thomson, Ochtersyne; *Flower Girl* by Baron Killerby (19,280), £31 10*s.*, Mr. R. Arklay, Ethiebeaton; *Chambermaid* by Lord Chamberlain (22,129), £25, Mr. Cochrane, Little Haddo; *Butterfly's Heiress* by Royal Butterfly 11th (20,719), £33 12*s.*, Mr. J. Balfour, Balbirnie; *White Rose* by Van Tromp (21,012), £31 10*s.*, Mr. J. Young, Waterton; Lady Oaksey by Oak Apple (16,873), £28 7*s.*, R. Lucas, Bridge of Allan; *Butterfly's Second* by Keir Butterfly 1st (24,235), £44 2*s.*, Mr. D. R. Williamson, Lawers; *Butterfly* by Prince Imperial (27,150), £28 7*s.*, Mr. J. Curris, Halkerston; *Red and White Butterfly* by Prince Imperial, £21, Mr. R. Arklay, Ethiebeaton; *Sunnyneuk's Pride* by Keir Butterfly 1st (24,235), £35 14*s.*, Mr. Scott, Glendronach; *Sweet Violet* by The Chieftain (20,942), Mr. R. Arklay, £23 2*s.* The following prices for Ayrshire cows were also given:—*Susan*, £17, Mr. R. Monro, Covesea; *Nancy*, £16, Mr. W. Christie, Ableyhill.

—— The following excellent prices for polled cattle were given at Mr. M'Combie's recent sale at Tillyfour, Aberdeen. Above half of the animals were calves and yearlings, many of which were sold at from 20 to 30 gs. each. We have restricted our list to those animals

which realised higher prices:—*Ely*, 37 gs., Lord Airlie; *Flora*, 30 gs., Lord Cawdor; *Daisy*, 33 gs., Mr. Stevenson, Tillyfour; *Edith*, 37 gs., Mr. Walker, Ardhunchart; *Dido* and heifer calf, 45 gs., Mr. Paterson, Mulben; *Dora*, 49 gs., Marquis of Huntly; *Deceit*, 31 gs., Mr. Martine, Aberdeen; *Lady Mary*, 33 gs., Mr. Adamson, Balquharn; *Hopeful*, 30 gs., Mr. Todd, West Brackla, Kinross; *Mina*, 34 gs., Colonel Farquharson, Invercauld; *Haida*, 32 gs., Mr. Adamson, Balquharn. 2-year-old heifers—*Grace*, 60 gs., Marquis of Huntly; *Joyce*, 50 gs., Colonel Ferguson; *Joan*, 30 gs., Mr. Adamson, Bocharn. Sir J. M. Grant bought a yearling heifer for 40 gs., and a bull calf for 56 gs.; Mr. Stevenson, of Tillyfour, also bought a yearling heifer for 42 gs.

—— The following instances of a fact generally recognised by breeders are taken from Mr. Finlay Dun's lecture on the Principles Concerned in the Breeding of Stock, delivered last June before the Midland Farmers' Club:—

"In all animals the progeny are occasionally found to bear a resemblance, not so much to the parents or their immediate ancestors, as to some previous male—very usually the first—with which the female has had fruitful intercourse. Most breeders recollect Lord Morton's often-quoted case of a nearly pure-bred Arabian mare having a foal by a quagga, and afterwards producing to three thorough-bred Arabians three several foals with distinct quagga markings, which were, however, less and less pronounced in each foal of the three successive foals. Frequently a valuable bitch gets lined by some mongrel cur, and for several of her litters her whelps by pure, well-bred sires will exhibit many of the characters of those first dropped to the mongrel. We know a well-known purchase, as pure Shorthorns, the progeny of a pure Shorthorn cow which had previously had a calf by a Hereford or Longhorned bull. We should consider that she would require to bear several calves to a pure-bred animal of her own kind before the stain of her earlier *mésalliance* would be obliterated. I have found it almost hopeless to obtain pure white pigs from a pure-bred white sow, if once she has been hogged by a black boar. Blaine, in his 'Canine Pathology,' records a similar case. 'D. Giles, Esq., had a sow of the black and white kind, which was bred with a boar of the wild breed, of a sandy chestnut colour; the pig produced by this intercourse were duly mixed, the colour of the boar being in some very prominent. The sow was afterwards bred from by two of Mr. Weston's boars, and in both instances chestnut marks were prevalent in the litter, which in other instances had never presented any appearance of the kind.'

"In breeding horses, practical advantage is sometimes taken of this. A thorough-bred mare that has had a colt by a good cart-horse will exhibit, in her subsequent progeny by a thorough-bred, an amount of substance and power which, however, gradually disappears with each successive union with the thorough-bred. Conversely, heavy cart mares are sometimes first put to thorough-bred or half-bred horses, in order that their subsequent offspring, by agricultural horses like themselves, may be possessed of greater cleanness of limb, and more energy and endurance.

"Two explanations are given of these curious phenomena. It is urged that the female, whilst pregnant with her first offspring, which is obviously half the male parent, becomes inoculated, as it were, with his characteristics. Another and more probable view is, that the first male that has fruitful connection with any female not only vivifies one or more of the ova, but also modifies others that are not fully developed, and which may not be fertilised for several years. The probability of this view is strengthened by analogy. It is well known that geese and turkeys will continue to lay perfectly fertilised eggs throughout the whole of a season, even if the male bird has only been with his mates for a short while when they first began to lay."

Mr. Darwin's explanation of the above described phenomena does not quite coincide with that of Mr. Dun. He considers that the *ovary* rather than the ova is affected by the male element, and this view is supported by many analogies in the vegetable world.

AGRICULTURAL NOTES.

By Mr. Mechi.

The Four-course Rotation of Cropping must, I think, especially on heavy lands, give way to a more free system. Under the old system of horse-ploughing, unaccompanied by guano, cake, or steam-power, such a system was well adapted to the circumstances, the horse work being regularly diffused or apportioned over the whole year; but now that we have the means by steam-power to cultivate the soil at our pleasure, and an abundance of artificial manures, the case is greatly altered. By steam cultivation we can now get our stubbles smashed up and cleaned; our winter Tares, winter Beans, winter Oats, and Rivett Wheat after red or white Wheat, can all be got in in good time, even if a late harvest. This cannot be done with the ordinary horse-power of the farm, because it would stop or retard other necessary farm operations, such as threshing, carting to market, carting home cake, guano, &c. The increased dryness of our soil and climate, owing to drainage, the removal of woods, trees, and fences, render it more and more desirable to take autumn-sown crops rather than risk the summer's drought. We know that heavy lands will grow Wheat more often and more abundantly than Barley, and that on light lands cake feeding will permit Barley to succeed Wheat, or Rivett Wheat to succeed white Wheat without injury to the soil. It is therefore very desirable that landowners and land stewards and agents should so modify leases that the tenant (if a good improving one) should be free to crop as he pleases, on condition of his not leaving the land in a deteriorated state. No farmer who farms profitably can injure the soil, if he produces heavy root and green crops as well as corn, and consumes them concurrently with the use of purchased feeding-stuffs, especially linseed and other cakes, Indian Corn, and bran and malt combs, &c. The great want of this country is more bread and meat, and I know from long practice that our supply of both can be very materially increased by making more meat and manure by means of purchased food, and by devoting a much larger area than 25,000,000 acres (one-seventh part of the entire area of the kingdom) to the growth of Wheat. I am more and more convinced that the pastoral age must, in this densely-populated country, be dispensed with, and that a large portion of the 22,000,000 of acres (nearly one-half of our agricultural area) will be gradually displaced by deeply-cultivated and well-manured corn and root-growing soil. Of course, every landowner on untentailed estates will do as he likes, but self-interest and sound calculation will gradually take the place of prejudiced attachment to ancient customs unsuited to the present steam age. Truth will prevail in the long run. It is enough to know that the average produce of our grass land can scarcely be 5*cr.* per acre.

Arable versus Pasture—either for breeding, rearing, or fattening, especially on heavy lands. Methinks I hear a thousand voices exclaim—"Mechi, you're quite wrong, and we entirely disagree with you." I am quite prepared to believe that the battle will be a long and big job, but mean to keep pegging away at it, and leave the rest to time and the steam-plough; the latter is sure to settle it in favour of arable, and that, too, with a high hand. It is a great mistake to suppose that heavy land farms are not stock farms—they will really produce much more food for stock than the light lands. It is true that we must on such farms give up the "roaming at large" principle, and instead summer fold and summer house cattle, and in winter provide shelter for our stock; great crops of winter Tares, winter and spring Beans, Clover, Cabbage, Mangel, and Kohl Rabi can be grown, and an abundance of straw, especially if we grow Rivett Swan Neck wheat, and all these are food for stock. Said my bailiff to me to-day, "We have ample food for 40 bullocks and 200 sheep," although we have only 14 acres of poor pasture, 8 of which I shall again break up. It is the stiff clays for which a "good time is coming." Drainage, deep steam cultivation, and the abundance of cake and feed manure will produce such crops as cannot be obtained on light soils. But then we must trust more to art and science, and less to Nature. Cultivation, deep and frequent, is the farmer's best friend, and the absence of it in great part is the individual and national loss, not only to the farmer, but to the people that it neither employs nor feeds. It is true that arable land well farmed demands much more capital and skill than grass land, but these abound in our country, and only require a profitable invitation. If this poor farm were in pasture, I believe that it would be very much on the wrong side. Why, the straw of a good Wheat or Bean crop is worth nearly or quite as much as the produce of many of our poor pastures.

Covered Yards.—While I strongly advocate the use of covered and enclosed yards for cattle, it would be very improper to have them too lofty, a mistake that is frequently made. If the roofs are thoroughly ventilated, on Watson's principle, they need not be high. Lofty roofs give too much space for cold air in winter, when animals require to be kept warm. By having open spaces under the wall-plate, we are enabled to regulate the temperature by closing them in extreme weather. In fact these should be means to close the yard entirely at night in cold weather. Sliding doors suspended from a raised bar on which the rollers travel are very convenient, as they can be opened little or much, according to weather. Cattle will certainly not fatten satisfactorily unless kept at a proper temperature.

Hard-worked Horses.—When their powers are very fully taxed, give each about 3 to 4 lb. of pure linseed cake daily in addition to their ordinary food. It puts a healthy glass on their skins. We give it late in the evening.

How much is the Total Money Value of our Available Annual Agricultural Produce, and What does it Amount to per Acre?—This is a question more easily asked than answered, for while proverbially doctors differ, so also do our statisticians, because, owing to the absence of those returns which we are now only beginning to obtain (and these of a very imperfect character), their calculations hitherto must necessarily have been mere guesswork. I hope, however, that we farmers will soon feel more disposed to give to Mr. Foublanque the fullest information in our power, as I am no believer in the necessity for, or the advantage of, secrecy; for if we try to persuade people that farming can only be carried on at a loss, no one will believe us. It is a singular and interesting fact, that of all statisticians on this subject the most successful and least incorrect is a French gentleman, who made his estimates 15 years ago, before there were any official English agricultural returns. Ireland was always in advance of us in this matter, and even now her returns are far more complete than our own. This is not creditable to English agriculturists. Monsieur Léonce de Lavergne, the eminent French statistician, published in 1855, for the information and instruction of his countrymen, a most valuable book, called "The Rural Economy of Great Britain." It contained the results of his personal examination, and his information obtained from our best agricultural mediums. This book was ably translated by a Scottish farmer, and published by Messrs. Blackwood. For many reasons I would strongly recommend this valuable work to every intelligent British agriculturist. His estimate that our agricultural productions are in value one-half animal and one-half vegetable is quite correct, although at one time I had my doubts on that point. The following are estimates in round or approximate numbers:—

Mechi	£183,000,000
Lavergne	200,000,000
M'Culloch	200,000,000
Spackman	250,000,000

I am inclined to believe that my estimate is still too high by several millions, although made this year. It certainly would have been much less had I made it 15 years ago, when the other estimates were formed. In reading Mr. Lavergne's book, it should be noticed that he reduces our values to the French prices —this rather misled me at first, as will be seen in my book. Mr. Spackman's estimate must be greatly excessive, for the total produce of wheat, 12,000,000 qr. (after deducting seed), he estimated it in 1847 at 22,000,000 qr., and at 60*s.* per qr., which is 4*l.* more than the average tithe commutation price. This alone reduces his estimate by £32,000,000. The total quantity of Wheat required annually by our population of 24,000,000 is 41 bush. per head, or 41,000,000 qr.; 10,000,000 of these quarters we are obliged to import from abroad. Our own Wheat produce gives only 3 bush. per head of population. The farmed area of the United Kingdom, as returned to the Board of Trade, is 46,177,370 acres; therefore my estimate gives less than 4*l.* per acre per annum for the farmed area. Should this be so? Permanent pasture occupies 22,085,295 acres, or nearly one half of the farmed area. Herein is a great source of our small acreable production. The total area of the United Kingdom is 77,514,385 acres. The total number of horses in the United Kingdom is 2,385,000, containing probably the produce of at least 10,000,000 of acres, or nearly one-fourth of the whole farmed land of the United Kingdom. 1,250,000 of these horses are used by farmers and market gardeners, 1,000,000 by the general public, and about 250,000 or more are breeding mares and horses for sale in the farmers' hands. According to my estimate, the farmers receive from the public and from themselves (so far as their food is concerned) less than £183,000,000 annually. Let us estimate roughly how they dispose of it:—

Rent	£60,000,000
Labour	10,000,000
Poor-rate	5,000,000
County rates for police, roads, justice, &c.	5,000,000
Labour	30,000,000
Tradesmen's bills	10,000,000
Purchased manure	10,000,000
Wear and tear and replacement of implements, losses by stock, &c.	7,000,000
Interest and profit on £200,000,000, farmer's capital, at 10 per cent.	20,000,000
	£177,000,000

This statement proves to me that I have overvalued our produce by some £6,000,000, or otherwise omitted some payments or charges. The grain, &c., used as seed would probably amount to more than 10*s.* per acre, or £11,500,000 on the arable land. I have deducted it in the case of Wheat, but think that it has not been deducted in the estimate of the other crops. My estimate of our Wheat production and consumption may be taken as accurate, for we have correct data to guide us, but our production and consumption of meat must remain an uncertain estimate. I have endeavoured to check my calculations by inquiries and observations of the ordinary consumption of meat as compared with bread and flour, by different classes of the community. With the upper ten thousand the meat bill is probably four to five times that of the bread and flour, the middle classes 2*l.* to three times—clerks 2*l.*, artisans 1*l.*, town labourers 1*l.*, agricultural labourers not above one-fourth the cost of bread and flour; for bread and cheese and flour puddings form the principal food of the agricultural labourer, aided by Potatos and vegetables from his garden or allotment. They know by experience that this is the cheapest diet that they can procure, having due regard to effective nutrition. The proof of the correctness of their judgment is afforded by their power to endure laborious exertion. I have in my book shown, by reference to chemical analyses, how much cheaper cheese is than meat as a nutritive substance. An observant friend of mine estimates the expenditure of individuals in London by the amount of rent they pay for their residences:—Careful people five times, ordinary people six to seven times, very liberal people eight to nine times the rent of their house. The agricultural labourer pays, as an average, £4 per annum for his cottage, and expends his income of £36 per annum, which is nine times his rent.

My object in writing this paper is to call attention to the humiliating fact that we are dependent on foreigners for a very large portion of our food, when we might, by the application of much more capital and skill on the part of landowner and tenant, profitably and greatly increase our supply of home-grown food, as has been done on my farm and very many others; £4 an acre produce is really a national disgrace. *F. F. Mechi, October.*

Mr. Lavergne's Estimate:—

Wheat	£16,000,000
Meat	70,000,000
Potatos	20,000,000
Milk, butter, cheese	10,000,000
Barley and Hops	8,000,000
Oats	4,500,000
Poultry	1,000,000
Wool, hides, tallow, and offal	15,000,000
Hay and Oats for non-agricultural horses	20,000,000
900,000 horses over three years, at £20	18,000,000
Flax, hemp, vegetables, and fruit	8,500,000
	£190,000,000
Landowner's timber	3,000,000
	£200,000,000

The above value of Barley and Oats are those for human use.

Details of my Valuation of our Annual Agricultural Produce.

Wheat	£13,600,000
Meat	48,000,000
Milk, butter, cheese, poultry, and eggs	16,000,000
Potatos	20,000,000
Barley and Hops for beer	15,000,000
Oats for man	4,500,000
Wool, hides, tallow, and offal	16,000,000
60,000 horses, £25 each	1,500,000
Hay, corn, and straw, for 1,000,000 of horses, non-agricultural	20,000,000
Flax, Hemp, vegetables, and fruit	8,500,000
	£183,100,000

The official value of cattle, sheep and pigs in Ireland is £32,000,000. The cattle, sheep and pigs of Great Britain, taken at the same value as in Ireland, come to £160,000,000. But our animals are in better condition and perhaps of larger growth, I have added the very liberal increase of 25 per cent. on the Irish valuation. It therefore stands thus:—

Irish live stock	£32,000,000
English live stock	65,000,000
25 per cent.	16,000,000
	£114,000,000

Of these probably £60,000,000 are slaughtered annually, giving most £48,000,000 offal, hides, wool and fat, say £12,000,000. I imagine that half the amount would be beef and veal, and the other half mutton and pork. I am inclined to believe that my estimate of meat at £40,000,000, made in my paper "On the Undeveloped Power of British Agriculture," is more correct than the present one.

TOWN SEWAGE AND DRY EARTH.

I BEG to thank your correspondent, "R. H. A.," for the encouragement afforded to me and my system by his sensible remarks in your last impression, especially on the important point that in the right disposal of town sewage there are three principal objects to be kept in view; not that, as to the ultimate prevalence of the dry-earth system, I have ever felt any great discouragement. The tediousness of delay, and the prejudice, the "flippancy," and, I may add, the injustice with which it has been opposed by some officials and some "semi-officials" of large public influence, have been painful for an exercise of patience. But with a full conviction from the first of the correctness of my principles—with a perception, growing clearer every year, of the adequacy of this system to compass all three of those principal objects, and so to confer untold benefits on this and other countries—I have never failed in my expectation of its ultimate success. And now, since the recent modification and enlargement of the system, of which I made to you a statement in the month of September last, and with reference to which I have had occasion since to write to the *Times* and to the *Echo*, I have the fullest confidence that it will speedily become that which no scheme for remedying "the great national evil" of the pollution of rivers by the water-sewerage system ever can be—a national system for the efficient and safe promotion of health and wealth. When by some mode of publication which, while opening a vast field of occupation to civil engineers shall keep the working of this system out of the hands of companies, I shall be able to make known its mode of action, I feel sure that "R. H. A." will admit "that it will single-handed manage all that is desired."

In the considerations referred to above, I protested against "compulsory legislation" as to irrigation and elsewhere, in reference to an assertion of Mr. Bailey Denton's, that on "confusion worse confounded," introduced into the irrigation theory by the report of the latest Rivers' Pollution Commission, "light is dawning." I have offered the remark, that at least until that light shall have cast its noonday radiance on such confusion, and until one or other of the many schemes for "separation," "precipitation, "filtration," or "irrigation," with or without filtration, shall be able to cleanse all our sewers and drains, and prevent the escape into our houses of offensive and noxious gases, any compulsory legislation on the subject would be reckless and unstatesmanlike. I now go far beyond this. Increasingly confident from daily practical experience that my mode of preventing the pollution of rivers will do all this in addition, and that in doing it the entire refuse of a town or village may be converted into a manure, the minimum value of which to that town or village shall be equal to £1 per head per annum of the entire population, I contend that voluntary action ought no more to be allowed as to irrigation schemes than it is with reference to the old system of middens and cesspools; for in the first place, as to health, those schemes will serve to perpetuate a system in which no due regard has been paid to the necessities of the working-classes. "A perfect water-closet in bed!" When did any inspector under any Board of Health ever dream of such a thing for the family of a working man? How can it be possible in any of those apologies for health and cleanliness set up under a Board of Health, for instance, in Sheffield? One place with a little trickling supply of water for the accommodation of a court of 30 houses! Mr. Rawlinson asserts, too, that earth-closets are much more frequently out of order than water-closets. I never asserted in the *Times* newspaper that the earth-closets, for some time constructed by the Earth-Closet Company, are almost incapable of disarrangement, and in particular those for cottages. And what, I pray, is the scale of comparison on which Mr. Rawlinson has grounded his assertion? Has he ascertained the fact that that horrid place I have mentioned in Sheffield (and there are thousands like it throughout England) was ever in order for a single day? Could he point to one dozen water-closets for the dwellings of the working classes within the parish of St. Giles, and especially in the yards of workshops, in anything like a state of decent order? If he can, then let him go and institute a comparison between those and the earth-closets in the village of Hulton, Herts, or in the Dorset County School for the Middle Classes, or at Queen's College, Cambridge, or at the works of Sir William Armstrong. Let him also pay some regard to the judgment of others on the subject, and if such an authority as Dr. Buchanan is not regarded by him, let him know this,—that after a careful inquiry into the subject a company has been formed in Sweden, with a capital of one million and a quarter of thalers for the manufacture of these very closets.

I object, however, to the continuance of voluntary action in irrigation and filtration schemes on another ground—that of the rights of property. If anything like that which I have stated in the case of the refuse of a town, there is in it a property, and that property belongs to the inhabitants. The authorities of such a town (and in my opinion the Legislature in its enactments on the subject) are under a moral obligation, with due regard of course to the health of the inhabitants, to turn that property to the best account. After its discovery they are no longer at liberty either to throw it into the river or, under the misnomer of utilisation, to waste on a few fields that which would supply manure to thousands of acres. Neither can they justly be allowed to hand over such a property under little more than a nominal rent to an individual, like the Earl of Warwick, or to a company, like the Native Guano Company, to get out of it such profits as shall pay from 12 to 50 per cent. on their capital.

Allow me to add a word with reference to national wealth. If, as it certainly may be, such an amount of valuable manure can be produced from towns and villages, and if, in addition to this, farmyard manure can be made of nearly equal value, and at the same time lessened in bulk, then within a few years both the produce of our fields and the live stock of the country may, with God's blessing, be doubled. *Henry Moule, Fordington Vicarage, Oct.* 23.

HEADS.

By HENRY CORBETT.

(*Continued from p.* 1402).

IF we go by heads, indisputably the highest-bred looking sheep are still the two breeds to which most of the other sorts trace something of their excellence. I refer, of course, to the Southdown and the Leicester, either in its way of a very patrician type. Next only, indeed, to the thorough-bred horse or the Jersey cow, there is not an animal on the show-ground which carries more style than the Southdown, or a countenance than the Southdown. Moreover, to see him at his best, you must bring him straight up from the Sussex Downs. I do not believe altogether in the positive advantage of mere size and weight, but I go rather with the conclusion to which Cline arrives in his admirable little book on Sheep, that he says that it is wrong to enlarge a native breed of animals, for in proportion to their increase of size they become worse in form, less hardy, and more liable to disease." And I would say, further, that they are apt to lose much of their fine character, so that they suffer alike in symmetry and quality. Thus, when we attempt to grow the Southdown to a greater size than he would reach to on the South Downs, we can only do this at the sacrifice of some other point. The best-bred sheep in appearance at this present time are surely to be found in the Duke of Richmond's flock; and no man could safely go further in improving the Southdown than the justly-celebrated Mr. John Ellman, of Glynde. It is to his standard that we must still look if we wish to work on right principles, as it is to him I shall turn for the definition, although he begins with a statement which cannot be passed without comment: "The smallness of a sheep's head is an indication of its being well-bred." There is nothing nearer than the head of a Southdown; but, as a rule, as I have said, a very small head is objectionable in any animal, more particularly a male, and that capital judge of a sheep, Mr. Henry Lugar, confirms me in this opinion: "The head of a Southdown," he writes, "may be too small, and if the sheep be kept on for breeding purposes, delicacy will in time be the result." Mr. Ellman's description runs on thus:—"The head should be neither too long nor too short, the lips thin, and the space between the nose and the eyes should be rather thin;" but, as Mr. Lugar adds, "a little wider just above the nostrils than nearer the eyes." Ellman, in continuation, says, "the under jaw or chap ought to be fine and thin, the ears tolerably wide, well covered with wool, and not too thin or handling too." Mr. Lugar, they should be "of a fair length, standing well up, but not prick-cared." Ellman could see "no merit in a very prominent eye;" he the rather "admires a tolerably full, bright-looking eye, but the eye-cap or bone should not project," for the reason, as he gives it, that the ewes would have more difficulty in lambing. In so smart a sheep as the Southdown the eye of the ram should be lively if not somewhat bold, in contradistinction to that placid gaze which men so covet in some other breeds of stock. Ellman concludes this description by stating that the sheep should be well covered with wool on the forehead, and especially between the ears, as it is a great protection against the fly." Noticeably enough this authority, who flourished about the beginning of the present century, says nothing of the colour of a Southdown's face—a point which I notice more often than I do any other, as one which breeders cannot always maintain. I have seen Southdowns exhibited but a few years since, from a very famous flock, nearly as light in their countenances as Leicesters, and I have heard of others gaining their laurels as dark as Hampshires. The happy medium, a proper tint as a beautiful mole colour, in admirable keeping with the structure of the head and the texture of the wool. Were I asked to name a "set" of the most thorough-bred Southdown heads I ever saw, I think I should turn to the Duke of Richmond's 2d prize pen of ewes at the Royal Oxford Show of last summer. About the best-headed sheep they ever sent up from Merton was a Smithfield Club fat shearling; and the ram with the finest head for a Southdown, which Mr. Jonas Webb bred, was Plenipo, and this sheep was out of a Glynde ewe. In fact, we must go back again to the Sussex Downs for fine character, and we must go to heads to get this. In the autumn of last year I was spending a day at Angmering, near Arundel, and, of course, looking over the famous Sussex cattle and still more famous Sussex sheep. On the shepherd turning a flock of ewes towards us I went to face them, when one of the Messrs. Heasman said, "You won't be able to see much of their legs of mutton in that way." "No," was my answer, "perhaps not, but I shall be able to see something I think even more of in a sheep than a leg of mutton," and as they met me, so matchy and breedy all showing a certain family likeness in their faces, I cannot but believe that I arrived at a glance at a better notion of their true character than by trying their backs, necks, or legs; and it is by his ewes you must prove a man's actual success as a sheep-breeder. A smart prize ewe and her descendants generally; but it is to his home flock you must look for established and reliable worth.

As I walked down the lines at Manchester, and noticed the brown faces, the grey faces, and even the white faces, the long, somewhat Roman-nosed, old-fashioned Hampshire countenance, and the great "mob" of the Down, and when I found that all these sheep, notwithstanding their diversity of character and expression, were classified as Shropshires, I must confess that I felt fairly at sea. The very judges, moreover, have not for some time past held very strongly to any particular line, and I think that it is the most prudent to say so much as I do here, on the strength of the best evidence I can call. "It is very curious that I had for some weeks been thinking of writing to you on this subject, as it is very essential that we should have judges who thoroughly understand the characteristics and the history of the breed. So wrote Mr. Thomas Horley, of The Fosse, in answer to my letter; and it is through his kindness that I am enabled to sketch out the head of a true Shropshire, being the more induced to avail myself of such assistance, as, like Mr. Lugar with Southdowns, I have not always exhibits sheep, although he frequently acts as a judge.

The head of a Shropshire ram should be black; but this colour should not extend to the wool on the neck. In size the head should not be too small nor effeminate, with a bold, broad, but not coarse, forehead, full eyes, not tolerably prominent or self-coloured, but not mottled. Many good rams have their ears tipped with black round the edges, and show a kind of copper or copper-and-gold colour farther down; and if they be well woolled this is not in any way objectionable, saving that such a tint is more generally perceptible in rams which have been forced into high condition. The ear, although not so long as to be remarkable, should not be so short as to be hidden by the wool, which should come well up round the back of the head and ears, with a tendency to cover the top of the head. The nostrils must be fairly expanded, but there should be no inclination to lareness about the ridge of

the nose nor between the nostril and eye,—any such want of covering being very objectionable, and never to be noticed in a ram of any repute. There is altogether a strength and force about the head of a true Shropshire that should never be disregarded when looking at such sheep. It will, indeed, be observed that this description does not go for the pretty grey mixture, as no doubt the Blackface is far more after the manner of the genuine Shropshire breed; but even from the true Blackfaces there will occasionally crop up a speckle-face cheek, which, as with the Hereford ox, is more a mark of being out of fashion than any positive detriment. The wool of the Shropshire should be close in texture, and not inclined to curl.

Any study of the heads of cross-bred animals or newly-established breeds is not so satisfactory in the way of a test, as the flock-masters themselves seem scarcely to have agreed as to precisely what they should go for. The subjoined synopsis of the head of an Oxfordshire Down ram may consequently not accord with the views of all, but it reads to me as a very good type to aim at. It should be long and tapering, with a forehead not too broad, but sufficiently so to give a good intelligence expression, with full eye, and ears well set back—that is, not too near the eyes. The poll must be well covered with wool, adorned with an ample top-knot on the forehead, and the face of a nice dark colour, between a jet black and a fawn. Some of the ewes, like those I have noticed at Biddenham, have really bloodlike heads; but the judges do not always go for suit, but prefer a rather coarser kind of animal, and I must admit that I am not quite satisfied with the lineage as traced by the head of an Oxford Down sheep. Neither is the first impression of a good old-fashioned Hampshire Down ram easily obliterated; for the lop ear, the Roman nose, and coarse, heavy features, if faithfully sketched, would make up, as Charles Surface says of his aunt Deborah, "a very formidable likeness." Some visible improvement, however, has taken place of late, as it is rather against the spirit of the times to maintain that the plainer an animal is to the eye proportionately greater must be his use and value.

There is something very taking in the clean, finely-cut features of a Leicester, over whose head those two great men—Bakewell and Ellman—used to differ. The Longwool man considered the prominent eye in a sheep an indication of good breeding, whereas the other "could see no merit in a very prominent eye." A very successful breeder of Leicesters, when these sheep were more in fashion than they are now, tells me that a well-placed prominent eye, standing decidedly rather beyond or outside the general contour of the head, must still be regarded as a good point. The face should be rather long, as denoting size, but should be shortened in effect by a broad indented forehead. The bridge of the nose should be somewhat broad and arched—or Roman-nosed—with wide, open nostrils, of a jet black in colour. The ears, of a fair length, should occupy a prominent position on the head, not too low, nor set very far apart; and the "high-quality" well-placed ear of the Leicester is a very safe sign of his purity. The ears and head should be covered with beautiful silky wool,—another proof of good breeding; while there must be a peculiarly delicate tint of blue visible just beneath the wool on the head, as, in fact, your true Leicester is as proud of his blue blood as a Spanish Hidalgo. If there be, on the contrary, a white ground, this is suspicious, or more directly indicative of inferior caste, strong, objectionable wool, and a taste of foreign or Lincoln blood. A red ground, again, is to be guarded against as telling of a weakly constitution, a feeble fleece, and a fineness of bone, exercising an undesirable extremity. The Leicester head should be especially bare and quite free from wool of any strength, the expression somewhat sedate, but of marked character in the ram, and his head set on rather bold and lofty, in preference to the low drooping carriage which, at one period in his history, was considered to be "the proper thing."

It is sufficiently suggestive to find that the breeders of Border Leicesters have a positive horror of the blue cast, a fact which of itself goes far to show that this variety of sheep has come from a cross, most probably with the Cheviot. The borderer, indeed, lacks much of the aristocrat in his appearance, so noticeable in the English Leicester of older pedigree. The head is longer and not so refined, the neck thin and weak; and, though the Border may by this time be perhaps ranked as a breed of itself, there is not much to go by in his frontispiece. He hardly looks as if he ever had a grandfather. *Bath and West of England Society's Journal.*

(*To be Continued.*)

SEWAGE IRRIGATION AND THE TAPEWORM.

[The following passage concluded one of Dr. Cobbold's lectures on the Parasites Residing in Food-producing Ruminants, delivered before the Society of Arts.]

As our time will not permit us to enter upon the consideration of certain other parasites, I shall conclude this course of lectures by some remarks having reference to the subject of sewage. I ought, perhaps, to feel very much honoured, in that the editor of the *Lancet* has been pleased to bestow a leading article upon my doings in this connection. Since, however, the aforesaid leader places me in a very unfavourable light, I will endeavour to defend myself in respect of all the hard things there said.

It would be immodest on my part to read the flattering remarks with which this article begins. But you can judge what occurs when I just mention that in the matter of helminthology, or study of parasites, the writer, employing the editorial "we," says that he is prepared to "sit most humbly at my feet." Then he passes on to observe, that when Dr. Cobbold "sets himself up for an oracle on sewage irrigation, we have a fair right to examine the facts upon which his reasoning is based." I wish to say in this respect, that I have never set myself up as an oracle on sewage irrigation. I have only stated my belief that sewage irrigation will certainly disperse the ova of various kinds of parasites, and be likely to give rise to a much greater degree of parasitic disease than at present exists. In proportion to the extent to which the irrigation of fresh sewage is employed, there will be a corresponding increase of parasitism. That is the proposition I had down, and to that I am prepared to adhere. After a while, the article proceeds as follows:—"But Dr. Cobbold has not helped us yet to enlighten them (*i. e.*, the butchers). For years past he has been engaged in search of parasites. No part of the animal kingdom has escaped his observation; no organ of their bodies (*i. e.*, of the hosts) has he left unexplored. He tells us how to use sewage as fodder die of parasitic disease by wholesale." I am really not aware that I ever made that last remark. "And yet we are compelled to retort that Dr. Cobbold has hitherto failed to produce a single specimen of beef measle (cysticercus) which he has not himself artificially produced, and the history of which was not confined to his own experiments at the Veterinary College."

Now, I beg respectfully to submit that I have placed before those of you who have honoured me with your presence on former occasions the most cogent evidence that every specimen of measly beef that could be met with be produced. I showed you Dr. T. G. Hewlett's official report from Bombay, and also the report of the Sanitary Commissioner of India, and by these reports you saw that scores, not to say hundreds, of cattle were burnt in order that people might not eat those very measly animals. I also showed you that the editor of the *Lancet* says I have never produced satisfactory evidence. The thing is quite clear. It is in the Punjab of India that the cattle are chiefly affected with beef measles. And why are they more affected there than elsewhere? Because irrigation is extensively employed throughout the Punjab. Enormous numbers of cattle are sacrificed there, and those cattle have access to grounds which are extensively irrigated. "But," some one will say, "this is not sewage irrigation." That is quite true; nevertheless, I can explain what it comes to. Sewage is a dilute solution of manure in the water which is used to irrigate these fields is let off from tanks, pools, or ponds (call them what you will), to which both the natives and the animals have free access. The natives are not particular in their habits, many of the bathing of our soldiers, being abundantly infested with the Tenia mediocanellata. So, when the editor of the *Lancet* says we have produced no facts, you see he is in error. But he says we have not seen a single specimen of beef or mutton measle in home-bred animals not subjected to experiment. This statement is correct as regards myself; but I have, on more than one occasion, removed cysticerci from joints on mutton brought to my own table. In the supplement to my large treatise on "Entozoa," I have figured a respectable cysticercus taken from the interior of a mutton chop. However, the writer goes on to say—"Our conviction is, that the butchers, fleshers, and professors of veterinary art are practically right in refusing to adopt the opinion of Dr. Cobbold, that measled beef or mutton is produced to any great extent, or that there is any necessity for the public to adopt a system of 'inspection of tapeworm.'" I am sure I should be the last man to encourage such a proceeding, and should be extremely sorry to adopt a vegetable diet myself. But the naughtiest thing I appear to have said is to the effect that "scores of animals are thoroughly measled." Now, what is the state of things in the Punjab. Only a few months ago a gentleman just arrived from India came to talk to me about this matter. He is an officer in Her Majesty's 92d Highlanders, and it his duty, as ordinary, to inspect the beef and other rations before they are served out. He has been giving me most valuable practical information. He is not acquainted with scientific matters, but he says:—"These are the steps we take when large portions of an animal are brought before us. We make a series of slices down the meat parallel to each other, and turn over these slices and inspect them. If we see any little cysts, we throw away the whole animal. If we only find one measle, the entire animal is burnt, or otherwise destroyed." Thus, you see, a valuable animal, worth many pounds, and enough to feed a whole regiment, is put aside and burnt. Now, the *Lancet* appears to think that that is exactly what I wish educated inspectors to do in this country. On the contrary, I protest that I never desired any such proceedings. I assert that the burning of these scores and hundreds of cattle is an entire mistake. Because you find a few measles, that is no reason for throwing away all this valuable food. What you have to do is, to instruct the men of the regiment that they have it well cooked; and, since even moderately well-cooked beef will preserve the men from danger, it were a sheer waste to burn the flesh of these animals. Now, the odd thing is that (according to my informant's statement) some of the authorities have very recently abandoned this stupid destruction of the flesh of cattle by burning. Why? Not because cooking will destroy the said measles, but, forsooth, because a medical gentleman has instructed the local government that these beef measles do not produce tapeworms. Was there ever such a farce! The authorities, you see, very properly put a stop to this unnecessary burning, but they do the right thing from instructions based on conclusions altogether erroneous. I venture to add that not one medical man in a hundred in England would display such ignorance as is hereby implied. We have proved incontestably that these little measles do produce tape-worms. The step to be taken, therefore, is simply this:—The cattle shall be inspected by one adequately accomplished man, and he shall pronounce whether the flesh is to be cooked with more care than is ordinarily observed. This would settle the whole matter.

The *Lancet*, turning to another part of the subject, says:—"Does Dr. Cobbold mean to say seriously that it is less dangerous to spread a field with manure than to irrigate it two or three times a year with sewage?" Certainly I do, if the sewage be tardily delivered. The irrigation process diffuses the eggs much more rapidly than any of the other processes; and I have been willing, on parasitic grounds, so to speak, to support what is called the dry-earth system. But it is not only on the main question that Dr. Cobbold flies in the face of facts. He is an adherent of the 'A B C' process—[I think that it is a good one, but I do not say it is perfect]—and talks of the dry-earth system as though it were absolutely safe. I do not say that; I think it is better than the other, but not absolutely safe. So that you see the criticism of the editor of the *Lancet* is not to the point. Not only in other matters which are touched upon, he also says:—"On one point we may avail ourselves of Dr. Cobbold's observations; he tells us that the ova are destroyed—[that is not quite correct; I did not say ova, but larval parasites]—by a continued moist temperature of 175° Fahr." Now, that is not perfectly true at that heat; even trichina will not stand that. A continuous moist temperature of 175°, or one considerably below boiling-point will kill trichina, and a temperature many degrees below 175° suffices to kill the cysticerci of our ox. If people will eat meat not raised throughout to a temperature of 140°, then they must take the consequences, and be liable to play the part of hosts. For my part, I should say that it serves them right. If they choose to put themselves in the same relation to their relation as the Cossacks and natives of the Baikal regions, and as the Abyssinians do, then they must, like the natives, become parasite bearers. In the Baikal territory all the natives play the part of hosts, being entertainers of the Tenia mediocanellata. And why? Because they like raw meat, which to them is nearly raw, and therefore, of course, they rejoice in the privilege of being the hosts in which these creatures flourish. No doubt one may say it is possible to be benevolent, and to give these lower creatures a chance of existence; but I respectfully submit that the comfort of one man is more to be valued than the existence of many tapeworms. "It is, therefore," concludes this not altogether unkindly-disposed article, "the duty of the Government to have the whole subject thoroughly investigated." That remark is to me highly gratifying. Clearly some of the facts I have brought forward must have been present to the mind of the writer as important, otherwise he would never have made that statement. Unfortunately, it is added—"Although Dr. Cobbold has so far exceeded—[see what I have done]—the bounds of scientific caution as to come to conclusions, it is not proof." Now that is too bad. I have every desire, as a teacher in various branches of science, to make no statement which does not rest upon a sound basis of fact. No man has a right to pretend to be a teacher of science who is not pre-eminently cautious in this matter. Science is good for nothing if its principles are asserted in a random fashion. A man who stands up and speaks on matters of social importance, and who is at the same time loose in his expressions, should be asked to leave the room, for such a man is not an ordinary nuisance, but he does unspeakable injury to fallow inquirers. Lastly, in order to smooth matters, the writer says:—"We cannot doubt that he (Dr. Cobbold) would be able to render valuable assistance whenever questions relating to the natural history of parasites present themselves to the commission we propose." I need not say that I shall be most willingly leave it to their discretion as to whether or not my services be worth seeking. I have come here, however, by favour of the authorities of the Society of Arts, and have unfolded to you a number of details, which I think you will allow are not only strange and astonishing, but are of real, practical, and social importance.

As to the final issue of such expositions, I care little or nothing, so long only as I retain the honest conviction that I have not been untruthful; yet, if the facts which I have enunciated are true, then, depend upon it, they must produce beneficial results. We can no more

stop the progress of truth than we can abrogate the revolutions of the planet on whose surface there are those who love to "play the parasite."

A FARM RECORD.

As you seem to think a short account of my farming will interest the readers of the *Agricultural Gazette*, I beg herewith to forward the same, first premising that the Clavering land, a few years back, was considered some of the worst in the neighbourhood: 3 to 4 qr. of Wheat per acre was thought to be a very fair crop, and five very good, and a great part of it has been sold within the last 30 years at from £17 to £25 per acre; but the greater part now, I believe, is farmed as well any land in the country. In 1862 I had been master of the boys' British School in the village 17 years, but finding the salary insufficient for the support of myself and family, I hired Curl's Farm, very pleasantly situated about seven or eight minutes' walk from the school, which I intended to keep on, as I did not expect to get a living from the farm; but after a few months found my mind was so much engrossed by the farming that I could not do justice to my scholars, I therefore gave it up.

I took the farm on lease for 14 or 21 years, at a high rent, with few restrictions as to the cultivation of the land, except that the last two years were to be on the four-course system. It consisted of 115 acres of arable land and 18 acres pasture, including the homestead, yard building, &c.; the acres of the arable land were underlaid to labourers for seven years, five of which were unexpired, and I underlet ten more. The greater part of the land, a heavy clay soil, having been rather badly managed for several years, abounded in Twitch, Charlock, Thistles, and the other weeds of the Stiff Clover sick. It would have been in a worse state, but my landlord, who had purchased the farm in 1861, and occupied the part not underlet one year, drained 9 acres 2 feet deep, clean fallowed 10 acres, and had roots and Tares on about 20 acres more. Having had but little previous practical experience in farming, and only Johnston's "Elements of Agricultural Chemistry and Geology," with several smaller books, I purchased Mr. Alderman Mechi's work on farming. I consider Mr. Mechi the great pioneer of agricultural improvement in this country. From these books I derived much useful information. It was not in my power to obtain covered yards, or any costly implements and appliances for cultivation, but I set to work and well drained the land 3 feet deep, my landlord finding pipes, for which I paid him 7 per cent. interest on the outlay. I had the Charlock pulled every year, but, as I had no capital for steam-power, hand and handweeded, as long as it could be done without injuring them.

I occupied only 85 acres of the arable land the first three years, 89 the next two, and 100 since, hedges included. I could not grow much corn the first five years. I only averaged 25 acres of Wheat, 17 of Barley, and rather more than 6 of Oats. In 1868 I grew 30½ acres of Wheat—produce, 214 qr.; of Barley 11¼ acres—produce, 75 qr. In 1869 I grew 52 acres of Wheat—produce, 325 qr.; of Barley 12 acres (after Wheat)—produce, 65¼ qr. In 1870 I grew 40½ acres of Wheat—produce, 237 qr.; of Barley 4½ acres (2½ after Wheat)—produce, 27 qr. In 1871 I grew 46½ acres of Wheat and 14 acres of Barley. In 1869 I grew of Oats 8½ acres—produce, 100 qr.; in 1868 I grew 9 acres—produce, 68½ qr., on land steam-ploughed after Wheat; in 1870 I grew 9 acres—produce, 85 qr., steam-ploughed after Wheat.

My average produce of Wheat has been for the eight years 5 qr. 7 bush., and Barley over 6 qr. per acre, although 22½ acres of the Wheat in the time only averaged 3 qr. 2 bush. If I take two years ont, the average Wheat would be over 6 qr. per acre. Mr. Rivett Wheat produced on 20½ acres 159 qr.; it had once before produced 96 qr. on 12 acres; in 1869, 38 acres 3 roods produced 267 qr. 2 bush., 7 acres after Wheat, steam-ploughed. In 1870, 31 acres after Wheat, steam-ploughed, produced 5½ qr. per acre; and 9 acres, after Potatos, 4 qr. per acre. This year, although blighted, I have, after Potatos, 6 qr. 5½ bush.; some after Clover, 7 qr. It has been very fine-headed the last three years, and I believe will produce a good crop on any heavy land, if in fair order, and sown as directed. I have sold a good deal of it for seed to my neighbours, and others in the vicinity who saw it growing, since advertising.

manure my land with farmyard dung, 8 loads per acre, every three years, and put a top-dressing on the crops amounting to from 20s. to 30s.; or if it be a second corn crop sometimes £2 per acre, when not manured. I clean fallowed 7 acres the first year, and since then 20 acres, through failure of crops, or of land that had been previously underlet. In the autumn of 1868 I had 36 acres of land steam-ploughed; in 1869, 31 acres; in 1870, 31 acres; and this autumn over 40 acres. This has been of great advantage to me, as I have kept a horse less the last three years; before, I kept five horses and the nag; I now get my work done much easier and better with four. The steam-plough is a fine thing on our heavy lands, where well drained, and seems to answer well for any kind of crop, especially for roots. I generally employ four or five men and as many lads, sometimes four or five extra men; and, during the summer, six or eight girls, from 13 to 16 or 18 years of age. The first four or five years I had 15 or 16.

I find my system of farming, by keeping the land clean and dry without fallow, with a fair quantity of artificial or farmyard manuring, has answered much better than I anticipated, and it does not exhaust the soil, as my crops have been very good the last three years, and worth 50 per cent. more than during the first five, and this year I believe will be as good—and would have been better, had it not been for the blight in Wheat and disease in Potatos. *W. Savill, Curl's Manor Farm, Clavering, Essex, Oct. 26.*

THE CULTIVATION OF SUGAR-BEET.

MR. W. VINCE writes to the *Bury Post*, from Wells Hall, Brent Sleigh, to say that he had grown Sugar-Beet for four years, averaging 10 or 12 acres a year, and realising 20 tons per acre and 20s. per ton. He believes he could have done better at stock feeding, and he advises farmers to consider the matter well, and to make a good bargain with Mr. Johnson or any one else who may wish to start a factory, and not to guarantee the greater growth for any number of years at any price, as he thinks they are worth more. To him Mr. D. T. Fish replies:—

Mr. W. Vince advises the farmers not to sell their Sugar-Beet at £1 per ton, as he considers it is worth more, and, in proof of its value, he states that 1 ton of Sugar-Beet is worth 2 tons of mangel or swede for feeding purposes, inasmuch as it contains 30 per cent. less water. His estimate of its superior worth is possibly nearly correct, though the reason assigned for it—Sugar-Beet being chosen to have likewise more nutritive matter in the same weight, and the cost of growing each ton of Sugar-Beet is not greater than that of growing a ton of mangel or swede, he thinks they are worth more. To him Mr. D. T. Fish replies:—

Mr. W. Vince advises the farmers not to sell their Sugar-Beet at £1 per ton, as he considers it is worth more, and, in proof of its value, he states that 1 ton of Sugar-Beet is worth 2 tons of mangel or swede for feeding purposes, inasmuch as it contains 30 per cent. less water. His estimate of its superior worth is possibly nearly correct, though the reason assigned for it—Sugar-Beet being chosen to have likewise more nutritive matter in the same weight, and the cost of growing each ton of Sugar-Beet is not greater than that of growing a ton of mangel or swede, he thinks they are worth more. To him Mr. D. T. Fish replies:—

But were this a mere question of a few shillings, more or less, between the farmer and the sugar-maker, I should not have troubled you upon the subject. Both of these parties are strong enough to take care of their own interests. But the public at large, and especially the manufacturing classes have likewise more or less at stake in the matter, and hence its importance. Farmers, for instance, are perfectly justified in getting as high a price as possible for their sugar, but suppose they ask more than it is worth, and the result is that the sugar-making industry should, and the working classes will thus lose £1000, £2000, or £3000 in wages, as the case might be. As a case in point—Mr. Johnson comes over to Stowmarket, and offers his factory £15 per ton for so many tons; they ask for 25s., and the project of a factory hangs fire. And the legitimate influence of such letters as that of Mr. Vince is to hinder a sugar factory from being opened at Stowmarket, or, if opened, from being a profitable one also. Fortunately, it is not likely to do either, as, with your permission, I intend to show that the reasons advanced are neither very sound nor strong, nor the statistics given the most trustworthy.

Mr. Vince endeavours to show that no profit can be made by the farmer growing Sugar-Beet at present prices. He exists the feeding properties of Sugar-Beet to the manufacturer, the expense of cultivation, the highest figure, and runs down the yield per acre as low as possible. As to the first. Suppose we accept his estimate of two to one in favour of the feeding properties of Sugar-Beet over Mangel, and that the value for Mangel be 20s., would still be a loser by the growth of Sugar-Beet, and so we need not dwell on the matter. However, it is impossible to be blind to the fact, that the introduction of sugar growing into a district seems to have the effect of raising the value of common Mangel or other crops which it has displaced. In the neighbourhood of towns where there is a demand for roots for dairy and other purposes, a fictitious value forced upon Mangel by the Sugar-Beet, but taking the average of the rural districts, the estimated value of common Mangel for conversion into beef, mutton, milk, cheese, and butter, would not exceed 7s. 6d. per ton—we have seen estimates, why then 25s. —and yet no sooner do our sugar factors appear on the scene, and offer £1 for Sugar-Beet, than up bounds common Mangel to the same figure. And then what a fresh field for speculation is obtained for Mangel. Vince and others have found in the cost of production. He even assures us that "he grows them on the flat, which is rather costly, compared with growing common Beet on the ridge," but our estimates, why then does he grow them on the flat? The yield of 10 tons per acre is not a very flattering testimonial to flat husbandry. Neither do I remember that extra expense was one of the recommendations for cropping on the flat. Mr. Edgar, in his instructive paper on this subject, read before the Lavenham Farmers' Club. But all helps to run up the price of growing roots for £12 per acre. Mr. Vince, in one of the most important and somewhat part of your paper last week, makes the total expense of an acre of Sugar-Beet, from the preparation of the tilth to its delivery at the factory, £11 15s., including rent, rates, tithes, and labour equal to the growth of 20 acres. Here we must accept them, although I have other statistics before me as I write, of the actual cost of growing an acre of Sugar-Beet in Ireland, which, exclusive of the rent of land, but including cost of two ploughings, two earthings, harrowing, rolling, spreading manure, and sowing 5 bush. of bones, 3 cwt. of guano, three hoelings, pulling, stripping leaves, and drawing to the factory, was but £5 6s. per acre, which is less than a third of the amount, and yet 25 tons per acre. Still, I will not higgle over a pound or two more or less put on to the cost of production. With all the extras we will take in a round number at £12 per acre. Now the matter will stand thus. If it cost £12 per acre to grow sugar, it costs £11 to grow common Mangel, or from £9 to £12 to grow common Turnips or Swedes. The vital question for farmers is, do any of these crops pay the cost of production? and further, Is it just and fair to charge them with the entire cost? On the contrary, have we not always been told that green crops don't pay? and is it not the constant practice to charge part of the manure, and the cost of superior cultivation given to such crops, to the succeeding Wheat and other crops? On what principle, then, does your correspondent charge the whole of this £12 against the Sugar-Beet? True, Mr. Biddell writes of an apparent profit of £3 12s. per acre; but most non-agricultural readers would think the expression meant more apparent than real. On the contrary, it means much more than is apparent; or, in other words, this £3 12s. should probably be doubled. Every farmer knows these green crops are preparatory to corn crops. They take the place of the bare fallow. To work this latter properly not much less than £5 per acre has been expended, and the yield was *nil*. It needed a tremendous yield of Wheat to recoup the farmer for this outlay, and, in fact, the expense used to be spread over the whole course. The same principle is applied to all green crops, and I have yet to learn on what principle of true profits in husbandry Sugar-Beet alone is burdened with an expense which is never charged against any other green crop. Mr. Vince, however, reserves what would appear his strongest argument against sugar-growing to the last. By reducing the yield to 10 tons per acre he appears to saddle sugar with an absolute loss of £3 per acre. I also find this statement in Mr. Vince's letter as a matter of advice to the Stowmarket farmers:—"Do not run away with the idea that 22 tons per acre will be grown. I believe that quantity never was grown at Lavenham." Happily, this fact and its unfounded nature has been published in all the local papers at the time, and verified by the growers in the presence of each other and myself. Now, these facts have never been challenged, that I am aware of, till now. In a leading article, as a matter of advice to the Stowmarket farmers:—"Do not run away with the idea that 22 tons per acre will be grown. I also find this statement in Mr. Vince's letter as a matter of advice to the Stowmarket farmers:—"Do not run away with the idea that 22 tons per acre will be grown. I believe that quantity never was grown at Lavenham." Happily, this fact and its unfounded nature has been published in all the local papers at the time, and verified by the growers in the presence of each other and myself. Now, these facts have never been challenged, that I am aware of, till now. In a leading article, as a matter of the *Agricultural Gazette* for October 16, 1869, I find the largest yield per acre was 30 tons gross, or 24 tons of roots and 6 tons of leaves. The next best crop was 31 tons gross, or 25 tons of roots and 6 of leaves. I leave these facts to balance the belief of your correspondent, and I confess nothing has surprised me more in connection with sugar-growing than these low estimates of the yield of Sugar-Beet. It is as plain as any simple sum in arithmetic, that if three or four small roots are grown in the place of one large one, the aggregate weight of the two yields should be equal. Especially should this be the case when, bulk for bulk, the smaller one weighs by far the heaviest.

It is something, however, to find that Mr. Biddell advances 5 tons on Mr. Vince. The seasons have hitherto been unfortunate, the doubtless before near the yield would have averaged 20, and be soon on the high road to 30 tons per acre. My experimental plots in the garden, without any manure, were one year at the rate of 36, and another year at the rate of 40 tons. Indeed, although we are told that such yields must never be looked for, far greater have been reached in Ireland. The commissioners appointed to inquire into the produce found that Sugar-Beet yielded from 18 to 40 tons per acre, and one crop, that of Lord Talbot's, reached from 48 to 52 tons per acre. In fact I quite believe with Mr. Samuel Copeland, the author of "Agriculture Ancient and Modern," whose authority will be acknowledged by even the Lavenham magnates, that "it is possible to raise as large a crop of the Silesian Beet as of the Mangel." Or if not, why not? I have met your correspondent with facts. I only ask in return that those who are afraid of the Sugar-Beet should be confirmed or destroyed by like arguments.

Of course every ton added to the yield swells the profit. As put by Mr. Biddell at 15 tons per acre, it pays better than any other green crop. But if it pays better than Swedes and Mangels, which cost almost as much to grow—is estimated at from £6 to £8 per acre. Any farmer may put this and that together, and see where his interest lies. By asking too much for roots, and self-interest or unsuiting ambition, may easily defeat itself. It is necessary to bear in mind that the price of commodities is determined less by the value put upon them by sellers than the ability of buyers, the natural law of consumption, and the abundance or scarcity of the thing produced. The commercial value of Sugar-Beet is likewise complicated by other considerations; such as the capital invested in machinery, the short season during which it is productive, the duties levied on the finished product, the price of labour, rent of land, and value of the roots at home and abroad, ranging from 13s. to 16s. per ton on the Continent; and the comparative profits on the manufacture of Sugar-Beet and that grown from the cane, &c. The price of Beetroot is therefore a question which requires careful consideration, and the farmers should ponder it seriously, wisely, and well, before rejecting the sugar-makers' liberal offer of £1 per ton. *D. T. Fish.*

Home Correspondence.

Pitting White Turnips.—Absence from home prevented my seeing Lord Essex' inquiry in your last week's number, as to whether white Turnips will keep good during the winter when put into pits. For many winters I have had them clamped like Swedes; and, if the work is properly done, they will keep very well up to March. I am going to pit 11 acres of Greystone Turnips immediately, and have no fear as to their keeping well. *J. Borlase Tibbits, Barton Seagrave, Kettering, October 27.*

Food for the People.—Without in the least desiring to cast doubt upon the propriety of following the advice of those who, like our good friend Mr. Mechi, insist upon improved and extended agriculture as the means of obtaining food and employment for our people, I would submit that after everything which they seek is accorded to them, there still remains the necessity of devising means by which the public shall be enabled to participate in the abundance which is in store. The introduction of fresh laws between landlord and tenant, which may invite the investment of more capital

—the employment of more labour—the general use of the new "key to the earth's treasures," or steam ploughing for deep tillage—the cultivation of every available foot of land, and although last not least, the acceptance by the country generally of its best fertiliser, town sewage, will all fail to accomplish the objects so dear to Mr. Mechi's heart, and to that of every thorough advocate of progress and improvement, unless the public directly feel the benefits which will result from all these. That no inducement is now given to market garden farmers either to invest more capital or incur more risk or labour, the present state of the markets will show; for although the prices paid by the public during this year of abundance have been the same as those which they paid with but slight variations during years of dearth, the growers have been at the expense of sending to market from two to thirty times as many loads of produce for the same money as one would have brought last season. Whilst Mr. Mechi and others have been fighting for improved cultivation, in order to secure large yields, farmers even within convenient distance from the metropolis have been ploughing in their crops because it would not pay them to market them, and discharging hands because they could no longer afford to keep them, whilst the public at the same moment have been complaining at being charged "war prices" for their vegetables, in ignorance of the heavy sacrifices entailed by the wholesale prices at which the farmers have been compelled, through its perishable nature, to part with their property. Some remedy for this might be found by the regular proportion of the wholesale prices, thus affording the consumer an opportunity of exercising his judgment of the fairness of the retail prices demanded of him, as in the case of all other comestibles. I would urge Mr. Mechi, without refraining from his efforts in behalf of the land, to give some consideration to this matter, so that his ultimate object may be secured when success otherwise crowns his efforts. *Henry J. Morgan, Lodge Farm, Barking, Oct.* 30.

