get a straight unbranched erect trunk, or a long trailing shoot. On the contrary, a check may come and then the growth is arrested. That arrest may be permanent, or temporary only; if permanent, the form of the tree or shoot is of necessity profoundly modified in consequence, and we get the series of forms known as definite. If temporary the shape is not necessarily modified, the arrest may be periodic, that is to say, there may be alternating periods of growth and of arrest of growth. It is so with our trees in winter, when their growth is arrested—in spring extension is resumed. If there should happen to be a bud on the end of the shoot, the direction of the growth will be the same as in the preceding season, and the general form will not be altered, but if there be no terminal bud, or if it be injured or removed by some accident, then the new growth in the following spring will be in another direction, and the shape of the branch will be altered in consequence. Take as another illustration the tier upon tier arrangement of

FIG. 320.—KOHL RABI IN FLOWER.

branches in many Conifers, such as the Araucaria or the Norway Spruce. The "habit" here is very striking, and it is brought about by periodic alternations of growth and arrest: the main stem grows continuously, the side branches are developed at regular periods, and arrested in the intervals.

Another cause producing great variations in the forms of stems is to be sought for in the unequal amount of growth in some directions as contrasted with that in others. In a bush or shrub the amount of growth in all the branches is nearly equal—all the older branches are therefore of about the same size, but in a tree with a lofty unbranched trunk, a Scots Fir, for instance, the growth of the trunk is, at least for a time, much more pronounced than that of the branches. Again, the main development may at one time be in one direction, at another time in another, and so great varieties of shape are produced. Let us take a bulb, such as that of the Hyacinth or the Tulip, before referred to, or a plant of any House-leek (Sempervivum). In any of these the growth of the leaves or of the scales, which are the representatives of leaves, is in excess of that of the stem bearing them; this latter remains short and contracted, the *internodes*, as they are called, *i. e.*, the spaces between the nodes or points of emergence of the leaves from the stem, are not developed, and the result is what is commonly called a stemless plant. The Daisy and the Dandelion afford illustrations of the

FIG. 321.—SAVOY.

same thing. The term "stemless" is botanically incorrect, for the stem is that portion of the plant bearing the leaves—it may be very short, but there it is; and the proof of this assertion may be seen when the flowers are produced — up goes the stem to bear aloft the newly formed flowers, and very often leaf separates from leaf in the process; the internodes, no longer undeveloped, manifest their presence unmistakably (see figs. 318, 320). In the cases just mentioned, the growth of the leaves, for a time at least, is greater than that of the stem. In the Cactus, or in the succulent Euphorbias, the reverse is the case. The stem grows, and the leaves are undeveloped, or appear only in the guise of spines.

Look, too, at the figure of the splendid Primula japonica, introduced by Mr. Bull (see fig. 318). It shows arrest of growth in the lower part of the stem, causing the leaves to be closely packed in tufts on the surface of the soil; the arrest is not permanent, however—the flower stem rises to bear in all its majesty that mass of flowers which has secured for the plant the title of Queen of the Primroses. In the arrangement of the

FIG. 322.—BRUSSELS SPROUT.

flowers of this plant, too, we see the principle of growth and arrest of growth manifested; a tier of flowers, then an interval, again a tier of blooms, and so on, just as in the Araucaria or the Spruce Fir above alluded to.

Another circumstance, which greatly modifies the form of the stem and branches is the direction which those branches assume—now horizonal, at other times ascending or descending more or less obliquely, and producing thereby the various forms of round-headed, fastigiate, or weeping trees, and their many modifications. We cannot enter into the explanation of all these forms, suffice it to say, in general terms, that the form assumed is that best calculated to favour,

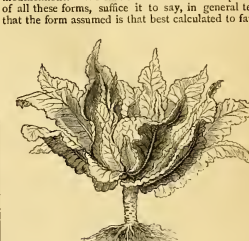

FIG. 323.—CAULIFLOWER.

not one particular leaf or set of leaves in their struggle for light and air, but the whole mass of the foliage, and to place each leaf in such a position that it shall infringe the least upon its neighbour's space, best accommodate itself to the exigencies of the situation, and most completely serve its office of feeding the plant and building up its stem. In this struggle, and in this process of adaptation, the weakly leaves and buds die and fall off; others, badly placed, or of necessity overshadowed by those more favourably located, also fall to the ground, the buds in their axils remain undeveloped, and thus again the form of the stem and its subdivisions becomes modified.

The different positions of the leaves and buds—alternate, opposite, whorled—have already been alluded to. The reader will need no further reminder as to the influence of the varying position of these organs on the

* It must be understood, of course, that these expressions are used in a relative sense.

form of the plant as a whole—all this has been told in previous articles.

It only seems requisite further to point out that the branching is not necessarily the result of the growth and extension of buds placed in particular positions, because in the case of the true root there are in the majority of cases no buds, certainly no terminal buds, and any subdivision that takes place must be the result of the forking of the growing point. But a "growing point" is in nowise different from a bud, except in the absence of investing scales, which indicate a periodic arrest of growth, as before explained, and which is not so noticeable in the case of a naked growing point as it is in that of a bud properly so called.

In immediate relation to the forms assumed by stems and roots is the necessity, in certain cases, of providing store room for water, for starch, or other products not immediately required, perhaps, but which will be wanted in the future for the supply of the tissues when growth commences, or for the use of the flower when its development begins. This necessity is provided for by those rounded succulent formations, which we call tubers, pseudobulbs, bulbs, and the like. Sometimes these are dilatations of the true stem, or of the branches, or of the buds (Potato), or of the roots themselves. Their purport is pretty much the same in all cases, their intrinsic nature, as we have just seen, is very varied, but what that is, the pupil who has followed us so far, should, in most cases, have little difficulty in deciding.

A last word as to the roots: the modifications in their form are due to pretty much the same causes as those already alluded to. A remembrance of the different effects the subdivisions of the root have to fulfil will serve to explain all the great larger ones are anchors or holdfasts, and their size and direction are in accordance with their functions, and the nature of the soil they are growing in; the smaller ones—the feeding roots—active, busy fellows, are to be found everywhere where healthy food is to be obtained, their tiny mouths swelling to enable them to absorb the liquid food from crannies often too small to be seen by the naked eye. Here again, varying conditions of soil, and varying forms or qualities of root, are found, as might be expected, in association one with the other.

The illustrations accompanying this article, some of which have been copied from a recent part of M. Baillon's "Histoire des Plantes," will suffice to explain much that we have alluded to in this article. Thus in fig. 310 we have the Kohl Rabi with its "tap" root surmounted by a globose stem; we have also the same, for it bears the same of fallen leaves. In this Turnip-like mass is a store of nourishment available for use in building up the inflorescence and flowers. At the top of this gouty-looking stem is a tuft of leaves closely crowded together, because the growth of the stem between them is for the time arrested. We say for the time, because it is evident from an inspection of the scars below that the stem has already grown between the leaves, causing their separation one from another, while should the plant produce flowers, as shown in fig. 311, the stem will again grow rapidly in length, the leaves will be spaced out, and lateral branches will be formed till a bushy pyramid of flowers is formed.

In fig. 321, representing the Savoy, we have an unbranched stem, which does not swell out, as in the Kohl Rabi, but, by way of compensation, produces a tuft of large leaves. This incidental mention of compensation bids us to remind the reader to remark the almost universal application of this principle in plants. If one portion of a plant be very large, some other is proportionately small, and so on.

In fig. 322, showing the "Brussels Sprouts" we have a case wherein the lateral buds—"sprouts"—are more numerously developed than usual, and also larger in size; their growth is usually more or less arrested —here it is allowed full play.

In fig. 323, the Cauliflower, we have a stem and tuft of leaves similar to those of the Savoy, but the inflorescence is arrested in its growth. Call you that great fleshy succulent mass an instance of arrest of growth? we fancy we hear some one say. We have only to look back to fig. 320, however, to demonstrate that it is an arrest of growth. The flower-stalks do not lengthen, and even the flowers themselves are for the most part imperfectly formed. But by compensation what is lost in one way is gained in another, and in place of the pyramid of stick-like branches we have that succulent vegetable mass so highly appreciated on our dinner-tables.

Home Correspondence.

The Price of Vegetables.—The following remarks are taken from the *Pall Mall Gazette*:—

"Some little idea may be formed of the necessity of a reform in our greengrocery arrangements by the following passage, which occurs in the report of Mr. H. J. MORGAN, on the cultivation by means of sewage irrigation of the Lodge Farm, Barking, for the year ending August 31 last, which has just been published. 'The average price,' says Mr. MORGAN, 'which our best Potatoes last year realised was from £6 to £7 per ton. This year we have obtained no more than £2 to £2 10s. Onions, which sold last year for £43 per acre in the ground, and realised a great deal more by marketing, have this year been sold by us at £28, the highest price I have heard of being £30 per acre. In the autumn of last year cut Cabbages (collards) fetched from 1s. to 1s. 3d. per dozen, while this year there has been a difficulty to get 6d. and 4d. per dozen. Some have even been sold, I hear, as low as 6d. for five dozen. Scarlet Runners, which made 8s., 10s., and 11s. a sieve last year, only reached 3d. and 6d. and 1s., until late, when they have made 2s., and 2s. 6d. a sieve. Bunching greens have not paid us to market, and we have hitherto fed cattle on them. I have been told by several farmers that they have ploughed in their crops, as it would pay them better to use them as manure than to market them. These differences in price have not at all arisen from difference in quality, as our produce has been, in most cases, as fine and as abundant this year as last. Speaking to me, also, Mr. Morgan, with refreshing *naïveté*, 'that in the face of all this the retail prices are as high as ever—a cut Cabbage ordinarily costing 1½d., and a small dish of Beans 4d. and 6d., with everything else in proportion.' It is more melancholy than strange. We have heard such things before, and at the same time we have heard that there are thousands of poor persons who, while vegetables are either used as manure or are almost given away by the grower, are well nigh starved for want of a dinner, being unable to pay the exorbitant prices demanded by the retailer."

I have no doubt that a great many of your readers, have, like myself, but too great a reason to endorse the above statement of Mr. Morgan as to the prices realised for vegetables this year as compared with last year, and also as to the retail prices charged to the consumers. Some friends of mine living at the West End, were complaining to me the other day of the very high price of Celery: "we can't get any," said they, "under 4*d.* a head." The best Celery in the market at that time was said to be fetching at 8*s.* per dozen, or 8*d.* at the rate of 1*d.* per head, so the consumers were paying 300 per cent. on the market price. Take another item, viz., Savoys; on Saturday, October 28, I had 90 dozen, unusually fine, as much as two horses could draw; the price realised was 3*d.*, or a little over 2*d.* per head. On Saturday, November 4, I had over 100 dozen, which fetched 43*s.*—considerably less than 6*d.*, and last Saturday 50 dozen for 30*s.* There would be some little consolation if the poorer inhabitants of London were reaping the benefit of the above ruinous prices, but on inquiry they find that the cheapest which is to have a dish of greens of any kind on their table, except on a Sunday. They should take a lesson from their neighbours over the water, for a French dinner is principally made up of vegetables, and they make 1 lb. of meat go further than we do three or four, which, at the present high prices, is not much to be wondered at. Vegetables, is an important matter in our domestic economy. I have often wondered who have been the lucky growers to obtain the nice little prices quoted in your Covent Garden list. In your last impression, for instance, from 1*s.* to 2*s.* per dozen for Savoys, and I have been sending as fine as any that go to Covent Garden, and I can't get 1*s.* per doz. Again, Brussels Sprouts, from 2*s.* 6*d.* to 3*s.* per half sieve; the average price for the last three weeks has been 2*s.* 6*d.* to 3*s.* per bush. Cucumbers, 2*s.* to 6*s.*; I believe the finest in the market have fetched over 2*s.* This certainly cannot be doing the growers or the public any good. What must the country growers, who consign large quantities of goods to our London salesmen in Covent Garden think, when they compare the prices market-days, and the proportionately small the sums returned to them for their goods? *M. C.* [We quite concur in the opinion that in the interest of the consumer the prices of vegetables in London and its suburbs require regulation; moreover, we quite believe the poorer classes suffer from the unnecessarily high cost of vegetables, and also that the grower very often fails to realise an adequate share of the prices gained by the retailers. The prices quoted in our report, it should be remembered, are, generally speaking, not wholesale but retail prices. There is, moreover, considerable difficulty in getting fair statistical quotations, because the prices vary from day to day, sometimes several times in a day according to the crop, the season, the supplies received from abroad, the demand, and various other contingencies, of which the grower knows little, the consumer still less. Moreover the "middle row" prices, or those obtained at a West End shop, are naturally enough considerably higher than those in less fashionable districts. We should be glad if "M. C." would furnish us with an accurate statement of the prices obtained by the growers on the market-days, and we propose now and then to cite "greengrocer's prices" about London, which will, we fear, amply bear out Mr. Morgan's statements. EDS.]

Seedling Willows.—I was walking a few days ago along a drive in a park in this neighbourhood, and saw upon the top of a low wall which ran along the side of the same what appeared to be undoubted "seedling Willows." I send a few gathered at random; the position in which I found them, I think, precludes the possibility of their being anything else but seedlings. *T. Smith, Revesby.*

The Gender of Cones.—I have had a conversation with the "hypercritical old gentleman with the spectacles" about the gender of cones. He says in his old Latin grammar "all trees are feminine," but as fashion changes, and old men and old Latin grammars are both getting out of date, it may be possible for both male and female cones to be produced in the South, still in the North we have never seen any. He goes on to say that if a young goose with her egg be had for dinner to-day, and the old gander with his ovum be tried to-morrow, we shall ever after be able to distinguish the true gender. *Neuter Gender.* [Our correspondent seems more hypercritical than his friend even, though he shifts the scene. We thought the original objection was made on botanical grounds, but it seems that it was our reporter's "genders of nouns" which was impeached. Had our reporter written in Latin, "Neuter's" objection would have been valid; as he wrote in plain English we can see no grounds for the criticism. Neither can we subscribe to the dictum that all trees were feminine in Latin, *e. g.*, Olea, feminine; Oleaster, masculine; Malabathrum, neuter. The question was discussed in our columns in 1867, when a learned correspondent of ours proposed to write Taxodium distichin, on the ground that trees were feminine in Latin. If the Romans had known the tree Taxodium, and given it a name derived from two Greek words with the neuter termination *um*, would they not also have written the adjective also in the neuter? We venture to think they would. EDS.]

Large Onions.—I incidentally attended a very extraordinary exhibition of roots which is annually held by Mr. P. J. Perry, of Banbury, and which took place on the 8th and 9th instant. The exhibition was particularly called to 12 Onions, of the respectable weight of 153 lb. which, I am informed on the highest authority, is 2½ lb. in weight greater than heretofore shown even in Banbury, which has of late attained a national notoriety for the growth of this bulb. I am constrained to make these remarks for the information of your readers, more especially as you have already referred to the Onions grown at Banbury, as surpassing all others in the kingdom. It is, however, but fair, and mere justice, to say that the 12 Onions in question, and which, of course, took the first prize, were grown by F. Coleman, Esq., Brook Street Farm, Bartonle-Clay, Bedfordshire. They were of the White Spanish variety. There were on this occasion 19 entries, and all shown were remarkably fine, but the 12 that gained the first prize were really astonishing in size. *L. H., Newender Ag.*

—— I beg to send you the result of my trials of 10 varieties of Onion, 1 rod of each. These gained the first prize at the Royal Horticultural Society's exhibition at South Kensington on September 6 last, and were also exhibited on Messrs. Suttons' stand at the harvest festival trophy at the Crystal Palace:—

	Bush.		Bush.

G. Farndell, Gr., Surrey County Asylum.

Peculiarities of Grapes.—May I suggest to Mr. Cramb that the West's St. Peter's may be defective as a stock for the Madresfield Court? I have a Mrs. Pince's Muscat and a Duchess of Buccleuch grafted on a St. Peter's, and as soon as they become ripe they shrivel almost to nothing, while West's St. Peter's, Burchardt's Prince, Muscat Hamburgh, and Black Lady Downe's, growing in the same house, keep in sound condition till March, and the last-named much later. As I have the Duchess and Mrs. Pince doing well on their own roots, I am not disposed to think they have any constitutional weakness because they are failures on the St. Peter's. Much has been said against Golden Hamburgh and Golden Champion. In some soils they may give disappointment, but such grand Grapes are worth the turning from the "beaten track" treatment, if necessary, to get them to perfection. I could do nothing with the Golden Hamburgh grafted on Marchioness of Hastings Vine; it was little better on its own roots, but, grafted on a Black Hamburgh Vine, it has done most satisfactorily for eight years, having carried heavy crops of fine fruit, and has always kept well from April to the end of November. It is always relished by my employers and their friends, being a companion to the Black Hamburgh. The Muscat of Alexandria, though one of the best of Grapes, soon cloys on the palate, and generally is not relished for any length of time without a change. I am glad that Mr. Cramb is successful with the Golden Champion, as it is by many, who have been successful in growing it to perfection, considered a great boon. I enclose a few Golden Hamburgh Grapes, which were ripe in July, and I think that I shall have no difficulty in keeping some which are still on the Vine till Christmas. [Capital sample.] Plants, such as Azaleas, Epacris, and some bedding plants, have stood under these Grapes, and none have been injured by damp. Patience with newcomers might be advantageous to some of us. *M. Temple, Babirmie.*

Masdevallias.—I have one more little fact to add relating to M. tovarensis, which will perhaps be interesting, if not novel, to some of your readers. In 1870 a robust plant of M. tovarensis flowered in the rich collection of E. Salt, Esq., at Fermiehurst, bearing three finely-developed flowers on one scape, a by no means singular occurrence. These

flowers withered in a week or two, as is usual, but the scape itself was not cut off, being allowed to remain on the plant, and this year is again producing three flowers from its apex. Another scape on the same plant bids fair for doing likewise. Phalænopsids often branch and flower from the latent buds down their flower-stems, if liberally treated, and the well-known Oncidium Papilio and its varieties continue to produce flowers after flower for years, from the same scape, but I believe it to be far from a common occurrence with Masdevallias; but perhaps this is because we eagerly cut off the flower-stems as soon as their floral ornaments are gone, or before, when cut flowers are required. *F. W. B.*

Successful Pine Culture.—An example of Pine-apple growing came under my notice when on a visit to Mr. Thomson at his establishment last week, which I think deserves to be recorded, viz., a smooth-leaved Cayenne Fine, 13 pips deep. It was one of many dozens of magnificent fruit swelling off, and ripe, and ripening. What weight this fruit will be when ripe, I will leave any Pine grower to guess; and when I say that all this splendid lot of Pines are growing in 9-inch pots, it makes them more remarkable. In my opinion this is the most successful piece of Pine-apple culture ever accomplished. Every plant, in its entirety, is as if it was cast in a die, so perfect are the whole. At Dalkeith, in my time, Mr. Thomson removed to the fruit-room in one day from 40 to 50 Queen Pines, ripe and ripening, in 10-inch pots, and not one of them was less than 4 lb. weight, for every one of them was weighed by myself, and booked as it ripened and was cut. What occurred 14 years ago is repeated with triple force to-day at the Cloveridge Vineyard, or rather Fineyard, I should say, for the enormous quantity of Fines grown there fully justifies the name. One may feast their eyes on hundreds of the beautiful mottled-leaved Black Jamaica Fine alone—a sight not common *aujourd'hui*. *H. Knight, Floors Gardens.*

Tomato Preserve.—I thank Mr. Burns for his kind information respecting the way in which he ripens his Tomatos, though I cannot see anything novel in the practice, having practised it myself for years as long as I can remember, and with satisfactory results in ordinary seasons, when the fruit has arrived at a pretty advanced state of maturity before being pulled up. But the past season has been unusually averse to the ripening of the Tomato, thereby causing a much greater number of green ones, some of which, if they were to hang by their roots from now till doomsday would never ripen; hence the necessity, or rather I should say the prudence, of snatching them from Jack Frost to make preserve, and risking getting into trouble with the cook. *E. Morgan, The Butts, Harrow-on-the-Hill.*

Cedar of Lebanon Seeding.—I beg leave to inform Mr. Earley that I have gathered perfect seed of this tree. In the month of November, 1860, I gathered a large number of cones from some of the grand specimens growing at Halden House, near Exeter, from which I extracted the seed, and sowed it the following March on a well-prepared bed in the open air. Not more than from 10 to 15 per cent. germinated, and nearly one-half of the number damped off a short time after appearing above ground. The remaining number were at the time I left (January of the present year) robust, healthy plants, from 6 to 9 inches in height. *T. J. Foote, Gr., Clevedon Court, Somerset.*

On the Importation of Oranges.—Allow me to mention an incident, which will not be without interest to some of your readers, perhaps in a nautical, certainly in a horticultural point of view. Captain John Spicer, of the ship Mary of London, received on board his ship at the island of Tobago, early in April last, a small chest, "contents unknown," addressed to a consignee in Scotland. On the ship's arrival at Greenock, May 28, the chest was opened by the customs; it was found to contain some clothes, and to be filled up with several dozens of Oranges (the large green variety), Shaddocks (Forbidden Fruit), and pieces of Sugar-cane. To his great surprise the whole were landed in perfectly sound and sweet condition, as if freshly gathered. The chest had been on board ship for fully eight weeks, stowed in the hold, which was filled with the steam of a sugar cargo, and probably 90° hot. It is not easy to account for the preservation of fruit under these conditions. But Captain Spicer thinks that a great deal is due to the chest having been nearly air-tight, the lid having been screwed closely down. Having the most perfect confidence in Captain Spicer, whom I have known for 30 years, and having just taken the narrative direct from his own lips, I need scarcely add that I do not entertain the slightest doubt of the accuracy of what he has stated to me. *G. S. Cundell, Clapham Park, November* 13.

The Certificated Grapes.—The remarks of Mr. John R. Pearson are fraught with his characteristic good sense, and though, like him, I have little sympathy with anonymous writers, yet in this age of cant and subterfuge, until "the glorious privilege of being independent" becomes more general, we must be content to allow secret writing. It is pretty well known that I have no sympathy with the committees of the Royal Horticultural Society—in fact, I have seen sufficient of committees to regard them as irresponsible bodies, for with neither persons to be kicked nor souls to be committed to the lower regions, men do things in secret conclave to which, indeed, really the majority would be ashamed to attach their names. I am free to admit there are upon these committees many persons for whose intellectual opinion I entertain great respect, but the public has no means of ascertaining that the awards are made by such men, and hence the whole of the awards are regarded with distrust. I object to secret judging altogether. More than 20 years ago I was one of the first to advocate both open exhibiting and open judging, and I must confess that in the case of either new fruits or new flowers the names of two or three men who are known to be practical judges would have more weight with me than that of a secret committee comprised of all the members of the Horticultural Society. The National Floricultural Society, which for many years held its meetings in the rooms of the Horticultural Society in Regent Street, was the best institution of the kind we have ever had. There the judges were selected for the special work they had to do. Was it Auriculas, Tulips, Carnations, Pelargoniums, Heaths, Azaleas, or Epacris? the best men in the country for each class were invited to judge them, and their signatures were attached to every certificate which the Society issued. If you were deceived you knew who had deceived you; with a committee like the present you get to a complaint "it was not at the meeting," or "I had nothing to do with it." This is not all, the best judges in the world may be deceived. No committee nor judge can avoid this except by consecutive examination for the whole season of the blooming or fruiting of the plant. This is impossible, and therefore, as I stated in the "Gardener's Magazine of Botany," many many years ago, would throw the onus of the award upon the exhibitor of the plant or fruit. I, as a judge, would say to the exhibitor, "We are disposed to make an award upon your exhibit, but the value of it must depend upon whether you are prepared to sign a declaration that the plant or fruit is constant in its habit, and that it is at all times as good as we have seen it to-day." Such a declaration would of course receive a special Certificate, and if not, no Certificate or none at all. In this way we should have something like a material guarantee of excellence, at present the onus falls upon the Royal Horticultural Society, which is blamed for certificating things got up for the day, and which may have no merit beyond it. This could be obviated by a rule being proposed by Mr. Pearson, to send certain practical men at the exhibitor's expense to see the growing plant on a certain day. Such a system would be no guarantee to me, indeed I would rather take Mr. Pearson's simple recommendation after a "single day plant-meeting" as the best men in the world. I have seen most of Mr. Pearson's seedlings for some years past in the growing state. Ferdinand de Lesseps is, as Mr. Pearson describes it, not only a new Grape, but a "new fruit," so sure and certain as I am of this, if it were placed in the mouth of strangers without their seeing it, it is questionable if the majority would not fail to state positively what fruit it was. A small plant in a 9-inch pot gave me this year 12 nice bunches, but it showed four times that number. Now, I do not say as Mr. Pearson does, "Rush in and grow this Grape," as what a great Grape-growing friend of mine calls "the vulgar rich," who worship size and symmetry, will surely be disappointed; but to connoisseurs I say, "Grow a Vine or two, and you will be delighted to have so choice a novelty to offer to your friends." The Chilwell White, which Mr. Pearson has withdrawn from sale, I saw last year before it was certificated, and considered it good and distinct, but it cracks. Dr. Hogg I also tasted before it was quite ripe, and considered it most promising, but after it was certificated I tasted it under very unfavourable circumstances. The two black Grapes—Emperor of Morocco, and what, for the want of a more euphonious name, I call Chilwell A 1—I believe to be really first-class and distinct. A 1 in my estimation comes nearer in flavour to that finest of all Grapes, the Black Hamburgh, than anything in cultivation at the present time; and, if it maintains that character, it will be a certificate of excellence good enough for all. Mr. Pearson is no foister upon the public of old kinds with new names, as has been the case with Novelties of late years, viz., Josling's St. Alban's, Kempsey Alicante, Golden and Muscat Hamburgh, and some others. The best abused Grape of the present time is the Champion Muscat, sent out some years ago by Messrs. Veitch. It is a dark purple Grape, when black, but when it cannot be induced to cast its coat, and become quite black, there is a howl against it amongst Grape growers as senseless as it is absurd. Royal Ascot, for prolificacy and constitution, is equal to the Black Hamburgh, and I can also from personal experience speak well of Mrs. Pince and Madresfield Court, which I could recommend the Golden Hamburgh, but the truth compels me to pass it by. *Wm. P. Ayres, Patent Hothouse Works, Newark-upon-Trent, Nov.* 13.

——It is astonishing to find a gentleman of the experience of Mr. Pearson opening his letter with the demand to know who is "Vitis" and who is "Lynx Eye," and raising the usual dust about stabs in the dark, &c. Why, the only direct reference to him was a most complimentary pat on the back. He did what no one has done before him—returned a certificate for a new Grape when he found it was unworthy of cultivation. And in criticising the action of public bodies, truth gains immensely by keeping clear of personalities. The Fruit Committee of the Royal Horticultural Society has either certificated fruit without sufficiently testing its merits, or it has not. If it has, it has laid itself open to criticism; if it has not, why does Mr. Pearson suggest inspection, &c., before certificating in future? or why, indeed, did he return his certificate? It is singular that Mr. Pearson, in his long letter, is totally silent about the Golden Champion Grape, which has mainly provoked these strictures. He confesses to have voted for the Golden Hamburgh being certificated, though most growers have discarded it. Most of us would be glad to learn if, and might "not be surprised to know" that, he also voted for the Golden Champion. At all events, he might have favoured us with an estimate of this new Grape. So little have any personal matters entered into my thoughts, that I was not aware that Mr. Pearson was on the Fruit Committee, neither do I remember whether he is the raiser of the new Grape, Dr. Hogg, or not; but since I had not the most distant idea of "attacking him." It is to be hoped, however, that the Fruit Committee will be able to offer a better defence than this gentleman has made on their behalf, else their case is hopeless indeed. He confesses great mistakes have been made in certificating Grapes, and likewise in withholding certificates. This is exactly what "Vitis" and myself have said. And yet no sooner have we specified examples of such mistakes, and suggested means of amending them in future, than Mr. Pearson rushes in with, "Who are?—name!—who are you?" It matters not a single straw, either to the Fruit Committee, the public, or to this gentleman, who we are. Only, what we have said is relevant to the question. Now Mr. Pearson finds no fault with that. He confesses to mistakes as much as we do. True, he conjures up difficulties, many of them imaginary, in the way of raising and of testing of new Grapes. We can get along very well with our old Grapes until better new ones offer, but we have a right to demand that worthless varieties shall not be certificated, and to this end I think we have a right to demand that means be taken to prevent its happening again. Your correspondent proposes a check upon certification,—that of personal inspection by a sub-committee of three before a certificate is granted. This is good as far as it goes, but it does not go far enough. One visit would not suffice to prove all points of quality, keeping growth. The visits would have to be repeated, and should be spread over two seasons; they would thus become very expensive, and it would beget greater confidence, and be more becoming to the dignity of the Royal Horticultural Society, to refuse to certificate Grapes unless proved in their own garden at Chiswick. As to varieties with peculiar constitutions that might refuse to grow at Chiswick, they are not such as would be generally useful, and ought to be left to find their way—if they can—or make their way—without the aid of a certificate. To intimate, as your correspondent does, that there are some who might not like to entrust their novelties to the officers of the Society, is a serious reflection upon their integrity, which I am unwilling to do. Under such a rule would be free to do as he pleased: those who valued the certificates of the Society would submit to its conditions, others, if there are any such, would not; but the great point would be, that the public would not be deceived, nor the Royal Horticultural Society brought into contempt. Under the present system, certificates for new Grapes will speedily be no better than waste paper. Permit me to ask your correspondent, in conclusion, How often the Fruit Committee saw the new Grape, Dr. Hogg, before certificating it? and wherein the Emperor of Morocco differs from its parent, the Black Morocco? Finally, I thought Ferdinand de Lesseps a curiosity in flavour, and agree with its raiser that it is not simply a new Grape, but a new fruit—in this sense, that it is larger than any of the musk-flavoured American Grapes that I have tasted, and I would have bought mine, not less of it, had the raiser now had thousands to offer, instead of not "a dozen left." Clearly, in his estimation it is not a Grape likely to sell, nor is it—unless to the curious. In this, also, I am at one with "Vitis." To Mr. Pearson, also, I am, as a Grape grower, thankful for his endeavours to raise new varieties; and no one will rejoice more than I, if many of his seedlings prove as first-rate as some of the Grapes certificated have proven worthless. Only let us have some efficient machinery to blow away the chaff from the grain, and the more grain—that is, new Grapes and other fruits superior to the old ones, the better. *Lynx Eye.*

Hoya bella.—I consider this one of the most beautiful plants for a hanging basket in conservatories that I have ever seen, when allowed to grow and hang down at will. The best treatment I have found for it is to keep it in a warm house near to the glass through the winter months, and, in fact, until the flowers begin to expand. Then remove it to the conservatory, where it should hang 7 or 8 feet high to see it to perfection. I have a plant flowering now in that position, covered with its pretty delicate waxy-looking flowers, it certainly is a beautiful sight. I expect it to remain in flower another month, and this is the second

time of flowering this season. In the months of May and June (although only a young plant), it had 120 heads of bloom, which lasted two months. I have seen large plants grown, neatly tied out with sticks, but in my opinion that is not the best way to grow it. *O. Orpet.*

The Madresfield Court Grape.—A correspondent in a contemporary, reviewing the gardens at Possingworth, where this Grape is largely cultivated, both on its own roots and grafted on a variety of stocks, states that it has shown a tendency to crack, more or less, on all of them, and this under the care of an experienced, energetic, and clever gardener. I had an opportunity of seeing many large fruit-growing establishments this season, both in the North and South of England, and its character as an early or late Grape was very promising. In an early vinery, in the last week in May, I saw a graft (on a Frontignan stock), carrying a fair-sized bunch, good in berry, as black as a sloe, with a beautiful bloom on. I saw it again about a fortnight later, with not a crack or fault to be seen, and the flavour excellent. Next came the fruit shows at Kensington, and the examples shown there stamped it as a first-class companion of the good old sorts. From the above I concluded at once to multiply its number pretty freely at Waterdale; but when I saw the Possingworth report, of its being so liable to crack, both on its own roots and grafted, I deferred planting till I should hear more about it. The liability to crack in a late keeping Grape is a bad fault, and I hope those gardeners who have an opportunity of fruiting it this season, and testing its merits, will freely give their experience to the readers of the *Gardener's Chronicle*. *James Smith, The Gardens, Waterdale, St. Helens.*

Coniferous Nomenclature.—I think Mr. Barron is rather hard upon me; still all lovers of Conifers must feel obliged for his remarks at p. 1227, and I thank him especially, notwithstanding the laughter at me, that I consider him one of the highest authorities on this subject I know, and he need offer me no apology for his "jocoseness;" but I don't see why he should consider my remarks at p. 1229 as odd,—they did not when I wrote them, neither do they now, appear odd to me. There is a Picea scattered far and wide over the country under three names, Iasiocarpa, Lowii, and Parsonsii, and not very long ago it was also called grandis. I received from the late Mr. Veitch, of Exeter, three plants of it, one under the first name, and also as P. grandis. All I said at p. 1229 was, that they were not P. grandis, and this I say now. I knew they were not P. grandis, because I had seen the true P. grandis growing in one of the pinetums at Elvaston Castle, but I did not know they were not Iasiocarpa; I also could see they were all three the same; and, as Mr. Veitch might be correct in calling one of them Iasiocarpa, I adopted that name for all three, but I only did so provisionally. I am by no means wedded to the name of Iasiocarpa, and will quite as soon call them Parsonsii, if Dr. Hooker or any recognised authority will authoritatively sanction it. It is, though not very euphonious, a very fair name, and for the reasons given by Mr. Barron I think a proper and appropriate one. But what's in a name?—call it what we will, it will still remain a very hardy, beautiful, fast growing tree, and will deserve every possible attention and a place in every collection: it ought indeed to be planted everywhere where any trees are planted. It is, however, I think, to be regretted that as it coned last season in the Knap Hill Nursery, a cone of it was not sent to Dr. Hooker, so that he might at once have settled question for once and all. I observe, in the very interesting catalogue of Conifers, evergreens, Roses, &c., sent out this autumn by Mr. Anthony Waterer, he adopts the name of Iasiocarpa. If this tree, which I have called Iasiocarpa, is not Iasiocarpa, is there such a tree in England? Mr. Barron tells us, "that no species of Picea exist at present in England to which the name of Iasiocarpa can be correctly applied." What, then, is the tree raised from Jeffrey's "first batch of seeds," and which is now at Borrowash? Is it the true Iasiocarpa by Dr. Balfour; and did Mr. Barron first see it in Edinburgh; and is it the same as that he was shown as Iasiocarpa by Mr. McNab, and which he did not think specifically distinct from Picea grandis of Douglas?" [See Mr. Barron's letter, p. 1300. Eds.] What is the origin of the name Iasiocarpa? Did Sir W. Hooker name a tree Iasiocarpa?—and if so, was the name given from the examination of a cone and specimen of foliage?—and if so, by whom was the tree found and the cones sent home? In Gordon's "Pinetum" the author gives "Pinus Iasiocarpa, Hooker," as a synonym for the "Picea amabilis, Loudon." I don't remember Mr. Loudon making any mention of this name (Iasiocarpa) in the "Arboretum Britannicum," but in Dr. Lindley's "Catalogue of Coniferous Plants with their Synonyms," published in the Horticultural Society's Journal, parts 3 and 4 for 1850, at p. 210, No. 18, I find † Abies Iasiocarpa, Hooker, with two notes of interrogation against it, and the sign † prefixed, signifying "not yet introduced." Must this sign be still retained? With respect to Picea magnifica, which I received as Picea amabilis, I knew it was not amabilis and I called it magnifica, instead of nobilis robusta, a name some adopted, because Mr. Barron told me he called it magnifica; but I and many others thought it looked very like nobilis, particularly those who adopted the name nobilis robusta. So, I said (p. 1229), "I suspect it will turn out to be only Picea nobilis, after all." To this "suspicion!" Mr. Barron also takes exception, but as he has sent a fine cone of it with a branch, and also a cone of P. nobilis, to Dr. Hooker, I hope the Doctor will, in the interest of us all, publish in your pages his opinion, by which I shall be proud to be guided. I must, however, put in a word for the retention of the name magnifica, if he decides it is not a nobilis, as magnifica appears to me a very appropriate name. It will some day, I feel sure, make a truly magnificent tree. As to Picea grandis, the tree which has been generally distributed in the last few years as the true P. grandis, and of which I have a specimen purchased of the late Mr. Veitch, of Chelsea, may be correctly named; but all I can say is, it has not hitherto done well with me, and it does not appear to do much better with Mr. Walrond, from what he says of it (p. 1229). As I have stated before, some years ago I saw the true P. grandis growing in one of the pinetums at Elvaston Castle, and I believe Mr. Barron has plants raised from it for sale; but whether or not the tree now generally called P. grandis is the same as that which I saw at Elvaston, Mr. Barron will know. My plant has "so tender" a look, I sometimes think it may be only a variety of Picea religiosa, and not a true P. grandis. I believe at Dropmore there is a specimen of the true grandis, but Mr. Frost calls it amabilis, as stated by Mr. Dod (p. 1328), while he also "shows a very handsome true P. amabilis under the name of P. grandis." I think, though I have no wish to speak dogmatically, that Mr. Barron is right and Mr. Frost is wrong. I should like to know whether either of those trees at Dropmore has cones, and a nice specimen of what I call the true P. amabilis, and which was planted for me here by Mr. Barron himself, and which I purchased of him; it was this spring covered with male blossoms, but I cannot see any cones upon it. Both Mr. Walrond's and Mr. Dod's communications are interesting, and, as the *Gardeners' Chronicle* always on the lookout for Coniferæ lore, I am thankful to them; but I am rather surprised they neither of them mention that king amongst the Pines, the Araucaria imbricata. I cannot suppose they have it not. May I inquire how the P. amabilis, and which was planted for me here by Mr. Barron himself, and which I purchased of him; it was this spring covered with male blossoms, but I cannot see any cones upon it. Both Mr. Walrond's and Mr. Dod's communications are interesting, and, as the *Gardeners' Chronicle* always on the lookout for Coniferæ lore, I am thankful to them; but I am rather surprised they neither of them mention that king amongst the Pines, the Araucaria imbricata. I cannot suppose they have it not. May I inquire how the P. amabilis, and which was planted for me here by Mr. Barron himself, and which I purchased of him; it was this spring covered with male blossoms, but I cannot see any cones upon it. Both Mr. Walrond's and Mr. Dod's communications are interesting, and, as the *Gardeners' Chronicle* always on the lookout for Coniferæ lore, I am thankful to them; but I am rather surprised they neither of them mention that king amongst the Pines, the Araucaria imbricata. I cannot suppose they have it not. May I inquire how

Cauliflowers.—I have been commending to some of the market gardeners in my neighbourhood Veitch's Giant Autumn Cauliflower as a first-rate variety for early autumn work, because of its great size and undoubted reliability of character. For market purposes, size is of immense importance in the Cauliflower, especially when combined with solidity, and whenever the seed shall be sufficiently cheapened Veitch's Cauliflower will certainly be found a prize turn for the London market in great quantities. I am, however, by no means prepared to commend it as forcibly for private growing. Like Mr. Gilbert, I hold that in this case "three heads in a dish is better than one," whilst the quality of small compact white heads as compared with that of large ones is vastly to the credit of the former. Of course the Giant Autumn variety can be cut small, but even then it is much larger in growth and requires more space than dwarf early kinds. Last winter I was furnished with a small quantity of Cauliflower seed that had been grown in the South of Europe; name, if any, unknown. Some of it was sown in a box the last week in January and placed in a cold house, from thence, a month later, the plants were pricked out into a frame, and finally transplanted into the open ground early in April. These headed in from the middle to the end of June, having the whitest, firmest, and dwarfest Cauliflower heads I have ever seen, and when cooked ate like marrow. On July 10 I sowed again in a box in the greenhouse, removing them into the open air when just showing rough leaf, and planting out finished growth of the time of sowing. From these I cut beautiful white, firm heads on October 20, and have obtained a constant supply since. From this experience of it I am induced to believe that it is the earliest fruiting Cauliflower that is grown. With the first batch of plants I was planting, plants raised from seed sown at the same time, of the Early Dwarf Mammoth; but the other kind beat that in earliness by a fortnight, and greatly excelled it in every other respect. I have, therefore, no hesitation in expressing my belief that, judged by its merits, it is the very best privately-grown Cauliflower I ever seen. I should add that Mr. Charles Lee, who saw it here in the summer, was quite enraptured with it, and expressed his conviction that the variety was quite distinct and new. *A. D.*

Vine Grafting.—Another very efficient mode of grafting the Vine, and which I would recommend to Grape growers, is the inarching of long pieces now, the end to be inserted in a bottle of water, suspended for the purpose. By grafting now you avoid bleeding, which in spring takes place. Old Vines, which have in too many cases bare wood, may be mended up in this way, and many varieties put on any one Vine. Men of ordinary tact will mend up lots of bare places in old Vines, and wherever, anywhere, will be the reward next year. I inserted several buds, too, of old wood last spring, as Mr. Miller has described Mr. Douglas to have done, and they each carried a bunch of Grapes. The former mode, however, I find to be preferable. The time when the scions are cut off the best for grafting is not nice long prunings may be selected and put on, and a small bottle of water to each will guarantee the whole. Our early Hamburgh house will get a mending this week, and any variety which may be considered desirable added. The late houses will get a mending when cutting *until*. The Muscat house, for instance, will get several of Golden Champion put on, Chasselas Napoléon, &c.; and the Lady Downe's houses will have an addition in Madresfield Court and Mrs. Pince's Black, and a good few of Gros Guilbaume and Gros Colman, &c. Grafting by the Vine in this simple and efficient manner I consider preferable to all others, since it throws new life and vigour into old Vines. The bottle of water will be understood to be in lieu of roots and soil in a pot. *H. Knight, Floors Gardens, Oct. 31.*

On the Growth of the Verbena.—I will begin my second letter on the growth of the Verbena by saying that I placed three of my spring-struck plants in a 7-inch pot, in a compost consisting of three parts of thoroughly decomposed cow-dung, two years old, and one part of good loam and leaf-mould and sand, all well mixed together. To make this light compost firm, I used a flat-headed pestle freely, taking care not to injure the plants or the roots. Having placed my tiles of crock cuttings out of the pit before referred to, I at once introduced my fresh potted plants there in place of them, plunging the pot to the rim in leaf-mould, giving both plants and plunging material a heavy sprinkling of soot-water. With plants so young and healthy, all making side growth up the stem, with compost so rich, and position in every way so favourable, no one will be surprised at a rapid progress being made. To all who have seen the common Vervain growing on a bare heap of cinders, and choosing that as its home, it will be no wonder to find the Verbena

1. Picea pectinata, the common Silver Fir.

2. Picea nobilis, most truly named. I have three grafted plants and two seedlings, which I believe came from Elvaston, and were raised from seeds ripened there; both are strong, handsome, very robust, but hardly so handsome in colour as the grafted plants.