More Manure, much more Manure, is the general desire of all good farmers, so one would naturally conclude that every care was taken individually and nationally to preserve it—is this done? We all know that it is not, but that on farms as well as in cities there is a suicidal waste. That will be remedied some time within a hundred years, which is not long in the history of a nation. The country is not half-manured or half cultivated—I mean as to quantity of one and depth of the other. Our stiffest and coldest clays, if dug and intimately mixed with good rich manure, and then covered again with the dug soil, would yield as well exposed between two strips of cultivated soil, as was so judiciously done by the late Rev. Samuel Smith, of Lois Weedon), would at once become useful feeding-ground for the roots of plants. It is the intimate intermixing of the subsoil with the rich vegetable manure that cooks the former and renders it good food. One of the best root growers I ever knew always, by several ploughings and rollings after manuring, effected a thorough intermixing of the soil with the manure. This is very much more effective than the mere depositing of the manure in a trench under the plants. Once get the poor subsoil dry, and then well saturated with town sewage or rich manure, and its noxious qualities will depart. I have heard farmers say they dare not manure too highly for their Wheat and Barley, because they would get it prematurely bad. Let me advise them, especially on heavy land, to richly manure the poor subsoil 12 inches below the plough-sole, and then take a great crop of Mangel or Kohl Rabi. Then their corn crops, to follow the removal of these roots, will bear 2 cwt. of guano and 2 cwt. of salt, and if not sown too thick, yield a handsome and abundant crop. These reflections arose upon reading the following extract of a letter I received from a clever, successful, and persevering friend of mine, who is applying business principles to his land. The time will come when the depth of cultivation, and the supply of manure will be trifling on British acres, and the meat-making produce proportionally increased, for it is not possible to cultivate and manure too deeply and heavily per acre gigantic root plants. But then what a lot of capital we must invest per acre to keep stock enough to consume them :—

"I grow about 50 tons of Mangel, perhaps 60, but I fear 50 is nearer. Those in the open fields are not first-rate, arising, in my opinion, from improper cultivation; but I have from 70 to 80 tons grown in my garden, of the most beautiful quality you ever saw. I was my own bailiff in this case. I had the land dug two spades deep, and put on a good quantity of good manure made in my cattleyard; but I had in the field was skimped by my bailiff in any way he thought proper, and the result is such that in future I mean to be my own farmer and bailiff as well. I also grew in my garden a few Cabbages for sheep and bullocks—perhaps I had a quarter in acre, but the feed I have from it is marvellous; one Cabbage weighed 31½ lb., and three weighed 80½ lb. My brother, who has seen both the Cabbages and Mangel in my garden, says he never saw anything to equal them. I don't know what the Cabbages are called, but the Mangel is the Golden Globe. I take possession this Michaelmas of 7 acres of land adjoining my park wall; for several years it has grown nothing but Lavender, Mint, and suchlike things, and I hardly know how to begin. I wish I had your good counsel in the matter. I want root plants for my cattle, so I think of trying Cabbages, Mangel, and suchlike; only I am this year so short of manure, and, betwixt you and me, I don't like artificial. I may be driven to use artificial this year, but 'never no more' if I can help it. In this matter I expect I am opposed by my friend, Mr. Mechi, who, I think, is not artificial in anything but manure." *J. J. Mechi.*

Dodder.—"Observer" and J. G. Nelson (pp. 1340, 1371) both notice the prevalence of Dodder amongst Clover that was sown last spring. This I have not seen, and my experience is, that it usually only appears with the full-grown Clover the second year; but in Cheshire, where I have lived nearly all my life, Dodder is exceedingly rare, and we see very little of it; it is certainly not a native plant with us. We have wide heaths and large peat bogs, and we have considerable stretches of moorland on the eastern borders of the county, all of which are covered with Heather and dwarf Gorse; but in botanising for 25 years I have never even once found a specimen of Cuscuta Epithymum, and during as many years I have seen the Clover Dodder in this county perhaps not more than five or six times. So rare is it, that no labourer to whom I have shown it has ever noticed it before, or has even a vernacular name for it. But, strange to say, our farm labourers are well acquainted with the same Dodder as they appearance it, "Dother;" but they apply it generically to Polygonum convolvulus, Vicia hirsuta, Fumaria officinalis, Spergula arvensis, and any other agrarian weed that is of a choking or strangling nature. The extreme rarity of the plant in Cheshire shows us pretty plainly that when it does make its appearance it has been introduced with the seed. I have no doubt that the seed of Dodder could and would remain in the soil for several years, and appear again after an interval, but I suspect this is seldom the case on any ordinary farm, as the Clover is mowed too soon to allow either itself or the Dodder to form mature seed. Certainly, where an ordinary farm does not reappear on the same ground, for I recollect finding many patches some years ago in a field which is cropped on a four-course rotation, but I have never had any more of the pest, though the field has been in Clover since. The reason that Dodder is observed this year amongst the Clover sown last spring I presume to be this: Being so purely parasitic, it grows simultaneously with the Clover, or rather, it requires the maturing Clover plant in order that itself may be fully developed. The Clover is secondary of the second year's crop, like the Mangels and Turnips mentioned by "Observer," arrived in a great measure at maturity during the first year. Where corn lost root during the winter, and was thin on the ground, Clover has gone a-head to such an extent that the "root" would have been a very respectable crop now. I have found it so, and I have at this present moment a stack of excellent Clover hay, of, at the least, 10 cwt. to the statute acre, which was shaken out of the butt ends of the Wheat sheaves before they were tied up, and there was almost as much of it amongst the straw. The Dodder having thus something to grow in, has probably imitated its foster parent, and has attained a considerable growth a year sooner than usual. Seeing that the Dodder plant is so far advanced, mowing may serve to check its growth, and will at any rate prevent its ripening any seeds; but cultivating does not serve to kill the Dodder, for in the field that I have mentioned, and on other occasions, I have seen none at all amongst the first crop of Clover, but have found it growing plentifully in the second crop. *Robert Holland, M.R.A.C., Mobberley, Cheshire.*

The Flax Crop in Ireland.—The great failure of this crop in Ulster has been more than counterbalanced by the growth in Munster, where, alike as regards yield and quality, it is above the average. In the South the yield is also very satisfactory, and the large supplies in the markets are excellent, some of the samples being described as "very prime." Some superior produce has realised 15*s.* and even 17*s.* per stone, but the average prices range from 7*s.* to 11*s.* 6*d.* per stone. Much reference to an article appeared some time since in the *Globe*, in which the writer argued that Ireland was not suited for Flax growing, and recommended the cultivation of Beetroot, the Earl of Bandon, in a speech at the Ballineen Farmers' Club, has shown that from the earliest times Ireland was a Flax growing country, and that even so long since as the reign of Henry VIII. an Act was passed to restore the manufacture of linen, which the old Irish chieftains used to wear. His lordship maintained that Ireland was peculiarly suited to Flax cultivation; and another agriculturist said that he had been an extensive Flax grower for the last three years, and intended to continue so, as he found the crop to be most remunerative. *G. H. P.*

Skilled Labourers.—When a farmer takes to himself steam machinery, his first difficulty will be the want of labourers accustomed to it, and a want of knowledge of it himself. I passed through this ordeal some 24 years ago, when farm steam machinery was unknown in this district, and of course proper machinists were wanting. Now the difficulty is much less, but it is highly desirable that the rising generation of farmers should at their schools, or, better still, at the Royal Agricultural College, Cirencester, get a theoretical knowledge of the steam-engine in its relation to the cultivating and other operations of the farm. The better education of our labourers will also give them a more ready insight to the use of steam machinery. How much we have improved in this respect during the last 25 years. My threshing-machine, on the Scotch principle, had at first feeding rollers, to prevent too much of the sheaf passing it at one time; but it was soon found out that increased velocity of the drum (mine revolves 1300 times per minute) speedily drew in the straw, and caused the ears (being the heaviest part) to fly off by centrifugal force, like water off a mop, and so strike or rub the grain out by a sharp blow against the concave, rendering it unnecessary to set the drum too close, a great risk grinding the grain, instead of merely releasing it from its covering. Slow movements of the drum are very objectionable. No doubt the complicated drill at first bothered and plagued the farmer and his men; but time and practice have obviated that difficulty. Most of my men have been with me nearly 30 years. It is a great mistake to part with experienced men, but temperand want of a proper understanding often cause great inconvenience and loss. We are threshing Wheat to-day with our fixed engine, and as I saw how handily our people were readjusting the machinery of the fixed threshing-machine—it having previously been threshing Beans—the thought struck me I have expressed on paper passed through my mind. We agriculturists are fast approaching what I would call the age of machinery and steam; therefore it is highly desirable that the rising generation of agriculturists should become gradually versed in this matter. No doubt our ordinary farm blacksmiths will have to be also improved, and become, in some degree, machinists, having lathes, &c. It must be so, if every farm is to have its steam ploughs and fixed steam machinery. We have much less difficulty now in Essex than we used to have, but there is great room for further improvements in facilities for machine repairs; in fact, our steam boiler house should not be without anvil, lathe, and tools, and a handy farm labourer to use them. My engine has been driven for 24 years by one of my farm labourers—a sort of handy man for any job. Wages, 15*s.* per week. *J. J. Mechi.*

Societies.

ROYAL AGRICULTURAL OF ENGLAND.

MONTHLY COUNCIL: *Wednesday, November* 1.—Present: Sir H. Verney, Bart., in the Chair, Vice-President, in the chair; the Earl of Lichfield, Viscount Bridport, Lord Chesham, Lord Tredegar, Lord Vernon, Mr. Baldwin, Mr. Barthropp, Mr. Barnett, Mr. Booth, Mr. Bowly, Mr. Cantrell, Colonel Challoner, Mr. Chaplin, Mr. Brandreth Gibbs, Mr. Hornsby, Mr. Bowen Jones, Colonel Kingscote, M.P.; Mr. Leeds, Mr. Milward, Mr. Pain, Mr. Randell, Mr. Shuttleworth, Mr. Thompson, Mr. Torr, Mr. Wakefield, Mr. John Wells, Mr. Wells, M.P.; Mr. Jacob Wilson, and Dr. Voelcker.

Sir Archibald Macdonald, Bart., Woolmer Lodge, Liphook, was elected a Governor of the Society.

The following members were elected:—

Bell, Robert, Mallsgate, Brampton.
Beswicke-Royds, C. R. N., Pyke House, Littleborough.
Bonehill, C. G., Bickford Grange, Penkridge.
Booth, E. Whitelock, Park Farm, Nether Burnet.
Campbell, Arthur J., St. James' Place, Fermoy, Ireland.
Carruthers, G. Brockbank, Westbourne Terrace, Lancaster.
Cawley, W. Payne, Ashby St. Ledgers, Rugby.
Downing, John, Ashfield, Fermoy, Ireland.
Du Plessis, Gustave, Château du Plassi, par Mettray, Indre et Loire, France.
Ellis, R. Trevithick, Pentonstone Hall, Milford Haven.
Grant, Colonel W. L., 13, Victoria Street, S.W.
Hurst, Robert, Rochdale.
Jowit, Thomas, The Old Weir, Hereford.
Keir, Captain G. Lawrence, 33, Pembroke Road, Kensington, W.
Lascelles, F. Henry, Mayfield, Rowledge, Farnham.
Lenthall, E. Kyffin, Besselsleigh Manor, Abingdon.
Lenton, W., Carlisle.
Norman, George, Dinnaton, Swimbridge, Barnstaple.
North, Charles, The Hall, Roughan.
Page, Joseph, Winnerton House, Kidderminster.
Parker, T. Townley, Charnock, Chorley.
Peterson, A. T. T., Drumdnar, Lymington, Hants.
Williams, Robert Ap Hugh, Bodelwyddan, St. Asaph.

FINANCES.—Viscount Bridport presented the report, from which it appeared that the Secretary's receipts during the past three months had been duly examined by the committee, and by Messrs. Quilter, Nash & Co., the Society's accountants, and found correct. The balance in the hands of the bankers on October 31 was £670 15*s.* 4*d.*, and £2000 at deposit. The quarterly statement of subscriptions and arrears to September 30, and the quarterly cash account, were laid on the table. The arrears then amounted to £1500. The committee recommended that 28 members in arrear of their subscriptions be removed from the list of members.—This report was adopted.

JOURNAL.—Mr. Thompson (chairman) reported that the committee requested the instructions of the Council in reference to the President's offer of a silver cup for the best managed farm in the South Wales district, but that they did not recommend the offer of a second

prize. They also reported that the cost of the farm prize competition of 1871 was as follows :—

Prizes offered by landowners and local committee..	£250
Society's prizes	100
Society's expenses, including advertising, inspection, and report	225
Total	£575

This report having been presented, a conversation ensued, in which Lord Bridport, Mr. Randell, Mr. Cantrell, and Mr. Bowly advocated the offering of a second prize, while Mr. Thompson and Mr. Jacob Wilson defended the recommendation of the committee, on the ground that the special circumstances of the district did not require it. Finally, it was moved by Mr. Bowly, seconded by Mr. Cantrell, and carried by 11 votes against 8, "that a second prize, of the value of £50, be offered by the Society."—Subject to this amendment the report of the Journal Committee was received and adopted.

CHEMICAL.—Mr. W. Wells, M.P. (chairman), reported that, in accordance with the resolution passed at a previous Council meeting, the opinion of counsel had been obtained on the questions then raised, and a letter had been written by the Secretary in the terms recommended ; but to this letter no reply had as yet been received.—This report was adopted.

GENERAL, CARDIFF.—Lord Vernon (chairman) reported that a correspondence had been held between Mr. Randell (at the request of the committee) and Mr. Corbett, the Steward of Forage for the Cardiff meeting, in reference to the quantities of forage and roots required for the ensuing exhibition, and that the committee recommended the purchase of the quantities which were likely to be required. This report was adopted. The President announced that in the course of a few days there would be a conference between the authorities of the London and North-Western and of the Great Western Railway in reference to the fares for passengers, stock, and implements, in connection with the Cardiff meeting, and the Honorary Director and the Secretary were thereupon instructed to draw up a memorandum of the concessions which the Society was desirous of obtaining for its members, visitors, and exhibitors.

IMPLEMENT.—Colonel Challoner (chairman) reported that with reference to the engineers' bill for additions to the Society's plant, they recommended that the Secretary be requested to inspect the plant with the consulting engineers, and ascertain whether some of the apparatus specially supplied for the Wolverhampton meeting might not with advantage be disposed of, and reported to the credit of the account. —This report was adopted.

SHOWYARD CONTRACTS.—Mr. Randell (chairman) reported that the whole of the works connected with the showyard at Wolverhampton were satisfactorily completed, and that the Society's portable buildings are now safely deposited within the intended showyard, at Cardiff, under the new contract with Mr. Penny, who is entitled to receive £361 9s. 3d., the final balance of the account for works at Wolverhampton. It was also recommended that the plan produced of the Cardiff showyard be adopted, subject to any modification which the Honorary Director may find necessary.—This report was adopted.

STOCK PRIZES.—Mr. Milward (chairman) reported that the committee had arranged a draft of the stock prize-sheet for the Cardiff meeting, and that they recommended that the Secretary be directed to prepare a proof, and send a copy to each member of the Council previous to their next meeting in December.—This report was adopted.

SELECTION.—Mr. Thompson (chairman) reported the following recommendations of the committee :—

1. That Mr. E. Holland be elected a trustee of the Society, in the place of Lord Berners, deceased.

2. That Sir A. K. Macdonald, Bart., be elected a trustee of the Society, in the room of the late Sir Thomas Dyke Acland, Bart.

3. That Mr. M'Intosh, of Havering Park, Essex, be elected a member of Council, to fill the vacancy caused by the death of Mr. Clayden.

4. That the Hon. W. Egerton, M.P., be elected a member of Council, to fill the vacancy caused by the election of Mr. B. T. Brandreth Gibbs as a Vice-President.

This report having been adopted, it was moved by Mr. Thompson, seconded by Mr. Shuttleworth, and carried unanimously, that Mr. Holland be elected a trustee of the Society. On the motion of Lord Bridport, seconded by Mr. Milward, Sir A. K. Macdonald, Bart., was unanimously elected a trustee of the Society. It was then moved by Mr. Milward, seconded by Colonel Kingscote, M.P., C.B., and carried unanimously, that Mr. M'Intosh, of Havering Park, Essex, be elected a member of the Council ; and, on the motion of Mr. Wells, M.P., seconded by Mr. Randell, it was unanimously resolved that the Hon. W. Egerton, M.P., be elected a member of the Council.

VETERINARY.—Major-General Viscount Bridport (chairman) presented the following report :—The Veterinary Committee have had under consideration the letter of the Principal of the Royal Veterinary College, dated July 17, stating that a reply to the communication of the Royal Agricultural Society would be sent after the next meeting of the "General Purposes Committee" of the College. The committee now recommend that the Secretary shall write to the governors of the College, stating that the Society has been anxiously awaiting such reply, and further to request that the same may be communicated not later than December 1 next, in ordered that it may be considered at a special meeting of the Veterinary Committee to be held previous to the next monthly Council. Mr. Torr, having called the attention of the committee to a disease prevalent amongst, and fatal to, lambs in various parts of the country, and also to a resolution of the Lincolnshire Agricultural Society, requesting him to bring the subject under the notice of the Council of the Royal Agricultural Society, the committee reported that they considered the subject of sufficient importance for this to be done, and that they had therefore requested Mr. Torr to take this step at the present Council meeting.—This report having been adopted, Mr. Torr submitted the following extract from the minutes of the general meeting of the Lincolnshire Agricultural Society, to the consideration of the Council :—

"The committee appointed at the last meeting of the Council are of opinion that the prevailing disease amongst lambs ought to be thoroughly investigated by competent authority.

"They, therefore, recommend that Mr. Torr be requested to bring this subject under the notice of the Council of the Royal Agricultural Society, at their meeting to be held on Wednesday next, and be requested to report to the Council of this Society on November 10 next.

"That in the event of the Royal Agricultural Society deciding not to take action in the matter, that the Council of this Society be empowered to nominate a committee to investigate the subject, and to expend such moneys in the investigation as may be found necessary.

"(Signed) J. H. THOROLD,

"October 27, 1871." "Chairman.

It was thereupon moved by Mr. Thompson, seconded by Lord Bridport, and carried unanimously—

"That the thanks of the Council be given to the Lincolnshire Agricultural Society for their communication, and that Professor Simonds be requested to make a thorough and immediate examination of the nature of the disease and the circumstances under which it most commonly occurs, and to give suggestions for its treatment and prevention."

The President having then called attention to the importation of foot-and-mouth disease through the medium of Irish cattle, his statement was confirmed by Mr. Thompson and Colonel Kingscote ; it was, therefore, moved by Colonel Kingscote, seconded by Mr. Torr, and carried unanimously, "That numerous complaints having been made of the unhealthy state of the Irish cattle imported into England, it is resolved that the Secretary be instructed to write to the clerk of the Privy Council, calling the attention of the Government to the subject." Lord Vernon then moved the resolution, of which he had given notice, slightly altering its terms, as follows :—

"That a special committee be appointed to consider the whole question of the receipts and expenditure of the Society, and the possibility of securing equal results at less cost."

In advocating the appointment of this committee, Lord Vernon gave a sketch of the causes which had led to a continual increase in the expenditure of the Society for many years, more particularly in connection with the annual shows. He particularly noticed the increase received of late for accommodating exhibitors and visitors, and the expenses attending the trials of implements and the exhibition of stock on so large a scale ; and while indicating generally several directions in which it was possible that inquiry might result in economy, he expressed his conviction that no body of men could be more vigilant than the Council in controlling the expenditure of the Society in accordance with the policy which was decided upon from time to time. He concluded by moving the appointment of the committee, suggesting that the following noblemen and gentlemen shall be invited to form the representatives of each of the standing committees of the Council :—*Finance :* Lord Bridport, Colonel Kingscote, and Mr. Davies. *Showyard Contracts :* Lord Vernon, Mr. Randell, and Mr. Shuttleworth. *Stock Prizes :* Mr. Dent, Mr. Milward, Mr. Torr, and Mr. Jacob Wilson. *Implements :* Lieut.-Colonel Wilson, Mr. Booth, Mr. Kansome, and Mr. Thompson. Lord Bridport, in seconding the motion, expressed his belief that there was no cause for alarm at the expenditure incurred by the Society of late years, for although it was undoubtedly large he considered that it had produced very good results, and he was not of opinion that the Society should lay by a large sum of money for the use of a future generation. At the same time, he thought that investigation might be beneficial without curtailing the usefulness of the Society. Mr. Thompson, in supporting the resolution, expressed his conviction that the control of the finances of the Society at the present time must meet with the approval of all members of the Society ; but as all old societies have a tendency to run in grooves without taking sufficiently into account the changes required by altered circumstances from time to time, he thought that Lord Vernon's committee might point out some improvements, which would otherwise not be accepted.

Letters were read from winners of farm prizes requesting certificates of their success, and the Secretary was instructed to prepare a document suitable to such occasions.

A letter was read from Messrs. Eastons, Amos & Anderson, announcing the retirement from the firm of Mr. J. C. Amos, and that in future their designation would be Eastons and Anderson.

The date of the general meeting in December was fixed for Thursday the 7th, at 12 o'clock.

Farmers' Clubs.

HEXHAM.

Insects Injurious to Turnips.—Mr. T. J. BOLD's paper, recently read before this Club, is here slightly abridged from the *Hexham Courant* :—

Instead of long descriptions, I have sent specimens of the insects treated of, hoping thereby both to add interest to a dry subject and help the farmer to more readily identify his enemies than he would be able to do by any array of words.

Turnip-fly.—Notorious above all other destroyers, most generally spread, found on all kinds of soil, and most persistent and destructive in its attacks, is the Turnip-fly or Turnip-flea ; under which names are included several species of small insects of the order Coleoptera, or beetles, belonging to the family Halticidæ so named from the leaping habits of the perfect insects. Every farmer knows how this pest revels out the destruction of his crop—on that I need not dilate, but will first glance at its economy, and then point out such of the many remedies proposed as appear to me of practical use. Differing from nearly all other pests of the farm—which do most damage when in their larve state—this is only to be feared when it has become a perfect beetle. The parent insect lays its eggs on the underside of the rough leaf of the Turnip, or other plant of the same order. As soon as hatched the young caterpillars eat their way into the leaf, where they feed between the membranes, till grown, when they fall to the ground, in which they become pupæ, assuming in the course of a few days the dress of imagos. There appears to be several broods in one year, all of which become beetles before the winter season, which they pass in a semi-torpid state, beneath the bark of trees or old thorns, in the chinks of posts or rails, in hedge-rows, or any other shelter that offers. Thence they issue on the first sunny days of the spring following to pursue anew their circle of destruction : falling in myriads upon the newly sown fields, they attack the Turnip plants when in the seed leaves, and, by the time the central portions, effectually prevent any further growth. This short lifehistory shows us, I think, that the egg, larva, and pupa, are beyond our reach, and, therefore, all remedial measures must be applied to the perfect insect.

Remedies.—To render the young Turnips plants distasteful to the beetles, many plans have been recommended, such as steeping the seed in brine, in oil, in turpentine, &c., or by keeping the seed mixed with sulphur, sowing the sulphur with the seed in the drill,* using offensively smelling manures and other substances of unsavoury odour ; but in most cases with little effect : nor could we expect it to be otherwise when we consider the powerful deodorising effects of the earth and atmosphere. No better effect appears to have attended the powdering of the plants with lime, soot, sulphur, guano, &c., as the creatures have been found to live and thrive in their midst. Tar barrows, tarred boards on wheels, and tarred cloths have all been recommended to catch the beetles when drawn over the drills, but it appears to me that if a method could be captured that would be practicable, an entomological "sweeping net" would prove a more efficient engine of destruction. This net is simply an iron ring† fixed to the end of a stout stick, with a bag from 2 to 3 feet deep made of stout linen sewed to it. This worked along the drills by a boy or woman (against the wind if possible), would take the insects in thousands, which might then be destroyed by emptying the net, at short intervals, into a large tub half-filled with soap-suds or dirty water of any kind. But I apprehend that the true cure must be sought for in another direction, to wit, in keeping the farm free from such foes as the beetle, which is in a state of nature, such as Runch, wild Mustard, refuse Turnips, and many others. Wherever such plants are allowed to prevail, swarms of beetles are sure to be found. Every means in the farmer's power should be used to induce rapid growth in the first stage of the Turnip ; once in the rough, they are safe. In dry years I have known great benefit derived from mixing salt, at the rate of 2 or 3 cwt. an acre, with Peruvian guano ; the salt creates moisture in the driest seasons, enables the guano to be sown without waste, and also fixes the ammonia. Water, or weak solutions of salt, nitrate of soda, guano, or liquid manure, applied twice a-week, would cause the plants to grow so rapidly that they would soon be out of all danger from the fly, which would be killed at the same time by the excessive moisture, for all insects are injuriously affected by wet, especially if accompanied by cold. Another remedy, and one well worthy of your attention, is that of sowing with the Swedes another variety of

* This was tried by several of our farmers some years ago, but was of little use, and in many instances the mixture was found to prevent the drill working.

† The ring may be of any width, but one from 12 to 18 inches across is the most handy.

Turnip, which, being of more rapid growth, will attract the fly and engage its attention until they are out of danger. The white varieties of Turnip are said to be the most attractive to the beetles, from their stronger smell, which Curtis fears would attract all those living in the neighbourhood and ensure the destruction of the whole crop. Now, if this be so, it points to a remedy. Sow all round the field, next the hedges, a row of whites (perhaps some of the yellow varieties may be equally attractive, and in case they escaped the fly they would keep better), and when they are found to have fly upon them set boys or women to work with the sweeping-nets.

Wireworms and Weevils.—Under the general name of wireworms we find the larvæ of several species of beetles of the family Elateridæ. Some of these creatures pass as much as five years in the larvæ state, all the while feeding upon the roots and stems of plants; the damage they do must, in the aggregate, be enormous. Those parts of the land most trodden down by the cattle during wet weather in winter are always least affected by the pests; perhaps heavy and repeated rolling might have the same effect. Bare fallowing, especially if weeds be carefully kept down, will undoubtedly cause numbers of larvæ to die from want of food, and if frequently turned over so much the better, as they would then be more exposed to their natural enemies, which are very numerous. They form a much relished article of food to birds; rooks devour immense numbers, so do partridges and pheasants, which are often found to have their crops distended by them in hundreds: a female of the latter, shot in January, was found to have swallowed 1225! Fowls and turkeys are said to eat them with great gusto. Lapwings, starlings, thrushes, and many others, are constantly on the look-out for them, and must destroy myriads. The robin comes to the gardener at his work, and picks them up as fast as they are exposed by his spade. They have also many enemies among the carnivorous ground beetles, which eat them with avidity.

The Saw-fly.—So called because the female is furnished with a serrated ovipositor, by which the eggs are deposited; it belongs to the order Hymenoptera, family Tenthredinidæ. This pretty little thing is the parent of the black caterpillars which in many years do such enormous damage to the Turnip crop, and at a time when, having outgrown the fly, it is generally considered to be safe. Fortunately, their visits to this district are not frequent, but when they do take place are most disastrous. The perfect insects appear with us in May and June, generally in small numbers; these deposits their eggs, which produce other and more numerous broods in July, August, and September; the last remaining in the ground as pupæ until the following spring. This short account will, I think, show that a remedy must be sought for more in the way of prevention than cure. When the pest is known to be astir, a sharp look-out should be kept for the first appearance of the perfect insects, and boys set to work to catch and kill them, which is easy to do, as they are only sluggish creatures. Every female of the first brood which is destroyed will, in all probability, prevent the birth of thousands afterwards. Should the eggs have become hatched, the Turnips should be looked over daily, and the infested plants, which are very few at first, collected into a sack, removed from the field and burnt. The sweeping net before mentioned would take them in numbers, and they could then be removed from the field and destroyed. Rooks are said to be very fond of the caterpillars, and swallows have been noticed to devour the imago. I doubt very much their being eaten by small birds, for they always refuse the larvæ of a nearly allied species which destroys the foliage of the gooseberry.* The parent insects are said to come over from the Continent, where they are abundant, being found even so far north as Lapland; and their arrival in clouds is said to have been observed on the Norfolk coast and elsewhere. Nothing of the kind, however, has been seen in our district, so far as I am aware; on the contrary, the mischief always had a small beginning. Thus, in the year 1858, when it was so abundant and destructive, I paid a good deal of attention to the Turnip fields in the vicinity of Newcastle, and the routine to be much as follows:—Small openings in different parts of the field would appear, which enlarged slowly for a few days, and then suddenly spread and run into each other with amazing rapidity. On going over the land, the caterpillars were found nearly full grown twisting about the stumps of the mid-ribs, every particle of green leaf having been devoured. Myriads must occasionally perish of hunger, as I have seen a field completely cleared of the young crop before the caterpillars were half grown, and nothing whatever left for them to feed upon, even the Runch having been eaten up.

Butterflies and Moths.—Next, we have a few individuals belonging to the great order Lepidoptera, so well known as butterflies and moths:—The large white Cabbage butterfly, the small white or Turnip butterfly, the rapeseed or green-veined Turnip butterfly. Wherever Turnips and Cabbages are cultivated, those three butterflies are of common occurrence. With us, they generally confine their ravages to gardens, only when exceptionally numerous becoming pests to the farm; and then it is generally the second broods in July and August to which that term can be applied. As these caterpillars feed during the day on the surface of the leaves, their presence in a Turnip field may be readily detected, and measures taken for their destruction. A very simple, good plan would be for himself or boys to work with sweeping nets; working simultaneously, one on each side of the row of Turnips: if industrious and careful, they would soon clear the infested portion or portions of the field, as this pest is seldom widely spread. When not so numerous, they may safely be left to their natural enemies. Poultry, and birds generally, are fond of them as food, devouring enormous numbers, besides which their insect enemies are numerous. The Cabbage moth, the common dart moth, the heart and dart moth, the yellow underwing moth, night-flying moths, and other larvæ known to farmers and gardeners as surface grubs. That of the cabbage-moth is exceedingly injurious to both Turnips and Cabbages; it devours the leaves of the first and penetrates to the very hearts of the latter, leaving its burrows filled with excrement, and often rendering a whole crop unfit for human food. The caterpillars of the two next are those to which the greatest amount of damage must be attributed. They conceal themselves in the earth, or beneath clods or stones, during the day, issuing thence on the approach of night, to prey upon such vegetation as they can reach; their tastes being so omnivorous that scarcely any cultivated plant comes amiss. When the Turnip plants are young, they are bitten through at the surface of the soil, and, as the caterpillars quickly travel from plant to plant, immense destruction is the result. When the bulbs themselves are developed, they eat eats holes in its lower part, beneath the soil, and there lives and thrives as long as the crop remains on the ground. The last, the yellow underwing moth, is also a frequenter of Turnip fields, but the damage done by it is trifling in comparison. The habits of these pests render them difficult to deal with, and no feasible plan has been suggested which is at all likely to be of use on the farm. The most promising is bare and clean fallowing, on which every weed is kept down, so as either to starve or compel them to shift their quarters. If land is known to be much infested, then frequent rolling or treading would be most beneficial. Should the caterpillars be numerous on the leaves, they could easily be taken in numbers by the net formerly mentioned, and destroyed.

Plant Lice, of all farm pests, are most difficult to deal with, for, soft and fragile as they individually are, their numbers and peculiar economy render them truly formidable. As these pests only frequent the under surface of the leaves, where they are completely sheltered, no remedy has yet been found which is not at the same time destructive to the Turnip. Powdering the leaves with lime or other substances can have very little effect, as the aphis draws its support from the interior of the leaves. Cutting off the leaves has been recommended: no doubt a perfect cure, but it must ruin the Turnips. There seems to be no better plan than to leave them to the mercies of their very numerous enemies. Small birds devour numbers; many Hymenoptera store them up in cells as provision for their young—acari and many plant bugs feed upon them, and so do the larvæ of several beetles, flies, and other creatures, as those historians set forth in many of the books of popular natural history.

Two-winged Flies.—Anthomyia radicum is a pest in the shape of a small white footless grub, which eats into the Turnip bulb when young, causing it to decay, and, admitting air and moisture, causes it to decay. This is quite common in our district, and seems to affect all kinds of Turnips, but is most destructive to the white varieties from their softer nature. The Greystone Turnip is very liable to be attacked. I have seen fine crops of it utterly ruined, and that, too, when the bulbs were very large. The parent fly appears to lay the eggs on the crown of the Turnip, between the leaf-stems, and the larvæ, as soon as hatched, eat directly downwards until full fed, when they enter the soil immediately below the bulb, and change into pupæ before the winter commences, not becoming flies until the following year. A large number of the pupæ, found just beneath the Turnips, were sent to me by a farmer friend in Yorkshire. He observed a flock of lapwings to frequent the field daily. Gams, from their scratching habits, will be very likely to be amongst their greatest enemies, and beyond doubt they will be sought for and eaten by smaller birds. Occasionally I have seen considerable damage done by the larvæ of one of the "Crane flies," or, as they are called here, "Tommy long legs." This has often been the case when damp land, which had lain long in grass, was broken up. Naturally they feed upon the roots of grass and other plants, and when those are destroyed they devour whatever may be sown on the land by the former. When Prestwick Carr was drained and cultivated, immense numbers of larvæ appeared, and for a year or two did great damage both to cereal and other crops. A phial full of these larvæ was brought to me by one of the occupiers, but all of them were dead; they were, I think, the produce of Tipula paludosa, a species very abundant in damp meadows. So numerous were they that from 10 to 20 would be found beneath a single clod.

Note on Books.—Curtis, "Farm Insects," royal 8vo, col. pl., Blackie & Son. Kirby and Spence, "Introduction to Entomology," crown 8vo, 9th edition, Longman & Co. These two books ought to be in every library. They not only contain an immense amount of general information on insects injurious or beneficial to mankind, but they are also of special value to every one connected with agriculture and horticulture. As the name implies, the first is more particularly devoted to the farm; most of the insects are beautifully figured, and the text is illustrated by a great number of woodcuts. The fame of the second is world wide, and its price a marvel of cheapness.

IXWORTH.

Double Ploughs.—Annual Meeting and Dinner.—On this occasion Mr. GEORGE SYMONDS, one of the judges of the ploughing, said he and his colleagues had done all they could to do justice in the matter of the ploughing. If they had not succeeded in pleasing everybody, he might say they had at any rate satisfied themselves. With respect to the character of the work, the judges considered that the ploughing in Class 1 (ploughing with wheel-ploughs) was remarkably good. Some of it, however, he might say was not quite so deep as the rules of this Club required, but taking it as a whole it was a very good piece of work. In the other classes the ploughing was not done so well. It missed several inches of being the required depth, according to his own opinion and the opinion of the other judges. He was now referring to the stubble land where it was ploughed for summer land—it was only 4 inches in depth, and he had thought it ought to be ploughed at least 8 inches in depth. After having gone over the ploughing for prizes, the judges went to the land ploughed by the double ploughs, without knowing the work of the particular ploughs. They observed one piece of land which had been ploughed particularly well, very much better than the others. The number was "3," and he was glad to find this evening that it was done by Messrs. Ransomes' double plough. He considered that that piece of land was ploughed much better than any other land he had inspected that day, with the exception of the first class.

Mr. JAMES EDWARD RANSOME said double-furrow ploughs had a good many advantages, which, perhaps, were not seen at first sight. On light land, two horses are usually employed to a single plough. That was generally an excess of power which was not really wanted, and if it was possible to divide the two horses into other subdivisions of the two parts, they would not probably use so much power as they now did, but, inasmuch as one horse was not sufficient, two had to be used; but the double-furrow plough, properly made, did not take more than half as much again draught-power as a single plough, and two horses were often sufficient to work a double plough on a light land farm. He was not, of course, speaking of special work, such as 10 or 9 inches deep, but of ordinary ploughing, at 5 or 6 inches. In the case of raixed soil land, three horses on a double plough were often equal to do the work of four, and there was, therefore, a saving of one horse out of four. On very heavy land, where three horses were employed on a single plough, four horses would generally be able to do the work with the double-furrow, and there would then be a saving of two horses out of six. As to the experiments which had been made that day, Mr. Manfield stated that the draught of their R. & D. working on a stubble soil, averaged 4¾ cwt., the furrow being each 9 inches wide and 6 inches deep. Taking the draught of a single plough on the same land at 3 cwt., it would be seen that their horses could comfortably perform the work with the double-furrow plough. The horses would not be working harder than with the single plough, inasmuch as they took only one-half more draught; and it must be patent to every one who considered the subject that there was an advantage beyond any reduction that could be made in the draught of the ordinary plough. Take, for instance, the single plough, which required two horses. In order to make that into a suitable draught for one horse, it would be necessary to reduce the draught one-half, and that would not be possible. It might be reduced a fourth, but by putting two together it was possible to effect some of it by using three horses, because then the draught power was exactly equal to the work. Another advantage was, there was not so much treading of the bottom of the work. There was also the saving of the men, and the getting over the work at the proper season of the year. There was in the new plough a considerable saving in the draught in some soils by the use of the friction-wheel. He might, perhaps, be allowed to point out what the actual money saving effected by the use of double ploughs would be. The ploughing per acre with two horses, putting them at 2s. 6d. each, and the man at 2s., with a single plough, would make 7s. per day. That was exclusive of the wear and tear of the implement. The double plough, with three horses at 2s. 6d., and the man at 2s., would make 9s. 6d., half

* This lays its eggs on the under side of the leaf along each side of the ribs, and the larvæ as soon as hatched eat small holes which are easily seen. If these leaves be taken off, or dusted with powdered white Hellebore, the larvæ will be prevented spreading, and the crop saved.

of which was 4*s.* 9*d.*, showing a saving of 2*s.* 3*d.* per acre on all the ploughing that was done. It would be found that on an average the whole of the arable land on a farm was ploughed twice a-year, some parts requiring but one ploughing, others three or four, and it therefore made a saving of 4*s.* 6*d.* per acre on all the ploughed land. On the other hand, there was no gain if the horses, which had been saved by the use of double ploughs, were standing still; but he took it that on most farms more horses were kept than would be necessary for the other operations, provided the ploughing could be got over, at the right time of the year, with a lesser number. He had made some remarks on this subject a short time since, and had given some data on this point, which had not been quite understood. It would now be understood that the basis upon which he went was this, that more horses were used than would be the case if the ploughing could be accomplished at the right time of the year. Supposing, to illustrate his remarks, he took a farm of 300 acres of arable land. He did not think it would be an extreme calculation to say that on such a farm 12 horses would be required, six men, and six single ploughs. If three double ploughs were used, only nine horses and three men would be required to work them, and they would get over the same quantity of work, and there would then be a saving of three men and three horses. These three horses, or at least two of them, might be dispensed with during the greater portion of the year, and perhaps the whole; and the time of the men who would otherwise have been employed in single ploughing would be saved. Taking an average of farms, some light, some mixed, and some heavy soils, an acre per day was considered with an ordinary plough, and double this quantity, or 2 acres a day, might be considered a fair day's work for a double plough. At this rate, the ploughing on the farm would take about 17 weeks per annum. The following calculation would show the saving effected:—

Interest on the value of three horses at £30=£90, at 5 per cent.	£4 10	0
Annual decrease in value, at £2 each	6	0
Hazard of loss at 5 per cent.	4	10
Annual value of food for three horses, at 12*s.* a week ..	93	12
Shoeing and farriery, at £1 each	3	0
Wages of three men, for 17 weeks, at 10*s.*	25	10
Total	£137	2
Deduct interest on value of three double ploughs, at £10, at 5 per cent.	1	10
	£135	12

On 300 acres this amounted to 9*s.* per acre. If only two out of the three horses could be dispensed with, the saving would still amount to £100, or 6*s.* 6*d.* per acre. If the gentlemen present would consider these figures, they would find that there was something substantial at the bottom of them. Some advocated the using of the spare horses in other work. If the horses were turned to another account, and the produce was increased thereby, there would, he thought, still be a saving of the amount he had named. It did not matter to the firm he represented whether they sold single or double ploughs, but it was a matter of considerable importance to farmers, if by the use of double ploughs they could effect such a saving, or even half as much as he had named.

HADDINGTON.

Harvest Wages.—The CHAIRMAN (Mr. George Hope, of Fenton Barns) said he might first make a remark or two on the past harvest. They all knew what a wet and disagreeable summer it had been. Indeed, until the end of July there was no summer; and it looked as if the grain was never to reach its golden hue: but the blaze of fine weather which set in at the beginning of August saved the crops, which generally were equal to an average. The Wheat crop, however, from having been in bloom during the wet weather, was by no means a good crop. His own estimate was that it was short a fourth, particularly when they took into consideration the quantity shaken by the high winds. The remarkably hot weather at the early part of August brought on all the crops with unexampled rapidity—ripening almost the whole country at once. He did not know what they would have done in Haddington in such extraordinary times; but fortunately they had now the reaping machines, which were of the greatest possible advantage in enabling them to secure their crops. Formerly, for every labourer on his farm, the farmer had at harvest to hire two at least. Now, it was the reverse; and for every two men they had on the farm they hardly required to hire one. Formerly, when so many were needed, labourers came to the county in considerable numbers, and a weekly market was held at Linton, at which great difficulty was often experienced in making the wages; but when these were once fixed, they were generally adhered to throughout the county. Since the introduction of the reaping-machine no such market was held; and the fixing of the wages was generally done by a number of farmers meeting together on the Fridays at the market, and arranging what the wages for that week were to be. Now, he did not think this was a very proper way of conducting the matter, and he was astonished that year by year the number of labourers was constantly diminishing. Thus this year those who were quick in beginning procured a number of hands; but those who were two or three days behind could scarcely get a single labourer. Now, the question was whether this system of settling the harvest wages in the market, after the week's work was actually nearly done, was a good and proper one. He di l not think it was, and he thought it must tend year by year to reduce the number of people who came here to work. If he was a labourer, he would not come to a district where beginning to work he knew not what wages he was going to get until the end of the week. Surely the labourer should know what he was going to work for. It was not possible to fix the wages for the county one way or another. It depended so much upon the supply and demand, and other circumstances; and so it was not possible for any committee to fix the hire of labourers before harvest began, or make the wage to last over the harvest. The wages were generally fixed for a single week, and varied from week to week. His opinion was that it would be better were farmers themselves to engage harvest hands and fix their own wages for the three or four weeks he was to have work for them. If that was done, and every man left at full liberty to do as he chose in the matter of wages, he thought it would be an improvement. The theory at present was that one man did not like to act differently from his neighbours, and feared that in fixing wages with labourers he was doing something wrong. It would be much better if it was at once understood that every man was to make his own bargain about wages, and that his own remuneration was to be good binders, and not to be held responsible in doing so that he was fixing what his neighbours should pay. That was his own solution of the question, and he believed it was the practice generally adopted in all other districts throughout Scotland.

Mr. DUDGEON (Athelstaneford) said there could be no doubt that reaping-machines had made farmers much more independent of outside aid at harvest. They could now command three-fourths of the necessary labour on their own farms; and strangers knowing this, did not now come in large numbers to the county. Still, a few strangers were necessary to get the work, and everything like good and fair encouragement should be offered to these people. He advocated a difference of wages between bandsters and stookers—the latter being considered the heavier work of the two, and requiring to be better paid; and if the system of fixing, he considered, were now absolutely obsolete, there being nearly no work for them. He agreed with Mr. Hope that it would be a good thing to engage hands at the beginning for the whole harvest—giving them a good respectable wage; but as there was diversity of labour in the county, he thought that must be taken into consideration. He did not wonder at reapers not liking the present system of fixing the wages on the Friday for the current week. They did not know when they began work how they were to be paid, and were apt to think that the matter was concocted by the farmers in their own interest. At the same time, a uniform wage throughout the harvest could not, he was afraid, be maintained. It would give rise to heart-burnings in different parts of the county. Some general approximation to uniformity was, however, more desirable than everyone being left to make his own bargain. At all events, whatever system was adopted, he was sure farmers had no desire to take advantage of their workpeople; on the contrary, he was convinced it was their desire to give fair and reasonable remuneration to those they employed.

Mr. HARVEY said that his experience of the old Linton port system was the reverse of satisfactory. Very considerable difficulty had then been experienced in making the wage; and he had known a second wage made after one had been agreed to, and, after all, farmers paying 2*s.* more than the port. As to the present system, he thought there had been little difficulty or complaints during the last two or three years in the matter of wages than previously. At the beginning of the harvest strangers were willing to work for anything they were offered; but after 10 days or so, they would go to Berwickshire, where they knew they would get 2*s.*, whatever the wages were offered them. It was therefore hopeless to expect to prevent them going into Berwickshire. For his own part, he generally gave 14*s.* for the first two weeks; and he had paid as high as 18*s.*, and found that the men so paid were the cheapest in the end. At the same time, when the labour market was so agitated, and strikes so rife, he thought it very injudicious to introduce and discuss this subject. The work-people might misconstrue their motives, and think it was for the purpose of keeping down wages. He was in favour of every man taking his own way in the matter, and he meant to do so, whatever decision the Club might come to.

Mr. SCOTT SKIRVING said that as far as he could see, Mr. Harvey was going to do very much what Mr. Hope had advised the Club to endorse with their approval. He thought that Mr. Hope, having introduced such a subject, was bound to have come before them with a more matured scheme. Mr. Hope proposed to unsettle something which existed, without putting anything definite in its place. The present plan of fixing wages was an improvement on the Linton port; but he did not think Mr. Hope's suggestion an improvement on the Haddington system. Personally, being an early man, he experienced no difficulty whatever in getting labourers at harvest time. On the contrary, his difficulty was to say "No" to those wanting work; and any year he could get his corn cut at 11*s.* and 12*s.* a week. He had therefore no interest in discussing the question. Had it been proposed to vary the wage according to the efficiency, he would have set his face against it because, however good in theory, that was quite wrong in practice, and would create a mutiny on every farm. The lifters were generally men from colliery districts, who came to the harvest for a change of air—a kind of holiday. They could make far higher wages at home than farmers could give them at harvest; and to give them lower wages than the binders would be to prevent them coming altogether. In the present discussion, they were dealing with a very limited number of the harvest labourers. Their own people, and wet-and-dry men, had their wages fixed before hand; and it was only with the residue that they had to deal. He held that the present system was a better than that Mr. Hope's proposal, that everybody should act on their own hook. Nothing could be worse than total absence of co-operation in the matter of the wages to be paid during the harvest. Unless Mr. Hope could propose something better, he would be inclined to suggest that a committee should be formally appointed to fix the wages week by week. The constitution of the committee might be made more formal and representative—if the work-people would take part in it by all means—but at any rate anything almost would be better than the Chairman's suggestion.

Mr. HARPER said there could be no doubt the subject was attended with difficulties; but he thought it would simplify matters very much, and remove most, if not all, grounds of complaint, if the wages, in place of being fixed at the end of the week, as at present, were settled a week in advance. It was a just cause of complaint to ask a man to work a week before telling him how much he was to get for his labour. Were that altered, he did not see how the present system could be further improved upon. The fluctuations of supply and demand, and the exigencies of different districts, rendered it impossible to fix one wage for the whole harvest. It was complained that larger wages were paid in Berwickshire. That was true, but it was only first-class men who were taken on there. The farmers in Berwickshire would not employ the hands employed in this county, and give them the high wages which they paid to first-class men. The case was in a nut-shell. Let them fix the wages before the work was begun, and then no one could have any reason to complain.

Mr. SMITH (Whittingham) did not like Mr. Hope's suggestion. Although not intended, it had an unfriendly and unsympathetic aspect, and would lead to greater complication and dissatisfaction among all parties than the present system. Mr. Harper's suggestion was a very good one, to fix the wages in advance, and he thought that was all the length they could go in the matter at present, and that it would go far to remove any complaints against the present system.

Mr. UPTON said that these travelling bands of bandsters and stookers, who went about making bargains, and then taking the highest wage offered after engaging with other farmers, were the curse of the district; and Mr. Hope was the friend of the agricultural community for the case of the kind which he had brought before the sheriff. He agreed with fixing the wage beforehand, and blamed the early men, by the low wages they paid, for driving labourers out of the county. They could not expect men to come to the county for 7*s.* or 8*s.* a week.

Mr. SKIRVING: I never paid 9*s.*

Mr. PATON: I have even heard 7*s.* 6*d.* mentioned.

Mr. DURIE likewise concurred with Mr. Harper's suggestion.

Mr. ROBERTSON (Newmains) thought the wages at the beginning of the harvest were generally fixed at too low a rate. It was absurd to ask an able-bodied man to work six days for 10*s.* The consequence was that after the first week they were left to get through the harvest with their own people on the farm. He proposed that wages should be fixed on the plan suggested by Mr. Harper, by a committee composed of representatives from different districts in the county meeting at Haddington every Friday.

Mr. SMITH (Stevenson Mains) said that even although a certain wage was agreed to by such a committee, no farmer in the county would be bound to adhere to it, if the circumstances of his farm, or other contingencies, were to make it advisable for him to pay a higher wage.

Mr. HOPE briefly replied. He thought that substantially most of the speakers seemed to be very much of his own opinion as to farmers being left at liberty to make their own terms for harvest work. He had no wish to act in an unneighbourly or unfriendly way towards his brother farmers. Quite the reverse. But the present system was admitted to be unsatisfactory, and although it would be an advantage to fix the wages for the coming in place of the current week, still he saw difficulties in the way of its working out, such as their forestalling the state of the labour supply. All he wished was, that, without doing any injury to their neighbour, they should be left to make their own terms for harvest labour.

Mr. SKIRVING said it would be a pity, since the subject had been brought up, not to do something in it, and with that view, he proposed that it should be remitted to a committee to consider the whole subject, and bring up a report at the December meeting of the Club.

Mr. DOUGLAS seconded the motion, which was agreed to; and the following committee appointed; Messrs. Hope (convener), Harvey, Douglas, Robertson, Scott Skirving, Durie, and Harper.

Notices of Books.

Annual Report on the Management of the Government Experimental Farm, for the Year ending March 31, 1871. Madras.

This blue book contains Mr. R. Robertson's report on the Government Experimental Farm and Farm Estate at Madras, with appendices on Dolichos uniflorus (Horse Gram) as a green fodder plant—on the Sorghum vulgare (yellow Cholum), another fodder crop—on the cultivation of Carolina Paddy—on cattle and sheep feeding experiments—on water lifts—on the cultivation of Queensland Maize. It bears, certainly, capital testimony to the energy and industry of the farm manager, and it contains a great deal of useful information for those interested in the agricultural prosperity of India. And the following extracts show that it contains good reading even for those interested in the agriculture of England:—

Deep Ploughing in Drought.—"Ransome & Sims', and Howard ploughs have been in constant use whenever weather permitted. Both large and small ploughs have been employed, the former we find useful when the ground is so dry and hard that the light plough cannot penetrate it. Both cattle and coolies work them well. The coolies readily learn the use of the plough; some are very good ploughmen, and are as proud of their skill as any English ploughman, indeed, I have seen some of them turn as straight and regular a furrow as I ever witnessed in any of our champion ploughing matches. A remarkable change has taken place in the observations of the ryots who come to see our operations during the months ago, one of their greatest objections to our ploughs was, that they ploughed too deep; now, after we have had a very dry season, and they have seen for themselves how our crops thrive and looked fresh and healthy while theirs were parched and dried up, they no longer make this objection. The chief objection they now advance against our ploughs is their great cost in comparison to native ploughs."

Boiling or Steeping Grain (Gram) for Food.—"In cattle feeding the results of my experiments with steeped gram have been most successful, For some time the cattle on these farms were all fed on steeped gram. Amongst many others the following experiments were made, to test the relative feeding values of boiled and steeped gram. A lot of 16 draught cattle, similarly worked, was equally divided. One lot was fed daily on 12 lb. of boiled gram and 12 lb. of ground-nut cake, while the other lot received daily 12 lb. of steeped gram and 12 lb. of ground-nut cake.

"The animals on the boiled gram—

	lb.
Weighed at the commencement of the experiment ..	6339
27 days afterwards they weighed	6576
Showing an increase of	237

The animals on the steeped gram—

Weighed at the commencement of the experiment ..	6310
27 days afterwards they weighed	6576
Showing an increase of	266

"I amso satisfied with the general results of these experiments that I will, in future, abandon altogether the boiling system, and adopt the cold water method.

"It is difficult to state the exact number of grains that it is necessary to step gram before it is fit for consumption; so much depends upon the temperature of the air: if the weather is very hot, a shorter time is necessary than during cold weather. But each experimenter can decide this for himself; it is only necessary, at a known time, to put, say, an ounce of raw gram into a tumbler of cold water, and to note at what time it ceases to expand. Under ordinary circumstances, 15 hours is sufficient."

Rotation of Crops.—"Undoubtedly many benefits result from the adoption of a rotation in cropping; still, these advantages may be purchased at too high a cost. In a well-cultivated district which is not subjected to any great atmospheric changes, but where the seasons recur with clockwork regularity and with perfect uniformity, it may be desirable to introduce a regular system of rotation. A proper arrangement of crops not only often enables the farmer to make the best use of the plant food in his soil, but tends to conserve these fertilising ingredients. One tribe of plants thrive and luxuriate upon food which may be only be useless, but even noxious to another tribe. One order of plants delight in lime, another in phosphoric acid, a third in potash, and so on. Some plants have tap-roots, some fibrous roots; the roots of some plants feed on the surface of the land, while the roots of others derive their sustenance from the lower stratum. Some plants are consumed by stock on the farm, and the excrements of the animals fed on them are again returned to the soil; while others are removed from the farm, and none of the fertilising matters they contain are returned to the soil. Some plants have narrow leaves, and have an upright habit of growth, and encourage the growth of weeds; while others have broad leaves, and put out lateral branches, which shade the ground and check the growth of weeds. If a certain crop is cultivated year after year on the same piece of ground, it will ultimately remove such a quantity of the particular plant food it delights in as to render the raising of a remunerative crop of this particular plant a matter of great difficulty. Granting that, by careful manuring, the elements of plant food taken up by a certain crop can be regularly returned to the soil, there are still many difficulties to contend against. Thus, it has been found that certain insects prey on particular crops, and that if these crops are repeated too frequently, they increase to such an extent as to interfere very seriously with the profitable culture of these particular crops. Again some plants—many of the leguminous for example—have large fleshy roots, in which they have stored up a large amount of nitrogenous matter, which they have elaborated from the ammoniacal matter their leaves have taken from the air; these roots, when left in the soil, decay, and afford a large quantity of excellent food for the following crop. This is well known in England, where a good Clover crop—and therefore plenty of fleshy roots—is invariably followed by a good crop of Wheat, and I have noticed here that the cereal crops after a grain crop is generally a good one. Though a large crop of gram removes a good deal of lime from the soil, it is nevertheless considered by ryots as a restorative crop, and the reason I have just given explains this apparent paradox. This farm being devoted exclusively to experimental cultivation, I have adopted no rotation of crops; it is useless to attempt to fix a rotation until we have discovered all the qualities and peculiarities of the different crops we are called upon to grow. We might afterwards devote a portion of the farm to experimental rotations, but at present we have not the space to lay aside for the purpose. On the 'Model Farm,' however, as we get the land under regular cultivation, I intend to adopt a rotation in cropping: still this cannot be done for some time. The uncertainty of our spring cropping in this locality, owing to the irregularity of the rainfall during the prevalence of the south-west monsoon, will always be a hindrance to the establishment of a fixed rotation, as the possibility or otherwise of growing a spring crop will always affect such a rotation. A fixed rotation of Turnips or Clover always upsets a rotation in England: but the case must be much worse here where the weather may be such as altogether to prevent the sowing of one of the crops in the rotation. As far as my experience in this country enables me to judge, I would suggest the following dry land rotation as one worth trying on the better kinds of sandy loams in districts circumstanced like this:—

"Autumn Crop.—Maize: well manured; followed by horse gram, consumed on the land by sheep.

"Spring Crop.—Gingelly.

"Autumn Crop.—Cumbo: manured with well rotted foldyard manure, with about 1 cwt. per acre of bonedust.

"Spring Crop.—Cumboo: as a fodder crop; consumed while green on the land by sheep and cattle.

"Autumn Crop.—Yellow Cholum: well manured with foldyard manure; first crop seeded, second crop eaten on the land by cattle and sheep.

"Spring Crop.—Cumboo.

"Autumn Crop.—Green gram: well manured; followed by Tenney.

"Spring Crop.—Indigo: ploughed in.

"Autumn Crop.—Maize: as before.

"This rotation would, I believe, if used only including four crops as it would in England, it includes ten crops. Of course many modifications of this rotation could be adopted; indeed it is impossible to suggest a rotation that would suit in this rotation the seven crops, the produce of which can be sold; the other three are restorative crops, being consumed on the land. This rotation provides for an abundant supply of fodder at all seasons of the year—also for the frequent change of crops—and it is arranged for the manure to be applied to the autumn crop during the heavier monsoon, as when applied to the spring crop with a light rainfall, as in either there the plant too much at first, rendering it unable to withstand the effects of a drought, or, if the weather be very dry, it remains undecomposed in the land, making the land light and porous, and adding greatly to the injurious effects of the drought. A 'hundred acre farm,' under this rotation, will annually have 25 acres under Cotton, a much larger area than I think it would be safe to grow under any paramount circumstances, while during the year a surface equal to 150 acres will be available for growing crops for human consumption."

Farm Memoranda.

BANFFSHIRE, BOYNE DISTRICT: *Oct.* 28.—Crops of every kind being now secured, the plough is again at work throughout the district, save where the ground is the frost. A good portion of the grain crops was secured in this district before the weather broke, and was got in good condition, and will be of fine colour and quality; but a remainder stood long under the wet weather, and was a good deal spoiled, and was taken to the barn-yard in very indifferent condition; but, thanks to steam, it has been quickly manufactured and put out of harm's way, and to all appearance the bulk is about an average of former years. But owing to it being in very indifferent condition when carried, on most farms a good portion of the stacks have stood in them, so that it is not so good judging by the size of the stackyard.

A great quantity of Barley has been threshed in this district, but is not turning out so well as last year, neither as to quantity or weight, 57 lb. and 58 lb. per bushel being the highest but Oats are turning out well and heavy. Beans were a very good crop, and have been got in fine condition. Potatos are mostly now lifted, and are an excellent crop, and almost free from disease. Turnips in some cases are almost a failure from want of rain, but where free from canker are a very heavy crop, and with the open weather we have in the meantime are bulbing well. They are letting at from £9 to £10 per acre, with straw and accommodation for cattle.

We have a long list of farms in the county infected with "foot-and-month," but it is not of a very severe kind—it wears off lightly, but spreads very rapidly; we are, however, nearly clear of the more fatal pleuropneumonia.

Draining is going on mostly on every farm in the district, and the quantities of tile pipes laid down on some fields indicate that they are to be thoroughly dried.

Wheat-sowing has been going on for some time, but there does not seem to be a great breadth laid down this season. What has been sown has been got in well.

Very little of the Wheat crop has been threshed yet, except for seed, but is expected to turn out well.

Live stock is very kind to selling at high prices, grain also at a fair price; so that farmers in the meantime have little to complain of, and labourers are mostly all employed at good wages: so we are, and ought to be, thankful. *W. Y.*

A PICTURE OF LANDLORD LIFE IN ABERDEENSHIRE.—We take from the *Aberdeen Press*, quoted by the *Farmer*, the following admirable speech by Sir John Clark, Bart., of Tillypronie, on the recent occasion of a dinner and ball given by his tenantry. It may be mentioned that Sir John made no response until the health of the "gudewife of the feast of the evening," as he phrased it, was proposed, "as he wanted to kill two birds with one stone." Sir John, after a few preliminary remarks to the effect that he believed the kindness shown to him and Lady Clark was due to the fact that both had resided among them, and both were sorry to confess that they had no been able to go about so much as they could have desired, observed:—

"It is a matter of pleasant surprise to us that you have been able to divine our good intentions, and taken them for the deed. Indeed, this over-appreciation of our merits is only explained to me by this—that it does sometimes that in this lone corner of the Braes, since the old House of Pronie, on the very spot where we now stand, was burnt down in the 45—you have never, I believe, had a 'laird o' the lan' fairly living and moving about among you, and really have not had an opportunity of knowing what manner of men lairds are,—in these days, at all events. I verily believe that the only ideas of many of you, as regards a laird, were those from the lairds' 'Twa Dogs.' Now, I am not one of those who are inclined to exaggerate the great benefit derived from the residence of the 'laird o' the lan'.' Not unfrequently, in their very anxiety to confer benefits, they bother the manners and habits of a district, they are all too apt to disregard too much the legitimate independence of their neighbours, and in their very benevolence, but too frequently by injudicious aid, they are apt to sap and destroy their self-respect and self-reliance. Indeed, I have often thought that if a landlord is but just, considerate, and reliable with his tenants and dependants, he may do many good things without the present himself from his door. Nevertheless, in the main, I do think it most desirable that all classes should see and try to know as much as possible of each other; and I do regard it as a great misfortune to you, and to us also—Lady Clark and I feel it very keenly—that by a most unlucky chance it does so happen that the three or four other owners in this little corner of Cromar of ours, are by circumstances precluded from living amongst us. I regret this the more, inasmuch as it also so chances that they are, one and all, as well as the good landlords we know them to be, exceptionally genial, courteous, kindly folk,—one and all of them eminently embued with the great Christian principle that 'a man's a man for a' that.' And if they could but live among us, we should all delight in their presence. Beginning, then, to the east, with Mr. Duguid Milne, at Migvie House, he is one of the most cultivated lawyers of Aberdeen—an accomplished writer, a genial, friendly man, full of Scotch humour, delighting in a Scotch joke, and, altogether, a man such as would delight us to have among us. Unfortunately, we enjoy the old saying, he has 'twa roods o' Don for ane o' Dee,' and we all know what that means, and on his 'roods o' Don' he has a large house; and he tells me that, although greatly tempted to build another here, he found he could not manage to live in three places; and therefore, to his loss and ours, we cannot have him among us. Coming over the sky line to Blackmill, young Lord Huntly, besides taking a deep interest in the improvement of his estates, the well-being of all on them, is full of frank, friendly courtesy to all, and we should delight to have him too with his young presence among us. But his interests are bound up in his castle in stupid swamp at Aboyne, instead of the dry braes here of Tulloch, and we can only have a gliff of him now and again. Hopewell is not up to our corner, rightly speaking. Then, Dr. Bertram is here among us, as it happens, to answer for himself; but I do not like to pass round so near it, without reminding you of the spirited manner in which he has improved that little estate. He has the advantage of as all in his great experience and knowledge of the wants of the district, and is turning that knowledge to account in bringing about improvements, sanitary and others, by which we shall all benefit. Then, Glenkindie, to the south, for that I am specially answering, and going west to Migvie, in Mr. Farquharson we have, too, the gentlest, kindliest of men, and one, if anything, most considerate of the feelings—I was almost going to say prejudices—of his neighbours—and in Migvie we have just an instance of what I was saying as to the absence of a landlord, when considerate and reliable—where will you find in the district tenants who have done and are doing so well? Still I do wish it was not so far a cry to the House of Finzean. Of my brother-in-law, Mr. Coltman, I have greater delicacy in speaking. Still, I think anybody looking down from the Birkhill tower but to the face of Cromar, and seeing all the snipe-bogs converted into fine farming land; whole hillsides drained and planted; crofts shaping out; plantations and belts made specially to shelter the farms; and labourers' cottages, so much wanted, gradually springing up—would be unobservant indeed if he did not perceive that we have a good landlord among us there. Unfortunately, as a comparatively young barrister, only rising into practice

at the Chancery bar, he does not feel himself justified in taking any but a very short holiday, but I know that it is great self-sacrifice to him not to be able to stay longer. And it is to be recollected that it is greatly and chiefly by sticking thus perseveringly to his profession that he is enabled to carry out more improvements at Deskry. I believe his own tenants have learnt already to value him; and when he does come to stay longer in the parish, and to be more generally known in the district, they will soon find how single-minded, simple, kindly, and public-spirited he is, too. Indeed, they are all, as I said, as well as good lairds, exceptionally good chiefs; and, moreover, Mr. Duguid Milne, who has written so sympathetically upon the rights of women, would never forgive me for forgetting this—they have every one of them couthy, weel-faur'd gudewives. It has been the intention of Lady Clark and myself to live more with more among you; and I can assure that this unmistakeable expression of good wishes on your part gives us that our presence among you is a pleasant one, will make us all the more inclined to do so. Indeed, if we go on piling stone upon stone, cutting drain upon drain, and making fence upon fence, as Corrie there wants me to do, upon this wee hillside, we shall very soon not be able to live anywhere else, and even to live here we shall be obliged to get you down there at the foot of the Braes to keep your eye on the bailiffs, and give us intimation of their approach in time to let us slip away, as the old laird did in the '45, by the pass of the Louise Well. But we are not come to that yet."

The Week's Work.

NOVEMBER 4: *Manure, Economy of.*—The old plan, still common, is to mix the daily cleanings from the stables, cow-houses, and stalls for fatting bullocks and young stock, in the strawyard, where the older store cattle are kept. Under this system, the liquid which flowed from the yards in wet weather, and the drainings from the housed stock were conveyed either into a tank for application to the land in a liquid form, or on to earth in a pit for making compost. Most farmers have both a liquid manure tank and a compost pit. The liquid from cattle fed in boxes or sheds is wholly absorbed in the manure. Under this mixed system there is a great waste of manure both from the housed stock and the yards, with the exception of the feeding boxes and sheds; and the two exceptions, more especially the latter (sheds), are often attended with much waste from being unequally trodden and mixed with the droppings of the cattle, so that decomposition sets in unequally. Where cattle have sheds to go under, for example, they leave much of their droppings outside, so that what is made is often poor—decreasingly taking place less or more all round the walls, in the corners and under racks, &c. The same takes place in feeding-boxes, where the droppings and wetted litter are neglected to be mixed equally all over the box, and trampled hard at the sides and corners with the foot, where the fatting bullock cannot tread it down.

A Covered Homestead is to be preferred to open yards, under proper ventilation and management, there being a threefold economy in favour of the former. Thus there is (1) a saving of food, (2) stock thrive better, and (3) there is no waste of manure. But the mere covering of a homestead will not of itself effect such results; on the contrary, it requires increased skill and labour under each of the above heads before the threefold economy can be effected; more attention requires to be paid to the preparation of food, the health of cattle, and the management of the manure, so as to have it of uniform quality, and free from waste and noxious gases. A sprinkling of dry earth, on the principle of the earth-closet system, is the best deodoriser, but unless the manure in the feeding-boxes and covered yards is properly mixed, the different kinds together, and the wet with the dry, and all uniformly consolidated, there will be a waste of both dry earth and manure.

Swedes and Kohl Rabi are harvested in the same way as Mangel Wurzel. They are less liable to be injured by frost than Mangels; but the difference, so far as storing is concerned, is not so great as is generally imagined; so that an equal degree of precaution is necessary to avoid rotting in the pits. Both crops suffer much in the pits, where the bulbs are broken or cut too close in topping and tailing so as to bleed, for although they may not rot, yet mouldiness takes place, thereby injuring their dietetic value to neat cattle and sheep. It is always better to throw aside broken bulbs for immediate use than to store them in pits, for, whether they become mouldy or rot, they affect and injure the whole.

The Stable.—Farm-horses keep in healthy working condition. Some begin about this time to reduce the allowance of corn for the winter months, but the practice is based upon old notions out of date; for by starting early and working late the horses can do nearly as much work in winter as in summer, whether ploughing or carting. Many farm-stables are dirty, badly lighted and ventilated, and horses suffer much during the long night's confinement in such places: the smell when they are entered in the morning is enough to kill a dog, so to speak.

Gorse comes into use when the grasses fail. When properly bruised it makes an excellent diet for milch cows, ewes, and lambs, and Gorse should be more extensively grown for both these purposes. Sheep also browse the plant greedily, and therefore it should be grown more largely on mountain walks both for shelter and food. If a man can cut as much in a day as will supply 16 cows, and if an acre and a half will yield this supply for a month, it is easy to calculate the value of an acre in comparison with grass or any other crop. The calculation thus made is at the rate of 3 bush. of bruised Gorse to each cow daily; with 2 bush., and roots of some kind, an acre would serve the 16 cows six weeks, and so on.

Fatting Stock, as they take to their winter food, will bear a little forcing. The expression will not perhaps be relished by some, any more than the practice itself, but successful experience has long ago proved to farmers that unless their bullocks and sheep begin to lay on carcase weight fast about this time, it will not pay; hence the practical rule, "Start your beef and mutton manufactories into full play in November." To have animals in the full enjoyment of the highest degree of health on winter food, is a totally different thing from gross obesity. The latter should be carefully avoided.

Notices to Correspondents.

BONE DUST: *H. T.* You had better boil the bones in the first place, as you propose, and then, when the bones are dry, they may be broken small with a hammer, if you have no other implement for the purpose. When broken small, half-inch dust, apply about 50 lb. of sulphuric acid to every cwt. of bones, in a small pit dug in the clay soil, having first poured in as much water as the dry bones will take up.

SUGAR-BEET: *Mush.* Land in good condition will grow Sugar-Beet without manure, but you ought to apply a dressing in autumn. It is worth your while to pay a visit to Lavenham, Suffolk, and learn their experience there. We do not know of any market for it on the South-Western Railway.

Markets.

HOPS.

BOROUGH MARKET, NOV. 1.

Messrs. Pattenden & Smith report the market very firm, with a good retail inquiry for consumption, and all the best brewing descriptions are rapidly becoming absorbed. Really choice sorts are with great difficulty to be met with.

MARK LANE.

MONDAY, Oct. 30.

The supply of English Wheat to this morning's market was moderate. The best samples were taken at last week's prices, but out-of-conditioned parcels were rather cheaper. The attendance was good, and for foreign there was a fair retail demand, at late rates. Malting Barley was 1*s.* per qr. cheaper, grinding unaltered in value. There was no change in Beans or Peas. New Oats were rather lower, good old Corn fully as dear. Maize was 6*d.* to 1*s.* per qr. cheaper. No alteration in the value of Flour.

WEDNESDAY, NOV. 1.

The Corn Exchange to-day was poorly attended, and the business transacted was insignificant. There was a limited supply of English Wheat, which changed hands slowly at about late rates. Foreign Wheat was a good supply. The demand was inactive, but prices were without important variation. Choice Barley was steady, but inferior was neglected. Malt was cautiously dealt in, at previous values. The supply of Oats was good. Sales were effected quietly, on former terms. Beans and Peas were without any value, with a fair supply. The Flour trade was dull, and prices occasionally easier.

LIVERPOOL, Oct. 31.—There was a fair average attendance. Fine qualities of old red Wheat bring Friday's full rates, whilst new is irregular in value, say 1*s.* to 2*d.* per cental lower; white unaltered, and the business is only small. Flour a dull sale, and nominally cheaper. Extensively grown for both these purposes. Sheep Corn pressed ex quay at 6*d.* per qr. decline; mixed, 33*s.* 6*d.*

METROPOLITAN CATTLE MARKET.

MONDAY, Oct. 30.

The number of Beasts is considerably larger, but the average quality is not so good as on last Monday; trade is active for the choicest descriptions, and slow for other kinds; prices on the average are very little altered. Sheep are more plentiful, both of English and foreign; we have a fair average demand, yet prices are scarcely as good as of late. Calves are lower in quality, and trade is slow. Our foreign supply consists of 3420 Beasts, 12,780 Sheep, 224 Calves, and 10 Pigs; from Ireland, there are 700 Beasts; and 1220 from the Midland and Home Counties.

			Pigs	3	4—4 8

Beasts, 5340; Sheep and Lambs, 21,930; Calves, 255; Pigs, 175.

THURSDAY, NOV. 2.

The number of Beasts is larger than last week, but choice qualities are not plentiful; in consequence there is little reduction in price, although trade is slow. The supply of English Sheep is again very small, of foreign rather larger than last Thursday; trade is not brisk, yet there is scarcely any alteration in prices. There is a better demand for Calves; choice qualities are readily disposed of, at considerably higher rates. Our foreign supply consists of 448 Beasts, 5920 Sheep, and 201 Calves.

ENGLISH WOOL.

During the past week we have had a steady market, without material change in price; the tendency, however, is good, and if monetary matters settle down quietly, we think there is every chance of an improvement before the close of the year. Prices of colonial wool are perceptibly dearer, and those kinds which compete with English are in short supply, and much inquired for.

JOSHUA BAKER.

SEED MARKET.

Our markets have been fairly attended during the past week, but the amount of business passing has been limited. New American red Clover excites as yet but little attention in this country; there is a large demand both from France and Germany. Cable advices just to hand from New York quote an advance there of 1*s.* to 2*s.* per cwt. White Clover is in fair supply, and is held at late rates. Alsike is without alteration. For new imported Italian we have a brisk trade, at enhanced currencies; prices are rising in France. Perennial Rye-grasses are also tending upwards. Of Saintfoin seed the English crop is said to be poor. Hemp seed is for the moment exceedingly scarce, and must be noted 2*s.* per qr. higher. Canary seed is now offering at a very moderate figure. For Rape and Mustard values are steady. Feeding Linseed is firm. Haricot Beans and Boiling Peas are without change.

JOHN SHAW & SONS, Seed Merchants, 37, Mark Lane, London, E.C.

COALS.—Nov. 1.

BICKLEY'S PATENT HORIZONTAL SASH-BARS require neither Point nor Putty; an orchard-house or greenhouse, &c., may be easily, cheaply, and quickly made with them by an amateur. Four hundred feet can be firmly glazed or unglazed in one hour. Drawings, &c., for 1 stamp, of the Inventor and Patentee, THOMAS A. BICKLEY, 69, Smallbrook-street, Birmingham.

Proceedings in Chancery will be taken against any person infringing this patent.

CHAPMAN'S "ANTI-CLOCHE" VENTILATED MULTUM-IN-PARVO PLANT, FLOWER and SEED PROTECTOR, preserves Plants, &c., from Snails, Slugs, Earwigs, Wind, Rain, and Frost; quite as useful for all purposes as the Hand Glass or Cloche, and at about half their cost. Any Gardener can repair them.

They are made in nests, of different sizes. Cost of Set, with one for protecting Gladiolus or Hollyhocks, Dahlias, Roses, or Chrysanthemums, for exhibition, with stake clip, and all complete, from One Guinea. The Anti-Cloche can be made any size.

Estimates given to Nurserymen, Market Gardeners, &c., for large quantities. When not in use, they pack in a very small compass, without liability to breakage. To be obtained from

W. E. CHAPMAN, Patentee, Bristol Road, Gloucester.

A remittance from unknown Correspondents will have attention.

Russia Mat Merchants.

Forwarders to all parts of the World.

THE PINE-APPLE NURSERY COMPANY, 28, Maiden Lane, Edgware Road, W.
JOHN BESTER, Manager of the Nursery and Seed Department.
The Company guarantees to their Customers Punctuality, Liberality, and Genuine Articles. The favour of a visit is earnestly solicited.

New Soft-wooded Plants, 1871.

H. CANNELL begs to inform his Friends and Customers that his AUTUMN CATALOGUE, containing all the above, is now ready, and will be sent free on application.
New Florist Flower and Florist Flower Seed Merchant, Wordwich.

To the Trade.

STUART AND CO., of Nice, and No. 5, Tavistock Row, Covent Garden, London, W.C., will shortly forward their WHOLESALE LIST for 1872, containing many NOVELTIES and CHOICE SEEDS.

EDWARD TAYLOR, Nurseryman, Malton, Yorkshire, offers as under :—

PAMPAS GRASS, strong, in pots, 20s. per 100.		
TRITOMA UVARIA, strong, 20s. per 100.		
	GRANDIFLORA, 25s. per 100.	
GIANT ASPARAGUS, 1-yr., 7s. 6d. per 1000.		
"	2-yr., 12s. 6d. per 1000.	
"	3-yr., 19s. per 1000.	
"	4-yr., 20s. per 1000.	
SEAKALE ROOTS, 1, 2, and 3 yr.		
GOOSEBERRIES, 100 varieties, F. T.'s selection, 9s. per 100, 80s. per 1000.		
DOUBLE GERMAN WALLFLOWERS, 5s. per 100.		
TRITONIA AUREA, fine bulbs, 8s. per 100.		
YUCCA FILAMENTOSA, strong, 4s. to 6s. per dozen.		
ROSEMARY, in pots, 4s. per dozen.		
SCILLA SIBERICA, 8s. 6d. per 100.		

CATALOGUES grats on application as above.

Transplanted Scotch Fir.

J. ROY, JUN., NURSERYMAN, Aberdeen, has a very extensive stock of Transplanted SCOTCH FIR, of various growths; a portion of the whole has to be cleared off this season he offers as under to the Trade :—

2-yr. SEEDLINGS, 2-yr. transplanted .. .. 5s. per 100.
3-yr. SEEDLINGS, 2-yr. transplanted .. .. 7s. 6d. per 1000.
Strong and fine do., 18 to 24 inches .. .. 10s. per 1000.
2-yr. Seedling Native SCOTCH FIR .. .. 1s. per 1000.

OF RHODODENDRONS he has a very extensive stock, and to clear out he now offers them, which consists of upwards of 100,000 of PONTICUMS and HYBRIDS and other excellent kinds, from 6 inches to 1 foot high, at 8s. to 30s. per 100.

LIMES.—His stock of these is upwards of 100,000, from 3 feet to 9 feet. Prices will be forwarded on application : they are all clean-grown and fine straight stems.

WM. VIRGO AND SON, Wonersh Nurseries, near Guildford, Surrey, respectfully call the attention of Noblemen, Gentlemen, Nurserymen and Others, to their undermentioned stock; the whole of which is particularly strong and healthy, and in excellent condition for removal :—

Standard, Half-Standard and Dwarf Roses, upwards of 300 varieties; Standard, Pyramid and Dwarf Apples, extra fine; ditto Pears; ditto Plums; Dwarf-trained Apples, Pears, Plums, Peaches and Nectarines; Gooseberries; Black, Red and White Currants; Filberts, extra fine.

EVERGREENS.

Common Laurel, 2 to 4 feet.	Spruce Fir, 2 to 6 feet, fine and bushy.
Portugal Laurel, 2 to 4 feet.	Berberis aquifolia, 1 to 1½ feet.
Green and Variegated Box, 2 to 3 feet.	American Arbor-vitæ for hedges, 3 to 6 feet.
Green Holly, 2 to 3 feet. [4 feet.	Evergreen Privet, 2 to 3 feet, fine.
Yew, 2 to 4 feet.	Hornbeam, 2 to 3 feet.
Siberian and Chinese Arbor-vitæ, 3 to 4 feet.	Cupressus Lawsoniana, 3 to 4 feet.
Pinus austriaca, 2 to 5 feet.	

ORNAMENTAL TREES

Spanish and Horse Chestnut, 6 to 8 feet.	Hornbeam, Laburnum, Lime, Norway Maple, Lombardy, Ontario, White or Abele, Balsam, &c.
Wych Elm, 6 to 8 feet.	
Double, Scarlet, White and Paul's New Thorn, 6 to 8 feet.	
Black Italian Poplar, 6 to 8 feet.	Sycamore, Sumach, Acacia, Weeping Willow and Birch, 6 to 8 feet.
Turkey, English and Scarlet Oak.	

Transplanted FOREST TREES for Covert and Copse Planting.

Ash, 2 to 3 feet.	Scotch Fir, 1 to 1½ foot, and 2½ to 3½ feet.
Alder, 3 to 5 feet.	Hazel, 2 to 3 feet.
Birch, 3 to 5 feet.	Hornbeam, 2½ to 3 feet.
Beech, 2 to 3 feet.	English Oak, 2½ to 3 feet.
Spanish Chestnut, 1½ to 2 feet.	Sycamore, 2 to 3 feet.
Horse Chestnut, 3 to 5 feet.	Plum-leaf Withy, 3 to 5 feet.
Spruce Fir, 2 to 3 feet.	

10,000 clean-grown CRAB STOCKS.
Strong transplanted QUICK, 2 to 2½ feet.
Priced CATALOGUE and samples on application.

The Nurseries are 1½ mile from Bromley Station, London, Brighton, and South Coast Railway; 2½ miles from Guildford Station, South Eastern Railway; and 4 miles from Guildford Station, London and South-Western Railway. Goods delivered free to the above stations.

TO WILLOW GROWERS.—The Planting Season having commenced, WILLIAM SCALING, Willow Nurseryman, Basford, Notts, is now ready to execute orders for

WILLOW PLANTS and CUTTINGS for Timber Trees and Shrubs.
WILLOW PLANTS and CUTTINGS for Ornamental Trees and Shrubs.
WILLOW CUTTINGS for Basket Makers' purposes.
BITTER WILLOW PLANTS and CUTTINGS for Hedges and Game Coverts.
WILLOW STICKS for Budding and Grafting.

Descriptive CATALOGUES free upon application as above.

THE SALIX, OR WILLOW," second edition, post free, 12. 1 of SIMPKIN, MARSHALL, and CO., London.

ORCHIDS. — Gentlemen interested in this class of Plants would do well to inspect our Establishment at Fairfield, and to judge of our mode of growing for themselves. The House we have recently erected, in which the plan of supplying moisture by continued precipitation, without any disadvantage to neatness in appearance, has been the admiration of every visitor, and excites universal surprise that means so simple should have been so long neglected.

JAMES BROOKE AND CO., 16 and 18, Victoria Street, Manchester. Nurseries : Fairfield, near Manchester.

Orchids.

HAVING A VERY LARGE STOCK,

MR. WILLIAM BULL begs to offer the following CHOICE and RARE ORCHIDS, at the extremely Low Prices annexed :—

Establishment for New and Rare Plants, King's Road, Chelsea, London, S.W.

Cerasus Watereri, New Double Japanese Cherry.

ORIGINALLY INTRODUCED by Mr. FORTUNE.

JOHN WATERER AND SONS are just now sending out the above new plant. The colour is white, edged with pink, very large double, and sweet scented. We recommend it as a very desirable plant. Price 10s. 6d. each, or 6 for 42s.

American Nurseries, Bagshot, Surrey.

STRONG STANDARD APPLES, PEARS, and WALNUTS.—Fine Standard and dwarf-trained APRICOTS, PEACHES, and NECTARINES, Standard and Dwarf Perpetual ROSES, Evergreen and Deciduous Flowering SHRUBS, FOREST TREES of sorts, from 2 to 20 feet. Prices on application to CHARLES BURGESS, The Nurseries, London Road, Cheltenham.

The Fairy Apple.

JOHN JENNINGS has fine PYRAMIDAL TREES, with bloom-buds, of the above beautiful dessert Fruit to DISPOSE OF, at 5s. each. The fruit is in season from December to April.

"Destined and worthy to take its place amongst the worthiest of its kind." Nurseries, Shipston-on-Stour.

WHEELER'S BROCKWORTH PARK PEAR.

"The handsomest and most valuable dessert Pear of recent years."

J. C. WHEELER AND SON offer fine young PYRAMIDS of this magnificent PEAR, at 10s. 6d. each, and a few DWARF-TRAINED TREES, at 15s. each. It obtained a First-class Certificate from the Fruit Committee of the Royal Horticultural Society, on September 20, 1870, and was exhibited a the Royal Horticultural Gardens on October 4, 1871, when it was again greatly admired. It is large, handsome, and fine flavoured, and is, without doubt, a great acquisition to our choicest and best dessert Pears. It may fairly be described (when grown against a wall, with a good aspect) as one of the handsomest, largest, and best dessert Pears ever introduced. It ripens the end of September and beginning of October.

J. C. WHEELER & SON have already received orders for it from nearly all parts of the United Kingdom; from Germany (for the Emperor's gardens at Sans Souci, Berlin); from France; and from the United States. Orders will be executed in rotation as received, the earliest getting the best plants.

J. C. WHEELER AND SON, Nurserymen,
Gloucester, and 59, Mark Lane, London.

Fastolf Raspberry (True).

ISAAC BRUNNING begs to offer strong, well-rooted CANES of the above unrivalled RASPBERRY, in packages containing 25, 50, 100 for 5s.; 200 for 8s. Also choice CARNATIONS and PICOTEES, 18s. per 100; 24s. per dozen pairs; FINKS, 8s. to 12s. per dozen pairs [List of varieties on application] ; true old CRIMSON CLOVE CARTIONS, 3s. per dozen; PRINCESS ALICE, fine, pure WHITE Fy, 6s. per dozen; BRUNNINGS PRINCE OF SCARLETS CLOVE, 4s. per dozen; TULIPS BYBLOEMENS, fine bulbs, 4s. per doz.; 25s. per 100; 12s. per 100; ditto flowering bulbs, 12s. 6d. per dozen, 9s. per 100. No charge for packing. Cash or reference to a well-known firm.

ISAAC BRUNNING, Great Varmouth Nurseries.

Eltham Nursery, Kent, S.E.

TWO MILES from BLACKHEATH STATION ;
ONE MILE from ELTHAM, LOOP-LINE.

THIRTY ACRES of healthy, well-grown NURSERY STOCK, of every description, comprising specimen HOLLIES and EVERGREENS of all sizes, Standard ROSES, FRUIT TREES, &c. Gentlemen who intend planting this season are invited to come and select for themselves.

JAMES WEIGHTMAN, Eltham Nursery, Kent, S.E.

ROBERT CORNWELL AND CO, office SILVER SCOTCH, and AUSTRIAN FIRS, 3 to 6 feet; ARBOR-VITÆ, 3 to 6 feet; AUCUBAS, 1½ to 4 feet; PRIVET, 3 to 4 feet; Variegated and Green HOLLY, 2 to 4 feet; do. Edging; IRISH YEWS, 3 to 4 feet; LAURELS, 4 to 8 feet; bushy LAURUSTINUS, 2 to 3 feet, some extra large specimens, 4 to 5 feet; Standard ROSES, strong stocks, Descriptive, CURRANTS, and STRAWBERRIES of sorts; ASPARAGUS, 1, 2, and 3 yr. old; RASPBERRIES, Cromwell's Seedling, 12s. per 100; do. Prolific, 20s.; Carter's Prolific, 10s.; Red and White Antwerp, 10s.; Fastolf, 10s.; Filbasket, 20s.; Fsd's White, 20s.; Semper Fidelis, 20s.; bushy RASPBERRIES, 4 fs., 4s. per 100.

NOTE—Opposite the Red Lion, Barnet, N.

To the Trade.

TWO MILLION 1 and 2-yr. Seedling THORN QUICKS.

300,000 Transplanted THORN QUICKS, 4-yr., 2 to 3 feet.
200,000 do. Common LAURELS, extra fine, 2 to 3 feet.
1,000,000 do. FOREST TREES, from 1 to 2 and 3 feet, consisting of Larch, Scotch, Spruce, and Silver Firs, Thorn, Elm, Birch, Sycamore, &c.

The above will be SOLD cheap. They are well rooted, fine stuff, healthy, and well grown.

GEO. R. DAVIDSON, The Newry Nurseries, Newry, Ireland.

MAGNIFICENT PLANTS of PINUS AUSTRIACA, 4 times transplanted, 4 to 5 feet (perfect specimens); strong ditto, 3½ to 4 feet, 2 to 3 feet, 40s. per 100; SCOTCH FIRS, extra fine, 3 times transplanted, 4 feet; smaller sizes, 2½ to 2 feet, 2 to 3 feet, and 3 to 4 feet, by the 1000. SILVER FIRS, very fine plants, 3 times transplanted, 4 feet.
COMMON LAURELS, 2½ to 2 feet, 2 to 3 feet, 3 to 4 feet, 4 to 5 feet, by the 100, 1000, or 10,000.

CATALOGUES and Prices on application.
WM. WOOD AND SON, The Nurseries, Maresfield, near Uckfield, Sussex.

Quicks and Forest Trees.

SAMUEL ROBINSON, Shaw House, Melbourne, near Derby, will offer, at his ANNUAL SALE, about the 20th of this month, of which due notice, with particulars, will be given—

A very large quantity of 3-, and 4-yr. transplanted QUICKS, suitable for Railway and Enclosure Planting; also about 50,000 LARCH, 3 to 4 feet; a large quantity of a smaller size, for planting out, 20,000 to 30,000 SCOTCH, 2 to 3 feet; a few hundreds of ELMS and BIRCH, 7 to 10 feet; and other sorts of well feathered SPRUCE, 3 to 5 feet; and strong OAKS, of similar size.

The Planting Season.

TO BE SOLD, well-grown SUPPLUS SHRUBS, to be shifted at once by the Purchaser, consisting principally of YEWS and LAURELS, PORTUGAL and COMMON—with a few MISCELLANEOUS SHRUBS, now growing less than a mile from the Whatstandwell Bridge Station of the Derby, Matlock, Buxton, and Manchester Railway.

The Shrubs are good, well-furnished specimens, that would be invaluable where an effect is desired at once, and, if carefully got up would move with perfect safety. Application to be made to the GARDENER, Chase Cliffe, Derby.

Is now sending out the above Currant, in not less than one dozen plants, at the following rates (orders booked as received) :—

1-yr. old Plants, 18s. per dozen Plants.
2 or more yr. old Plants, 24s. to 30s. the dozen Plants.

It will be found a great acquisition on account of its fertility and other good qualities. It is very prolific (name given by the Committee of the Royal Horticultural Society), does not require much room, and is a Nursery the second year after planting producing over 5 cwt. of fine fruit. The bunches are medium length, of almost uniform size in berry, long-stemmed, so as to be gathered without crushing the upper berries. It is very sweet, much more so than the Black Naples, which he has grown largely for near 20 years. It is much enjoyed as a dessert. Is very thin-skinned, and makes a fine preserve. Fetches a much higher price in the market. It will be a good variety for the Market Gardener. Plants can also be supplied by the following Nurserymen :—

Messrs. P. LAWSON AND SON, Edinburgh.
Messrs. T. RIVERS AND SON, Sawbridgeworth.
Messrs. J. GARAWAY AND CO., Bristol.
Mr. C. TURNER, Slough.
Messrs. FISHER AND HOLMES, Sheffield.
Messrs. J. AND C. LEE, Hammersmith.
Messrs. J. VEITCH AND SONS, Chelsea.
Mr. C. PERKINS, Northampton.

EAST SOMERSETSHIRE CHAMPION POTATO.
Report of the Royal Horticultural Society's Trial Committee.
"*Late Kidney, allied to the Fluke.*—A most extraordinary cropper, very handsome, and of good quality."

This is a Potato that we confidently recommend, not only as a late but as a second early, quite fit for the table second week in July, but good late-keeping.

This will be sent out in September and October, in not less than 28lb., 6s. ; 56lb., 11s. ; 112 lb., 18s.—bags included. Remittances from unknown Correspondents. ☞ Stock limited. Trade not supplied this Season.

Five per cent. discount allowed for prompt cash.

RENDLE'S PATENT PLANT PROTECTORS,

All complete, with Patent Grooved Bricks, Glass, and Central Platform.

A Protector 100 feet long by 4 feet wide will cover a piece of ground containing 400 square feet.

These Span-Roof Proectors have given the greatest satisfaction. They can be made to cover a large space of ground by the addition of the Patent Zinc or Galvanized Iron Grooves.

NEW PATENT SPAN-ROOF ENVILLE PATTERN, TWO SECTIONS.—This is a vast improvement on the original Pattern, as all the Glass can be instantaneously removed. Purchasers who have been supplied with the Old Pattern can have the New one at 6*d.* per foot.

The New Illustrated Catalogue for the present season is now published, and contains many novelties. Copies can be had gratis on application to the Inventor and Patentee,

MR. WILLIAM E. RENDLE,
3, WESTMINSTER CHAMBERS, VICTORIA STREET, S.W.

The Gardeners' Chronicle

SATURDAY, NOVEMBER 11, 1871.

MEETING FOR THE ENSUING WEEK.

THURSDAY, Nov. 16 { Royal Horticultural at Ireland (Winter Exhibition).

SOME time since we had occasion to refer to the FERTILISATION of the VINE, and we pointed out certain circumstances which were favourable or unfavourable, as the case may be, to the proper SETTING of the FLOWER in that plant. By way of supplementing these remarks, which were founded on our own personal examination of the flowers of several varieties of Vine, we now call attention to a recent publication of M. CHARLES BALTET, the well-known nurseryman, of Troyes.* The design of the writer is to explain the causes of the imperfect fertilisation or abortion of the fruit in the Vine, a condition known in France as *coulure*, and to point out the appropriate remedies for this defect. M. BALTET'S remarks of course apply to the culture of the Grape on a large scale in the vineyard, but there is much in them that may profitably be applied, *mutatis mutandis*, to the cultivation of the fruit under glass. Moreover, M. BALTET'S remarks are stated with a clearness, precision, and brevity of expression which will go far to recommend them to the attention of practical men. M. BALTET does not refer to what we believe to be a natural tendency in the Vine to assume a unisexual condition, neither does he allude to the numerous observations and experiments that have been made on the fertilisation of plants in general, and the circumstances favouring or opposing the process, which have been made known of late years, and some of which are referred to in our previous article. He looks

* La Coulure du Raisin, ses causes et ses effets, moyens de l'empêcher. Par Charles Baltet. Troyes, 1871. Pamphlet.

at the matter from the point of view that a practical man might be expected to do: his remarks are founded on his own experience—and the experience of such a man is eminently worth having. The principal causes of the "bad setting of the Vine," says M. BALTET, "are to be attributed to abrupt alternations of the temperature, or to its sudden lowering in spring, to excessive vigour or grossness of the vegetative organs (leaves, &c.), or to the opposite condition of feeble growth."

Establishing these as the principal causes of the imperfect fertilisation of the Vine, M. BALTET then goes on to show how they may be prevented, and their injurious effects obviated.

An excessive vegetative growth may be checked, or rather diverted into a profitable channel, by a judicious mode of cultivation; feeble growth may be stimulated by the proper use of manure; unfavourable climatic influences may be counteracted by causing an accumulation of nutritive material in the flower by means of one or other of the following processes—stopping the fruit-bearing branches, suppression of the tendrils, removal of the extremity of the bunch, girdling of the rods.

If the vegetative organs are unduly vigorous, the following methods are recommended:—Long spur-pruning, moderate removal of buds, continual pinching, suppression of gross shoots, gradual removal of leaves, and abstinence from the use of liquid or other manures. By such procedures, and others which need not be referred to here, as they apply more particularly to the cultivation of the Vine in the vineyards, the overvigour of growth may be checked.

For an opposite state of things, as that wherein a Vine has been weakened by over-cropping or other causes, a compost of well fermented dung and loam may be employed, and to this may be added, if wood formation is to be encouraged, fertilising matters of tardy decomposition, such as night-soil, street sweepings, pond mud, wood ashes, cinders, woollen rags, leaves, horn shavings, nitrate of potash, sulphate of iron, and a variety of similar materials, which it is recommended should be mixed with the compost, and watered with house slops, &c. The whole should be frequently stirred and turned. This compost should be judiciously applied after the fall of the leaf. If the fault arise from climatic causes, the shoots are to be stopped by pinching off their extremities at the end of May, when vegetation is in full vigour; and this pinching is to be repeated as circumstances demand, taking care not to remove too many leaves, and thus deprive the fruit of the requisite amount of leaf-action. The principle of this suppression of leaves is no doubt good, but it would require to be carried out with judgment.

Removal of the tendrils is also advocated, on the ground that it favours the development of the berries. This may be done at any time, but those tendrils which form on the same stalk as the bunch should of course be removed before the full maturity of the flower is reached, otherwise it will be too late.

Removal of the end of the flower-bunch serves to concentrate the vigour in the flowers that are suffered to remain—has the same effect, indeed, as the thinning of the berries subsequently practised.

The ringing of a branch, which is effected by the removal of a very narrow band of bark from the branch, is an old practice as regards fruit trees. In some cases M. BALTET recommends only the making of a circular incision around the branch, without the removal of any of the bark. This should be done when the Vine is in flower, and at a short distance below the blossom. The *rationale* of this process has long been known and acted on, and M. BALTET cites the experience of numerous practitioners and authors in its favour, and also goes into detail as to the merits of the Grapes and of the wine made from them, in the case of Vines so treated, in comparison with those of Vines left to themselves. On this latter point the evidence is conflicting, though the general advantages of the procedure are, according to M. BALTET, incontestible.

WE have lately met with an example of COMMON SENSE GARDENING, to which, inasmuch as the results have been marked by real and substantial success, it may be of advantage to some classes of our readers that we should devote a few brief observations.

Thirteen years ago, the garden to which our remarks refer was, as we are informed, comparatively sterile, and anything but well suited for the growth of good crops of vegetables and fruits. The soil was naturally light and poor, and beneath, at no great depth, was a pan, which intercepted the descent of the roots, and which, of course, rendered the production of well-developed vigorous growth, under ordinary treatment, a matter of impossibility in all ordinary seasons. The first thing done in the remedial process was to trench the ground deeply, and to break up and remove this pan, which prevented the roots from striking freely downwards and drawing up adequate support and nourishment from the well-furnished storehouse which is formed by a soil of deep tilth. Into a soil of this latter description the fertilising rains of heaven penetrate, and become, as it were, fountains in the desert ready to supply the requirements of the thirsty vegetation during the hot summer months, when most of our succulent garden crops and our fruit trees should be actively engaged in the processes of development or maturation—both of which require the ungrudging assistance of the roots.

A deep tilth having thus been secured, the next consideration was that of manuring the soil, and this in many small gardens—and it is a comparatively small garden we are alluding to—is either a matter of some difficulty, or of considerable cost. Now we must at the outset confess to having great faith in the stimulating virtues of sound honest muck, whether it be in the shape of farmyard manure, hotbed manure, or in whatever form the gardener can lay hold of it. Therefore we say not a word in disparagement of the manure or muck-heap as a garden institution. But what if the muck-heap is either of a very limited capacity, or altogether *nil?* Where shall we look for the substitute? A substitute may indeed be found, for we have a record of the garden to which we now refer that during this course of years it has scarcely had any dressing of ordinary animal manure, such as gardeners use whenever they can get it. Dressings of green Mustard — one of the most efficient of quick acting manurial agents—have been occasionally dug in, and dilute waterings from a house-tank have been to some extent resorted to in dry weather, but the chief of its manurial supply has been the refuse vegetable matter produced on the premises. The motto adopted has been, "Waste not, want not." A sunk bed of sufficient capacity is formed in a convenient part of the garden. Here are brought together all rakings and sweepings and trimmings, in fact the entire waste produce of the garden; as this accumulates, it is levelled down, sprinkled with quicklime to hasten decomposition, and covered up, layer after layer, with soil or compost. The heap is turned over after a month or two, again covered up if necessary to secure more thorough decomposition, and eventually the matter is sifted through a coarse sieve, so as to get out the undecayed portions, which are returned to the rot heap, while the finer portion, which is sufficiently decayed, is reserved to be applied as required to form a dressing to the ground.

This, briefly and hastily sketched, is the manner in which Mr. F. H. ROOKE, of Weybridge, manages his neat and well-kept garden, on which we have ventured to describe as common-sense principles. The system he adopts, it will be seen at once, is one which any person similarly circumstanced may carry out for himself. Its results show vegetable crops as vigorous and thriving as can be desired, on what was formerly poor panbound and unfertile land, and fruit trees, such as espalier Pears, in excellent health and in the most fruitful condition, covered with short sturdy spurs, and producing, as we can testify, fruit of first-rate size and quality. The plan followed out, which is simplicity itself, is one which commends itself to the good sense of cultivators; and we should be extremely glad if Mr. ROOKE could be induced, for the benefit of others who may have similar difficulties to contend with, to describe his garden operations more completely than we have here been enabled to do.

— FELLOWS of the Royal Horticultural Society, paying a subscription of four guineas, will, it appears from an official circular now before us, be entitled "to receive gratis two non-transferable season tickets for the INTERNATIONAL EXHIBITION (of 1872), admitting their owners at all times that the Exhibition is open to the public. Subscribers of two guineas are entitled to one such ticket." Another privilege is offered to the Fellows of the Royal Horticultural Society. Mr. MAPLESON, the Director of the Royal Italian Opera, has expressed his willingness to allow Fellows of the Society to purchase tickets for any concert in the Albert Hall that may be given by him during the remainder of this year at a reduced rate, on production of their tickets at the offices of the Royal Albert Hall.

— Our contemporary, the *Gardeners' Record*, in its report of the last meeting of the Dublin Horticultural Club, states that "Mr. MCGUIRE showed the meeting a new, beautiful, and unique VARIEGATED CINERARIA, of his own raising, which elicited from the members present the most unqualified remarks of approval, and was pronounced by them to be a very decided and most useful addition to this class of plants. About one-third of the centre of each leaf is composed of a mixture of light and dark green colour, whilst the remaining two-thirds of the outer margin is white, of a light purple shade. The colour of the flower is bright lake, forming a nice contrast to the rich foliage. As a plant for house or dinner-table decoration it was thought to be a most desirable and useful acquisition. The under-surface of the foliage had a very pleasing effect by gas-light."

— With regard to the suggestions made by correspondents in our columns, during the past few weeks, that some one "should address himself to the task of collecting and tabulating particulars as to the ELEVATION at which ORCHIDS GROW in their native countries, and also as to the temperature and rainfall of the respective districts," we are enabled to give the following Table, from a Moulmein paper, communicated by Mr. J. H. GILBERT to Dr. HOOKER, showing the comparative rainfall (in inches and tenths) at Rangoon and Moulmein during the months of May, June, and July last:—

Rangoon.		*Moulmein.*	
May	27.0	May	36.0
June	30.9	June	55.4
July	26.0	July	42.4
Total	83.9	Total	133.8

It is also stated that from August 1 to 15 the total rainfall at Moulmein amounted to 37.84. The heaviest fall yet on record occurred on August 30, 1865, when Moulmein was almost deluged with 15 inches of rain in one day! A Table, showing the monthly rainfall at Moulmein for the past 20 years, also accompanies this extract. From this Table we learn that the largest fall occurred in 1865, when 279 inches are recorded; this was made up as follows:—April, 0.4 in.; May, 26.74; June, 51.14; July, 68.34; August, 72.2; September, 38.7; October, 12.5; November, 8.6. The average yearly rainfall in Moulmein may be set down at about 216 inches.

— The MAXIMUM TEMPERATURES of the AIR during the week ending November 4 ranged from 57°.8 at Blackheath to 49°.7 at Edinburgh, with a mean for English stations of 54°.2, and for Scottish of 51°.5. The MINIMUM TEMPERATURES of the air ranged from 42°.5 at Manchester to 32°.9 at Nottingham, with a mean for the several places in England of 38°.7, and for those in Scotland of 38°.2. The highest MEAN TEMPERATURE was recorded at Manchester, viz., 47°.9, and the lowest (43°.8) at Edinburgh. This week the mean temperatures were, as a rule, higher at the English stations than at the Scottish, the mean for the former being 40°.5, and for the latter 40°.2. RAIN is recorded as having fallen at all stations on one day or another during the week, but, as was observed last week, heavier in the northern country than in the southern. The greatest fall in England was 0.98 inch at Bradford, and in Scotland 1.11 inch at Greenock. The mean fall for the English stations amounted to 0.39 inch, and for the Scottish 0.75 inch. (See MR. GLAISHER'S Tables, p. 1459.)

— A series of photographs devoted to the illustration of LINNEAN RELICS has been recently issued in Sweden, and copies are, we believe, to be procured in London. We subjoin the description of these plates, which are of the greatest interest to naturalists and gardeners. The photographs themselves are excellent, and the series forms a worthy tribute to the memory of the great naturalist. We are indebted to Mr. JAMES DICKSON, of Gothenburgh, Sweden, for the privilege of inspecting them. A similar series was exhibited some months since at one of the meetings of the Linnean Society, and is, we believe, deposited in the library:—

"Plates 1 and 2 portray the marble statue of LINNÉ, erected in the botanical garden, seen from different points of view: it was erected at the expense of the Upsala students, who, by contributions raised each term, collected the means necessary for the purpose. The statue is the work of our renowned BYSTROM.

"Plate 3.—The botanical garden with the entrance to the botanical lecture-room, where the statue erected by the students of Upsala stands. This garden, which formerly belonged to Upsala Castle, was by King GUSTAVUS III. attached to LINNÉ's professional chair, as an acknowledgment of his vast services to science and to his country.

"Plate 4 delineates LINNÉ's dwelling-house in the town, situated at the south-east angle of the old botanical garden. It is still preserved in unaltered condition, but it contains no relics of LINNÉ.

"Plate 5 shows the old Linnean garden, in which LINNÉ made his observations. The aspect of this garden with its small and humble greenhouses, is upon the whole very well preserved, but the inner arrangements have been changed by the removal of the hedges, the transforming of the flower-beds into grass-plats and filling up of the ponds.

"As the old garden was situated in a low and swampy tract, the new one has been formed in a higher locality, to the south of the town. But the old garden still retains its historical interest: trees are there shown, planted by the hand of LINNÉ.

"At present it is let out as a place of meeting for the students of the East-Gothland Nation (Österl).

"Plate 6 is a view of Upsala Cathedral, in which the ashes of LINNÉ are deposited. This magnificent edifice is also considered as an architectural monument deserving of attention, and contains the tombs of many men celebrated in the history of Swedeo.

"Plate 7.—LINNÉ'S monument erected in the old baronial chaurch of the Banérs in Upsala Cathedral, and bearing the inscription: 'CAROLA v. LINNÉ Botanicorum principi Amici et discipuli MDCCXCVII.' Outside the chantry, in the floor of the church, is the stone that covers the grave in which LINNÉ and his only son and successor, together with his wife, repose, and on which are the following words: 'OSSA CAROLI v. LINNÉ, equ. aur. marito optimo filio unico CAROLO v. LINNÉ patris successori et sibi ELISABETH MOREA.'

"Plate 8 represents LINNÉ'S country seat, Hammarby, situated in the parish of Danmark, five English miles from Upsala.

"The main building has been preserved unchanged, not only externally, but to the minutest measure also as regards the division of the interior into rooms, but the surrounding houses have in part been rebuilt.

"Here it was that LINNÉ spent the summer months, here his most important works were written; and hither he was often accompanied by his pupils, who desired to profit by his instruction during the summer.

"At Hammarby LINNÉ had laid out his own botanical garden, and LINNÉ's time was together with Siberian plants. Now it is a wilderness, but still a few decennia ago several plants were remaining that had been there in the time of the great naturalist. Even to this day one may see Sempervivum globiferum, Crepis sibirica, Asarum, and some others.

Plates 9 and 10 represent two rooms (LINNÉ's study and bed-chamber) at Hammarby, preserved in the same condition as LINNÉ's times, together with sundry instruments and pieces of furniture used by him.

"Plate 11 gives us a view of LINNÉ's museum, situated on a hill above Hammarby, surrounded by a Pine wood, and thus protected from fire. Here LINNÉ also spent lectures to the number of pupils who there gathered round him during the vacations. Now it is deserted, but as regards its exterior it is unaltered.

"Plate 12 is a portrait of LINNÉ at the age of 40, together with sundry articles belonging to him, *e. g.*, his doctor's hat, his walking-stick, his easy chair, together with tea-cups on which the 'Linnæa' is represented, and which belonged to a service which one of his admirers in Holland had caused to be manufactured especially for him in the far distant empire of China.

"Plate 13 is a portrait of LINNÉ after an original picture (by ROSLIN), which LINNÉ himself declared to be the best among his portraits; there are, it is true, three portraits of LINNÉ published, but they are generally not successful.

"Plate 14.—One of LINNÉ's letters, one of the last written with his own hand, being dated '1776, Maji 26,' and accordingly written during the period of his last illness and bodily weakness, one year and seven and a half months before his death (1778, Jan. 10).

"Plate 15 represents, on a diminished scale, but taken from Nature, one of the prettiest plants that, by its colours and its exquisite Vanilla-like perfume, enlivens the dark Pine woods of Sweden, and which has been considered worthy to bear the great naturalist's name, and is accordingly called Linnæa borealis. *E. Fries.*"

New Garden Plants.

ONCIDIUM PELIOGRAMMA, *Lindl., Rchb. f.*

(Pentapetala macropetala.) Panicultum; sepalis lanceis, lateralibus valde divaricatis; tepalis oblongis acutis; labello basi subhumerato, trilobo; lobulis propinquis, lateralibus serrato-dentatis portione antica reniformi, lobulosa, nunc quadrilobula; callo baseos oblongo medio apiculato, seu antice tridentato; columna exalata, basi dente porrecto, apiculato porrecto.

This plant has pale-coloured flowers, in the way of those of Oncidium Baueri, with very pale dots and a similar bar over the isthmus of the lips. It flowered with Director Linden, who obtained it from Chiriqui through Mr. Wallis. *H. G. Rchb. fil.*

KOELLENSTEINIA IONOPTERA, *Lindl., Rchb. f.*

Aff. Koellensteinie Kellerianæ, Rchb. f. Labello sessili pandurato quadrilobo, lobis lateralibus lanceolatis, intermedio ligulato; laciniis lateralibus oblongis obtusis, lacinia antica brevi emarginata, callo inter sinus humili carnoso bilobo seu quadrilobo; columnæ dentibus duobus lanceolatis, lacinia antica brevi, laciniis anticis porrectis retusis; pede recte deciso supra labellum. — *Koellensteinia ionoptera*, Lind., Rchb. f. ; Cat. Lind. an. 1872.

Caules foliati basi vaginis nonnullis, sursum monophylli folio cuneato oblongo ligulato acuto usque ultra pedali. Pedunculus basilaris, vix pedalis, vaginis paucis distantibus apice racemum bractææ triangulæ ovaris pedicellatis bene breviores; sepala oblonga obtusa acuta, lateralia subfalcata; tepala oblonga acuta; labellum sessile transversum pandurato-constrictum, lacinize laterales oblongæ transversæ. lacinia antica emarginata transversa: callus carnosus retusus bilobus inter sinus isthmi: columna utrinque retuso brachiata juxta androclinium, cucullo postico abbreviata.

A very interesting member of that herd of old plants allied to Warrea, Aganisia, Zygopetalum, &c. The flowers, not very much larger than those of the Lily of the Valley, are white, with violet petals, and violet tips and streaks on the sepals; the lip has numerous transverse violet bars. I am not very sure what are the results of management on these plants. From what I have observed they are not much to be relied upon, since they grow one year well, while the next year they will not do well at all. Hence it appears they will never be good guests in our collections, but will now and then appear and disappear. There would appear not to be enough of a bulb on these plants. Our species, a very nice thing, which was discovered in Peru by Mr. Wallis, flowered freely enough with Mr. Linden. I have three dry spikes at hand. *H. G. Rchb. fil.*

POLYCYCNIS GRATIOSA, *Endr., Rchb. f.*

Racemo deflexo nec nutante plurifloro, rhachi velutina, bracteis lanceis, ovario pedicellato glabro, ovaria vix duplo longis attingentibus; sepalis ligulatis acutis extus barbulatis; tepalis a basi lineari-lanceis, brevissime unguiculatis; labelli auribus in basi oblongis retusis antice juxta callum medium utrinque obtusangulis; callo interposito rhombeo antrorso velutino, disco setebellatim papillis linearibus obsito, ima basi callo eridentato, lacinia antica a basi oblonga late attenuata in apicilaroem partem ligulatam.

This is a species in the way of Polycycnis lepida, yet it appears very distinct by the very short claw of the lip and the attenuate part of the same lobe. As to the size of the flowers there are two varieties, the finer one reaching that of the Polycycnis barbata, the other minor one that of P. lepida. It is a very elegant thing, discovered by M. Endres in Costa Rica. Last autumn I flowered in the celebrated collection of Messrs. Veitch. *H. G. Rchb. fil.*

INDIAN LORANTHS.

THE following remarks on the structure and habits of the parasitical Loranths, are taken from a paper of Mr. Scott's, in the "Journal of the Agricultural and Horticultural Society of India." We insert them here, in the hope that, some day or other, some zealous experimentalist will be able to hit upon a plan of cultivating these splendid plants. To such experimentalists Mr. Scott's hints are very suggestive.

"It is generally believed that as the Mistletoes have an independent eliminating power, these qualities will be but slightly, if at all, modified by any particular of the qualities of their foster-parent. As opposed to this view, I may here give the following quotation from Balfour's 'Cyclopædia of India,' under Viscum monoicum, which has been supposed to have been introduced to us in 1837. Lieutenant Kittoe, then with his regiment at Cuttack, received information of the existence of a parasite on the Nux vomica trees, to which extraordinary medicinal powers were attributed by the natives. They gave the name of mulung, held it to be an extremely powerful narcotic, and poisonous in small doses, and they used it in the treatment of agues and rheumatism. Lieutenant Kittoe having procured specimens of the leaves, sent them to Dr. O'Shaughnessy, for experiment. Given in three grain doses to dogs and kids, tetanic spasms set in, in the course of from five minutes to a quarter of an hour, remedies which had only heard from the natives of the existence of such a parasite, and been furnished with leaves only (not improbably in a dry state) to determine the character of the plant. It must also be remembered, that the natives do not usually distinguish parasites from epiphytes, so that considering the innocuous qualities of all the known plants of the order, there is a pardonable suspicion of the Nux vomica having other than an analogical relationship to Mistletos. I have looked in vain on all the trees of Nux vomica which I have seen for Loranthi, but have never found them fostering one, even though surrounded by other kinds, truly overburdened."

Mr. Scott describes the mode of attachment of the seed, its germination, the penetration of the root through the bark, and then goes on to say :—

"A simultaneous growth is afterwards maintained between the parasite and prey, and the consequent result is the imbedding of the lower parts of the former in the subsequently formed woody layers of the latter. The cambium tissue of both being thus on the same plane and in close contact, it is important to observe that they never, as I believe, effect with each other anything approaching a permanent organic union; and thus as it appears to me, the relations of the Loranthi and their allies, as probably throughout the vegetable kingdom, is essentially dependent on the immediate contact of the cellular regions of parasite and prey. I am aware that the physiological relations of parasitic Loranthi have been regarded as analogous to the scion and stock in grafting; this is a mistake, they are essentially distinct, the relations of the parasite and the prey being strictly analogous to the bud and the stock in which it grows, the individuality—organically and physically—being equally as complete; and thus we find the stems of the Loranthi forming snags in the branches in which they have been imbedded: a somewhat remarkable result when we reflect on the interconnexion of their respective cambium regions. This view is, I am aware, opposed to the observations of Unger and others, who consider the inosculation of the vascular tissues of the parasite and its prey an essential condition of all cases of parisitism. I quote from Dr. Harley, in his elaborate paper on the 'Parasitism of the Mistleto' (see Transactions of the Linnean Society, vol. xxiv., p. 183) : 'In fig. 17, tab. iii., he has represented the scalariform ducts of the extremity of the root-substance of Viscum regularly opposed to, and directly inosculating with, the dotted vessels of Crataegus, and opposed to none other of its tissues.' A similar view appears to have been adopted by Adolphe Pitra, in the 'Botanical Zeitung' for 1861, and in the figure he represents the fibro-vascular bundles of the foster-plant curving towards the sides of the roots against which their extremities terminate. Dr. Harley, on the other hand, considers that the phenomena in question are produced by the absorption of the fibro-vascular bundles about the angles of convergence or of divergence, in the extension of the root in these directions, and, therefore, to be independent of any tendency to inosculation of the ducts. Though Dr. Harley thus opposes the inosculation of the vascular tissues of the parasite and foster-parent, he, on the other hand, considers that a confluence does take place in the cellular system, and that, indeed, this is an essential condition of the parasitism of the Mistleto. Thus, in his remarks on the cortical systems of the two plants, he says that 'the growth of the Mistleto causes great thickening of the bark in its vicinity, and its older layers are pushed outwards and cracked by the distending base of the parasite, and thus a superficial appearance of necrosis is produced; but on closer examination, it is found that the younger layers of the bark are in intimate living contact with the corresponding layers of the bark of the Viscum. The contiguous walls of the cells are mutually levelled—that of the Mistleto at the expense of its outer surface, that of the nourishing plant at the expense of its inner surface; and the bark of the parasite is received within and thus shortly invaginated by the bark of the nourishing plant. At the surface, and for some little distance inwards, the barks are often separated by a little chink; but, at no other point, is the original and outer layers of the barks; but more internally they form a continuous living stratum, covering over the smooth line of junction the wood of the two plants, and thus the uninterrupted passage of the sap through both is secured.' Again, he states that 'the young roots of the Mistleto and the bark of the nourishing plant live contiguously in organic union with each other.' My observations on the Loranthi of this country are quite in accordance with those of Dr. Harley's; though it may be as well to state that Dr. Harley's have reference to the Viscum album, whereas mine have been made on Loranthus buddleoides, L. longiflorus and L. bicolor. Dr. Harley, in particularly examined these relations under lenses of 150 to 300 diameters, in both milky and limpid juiced plants, as also in that of the gamboge-coloured Xanthochymus; and I am convinced that in the two cellular systems of these, form true inosculations: the two tissues, though closely applied to each other, seem to me to preserve their individuality, and are in most cases separable without mutilation of the cells. This of course not be effected in a living and organically united tissue."

With reference to Dr. Harley's theory, according to which there is a direct relation between the number and magnitude of the medullary rays and the attachment of the parasite, Mr. Scott observes—

"In all my observations on Loranthi, the relations between the medullary rays and the ramifications of roots in any infected branch are decidedly casual; and the parallelism that may exist between them is but a natural result of the mode of development of their rhizomes. Thus, as Dr. Harley has shown, in the case of other orders growing equally favourable, the size and number of the medullary rays is the chief cause which determine in any given case the attachment of the Mistleto' is untenable.

"On the other hand, I have found the habit and chemical qualities of the bark of plants chiefly determine their relations to the Loranthi, as indicated by the following observations. First, *habit*: trees of compact habit are rarely infected, as a theory by which some of Anonaceæ, Guatteria, Garcinia, Nephelium, Jambosa, Diospyros, Artocarpi, Putranjiva, &c., are all unsuited to the Loranthi, and apparently for no other reason than the above. I have not observed how strictly the Loranthi, when seen on healthy specimens of any of the heavier foliaged species of the above genera, are confined to the extremities of the shoots. There they live and flourish, only so long as they can extend apace with the lengthening shoots; failing this, as they become enveloped in the dense foliage, their vigour fails them, and sooner or later they die out. Generally, heavy-foliaged deciduous trees are also generally unfavourable, partly owing to the dry, scaly nature of the bark, the loss of foliage in the cold and hot season, and the heavy shade afforded throughout the rains. It is thus as I believe that we may account for many on several of the species of the following genera: Dillenia, Flacourtia, Salmalia, Sterculia, Schleichera, Melicocca, Spondias, Erythrina, Terminalia, Nauclea, &c. Again, although thick-foliaged species, as Eucalyptus and Acacia of various sorts, Adansonia, Xanthoxylon, Ailantus, Poupartia, Boswellia, Balsamodendron, various Araliaceæ, &c., are all unfavourable; and though I have frequently found seedlings on some of them, I have never found them supporting old plants: the seedlings generally dying ere their roots can penetrate and draw support from the inner layers of bark. I find also that trees whose bark has acrid, bitter, or astringent qualities, whether limpid or milky juiced, are but little liable to the attacks of Loranthi, and the six or so of these qualities become the more pronounced. Thus: on Melia Azadirachta, with a nauseous and bitter bark, we never find a Loranthus; and so also on that of the blander Melia composita and sempervirens they are by no means uncommon. On the specimens of the following genera, growing in the Botanic Gardens which I have seen a single plant of Loranthus establish itself, though all are more or less in proximity to other trees bearing them. These are:—Ochna, Bruced, Simaruba, Averrhoa, Rhamnus, Casalpinia, Haematoxylon, Acacia Catechu and A. arabica, Lebidibia, Hymenodictyon, Ilex paraguayensis, all of our Apocynaceæ (with the exception of Nerium), Loganiaceæ, and Embliea, &c. The rare occurrence of the Mistleto on the Oak is probably largely due to the astringent qualities in the bark

the latter, and partly, as in the case of Elms, Chestnuts, and others, from the heavy foliage which shrouds them in the growing season, and drops to expose their unripened shoots to a winter's rigour. Again, those with a resinous juice, as the Dipterocarpi generally, the Canariums, many of the Guttiferæ, Melanorrhœa usitatissima, Piscidia, Schinus Molle, Semecarpus, Styrax, and others, are not at all liable to the attacks of the parasitic Loranthi, and indeed I have never found specimens on any of them in the Botanic Gardens here. On the other hand, light airy foliaged trees, with a bland, limpid, or milky juice, and a soft, thinnish, coarse-textured bark, are all especially liable to become the prey of the Loranthi.

(To be Continued.)

KEELE HALL GARDENS.

FOR picturesque arrangement, as well as for completeness, Keele Hall is a most enjoyable place for a horticulturist to visit. Its position, its surroundings of woodland, hill, and dale, its pleasant grounds, excellently kept, with many charming and unique features met with here and there, constitute it one of those fine places, the which, while they excite the envy of Continental visitors, are at once the glory and the boast of Old England. Sameness cannot be laid to the charge of Keele, for there is so much of variety in its manifold features that chill monotony is far removed. "The bounties and tendernesses" of Nature are there in rich profusion, and there are also touches of wild, and even rugged, outlines.