3. Picea magnifica, in appearance like nobilis, but more glaucous.

4. Picea amabilis, from Elvaston, doing very well, but hardly so well furnished as a seedling plant would be.

5. Picea grandis, purchased of the late Mr. Veitch, of Chelsea; does not do well with me.

6. Picea religiosa, received from Mr. Veitch, of Exeter, but died either the second or third winter I had it.

7. Picea Webbiana, grew well here for some years, but was cut down for want of room.

8. Picea Pichta, not worth growing; cut down for want of room.

9. Picea balsamea, handsome and quick growing when young; dies here in seven or eight years.

10. Picea Nordmanniana, handsome, hardy, and quick growing; now coning.

11. Picea Pinsapo, handsome, hardy, and quick growing; now coning.

12. Picea cephalonica, handsome, hardy, and quick growing; now coning.

13. Picea bracteata, very handsome, very robust and distinct.

14. Picea Parsonsii!! called by me and many other folks hitherto lasiocarpa, very hardy, very handsome, very quick-growing, and very robust.

To this list I will add Picea Pindrow, though I have not got it, but there are several trees from 12 to 15 feet high, growing at Felton, the beautiful seat of the Hon. Alan Hopetoun, near here, which I believe to be P. Pindrow, and which are very handsome, and to all appearance hardier than F. Webbiana, and much greener in colour. F. lasiocarpa, true, I suppose I must mark, as Dr. Lindley did in his catalogue, not yet introduced. *C. F. P., The Grange, Kingston, near Taunton.*

delighting in the rich food I have described. Stopping now was a daily operation with some plant, or some parts of a plant, till within eight weeks of the show day, when I was bound to cease altogether from this work, and attend to training only. The bulk of my plants by show day were as large as a fair-sized common beehive, and not unlike it in shape, but not so with all. I remember one called Mrs. Yowell, a white one, and with the best formed flower I ever saw, the segments being so well filled up that it looked like a white Phlox, but it was a bad grower. This I trained to a flat face, but all the rest were cone-shaped. To say exactly how I trained each sort would be difficult. Suffice it to say, I so disposed the trusses of flowers over each cone as seemed to set it off best, and the trusses were both fine and plentiful. Finding I might have them in bloom a little too soon for the show, I removed them from their warm berth in the pit to the open wall by day, and took them into the greenhouse by night, doing this for a fortnight before the show. The key to my success here appears to me to be good living, bottom heat, and top air. To say I felt proud of my plants would be wrong, but that I felt pleased with them I must confess, even to a weakness, for all who saw them seemed delighted with their beauty. Should there be anything in the above remarks not sufficiently clear to the readers of the *Gardeners' Chronicle*, and I can in any way further elucidate the subject, would give me pleasure to do so. *R. T.*

Figs on the Open Walls.—The crops of these have been very late with us this season. The first crop was late to begin with, on account of the fine autumnal weather which we had last year. In fact, the year throughout was quite a Fig-season, bringing many of the successional fruits to maturity before the early frosts set in. At the same time, such fine seasons as the one of 1870, have their drawbacks by nearly forcing to maturity the majority of the crops for the following season, at least if they do not ripen they are so advanced in size, that, except the trees are big, all the fruit exceeding the size of green Peas prematurely drop off during the winter, or more particularly in the spring when the trees start into growth. In the spring of this year such was the case. Upon the removal of their winter covering only a few fruit were to be seen peeping out from the tips of the branches, consequently our principal crop was so late that all the leaves dropped off on October 11, with 7° of frost, and left the branches studded with fine black half-ripened fruit. Our Fig walls are about 120 feet long, and about 12 feet high, and well covered with fan-trained trees. The principal and most useful sort is the Brown Turkey, and I find it so for indoor purposes: it is almost an everlasting bearer with kind treatment. The Fig trees in question are very old, and I cannot well understand how they came to be planted upon a north aspect; I presume a south aspect would have been the best of the two for Figs. But be that as it may, taking the run of seasons we have generally fine autumnal crops of large-sized fruit. The shoots of this season are pretty well studded with small fruit for another year. Our system of cultivating the out-door Fig is somewhat different to that which I adopt for the Fig under glass. Against the wall out-of-doors the trees are kept thin of wood, giving them a good thinning about the month of July, to enable the remaining shoots to get well ripened before the end of the season. When all the leaves drop off with frost the shoots are regulated and nailed to the wall, and ultimately covered up for the winter. *J. Miller, Workshop Manor.*

Foreign Correspondence.

COLLIOURE: *October 26.*—Some time since, my friend Mr. Richard Hadmany requested me to collect seeds of the PHRAGMITES GIGANTEA, which grows at La Fontaine de Salces, between Narbonne and Perpignan, and to ascertain if this plant could be introduced into our gardens. I have just returned from Salces, whither I went in search of the reed in question, which is a plant of so much interest that I send you the following particulars concerning it.

This plant has been named Phragmites gigantea by Gay, P. isiacus by Kunth, Arundo maxima by Forskahl, and A. altissima by Bentham. Be its name what it may, the plant is a native of Egypt, and appears as an outlier in our northern latitudes. How is it that this plant should occur in this one spot only in France, or probably in Europe? Can it be a remnant of the ancient miocene or pliocene vegetation, as the Chamærops, the Myrtle, the Anagyris, and some other plants of exotic aspect are suspected to be by M. Martins, of Montpellier? The so-called Fontaine of Salces is a copious spring, almost a streamlet, which arises at the foot of a rock of a semicircular form, and whose concavity is turned to the south, and is completely sheltered from the north wind. The water of this stream is very limpid, and it is probable that it does not freeze in winter time. At the point where it issues from the rock it forms a little lake some 70—80 feet across, and of great depth. The waters of this lake are lost in the adjoining marshes. The reed grows on the borders of the lake throughout its whole circumference, forming compact tufts, and occupying a space of some 300 feet round the lake, but not extending beyond this distance, probably on account of the diminished temperature of the water. At the time of my visit the stems of this fine plant were 15—20 feet in height, and bore at their summit very elegant panicles of flowers, very like those of the Arundo Donax. These stems are annual, straight as an arrow, of the thickness of the finger, well furnished with large and beautiful leaves, of a tender green colour, not quite so thick or so stout as those of the Arundo Donax, but considerably taller. The Phragmites gigantea would indeed be worth introducing into gardens as an ornamental plant, but it is doubtful whether it would succeed out of the Mediterranean district. It is, moreover, essentially an aquatic plant, with its roots constantly under water. The surest method of propagation would be by division of the root-stocks, but it would be no easy labour for the workman to extricate them from the mud in which they grow.

Some of your readers may also be interested in knowing that I have succeeded in flowering in my garden at Collioure the curious GERRARDANTHUS MEGARHIZA, a Cucurbit, producing a large tuber 3—4 feet in diameter, and 1—2 feet thick, which lies on the surface of the soil, and is used by the Kaffirs for medicinal purposes. The plant is dioecious; my flowers are those of the male only. The dilatation of the stem is observable soon after the seed begins to germinate. From the stock spring a number of slender stems, which ultimately twine round a support. The flowers are about the size of those of the white Bryony, and are of a pale yellow-colour, and of a character unknown in Cucurbits. The three carpels of the ovary do not meet in the centre, so that the cavity remains, truly one-celled, though at first sight it appears to be three-celled. By the character of the ovules, Gerrardanthus forms a member of that group of Cucurbits in which the seeds are straight and pendulous.

Since the beginning of October we have had a plague of caterpillars. They have eaten up every green thing, even destroying plants which, under ordinary circumstances, they leave unhurt, such as Oranges, Cottons, Opuntias, Pyrethrums, and Leguminosæ, on the

Two or three years since I planted a plant of Passiflora cœrulea in my garden, a rooted cutting. It has grown so much, and suckers so abundantly, that it would soon occupy the whole garden! It is looked on as a weed, how it must destroy, as I do the Convolvulus, the Cynodon dactylon, the Sorghum halepense, and the Amaranthus prostratus, which are the pests of the garden here. This Passion-flower produces hundreds of flowers; but, though I have fertilised several artificially, none have set their fruits. Probably this species requires the pollen from another individual* in order to complete its fertilisation. *Charles Naudin, F.L.S.*

Societies.

STOKE NEWINGTON CHRYSANTHEMUM SHOW: *Nov. 14 and 15.*—The past season has been one of the most unfavourable for successful Chrysanthemum culture that has been experienced for many years. Such is the opinion expressed by the leading growers of this late autumn flower, and it needed only a visit to the show held on the above dates, in the New Assembly Rooms, Church Street, Stoke Newington, to confirm it, so far as that district is concerned. The show in question, which can lay claim as to numbers, and but very moderate in point of quality. We missed, too, the well-grown specimens which have heretofore usually been sent from the Brunswick Nursery, owing, no doubt, to the unfavourable to the backwardness of the season. Amongst the cut flowers, a few sorts of recognised excellence were fairly well shown in most of the stands, such as Mr. Brudeles, Indian red, with gold; John Salter, Primrosiana, white and fine; Cherub, golden-amber; Lady Hardinge, rose; Lady Slade, lilac and pink; Princess of Wales, white, tipped with rose; Empress of India, white, very fine; Prince Arthur, deep crimson; Guernsey Nugget, yellow; White Globe, good; Miss Mary Morgan, faint pink, a comparatively new variety, with broad incurved petals; Mrs. George Rundel, white; Golden Beverley, and White Formosum, both with pale yellow centres. With Ferns, a few Chrysaothemums, &c., which occupied a prominent position on a raised platform, and for which a special prize was awarded.

Notices of Books.

Flora of Tropical Africa. By Daniel Oliver, F.R.S., &c. Vol. ii. 8vo, pp. 613. Reeve & Co.

In our notice of the first volume of this work (1869, pp. 1238, 1264, we alluded to its general plan as being identical with that adopted in the case of the Colonial Floras of Australia, and Hong Kong. The arrangement is very different, in some respects, from that followed in the case of the Flora of the West India Islands and of New Zealand respectively, but not so different as to preclude them all from forming a single series — a series of very great present value to systematic botanists, but hereafter destined to serve the purposes of a wider class. The volume before us contains the description in English of all the members of the vast order Leguminosæ, the Rosaceæ, the Myrtaceæ, Cucurbitaceæ, and several smaller orders. As before Professor Oliver has availed himself of the assistance of other botanists in working up these families: thus while the Editor himself monographs the Cæsalpiniæ, Mimoseæ, Rosaceæ, Saxifragaceæ, and some smaller groups, Mr. Baker has dealt with the Papilionaceæ, considerably the largest series in point of numbers; Mr. Britten has described the Crassulaceæ; Prof. Lawson the Myrtaceæ and Combretaceæ; Dr. Hooker the Melastomaceæ, Cucurbitaceæ, and Begoniaceæ; Prof. Masters the Samydaceæ, Passifloraceæ, and the nearly allied families; Mr. Hiern, the Lythraceæ, &c.

The total number of species described in this volume we may reckon at over 1300, of which the larger number are peculiar to tropical Africa, and not found elsewhere. Among the Papilionaceæ there are no less than 91 genera, nine of which are peculiar. Some of the genera of this group are also very rich in species, *e.g.*, Crotalaria, with over 100 species, three-fourths of which, or even a larger proportion, are endemic. Indigofera is another instance of this kind; most of the Combretums and Melastomads, a very large proportion of the Cucurbits, and all the species of Begonia, are peculiar to the flora. Among the smaller groups we find a relatively large proportion of genera to species, and the latter almost all peculiar, as in the Samydaceæ, Turneraceæ, and Passifloraceæ, though not large as to number of species, have a relatively large number of genera, most of the members of which are absolutely peculiar to tropical Africa. On the other hand, some of the genera are widely dispersed, such as Sesbania, which has few peculiar African species, Onagraceæ also, especially in the case of the genus Jussiæa, are widely dispersed.

Considering now the species common to tropical Africa and to some other regions, and excluding a considerable proportion of plants found throughout the tropics of both hemispheres, we find that a large number are plants found not only in Africa, but also more or less diffused in all countries lying to the eastward as far as India, the Malay peninsula, and North Australia. It is strange that of these comparatively few are found in the islands of the Indian Archipelago, though there are two reasons for the exemption,—1st, in the moist climate; and 2d, in the imperfect state of our knowledge of the floras of many of those islands. Next to these is a much smaller group, common to the Cape and to tropical Africa. Still smaller is the number common to tropical Africa, and to the West Indies or tropical America. There is a slight infusion of Mediterranean types, while the mountains of Abyssinia furnish a few types identical with those of temperate Europe.

The above rough estimate of the plants common to tropical Africa and to other regions of the globe, is about the same as for the first volume. We may hence take it as established that the main features of the distribution are as we have stated them, and those who study the question will be provided with knowledge connected with the origin and mode of dispersal of species, whether by existing means of transport, or as effected by geological changes of level long since accomplished, or influenced by variations of climate, will have in these volumes—nay, have already—a vast body of carefully sifted facts whereon to base their speculations. To systematists, also, it is a great gain to get so large a number of forms described and arranged in order. Some of the plants, too, are of great interest from a morphological point of view, and here it may be noted that many of those plants which are peculiar in tropical Africa have marked peculiarities of structure; thus among the Passifloreæ are some eight or ten genera almost wholly limited to tropical Africa, and presenting structural features of much interest, and very different from those found in other members of the order in India, South America, or Australia. This again, is a subject which deserves the serious attention of those who are endeavouring to find some clue as to the mode in which the globe was stocked with plants, and at what times, in what directions, and by what means migrations of species took place.

A word as to Abyssinia. Any one looking through this volume and seeing the number of species described from that country, might naturally be led to the inference that our knowledge of the flora of that country had been largely increased in consequence of the campaign against Theodoros, but it is not so. We believe that all the materials were collected, and for the most part studied, before that memorable war, and that the expedition added nothing of moment to our knowledge of the botany of the country.

Of plants of economic importance mentioned in the present volume there is the Calabar Bean, yielding a poison made use of as an ordeal in Calabar, and as a useful remedy in ophthalmic disease in this country; the Kousso, an Abyssinian vermifuge; several of the Cassias and gum-bearing Acacias, besides numerous species useful as furnishing dyes, fibres, or other products.

* The circumstance alluded to by M. Naudin is noteworthy, as about London Passiflora cœrules produces fruit abundantly in the open air without artificial aid. We are not aware, however, if perfect seeds are produced out-of-doors in this country. ED.

Many of the plants, too, are of great interest to the horticulturist. We will name only one—we have named it before, and we shall call attention to it again and again, till we have the satisfaction of seeing so glorious a plant in our stoves. We mean the Camoecasia, the most splendid of Papilionaceous plants, with its large cream-coloured flowers, fringed at the edges and margined with gold. Even the Amherstia would seem to be no rival for this glorious plant.

The materials from which this book has been compiled are for the most part derived from the same sources as those made use of in the preceding volume, Dr. Welwitsch's specimens and notes have, as before, proved of the greatest value and importance; the remainder have been furnished by the collections of Barter, Mann, Kirk, Speke and Grant, and many others.

—— The fourth and concluding part of Mr. J. T. Moggridge's *Contributions to the Flora of Mentone* (Reeve) has lately been issued. It is characterised by all the good features which rendered the previous parts noteworthy, and those interested in the "critical" botany of Mediterranean plants, and specially those taking an interest in the relations of structure to function, and in the infinite modifications and adaptations of the former to varying conditions of the latter as well as in the nature and mode of operation of those conditions, will learn our regret at the announcement that the present is the last part of Mr. Moggridge's valuable and suggestive work. Our space will not permit us to allude to more than a very few of the interesting plants figured in this part, or to the many subjects of physiological importance connected with them. In Campanula Erinoides we have a plant worthy of being introduced into British gardens, if not already in cultivation. It is allied to C. fragilis, and is remarkable as growing along with Convolvulus sabatius on a little strip of coast near the town of Noli, and nowhere else. Nectarodon siculum is remarkable, *inter alia*, for the varying number of parts in the central as contrasted with the outer portions of its umbel—in this respect analogous to our British Gagea lutea, specimens of which exhibit very great diversity in this respect, as observed long since by the late Professor Henslow. Aphyllanthes monspeliensis has the habit and the capsule of a Restio with the flowers of a Squill. It is a very interesting plant, from its forming a link between the Rushes and Restios and the Lilies, and is altogether a plant that one would expect to find at the Cape or in South-west Australia, but not along the Mediterranean. In spite of its interest and its beauty it is rarely met with in English gardens. We saw it doing well, this summer, in Mr. Smee's garden at Carshalton.

The Apiary.

IT is an old saying that "to give advice, to find fault, and spend other people's money," are three of the most easy things in life; it is a truism. Mr. A. Boyle, taking up the first, in answer to "A. H.'s" questions at p. 1363 (very properly in my opinion), advises them to go to the idea of lining a bee-hive altogether. This was done on the outside with straw by a late very practical apiarian, the "Devonshire Bee-keeper" (or Mr. Woodbury, of Exeter); but how far it has answered for such purposes Mr. Neighbour may be able to inform "A. H.," as also arranging these long boxes, to be thus made into perfect harbours for all the insects of a garden. I am ready to find fault, and to add, this plan of attempting to make wooden boxes non-conductors by thatching them externally has never realised the expectations even of those who had adopted a similar plan for the interior, as I have proofs in six boxes I opened this season for a cottage bee-keeper. Mr. A. Boyle has truly advised "A. H." to retain the form of the hive and put on a cover; but my belief is, that no hive made on the true principles of the bar-and-frame hive can require any protection from heat, or cold, or wet. The square gives the best form for cheap carpenter's work. I shall be happy to give any bee-master who may apply through your columns for information a sheet containing all the directions necessary for constructing a cheap and effective bee-hive, requiring no sheds or covering; but I do so only on these conditions—there shall be no alteration of the sizes, or any introduction of glass windows or metal slides, &c., and that I may have the privilege of examining the hives when in the neighbourhood once they may have been made and used. This, you will admit, is "spending other people's money." *W. A. Munn.* [Major Munn has furnished us with a few copies of the drawings and directions herein referred to, which are at the service of those who make application to us, and observe the conditions. Eds.]

Garden Memoranda.

PENGERRICK, THE SEAT OF R. W. FOX, ESQ., lies a mile or two west of the busy town and lively harbour of Falmouth, and although shut out from view —that is, the beauties of it—from all but the happy residents, those who have the acquaintance of the noble-hearted proprietor might well ask, who has not seen Pengerrick? The owner and family are always pleased to allow visitors the enjoyment which the sight of their place never fails to give, and people never tire of it. Although small in extent, it is one of those lovely spots which Nature seems to have dressed herself, to give to the beholder feelings something akin to those which man must have felt when he gazed on her loveliness in primeval days. There is something so captivating to the eye when from the house you look down the valley and out to sea. Expressions of delight are heard from all who behold it. When the moon in silence sails over the sea, and yet seems to bathe herself in the freshwater lakes which extend up the valley, she gives birth to feelings which long afterwards are recalled with pleasure.

Adjoining one of the principal rooms Mr. Fox has constructed a cave-like passage, which leads into what may be termed an underground grotto, with a sky-light. It is here that the flimy Ferns are seen enjoying their situations, as if they were in a state of Nature. One of the pieces of Trichomanes radicans growing here was found in a wild state in Cornwall. It has not exactly the appearance of the plants generally seen, the fronds being shorter and more closely set together, giving it the appearance of another variety. Many other Ferns are growing out of the crevices at the sides, as well as Mosses, and all are in health and beauty.

In the grotto before mentioned are more Ferns. A fine plant of Trichomanes, peeping out of a miniature rock basin, is worthy a little walk, to see it at home. In the centre of this place, and resting on what appeared to be an old stump of a tree, is a nice plant of Todea superba. It is in perfect health, and although no glass covers are used to protect any of this class of plants, their fronds sparkle with moisture, which hangs like diamonds at their tips.

In a house connected with the above interesting spot is a more varied collection of Ferns. These are planted around on the borders, underneath which are pipes, which allow the air of the house to circulate. By this arrangement, the soil is kept moist, being warm, a less temperature is needed above. Tender Ferns often suffer more from cold at the root than at the top. The constant evaporation which is going on keeps the air in the house just in that humid state which Ferns delight in, and they are certainly contented with their quarters.

In another house, leading from a room at the opposite side, are some Tree Ferns, some of which have magnificent fronds, 10 feet long with proportionate width. This house is not heated, as the subjects in it are chiefly from New Zealand and Australia.

The front of the dwelling-house is covered with choice things, such as Passiflora cœrulea, Habrothamnus elegans, Virginian Creeper, variegated Ivy, the scarlet Begonia, &c. On looking down from the house the eye rests on the valley throughout, the blue sea in the distance giving the whole a beautiful finish. Each side is embellished with forest and other trees of choice kinds, with shrubs between.

The natural aspect of the place, together with its contiguity to the sea, from which the air is drawn up the valley, renders it with a comparatively mild climate. Hence Mr. Fox plants many things that any one situated a few miles distant would not think of doing. The severe winter of 1860-61, and those since that date, have, however, made sad havoc amongst the Arbutus and Tree Ferns, &c., which might previously have been seen. Of Palms, Chamærops excelsa is still there, apparently not at all hurt.

On going down the winding walks one is struck with something at every turn, and I noticed particularly a fine plant of Rhododendron Falconeri, which flowered in November. The bush is from 16 feet high—the previous season R. Thomsoni flowered in profusion; fine plants of Bambusa Metake and arundinacea; a grand example of Embothrium coccineum, 15 feet high, a beautiful object when covered with its scarlet Honeysuckle-like flowers—this is in a flourishing condition; several Oleanders, growing unpruned; Dracæna indivisa (one broken off was 18 feet high by 15 feet across) and D. australis; Aralia Sieboldii (Fatsia japonica); Laurus aromatica; Mitraria coccinea; the Olive tree; Eugenia Ugni, which grows into fine bushes, 6 feet by 4 feet, and fruits; Laurus Camphora, a fine plant, 20 feet by 16 feet; Chamærops Fortunei; the Loquat; Lapageria rosea, even, but not a large plant; Mesembryanthemums, and Echeverias of sorts, which stand out all the year round; and a variegated Yucca. There is also the Alexandria Laurel, or the Laurel of Victory, Melaleuca myrtifolia, fine bushy Acacias of sorts, as lophantha, affinis, and others, from New Zealand and Australia. Also Arundo Donax variegata, Phormium tenax, Bottle Brush, several Eucalypti, and Edwardsia microphylla. Indian Azaleas in a bed here are as healthy as any can be. A fine Araucaria, 30 feet high, stands boldly forward, a picture of health; also A. brasiliensis, looking well. Magnolias grown as standards do well, and flower well. The finest plant of Arundo conspicua I have ever seen is growing near a pond. Camellias do well here, as also do Rhododendrons, as witness a large specimen of R. ponticum, measuring 300 feet in circumference. The beautiful Woodwardia radicans (the Madeira Fern) grows to a fine size, some of the fronds being 8 feet long. I must not forget to mention the Sciadopitys verticillata, the Umbrella Pine; Gunnera scabra is also very fine, the flower stems, *i.e.*, isoluding the flowers, which look more like fruit, being 3 feet long and 8 inches through; Grevillea sulphurea and rosmarinifolia. Veronicas of sorts do well—one, a seedling raised on the place, is a very good scarlet. Daturas, Pittosporums, and Benthamias also do well; the latter, in their season, are a picture; the berries, however, are a great attraction to birds, and they soon destroy the beauty of the tree when the fruit is ripe. Here is also the Olive tree, and a few things which we could not recognise. Mr. Fox receives seeds from all quarters, and buys anything which he thinks will grow at Pengerrick. Variegated plants are well represented, both in shrubs and trees. Mr. Fox is an ardent lover of Conifers, and has a good collection. The variegated Pteris, Lomaria magellanica, and others we see in greenhouse collections, are here enjoying themselves in the open air. Heaths in varieties are planted in groups, and are looking well.

Passing over a rustic bridge covered with variegated Ivy, the visitor comes amongst water-ponds, fountains, grottoes, and their accompaniments, Water Lilies, grasses, Ferns, &c., which luxuriate. In the month of May and beginning of June, when spring is full dressed, the place is delightful, the yellow of Broom from the Rhododendrons, Azaleas, Roses, giving it splendour. In the autumn the tints of the various leaves on such a choice collection of things as is seldom seen elsewhere, are most charming. Spring begins here with the Snowdrop and ends with the Forget-me-not, in full bloom, standing side by side with it. The size of the place will not admit of any great display of flowergardening or spring-gardening, yet, with the indigenous plants and so many other subjects, there is never any want of interesting objects upon which to cast the eye.

Mr. Fox has a Conifer-ry of extra kinds and sizes. I noticed fine specimens of Abies Douglasii and Pinus insignis; there are also nice plants of Pinus patula, Abies Brunoniana, Pinus canariensis, variegated Thujas, Thujopsis, Yews, with other hardier and commoner things—such as flowering shrubs, and plants grown for their foliage.

The kitchen and fruit garden is small. Mr. Evans, the respected gardener, as well as his good employer, takes the greatest delight in the shrubs and Ferns, and in keeping up the characteristics of the place, so as to show forth the beauties of Nature. Although there are so many things of interest for visitors to see, yet it must be admitted that the chief thing after all is the place itself as a whole, as seen when standing in the front of the house, the beauties of which are very inadequately described in this brief sketch. *H. M.*

Obituary.

DIED, on October 31, at Euston Park, near Thetford, the seat of his Grace the Duke of Grafton, Mr. JOHN BORRIE, aged 73 years, and for upwards of 25 years head gardener at the above place. He was much respected and esteemed by his employers, the present and the late Duke of Grafton, being an excellent gardener, and, what is more, he was in all respects a very worthy man; his modest and unassumiug manners, and his kind and obliging disposition, gaining for him the love and respect of all who had the pleasure of knowing him. He was a native of Torloisk, N.B., and commenced his gardening career in the famous gardens of Dunkeld, the well-known seat of the Duke of Atholl. He was also for some years head gardener to Mr. Campbell, of Jura, and afterwards held a situation as gardener and land-steward at Torloisk, in the Isle of Mull. About 12 months since serious illness compelled him to retire from the duties of his situation, a pension being kindly granted him by his noble employer, which he has only lived to enjoy for one year.

Nov. 9.—A very fine day. Small amounts of cloud prevalent at times. Hazy and foggy. Aurora at night.
— 10.—A little cloud present at times. Very fine. Brilliant Aurora at night.
— 11.—Cloudless in the morning and at night. Overcast at mid-day. A little thin rain fell in the afternoon.
— 12.—Generally cloudless. Very fine. Dense fog.
— 13.—Cloudy in the middle of the day. Cloudless at other times. Foggy.
— 14.—Cloudless till about 3 P.M. Overcast after 4 P.M. Rainfall from 7 P.M. onwards.
— 15.—Generally cloudless, with the exception of a short period at mid-day, when the sky was overcast, and rain fell. Generally very fine.

JAMES GLAISHER.

Miscellaneous.

EARLY AUTUMN.

Along the brook the yellow golden-reeds,
With nodding plumes, stand idly swaying there;
Above the stream the summer's flying seeds,
Like tuneless insects, fill the balmy air.

A golden light upon the mountain sleeps;
Its feet are hid in valley vapours wet;
The highland Blackberry on the wooded steeps
Wears its ripe berries of enamelled jet.

The pearly clouds, becalmed within the sky,
Edged with pale gold, like summer castles stand,
Seen in a vision by some dreamer's eye,
Crowning the slopes of fairy-land.

The gentle winds scarce stir the fading leaves,
Scarce move the brown and withered clover-heads;
And undisturbed the busy spider weaves,
From bough to bough, her web of filmy threads.

Warm on the grass the brooding sunbeam lies;
The wandering airs are filled with faint perfumes;
The gazer's eye eaches each ridge descries
The upland Sumach's crimson-painted plumes.

Upon the topmost spray the blackbird sings,
With mellow note, his silvery-throated song;
The drowsy bee, with purple grossamer wings,
Hums his low, surly hymn the whole day long.

Idly I lie, with half-shut, dreamful eyes,
And listen to the sounds that fill the air—
The bee's low hum; the wind's melodious sigh;
The wanton blackbird twittering blithely there.

Oh, soon will come the melancholy days,
When Nature seems to wear a hidden grief,
And bleak and bare will be these pleasant ways,
Where moaning winds shall whirl the faded leaf!

GARDEN PIRATES.—Their "name is legion," and the wise gardener will always encourage feathered auxiliaries, as the insectivorous robin, tomtit, woodpecker, swallow, wren, starling, &c., all of which birds are indefatigable destroyers of garden pests. A hedgehog, a toad, a seagull or two, and a sparrow-hawk, all domesticated, will keep the soil and ground clear of mischievous vermin. The old-fashioned, but effective, mode of trapping earwigs, consists in putting tubes of elder-wood, open at each end, pretty thickly on the walls to which your fruit trees are trained. Every 24 hours these are gently removed and shaken into a pan of hot water and re-set. I have taken great quantities this way, but a robin will catch more in one day than all your traps together. A toad will subsist entirely on woodlice and slugs, and quite clear a Cucumber-frame if put there for a day or two. The common lizard or "eft" will eat up every flying or creeping thing he can swallow; the gull will stick to the slugs, Cabbage-grubs, and earthworms; the tomtit will search every bough for aphides, ants, &c., and if you do not fire off guns, or allow birds'-nesting, you will have plenty of useful friends among the birds of the air, to whom I do not grudge a little fruit, and if you do wish to reserve it all for your own eating, make or buy a net to screen it. The wireworm is the most unassailable of plagues, and he will prefer to attack all the neat edgings of Box. Where he abounds most, be always digging and putting ammoniacal manures or wood ashes, which will end in his gradual extermination. A crop of Mustard has been known to poison his strong-holds when all else had been tried in vain. Ants are very annoying; but, being dainty feeders, can be enticed into destruction. For the larger kinds, get some hones from fresh meat, and put them near the holes. When the horde is collected, sprinkle boiling water from the watering-pot over them, and then put in this till all are done for. Treacle and bird-lime, mixed rather soft, and put about in saucers, is a quiet and less troublesome mode of procedure, and sundry wasps will perish in the miscellaneous crowd. Here is a wasp-trap; but if you are a bee proprietor do not use it, as you will cause the death of many of your friends. Mount four panes of glass of equal dimensions in tin framing (like a lantern), leave the top and bottom open, cover the latter end with thick white paper, well attached with strong waterproof glue, and the paper well oiled, and protected from damp or rain. In this make a hole about 6 inches in diameter, and then place this hole over a plate on which three pieces of brick are put; in this plate you will have put a mixture of beer, sugar, and a little rum. On the top end you will have fitted in a glass pane, removable at pleasure, to clean the trap. Now prepare some long matches of stout paper dipped in brimstone; when your trap is "all alive" with captives, ignite a match and put it under the hole; they will soon be suffocated. Remember to carry out the same for your toad's meals. I once saw a most ingenious insect-catcher in Africa, invented by some English artisan. There was a wirework dome like a meat-cover, just below it a roller covered with cloth, saturated in syrup, slowly revolved when the clockwork adjustment had been wound up. Into this "Sirens' cave" every flying thing tempted to settle on the sweetstuff was unconsciously drawn, and the cage was soon a museum of Diptera and Hymenopetra! There was a trap-door at which the suffocating operation was carried out (as in the first-mentioned trap). It was altogether a great success, and I heard a "sweet young lady" call it a "capital dodge." *Eos*, in *"English Mechanic and World of Science."*

A FRUIT-GROWER in Jersey, annoyed by depredators, obtained a human leg from a hospital, put it in a steel trap in his grapery; made himself known to the owner; the neighbourhood flocked to see it, and—no more fruit was stolen.