Keele wants to be seen in the spring, when rolling wave after wave of green—every shade of green, too—comes stealing over the mass of trees, shrubs, and underwood, and soft, balmy days are reversing the wrong done by winter; when huge tree-like examples of Rhododendron arboreum are aglow with tints that gleam and glisten in the sun; and many spring flowers blossoming at the foot of the broad Elms and kindred trees, peep out from the dense undergrowth of shrubbery, and light up sundry nooks and woodland ways; or in the full glow of summer, when the sweet sunlight falls in silvery brightness over all the land, and mellows the landscape—when Nature presents herself laden with the teeming wealth of harvest yet unreaped, of clustering fruits and lovely flowers.

There is one defect about Keele—it is too much shut in by outlying belts of woodland. Outside these limitations—not to be too hastily denounced, notwithstanding, for it is right and fitting that we be conservative of our wood-crowned heights—there lie magnificent stretches of vision—

> "Scenes so fair,
> Of stream, and vale, and hill, and flocks, and herds,"

that it seems a pity to lose them. The Rev. W. Sneyd has already opened up charming vistas at a few points, where grand natural pictures can be seen through the "skyed looping and windy spaces;" and as the undoubted advantage of doing this presents itself, more openings will probably be made in the dense growth of the trees that are everywhere present.

Keele Hall being close to that busy commercial centre, the Staffordshire Potteries, can be reached by rail from three different points, viz., Keele Hall Station, Newcastle-under-Lyne, and Whitmore, on the North-Western Railway. It is by the latter that any one visiting the Hall should approach it, the route being through an avenue of great beauty. The view southwards, from a handsome gateway forming the entrance to the stable-yard, is supported by fine specimens of pyramidal Hollies on either side, and then there stretches away for a considerable distance an avenue of fine young Sweet Chestnuts. From the stable entrance the road dips for a considerable distance, and then rises again. The view from this point is very striking, and the eye is enabled to range over a considerable tract of country. The road passes through the stable-yard, and on leaving it, by a ravine excavated out of the sandstone rock, and passing under a handsome stone bridge in the pleasure-grounds above, is continued on to the mansion in the form of a bold sweep, which passes under a grove of Beeches and Sycamores. The ravine is 20 feet in depth, and is overhung by trees on both sides, and with an undergrowth of Hemlock Spruce hanging down over the sides, Yews, Rhododendron ponticum, British Ferns, Ivy, &c. The common Ferns grow out of the crevices of the rocks with native luxuriance; and this passage, during the greatest heat of summer, is always deliciously cool and inviting. The mansion can also be reached, from the entrance to the stable-yard, by means of a winding path, with fine pyramidal Hollies on either side, overtopped in their turn by tall trees, and with a free growth of Laurels and other evergreen shrubs beneath. The mansion is quite new, and is a square solid superstructure, built of the native stone of the district. That used for the facings was brought from Hillington, near to Alton Towers. The foundation stone was laid in 1855, and the gables are in true Elizabethan style. On the south side there is a sunken garden, as seen in the figure opposite (fig. 314), which is separated from the mansion only by an open terrace walk, and reached by means of a descending flight of steps. The various beds in the garden were filled with flowering and foliaged plants, and Irish Yews are dotted about also. At the southern extremity is a handsome stone fountain, and on either side such examples of the variegated Agave americana as are

FIGS. 312, 313.—VISTA AND HOLLY HEDGE AT KEELE HALL.

rarely met with. Beyond these stretches away in a gentle declivity a rich grassy sward, and about it are planted very fine specimens of pyramidal Yews, Hemlock Spruce, &c. Much more steeply the ground slopes away from the mansion on the east side. It is a soft green sward, on which are set down beds of flowering shrubs, both deciduous and evergreen; masses of various coloured Belgian Azaleas, that are very fine in the spring months, &c., with specimen ornamental and Coniferous trees beyond.

From this point are obtained fine views of woodland, overlooking Trentham and Barlaston Halls. On the left, and to a great extent hidden from view by the umbrageous branches of thriving trees, lies a sheet of ornamental water, behind which is a thickly wooded tract; and further on lies Springpool Wood, covering a considerable space, and extending a long distance. Semi-wild woodland walks traverse these woods, and are lined with countless numbers of Rhododendron ponticum that thrive here with great luxuriance. This and the Hemlock Spruce line the sloping banks on either side of a natural valley, with water along the bottom—sometimes only a narrow running stream, and occasionally widening out to a large pool. Everywhere, especially where the trees are thickest, the Hemlock Spruce luxuriates; moisture and shade it has in abundance, and it flourishes with unwonted vigour. Spring flowers innumerable light up these woodland ways,—the vernal Squill, the wood Anemone, Primroses, Cowslips, a wild Allium growing in huge masses crowned with numberless white flowers (but a thing to be kept on the leeward side of one's track), and others can be seen here, growing unchecked amid the quiet of the woods. On the opposite side of the pool from the house there is a nice piece of artificial rockwork and waterfall, a glimpse of which is obtained from the north and west sides, and partly so on the east; huge Beeches and other trees serve as screens from the rude winds that come from these quarters, and beneath the trees, in one or two places, a piece of artificial rockery has been thrown up, that comes into the panorama with excellent effect.

To describe in detail the other parts of the pleasure grounds, it is necessary to start from the gardener's residence, which forms the north-western corner of the quadrangle, of which the stables are a part. Mr. William Hill, the gardener at Keele Hall, has made the place famous for the high class quality of the Grapes he has grown there in times past, and is no less successful now that he has retired with the laurels he so worthily won. He has been many years at Keele, enjoying the confidence and respect of the late and present proprietors of the Hall, as well as the kindly regard of many brother gardeners the country through. In such a cottage as the one he occupies, so charmingly situated and fitted up, and finished with such unobtrusive elegance, one could wish to spend the decline of life, softly sinking down in age to the quiet sleep of the grave. Before it lies stretched out three oblong gardens, two of them walled in, and known as the upper and lower kitchen gardens, and in these are contained the glass structures. A central walk runs longitudinally through each garden, till the third is reached. It is here the descriptive account of the pleasure grounds will be resumed, leaving the glass structures and the kitchen gardens (which are full of interest) for a later paper.

Passing from the second oblong garden in a westerly direction, admittance is gained to a third by means of a leafy archway, under the shade of splendid Beeches and other trees; and here is an orchard, and also a rosary, with other features. A broad turf walk, 8 feet in width, and about 160 yards in length, runs throughout it, and for a considerable distance there is a broad ribbon border on either side. These borders are very effective indeed during the summer months. They were planted thus:—At back, Hollyhocks and Tritoma Uvaria alternately, the latter fine plants but showing the scathing effects of the severe winter; next, the purple Zelinda Dahlia; then double white Feverfew, one of the best white flowering bedding plants we possess; then Stella Nosegay Pelargoniums, Lobelia Erinus speciosa, and an outer margin of Cerastium. Right and left was a fruit garden containing pyramidal Pears and Apples; then, passing on, came a rosary in the centre of the garden, having in a centre a huge conically trained Yew, and round this a series of girdles divided into segments, each about 3 feet in width, edged either with Yew, Cotoneaster, or Box, with narrow circular gravel walks between each girdle. Outside this was a flower border, backed up by a ring of standard and dwarf Roses. Then another divison, forming fruit gardens right and left. The ribbon border here diverges to the right and left, and, taking a transverse direction, is continued till the sides of the garden are reached. Next comes one of the features of Keele, viz., a splendid avenue of Cedrus Deodara, 20 yards in width, the specimens planted on a fine piece of closely-shaven turf; there are 12 trees in each line, planted about 24 feet apart; the length of the avenue being about 100 yards. The specimens, which were all of handsome proportions and well trained, averaged in height 30 feet. In the first flush of their early growth they might have been likened to fountains of living liquid green. Looking down this avenue, a magnificent vista is opened out, and the visitor can look away for miles over a fertile country on to the splendid woodlands of Shropshire. Next the avenue of Deodars ran a Holly hedge in the same direction, and between this and an avenue of Limes, kept very closely clipped

because planted so closely together, were a number of flower beds, mainly oblong in shape, and planted with Stocks, Asters, Lavender, Honeysuckle, Cabbage Roses, Moss and old Provence Roses, Clove Carnations, &c., from which to obtain supplies of cut flowers. At the extreme end of this garden, westward, there is a Holly hedge, forming the boundary line between it and the Park; and between the Limes and this hedge, which is kept well clipped, was a promenade on the turf, running parallel with the Cedar avenue, and shaded by the Limes. The northern boundary of this garden, parallel with the broad turf walk between the ribbon borders, is a magnificent Holly hedge, perhaps without a parallel in the United Kingdom; and running parallel with it a broad gravel walk. This hedge is an arboreal wonder, and when it was planted is a matter for conjecture, but it is supposed quite 100 years ago. In length it is 200 yards, height 25 feet; it is 20 feet in width at the bottom, and 8 feet at the top. It is kept closely clipped, and in appearance looks like a solid piece of masonry, or a powerful breakwater. One could almost walk on the top of it, so dense is the growth; and at all parts it is like a compact fortress wall. The opposite view (fig. 313) gives this magnificent hedge as looked at from the north-west corner of the garden, and the commencement of the Cedrus Deodara avenue can be seen on the right. Rather more than half way down the walk seen in the view, the hedge is carried across it in the form of an archway, which is 25 feet in height. The annexed view of the hedge (fig. 313), taken from the north-east corner of the garden, brings out more fully the outline of the archway. This hedge is a most effectual screen from the northern blasts, and Mr. Hill stated that during the winter months hundreds of small birds make it a roosting place. The girth of the stems of some of these Hollies equals that of the trunks of the Beech, and a great deal of labour is requisite to keep the hedge nicely clipped and trimmed.

At the end of the walk, and just at that point from which the first view is taken, there is a handsome pair of gates, which open into the park, and close by, inserted in the Holly hedge, and commanding a view of the promenade under the Lime trees, quite an unique summer-house, the walls of which are lined with handsomely designed examples of Minton's tiles.

From this point, passing along by the broad walk under the Holly hedge, there is reached at the north-east end of it a small circular garden, surrounding a thick closely trimmed Holly hedge, with niches cut in it for the reception of statuary, and with marble busts on tall pedestals. The centre is occupied by a raised turf mound, surmounted by statuary, with wedge-shaped beds cut in the sloping banks, and round these, on the ground level, a girdle of circular beds. Then passing through a shady grove, with spreading Beeches overhead, and Rhododendrons beneath, and on through a pair of handsome iron gates, a charming Italian garden is reached, formerly the site of an old bowling-green. A magnificent grove of Beeches and other trees come in on the west and north, with shrubs as an undergrowth; there is a Yew hedge on the south, and large examples of Rhododendron arboreum and R. ponticum on the east. Perhaps the former are among some of the finest to be found. In the Rhododendron bank is placed a very curious sun-dial.

Passing from the Italian garden, access is gained to a broad gravel walk running eastwards towards the mansion. Evergreen shrubs and Rhododendrons closely grown together as a hedge skirt the walk on the left hand; on the right, further fine examples of Rhododendron arboreum and various ornamental trees. We give (fig. 312) a view of the vista formed by this walk. A delightful repose prevails here, broken only by the soft summer breeze fanning the trees, or the pleasant music of singing birds. The far end of this walk forms a terrace, from which the kitchen garden can be overlooked. Running parallel with this walk, but at a higher elevation, reached by a flight of steps, is a Chestnut grove, containing some fine old trees of great age, their time-honoured trunks memorials of past generations. There is a line of these Chestnuts on the left hand; on the right, a corresponding line of Scotch Firs, also of great age, with huge trunks that must represent the growth of many, many years, and with heads towering aloft above the trees that surround them. On either side, at their feet, are Rhododendrons, Hollies, &c. A broad grassy walk runs beneath these trees, a spacious and most pleasant promenade—a truly delightful spot to lounge in, and hold communion with the visible forms of Nature—

"When winter storms have ceased to chide,
And all the new-leaved woods, resounding wide,
Send out wild hymns upon the scented air;"

or when the sun goes down in glory over the western mountains on a calm summer's eve.

Skirting the grove on the left, we strike into a walk through the pleasure ground, and find ourselves among handsome specimen Coniferous trees, such as Cedrus Deodara, Araucaria imbricata, &c. Specially noticeable are the really grand specimens of the large-leaved Ilex Aquifolium Hodginsii, very tall and splendidly furnished. The examples of this Holly, met with all over the pleasure grounds, are an admirable feature at Keele. Fine old Sycamores come in at this point, and near them other towering Scotch Firs; and it is a matter for deep regret that evidences of decay are appearing in some of them. Close by is a remarkable group of large specimens of Rhododendron arboreum, of great height, and there is a good example of the Fern-leaved Beech, but the top of the tree has sported back to the old form. Hard by these is gained a charming peep at a piece of artificial work in a secluded valley, like the half-dried course of a mountain stream. Round it are growing Cedars covered with climbing Roses, and there is a thick growth of underwood. It reminds one of a mountain pass, and it would form an excellent site for an alpine and rock garden. Artificial walls formed of stone surround it in part, and in the crevices such things as Viola cornuta, London Pride, and other things were growing must luxuriantly. Then passing from this by means of a subterranean passage, access is gained to a secluded garden, with rocky dells here and there under overhanging trees, and a rustic summer-house, forming a most refreshing retreat from the heat of the noon-day sun. Then, by means of an ascending path, the end of the Chestnut grove is reached, hard by the gardener's residence, and the visitor emerges on to the terrace overlooking the kitchen garden. From this point fine views of the surrounding country could be had southward, were it not that the thick belt of trees on that side of the kitchen garden obstructs the view. A few fine vistas could be opened up by thinning the trees, some of which could be well spared, as they are planted very thickly.

Such, then, is a sketch of some of the leading features of Keele Hall. But no visitor should go there without walking through the pleasant village of Keele, where the tasteful cottage residences remind one of villa residences about the suburbs of a well-to-do town. The handsome new church well repays an inspection. It stands a monument to attest the generosity and the piety of a fine example of the English country gentleman—the late Ralph Sneyd, of Keele Hall. *D.*

FIGS. 314, 315.—FLOWER GARDEN AND HOLLY HEDGE AT KEELE HALL.

POTATOS.

MESSRS. SUTTON & SONS, the well-known seedsmen of Reading, recently lifted a large trial of Potatos, in their trial ground, near Reading. This ground occupies a huge angle between the Great Western and South-Eastern Railways, and is mainly used for selecting stocks of various agricultural and garden seeds, from which to grow produce for general sale. Such a trial ground as this is not only indispensable to, but of the highest value to a large business establishment, and at no season of the year is it destitute of interest. It was in this ground that the trial of Potatos was exhibited.

The soil having recently been converted from pasture into arable land, and being somewhat stony and shallow in regard to the surface soil, the Potatos were not so much remarkable for size as for general good cropping qualities, moderate-sized handsome tubers, and a pretty general freedom from disease. To save time, several roots of each variety included in the trial were lifted, ready for inspection. It may here be stated that Messrs. Sutton & Sons do a very large business in seed Potatos, which are grown for them by neighbouring farmers and others; and it is their invariable rule to plant a line of any variety received from their growers; thus it may, and does happen, there may be six, or eight, or even more samples of any one variety. It was noticeable that these were all of one general excellence of character.

A few odd sorts were at first looked over. Among these were the Canadian Kidney, which was identical with Dave's Matchless; Paterson's White Kidney, which nearly resembled the latter, but had a rather stronger and stouter growth; a good early round variety, not yet distributed, and provisionally named Sutton's Berkshire Round; the Ram's Horn Kidney, a somewhat mean-looking Potato, turned up at the ends, and leading one to wonder why it was ever distributed; Erdington Monarch, a good Lapstone type, but producing many round tubers; Oxfordshire Kidney, a large, but with very compact foliage; and Golden Zone, a golden-foliaged Regent, and a much stronger grower than Golden Gem.

Passing on now to inspect the trial varieties, which came in regular order, commencing with the earliest, the first to challenge attention was Sutton's Early Racehorse, a very good-looking early kidney, said by the Messrs. Sutton to be the very best early kidney grown; the foliage is somewhat curled, and the tubers larger than the Early Ashleaf. Next came Rivers' Royal Ashleaf, a fine free-cropping variety, but three weeks later than Racehorse; the samples clean and handsome. Caversham Defiance had a sort of half Lapstone shape, and was early, a good cropper, and short in the haulm; Sandringham Kidney, a good walnut-leaved kidney type; the Old Ashleaf, cropping better than is generally seen; Mona's Ashleaf, the tubers large and good-looking, a variety much grown to give an early supply to the Liverpool markets; several capital samples of Myatt's Ashleaf, looking as nice as anyone could desire to see this variety; some good samples of the American Rose, the tubers fine and handsome, and without the coarseness frequently observed in that variety during the past summer; the Early Goodrich, one of the best of the American varieties, white flesh, and a good cropper: this Potato many persons seem to be much pleased with;

Jackson's Kidney, a sound early kidney of the type of the Prince of Wales; King of Potatos, a good second early variety that keeps well, being a large cropper, and the produce being round, flat, and kidney-shaped; Prince of Wales, a coarse kidney, but yielding handsome tubers; Sutton's Berkshire Kidney, a seedling, raised from the Fluke, a free bearing main-crop variety; Haigh's Kidney, very handsome in shape, and a stronger grower than the Lapstone, which it much resembles; Headley's Nonpareil, a handsome clear-skinned Potato, but in the case of the trial here not a heavy cropper; Golden Blossomed Kidney, much recommended as a fine main-crop Potato; some excellent tubers of the old Lapstone, all handsome in appearance and worth a trial; the Belgian Fluke, a large white kidney of coarse appearance, the foliage distinct in character from that of the Fluke; some good samples of the Fluke and Red Ashleaf; the Early Coldstream, a capital round variety, handsome in shape, and a good cropper; Shaw's and Early Oxford, shape, and a good cropper; Shaw's and Early Oxford, both deep in the eye, and spare producers; Fox's Seedling, a good-looking round type; Daintree's Seedling, Drummond's Prolific, Dalmahoy and Early Regents—four round types, appearing to be identical; Wellington, a good-looking variety with coloured eyes, and fine in sample; Cuffe Castle Seedling, said to be one of the best of the Regent type; Wood's Scarlet Kidney, which appeared to have been selected from the Early Red Emperor, and, like many other Potatos, has a tendency to throw kidney-shaped tubers; and Milky White and Paterson's Victoria represented by excellent tubers of each. Sutton's Red-skinned Flourball proved to be remarkably good in the light soil of the trial ground. It is only just to Messrs. Sutton and Sons to mention that this variety was said to have been raised as a seedling within a very short distance of their trial ground, and that they distributed it with the full belief that it was entirely distinct in character, an opinion which they still hold, notwithstanding what has been stated to the contrary. Snowball, Walker's Regent, Paterson's Regent, Improved Rock, and the Old Rock, appeared to be very similar.

Several of the American varieties could here be seen; in fact, there had been a very interesting trial of them. Peach-blossom was as like the Red-skinned Flourball as could be, but paler in the skin, it also had a clear white flesh; Prairie Seedling, apparently the same type as the Goodrich, but larger and later, and said to be the best of the American varieties. Pink-eyed Rusty Coat, a dark red round Potato, white flesh, said to be of good quality, and a fine cropper; King of Earlies, white tubers, slightly suffused with pink, short haulm; appears early. Breese's Prolific, the tubers slightly tinted with red round the eyes, a very heavy cropper, and said to be good. Peerless, the type of Early Goodrich, and a heavy cropper; and Early Silver, apparently a worthless yellow-fleshed round variety.

Yet another miscellaneous group, formed of a few sorts that came too late to be classed with the others. This included Early May, a second early kidney of little merit; Gloucestershire Kidney, which seemed to be identical with Prince of Wales; Lady Duff Kidney, same as the Old Walnutleaf; Paterson's Zebra, a rough-looking red round, blotched with white; Paterson's Red, a red round, not large in size, but a great cropper; Rivers' Early Ten-week, a handsome round Potato, apparently a good cropper; Fox's Scarlet King, a second early kidney variety, with a clear red skin; Red Fluke, a half round, pale red-coloured tuber of very coarse growth; Early Red-skin, a kidney-shaped variety, rather paler in the skin than Scarlet King; Prussian Raspberry-leaved, a red tuber, much like the Red Emperor, the foliage said to resemble that of the Raspberry; and the New Giant Red Mammoth, and New Giant White Mammoth, the former a red, the latter a white Bovinia, both received from Messrs. Carter, of Erfurt, and altogether worthless for table purposes.

As some prominence is now being given to the Potato, a record of this trial may be of service to those who are interested in a more correct classification of the many reputed varieties in cultivation. *R. D.*

THE RATIONALE OF HOT-WATER CIRCULATION.

PERMIT me to thank your able correspondent, the Rev. J. M. Taylor, for his paper in reply to mine. So-called controversialists, that is, those who see different phases of the same truth from different stand-points, should be like schoolboys—hit each other hard if the interests of truth, or right, fancied or real, seem to require it, and love equally hard and fast ever afterwards. I never, either as boy or man, could understand why difference of opinion should sever or prevent the formation of friendship. It is less our opinions than the spirit in which we hold or relinquish them that ought to command us to each other. Hence I gladly take the proffered hand of friendship held out to me in the concluding sentence of Mr. Taylor's letter, and re-echo his wish that the discussion may be perfectly friendly. I think it was Charles Lamb who paid Scotchmen the equivocal compliment, that they knew but one mood—the positive. Their attitude, he declared, was never a doubtful or uncertain one. They were ever ready to cut the subtle web of speculative doubt with their sharp, incisive "I know." Your correspondent seems to have formed a similar opinion of me, when he ventured to open his paper with, "Caloric, Mr. Fish says, is the driving force of the universe." Rather a sledge-hammer style of announcing a virtual fact. My statement was somewhat more modest, as will be seen on turning to p. 1237, col. *b*: "We speak and write of caloric as the moving force of the universe. . . . Nevertheless, this seems but one side of the truth." And what is the other side presented by me? Why, this—that gravitation is a motive power of equal or perhaps greater potency. That, in fact, is the whole purport of my article, as proved by my illustration from the natural circulation of hot air and water from the equator to the poles and back. Motion, I contend, is not solely the product of either caloric or gravitation; it is born of the difference between the two. Does your correspondent mean to affirm that gravitation alone is the cause of motion? If so, then we differ widely indeed; but if not, it seems to me we are substantially agreed. So far am I from contending that heat alone is the cause of motion, that I even state that it is difficult at times to affirm whether heat or cold takes the initiative. The sentence is severely censured by your correspondent, who, however, does not stop to explain which of the racers, heat or cold, is first or last in the contest for equality. Had he done so, I submit, greater service would have been rendered to the theory and practice of perfect heating by the criticism than a host of sentences such as that referring to the upward bounding of caloric, &c.

Such severe handling of detached sentences may be all very well in literary reviews, but seem hardly in character in the pages of the *Gardeners' Chronicle*, where we are more concerned about the facts taught than the trappings or style of their dress. Neither is so severe a handling of mere phrases quite in character with the spirit of an age in which a distinct function is assigned to the imagination—in scientific investigations and the wildest dreams of speculation, the most erratic flights of fancy—to none more than the presidents of our most philosophical associations, when they venture to clothe our earth with the left-off clothing of other and older worlds, or to stock it with the fragmentary *débris* of worn-out or fractured planets. In comparison with such fancies as these, my expression of caloric "ever acting at its source, by means, mild and common-place, "the spokes of the wheel and the hands of the clock" notwithstanding. Indeed, such corrections are just as *apropos* to our everyday "up and down," as to the upward bound or rush of heat—neither less nor more. From this severe dissection of sentences which the writer himself virtually confesses to have overdone, I invite your readers to read my paper on p. 1327, in connection with that of your correspondent on pp. 1389, 1390.

Unless the Rev. J. M. Taylor is prepared to hold that gravitation is the sole motive power in heating—which he cannot mean—our theory seems identical; and we differ, if at all, about the relative proportions of the two motive forces, and the mode of their application, rather than about these forces themselves. But as this gentleman has promised further contentions on as to principles that govern the movement of fluids and bodies immersed in them, and their bearing among other things upon hot-water apparatus, I shall gladly await their appearance before going at any length into the subject.

There is one point, however, of so much practical importance, that it will brook no delay. It is this. I advised, as a means of adding to the force of the circulation, the keeping of the crown of the boiler hot, and its base cool. "Now," says the Rev. J. M. Taylor, "if gravitation be the motive power, no instruction with respect to the lower part of the boiler could be more mischievous." I stop not to inquire a second time whether this gentleman holds gravitation to be the sole power,—from other parts of his letter, it would seem that he is totally opposed to caloric being recognised as a mode of motion. He cites other cases of a change of condition in bodies being the cause of motion, though but surely such changes are also the result of heat previously expended on such bodies, and hence attributable to caloric.

Again, supposing gravitation the sole cause of motion, it by no means follows that my instructions to keep the crown of boilers hot and their base cool, would be half so mischievous as the Rev. J. M. Taylor supposes. Surely there are degrees of coolness. Your correspondent assumes that the water in the bottom of the boiler, and that returning in the return-pipe, would be of equal temperature. His calculations of the 6 or 12 inches of cool water in the base of the boiler being an equipose to the cool water in the bottom of the descending pipe, is based upon this assumption. Such, however, would assuredly not be the case. The water that had made the circuit of the boiler would of necessity be much colder than that at the base of the boiler, and every increment of heat to the latter would lessen the power of resistance to the returning stream. In fact, practically, and with a fair elevation, the resistance offered by the water in the bottom of the boiler, being somewhat cooler than that at the crown, would not prove a perceptible obstacle to circulation. But all this is on the assumption that gravitation alone is the motive power, a hypothesis which I by no means accept, any more than that caloric alone is the sole moving force; but admitting the action of both, my instruction to keep the crown of the boiler hotter than its base, is sound in theory as it is helpful to a vigorous circulation in practice. It hinders the possibility of that reverse action, which is one of the greatest hindrances to the continued and regular circulation of hot water. Allow the base of the boiler to be as hot, or hotter, than its crown, and back circulation will happen at times in almost all heating apparatuses. Make the highest pipe the return, and you increase the risk, the certainty of this reverse action, by every inch you gain in altitude, by the reversal of the usual arrangements. Your correspondent seems to ignore the fact, that the higher the vertical plunge of the cold water, the greater the inducement of the hot current to meet and master it on its own ground. Hence the economy of fuel in the advice to keep the base of your boiler cooler than its crown. In other words, offer no resistance to gravitation in its proper mission of returning back the cold, and aid caloric all you can in sending forth the hot water.

Thus will these two seemingly opposing forces be so disposed of as to aid each other in maintaining a constant and vigorous circulation. If the Rev. J. M. Taylor can show us how gravitation alone does all the work, then may not only my instruction about boilers but probably fires likewise be dispensed with, as the more cold the more weighs, and hence the stronger the moving power. *D. T. Fish.*

Home Correspondence.

Fern Fronds for Decoration.—Lovers of Ferns must often have remarked with surprise that the London flower markets offer so miserably small a variety of kinds of Fern fronds for decoration. The sort most commonly met with is Maidenhair, not our English species, but Adiantum cuneatum; and this is too frequently grown in heat instead of in a greenhouse. Besides Maidenhair there is only one other that comes into the market in any quantity, and that is Pteris serrulata. It may be that, as these two species come up like weeds in every part of a Fernhouse and are found suitable by the florists, there has been no pressure put upon growers to produce a greater variety. Yet I cannot help thinking that if any one were to grow for market some of the Ferns I propose now to mention, their fronds would command remunerative prices. The demand for fronds from 4 to 6 feet long is so exceptional, that it would of course not pay to grow Cyathea dealbata, Cibotium Schiedei, or Goniophlebium subauriculatum, though for large decorations their fronds are probably the most glorious examples of foliage that could be picked out. But of fronds of the size generally used, from 6 to 18 inches long, surely we might have a little more variety. Of the most beautiful is Pteris scaberula, a finely divided, hard, wiry kind, which lasts a long time in a vase. Another very elegant and durable sort is Hypolepis distans, a deep green, though not a dark green. As a contrast to this, Lastrea decurrens, Pteris flabellata, P. straminea, and Gymnogramma dictyon. Phyllitis scolopendrium, which I fancy must force its way as a market plant; indeed, I received one frond of it the other day (with some Maidenhair and other Ferns) from Covent Garden, so I have hopes of finding it plentiful there in the course of time. But I fear that it is of little use hoping that Gleichenias will ever be grown for the sake of their fronds. Their lasting powers are unequalled amongst Ferns, since they are so firm, hard, and dry, that they will preserve their good looks well for many hours without water, and for many days in a vase. For forming light arches over a dinner table there is nothing so pretty; Gleichenia dicotophylla, rupestris, and Speluncæ (true, and of gardens) are, I think, the four most suitable for this purpose, while G. flabellata stands unrivalled as a drooping fringe for flower vases. I have repeatedly been under obligations to Mr. Sim, the nurseryman at Foot's Cray, for opportunities of using all these and several as very many other kinds of rare Ferns, when the size of his plants would admit of his cutting fronds from them. *W. T.*

The Seedsman's Assistant.—The public generally, and but few gardeners, are aware of the "four months' hard labour" to which the seedsman's assistants have to submit every year, viz., January, February, March, and April. When I say "hard labour," I mean not so much hard work as the long hours during these months. As an assistant, I have been connected with the retail seed trade both in England, Ireland, and Scotland for upwards of 18 years, and on an average during the "busy season" (the four months named) had to be hard at it, so as to meet the requirements of the season, from 8 o'clock in the morning till 11 and 12 at night, and very often till 1 and 2 o'clock the following morning, and this I believe to be the general rule of the trade. Of course all seed establishments are closed (with but few exceptions) at not later than 8 o'clock P.M. during these months, the remaining

eight months somewhat earlier, but still we are working inside for hours after the shop is closed to the public. We lose our rest in consequence of these long hours, and as a consequence our health. This is a well-known fact in the trade. Again, it is of the utmost importance that all orders be executed with the greatest care. It is a very serious thing for the gardener to have sent him Cabbage seed instead of Cauliflower, or Borecole instead of Broccoli, but how can mistakes be prevented when it is "all work and no play" (or, if you please, little sleep) ? Can any of your numerous readers suggest a remedy for this mutual evil and disadvantage? I know many gardeners in reply will say,—Why not employ extra hands? Quite right, but how would you employ "extra hands" during the remaining eight months? It is not reasonable to suppose the employer would keep the young men to do nothing. There are two or three remedies which suggest themselves to me, and which I think are to the point. The first, and perhaps not the least important, is to have early orders. Most gardeners know their requirements for the season, but how few there are who send in their orders till actually required; the consequence is, all the orders come in a rush, and are wanted at once, and we poor assistants have to suffer. Do think on us early in January or even mind the frost; and, though the ground be covered a foot deep in snow, we are in a position then to execute your orders, only let us have them early; they can be forwarded any time to suit your convenience. Another remedy is, for gardeners to write their orders distinctly; not bad-a-dozen articles in one line and on both sides of the paper; this gives the assistant endless trouble and annoyance: he very often has to write the order out afresh before it can be executed or passed to the clerk for booking. For the sake of convenience, and to obviate the trouble of writing out a seed order, most seedsmen now send out with their seed catalogue what we call a "return list," with blank columns, so that the quantity required may readily be filled in. I hope all gardeners who are fortunate enough to receive these "return lists" will kindly use them. My third remedy I may at some future time suggest, in the meantime I wait the opinion of others. *An Assistant, October* 27.

Cedar of Lebanon Seeding.—May I ask you readers whether they have ever known a Cedar of Lebanon to produce perfect seeds in this country? We are all intimately acquainted with their very characteristic-looking cones, so densely borne by some trees. I have personally seen squirrels very busily engaged amongst them, but whether on a test search, or for absolution of the sins which they were in the habit of having known them to possess, I could not define. *Williams' Earley, Valentines.* [We have seen perfect seeds in the cones of this tree, and believe they are made use of by the nurserymen to keep up their stock of plants. Eds.]

Bees Combing Outside Trees. — It may be interesting to some of your readers to know that instances of the honey bee forming combs outside of trees are not so rare as your correspondent, "M. B." imagines. I have observed it on three occasions since 1866. The most extensive was seen at Cargen, Kirkcudbrightshire, in September, 1866; three large pieces of comb were suspended from a branch in the centre of a common green Holly; the three combs weighed 5 lb., and were all very pure. The combs were invisible on account of the bees clustering on them, and before disturbing the bees you had to be prepared to make a speedy exit. The other two cases were not so remarkable; they were at Jardine Hall, near Dumfries, in October, 1868. In both cases, pieces of comb were suspended from the boards on which hives were set. *J. F.*

Evergreen Firs at Zurich.—Your correspondent, A. Boyle, holds a very common error, that trees have their branches killed by the influence of their upper branches. Any tree of our climate, except a few with perpendicular growing branches, will have its lower branches feather towards the ground, if it be planted originally far from other trees or shrubs, and kept so. The "evergreens" were probably Spruce or Silver Fir (or Pinus Laricio?) for these would be too cold for most of the newly imported Conifers, such as P. insignis, P. excelsa, or even the Weymouth Pine. *Somerset.*

Deodar Catkins and Cones.—Your reporter says, p. 1425, "Dr. Masters showed male and female cones of the Deodar, which seem frequent this season"! Some of your readers may be able to swallow both kinds, but an old man with spectacles cannot possibly bolt a "male cone"—a male catkin or flower consolidly formed, if you please; but a male cone is too much akin to an "Irish bull" being "a good milker." *W. B.* [Our correspondent is hypercritical. The female cone is a catkin, and there is nothing botanically wrong in calling the male catkin of a Conifer a cone, using the word in a general sense. We have long, moreover, several male catkins of the Deodar sent to us as "cones,"—*i.e.*, seed-cones—by persons who did not recognise the pollen cone from the seed cone, which is a worse lapse than the use of the word cone in a general and not in a restricted sense. Eds.]

The Effects of Snow on the Douglas Fir.—My friend, "G. F. M.," will hardly be satisfied with your answer to his query, viz., a heavy fall of snow is assuredly likely to break the branches of the Douglas Fir, &c. My experience is opposed to this assurance; 1st, practically, after 35 years' observation with hundreds of specimens; 2d, the comparison between the Cedar of Lebanon and Douglas Fir does not hold good, because the ramification of the Cedar is totally different to that of the Douglas Fir. The former forms limbs with tabulæform branches, and will not bend, but break; and for a twofold reason, because the texture of Cedrus Libani is very fragile. *W. B.* [We believe we have seen a branch of Douglas Fir broken off by weight of snow. Eds.]

Araucaria imbricata Gumming.—If Mr. Stalker will examine his trees, he will find they have been rootbound from infancy. In such cases, when the compressed roots become strangled, the elaborated sap cannot descend to elongate the roots, and the corresponding vessels in the trunk become distended; sap oozes out to the surface, the aqueous portion evaporates, and the resinous portion forms a white deposit, not "gummy," as it is erroneously called, as gum does not belong to resinous trees, but to stone fruit trees. *W. B.*

—— I observe some remarks at p. 1424, by Mr. Stalker, Hempsted Park, respecting the gumming, or rather the oozing out of turpentine from the stem of the Araucaria imbricata. It should imagine by the description, that all the trees are badly low-and that is, level with the earth's surface, so that the loose soil about them absorbs the moisture from the surrounding locality; or else that the subsoil is cold and unkindly. But then the one forked about was filled round with turfy healthy soil and manure. I don't know about manure, as I don't believe in its use for Coniferous plants of any kind. Well decomposed vegetable soil and leaf-mould, if intermixed with plenty of coarse sand or stones, would do good on cold, stiff soils. Moreover, all Araucarias, when planted on stiff cold soil, to ensure healthiness, should be planted on methodically raised mounds, as they are naturally mountainous plants, growing in high and dry localities. I was obliged to have every Araucaria at Bicton removed, and placed on a mound, in consequence of their oozing out turpentine, or gum if you like, and they all and everyone recovered and became healthy. I have just returned from my tour, and in my travels have been through France, the Channel and other islands, and every county in England, Wales, and Scotland. During this journey I have seen many Araucarias, and have observed many of them to be affected in this gumming localities, mourning rusty and unhealthy, losing their lower branches, &c. I am also able to assure my friends that I am still alive, although it has been currently reported that I and my wife were both lost at sea; and, therefore, Messrs. Editors, I hope, through long experience, as well as from observations made during my tour, to be able to give you some interesting articles respecting this noble, curious, and interesting tree, as promised some time since. *James Barnes, Exmouth.* [Pray do. Eds.]

Glass Copings for Walls.—When I wrote the notice of Mr. Rendle's glass copings I had forgotten those of Mr. Webb, otherwise, in justice to that gentleman, I should have noticed them—though, indeed, in that case I should likewise to have described a very efficient protector offered by Mr. Beard, whose patent system of glazing Mr. Webb touches, if he does not infringe, by the use of felt as a buffer between the glass and iron. And after all, Mr. Rendle's invention is none the worse, but the better, for something very similar having been tried and found efficient by others. As to the question of novelty or originality of invention, I say only this, that the origination of grooved bricks for glazing of necessity suggested grooved metal bars; and for such purposes as copings the latter are by far the more useful. I hope these few sentences will satisfy both inventors; and, what is of more consequence, that your readers will find glass copings capable of sustaining the high character Mr. Webb is able to give them from experience. *F.*

[We have received a letter from Mr. E. Webb in your last week's paper, and had not the least idea that he had introduced my glass copings. I do not think either he or I can lay any claim to originality in these, but I do lay claim to a new system of fixing the glass in metal grooves. You will observe that Mr. Webb uses a wooden strip to fix the glass; this will soon perish and decay. I use only metal, and have not any wood exposed to the action of the atmosphere. I am glad to find that the copings answer so well, and hope they will soon get into general use. *William Edgcumbe Rendle*, 3, *Westminster Chambers, Victoria Street, S.W.*

Fruiting of Pteris scaberula.—Seeing a paragraph at p. 1359 respecting the rare production of fruitful fronds on Pteris scaberula, I enclose you a few in that condition, and for the information of your readers may state that my plants constantly produce spores on some of their fronds. I account for it by the mode of treatment, for the plants that bear spores are growing in a wall built up of sods of bog peat, and run freely over the surface, rooting as they run. Other plants, grown in pans, fruited as long as they had plenty of room, but since the pans have become full they have ceased to produce. I may add that another Fern on the same wall, Hypolepis distans, which rarely produces spores, is now full of them. *Thomas C. Copland, Dublin.* [The specimens sent are abundantly fructified, as are others from Welwyn, where Mr. Parsons informs us he obtains an abundance of young seedling plants. On the other hand, the magnificent specimen from Mr. Smee's garden, shown on the 1st inst. at Kensington, did not, so far as we could discover, bear any fertile fronds. Eds.]

Certificating Grapes.—Who is "Vitis?" who if "Lynx Eye?" I think I can guess one of them. It either has any fault to find with the Fruit Committee, why does he not sign his real name? I hate anonymous writing. If there is in anything an authority, his communications will have the greater weight if his name be attached, whatever the subject he writes about; but to attack any man, or any body of men, under the mask of a cognomen, is unworthy of a man. I am thankful that no Editor can say he has received a paper from me on any subject without my real name. I owe no man a grudge for pricking me in a bout at fencing, but a stab in the back is another affair. We have had too much of this bush fighting: come out into the open and say what you want. It would be well if the names of the gentlemen sitting on the Fruit Committee were published in the *Gardeners' Chronicle*. Many are unknown to me except by sight, but amongst them I do know there are men whose honour and whose knowledge cannot be called in question. When a fault is shown its merits are candidly freely, and its character is established by facts, and I have seen no instance where fear or favour has influenced the vote. No doubt great mistakes have been made in certificating Grapes, and equally great ones in refusing certificates. I myself voted for Golden Hamburgh in having a certificate, and so would any one who saw it as it was shown, and yet most people have discarded it. The fact is, too much is demanded of the committee. No man, no body of men, can determine the value of a Grape by viewing a bunch or two. The bunch submitted may have been from a weak pot Vine; it may be so shaded that it cannot colour the same as a full, alas! if the committee take such statements into consideration in determining the value of a variety, they will soon be reminded of David's exclamation—"All men are liars!" On the other hand, if they take it for granted the bunch is the product of first-rate culture, they are still more likely to be mistaken. Then again there are more things to be considered than can be settled by a sight or a taste of the fruit alone. A Vine to be valuable must be a good healthy grower; its fruit ought to set freely, and continue good after it is ripe, which can, without seeing the Vine, determine these points? I well remember a committee meeting many years ago, when Mr. Rivers was in the chair, and many of our best cultivators present. On that occasion some bunches of the old Black Morocco, beautifully grown, were judged as new, and a certificate given to them under a new name, "Kempton Alicante." Now, if some of us had seen the Vines from which these Grapes were cut, we should have recognised them as belonging to the worst setting kind known. "Vitis" says it is so easy to raise a new Grape. Is it indeed? Well of course it is easy to raise Grape seeds, but it is anything but an easy matter to cross-breed Grapes, and there are few things more difficult or expensive than the raising a new good Grape. Ferdinand de Lesseps was the only Vine I saved out of about 100 seedlings. Now to fruit 100 seedlings will cost, say £150, and according to "Vitis" will be a good one only, a "curiosity." That it is curious I grant; it is not only a new Grape, but a new fruit. The flavour is so peculiar that it is unlike any known variety, whilst a few bunches will fill a house with the scent of Strawberries. I never puffed it, and nearly every plant I sold was bought by persons who never tasted it, and I have not a dozen left; so, as far as my interest is concerned, "Vitis" may write what he likes. I should not have alluded to the subject except to prove that it is no such easy thing to raise a new good Vine. The certificating of fruits is an important matter: it is important to the public, who wish to buy good ones and avoid bad ones; and it is still more important to a raiser, who has spent hundreds of pounds in getting one or more be thinks good. As to the Royal Horticultural Society proving every seedling submitted to their notice, that is out of the question; those thought worthy of a commendation might be proved before getting a First-class Certificate. But some would be found to object to this, fearing to part with their pets to anyone's care. Then, again, I contend that some things will do well in some places, and a variety might do badly even at Chiswick. In such a case the raiser might, and perhaps would say, he had been unfairly treated, which would be a very disagreeable affair for our "directors." Some persons like and speak well of Royal Ascot: it is my second-rate with me, producing bunches of 1 lb. only, though otherwise good; and yet at Chiswick it was a perfect wretch, which no one would have at any price. Vines, like other plants, have their specialities, and will not do equally well in all situations; hence we find one gardener famous for one thing and one for another. Surrounded as the subject is with difficulties, what steps are the committee to take to arrive at a just conclusion? I would recommend the following course. When a Grape, or other fruit, is

shown, which meets with general approbation, let it be commended or highly commended. This will signify that the Grapes shown are good. If the raiser has confidence enough to demand it, let the committee appoint a sub-committee of, say, three members, who shall, at a fixed expense, say £5, go down and report on the growing Vines; and after such report, and not till then, let a certificate be awarded, if the report be favourable. It would always be easy to select three men, in whom all had confidence, who would give their time for such an object. Granted after such an investigation, a certificate would have an increased value in the estimation of the public. *I. R. Pearson, Chilwell.* [We are not at liberty to say who "Vitis" and "Lynx Eye" are, neither has our correspondent any right to require these gentlemen to abandon their *incognito* unless they choose to do so. It may be of some interest to him to know that both are practical men of the highest standing, and we believe with no personal interests of their own to serve in this matter. Eds.]

Aucubas.—I enclose for your inspection two leaves of Aucuba japonica taken from the same plant, the one spotted in the usual manner, the other with a large unequally defined blotch in the centre of the leaf, not unlike some of the new Japanese variegated; the plant from which these leaves were taken is growing at Restalrig Park, near Edinburgh, and is about 15 or 20 years old. One side of the plant has all the leaves with the large spot on each. I suspect most, if not all of the new varieties have been procured from sports, for I observed several striking plants in the same nursery most of those which came up quite green, and remained so for two or three years, are now becoming more or less spotted, and appear as if they had a tendency to revert to the common spotted form. *Peter S. Robinson, Trinity Nursery, Edinburgh.*

Preserving Tomatos.—The Tomato is a native of South America and Mexico, but is also found in the East Indies, and the recipe which I give herewith was given to me by a distinguished admiral who had spent some time in the East Indies, and who was on a visit to the late Dowager Countess of Ellesmere, at Hatchford, near Cobham, Surrey. We had a great quantity of Tomatos at the time, and the admiral kindly informed me how they preserved them in the East Indies, and gave me the recipe:—Make a strong hot pickle of salt and water; it should be made strong enough to float an egg on the surface; then gather your ripe Tomatos, perfectly dry, and free from cracks in the skin or bruises of any description—or, in other words, they must be perfectly sound, and free from blemish of any kind; put them carefully down in large wide-mouthed earthenware jars (with lids to them) until filled, then pour the pickle over the Tomatos so as to completely cover them, place the lids on the jars, then cover with a piece of bladder, and tie tight round the neck of the jar to keep air-tight. Keep them in a dry, cool place, and the operation is completed. If these directions are attended to, they will keep good for any length of time. When wanted for use, take the quantity required, and soak them in fresh water for a while to extract the salt previous to using, and season the jar again. *Thomas Campbell, Chorlton Road, Manchester.*

—— Seeing, at p. 1391, that Mr. Morgan prefers making green Tomato preserve to leaving them to Jack Frost, allow me to inform him that there is no necessity for either, as the Tomato ripens its fruit well if pulled by the roots, and hung up in a dry warm shed. I hang about one-half of mine along the back wall of a late vinery, and they never fail to ripen equally as well as those ripened outside. They come into use from now to Christmas, and those in the potting shed from January to March. I fear I should get into trouble with the cook before the winter was over if I were to send them all in green as I took them from the walls. *John T. Burns, Gr. to J. B. Rudd, Esq., Tollesby Hall, Middlesboro'-on-Tees.*

Shade Trees to stand about Ems.—Your correspondent, "Somerset," in a short paragraph on the vintage at Ems, asks for information regarding some large slugs which he saw there. Without a more minute description of the large black slug, it is rather perilous to give a positive opinion, as there are three species, belonging to two distinct genera, which occasionally assume this colour; but my impression is, that he alludes to Limax cinereo-niger of Nillson, an animal entirely unknown in the British Islands, although reported as native many years since. It is generally of a brilliant black on the back and sides, the foot-belly has three stripes, the two outer nearly the same colour as the back, but the middle pure white; length of a fine adult specimen, from 4 to 6 inches. They are occasionally, but rarely, found of an olive-green and dirty white colour. They are not so nocturnal in their habits as Limax maximus, which is nearly as large, but is more generally of an ashy-grey or brown-yellow colour, often in that neighbourhood beautifully marked with large blotches of black. This is rarely entirely black, but Arion empiricorum assumes many liveries—in England more generally black, but in Germany orange, red, brown, and yellow, and generally with a band of bright orange along each side of the foot. Your correspondent might also have met with several other species, had he used diligence or been desirous of so doing—as Limax flavus, L. arborum, L. agrestis, L. Sowerbii, and possibly L. tenellus, a rare and interesting little slug, as also the not well-known Arion flavus. *John E. Daniel, Epsom.*

Cedrus Deodara and Wellingtonia gigantea Coning.—We have here a Cedrus Deodara, and also a Wellingtonia gigantea, with cones on them. The Cedrus is a very nice specimen, about 18 or 20 feet in height, and has been planted, so I am told, about 10 or 12 years, in a very exposed situation. There are several cones on the tree, but almost hidden from sight by the overhanging branches. The Wellingtonia is about 12 or 14 feet in height, with a fair number of cones upon it. *G. Warren, Balcombe Place, Sussex.*

Notes on Pine-apples.—I have this day cut a fruit of the Smooth Cayenne Pine, weighing 7 lb. 11 oz., the produce of a rootless sucker planted exactly 16 months ago. On the 4th of last July, too, I exhibited at our Chelmsford Flower Show seven Queen Pines weighing collectively 34¾ lb., the largest being 5 lb. 9 oz., and the smallest 4 lb. 10 oz., the produce of plants from 14 to 17 months old. These results help to confirm Mr. Miles' statement, as mentioned by you at p. 1426. For the past two years I have grown all my Pines in one enlarged house, instead of two houses and a pit, as formerly, and the result is a very much quicker return, at a correspondingly less cost. I should be happy to lay before your readers my experience in this matter, when I could show that, except for the sake of mere numbers, it is quite unnecessary to employ two or three or more houses to maintain a constant supply of good Pines. The truth is, there is a great deal too much "fuss" about Pine-growing, and many a gentleman with small means is afraid to grow them in consequence. *Thomas Simpson.* [We shall be glad to hear further of your success in Pine-growing. Eds.]

Lee's Prolific Black Currant.—This new variety is I see being advertised in your columns, and if any one can judge of its merits by seeing it growing on two different occasions in season, I can truly say that I believe it is the very best variety we have in cultivation. The habit of the plant is good, and I should think it is impossible to have a more prolific variety, as the bushes that I saw (several hundreds in number) were huddled thickly together in nursery beds, and they were this season (1871) a perfect mass of fruit, and the Black Currants in this neighbourhood) literally covered with fruit of a large and very even size. They are much sweeter than any variety I ever tasted, and will hang on the bushes a long time after being ripe without dropping or shrivelling. This latter quality in itself is sufficient to recommend it, especially to those who prize the Black Currant for dessert. I venture to predict that this variety will, when better known, become the general favourite of its class in every garden establishment. *Thomas Foote, Gr. to Sir Arthur H. Elton, Bart., Clevedon Court, Somerset.*

Artichoke Galls.—If your correspondent, Mr. Andrew Murray (p. 1423), will open what he calls the small, stunted acorn within the foliaceous covering, I think he will find a grub of the Cynips that produces the one grub, but sometimes two. I have opened many of these galls in which I could not see the small acorn-shaped body, and am of the opinion that they would have produced no gall-flies. *T. F. W.*

Trees for the Yorkshire Coast.—Perhaps the experience gained by a 14 years' residence on a most exposed part of the coast of the adjoining county (Durham), may be of use to your correspondent, "Arbor," who inquires what trees, shrubs, &c., he should plant on an exposed part of the coast of Yorkshire. I would recommend him to plant at once,—the size to be, what nurserymen call, for the trees, 4 feet to 5 feet; deciduous shrubs, 2 feet to 3 feet; evergreens, 1½ foot to 2 feet. The following thrive best here; but, with indifference, tried many others:—Trees: *Sycamore, Turkey Oak, Horse Chestnut, and Beech. Deciduous Shrubs: *Elder, *Lilac, Ribes, Syringa, Snowberry, Privet, &c. Evergreens: *Aucuba, *Laurustinus, *Portugal Laurel, *Minorca Holly, Wild Privet or Gorsely, double and single; and *Double-flowering Furze, if planted in pest. Pampas grass also does well. Those marked * do best of all. *T. Dobson, Whitburn Hall, Sunderland.*

Roses for North and South Walls.—Kindly inform me what Roses (name sorts) you think are best adapted for a north wall, 4 feet high. The border is well made and drained. They will have to be nailed to the wall. Also say what sorts will suit a south wall of the same description. *Hortus Rosarum.* [We forwarded your note to our valued correspondent, the Rev. W. F. Radclyffe, who kindly replies as follows:—"I am always pleased to answer any question. If, however, such questions were more explicit I could answer them better, and in a shorter space. The length of the wall is not stated. I suppose the north and south walls are the same height. The best Roses for a south wall are the yellow Roses; they are the most prolific—early, mid-season, and late—of all Roses. They are: Solfaterre, Lamarque, Céline Forestier, Triomphe de Rennes, Maréchal Niel, and Gloire de Dijon. The three first will fill a great space of wall; the three last, still in abundant bloom here, would not require so large a space; still, trained against a wall 4 feet high, they will fill a great space. Beware of cutting the flowers or branches from the base and centre, as when these strong growers become bare there you will never fill them up again, unless you cut the trees back very hard at the terminals. If coloured Roses are wanted—Empereur de Maroc, Jules Margottin, Charles Lefebvre, Anna Alexieff, Mademoiselle Louise Casique, may be planted between the yellow Roses to break the "jaundice." Lamarque is the finest scented of all Roses, but it is tenderer than any of the other yellow Roses named. You might devote the whole south wall to yellow Roses; and, if your border is wide enough, you might plant coloured Roses in advance between the yellow ones. In such cases Casique and Anna Alexieff would grow too high for this purpose. The following would suit—Maroon: Dr. Jamin or Maroc; cerise: Edward Morren; rich red: either Sénateur Vaisse or Mademoiselle V. Verdier; rose: Felix Genero or Marguerite de St. Amand; deep crimson-purple: Pierre Notting; pink: Cécile Chabrillant. For a north wall—Gloire de Dijon, Louise Casique, Anna Alexieff, Jules Margottin, Baronne Prevost, W. Griffiths, and Général Jacqueminot. For this situation they must be free-bloomers, and must have a little extra protection in winter if the wall is much exposed. *W. F. Radclyffe.*]

Grapes and their Merits.—The merits of different kinds of Grapes being under discussion in your columns, I venture to offer my experience, which is somewhat to that of many of your correspondents. Mrs. Pince's Muscat is described (p. 1425) as being a free setter but I have found it, when grown side by side with Muscat of Alexandria, neither to set as well nor keep so long as that variety; when grown by the side of Hamburghs it was simply worthless. But as regards the Madresfield Court, when grown under the same conditions I found to be first-class. As a pot Vine I consider this last the finest Grape grown; it is a free setter and very prolific, both when grown by the side of the Black Hamburgh and Muscat of Alexandria. Muscat Hamburgh I have found to do best on its own roots, at least the variety under my care. There are, I think, two varieties of this Grape, which accounts for the different opinions regarding its merits: one is a Grape which sets badly when on its own roots, but better when inarched on Black Hamburgh, and is of a much finer colour; the other is the best flavoured, and comes best on its own roots, but does not colour so well as the other variety when inarched. The Alicante is a true gardener's Grape; it has a strong constitution, is of good flavour, and keeps well. Foster's Seedling is one of the best White Grapes; it forces well by the side of the Black Hamburgh, but requires using immediately, as it will not hang long in perfection. The old Black Morocco, when true, is one of the finest late Grapes, and keeps well. *J. H. H., Twickenham.*

Parasitic Trees.—In a recent number you allude to so-called parasitic trees, and instance one that existed on the Cherwell. I beg to inform you that the tree is still increasing in growth. It stands on the outer bank of the stream that winds round it "Magdalen Walks," and is a few yards distant from the mill. *Edward Charrington, Beachborough, Hythe.*

Golden Champion Grape.—Seeing that writers in the *Gardeners' Chronicle* are condemning this fine Grape, I beg to state that it has done wonders with me this year, inarched on the Bowood Muscat. I had 11 bunches of it, weighing 28 lb., on one rod, 5 feet long, every berry being perfect. My employers were so delighted with it that they wish me to plant a whole house of it. These are simple facts, that are well known in this neighbourhood. *William Atkes, Gr. to James Dalrymple, Esq., Langlee, Galashiels.*

—— The prospects of this Grape are improving, for has not Mr. Cramb taken it under his wing (p. 1393). The raisers of some of the new Grapes ought to return him their sincere thanks, for when any of the varieties they send out lose their characters, he is sure to come to the rescue with a vengeance. Bear witness the Golden Hamburgh, as one of the varieties he tried hard to make us believe to be one of the best white Grapes in existence, but somehow or other it is now seldom seen on the exhibition tables. The Madresfield Court, however, having a good character, Mr. Cramb quite upsets it, and his description of the shrivelling and atrophy of its bunches with him this year is one of the most melancholy records of Grape failure known, far outdoing the death of Mr. Cannell's Vines at Portnall Park. Facts, however, are "chiels that winna ding," for in the last two or three years the murmurs have been loud and deep amongst nearly all growers of the Golden Champion as to its spotting propensities and general bad properties. Now, the Madresfield Court has not come under this category, and has been exhibited in very fine condition this year, even when ripened in a cool vinery; there is no question about its flavour, and it has likewise been recommended for its keeping qualities in late vineries. As Mr. Cramb does not state whether the Vine borders on which he grew the Madresfield Court and Golden Champion were composed of soil from the magnesian limestone or red sand formation, we are warranted

in believing that the soil had nothing to do with the shrivelling of the one, or the beautiful finish of the other. It would be a most instructive example should Mr. Cramb send a few of the withered husks of bunches of his Madresfield Court to the next meeting of the Horticultural Society; and if one of the fine finished bunches of the Golden Champion could be sent with them, many growers would be glad to see it when grown as it should be. *Vitis.*

To Protect Fruit Trees from the Attacks of Rabbits.—About 12 years ago I planted some hundreds of Apple and Pear trees, numbers of which were barked by the hares and rabbits. I tried tar, oil, and grease, but did no good until I tried the following very simple plan:—As soon as a tree was planted I set my boy to bind a sheet of newspaper (I used that of the *Gardeners' Chronicle*) [You are *too* complimentary.] round the stem from the ground upwards, which will reach about 15 inches. Take a piece of bast matting, tie the bottom of the paper, give it a turn or two round the tree, and tie it again at the top, so as to keep the wind from blowing the paper off. It will last a year, can be put on in a minute, and no hare or rabbit will touch the tree so simply guarded. Another preventive is to place a 3-inch drain-pipe without a bottom against the tree so as not to touch it, or else when the wind blows it will bark the tree. Hares or rabbits will not go near it. I have planted hundreds of trees, and have not had one bitten or barked since I have bound the trees with paper, and used the drain-pipes. *T. T.*

Veitch's Giant and Waldeck Cauliflower.—Allow me to inform your correspondent, Mr. Gilbert, that the condemnatory remarks which I made at p. 1359 respecting the Walcheren Cauliflower, is simply drawn from my own personal experience, and which did not in any way villify the merits which this old and valued friend of so long standing possesses. My stock of Walcheren might be an exception, but I doubt if a great many of your readers have not experienced the same disappointment, the cause of which I need not attempt to particularise, since Mr. Earley and Mr. Fish have so ably endeavoured to explain it. I certainly agree with Mr. Gilbert, that small compact heads are more desirable than large ones for the table. But allow me to remind him that the Giant, although large, possesses the most delicate flavour, and is fit for the purest palates. If Mr. Gilbert prefers small heads, three to a dish, he has only to cut them before getting too large. *E. Morgan, The Butts, Harrow-on-the-Hill.*

Mixed Bedding Plants.—I was surprised to find at p. 1392 a statement to the effect that Viola cornuta Perfection was raised at Rotherfield Park. If your correspondent will look at p. 410 of the *Gardeners' Chronicle* for 1870 he will see that I denied its being a seedling, or that Mr. Jobson was the raiser of it, and which Mr. Jobson has not disputed. The beauty of my Viola during the last spring and summer, in fact, for years past, has been beyond all praise. My own experience in this respect is corroborated by many correspondents from distant parts of the country. Many persons who have bought seed, have no doubt been disappointed, and I do not wonder at it. The plant flowers too freely to seed much; and much of the seed produced does not "come true." The only successful mode of propagation is by means of cuttings. *George Smith, Wilton Road Nursery, Salisbury.*

Trees for Seaside Planting.—Tamarisk, Atriplex glauca, Phlomis, and Euonymus will stand the best in exposed positions near the sea; next to which come the Ilex Oaks, Pinus austriaca, Poplars of sorts, Euphorbium, Rock Cistus, Double Gorse, Escallonia, Lilacs, Laurustinus, and Phillyrea. *W. Rossiter, Paington, Devon.* [At Folkestone this year we saw Pittosporum Tobira forming a fine bush. EDS.]

Foreign Correspondence.

CALAIS: *October* 10.—There is not much that can be called of horticultural interest in this place. Historical associations as many as you please,—quaint old gateways, forbidding looking walls, stagnant fosses, a busy port, consequential police-officers, bangdog soldiers, pictural fishwives, tall lighthouses, antique spires, two long piers stretching out as it would seem into illimitable distance (but the sand is reached even at high water at a depth of but a few metres), and outside the town on all sides sands and dunes, dunes and sands; and away in the offing sail-flecked sea, and on the horizon a dim cloudy mass which represents the shores of Old England. Yes! we are only an hour and a half's steam journey from Dover, and yet we are in a different world. Everything, if not novel, is at least strange. I don't believe, if I were set down in the steppes of Tartary, I should find much greater difference, barring the language, in the manners and customs of the people, as compared with those of London, than I do in the course of an hour's walk in the streets of this old, old town. Certainly those who rush on direct to Paris, as most do who land here, will find in that capital less difference at 12 hours' distance from the Strand than they might do here at four hours' journey from Charing Cross. "But what has all this to do with horticulture?" Mr. Editor,* I told you at the outset I had no story to tell; let me go on in my own way.

I implied, only a sentence ago, that I was in a foreign land, and if it were not for the language, I might think it was Holland—somewhere between Scheveningen and Leyden—but happily for me they don't speak Dutch hereabouts; or if I look to the dunes only, I might fancy myself among the sandhills of Kent, away beyond Deal. Patience, good Mr. Editor, I am coming to the point; those busy, cleanly, cheerful, chattering, brightly-clad fishwives, those storied walls and spires and chirruping chimes shall not disturb all my thoughts, I will roam among the sandhills, and see what I can pick up that may interest your readers. First of all the shells—not oysters, for they have vanished since my former visit to this place, but mussels and cockles, and cyclas, and a great number of others —not found on the coast directly opposite, though found higher up on the Norfolk shores. "Shells are not plants." Well, well! they are not, but I found among them a real live Fungus—only just beyond high water-mark—an ochrey-brown Agaric, with alternate long and short gills, confluent with the stem, growing in solitary state—one at a time, so to speak. I didn't know its name, but I wondered when I saw it growing in so salt a place, and in so close proximity to edible fungi, whether it be edible, would not prove good eating. Whether or no, there it grows in company with Mat-grass, Elymus arenarius, and other sand grasses, which serve to bind the loose sand in some degree; and here is that really noble plant, for its size, the Eryngium maritimum, the Sea Holly. I repeat, it is a noble plant, and a neighbour—I could not from a sense of botanical propriety, call it its ally—the horned Poppy, Glaucium luteum, is close by. Not far inland, say a stone's throw from the tidal marge, are bushes of Hippophaë rhamnoides, the Sea Buckthorn, covered with orange berries—a sturdy plant in truth, and almost indifferent as to what sort of soil it grows in which it grows; here it is in sea-sand, on the other side of the water you may see it indifferently on chalk and on the greensand; but you won't see it, or much else either, save Rushes and Coltsfoot, on the gault.

Quite close to the beach I mark the Sea Buckthorn for your outer fence; back up with the elegant Eryngium, with which is in bloom nearly all the year round; fill in with Lavateria arborea, Eryngium and Glaucium. If you want colour, look at the autumn leaves of that lowly Glaux maritima and the Convolvulus Soldanella: Golden Feather on the one hand, and the silver side of the autumn leaves of the Glaux. How it would be inland I cannot say, but where it grows; here it is in sea-sand, on the other side of the water you may see it indifferently on chalk and on the greensand; but you won't see it, or much else either, save Rushes and Coltsfoot, on the gault.

Quite close to the beach I mark the Sea Buckthorn for your outer fence; back up with the elegant Eryngium, with which is in bloom nearly all the year round; fill in with Lavateria arborea, Eryngium and Glaucium. If you want colour, look at the autumn leaves of that lowly Glaux maritima and the Convolvulus Soldanella: Golden Feather on the one hand, and the silver side of the autumn leaves of the Glaux. How it would be inland I cannot say, but where it grows, I speak of time present. Glaux in summer time is of an unpleasant green in gardeners' eyes. And here is Silene conica, no gardener's plant truly, but pleasurable to meet with, as it shows the analogy of situation with the Deal sandhills, where you will find it also grows. Here, too, is the Erodium, white and pink, also a Deal plant; the Sea Pink, Armeria, and a fine variety of Viola tricolor, the so-called V. lutea. On the shore, inland, on the walls, in chinks, under bridges, and on towers, grows that pretty weed Senebiera. This is not a Deal plant, so far as I remember, but it is a shore plant; there it grows on the chalk. There is no chalk here, nevertheless it flourishes to perfection, and its flowers put the Dover ones to shame by their greater size and brilliancy. Here and there, too, the lucky botanist may find a rarity or two—Eryngium, E. campestre—not to be mentioned in the same breath, as far as beauty is concerned, with its brother, but so much rarer than it, and no doubt with more elegant foliage. Deal sandhills—no, nor Dover cliffs, nor Folkestone Leas, possess that rarity any more than they do Euphorbia Paralias. Why? It can't be discrepancy of soil or climate; but when one sees, year after year, such a plant as Erigeron canadense in profusion on one side of the railway cutting at Kew Bridge, and not a plant of it on the opposite bank, the fact does not seem so strange.

But our walk has brought us to a cemetery—a resting place for ashes in the midst of sand. Road or path there is none; if there were, the sand would obliterate it, but there is an enclosure, and a few planted sea-spoil Poplars try to form a shrubbery, and fail lamentably in the attempt. Graves are graves and monuments, so simple in some particulars, so childish in others. No pompous, fulsome epitaphs—no stonemason's eulogies on the character of the departed. A simple cross at the head, four planks sunk in the sand, and wire to keep together a little flower bed—a little sand-heap, one may say—but there is an attempt at floral decoration here and there, and, as showing what will grow in pure sand, I note the plants used by these simple faithful village folk to testify their love for the departed ones. Crambe maritima thrives, pinkish flowers and blue-green leaves answer the intended purpose well. The old-fashioned Costmary, so seldom seen now-a-days, also thrives; Diplotaxis, of course, Marigolds and China Asters, and Lycium, the so-called Tea tree, also do well: but it is but a scanty garden, to say the best, and the Japwings with their shrill wee pipping note, don't make it look any the more horticultural. One does not like to comment on such sacred matters, but it cannot hurt any prejudice or wound any higher feeling, to note the contrast between the simplicity and pure faith shown by the monumental crosses with their simple legends, the humble but appropriate attempts at floral decoration, and the tawdry-babyish decorations of toys, beads, and what-not, with which they are associated. However, here of all places one feels that prejudice and difference of opinion should have no place, and so let us walk across to the public garden of the manufacturing suburb of St. Pierre. Though called a suburb, this is really a manufacturing town of no small importance, larger and more populous than the old fortified town it adjoins. There is here a noble modern church in the Late Norman style of architecture, with a lofty spire; but not to wander into such irrelevant details, let me note the most splendid plant, some 9 or 12 feet high, the Campanula pyramidalis, or some closely allied species, that I ever set eyes on. It was placed before a picture of the Madonna, and, apart from all questions of dogma, a more beautiful thank or praise-offering could hardly be conceived. In all the London shows this season—and I saw most of them—there was not a plant to come near this one for symmetry of proportion, beauty, and profusion of bloom. It was the feature, in the horticultural way, of Calais. In truth it must be said, this ancient city does not excel in matters horticultural; the public park of St. Pierre is well nigh a desert; the garden reserved for the poor is much better; the grass is comparable only to that of a suburban villa in a third-rate suburb of London, which has been to let for the last five years; not an evergreen is to be seen, and the flowers are for the most part prickled with salt air, and stunted with sand. Gravel and grit are everywhere—no gravel, none is to be had,—but good paths may be had without gravel, a fact the Calais folk don't seem to know. Poplars of many sorts, and Sycamores stand the salt air well; the Limes look miserable; the feathery Tamarisk, the Snowberry, and the Bladder Senna all do well, the first especially. But clearly the taste of Calais folk does not lie in the direction of gardening. An hour on the opposite coast of Dover, or Folkestone, would show more in the gardening line than a week in the neighbourhood of Calais.—I told you I had nothing of horticultural interest to relate, and I have kept my word. *The Rambler.*

Societies.

SCOTTISH ARBORICULTURAL: *Nov.* 1 (*Annual Meeting*).—R. Hutchison, Esq., F.R.S.E., Carlowrie, in the chair. The annual meeting was held in the Corn Exchange Hall, St. Andrew Square, Edinburgh. There was a large attendance of members from England, Ireland, and all parts of Scotland, including Dr. Cleghorn, Professor Balfour, Messrs. E. Lorden, W. Nab, Botanic Gardens; Gorrie, M'Corquodale, Scone Palace; France, Methven, J. Sadler, Syme, M'Donald; Anderson, Perth; W. Gilchrist, J. Grant, Thomson, Strathspey, &c. After the usual formal opening of the meeting, Mr. Hutchison was again unanimously re-elected President of the Society, and proceeded to deliver the inaugural address. They had, he observed, much cause to congratulate themselves on the progress they had made as a society. Not only had the roll of membership continued to increase, as in former years, but the zeal and interest of the members in the objects of arboriculture had been abundantly evidenced by the number, quality, and variety of the papers sent in for competition. He suggested that in future the annual meeting should extend over at least two, if not more days, during which time papers on various subjects connected with horticulture might be read and discussed, and any new theories or observations bearing upon them might be ventilated and criticised. He then at length on the value of correct observation and practical work in the forest and woods, and he hoped that the different members would pay attention to and in the course of next year's ordinary operations bear their eye to the test the theory we had lately seen he had started;—Having observed in pruning that at one time the surface of the wounds made upon the tree limbs seemed fresher and more moist than at others, and that this phenomenon varied almost to a minute from time to time, there being apparently frequently less exudation of sap, or bleeding, the one week than there had been during the previous one, or even during the previous month, he was led to advance the theory that there is a periodicity in the circulation of sap in trees, both Coniferous and hard wood, and perhaps in vegetation generally, during those months when we are accustomed to look upon Nature as dormant, and in her ordinary functions as suspended; that this periodicity is caused and regulated by lunar influence. For example, he observed that for about four or five days from the third day after new moon, the action of the sap seems to be disturbed, and the circulation more free and abundant, than it is during the other parts of the month. If this were so, and he thought he was justified in asserting that it was, pruning operations performed during those few days, when the circulation seemed could be not only better done than when it was drier and less quickened, and was not only more easily performed, but more good work could be done in less time, and with equal safety to the tree. This theory was evidently wrong so akin to a universal law of Nature necessary for the procreation of life in the animal kingdom that it might be a similar process was equally necessary for the reproduction, growth, and in sustaining vitality, in all perennial vegetation—a strange and mysterious process by which, during the cold bleak months of frost and winter-storm, when the snow-wreaths drift athwart the silent forest, the silvery beams of our earth's attendant planet were exciting and controlling, by their benign, attractive influence, not merely the regulation and movements of the tides of ocean, but were aiding likewise in maintaining the vitality of growth in the vegetable kingdom for the future benefit of the human race.

A vote of thanks was accorded to the President for his interesting address. Professor Balfour, Dr. Il. Cleghorn,

of Strawithy, F.R.S.E.; Mr. E. Loraine, The Riding Mill; Mr. W. M'Corquodale, Scone Palace; and Mr. J. G. Thomson, Strathspey, were elected Vice-Presidents for the ensuing year. Mr. J. Sadler, F.R.P.S., was re-elected secretary; Mr. T. Methven, treasurer; and Mr. D. Syme, of Messrs. Peter Lawson & Sons', auditor. Sixty-two new members were afterwards admitted. The Chairman stated that the British Association Committee had succeeded in getting the donation of £20 renewed from the British Association for the purpose of making observations of the effects of the denudation of trees upon the rainfall of this country. Last year a grant of £20 had been apportioned, but for want of observers the money was not taken up. This year, however, more care would be taken that careful and trustworthy observers would be got. The President, Dr. Cleghorn, and Professor Balfour, were appointed to attend the British Association meeting at Brighton, as representing the Society. The Treasurer's report showed that the expenditure for the past year had been £178 15s. 7d., and the income £192 9s. 6d., leaving a balance of £13 13s. 11d., including a donation of £5 from the President, who had agreed to give £5 for every 100 members who doubled their subscription. The Secretary reported as to the publication of the Society during the past year. It was that 25 miles of printed message, inches broad, and weighing 6 cwt., had been issued to the members within 10 months. Dr. Cleghorn reported that the judges on the competitive essays had awarded the following prizes:—The medals best suited for the various kinds of forest trees indicated by the plants that grow naturally upon them (silver medal)—W. Gilchrist, forester, Cluny Castle, Aberdeen. Report on plantations under the management of the competitor (gold medal)—J. Peebles, forester, Highclere Castle, Newbury, Berks. On the effects of the dry seasons of 1868-69-70 on forest trees and shrubs (gold medal)—Mr. R. Hutchison, of Carbonrie. [Note.—Mr. Hutchison presented his claim for the medal, £5 5s., as an additional donation to the Society.] Report on the comparative advantages of home-grown timber to foreign (bronze medal)—D. Hamilton, forester, Tullichewan Castle (silver medal). On the best mode of cultivation and varieties (silver medal)—W. Gilchrist. Report on the more extended cultivation in Scotland of charcoal-producing plants for gunpowder manufacture—grown either as a crop or as underwood (silver medal)—J. Michie, forester, Cullen House, Banff. For the best and approved collection of Cones, exhibited by a practical forester, and produced in Britain—1st prize, 5 guineas (offered by Messrs. T. Methven & Sons, nurserymen and seedsmen, Edinburgh)—C. Y. Michie, Cullen House; 2d (a gold medal). J. Bell, forester to the Duke of Wellington, Hampshire. On a simple method of measuring the heights of plantations (bronze medal)—J. Kay, forester, Bute estates. Report on trees grown on undrained moorband pan (silver medal)—A. Gilchrist, Ury House, Stonehaven. Report on a new pruning chisel (silver medal)—W. Gilchrist. Report on a tape for measuring timber (bronze medal)—D. Tait, Ouston Park, Doncaster.

The remainder of the business was of a formal nature. The members dined in the evening in the Albert Hotel—the President in the chair, when, after the usual loyal toasts, the following, among others, were given:—"The British Association," by the Chairman; Prof. Balfour replied. "The Forest Department of India," by Mr. Sadler; replied to by Dr. Cleghorn, late Conservator of Forests in India.

YORKSHIRE GALA: *Oct.* 24.—The annual dinner of the guarantors and friends of the Yorkshire Gala took place at Harker's Hotel, York. About 60 gentlemen sat down under the presidency of Mr. Alderman Steward and vice-chairmanship of Mr. Alderman Dove (two gentlemen holding the same position in connection with the Gala). After the usual loyal and patriotic toasts had been disposed of, the Lord Mayor proposed "Success to the Yorkshire Gala." He said he need not say a single word to those who had not only been the originators, but who had subsequently been the earnest supporters of the Yorkshire Gala, to ensure for that proposition a very enthusiastic reception. It was desirable on all those occasions to try to realise what was the position of an institution like that. He would remind them that that gala had now been in existence 12 years—that it was formed for the purpose of giving floriculture a fair and immediate district—that it had a further object in the advantage of the city at large—and also in its origin there was the desire on the part of the promoters to contribute to the public charities of the city. Well, for the 12 years he need not remind them that it had a somewhat varying success. From 1859, when the society was formed, down to 1864, there was no doubt that the success that attended it was of a very varied character, but still during the whole of that time it had an extent of success which did enable it to divide £300 amongst the public charities of the city. In 1864, as they would be aware, the mode of operation was in a degree changed, it was felt desirable that a guarantee fund should be formed, and those who became the guarantors had had the satisfaction of having their money returned to them, inasmuch as from 1864 to 1869, such was the success that attended the institution, that it was enabled to amass to itself the sum of £1000. That £1000, with the exception he was just about to mention, remained as a reserve fund. And he believed the true source of that gala would depend upon that reserve fund being retained at the amount to which it had now arrived. The gala in 1870, as they knew, was marked by unpropitious weather, and the effect had been to reduce that fund from £1000 to £700; and in 1871 there was a great fear on the part of those who had the management—especially on the first unfavourable day—that the reserve fund would be more diminished. But the weather on the second and third days was better, and it was satisfactory to know that at all events they came out of the gala of 1871 without loss. Accordingly there remained that £700 still invested to the credit of the gala fund. The point he wished to bring them to was this. Those who were present at the luncheon held at the gala ground, on the first day of the exhibition this year, would not fail to remember what was said by Mr. Williams, of London. He said that the York show stood the third in the kingdom, London being the first, and Manchester the second. He (Mr. Williams) also supplemented that statement by saying that it was most important to the continuance of the success of the gala that there should be somewhat more of special prizes than they offered them. It was perfectly true that the prizes at the last show amounted to £500. It was perfectly true that it was a strong inducement for gentlemen to send their flowers and fruits to the gala. But those prizes were not only taken by their own citizens, but by parties who were good enough to send to the gala from very considerable distances. They had exhibitors from London, Manchester, Cheshire, Hereford, and nearly every part of the kingdom; and if they were to preserve the interest that had been so strongly manifested, it was necessary to tempt in the way of special prizes. How then were the special prizes to be obtained? He believed that the annual subscribers to that institution had been reduced to ten, and he asked if that was creditable to the city, or for the interests of the institution that it should be so? They should bear in mind what the gala did for York. He had said that one of the original objects was to benefit the city by attracting within its walls large numbers of people. He made these remarks because he knew they would go forth to the public, and with the object of inducing his fellow-citizens to look upon the gala as a beneficial institution.

Notices of Books.

The fourth part of the 27th volume of the *Transactions of the Linnean Society* has recently been issued. It contains three papers only, but those of considerable importance. The first is devoted to the description of sundry fishes or molluscs, &c., collected by Dr. Cunninghan during the voyage of H.M.S. Nassau, during the years 1866-69-70-71, and calls for no special notice at our hands. The second paper is entitled a Revision of the Genus Cassia, and is from the pen of our great systematist, the President of the Society. Mr. Bentham gives a complete monograph of the genus, which consists, according to this enumerator, of "not more than 300 species, many of great beauty, some of great interest from the variety or singularity of their forms, and some, such as the species producing Senna and the Cassia Fistula, of importance from a medicinal point of view. The following remarks are invested with additional weight, as coming from one whose experience, practical sagacity, and long-continued attention to the study of species, in the determination of what is a species, which no one has yet succeeded in giving; whereas, by adopting the doctrine of descent, natural genera, sections, species, and varieties become superior, and (or) subordinate groups, similar in nature and differing only in degree. Under this aspect, when treating of the area occupied by a group, it matters little whether you call it section, species, or variety, provided you make yourself clearly intelligible as to what is the grade of subordination you have in view, and, following the terminology which you believe to be the most generally received, you keep to the same unity even when you consider the same grade throughout the genus or order you are considering."

These words, from so eminently cautious a naturalist as Mr. Bentham, and one who for so many years was an adherent of the opposite views, redound as greatly to his credit for freedom from prejudice as the similar exemplification on the part of Sir Charles Lyell. The doctrine of evolution, however, seems so natural in its application to classification, that it seems now only wonderful how it could so long have been disputed. The so-called natural system, apart from chronological relationship, group from group, is an utter paradox. In what manner the evolution took place is another question, and one on which there is still room for much diversity of opinion. The third paper is entitled "Contributions to the Natural History of the Passifloraceæ," by Dr. Masters, and includes a general sketch of the structural modifications and development of the organs in the principal genera, together with notes on their physiological office. A complete classified list of all the species of the tribe Passifloreæ, with the principal synonyms, is given, which may be of some service to horticulturists. In connection with this part of the subject, the author goes into some detail as to the relative importance of "characters" and the use to be made of them in classifying plants upon philosophical principles, the main points insisted on being the great relative importance of morphological characters in the formation and distinction of the larger groups of plants, and of the secondary or "acquired" characters in distinguishing the smaller groups. These acquired characters are often furnished by special developments intended to fill a particular office, or are adaptations of the fundamental organs to fulfil a special end. The congenital characters are present in all cases, are essential to the life of the plant, and are subject comparatively to but little variation, while the acquired "characters" may be peculiar in each separate species, and are, of course, associated with peculiarities in the manner in which the life-functions are carried on.

The Apiary.

IN answer to "A. H.'s" questions, at p. 1363, I advise him to give up his idea of lining a beehive altogether. No practical apiarian has ever even attempted such a thing, and there are numerous objections to it. Instead of that, let him case the outside of the hive described in the number for September 10, 1870, either with a movable case standing on legs, and a ridge roof, or, what appears better, by nailing slips 2 inches broad, and half an inch thick, at each corner, and then ¾-inch stuff over to cover all the hive, with a space of half an inch between. Either a flat or a ridged top could be placed upon this, care being taken that ample space be left for the escape of heated air from the sides. It is difficult to understand how it could have been intended to place the hive, as described and figured, in the open air, without protection from sun-beat, &c., as the combs would almost certainly melt down in a warm situation. Perhaps it was intended that it should be covered in the rough and ready way that Mr. Pagden puts it in his book he practises — throwing a washed superphosphate bag over, and then putting an earthern pan, &c., on the top.

By acting as above advised, "A. H." can preserve the form of the hive as figured by "D.," and will require no feeding drawer, as a bottle feeder can be placed over a hole in the flat cover. Of course, supers would require some similar casing, which could be made to fit over that of the hive by a hip, that is, a slip nailed on the bottom of the upper case. The cover for the super should be movable. Outside covers may be painted a light colour with advantage, hives themselves not at all. *A. Boyle, Whitland, Nov.* 4.

Obituary.

WE regret very much having to announce the death of Mr. ALEXANDER CAMPBELL, SEN., which took place at his residence, Churchill, Glasnevin, on Monday, October 30, at the age of 67 years. For a considerable time he had been suffering severely, so that his death was not altogether unexpected. There are numerous who Mr. Campbell personally who will not regret to bear of this event. For many years he led the van of Irish horticulture with Roses, Dahlias, Pelargoniums, and other florists' flowers. As a friend he was constant, cordial, and sincere; and as a neighbour kind, generous, and benevolent, upholding in all his relations through life a charitable feeling and an honourable forgiving disposition towards all he came in contact with. The members of the Dublin Horticultural Club will have cause to regret his death. In him they always had a willing fellow worker, ever ready to aid with his purse and sound advice any object for the good of Irish horticulture. *Gardeners' Record.*

THE WEATHER.

JAMES GLAISHER.

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

As *Liliums* succeed well if potted about this time, those who intend to perform the operation should do so now; though I shall take the opportunity of calling attention to the subject at a later date, when the subtle influences of increased light suggest an early return of spring. I wish, however, to impress upon my readers that, whichever period is chosen for potting Lilies, they should not under any consideration allow the bulbs which are now resting to become too dry, or, as some would say, to "dry off." Encourage the surface-growth to increase effectually by natural exposure; nevertheless, if there is one thing more hostile than another to the successful culture of the gorgeous *L. auratum*, it is to be found in this practice of "drying off" the bulbs and the balls of soil containing them. It must be understood, however, that there is a great difference between keeping an unvarying latent moisture in the soil, and the actual resort to periodical waterings. The main thing is to keep them in a cool temperature, without going much below 45°; but in this respect no better lesson can be inculcated than a study of the climatic condition of their native country—Japan, which, notwithstanding that we have no extensive data to guide us is, so far as we know at present, remarkably free from great or sudden fluctuations. Perhaps, too, more rain falls there on the average than upon the British Isles; whilst the mean summer temperature does not exceed 60°, that of winter being about 50°. These, I take it, are as essential and reliable guide to us in the culture of Japanese Lilies. With such a moderate winter temperature the soil of necessity maintains a certain amount of latent moisture, apart from rainfall, in consequence of the no very great extent of evaporation going on, whilst the incessant condensation of aqueous vapours takes place. Besides, Japan is within the margin of the limit of the fall of snow on the northern hemisphere, and snow, as we are all aware, possesses a great moisture capacity. If we consider these simple facts with the practice of placing our "resting" *Liliums* near to flues, &c., at a temperature in excess of the above, and dry to a degree, we cannot fail to see wherein we err. A cool frame wherein they can be plunged in cocoanut-fibre or cinder ashes, will proper protection from frost, will be found of all situations the best for them, and one more in keeping with the conditions which surround them in their far distant habitat. In potting them, efficient drainage is of the first importance, and the soil they thrive best in is an admixture of equal parts of peat and good fibrous loam, a good dash of silver sand, and a fourth of the whole of thoroughly decayed manure. Press the soil moderately firm, and bury the crowns of the bulbs to just above their tips. Persist at this date in watering all plants as early in the day as possible, more especially those growing in cool houses, conservatories, &c. By these means much of the extraneous water distributed will dry up during the day, and the plants will be in a more fitting condition to withstand the adversely moist air of night. I would urgently suggest that "damp" should be constantly dispelled from all such cool structures by the aid of occasional firings, as it often takes hold of plants in an incredibly short time at this season, and prevention in this manner saves disappointment, and a material outlay of both time and subsequent fuel.

FORCING HOUSES.

A fine day should now, if possible, be chosen upon which always to water the younger stock of *Pines*, an operation not calling for very frequent attention at this time. Always be particularly careful with those which have their pots in the vicinity of pipes, flues, &c., as they will require watering more frequently than others. Those *Pines* which are progressing for a "show" in a couple of months' time or so, must only be pushed along very gently, and so as to "get them up" when the influences of lengthened days and increased light become more felt, and good sound progress can be anticipated. On the other hand, in all instances where the fruit is in process of formation, no check whatever must in any shape be permitted. As the fruit is the aim and the end, all ulterior considerations regarding the plant must be set aside, and the operations of swelling, ripening, &c., be excited to the end. Finish pruning *Pot Vines*, and treat them once with the usual preventives of mildew and insects. Lay such as are not required for the present upon their sides in a dry situation. Keep all *Vineries* which are just now being denuded of their last bunches of Grapes as cold as possible by giving air freely was to cause the Vines to go to rest with all possible dispatch, as the longer they rest naturally, so much the better for their future vigour. *Figs* in pots may now be either potted or deeply mulched. If they are potted, a very moderate "shift" only should be given, and, if the main object is fruiting, a light, somewhat poor soil, composed of loam, old mortar, rubbish, &c., be used. It should be borne in mind, however, that much potting is more conducive of growth than of an abundant crop of fruit.

HARDY FRUIT GARDEN.

Prepare the necessary protection for *Fig-trees* grown in exposed situations. In some counties this is not so much required as in others, but in northern latitudes the protection cannot be dispensed with. Now that the leaves have mainly fallen off *Peach* and *Nectarine trees*, it will be desirable to remove the little sticks which supported the latest summer growths, to unnail some of the younger wood, and so aid the atmosphere in surrounding them more freely, to insure better ripened wood and greater hardihood.

HARDY FLOWER GARDEN.

As soon as the frost destroys the upper growths of the following and similar subjects, cut away their destroyed parts to within a few inches of the ground line, and subsequently take them up carefully:—*Marvel of Peru, Salvia patens, Lobelias* of the fulgens type, and *Dahlias*, &c. *Gladiolus* bulbs should also be taken up now without further delay. Do not cut away the decaying leaves and old flower-stalks, but by hanging them up together in a dry shed, or, what is better, a dry vinery, aid and encourage them to ripen off effectively. Very minute bulbs will, in many instances, be found around the base of the old ones, and should not be rubbed off at this time.

KITCHEN GARDEN.

The frost experienced on the morning of the 6th inst., which here in south Essex approached nearly to 6°, will oblige those who have hesitated hitherto to do so, to make their final arrangements for the approaching winter. Where fine flourishing rows of *Endive*, &c., have not yet been covered, and it is not materially injured when it appears, have recourse to the customary coverings forthwith. For this purpose, Rendle's plant protectors are an excellent and very economical aid, as they may be placed over the rows as they now exist, without the too general drawback of having to uproot them and carry them hence to frames, sheds, &c., which, to say the least, makes the young growths tough, however well they may be blanched. *Sorrel, Mint, Tarragon*, &c., may now be potted up for forcing by all who would be prepared for eventualities. Finish getting in all crops of *Beet*, and the like, and clean and protect *Globe Artichokes* from frosts. *W. E.*

Notices to Correspondents.

*** CARRIAGE OF PARCELS.—We are at all times willing to render assistance in the matter of naming plants, fruits, fungi, &c., but our correspondents should remember that this entails, on our part, a very considerable expenditure of time, labour, and expense, and the least they can do is to pay the carriage of their parcels. In cases where this is not done we shall rigidly adhere to our rule of not receiving such communications. We cannot undertake to name more than six varieties at one time.

BEGONIA : *A. R.* The flowers of your seedling were so much faded and shrivelled that we are unable to pass any opinion upon it. It does not appear to have any very striking characteristics.

BEET : *S. S.* We have tried your Beet, and can report favourably on it. In comparison with Waterloo, it is of fuller flavour, while it is not so coarse as the Pine-apple. The colour is rich.

BOOKS : *Ad. B.* McIntosh's "Book of the Garden" (Blackwood & Sons), and Thompson's "Gardener's Assistant" (Blackie & Son), will probably meet your requirements.

BRONZE-LEAVED HARDY PLANTS : *Devonian*. The best we remember are the dark-leaved forms of Oxalis corniculata and of Ajuga reptans, which you mention. You might add to them the somewhat larger and coarser purple-leaved Plantain, Plantago major purpurea.

CLEMATIS : *T. H.* Clematis seed, in many cases, comes up very slowly, and comparatively few seeds vegetate. It is best to sow as soon as ripe, and keep the seed-pans in a warm propagating-house, waiting patiently for the result. As an exception, it may be mentioned that the small yellow C. graveolens, sown as soon as moderately ripe, germinates in a few days, as freely as Mustard and Cress.

GERMINATION OF SEEDS : *R. D.* asks if any of our correspondents could inform him where he can find a Table showing the depth or degree at which different seeds will not germinate.

GOOSEBERRY, MAYOR OF OLDHAM : *G. S.* We do not see this variety mentioned in any of the catalogues before us, but should think that any of the Lancashire growers could supply you with it. Will some of our correspondents kindly assist "G. S." in the matter?

GRUBS : *S. S.* We can't pretend to tell you what they are without seeing them.

INSECTS : *R. W.* Your "two species of beetles," which have proved so pernicious to Pines, by gnawing the flowers and burrowing into the fruit, are the male and female of one of the many species of Blatte, or cockroaches, which has been imported with the plants. The eggs are deposited in a mass enclosed in a large bean-shaped case, fixed in some corner of the frames, where they might be looked for, and the insects may be trapped by sinking baslns or cups in the plunging material, baited with crumbs of bread, the insects not being able to crawl up the sides. *I. O. W.*

MAGNOLIA : *G. P.* It is rare for Magnolia conspicua to set and perfect its seeds in this country.

NAMES OF FUNGUS : *G. E.* A fine specimen of Clavaria abietina, a fleshy branching Fungus, of which we give an illustration. It varies in character in different

FIG. 316.—CLAVARIA ABIETINA.

situations, and sometimes assumes a green appearance when bruised.—*T. W., Eastwell Park.* Agaricus egenetipes, common in such situations, viz., Cucumber frames, &c.—*G. H. S.* Merulius tremellosus, a rare Fungus.—*J. McD., Magnell Langley.* Agaricus nudus, scarcely edible. *W. G. S.*

NAMES OF PLANTS : *A. C. S.* Asplenium lucidum.—*D. G.* 1, Cyrtomium falcatum; 2, Athyrium Filix-fœmina.—*J. Robson, Bowdon.* Lonas inodora, Gaertn. (syn. L. annua); otherwise Athanasia annua, L., or Achillea inodora, L.; native of Sicily and the S. Mediterranean shores generally.—*Rev. H. H. Crewe.* Fuchsia magellanica (F. macrostemma, F. gracilis), the plant long cultivated in gardens under the erroneous name of F. coccinea.—*J. Carter & Co.* Salvia Horminum.—*J. T. M.* Iochroma grandiflora, *not* I. tubulosa.—*C. B.* Polygocum vaccinifolium.—*F. F. S.* 1, Amaranthus tricolor, E. Iedies; 2, Ruscus Hypophyllum, Italy.—*Mrs. F. F. B.* Francea ramosa.

SOIL FOR TRICOLOR PELARGONIUMS : *Amateur.* Mr. Grieve in that excellent little work of his on "Ornamental Foliaged Pelargoniums," recommends the use of "a somewhat rich soil, composed of turfy loam, enriched with a small portion of thoroughly rotted hotbed manure or leaf-mould."

SWEET POTATO : *A. Y., Hereford.* Batatas edulis, sometimes met with in Covent Garden.

VARIEGATED FLOWER : *J. B.* A very beautiful form of variegation, more distinctly mottled than any we remember to have previously seen. The Lycopodium is difficult to cultivate; the best plan is to pot in sphagnum and peat, and keep in a cool, moist frame.

VINE DISEASE : *J. B.* We are sorry to say that it is the true Phyllovera. Either destroy the Vines, if only one or two are affected, or lift; root prune wherever you see the insect, wash the roots well, burn all dead leaves, and replant in fresh soil. When the insect forms little bags on the upper surface of the leaves, immediately remove and burn them. It will require constant watching to get rid of the pest. *M. T. B.*

WILD GARLIC : *H. L. C.* asks if any of our subscribers will kindly inform him as to the quickest and best way to eradicate Wild Garlic. He has a wood of about 40

acres (adjoining the lawn and pleasure-grounds) full of it, and in summer the smell is most disagreeable.

Wintering Mesembryanthemums, &c. : *J. H.* The heat in which you have the plants named at present will make them tender, therefore the sooner it is reduced the better. The Mesembryanthemums will stand with impunity a temperature of 25° if dry. They will keep well in the spare room you mention, if they have plenty of light. The latter consideration is essentially necessary, as they have a natural tendency to grow during winter. Echeveria glauca will keep in a cold frame ; E. metallica, however, must be kept in a temperature above 35°. Sempervivum calliferum is hardy, but *S. tabuleni* must be kept in a temperature above 40° to keep it sound.

Markets.

COVENT GARDEN.—Nov. 10.

The markets are not so firm as they were a week ago. The provincial inquiries for goods will now relax still we get nearer to Christmas. Outdoor produce is plentiful and good, especially some of the Broccolis. Some large shipments of Almeira Grapes are to hand, but the fruit bears no comparison with that received last autumn. Hothouse Grapes and Pears are sufficient for the trade, and Peaches are nearly over. Potatos have very much advanced in price, Regents making 100. to 130., Flukes 120. to 140., and Shaws 80. per ton.

Fruit.			
	s.d.	*s.d.*	
Apples, per ½ sieve	2 0	10	5 0

Chrysanthemums.

Adam Forsyth begs to offer several thousand, A large flowering and POMPONS, in 48's, well set with flowerbuds, suitable for conservatory or outdoor decoration, at 8*s.* per dozen.

A fine general Collection, which is the largest in England, will be in FLOWER throughout the months of NOVEMBER and DECEMBER, when a VISIT is respectfully solicited.

Stoke Newington, Stoke Newington, N.

Chrysanthemums, both New and Old.

H. Cannell begs to inform his friends and Customers that he has now the best stock of PLANTS in his career perhaps ever seen, consisting of 300 of all the most popular varieties, and about three dozen of each kind are continually being added. Being well planted out of pots during every season, on purpose to keep the whole collection perfectly true. They are now in splendid condition, and admirers of this family are invited. For price of Plants, Rooted Cuttings, and Cuttings, see H. C's Floral Guide, which contains a great deal of valuable information, including how to grow them to the highest perfection for decorating, and for cut flowers. Two stamps.

New Florist Flower and Florist Flower-Seed Merchant, Woolwich.

New Catalogue of Bulbs, Plants, Fruits, &c.

Robert Parker begs to announce that the CATALOGUE, with descriptive Selection of Novelties and Priced Lists of Dutch and other Bulbs, Plants suitable for Bedding and Flowering Purposes, Fruit Trees, Grape Vines, Sweet Violets, &c., is now published, and will be forwarded to applicants.

Russell Nursery, Stirling, Surrey, S.W.

Fern and Alpine Catalogues.

A. Stansfield and Son will forward their NEW CATALOGUE of FERNS, No. 9, for 1871-72, containing 40 pages, with descriptive and cultural remarks, for three penny stamps; also their HERBACEOUS and ALPINE PLANT LIST for 1871, containing more than 1000 species for two stamps.

Vale Nurseries, Todmorden, Lancashire.

To the Trade.

To be disposed of, 20,000 EVERGREEN PRIVET, 2 to 3 feet, bushy, at 30*s.* per 1000.

8000 GREEN BOX, 15*s.* to 2 feet, 18*s.* per 100.

3000 IVIES of sorts, 18*s.* per 100.

2000 AMERICAN ARBOR-VITÆ, 2 to 2½ feet, at 10*s.* per 100.

50 bushels HERTSABER ARTICHOKES, at 3*s.* 6*d.* per bushel.

WILLIAM RUSHFORTH, Woodhouse Hill, near Leeds.

Moor Edge Nurseries, Tansley, near Matlock, Derbyshire.

Joseph Smith, Jun., begs to announce that he holds large stocks of FOREST TREES, COVERT and HEDGE PLANTS of every description, suitable for planting; also EVERGREEN and FLOWERING SHRUBS, &c., of which CATALOGUES will be forwarded free on application, and special offers given for large quantities.

SURPLUS STOCK of the following to be SOLD, cheap:—PRINCE ALBERT, LINNÆUS, and VICTORIA RHUBARB; PASTOLE RASPBERRIES; 437 old ASPARAGUS; SKIMMIA JAPONICA; CLEMATIS LANUGINOSA; CUPRESSUS LAWSONIANA; PERNETTYA SPECIOSA, the berry-bearing variety; AUCUBA LIMBATA, bicolor and viridis; SALIX BABYLONICA PENDULA; MONOMII, the best WHITE WILLOW. Prices, &c., on application.

ISAAC DAVIES, Nurseryman, Ormskirk.

New Tea-scented, Noisette and other Roses.

John Waterer and Sons are offering strong plants, in pots, at 12*s.* per dozen, comprising the following sorts:—Maréchal Niel, Climbing Devoniensis, Belle Lyonnaise, Chamois, Jeanne d'Arc, Le Mont Blanc, Madame Dachez Duchet, Comte Tour Bertrand, Lamarque a fleurs Jaunes, Rêve d'Or, Isabella Sprunt.

Clematis Jackmanii, *i* Clematis rubra violacea, Clematis Standishii, and others, 12*s.* per dozen, very strong stuff. Trade price on application.

American Nurseries, Bagshot, Surrey.

New English Rose (Hybrid Perpetual Climbing), Victoria Adelaide.

Wm. Knight, Floral Nursery, Hailsham, Sussex, the raiser of this Rose, to be sent out this month for the first time. Good plants, 18*s.* per doz.; 4 each, 12*s.* Price list gratis on application. Three First-class Certificates. See Report of Floral Committee in *Gardeners' Chronicle*, September 30, 1871.

It will be figured in the "Floral Magazine" for November.

Coloured Drawings will shortly be ready, for 12 stamps, post free.

Persons Priced CATALOGUES free on application.

Notice.

H. Lane and Son's Descriptive Catalogue of ROSES, FRUIT TREES, VINES, CONIFERS, DECIDUOUS and EVERGREEN TREES and SHRUBS, RHODODENDRONS, AZALEAS (Indian), CAMELLIAS, &c., may now be had free on application. The prices will be found moderate, combined with quality. An inspection of the growing stock is earnestly invited.

The Nurseries, Great Berkhamsted, Herts.

Standard Tea Roses, and Others, from Paris.

Lequeux & Cuillerois, Nurserymen, Bois-sur-Seine, near Paris (late Boulevard de l'Hopital), beg to offer the largest stock of ROSES ever seen, at the following prices :—

Standard Tea Roses, all the best sorts, 42*s.* per 100. (This stock is beautiful, and very extensive.)

Standard Hybrid Perpetuals and Moss, £4 per 100.

Half-Standard Hybrid Perpetuals and Moss, £3 4*s.* per 100.

Dwarf Hybrid Perpetuals and Moss, 30*s.* per 100.

On their own roots, grown in pots, splendid stock, £3 per 100.

Tea sorts, Dwarfs—Souvenir d'Elise, Devoniensis, Jean Cornet, Madame Margottin, and all the best, £3 per 100.

Maréchal Niel, Standards, £5 per 100 : Dwarfs, £4 per 100.

Plants per cent. per cent. on the new sorts of 1870.

LISTS on application. CATALOGUES now ready.

Gladioli Seedlings, by Name, from Paris.

Lequeux & Cuillerois, Nurserymen, Bois-sur-Seine, near Paris (late Boulevard de l'Hopital), offer the following :—

Gladioli seedlings, first-rate strong, 7*s.* per 100 ; £3 per 1000.

100 Gladioli, by name, 10 sorts			£0 8 0
100 "	" 25 "	"	0 12 0
100 "	" 50 "	"	£1 10 0
100 "	" 100 "	"	£4 10 0

And upwards, according to the novelty of the sorts; all in good flowering bulbs.

Caladiums.

Charles Verdier, 63, Nurseryman, 12, Rue Dumfeil, Paris, begs to offer this autumn for the first time the SIX UNDERMENTIONED CALADIUMS (Mr. Bleu's Seedlings). These plants have been carefully studied during three years and surpass any that exist up to this time.

C. Bleuet	25*c.*	C. Lefeschkinii	30*c.*
C. Donizettii	12*c.*	C. Leplay	16*c.*
C. Laurentii	16*c.*	C. Rose	16*c.*

Full description will be sent on application.

CATALOGUES of Fine Orchids, Gesneras and Gladioli are now ready, and may be had post free either from

CH. VERDIER, or of his London Agents, Messrs. R. Silberrad and Son, 5, Blair Lane, Great Yarmouth.

Choice Tricolor Geraniums.

Prince of Wales	Mrs. Dunnett	Sunray
Princess Beatrice	Sir R. Napier	Italian Beauty
Coronet	Phœbus	Mrs. John Clutton
Pre-eminent	Lowbanian	Mabel Morris

The 12 for 21*s.*, package included. Terms cash. Remittances requested from unknown Correspondents. A LIST of 250 varieties post free.

ALFRED FRYER, Nurseries, Chatteris, Cambridgeshire.

Hardy Spring Bedders. Surplus Stock, Cheap.

Mount Ephraim Nurseries, Tunbridge Wells, Sussex.—Blue Forget-me-Not ; DACTYLIS GLOMERATA VARIEGATA ; Silver Ribbon Grass, 6 inches The Arabis Variegata will not less than 100, separately or assorted, for 8*s.* Stamps to accompany orders by post.

W. STANDEN, Gardener, Chase Side, Southgate, near London, N.

Maurice Young's New Descriptive LIST of CONIFERÆ, HARDY ORNAMENTAL TREES and SHRUBS, EVERGREENS, FRUIT TREES, and ROSES, cheap. EVERGREENS for cover, WINTER BEDDING PLANTS, FUCHSIA, JAPANESE MAPLES, FRUIT and FOREST TREES, &c., is now ready, and will be forwarded on receipt of stamp for postage.

Milford Nurseries, near Godalming, Surrey.

Ornamental Trees and Shrubs.

Thomas Kennedy and Co., Nurserymen and Seedsmen, Dumfries, beg to intimate that, in consequence of a large portion of their Ornamental Grounds having been Disposed of for Building Purposes, they are now offering their large and FINE STOCK of ORNAMENTAL TREES and SHRUBS, at reduced prices their splendid stock of ORNAMENTAL TREES and SHRUBS. These being of all ages and sizes, are particularly well suited for Immediate Effect, and will repay inspection by Planters improving of Ornamental Parks, Pleasure Grounds, &c. Inspection invited.

Wanted, as working ground foreman, for a Nursery in the United States, a steady, active young Man—good Budder and Grafter, with a general knowledge of Nursery Stock. Wages, £100 per annum, with a rise. Apply to A. JUNIOR, CLERK.—one acquainted with Packing small Packages of Seeds and Plants by Post preferred. Both to be active, good Penmanship, and, in order to avoid delay, enclose references or testimonials to J. S., Mitre, Hanover Square, London, W. Shrubs Direct, Hanover, W.

Wanted, by a Florist, at a distance from London, a steady, active, young MAN, who thoroughly understands the Propagation of Bedding Geraniums, Calceolarias, Cinerarias, and Verbenas, as well as the general treatment of Greenhouse and Stove Plants.—Address, stating full particulars, FLORIST, *Gardeners' Chronicle* Office, W.C.

Wanted, a PROPAGATOR and GROWER of PLANTS.—A married Man, without family preferred.—JAMES HUDDART, Farrington Hall Nursery, Preston.

Required, the SERVICES of FOUR or FIVE YOUNG MEN accustomed to Nursery and Outdoor Propagating.—Address, stating terms, to WM. WOOD and SON, Nurseries, Maresfield, Uckfield, Sussex.

To Nursery Foremen.

Wanted, a good SECOND MAN, who understands Grafting and Budding, and general Outdoor work.—Apply to J. C. WHEELER and SON, Nurseryman, Gloucester.

Seed Trade.

Wanted, as IMPROVER, a young Man or Youth, Temperate habits, and who wishes to learn the business of the Trade. State age, wages, in what capacity lately employed, &c.—S. FINNEY and CO., Seed Merchants, Newcastle-upon-Tyne.

Wholesale.

Wanted, an INVOICE CLERK.—Must be thoroughly conversant with the London Trade, and have filled a similar situation.—Apply, by letter only, to C. A. S., 29, Maude Road, Camberwell, S.E.

Wanted IMMEDIATELY, in a Wholesale Provincial Nursery, an energetic Man as SALESMAN and OFFICE ASSISTANT.—Apply, enclosing references, to R. N. N., Messrs. Nutting & Co., 60, Barbican, London, E.C.

James Veitch and Sons Require for their SEED WAREHOUSE an ASSISTANT, who has had two or three years' experience. He must be expert at Penciling, and a good Penman.—Apply by letter, stating age, experience, and wages required, Royal Exotic Nursery, Chelsea, S.W.

WANT PLACES.—Letters to be Post Paid.

Experienced GARDENERS (or as GARDENER and BAILIFF), of various qualifications, recommended to Gentlemen.—Further particulars given on application to Messrs. E. G. Henderson and Son, Wellington Nursery, St. John's Wood, N.W.

Gardeners and Under Gardeners.

W. Cutbush and Son beg to state that they have at all times on their books MEN of various qualifications, whose characters will bear the strictest inquiry. Any Gentleman making application would save time by clearly stating the duties to be undertaken, wages offered, &c., so that suitable Men may be selected. —Highgate Nurseries, London, N.

To Curators, Nurserymen, &c.—A well-educated young Man, having an extensive knowledge of Orchids and other Exotics, desires a situation as Botanic Garden or first-class Nursery at home or abroad. Is an excellent Correspondent, and a good Botanical Artist. No objection to Travel. Experienced as Amanuensis, &c. Certificated in Botany and Drawing by the Society of Arts, and in practical Horticulture by the Royal Horticultural Society, London. Excellent references, &c.—LITHO, 19, Alfreton Road, Nottingham.

Gale (Head).—Married, one child ; thoroughly understands the duties in every branch. Eight years' unexceptionable reference.—C. W., Post Office, Gumby, Market Harborough.

Gardener (Head).—Age 32, married ; has had many years' experience in all branches of Gardening. Can be highly recommended by his present employer, with whom he has been a few years, and is leaving in consequence of the place being given up. No single-handed place accepted.—W. M. Greenwood, Aldersawley Hall, Derby.

Gardener (Head).—Age 40, married, family. The advertiser, who is now disengaged, begs to offer his services to any Nobleman or Gentleman as thoroughly practical Gardener. Twenty years in the previous situation, and three years in the present. Can be highly recommended. Unexceptionable character will bear the strictest investigation.—J. Adams, 4, Southsea Road, Surbiton, Surrey.

Gardener (Head, Working).—Age 28, married ; thoroughly practical in every branch of the profession. Good character.—H., Cook's, 4, St. Mark's Villas, Tollington Park, Horsey, N.

Gardener (Head, Working).—Age 35, married, no family ; well up in Early and Late Forcing of all kinds of Fruits, Flowers, and Vegetables, also Flower and Kitchen Gardening. Has been nine years Head Gardener. Good character.—A. B., 3, Myrtle Terrace, Hamilton Road, Norwood, S.E.

Gardener (Head), where one or more are kept. —To prevent delay, the best first-class reference.—G. L., Ivy Cottage, Esher Road, Leytonstone, N.E.

Gardener (Head), where one or more are kept, and where a Young Man could be had—active, and trustworthy Scotchman, who understands all Indoor Work, also Flower and Kitchen Gardening. Two years' character for leaving, Good reference from present and previous employers.—J. K., Post Office, Tarland, Aboyne.

Gardener.—Age 21 ; has had experience in Stove and Greenhouse Plants, Vines and Pines, and Flower and Kitchen Gardening. Can have first-class character from last situation. —J. W., Post Office, Sandhurst, near Wokingham, Berks.

Gardener (Journeyman).—A strong, active Man, who wants an insight, and is not afraid of work. First-rate character as a Man and Workman.—Apply to George Edward, Seedsman, Aberdeen.

Foreman, in a good Establishment.—Age 22 ; strong, active, and well up in all branches. Good reference.—Mr. Budd's Nursery, Hatfield, Herts.

Foreman, or Single-handed.—Age 27, single ; five years' experience in Gardens. Can Milk or take care of Horse and Carriage.—A. Sheffield, Beckley, near Oxford.

Propagator in general, or Propagator and Grower.—Age 26 ; good character from last situation.—A. B., Post Office, Ascot, Berks.

Propagator (Soft-wooded) and Grower.—A thorough knowledge of the profession ; can grow for Exhibition or Market.—Age 25, good character.—R. C., 13, Hill Street, Stoke Newington, N.

To Head Gardeners.

Improver (age 20).—Scott, The Gardens, Stourton, Knaresborough, can with confidence recommend a very steady, respectable, and industrious Man, as above.

ADVANCER	CHAMPION OF ENGLAND
NELSON'S VANGUARD	BRITISH QUEEN
VEITCH'S PERFECTION	SCIMITAR
and others.	

Lowest price per bushel or quarter on application.
SUTTON AND SONS, Seed Growers, Reading.

Late Rose Potato.

THIS valuable NEW SEEDLING WINTER POTATO is now for the first time offered to the Public. In its colour, habits of growth and general appearance, it resembles its parent, the Late Rose, but is superior to that variety in the following highly important particulars:—
1st, It is of much better quality for table use, being white fleshed and fine grained, cooking mealy and remaining so, and of a delicate, peculiar, rich and delicate flavour, not surpassed by any variety yet tested.
2d, Its yield is enormous. The stock was grown at the rate of from 230 to 300 bushels per acre, considerably field-cultivated, to make special quotations for large quantities.
3d, Its vigour. Unsurpassed. In the same cellar, at planting time, when the Early Rose were so badly sprouted and wilted as to be unfit for table use, this Seedling was found not sprouted, and were as crisp and solid as when first dug. They remained in good condition for cooking until the new crop of Early Rose came upon the table.

☞ For Sale by the London Seed Trade generally.

MR. JAMES FRASER, HORTICULTURAL and AGRICULTURAL VALUER and AUCTIONEER, Mayland's Farm, Romford, Essex; late of the firm of J. & J. Fraser, Lea Bridge Road.

MR. LEWIS S. WOODTHORPE, HORTICULTURAL AUCTIONEER and VALUER, Munro Nursery, Sible Hedingham, Essex. SALES conducted free of charge.

JOHN B. LYTHALL, Secretary.
Offices of the Society, 39, New Street, Birmingham.

The Agricultural Gazette.

SATURDAY, NOVEMBER 11, 1871.

MEETING FOR THE ENSUING WEEK.
MONDAY, Nov. 13 { Institute of Surveyors (10, Great George Street, Westminster)—8 P.M.

THE discussion which followed the very able speech made by Mr. C. S. READ, M.P., on "THE AGRICULTURAL LABOURER, his Employment, Wages, and Education," before the London Farmers' Club on Monday evening was full of interest, but by no means exhaustive; indeed, so much was this felt, that it was suggested by the Chairman, Mr. SPEARING, that the same subject, or one closely related to it, should be brought forward early next year, so that the debate might in a manner be adjourned until that time.

The first speaker was Mr. S. SIDNEY, who compared the condition of the agricultural labourer with that of the artisan employed in towns, and stated his belief that the former was generally but a few degrees removed from the condition of pauperism, a remark which called forth expressions of dissent. He proceeded to explain that this was in a measure the effect of the great agricultural depression which followed the wars of the early part of the century, but that it was especially due to the pernicious system of supporting parish relief in such a manner that he who had the largest family had the largest share of support, thus at once lowering his independence, and putting self-help in his case very much out of the question. To raise the standard of the agricultural labourer, he must be made to feel himself an independent man; and the first thing to be done in this direction is to provide him with a good cottage to live in, and with that a suitable amount of garden ground. As to the education question, he believed that it would do but little good until the labourer was raised into a position above that of a pauper, which can only be done by giving him constant employment, better

cottages, and good garden accommodation. But this, he intimated, cannot be accomplished until the land is relieved from the fetters of entail; though by that he did not mean that it was desirable to convert all the country into small freeholds.

Mr. Masfen indorsed some of Mr. Sidney's observations, but was directly at issue with him upon others. He would like to know in what county he could go and not find a good garden attached to the labourer's cottage. He also said that the great occupiers are frequently accused that they do not adequately pay the labourer; but the fact is, that they pay much more per acre now than they did 20 years ago, though the labourers do not put so much muscle into their work as they used to do. He compared their circumstances with those of the skilled artisans and colliers in his district; and it was forcibly shown that the labourer did not lose anything by the comparison. The only complaint he could make against his brother farmers was their continuance of the system of doling out beer during harvest.

Mr. Albert Pell, M.P., thought the condition of the agricultural labourer was on the whole satisfactory. He commented upon the long hours of toil and meagre pay of railway servants, a class largely recruited from the rural population, and explained his views on the nine hours movement and the gang system of employment. It should not be forgotten that the pay of the labourer is good and increasing. He referred to the immense advantage which the keeping of a cow gave to the labourer, and on the subject of cottages stated, that he knew a large landed proprietor who had a system on his property of granting building leases of ground for the erection of cottages. He mentioned a curious case of entail on an estate in Norfolk, which had very recently come under his notice, and which was that the rent of certain cottages was not to exceed a stated sum, and that so much land was always to be attached to them. He thought something in this way might be usefully done by philanthropists.

Mr. James Howard, M.P., thought the farmer need not trouble himself much in making comparisons between the labourer and the artisan, in relation to the supply of skilled labour, as this question would settle itself by natural laws. He thought that when they talked of the increased cost per acre, they should remember that the production also was double that of 20 years ago. He agreed with Mr. Read, that the old men on the farm should, where capable, be employed in tutoring the young hands; and it would be much to the interest of the farmer if they also initiated them into the way of working and properly looking after machinery.

Mr. Neild said that in no place was the question of labour so much felt as in Lancashire. He stated that at his harvest dinner a fortnight ago, one of his labourers had suggested that they ought to grow more stuff, and his machineman had told the farm labourers that it was a great mistake on their part to condemn machinery, as he believed the time would come when no farmer would be able to do without it. After that statement he thought it was time for farmers to see to the education of their sons, or the agricultural labourer would soon beat them. He was of opinion that the more they improved the land and increased the crops, so would the price of labour increase. In the matter of cottages there ought to be built on every estate as many cottages as there were families of labourers to occupy them. Much might also be done on farms of mixed soils, if the farmers would endeavour to keep on the same number of men in winter as in summer, which he could easily manage to do.

Mr. Trethewy quite concurred in the opinions expressed by Mr. Read on the subject of cottages, and expressed his opinion that the labouring class would be much benefited if they would endeavour to equalise the supply and demand for labour by migrating from those districts where work is scarce to others where it is more plentiful.

The Rev. E. Smythies thought the question one of the most important ever discussed—farmers never having passed through such a difficult period as the last harvest, in consequence of their inability to command the amount of labour required to get in the crops.

Mr. Read, in replying, said that he agreed with Mr. Sidney that they could not expect much from the agricultural labourer whilst the present Poor-laws exist; and he agreed with Mr. Masfen on the question of beer, which he did not give on his own farm as a part of the wages. As regards the increase of crops mentioned by Mr. Howard, he found the thickest crops the cheapest to cultivate and keep clean.—The usual vote of thanks concluded the meeting.

Russia is entering with eagerness on the career of Progress which the recent alterations in the political and social *status* of her inhabitants have thrown open to her. These alterations (however much some individuals may have suffered from them) have already conferred a certain degree of material prosperity on the great body of the people, which is obviously only a foretaste of what is to come; and the State itself, the Government in contradistinction to the governed, has shared in the general amelioration. We have it on excellent authority, that the heavy arrears of unpaid taxes, which used to burden the State ledger, have, since the liberation of the serfs, gradually and rapidly diminished. The people are able to pay, and do pay, the assessments which their owners formerly were unable to do, or at least did not. This prosperous state of things naturally encourages the Government to persevere in the liberal and enlightened course which has proved so successful, and a general impulse is being given, by judicious patronage and support, to all enterprises that hold out a fair prospect of benefiting the country.

There is no doubt a great deal yet to be done, and in many points the Russian statesmen still follow what we here consider a very erroneous policy. But let us not on that account depreciate or undervalue the good they are really doing. We are not without expectation, too, that even on those points where they appear to us to go farthest astray (their prohibitive protectionist tariff), their eyes may in time be opened. They are learning that commerce, like mercy, is twice blessed,—blessing him that gives as well as him that takes. A great International Polytechnic Exhibition is by Imperial permission to be held at Moscow next year, and for its purposes a relaxation of the tariff is to be made so far as concerns it. It is to be opened on May 30 (June 11), 1872 (the 200th anniversary of the birth of Peter the Great), and a long list of the highest dignitaries of the Empire lend it their support, so as to make it worthy of the great name with which they have connected it.

This exhibition is intended to represent a consecutive series of scientific appliances, or the results of the influence of science on practice, and will admit within its limits not only models worthy of imitation in the respective spheres of domestic economy, trade, and art, but also indications of all the ways and means by which the best results may be obtained therein. All competition among the exhibitors is excluded, the exhibition being based on the principle of invitation and selection by competent judges. The great object which lies at the basis of this undertaking is that of the education of the people, and the exhibition will, therefore, endeavour to supplement all the objects exhibited in it by, as far as possible, full explanations, informations, and practical illustrations. It is therefore desired that exhibitors should take part in the Exhibition, not with the object of comparing their products with those of other exhibitors, but for the purpose of acquainting the public with those ways and means which a certain manufacture, &c., possesses for the attainment of the best possible results.

This, of course, so far as concerns us and other nations similarly situated, is very much like an invitation to teach them how to beat us; but the dread of that has never yet deterred exhibitors from showing their skill. They know that the chance of such a result is small, distant, and problematical, while the benefits of showing the articles manufactured is immediate and practical.

This is the light in which it has been viewed by the Society of Arts, which has readily met the wishes of the Muscovites, and taken up the subject with zeal. A powerful committee to aid in obtaining exhibits from this country has been appointed, and we do not doubt that many of our manufacturers, and notably a section of our own readers (the agricultural implement makers) will see it their interest to avail themselves of the opportunity. Hitherto, although some of our manufacturers, particularly of machinery, have been pushing their way, and have indeed succeeded in establishing a large trade in Russia, this has only been done to a small extent compared with what may be done; and no more effectual way of getting over the difficulties which stand in the way could be devised than the exhibition of the articles with their prices in the heart of the country whose inhabitants we wish to tempt to buy them.

—— There was a moderate supply of English Wheat on Monday at Mark Lane, and as it was mostly in an inferior condition, less money had to be accepted to effect sales. On Wednesday, though the supply was short, it was in excess of requirements.—— At the Metropolitan Cattle Market on Monday there was an increase in the supply of beasts, but as the average quality was only middling, prices were lower than last reported—prime qualities, which were scarce, brought fully late rates. Sheep maintained previous quotations, and choice calves were scarce and dear. At Thursday's market beasts sold at Monday's quotations; and though it was difficult to effect a clearance in sheep, there was no quotable alteration in prices.——Hops are reported firm, choice sorts being difficult to procure.—In the Seed Market there is an increased animation to report.