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

CLIMBING stove plants should now be pruned and thinned out decisively and finally for the winter. Such plants as *Combretum*, *Ipomœa Learii*, &c., will already have suggested this proceeding, having become denuded of their foliage. Others, on the contrary, such as *Dipladenias*, some *Passifloras*, *Allamandas*, *Bougainvillæa*, *Thunbergias* and even tying *Stephanotis*, &c., should not only be cut back now to afford more light to the humbler subjects growing beneath them, but also as a means for inducing greater vigour next season, and to aid in assuring a season of rest. Especially is this thinning-out process essential in regard to the Stephanotis which, when very vigorous it may appear at this time, is very materially benefitted by being cut back pretty close to the older wood. I must qualify this statement, however, by remarking that though severe pruning has its advantages, we must not overlook the fact that, being an evergreen plant, it must be treated as such, and consequently should not be denuded of all its foliage, as deciduous plants often are. It is, perhaps, scarcely necessary for me to observe that water must in a great measure be withheld for a time from all such subjects. During inclement weather advantage should be taken to eradicate insect pests, such as mealy bug, &c.; *Orange trees* and others of the *Citrus* family should also, under similar opportunities, have their foliage thoroughly sponged and cleaned. Prune back old plants of *Vellozia*, *Pancratium*, &c., which have lost the back or sides of stoves, &c. Attend to *Lapagerias* also in the matter of tying out shoots and sponging the leaves, &c. Here is an instance where we are loth to use the pruning knife, but rather choose to maintain the whole growth for flowering purposes. Keep a watch upon any young shoots forming at the base, and which may be through the ground before many weeks are past, to save them from any slugs which may be lurking in their vicinity, as these creatures are very partial to them. Some care will now have to be taken not to expose the more delicate New Holland plants to draughts, the more so as we must give air with moderate freedom to cool greenhouses during moderately fine weather. Where seedling or other plants of *Solanums* of the Capsicastrum type are backward in ripening their fruit, and the plants are wanted for the winter festivities, it will be advisable to place them into a little warmth to forward them, as that season will shortly arrive. Plants of *Adiantum cuneatum* never succeed better than when allowed a season of rest at this time of the year. The best way of assuring this is to lay the pots on their sides, and to let them dry off gradually. The old leaves will by these means die down, and subsequently the crown of the plant will rest for a month or two; again showing vigorously by pushing up strong fronds about February. In drying-off these, as also many similar subjects, it is not necessary or proper to place them near flues or pipes. They simply require placing upon their sides on a cool and moderately moist bottom; in this way, the process will be carried out gradually, and far more naturally than when the end is sought for in more decided artificial means. Old plants of *Plumbago capensis* should now be headed-back roughly, so as as to occupy less room for storing, but do not throw any away; they will come in very useful for flowering in pots next autumn.

FORCING HOUSES.

I have frequently stated in these columns how very important I consider the practice of early pruning *Vines*. Immediately the leaves are shed, in succession houses, set about pruning. It matters not how long the Vines have to rest, as they will subsequently do so far more effectually than when they have to elaborate and prepare all the sap in the whole of the young wood. Those who force early cannot do better than have resort to the good old practice of getting assistance by means of a heap of fermenting materials placed within the structure. The advantages rendered thereby, deposited as it is in warm moist sweatings upon the Vines, so very unlike other artificial moisture we are enabled to apply, acts very beneficially, and tends to increase the strength of the buds and the young shoots as they unfold. If any Vine borders have been exposed to the past slight frosts, and are still uncovered, it will be well to have them covered forthwith, and a quantity of fermenting material should be prepared to cover them with shortly. Keep the early *Peach* and *Nectarine house* shut up closely on all occasions during the present, but three or four hours during the warmest part of the day,—this for a short time only at the start. *Cucumber houses* must now have the heating apparatus put in order for all eventualities, as without a full command of bottom-heat when wanted, added to both atmospheric heat and moisture in moderation, no very great success is possible. The plants, however vigorously they may be growing, should be so treated that all the moisture resting upon any of their parts is thoroughly dispelled daily, by means of fresh air, &c. I have lately urged the importance of covering the roofs of *Cucumber* and *Fine pits* by night, by which means the internal warmth is maintained without a tithe of the expenditure which otherwise occurs when the outer elements have full play upon the bare glass roof. As in very many establishments the supply of fallen leaves, to be depended upon to forward forcing operations, it will be necessary to use the utmost dispatch in collecting such as have fallen, many kinds being very late in falling this season.

HARDY FLOWER GARDEN.

It is very important that all who contemplate making alterations or improvements in their flower gardens should not delay doing so, as the best possible weather for such a purpose is generally whilst I write, and has continued for some time past, and might give way to an inclement and adverse period of lengthy duration. Make all necessary preparation against frost. I am trying a mode of protecting half hardy trees to which I may be allowed to call attention. *Passiflora Neumanni* and similar plants, as well as *Yuccas*, are frequently frozen to death when exposed, and not often improved in health when covered up for the winter. I am having small, thin haybands made, and these I twist around the main stems somewhat loosely, so that between and at the back the bark is just perceptible. I opine that whilst this does not exclude the air with its hardening influence, it will so protect the stem from the action of the frost as to save those portions of the protected wood which will afford the necessary shoots next season. To *Magnolias* this proceeding would also prove beneficial, especially in those home and seaside counties where it thrives well without any protection, excepting during very severe winters. The small haybands I describe might also be usefully twisted around the collar and lower portions of the wood of standard Tea and other Roses, which have been budded on *Rosa canina* without further delay. Should the grass upon lawns somewhat protected by trees again need mowing—and the grass should not be permitted to become too long during the winter, as the work of sweeping then becomes so much heavier, independent of appearance—care must be taken to mow it during "open" weather only. Neither should it be cut down so close at this period as to expose the heart too much to the winter's severity. Fallen leaves should not be permitted to lie upon lawns longer than possible, more especially in the vicinity of trees, as they cause the grass to grow weakly.

KITCHEN GARDEN.

All vacant ground should be deeply dug, ridged, or trenched before Christmas. Not only will it be better for the soils so operated upon, but it will also conduce to forward the work, which is always such as to keep the gardener fully occupied at the advent of the new year and subsequently. *Celery*, whether the first or last of the successional crop, should now be so protected that no injury from future frosts need be ex-

pected. The necessary fermenting materials, in the form of leaves, or half leaves and half stable litter, should be placed upon plantations of *Rhododrn* and *Sorkale*, in all instances where this method of forcing is adopted, and when a supply is required at Christmas or before—that is, if the leaves have so far ripened upon the Sealake as to part freely from the crowns, otherwise it is better to wait a week, as the last frosts will do their work in this way, and equal progress will subsequently be made by adhering to natural laws. *W. E.*

Notices to Correspondents.

APPLES, &c. : *C. P. Stewbley, Rucks.* We do not know either of the Apples you name. Their names savour of northern origin. You should inquire of the nurserymen who supplied them, and call their attention to the disgraceful manner in which the names were written on the labels. Beurré Bosc Pear is a very excellent dessert Pear, in use in October and November.

BOOKS : *T. F.* Kemp's "How to Lay out a Garden" (Bradbury, Evans & Co.); Repton's "Landscape Gardening," edited by J. C. Loudon.

ECHEVERIAS : *T. D.* These plants may be propagated by plentiful side shoots, and cuttings. The leaves on the flowering stems are equally efficient with the ordinary leaves. They should be taken off without injury to the base, and planted rather shallow, the larger ones being made firm by a small stick. Like other succulents, they must not be kept wet. Whenever seeds can be procured, they may be more extensively propagated by this means. A warm propagating pit is the best place for either cuttings or seeds.

FUNGUS : *Lattenbury.* Cyathus vernicosus, Bird's-nest Fungus,—"Silkercup" of the Scotch. *W. G. S.*

GEORGE'S PATENT CALORIGEN : Should any of our readers have used this stove for heating a plant-house, either by gas or coal, "T. C. W." would feel greatly obliged if they would kindly state their experience of it for this purpose.

GRAPES : *D. P.* The Grapes you have sent us are in a sad state, and half-ripe and unripe. Many similar failures are all caused through the low, damp, cold borders in which the roots are. The whole of the vessels of the plant are overcharged with moisture—the wood, fruit, &c., is soft and, so, consequently, liable to decay.

NAMES OF FRUITS : *S. C. H. Pear:* Crassane. *H. & S. Apple :* Nelson's Codlin.—*K. J. Apples:* 1, Holland Pippin; 3, Stamford Pippin; 5, Old Nonpareil; 6, Norfolk Beaufin. *Pears :* 2, Glou Morceau; 3, Vicar of Winkfield; 5, Flemish Bon Chrétien; 6, Glou Morceau.

NAMES OF PLANTS : *T. Rivers.* The Edelweiss is Gnaphalium (Leontopodium) alpinum. We copy the following particulars from Robinson's "Alpine Flowers:" —"The flowers are small, yellowish, and not ornamental; the leaves covered with white down, like those of many mountain Composite plants, but it has once distinguished by that to which it owes its popularity—a beautiful whorl of oblong leaves, springing, star-like, from beneath the closely set and somewhat inconspicuous flowers, and almost covered with pure white dense short down. It is a perfectly hardy perennial, growing from 4—8 inches high, and thriving in firm, sandy, or gritty and well-drained soil in thoroughly exposed places in the rockwork, and is one of the most interesting and desirable inhabitants of the rock garden."—*C. W.* Polystichum capense.

NOTICE TO LEAVE : *X. Y. Z.* You do not say what the agreement with your employer was. If there is no agreement, and you are paid weekly, you can only claim a week's notice.

PINE BORERS : *W. T., Cork.* This is the work of the small beetle called Hylurgus piniperda. No absolute remedy has yet been found, but care in removing all dead wood from the plantations is the best preventive. *A. M.*

PINUS INSIGNIS : *R. A.* The removal of dead branches, properly done, can do no harm.

PLANT NAMES : *L. H. G.* Acineta is derived from *akineta*, immovable, and refers to the jointless lip. Anguloa is commemorative of Don Francisco de Angulo. Cuitlauzina is commemorative of Cuitlauzin. Aida, Disa, and Limatodes appear to be unexplained. The specific names Brysiana, Cervantesii, Pinelli Schlieperiannm, and Weltoni, are all commemorative.

POTTING : *T. G., Forest Lodge.* We have grave doubts as to the policy of starting such a testimonial as you allude to. If the friends of the gentleman in question like to do so among themselves well and good, but the public is sick, and with good reason, of appeals to its purse; and, moreover, it would impose yet another tax upon the hardly-earned wages of many gardeners who would from many motives, personal interest not the least, feel compelled to subscribe.

TUBEROSES : *A Young Gardener.* We should certainly not think of "covering tuberoses over with ashes like other bulbs." Nor would we put them out, even if we possessed the new bulbs, but would rather wait until February, or even later. Pot them firmly in good staple fibrous sandy loam, subsequently placing them in a warm, sunny situation, there to remain for at least three weeks or a month without water, when, if they do not begin growing, give a little water and wait again. Supposing the plants to have made a fair start, and the roots to have pushed freely, water them more copiously both at the root and superficially, until a good tuft of leaves are formed; then, by withholding water, induce the flower-spikes to push, after which a return to a very liberal regimen will be requisite. *W. E.*

Markets.

COVENT GARDEN.—Nov. 17.

Business transactions have not improved during the week, and some difficulty has been experienced in maintaining our last quotations. The open weather enables the growers to keep us well supplied with all the outdoor produce, and fruit from under glass is also ample. Good dessert Apples are comparatively scarce. Pears are plentiful, and comprise Chaumontelle, Nelis d'Hiver, Glou Morceau, Crassane, and others.

FRUIT.

	s. d.	*s. d.*
Apples, per ½ sieve	2 0 to 5 0	
Cobs, per 100 lb.	60 to 65	
Filberts, per lb.	0 5 to 0 6	
Grapes, per lb.	1 6 to 5 0	
Lemons, per 100	7 0 to 10 0	
Melons, each	2 0 to 3 0	
Oranges, per 100	6 0 to 10 0	
Peaches, per doz.	8 0 to 15 0	
Pears, per dozen	1 6 to 2 0	
Pine-apples, per lb.	2 6 to 6 0	
Pomegranates, each	0 4 to 0 8	

VEGETABLES.

	s. d.	*s. d.*
Artichokes, per doz.	6 0 to 8 0	
Beet, per doz.	1 0 to 2 0	
Broccoli, purple, per bundle	1 0 to 1 3	
Brussels Sprouts, per ½ sieve	1 6 to 2 6	
Cabbages, per doz.	1 6 to 2 6	
Capsicums, per 100	1 6 to 2 0	
Carrots, per bunch	0 5 to 0 7	
Cauliflowers, per doz.	2 0 to 4 0	
Celery, red, per bun.	1 6 to 2 0	
white, do.	1 0 to 1 6	
Chilies, per 100	1 6 to 2 0	
Cucumbers, each	0 6 to 1 0	
Herbs, per bunch	0 2 to 0 4	
Horse Radish, per bundle	0 3 to 0 6	
Leeks, per bunch	0 2 to 0 4	
Lettuces, per score	1 6 to 2 0	
Mushrooms, per pott.	1 0 to 2 0	
Onions, per bunch	0 4 to 0 9	
Parsley, per bunch	0 2 to 0 4	
Radishes, per bunch	0 2 to 0 3	
Salsafy, per bun.	0 9 to 1 3	
Scorzonera, per bun.	0 9 to 1 3	
Seakale, per punnet	2 6 to 3 6	
Shallots, per lb.	0 8 to 1 0	
Spinach, per bush.	2 0 to 3 0	
Tomatos, per sieve	4 0 to 6 0	
Turnips, per bunch	0 2 to 0 4	

Potatos, Regents, per ton, 170*s.* to 190*s.*; Flukes, 120*s.* to 140*s.*; and Shaws, 80*s.* per ton.

POTATOS.—Southwark, Nov. 13.

During the past week the arrivals coastwise have been small, and very various in quality; best sorts sold well, inferior samples a drag. The following are this day's quotations:—Yorkshire Flukes, 100*s.* to 140*s.*; Yorkshire Regents, 60*s.* to 120*s.*; Dunbar and East Lothian do., 120*s.* to 140*s.*; Perth, Forfar, and Fifeshire do., 110*s.* to 120*s.*; do. Rocks, 95*s.* to 100*s.*; Kent and Essex Regents, 50*s.* to 110*s.*; do. Rocks, 90*s.* to 100*s.*

SALES BY AUCTION.

The Agricultural Gazette.

SATURDAY, NOVEMBER 18, 1871.

MEETING FOR THE ENSUING WEEK.

SATURDAY, Nov. 25 { Midland Counties Cattle Show, at Bingley Hall, Birmingham.

WE were on LODGE FARM, near BARKING, the other day, when the last loads of Mangel Wurzel were being weighed from a field of 8 acres and 24 perches, the whole produce of it having been thus passed over the weighbridge. The total weight brought home had been close on 437 tons. They were a remarkably large, well formed, clean set of roots, so that certainly not a tenth of what had been thus harvested would be cleaned or cut to waste in preparing them for cattle food, and we may therefore fairly put the nett produce of the field at 50 tons per acre. It is not a remarkably good soil naturally, and for the five years during which we have known it the land has borne large crops annually, and is being cleaned and worked in a manner. The whole of this enormous produce has thus been due to irrigation with town sewage; and those who know what a cost for dung and fertilisers must be incurred to grow a heavy crop of Mangel will probably learn more from a fact like this, than from a more elaborate proof, of the value of these great fertilising streams which are now running to waste from almost all large towns.

Mr. MORGAN'S "Report on the Cultivation, by Means of Sewage Irrigation, of the Lodge Farm, for the year ending August 31, 1871," * containing a number of such facts as the above, has just been issued, and will be read with interest as by far the most detailed and explicit annual statement on the general subject of town sewage that appears. It describes the experience of a year, which has presented a great contrast to that of 1870; and the present report is, therefore, in many respects in similar contrast to that which preceded it. Last year succulent growth was slow and scanty; this year it is abundant—last year, therefore, liquid manures were especially efficient—this year, comparatively speaking, they have not been needed. A dressing of farmyard dung has been washed into the soil by so much rain throughout the summer of 1871 that the market gardens have everywhere been unusually productive, and the great contrast to them which the sewaged grounds exhibited in 1870 has not been shown this year. Nevertheless, Mr. MORGAN reports as large a profit on Lodge Farm this year as was realised in the previous twelvemonth, and we doubt not this will be largely increased, as the farm is more and more cultivated, not merely for the purpose of exhibiting the fertilising power of sewage, but for the purpose of making the largest possible income in a case where sewage is accessible as an aid, and the farmer chooses to employ it.

The principal features of the report, we are informed, are "(1) a severe winter, followed by a very unusually long, cold, wet spring, and a short, broken summer—(2) 162 acres, 3 roods, 6 perches of land under irrigation—(3) 622,324 tons of sewage (weakened by previous admixture with excessive rainfall)—(4) very large crops—and (5) exceptionally low prices."

We must refer hereafter in greater detail to the several crops; meanwhile, we may name some of the plots, with the produce they have yielded —9 acres 2 roods and 11 perches (plot A) yielded £600 worth of Cabbage, Mangel, Sugar-Beet, and Onions within the year; 6 acres 1 rood and 5 perches (plot B) yielded £275 worth of grass, Potatos, and Savoys; 6 acres 3 roods and 4 perches (plot D) yielded £280 worth of grass and Oats. On the whole, 189 acres 2 roods and 23 perches yielded £5739, or £30 per acre—having received 3800 tons of sewage per acre during the year. Of course, a smaller yield would have been much greater had it not been for the immense quantities of irrigated produce which this year competed for a sale in the markets of the metropolis. "The average price," says Mr. MORGAN, "which our best Potatos last year realised was from £6 to £7 per ton. This year we have obtained no more than £2 to £2 10s. Onions, which sold last year for £43 per acre in the autumn, realised no great deal more by marketing, have this year been sold by us at £28, the highest price I have heard of being £30 per acre. In the autumn of last year cut Cabbages (collards) fetched from 1s. to 2s. 3d. per dozen, while this year there has been a difficulty to obtain 3d. and 4d. per dozen, some having even been sold, I hear, as low as 6d. for five dozen. Scarlet Runners, which made 8s., 10s., and 11s. a sieve last year, only reached 3d. and 6d. and 1s. until lately, when they have made 2s. and 2s. 6d. a sieve. Bunching greens have not paid us to market, and we have hitherto fed cattle on them. I have been told by several farmers that they have ploughed in their crops, as it would pay them better to use them as manure than to market them. These differences in price have not at all arisen from difference in quality, as our produce has been in most cases as fine and as abundant this year as last. Strange to say, that in the face of all this the retail prices are as high as ever, a cut Cabbage ordinarily costing 1½d., and a small dish of Beans 4d. and 6d., with everything else in proportion." To this we add the comment of the *Pall Mall Gazette*:—"It is more melancholy than strange. There are thousands of poor persons to whom vegetables are either used as manure or are almost given away by the grower, are well nigh starved for want of a dinner, being unable to pay the exorbitant price demanded by the retailer."

The report of Lodge Farm is of annually increasing interest, and the present publication will no doubt be very widely circulated.

THAT was a capital question asked the other day before the Botley and South Hants Farmers' Club—WHAT SHALL WE DO WITH OUR ROOT

* Metchim & Son, 32, Clement's Lane, E.C., and 20, Parliament Street, S.W.

CROP? We have a most abundant store of cattle food in the country, and all kinds of fatting stock are in great demand accordingly, and the price at which they must be bought in will thus, in all probability, leave but little margin for a profit on the feeding process. The many difficulties of the whole subject were well represented in the paper in which Mr. SPOONER attempted to answer the above question, and in the discussion which ensued. Notwithstanding these difficulties, Mr. SPOONER did not altogether despair of realising this profit. Mutton might be depended on to sell well, and the skin as well as the carcase would be valuable. He thought the value of the skin of a good teg in the spring would be nearly a sovereign, and though they did not directly get paid for it, yet it was done indirectly. Therefore they must not think of entirely ploughing in their root crop as manure.

Mr. SPOONER proceeded to discuss the value of the crop as food and as manure, supposing it to be either used in feeding fatting stock or ploughed under. It had been proposed by those who despaired of realising any return from its consumption. The manuring value of linseed cake was £4 10*s.*, of Wheat, 35*s.*, of Barley 37*s.* per ton, of Turnips only 4*s.* per ton. Applying the same rule of valuation, as when applied to guano and superphosphate, to bring out the market value of these substances, it is found that the manure value of a crop of 20 tons of Turnips is not more than £4. The value of the grains for manuring purposes was now nearly double that of the bulb—in proportion to their weight. This was a good reason why this year all greens should be ploughed in as manure. Lothian farmers, with whom he had lately conversed, had told Mr. SPOONER that they sometimes sold their roots to cowkeepers, and offered £2 per acre to allow the greens to remain on the land, and the cowkeepers universally refused to part with the greens. Returning to the question of root value as food, Mr. SPOONER, comparing Turnips with linseed cake, stated that the theoretical value of a ton of Swedes was something like 16*s.* 6*d.*, the great obstacle to the practical realisation of this value being the immense surplus of water which a Turnip root contains.

Experiments had been tried with five sheep, which ate on an average 23 lb. of chaff per week, or 3 lb. 4 oz. per day, and they drank 5 lb. 11 oz. of water per day, or 40 lb. per week apiece. Others consumed 18 lb. of hay, and 7 lb. of beans, and drank 43 lb. of water per week, or 6 lb. 2 oz. per day. He pointed out that this quantity of water was only equal to that contained in a daily allowance of 7 lb. of Swedes, and this would show that when Turnips were given in large quantities to sheep an immense quantity of water is taken into the system. By eating roots to excess, they take up four times the quantity of water they require, and it does them no good. It might be asked, then, what is a reasonable use of the root crop in the feeding process, a greater value per ton might be obtained from it. The following were the recommendations to which the lecturer pointed :—(1) to cut off the greens, and plough them in as manure ; (2) to pit the roots as much as possible, for after they were kept some time they would lose 10 per cent. of water, and then they would be quite as valuable if, after all, they had to plough them in. They would thus get the roots more nutritious by the loss of this water, and prevent the starchy matter from being converted into woody fibre. The remainder of Mr. SPOONER'S lecture was devoted to the consideration of the policy of growing Sugar-Beet, a point somewhat beyond the strict limits of the question under consideration.

Mr. SPOONER was followed by Mr. J. BLUNDELL, whose speech was full of useful information and good advice. His answer to questions in the first place seemed to be—"Wait, wait." How did they know what the winter would be? They would not know before February 1 how their root crop might turn out. Some of their roots were grown very quickly, but how did they know whether they would withstand the frost?—and therefore he said that ploughing-in the roots in a reckless manner would expose them to a great risk. It might, however, be desirable, if they ultimately found they had too many for feeding the cattle, to plough them in, and in that case his recommendation was to get them cut up. He would take the cutter into the field ; the roots could be pulled up and put into it, and then the pieces could be put in heaps and spread over the land as manure. There would be a profit off sheep, but they were exceedingly short of them. Of wether sheep there were only a few left. In another year, drawing on them as they had been doing, they would dispose of the whole of them. This was a very serious matter for the consideration of the people of this country. It was a matter of the greatest possible moment to the consumer, because every day the quantity of sheep was diminishing, and they must be dependant on beef only. They had ransacked the whole of Europe for cattle, and the importations only amounted to 9½ per cent. of the home consumption. This diminution in the supply of cattle and sheep was no doubt owing to the shortness of keep in previous years, and sheep and cattle had to be slaughtered because there was no food for them. While the relations between landlord and tenant existed as they now were, that deficiency would never be made up. A tenant would not lay out his capital in the purchase and rearing of stock while the relations with his landlord were unsatisfactory ; but let the restrictions which at present encumber leases be removed, and then the tenant would bestir himself. Even in respect of Sugar-Beet, to which reference had been made, the same truth applied. He would not go into the calculations about growing it, but ask how many tenant-farmers were there who dared grow it for sale? He asked any gentleman present who did not farm his own land to look into his lease, and see whether he had any power to sell Sugar-Beet. [We do not refer at any greater length to the discussion on the growth of Sugar-Beet, to which several subsequent speakers contributed.]

The question on the card ultimately regained the attention of the meeting. Mr. C. HOLDWAY recollected 25 years ago having had a large supply of Turnips, and he was about to turn them into the ground, when a neighbour came along and called him a destroyer of food, and he gave him permission to feed 200 sheep on the Turnips for a fortnight. He, however, ploughed the crop into the land, by the side where the sheep had fed. He sowed the land with Barley, and had a sack per acre more there than on the place where the Turnips had been fed off by the sheep. His neighbour said it was all chance. But that did not satisfy him, for he felt that the sheep, having come to feed, took something away. What they left was about 4*s.* per ton as manure, whereas the Turnips would have been worth more if he had ploughed them in instead of given them away.

Mr. SPOONER, in reply, said young animals would certainly take up more of their food than old ones. A young animal would take up more of the albuminous parts and retain them in the flesh than the older one, and thus the manure of an older animal was much more valuable than that of a young one, as more of the nitrogenous parts were retained in the system. The more food food they gave an animal the more valuable the manure became. The larger the quantity of nutritious food the better would be the manure from it. The most profitable way was to give the food in that proportion which would best suit the animal.

—— A small supply of English Wheat at Mark Lane on Monday was sold at the extreme prices of that day se'nnight ; less firmness, however, was observable on Wednesday.——The prices of beasts recovered at the Metropolitan Market on Monday, owing to a short supply and the weather being favourable for slaughtering. It was difficult to realise late rates for choice sheep. Wednesday's trade was dull, at about Monday's rates.——The prices of Hops are fully maintained.

—— Owing to Mr. MECHI's advanced age, the pressure on his time, and his not having a secretary, he desires to apologise for any default in replying to correspondents.

—— Mr. HENRY CHEFFINS, of Easton Manor, Dunmow, is elected Chairman of the Farmer's Club for 1872.

—— Last Friday's "London Gazette" contained a long series of Orders in Council, giving such licence as is needed to enable the Smithfield Club to hold, at the Agricultural Hall, in the parish of Islington, in the metropolis, on December 4, 5, 6, 7, and 8, 1871, their exhibition of cattle and other animals. The following are the more important regulations and exceptions enacted :—

"Cattle that have been in the metropolis for more than seven days before the opening of the show shall not be admitted thereto, and cattle brought to the metropolis for the show shall be taken direct thereto.

"No cattle shall be admitted to the show without a licence for the purpose from the Commissioner of Police of the metropolis, or of the City of London.

"Each animal before admission to the show shall be examined by the veterinary surgeons for the show, or one of them ; and if on such examination any animal is found to be affected with any contagious or infectious disease, it shall not be admitted to the show.

"If any case of cattle plague occurs in the show the Council of the Smithfield Club shall cause all the animals in the show to be forthwith slaughtered, in pursuance of the condition to that effect contained in the licence.

"If any case of foot-and-mouth disease occurs in the show the following regulations shall have effect :—(1.) The animals affected with foot-and-mouth disease shall be slaughtered in the metropolis, and for that purpose shall be moved to a slaughter-house, with a pass of the pass-master of the show ; (2.) The animals not so affected may be moved and dealt with as if a case of foot-and-mouth disease had not occurred in the show.

"If no case of contagious or infectious disease occurs in the show, cattle exhibited in the show may be moved (in accordance with the provisions of this order, and not otherwise), as follows :—(1.) They may be moved out of the show for slaughter in the metropolis ; (2.) They may be moved out of the show, and then alive out of the metropolis.

"All cattle exhibited in the show and not moved out of the metropolis, shall be slaughtered in the metropolis on or before December 21, 1871.

"If the cattle are moved out of the metropolis otherwise than by railway they shall be conveyed, without stopping, from the show out of the metropolis in properly constructed cattle-vans.

"Provided that if any cattle being so moved, while in the metropolis, accidently or otherwise in contact with any cattle not having been exhibited at the show, they shall not be moved out of the metropolis, but shall be slaughtered in the metropolis."

—— The *Midland Counties Herald* thus refers to the forthcoming Cattle and Poultry Show at Birmingham :—

"The aggregate entries are considerably more numerous than for either of the two last years ; the increase being most apparent in sheep, pigs, roots and pigeons. As regards cattle, we believe there is good reason to anticipate that while all breeds will be adequately represented, the Scots will be especially strong ; while the miscellaneous class of pure-bred sheep will include two varieties which have never yet made their appearance in these annual competitions—namely, the Border Leicester and the Dorset horned. The root department, which, by-the-bye, is also an interesting feature, will be more so than usual on this occasion. The display of Potatos will be unprecedentedly large, and all the sections will be well filled ; the very elaborate system of classification adopted by the Council having been received with general satisfaction by the leading growers of that valuable esculent. A new gallery, 220 feet long by 15 feet wide, has been erected on the Cambridge Street side of the hall ; and will be devoted to the stalls of seedsmen, and to light articles : the existing galleries being reserved for the roots and pigeons. Altogether, therefore, the prospects of the 23d of these great exhibitions are very encouraging."

The following figures give the statistics of the last four years in comparison with the figures of the forthcoming show :—

	1867.	1868.	1869.	1870.	1871.
Cattle	122	173	111	151	152
Sheep	82	103	50	75	84
Pigs	51	47	45	61	73
Roots	76	170	126	234	253
Corn	45	44	36	46	45
Poultry	2111	2315	1674	2122	2089
Pigeons	565	432	482	441	546
Total ..	3083	3284	2823	3130	3342

—— The third anniversary of the BANBURY ROOT SHOW took place in Mr. PERRY'S grounds last week, and was remarkably well attended. Three hundred entries competed for the prizes. The judges were Mr. GEORGE GARNE, of Churchill Heath, Chipping Norton ; and Mr. HENRY SIMMONS, of Bearwood Farm, Wokingham, Berks. Mr. W. FRENCH'S 12 Swedes of Perry's Bangholm Purple-top variety, weighed 191½ lb., and took the 1st prize. There were 61 entries in this class. The prize Yellow Globe Mangels weighed nearly 20 lb. a-piece, and the Long Reds averaged exactly 30 lb. each ; and in this class a special prize was also awarded to the Banbury Local Board of Health for Mangels grown under sewage irrigation.

—— The reply from the Privy Council Office to Sir GEORGE JENKINSON'S letter, published in the *Agricultural Gazette* last week, states, among other things, that—

"Their lordships are of opinion that the provisions of the Contagious Diseases (Animals) Act, 1869, which prohibit the movement of affected animals and provide for general disinfection, and the powers conferred on the local authorities by the Order of Council of October 1, 1870, for making regulations with regard to local disinfection, and the movement of animals herded with affected animals, would, if effectually carried out, be sufficient to check the spread of foot-and-mouth disease ; but their lordships are also of opinion that no action on their part, short of stopping all markets, fairs, exhibitions, and sales of animals, and putting very severe restrictions on their movement, would actually eradicate this disease, even for a time ; and they believe that such stringent measures, although submitted to in order to stamp out cattle plague, would not readily be borne in the case of foot-and-mouth disease. The experience of the last two years confirms their lordships in this belief. In 1869, owing to the pre-

valence of foot-and-mouth disease, the Privy Council issued an Order applying thereto, throughout Great Britain, regulations somewhat similar to the pleuro-pneumonia rules in the 7th schedule of the Contagious Diseases (Animals) Act, 1869; but, owing to strong representations from many counties, they revoked this general order, and came to the conclusion that, as regards this disease, it was better to give discretion to the local authorities to act according to local circumstances and the opinion of their districts. By an Order of Council, therefore, of October 21, 1870, local authorities were given power to supplement the Act by regulating the movement of animals herded with those suffering from the disease, and thus provide, if they thought fit, against its spread; but less than half the counties in Great Britain appear to have exercised this power. . . . With regard to the opinion expressed in the resolution, that only compulsory slaughter at the ports of quarantine of foreign stock will prevent the introduction of contagious or infectious diseases into this country by the importation of such stock, it appears to be assumed that the presence of these diseases in Great Britain is due to this importation. No doubt it will be difficult in this, as in any other negative case, to prove the contrary, but especially as regards the prevalence of the foot-and-mouth disease, the facts do not seem to support this assumption. It appears that foot-and-mouth disease existed in this country three years before the prohibition on the importation of foreign animals was rescinded; and that the prevalence of the disease since that time has not been greater numerically than before, increased with increased imports, nor decreased with a lessened import of foreign animals. Their lordships have been informed that the late outbreak is attributed to the increased importation of Irish cattle through not at any other port in this country except London, that the cow-keepers at Harwich and Dovercourt are in the habit of filling up their dairies with Irish cows, and that there is scarcely a farmer in Dovercourt parish who has not taken these cattle into keep."

—— The following account of a meeting of the NEWCASTLE FARMERS' CLUB, held to receive the report of a deputation which had visited the Wolverhampton trial-grounds, looks rather as if there had been a foregone conclusion in favour of FISKEN'S SYSTEM of STEAM CULTIVATION :—

"Mr. JOHN GREGORY (Westoe), advised farmers to see such trials with their own eyes. It was his opinion that two 20-horse engines, 'weighing about 40 tons,' were quite impracticable for steam cultivation. He coincided in the opinion that even if there were any difficulty in a traction engine hauling all the tackle connected with the FISKEN system from one field to another, or from farm to farm, it would be better it would take from finishing work in one field and starting work in another, the fields being one mile apart?

"These two questions, Mr. WALLACE (one of the deputation) said were of a somewhat difficult character. One farm might be situated upon an elevation, while another might lie in a deep valley; in either of which cases there would be some difficulty in getting a traction engine—for FISKEN'S engine is a traction engine. On an ordinary road, however, any engine could travel; and he could not see the slightest difficulty in getting the traction engine and tackle connected with FISKEN'S system removed from one farm along such a road as that separating the second question, it was shown that a correct answer dependend entirely upon the state of the roads, and that if the field was large much work could be got through without shifting the tackle; while, on the other hand, if the field were small, considerable trouble would be occasioned. He contended, however, that FISKEN'S was a most efficacious system for fields of any size, far surpassing that of Smith in this respect. That system also most advantageous for the purpose of removing from field to field. The engine could stand on the road, or near a well, and from this position every one of the fields in fallow—and as steam ploughing became more associated, farmers would quit their fallow, and have as many fields adjoining as possible—could be ploughed, so that it would be only shifting the tackle from field to field, and not the engine and the tackle. He had no doubt that when once a farmer got FISKEN'S tackle on his place, he would not part with them until he got the whole ploughed, or any rotation of cropping which he might have for the time being."

—— We learn from the *North of England Farmer* that the best SCOTTISH DAIRYMEN have at length beaten the best men of Somersetshire in their strongest point, the quality of the hitherto unrivalled Cheddar cheese :—

"A few cheese-makers in Somersetshire—10, or 15, or so in number—still, it is said, surpass the best makers of Cheddar cheese in Scotland. Last year the men of Galloway, with great spirit, offered to bring the matter to a practical test by a competition, but the Somerset men declined to meet them. This year a competition, though on a small scale, a few of the Galloway men this year applied to an eminent English cheese-factor who gets the produce of some of the best dairies in Somersetshire; and he selected two "thoroughly fine" specimens for exhibition at Kilmarnock. A Scotch cheese was selected for comparison with the best English one. The Scotch cheese was one of the two which had been placed 1st at the late show of the Ayrshire Agricultural Association by Lady STUART MENTEATH'S prize. The judges took half an hour to come to a decision, and they were not satisfied till they cut both cheeses through the middle. The quality of the two was wonderfully near. The Somerset cheese appeared to have the advantage of being a month older than the other, and it excelled a little in 'style.' Though no more than the usual width, it weighed 170 lb. The Galloway cheese might be three-fourths of that weight. It was equally fine in colour, 'texture,' and quality, and rather excelled the other in flavour. In the end, the unanimous decision was in favour of the Scotch cheese. The result is honourable to Mr. GARDINER, Baldoon, the maker of the Scotch cheese, and encouraging to his countrymen, who do not wish to rest in the second rank."

OUR LIVE STOCK.

CATTLE.

A NEW catalogue of the Kingscote herd, dated November, 1871, has appeared. It contains a list of 49 females and 13 bulls, most of which trace back to Mr. Bates' stock. The 3D DUKE OF CLARENCE'S bull *Ariel Duchess*, by Major Gunter's DUKE OF WHARFEDALE (19,648), and tracing back to *Ariel* by 2D CLEVELAND LAD (3408). This family is further represented by *Ariel Marchioness* by 3D DUKE OF CLARENCE, and daughter of *Ariel Duchess*, a very grand roan calf. The "Bickerstaffes" form a group of four, at the head of which is *Countess of Bickerstaffe* by 4TH DUKE OF OXFORD (11,387), dam *Capsicum* by GENERAL CANROBERT (12,927), g.d. *Clevelard* by Mr. BELL'S BELLFOUNDER (13,586). This last-named cow is also the common ancestress of a family represented by *Clove, Comfort*, and *Cordial*, all descendants of *Cinnamon*, own sister to *Capsicum*. We next find four "Wild Eyes" cows and heifers, after which we find a long array of "Georgianas," tracing from Earl Ducie's 4TH DUKE OF OXFORD, and a fine succession of sires bred by Mr. R. Bell. The "Honeys" have long been identified with Kingscote, and are at present represented by no fewer than 16 females and five young bulls. This very considerable group of 21 in all is headed by *Honeymoon*, bred by Col. Kingscote, got by CALEB (15,718), dam by VICEROY (13,945), g.d. by OREGON (8371), all three sires being Kingscote bred. Next in order we find PREMIER (7344), bred by Mr. B. Wilson, and previously Mr. J. Stephenson's BELLEROPHON (5140), ALDERMAN (2976), and Mr. Stapleson's WATERLOO (2816). Two Oxfords, two Acombs, several members of Mr. T. Bell's Poppy and Peach tribes, two Seraphinas and a Surmise heifer bring the list to a conclusion. The young stock is by 3D DUKE OF CLARENCE, the cows and heifers are in calf to this sire and the American importation, DUKE OF HILLHURST, bred by Mr. M. H. Cochrane, of Hillhurst, Compton, Canada. This promising young bull is unexceptionably bred, being by Mr. S. Thorne's 14TH DUKE OF THORNDALE, dam *Duchess 97th* by 3D DUKE OF WHARFEDALE (21,619).