—— The Council of the Central Chamber of Agriculture met on Tuesday at the Farmers' Club, Salisbury Square, Fleet Street, Sir Massey Lopes, M.P., in the chair. The secretary, Mr. J. A. Clarke, announced that the Duke of Rutland, the Earl of Leicester, and Lord Leigh had become life members, and that the Shropshire Chamber had doubled its subscription. The chairman presented the report of the Committee on Local Taxation, congratulating the Chamber on the increased interest taken by the public in the subjects connected with this important matter since it had been pressed by the Chamber. The report entered very fully into a history of the last Parliamentary session in connection with the proposals to throw increased burdens upon the local rates, and concluded by saying:—

"The committee would point out that the tendency of legislation has hitherto been to throw upon the ratepayers various new charges for objects which, however good in themselves, are matters of national rather than local interest. Chancellors of the Exchequer have thus been enabled to take credit for Budgets which by no means represent the actual taxation of the country, but, by relieving Imperial at the expense of local taxation, give a very delusive impression of the actual amount of our national imposts. The committee, therefore, feel it incumbent upon them to urge upon all their supporters the necessity for increased exertions. Those of the committee who are members of the House of Commons will not fail, when addressing their constituents, to place the bearings and present aspect of the subject fully before them, and when they re-assemble next session they hope that the influence of their supporters will be so increased as to insure a speedy attention on the part of the Government to the injustice of the anomalies complained of. The prospect of the more prominent place in the legislative labours of next Session which the revision of local taxation may fairly expect to claim will, the committee trust, induce all ratepayers, urban and rural alike, to press on their representatives the interest they individually feel on a subject of such vast import to the social well-being of the entire community."

The report was adopted, and ordered to be printed and circulated. A long conversational debate then ensued upon the subject of the cattle disease. On the motion of Mr. C. S. Read, M.P., seconded by Mr. H. Bell, it was decided "That the meeting considers the failure of the Contagious Diseases (Animals) Act has demonstrated the necessity for compulsory slaughter or 14 days' quarantine of all imported foreign animals, as uniformly demanded by this Chamber." A second resolution on the subject was moved by Mr. A. Pell, M.P., seconded by Mr. Smith, of the Essex Chamber, "That Government officers should make their present inspection of all cattle and sheep previous to embarkation in Ireland, and of all vessels engaged in conveying animals between Ireland and Great Britain, as complete as possible." This was also carried, as was a third, moved by Mr. T. Duckham, seconded by Mr. Jabez Turner, "That Government officers should be appointed to enforce the provisions of the Act with reference to the cleansing and disinfecting of railway trucks, yards, and pens, and the watering and transit of animals on railways in Great Britain and Ireland." A fourth resolution expressed the opinion that, if the objects contemplated by the foregoing resolution were secured, the interests of stock-owners and consumers alike demanded the removal of the cattle *cordon* from the metropolitan district. It was also agreed that copies of these resolutions should be forwarded to Mr. Gladstone and Mr. Forster, and that the former should be requested to see a deputation from the Chambers of Agriculture on this subject.

—— Mr. Mechi returns, undaunted by his opponents, to his attack upon the Pasture Lands of the country—now, however, confining his remarks to poor pasture. Writing to the *Times*, he says:—

"Despite the outcry against breaking-up poor pasture land, its doom is sealed. It is a mere question of time, for mighty and driving steam will enable farmers to offer a much greater rent than poor pasture can afford to pay. Pasture must have greatly decreased in this country, for I

find the following remark in the history of our agriculture relative to the period prior to 1400 :—

"'The proportion of pasture land to arable gradually decreased, but was still as 20 to 1.'

"Now it is barely 1 for 1. I also see it recorded that in 1490 the Abbot of Bury, in Suffolk, let 18 acres of pasture on a lease of 80 years at 4½d. per acre. This was before the discovery and conquest of South America by the Spaniards and Portuguese, which flooded Europe with gold and silver, and increased the price (if not the value) of land and its productions 500 per cent.—There exists a mistaken belief that grass land is the main or only source of our meat supply; much more meat may be, and is, in fact, produced on our arable land by means of root and green crops and by the consumption of cake and corn, the result being also a large produce of Wheat and Barley for human use. No doubt, the change from pasture to arable will necessitate a great additional investment of capital on the part of both landowner and tenant; but this should be a source of congratulation, for our large surplus population and capital would then find profitable employment at home, instead of being sent to foreign countries to enable them to grow food for us which we might produce here.

"The aggregate capital of British agriculture is about £5 per acre. That will be multiplied by four when we have arable land, our own steam machines, and plenty of live stock. I know many farmers who have a capital varying from £20 to £30 per acre."

—— Here is another note of the importance of MECHI's on SUGAR-BEET and BEET-ROOT :—

"The great fertilizers of our poor pasture system will be the steam-plough and the growth of Beetroot for sugar. We shall then see these pastures producing from 15 to 20 tons of Beetroot, sold to the sugar factories at 20s. per ton, or an average of £16 per acre, their present produce being only about £2 10s. per acre. The intermediate crops will be valuable grain, pulse, and artificial grasses; and, in lieu of a wretched pastoral inactivity, there will be a vast employment of labour and supply of the increased rents for the landowner and food for the people. This is no speculative anticipation, for its realisation is successfully proved at Lavenham, in Suffolk, and is about to be extended over the south Devon and other districts in considerable portion of the United Kingdom. There is one difficulty about the matter—that is, the conveyance of the roots to the factory. The cartage of roots costs about 1s. per ton per mile, and a radius of supply of 10 to 12 miles is considered a limit of distance by road, unless brought by rail; but the steam pump and underground iron pipes will remedy this, and cause the juice of the Beetroot 17-20ths of its weight to flow to the factories at a probable cost of less than 1d. per ton per mile. I am told that in France this plan is adopted for a distance of 10 miles by one large sugar factory. Squeezing of the juice from the roots is a simple matter, and only requires but little machinery, and no supervising by the revenue officer, who only attends constantly at the central factory, where the machinery for converting the juice into sugar is of the most costly and complicated description. The pulp to be returned to the farmer is only one-eighth the weight of the root, so that he pays 12s. for the pulp of 8 tons of roots, and uses it mixed with other feeding stuffs for his cattle. Dr. VOELCKER values it at 40s. per ton. The difficulty of passing a line of underground pipes through other people's properties will probably be met by Act of Parliament, as it has been with drainage, under the late Lord LINCOLN'S Act, and its compulsory, irrespective of the owner, the outfall drain pipes may be carried through any property, even a garden or park, under condition, of course, of restoration or avoidance of damage. The growth of Beetroot tends to increase the supply of meat by the consumption of the pulp, mixed with other food."

—— The demand which has been made during the past few years for increased remuneration for all classes of paid labour, on the plea of increased prices in most articles of daily necessity, seems not to be confined to our own shores. From a report on the CONDITION of the INDUSTRIAL CLASSES of the AZORES, we learn that the labouring population is extremely depressed. In St. Michael's, where wages are highest, the pay of an agricultural labourer varies from 9d. to 10½d. per day. These low rates of pay are said to be probably 50 per cent. higher than which prevailed a few years ago. But as, within the same period, a large advance had taken place in the price in the Azores of Indian Corn and some other articles largely consumed by the labouring class, it may be doubted whether, notwithstanding the rise in wages, the labourer is better off now than formerly. The introduction of labour has had an effect on the tenure and cultivation of land in the Azores, similar to what has been observed in Ireland and in other countries. Nearly all the arable land is let in very small portions to labourers (or men whose means are little above the very little of those labourers), who, cultivating the soil in great measure with their own hands and those of their families, can, and do, pay their rents which no farmer with capital could afford to pay for any considerable portion of land. In the Island of St. Michael's good arable land is very commonly let at rents equivalent to from £5 to £7 10s. per English acre. The produce of the land, however, though large, must be much less than it might be under a different system, for very little manure is used, and the agricultural tools and implements commonly employed are of the rudest kind, consisting almost entirely of a large hoe, which the peasant uses with great dexterity, and a small rough plough and harrow drawn by oxen. A few of the large proprietors have made efforts to introduce agricultural improvements and modern inventions, and in perhaps half-a-dozen of the largest farms the threshing and winnowing machines of Messrs. Clayton & Shuttleworth and other eminent English firms may be found in use, but such novelties have not found any very general acceptance. The soil of the islands is volcanic and rich in decomposed vegetable matter; it is, consequently, very fertile, and the same land will yield, year after year, crops of Wheat and Indian Corn. In the months of November and December the land is ploughed and sown with the large blue Lupin; this, in April and May, is eaten down by the cattle, and the stalks and roots hoed into the land to enrich it. This system of culture is asserted to be peculiarly successful, and suitable to the nature of the soil; at any rate, it is implicitly believed in, and considered incapable of alteration for the better. The country population live in villages, scattered all over the island, and isolated homesteads being unknown. They go in gangs very early in the morning to their labour, and return together at night. In summer the peasant works from half-past 5 or 6 A.M., to half-past 7 or 8 P.M., or until dark (in these latitudes the longest day closes at 8 P.M., with a brief twilight); and in winter from daylight to dark, having first had a bowl of milk for his breakfast, and an hour at noon for his dinner. He takes his supper on his return home. The diet of the peasant consists of a light morning meal of Indian Corn bread —very substantial and wholesome—made of Indian Corn flour, once slightly sifted, less frequently of unsifted meal, and of fermented Indian Corn. With this they generally eat a few little fried fish, cooked Yams, Pepper-pods, or in the summer season, Cucumbers, Water Melons, or other fruit. A species of small fish, resembling sprats, is largely taken off these islands, and is sold very cheaply, at about 2d. per 100. The peasant's dinner is merely a repetition of his breakfast, and at night his supper consists of some kind of vegetable soup. Meat is rarely eaten by the poorer classes, except at Christmas-time, when every poor household kills its fatted pig; but the best joints, such as the hams, are almost invariably sold.

—— We give in another column a letter from Sir G. JENKINSON, Bart., to Mr. FORSTER, M.P., for which he desires publicity, on the subject of the foot-and-mouth disease.

OUR LIVE STOCK.

WE have received accounts of two Shorthorn sales from the far North, while they do not speak of hundreds of guineas given for a single high-bred heifer, at least show us that the favourite breed is steadily encroaching upon Kyloes and Polls even on their own ground. The annual sale of a portion of the Keithmore herd, the property of Mr. Cantley, took place on Thursday, the 9th inst., at Keithmore, near Dufftown, Banffshire. Mr. Cantley has improved his stock by the use of the Duke of Richmond's RESOURCE, the Duke of Buccleuch's ARGUS, and other good bulls, until his herd is looked upon by many persons as the best—reared at such a height above the sea—in the north of Scotland. The attendance was good, and the sale was considered successful. The following prices were given for yearling bulls :—IVAN, 26gs., Mr. Smith; KEITHMORE, 53 gs., Mr. Gewall; WALLACE, 38 gs., Mr. Gordon; RICHMOND, 37 gs., Mr. Peter Grant; JARNAC, 27 gs., Mr. Green; RUBY, 20 gs., Mr. Green; BEZIQUE, 31 gs., Mr. Russell. Heifers made from 20 to 29 gs. each. Cows: *Ella*, 50 gs., Mr. Gewall; *Victoria*, 30 gs., Mr. Morrison; *Money*, 35 gs., Mr. Bruce. At Mr. William Johnston's sale of Shorthorns, at Cairnbeg, Laurencekirk, Mr. Mc. Combie, 43 gs. for a cow; 20 heifers were sold at from 24 to 40 gs. Yearling heifers brought 28 gs., 19 gs., 21 gs., and 13 gs. each. DUKE OF KENT was bought by Mr. Duttrie for 48 gs., and GLADIATEUR for 24 gs. by Mr. Mitchell.

—— The *Albany Cultivator* calls attention to the increasing demand for Ayrshire cattle in the United States. Messrs. E. L. and J. N. Sturtevant, of Massachusetts, propose to publish a monograph of the breed, and have already issued circulars to breeders, asking for information. Mr. N. S. Whitney, of Montreal, Canada, has just imported some of these cattle, comprising *Rosie*, winner of the 1st prize at Perth last July, as best cow in calf, and also of other prizes; *Kyra*, two years old, prize at Strathaven; *Beauty*, three years, and heifer calf born on the voyage; *Stately*, two years, 2d prize at Strathaven; and a handsome yearling heifer.

—— The condition of "our live stock" in mediæval times contrasts strangely with the highly artificial rural economy of the present day. This comparison becomes possible to us by reference to Professor Rogers' "History of Agriculture and Prices" (vol. i. p. 51), a work consisting of the edited records of Merton College, Oxford, during the 13th and 14th centuries. At that time the estates belonging to this Society were visited periodically, and "the most minute and varied examination of income and expenses was taken," and it is in these careful accounts that Professor Rogers found materials for his work. The following passage has reference to the condition of live stock before systematic breeding was rendered possible by a continuous supply of food throughout the year :—

"Winter roots and artificial grasses were, as I have said before entirel unknown. Hence stock were always starved in winter. The practice was to keep the oxen and to kill down sheep to the largest number which could be maintained from the produce of the farm, that is, from its winter pasture, and such hay as could be spared for their subsistence. The sheep, too, must have been small. The price at which they are commonly sold, even taking into account the general cheapness of meat, is conclusive as to their being like the Welsh, or mountain sheep of modern times. Besides, the weight of a fleece is seldom more than 2 lb., often very much less, as may be seen from the Table; and the quality of the wool, as may be gathered from existing specimens of cloth, was coarse, and the fibre was full of hairs. Under such unfavourable conditions it is not likely that cattle should be large. I have, indeed, no direct evidence of the time before me as to the weight they reached, for meat is never, or very rarely, sold by the pound. But I have copied an account from the Public Record Office of the weights of 40 oxen purchased for the navy in 1547. There is no reason to believe that cattle had deteriorated in this time; it is possible that the race may have improved, judging from the rise in price in the period before me. But the average weight of these oxen is less than four hundred.

"There are occasional entries of the price of sheep, which suggest attempts to improve the breed. Rams, called invariably *hurtardi* in these accounts, are generally high priced, and sometimes, relatively speaking, costly. Thus (vol. ii. p. 221, ii.), the bailiff of Wrangdune hires and long after an estate of the king) purchases some rams in Essex at prices varying from 5s. 5d. to 3s. 6d.—the latter being a rate seldom reached, the two-shilling piece usually ruling the highest. But no such attempts to be made with cattle. Bulls are always low priced. The losses of stock sustained by the mediæval farmer were enormous. As has been said, all deaths were grouped under the general name murrain. But at Maldon the farmer, in 1333, reports the loss of more than half his sheep and lambs; at Leatherhead the loss is little short of the same rate; at Farley it is more than 25 per cent.; at Watford and Wrangdune it is about 24 per cent.; at Watford a little less than 14, and at Cuxham about 11. Similarly heavy losses will be found in the other years, and it will be remembered, again, that these are times of singular cheapness (see also vol. ii. p. 690). It must not be imagined that the loss in these cases was absolute. Though meat was, comparatively speaking, cheap, according to the lowest estimate of the size of the animal, the flesh of animals who died of disease was often eaten. Braxy mutton, that is, the flesh of sheep who had died of disease, was, perhaps is, a common dish with the Highland shepherds. Besides, there was the woolfell, and the skin of cattle. It is possible, however, that diseased meat is as much consumed now as it was in bygone times."

SWINE.

AT the National Swine Exposition, Chicago, 5000 hogs from the best American herds were exhibited. Mr. Swanwick's two boars, "Sambo" and "Sambo 2d," which received 1st prizes at Wolverhampton, were purchased by Mr. John R. Craig, of Edmonton, Canada, for high prices, and again appeared as successful competitors at Chicago. The first animal received 40 dols. as the best Berkshire boar of two years old and over; the second received 100 dols. as the best Berkshire boar of any age; and these two exceptional Englishmen have no doubt contributed much to the success of the same gentleman in obtaining the 500 dols. prize for the best display of hogs of one breed, not less than 10 or over 20, and the 100 dols. prize for the best boar and three sows.

THE FOOT AND MOUTH DISEASE.

To the Right Honourable W. E. Forster, M.P.

Eastwood Park, Falfield, R.S.O., Gloucestershire.
October 26, 1871.

SIR,—As President of the West Gloucestershire Chamber of Agriculture, I have the honour to forward to you the copy of the resolutions unanimously passed at a meeting held by that Chamber at Thornbury last Thursday last. I may also be allowed to take this opportunity of asking your attention to other resolutions passed unanimously at Gloucester on Saturday last by the Gloucestershire Chamber of Agriculture, presided over by Captain de Winton, and at which I was also chairman, Mr. Arkell's Report, attended, as well as myself and others; those resolutions, as well as some extracts from newspapers relating to the spread of foot-and-mouth disease, will be forwarded to you by Captain de Winton, on behalf of the Chamber. I beg also to ask your attention to the enclosed report of a discussion that took place on 17th inst. at the quarter sessions held at Gloucester, at which I was prevented attending by illness. I beg also to point to some resolutions of a similar nature on the foot-and-mouth disease to be sent to the Privy Council from Shropshire and Warwickshire quarter sessions and Hertfordshire and Warwickshire, of which I have seen reports in the public journals, as well as from other counties which I cannot now recollect. To these may also be added the letter on this subject not very long ago addressed to the Privy Council by the lord-lieutenant of the county of Northampton. Surely all these prove beyond the possibility of doubt the existence of the pressing evil of the want of means for guarding against the spread of the disease, which can be traced beyond all question to the importation of diseased and infected cattle from Ireland, and notably to the port of Bristol, whence they are recklessly dispersed into the neighbouring districts and to London and other places.

"At the Bristol police-court an Irish cattle dealer,

named Joseph Steady, was fined £15 and costs for exposing for sale in the Bristol cattle market a cow infected with the foot-and-mouth disease. The defendant said he sold the cow to a person who was going to send it to London. The market inspector (Mr. Cade) stated that these diseased animals were sent to London, and sold to persons there who made them into soup.

"Mr. John Fenner, cattle dealer, of Dedham, near Colchester, has been fined by the Cambridge borough magistrates £12 10s. and costs, for sending 41 bullocks from Leicester to Cambridge, 25 of which were suffering from foot-and-mouth disease. It appears that Mr. Fenner purchased them at Leicester Fair, whence they had come from Ballinasloe, Ireland. The cattle have all been since attacked."

From the proceedings above reported it would appear that, beyond fining the cattle dealer for the exposure in the market of the one palpably diseased animal, no steps are taken to prevent that diseased animal being sent in a cattle truck to London with the other lot of (probably) infected animals, thereby infecting the cattle truck, and spreading to an infinite degree the infection; while the ship that brought over these diseased and infected beasts, as well as the market at Bristol, where so many diseased beasts have been for sale, and the past exposed for sale, are still used without any let or hindrance, to spread the infection far and wide.

Sir, I ask you in the interest, not only of the agricultural classes—especially of the dairy farmers in these western counties now filled with the disease from Ireland by Bristol—but also in the interest, and the consuming part of the public, will you not, as a member of the Government, take some step—by the issue of some more effectual regulations than now exist—to enable and to compel the local authorities of infected places and markets to prevent the further spread of infection from diseased imported cattle? There can be no doubt—from a perusal of the various resolutions sent to the Privy Council from several counties, both from courts of quarter sessions, as well as from Chambers of Agriculture—as to what the universal wishes of farmers are upon this subject, which to them is of such great importance. The argument that the slaughter of fat cattle at the port where landed, and the compulsory quarantine of store stock, and even the stoppage temporarily of the importation of cattle from counties where disease exists—I heard indicated—will largely increase the price of meat to the public is, I believe, entirely fallacious, because the spread of disease entirely destroys the produce of dairy stock, and also injures the meat of fat stock, which must increase the price of sound stock and meat to the consumer. But, setting that aside, surely the wholesale indiscriminate spread of disease amongst the cattle of this country is a more serious consideration as regards the future than the temporary rise in the price of meat, even if that allegation were true, which I do not believe to be the case.

One other point remains to be mentioned. By the regulations now in force in counties whenever the disease appears among the stock on any farm the occupier is bound to give instant notice to the police (a magistrate in this county was lately fined by his brother justices for not doing so, though he explained that he had only just returned home, and had not had time to learn facts as to his cattle being diseased); on this notice being sent to the police the owner of the diseased cattle is bound to keep them wherever they may be located, and not to move them to any other part of his own farm, under a penalty if convicted. The regulations on this point, as against every farmer, are most stringent, and while the police inspector gives him a clean bill of health, the diseased cattle, and all others with them, must remain in the one place. That is my own case at this time with respect to 12 Irish steers bought by me six weeks ago at Bristol; and I consider the regulation a most proper and salutary one. But why is it not equally applied to infected market places, crowded with diseased and infected cattle, week after week? Why are such cattle allowed to be removed from such infected places by rail and by road, spreading the disease broadcast, and no stop put to such removal; and still more, why are fresh cattle allowed to be sent to such infected markets each succeeding week, for even if such are sent there sound, they are bound to become infected from being placed in the pens reeking with the disease, as the Bristol market is and has been for months past? Why not apply the same regulations to the towns and markets as to farms? I must apologise for the length of this letter, but the serious importance of the subject must be my excuse; and as the subject will come on for discussion at the Council meeting of the Central Chamber of Agriculture in London, on the 7th of next month, I hope you will not object to my writing public both what I have now written to you as well as any reply with which you may favour me.—I have the honour to be your obedient servant, *George S. Jenkinson.*

TOWN SEWAGE.

In reply to your question, where sewage irrigation plans have failed and been abandoned for others, I should have said wet plans of treating sewage. That was what I intended. Still, considering the great confusion of opinion on the whole subject of sewage treatment, both in regard to details and to fundamental principles, I think the charge of several instances of failure might be readily sustained, and even that failures must still be expected until we pass still further "out of the domain of opinion into that of knowledge."

As to sewage irrigation being abandoned, I do not know of an instance. To adopt sewage irrigation is to accept an enormous responsibility, and it may not be lightly abandoned even though its success should be only partial. I have seen it stated that the Aldershot irrigation farm is the greatest success in England, and I have also seen it stated that it was a very great nuisance.

It has been stated on the one hand that the sewage at Hertford is too weak for sewage irrigation, and on the other, that after it has passed through all the processes that are in operation to purify it, the effluent water is strong enough for the purpose.

At Hertford they try to keep out as much of the spring water as possible, but we are told by a high authority that one principal use of sewers is to drain the subsoil. The Edinburgh meadows have been generally unfavourably spoken of, but we are told by an upholder of sewage irrigation it is because the principle adopted there is fundamentally wrong.

I dare scarcely say a word about cattle dying of pleuro-pneumonia or entozoa, with other disagreeables of the kind asserted to be attendant conditions of sewage irrigation, which assertions however have been promptly contradicted; nor even about ridges and furrows, flooding, and whether impervious or otherwise drains or the want of them, excepting that one set of people would have no drains at all, while others would construct them with the greatest system and regularity 6 feet deep.

Some authorities give us as a basis of calculation 5 acres of ground for 10,000 inhabitants. This has been characterised as "a gross arithmetical blunder." I express no opinion, but should like to see the case of Hertford successfully worked out on that basis. It is a town of under 8000 inhabitants. If it admits all its subsoil water into the sewers it produces 1,750,000 galls. of sewage daily: at present it produces 1,000,000 galls., and if the remaining spring water were stopped out as far practicable, there will still be 800,000 galls. daily left, and we must also take into account the rainfall on the 5 acres—sufficient moisture by itself for natural vegetation.

I say as to the value of manure,—sewage irrigationists, if they do not assert that there is no manure of any use excepting ammonia, have latterly made it the sole guage of the value of sewage, and have carried this idea so far as to call solid refuse worthless. Yet the managers of the "A B C" process at Leeds believe that their "native guano" is worth £3 10s. a ton, because they can readily obtain that price after preliminary trials by farmers, and they do not profess to eliminate the ammonia from the sewage at all, or not to any appreciable extent.

Again, some say that earth-manure contains only a small proportion of ammonia, and that it has therefore very little value, yet there are not wanting those who believe that it is as valuable as Peruvian guano in practice, notwithstanding the small quantity of ammonia compared with the bulk.

It may be said that there always were differences of opinion and crotchetty people, and that though these contentions may be amusing, they are in no way important or instructive; and this might be so, were it not that, conflicting though they are, they are the opinions of thoughtful, honest, earnest, and able men, and that the question itself is one of, if not the most important of the day.

Some of the conclusions arrived at must be erroneous, but it is probable that there is something of good in most of the various schemes that have been advanced, whether wet or dry, and that the problem, "How to deal with town sewage," will be solved by a combination of them, and by none singly. *R. U. A.*

ANOTHER FARM RECORD.

The following is a copy of my steam-plough diary for 1871:—

September 18, 1871. Finished harvest.
October 10. Started the smasher on No. 1, heavy land, 39 acres, and did about 6 acres.
11. Did about 6 acres.
12. Did about 8 acres.
13. Did about 8 acres.
14. Finished No. 1 at 4.50 P.M., then shifted the tackle to No. 2, heavy land, 29 acres. Consumption of coal, 3 tons 5 cwt., at 12s. per ton.

The cost of the 39 acres stands thus:—

Men at 16s. per day for five days	..	.. £4 0 0
Coal—3 tons 5 cwt., at 12s.	..	.. 1 19 0
Oil, at 9d. per day for five days	..	.. 0 3 9
Extras, at 1s. 6d. per acre	..	.. 2 18 6
Total	..	.. £9 1 3

Or an average of 4s. 7¼d. per acre for the 39 acres.

15. Sunday (I note Sundays to make all quite understandable).
16. Did about 5 acres ridging and subsoiling.
17. Did about 5 acres.
18. Did about 6 acres.
19. Did about 5 acres.
20. Did about 6 acres.
21. Finished No. 2, 29 acres, at 9.20 A.M.; then shifted the tackle to No. 3, 24 acres, and just started when it came on very wet at 1 P.M., thereby we lost half a day's working.
22. Sunday.
23. Did about 6 acres ridging and subsoiling.
24. Did about 6 acres.
25. Did about 6 acres.
26. Finished No. 3 heavy land, 24 acres, at 3.50 P.M., and then shifted the engine and windlass to No. 6, light land, 14 acres.
27. Shifted the rest of the tackle to No. 6 light land, and did about 5 acres ridging and subsoiling.
28. Did about 6 acres.
29. Sunday.
30. Finished No. 6, light land, at 11.30 A.M.; then shifted the tackle to No. 2 light land, 13 acres, and just started the ridger and subsoiler.
31. Did quite 6 acres.

Nov. 1. Finished No. 2, light land, 13 acres, at 4.40 P.M.; then shifted the tackle to No. 5 light land, 12 acres.
2. Did about 6 acres.
3. Finished No. 5, 12 acres, at 5.15 P.M.

Consumption of coal for the 92 acres, 9 tons 5 cwt.
The cost of the work stands thus:—

Men at 16s. 4d. per day for 17 days	..	.. £15 14 6
Coal, 9 tons 5 cwt., at 12s.	..	.. 5 11 0
Oil, at 9d. per day for 17 days	..	.. 0 12 9
Extras, at 1s. 6d. an acre on the 92 acres	..	.. 6 18 0
Total	..	.. £28 16 3

Or an average on the 92 acres of 6s. 2d. an acre.

Now, I will take each field separately, and remark upon the several operation.

No. 1, heavy land, 39 acres. It may now be seen how the 4s. 7¼d. an acre for a smashing (as shown in my last letter) is made up. I showed a fortnight ago that it had been planted with Wheat; I will now add that the Wheat is up-looking, strong, and well. This is my old heavy land, and has got its 17th crop under steam upon it.

No. 2, heavy land, 29 acres, is for Beans next year, and the ridging and subsoiling is all that will be done to it; therefore, the cost of seed-bed will be only 6s. 2d. per acre. This field has been in my occupation only two years. I have had Beans the first year, Wheat the second year, and next year it will be in Beans again. The cost of seed-bed for the three crops is as follows:—

1870. For Beans	..	..	..	4s. 8d. an acre.
1871. For Wheat	..	..	..	5s. 6d. an acre.
1872. For Beans	..	..	..	6s. 2d. an acre.

This field is not quite clean; but when the Beans come off next year, it will be quite so. The ridges will be forked and picked this winter. Heretofore it has been forked, leaving the Twitch on the surface to be killed by the harrow. The cost of forking this winter will be about 5s. an acre. The two years before it was not so much.

No. 3, heavy land, 24 acres, is for Barley next year. The ridges will, after picking the same as No. 2, need splitting by a subsoiler worked by horses in the winter, at a cost of 3s. an acre. This, added to the ridging and subsoiling at 6s. 2d. per acre, brings the total cost of seed-bed up to 9s. 2d. per acre. This, like No. 2, has been in my occupation only two years. The forking this winter will cost about 5s. per acre.

No. 6. Light land, 14 acres, is for Barley next year, which will be the sixth white-straw crop in succession. The ridging and subsoiling is all that it will require; therefore the cost of seed-bed stands at 6s. 2d. per acre. This field is very clean, although it has had five white-straw crops in succession. Thirty years ago this field was in grass. The grasses that it grew were of the worst possible, giving a very light produce on an average of years. From 20 to 30 years ago, when I ploughed it up, the yellow clay, which ploughed up at not over 4 inches from the surface, looking like good stuff to ameliterate butter with, yet, by the aid of the ridger and subsoiler, I have managed to convert this yellow stuff into what must be 18 inches deep.

No. 2, light land, 13 acres, is for Beans, and the ridging and subsoiling is all that will be done to it, therefore the cost of seed-bed will be 6s. 2d. per acre. This field is by the roadside, so farmers look at it as they pass by. Their remarks are various, yet they all admire the work, seeing that neither the spade nor plough, worked by man or horse, can equal it in quality at any cost. The fact is, it is this kind of work that enables me to keep my land clean under a yearly system of corn cropping, and it has a great deal to do with keeping it in condition. Voelcker witness upon the point. Here is what he says in a report written nearly twelve years ago on the soils of my farm:—

"At the request of Mr. Smith I paid a visit to Woolston Farm in November, 1859, and on that occasion took for analysis four samples of soil. The chemical examination of these soils, I think, will throw some light on the *rationale* of the particular mode of steam cultivation which has been adopted with manifest success by Mr. Smith."

A brief note on each field follows, then comes the analysis of the soils, and he sums up thus:—

"It must ever be the aim of the intelligent farmer to prepare a good seed-bed, and this cannot be obtained if the well-pulverised surface is mixed up with a large mass of obdurate clay subsoil. Mr. Smith's plan of cultivation altogether avoids the temporary injury which a wholesale turning up of the subsoil is sure to produce in almost every instance. In all three subsoils we have seen a large proportion of mineral food exists in an unavailable condition. Mr. Smith's subsoil implement provides for the

admission of abundance of air into the subsoil, mineral food thereby is gradually rendered soluble, and prepared for assimilation by plants.

"By breaking up the land thus treated the second year a good deal of aerated and partially prepared subsoil is mixed with the surface, and thus a constant supply of new mineral food is provided. It is foreign to my chemical pursuits to inquire into the economic advantages likely to result from steam cultivation in general, and from the system pursued by Mr. Smith in particular, but I cannot help observing that his plan of preparing the land is in many respects in singular accordance with my own scientific views on the subject. I have long maintained that steam cultivation is indispensable to the improvement of clay land; that it is undesirable to bring up much of the subsoil at one time; that putting up the land into ridges before the frost sets in, and subsoiling between the ridges completely alters the character of clay land, and that many heavy soils will yield abundant crops, with scarcely any manure, when due care is bestowed upon the mechanical preparation of the land."

No. 5, light land, must now come in for a notice, to clear up the year's work. It is for roots, and the ridging and subsoiling is all (excepting a couple of harrowings in the spring) that will be needed for a seed-bed, then the cost will stand at 6*s.* 2*d.* per acre.

No. 3, light land, 11 acres, has been ploughed with horses and planted with Wheat after Clover; No. 1, light land, 12 acres, is in Clover; and No. 4, light land, 12 acres, in roots; therefore the whole of the work for 1871 is done, excepting job work for my horses. My land for Barley, Beans, and roots, 92 acres in all, is "put into ridges before the frost sets in," as Dr. Voelcker says should be done.

Some of our best farmers will grin at the cost of my seed-beds—4*s.* 7½*d.* an acre for Wheat and 6*s.* 2*d.* an acre for Beans on my heavy clay land—and they may do so, for my land is not only heavy but it is very hilly and uneven, such that needed, under horse culture, four good horses to plough 3 roods per day. Our best horse farmers cannot on such land make a clean seed-bed on an average of years for so little as 5*s.* per acre, yet some of them would give me a leg up. One would put digger-breasts into my implements, another would hook on a harrow, and so on; in fact they want to be teaching me, instead of taking a lesson themselves from my 17 years' practice. The other day, one of the best horse farmers in this neighbourhood told me that we should soon have something marvellous from our big makers that would do the job almost for nothing. I told him at once that they had got a job to beat my little figures. The fact is, they are looking to our great makers for help, who know nothing of farming, or will make anything that they can sell. My win is, that I am a practical farmer, with mechanics enough in my head to know how to make implements that are of use to me. Look back to Chelmsford in 1856. I insisted upon it, that a smasher and ridger and subsoiler was the thing needed. My 17 years' practice, with cost of seed-beds as they now stand, backed up by the great makers who have adopted my smasher, is good evidence that I was right; and my ridger and subsoiler, which at Chelmsford was the only cultivator that attempted to turn over the soil, as in practice beat both the plough and the spade, therefore it must have won the Chelmsford prize. The Royal Agricultural Society asked for a cultivator that the most efficiently turned over the soil, as a substitute for the plough or the spade. It was known to some that I would have the old plough. The great makers knew it, and tried a bit to make it for them.

Some persons who visit Woolston go away with the notion that the clay land in their own neighbourhood is of a lower class than my clay lands are. That may be. I do not pretend to know the exact quality of any particular district but my own. What much I do know, —that my own clay land under horse culture did not produce on an average of years over 20 bush. of corn per acre, and that the best-farmed land of a like kind in this neighbourhood does not now produce over 24 bush. per acre on an average, taking the cropping thus: 1st, Seed on Barley; 2nd, Seed on Wheat, Beans, and Wheat. The profits on the Vetches and Clover are but a mere trifle. They go to make the other four fields, when divided by six, give an average of 24 bush. per acre. My own clay land now produces full 36 bush. of corn per acre on an average, and Dr. Voelcker, above cited, gives good and sufficient reasons why I should obtain such results. I can see by my own eye that the character of my land appears entirely changed, and my candid opinion is, that clay soils in other districts would change if they were treated as mine are. I will call Dr. Voelcker into the witness-box upon the point. "The examination of the soil and subsoils from Woolston Farm fairly represent the chemical constitution of a great many heavy and light soils in England."

The landlords and farmers of England must bestir themselves, if they mean to pick up treasure from beneath their feet. The latter would do well to teach their sons how to work an engine and superintend the working of tackle, instead of crying out "Help, help!" to the contractor; and this makes it clear to the world that the farmers of England are rich enough to stock their own farms again, and the former would do well to make agreements and buildings, &c., that would enable their tenants to do so. Tenants now-a-days look very shy at their landlords upon many points. One tenant says that they are obliged to be as mute as mice in the presence of their landlords; another says that they dare not spend their money to increase their produce as I have done, lest their landlords were to pounce unfairly upon them. These two tenants tell truly. I have one word to say upon the point. The mineral in the land belongs to the landlord, but the skill in working it out does not; therefore landlords ought at once to make substantial arrangements that would benefit not only landlords and tenants, but the busy hive of England. *William Smith, Woolston, Bletchley Station, Bucks, Nov.* 3.

HEADS.

By Henry Corbett.

(*Concluded from p.* 1433).

I WISH we could see more at the West of England meetings of a far more ancient family, which should furnish one of the leading sections of the show. I, of course, refer to the grand towering Cotswolds, of which Mr. Well, of Hampnett, writing many years since, says, "The head should be long and thin, the ears rather wide and not too thin, having no wool but a tuft on the poll; whilst I am indebted to Mr. Robert Garne of Aldsworth for a better and more elaborate description of a Cotswold countenance. The head should be wide between the eyes, and the eye itself full, dark, and prominent, but mild and kindly, and in no way coarse about the brow. The face should be proportionately wide to the space within the eyes, but not too flat, and should be of medium length down to the nostrils, which must be well expanded, and somewhat broader than the face, with the skin on the nose of a dark colour. The cheek is full, and, as the face, well covered with white hair; a just perceptible blue tinge on the cheek and round the eye being rather a fancied." The ear, long but not heavy, of medium thickness, and covered with the same short soft hair, should be carried well up, while black spots on the point of the ear are not considered objectionable. The top of the head should not be coarse nor bald, but covered with wool, not hair, and the forehead is to be distinguished by a fine tuft of wool on the forehead. Mr. Wells says the head should be long and thin; Mr. Garne, that it should be sufficiently long to save it from being called a short thick head, but that it should not have a long lean appearance. Grey faces still crop up occasionally in all the Cotswold flocks, but these are the exception.

Of the other breeds the improved Lincoln now looks to take much after the Leicester head, although coarser in its character; while the true Dorset, with his nicely curled horn, should have a white eye in harmony with the colour of his countenance, although the best sheep I last season had an eye as dark as a mole. Ideal for the Scotch Black-face, he is as handsome in his degree as the Highland beast, as he tells alike by his head of the wild country from which he springs.

Can there be anything more terrible than the long-snouted, narrow-jawed head of such a pig as we may still occasionally see by the roadside, who breaks away as you approach him, with a rush and a grunt, into a round swinging trot, and is out of reach before you can attempt to reckon him up. Does not such a head augur too surely of his pinched razor back, his lank sides, and coarse quality? A pig who will eat any given quantity, without this having "the least effect on him," as the three-bottle men would boast of their potations. On the contrary, what can be a better assurance of "breeding nice pork," as the Fat Boy said of his master, than the round dumpling head of a small breed? Fat and yet fine, positively pretty in its plump contented expression, and bound to make flesh even in its sleep. Mr. Fisher, of Carhead, in his scale of 110 points for a perfect pig, allows eight for the head, while he has this sketched for me the head of feeling, of a good breed, to be broad, as indicating a general width of frame and strength of constitution, with a face just long enough to enable the animal to collect its food, for anything beyond this indicates excess of offal. The ears should be slightly pointed forwards to keep out the wet, and sufficiently erect not to interfere with the sight, as these should be well covered with hair, more particularly on the under side, and the orifice nicely filled in to keep out litter, dirt, and so forth. The ear should further show a good fringe of hair on the outer edge. In a full-grown pig of the small breed, the length of the ear from the tip to its insertion in the forehead should be from 6 to 7 inches, and in the improved large breed from 8 to 9 inches may be taken as a fair length. The chap should be well filled up to the eyes and ears; and, commencing near the point of the under jaw, should extend to the brisket, leaving no tucked-up appearance under the gullet. The head of the improved Berkshire, of course a very different animal from the old-fashioned Berkshire or Hampshire hog, should be something after the shape of a cone, though not too pointed nor at all turned up at the nose, but short, straight, and dainty in fact, about as long as thick through, at a line to be taken from between the ears. There should be but little white about the face, if still with a sprinkling of lighter coloured hair on the centre of the forehead, as well as on one or both eyes; whereas black markings on a white pig are not liked, and I have known very keen hands try to burn them out by show time.

This paper might be extended to almost any length, as where, for instance, could we wish to see more character than in the head of the dog—the long square, if I may so put it, head of the foxhound, so thoughtful and dignified in repose,—

> The wise, benchlike sagacity of brow; the same
> Jaw of the old Ellenborough-size;

or the handsome intelligent countenance of the colley, which Landseer loves to paint; or the refined features of the greyhound, which Miss Mitford sketches so charmingly, when writing of her own Moss-trooper:—"His ears beautiful; beautiful; the finest black eyes, very bright, and yet sweet, and fond, and tender—eyes that seemed to speak; a beautiful complaisant mouth, which used sometimes to show one of the long white teeth at the side; a jet black nose; a brow which was bent and flexible, like Mr. Fox's, and gave great sweetness and expression, and a look of thought to his dear face—there never was such a dog!" It is noticeable that while one writer compares the jaw of a foxhound to that of a chancellor, we have here the brow of the greyhound likened to that of a statesman, and the idea in either case is almost equally happy. Or, looking in another direction, how thoroughbred is the long, thin head of the game-cock, set off by his quick, bright, defiant eye; a bird who, by way of exception, seems scarcely "natural" unless he be in close cut fighting trim! Foxhounds and fighting cocks, however, may be not altogether in place in an agricultural journal, and so let me conclude, as I commenced, with a word from Lavater:—The farmer walking through his grounds, regulates his future expectations by the colour, the size, the growth, the exterior; that is to say, by the physiognomy of the bloom, the stalk, or the ear of the corn, the stem and roots of his vine-tree. He remarks in their appearance, as the physiognomist in the countenance of shallow men, any want of native energy. It is tolerably clear from this that Lavater was the first man who cultivated Pedigree Wheat, when he extended his theory to the study of the ear, or head of corn. *Bath and West of England Society's Journal.*

Home Correspondence.

The Leicester Head.—Your critic asks if I take my type of the head of a Leicester "from the well-trimmed showyard countenances of fat stock and other agricultural meetings?" Most assuredly I do. Can he point to a better type, or are we to assume that the judges and exhibitors at the national meetings are all wrong? If so, the sooner your critic puts us all right the better, although I should say, from the tone of his letter, that he is not a breeder of the Lincoln breeder, and of a somewhat old-fashioned order. Picking out certain words to suit certain purposes is a trick best answered, perhaps, by giving the text itself, and, as I infer that you will pay me the compliment of giving my paper in full, I am quite content to leave the answer in his way. Your critic, however, avoids one material point. I said in the outset that my Leicester authority was "a very successful breeder of Leicesters," a frequent exhibitor and judge; and he still assures me that I have taken the right type, although I may have gone away from the top-knots and coarser sorts. *Henry Corbett, Nov.* 1.

The Cultivation of Sugar-Beet.—The consideration of this subject having been recently revived by letters from some of your correspondents, I venture to contribute the results of recent experiments, in the hope that they may be interesting to your readers. I regret that no record has been kept of the weight of the leaves which have been left upon the ground, but the weight of the roots passed over the weighbridge gives a return of 38 tons an acre. The tendency of the plants to "bolt" has been general, and the weight per acre has been somewhat diminished by the numbers which were from this cause pulled for the cattle during the growth of the crop; on the other hand, no reduction in the general weight has been made for the dirt which adheres to the root in a greater or less degree as they are grown in light or stiff soils. Ours being grown in the former description of land, and lifted in dry weather, come out tolerably clean; but those who are accustomed to the growth of the crop will be enabled to form some idea of the sufficiency of the allowance when put at from 10 to 15 per cent. The season has been unfavourable to the growth of this crop, and the cry comes from all quarters that the yield of saccharine matter is at least 2 per cent. below that which is ordinarily obtained. It is very satisfactory that the application of sewage at the proper time, and in such quantities as shall be sufficient to secure a good crop, may be made without injuring the percentage of sugar in the roots. Amongst the roots sent for analysis were some (as will be seen by reference to the accompanying Table) of as much as 10 lb. in weight, the sugar in which is in all cases insufficient for sugar-making purposes though the roots are still valuable to the distiller. These roots grew in the neighbourhood of an earthen main sewage carrier, the soakage from which encouraged a luxuriant growth, but they are not examples of the crop generally, the roots averaging about 4 lb. each. The experiments were two. The first consisted in the growth of Sugar-Beet in land which had been cultivated for some years under sewage irrigation, which, with the addition of 2 cwt. of super-

phosphate of lime per acre, was considered sufficiently manured for the crop. The second consisted in the growth of the crop in land of similar nature and under similar conditions, direct dressings of sewage being substituted for the superphosphate of lime. The great advantages which would have belonged to the second experiment in a dry season were lessened last summer, owing to the great quantity of rain which fell, but, nevertheless, the percentage of sugar in the roots grown under it is higher than that found in the roots in the superphosphated land. There is scarcely any difference in the weight taken from either plot, and, therefore, if in considering the expense of cultivation we do not include the cost either of sewage or of superphosphate, it may in both cases be taken at £10 per acre. To the one, however, may be added 11s. for the superphosphate and to the other £1 for levelling, gutter cuttings, and labour in applying the sewage, and whatever is a proper charge for the sewage used. In either case there should be a charge per acre for general expenses on the farm. In the charge of £10 per acre I include an item of £4 for rent and taxes, but as this is probably greater than that for which suitable land may often be obtained, and as experiments are always costly, it will be quite safe to accept the charge of £12 per acre, which Mr. Fish takes to be a sufficiently accurate estimate of the cost of growing this crop. It is very desirable that it should be made known what percentage of sugar is given by the roots for which £1 per ton is being offered this year by sugar manufacturers. If the percentage is less than 8 per cent. on an average, as I understand is the case, the same amount of labour in the manufacture will be required to produce 2 per cent. more sugar, without, under the present rates, any advantage being offered to the producer. If it pays the sugar-maker this year, it will pay him very much better when the season is favourable to the formation of saccharine in the roots; and although I should be very glad to obtain a ready sale for large quantities of Sugar-Beet at £1 per ton (and we sold it last year in small quantities for feeding purposes for 25s. a ton), yet it must be evident that the object of the sugar manufacturer will be better obtained by his offering to the growers of roots which average 10 cent. of sugar the same price than he does to those whose roots yield but 7 or 8 per cent. I have been informed that after 7 per cent. is obtained every ½ per cent. of sugar which the roots yield is 3s. clear profit to the manufacturer. I put this forward with great submission to correction, but if it be true—or nearly true—that £1 per ton is paid for roots yielding 7 or 8 per cent., there is room for a fair division of profits between the grower and the manufacturer when roots yielding 10 per cent. and upwards are purchased. The superiority of Sugar-Beet for feeding purposes is becoming understood, and when people see their interest in paying for quality instead of for quantity, I have no doubt its growth will become general. Our friends must not turn with disdain from the prospects of 20 to 25 tons of Sugar-Beet because they sometimes grow 35 or 40 tons of Mangel per acre. Whilst I write there are carting off a crop of Yellow Globe Mangel which it will be very difficult anywhere to equal, the weight of which is over 50 tons an acre (over the weighbridge), but if the value of the crop could have been more concentrated (as in the case of Sugar-Beet), how much less costly would have been the labour of transport, and above all things what a saving of time in the removal of the crop—time which is now so valuable. The following is the Table referred to above :—

No. 1.—*Dressed with 1 cwt. of Superphosphate of Lime per Acre.*

Weight of Roots.		Average Weight.		Percentage of Sugar in Roots.
lb.	oz.	lb.	oz.	
1	13 to 3	2	9	7.83
2	1 to 4	3	2	6.93
6	11 to 9	8	10	4.09

No. 2.—*Dressed with 5½ Tons of Sewage per Acre.*

Weight of Roots.		Average Weight.		Percentage of Sugar in Roots.
lb.	oz. to	lb.	oz.	
1	0 to 3	1	10	8.03
4	8 to 5	4	15	7.23
9	2 to 10	9	13	3.06

Henry J. Morgan, Lodge Farm, Barking, Nov. 8.

Australian Meat.—The following is one of the many communications I receive from various parts of the globe on agricultural subjects. I send it for publication, for the information of those who could probably turn it to good account, and thus add something to our profit and manurial wealth. I know that a great many pigs are in this country fattened on butchers' offal. I could of course give the name of my correspondent, if required for business transactions. It is certainly a pity that we have not yet been able to avail ourselves of the flesh of the vast flocks and herds of Australia. *J. T. Mechi, Tiptree, Nov.* 1871.

"*To J. T. Mechi, Esq., Tiptree Farm, Essex.*—Although living at your antipodes, I hear and read of the lively interest you have always taken in any matter appertaining to agriculture, so this has induced me to bring under your notice an article of food which I think is admirably suited for pigs, and to request you will give it a trial on your farm; for this purpose I forward you by the overland mail one case, containing four kegs, of about 28 lb. each. This you will receive through my agents, who will first take a sample from one of the kegs. The article is concentrated mutton soup. I may mention that I am largely engaged in boiling down sheep for tallow, and in that process obtain a large quantity of very rich soup. This I have hitherto only made into a manure compost, but feeling that such was a great waste, I have been making experiments to utilise it, and I think have succeeded. I make 1st quality for human food, a tin of which you will also receive; and 2d quality as per sample. From the number of sheep (80,000 to 100,000) I boil down for tallow during the season, from August to February, I can get a large quantity of this essence 1st & 2d quality, 2½ lb. 2d) per sheep, amounting to several tons during the season, and shall require a corresponding market for it. The introduction of any new food, I am aware, is always attended with great difficulty, owing to a prejudice against novelties. This has been a further inducement to me to apply to you to give this new article of food a trial, as I believe from what I have for years read of your doings, you are just the man to take this matter up, and show that this essence is of value, as I am certain it must be. Of course, the question of cost will be a material consideration after the quantity of this essence is proved. This I am not at present able to determine, but I think I shall be able to deliver it at London wharfs at about £25 per ton, in three casks. Per No. 1 keg you will receive a sample of each of the other three. I should be glad of your opinion as to which state is best. I find that when highly concentrated this essence takes some time to dissolve in water, so have sent No. 2 less concentrated. I must apologise for troubling you in this matter, but knowing that this essence can be produced in very large quantities in these colonies if once a market is established for it, thereby partaking of a national character, must be my excuse. Messrs. & Co. will communicate with you, and I shall gladly receive your reply to this. *Adelaide, South Australia.*"

"*Mechi's Sample of Concentrated Mutton Soup for Pigs and Dogs.*—This consists of the concentrated soup from the bones, flesh, and cuttings, and contains the portions of the flesh and bone, but is not fit for human consumption on account of flavour. It is most nutritious, and contains abundance of flesh-producing nitrogenous compounds. The part that will principally settle as the portion of eight parts of flesh, and will make, when dissolved in boiling water, a due proportion of soup, which can be used for pig wash, or with biscuits for sporting dogs. The fish, amounting to 3 parts in 100, consists of chlorides of potash and soda, phosphates of lime, magnesia, &c., and other salts found in flesh. There is no chemical of any kind or salt used in the manufacture, and the water employed is quite soft, like rain water; it therefore will not be scouring, but will, with the meal food, give as much strength as about six times its weight of fresh flesh, which includes all the consolidate and fibrinous matters not dissolved in soup, as the same intelligent people believe that a man cannot be a skilful physician unless he be a seventh son of a seventh son; and if he happens to be such he is lauded up and employed as the prince of all doctors, whether he has walked the hospitals, as it is called, and received a skilful practical education, or other learned treatises on the science of medicine and the knowledge of diseases, or not. But there have been eminently skilful physicians who were not the seventh sons of such prolific parents, and there have been skilful farmers whose fathers and grandfathers, aye, and grandmothers, knew nothing whatever about farming. But as it is my intention to adduce some gentlemen of learning and science, who have studied the art of land cultivating and seeding, I shall not now go to those who know little or nothing of the profession they are practising for their livelihood (though they are not a few), but to those who have taken their fathers and ancestors. Now, as a proof or two of this. I have taken a handful of Wheat and another of Barley and another of Oats from bins or heaps of each kind, and without counting the number of either handful, I then gave them to some of our union workhouse boys' school, and there told the boys to inform me how many grains of each a bushel of it would put into every square foot of an acre of ground, and they have given me the exact number of each. I have said also to the same boys, "There is a stack of hay near the workhouse, know how many pounds feet the stack contains;" and they have let me know near enough for any practical purpose for using or buying or selling the hay. Now, I have my doubts whether I should obtain equally correct answers were I to put the same questions at any meeting of the Royal Agricultural Society. But if I am correct, what does this prove? but that of all the arts practised by mankind, the practice of agriculture is the least understood by those who make a livelihood by it; or would it be believed that the members of the Royal Agricultural Society would have decided that a bushel of Wheat, and of all kinds of Wheat, and at all times of the Wheat-seeding season, should be put into an acre of land? Now, my respected readers, you would consider a gardener as a mere duffer who should put into the ground Knight's Marrowfat Peas, which will run 8 and 10 feet high, in rows no wider apart, and as thickly in the rows, and at the same time of the year, that he would seed his plot of ground with my late lamented friend, that pre-eminent naturalist, Dr. Maclean's Little Gem Pea, which grows but about 1 foot or 1½ foot high! If, therefore, the gardener would be justly considered to be an ignorant one who would act in this way in the growing of Peas, what is your opinion of a farmer who acts in the same way, and is by authority advised to do the same in the growing of Wheat? For anywhere, there is nearly as much difference in the kinds of Wheat as in the kinds of Peas. For example, there are long-strawed kinds and short-strawed kinds, and there are kinds which branch out very much more than other kinds, and there are kinds of Wheat which are so delicate and tender that if they are not sown in the autumn, frosts set in and clear cloudless nights, and thus great parts of such crops are destroyed by the severities of winter, whilst other kinds are so hardy that no weather can injure them: and yet the intelligent farmer treats all kinds alike, and is commended for doing so by those who, from the position they assume among their fellow men, ought to be pioneers, leading them out of the darkness visible into the glowing and refulgent light which science never fails to shed around all its votaries who have wisdom and discretion enough to be led by it. *George Wilkins, Vicarage, Wix, Oct.* 31.

Asphalte Walks.—Everyone would prefer a clean, smooth path of a cheerful colour, to either a rough, dirty, or black mournful walk. The expense, however, of carrying out any improvement is a most material consideration to every class of ordinary mortals. I have read from time to time of various methods of asphalting walks with different kinds of materials, but the expense of the operations has been so high as to deter one from entering upon such an outlay. The asphalting of the London streets is said to cost about 14s. per square yard. Some gardens will be found to cost as much as 4s. per yard. Now, the asphalting I am to describe need not cost 3d. per yard. The materials used were merely tar and burned tarf ashes. The ashes were burned in large heaps in the course of converting old pasture into arable. The cost of burning 20 cubic yards of ashes, or rather under 2d. per yard after the ground was ploughed; the cost of the tar, 1d. per gallon. The ashes were procured from the middle of a heap of a bright red colour. About 450 square yards of paths, &c., were asphalted with 336 galls. of tar, or rather less than 1 gall. per yard. The garden walks were quite firm with fine gravel previously to being operated upon with tar and ashes. The walks were asphalted by various systems. Only 10 cubic yards of ashes were required for the 450 superficial yards, as previously mentioned. The modes of proceeding were as follows:—A strong stand about a foot high was placed against the ashes shot down in cart-loads. Every barrel of tar, containing 36 galls., was placed upon the ashes in the first place, and from the ashes was easily rolled upon the stand. A common pail was used to pour the tar on, which for convenience in emptying was filled about two-thirds full. About a barrowful of ashes was then mixed up with the tar until saturated enough, so that when patted with the back of a shovel the mixture did not adhere to it. After the mixture was prepared it was wheeled to the spot where required, shovelled out of the barrow, laid upon the walk with a brick, patted down quite smooth, and after some 10 or 20 yards was so prepared a sprinkling of dry ashes was thrown regularly over the top of the asphalte. The time the work was done, we refer to, was in June and July, so that the surface of the asphalting generally became dry enough to bear a garden roller after it in about half a day after being done. The rolling cannot be overdone, and may be continued day after day for a week, until so solid as to bear walking upon without showing any impression of the feet. In a few weeks the asphalting becomes solid enough to bear a cart or carriage without doing any material injury, merely making a slight mark, which either disappears of itself, or may be rolled out of sight. The other methods of asphalting were merely, in some cases, to hoe the walks, pour tar over them, and then throw ashes over the tar, rolling afterwards, as before; or by picking up the surface about 2 inches deep, smoothing down, applying the tar to soak the gravel regularly, then adding dry ashes on the surface, and rolling as stated. The hoeing or picking of the walks is a much quicker process than by mixing the tar and ashes together first, but at the same time this—the mixing first—makes the most finished job. A man may asphalte about 40 square yards a day. Burned soil of a clayey character turns quite red in the middle of a heap of considerable size. The greater part of the ashes is so fine as to be readily blown away by the wind, while there is a part in small lumps of various sizes. Without a most intense heat, however, in the course of burning every lump is easily reduced to comparative dust. The small lumps, about the size of Peas or Beans, are most suitable for applying on the surface of the asphalting. The roller presses these into the yielding mass, renders it firm, and in course of wearing afterwards gives a gravelly colour to the walks, which cannot of course be obtained by using coal-ashes alone with tar. Tar walks have rather an unpleasant smell for some time after being done. Hot weather softens the asphalte a little, but by using ashes liberally upon the surface, there is no danger of the tar adhering

to the feet. The surface ashes can be swept up after the walk becomes firm, or in the course of time they wash away by the ordinary rainfall. The walks above referred to were asphalted in the course of some weeks when some half dozen children and others were constantly moving about; yet, in no instance was any one smeared with tar. If the soil to be burned contains stones, of course the ashes will also contain stones; these must be either picked out by the hand, or the ashes must be sifted. There could be no difficulty in procuring materials for burning about any farm, and if ashes were required in towns, the cost of carriage would not much increase the expense of asphalting. *Leighton Buzzard.*

Foreign Correspondence.

BERLIN: *Schleswig-Holstein.*—I have just, at least not long, returned from a trip through Schleswig-Holstein, that famous land, which was all German in sympathies when it belonged to Denmark, and which is all Danish in its desires now it belongs to Germany. Such, you see, is life. What you can have, you don't care for. Coming home, I saw a heap of papers ready, like a snake, to devour me; and it would have been a most melancholy sight, but for the *Agricultural Gazette* on the top,—which I may here publicly declare there is not the like of in Germany, and which always reminds me of those dear old English homes, jolly lanes and greens, verdant fields and copses, parks, pies and plum-puddings; all of which, however good acountry it may be, Germany as yet has not been able to afford—afford being the very term I want, though it may sound queer, somehow.

I have been thinking much of England all these days, so long as I have been in Schleswig-Holstein; for there is a very close resemblance between the two countries, if you look at the landscape side of them. Beef, sir, beef also is the ideal product of both. There are more cattle in Schleswig than people. The difference, however, is also obvious. For Schleswig-Holstein, being so thinly populated, cares little for grain—Wheat, Barley, &c.; and there is, I am tempted to say, not a steam-plough, nor any implement of intense culture in the whole land—excepting the exceptions. All the western slope of—Schleswig—up into Denmark consists of permanent pastures, which are done nothing to, being fertile in the highest degree. The middle part is elevated, like the spine of a fat-sided pig, and, indeed, meagre in proportion; full of bogs and mires, Alder beds, Buckwheat fields, peat moors, rushes, stories talking about, and grey clouds hanging above—altogether, a Cambridge-Boston panorama. Then, again, there is the eastern slope down to the Baltic, with regular landscapes, such as painters paint to put nymphs and satyrs in, and reminding you of Kent, Surrey, Sussex, with regular cornfields, hedges, Oak woods, but no Hops, Beetroots, great Potato fields, nor anything connected with the factory principle. The main character of the Schleswig-Holstein economy will be at once apparent when I tell you, confidentially, that I boarded and lodged for 60 dols. a month; which is exactly a pound and a-half a month, I emphatically repeat.

Supposing a few hundred working people, hearing of these paradisiacal prices, to come over and settle in this land, where they can having everything for nearly nothing (excepting books, though, and looking-glasses), how long would they like it, and how soon would they go back to, let us say, Manchester? There is no work to be done here, no money, no intelligence, no risking, there are not even houses to live in.

May I talk politics? I believe I may, for it has been politics that has kept Schleswig-Holstein out of the stream of the financial, industrial, and commercial progress, and has reduced the home value of her products to so low a level: England, you see, has had the best of it, and Denmark has done it. Look at the market prices of meat in 1866, and you will find a sudden rise—nor is there any mystery about it. For these neglected provinces have, indeed, been systematically stupified by Denmark, and are now slowly, but surely, and somewhat severely, too, being re-cultivated and educated by Prussia. There is, in proportion, a rise in the value of money, as new ideas, desires, and wants are springing into life; and this will be apparent when the new generation, which has gone through the course of compulsory instruction, has been taken out of the country for military training, has seen what a source of wealth even the poor soils of Brandenburg can be converted into—when, I say, this generation will come to the helm.

England of course, I am in duty bound to say, has had a hand in the brutalising process which Denmark has kept up in Schleswig-Holstein; on the contrary, English trade and demand for the products of the land have in a great measure counteracted the influence of Copenhagen, so likewise has Hamburgh on the western coast. But come to the east; there you are, I should like to say, in a land of fettered minds. Nor would the Danish Government have followed so unprofitable a policy but for the necessity of exterminating the German language in the two Duchies, and of dislocating, as much as possible, their natural vocation, viz., of being the great colonial soils for Germany. The German language, however, it was impossible to extinguish, without first extinguishing all the mental wealth of the people, inseparably connected with this language, and ever and ever repleted from the old source. This would have been a work of centuries. In the meanwhile Denmark might have moderated her own language for the science, life, and literature of our days, and might then have followed in office. This, however, could never have been attained without first creating a blank. A country that is unable to keep up her integrity without allowing her subjects full liberty of thought, speech, and individual culture—to say nothing of trade, industry, and locomotion—is unable to be a country at all. For men are men before they are subjects, and even Englishmen are born as human beings ignorant of their future station; are not like the Jews, like the capitalists and tradesmen before they are anything else, or like the Paris Communists, who were setting aside every mortal consideration, Parisians only. One's country is one's house, not one's prison.

There is no mistake about this, Prussia's victories are but the ripe fruits of economical development, and she could hardly help gaining them. It is natural for the Duchies to see what they are growing into being, the marine forelands of Germany. This consideration is in some way, I believe, important for English agriculturists, for, if the Duchies be Danish, we have beef, butter, and cheese suppliers to England; up to this time there has only been one single railway through these rich and fruitful regions, and they have had hardly any connection with Germany at all; up to this time no more than two trains a day have gone up and down this single line, and did that slowly too; up to this time no part of the Duchies has been densely populated except the mad-house in Schleswig, idiotcy and delirium being quite at home in so secluded and slow alcohol-consuming and meat-eating a country. But all this is rapidly changing, people are already beginning to stir, exceptions to be the standard, and, ere long, the rule. There is a great Beet-root factory building, brightening eyes are squinting after all sorts of machinery and after hands to work them, Governments and Boards are projecting and exploring about the Duchies, sea-ships to pass in from the Baltic to the German Ocean and back, the University in Kiel has been enlarged, the harbours on the eastern coast are beginning to be alive; Holstein beef, butter, cheese, fish, and oysters are becoming in vogue in Berlin; and those Danish sympathies I spoke of in the beginning of this letter are slowly vanishing, like the drowsiness after a long sleep.

Here then, again, is a reason for the English agriculturist to turn to the production of meat on a greater scale, for one of England's chief markets is gradually at first, but fast after a while, growing into a home-consuming district of trade and industry; and is at all events, with every year becoming more and more overcrowded by the growing demands of the Germans, who have, till now, hardly been a meat-consuming people at all. There are some other points of interest, for Englishmen, in Schleswig-Holstein, and upon these I will touch in a subsequent letter. *O. Beta.*

Societies.

SMITHFIELD CLUB.

COUNCIL MEETING: *Nov.* 1.—Present, the Most Hon. the Marquis of Exeter (President), in the chair; Lord Walsingham, M.P., Vice-President; Messrs. C. S. Bigge, T. C. Booth, J. N. Beasley, Thos. Duckham, J. Druce, Brandreth Gibbs (Hon. Sec.), John Giblett, R. Hornsby, R. Leeds, E. W. Moore, R. J. Newton, Wm. Sanday, C. Stephenson, T. L. Senior, Wm. Torr, and Jacob Wilson.

The minutes of the last Council meeting were read and confirmed.

The report of the stewards on the detention of the animals destined for the country, in consequence of one having been attacked with foot-and-mouth disease at the last show, having been read, it was adopted, the Hon. Secretary was authorised, in reference to the licence from the Privy Council, to take the necessary steps to secure, as far as possible, the recommendations of the stewards being carried out, the particulars of which will be communicated to exhibitors and made public as soon as finally determined upon.

The Council appointed the usual committee in reference to the arrangements for cattle conveyances, and their being disinfected under the superintendence of a properly appointed officer.

Mr. Joseph Overton, of Manningford Bruce, Marlborough, was elected a member of the Council, in the place of the late Mr. Richard Stratton.

The Council prepared the house list of the eight members recommended for election on the Council at the next general meeting, in the place of the eight who retire by rotation, and who are not eligible for re-election for one year.

The Right Hon. Lord Tredegar, V.P., was elected President for the year 1872, in place of the Right Hon. Lord Penrhyn, who had signified to the last meeting his inability to act, and had at the same time presented £100 donation to the funds of the Club.

The proposition of the Agricultural Hall Company, in reference to the implement catalogue, was agreed to, viz., that the separate catalogue of implements be discontinued, but that in lieu there shall be added to the stock catalogue an index giving:—1. The name, address, and trade of each exhibitor or firm; 2. The number of the stand; 3. A plan of the galleries, showing the position of each stand, and its reference number; also, 4. The name, address, trade, and number of stand of each exhibitor or firm, on the ground floor.

The reply of the Agricultural Hall Company to the Council respecting the ventilation of the pig hall was read.

The chairman of the Agricultural Hall Company engaged to see that the matter of ventilation in the pig department should be seen to, and as far as practicable remedied.

It was resolved that the Hon. Secretary be requested to invite the butchers, purchasing cattle at the Club's shows, to send an account of the dead weights for publication, and that the name and address of each butcher complying with this request be published in conjunction with his return.

Authority was given for the silver cups, &c., to be ordered as usual of the Club's silversmiths, Messrs. Thomas, of Bond Street.

A letter from Mr. Robert Wortley, suggesting that no animal exhibited at Birmingham should be admitted to the Club's show, was read, and the Council determined that it was too late to entertain this proposition under existing circumstances.

The following were elected members of the Club:—

The Right Hon. the Earl of Aylesford, Packington, Coventry.
Jeremiah James Colman, M.P., of Carrow House and Easton Lodge, Norwich.
The Right Hon. Earl Cowper.
R. B. Baxendale, Kimpton, Welwyn, Herts, and Gresham Street, E.C.
John Seaman Postle, Smallburgh Hall, Norwich.
Hedworth Barclay, Eastwick Park, Leatherhead.
Charles Dorridant, Aldershot Park, Aldershot.
Charles Whitehead, Barming House, Maidstone.
W. A. Hope, Wellingborough.
Thomas Latham, Whittenham, Abingdon.
John Pears, Mere, Lincoln.
Walter Scott, Gilmerton, Huntly, N.B.
John J. L. Lubbock, Catfield Hall, Norfolk.
John Gervis Sharp, Bronghton, Kettering.
John Carter Clayden, Barnet, Herts.
Joseph Stratton, Alton Priors, Marlborough.
W. de Chair Baker, St. Stephens, Canterbury. [Edge.
Colonel Kingscote, M.P., Kingscote, Wootton-under-The Right Hon. Lord Burghley, Burghley House, James Mespr, Cavendish, Reading.

The best thanks of the meeting were voted to the Most Hon. the Marquis of Exeter, President, for his Lordship's able conduct in the chair.

Farmers' Clubs.

LONDON.

Nov. 6: The Agricultural Labourer—his Employment, Wages, and Education.—At a meeting of this Club last Monday evening—the first after the summer and autumn recess—which was presided over by the Chairman of the year, Mr. J. B. Spearing, the subject fixed for discussion was introduced by Mr. C. S. Read, M.P., after a few opening remarks from the Chairman, in which he alluded to the great damage done to the crops during the late harvest for want of an adequate supply of manual labour—

Mr. READ delivered—not reading—an address which occupied an hour and a quarter, and of which the following is an epitome: After observing that at no period of English history had the transitional position of the labourer been more remarkable than it is now, the hon. gentleman said that not wishing so much to give his own opinions as to show what were the conclusions of impartial and competent witnesses, he had consulted the Reports of the Commissioners on the agricultural gang system, and the employment of women, young persons and children; Mr. Kebbel's book entitled "The Agricultural Labourer;" Mr. Bailey Denton's paper on the same subject, read before the Society of Arts; and Mr. Dent's recent and excellent essay in the Journal of the Royal Agricultural Society. The division of agriculturists into landlord, tenant, and labourer, he went on to say, though recently assailed, was, he believed, in a small, rich country like this a wise division; the rent being better rents, larger produce, and higher wages than were obtained in any other country in the world. The "middle ages" were very well to write about, but very middling times to have lived in. The labourer was then nothing but a slave. He was the villein of his lord; he was confined to one parish, and if he left it was branded with the letter F; and his wages were settled by statute. History taught us that in times of civil strife and commotion the agricultural labourer suffered as much as his rich neighbour, and that he flourished most when monarchical and aristocratic institutions, now so much assailed, were in the ascendant. Did any one present, he asked, remember a time when the labourer was better off than he is now? (A voice: "Certainly not.") His wages were slowly but surely rising. In 1851 Mr. Caird, after visiting six of the lowest-waged counties—Gloucestershire, Wilts, Suffolk, Cambridgeshire, Berkshire, and Dorsetshire—reported in the *Times* that in those counties the average pay of agricultural labourers was 7*s.* 1½*d.* per week. The Agricultural Commissioners said that Dorsetshire was still the

lowest county as regarded wages, and, according to those gentlemen, the average there was now 8s. per week; but then the labourer had a cottage, fuel, and perquisites, and Mr. Stanhope said that he really obtained from 10s. to 12s. In the Cotswold Hills, Bishop Fraser said, wages ranged from 10s. to 14s. Thus, they had now a medium of something like 12s. against 7s. 1½d. in 1851. Mr. Bailey Denton divided the country into seven districts, and said :—

"The mean weekly day-labour wages of able-bodied men throughout the whole of England may be taken at 12s. 6d. To this must be added the gains by occasional piece-work, extra payments at hay-time and harvest, when double the ordinary wages is frequently given. In the aggregate, the actual income derived from these employments is equal to from 1l. 6d. to 3s. a-week, according to the custom of different districts. When piece-work can wholly take the place of day labour a labourer may earn 25 per cent. more than by the day. The total value of the beer and cyder supplied to each labourer as his allowance at hay-time and harvest, when employed in drilling and machine-threshing, and when engaged in piece-work, if spread over the whole year, would amount to from 1s. to 2s. a-week more, according to locality. With these additions to his direct money wages, the farm-labourer gains from 13s. to 15s. per week, taking the mean of England."

Thirteen to fifteen shillings a week without the earnings of his wife or children! Any farmer who examined his labour-book would find that he paid a good deal more per acre than he did then. He (Mr. Read) recollected a time when 25s. per acre, on light arable land, was considered a good amount to spend on wages; now the expenditure under that head was often 35s., and he feared that he did not get off under 40s. This increase of wages occurred in spite of the increased use of machinery. He believed that in future the cost of manual labour would be one of the most difficult items that farmers would have to deal with, and it would tend more than anything else to turn the land into grass, notwithstanding all Mr. Mechi's efforts to put it under the plough. The rural labourer had many advantages over the urban labourer; he had pure air, and consequently as a rule good health; the rent of his cottage was about 1l. 6d. a week, 'against 3s. or 4s. for a similar dwelling in a town, while the use of a fruit and vegetable garden raised this pecuniary advantage to 4s. a-week; there was less work than in many of the artizans, and there was more demand for the children's labour. Mr. James Howard, in the paper which he read before that Club on Continental farms, showed that English agricultural labourers, in the receipt of good wages, were better off than the poor peasant proprietors or farmers of Belgium and the countries, and Mr. Caird Read was told the other day by a gentleman from New York that the wages of an English agricultural labourer, if they amounted to £35 a year, were, taking into account the cost of the necessaries of life in America, quite equal to £80 a year in the United States, due to the varying rates of prices, any single man who chose to save a week or two's wages might transfer himself to any part of England. From 1800 to 1841 there was a gradual increase in the agricultural population. It was checked by about 1851, and had since declined, except in sheep-farming or stall-feeding districts. Machinery did not account for the decrease, but it was not surprising when, as the Registrar-General had stated, half London came from the country, and the ranks of soldiers, policemen, railway guards, porters, carters, &c., were all more or less recruited from the rural districts.

Correspondents of newspapers asked how a labouring man and his family could live on 2s. a day. If the labourer got 2s. a day all the year round, winter and summer, he ought to be well contented. Taking the bricklayer's slab, the dock labourer, shoemakers, hand-loom weavers, and the lower class of manufacturing operatives, he maintained that agricultural labourers generally received as much as was paid for the same style of work in towns. His hours of labour were not excessive, nor his strength unduly taxed. They had all heard a great deal lately about the nine hours' movement in towns. He, for one, was quite ready to accept nine hours for actual work on the farm, the agricultural labourer's working day being sometimes only about seven hours. He looked to task, or piece, or taken work, as it was differently styled in different localities, as "the future" of the agricultural labourer. If a high rate of day wages were paid there would not be much piece-work. It was remarkable that in all trades in which piece-work prevailed there existed great development and great prosperity, both of masters and men. He was sorry to be obliged to confess that in agriculture task-work was rather losing than gaining ground. Perhaps the chief cause of this was, that a great many young farmers were not at all acquainted with the value of piece-work. If they were to take many of the young dandies of the present day round their farms, and ask them the prices of hedging, ditching, hoeing, and ploughing, half of them, he believed, would be unable to tell. Piece-work not only made better and more skilful labourers, it also made more practical and intelligent farmers. He admitted that there were some things which could not be paid for by piece. There was hardly an old man on their farms who had not some special qualification for usefulness. One old labourer had the bump of order, tidiness, and neatness; another was great in the management of implements, another in dressing corn, another in training lads, another in preserving the health of stock; and such persons might often be found as useful as younger and stronger men. Notwithstanding all that had been said on the subject, there was still a kindly interest in the relations between farmers and labourers, and long might it last. In many cases he feared all the 'skim milk was given to the pigs. Why should it not be given to the labourer whose family required it? Surely that would be much better than every man's keeping a cow, with all the expense and risks attending that, including the loss of the animal by death! Twenty years ago, agricultural machinery was in its infancy, and it was still often regarded as having been invented for the sole purpose of depriving the poor man of his hard-earned wages. Machinery had eased the labourer's occasional toil, and left what remained to be done by him easier for the muscles, though, perhaps, harder for the brain. It was surely easier to direct a great power than to exert that power oneself. There was no severer labour than swinging a flail all day, no stronger exertion than mowing with a scythe, no more back-breaking work than reaping; and harvest wages were now certainly no less than they were, and men were better employed and better paid during winter. Where the steam-plough was used the best man got the best wages. Moreover, the best engineers employed on the steam-engines were agricultural labourers, a fact which showed that many men of that class had a great deal in them, and that it was only waiting to be brought out.

As regarded cottages a great evil still existed, although a great work had been accomplished all over the country; and the labourers' friends were men who were constantly to have interested themselves in the new "social movement," as it was called, could not be better employed than in improving the cottage accommodation for the labourers on their estates. On settled estates great facilities had been lately afforded for the erection of these cottages, but unfortunately the Inclosure Commissioners did not advance money for altering and repairing old ones. He had never seen any reasonable objection to the letting of the cottages with the farm; and if the landlord did not like that, he should, at all events, allow the tenant to nominate the tenants. He (Mr. Read) entirely objected to weekly notices to quit. However badly a labourer might have behaved, he should have at least three months to remove. Allotments, to be of any use, must be near the labourer's home, and they should never exceed a quarter of an acre.

As regarded the employment of women in agriculture, he did not know any subject on which a greater amount of twaddle had been uttered. The Commissioners who investigated the matter, said there was a great deal of farm work which might be done by women with benefit to agriculture and without injury to themselves. Bishop Fraser had attacked the dress of women employed in farming operations as unfeminine, instancing nailed boots, leather gaiters, and short skirts. Such things, if not ornamental, might be useful, and Bishop Fraser would be the last to undermine than the pilot jackets and billycock hats which adorn many of the young ladies of the present day. Lengthening the field-dress condemned was certainly not more likely to unsex those who wore it than half what was uttered on the subject of "women's rights." He believed that the employment of women in agriculture was dying out, and with better wages and openings for more suitable employment would in time become extinct. He did not at all agree with the Commissioners that 16 was the lowest age at which girls should go out to work. Build a limit was too high for many cases, and was wrong also in relation to morality and health. With respect to the prohibition of the employment of boys under 10 years of age, one of the Commissioners, Mr. Tremenhere differed from his brother Commissioners. In Mr. Kebbel's work, to which he had before referred, Mr. Tremenhere's views were thus stated :—

"He contends, first of all, that the earnings of children under ten are often indispensable to the parents, while in many of the most important agricultural counties there is an 'imperious demand' for their labour. He observes that their earnings are more than absorbed by the extra food which they require, and the extra wear and tear of clothes which ensue when they are at work; and he scouts the notion that, with the exception of bird-scaring, which children are put to any kind of agricultural labour which is physically injurious to them. He draws a very clear distinction between the farm and the factory. 'In a factory or a workshop a child is liable to work in a close and unwholesome atmosphere; and when working in connection with machinery, its attention is ever on the stretch, and its movements are often rapid and continuous for various periods of time together. The effect of such a mode of employment upon the very young was shown to be physically injurious to them, and therefore to justify legislative measures for their protection. But it has been seen that employment in the healthy occupation of agriculture cannot be shown to be attended with physical injury, even to the very young."

The working of the Agricultural Gangs Act had, on the whole, been satisfactory. Being a mild measure it was more likely to be accepted than a violent one. Agricultural gangs were, after all, a transitory evil, arising out of the peculiar character of the fen district while being drained. Now the fens were drained, cottages were built, ague was gone, and in a few years agricultural gangs would be a thing of the past. As to commons it was generally better for the country that they should be enclosed; that more corn might be grown, and more people employed. As a rule they were surrounded by the worst description of cottages, and a miserable race of squatters, and in many cases some sharp farmer, or dishonest dealer, reaped the chief benefit of the grass. As to the comparative value of large and small farms it would, he thought, be a mistake to do away with all small holdings, particularly near large towns, but, on the other hand, a good skilled labourer would generally save more money than a very small farmer; and if the latter succeeded, it was, as Mr. Charles Howard had well remarked, by doing the work of two labourers while living at the expense of one.

They all knew his (Mr. Read's) opinion about game; but let him read the following words of Mr. Kebbel :—

"Among the peculiar sources of demoralisation to which the English peasant is exposed, the preservation of game is often cited as the worst. This is a very great mistake. Nobody knows better than the poacher the real character of the game. If his apologists like to shelter him behind a wilfully mistaken commiseration, the sentence he will avail himself of their kindness; but as for supposing that the poacher himself is led away by the delusion that pheasants are wild animals, in which nobody has any right of property, it is one of those foolish conventions which only personal acquaintance with a single member of the profession is required to dispel. Game is no more a temptation to dishonesty than other luxuries; and whatever is to be said against the Game Laws is to be said against them rather as a farmer's grievance than a labourer's."

They could not farm against ground game, and on estates where game was preserved to an unlimited extent, the land was but half cultivated, and labourers often took to poaching for want of employment. Farmers, generally, should encourage village benefit clubs more than they did. They should encourage clothing societies, shoe clubs, building societies, saving's banks, even co-operative stores—anything, in short, that tended to make the labourer thrifty and provident. At present, labourers, as a rule, had not the slightest thought for future years, which Mr. Welch arose, no doubt, in a great degree from the operation of the Poor-law. Some distinction should be made in England as well as in Ireland between sickness and destitution, so that, through the action of dispensaries, medical assistance would no longer pauperise a man. The cutting system was partly in use, he was glad, happily, going out of fashion. Wherever it existed the matter should certainly be optional. Public-houses in the rural districts were very generally condemned. The subject of education had now been thoroughly threshed out. It was once said that the agricultural labourer had two things to do to get a living and to get to heaven." He did not believe the compulsory attendance of children up to 12 years of age at a secular school would help them to do either of those things. Education would enable labourers to leave farms with a little more alacrity than they did now, and therefore the body would probably derive less benefit from it than any other class of society. The Elementary Education Act would not work in the rural districts. In the towns he hoped it would do some good, but thus far it had produced no end of talking without teaching a single child to say its A, B, C. There was in favour some indirect compulsion among the agricultural population. If it were determined that no child should go out to work until it could pass an examination in the three R's, that would be a great inducement to parents to send their children to school early, and regularly, and to keep them there a considerable period. Man's primary object and desire was to satisfy his animal wants: that done, he began, as a reasoning being, to think of comfort and decency. The Legislature appeared inclined to force upon the labourer mental culture, hoping thereby to give him sounder ideas of his own comfort; but he must first earn more wages before he could materially increase his comforts, and this he could not do without becoming a better workman. Fortunately, the mitigation of the labourer's hardships pointed to reform rather than revolution. All the suggestions of the Commissioners were in that direction, and he could not conclude his remarks better than by quoting from Mr. Kebbel, who thus fairly summed up and impartially balanced the present condition and future prospects of the agricultural labourer :—

"On the one hand is his life of silent, secluded, uncomplaining toil, his undeniable privations, his honesty, his simplicity, his helplessness, so unlike the loud self-assertion and menacing pugnacity of the city artisan; all prepossessing us in his favour, all imbuing us with the idea that a system which does not do more for him must be radically indefensible. On the other hand, we see in him but one link in the social chain which has endured for centuries, the origin of which was noble and generous, and the continuation of which has been sanctified from age to age by the accumulative force of kindly traditions and immemorial symathies. If we fail to give its full value to every reflection which is suggested by every side of the shield we are dashed headlong into error; and it is the certainty of this which should make us so cautious of dogmatising. But I am happy in believing that the more the question is studied, the more will it be seen that the highest interests of the landlord, the tenant, and the labourer, harmonise with each other, and that in a logical

development of, rather than a total departure from, the ancient social system of England lies our best hope for the future."

BOROUGHBRIDGE.

Grass Lands.—Mr. JACOB SMITH lately read a paper on this subject. He said :—

Although at present the improvement of grass land is very little attended to by many farmers, I feel sure the day is not far distant when it will be much more seriously considered than it is at present, for when we look at the great increase of population, and, what is more, the greater increase of meat consumers, we may well ask how these wants are to be supplied ; for though the increase of cattle from abroad has been large, still there are many difficulties and much uncertainty attending the importation of foreign cattle. If, then, we have to increase our supply of beef, how is it to be done ? Certainly not by adopting Mr. Mechi's idea of ploughing out all our old pasture land. I think in this Mr. Mechi will have very few supporters ; but I am sure a great deal may be done by improving these pastures. When we look back at the great advance made within the last 20 years both in the cultivation and the increase of beef and mutton from arable land, it does appear wonderful that grass land should remain very little, if at all, improved during the same period. This is perhaps accounted for in a great measure, because the improvement in many ways is not immediately seen. Then, again, some manures have great value upon some land, upon others none, and in using artificial manures it is necessary to be careful.

I will briefly state to you what experience I have had in some of these manures. Bones I have seen applied with wonderful results, so marked that, in walking over the fields, no one could fail to notice the difference where the bones had been put on—grass, beautiful and rich, where there had not been any, and not a bite for anything to eat ; but I put 30 qr. on to acres in the middle of a 30-acre field some years ago, and I have never been able to see that they did any good. Lime, too, I have seen great results from in some fields, and in others a slight improvement the first year, but very little afterwards. Prepared manures, and guano, I have tried, and found in a wet summer a great increase ; in a dry one none, and I cannot say much for the lasting improvement. I might now give you my ideas as to the effectual way of benefiting grass lands. In the way of manures, I think there is no doubt that good farmyard manure has no equal, it always shows itself, and in mixed farms (by mixed farms, I mean those that are partly tillage and partly grass) I think more manure might be spared for the grass land than there is at present. In farms, principally grass, of course farmyard manure is not to any great extent available, and what there is is generally used for the meadow land.

In order to improve pastures you must stock properly ; grass lands must be stocked with beasts, as sheep are injurious to grass—especially good grass. Some landlords are very particular about tenants taking two white crops, &c., off arable lands, but in my opinion a tenant that stocks grass land with sheep, damages the landlord's property far more. I think you may stock good grass with sheep until it will scarcely grow anything ; many people run a few sheep amongst their cattle, but it is bad both for the cattle and the land. Keep horses out of grass if you wish to improve it. I do not say that one or two horses in a field will do much, if any, harm, but you see many who have mixed farms, and many who have only a small proportion of grass, turning all their cart-horses out into pasture fields. They will probably tell you it is only poor land, and well it may be, when grazed year after year with a lot of cart-horses. You may take the best field in the country and graze it with cart-horses until it is a very poor one ; besides, cart-horses can be so much more cheaply kept in the yards by mowing green meat. Therefore, if you wish to improve your grass keep sheep and horses out of it, and stock with such cattle as are best adapted to the nature of the land, and give them a liberal allowance of cake, and you will soon see a marked improvement. Of course, you do not see it the first year, but you see your cattle feed much faster, and every year you will see your land alter, keeping more stock year by year, and the quality of grass wonderfully improved. I have tried it now for some years, and I am quite satisfied with the results. I think, in most years, the cattle quite pay for the cake, and sometimes more. I am sorry I am not able to give you a quicker remedy.

I have no wonderful specific which will transform all the grass land in the country in a year or two into rich pastures, but, if my remedy is slow, it is sure, and by using cake you are always increasing the amount of beef for consumption. Some men may say it is all very well for men to do so who feed cattle for the butcher, but it will not do for a man who only breeds. I don't agree with this, as I think no cattle pay better for cake than young cattle. By keeping young calves well, you may make a 2-year-old nearly as good as, with ordinary keep, it would be at three. If so, this is going a great way to an equivalent to making two blades of grass grow instead of one ; and so sure am I that there is scope for improvement in grass land that I think we shall soon live to see two blades of grass growing where only one grows now. If by reason of this discussion we help to bring this about, our time will not have been mis-spent, and surely there never was a time when there was such inducement to rear and feed as much stock as we can. I have mentioned Mr. Mechi before, because just now we all, I dare say, know he has been writing letters, advocating the ploughing out of grass. So far from this, I think there is poor, bad land, especially any that is far from the homestead, that would be much more profitably farmed were it laid down to grass, as it would answer well for the rearing of young cattle. For breeding purposes, care ought to be taken that it should be clean, and in good order, where laid down ; and liberal treatment used afterwards will greatly assist it after it has been laid a few years. I should strongly advise anyone who has a field of this kind to let it rest for one half-year, that is, neither stock it nor mow it, but let the crop of grass grow. The seeds will shake, the roots will spread, and the land be warmer. The next spring the cure will be as much keep for stock as if you had the hay crop. I have tried it myself, and I am sure I had more keep on the land in spring than if I had taken the hay and fog as well. It was perfectly astonishing. Since then, the field has been more like an old pasture, and readiness to work, and I dare say I have now introduced the subject, and I am sure I have left room for plenty of discussion. If gentlemen will give some of their experience, and also their opinions, I shall be in hopes that good may come out of the consideration of the subject.

Mr. FORD said : Undoubtedly grass lands were capable of great improvement to make them properly available for the production of beef. He looked forward to the time when every rood of sward land should be brought into thorough grass cultivation. As agriculturists the question was asked them, How were they to provide the nation with beef and mutton ? He was not quite sure whether Mr. Mechi was not right in his views with regard to the ploughing out of grass land, as he adopted enlightened ideas on farming. He did not advocate the ploughing out of grass land in a wild and reckless manner, but considered that such operations as such a course of husbandry must be regulated according to their knowledge of the condition and capabilities of the land. He considered that a great quantity of land in the country now in grass would be better in tillage, and at the same time he thought there was a great area of land which ought to be laid down in grass. He did not agree with Mr. Smith as to allowing certain kinds of fields to rest for a time by neither mowing nor stocking them, because, in his opinion, a close, compact sod could not be obtained without cutting the grass, and thus promoting and procuring rich grass.

Mr. BENNETT said that Mr. Smith had not alluded to the drainage of grass lands. Where there was a bad description of grass, it could not be improved without the land being drained. He agreed with Mr. Ford as to the ploughing out of certain kinds of land ; but this ought to be very carefully done. The general land of the country might be materially improved by a judicious system of management.

Mr. CALDER said that the price of beef and mutton made the subject under discussion of very great importance, especially at the present time, and as a great demand for beef and mutton was to be met, there must be great improvements made in the condition of grass land. He did not agree with Mr. Mechi in his opinions about the ploughing out of grass lands. For his own part he did not like the idea of ploughing pasture lands, which could be improved by means of a liberal application of manure, and by giving the animals grazing on such land as much cake as they could eat in a reasonable way. From what he knew of grass land, great judgment was required in draining it. In the laying down of grass land he should advocate cutting it the first year, and keeping it off with sheep.

Mr. T. SCOTT, said that he trusted the laying down of grass land would not be introduced into the discussion that day, but that some gentleman would deal with it on a future occasion, when it would form the subject of other interesting discussions. In relation to the effect produced upon lands by the application of lime and bones, he recommended the trying of a small portion of these substances as an experiment before they embarked upon their use in an extended manner. He quite agreed that it was judicious to use linseed and other cakes upon land in preparing their stock for the butcher, as by this plan the grass was improved. He scarcely agreed with Mr. Smith in letting the grass rot upon the land for a season as a means of improving it, because he knew that, in some districts especially, the grass matured so rapidly that such pastures they should not put on sheep and horses, and he agreed with Mr. Ford that grass land was improved by cutting, as it made the roots spread, and the crop grew closer and more compact.

Mr. POWELL said that he knew many farmers who applied all their manure to arable land, and left the pastures to Providence, a course which he condemned.

Mr. FORD said that sheep eat very deeply into the roots of grass, which were permanently injured, and some kinds of grass were so eaten down as to cause them to die out. Sheep undoubtedly did injury to grass land.

Mr. SMITH entered into some details in justification of the course he pursued with regard to allowing some land in his occupation to rest for a time by neither stocking nor mowing, showing that the plan had answered remarkably well, and that the land had become improved. He quite agreed, however, that old and permanent grass land wanted eating down once a year, but not too bare. He condemned the folding of sheep on grass land, and horses, especially cart horses, did harm to grass fields. He did as little as possible in feeding sheep on grass land, besides which the animals did not do so well on such land. Beasts ought to be kept on grass land. As to the drainage of land, it was a great advantage in low wet districts. Wet grass land required drainage, but drainage upon this kind of land was not so much required as upon arable land.

Mr. T. SCOTT referred to some grass lands which he knew being worth very little an acre, because they received little or no attention from the occupiers, whereas the same description of land, when occupied in small parcels by cottagers who cultivated it, was worth 50*s.* per acre, when before it was not worth 2*s. 6d.* per acre. This fact showed that land, however inferior it might be, was capable of very great and wonderful improvement.

Notices of Books.

On the Economical Production of Peat and Peat Charcoal ; *with Incidental References to the Processes Pursued at the Red Moss Works, Horwich, near Bolton, Lancashire.* By W. Bunch. London : 1871.

This is an advertisement pamphlet, issued by the company whose cause it advocates, and whose works it describes. "Nearly every acre," it declares, "of the 6,000,000 of peat bog in the United Kingdom is capable of yielding, in charcoal alone, after deducting all manufacturing expenses, not less than a thousand pounds sterling."

"Assuming that only half these acres were suitable for the manufacture of charcoal, their most valuable product, and excluding all other means of profit, the aggregate value of the peat-bog property of the country would be greatly under-estimated at 3000 millions (£3,000,000,000), nearly four times the amount of the national debt. Add to this the value to the State of thousands of labourers finding reproductive employment in a new industry, and the further consideration that, when the land has been divested of its peat, it is ready for national tillage, in a rich virgin condition, ready for agricultural and pastoral purposes, and how much is its importance magnified !"

So much is extract, which we prefer to place within inverted commas, and thus put the responsibility of the statement on its author. The next two sentences of the pamphlet, however, we might very well take for our own.

It must be granted that if this view of the real, though at present latent, value of the peat-bogs of the United Kingdom be only approximately true, the practical means of realising and rendering active such enormous wealth deserves attention. Nor will the importance and immediate pertinence of this be diminished by the consideration that the rapid consumption of our staple fuel, coal, has already begun to create anxiety for the future of manufacturing England.

It is unquestionably a remarkable circumstance that, in itself a fuel, and therefore capable of generating all the power required, no attempt at manufacturing peat, or manufacturing from it, has yet been a complete success. Even the attempt to manufacture food upon its surface has, when all is told, proved a very doubtful venture. It is not, in its relation to the fuel question, an example of the superiority of what may be called the small farm, or allotment system, to operation on the great scale. Everyone living near the bog finds it his interest to manufacture fuel for himself, but a company started for the same purpose, and bringing its power to bear, generally fails. The reason, no doubt, is twofold. There is first the fact, that it is only for home consumption that the residents find it answer. It would probably be unprofitable even for them were coal as cheap as it is nearer the wharf or station, or if they had to carry it to many places for consumption. And the second reason probably is that the power wanted is simply one which can cut the turves and lay them out to dry. The application of steam-power to crush or squeeze the turf, or drive off the water by evaporation, has been blended to failure essentially when a company with steam-power at its command must in the first place use a man to dig the turf. That man, if he were digging for himself, lays it out to dry, and is at no further expense. The company, on the other hand, proceeds perhaps to grind the material up or make it into bricks, or possibly to apply artificial heat to drive the water off. And most of these processes hitherto have failed to "pay." "But," says the writer of this pamphlet :—

"Because of these failures, it would be a great mistake to suppose that peat cannot be worked with profit. In France, Germany, Holland, Denmark, Sweden, and other parts of the Continent, peat works are as common as coal pits in England and Scotland, and that not merely because of the scarcity of coal, but also because of economical reasons peculiar to themselves. In the United States also, they have been of late carried out extensively. In some of the larger towns on the Continent, such as Hamburg, Copenhagen, Bremen, Berlin, and many others, peat is the staple fuel for household use. In whole districts along the Weser, the Oder, and other rivers ; in Holstein, Hanover, Westphalia, Lower Saxony, Pomerania, Mecklenburg, &c., hardly any other fuel is known but peat. It must be presumed that its producers find it pay, or they

would not continue, year after year, to supply these markets. In France, near Liancourt, on the Northern Railway, Messrs. Debonne & Co. employ about 300 workmen during five months every year, producing annually from 10,000 to 12,000 tons, a large portion of which is converted into charcoal for the supply of the Paris market, where it fetches from 14 to 16 f. per 100 kilogrammes—equal to 140 to 160 francs, or £5 10s. to £6 per ton. In Rheims large quantities of excellent peat are produced. One firm alone produces about 14,000 tons per annum, part of which is likewise made into charcoal. Peat fuel is made and used in the departments of Somme, Loire Inferieure, Pas de Calais, Oise, Marne, Eure, Seine et Oise, Meurthe, Vosges, and others. The French official statistics of 1852 show that the actual annual consumption of raw and carbonised peat was then 359,319 tons, since, no doubt, largely increased.

"The process of peat-making on the Continent is mostly carried on by hand labour. The peat is either cut in sods of from 4 to 5 inches square, and 12 to 15 inches long, direct out of the bog, and, without any further operation, dried in the open air; or it is dug anyhow with a common spade, as in Ireland, with a tool fixed to a long shaft, cut and raised from under the water, and prepared into a pulp by men tramping it with their feet, after which it is struck into moulds similar to those used in brick-making, and then laid out to dry.

"The first process requires two men, one cutting, the other wheeling the peat to the drying place and spreading it there. An average of 3000 sods per day are cut and laid out in this way, making about 60 tons of dry peat.

"The second process requires four men; two digging and pulping, one moulding, and one wheeling, &c. In this way 4000 bricks or sods are made daily, corresponding to about 12 tons of wet peat.

"In the former, the daily yield is about 5 tons per man; in the latter, 3 tons per man. The former, therefore, has the advantage in quantity, but the latter has it in quality; for in the latter, the peat, being reformed more dense, equal and homogeneous, gives an intenser heat, is less liable to break into fragments when dry, and yields, when charred, a better charcoal. An additional recommendation for the latter process is, that it is applicable to almost any bog; whereas the former can be applied only where the bog is sufficiently dry, or where it can be drained so as to leave the part intended for cutting dry."

We do not proceed further to describe the works at Red Moss near Bolton. The pamphlet is worth reading for the information on this point which it gives. We believe, however, that there would have been a better use of the bog near Bolton if, after drainage, the sewage of that town had been pumped upon it, than is likely to be realised even by the manufacture of a fuel from its substance.

Farm Memoranda.

CASTLE ACRE, NORFOLK.—The following report of a day at the farm of Mr. Robert Leeds, appears in the *Albany Cultivator*:—

The farm is some 20 miles or more east of Lynn, and is reached by a carriage drive of 6 miles north from Swaffham station on the railway between Lynn and Norfolk. It lies in the chalk district, and the soil is everywhere underlaid by that substance, which is only a foot or two beneath the surface. The land is rolling, the soil loamy, and sufficiently dry to need no artificial drainage. The farm comprises 1200 acres, of which 1060 are under cultivation, 70 in permanent pasture, and the remainder in the grounds about the homestead and buildings. There are cattle sheds and feeding places at four places on the farm, so that the hauling of manure and of heavy crops for feeding may be shortened. No farms or sheds are provided for storing grain or hay, stacks being considered as economical and safe. Neither is any shelter provided for the sheep.

Mr. Leeds went with me over the farm, walking steadily for more than five hours. He explained in detail his method of manuring, cropping, tillage, and stock-keeping. His aim is to keep one quarter of his farm in Wheat, one quarter in Barley, one quarter in roots, Mangels, Swedes, and common Turnips; and the remaining quarter in Clover and cultivated grasses. It should be remarked, however, that the rotation is varied from the exigencies of the season and the judgment of the farmer dictate; thus, on very good ground two crops of Wheat are taken in succession, and a crop of Turnips between them. Mr. Leeds had a fine field of early sown Rye after Wheat, which was intended for early pasturage for sheep—3½ bush. of seed per acre were sown. A crop of Oats may take the place of the Barley, and for purposes of tillage or improvement some one of the leading crops may be greatly in excess of the others; for example, the root crop on this farm covered more than 300 acres last year.

The tillage of the land is thorough—steam cultivation is used as far as possible, pulverising the soil to the depth of 10 inches. For the crop of Mangels the ploughing is done in the late autumn to the depth of 11 inches; and it is again ploughed to the same depth in the spring. For the Turnip crop, simple cultivation, without inverting the soil, is generally practised. The ploughing for Wheat is very shallow, only about 4 inches; and after the ploughing the ground is rolled, and then harrowed with a very large harrow with numerous small teeth; the intention being to get a very fine seed-bed of 1½ or 2 inches deep, leaving the rest of the soil pretty solid. The Wheat is drilled in, and on the light soil the ground is again rolled after sowing.

The crop of Wheat averages from 32 to 36 bush. an acre, though in exceptional seasons it has gone as high as 56 and even 60 bush. an acre, and in other unfavourable seasons, on the same land, has fallen to 28 bush. The Barley varies from 40 to 48 bush. an acre—last year it was only 40 bush. Of the weight of the root crop I can give no distinct report; it is enormously large both in the Turnips and the Beets. The roots were gathering a crop of long red Mangels, and hauling them off to clear the ground for Wheat. The foreman said they were taking off 35 large cartloads from an acre. The cart had high side boards, and must have held nearly a ton. They were gathering the Turnips in other fields, and the piles seemed to be nearly as large as those of the Beets. Of the crops of Clover and cultivated grass I got no definite idea. They are not so highly valued as with us, and are used in feeding stock nearly in the same way that straw is.

Thatching the soil is an important part of the farm economy; everything that will help to increase the manure heap, or improve its quality, is most carefully done. The manure is kept under shelter; enormous quantities of feed for cattle and sheep are bought; artificial fertilisers are used largely; and only the sheep, cattle, Wheat and Barley, are sold off the farms, and just as large a stock of bullocks and sheep is kept as the straw, hay, and Turnips will support. The amount of dung made is 3 tons or more an acre for the whole farm. This is used mainly on the Wheat and Turnips; none is used on the grasses or Barley, and artificial manures bought for the Mangels, and some additional fertilisers for the Turnips and Wheat. Both superphosphates and Peruvian guano are used.

Mr. Leeds feeds and fattens about 2000 sheep yearly. He keeps Hampshire and other Southdowns, and the lambs raised are a cross of these with the Lincolnshire. I noticed in particular a flock of 300 fine Southdown ewes, which were to be kept over the winter for raising lambs. From these he expected to get from 450 to 500 lambs. But the largest part of the sheep are bought to fatten, change the Turnips into meat, and help to prepare the ground for crops. They were feeding off the Turnips when I was there—a plot just large enough to yard comfortably; the sheep were enclosed by hurdles; feeding-troughs were regularly arranged in the yard for the sheep; the Turnips thrown over the hurdles, and put in these troughs by boys, and the sheep stood up to these troughs in ranks on both sides. As fast as the Turnips were consumed from the ground, the hurdles and troughs were moved forward, the latter being moved about 6 feet each time, so that ultimately the whole ground was trodden by the sheep, and covered with their dropping. In addition to the Turnips, the fattening sheep are fed from half a pound to a pound of oilcake daily.

One hundred and fifty bullocks were fattening for the butcher, and 250 are intended on the farm every year. They are all Shorthorns, mostly 3-years-olds, but a few are 4-year-olds. They are bought at the markets, and are intended to be fattened in the shortest time possible. A judicious selection of these cattle, so as to get those which will make the most growth for the time and feed consumed, is the first element for success in this business. They are bought at prices varying from £20 to £30, and sold at from £28 to £35, and some very fine ones he had were engaged at £48. The average increase in value while fattening is about £10 each. These bullocks are all kept in yards or boxes, and never have to graze. The yards have four sets of sheds there are boxes for 30 or 40 cattle, and these are occupied by the fattest animals; and the remaining ones are kept in the yards waiting their turns to enter those little boxes, from which they are never turned out till ready for the butcher. The boxes have a trough in front, and the cattle stand in a passage-way between the rows by which the feed is carried in. They may be 10 feet square; the trough is along the side next the passage, and has parts in it for holding water, Turnips, cake, meal, and cut straw. The boxes are not cleaned out from day to day, but are kept littered by throwing in fresh straw; and as they fill up, the feeding-troughs have to be raised. The manure accumulates in the boxes until they contain 8 or 9 tons each. The daily feed averages 2 bushels of roots, from 12 to 14 lb. of oilcake, and as much cut straw as these cattle will eat. He cut 300 tons of oilcake last year to his cattle and sheep.

The work on the farm requires 28 or 30 horses. The number of hands employed is variable; labourers' wages, at the time I was there in November, were 10s. a week, and the average through the year is about 15s. a week. Much of the harvesting is done by contract, a gang of hands taking the whole work to do at a fixed price. In the dry weather of last year it was very favourable to the workmen, and for the 17 days it lasted they earned between 7s. and 8s. a day. The expense for labour on the farm is usually said to be equal to the rent, which may be 35s. to 40s. an acre. The amount paid out for labour on Mr. Leeds' farm is not far from £1800 a year. The amount paid out for fertilisers I could not learn.

A visit to such a farm was of the highest interest to me, and the skill, the energy, and the success with which all the operations of the farm were carried on, made it both instructive and encouraging. With such examples before us, we cannot but feel that farming is worthy the attention of the ablest men. *Geo. H. Cook.*

The Week's Work.

NOVEMBER 11.—*Thorough Drainage* execute on all wet lands requiring it, placing the drains sufficiently near each other, and the pipes of a proper size, to remove the heaviest shower of rain as fast as it falls. Much clay land is only half drained, from the drains being placed too far asunder. Thus, when placed 24 and 36 feet apart, it will often pay to put an additional drain between every two, and when 36 feet apart we have found that two drains with pipes, the distance being then 12 feet apart. At this season the pipes or stones should be put in, and covered close up to the digging, so as to obviate falling in of the sides from the weather.

Subsoiling is subsidiary to drainage, whether the land is drained naturally or artificially, and therefore all lands ploughed this month should also be subsoiled, if the bottom requires loosening, as all subsoils occasionally do. Thus, the soleing of the plough, and the treading of the horses in the bottom of the furrow, together with the action of the roots of plants, produce "bottom-bound," "heath-pan," or "moorband," which covers a much larger area of the country than is generally imagined; and now that ploughing and subsoiling can be done at one operation by steam or double-furrow horse-ploughs, the work should be done at this season. Retentive limestone and gravelly soils require subsoiling as well as ferruginous, sandy, and gravelly soils, on which a hard pan of moorband often exists several inches deep, through which the roots of plants cannot penetrate. And, besides being improvious, it is generally poisonous also, so that in subsoiling it should be broken as fine as possible, and left below until either changed by oxidation, or else washed out by the rains. It has justly been said that to double the depth of the staple by subsoiling and after deep cultivation is equivalent to doubling the area of the land subsoiled; *i. e.*, the roots of plants have twice the area of land in which to obtain plant-food.

Straightening Watercourses, if not already done in cases where the new cuts could not be opened in the summer time when the crops were on the land, should now be finished without delay. Where there is much cutting in filled ground, and in marshy, the work may be delayed until frosty weather. A drainpipe should be placed in the bottom of the old cut before it is filled and levelled.

Live Fences finish plashing and switching, grub up crooked and superfluous ones, and plant new where required, so as to lay out the land in the most profitable manner for steam culture. Where there is a command of stone from quarries near at hand, walls built with lime mortar make the best fences, and they are cheaper in the end than either dry stone dykes or live fences, as they occupy less ground, last longer, afford better and healthier shelter for live stock, and are free from the objection of nursing weeds and harbouring vermin of various kinds.

Land-fast Stones, and other obstructions to steam culture and subsoiling, remove. A great many stones in the subsoil that cannot be brought to the surface by horse-teams, can be loosened by steam; others require very little manual labour to enable steam to bring them to the surface. There are, however, large stones that require to be blasted with blasting powder, and rock cropping out to the surface that requires to be quarried and removed before steam can be started. Few improvements pay better than the removal of large stones and the deepening of shallow rocky ground, such soils being naturally grateful for all they receive.

Trenching, with pick and spade, when the land is very full of large stones or rock, is generally to be preferred, and often absolutely necessary, both in reclaiming new lands and in deepening old. If the land requires to be drained, the stones may be broken and used in filling the drains; and the several works of draining, trenching, removing the stones, and filling the drains, may proceed together. Thus open and fill two or three drains—let the draining proceed,—start a "gang" or company of hands to trench each space between the drains, the one gang keeping in advance of the other; start a third set of hands to gather the stones into heaps, and boys made for the purpose, to carry them across the untrenched land to the drains. Let a fourth company break the stones and fill in the drains. In this way we have drained and trenched large areas of old and new land by contract, at about £10 per acre. Any quantity of stones may be consumed in the drains, but when the stones from the land do not fill them, either tiles must be used, or a supply of stones got from somewhere else to fill up deficiencies. In each case the increase of produce redeemed the expenses within two rotations. In two cases the first crop paid off the whole, with a large margin over.

Surface Drainage attend to everywhere, so as to prevent pools of stagnant water after heavy rains, on farm roads, grass lands, and in water furrows. Thorough underdrainage should render open water furrows unnecessary, but such thorough drainage is more frequently the exception than the rule, and therefore open water

furrows, in which water flows, should be gone along after every heavy storm, and any clod that has fallen in, or silting up that has taken place, should be removed, the clods and silt being spread thinly over the land. Where land is being ploughed that requires cross water furrows they should be opened with the spade daily as the work advances, so as effectually to remove any rainwater overnight, or what may fall during the day. The ditches should also be gone over, and the mouths of the main drains, so as to detect in time any stoppage that may have taken place. As a general rule, half the expense will keep things right that is required to put them to rights when once they are allowed to go wrong, and it must be borne in mind that that latter expense is but a fraction of the loss sustained.

Notices to Correspondents.

BOOKS: *W. Carr.* "Stephens' Book of the Farm," "Morton's Cyclopædia of Agriculture,"—published, the one by Blackwood, the other by Blackie, Paternoster Row,—are £3 2*s.* and £3 3*s.* books. The "Farmers' Calendar" (Warne & Co., Bedford Street, Covent Garden), price 15*s.*, will, perhaps, be as good a book to begin with as any. It should be read and studied, month by month, upon a farm.

BRUISED GORSE: *Mr. E. H. Palmer* writes:—At p. 1440 of your paper, under the heading of "The Week's Work," is a recommendation of bruised Gorse as an article of food for cows in the winter time. As I have a tract in a county where Gorse is plentiful I should like to act upon the advice, and shall feel obliged if you can tell me in your next paper what is the implement or machine that I ought to have for the purpose of bruising the Gorse. Messrs. Barrett, Exall & Andrews used to manufacture a Gorse crushing machine. Probably their successors, the Reading Company, can supply one.]

MANURE PIT: *R. R. P.* asks our correspondent, Mr. Forsyth, to give our readers a more detailed account of the mode of construction of the manure pit made for "Mr. Fraser."

ERRATUM.—In p. 1432, col. *b*, line 17, for "never," read "have."

Markets.

ENGLISH WOOL.

The market keeps good, more especially for the choicer grades, and prices are bardening; and when manufacturers have worked out their present stocks—which, at the actual rate of consumption, will not take long to do—we may anticipate a very good demand and a still higher range of prices.

MARK LANE.

MONDAY, Nov. 6.

There was a moderate supply of English Wheat to this morning's market, the condition of which was mostly inferior, and for sale sales it was necessary to accept rather less money. The attendance was good, and for foreign Wheat, particularly Russian, there was a fair consumptive demand at last week's prices. Barley, Beans, and Peas were unchanged in value. The Oat trade was steady at late rates. Flour as last quoted.

WEDNESDAY, Nov. 8.

An increased amount of dulness was apparent here today. The supply of English Wheat was short; but it was much in excess of requirements. Foreign Wheat was in large supply. The demand was inactive, and prices generally were easier. Barley changed hands quietly on former terms. The malt trade was dull, at drooping prices. There were good supplies of Oats on offer. Trade was slow, at about late rates. Beans and Pears were purchased cautiously, at previous quotations. Flour was depressed, prices ruling in favour of buyers.

LIVERPOOL, Nov. 7.—There was a fair attendance of millers, but they bought Wheat only on a limited scale, and prices were 2*d.* per cental lower than on Tuesday last. Flour was quiet, at a reduction of 6*d.* per barrel and 1*s.* per sack. Beans 6*d.* per qr. lower. Oats are rather in sellers' favour, and Oatmeal realised fully previous rates. Indian Corn dull of sale, at the rates of this day week.

METROPOLITAN CATTLE MARKET.

MONDAY, Nov. 6.

We have a considerable increase in the number of Beasts, but the average quality is very middling. Choice qualities being scarce are readily disposed of, at fully late rates; trade is slow for other descriptions, at lower prices. There are a few more Sheep than last Monday; the demand is, however, good, and that day's quotations are pretty well maintained. Choice Calves are still scarce and dear. During the supply consists of 3550 Beasts, 14,170 Sheep, and 362 Calves; from Ireland, there are 800 Beasts; and 1530 from the Midland and Home Counties.

Pigs	3	4—5	0	

Beasts, 3880; Sheep and Lambs, 22,190; Calves, 382; Pigs, 155.

THURSDAY, Nov. 9.

The supply of Beasts is shorter than last week, quite sufficient, however, for the demand. Choice qualities are scarce, and Monday's quotations are maintained. The number of Sheep is small, but buyers are by no means numerous. A clearance can scarcely be effected; there is no alteration in prices. Choice Calves continue to be scarce and dear. During supply consists of 3320 Beasts, 3270 Sheep, and 123 Calves.

JOSHUA BAKER.

SEED MARKET.

We have an increase of animation in our markets. Red Clover is in brisker demand, and has advanced during the week 2*s.* to 3*s.* per cwt. Higher quotations are reported by cable from New York, and German advices speak also of enhanced currencies. White Clover is now receiving more attention, and must be noted 3*s.* to 4*s.* per cwt. higher. Trefoil is exceedingly firm. For French Italian there is a strong demand, at the recent advance. Perennial Rye-grasses are steady. Winter Tares have now reached so low a limit, that they are being bought up for speculation. New Dutch Hemp has come to market, at a moderate figure. Canary seed is without alteration. Blue Peas are in good request. For feeding Linseed there is a fair trade. Rape and Mustard seed are firm.

CONTENTS :—

MR. LAXTON'S NEW PEAS FOR 1872.

MESSRS. HURST & SON,

HAVING BEEN ENTRUSTED WITH THE DISTRIBUTION OF

THE FOLLOWING DISTINCT NOVELTIES IN GARDEN PEAS,

THE LATEST PRODUCTIONS OF MR. LAXTON, WILL, THIS SEASON, BE PREPARED TO SUPPLY A LIMITED QUANTITY OF EACH IN SMALL PACKETS, FOR TRIAL ONLY.

SUPERLATIVE
Average Size.
(From a Photograph.)

WILLIAM THE FIRST.

The finest Pea yet sent out for earliness, flavour, and appearance combined. It is a first early variety, with long and well-filled deep greenish pods; ripe seed parti-coloured, like "Ne Plus Ultra." It has been thoroughly tested and recommended at the Royal Horticultural Society's Gardens at Chiswick on several occasions, and was the only Pea exhibited in Mr. Gilbert's first prize "Gardener's" collection of Vegetables at the Society's Exhibition at Nottingham in July last. Height 3 feet.—For further description see "Hogg's Gardeners' Year Book for 1871," page 73.

GRIFFIN.

A remarkable and distinct variety, as early as "Sangster's No. 1," of a fine colour and flavour when cooked; the ripe seed is also of a bright grass-green colour, and well calculated to supply "Green Peas all the year round." Pods medium-sized: height about 2 feet 6 inches.

POPULAR.

For general crop this Blue Wrinkled Marrow will be found earlier, more prolific, and to have better filled pods than those of "Champion of England," to which variety it is quite equal in flavour, and against which it should be tried. Height above 4 feet

SUPERLATIVE.

The largest and finest podded variety yet raised: indispensable as an Exhibition Pea. The pods, which have been exhibited 7 inches in length, are more than twice the size of those of the parent Pea, "Laxton's Supreme," which during the last three seasons has taken nearly every first prize when shown in competition. It is also quite as early as that variety, and very prolific. As "Superlative" sometimes runs 7 or 8 feet in height, it should be slightly pinched in when the growth is about 5 feet. The colour and flavour of the Peas, when cooked, are excellent.

OMEGA.

This dwarfish late Pea was raised by fertilising "Ne Plus Ultra" with "Veitch's Perfection," and has all the valuable characteristics of the former variety. It is remarkably prolific, the pods are very fine and closely filled, and the flavour and colour of the Peas, when cooked, unequalled. Ripe seed like "Ne Plus Ultra." Height 2 feet 6 inches.

These Peas can be confidently recommended by Mr. LAXTON as decided acquisitions, having been thoroughly tested by him for several years, and selected at great expense from hundreds of cross-fertilised varieties, the majority of which, although far in advance of older sorts in cultivation, have been discarded and suppressed.

They will be sent out in sealed Packets only, at £1 1s. the Collection,

AND MAY BE OBTAINED RETAIL OF THE PRINCIPAL SEEDSMEN IN LONDON AND THE PROVINCES.

For the Orchard:—Pyramid, Dwarf Maiden, Cutback, and Trained Fruit Trees. For the Garden:—Embracing all the finest and popular varieties of Apple, Pear, Plum, Cherry, Peach, Nectarine, Apricot, &c.

Miscellaneous Fruits.

Almonds, Chestnuts, Walnuts, Figs, Cobnuts, Currants, Gooseberries, Strawberries, Medlars, &c.

Standard and Dwarf Roses,

Of all the best new and old varieties of Perpetuals, Moss, Hybrid Perpetual, Bourbon, Noisette, China, Tea, Climbing Roses, &c.

Climbing and Trailing Shrubs

(Including the Clematis).—Well adapted for covering Verandahs, Pillars, Festoons, Walls, Porticos, Trelliswork, &c.

Forest Trees (for Covert and Coppice Planting)—All carefully transplanted, free grown, and good rooted.

American Plants,

Including the Andromeda, Azalea, Erica, Kalmia, and Menziesia; also Rhododendrons of the best scarlets, whites, and other choice varieties, &c.

Hardy and Rare Coniferæ

(For Lawn and Pleasure Grounds)—which embrace most of the fine hardy species and varieties in cultivation.

Ornamental Deciduous Trees

(For Park and General Planting)—including Trees with either remarkable growth or foliage, such as weeping, cut-leaved, or purple, variegated, &c.

Evergreen Trees and Shrubs

(Suitable for Clumps, Belts, Screens, &c.)—containing a choice collection of all shades of foliage.

N.B.—G. J. & SON, knowing that Nursery credited accounts are generally very long, compared with many other businesses, have, after due consideration, decided to offer advantageous cash terms (see cover of Catalogue). This old-established Firm being large Wholesale Growers, the Public (favouring them with orders) will also derive the benefit of obtaining their goods direct from the producers.

WOKING NURSERY, SURREY.

New English Rose (Hybrid Perpetual Climbing),
PRINCESS LOUISE VICTORIA.

WM. KNIGHT, Floral Nursery, Hailsham, the raiser of this ROSE, will send it out this month (in strict rotation), in good plants, at 7s. 6d. each, three for 21s. Has been awarded Three First-class Certificates. See Report of Floral Committee in *Gardeners' Chronicle*, September 30, 1871.
Coloured Drawing, post free, for 12 stamps.
Descriptive Priced CATALOGUES free on application.

Notice.

H. LANE AND SON'S Descriptive CATALOGUE of ROSES, FRUIT TREES, VINES, CONIFERS, DECIDUOUS and EVERGREEN TREES and SHRUBS, RHODODENDRONS, AZALEAS (Indian), CAMELLIAS, &c., may now be had free on application. The prices will be found moderate, combined with quality. An inspection of the growing stock is earnestly solicited.
The Nurseries, Great Berkhamsted, Herts.

New Tea-scented, Noisette and other Roses.

JOHN WATERER AND SONS are offering strong plants, in pots, at 12s. per dozen, comprising the following sorts:—MARECHAL NIEL, CLIMBING DEVONIENSIS, BELLE LYONNAISE, Chamois, Jeanne d'Arc, Le Mont Blanc, Madame Ducher, Madame Levet, Tour Bertrand, Lamarque a fleurs Jaunes, Reve d'Or, Isabella Sprunt.

CLEMATIS JACKMANII, | CLEMATIS RUBRA VIOLACEA, CLEMATIS STANDISHII, and others, 12s. per dozen, very strong stuff. Trade price on application.
American Nurseries, Bagshot, Surrey.

TEA-SCENTED ROSES, in pots.—The largest stock of Tea-scented Roses in the Kingdom. They may be had in small pots, also established in 6-inch pots, for forcing and greenhouse culture.
WM. WOOD AND SON, The Nurseries, Maresfield, near Uckfield, Sussex.

Pelargoniums for the Million.

JAMES HOLDEN'S unrivalled COLLECTION of FRENCH, FANCY and SHOW VARIETIES are now ready, in strong Plants. CATALOGUES gratis on application.
HUNT'S superb SWEET WILLIAM, in 24 varieties, seed or plants, as per former Advertisement.
Crown Nursery, Reading.

Geraniums to Offer.