The 3D DUKE OF CLARENCE'S 2-year-old stock at Kingscote are a grand lot—all roans but one, which is red. The Burnett blood seems to the calves of the present season by this bull are better than those of preceding years, which fully bears out what he stated in our impression of May 20, as follows :—

"The calves by the 3D DUKE OF CLARENCE in 1868 and 1869 were not so well formed as those of 1870, and the calves of the present season are of still better form in appearance. This agrees with a case recorded by Mr. Bates of one of his best stock-getters, that his first season's calves were nothing grand, that his second season's calves were better, and that his third and fourth seasons' stock were really grand animals."

Mr. Burnett considers that a bull is most valuable as a sire from three to six years old. Before that age the produce is as large, but lacks "smartness" and "grandeur."

—— The following are the most recent additions to the Towneley Park herd :—

July 3. *Duchess of Lancaster 2d*, a red cow calf by BARON OXFORD.

Aug. 5. *Towneley Butterfly*, a roan cow calf by BARON OXFORD.

Aug. 12. *Duchess of Lancaster 5th*, a red with a little white bull calf by BARON HUBBACK.

Aug. 14. *4th Maid of Oxford*, a red and white bull calf by BARON OXFORD.

Sept. 4. *Gipsy Gwynne*, a red bull calf by Mr. Barber's OXFORD BARON.

Sept. 13. *Puff*, a red and white bull calf by BARON OXFORD.

Sept. 13. *Baron Oxford's Duchess*, a roan cow calf by OXFORD BARON.

Oct. 7. *Cheerful*, a red with white bull calf by BARON OXFORD.

Oct. 12. *Butterfly's Wing*, a red and white bull calf by ROYAL BUTTERFLY 21ST.

SHEEP.

MR. CORBETT informs us that he does take his types of Leicester and Lincoln beads from the shaven and trimmed countenances exhibited at our shows, and challenges us to point to a better type. The question raised by our critic three weeks since entirely concerned the presence or absence of a top-knot in these two breeds, and we cannot see how a shaven crown can be taken as evidence in deciding the "knotty" point. In describing the head of an animal we must take perfectly normal and not modified examples, which the heads of show Lincolns and Leicesters undoubtedly are. It is a common custom to shave the legs of show sheep as well as their heads; but we should certainly be surprised to learn that Leicester sheep are especially free from hair upon their legs, or that Cotswolds are distinguished by a peculiar ochrey-colonred wool, while Lincoln and Leicester wool is of a greyish tinge. And yet if the shaven countenance is to be taken as the type, why not describe other artificial differences? Why not, indeed, give this admirable system a wider application, and describe the Chinese race of men as furnished with a peculiar appendage known as a "pig-tail," or the New Zealander as distinguished from his fellow mortals by curious *tatoo* markings? We cannot bring ourselves to answer "most assuredly" yes to such questions, and, returning to sheep, we should most certainly like to see them appear with their features in a natural state. If the top-knot is to be considered old-fashioned and coarse, why shave it off? Surely, by so doing, all the sheep exhibited are reduced, in "character," to a dead level, and the judges lose one means at least of deciding their awards. We, however, cannot agree with Mr. Corbett or his authority, the "very successful breeder of Leicesters," who no doubt keeps his sheep bare on the head: other breeders do not.

—— The *Yorkshire Post* thus calculates the mutton-producing power of the existing root crop :—

"The cost of taking the field has been enormous, owing to the high price of lean stock, but the investment will be successful in a pecuniary sense. Thus, if grazing sheep have cost more than usual this year, they will sell out unquestionably at as high rates, and they will, as last year, require to be sold until they are fully fed. And we may calculate that sheep will come into the shambles after Christmas, and at Candlemas, at 10 lb. per head heavier than they did after last winter. This will be an increase of 12s. per head upon the sale value of the sheep at 8*d*. per lb., over last year, and is a fair prospect for the farmers, who are to realise. Now the root of the grand Turnip crop of the year. It is also a fair prospect for the country. We have at present 29,000,000 sheep in Great Britain and Ireland, and 2,210,911 acres Turnips, and about 1,300,000 other green crops (except Clover and grass). Now, allowing the other green crops to be all pulled off the land for cattle, and one-third the Turnips, we shall still have 1,473,941, or, in round numbers, one-and-a-half million acres of Turnips on which to feed the sheep, at an average of eight sheep per acre, will fatten 12,000,000 sheep. Now, the extra weight upon these sheep, from the extra length of time which the abundant crops will maintain them, at 2 lb. each, (except Clover and grass), will amount to 192,000,000 lb., which, at 8*d*. per lb., has a gross value of £6,400,000. This, then, is assuredly a great gain to the country, and a fine sum for the agriculturist to look forward to as his harvest. It must, however, be forgotten that last year he lost a greater amount than this. He then grew 3,000,000 acres of roots, and the crop was certainly not a fourth of an average, showing, at the low value of £6 per acre, a loss of £13,500,000. That the result arrived at above, that we have winter food on Turnips available for 12,000,000 sheep, is not a far approximation from truth is confirmed by the fact that we have 29,000,000 sheep in the United Kingdom, and it has usually been considered that about half the number went to Turnips."

SOD.

WHEN one of our best farmers was asked the secret, on the whole, of his success, he replied, Sod. It is the cheapest manure, comes from the atmosphere mostly, dispenses with ploughing and draining, and is among the best of fertilisers. "Give me a stiff, deep sod, such as I usually try to make, and I wish for nothing better," said our friend. The top-dressings which are used to aid in making the sod have also an influence, especially if this is manured in the barnyard or in the compost wheer soil is used, loam or clay, as needed for the land, where applied for this, makes soil; you raise your land, that is, add to it, and the sod rises with it, thus restoring the land eventually to its original level.

Sod contains the elements of vegetable growth, and will grow anything. It is its advantage. It is this respect related to barnyard manure. But it will rot sooner than green manure; it is better distributed through the soil than can be done with any manure or with any instruments.

Turn down a very dense, thick sod; let it thoroughly rot; plough again (of course when dry); keep ploughing and cultivating, and harrowing more or less during the summer, and what have you got? A heap of manure spread 5 or 6 inches deep over your land; in other words a crop or more good loads of the best of manure. None of its strength lost; a perfect distribution so as to have plant food wherever the minutest root may find its way.

Such land is fit for a garden, fit for anything, but the most fit to seed down to sod again, forming a still better turf, and thereafter, sooner, or later, forever running down our land, and then putting it in grass to bring it up again. It takes long to do this, at considerable expense, whereas the other is the ready way to large yields, two crops a season and good ones, with seldom a failure, as land will withstand both drought and also the rains better if in excess.

But can such a sod be formed without too much expense or risk? There is no risk attending it. The outlay goes to increase the crop; the benefit follows right along each year. Apply plentifully of manure, and there will be plentiful crops. Plaster, ashes, salt, lime, the phosphates honestly manufactured, all will not only help to make sod, but give immediate returns. The only difficulty is, we are afraid to use enough of them, particularly the prime feeder—barnyard manure.

It is for this reason—sod reason—that our dairy

regions are so improving. Having been run down by over-cropping, they are now not only restored, but they exceed the original fertility—this generally and decidedly. The secret is, when we make our sod, that we make it good, not a straggling thing of roots, seeking for subsistence and barely finding support. This will not pay. There must be healthy, vigorous root life, giving good returns. The point to get the greatest gain is, to make your sod the soonest and the thickest that you can. The more you apply the more you get, and, remember, always at a gain. The crops will be according to the application judiciously made. Why, then, are we afraid to apply the dressings? We know farms where this has been done that it does you good to look at; the treatment, liberal, made from the beginning.

The point, then, is, prepare your land in the best possible manner for seeding; have a good seed-bed, improve it. It will mellow the land by the motion of its roots and enrich it, and enrich it with just the *pabulum* that is wanted. A thick sod of Clover roots is probably the best thing that can be done to improve it, as it makes deep work as well as surface improvement. But use the means freely to do it. If not on a large scale, then on a small scale, field after field, for it is the thorough work wherein the advantage consists. Once established, the air will feed and continue it, and with comparatively cheap outlay of top-dressings. But whether continued or not, when once established, you have the benefit, ready for the plough, or to continue its heavy crops of grass. The advantage is mainly what is derived from the atmosphere. The grain gets less of that and takes more from the soil; hence the grass improves the land. Begin with Clover and continue with grass till the plough is resorted to, then repeat with Clover and grass again.

Shirreff's Bearded Wheat. Talavera. Pringle's Bearded Wheat. April Wheat. Hallett's Pedigree Wheat. Shirreff's Red Wheat.

FIG. 324.—VARIETIES OF WHEAT.

and have the ground mellow below. Get a good start. If manure is harrowed in with the grain, that is a help, whether in the fall on Wheat, or on spring grain, only see that your spring grain is put in early. This is important. The best way is to prepare the land in the fall by ploughing and applying the manure; apply during the winter fresh from the stables. In the spring you have what you want. And use plenty of seed to seed down. This will make a thick stand and a thick set of roots. Follow up yearly by plentiful surface applications, and the thing is done. Your sod is established; you have made profit out of the crops as you established it, so that it may be said you have the sod—a heavier and better coating of manure than is otherwise obtained—for nothing.

This is the way to improve land, and the best, all things considered, that we know of. Not only in grazing countries proper is this the best, but it will do where grain is made the chief product. Clover here may be used generally to the greatest advantage. We particularly fancy Clover on a stubborn clay soil to

But why a thick sod? it may be asked. Because it is a protection; in a multitude of connsellors there is safety; in an aggregate there is power. A rich soil, especially a thick rich sod, will ward off the hurts of the season; it is a guard against drought and over-moisture, keeping the soil cool comparatively in summer and warm in winter. It is a concentration of the good, and you are not apt to miss a crop. Here is the live thing in the soil to do all this. Is it not so? Are not the good crops in a drought raised from just such land? And, remember, it takes but a few years, with judicious treatment, to form just such a soil, and but little trouble, comparatively, to keep it. *F. G.* (*Albany Cultivator*).

SORTS OF WHEAT.

THE subjoined drawings (figs. 324, 325) are portraits, *i. e.*, they are sketches of particular ears, which, though selected with some anxiety that they should be fairly representative of the several kinds, were yet obviously more luxuriantly grown in some instances than in others. They are republished from Warne & Co.'s "Farm Calendar," and appeared some years ago in these columns. We repeat them now at a time when the selection of seed Wheat is still to some extent an open question, and with them we repeat, in a very abridged form, the characters given of the sorts in the work referred to:—

1. Shirreff, bearded white Wheat, selected and grown by Mr. Patrick Shirreff, of Haddington; grain short, small, white, translucent.

2. Talavera, capital for spring sowing; recognisable by distance between the sets of florets on the central rib of ear.

3. Pringle's White Wheat, differing from 1 chiefly in the larger size of its grains, and their shining, white, creamy tinge.

4. April Wheat, rather a shabby specimen of our latest-sowing red Wheats.

5. Hallett's Pedigree, grown from selected grains care fully cultivated, and thus possessed of an acquired robustness and size of growth.

6. Shirreff's Bearded Red, for autumn sowing, ripening early, stiff strawed.

7. Common Red Lammas, a red Wheat, of good quality and fair productiveness.

8. White Essex Wheat, good quality of grain, considerable length of straw.

9. Spalding Red Wheat, coarse, productive, strong strawed.

10. An unusually strong specimen of Chidham Wheat, one of the best white Wheats for quality.

11. Mungeswell's Wheat, another of Mr. Shirreff's sorts; like Hunter's, but earlier.

12. Hunter's Wheat, an old standard Scottish variety of white Wheat.

13. Hopetoun White Wheat, also originating with Mr. Shirreff; stiff, long straw, smooth chaffed, very handsome in the field.

14. Fenton White Wheat, originating with Mr. Hope, of Fenton Barns, Haddingtonshire; of various length in straw, presenting usually the appearance of a ragged crop, but almost always yielding better than it promises.

THE AGRICULTURAL LABOURER.

BRITISH agriculture is a great fact, that will never go out of fashion so long as there are stomachs that must be filled and daily replenished. Our agricultural power is composed of landowners, farmers, and labourers combined, just as steam-power is formed of coal, water, and machinery. Each part is connected with, and dependent on, the other for a profitable result. The three interests are governed by the law of supply and demand, which no Legislative Act can regulate or control, although the attempt has often been made and failed.* It is not at all difficult to perceive that, of the three interests, the landowner has the vantage ground in this densely populated country, for the land never had any children, while both farmers and labourers have very large families, wanting land and wanting employment. On my farm, the labourers have an average of five children each, including two who have none; and I have also five children. This question of mutual dependence is quite independent of the pecuniary arrangements between the parties, which, rectitude are to be found in every class of society, but I look upon landowners, tenants, and labourers as actuated by ordinary and proper feelings, each trying to do the best he can for himself, which is a sound commercial or business sentiment. Circumstances, and opinions founded on any changes in these circumstances, may and do greatly alter the conditions that govern British agriculture. Manufactures, commerce, and population, have been so increased and stimulated by the new power of steam, that agriculture must come out of its old rut, and enter on a new and more rapid route; therefore landowners, farmers, and labourers, must all change and improve and take their part in the general advance. We were 15,000,000 in 1800, we are now 32,000,000. The acres are numerically the same, but are being improved, and farming must be still further improved by less prejudices in favour of old customs on the part of the landowner, his tenants, and the labourer. There must be an improved mental and physical condition of the labourer: with the value of his labour we have nothing to do, that must follow the law of supply and demand, but there are certain things must depend in a great degree on the intelligence and knowledge of the landowner and his tenant, and, to speak honestly, there is plenty of improvement required in this respect. If the farm is managed on the best modern principles, with steam-power at the homestead and in the field—if the farm is in proper condition as to its drainage, water supply, roads, fences, and residential and animal accommodation—the juvenile labourer will grow up in the presence of intelligent agricultural practice, which will naturally impress itself on his mind. I have practical proof of this, for when our men and boys eat their frugal meal in the warm boiler-house, the untiring engine teaches them a lesson; so much so that many of them are now handy at turning the steam off or on, or even attending to the engine in the absence of the driver, and can lend a useful help in the manipulation of the various machinery worked by the engine.

I am strongly in favour of permitting the juveniles at an early age to take some part in agricultural practice. The little urchins (although, like monkeys, sometimes troublesome) assist their older brothers in collecting

FIG. 325.—VARIETIES OF WHEAT.

of course, must be like other business transactions, and governed by circumstances. Farmers and labourers must both gain a living, and the rent of land must be subservient to that end.

It is very wrong to impute to any class, as a class, wrong doing. Of course, individual deviations from that should be done for the labourer that he has no power to do for himself. I mean education and decent house accommodation. What I mean by education is reading, writing, and ordinary arithmetic; these are the means by which he can acquire knowledge if he desires so to do, but without them his mind must remain a comparative blank. Education is the basis on which knowledge and power are founded. The Scotch, thanks to John Knox, are in this respect in advance of us, hence the employment of Scotch managers, bailiffs, stewards, gardeners, &c., almost everywhere out of Scotland.

Technical education for the agricultural labourer must be rebuilt compulsorily, and 20 to 40 acres of land attached to them."

Note.—In the 15th century agricultural labour became scarce, for the villeins, having been made free labourers, betook themselves to handicrafts and manufactures.

Although the labourer gets more money, by 2*s.* or more per week, than he did 30 years ago, he cannot, in exchange for his labour, obtain more bread, meat, cheese, or butter, than he did formerly. The fact is, that money has become cheaper since the gold findings in Australia and California—annuitants have a painful conviction of that fact. As regards tea, sugar, and coffee, the labourer has the benefit of reduced taxation, and he has to thank our manufacturers for supplying him with cheaper and better clothing. He also saves something in his rent by paying for it in a depreciated currency, if the price has not been raised.

and preparing food for stock, cleaning out the henhouse, looking up the eggs, &c. The donkey and donkey-cart are their delight; they soon learn to harness, guide, and feed him, and so pass on to leading or riding the big horses, who soon become accustomed to and obedient to their juvenile commands. They are handy in helping their parents or relatives in picking Twitch, stone picking, gleaning, Pea picking. Where would they be during the absence of their parents, when not at school? Of course a certain portion of schooling is most desirable, and there is plenty of time for that during the short days and long evenings, when it is unfit for them to take part in agricultural work. I am told that in the rural districts of the United States, many of their schools are only used about half the year. In fact, I consider it most important for the agricultural labourer that he should acquire in early life the necessary technical knowledge, for there is a great deal to be learned on agricultural matters.

As regards the housing of the agricultural labourer, a great reform is needed. Many of us remember that the most strenuous efforts of both landowners and farmers were formerly directed to preventing the erection of cottages on their property or farms; so that, in cases of non-employment, illness, or old age, the charge for his maintenance should fall on somebody

* There are certain things beyond Parliamentary control. The law may and does very properly punish drunkenness and dishonesty, but it fails to make people honest and sober. This has been often tried and failed. Nor can any Parliamentary Act regulate or fix prices, or quantities, in trade or agriculture. In the paper which I read in February, 1861, before the London Farmers' Club, on the past, present, and future of British agriculture, I made the following quotation from history, bearing upon this subject:—

"*Legislation affecting Agriculture.*—Our senators appear to have been constantly attempting to set agriculture in order according to their own notions by Acts of Parliament. They do not appear to have succeeded very well in their objects, for most of the Acts fell into disuetude or were evaded. Some of them would sound oddly at the present day, such as:—No tenant should rent two farms. No tenant-farmer should have more than 2000 sheep. 1538. That the King was to have half the profits from all land converted from tillage into pasture until a suitable house could be built upon it. Every cottage was to have 4 acres of land, and no more than one family in each cottage. There was an Act to restrain the excessive use of malt, and justices were empowered in quarter sessions to suppress the making of malt and the number of maltsters. (What will Mr. Bruce think of this? Not very encouraging!) Farmhouses that had decayed were to

else, in some other town or parish. Never mind how far he had to walk to and from his work—never mind how much his morals and health were undermined by close packing and indecent propinquity—the great aim of each parish was to shuffle its labourers on to or into another parish, and wasted money in litigation for this object.

Near a town scarcely a cottage could be found on certain estates, because the town should bear the poor-rate. But since the wise law of uniting parishes has come into operation the opportunities for such unworthy practices have ceased, and the result is, as we see, a sudden appreciation of the necessity for improved cottage accommodation. This may be of the plainest description—so long as the space and rooms are sufficient. Of course wealthy landowners, who desire their property to be ornamental as well as useful, can indulge their desire, but cannot expect to be paid for it out of the scanty means of the labourer —£4 a year is hereabout considered the proper rent, or even £4 10*s.*, with at least 20 rods of ground,—therefore it is quite clear that each cottage should not cost more in building than £60 to £80, if interest for money is expected. There are several built hereabout of brick, with tiles, at a cost of £130 to £140 a pair—the latter having two bed-rooms and an extra large bed-room in the roof. 'Tis true we have bricks and tiles close at hand. A farm labourer who is doing rough and hard work all day wants no ornament or finery in his house, and most certainly he cannot afford to pay for it. Good plain whitewashed (or cheaply papered walls, wood (not bricked) floors (except in the scullery), a good oven, an underground tank with a pump in it supplied with water from the roof, his house and garden well drained, are much more important considerations than indoor or outdoor ornamentation.

The importance of draining the ground on which the cottage stands, and also of draining the garden, is paramount, and so is the matter of water supply, and too frequently these are wanting.

Of course when I speak of draining I allude to lands not naturally filtrative. The underground tank should be bricked, cemented, and arched. Twenty-four inches of rainfall annually will give 12 galls. for each square foot of the size of the house. The same plan applied to farm buildings would give an ample supply of water where required. It is really disgraceful that most unprofitable that fevers and other evils resulting from bad water should be permitted, for they cause heavy charges on agriculture in the shape of increased poor-rate. The mere drainage from the land would give an ample supply if stored.

It is quite clear that there must be a constant migration of our agricultural population, either to other climes or to other occupations. The acres have no children, and can absorb no increase of population, unless they are greatly improved, and also, above all, converted from grass land to arable. This has taken place for many years, for, four centuries ago, it was stated that pasture had then decreased but still was as 20 to 1 of arable, now it is about 1 for 1, or 22,000,000 of acres.

Fortunately steam-power has so enriched this country and so multiplied its wants, that vast numbers of our agricultural surplus labourers, male and female, find their way into our towns and factories. As the labourer becomes better educated and informed that migration will increase, for his local attachments will no longer withstand the claims of an improved condition. Our agricultural females find much employment in needlework for the clothing contractors in towns and cities. Pea picking for the London market has been a source of considerable profit to the labourer's family; fruit and seed growing also add to their means, for all this we are indebted to the mighty power, steam, which has shortened time and space between man and man, and has permitted and encouraged an enormous increase of town population.

Those who study economy should learn from the agricultural labourer. On an average his family consists of himself, wife, and three children. His wages average at most £36 per annum; his house rent (no taxes) costs £4 per year; so that five persons have to be clothed and fed for £6 8*s.* each per annum, or 2*s.* 6*d.* each per week. How is this disposed of? Bread and flour, puddings aided by vegetables, are the small portion of cheese, butter, and meat form the labourers' food, and no doubt are the most effective economical arrangement that could be made. The consumption of meat is at most 1 oz. per head per day, and that generally fat pork. In my prosperity and in my adversity I often used to say that I could live independently on £50 per annum—not as Mr. Mechi, but as John Brown or Tom Jones, in a good fustian suit, my own gardener and librarian, luxuriating in one or two daily penny papers and a pipe of mild tobacco. Surely I could do this when I see so many hard workers with large families living on less than £36 per annum. Skimmed milk is sold about here at 1*d.* per quart when once skimmed, but only a halfpenny if twice skimmed; but there are so few cows kept that it is difficult to get any. It is a great boon to a labourer's family of small children.

One great drawback is the loss of time that a labourer must occasionally suffer from want of employment, especially the odd men who are only availed of at busy periods. Here we see the necessity for, and national advantage of, allotments or large gardens. Reasonable masters, with a fair proportion of kindly feeling, looking at the labourer as something more than a mere piece of machinery, but rather as a tool to be kept bright and in good working condition, mentally and physically, have no difficulty in selecting useful labourers who are content to continue their services, which is very much to the master's comfort and advantage. Labourers with violent tempers and changeable and unsettled habits, can only be expected to be employed just when the farmer may happen to want them.

In the west, south, and east of England we know little, if anything, of the hops, or yearly hirings. It is no uncommon thing to find labourers who, although only weekly servants, have worked all their lives on one farm, to be gradually replaced by their sons. I don't quite know whether the Scotch farmer changes his men at the yearly hirings, or whether it arises from a desire of change on the part of the young educated Scotch farm labourer. Their food seems economical and nutritious—oatmeal and milk, with fish when it can be got. I don't hear much about meat.

Agriculture owes much to manufactures and to commerce. The labourer and his family are cheaply and decently clad in cotton manufactures, at a low, quality, and of patterns unknown or unobtainable by him in ancient times. The cotton famine caused much extra cost and deprivation to the labourer in his clothing. Farm implements owe to steam a cheapness and quality previously unattainable.

I have much respect and esteem for our agricultural labourers as a class. My own men have been with me, most of them, for nearly 30 years, and we have grown older together.

I am no believer in their being drunkards and sottish. The percentage of drunkards is very small. It is the poachers, and odd, unsettled, and irregular men who frequent the beer shops. Labourers who marry young, and have a large family of young children in a few years, are rather sorely pressed, and have nothing to spare for beer, while the single, or non-familied married couples, appear well on quite limited means.

As in other matters, so it is in agriculture, good and intelligent masters make good and intelligent servants. We are none of us perfection. Piece-work is the great boon to both master and man in agriculture as it is in manufactures. To keep a man on day-work wages you don't like to see him earn money, is a narrow-minded and unprofitable mistake; and, to say the least of it, it is most unfair to estimate fields at a measure much smaller than the actual ploughable quantity in order to diminish the labourer's earnings. I have seen much of this abroad.

A little care for the labourer's welfare, or for his family in time of sickness or other misfortune, is amply repaid by kindly feeling towards the master, and a sense of gratitude. These are the ties that bind society harmoniously, and they need by no means be costly.

Labourers have a great aversion to enter the hated union house. Boards of Guardians know this, and sometimes take advantage of it, thus causing to respectable labourers great privations. Irregular or loose characters, who always have a loaf in the house, generally get the most readily outdoor relief, because the guardians know that it costs very much more to keep them in the house than to allow them out of it. When a respectable labourer is past work, 3*s.* to 4*s.* and a couple of 4 lb. loaves weekly is all that he can expect, to pay rent, coal, and clothe himself and his wife. I am always sorry to see the good old couples separated when they are obliged to go into the union house. But these things must be, for it will not answer to make the union house too attractive.

In short, the skilled and kindly act to employ very old men, who are past severe work, to attend to the fences, roads, and other easy matters, a few hours daily, at 2*s.* 6*d.* a week, provided the guardians will permit it. An industrious, well-conducted labourer, who has laboured away most of his life on a farm, is entitled to such consideration for he dislikes compulsory idleness.

J. F. Mechi, Tiptree, November.

THE SHEEP OF NEW SOUTH WALES.

[We extract the following interesting report by Dr. Garran, from the Journal of the Agricultural Society of New South Wales.]

A STRANGER visiting our exhibition (1870), and ignorant of the affairs of this colony, would never have judged that the production of wool was the foundation of our commercial prosperity, and was still our most important industry. The specimens exhibited were few in number, and none of them represented the excellence to which wool-bearing sheep have attained in this colony. The reason of this great shortcoming is to be found in the stringent operations of the Scab Act. When, a few years ago, the scab re-appeared in this colony, rigorous measures were adopted to stamp it out. They succeeded, but the utmost vigilance is still required to prevent the re-introduction of the disease, as, owing to lamentable neglect in Victoria, the disease continues there almost unabated. It is necessary to maintain boundary-riders incessantly to watch the Murray frontier, and prevent the incursion of diseased sheep; and strict quarantine regulations are enforced at the seaports to prevent the disease being surreptitiously introduced by the agency of imported stock. No sheep are allowed to pass from the coast district into the interior until they have been detained a certain length of time, and dipped and dressed repeatedly. Stock brought down from the interior, and entering the coast district, would have to submit to this ordeal, and the owners of fine-woolled sheep did not care to run the risk of sending their best animals to be so detained and treated, or to run the risk of possible infection. Even apart from this reason, the frightful state of the roads would have militated against a good sheep show in Sydney. The long-continued rains had made the country roads almost impassable. Sheep driven down would have brought with them more mud than wool, and to have brought them in carts would have been very expensive, and nearly impracticable.

It was to be regretted that at a Metropolitan Agricultural and General Exhibition so little could be done to display the great staple of colonial industry, for notwithstanding the great and growing variety of articles the colony is now producing, there is nothing as yet that approaches in importance the production of sheep and wool.

The first sheep imported came from the Cape. Twenty-nine were landed in 1788, and in 1792 the Government flock numbered 105. A few, too, came in westward, via India—the Laureston brought one in 1793; but for a long time sheep were few in number, and of great value. Mrs. Macarthur's letters mention as something wonderful that in the year 1795 her husband had a flock of not less than a thousand sheep, and that he took kept in their establishment show that in the year 1805 a fine wether was worth £100. It was from observing the improvement in the character of wool, effected by a little careful breeding in the mongrel flock he had accumulated, that Mr. Macarthur was led to speculate on the advantages that would accrue from the importation of superior rams; and when he afterwards developed that idea into practice, the beginning was made of the fine wool trade of Australia. It took some time to work out the inferior strain of the ewes, but the care bestowed on the breeding of the Camden stud flock soon established a reputation that was world-wide in its fame.

The first introduction of fine-woolled sheep to the colony was due to an accidental circumstance. Some very fine sheep of the Escurial breed (which was considered the best of the three principal descriptions of Spanish sheep) were presented by the king of Spain to the Dutch Government. Some of these were seized from the Dutch Government into the possession of Colonel Gordon at the Cape of Good Hope, who was then an officer in the Dutch East India service. Colonel Gordon shot himself, and his sheep were sold by his widow. It fortunately happened that at the time there were two English ships of war—the Reliance and the Supply—had arrived at the Cape from New South Wales for supplies. Twenty-nine were put on board the two vessels bound for Sydney. Some died on the passage. On their arrival, which was in 1797, Captain Macarthur offered £15 a-head for the whole; but Captain Waterhouse refused to sell them all to one person, and distributed them, keeping a small flock for himself, which, on his subsequently leaving the colony, he sold mostly to Mr. Cox. Col. Gordon's flock, or part of it, was in 1804 purchased by the colony's New South Head though some half-dozen persons had thus equal opportunities of forming stud flocks, Captain Macarthur, whose share consisted of three rams and five ewes, was the only one with the foresight and sagacity to appreciate the importance of maintaining a pure breed. The ewes then in the colony were especially fine-woolled, though producing only a coarse hairy wool, were very hardy and prolific, and fat wethers ruled at a very high price. The presumption is, that the other owners of Colonel Gordon's sheep thought only of quantity and of immediate profit, and not of quality, and that when Governor King made inquiries on the subject, the fine strain had vanished, except in the case of the one flock. In 1802, Captain Macarthur went to England. The woollen manufacture at that time was a close corporation; workmen were jealous of the introduction of new hands, and only those who had served their apprenticeship could be employed. The master manufacturers rebelled against the restrictions thus placed on their trade, and in memorials to Parliament pointed out how the commerce of the country was limited thereby. The workmen, who considered that the interest of their order imperilled by free trade, replied that the allegation of the masters was false; that there was only one country in the world, namely, Spain, from where the fine wool came, and, as the quantity was limited, the manufacturers could not possibly expand the trade. Just at this juncture Captain Macarthur produced specimens of the Australian wool, thus demonstrating that there was another country, and that one of indefinite capabilities, where fine wool could be grown. The exhibition of these samples greatly facilitated his efforts for pushing the wool trade in Australia. Before returning to the colony in 1805, he purchased at Kew, at the annual sale of George the Third's stock, eight or ten rams and ewes. These also were of the Spanish breed, and had been a present from the King of Spain. But they were not quite identical in quality with the sheep from Colonel Gordon's flock, and were considered a shade inferior. It is a curious fact that an effort was made to prevent the transmission of these sheep to Sydney. The day after the sale a paragraph appeared in the *Times*, expressing regret that the colonist who had so invested his capital had not previously

made himself acquainted with the laws of the country, as their exportation was illegal. But when it was found that the penalty was cutting off the right hand and branding the forehead, and that the prohibition was to be found in an old unrepealed statute of Edward the First—one of the many measures intended to protect the trade of the country—the difficulty ceased to be formidable.

The Camden stud thus founded by Captain Macarthur was kept for more than 50 years, and was not finally dispersed till 1858. The flock at its maximum numbered about 400 ewes of the first class, and 500 of the second class. A large part of the flock went over to Victoria, where, under careful management, the weight of the fleece has been considerably increased. In 1823 there were several private importations of fine-woolled Saxon sheep, and in 1825 the Australian Agricultural Company imported sheep from France and Saxony. Both breeds, however, had been derived originally from the Spanish. It is worthy of remark that catarrh was not known in the colony till after the arrival of the Saxon sheep.

Mr. Riley was one of the first to follow the lead of Captain Macarthur in bestowing attention on the breed, and at his estate in Raby began the formation of a flock gathered from various quarters. This flock passed into the hands of his neighbour, Mr. Cox, of Mulgoa, who was also devoting his attention to the matter, who had received some important French ewes from the Empress's flock, and who ultimately moved his stock to Mudgee. This removal may be considered the second epoch in the fine-wool trade of the colony, for it placed the sheep in the climate best adapted for the production of wool. In the coast country it is impossible to grow the finest wool. Those on Camden, Raby, or Mulgoa, could studs flocks ever attain the excellence they have at Mudgee. It is now fully 35 years since Mr. Cox's flock was removed to the high lands, and during that time careful persistent breeding has developed a breed to be yet established as the New South Wales merino. The process of acclimatisation has modified the original type of the Spanish merino. There has been a very decided gain in the softness of the wool, and an improvement in its elasticity; but there has been a diminution of the felting quality, which could not be considered a defect. The wool has also increased in length, but diminished in density, so that the weight of the fleece remains about the same. The best Mudgee sheep yield about 3 lb. of clean, spout-washed wool, which is equal to 6 lb. of greasy wool. How far a longer process of acclimatisation will still further vary these results, remains to be proved, but it is already sufficiently demonstrated that the merino is by Australian acclimatistion improved in some important particulars. Nor is there any trace of degeneracy of constitutional vigour, except so far as injury is received by deficiency of food in seasons of drought.

We have no available information as to the exact annual growth of the clip of the colony, or of its value. But for the year 1821, the second year in which the colonial wool was sold by auction, a brief catalogue has been accidentally preserved, with the prices attached in MSS., and from this we find that 329 bales were sent home in the Shipley, and sold at Garraway's. The Camden wool realised from 2s. 5d. per lb. up to 3s. 2d. The Bathurst wool fetched 5s. 6d., and some even went as high as 10s. 4d. Jones, Riley, and Walker's wool ranged from 1s. 1d. to 1s. 9d.; Hanibal Macarthur's, from 2s. 2d. to 2s. 10d.; John Oxley's, from 1s. 8d. to 2s. 2d.; John Wood's, from 1s. 9d. to 2s. 2d.; William How's, from 2s. to 2s. 6d.; Berry and Wolstoncroft's, from 1s. 1d. to 1s. 8½d.

The wool trade once established was so natural to the soil and climate that it expanded with great rapidity, and until the last two or three years, colonists have been incessantly exploring fresh country, taking up runs, and multiplying flocks, in the full belief that it was impossible to glut the markets of Europe, or bring wool down to an unremunerative price. Against this expansive tendency a reaction has now set in. The great and rapid decline of wool has stopped for the present all extension of this industry. In the north-west of Queensland many projected runs have been abandoned, and in this colony some of the remoter country, eagerly taken up during the speculative era, has not yet been stocked. Instead of the production of quantity, the attention of squatters is now directed to quality. They have been forced by a painful experience to see that, in the hurried attempt to overspread the whole available portion of the continent with sheep, the flocks have not been sufficiently culled, and a deterioration has taken place in the general average of the stock, which it will require some years to retrieve.

Capabilities of different parts of the Colony for Wool-growing.—The different degree of success attending sheep-farming in different parts of the country, has also compelled attention to the fact that the whole of Australia is not equally fitted for the production of fine wools, and we have now commenced a careful and discriminating inquiry into the special characteristics of the different parts of the colony, and are slowly ascertaining what districts are best suited for the different purposes. Roughly speaking, the colony of New South Wales may be climatically divided into four zones or belts:—First, the coast country, extending from the seaboard to the main range, and the breadth of which belt varies at intervals from 20 to 100 miles; secondly, the table-land or upland districts on the flat or undulating summit of the range; thirdly, the upper part of the western slopes; and fourthly, the level arid interior, or, as it is called, from the chief characteristic of its vegetation, the salt-bush country.

Along the eastern seaboard, and for some distance inland, the climate is too moist, and the country generally too poor and unsound for Merinos. How far the coarser-woolled sheep could thrive in these parts is still an unsettled question, and even were it determined in the affirmative, it would still remain to ascertain whether the country could not be put to better account in other ways. Where the soil is good, as on the Hunter and other northern rivers, and as in the coast districts to the south, it is devoted to dairying purposes and arable culture; and it is probable that the country is thus more profitably used than in producing large-framed, coarse-woolled sheep.

On the higher country, towards the top of the coast range, some sheep are kept, but, generally speaking, the pasture is too rank and sour, as well as too exposed, for sheep to thrive there. The land around the Goulburn, Braidwood, Yass, Hunter, Lachlan, and Clarence rivers, however, must not be thus disparaged, as these rivers rise far inland, where the soil is of a different quality, and where the climate is less influenced by the sea. In the upper watersheds of these rivers there are about 1,360,000 sheep.

After surmounting the coast range, the grazing and wool-growing capabilities of the country improve, although the more upland and mountainous portions are still inferior; and, owing to the comparative wetness of the soil, the sheep depastured there are liable to fluke and foot-rot. Further westward, as the altitude of the country diminishes, the climate and pasturage for wool-growing purposes improve, and the intermediate country between the table-land and salt-bush plains is first-class. Even here, however, there are better and worse, for those portions which, like the districts of Mudgee and Wickedbeyan, have limestone strata are found to be the best for wool-growing. Next in value to these are the southern portions of what is popularly termed Riverina, or the plains watered by the westward flowing rivers, and those portions of the salt-bush country which are nearest to the intermediate. Here the fibre gets coarser, but as the pasturage is plentiful and nutritious, the fleeces are heavy and the staple generally sound. As we go further into the salt-bush country, the fleeces become lighter, and the wool harsher; but by way of compensation for this defect, the sheep are more vigorous, as well as more healthy and sound, than in the intermediate district. The extreme south-western, western, and north-western portions of the colony are, from the heat and dryness of the climate, less favourable to the production of fine wool and heavy fleeces, but that even there, with careful management and a periodical introduction of fresh blood, a good wool and fair fleeces can be produced, was demonstrated at the Exhibition in 1869. Some of the disparagement under which wool from this district has suffered, is to be ascribed less to the climate than to the deficiency of the stock. Many of the runs there were taken up a time when there was a great rage for this country, and when, in order to fulfil the Government conditions of the lease, it was necessary that the country should be stocked to a certain point. Anything was sent that would count as a sheep, and scrub so sent came not worth the carriage from. This inferior stock has the more readily succumbed to the deteriorating influences of the climate, but this early defect may be retrieved in course of time by patient care in culling and breeding.

(To be Continued.)

Home Correspondence.

Town Sewage.—I have been much surprised in reading your *Agricultural Gazette* at the diversity of opinion still existing amongst engineers and sanitary improvers on the subject of town draining. There are four descriptions still in vogue, some old-fashioned friends recommending cesspools still, some advocating drainage and running it into rivers, polluting the water and injuring all their neighbours below them; then there is the "A B C" process of precipitating by dry earth, then filtration in tanks before entering the river, selling the solid as manure; the last is by irrigation, the sewage lifted by steam power, filtered or not, and then distributed over the land by gravitation, or, if not high enough, again lifted by steam power. Having had some experience in drainage for many years—having been a member of the Chelmsford Board of Health for nearly 30 years, and for several years chairman, I have been led to take particular interest in the subject. I have read most of the publications on drainage, and have thus had opportunities of obtaining information. Now taking the several matters of drainage. First, the old cesspool, with open ditches; this was the former plan in this place, contaminating the air and subsoil: scarcely one pit was covered air-tight, or cemented in the bottom, consequently most of the sewage escaped, penetrating nearly all the wells, and contaminating the water which the inhabitants drank. This plan is given up by nearly all, excepting in some country places where there are no drains whatever or outlet for the drainage. The second plan of draining and running the contents into rivers is continuing in some towns, but the owners of property below the outlets are obtaining injunctions against the towns; and this plan must cease. The third plan is the "A B C" process. This I do not think will ever pay. It never can be too much impressed upon the minds of persons who are seeking to make a profit from the manure, that the residuum left by precipitation in tanks is of very little value, being only insoluble matters; but as for getting out of the supernatant liquor the ammonia, soluble salts, and the best part of the urine, it is absurd, and not to be accomplished. In addition, if the supernatant liquor is permitted to stand or flow into a river it will decompose in hot weather, and become offensive. The next mode is the best, and that is filtration in tanks, and then discharging the liquid parts in gutters over lands. I am surprised that this plan has not been widely extended. I know some towns are so situated, that they cannot adopt it. Take London, for instance; the system still pollutes the lower part of the river, but the amount is so immense that everybody fears to touch it. The time will come when something must be done to remedy the evil, or the navigation may be so obstructed by the deposit as seriously to injure the port of London. If you have space, will you permit me to give an account of what has been done in Chelmsford, and the experience which I have gained at the first formation of our town? A survey was made by the Board of Ordnance, at our expense, of the whole town and surrounding district, and the levels were taken accurately. A surveyor was employed, and a complete system of drainage laid down, with plans as well; the drainage was to be all brought to one point, and discharged into a stream at the tail-water of a mill. This soon became polluted and offensive in the stream. Actions were brought against some of the members of the board, which were carried against them; an order was made for the abatement of the nuisance. I should state, before I pass on to a further part of my history, that our water supply consists of about 100,000 gallons a day of artesian soft water, pumped all over the town, and about the same quantity of beautiful water from an adjacent hill called Springfield Spring. This is carried by gravitation into the Board of Health yard, collected in a large covered reservoir, and pumped into the town. Those who get soft water on Monday get hard on Tuesday; those who get spring on Monday get soft on Tuesday, so two kinds of water are delivered to the inhabitants, who number about 9000. To abate the nuisance in the river it was necessary to take up some of the large discharging sewers, alter their level, and make them discharge all their contents into a water-tight tank in the Board of Health yard. There was still the same pumping engine which pumped the water; gearing was attached to the shaft, pumps were inserted into the sewage well, and the contents of it were forced up a considerable height to two large filtering-beds or tanks. The sewage, after passing through several of these tanks, escaped in a nearly transparent and colourless state into the river. The solid part, which settled in the tanks, was thrown out alternately and then sold for manure. The farmers would give but little for it. This filtration plan lasted for some time, but it was found in hot-water time or in any weather that even the supernatant fluid, although clean became offensive, and a fresh plan was devised; the former outlet was lengthened and iron pipes carried under the bed of the river, and the sewage, unfiltered, was delivered on to agricultural land where splendid crops of Italian Rye-grass, Carrots, Mangel, Cabbages, and Wheat have been grown; no complaints are now made, and everything works satisfactorily. In conclusion, I think all Boards of Health now beginning should learn by the experience of others what I think are very important things to be remembered; they are the following:—Give the drains as much fall as possible; have them plenty large enough; the water mains should be also of good size, or they will be useless in case of fire, not having force enough on the hose. The water-pipes should not be laid in the same trench as the drains, as the ground on settling will crack the water mains, and another reason is that if a leak takes place at a joint it is difficult to find it as the water percolates into the moved soil. The sewerage should not be laid in small streams, but distributed by gravitation on to land by open gutters and counters, or, what is better, as the treading of cattle does not fill them up, let common red pipes, like draining-pipes, only larger, be placed in the gutters and covered over with earth, one tile to be taken up and a stopper put in each gutter when the part of the field where they are is in want of irrigation. There should be ample ventilation of the sewers, to prevent the poisonous gases produced by decomposition in the drains getting into the houses; the water mains also ought so to be laid that flushing of the sewers may be constantly done. Each house ought to have a separate water supply from a cistern, and in cottages the supply of water to the closets ought not to be through the closed paus; this causes a great waste of water. I have seen scores and scores of handles propped, up with wood, bricks, and tied up, so that the water is running to waste all day; if a tap is fixed in each closet attached to a pipe the water can be

drawn in a pail and poured down the pan, if the tap is left open it floods the closet, and that the occupier will soon stop. *Oswald Copland, Chelmsford, Nov.* 9.

Landowners and Agricultural Labourers.—Mr. E. Minshall, offering a word or two of explanation on the above subject, admits that "it is possible that the increase of labourers' sons on an estate is likely to exceed the demand," that "whatever might be done to keep these lads in the country, some would go into the towns and cities to seek for employment more suited to their tastes;" and adds, "just for the time, of course, the supply would exceed the demand, but it is probable that things would soon right themselves by the surplus workmen finding employment elsewhere." It is precisely this, "things righting themselves," that has been going on; from time to time, youths or men, finding the work unsuited to their tastes, or that they are being crowded out, seek employment elsewhere; or other words, the natural law of supply and demand takes effect. On the cottage question he admits that "by the majority of the farmers this power would be rightly used, but on the other hand there are many who make use of it to gain their own ends; and it would be unfair to 'make fish of one and flesh of another,' to remedy the evil, it is necessary to take the cottage from all, and let it to their workmen direct" . . . his suggestions were made "with a view to improve the labourer's condition rather than of showing up the iniquity of some tenant-farmers." &c. That Mr. E. Minshall should inform the public why they should expect these labourers to receive justice more strictly at his hands, as the agent, than from the tenant-farmer's. The agent had better keep his attention directed to the development of the natural and other latent resources of the estate under his surveillance, by facilitating removal of unnecessary hedges, useless and damaging timber, and to the opening up of other agricultural industries—Sugar-Beet, for instance; restraining and checking, by every means in his power, any unworthy excess of game. In a position of more honourable and responsible, let him urge upon his employer the advantages of breaking through those antiquated covenants and deep-rooted prejudices) which are a disgrace to England's agriculture, and by which the progress and enterprise of the skilful tenant, the man who brings energy and a command of capital, are hampered by scores to guide him in his every operation of the farm, is at present checked. The march of England's agriculture, and with it the well-being of the nation, will be advanced by such measures, and not by the pigmy crotchet of interfering in what is another man's business. There is scope enough for his energy, untiring though it be, in giving liberty and encouragement to proper (high) farming, or, in the words of Lord Leicester, "to frame a lease more in accordance with the spirit of the age, avoiding all interference with the capital of the tenant, removing all clauses that dictate as to the cropping of the soil, or as to the sale of the produce, and, as far as I can, giving him security for the capital invested." Such measures will, without fail, ensure steady employment and better wages to his increasingly population; more hands, with more intelligence, will be required on the farm, more corn and meal produced. From the man, labouring for his daily wage, each and every grade in the nation at large will be benefited, and then these farming lads, whose well-being causes Mr. E. Minshall some anxiety, will find employment suited to their tastes, in the multiplicity and variety of occupations which will then arise, preventing, at least it is to be hoped obviating, his having recourse to that unjust principle he advocates, of punishing the majority for the few. It is such misconception of duty, from time to time, which has given rise in the present day to so many flighty ideas on what is termed the "land question," that even one of our greatest living statesmen has been compelled to admit it is "ticklish." *A Farmer.*

—— I do not at all doubt that your correspondent (Mr. Minshall) is desirous to improve, as far as it is possible, the condition of the agricultural labourer, but I think his letter, which appeared a few weeks since in the *Agricultural Gazette*, fails to show that his position would be at all improved, or his independence in any degree secured, by renting his cottage from the landlord or his agent, instead of his employer, the farmer,—unless it can be shown that it would be an advantage to him to have two masters to please instead of one. It must always be of the greatest importance to the farmer to secure the services of honest and efficient labourers; and this secured, it is equally his interest and his duty to do what he can to render their homes comfortable, and I fail to see with Mr. Minshall in what respect he would be likely to take any undue advantage of the circumstance of their being his tenants as well as his servants. But, if it is to be considered a *time qua non* for the farmer to obtain the approval of the estate agent before appointing his new labourers, this would, I fear, tend to diminish his interest in their well-being, and would, moreover, be likely to lead to misunderstanding. Probably, if all agents were like your correspondent, Mr. Minshall, this might not be the case, but it must be borne in mind that there are agents and agents, and landowners have sometimes a tendency to improvise agents of rather questionable materials, and amongst the results of this are instances of petty tyranny, of which the cottagers on many estates are too frequently the victims. As to retaining the sons of labourers upon the estate, it must be obvious that if only a moiety of these young men remained, the supply would in a few years exceed the demand. But on many estates at the present time the best and most intelligent generally betake themselves to cities or towns, where their services are better remunerated, and, generally speaking, only the least worthy remain. And doubtless this will always be the case until a very different policy is pursued with regard to them, which might go far to counteract the undesirable tendency complained of. This would simply be to give better encouragement to deserving men, to recognise merit even in agricultural labourers, and pay them in accordance with the same, and not, as at present, by a uniform rate of 10*s.* or 11*s.* per week, as the case may be, and which, by-the-by, some men may barely earn, while others may be cheap at double the amount. *G. P. C.*

The Origin of the Swede Turnip. — I have occasionally seen the question asked, Where, when, and how did the Swede Turnip originate? but as yet I have never seen a satisfactory reply; I will therefore (if you will permit) state what I have done to try and throw some light on the subject. In the year 1863 I planted a common white Turnip in the centre of four plants of the purple Asparagus Kale; the plants grew up and flowered together, and when the white Turnip had ripened its seed, some were sowed immediately to ascertain whether any of them had cross-bred with the purple Kale. It was found that they had done so, and the seed (of the white Turnip) was saved until the following spring and then sowed. There were, of course, both green and purple top in the young plants; all the former were destroyed, and from that time to the present has been carefully done every year, except that last winter the frost killed all my Turnips, so that next spring I shall have to sow from the same parcel of seed as last year. I was led to try this experiment by observing a plant of the Asparagus Kale in my garden with a large fleshy bulbous root—ugly and tasteless, but which I thought might apparently a large quantity of eatable matter in it. In my experiments I found that although the white Turnip (as female parent) readily crossed with the Kale, I never could perceive that the contrary cross had taken place, or that the pollen of the white Turnip had influenced the seed of the Kale. On looking back at what I have written, I see that I have not stated as explicitly as I ought to have done that the seed I sowed last spring was the produce of plants which had been raised in regular yearly succession from the time of the original cross; and, although I can't say that, so far, I have got a Turnip possessing a good fixity of character, I can say that I have got a Swede (in appearance) of good quality, and that would require a good judge to select from the Swedes of ordinary growth a more speaking of my best specimens. There are others in the same drills, which are nothing to boast of. For two or three of the first years it was difficult to find a ripened seed. The plants flowered profusely, but showed no tendency to ripen their seed, and it was only by a careful search that I was able to find half-a-dozen seeds in the same number of flowering plants. *J. G., Clitheroe, November* 11.

The Price of Butcher's Meat.—In a letter of mine to the *Times*, which you did me the honour to transfer to your columns, a most mortifying typographical error had occurred, seriously affecting the very purport of the letter itself. The words *6d.* and *7d.* per lb. were printed *16d.* and *17d.*, completely destroying the effect of the comparison I wished to have drawn. My intention was to show to all housekeepers to whom the price of butcher's meat was an object, that the cooked slice of a roast leg of mutton cost them rather more per pound than twice the price paid to the butcher for the uncooked joint. And that equally nutritious and nearly as palatable meat was now being sold by the grocers, imported from Australia, at *6d.* per lb., as that which, bought from the butcher at 9½*d.*, cost 19*d.* per lb. when eaten. In a journal so devoted to the "practically useful" as yours, it would be waste of time to enlarge upon the importance of this consideration in the case of thousands of families in which the daily ration of wholesome fresh meat is an object of considerable importance. *Edward Wilson, Hayes, Kent.*

The Potato Crop in the North of Ireland.—I told you at the commencement of last month, that I had ascertained by personal observation and inquiry, that the current rumours respecting the failure of the Potato crop were in many cases totally untrue, and in others much exaggerated. My information was then necessarily premature, as the bulk of the crop was in the ground; and the Potatoes at that time diseased were just those which every season catch the blight early, more or less. Now that the greater portion of this year's growth has been dug up, I am in a position to form an approximate opinion of the yield, at least so far as the province of Ulster is concerned. In the majority of cases, the Skerries are sound, one large grower assuring me that on 70 perches he has not found 70 unsound Potatos. This was on a light sandy soil. On another farm, of a heavier soil, out of the produce of a ridge 7 perches long, there were not more than 3 stones diseased, and that is no excess upon last year. As a rule, the Potatos are smaller than in previous years, and this is particularly so where they were planted late. White Rocks, where planted early, have grown well, and contain about 9 stones of diseased Potatos to the 7-perch (Irish) ridge. Red Rocks, which up to this season have been considered a tolerably safe Potato against the disease, are more affected than the White Rocks, showing as many as 25 stones to the ridge. Where planted early, they are large, and very pleasant for the table; indeed, the whole of the sound portions of the crop are this year exceptionally good in that respect. In some of the low-lying districts, with strong loamy soils, one-half, and in some cases two-thirds, of the crop are lost; but this does not apply to any considerable extent of land, and will not be appreciably felt. In the county Monaghan, where the blight was supposed to have been very general, fully three-fourths of the crop has turned out sound. *G. H. P., Belfast.*

Theory and Practice of Agriculture: Seeding.—I state *in limine* that the foundation of profitable farming is, and ever must be, good cultivation. The kind of seeding, whether thick or thin, can compensate for imperfect cultivation; the soil must be deeply and as completely as possible comminuted, or the crops will be always hazardous, or not pay for the expense and trouble incurred in producing them; and further *Nebula* must be given to each portion of plants, whether cereals or legumes. But my object now is to treat of cereal seeding only, and chiefly of Wheat. My readers, I believe, are nearly all aware that I have now for more than 60 years practised what is called thin seeding, that is, sown with 1 peck of seed per acre and, as I have often explained, the crop answered admirably, being a yield of 204 pecks. Since then, which is now upwards of 60 years, I have, but with few years of intermission, grown Wheat from various quantities of seed per acre, but have never exceeded 2 pecks an acre until last year, when I sowed for seeding being very late, namely, November 26, 1 put in 2½ pecks; but still, as I have published, the crop was tolerably good, the yield being 49 bush. an acre, and it would have been more but that the crop became lodged from over-seeding, which of course caused the yield to be less. Some of you may think that I have not heard of this before, will probably be sceptical at this account; but what will they think when I tell them of three gentlemen farmers, each seeding many acres of land with much less seed per acre. One of them continued to sow 1½ peck per acre land for nearly 20 years in succession, and with marvellous success, and his profits, as he yearly advertised, were on an average more than £5 an acre, after allowing for every kind of expense, rent, tithe, rates, &c. Another of the trio, whose crops were equal in a square foot of ground, wrote to me a fortnight back, saying he was pursuing the same plan now, and with his former success, though he is now in his 86th year; and the other, who farmed nearly 2000 acres of chiefly arable land, never exceeded 4 pecks of seed an acre, and his crops were equally fine. These three gentlemen live in three different counties, and I could give the names of more who have pursued the same system. One of these (the gentleman who is 86 years old) begs of me not to mention his name, on account of the opposition that would be raised against him by the neighbouring farmers, but I may give the name of my friend, with so large a profit, put in his ¼ peck of seed only, and continued doing so for so many years: and he was a Mr. Piper, of Colne Engaine, Essex. Now, although I have long made up my mind that the man who cannot grow as good crops of Wheat from 2 pecks of seed as from more is not a good farmer, yet there is a danger in using much less than this, though there is also danger in using much more; but I will stop here, and explain each another time. *Geo. Wilkins, Vicarage, Wix, November* 6.

Societies.

HIGHLAND AND AGRICULTURAL.

Monthly Meeting.—Before proceeding to the business of the meeting, Sir JAMES GARDINER BAIRD reported the death of Mr. Russell, Pilmuir. In referring to his connection with the Society, Sir James stated that in 1856 Mr. Russell was named by the Society a member of the Council on Agricultural Education, and he held that office and acted as one of the board of examiners from that period till his death. Besides contributing various papers to the Society's Transactions, he acted as editor of that publication from 1860 to 1866. He was appointed a director of the Society in 1867, and his term of office would not have expired till January, 1872. The Society was indebted to Mr. Russell for acting as a member of various committees. Sir James Baird then moved:—"1. That the death of Mr. Russell, Pilmuir, having been communicated to the directors of the Highland and Agricultural Society of Scotland, they resolved to record in the minutes their deep regret for his loss, and their sense of the obligations which the Society owes to him as a director and an examiner in agricultural education. 2. That the Board direct that a copy of this resolution be transmitted to Mrs. Russell, with their respectful

condolence with her and her family under so painful a bereavement."—The resolution was unanimously adopted.

Trial of Potato Diggers.—At a meeting of the Inspecting Committee on Implements, held at Perth during the show, it was resolved that the implement left for them to select for special trial should be Potato diggers. The following is the report by the committee:—

The local committee of superintendence of implements in the showyard of the Highland and Agricultural Society at their last exhibition at Perth having resolved to give the exhibitors of the Potato diggers an opportunity for competitive trial, intimated this to all the exhibitors in the showyard. On Saturday, September 30, the trial came off in a field on the farm of Hilton, near Perth, kindly granted to the committee by Mr. Thomas Richmond, the tenant. The field was dry crofttand, deep soil, and free from stones. The crop of Potatos was first-class, being comparatively free from disease; but as the crop had been planted after ley there was here and there a good deal of unbroken turf intermixed with the soil, which, together with the strong crop of Potato tops, tested fully the machines exhibited, and their capabilities of working under difficulties was fairly tried. The members of committee of superintendence were Mr. Richmond of Balhaddies; Mr. Ross, Bachilton; Mr. Wilson, Fairmount Villas, Perth; Mr. Gardener, Chapelbank; and Mr. Elliot, Laighwood. The exhibitors who brought machines forward were the following:—

	Price of Machine.
J. Bisset & Sons, Marlee, Blairgowrie ..	£10 0 0
William Dewar, Kilis, Dundee ..	12 0 0
Law, Duncan & Co., Shettleston ..	16 0 0
James Mollison, Ruthrieg, Meigle ..	15 0 0
James Robertson, Coupar-Angus ..	21 0 0
R. Stewart, Buttergask, Coupar-Angus ..	12 0 0

The committee, after careful examination and full consideration, were unanimously of opinion that the diggers exhibited did the work remarkably well. The machine exhibited by Law, Duncan & Co., appeared to be more complicated, and some time was occupied in adjusting it; the work at first being imperfect; it made good work, however, after being taken aside and properly adjusted. Even if it had done its work equal to the others, the price, £16, in the opinion of the committee, would have told much against it. All the other machines did their work well, so much so that the committee came to the conclusion that they ought not to select any individual machine for special recommendation. The machines exhibited by J. Bisset & Sons, James Mollison, and James Robertson, in particular, did their work remarkably well, and although the committee do not feel themselves justified in selecting any particular machine and giving it precedence over the others tried, they would be pleased if the directors of the Society would intimate to the exhibitors the approval by the committee of the machines exhibited; and further the committee consider that the directors may call the attention of the public to Potato diggers, as there are many districts in the country where they are comparatively unknown, and to recommend them for general use on the recommendation of the committee, as the members of committee were of opinion that the work performed by the machines exhibited was in every way superior to what could have been done by either a single or double mouldboard-plough in the common way, the diggers laying the Potatos on the surface of the ground in a ready form for gathering, and taking them clean out of the soil, so that none can be subsequently found where a furrow was afterwards put across the land from which the Potatos had been raised. The committee, therefore, can with confidence recommend Potato diggers to the public, and to all farmers who cultivate Potatos generally, anything like a large scale. The machines are easily drawn, a pair of horses working them without difficulty.

The directors agreed to award the medium silver medal to each of the exhibitors of Potato diggers who attended the trial, and to record their thanks to the committee for carrying out the trial, and for their report.

Kelso Show, 1872.—It was remitted to the Committee on General Shows to fix the premiums and adjust the regulations for the show to be held at Kelso next year.

Proposed Show in 1873.—Requisitions in the directons to hold the general show at Stirling in 1873 for the district comprising the counties of Stirling, Dumbarton, and Clackmannan, and the western division of Perthshire, were submitted. The Board resolved to recommend to the general meeting in January to comply with the requisition, and it was remitted to the General Show Committee to suggest the classes of stock and make other necessary preliminary arrangements.

Register for Farm Servants.—At the meeting of the directors on February 1 last a special committee was appointed to consider and report on the propriety of recommending the adoption of registers throughout the country. At a meeting of this committee, held on July 12, Mr. Irvine of Drum reported that the subject of hiring markets had been before the directors in 1849 and 1860, when reports had been drawn up and published in the Society's Transactions. The queries issued in 1860 were submitted to the committee, and after careful revision it was resolved that they should be recommended to the Board to be again circulated among some of the leading farmers in each county in Scotland. The queries are as follow:—1st, How are farm-servants, male and female, including those for house or dairy work, engaged in your district? 2d, If hiring markets exist, do they work satisfactorily, or the reverse, in the way of obtaining good servants? 3d, Is attention paid at hiring markets to the previous character of servants, or are they generally engaged irrespective of character? 4th, Do country tradesmen, such as millers, smiths, wrights, &c., engage servants at hiring markets, and do any other persons attend them for a like purpose? 5th, Is it chiefly the younger class of servants who attend these markets, and are they regarded as holidays? 6th, Is earnest-money given when a servant is engaged, and if so, is there any disadvantage from the practice? 7th, Are hiring markets productive, directly or indirectly, of evil in your district? 8th, Are you of opinion that hiring markets are susceptible of improvement, or that they should be abolished? 9th, If susceptible of improvement, what means would you employ? 10th, If they should be abolished, what means would you employ, and what substitute would you suggest? 11th, If servants are obtained in your district without hiring markets, be pleased to specify the means, whether by a register, by certificate of character, or otherwise? 12th, Does your system work well? 13th, Do any registers exist in your district, and are they much used? 14th, Be good enough to furnish any suggestions or information not embraced in the foregoing queries. The queries were approved, and ordered to be circulated.

Chemical Department.—A meeting of the committee in charge of this department was held on October 25, to report on two remits from the directors.

The first was a motion made by Sir Thomas Buchan Hepburn, "to consider how far it may be possible or desirable to prepare a short account on the present state of chemistry as applied to practical agriculture." After various explanations had been asked and given, the committee agreed to report that the motion is further consideration as to the manner in which it can be carried out was deemed necessary, it was agreed to adjourn the meeting to a future day.

The second remit was a motion made by Mr. Scot Skirving, Camptoun, with reference to the sale of manures and feeding stuffs. The minute bears that the subject had been carefully considered by the committee, and that it had been resolved to recommend the directors to instruct Dr. Anderson to publish in the reports of the directors' meetings, the names of those selling manures and feeding stuffs with a guaranteed analysis differing materially from the analysis made by him in the laboratory.

The Board approved of the minute, and it was remitted to the committee to consider the discussion as to the chemical department which took place at the general meeting on June 21. Sir James Gardiner Baird was added to the committee.

Improvement of Land.—It was reported that the special committee on the improvement of land had held a meeting on October 25, when it was resolved to print the minutes of the proceedings of the committee a statement on the subject by Mr. Elliot, Laighwood, and to hold another meeting in January.

PETERBOROUGH.

Beet-Sugar Cultivation.—Mr. J. A. Clarke lately read a paper on this subject before the Peterborough District Chamber of Agriculture, commencing by asking his hearers to dismiss from their minds all unpleasant remembrances of former failures in attempts of a similar kind. For, in the first place, nearly all the experiments made in this country a few years ago, either in sugar making or in the distillation of spirit from roots, were made from the white sweet variety of the common Mangel Wurzel, which contains a very much smaller proportion of saccharine matter than the true Sugar-Beet. As to the manufacture upon the Continent, he said, it is sufficient to observe that experience, alike in France, Belgium, Holland, Prussia, Austria, and Russia, has convinced all parties that the Beet is a root culture and manufacture into such favour that, according to official estimates, the sugar production of Europe in the present season amounts to no less than 1,000,000 tons, this quantity of sugar being the product of probably 14,000,000 of acres of land from some 800,000 acres. And, in addition, there is a very great area of land under Beetroot for distilleries. When the crop is grown successfully in so many of the countries of Europe, under climates embracing great diversities of temperature and rainfall, and specially in Holland, Belgium, and northern France, which are visited by sunshine and drought, cloud and shower, snow and frost, about similarly to ourselves, it appears absurd to put the inquiry—"Are not the peculiar atmospheric conditions which prevail over the United Kingdom unfavourable to the growth of Sugar-Beet?" An effectual answer, however, is furnished by the quality of the roots themselves when grown here. In March last, Dr. Voelcker said, before the Society of Arts, "During the last three seasons, viz., 1868, 1869, and 1870, many samples of Beets from different parts of England, Scotland, and Ireland, brought me for a variety of soils and under different condition, have been analyzed by me, and I have thus been placed in a position to form a good idea of the quality of Sugar-Beets grown in the United Kingdom; and I may state without fear that the majority of the Beets I have inspected mens examined by me were found fully equal to the average quality of some good Sugar-Beets grown in the same seasons in France, Belgium, Holland, and Germany; and some I find as rich in sugar as the best specimens of French Beets."

Soils and Manures.—The soil most suitable for Sugar-beet is a free-working loam, the deeper the better; a good Mangel Wurzel or Turnip soil, or land which produces good Potatos, and is calcareous, containing as much lime as you like, so as to prevent "finger-and-toe" in the roots; and it must be capable of deep cultivation, as digging to a depth of 10 inches, and subsoiling 6 inches below that. I should think the very best implement to use would be a steam plough having a subsoiling tine following each plough body. Strong land is available, provided that deep tillage is practised before winter; but as the seed, the manner of sowing, and the growth of the young plants precisely resemble the same thing in common Mangel Wurzel, of course on stiff land you are more liable to a backward and gappy plant than upon a powdery mould, which the young plants can easily pierce through. Some light soils will produce good Beet, but a thin staple close upon rock will not do; and peaty or "skirty" land, as well as salt marsh enclosed, say within 20 years, is injurious to the properties of the root for sugar-making. But, as I have said, loams and clay-loams admitting of deep culture are the proper soils for the purpose. Sugar-Beet is not a cleansing fallow crop, or to be forced with heavy doses of farmyard dung, like Mangels or Potatos. The artificials to be used are superphosphate of lime, bone-dust, rape-cake, and other manures not containing much ammonia. The first was the direct employment of Peruvian guano, nitrate of soda, and other highly concentrated ammonia manures, must be avoided. Common salt, so beneficial to ordinary Mangel Wurzel, is to be eschewed like poison, for a very slight quantity of salt in the juice is found even worse than nitrogenous matters in hindering crystallisation of the sugar. There is this peculiarity about the crop; although not greedy of manure, and although producing a moderate weight per acre, which, with the exception of the tops, is all carted off the field, it is found to be a great exhauster of heart. Wherever this industry has been introduced on the Continent, it has heightened the style of cultivation, augmented the total production both of grain and meat, and at the same time added to the productive capacity of the soil. Thus, when the Emperor of the French visited his estate of Chambord, in 1853, the municipal authorities had inscribed upon a triumphal arch a statement of the increase of Wheat cultivation and the multiplication in the number of cattle and produce of meat and milk since the adoption of the Beetroot industry there. Prussia and Austria-Hungary I am acquainted with, give the same testimony to the advancement of agriculture by the establishment of beet-sugar factories and distilleries, whether in France, Germany, or other parts of Europe.

Growing, say 30 acres of Sugar-Beet, averaging 20 tons per acre, and bringing back from the factory your share of the pressed pulp or beet-cake, you will have about 120 tons of this new feeding material for cows or fatting bullocks. This would enable you to have as much root food as usual, with a somewhat less acreage of Mangels. For what is effective value of the beet pulp? Mr. Lavenham the price to growers is 12*s.* per ton, but I am informed that there are instances of farmers not wanting their share, and re-selling to neighbouring farmers at 15*s.* per ton.

Details of Cost and Cultivation.—To keep our Sugar-Beets small, and weighing from 1 lb. to 3 lb. or 4 lb. a-piece, and at the same time secure a sufficient number of them to give a paying weight per acre, we must crowd them on the land, so far as we can do so consistently with perfect "singling" and space for every root to thrive freely. On the Continent, a favourite plan is to drill in rows 12 inches apart, and set out the plants 12 inches asunder in the rows. If there were no gaps or failures, this would allow for 43,560 plants per acre, and at an average of 1½ lb. per root, the yield would be nearly 30 tons per acre. Undoubtedly this weight is much more than would be commonly obtained; but the calculation shows a result which is quite possible on good land with first-class management and in a favourable season. The time for sowing is about the middle of April, or, according to season, contemporaneously with early sowing of Mangels. The manner of putting in the seed, and the quantity of seed per row, are the same as for common Mangels; and, in the first instance, at any rate, best varieties will be bought on the Continent, and the whole of the seed be supplied from that source. The crop is ripe when the leaves begin to turn yellow, and when a freshly cut slice of root will remain exposed to the air for some time without turning a dark brown colour, although it may present a pink hue. The time will generally be early in October. Very varying estimates of the cost of producing Sugar-Beet have been published. Mr. William Biddell—an eminent practical farmer and land agent, and looked upon in his own county of Suffolk as a very high agricultural authority, who has grown the crop for several years, and had 60 acres last year, reckons the cost at 41*s.* 6*d.* per acre, without including interest of capital. This is when applying 16 loads of farmyard manure dung, 3 cwt. of superphosphate, and 1 cwt. of guano, and delivering the crop, 15 tons, at once to the factory. Rent is put at 33*s.*, and tithe 7*s.* 6*d.* per acre. On the Lavenham land, by no means first-class for producing heavy crops, and soil of a quality commanding only 33*s.* per acre rent, Mr. Biddell puts the yield at 15 tons per acre. This, however, is not gross weight as lifted from the ground, but the nett weight after the roots have had their crowns cut off, and have been washed perfectly clean. But 24 tons per acre have been grown at Lavenham:

five of the best crops in 1869 weighed 24, 21½, 19, 15, and 14¼ tons respectively.

The conclusions to be gathered from what I have now said, may be stated thus:—

1. Past figures form no guide as to the desirability of adopting the beetroot-sugar industry at the present time.

2. Sugar-Beets grow in this country fully equal to those of France, Belgium, and Germany, in the proportion of saccharine matter which they contain.

3. On suitable soils, in proper rotation, and under a liberal system of cattle feeding or manuring, there is no danger whatever of Sugar-Beets being exhaustive of fertility.

4. Owing to the nutritious and keeping properties of the pressed pulp or residue from the sugar factory it is easy to substitute Sugar-Beet for other crops, in such a way as to keep up or increase the ordinary supply of food for live stock.

5. Delivery to the factory by means of traction-engines may be arranged so as not to overtask the common force of horses upon a farm, so as to haul at a cheaper rate than by a grower's teams, and admit of the roots being grown within a radius extending to 7 or 8 miles from the factory.

6. The total cost of production, including £3 per acre for rent, tithe, taxes, and other common charges, can hardly exceed £11 7s. 6d. per acre, or, valuing the farm-yard manure, £13 7s. 6d. per acre.

7. The probable yield per acre may be put at 20 tons on an average of good and moderate seasons, ranging from less than 15 up to 25 or 30 tons gross weight, topped and cleaned as for cattle-feeding.

8. The price at which factories will contract with growers is 20s. per ton nett weight, the roots clear from earth and with their crowns cut off; or 18s. 6d. per ton for gross weight as delivered.

9. While a yield of 15 tons per acre would save the grower from loss, the expected average of 20 tons would give for profit and interest of capital £4 5s. 6d. per acre, or 38½ per cent. upon the outlay; a yield of 23 tons would leave £9 15s. 10d. per acre, or 73 per cent. upon the outlay; and the quite possible yield of 30 tons would return the very handsome profit of £14 7s. 6d. per acre, or 120 per cent. upon the outlay. This leaves an ample margin for covering a loss of say £4 or £5 per acre in an exceptionally bad season, when there might be only half a crop.

CORNWALL.

Foot-and-Mouth Disease.—At a recent meeting of the Cornwall County Chamber of Agriculture, held to consider what steps should be taken towards securing effectual legislation with reference to the contagious diseases of live stock,

Mr. W. TRETHEWY, who had undertaken to introduce the subject, said he had been unfortunate enough to buy a number of cattle at Bristol which turned out to have the disease. He thought it was absolutely necessary that something should be done to protect the herds of Great Britain from those diseases incident to the importation of foreign animals. It was in August last when he went to Bristol for the purpose of purchasing some stock for grazing purposes. Whilst there he observed that a great many of the animals were lame, and he called the attention of the salesmen to the fact, but he was told that it was in consequence of the animals having been driven a considerable distance by rail, and on board the steamer, and being unshipped the evening before. It did not for a moment occur to him that the animals were suffering from foot-and-mouth disease, as he had heard very little about it then, and he was not aware at the time that there was a single animal in the market diseased. When the 25 head of cattle arrived at Grampound Road next day, there were four or five of them very lame, and there was great difficulty in driving them to the field, about 2 miles from the station. In a few days afterwards Mr. Oliver, the veterinary surgeon, pronounced them to have the foot-and-mouth disease. Irish beasts were thus being brought in continually, week after week, with little or no inspection, and they were sent all over the kingdom. The result was that the disease was to be found in every parish in the county. He concluded by moving a resolution expressing the opinion of the Chamber that nothing short of slaughter of foreign fat stock at ports, and an efficient quarantine of store stock, would be sufficient to prevent the spread of the disease.

Mr. HOSKEN seconded the motion.

Mr. FREMANTLE suggested that some addition should be made to the resolution. He believed it to be the duty of the Government to take steps in two directions. In the first place, where the disease existed they should take such steps as would prevent its spreading in the neighbourhood, and he would ask Mr. Trethewy to embody that point in the resolution. It was the duty of the Government also to place such proper restrictions upon the importation of foreign cattle as that they should not communicate the disease to cattle on the English shores. The quarantine existing at present was utterly insufficient. There was not a veterinary surgeon in the country who could tell that the germs of this disease were not existing in an animal for weeks before it showed itself. The quarantine at present consisted of a veterinary examination, which was no quarantine at all. Such examination as was shown in the case of the Bristol market, where Mr. Trethewy was unfortunate enough to buy his cattle, was an utter absurdity. A veterinary examination without a quarantine could not be safe. He would therefore ask that they should embody in the resolution a request that the Government should put into their hands a power to deal with the disease at home, as well as dealing themselves more stringently with reference to the importation of foreign cattle. He mentioned a case in the parish of Antony, where a man had been brought before the magistrates for removing manure from a farm where the disease existed and taking it to an unaffected place; but the magistrates found that, though this would be an offence under the cattle plague regulations, the law did not apply in this particular to foot-and-mouth disease. Greater powers ought certainly to be put in the hands of local authorities.