CHOICE GOLD and SILVER TRICOLORS, 18 new and distinct sorts, including PRINCE of WALES (Carter's), and LASS O'GOWRIE, for 30s.
12 NEW and CHOICE GOLD and BRONZE for 15s.
12 NEW DOUBLES for 6s.
12 NEW ZONALS of 1871 for 12s. All package free.
A List of Names of each Collection sent on application to
WM. POTTS, Seedsman and Florist, Swanley Nurseries, Staplehurst, Kent.

Lilies of the Valley.

E. H. KRELAGE AND SON, NURSERYMEN, SEEDSMEN, and FLORISTS, Haarlem, Holland, have yet to offer a few thousand extra fine and strong 3-yr. old CONVALLARIA CLUMPS. Price on application. As now is the best season for sending them out, early orders are solicited.

JEAN VERSCHAFFELT'S New Descriptive CATALOGUE for 1872-73, containing, besides a great number of New and Rare Plants, is just issued, and can be obtained gratis on application, either to himself or to his Agents, Messrs. R. SILLEM AND SON, 8, Bury Lane, Upper Thames Street, London, E.C. All orders should be sent direct to
JEAN VERSCHAFFELT, 134, Faubourg de Bruxelles, Ghent, Belgium.

JOHN WATERER AND SONS, Bagshot, Surrey, are the EXHIBITORS of RHODODENDRONS at the ROYAL BOTANIC GARDENS, Regent's Park. Their Descriptive CATALOGUE of these Plants is now ready, and may be had on application, by letter, addressed to Bagshot.
☞ The Catalogue fully describes colours, prices, &c., of the Rhododendrons.

Novelties of the Season.

SWEET-SCENTED RHODODENDRONS and AZALEAS, raised by ISAAC DAVIES, and awarded First-class Certificates of Merit at the Spring Flower Shows of Manchester and Liverpool. A descriptive priced LIST forwarded to any address on application to
ISAAC DAVIES, Nurseryman, Ormskirk.

Chrysanthemums, both New and Old.

H. CANNELL begs to inform his friends and Customers that he has now the largest lot of STOCK PLANTS in 60's perhaps ever seen, consisting of 300 of all the most popular varieties, and about three dozen of each kind are continually kept on hand. Every kind is planted out and bloomed every season, on purpose to keep the whole collection genuine, so that they are now in fine condition, and all admirers of this family are invited. For price of Plants, Rooted Cuttings, and Cuttings, see H. C.'s FLORAL GUIDE, which also contains a great deal of valuable information, including how to grow them to the highest perfection for decoration. Sent free for four stamps.
New Florist Flower and Florist Flower-Seed Merchant, Woolwich.

Chrysanthemums.

ADAM FORSYTH begs to offer several thousand, large flowering and POMPONS, in 48's, well set with flowerbuds, suitable for either Conservatory or outdoor decoration; 6s. and 8s. per dozen.
A. F.'s general Collection, which is the largest in England, will be IN FLOWER throughout the months of NOVEMBER and DECEMBER, when a VISIT is respectfully solicited.
Brunswick Nursery, Stoke Newington, N.

Liliums.

STEPHEN BROWN offers the following rare and beautiful sorts :—

	Each.—*s. d.*		Each.—*s. d.*
Auratum Beauty ..	21 0	Leichtlinii	10 6
„ picta ..	15 0	Tenuifolium	5s. to 7 6
Brownii ..	7 6	Tigrinum splendens ..	7 6
Lancifolium "atrorubens (cruentum), true,	2s. 6d. to 5 0	Vestalis	3 6

Choice selections, from 75 superb varieties, 5s., 9s., 12s., 18s., and 24s. per dozen.

GLADIOLI.

An extensive collection of the finest choice selections, 3s., 5s., 9s., 12s., 20s., and 30s. per dozen.
Also superb new varieties of 1870. See CATALOGUE.
The BULB CATALOGUE, Illustrated, Cultural, and Descriptive, free for six stamps, gratis to customers.
Seed, Bulb, and Plant Establishment, 4 Weston-super-Mare.

Orchids.

JAMES BROOKE AND CO., Nurseries, Fairfield, near Manchester.—Our recent importations of choice ORCHIDS, especially of the best winter flowering kinds, have been extensive, and the plants being all in excellent condition, we are enabled to offer them on terms unusually advantageous. We make reductions to a fixed value, say £10 to £50, as desired, and the choice is left to ourselves, the purchaser pays less than the catalogue prices, and is no loser in regard to merit and variety. The plants we have sent out in execution of such orders have, we are informed, given unmixed satisfaction. The following list, with prices annexed, will be some guide to intending purchasers :—

Dendrobium Falconeri, 21s. to 63s. each; D. Wardianum, 63s. to 105s.; D. chrysotis, 21s. to 63s.; D. McCarthiæ, 42s. to 84s.; D. heterocarpum, 5s. to 21s. D. moniliforme, 2s. 6d. to 21s.; D. transparens, 5s. to 21s.; D. Devonianum, 7s. 6d. to 21s.; D. nobile, 5s. to 105s.; Cœlogyne cristata grande, 5s. 6d. to 21s.; C. Dayana, 7s. 6d. to 10s. 6d.; O. citrosmum, 7s. 6d. to 10s. 6d.; O. luteo-purpurum, 25s.; O. gloriosum, 25s.; O. Alexandræ (Blumii), 21s. to 63s.; O. Pescatorei, 42s.; O. Rossi superbum, 21s. to 31s. 6d.; O. crocidipterum, 42s.; O. pistoides, 31s. 6d.; O. ramulosum, 31s. 6d.; O. Bictonense, Pleione Wallichii, 3s. 6d. each, 30s. per dozen; P. lagenaria, 5s. to 10s. 6d.; Cypripedium hirsutissimum, 7s. 6d. to 21s.; Cattleya Mossiæ, 7s. 6d. to 21s.; C. maxima, 31s. 6d.; C. Trianæ, 15s.; C. Warneri, 21s.; Barkeria Skinneri, 10s. 6d. to 63s.; B. speciabilis, 10s. 6d. to 63s.; Calanthe vestita, 5s. 6d. to 21s.; C. Veitchii, 10s. 6d. to 42s.; Cœlogyne cristata, 10s. 6d. to 63s.; Oncidium Papilio, 7s. 6d. to 10s. 6d.; O. Krameri, 21s.; O. Lanceanum, fine variety, 25s.

New Catalogue of Bulbs, Plants, Fruits, &c.

ROBERT PARKER begs to announce that his NEW CATALOGUE, containing Select Descriptive and Priced Lists of Dutch and other Bulbs, Plants suitable for Bedding and Decorative Purposes, Fruit Trees, Grape Vines, Sweet Violets, &c., is now published, and will be forwarded to applicants.
Exotic Nursery, Tooting, Surrey, S.W.

Dutch Flower Roots.

G. M. KEMP-WELCH'S CATALOGUE of the above is just published, and will be sent free by post on application. The Bulbs are of the finest quality, and moderate in price. Early orders will oblige. The Catalogue is of a convenient size for the pocket.
Seedsman and Florist, Cotham, Bristol.

CARTER'S "SUBURBAN" COLLECTION of choice FLOWER ROOTS for the Conservatory, Greenhouse, or Decoration of the Drawing-room and Garden contains—

12	HYACINTHS, choice named	
12	„ mixed, bedding	
6	NARCISSUS—Poeticus	
6	„ Double Roman	
6	„ Fager White	
36	„ van Sion

WHEELERS' BROCKWORTH PARK PEAR.

J. C. WHEELER AND SON Gloster

"The handsomest and most valuable dessert Pear of recent years."

J. C. WHEELER AND SON offer fine young PYRAMIDS of this magnificent PEAR, at 10s. 6d. each, and a few DWARF-TRAINED TREES, at 15s. each. It obtained a First-class Certificate from the Fruit Committee of the Royal Horticultural Society, on September 20, 1870, and was exhibited at the Royal Horticultural Gardens on October 4, 1871, when it was again greatly admired. It is large, handsome, and fine flavoured, and is, without doubt, a great acquisition to our choicest and best dessert Pears. It may fairly be described (when grown against a wall, with a good aspect) as one of the handsomest, largest, and best dessert Pears ever introduced. It ripens the end of September and beginning of October.

J. C. WHEELER & SON have already received orders for it from nearly all parts of the United Kingdom; from Germany (for the Emperor's gardens at Sans Souci, Berlin); from France; and from the United States. Orders will be executed in rotation as received, the earliest getting the best plants.

J. C. WHEELER AND SON, Nurserymen,
Gloucester, and 59, Mark Lane, London.

The Fairy Apple.

JOHN JENNINGS has fine PYRAMIDAL TREES, with bloom-buds, of the above beautiful dessert Fruit to DISPOSE OF, at 5s. each. The fruit is in season from December to April.
"Destined and worthy to take its place amongst the worthiest of its kind." Nurseries, Shirston-on-Stour.

Cerasus Watereril, New Double Japanese Cherry.
ORIGINALLY INTRODUCED by MR. FORTUNE.

JOHN WATERER AND SONS are just now sending out the above new plant. The colour is white, edged with pink, very large double, and sweet scented. We recommend it as a very desirable plant. Price 10s. 6d. each, or 6 for 42s.
American Nurseries, Bagshot, Surrey.

The Gardeners' Chronicle

SATURDAY, NOVEMBER 18, 1871.

SO much has been done of late years in the search for and study of variegated plants, that it might be expected that we should now pretty well understand the phenomena and causes of VARIEGATION. Instead of this, however, we are still only at the threshold of a large subject, and new cases are every now and then observed which show us that no one explanation will answer for all the kinds of variegation, and that in all probability more than one principle is concerned in producing them. Thus, in the first place some plants whose normal condition is to be variegated, and in which the absence of variegation would be a deviation from their natural state, as, for example, such plants as Bertolonia margaritifera, where the leaf is sprinkled with well-defined pure white spots. There are others where, although the variegation is due to a natural sport, it is constant, as in the Golden Yew and Holly; others where, although generally present, it varies in quantity in every different plant, as in the Aucubas and Crotons. In others, again, it is manifestly a symptom of weakness of constitution, disappearing when the plant by treatment becomes strong and healthy. There is yet another kind where, like BOB ACRES' valour, the variegation comes and goes, and as suddenly, so with us, the advice of no horticultural Sir LUCIUS can enable us to call it fast when we have it. We had the opportunity lately of seeing two remarkable instances of this, both producing a nearly absolutely white variegation, which in both is temporary and periodical, but each differing from the other so essentially in their particulars that it seems impossible to refer them to the same cause; at all events, if due to the same physiological principle, there must be some important difference in the exciting cause which sets it in operation, or in the constitution of the different trees in which it appears.

The first case was that of an Abies Douglasii, which we saw at Castle Kennedy, one of the seats of the Earl of STAIR. It was almost white from head to foot. In the early part of the season we were told it was absolutely so; so much so that at a distance it might be mistaken for a white sheet, or a white Hawthorn in luxuriant bloom. Mr. FOWLER, the gardener at Castle Kennedy (whom, by the way, we cannot mention without paying a passing tribute of admiration to the rare ability he has displayed in all matters connected with his profession, and with much outside of it), informed us that he picked it out from a group of seedlings some years since; it is now a well-grown plant, about 8 feet high, and constantly exhibits the same phenomena, as do also a number of other plants raised from it by grafts or cuttings. When it first puts out its leaves they are perfectly white, and they continue so until the end of August, by which time a shade of green begins to spread over them; it first appears at the base of the older leaves, gradually creeps up towards the tip, doing the same successively with all the leaves until by the end of September the variegation is wholly, or almost wholly gone. In this case there is obviously at first a want of chlorophyll in the leaves, which is gradually supplied as the plant is strengthened by the summer's growth; there is, however, nothing the matter with the tree itself—it is strong and healthy as any Douglas Fir around it, and so are the young plants raised from it. It is not as if the tree was originally weak, and on acquiring strength threw off the pallor of ill health; the same thing is repeated year after year with the unvarying regularity of a normal action inherent in the plant.

The other case to which we refer was very much the converse of this. It occurs in an Oak of about 20 feet high, growing in the policy of Munches, or the stewartry of Kirkcudbright, the property of Mr. WELLWOOD MAXWELL, the member for the stewartry—a place which, besides the most lovely scenery, contains many things most interesting to an arboricultural sense, of which we may at some future time take occasion to notice. This tree shows nothing peculiar until the end of August, when, in many places, it throws out young shoots of the purest white. We cannot say that it has the beauty of the white Douglas Fir at Castle Kennedy, the white only appearing here and there, giving the tree a speckled or piebald appearance, but the question is not of their respective beauty; it is why does the one show its periodical variegation or pallor early in the spring, and the other in the autumn? For ourselves, we take no shame to say that we do not know, but perhaps some of our readers may; and we shall be glad to receive instruction from any of those who do.

THE PROVINCIAL SHOW of the ROYAL HORTICULTURAL SOCIETY is, we hear, to be held next year in Birmingham. The Lower Grounds at Aston have, on due consideration, been selected by the Council as the site of the exhibition, and from the descriptions of these grounds which have from time to time appeared in our columns, it will be evident that the locality has been well chosen. Birmingham is a most important centre, from a horticultural as well as a commercial point of view, and there is every reason to believe that if judicious arrangements are made, and properly carried out, the result will be a satisfactory one. Our local contemporary, the *Midland Counties Herald*, states that—

"Already many influential residents of the town and neighbourhood have expressed their willingness to become members of the local committee which will be formed; and those who are interested in horticulture, and may be willing to join this committee, are invited to send in their names forthwith to the secretary *pro tem.*, Mr. ALEXANDER FORREST, Cherry Street. It is very desirable that the local committee should consist of gentlemen representing not only the town of Birmingham, but Warwickshire and the adjoining counties, and we have no doubt this will be the case. In fact, the forthcoming visit of our National Horticultural Society should be considered in the light of a visit to the Midland Counties. So soon as the preliminaries are in a sufficiently forward state, a public meeting will be held for the purpose of appointing the committee and officers, and arranging for the creation of a fund for the purpose of offering extra prizes, &c. At Manchester, Oxford, Nottingham, and elsewhere, these country shows, under the auspices of the Royal Horticultural Society, have given a great stimulus to horticultural pursuits in those localities. Last year the show at Nottingham was the most interesting yet held by the Society, and we see no reason why the one to be held at Birmingham should not be equally satisfactory."

We understand that a most influential committee has, in fact, already been got together; and we now merely add to this announcement, that we trust neither the Council of the Society nor the Local Committee will omit to make such arrangements as may secure the complete sociality of this meeting—a point which has hitherto been too much left to mere chance, and hence has not been satisfactorily attained to. The programme should include, besides the show proper, a well-ordered congress meeting, by whatever name it may be called, a gardeners' dinner without the cold shoulder, and an assembly room where all lovers of horticulture, who may be attracted to the show, may have the opportunity of meeting their horticultural friends. So far as we can help to forward any of these arrangements we shall be pleased to do so, in the general interests of horticulture and horticulturists.

— The following quotation from that useful little volume, "How Crops Grow" (MACMILLAN), may serve to some extent as an answer to the inquiry made by one of our correspondents as to the proper DEPTH at which to SOW SEEDS :—

"While it is the almost universal result of experience in temperate regions that agricultural seeds germinate most surely when sown at a depth not exceeding 1—3 inches, there are circumstances under which a widely different practice is admissible, or even essential. In the light and porous soil of the gardens of New Haven [U.S.], Peas may be sown 6—8 inches deep without detriment, and are thereby better secured from the ravages of the domestic pigeon. The Moqui Indians, dwelling upon the table lands of the higher Colorado, deposit the seeds of Maize at a depth of 14 inches below the surface. Thus sown, the plant thrives, while, if treated according to the plan usual in the United States and Europe, it might never appear above ground. The reasons for such a procedure are the following :—

"The country is without rain and almost without dew. In summer the sandy soil is continously parched by the sun at a temperature often exceeding 100° in the shade. It is only at the depth of a foot or more that the seed finds the moisture needful for its growth, moisture furnished by the melting of the winter's snow.

"R. HOFFMANN, experimenting in a light loamy sand upon 24 kinds of agricultural and market garden seeds, found that all perished when buried 12 inches. When planted 10 inches deep, Peas, Vetches, Beans, and Maize alone came up. At 7 inches there appeared, beside the above, Wheat, Millet, Oats, Barley, and Colza; at 6 inches those already mentioned, together with winter Colza, Buckwheat, and Sugar-Beets; at 4 inches in depth Flaxe and Lucerne; at 3 inches Chervil, Flax, Horseradish, Hemp, and Turnips; finally, at 3 inches Lucerne also appeared. HOFFMANN states that the deep planted seeds generally sprouted most quickly, and all differences in density disappeared before the plant blossomed. On the other hand, GROUVEN, in trials with Sugar-Beet seed, made most probably in a well manured and rather heavy soil, found that seed at a depth of 1—1½ inch gave the earliest and strongest plants; seeds deposited at a depth of 2½ inches required five days longer to come up than those planted at ½ inch. It was further shown that seeds sown shallow in a fine wet clay required four to five days longer to come up than those placed at the same depth in the ordinary soil."

— We reprint the following passage from the recently delivered address of Mr. HUTCHISON to the Scottish Arboricultural Society, on the occasion of their annual meeting (see p. 1457). Though we quite believe in the periodicity of the sap-flow in trees, even in winter, we demur to the conclusion that this is directly regulated by lunar influence. In any case the subject is one for inquiry, and we commend it to the notice of our readers :—

"Having observed in pruning trees during the winter and early spring months that at one time the surface of the wounds more readily bleeds limbs under the knife and more moist than at others, and that this phenomenon varied during winter from time to time, there being apparently frequently less exudation of sap, or bleeding, the one week than there had been during the previous one, or even during the previous month, I am led to advance the theory that there is a periodicity in the circulation of sap in trees, both coniferous and hard wood, and perhaps in vegetation, during those months when we are accustomed to look upon Nature as dormant, and her ordinary functions as suspended, and that this periodicity is caused more or less by lunar influence. For example, I observed that for about four or five days from the third day after new moon the action of the sap seems to be disturbed, and the circulation more free and abundant than during the intervening days of the month. If this be so, and I think I am justified in asserting that it is, pruning operations performed during these few days, when the wood is greener, can be not only better done than when it is dry and less quickened, and is not only more easily performed, but more good work can be done in less time, and with equal safety to the tree."

— CURTIS gives a remarkable instance of the rapidity of the GROWTH of the COMMON CORN THISTLE (Carduus arvensis). He planted a portion of a root, about 2 inches in length, in his garden in April, and allowed it to remain till the following November. It was then taken up, and found to weigh 4 lb., and had thrown out several underground shoots, one of which was 8 feet long, as well as leafy shoots 5 feet high. Although to all appearance eradicated, fragments of the root-stock were left in the ground, as was shown by the appearance in the following spring of from 40 to 60 young plants.

— On the authority of the "Revue Horticole" we call attention to a DWARF PEACH, which its raiser, M. AUBINEL, of Grenade (Haute Garonne), France, says is reproduced with certainty from seed. It is a very ornamental bush, requiring no training. The fruit is a free-stone of an orange-yellow colour, melting and sugary, with an agreeable flavour. The parent plant is eight years old, and is between 3 and 4 feet in height, with a circumference of less than an inch and a half, so that it may be planted in the borders of the

kitchen garden like a Gooseberry bush (in France). M. Carrière has named this Peach the Dwarf Aubinel Peach.

—— Many of the statements which are demonstrated in the progress of science to be erroneous have, as a foundation, a substratum of fact. The popular notion that the Sunflower follows the Sun in its course has been often combated and contradicted, but, according to Mr. J. A. Allen, one species at least of the genus Helianthus has this peculiarity. He says:—"It is a popular belief that the Sunflower always turns its flowers towards the sun, but in reality, so numerous are the exceptions to this rule in our garden Sunflowers and in our common [American] wild species of the East, that few observing people regard it, doubtless, as otherwise than an idle whim. With many of the prairie Sunflowers, however, the facts are different; especially is this so in the case of H. rigidus. Morning after morning, at flowering time, the heads of this species may be seen bending gently towards the east; they are erect at mid-day, and at evening gracefully droop towards the west. This continues day after day for weeks, with surprising regularity and uniformity; later, however, the stems grow rigid, and remain nearly vertical. In this case at least the popular notion referred to above seems well founded."

—— We are glad to learn that a new part of the Rev. R. T. Lowe's Flora of Madeira is in the hands of the printer. It will contain the orders Ericaceæ to Labiatæ.

—— The Tussock Sedge of American Bogs is Carex stricta, which occupies a position similar to that of C. paniculata in England. Dr. Darlington says that it is the most common and the most troublesome of all the species. It is true that a pedestrian, in crossing neglected boggy meadows, finds its dense tufts quite a convenience to step on; but this does not compensate for the annoyance which it causes in cultivated land. The tussocks formed by the matted fibrous roots of this species of Carex are often very large and very durable. "I once hauled a quantity of them into the barnyard, with a hope that they might decompose and make manure; but they effectually resisted decomposition, and were used about the yard for years, as large and almost as indestructible as so many hatter's blocks. The best way to dispose of them is to collect them, when cut out and dried, into a heap, and burn them; taking care, afterwards, by appropriate draining, to prevent the growth of others."

—— We have received from Mr. Lamb, gr. to G. T. Davie, Esq., Colwon Basset, Bingham, Notts, two examples of Abutilon Thompsoni, one from a shaded west aspect, and the other from a drier position fully exposed to the south-west. In both cases the shoots are vigorous, and the foliage beautifully marked and deep in colour, notwithstanding that they have now stood 8° of frost. "The object I have in sending them," writes our correspondent, "is to show the suitability of the plant as a decorative subject for shady nooks amongst evergreens, as well as for the flower garden." Mr. Lamb further states that his plants "were equally as effective at Christmas last as they are at the present time, though of course they succumbed to the extremely severe weather subsequently experienced."

—— For the Meetings of the Society for the Encouragement of Arts previous to Christmas, the following among other arrangements have been made:—

November 29.—"On Tramways and their Structure, Vehicles, Haulage, and Uses." By W. Bridges Adams, Esq.

December 6.—"On Sewage as a Fertiliser of Land, and Land as a Purifier of Sewage." By J. Bailey Denton, Esq.

December 13.—"Observations on the Esparto Plant." By Robert Johnston, Esq.

December 20.—"On the Study of Economic Botany, and its Claims Educationally and Commercially Considered." By James Collins, Esq.

—— The Maximum Temperatures of the Air for the week ending November 11 at the stations in England ranged from 55°.4 at Portsmouth to 47°.5 at Norwich, the mean being 49°.8, being 1°.7 above the mean of the stations in Scotland, where the extremes were 50° (at Glasgow and Perth), and 45°.5 (at Greenock). The Minimum Temperatures at the English stations ranged from 35° at Liverpool to 24°.2 at Eccles, the mean being 29°.5, being 2°.8 above that of the stations in Scotland. Mean Temperatures.—The highest mean temperatures recorded at the stations in England were 41°.2 at Liverpool, and 40°.9 at Portsmouth, and in Scotland 39°.8 at Perth. The mean value for the several stations in England was 39°.5, and for that in Scotland 39°.3. Rainfall.—Rain fell at every station except Portsmouth, the greatest quantity registered in England being 0.43 inch at Eccles, and in Scotland at Aberdeen 1.16 inch, the mean fall being 0.22 inch to 0.46 inch for the several stations of each country.

—— A case of some importance to owners of Land abutting on to a Public Way has lately been argued. The defendant in the cause had lately opened a gate from his land into the lane, and the plaintiff, as the owner of the soil, complained of this as an unlawful encroachment. The case was tried at the last Surrey Assizes before Baron Bramwell, and it was found that the plaintiff was the owner of the soil in the lane, and that the lane was a public highway. On this the learned Baron directed a verdict for the defendant, holding that any one whose land abuts on a highway has a right to open gates or doors into it at pleasure. Mr. J. Brown, Q.C., moved, on the part of the plaintiff, to set aside this verdict, arguing at some length that the public were limited in their right to use the lane, and could only go up and down from end to end, and that the defendant had no greater right than any one else. The Court, however, were from the first quite clear that this view could not be sustained, and that it involved a downright absurdity. Suppose, said the Lord Chief Justice, that I dropped in the lane from a balloon, or took my horse over it in hunting, should I be a trespasser? It was manifest, and, indeed, it was admitted, that this would be so according to the contention of the plaintiff; and surely, said the Lord Chief Justice, this would be contrary to common sense. Is a gentleman a trespasser who jumps over his park wall into the road? There was no trace here of any limitation of the ordinary right of the public on a highway, and that was to go over it in any direction, and to open gates into it for pleasure. This was too clear to be disputed. The rest of the Court concurred, and the application was refused.

—— A new and somewhat Novel Milestone,—a reminder to the wayfarer, says the *Builder*—has been recently erected on the road between Shipston and Stratford-on-Avon, near the new lodge leading to Eatington Park. The memorial is formed of a double cube of hard stone, forming the base of an ornamental cross, which surmounts the whole. The sides are panelled, and on the west and east bear the arms of the Bishop of Worcester and Shirley of Eatington. On the south is the following inscription:—

"6 Miles
To Shakespeare's town, whose name
Is known throughout the earth;
To Shipston 4, whose lesser fame
Boasts no such poet's birth."

On the northern face is:—

"Crux mea lux."
"After Darkness, Light;
From light hope flows,
And peace in Death,
In Christ a sure repose."
"Spes, 1871."

Round the base of the cross, which rises angular-wise from the weatherings of the pedestal, are similar sentiments in Latin. The whole has been designed, and the expense borne, by Mr. E. P. Shirley, of Eatington Park.

—— We learn from the *English Mechanic* that the plant called Condurango, referred to at p. 970, and the extract or decoction of which was said to effect such wonderful cures in cases of cancer, has been analysed by Dr. Antell, chemist to the Agricultural Bureau at Washington. The doctor finds the ratio of the wood to the bark to be as 50.28 to 49.72. The centesimal composition of the bark was as follows:—Moisture expelled at 212° Fahr., 8; ash matters or mineral salts, 12; vegetable substances, 80. The vegetable matters were separated, and found to be composed as follows:—

Fatty matters, soluble in ether and partly in strong alcohol	0.7
Yellow resin, soluble in alcohol	2.7
Gum and glucose from starch	0.5
Tannin, yellow and brown colouring matters (extractive)	12.6
Cellulose, lignin, &c.	63.5
	80.0

No crystalline alkaloid could be detected, and, according to the above results, the therapeutic position of the plant must be among the aromatic bitters. That it is a specific in cancer, requires proof. In this country the trials so far have been, as in the case of other so-called specifics, quite negative.

—— The wood of the Osage Orange, or Bois d'Arc (Maclura aurantiaca), is highly valued in Texas for carriage and waggon building. Changes of weather do not affect it, and wheels made of it have been in use for 10 or 15 years without needing repair, while other wheels in the same locality require to have the tires shrunk once a year. Vehicles built of this wood command higher prices by 25 per cent. than those of ordinary timber. The wood yields a beautiful orange dye, and it is proposed to attempt obtaining this from the sawdust, which is at present valueless. It is frequently kept dwarf, and used as a hedge plant, for which purpose its strong spines render it very suitable.

—— Professor Böttger prepares Cement of Diverse Colours and great hardness, by mixing various bases with soluble glass. Soluble soda glass of 33° is to be thoroughly stirred and mixed with fine chalk, and the colouring matter well incorporated. In the course of six or eight hours a hard cement will set, which is capable of a great variety of uses. Böttger recommends the following colouring matters:—(1) Well sifted sulphate of antimony gives a black mass, which, after calcining, can be polished with agate, and then possesses a fine metallic lustre; (2) fine iron dust, which gives a grey-black cement; (3) zinc dust, which makes a grey mass, exceedingly hard, which, on polishing, exhibits a brilliant metallic lustre of zinc, so that broken or defective zinc castings can be mended and restored by a cement that might be called a cold zinc casting; it adheres firmly to metal, stone, and wood; (4) carbonate of copper, which gives a bright green cement; (5) sesqui-oxide of chromium, which gives a dark green cement; (6) Thenard's blue, which gives a blue cement; (7) litharge, which gives a yellow; (8) cinnabar, a bright red; and (9) carmine, a violet-red cement. The soluble glass, with fine chalk alone, gives a white cement of great beauty and hardness. Sulphate of antimony and iron dust, in equal proportions, stirred in with soluble glass, afford an exceedingly firm, black cement; zinc dust and iron, in equal proportions, yield a hard, dark grey cement. As soluble glass can be kept on hand in liquid form, and the chalk and colouring matters are permanent and cheap, the coloured cements can be readily prepared when wanted, and the material can be kept in stock, ready for use, at little expense. Soluble glass is fast becoming a most important article of chemical production.

—— We hear that the late Chrysanthemum Show at Stratford was a very successful one, Mr. Douglas, gr. to F. Whitbourne, Esq., Loxford Hall, Ilford, exhibiting the finest specimen Pompons that have been seen for several years. Next week connoisseurs will be busy, as the flowers will be in fine order by that time, both in the Temple Gardens and at Mr. A. Forsyth's, Brunswick Nursery, Stoke Newington, both of which collections will be well worthy of a visit of inspection.

—— Many of the Anthemidæ, such as Chrysanthemums, Chamomiles, &c., possess in the sexual parts of the flower a Narcotic matter which has a great effect upon insects, and will even kill small ones. In Pyrethrum roseum and P. carneum, just within the disk, this matter is found in considerable quantity. In order to prepare the powder to advantage, only the centre of the flower must be used, which must be cut before the seed is fully formed. The Spaniards, to keep off gnats, burn the centres of the flowers of the Horse Daisy (Chrysanthemum Leucanthemum); and the powder of the Mayweed (Anthemis Cotula) has also been used for destroying insects. In some parts of Belgium this plant is fastened by the country people to branches where swarms of bees have settled (after they have been secured), to prevent them from leaving the hive. The Mohammedans and Tartars have long employed the powder of the Pyrethrums against all insects indiscriminately. To destroy flies, gnats, and bugs, they burn it on an iron plate, which they heat slowly, in order to produce more smoke.

New Garden Plants.

Masdevallia ignea, *n. sp.*

Aff. Masdevalliæ coccineæ: floris tubo incurvo: sepalo dorsali cucullato in caudam longam recurvam producto, lateral inter sinum sepalorum lateralium inflexo: sepalis lateralibus parte liberi semiovatis acutis obliquis: sepalis ligulatis acutis, supra basin inferiorem inflexo hastatis: labello a basi subcordato-ligulato antice dilatato crenulato: columnæ sodroclinio serrulato lobulato.

This is one of the smallest of its tribe. As far as I remember, from having seen it at Messrs. Veitch's and Van Branteghem's, the leaves are middle-sized, markedly cuneate, oblong, with three small teeth at the apex. The flower is very bright cinnabar-coloured, and may be easily recognised by the great peculiarity, observed immediately by Mess. Van Brantegham and Day, that the upper sepal is bent down between the sinus of the lateral sepals. It is, although not the most prominent, a very worthy member of its gay society. I obtained it from Messrs. Veitch, Van Brantegham, and Day. I have particularly to thank Mr. Day for the following information concerning the plant:—"It came from New Grenada in March, 1870, and was sold at Stevens'. The colour is now redder and more purplish than it was at first—it was then of a dazzling scarlet with orange-scarlet colour, too dazzling to look at long. The leaves are 7 inches long, the upper half expanded into a blade, oval in shape, 1¼ inch broad, tapering below into a slender chanelled footstalk; scape 11 inches long." *H. G. Rchb. fil.*

Bolbophyllum nasutum, *n. sp.*

Pseudobulbis approximatis subpyriformibus, fasciculis retusis vaginarum varie textis hinc maculatis; folio carnoso coriaceo lato basi conduplicato-petiolato; pedunculo brevi, bracteis minutis; pedunculo unifloro brevi, mento obtusangulo; sepalo dorsali lanceo, sepalis lateralibus (semper?) reflexis majoribus: tepalis unguis ligulatis obtusis: labelli trifidi lacinia lateralibus a cuneata basi acutangulis, abbreviatis, lacinia media ligulata antice obtuse acuta longe producta, carinis inclinatibus a lacinis lateralibus erectis vetosis remotis, labelli: columnæ androclinio marginato crenulato, setis nullis, anthera longa conica.

I had the pleasure of observing the living plant in the celebrated Saundersian collection, in 1867. The older bulbs become quite turbinate from a very circumscribed retuse base. The flowers are a third to a quarter of the size of those of Bolbophyllum Lobbii; sepals pallid sulphur-coloured; lip purple at the base, dark orange in the anterior part. Both tepals and column are whitish, with some little circumscribed purplish hue. The anther has a long conical point,

whence the specific name of nasutum. The plant, a very interesting thing, was obtained by W. Wilson Saunders, Esq., at one of the Stevensian sales. *H. G. Rchb. fil.*

ONCIDIUM OCHTHODES, *n. sp.*

Affine Oncidio pyramidali, Lindl. Panicula effusa, ramulis ascendentibus rectis (nec fractiflexis): floribus magis distantibus; sepalis subtilissime undato obscure obtuse acutis; sepalis lateralibus ligulatis-acutis; tepalis subrequalibus bene acutis, supra basin inferiorem obscure angulatis; labello basi latissime cordato, juxta columnam utrinque lacuca verrucosa, auriculis brevibus obtusatis in isthmum sensim decurrentibus, portione antica reniformi-bilobo angustiori; callo depresso pentadactylo, callulis geniculi internis; columna curva, alis lobatis falcatis, tabula infrastigmatica prona: rostello ornithorhynchio.

A species in the way of Oncidium pyramidale, with numerous bright yellow flowers, the lip painted with brownish bars; it would be that species, if its petals, columnar wings, and lip were not very distinct. What appears to be the true O. pyramidale flowered with W. Wilson Saunders, Esq. (N. 1876, Bowmann), yet the very narrow apex of the lip made it desirable to see the flowers once more, to judge whether that feature was a consequence of first flowering or a really distinct mark. The Oncidium ochthodes comes from Ecuador, and was kindly sent by Mr. William Bull, Chelsea. *H. G. Rchb. fil.*

PLEUROTHALLIS POLYLIRIA, *Endr., Rchb. f.*

(Macrophyllæ racemosæ.) Vaginis in caule secundario fissis laceris, caule secundario spathamaeo, folio a basi petiolari oblongo obtuso, vaginis inflorescentiarum 3–4 imbricatis; racemis duobus ad sex foliis laminam æquantibus seu superantibus, usque supra quartam infirmam subsecundiloris; bracteis vaginatis ovaria pedicellata subæquantibus; sepalis im basi et lateralibus ad medium coalitis oblongis obtusis acutis, antice intus velutino tomentosis, lateralibus ante mentum constrictis; sepalis subrhombeis truncatis, apiculo brevissimo; labello ligulato antice retuso, utrinque medio obtusangulo; carina adjecta obtusangula utrinque; columnæ clavatæ androclinio dentiulato.

A species very remarkable for the beauty of its shining broad leaf, very much like that of the Hookerian cauliflora (Icones, i. 50 ?), but it has no large sheath to the inflorescence, and the flowers are totally distinct. The flowers are small, whitish green, in one-sided racemes, which in their totality are of a gay appearance, making one think of small Lilies of the Valley. A beautiful specimen at hand is kindly sent by W. Wilson Saunders, Esq., who remarks that the plant is totally cæspitose. Quite the same plant with narrower leaves and much more numerous inflorescence is at hand in dried specimens, gathered at Costa Rica by M. Endres. What an immense distance between such dry specimens and the beautiful fresh plant! *H. G. Rchb. fil.*

THE AMATEUR GARDENER.

Clearing-up for the Winter.—A large class of gardeners pay little or no attention to their gardens from November till spring returns, and awakes in them those floral tastes which, like the productive powers of Nature, have slept during the winter months. With the withering of their bedding plants all interest in their garden seems to cease, and the beds and borders present a sorry appearance during four or five months of the year. This is slovenly, and it indicates that horticulture is not loved for its own sake, but only for the gay flowers which make a dwelling-house look more attractive to the visitor or the passer-by. The genuine amateur cannot act in this way. His love of neatness, if no other motive, compels him to "clear up" his garden for the winter season. And is there not a great charm in the aspect of a garden as well as in an apartment or in personal appearance? Even if there were no growth or floral development in the winter months, the trim and clean appearance of a flower-bed or a kitchen garden would repay for the necessary labour. But a most interesting series of operations are going on at that period, such as the pushing up of early bulbs, the flowering of the saffron Crocus, the Helleborus, &c., and the peeping out of the flower-buds of the Polyanthus and the Auricula.

The first thing in "clearing up" is, of course, the removal of decaying leaves and stems. This is followed by a forking or digging over of the soil, which must be done very carefully in a garden containing herbaceous plants and spring bulbs. A careful gardener will always know where there is anything of value beneath the surface, and will not cut through a bulb of a Lily or a Hyacinth as will be often done by a clumsy performer. It is during the process of forking or digging that new bulbs should be introduced, and Roses and other trees planted, and the whole arrangement of the garden settled for the spring. Do not be stingy in purchasing bulbs for this purpose, though, as we have said on a former occasion, November is later than bulb planting should be ordinarily performed. Tulips are, perhaps, an exception, but Hyacinths and Crocuses we have found to decay if planted late, especially if a hard frost should occur before they are rooted.

Roses should be pruned at this time, an exception being made of the more tender sorts, which are apt to die down from the wound, and, therefore, the pruning should be left till the spring. In the kitchen garden, all pruning should be finished in November, and the dressing applied to such trees as are liable to be robbed of their buds by the birds. Gooseberries are often quite stripped in this way, as are some sorts of Plums and Cherries. We use a mixture of lime, soot, and cowdung, in about equal proportions, and we find it is tenacious enough to cleave to the branches till the spring, and bitter enough effectually to keep the birds away. These ingredients are mixed in water to the consistence of paint, and applied with a brush. Our Morello Cherries used to be almost barren till we adopted this plan, and now they seldom fail to bear well.

As to dressing the beds at this season a word must be said. Roses will bear any amount of manuring, but if flower-beds are composed of tolerably good soil they require but little replenishing. Rich manures promote a vigorous vegetation, which is not what we want with most flowers. A skilful amateur will collect together every portion of leaf and stem during the year, and put the refuse of the garden in a corner to rot. When this is turned into leaf-mould, nothing is better for top-dressing. Sprinkle it over the beds before forking or digging, and nothing more will be needed. If this cannot be had, some new mould from a loamy pasture will do as well. *H. B.*

PRUNING SCISSORS.

THE illustration subjoined (fig. 317) is taken from a "secateur" exhibited at one of the meetings of the Royal Horticultural Society during the past season by M. Gustave Couvreux, of Nogent (Haute Marne), France. Similar ones, we believe, may be had of Messrs. Carter & Co., of Holborn. It has the advantage of great firmness and solidity, and as the handles

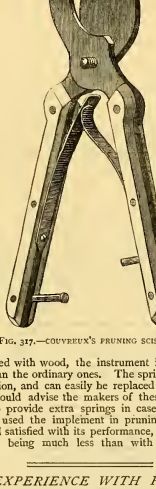

FIG. 317.—COUVREUX'S PRUNING SCISSORS.

are covered with wood, the instrument is much easier to use than the ordinary ones. The spring is of simple construction, and can easily be replaced when broken, but we would advise the makers of these instruments always to provide extra springs in case of accidents. We have used the implement in pruning shrubs, and were well satisfied with its performance, the fatigue to the hand being much less than with the ordinary scissors.

MY EXPERIENCE WITH POTATOS.

ADDISON wrote an article in the *Spectator*, headed "Cacoethes scribendi," or the itch of writing; in the same article he says "there is no bore so great as your periodical scribbler." Perhaps the "button-hole bore" approximates; I mean the man who catches hold of your button-hole, and looking seriously in your face proves by a lengthy argument that six and four make 10, and that as long as time lasts seven will always be more than six. I do not think, seeing how interesting the Potato malady is and how essential a vegetable it is to the comfort of every family, that any one writing on the subject can be reprobated as a "periodical scribbler," or "button-hole bore!"

I will begin with what may prove a valuable suggestion. Some years ago, soon after I became Rector of Rushton, a place of nightsoil was cleaned out. It was at least 6 or 7 feet deep in nightsoil. The old man who cleaned out the pit, and had lived at the rectory 20 years or more, brought me some nice fresh-looking Potatos, Salmon Kidneys, and said "These Potatos were taken from the lowest 'spit.' They must have been there twenty years, for I remember the time when it was last cleaned out." They were not grown out at all; and having been washed were as bright as I ever saw the same kind when freshly dug. I mean to try two experiments at once. I shall put a barrel with a cover on the northern side of my fruit wall and sink some Potatos in water; and I shall dig a deep hole, and sink the Potatos under some material of a cleaner nature than nightsoil. It is plain to me that the way to preserve Potatos over the year and longer is to exclude the air, light, and heat. Perhaps Mr. Fenn may devise some better plan. Potatos will grow out when the time of year comes, unless heat specially, light, and air are excluded.

I will now assume the catechetical form. Will antiseptics, applied to the tubers before, or at planting time, prevent disease? I think not; because two years ago I dipped Potatos at planting time into a strong solution of vitriol and water (!), and saw no difference. I think, however, Mr. Tillery's suggestion, to apply lime to them in the storehouse, is very good. Will lime, soot, or salt strewed in the trench at planting time stop or ameliorate the disease? Certainly not; I tried this plan at Rushton with the Old Ashleaf, Mona's Pride, and the Royal Ashleaf. I had not one dish of Potatos from them; they were complete "slime." By their side I planted the Rough Reds (Grammas); not one tuber was affected. I planted them next year on a chalky hill, exposed to all four winds, in a Potato trench, no Potato having been planted there for 10 years; hardly a Potato was good, and the main crop was "slime." Will Potatos fresh raised from seed prevent the malady? Nothing of the kind; I had some seedlings sent here by Mr. Taylor, of Almond's raising. They were no freer from disease than others. Will planting Potatos in single file at yard distances, without any other Potatos near, ward off the evil? Nothing of the kind; I planted some this year as above, but, though the crop was splendid, three out of four were bad, and chiefly the large Potatos. They were the worst affected of all my Potatos. After they came up they were earthed-up on all sides, like mole-hills. Mr. Brymer (Toronto) and Mr. Marriott were here when they were dug; I gave to the former from twelve to twenty each of all the sorts here to take to Canada. With regard to the remedy, as it comes from above and not beneath the soil, I suggest the fumigating the haulm once or twice after it is up. I mean to try it next year: I shall put heaps of straw on the windward side of the plantations, set fire to it, and sprinkle sulphur into the heaps. If the disease arises from Fungus, as stated by some—I have never yet seen any Fungus, but I still greatly defer to "M. J. B.," our greatest mycologist—the sulphur fumes may be of some use. I shall also try a line or two with a very weak solution of vitriol. It must be weak, because the haulm is very sensitive. I will drive all my readers into despair by saying "you may hear from me again," but I will make a clean breast of it at once. I have planted a considerable portion of my Potatos (beginning October 24) with grassy furze from a two year old rick, and some with clean wheat straw. I have no fear of frosts under the circumstances. Last January 17, I planted my field garden without either straw or furze, and there was hardly a plant missing, though the field leans to north and east in this cold open vale. My garden Potatos were planted at the same time, and had a light covering of straw. Those hyperboreon frosts affected not the sets under ground. The poor people here planted in March, and their sets, being sprouted, were soon up; and when 6 inches high the frosts cut them down to the ground. My January tubers I never cut, though were them only just peeping. I do not flat-hoe Potatos but use Parkes' fork as soon as I descry the lines; and then I immediately earth them up, which keeps them safe till severe spring frosts are over. I began this year digging the sorts I keep August 17, perfectly ripe. In 1869 and 1870 I began digging August 1, respectively. Nothing can be better than the quality of the Potatos. I am eating Gryffe Castle Seeding, a round white Regent: it is nearly as good as a kidney. It is a short-haulmed early-ripening Potato. Long-haulmed and deep-eyed Potatos, which I much larger in ripening than kidneys, are sure to suffer most. I asked my man, "Steevie," about cutting off the haulm. He says he tried several ranks some years ago this way, and got worse off; for it did not stop the disease a whit, and the unaffected "taters" were so waxy and close he could not eat them; but he could eat those that were left untouched. I agree with much that Mr. Rogers has written, but not with the suggestion that we should plant less. To meet possibilities and probabilities, I plant a great many more than I am likely to want, and also plant a strong lot of Student Parsnips, underground Artichokes, Savoys, and suchlike.

Finally, a word about the American Potatos. I have had them all except Early Goderich. I found them to be all good croppers and with wonderful foliage; here they were squashy and ill-flavoured, and not to be compared with our round or kidney Potatos; but still they may be very good for cottagers, who boil Potatos in one net and Cabbage in another, flavoured by a lump of bacon. I think that in poor grounds their flavour and quality might improve. At any rate, I think we should not be hasty in coming to a conclusion about newly introduced things. We are apt to puff things up and also puff them out before we have given them a fair trial. A commodity that may

be very bad in one kind of sort or season may be very good in different ones. Of all the American 'otatos sent here the best by far was the Early Rose (not early here). It is a kidney Potato, of good shape, of a dull pink colour, with nuclei of small eyes, like the Pleiades. I gave it to our policeman, who won a prize at our cottage allotment show last year, and took a capital sample of them this year. There is one point I admired much in all the American Potatos, round as well as kidney: their eyes were small and on a level surface. The whites were defective in colour, being dingy. One word at parting; I earth-up Potatos,—in the long run I believe people will find it best. In some soils and seasons the unearthing system may be best. Plant a Potato as deep as you will, it forms its crop close under the base of the plant; and when the crop swells, a great many will be greened unless earthed-up. Notwithstanding the above I cry, louder and louder, "O dark, dark, dark." *W. E. Radclyffe.*

INDIAN LORANTHS.

(Concluded from p. 1452).

"The following list is confined to the different kinds of trees more or less infected with Loranthus longiflorus in the Botanic Gardens here:—

Simaba malabarica	Gleditschia sinensis
Sterculia villosa	Pyrus sinensis
Ægle Marmelos	Terminalia Catappa
Citrus decumana	,, angustifolia
Xanthochymus ovalifolius	Jambosa vulgaris
Banisteria laurifolia	,, polypetala
Cupania racemosa	Lagerstræmia speciosa
Melia composita	Bassia butyracea
,, sempervirens	Mimusops Elengi
Chloroxylon Swietenia	,, Kauki
Zizyphus Jujuba	Tectona grandis
Mangifera indica	Ulmus wallichiana
Garuga pinnata	Ficus nitida
Inga dulcis	,, religiosa
,, Huntoxylon	,, glomerata
Dalbergia Sissoo	Antidesma Bunias

"The branches of Teak trees, when attacked by Loranthus, generally become much hypertrophied, but fortunately it seems to be one of those heavy-foliaged, deciduous trees, on which these parasites are driven to the extremities of the branches, and are thus not likely to do much damage to the trunk or heavier branches. It is also interesting to observe that while on light, airy foliaged trees, the rhizomes extending towards the base of the branch are generally much stouter and more vigorous than those extending towards the apex, whereas under the above conditions there verse is the rule, and we find the inwardly directed rhizome weak in the extreme, and soon becoming imbedded in the thickening branch, the apically-directed shoot absorbing all the vigour. I have specially noticed this on Teak and Jambosa vulgaris.

"The development of the nourishing branch, in some instances, is utterly arrested (as I can see no traces of subsequent deposits) for a period of six years, forming a mere nuicle for the supply of crude sap to the parasite. It is thus functionally analogous to the woody adventitious roots of the arborescent Monocotyledons, and similarly destitute of medial foci of development. It is important also to observe, that the cambium tissues and bark differed in no respect from those on active or organising portions of the stem. Again, the branch supporting the parasite was 14 inches long, and a secondary shoot from a stout branch of which those lately developed and unburdened with parasites were many times stouter. Throughout the whole length of the parasite-bearing shoot the diameter was nearly uniform, with a slight thickening towards the base, where it appeared to have received a modicum of elaborated sap from the branch from which it springs. I have already pointed out important structural and physiological differences between the phenomena of parasitism and grafting; but I know of none more important than that which I have now illustrated.

"Two other specimens in my possession are worthy of description from the novelty of the attachment of the parasite to its prey: both are on Nerium odorum. The first is attached on the upper surface of the petiole of a leaf, and has a main stem 5 inches in length, with two lateral ones of about 4 inches; the main stem and the main stem being four lines. Several rhizomes have been produced, but one only has extended along the stem, forming firm attachments for the length of 9 inches: the others—three—extending along the surface of the leaf, have failed in effecting a secure attachment, and continued slender and contorted, giving out, in place of the disc-like processes, numerous slender rhizomes in search of fixed attaching surfaces. The branch on which it is thus attached, was dry and dead, all nourishment having been arrested by the parasite. The foot-stalk had increased much in thickness: the lateral measurement being five lines, the vertical three lines, whereas in the normal condition we find them respectively one and-a-half and one line. Again, while a section of the petiole in its ordinary state exposes a minute semi-lunar band of fibro-vascular tissue, we find it supporting the Loranthus with a hard woody band, three lines broad by two in depth. In the second specimen, the attachment is on the midrib of the leaf, and 1½ inch from the base. The Loranthus has a vigorous, though solitary, shoot, 2½ inches high, with two lateral rhizomes; the one extending downwards to the stem, with which, however, it has failed to attach itself, owing to the frequent movements of the leaf, though midway it has formed a normal disc-union with the midrib. The other rhizome, extending towards the apex of the leaf, is unattached, slender, contorted, and ramifying, as in those previously described. In this case, also, the thickness of the petiole and midrib has been considerably increased. The root-processes pass completely through the midrib, causing a slight local hypertrophy of the tissues on the lower side, though, strangely enough, none whatever on the adjoining portion of the blade of the leaf, either above or below.

"The L. longiflorus, naturally an evergreen shrub, becomes, as I have observed, quite deciduous when growing on some of the deciduous trees in this garden. Thus specimens on Sterculia villosa, Salmalia malabarica and Lagerstræmia reginæ, remain leafless, or nearly so, with their foster-parents, from the end of December until the latter burst anew into flower and foliage in the hot season. Again, on such trees as Terminalia Catappa, which suddenly cast their leaves in February, and in a few days are again covered with expanding buds, the Loranthi (as in their native country) remain quiescent for a month or more, and then present an odd appearance as they hang out in great tufts from the leafless and bud-expanding branches of those lofty trees.

"In the Botanic Gardens here, having had frequent occasion to transplant specimens of the common Sandalwood (Santalum album) I was struck with the repeated failures of all the older plants, as indeed those of smaller size also, unless removed with an unusually extensive ball of soil. The cases of root parasitism in the allied genera, Thesium and Comandra, naturally occurred to me, and I determined to take an early opportunity of investigating the relations. This I have now done, and, as I suspected, found, on carefully tracing out the more slender ramification (no easy matter), abundant evidence of parasitic attachments to the roots of the surrounding grass. I have since amplified my method by planting seedling plants of the Sandal-wood and other plants together in the same pot. Under these conditions it has formed attachments to the roots of Saccharum spontaneum, Eleusine indica, Arenga saccharifera, Cyperus arenus, and C. sobolifera, Cocos nucifera, Phœnix sylvestris, Heptapleurum venulosum, H. umbraculiferum, and Inga dulcis.

"I can find more especially to try my experiments with Palms, from having observed the Sandal-wood trees growing with unusual vigour in the vicinity of Arenga, and on examination, exposed its copious parasitic root relations with this Palm. I also will have Saccharum spontaneum (Saccharum spontaneum). With the Araliaceæ, I had most demonstrative evidence; first in a vigorous old tree of Sandal-wood, growing in the vicinity of a large specimen of Heptapleurum umbraculiferum, which I had occasion to cut out. A few months after this I was surprised to find the tree nearly destitute of leaves, and altogether in a most unhealthy state, though for some time after the Ivy-worn had left the tree no other insects were observed. This, however, was probably due to the strong vitality of the Ivy-wort's roots, which may have remained fresh for weeks after the stems had been cut out. The tree has since made a vigorous and weak growth, rarely yielding an abundance of flowers; and now—the fourth year—it seems to be acquiring fresh vigour, probably from having formed new root attachments. The second case was of a young tree, 3 feet in height, and grown in a pot, which was of a bush of Heptapleurum venulosum. The latter having been cut out, the young Sandal-wood tree shortly after lost the whole of its leaves, and died, as in the former case, afterwards in a most unhealthy state. These illustrations, conjoined with the results of transplanting the larger and smaller sized specimens of Sandal-wood, and the copious illustrations of parasitism in the Loranthaceæ and Araliaceæ, afford unquestionable evidence of the parasitic root relations of the above tree with those of environing plants.

"In the above cases, and all others that I have observed, I have been unable to find any indications of swelling or hypertrophy of the parts of the root around the parasitic attachment. This apparently indicates important differences in the physiological relations of those cases of parasitism, as compared with that of the Mistletoe and the Loranthi; though they may be but the results of differences in the chemico-physical relations. Loranthi, we know, are utterly dependent for their existence on the supporting tree, and, as I have elsewhere shown, by reason of growth, incessantly absorbing crude or elaborated juices, thus disturbing the circulation and causing reactions which are very likely to induce a hypertrophied development in the supporting tissues; the root-parasites, on the other hand, are but quasi-parasitic, and though as I have shown, they do form parasitic attachments, and suffer in transplantation from sites on which they are established, or even by removal from their accustomed situations, they can, nevertheless, live, grow, and even thrive in soil destitute of other vegetable roots. This leads me to remark that parasitism seems to have been a much more essential condition of the existence of the root-parasites than it is now. I suspect this from the copious production of the parasitic tubercles and the proportionately small number which ever form attachments, and are thus compensated for the expenditure of nutritive material. This is truly a remarkable morphogenetic alternation, considering the stability of the physical conditions under which it was evoked; the spontaneity, so to speak, of the change; the definite end to which it is subservient, the vital economy of the organism, verging, indeed, wondrously close on those phenomena which in the other kingdom of organic life we dignify by the name of instinct. In the quasi-parasitic Sandal-wood we see no such economic dispositions of the vegetative forces, as we find a large proportion of their parasitic tubercles, depending, loose, and functionless from the roots, or at least in so far as related to their normal function as channels for the absorption and transmission of the juices of the surrounding plants. It is thus by no means improbable, from the evident abeyance of parasitism in existing Sandal-woods, and the truly prodigal production of parasitic organs (which, while retaining their potentiality, by no means generally exercise the function), that they have acquired a last stage in the transition from parasites to self-sustainers. From this point of view the relationship of Sandal-worts becomes less dubious, and supports the view of those systematic botanists who have correlated them with the pre-eminently parasitic Loranths. As bearing on this, also, the embryonic relations of the two orders as demonstrated by Griffith are of great significance, seeing that 'community in embryonic structure reveals community of descent . . . and thus in two groups,' I quote from Mr. Darwin, 'however much they may at present differ from each other in structure and habit, if they pass through the same or similar embryonic stages, we may feel assured that they have both descended from the same or nearly similar parents, and are therefore in that degree closely related.' *Origin of Species*, p. 381.

"Several of our Indian species of Loranthi, however, are of a highly ornamental character, and are well worthy a position on trees suited to their growth in our gardens. To effect this, traces of a characteristic to the habits of these parasites, and of which we have above afforded numerous examples, should be selected, a notch cut in the bark on the north—or cooler and more shady, though airy, side of the tree, and the portions of the parasite inserted there: care being taken that it is not crushed in the operation. In Europe the common Mistleto is also frequently transferred from one tree to another by grafting and budding processes, which might doubtless be effected with the Indian Loranthi also during the rains. The mode of operation in the case of the Mistleto is thus described by Loudon, and it is equally applicable to our indigenous Loranthi:—'Where the stem is not more than half an inch in diameter, an incision is made in the bark, into which a scion of Mistleto pared thin is inserted, having a bud and a leaf at the upper end. In grafting longer pieces, a notch should be cut out of the stock; an incision made below the notch, and a shoulder left on the scion to rest on the notch, in the manner of crown grafting. In every case there must be a joint in the lower extremity of the scion. In budding it must be seen to that a bud of wood and a joint at the lower extremity of the bud, and over all, if available, add a coating of the viscous matter from the berries, or some protecting substitute."

BOTANY FOR BEGINNERS.—XVI.

In the two preceding articles we explained the structure of the seedling Oak and Wheat respectively, with a view to show, amongst other things, how some of the main characteristics we meet with in adult stems and branches are quite distinguishable in this early stage. We have also, in former notices, given illustrations of what is meant by *definite* and *indefinite* modes of growth, and what are the conditions to which botanists apply the terms *alternate*, *opposite*, *decussate*, and the like. So far, then, we hope to have cleared the ground for the comprehension of the different forms which the stem and its subdivisions assume in different cases. To enter into details on these matters would demand a book as bulky as the annual volume of the *Gardeners' Chronicle* itself; besides, it has been our object throughout to keep in view the principles of plant construction before the reader, and to give him only such an amount of detail as should insure his due comprehension of the principles. These mastered, their application to particular cases is a matter of comparative facility. So far, then, as details are concerned, it may suffice to say that the chief differing aspects of "habit" of shrubs, of trees, or of herbs, *e. g.*, the spreading Cedar, the tapering Poplar, the "weeping" Willow, the mop-headed Robinia, the dumb-waiter-like arrangement of the branches of Araucaria, the flat-bloated-looking Echinocactus, the tufted Grass, the tunicate Hyacinth, the globular bulbs of the Hyacinth, the dense rosettes of the Sempervivum, and—but the variety is infinite. We have, however, introduced a few illustrations showing how the "habit" may vary even within the limits of a single species, and of which we may refer to the cases of Sedum and Oak. Let us now attempt to show that the causes bringing about all these modifications are as simple in nature as they are few in number. "'Spects I grow'd," said Topsy, and to growth, and cessation of growth, in various directions and degrees, and at different periods of time, may the phenomena as we have alluded to be attributed. Let us explain. There is growth in lines, where development takes place principally in the longitudinal direction—a reed, or the long unbranched stem of a Palm, sufficiently illustrates our meaning; there is growth in planes, as masses of buckwheat (Lemna), floating on the first pond you come to, or a leaf off the nearest plant, will sufficiently exemplify that mode of growth. There is growth in spheres, perhaps the most important and general of all methods, at least at first. Suppose food and other requisites to be in equal quantities, and the facilities for getting them also equal on all sides—and this is pretty much the case in the earliest stages of life vegetable or life animal—and the growth will be spherical. Suppose, on the other hand, there is more food in one direction than in another, the great amount of growth will be in the direction of the supply. So, if one kind of food, light, and air, be in one direction, and another kind of food, water, and earthy matter be in another, there is an obvious reason why the primitively globose form should be replaced by a linear shape, better adapted to fulfil the requirements of the case.

Growth, then, is intimately dependent on food, the mode of growth on the nature of that food, and the place wherein it is to be found. Further, given the food, given also the means of getting it, no plant—no living being, be it what it may—lives entirely for itself. It lives with, in, for,

amongst other beings, in harmony or in hostility with them. Erasmus Darwin sang the "Loves of the plants;" his descendant, Charles Darwin, has become the historian of their wars; and besides all this reciprocal help or antagonism of plant and plant, as the case may be, there are the varying conditions of atmosphere, of climate, of soil, and all these are calculated to modify the growth of plants. And then it must be remembered, that these modifying circumstances do not act singly, or one at a time, but in combination, and thus endless complexity and innumerable compromises are brought about. The general result of all this is to be seen in that marvellous variety of form, that wonder-

FIG. 318.—JAPAN PRIMROSE.

ful adaptation of living creatures to the circumstances around them, which compels the most thoughtless to exclaim, "The hand that made them is Divine."

Starting then with the sphere as the primitive form, and the line and the surface as the immediate derivatives from it, and bearing in mind the infinite variety of modifying conditions, the causes of the forms of stems, including here roots and branches, are not far to seek. Growth may be continuous and uninterrupted* — indefinite, in fact; and then we