Mr. MAGOR supposed he had been blamed by certain parties for going to Bristol to buy foreign stock, but he thought he was less likely to get the disease there, buying all his cattle together, than having them from several different places. He and Mr. Trethewy had gone carefully through the market, and they could not perceive anything like disease. When he got the bullocks home he told his son to fasten them up, away from the other cattle. There were no symptoms of lameness among them, and they appeared quite fresh, considering the journey they had travelled. A week afterwards he perceived one or two of the bullocks when eating cold not bite the grass off nicely, and he then expressed his fear that they had got the disease. There were only five or six of them that suffered considerably. He believed they all had had it, but they were all getting on very well now except one or two that were still lame, but he believed this was from the bruising. He quite agreed that the disease did not affect store bullocks as it did fat ones, but it was quite necessary that some steps should be taken to prevent its spread. Some of the people who bought at Summercourt fair had taken the disease east and west. It had not spread from his farm to any of his neighbours, nor had any of his other stock got it. He did not think it did nearly so much injury out of the house as it did in the house.

In reply to a question from Mr. Allanson, Mr. POLWHELE stated that when a farm had been isolated on account of the disease, 14 days must elapse after the veterinary surgeon had pronounced it to be free of disease before the farm was beyond prohibition.

Mr. ALLANSON said it was complained that those who had diseased cattle put them in fields too near their neighbours and as far off themselves as possible.

Mr. CHERMSIDE then put the altered resolution to the meeting, and it was as follows:—

"That, owing to the prevalence of the foot-and-mouth disease in this county, it is advisable that more stringent powers should be vested in the hands of local authorities, to prevent the spreading of the disease in places where it has appeared; and that, in order to prevent the introduction of contagious diseases through the importation of foreign stock, it is the opinion of this Chamber that nothing short of absolute and compulsory slaughter of foreign fat stock, &c., and efficient quarantine of store stock in separate parts of ports set aside for that purpose, will be effectual, and that this Chamber considers it is the duty of the Privy Council at once to place temporary restrictions upon the importation of stock from Ireland, as well as from foreign countries."

The resolution was carried unanimously.

PENRITH.

Steam Cultivation.—At a recent meeting of this Society Mr. FARRELL said:—

(1.) *Cleaning the Land.*—Supposing a practical farmer entered on a parcel of land which had been previously overrun with weeds, it would evidently be his first thought to rid the land of these unsightly pests. I therefore consider the question of thoroughly cleansing the soil from weeds to be one which demands our first attention. It is a well known fact, to those, at least, who have had proof by eyesight, that land can be better cleansed from weeds by steam-power than by any other. Where the soil is tilled to a depth not exceeding 5 or 6 inches, the surface is always full of the seeds of weeds—it becomes dirty and foul from the very face of its thinness, and the presence of water in any which I have to refer arises from the want of deeper cultivation, the absence of which fosters water-loving plants, which choke up the crops intended to be produced in the field. Again, having the advantage of cultivating at nearly all seasons of the year, farmers can nip the weeds in the bud and keep them under just when they are beginning to push forth their energies. With the ordinary system of ploughing, especially in wet weather, the seeds, weeds, and roots are all deposited beneath the surface, and the weeds which are propagated from roots or layers, such as Couch-grass—that horrid pest of the farmer (Triticum repens)—water-grass, Coltsfoot, and the like, being cut in pieces by the coulter, are indefinitely multiplied, and are placed in the best position for growing, as though the farmer had been studying how to get the best crop. Under the system I shall under this kind of management gets so wild that it takes a whole summer's fallow before it can be got into a fit state for producing another crop. Moreover, several roots seat themselves firmly beneath the track of the plough: it is, therefore, almost an impossibility to entirely eradicate them without having recourse to steam-power, or at least deeper cultivation of some kind, which is best carried out by implements driven by steam. Were steam cultivation more universal, large breadths of stubble would be thoroughly acted upon in the autumn months, that is, immediately after harvest, especially when we experience one of those glorious "second summers," which so often favour the British farmer—when the land is dry and the underground temperature high, the weeds are most easily destroyed, and farmers can give half a fallow to their lands, because one day's work then is equal to three in the spring. If only for the facile extirpation, or, better still, the total eradication of weeds, steam cultivation ought to be prized, for weeds are the pests of the farmer; they are the drones of the field—they feed and fatten on the various constituents of the soil which should go towards the growth and development of the crops.

(2.) *Treading is avoided by Steam Cultivation.*—The next great advantage to be derived from steam cultivation, on all strong or clay lands especially, is that treading is avoided. Suppose, for convenience sake, that a pair of horses, when ploughing, are half a yard at each movement, we have eight footprints per lineal yard. In ploughing a 9-inch furrow, the horses will travel 19,360 yards in order to complete an acre. Multiply this by eight, we have a total of 154,880 footprints upon an acre, or about 32 upon each square yard, and as these necessarily cover the ground the effect will be a hard subsoil or "pan" beneath the cultivated ground, which becomes worse at every successive ploughing, where the depth of furrow is taken; and, as if to perform the consolidating process more effectually, one horse is continually treading directly upon the subsoil, while the footsteps of the other are confined to the surface soil. Whoever has held a plough on land which has never been ploughed beyond a depth of 5 or 6 inches will know how difficult it is to penetrate the hardened subsoil even an inch below the depth of the ordinary cultivation of the field. The exceptions which horses make when drawing the plough over the stiff land are rendered almost double by the consolidated state of the soil, so that, anomalous though it may appear to the uninitiated, it requires much more power to cultivate land by horses than by steam. By the steam-engine there is no pressing or consolidating. The engine stands upon the headland, and draws the cultivating implement to and fro with a wire rope. The speed is also much more rapid, and consequently the soil is thrown up in the lightest possible state, so that it will receive the utmost benefit from the ameliorating influences of the atmosphere. When the pan or subsoil has been broken up the showers of rain pass off at once into the drains, and leave the various fertilising properties contained in them equally distributed throughout the soil, to be drawn off by future crops as occasion requires. On the other hand, when the subsoil is pressed year after year by heavy weights, it becomes so hard that a very long time is required before the water can get into the channels formed for its reception. This is especially the case with clay soil, which in time becomes almost like a disk, retaining the water so long that the surface soil is saturated in wet seasons, and this is one of the principal reasons why so much land is "starved," as it is locally termed. Deep cultivation is, therefore, an essential part of husbandry at the present day, because it makes the land a reservoir for crops and provides food for an increased population.

(3.) *Temperature of the Soil.*—Under this head, Mr. Farrel brought out some interesting facts. In the course of his observations he said the more uniformity there was maintained in the temperature of the soil, the more uniform were the results. What was the best temperature for the crops was a question not easily answered, but it was certain if we could raise it from the low point which retards and keeps at that point which hastens on and increases healthy growth, then evidently some good had been done. By having all the land equally loose, we get an equal temperature, and an equal temperature promotes equal growth, and equal growth produces equal grain crops, and equal grain crops produce equal samples, equal samples please both the miller and the maltster, and bring the greatest gain to the farmer's pocket. By raising the underground temperature, the temperature of the air is also improved and modulated, for it had been proved over and over again that thorough drainage has considerable effect on the climate. He maintained that the yellow and sickly appearance of the corn crops in the spring of the year, frequently attributed to grub, was caused by the plant coming in contact with stagnant water, aided by the lowness and inequality of the temperature. If they wanted wheat that the subsoil should be opened out and made free for water to pass through, taking with it air and manure, and the roots of plants would follow; and depend upon it, for every rootlet bent down in the mellow subsoil there will be a corresponding growth above. Therefore, he said, "dig deep and find the gold."

(4.) *Cost.*—The cost of cultivating land by steam power has been variously estimated, as, indeed, it is natural that it should be, considering the kind of land, depth of cultivation, and the different sorts of apparatus in use; but my idea is that, say 4s. to 5s. per acre will fairly represent the outlay, including interest upon money invested, depreciation and allowance for wear and tear. A really good farm horse cannot be kept for less than £34 per year, everything included. Double

this sum makes £68, and a man to work them about £35, making a total of £103, besides which an allowance must be made for implements used in cultivating. Taking interest on these, and wear and tear, it takes £110 per annum to work a pair of horses, and, although few farmers feel this directly, it is the case. A very large farm—within a certain limit—can be wrought much more economically than a small one. Take, for instance, a farm of 2000 acres, which can be cultivated to the depth of 6 or 8 inches for £400—or 4s. per acre, inclusive of depreciation and repairs. How many horses would it take to cultivate 2000 acres? Suppose a pair to plough 1 acre a day, it would require a team of 20 to average 10 acres per day, or 240 acres per month, and they would be employed between eight and nine months before they had completed the 2000 acres. Then the harness, implements, farriers' bills, wear and tear, interest, and depreciation, of those horses, would be something serious—nearly twice the original cost of the steam ploughing tackle. The average price of coals per horse-power per day, *i.e.*, the quantity of coals we should burn in an engine to get out of it work equal to one horse per day, would only amount to about 6cwt. a very small sum when compared with the food of a horse; for an engine, as I have said, only requires food when working, whereas horses eat night and day, and require several hours' rest out of the 24, but an engine will work the whole 24 hours if required. Then the work done by steam is not only more economical, but more efficient; not only is the cost of production decreased, but the production itself is much increased, especially in unfavourable years, when produce is at the maximum value. The expenses attending an ordinary engine for a day's work will be: Interest on outlay, 2*s.* 6*d.*; wear and tear, 2*s.*; engine-man, 3*s.*; cultivator man, 2*s.* 6*d.*; anchor man, 2*s.* 6*d.*; porter man, 2*s.* 6*d.*; boy attending engine, 1*s.* 4*d.*; man and horse fetching coals and water, 5*s.*; 6 cwt. coals at 8*d.*, 4*s.*; oil, grease, &c., 1*s.*; total, £1 8*s.* 4*d.* These are actual facts, given me by one connected with the working of an engine, although for the locality the wages are perhaps understated. Suppose the engine cultivates six acres per day, the total cost per acre is only from 4*s.* to 5*s.*

Farmers' Clubs.

WEST TEVIOTDALE.

Loss of Turnips from Frost.—Mr. Aitchison, Winningtonrig, read a paper on the "Best Means of Storing Turnips for Sheep and Cattle during the Winter Months." He said:—

From the Government statistics for 1870 it appeared there were 408,542 acres under Turnips in Scotland, which is nearly one-ninth of the land under cultivation. It is absolutely necessary that the enterprise the farmer displays should not be at an end when the Turnip crop comes to maturity. It is not so when grain crops are ripe; they are secured from the grasp of winter as rapidly as possible. It is true grain is more liable to injury by rain or snow than Turnips. But if the experience of the past two winters does not convince farmers that Turnips are liable to suffer damage by exposure to the frosts, it would be a hopeless task to convince them in any other way. The winter of 1869 and 1870 inflicted very heavy losses on the farmers, the frost coming on early in both seasons before a supply of Turnips could be secured on every farm. It continued till some time in February with such severity that from the want of snow on the ground more than two-thirds of the crop all over this country was in the middle of February rendered useless. The quality of the bulbs was very much injured more than a month before that, making a moderate allowance for the early destruction by frost and vermin. The total loss on Turnips in Scotland could not be less than £1,000,000 sterling. The winter matters very little better. Farmers had a little more time in the autumn to store Turnips, and from various causes the proportion was very small. In some districts there was a thin coating of snow on the ground during the intense frost, and this saved a little. Still the total loss this year was in some counties heavier than the last, and we may say that nearly another £1,000,000 was lost in 1870-71 in consequence of the ravages of the frost. There is no doubt that farmers must suffer first from such losses, and then the nation. A remedy must be provided when we have a large crop raised at great expense. But when the Turnips are not available in the spring, farmers have to resort to artificial feeding to carry their cattle forward to the grass, and have to spend a large amount of money on cake to maintain their store cattle, which the Turnips would do were they all saved. Further evidence is not wanted to bring the fact home to every farmer that the Turnip crop cannot stand the winter frost unless he successfully strive to preserve it. In regard to the storing of Turnips for winter use, as a very little frost is prejudicial to them when stored up into heaps, more particularly when they get frost after they are topped and tailed and lying in the ridges, the sure way is to carry them from the field immediately. In topping them, do not cut the skin of the Turnip either on the top or tail, as a Turnip of which the skin is broken always rots first. There is a mode of storing Turnips for winter use of which I think we will all have had some experience. After they are topped and tailed, they are thrown into small pits and covered up with clay. They keep very well in these pits, but if you have to go to the field in wet weather you injure the land very much, and, at the same time they come out very dirty. They must be washed before you can give them to cattle. I do not think this mode will preserve them from frost altogether, for I have gone to these pits on a hard frost and could not get a Turnip that cattle could eat. The Turnips were all hard frozen.

Another way is carting them off the field and putting them into long rows, about 6 feet at the bottom, tapering to a top. These pits must have a great quantity of straw put on them. It is almost impossible to keep out frost by storing them in this form, and in a high situation the spring winds wither them very much; so they must lose a considerable portion of their feeding qualities. The mode that I would recommend for winter use is to cart the Turnips off the land and put them into large heaps, something like the shape of a dunghill, about 3 feet in depth, covered well with straw and some rank horse-dung, taken from the stable, and put round the sides of the heap. Having Turnips stored in this way, the feeding qualities if stored in this way than by any other of the two modes mentioned.

Next, as to the best mode of storing Turnips for both sheep and cattle for spring use. When you enter the field to commence make your yard bones and plough—you must pull one row and throw it to a side. Then you take a single plough and go along the side of the growing row and lay out an ordinary furrow. Then you must have five or six labourers set at equal distances from each other; they pull two rows and set them into the furrow that is made. You next go down with the plough and turn back the furrow that was put out in coming up on to the top of the Turnips. On a level-lying field they may be covered both up and down; it answers much better when they are ploughed up. Set the rows. A man with a horse and rake and six labourers will level 3 acres per day. This is a more speedy system than topping and tailing: and it has another advantage, that it can be accomplished without any serious consequences, and answers well when the Turnips are too wet for carting otherwise. When you plough the Turnips up in the spring to the sheep or cattle, you will find that the roots have lost none of their feeding qualities; they are as good as when they were put down. Some will have this objection—how are the Turnips eaten off on wet land in wet weather? Well, I think this will be easily overcome. If you have a lot of sheep of 20 or 25 score, give them a break of 8 or 9 acres, then plough up one row and leave two over all the break; when they are well eaten-up, open one row and leave one, and so on. You will find that the sheep do very well, and the land is not much injured. If the spring happens to be an early one, and the Turnips running to seed, you can give your sheep all the field, and plough the rows up as they are required. I have been of opinion when we ploughed up the crop in the spring that it was a little lighter compared with the ordinary up; so I made a trial in November last. I selected nine Swede Turnips, 19 inches in circumference, and covered them up the same way, putting up a mark, and when I ploughed them up in the month of April two of the Turnips measured 20 inches, and the remaining seven did only 20 inches. I think this covering system should be commenced, if possible, before the frost sets in, and even before the Turnips arrive at full maturity.

Notices of Books.

Superphosphate and Allied Manures; *How to Make, Buy, Value, and Use.* By Alfred Sibson, F.C.S., 3, Eaton Terrace, St. John's Wood, London, S.W.

There can hardly be a more directly useful subject for the study of the farmer than the one here named; and the author of this little pamphlet is perfectly competent to give full and trustworthy information and instruction on it. Unfortunately, however, the sentences are often so vaguely worded that they do not convey their intended meaning, or, indeed, any other, with sufficient distinctness to be understood. Take the following account, for example, of the theory of the superphosphate manufacture:—

"The theory of the process may be thus described: the natural phosphate of lime consists of three equivalents of lime to one of phosphoric acid (hence called tribasic), and in this form is insoluble in water. The sulphuric acid added, being a much stronger acid than phosphoric acid, takes away two of the three equivalents of lime, and forms sulphate of lime, leaving the phosphoric acid combined with the remaining one equivalent of lime to form 'bi-phosphate of lime,' or 'mono-phosphate of lime,' which is soluble in water, that is to say, dissolves, or goes out of itself in water, like sugar or salt does. The bi-phosphate signifies the amount of tribasic phosphate (also called 'bone-earth,' because it is the characteristic constituent of the bones of animals) decomposed by acid; hence, in stating the analysis, we say, 'bi-phosphate of lime,' so much, 'equal to bone-earth made soluble,' so much,—this latter is the soluble phosphate because it is the percentage of the original phosphate made soluble in the process. Hence also when the soluble phosphate only is determined by analysis, it is usual to say, 'phosphate of lime made soluble'—so much per cent., which is the bone-earth above stated, and not the bi-phosphate."

Beyond the main fact of the solubility of the formed superphosphate, an ordinary reader is, we imagine, rather confounded than informed by the details of the explanation thus offered to him. The following practical instructions in making superphosphates are, however, clear enough:—

"The sulphuric acid is usually purchased as brown acid, having a specific gravity of about 1.700.

"In making on the large scale it is, of course, advisable to purchase the materials in large quantities, generally by the ship-load, in their natural state, and to grind them oneself: it is also an obvious advantage, and is the practice with most large manufacturers, to make the sulphuric acid they require from sulphur or pyrites and nitrate in acid chambers, while the mixing or dissolving process is effected by steam-power. For making on the smaller scale, however, the phosphates are obtained ready ground, and the acid as above stated, the mixing being effected in strong wooden troughs by hand.

"On mixing the phosphate with the acid, a brisk action at first ensues, owing to the liberation of carbonic acid gas, &c., but after a few minutes' stirring it ceases, and the creamy fluid gradually thickens and dries up until, in about 24 hours, if properly made, it is quite solid. The proportions in which to mix the materials are varied somewhat by different makers, but the following proportions are well adapted for making either on the large or smaller scales, and are offered for the benefit both of farmers and intending manufacturers.

"For a mineral superphosphate:—

20 cwt. of Cambridge copro-lite		17 cwt. of brown acid	
		3 ,, water*	

"For a bone superphosphate:—

6 cwt. of ½-inch bones		16 cwt. of brown acid	
14 ,, Cambridge copro-lite		3 ,, water	
		2 ,, gypsum	

"For a concentrated bone-superphosphate:—

20 cwt. of bone-ash		2½ cwt. of water	
16 ,, brown acid			

Other phosphates are, of course, equally suitable, but the above are generally most easy to obtain in small quantities.

"The water should be added to the acid before it is mixed with the phosphates: it should be carefully mixed with a portion of the acid, and well stirred, and the whole afterwards added, otherwise the water will not be uniformly distributed, and its being so is one of the chief points of success. It is less trouble to add the water to the dry materials, and afterwards the acid, but in this case the action is too violent and the product does not dry so well.

"The mixing may be effected in a trough of stout plank, about 9 feet by 4 feet by 3 feet, pitched inside; and thoroughly stirred with a wooden rake for three or four minutes, or until the mass begins to thicken, when it should be left untouched for at least 24 hours, or until it allows of being taken out. The materials lose from 7 to 10 per cent. in mixing."

In valuing manures, Mr. Sibson proposes the following prices per unit of the several ingredients:—

"At the following prices for the phosphates† and nitrogen, we may leave out of consideration the gypsum, organic matter, and alkaline salts (except in ease of potash), and so simplify the calculation.

	Per unit.	Per ½ unit.	Per ¼ unit.
	s. d.	*s. d.*	*s. d.*
Soluble phosphate	4 3	2 0	1 0
Precipitated phosphate ..	3 0	1 6	0 9
Insoluble phosphate in bone	3 3	1 6	0 9
Insoluble mineral phosphate } up to 7 per cent. .. }	0 9	—	—
Potash	3 0	1 6	0 9
Ammonia	25 0‡	—	—

To this he has since added, by a post-card, issued wherever his pamphlet has been sent:—

"The price per unit for ammonia is intended to apply only to manures of the kind treated of—viz., 'Superphosphates and allied manures,' in which the ammonia forms a comparatively small item, and in conjunction with phosphates at the prices given. For corn manures, or those containing much nitrogen, a higher value per unit would be adopted, but in view of the rapidly increasing price of this item, it would be inadvisable, at present, to name a general value."

Several examples are given of valuation by means of these data, and they appear to apply with accuracy to the instances of both genuine and adulterated manures which are quoted.

A few sentences at the close of the tract are all that the author says upon the "use" of these manures; but this is a point wherein the want of information is often very costly. It is very properly stated that—

"A thorough dissemination of the manure with the soil is the most important point to be attended to, and the more care bestowed on this the better return we shall be likely to get for the money expended. For this reason a dry and powdery condition is now deemed an essential quality of all good manures, and to attain this in conjunction with a good chemical composition is the chief object to be sought by all manure manufacturers."

And we conclude with the author by quoting his last sentences, which are equally trustworthy:—

"A fine condition of the soil, as obtained by careful cultivation and management to secure the benefit of the

* A gallon of water weighs about 10 lb.

† Soluble phosphate can, of course, be had for lower prices than this in quantities, and under special circumstances.

‡ Or 1*s.* 6*d.* per unit.

frost, &c., adds much, as well-known, to the efficiency of manures, in fact is tantamount to a further dressing of manure,—a smaller quantity thus supplemented being more effective than a larger quantity on a roughly prepared soil, where much of the manure added gets buried under clods out of the reach of the plants. By attention to these points, it is quite possible to make 3 or 4 cwt. per acre do the work of 5 or 6. Finally, it may be added that steam cultivation, when applicable, affords us invaluable assistance to this end, and, conjointly with good artificial manures, consistent, without doubt, one of the main stays of modern agriculture."

Farm Memoranda.

TATTENHALL FARM.—The following notes, revised by the late Mr. Jackson, of Tattenhall Hall, are from the pen of Mr. R. Heath :—

The dairy farm here, in the tenancy of Mr. Jackson, is an example of the factory system of cheese-making, and is on a sufficiently large scale to admit of the application of every economic advantage.

The farm contains about 330 acres, two-thirds pasture land, and the remainder under tillage. Behind the house, a fine old mansion of red brick and stone, built more than 200 years ago, rise extensive farm buildings, designed by the present tenant. The cow-houses, or shippons, will accommodate 80 cows. Here they are brought as soon as the cold weather sets in and the supply of grass begins to fail. They stand in stalls on each side of the feeding passage, down which their food is carried by a truck to the troughs, while a constant stream of fresh water is flowing along the two lines, affording the cows as much drink as they choose to take. During the first month of their indoor life, that is, until about the middle of December, the cows are fed with straw-chaff and Turnip-tops; from that time until March, Swede Turnips take the place of the green food. Then the quantity of roots is diminished, and in their place they get a mixture of hay and straw-chaff, crushed Indian Corn, and oilcake. Everything is done by machinery moved by steam, the roots chopped, and the chaff, &c., steamed with hot water and oilcake grud.

The calves, too, go through a regular course of diet, beginning with their mother's milk and going on to oatmeal gruel, and then Linseed and gruel, until they take to pasture freely.

The cows are milked twice a-day in the shippons; the average amount produced by 80 cows during the months of May and June is 240 galls. per day, from which four cheeses of 60 lb. weight each are made.

From the shippons I went into the cheese factory. Here the heavy work is done by water-power, the situation affording an unusually good supply of spring water, three streams running through the farm, not only irrigating the pastures, but also working a corn mill. The machinery of the cheese factory is set in motion by means of a small water-wheel called "a turbine."

Every evening the milk is brought into the dairy and put into a large vat, beneath which a constant stream of cold water is kept flowing to prevent it turning sour. In the morning the new milk is added, and also that from another farm two miles distant. The whole quantity is then placed in a large tin bath, and the temperature kept to 84°, by hot and cold water-pipes. It is then coloured, and the rennet put in, coagulation occurring in about an hour. The curd is cut with an American knife containing 12 parallel steel blades of about 20 inches long. This is drawn both ways through the bath, and the curds being cut in pieces, sink to the bottom. They are then carefully turned over by the hand, and kept moving while the temperature is gradually raised to 80° or 90°. A syphon is now introduced, and the whey partially drawn off, enough being left to float the curds, which are occasionally stirred to prevent them packing too closely. When the acid is sufficiently developed, the curds are dipped into a cloth strainer and drained, and then passed through the curd-mill, salt being added at the rate of 1 lb. for every 35 lb. of curd.

After this has been done, the cheeses are carried into the press-room, and put in round wooden vats, and placed in the presses. The pressure at first gentle, but afterwards increased for three or four days. They are then removed by a crane to the drying-room above, where they are kept for six weeks and then sold, commanding the best price in the markets.

Miscellaneous.

PAUPERISM AND THE POOR-LAW.—There is an association, co-extensive with the Poor-law districts, now rapidly spreading over London, and known as the "Society for Organising Charity and Repressing Mendicity," some of the members of which from the first commencement realized this difficulty, namely, when John Thrift and William Spendall appear before a Board of Guardians, John Thrift, who has made some provision for himself and family, is sent empty away, but William Spendall, who has never saved a farthing, is provided and cared for by the other ratepayers, and goes home rejoicing to pauperize his friends and neighbours. This society, through some of its committees, has attempted, as far as might be in the two or three years of its existence, to reverse this principle. John Thrift is to them a subject for assistance and sympathy, but William Spendall must look to the bare subsistence of the Poor-law. Is it impracticable to introduce such a policy into our present Poor-law? Here is a sort of outline for consideration, *quantum valeat* :—

1. Administer generally your relief on a more liberal scale to those who have made some attempt at provision for themselves than to those who have not, and so set a premium on thrift.

2. As a rule the annuity or allowance of a friendly society should not be directly supplemented, since it ought to be adequate ; but give to non-subscribers, *ceteris paribus*, two-thirds only of what members are receiving, or the offer of the workhouse.

3. As a matter of principle and general rule, make it extensively known that those who when able make no provision for themselves will get less favour, if, indeed, short out-relief given at all. This need in no way be adopted at first as a hard-and-fast rule, but merely declared as the ulterior practice gradually to be taught to the poor, and the example of a few cases will soon be found sufficient.

4. A Government recognition and insurance of all benefit societies that will pass a liberal scale drawn up by actuaries ; namely, on the principle that one generation shoulds not burden itself to nurse—that cares him that takes and him that gives ; no, not that, but hearty co-operation and personal service, with money spent on sound economic 5 per cent. principles, such as the improvement of the dwellings of the poor in towns has proved to be, and which is all an associated power of repression towards vagrancy and improvidence. To sum up, then, and to repeat the practical causes that have been found to reduce pauperism to a minimum, and out-door relief to the smallest in England, they are these :—1, a strict administration of out-relief ; 2, personal charity, supervision, and sympathy ; 3, sanitary precaution ; 4, and last, but not least, a practical reversal of the present Poor-law policy, and a revolution by administration in setting a premium on thrift. *Sir Baldwyn Leighton, at the Leeds Social Science Congress.*

Side by side with a strictly administered Poor-law we should require and desire, especially in towns, a thorough co-extensive administration of localised and organised charity ; not that thoughtless, easy giving, miscalled charity ; not that vicarious system of paid secretaries, endowments, subscriptions, and sympathy by deputy, which we have ourself-that cures him that takes and him that gives ; no, not that, but hearty co-operation and personal service, with money spent on sound economic 5 per cent. principles, such as the improvement of the dwellings of the poor in towns has proved to be, and which is all an associated power of repression towards vagrancy and improvidence. To sum up, then, and to repeat the practical causes that have been found to reduce pauperism to a minimum, and out-door relief to the smallest in England, they are these :—1, a strict administration of out-relief ; 2, personal charity, supervision, and sympathy ; 3, sanitary precaution ; 4, and last, but not least, a practical reversal of the present Poor-law policy, and a revolution by administration in setting a premium on thrift. *Sir Baldwyn Leighton, at the Leeds Social Science Congress.*

The Week's Work.

NOVEMBER 21.—*Stubble Land* early receives a thorough autumn fallow in the North as in the South of England—ploughing the stubble being the principal team-work during this month, the deep winter furrow with four horses being all that the land gets. When stubble land is clean and free from weeds, as it always should be, and very generally now is, many prefer laying the ridges in a deep winter furrow, under the conviction that teasing it afterwards with the scarifier does more harm than good. For Peas and Beans, farmyard manure is not unfrequently spread upon the stubbles, and either ploughed or ribbed in. In such cases the bottom should be subsoiled, as the manure should be covered with a shallow furrow. Manuring at this season is to be preferred to manuring in early spring, on the twofold ground that it suits the Bean crop better, and that any injury done the land in carting manure is rectified by the winter frost. The work of ridging, subsoiling, and covering the manure is much better and more effectually done by steam ridging and subsoil ploughing than by horse-ploughs—the land being left better drained, and exposed to the weather during winter. The above, however, chiefly applies to clean land. In all cases where the staple is thin or poor, the subsoil or other drainage should be taken in an early season like this of giving the stubbles a thorough cleansing autumn fallow during this and the previous month in our northern counties, where stubble Turnips and smothering crops cannot be profitably grown.

Lea-ploughing for spring corn—and this again is northern practice—follows stubble-ploughing for root crops, and is usually the second year's work in the bottom of the open furrow, covering it thoroughly with the furrow-slice, so as effectually to rot the whole of the vegetable and animal matter it contains. The rotten organic matter thus reduced to the form of plant food will start spring corn rapidly, placing it beyond harm. On the other hand, when a great crop of grass is growing between every two furrow-slices, it not only robs the land of manure, but the tender roots of such grass furnish a plentiful supply of food for insects until the roots of the corn are available. Old lea, with much effete vegetable matter on the surface, should have a light dressing of lime 10 days or a month before ploughing, purposely to rot the green sod when skimmed into and covered in the bottom of the furrow.

Sheep in the pastures should be greatly thinned, and should have ample hovel-room at night. Fields possessing suitable shelter should be reserved for breeding ewes in stormy weather, and where shelter does not exist naturally it should be provided artificially, not only for ewes and lambs, and in-lamb ewes, but also for young store sheep intended for breeding.

Notices to Correspondents.

CHICORY FOR GRAZING : *Subscriber.* The soil should be prepared by thorough cleaning early in spring, and a good coat of rotten dung applied. Drill 4 lb. of seed per acre in March, in rows 9 inches apart. Single them out when 5 inches high to 6 inches apart. The crop will continue luxuriant under good management for six or eight years. After full growth is obtained, cut it down before flowering, and carry it to stock in the house. It may also be depastured with sheep, but the other is the more productive use of it.

HORSE SHOEING : *An Original Subscriber* asks if any of our readers will kindly say whether they know of any one who shoes horses on the "Charlier" or Good-enough system within 10 miles of Ascot Heath ?

SALT : *Northumberland.* Four cwt. per acre will not kill weeds on light land. You must get the weeds up by scarifying, harrowing, gathering, and burning. Earlier in the year you might have done a great deal to it by mere sunshine.

TO LAY DOWN GRASS : *T. F. M.* says :—We have a small pasture in which the roots of Yarrow (Achillea Millefolium) have so far spread as to outstrip in growth the grass herbage. In order to rid the pasture of what we consider a weedy pest, we have commenced digging up and carting away the surface soil for about 6 inches, that is, such as we can discern contains the least particle of the Yarrow root. By this means we hope to destroy it, or at least to arrest its progress for some time to come. After we have applied the remaining soil and dug it throughout one spit deep, we intend sowing it for a permanent pasture wherein to feed our milch cows, as formerly. As we shall not have finished the preparation of the soil for sowing until the beginning of December, we are desirous of ascertaining whether you consider it would be too late in the season to sow the seed. [It is now too late to sow grass seeds. The sowing should be delayed till March. Sheep feeding is generally harder and later, and therefore more injurious to young grass than depasturing by cattle. Read Mr. Thompson's essay on this subject in the English Agricultural Society's Journal.]

Markets.

ENGLISH WOOL.

The market during the last week has been very strong, and with a continuance of the export demand for France and America, which has already commenced, we think prices likely to advance at least another *1d.* per lb.

MARK LANE.

MONDAY, Nov. 13.

The supply of English Wheat to this morning's market was small, and was sold at the extreme prices of this day se'nnight. There was a good attendance, and rather more demand for foreign, at late rates. Barley sold slowly, at prices of last week. Beans and Peas were unchanged in value. The Oat trade was firm, and new brought rather more money. Maize was *6d.* per qr. dearer. Flour was steady, without alteration.

WEDNESDAY, Nov. 15.

Less firmness was apparent here to-day, owing to the warmer temperature. The supplies of English Wheat were short, but those from abroad were liberal. Sales in all descriptions were effected quietly, at the rates current on Monday last. Barley was dealt in cautiously, on former terms. Malt was inactive, but not quotably lower. Of Oats there was a good show, which changed hands less freely at previous quotations. Beans and Peas were quiet, without change in prices. Transactions in Flour were restricted, and prices occasionally favoured buyers.

LIVERPOOL, Nov. 14.—The market was numerously attended by millers, and ultimately the business in Wheat reached a moderately fair total, prices being *1d.* to *2d.* per cental dearer on the week for American white and winter red. Flour quiet, at previous rates. Peas in fair demand. Beans unchanged. Indian Corn in moderate request from consumers, prices showing no alteration.

METROPOLITAN CATTLE MARKET.

MONDAY, Nov. 13.

The number of Beasts is very much smaller than on last Monday, and consequently trade has recovered from that day's slight depression in price. The weather being favourable for slaughtering, a fair clearance is effected. Although the supply of Sheep is much smaller than last week, trade is not so brisk. It is difficult to realise late prices even for choicest qualities. Trade is less active for Calves. Our foreign supply consists of 2420 Beasts, 10,800 Sheep, 284 Calves, and 20 Pigs ; from Scotland there are 50 Beasts ; from Ireland, 1000 ; and 1380 from the Midland and Home Counties.

			Pigs	3	4—5 0

Beasts, 4830 ; Sheep and Lambs, 18,030 ; Calves, 288 ; Pigs, 30.

THURSDAY, Nov. 16.

There are a few more foreign Beasts than last Thursday, but scarcely as many English ; the trade is dull, yet choice qualities are so scarce they make about the same as on Monday. The supply of English Sheep is also very short, of foreign rather larger ; there is very little business doing, but quotations remain unaltered. There is no alteration in the Calf trade. Our foreign supply consists of 415 Beasts, 5140 Sheep, and 139 Calves.

HOPS.

BOROUGH MARKET, Nov. 15.

The trade during the week has not been heavy, nevertheless planters have not pressed their Hops on the market, and the stocks remaining unsold being small, prices are fully maintained. The demand has been chiefly confined to the middle qualities of Mid and Weald of Kent Hops. The Bavarian and Alsace markets have advanced 5s. to 10s. per cwt., and the Alost market has declined to an equal extent.

SEED MARKET.

Red Clover has excited during the past few days considerable attention, and values have advanced 4s. to 5s. per cwt. Of American seed there is no great quantity on offer ; what little has appeared in the market has been eagerly bought up. Yearling parcels of Clover have also met with a brisk inquiry. White Clover must be quoted 2s. to 3s. per cwt. dearer. Trefoils are firm. In French Italian the recent advance has been well maintained. Perennial Grasses are steady. Winter Tares are in slow request. In Mustard and Rape seed there is but little passing. Other articles show no alteration.

ORCHIDS. — Gentlemen interested in this class of Plants would do well to inspect our Establishment at Fairfield, and to judge of our mode of growing for themselves. The House we have recently erected, in which the plan of supplying moisture by continued precipitation, without any disadvantage to neatness in appearance, has been the admiration of every visitor, and excites universal surprise that means so simple should have been so long neglected.

JAMES BROOKE AND CO., 16 and 18, Victoria Street, Manchester Nurseries: Fairfield, near Manchester.

Forest Trees.

WOOD AND INGRAM offer as follows, very fine stuff:—

To Planters.
J. SCOTT, Merriott, Somerset, advises Planters to send for his ORCHARDIST and its COMPANION, price 2s., before ordering their Fruit Trees. Ornamental planters, amateurs, and gardening folks generally, will find much useful information in J. S.'s CEMETERY, PARK, LAWN, and SEED CATALOGUES: they are full of interesting matter suited for gardens and gardeners, gratis.
THE FRUIT TREES cover many acres, and are in perfect health: soon sorted for Forest or Fruit Plantations, or to improve and thin out fruits in proportion.
The FOREST TREES and ORNAMENTAL SHRUBS occupy a large space, more especially Alder, Ash, Birch, Beech, Chestnuts, Elms, Firs, Hollies, Limes, Larches, Spruces, Hazel, Maple, Poplars, and at least one million of healthy Thorns, in all the usual sizes.
A NEW CATALOGUE, coming all the above enumerated in the "Orchardist," and many new sorts introduced since that work was printed, gratis on application.

Planting Season.
To PLANTERS of PUBLIC PARKS, CEMETERIES, or PRIVATE GARDENS.
WILLIAM CRIPPS solicits inspection of his unrivalled Stock of choice EVERGREEN SHRUBS, FOREST and ORNAMENTAL TREES, which he is disposing of at very moderate prices, in order to clear the land for building purposes.
Among the Evergreens are many thousands of fine specimens of Variegated and Broad-leaved GREEN HOLLIES, and an immense stock of all other HARDY EVERGREEN FLOWERING SHRUBS and OAKS which have been grown expressly for cultivation, many of which are of large size, well calculated for giving immediate effect.
To Gentlemen about to form new or to improve old Pleasure Grounds this is an excellent opportunity; for such an extensive and well-grown stock of Trees rarely can be had so seldom if ever before been offered for Sale, either for extent or variety.
Nursery and Seed Stores—Walton-on-the-Hill.
Seed Warehouse—15, Queen Square.
Liverpool, September, 1871.

Orchids.
JAMES BROOKE AND CO., Nurseries, Fairfield, near Manchester.—Our recent importations of choice ORCHIDS, especially of the best and most showy kinds, having been extensive, and the plants being all in excellent condition, we are enabled to offer them on terms unusually advantageous. Where they have not yet flowered in this country, and the choice is left to ourselves, the purchaser pays less than the catalogue prices, and is no loser in regard to any variety he may obtain. The plants we have now in succession of such orders have, we are informed, given unmixed satisfaction. The following, offered at moderate prices, will be found worthy the attention of purchasers:—
Dendrobium Falconeri, 21s. to 63s. each; D. Wardianum, 63s. to 105s.; D. chrysotis, 21s. to 63s.; D. McCarthiæ, 42s. to 84s.; D. heterocarpum, 5s. to 10s. 6d.; D. Griffithsianum, 10s. 6d. to 21s.; D. parishii, 5s. to 10s. 6d.; D. Devonianum, 7s. 6d. to 21s.; D. nobile, 5s. to 10s. 6d.; Odontoglossum grande, 7s. 6d. to 10s. 6d.; O. Insleayi, 7s. 6d. to 10s. 6d.; O. Lindleyanum, 5s. 6d. to 7s. 6d.; O. luteo-purpureum, 5s. 6d. to 7s. 6d.; O. gloriosum, 25s.; O. Alexandræ (Blumii), 21s. to 63s.; O. Pescatorei, 21s. to 63s.; O. hastilabium, 21s. to 31s. 6d.; O. Rossii majus, Cymbidium eburneum, 21s. to 31s. 6d.; C. Lowianum, 21s. to 31s. 6d.; C. Mastersii, 21s. to 31s. 6d.; C. Tracyanum, 15s.; C. Wiganianum, 21s. to 31s. 6d.; Barkeria Skinneri, 10s. 6d. to 63s.; B. spectabilis, 7s. 6d. to 10s. 6d.; Calanthe vestita, 5s. 6d. to 21s.; C. Veitchii, 21s. 6d. to 42s.; Cœlogyne cristatum, 10s. 6d. to 63s.; Oncidium Phalænopsis, 7s. 6d. to 10s. 6d.; O. Krameri, 42s.; O. Cavendishianum, 5s. 6d. to 7s. 6d.; O. Marshallianum, 5s. 6d. to 7s. 6d.; O. Rossii, 5s. 6d. to 7s. 6d.; O. Rossii majus, 5s. 6d. to 7s. 6d.; O. Rossii majus, 5s. 6d. to 7s. 6d.; O. Rossii majus

The Gardeners' Chronicle

SATURDAY, NOVEMBER 25, 1871.

GENERALISATIONS and general terms are so extremely convenient, that we are all glad to make use of them when occasion demands; those of us who are oppressed with facts more especially. But just as he who deals too exclusively with facts fails to get a clear view of the wood by reason of the trees, so he who from a vantage ground surveys the wood is very apt to disregard the individual trees composing it. Is it true with GARDENS and GARDENING? Do we not every day make use of these words, and only now and then give a thought to the multiplicity of things those words imply? It is only occasionally, so to speak, that the vast differences between gardens and gardens strike us. And yet how different one from the other are those, even, which we speak of as complete establishments. Every place has some special feature of its own. Here is a garden in its formal terrace walk, its severe geometric beds, all a-blaze with boldly contrasted colours; its clipped shrubs, its vases, and its statuary. All here is formal, but all is balanced and accurate to a hair's-breadth. It is architecture supplemented by flowers. Look from the walk or descend the steps, and see stretching away in simple lines a vast sward of greenest turf. This serves as a setting for beds which in spring are filled with flowers of the softest shades of colour, merging one into the other, as the tints on a peacock's feather do—pleasing from any aspect, beautiful in any light. In the distance, it may be, is a winding stream or a lake, and beyond are the blue hills, with dense masses of forest growth at the base, varying in tint with every change of season, ay, with every passing cloud.

It may be that we find ourselves in some sheltered spots amid these woods, and there, protected by undulating mounds and spreading trees, we find standing out in relief the bold foliage of the Palms, the Yuccas, the Dracænas, the Cannas, or the more graceful fronds of the Tree Ferns. Here we taste something of the delights of those whose privilege it is to roam amid tropical vegetation. There is the additional advantage of freedom from such disagreeables as jungle fevers, inundating rains, savage beasts, and exasperating insects.

Again we enter a spacious domain through an avenue of giant Limes, allowing glimpses here and there of an undulating park, and giving access to a pleasure ground whose every path is a line of grace, every mound a wave of beauty. Here are noble vistas between the trees, terminating in some striking architectural feature or enticing the eye to rest on some beautiful prospect. Here are mounds skilfully disposed to carry the view on from point to point till the sense of limitation is lost. Specimen trees of beautiful proportions dotted here and there to break up the scene and give it life, or disposed in groups to afford imposing masses of foliage, supply tone and colour to the picture, and, perchance, give shelter to the garden or conceal less attractive features. A few steps may bring us to a rustic arch, and passing through it we may find ourselves in a wilderness of weird, rugged, gnarled stumps, which look as if some CALIBAN or CYCLOPS had got them together and thrown them down haphazard, and Time had draped them with Ferns, and Moss, and Ivy, and wild flowers. Every chink, every cranny, is full of verdure and graceful forms. Below, with many a flashing ripple, is a brook, and in and about it grow Osmunda, and Marsh Fern, and yellow Flags, Forget-me-Nots, and Water Lilies; while above are graceful Birch trees, and Willows, and silvery Poplars, intermixed here and there with the darker hue and sterner form of some Conifer. Or we may be in a grotesque garden, where grinning satyrs, yawning dragons, mocking monkeys, or their counterfeits in quaintly-shaped roots or rocks, amuse or astonish us. Here we are very likely to find a rockery glowing with the brilliant colours of the "alpines"—the flowers individually small, perhaps, but they are pure and brilliant as a summer's sky. They grow in hummocks, and they often have quaint, stiff, formal leaves, assorting well with their surroundings.

Again, another type of garden is before us. It is in fragments like a puzzle, but each fragment has a definite purpose, and is devised for the fulfilment of that purpose. This plant, or this group of plants requires shelter, that demands full exposure; a light dry soil pleases this one, a rich deep loam is essential to that; a dry well-drained subsoil is necessary for the one, a stiff retentive one is the chosen home of the other. And so with the houses: in this type of garden they are small, they are numerous in all aspects, they are of all shapes, all heights. The temperature and humidity maintained in them vary proportionately. Each plant, be it Orchid or Fern, Agave or bulb, Palm or cactus, is carefully studied and noted to ascertain what are its requirements, and how they can be best fulfilled.

And then there are the gardens of the florist proper; he careth not for effect, for diversity, for harmony,—his purpose is a single one, and he pursues it singly. Absolute perfection in one thing, as judged by his standard, is what he aims at. Does a truss of Roses heedlessly appear on his budded Briers? All save one are sacrificed with as little or less compunction than is felt in the consignment of a litter of kittens to the nearest horse-pond. His Dahlias are carefully staked and shaded, flower-pots culminate on the top of the sticks, or perchance even a lobster claw forms the finial to the friendly staff, and serves to entrap the unwary earwig.

And then there is that which is assuredly not the least grateful of all gardens, the "nice little place," such as Mr. GARLAND and Mrs. GARLAND, with some aid from KIT, managed for themselves,—full of Roses, and Lilies, and Larkspurs, and Wallflowers, Polyanthus, and Sweet Peas, and we know not what besides; and a little greenhouse stocked with gay plants, and with room below the stage for wintering the bedding plants—

"Who loves a garden loves a greenhouse too."

Here also is a tiny frame, to which the visitor is taken with pride to inspect the Auriculas and so forth.

And besides these there are the kitchen gardens, and the orchards, and the cottagers' gardens, and the ferneries, and the conservatories, the Pine-pits, the vineries, the orchard-houses and Mushroom-sheds—all possessing some features in common, but all bearing the distinctive impress of those who own or of those who manage them—a mark as distinctly characteristic of the individual and his tastes and proclivities as any that could be found. And so we might pursue the subject till we wearied the reader, yet always find each garden different from its neighbour. In spite of this never-ending diversity, we believe that there are but two great classes of gardeners. The gardens under their charge assume special characteristics, according as the owner loves his garden for the garden's sake, or cherishes it for the sake of the plants that are in it. There is no sharply defined limit between the two classes, the one merges into the other, each has some of the characteristics of the other, the sympathies of either are reciprocal.

And what a world of innocent pleasure all this opens up, what an amount of knowledge, forethought, skill, must be brought to bear by him who would be a gardener, even though his object be merely one of selfish gratification or relaxation. Happy ought he to be whose lot is cast in a garden.

WE last week devoted a few remarks to the subject of the next great country meeting of the ROYAL HORTICULTURAL SOCIETY, which, as we then stated, is to be held in 1872 at Birmingham. As in the course of the ensuing month a public meeting is to be held in that town for the appointment of the local committee—which, as we stated last week, promises to be a most influential and representative one—we revert to the subject of the social arrangements in connection with the Society's visit, because we feel that the influence which these movable meetings are calculated and ought to exert is not as yet, by any means, fully appreciated. Their avowed object is the advancement of horticulture; and in no respect can it be more beneficially furthered than by a judicious use of the opportunities which they afford for social intercourse between those resident in various parts of the country engaged in the practical pursuit of horticulture; and for the expression of opinions and the interchange of thought on the many debated points in which all are more or less interested. Hitherto, from a variety of causes, this aspect of these important meetings has failed in producing the results which some of the more sanguine amongst us not unreasonably anticipated. Let us hope that at Birmingham—a town not unfamed for its practical solution of social problems—the Gordian knot may be severed; and that the intellectual and social aspects of the question, as separated from the mere exhibitional and spectacular points of view, may meet with thoughtful and satisfactory consideration.

At the forthcoming public meeting we would suggest the appointment of a sub-committee, whose special province it shall be to make suitable arrangements for the social meetings of those who will be brought together in the midland metropolis in June next; and whose duty, *inter alia*, it shall be to consider and duly weigh the many suggestions which those who are interested will be certain to make on the subject in the columns of the *Gardeners' Chronicle*, or in those of other gardening journals.

There are really so many important topics which from year to year arise—our weekly Correspondence bears abundant testimony to the fact—about which differences of opinion exists, and which our practical gardeners are particularly qualified to discuss and elucidate, that the chief difficulty will be to select such as, on the one hand, may most claim consideration on the grounds of general importance and interest, while on the other avoiding anything approaching to too great a onesidedness. At the same time the opportunities for social intercourse, and for the ventilation of individual views are so few, that it is clearly false policy, and a very wasteful one too, to neglect or misuse those which do occur. We must confess to having great expectations as to the result of the Birmingham meeting next year; and that there may be no miscarriage for want of due pre-consideration, we invite such of our readers as are interested in the matter, and who have good suggestions to make, to communicate them through our columns without delay. Experience of what the deficiencies of former meetings have been will give practical value to such suggestions as are based on them. It will be well if those most concerned will at once address themselves to the expression of what it is they would have the Birmingham committee do, in order to add to and enhance the interest of these annual gatherings, by rendering them more popular, more generally beneficial, and a greater means

than they have been hitherto of social intercourse between those who, by a variety of circumstances, have but few chances of meeting together.

—— We are pleased to learn from the 42d Annual Report of the Royal Horticultural Society of Ireland that the condition of the Society in question is encouraging and satisfactory, the Council being enabled, after discharging all liabilities, to invest a further sum of £1000 in Government stock, leaving a balance in the bank to current account of £68 5s. 6d. In revising the schedule of prizes for 1872 the Council has also made considerable additions both to their number and value; and has resolved to discontinue the private winter exhibition of fruits, provision being made instead for a great public fruit show, to be held in October, which it is hoped will prove both publicly interesting, and of much practical value.

—— It has been definitely resolved that an International Fruit and Flower Show shall take place in Glasgow in the 2d week of September, 1872. At a meeting of gentlemen nominated to organise and carry out the undertaking, on Wednesday, the 22d inst., held in the Religious Institution Rooms, the Lord Provost in the chair, it was unanimously resolved that subscriptions to the amount of £1000 should be collected, and that a prize schedule should be issued forthwith, in which prizes to about that amount should be offered. The following gentleman were named to draw up rules and regulations, and to get the schedule:—Messrs. James Anderson, Meadow Bank; Lant, Ardgowan; Methven, Blythswood; Graham, Garscube; Austin, of Austin & McAslan; Smith, of Smith & Symons, and Thyne 'McCallum, of J & R. Thyne, Glasgow. A committee was appointed to look out the most suitable place for holding a show of the character decided upon. The Botanic Gardens, and the Burnbank Drill Hall were specially named as suitable places. Sir George Campbell, of Garscube, and J. C. Wakefield, Esq., of Eastwood Park, urged the propriety of proceeding with the work in hand, which they and others heartily supported, as speedily as possible. The number of days during which the show should continue was, on the motion of the Lord Provost, remitted to the consideration of a sub-committee, which was to report to a meeting to be held on that day fortnight. The secretary and treasurer of the Glasgow and West of Scotland Horticultural Society—Mr. Frank Gibb Dougall and Mr. Hoggan—officiate in their respective capacities.

—— The 14th annual issue of the Garden Oracle is announced for publication next month. Mr. Shirley Hibberd still fills the post of editor, and promises some important novelties.

—— The Botanical Society of Edinburgh numbers upwards of 600 members—honorary, foreign, corresponding, extraordinary, associate, resident, and non-resident—of nearly every civilised nationality, and scattered over nearly every part of the world. Yet it may perhaps be held as a curious proof of the healthy character of the natural-history pursuits, that at the recent anniversary meeting the President announced that he had not a single death to record among all these members for the last 12 months.

—— In a letter referring to that of our correspondent, "M. C.," on the Price of Vegetables, in our last issue, and comparing the prices quoted in our Covent Garden Market report with those received by the producer, "A Market Gardener," hailing from Kent, states that he calculates the latter tolerably accurately by taking the lowest quotation in our list of prices and dividing it by two, "which although invariably gives the salesman's return to the grower"!

—— The Maximum Temperatures of the Air during the week ending November 18 ranged from 55°.8 at Portsmouth to 48° at Newcastle-on-Tyne, with a mean for the English stations of 51°.4, and for the Scottish of 51°.8. The Minimum Temperatures of the Air ranged from 30°.2 at Liverpool to 22° at Hull and Edinburgh. The present cold weather set in on the 2d of the present month, but the minimum temperatures did not go below 30° till the 11th, when 26°.4 was recorded. Since that day the minimum values have been as follows:—12th, 25°.8; 13th, 25°.9; 14th, 26°; 15th, 30°; 16th, 32°.1; 17th, 31°; 18th, 25°. The Mean Temperatures ranged from 39°.8 at Liverpool to 35°.2 at Hull, with a mean for the several English stations of 36°.9, and for the Scottish of 37°, thus showing a slightly warmer temperature for the northern country. Rain fell at all stations with the exception of Edinburgh, the maximum falls being 1.67 inch at Greenock, 1.18 inch at Liverpool, and 1.10 inch at Norwich. The mean fall for the English stations was 0.54 inch, and for the Scottish 0.44 inch. (See Mr. Glaisher's Tables, p. 1523.)

—— At the Westminster County Court on Monday last a case, important to Growers and Covent Garden Salesmen—Shrubsole *v.* Skinner—was heard, in which Mr. Cottman, solicitor, appeared for the defendants, the well-known commission salesmen of Covent Garden. The facts of the case were as follows:—The plaintiff, a grower at Sittingbourne, Kent, transmitted his goods to the defendants in baskets, 13 of which were never returned, and for the value of which the present action was brought. Mr. T. R. Skinner, of the firm of Skinner & Sons, commission salesmen of Covent Garden, stated that they were the defendants in this action; that it was the universal custom of the trade to supply goods to their customers in baskets without charge; that their expenses for baskets were nearly £1000 a-year; that their losses were estimated at nearly £500 per annum; and that it was not the custom for growers to charge for baskets not returned, as they were frequently lost and mixed with others, as in the present instance. Three of the baskets sued for had been returned since the commencement of the action. The defendants' manager, his porter, and a salesman were called to support the defendants' case, whose evidence was lengthy, but which proved that the custom of the market was, that baskets were trusted to the buyers without money being left upon them. After Mr. Cottman had cross-examined the plaintiff at considerable length, the judge (F. Bayley, Esq.), considered the defendants clearly entitled to a verdict, as the baskets appeared in him to be nothing more in relative value than the paper bags or fancy boxes used by confectioners, haberdashers, or others to send their goods home in. His Honor gave judgment for the defendants, and on the application of Mr. Cottman allowed the full costs of defendants' solicitor and of five witnesses.

—— The will of Lady Paxton directs that the sheet of blotting-paper on which the First Sketch of the Exhibition Building in Hyde Park was made shall be held as one of the heirlooms, and go with the family estates.

—— Sheet-zinc for Roofing is, in many respects, very useful, but hitherto it has not been found to be durable. The *Comtes Rendus* reports that M. Artus, of the Vieille Montagne Company, has introduced a zinc white paint, with silicate of potash as a vehicle, which is said to be exceedingly durable, and to keep the metal roofing very cool.

NEW PLANTS, &c., CERTIFICATED

At the Royal Botanic Society's Exhibitions, 1871.

JAMES BATEMAN, F.R.S.

Mr. Bateman has now for many years been known as an ardent and enthusiastic horticulturist—not so exclusively devoted to Orchids as his name is supposed from some of his utterances, though truly they have been to him, so far as plants are concerned, the master passion of his life. They were not, however, his first love, for while still a very young man he took great interest in the cultivation of tropical fruits, and amongst other things successfully ripened in fruiting, at Kyre Park, for the first time in England, the Carambola, Averrhoa Carambola, of which a coloured plate appeared in the Transactions of the Horticultural Society. Now and then there have been symptoms of a return to his first love, as happened a year or two since, when the Wampee, Cookia punctata, was exhibited at one of the meetings of the Royal Horticultural Society; indeed, it rarely happens that a tropical fruit of any kind is shown but that Mr. Bateman is stimulated by his old zeal to communicate the knowledge he possesses as to its history and cultivation. The allusion to this circumstance at once leads us to make mention of those pleasant lectures—lecturets as Prof. Henslow would have called them—which Mr. Bateman has been in the habit of giving at the Royal Horticultural Society from time to time for some years past, and in which he contrives to convey a great deal of valuable and interesting information in a pleasant gossiping style.

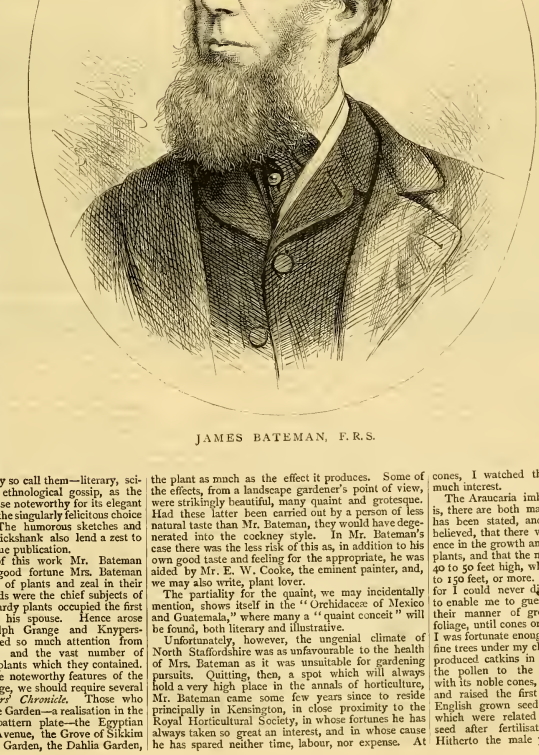
Now and then autobiographical details are interspersed in the most natural way with the remarks on plants and how to grow them. Thus many who read these lines must have heard how the exhibition of a colossal Cypripedium concolor, which Mr. Bateman awoke the latent passion for Orchids, and how the first Orchid was purchased—a plant of Renanthera—of Fairbairn, a nurseryman at Oxford, who had formerly been in the service of Sir Joseph Banks; and how, still doting over the glories of the Renanthera, Mr. Bateman, as a gentleman-commoner of Magdalen College, Oxford, incurred the wrath of the Vice-President of the College—no less a person than Dr. Daubeny, who subsequently became Professor of Botany in the University. The wrath of the Vice-President was occasioned by the fact that the rules within those *in statu pupillari* are bound to obey had been infringed by Mr. Bateman, as the charms of Renanthera proved a stronger attraction even than the architectural beauty of Magdalen, and detained the undergraduate beyond the prescribed period. The punishment awarded for this misdemeanor was not, as might have been expected, the compulsory eulogium in the choicest Greek iambics of the syren Renanthera, but took the shape of a command to write out half the Psalms, wherein, so far as we remember, no special allusion is made to any of the Orchid family.

Botany was at a very low ebb at that time in the University. Dr. Daubeny, who afterwards did so much for that and other sciences, had not then acquired the position and influence which subsequently he exercised with so much power and discretion to advance the

cause of natural science. But although Mr. Bateman's botanical proclivities met with little encouragement on the part of his *alma mater*, they were more favourably regarded by others. Encouraged by his father's support and assistance, Mr. Bateman despatched a botanical collector, the late Mr. Colley, to Demerara and Berbice. An account of this expedition — one of the first of Mr. Bateman's contributions to horticultural literature—was published in "Loudon's Gardeners' Magazine." The results, however, of this journey were not remarkable, the Orchids obtained were few in number, and of no special beauty or interest. The novelties obtained were not numerous; to one of them, one of the ugliest as it happened, Dr. Lindley affixed the names of Batemannia Colleyi, thus associating the names of employer and collector. A short time afterwards Mr. Bateman made the acquaintance of the late Mr. G. Ure Skinner, then resident in Guatemala, and the friendship then inaugurated proved of the greatest service to the two persons most concerned, and promoted in no ordinary degree the knowledge of Orchids, and their diffusion among the cultivators of Europe. Thanks to the energy of Mr. Skinner, numerous Orchids were collected and introduced to our stoves, and abundant material placed at Mr. Bateman's disposal for use in his work on the "Orchidaceæ of Mexico and Guatemala," atlas folio, 1837—41. This work, in some respects the most remarkable series of plates ever published, demands a few words of notice at our hands, inasmuch as from its costliness and size, and the limited number of impressions struck off, it is not readily accessible to the majority of horticulturists.

It consists of a series of coloured illustrations, of life size, of a great number of species of Orchids, accompanied with descriptive details and cultural hints. It is worth while recording some of Mr. Bateman's axioms on this latter point. The plants, says he, can scarcely have too much light or too little sun. Take care of the roots. Beware of noxious insects. Give the plants a rest. Attend to the condition of the air; let it have on the average a temperature of 60° in winter and of 75° in summer. Do not over-water. These directions were written before the days of cool Orchid culture, to which, however, Mr. Bateman subsequently became a convert and zealous proselyte, as witness his lecture on cool Orchids before the Royal Horticultural Society in 1864. But to return to Mr. Bateman's *mega biblion*. The illustrations are accompanied not only with suitable descriptions and hints for culture, but with little scraps of gossip, if we may so call them—literary, scientific, archæological, or ethnological gossip, as the case may be, but in any case noteworthy for its elegant piquancy of style, and for the singularly felicitous choice of classical quotations. The humorous sketches and tail pieces of George Cruickshank also lend a zest to this in many respects unique publication.

During the progress of this work Mr. Bateman married, and by happy good fortune Mrs. Bateman shared her husband's love of plants and zeal in their culture. But while Orchids were the chief subjects of Mr. Bateman's regards, hardy plants occupied the first place in the regards of his spouse. Hence arose those gardens at Biddulph Grange and Knypersley, which have attracted so much attention from their artistic disposition, and the vast number of beautiful and interesting plants which they contained. Were we to tell of all the noteworthy features of the gardens at Biddulph Grange, we should require several numbers of the *Gardeners' Chronicle*. Those who would know of the Chinese Garden—a realisation in the garden of the Willow-pattern plate—the Egyptian Court, the Wellingtonia Avenue, the Grove of Sikkim Rhododendrons, the Bulb Garden, the Dahlia Garden, the Rose Garden, the Pinetum, the Stumpery, the Tree Peonies, the Orchids of course, and a host of other things,—we would refer to the lengthened notices given in these columns in 1856, and 1862, by Mr. Kemp and Mr. Anderson. Suffice it here to say, in general terms, that by skilful arrangement of artificial hill and dale a wonderful diversity of surface was obtained, and a number of distinct sections parcelled out, each devoted to a particular purpose, as may be gathered from what has been already said. If this multiplication of parts interfered with the breadth and repose one looks for in a garden of such pretensions, it had the compensating advantage of affording endless variety at all seasons. Moreover, it enabled Mr. Bateman, as a true lover of plants, to place each plant, so to speak, in the place and under the conditions most suitable to its requirements. It would not be fair to infer that the art of the landscape gardener was entirely subordinated to the solicitude of the cultivator; rather let us say that the landscape gardener, in this case, did what landscape gardeners do not always do, study the welfare of the plant as much as the effect it produces. Some of the effects, from a landscape gardener's point of view, were strikingly beautiful, many quaint and grotesque. Had these latter been carried out by a person of less natural taste than Mr. Bateman, they would have degenerated into the cockney style. In Mr. Bateman's case there was the less risk of this as, in addition to his own good taste and feeling for the appropriate, he was aided by Mr. E. W. Cooke, the eminent painter, and, we may also write, plant lover.



JAMES BATEMAN, F.R.S.

The partiality for the quaint, we may incidentally mention, shows itself in the "Orchidaceæ of Mexico and Guatemala," where many a "quaint conceit" will be found, both literary and illustrative.

Unfortunately, however, the ungenial climate of North Staffordshire was as unfavourable to the health of Mrs. Bateman as it was unsuitable for gardening pursuits. Quitting, then, a spot which will always hold a very high place in the annals of horticulture, Mr. Bateman came some few years since to reside principally in Kensington, in close proximity to the Royal Horticultural Society, in whose fortunes he has always taken so great an interest, and in whose cause he has spared neither time, labour, nor expense. At the time of his removal from Staffordshire he gave proof of his attachment to the Society by presenting it with a portion of his collection of Orchids, which forms one of the most attractive features in the western approach to the Society's garden. Mr. Bateman has also for many years rendered material aid to the editors of the *Gardeners' Chronicle*—an assistance they are pleased to have this opportunity of gratefully acknowledging.

ARAUCARIA IMBRICATA.—No. I.

According to my promise I will proceed to record some practical observations concerning the Chili Pine, which I hope may prove of use to those who, like myself, are seeking for knowledge, through the aid of your valuable journal. They may also interest some readers and amateurs who may not yet have had the opportunity of making practical observations for themselves. I have had such an opportunity, and this is my reason for throwing my humble mite into the treasury of practical knowledge, as a guide to others in forming their ideas concerning the useful and ornamental properties of this remarkable tree.

As every one knows, it is an evergreen, a native of South America, and as hardy throughout the United Kingdom as a Cedar of Lebanon; and if only it were judiciously and methodically planted, it would become a general ornament in our landscapes, since when maintained in robust health it looks well in sunshine or in shade—and that every day in the year. This statement may be said to require a good bit of explanation, and this I hope to give faithfully, as far as my powers of observation will serve me. It is stated that this noble tree grows on its native mountains to the height of 150 feet or more, spreading its branched wire-like roots over the rocks amongst the decayed vegetation (what little there is), and down into every fissure and cranny it can find, in search of food and moisture. The Araucaria forests are said to grow solely on the western declivities of the Andes, at from 1500 to 2000 feet below the snow line, and to be as bare of all other vegetation as our Pine plantations when 100 years old. Sir Joseph Banks, in 1795, brought home living plants raised from seeds sown on board ship by Mr. Menzies. He planted one in his own garden, and sent the others to Kew; and from Kew the first batch was no doubt distributed, some of the plants being still to be found in this country. One, a female, is, as everybody knows, still growing in Kew Gardens, and last spring, during April and May, when it was showing its cones, I watched their progress almost daily with much interest.

The Araucaria imbricata is normally dioecious, that is, there are both male and female trees distinct. It has been stated, and it was at one time generally believed, that there was some very considerable difference in the growth and foliage of the male and female plants, and that the male did not grow more than from 40 to 50 feet high, while the female grew from 50 feet to 150 feet, or more. This must certainly be a mistake, for I could never discover any distinction whatever to enable me to guess which was male or female by their manner of growth or from any variation of foliage, until cones or catkins were actually produced. I was fortunate enough to discover, amongst the many fine trees under my charge, the first male plant which produced catkins in this country, and by introducing the pollen to the fine female tree fully covered with its noble cones, I secured the first crop of seeds, and raised the first batch of plants obtained from English grown seed. These are well known facts, which were related years ago. The growth of the seed after fertilisation was extraordinarily rapid. Hitherto the male plants have proved to be the most

numerous at Bicton; as also in Lord Poltimore's garden in Devonshire, where there are some splendid female plants covered with cones, and a large number of male plants with crops of catkins.

Previous to the catkins having been produced in this country, it was asserted that they were teasel-shaped, and in so far as regards their hooked scales and their combing properties this is true, but they run from 4 inches to 8 inches in length, and curve like a cow's horn; indeed they are about the size and colour of the cones of the common Spruce Fir, and when ripe hang down full of pollen, which is wafted about on a fine dry breezy day, so as to fill the atmosphere with the fine sulphur-coloured vivifying dust. The female cones are produced from the ends of the previous years' shoots, and mostly stand erect, none being pendulous. They are of an immense size. I have exhibited cones that weighed from 7 lb. to 8 lb. each, with a diameter of from 6 to 7 inches, and a height of from 8 to 10 inches. There must evidently have been some mistake in describing such a vast difference in growth and height between the male and female Araucarias. I have in the course of my tours during the last few years in various countries met with many male plants having catkins on them, but have seen very few females.

The finest Araucaria outside Bicton is at Poltimore, that is to say, the handsomest tree, a model in shape, thickly furnished to the base with healthy branches, having also height, and bearing cones. That there is at Kew a large female Araucaria imbricata is well known, but in this case the bole is naked a long way up, neither is the head very handsome. I have seen many splendid Araucaria trees scattered over the country that have not as yet proved their sex. Those at Dropmore, which I have not seen for several years, cannot be surpassed by any in the United Kingdom. There is a splendid symmetrically-grown tree at Sir T. Acland's, at Killerton; a splendid male tree at Lady Molesworth's, in Cornwall; also one at Sir Clement Kinloch's years ago, at Redleaf; besides noble plants at Chatsworth, Elvaston, and many other places which I need not particularise, but I will rather relate more fully my own practical observations. *James Barnes, Exmouth.*

(To be Continued.)

THE ÆSTHETICS OF ROCKWORK.

IT is, perhaps, now advisable in continuing this subject (see p. 1326), to give what are, in the writer's opinion, the various forms in which rockwork should be disposed in the broadly defined geological divisions of this country.

England is, for its size, as we all know, remarkably rich in the variety of its strata. A line drawn across it from the Isle of Thanet to the Solway Frith cuts through almost every conceivable kind of rocks, the majority of which extend in right angles to this line in bands of greater or less breadth, according to the thickness and inclination of the beds of which they are formed. Any geological map of England will show this arrangement, but this, although very useful so far as it goes, does not satisfy the requirements of the landscape gardener, for many of these bands of country should, for his purpose, be classed together, the lithological characters of rocks of many distinct ages being frequently almost identical. Thus, all the grits and sandstones which are so useful to horticultural designers, appear at very many horizons, vastly different in the time of their formation as viewed by geologists, but entirely similar from our technical standpoint. The traps, basalts, greenstones, &c., may also be grouped together, and, as will be seen presently, they often some very useful material in rockery building for certain purposes. All the clays, again, of whatever age they may be, we may place together aside, in company with the innumerable soft shales and more earthy marls of every formation, as our most useless material; likewise the various gravels constitute a class of material which skilful manipulation alone renders applicable to our wants.

The granites, porphyries, and gneiss may possibly be also grouped together with advantage to us; but this is a point which the writer wishes to reserve. All those metamorphic rocks, again, which are roughly call mica-schists form a very marked and useful division, as well as the hard shales and slates which abound in some parts of the country, and which, although scarcely ever used for the purpose, may be made, with taste and knowledge, to greatly enhance the picturesqueness of rockwork under certain conditions of its

markets have all been erected within the last few years, and each has been designed for its particular trade; but the one on which most favour has been lavished, one may say, both by Nature and Art, is that which we are most interested in—the fruit and vegetable market. As we get down at the porch, we hear the busy hum of bargaining crowds, and as we enter, the picture that opens to us beggars description. We are in a large iron building, something like a metropolitan railway station. In front is a beautiful drinking fountain, and on either hand stretch the lines of stalls. To the right they are loaded with fruit and flowers; to the left, with vegetables.

Let us turn to the right. Here are three lanes running lengthways down the building, with stalls on either side. The lanes are crowded with buyers of as varied race and appearance as the fruits that are offered. Here a Parsee butler is culling the finest for the table of some rich fire-worshipper; there a tall ebony-faced African is haggling over the price of a dozen Plantains. Here the "mild" Hindoo is buying the Plantain leaves that will serve as plates at a feast; the Kutchee Bunia, who not only eschews animal food, but will eat nothing that grows under the soil; the British Jack Tar, the tall grave Arab, the fair European lady and her sable sister are here—every one wants fruit. As

Vegetables are in great force; they are almost all European sorts, and a great host of Eastern ones are to be had. Of European sorts, Asparagus, Broad Beans, and Seakale, are absent; the two former can be grown, but don't pay.

Cabbage, Cauliflower, Kohl Rabi, Turnips, Carrots, Peas, Vegetable Marrows, &c., are plentiful, and sold at about the same price as in London. Here is the wonderful Radish that created such a sensation in London a few years ago: the unripe pods are selling at 1½*d.* per lb.; and the Dudia, with a striking resemblance to the "new species of Cucumber from China," that we see advertised at 3*s.* 6*d.* per seed; it is a delicious vegetable, and is offered at 3*d.* each. Cucurbitaceæ are in great variety, from the Dudia, a fit load for a man, or the Snake Gourd, 5 feet long, to the Gherkin, the size of his finger.

Cocoa-nuts are 1*d.* each, Betel-nuts, the fruit of the Areca Catechu, 6*d.* per lb. Tarwara, the albumen from the fruit of Borassus flabelliformis, is a mawkish, tasteless fruit (at least, when uncooked), but it is in great demand. Seedlings of this stupendous Palm are offered, and are said to be a delicate vegetable; these, with Dates, in the dried fruit department, are all which the Palm tribe supplies here.

The division of labour seems perfect, for here are the dealers in pot herbs and small salads; Mint, Thyme, and Parsley are plentiful, with Mustard and Cress in perfection. Then comes the herbalist; he has leaves of Calotropis gigantea, for sores, the flowers for affections of the eyes; Euphorbias, for cough mixtures; Datura leaves, for reducing swelled glands, Lemon-grass, for fevers, and many others.

On the other side are the dried fruit stalls, with the same variety and prices as in London.

Outside, but close at hand, is a long iron shed, divided by partitions, where the dealers have their stores, and above the porch is a clock tower, with the superintendent's house, the bazaar office, wholesale business rooms, &c. In reviewing the whole, it is hard to say which is most striking—the grand proportions of the building, or its minute adaptation for its intended purpose; the noble iron columns supporting the roof—high enough to afford fresh air to the thousands of buyers—or the spotless pavement they tread. The building covers 56,600 square feet, cost £41,550, and yields an income of 10 per cent. on its cost. Certainly the arrangements bear the mark of a master mind, and the name of the "Crawford" Market is a fitting tribute to its possessor, the Municipal Commissioner of Bombay. In any city a good supply of fruit and vegetables, sold in a well kept building, is a matter of great moment, but in Bombay, where a great part of the population are strict vegetarians, its importance can scarcely be conceived. The space enclosed by this and the other departments is nicely laid out and planted with Bananas, it has a large fountain in the centre, and all round are plant dealers offering flowering and foliage plants in great variety. Time forbids us looking in on the other departments just now; they and horticultural matters in Bombay will form the subjects of other letters. *G. M. Woodrow.*

FIG. 327.—VIEW OF INTERIOR QUADRANGLE OF CRAWFORD MARKET, BOMBAY.

we press through the motley crowd we are pressed, in a mixture of English and Hindostanee, to buy, but we don't buy much; we see what can be bought, and learn the prices:—Grapes, 6*d.* per lb.; they are a small white Grape, sweeter, but not so good looking as we get at home for 10*d.* to 1*s.* per lb. Cabul Grapes are generally plentiful, but are not to be seen now; they are a large, white, oblong berry, of delicious flavour; they come to market in little boxes, with the berries laid out separately in cotton wool, and usually sell at about 1*s.* 6*d.* a box of 100 berries. Oranges, 2*s.* a dozen; Pine-apples, 3*d.* each; Bananas and Plantains, 2*d.* to 6*d.* a dozen; Peaches and Strawberries are to be seen occasionally, but are out just now. The stalls are about 3 feet high; underneath is a small store, and above the dealer sits squat among his wares, while behind, on a strong iron railing, hang the grand bunches of Bananas, some of them half a hundredweight.

Here are the flowers. Roses, 6*d.* a hundred; they are gathered without stalks, and strung into garlands, that are worn on festive occasions: their fragrance is delightful. Bouquets of Jasmine, white and red Oleanders, Hibiscus of sorts, a pretty Poinciana, and Allamanda flowers, made up in the showy bracts of Poinsettia pulcherrima and the leaves of Croton longifolium, rival, in brilliancy of colour, at least, if not in tasteful arrangement, the products of Covent Garden; the best may be had for 3*d.*

Home Correspondence.

Variation of Trees.—One or two things touched on in your leader of last week are well worthy of the attention of such of your correspondents as may be qualified to enlighten us thereupon. As to the peculiar type of variegation in a seedling Abies Douglasii tree at Castle Kennedy, described in your leader as being so white that "at a distance it might be mistaken for a white sheet, or a white Hawthorn in luxuriant bloom," I have to mention that I have seen an Abies Douglasii, when on a visit to Mr. Patton, at his residence of Glenalmond, and of which he presented me with a specimen, now 4½ feet high. The tree is not so absolutely white as a sheet, but in June it might be mistaken for a Hawthorn in flower. As with Lord Stair's tree so it is with this. As the season advances the green gradually begins to show itself, running from the bottom to about half way up the leaves, which, with me, are never wholly green, the tips remaining white or pale throughout the winter, at least so much so as to make it easily distinguishable from those of the normal type. It is farther, like Lord Stair's tree, in excellent health, notwithstanding it has with me borne much bad treatment by frequent shifting. Neither does the variegation suffer much, if at all, by any soil it may be put into. It was in this particular I had most fears for its permanence, inasmuch as the Glenalmond soil was fertile in variegations. Mr. Patton had farther a seedling Pinus sylvestris, of which he also presented me with a plant, which was light in summer and green in winter. This I have lost. He had also a finely variegated Spruce (Abies excelsa), and several other variegated things, of which I do not now remember the names. I entirely concur with you that this periodical type of variegation cannot be ascribed to ill-health, but I cannot assign any other legitimate cause for it, unless, perhaps, it may arise from some peculiarity in the soil on which such seedlings are raised, from containing, it may be, a superabundance of alkali; but then one would think that, being transplanted to a different kind of soil, the variegation would cease. But this Abies, growing with me in a light sandy soil, so different from that of Glenalmond, which is a light, gravelly loam, proves it is indelible, for I have had the tree

about five years, and there is no change upon it. Those white spots on Mr. W. Maxwell's Oak tree are not less difficult to account for. I have had such shoots often on variegated-leaved seedling Pelargoniums, which, when less familiar with their occurrence, I tried, but in vain, to strike as separate plants, but I was soon taught to know that no life could be maintained in them after being detached from the parent plant. It occurs to me, however, that such life might be preserved by grafting or inarching; and might not this be a pretty experiment to bring out variegation on the plant made use of as the stock? Those white shoots on Mr. Maxwell's Oak by like engrafting might produce a like result; I do not mean similar to the albino form, but a more equable, and hence more elegant, diversity of colour. Altogether, this is a subject on which you do well to invite those who can enlighten us to do so. For myself, I have no pretension to do more than notice instances, and humbly to endorse your call. *I. Anderson-Henry.*

Hardiness of Abutilon Thompsoni.—Many will feel interested in Mr. Lamb's communication, also noticed in your leader, of the hardihood of, and the beautiful effect produced by, Abutilon Thompsoni planted among Evergreens. I have hitherto regarded this as a plant for the intermediate house, if not for the stove. Instances, too, are recent of its variegation being imprinted, by the operation of grafting, to kindred species in the normal state. I have myself been trying my hand to produce the same result, not by ingrafting but by hybridisation. In this cross A. Thompsoni was the male and A. vexillarium the female parent. I have plants of it now ranging from 6 to 8 inches high, but yet not a flower, nor has shown [a tendency to take after the male parent, which it does in a decidedly lighter green foliage, with a few pale spots upon the leaves. I may observe, by the way, that the affinity of these species is not very strong, at least if we may form the opinion obtained from the cross (only four), and their obstinacy to vegetate. For while they were sown in December, 1869 (?), the first sprung only in November following, and the others in March, April, and June, 1871, respectively. But as some compensation, it is worthy of notice that the foliage is already variegated slightly. While at one time I regarded all these variegations as due to disease or ill-health, and no doubt a large proportion of them are owing to this cause, yet many have it in their nature, and are as vigorous in health as any are in the normal green state. A remarkable illustration of this occurs in the kale, which a lady in my neighbourhood (Miss Hope) if she did not originate contributed largely to bring into notice. I have seen these take on almost every tint and dye of the prismatic spectrum, and yet all were in the most perfect health. Is it not so? Is it in the soil? or in what else is it? since disease can only account for a portion of these variegated things. *Ibid.*

The Effects of Snow on the Douglas Fir.—There is in the grounds here a very fine specimen of the Douglas Fir, nearly 90 feet high, and over 9 feet in circumference at 3 feet from the ground. During the time I have known it, viz., five years, it has not in any way suffered from snow, though I am informed that when younger it suffered on one or two occasions from that cause. The leading shoot has been broken once, otherwise it would have been higher than at present. I should be glad if any of your correspondents would inform me, through your columns, if they have been able to procure fertile cones from this Fir. The tree here has quantities of cones on every year, but we have been unable to procure any seeds from them that would grow. *Gardener, Hackwood Park, Basingstoke.*

Pelargonium crispum.—For general decoration we have not a more useful plant than this little gem of a Pelargonium. As plants, we find it most useful in small pots, 2-inch and 4-inch. Being very sweet-scented, it is nearly worshipped here in the bondoir and other rooms. As a backing for a bouquet, it is superior to Myrtle, and equal to the small-leaved Myrtle for a button-hole flower. *H. Knight, Floors Castle.*

Loranths *v.* Nux-vomica.—In the interesting quotations from Mr. Scott's remarks in the "Journal of the Agricultural and Horticultural Society of India," I see that it is supposed—though the supposition seems to be based only upon unsupported, vague testimony—that some parasitical Loranths possess the power of abstracting from their foster parents in a remarkable degree the peculiar attributes they are known to be possessed of. As, however, this subtle attribute, known to be possessed by the Nux-vomica, is suggested to belong to the leaves of no parasite given upon it, may I ask whether any one conversant with the subject can inform us whether the leaves of Strychnos Nux-vomica themselves possess the same remarkable properties as do the seeds, the properties of which are so generally known? I cannot help thinking that this is where the native mistake is made; if not, the subject is such as to demand earnest attention in a physiological point of view. I should also like to ask whether anyone has ever attempted to inarch any of these parasites upon such trees as are known to be efficient foster parents, the Mistleto to boot. *William Earley, Valentines.* [We are not aware of any analysis of the leaves of the Nux-vomica. No doubt they would contain to a small extent strychnine. EDS.]

Artichoke Galls. — Mr. Murray (at p. 1422) explains that the insect which I have called Aphilothrix gemmus, is better known as Cynips gemmæ (Lin.). Whether it is really so well known by this passage implies we shall see presently, but has Mr. Murray really considered how my reply would have read, if, as he proposes, the word "Cynips" had been substituted for "Aphilothrix?" It would have read,—"caused by the puncture of a female Cynipideous fly, called Cynips gemmæ (Lin.)." Let us now examine why I said "Cynipideous" fly, called "Aphilothrix gemmæ." The old Linnean genus, Cynips, used to comprise, in Linné's time, real Cynipidæ or gall-makers, inquilinous Cynipidæ or guest-flies, parasitical Hymenoptera of various other groups, Tenthredinidæ or gall-making saw-flies, Cecidomyidæ or gall-midges, one and all of which were once entitled to the generic name of "Cynips." But modern research has divided the party, and has assigned to each set of members their own genus; in the latter, subordinate set of members has even been placed into a different order of flies, namely, among the Diptera. The terms "Cynips" and "Cynipideous" have been restricted to designate only the first two groups I have mentioned above, and subsequently the term "Cynips" has been further restricted to the sole use of some of the members of the first group. It has, however, been found out lately that structural differences exist even among the species of the restricted genus "Cynips" to such an extent as to necessitate its further division into subgenera, for one of which is called "Aphilothrix," and to this the real Cynips gemmæ or maker of the Oak gall belongs. According to the rules of nomenclature its name is therefore now Aphilothrix gemmæ of Linné, unless we tolerate the subsequently created name of C. fecundatrix of Hartig for it. Now my friend Mr. Murray knows these facts as well as myself, but he prefers to call the insect a "Cynips," long after it has been shown that this term has been formerly used to designate a heterogeneous mass of ill-understood insect forms of different families and even of different orders. I dissent from him on this point; it is the latest well-ascertained results of science which must be given to an inquirer, not the views of a century ago. Mr. Murray further finds fault with almost every statement of mine concerning the natural history and injurious nature of Aphilothrix gemmæ. But, to my surprise, the only authority he quotes in support of his charges is precisely the one fact which I have myself, to leave alone, if he wishes to see his ideas entertained. Mr. Murray writes:—"Linnæus, at least, who gave the insect its name, did not look upon it as a denizen of the acorn, but of the bud. He called it Cynips gemmæ, not Cynips quercus-folii—the oak-bud, not the gall-fly of the acorn." I can but infer from this that my friend Mr. Murray is not acquainted with the worker of the Artichoke gall, nor the perfect state of the gall itself. Linné knew only the outward appearance of the gall, and has sketched it in a few happy touches of his pen. It is true he quotes Reaumur's plate 43, vol. iii., where the acorn-cell is well figured, but Linné did not know the real Cynips; his description of the insect [omitted for want of space. EDS.] refers to some parasitical Hymenopteron. Now, if Mr. Murray knows the maker of the Artichoke gall, how is it that this glaring discrepancy between the Linnean diagnosis and the looks of the real gall-maker has escaped his experienced entomological eye? I explain Mr. Murray's silence on this head by the supposition that he has never bred Aphilothrix gemmæ, although he suggested to others its proper source. As I ever injuriously Aphilothrix gemmæ acts, and however abundant it may be, the insect is very difficult to get hold of. I have the word of the first hymenopterist among us that he has bred it, and, after years of trial, I have bred it myself; but Mr. Murray's paper shows that he himself does not know the insect. What is the explanation of this mystery? I am not the first who explains it, and if Mr. Murray had taken the trouble of reading the literature of the subject before rushing into print, the works of Hartig, Schenck, Mayer, von Schlechtendal, &c., would have solved the riddle for him. Even without consulting foreign authors Mr. Murray could have found all he requires in a paper published by the Rev. T. A. Marshall in the "Entomologists' Monthly Magazine," vol. iv., p. 8. He might have read there that Linné's insect belongs probably to Neuroterus, a genus of the parasitical Cynipidæ; he might have read further, that for this reason the later name of C. fecundatrix of Hartig has been retained by Mr. Marshall; he would have ascertained that Mr. Marshall did not consider Aphilothrix gemmæ to be Cynips gemmæ; he would then probably understand why I chose to eliminate the generic name Cynips, and term the maker of the Artichoke gall Aphilothrix gemmæ, under which name it is now generally known abroad. Linné called his insect Cynips glandis, Cynips Quercus gemmæ, the gall-fly of the Oak bud, because he only knew the gall in that state when the acorn, instead of growing to a maximum length of 5 millimètres and serving as the larval cell of the real gall-maker, remains in such an abortive state as to be almost obliterated or scarcely recognisable. In that state of the gall the basal part of the foliaceous cup will be found to be harbouring one or several inquilinous insects, whose presence effectually stops the growth of the acorn, or if the acorn does at all put in an appearance, a parasitical larva is found to be feeding on the Aphilothrix larva within, in which case the acorn is scarcely ever more than 2 millimètres in length and very often distorted. I must not waste time and paper in further explanations, and must abstain from further remarks on the nomenclature of either the maker or its parasite. I feel sure Mr. Murray will forgive me, if under the circumstances I decline most respectfully to continue to discuss this subject with him. Sound theories can only be built up on the basis of well grounded biological knowledge, and we have seen that my friend moves still in the Linnean era as regards his acquaintance with the Artichoke gall and its inhabitants. *Albert Müller.*

Bees Combing Outside Trees.—I am much annoyed by bees suspending their combs on the outside of trees in every good honey season. I keep my bees in straw hives placed in a bee-house with glass front. When the hives get very full of bees, and the weather is warm, the bees very frequently build their combs, filling them with the purest honey, in the corners of the bee-house, where it is not only very difficult to take their store, but the exposure draws wasps and hornets, and often causes fighting amongst the stocks. To avoid disputes, I usually give up to the bees that which I find it dangerous to rob them of; but by having made my front movable on hinges in another house, I have deprived them of the quiet corners of which they availed themselves. *J. E. Gray, Wembley Park, near Harrow, Middlesex, Nov.* 17.

Cedar of Lebanon Seeding.—I have a few trees which were good-sized at the beginning of this century, and perfected their seeds in the autumn of 1869. I first became conscious of this by finding a considerable number of self-sown Cedars coming up among my shrubs, many of which I took up, and now have growing in nursery beds. This drew my attention to the trees, from which I gathered some cones; and on the 17th of Mr. March last I found many good seeds in a cone (upwards of 80), asked his advice as to the best time to sow them. His reply was, "Try the seeds you have taken out, but for the future let the seeds remain in the cone till you are ready to sow them, for which April is the best month." I have found his advice valuable. I still have a cone of that date left, which is at your service; and I have now on one of my trees some brown cones fully ripe and opening, others much younger, which are quite close and greenish, and also innumerable catkins. *F. E. Gray, Wembley Park, near Harrow, Middlesex, Nov.* 17.

——I beg to inform Mr. Earley that about 24 years since a fine large tree of the Cedar of Lebanon had, in the course of alterations, to be cut down at Ampton, near Bury St. Edmund's. It bore a heavy crop of fine cones, some of which I had found the seeds in seeds secured, and they ultimately vegetated freely, producing a batch of upwards of 1000 healthy plants—the greater portion of which, however, unfortunately perished during the severe winter of 1860, when about 3 or 4 feet in height. I have just measured one of the few survivors, and find it to be upwards of 24 feet high. *P. Grieve, Culford, November* 15.

——There are some hundreds of Cedars here, and many of them, it is said, were planted 200 years ago [?]; all of them are now producing good seed. In November I gathered a few cones from one, and sent one cone to the Editors of the *Gardeners' Chronicle*, and many others were given to friends at the same time: but I have never heard the result. I sowed a quantity of the same seed, and have now some 150 trees. There were no cones produced last year, but this year there is a great quantity. If Mr. Earley would like to have some cones when ripe, I will send him some. A specimen of Pinus excelsa here has also produced cones from 9 to 10 inches long, containing good seed. I do not know whether this is uncommon or not. *T. Seaman, The Gardens, Kingston Lacy, Wimbourne, Dorset.*

Magnolia conspicua Fruiting.—I have enclosed for your inspection two seeds of Magnolia conspicua as picked from the tree this morning, also a seed out of the husk picked a week ago, and placed in a mean temperature of 65°, the result being the cracking of the husk and release of the seed. So that properly speaking the seed was not perfected "out-of-doors" in this country, unless you consider those sent in husk to be sufficiently ripe to be perfect. I have some 25 seeds in all. *George Palmer, Carclew, Penanvworthal, Cornwall, November* 14.

Seedsmen's Assistants.—The well-timed remarks of "An Assistant," in your impression of 11th inst., will, I trust, be taken into consideration by all who noticed them, and are in the habit of ordering seeds—that each may use his influence to lessen the long hours of arduous labour entailed on the seedsmen's assistants. In my experience I have always found that orders come in very slowly during frost, the consequence being an influx with the open weather, thus causing considerable hurry, longer hours, more fatigue, and, as a result (even with the utmost care), mistakes that at

times cause much annoyance; these, however, are often traceable to the indifferent way in which the orders are made out, sometimes so as to be almost unintelligible, mixed up in the form of a letter, and in many other outlandish ways, rendering correct execution almost an impossibility. Seedsmen might, in many instances, improve their internal working arrangements, and reduce the hours of the "busy season" by making up in parcels many sorts of seeds during the month of December; but no rule could be laid down, as different businesses have different requirements, accommodation, &c. Probably all that the consumer can do is to send his order early, written distinctly, and with full instructions. If the following simple rules were followed, a mutual benefit would accrue to buyers and "assistants," the former in having his orders better attended to, and the latter in having more time for rest or relaxation than is afforded after 16 or 18 hours' daily toil, for three or four months—which is very trying, even to strong constitutions:—1. Take the first opportunity, after receiving the catalogue from which selection is to be made, to draw out and send in the order, that it may be carefully executed, and the seeds will be at hand when required. 2. If the catalogue is accompanied by a printed "order list," use it in preference, and in any case write legibly. 3. If a list is written, let the names of the various articles be placed in columns, one only on a page, and mark the quantity required distinctly, opposite each. 4. Be particular to name the most convenient railway station, for where the postal address only is given packages are apt to be wrongly sent. 5. Affix signature, state on whose account the goods are to be supplied, and give full postal address to facilitate communication. Sometimes these particulars are omitted causing orders to remain entirely unattended to, while the seedsmen are no doubt being blamed. *Industria.*

Coleus Tryoni.—A number of inquiries havings been put to me of late, as to whether Coleus Tryoni is still maintaining its original character as to markings and colours, I wish to inform the inquirers and the public generally through the *Gardeners' Chronicle*, that it is most certainly keeping true, and that the plant exhibited last August at the Horticultural Society's meeting, good as it was, is now, fairly speaking, in the shade when placed beside plants propagated from it since it came back from London. I may also say that the entire stock, if not yet beyond danger, is secured for sure, and unless disposed of before the coming spring meetings, it will most probably be then exhibited again. *John Guildford, Loddington Hall, Leicester.*

Growing Shallots from Seed.—I first grew Shallots from seed in 1868, sowing the seed the previous autumn, and transplanting in March. I had bulbs about 2 inches across, but leaving England at the end of the year, and being absent for two years, I have had no chance of experiencing, and this year my seed crop failed, owing to the bulbs rotting from mildew. As we get large Onions from autumn sowing, why not larger Shallots, if it is size that is required? *T. Frances, Emsworth, Hants,*

The Walcheren Cauliflower.—I have found the true Walcheren Cauliflower to be the very best of all varieties for the summer and autumn supply. Where three sowings are made, one early in the spring, and two in the course of the summer, arranged so as to meet the consumption when greatest, I have always found this variety to be depended upon better than others to stand either wet or dry seasons. Veitch's late Autumn Giant Cauliflower I have likewise grown this season, and have had the heads very large and fine, and with the Walcheren there is really no occasion for gardeners to grow any other varieties. In the seedsmen's catalogues we find London Early Market, Asiatic large and late, Frogmore early forcing, Stadtholder, Dwarf Erfurt, Mammoth, Autumnal's, and others, which might all be discarded with advantage to the pockets of purchasers. The Continental dwarf varieties of Cauliflower are no better, if so good as an old variety named Squibb's Dwarf. *William Tillery, Welbeck.*

Indian Loranths.—I think I some time ago had something to say in the supplementary way about the above plants, and, if my memory serves me aright, I mentioned that the Fuchsia and Loranth were both trees of which two or three of the species were very fond. I mentioned these plants because they may be found in many gardens of a size suitable for the growth of Loranths. If I did not mention it before, I may now add that Rhododendron nilagiricum (arboreum?) is a great favourite of one species. I think the greatest success will attend the introduction of the kinds from high elevations, because plenty of trees are ready to hand upon which to grow them, large "stove" trees being more rare. I do not mean that large trees are absolutely necessary, but would advise any one attempting to introduce Loranths to gather the seeding branches, and pluck off the leaves (as they might ferment and get mouldy), retaining the berries in as perfect and unbroken a state as possible, so that the glutinous matter may be preserved, and packing the branches in a rough box with sand, pounded bricks, or charcoal. Looking to the fact that a parcel may be received through the post or otherways) in a month or less from the date of packing, there ought to be little difficulty in at once setting to work at the experimental cultivation of Loranths, and parties having orchard-houses and conservatories should at once communicate with friends (if they have them) at elevations of from 5000 feet upwards in Southern India, and from 4000 feet upwards in the North, to send them a case of unbroken Mistleto seed, and upon receipt stick it about the branches of such trees as they may learn are suited to its growth. *James MacPherson.* P.S. The packing case should have air-holes in it.

Soot Water.—With pleasure I answer "S." (p. 1428), and in order to do so as briefly as is compatible with clearness, I will give my *modus operandi*. The vessel in which the soot-water was an old boiler, holding 50 or 60 gallons of water. There was a pump close by, and a peck of lime was at hand, and enough of soot passed through a fine sieve to fill a 4-gallon watering can (a bucket would be better). In this can I gradually and thoroughly mixed the soot with water, nearly filling the can, and then poured this mixture into the old boiler, filling that up with water from the pump, taking good care that there should be no lumps, but that the soot should be very evenly mixed in the water. Then I gently pushed all the scum off the surface with a new broom, and had the lime slied over the whole surface of the mixture, and my soot-water was made—the lime carrying every impurity quickly to the bottom. Pond-water is better than pump, and rain-water better than either. If I did not want the soot-water for a fortnight, I should not use lime, but let the mixture clear itself, but if in a hurry, I should not hesitate to use the lime. I have seen a very clever florist fail completely in his attempt to make the soot-water, but I could never tell why, as nothing can, to my mind, be easier. Often I used to put one of my men to do it without my superintendence. I used to syringe my Pelargonium-house, especially, but everything seemed to like it, and I liked the smell, it appeared so healthy. If lime is employed, the besom should be put into use for taking off a very thin glaze, which is sure to be formed on the surface of the water, as this glaze might injure the leaves of the plants. *R. Y.*

The Price of Vegetables.—I should be glad if Mr. Morgan would state what his average prices are from 4 o'clock to 7 o'clock in the morning, because during that time I think very few retailers can buy at the prices named. I think that the fault lies somewhat at their own door, because they ask such high prices early in the morning, knowing that greengrocers must buy and get home to do their rounds, and cannot wait for the going down of the sun. The consequence is, they do not sell half their load, when in walks Mr. Costermonger, and he, knowing that it does not pay for them to take back, offers so low a price that, were it to be offered during the early morning, the buyer would be laughed at, and then down comes the average. Take the Pea season, for instance. I have been compelled to pay 2*s.* per bush. at 6 o'clock, and that was considerably less than the price asked, and at 10 o'clock I was offered the same article at 9*d.*—rather a serious fluctuation on the same morn; but thus it will be seen that Mr. Coster, who can wait, gets the benefit of the low prices instead of the shopkeeper, who is blamed for exorbitant charges. Still, I am willing to admit that some of the West End retailers get prices for their articles that in a poor neighbourhood would frighten every customer away. *W. H.*

In accordance with your request, at p. 1486) I send you the following list of prices obtained by me on the dates mentioned, in the Borough Market:—

1871.	Savoys.	Punched Greens.	Best Parsnips.	Red Beet.
	Per doz.	Per doz.	Per score.	Per doz.
Nov. 14..	9*d.*	1*s.* 1*d.*	9½*d.*	3*d.*
,, 16..	8*d.*	1*s.* 9*d.*	8½*d.*	3½*d.*
,, 18..	4½*d.* to 8*d.*	1*s.* 10½*d.*	9½*d.*	No sale.
,, 21..	*a*2½*d.* to 7*d.*	1*s.* 8*d.*	10*d.* to 1*s.*	No sale.

A Market Gardener.

Madresfield Court and Golden Champion Grapes.—Your correspondent, "Vitis," has evidently no facts to rebut my statements. What I have said on this subject has been derived exclusively from my own experience, and the evidence is direct and unquestionable; so that my opinion on the properties of these two Grapes has been given unreservedly, and without the slightest regard to the ideas of others. Since my first communication I have accidentally had some conversation with a Grape grower of considerable reputation, who assured me that his Madresfield Court was a complete failure, that every berry dropped off, and that no amount of care could save them. At the same time he suggested that a cool house culture might prove more satisfactory. To this opinion I cannot assent, as with me the damage was equal, whether grown under a high or a cool temperature. I highly esteem "Vitis'" invitation to send specimens to the Fruit Committee of the Royal Horticultural Society. This I respectfully decline, but I shall be glad to see him at Tortworth, where he can judge for himself. I shall keep this Grape hanging till the last berry passes out of existence, as a spectacle to visitors, and as a proof that what I have said is true. When "Vitis" honours me with a visit, no formal introduction will be required, as we are not, I imagine, altogether strangers. Let me now come to describe the qualities of the Golden Hamburgh, and I will point out one among many more of the inaccurate assumptions of "Vitis." He, with not a little perseverance, endeavours to convince the readers of the *Gardeners' Chronicle* that I have always held up this as the best white Grape in cultivation. What I have said many times over is, that it is the best of its class, and most distinctly I say so again. Am I not justified in speaking well of it, when for years it has produced bunches of 4lb. weight, and the berries measuring in numerous instances 4 inches in circumference, highly coloured, and of a delicious flavour? What more does "Vitis" require? I have constantly said that this Grape keeps badly, and I also know that in some gardens it has been a failure, but I have described its qualities as developed under my care. *Alexander Cramb, Tortworth.*

Large Onions.—In reference to the remarks of your correspondents at p. 1486, allow me to state that the 12 prize Onions exhibited by Mr. Castleman, Brook End Green Farm, Barton, Beds, and made weighing 15¾ lb., were not "the heaviest by 2¼ lb. that have been before shown in Banbury," as stated, for Mr. Sims' 12 prize bulbs exhibited at the Banbury root show last year weighed 15¾ lb. I believe I am right in saying that the 12 Onions (Banbury Improved White Spanish) shown by Mr. Castleman are the heaviest by 4 oz. that have ever been shown in Banbury; the largest bulb in the prize 12 this year weighed 2¼ oz. *H. Deverill.*

Foreign Correspondence.

South Amboy, N. J.—I noticed in your columns, at p. 1256, an extract from the Journal of the Society of Arts, on the comparative condition of working men in various countries, including America, in which it is inferred that a first-class workman is no better off in this country than in England. This may be true in some cases, but it is not so in all. To take something like a general view of the case, I will say, in the first place, that the cost of living here is about the same as in England, including, of course, house rent. To keep a servant is to increase your expenses, and entail upon you no inconsiderable amount of trouble, for which reason those who can do without one do so. Those who do engage a servant have to pay 12 dols. and upwards a month for the greatest of bridgets from old Ireland. You can obtain a much better servant in England for £5 a year. What an excellent opening for a lot of neat, handy, young women from the country districts of England. They would be quite a "godsend" to the American ladies.

Upon the character of the education given in the public schools here I will say nothing, but I much question there being 25,000 children in Philadelphia leading a Bohemian life; and if this were so it would be found that 24,000 out of the 25,000 children belonged to Irish parents, for Americans, as a rule, are particular on the point of sending their children to school, and in some parts of New England they are obliged to do so, although they are frequently taken from school when young, from the fact that a boy of 14 can often earn a dollar a day.

As regards gardeners, I may say that there is always a demand here for good men, either as assistants or in the higher grades, but it is of no use for kid-glove gentlemen or one-idea men to come here as head gardeners; they are but of little use at home, and would be of none here. Let me illustrate this by stating that I once met a young Englishman here who told me he was "hard up," and would be glad if I would help him. I sent him to a very respectable place in Philadelphia, and he refused it because the remuneration was only 40 dols. a month, which, by a certain knowledge, is short indeed to what is to his leaving England he was working for 14*s.* a week, and was probably dear at that. For the benefit of this class of men I say most decidedly stay at home, for you would only swell the class who loiter around the seed stores in New York waiting for something to turn up, and who write home to friends informing them that they made a mistake in coming here; that the streets are not paved with gold; that all the easy jobs, which they expected would be reserved for their especial benefit, had been taken; that there was not even a nigger left to black their boots, and that they wished they had not given up the three or four dollars a-week in England, expecting to get 20 here for doing nothing. This is no fancy sketch, but matter of fact.

On the other hand, gardeners, who can earn and obtain a first-rate living in England, can do so here. If they are unknown, my advice to them is take any job which offers, for if they have no definite idea of any locality, it will give them time to make inquiries, &c. If known here good men can generally engage previous to coming out, for these in every calling are always in demand here, and, as a rule, at better wages than in England. If ambitious to hold land, it can be purchased for less than £1 an acre up to the fancy price paid in the City of London; but I would advise intending purchasers to keep their money until they get here, and

* Of 90 dozen sent, 30 dozen were sold at 7*d.* per dozen, and 60 dozen for 2½*d.* per dozen.

not be led by the glowing accounts in newspapers, or they may find themselves, like Mark Tapley, in another Garden of Eden. *James Tiplin, South Amboy, New Jersey, U. S. A.*

Societies.

LINNEAN: *Nov. 2.*—G. Bentham, Esq., President, in the chair. Dried specimens and photographs of Clathrus cancellatus and Lysurus Mokusin, from D. Hanbury, Esq., were exhibited by Mr. Currey. The plants were gathered in the garden of M. Thuret, at Antibes, in October, and the photographs exhibited them in different stages of growth. The Clathrus, though not uncommon in the South of Europe, is rarely seen in England, where, however, it has been observed in the Isle of Wight, in a copse near Ryde, by Mr. Kippist, and in woods near St. Lawrence, by Dr. Bromfield; also in Devonshire, and at Lyme Regis. The Colus was originally discovered at Toulon, by MM. Cavalier and Séchier, and was described by them ("Ann. des Sciences," 1835) as a new genus, differing from Clathrus in the contents of the volva, in the absence of any foul smell, and in the branches anastomosing at the summit only, and not from the base upwards. Colus differs from Colonnaria and Laternea in the character of the network, at the apex formed by the anastomosing branches. The following papers were read:—1. *On the Origin of Insects.* By Sir John Lubbock, Bart. The author observed that he had always regarded the metamorphosis of insects as one of the greatest difficulties of the Darwinian theory. In most cases the development of the individual reproduces to a certain extent that of the race, but the motionless imbecile pupa cannot represent a mature form. Fritz Müller considers that the wingless Blattidæ, probably, most closely represent the insect stock, and Haeckel is inclined rather to the pseudo-Neuroptera; but the author felt great difficulty in conceiving by what natural process an insect with a suctorial mouth, like that of a gnat or a butterfly, could be developed from a powerful mandibulated type like the Orthoptera, or even from the Neuroptera. M. Brauer has recently suggested that the genus Campodea, is, of all known existing forms, that which probably most nearly resembles the parent insect stock. The grub form of larva he regards as a retrograde type, an opinion in which the author did not concur, though disposed to agree with him on the other point. M. Brauer, in forming his conclusion, relied partly on geological considerations, partly on the fact that larvæ more or less resembling Campodea are found amongst widely different groups of insects. The author went on to explain the distinction between what he called developmental and adaptive changes, observing that the larvæ of insects are by no means mere stages in the development of the perfect animal, but, on the contrary, are subject to the influence of natural selection, and undergo changes which have reference entirely to their own requirements and condition. The embryonic development of an animal in the egg gives us an epitome of its specific history; but this is by no means the case with species in which the immature forms have a separate and indefinite existence. Hence, if an animal when young possesses one mode of life, and lives on one kind of food, and subsequently, from its own growth in size and strength, or from any change of season, alters its habits or food, however slightly, it immediately becomes subject to the action of distinct forces. Natural selection affects it in two different, and it may be very distinct manners, gradually leading to differences which may become so great as to involve an intermediate period of change and quiescence. There are, however, peculiar difficulties in those cases in which, as among the Lepidoptera, the same species is mandibulate as a larva, and suctorial as an imago. In discussing how these difficulties may possibly be overcome, the author continues:—In Campodea and the Collembola (Podura, &c.) we have a type of animal closely resembling certain larvæ which occur both in the mandibulate and suctorial series of insects, and which possesses a mouth neither distinctly mandibulate nor distinctly suctorial, but constituted on a peculiar type capable of modification in either direction by gradual changes without loss of utility. If these views are correct, he argued, the genus Campodea must be regarded as a form of remarkable interest, since it is the living representation of a primæval type from which insects have all derived their origin.—H. *On Exocætus volitans.* By Captain Chimmo, of H.M.S. Nassau; communicated by H. T. Stainton, Esq. The Flying Fish was stated by the author to be able to live for a period of seven to nine minutes out of water, and to possess the power of changing the direction of its flight by using its tail as a rudder.

Nov. 16.—G. Bentham, Esq., President, in the chair. E. J. Beale, Esq., and Andrew Henderson, Esq., were elected Fellows. Mr. Jansen exhibited specimens of Centaurea solstitialis, found in October last in a cornfield above Combe Marten, North Devon. The following papers were read:—I. *On the Floral Structure of Impatiens fulva, with especial reference to the imperfect self-fertilised flowers.* By A. W. Bennett, Esq. The existence of inconspicuous self-fertilised flowers, extremely different from the large and conspicuously-coloured ones, in at least three species of Impatiens—Noli-me-tangere, fulva, and parviflora—though well known to Continental and American botanists, appears to have received but little notice from most English observers. The author's own observations were made on I. fulva, growing on the banks of the Tillingbourne, an affluent of the Wey, near Shalford, in Surrey, and his attention was first attracted to the subject by the great abundance of seed vessels, notwithstanding the difficulty he experienced in finding flowers earlier in the summer, and by the remarks of a local naturalist that it is "one of those plants which bear seeds without producing any flowers." The development of the inconspicuous or "cleistogenous" flowers was described as entirely different from that of the others. The bud remains much more minute, and the calycine and corolline whorls are more regular. The buds never open, but the envelopes are pushed off from the already fertilised ovary in the form of a cap, at so early a stage that it is difficult to detect the process; indeed hundreds of specimens were examined without finding more than three or four instances of the half-expelled cap. The stamens are very different from those of the normal flower, being equal in length, with the filaments perfectly free, and the quantity of pollen exceedingly small. There can be no doubt that in I. fulva self-impregnation takes place in the "cleistogenous" flowers at a very early period, fruitful capsules appearing almost invariably to result from them, while the conspicuous flowers are stated by all observers to be usually barren, though undoubtedly they sometimes produce seed-vessels, apparently equalling those of the "cleistogenous" flowers in the average number of seeds. The author had never found the two kinds of flowers on the same branch; occasionally on different branches of the same plant, but much more frequently on separate plants, which would account for the fact of their absence from herbaria. In the early part of September the inconspicuous flowered plants outnumbered those with conspicuous flowers in the proportion of 20 to 1, though growing completely intermixed. Mr. Bennett's observations lead him to suppose that the two kinds of flowers are absolutely synchronous.

—II. *Flora Hongkongensis Supplementum.* By H. F. Hance, Ph.D., communicated by Dr. Hooker, which may be described, in the words of the secondary title, as a Compendious Supplement to Mr. Bentham's Description of the Plants of Hong Kong.

—III. *Remarks on the Dolichos uniflorus of Lamarck.* By N. A. Dalzell, Esq., communicated by Dr. Hooker. The author believes that the characters of this plant remove it far from Dolichos, and place it in the Glycineæ, uniting it more closely with the Johnia of Wight and Arnott. In 1860 he had entered it in the Bombay Flora as a species of Johnia, and he now proposes to call it Glycine (Johnia) uniflora. The specific name is an unfortunate one, as there are always more than one flower in the axil. The plant is extensively cultivated in India under the name of Kooltee, and is used for feeding cattle.

Notices of Books

Insects at Home, &c. By the Rev. J. J. Wood, M.A., F.L.S. 8vo, pp. 670, 700 cuts. Longmans.

If it were not for the necessity of killing and slaying, and of employing mean devices and subterfuges to entrap the prey, we should be disposed to rank the entomologist's pursuit as the most fascinating of all branches of natural history for young persons. So fascinating is it that any qualms of conscience, such as we have alluded to, are soon got over, and boys moreover are not usually very sensitive on these matters to begin with. So attractive is the mere search for, preservation, and classification of insects, at any rate of the beetles and butterflies, that it too often happens that the far greater, deeper seated, and more abiding pleasures to be derived by him who subordinates his passion for collecting to that of observing, are left wholly untasted. The loss thus entailed is great, not only as regards the gratification of the individual, but also from a scientific and a practical point of view. As an important step in the right direction, we may commend Mr. Wood's book now before us. The author has long since given evidence of the possession of an agreeable style and of correct information on the subjects on which he writes, and the present volume will, we venture to say, largely add to his reputation. The work is intended to give an account of the insects inhabiting England, together with the principal details of their structure, and the most interesting incidents in their mode of life. In glancing through Mr. Wood's necessarily somewhat bulky volume, we are at once struck with the pains that he has taken to explain and illustrate the anatomical construction of the principal groups of insects. This is an immense help to beginners—would that we had had such in our time. The account would, however, have been more complete had Mr. Wood devoted a little more space to the explanation of the differences between the mouth of the mandibulate and of the sucking insects, and of the adaptive

modifications which result in so very different looking an apparatus, being constructed of similar parts. We are indebted to the publishers for permission to use the accompanying cuts. Fig. 329 refers to the dissection of the stag-beetle, and requires no further explanation than that offered by the legend. Fig. 328 shows certain of the saw-flies whose habits are not such as to recommend them to gardeners. We quote what Mr. Wood has to say of that portion of the structure of these insects from which they derive their name, and refer our readers to the original work for more detailed descriptions of the insects shown in the figure :—

"We will begin with the insects which are so well known as saw-flies, and are scientifically termed Tenthredinidæ. This word is a very old one, being used by Aristotle in his 'History of Animals' to signify some kind of bee or wasp. It is formed from a Greek word signifying to gnaw or nibble. The names andrena, pemphredon, &c., are derived from the same source. In these insects, the wings are large, with many 'complete' cells, *i.e.*, cells closed on every side by nervures, and having a large stigma or spot. The abdomen has no footstalk, and is furnished in the females with the extraordinary apparatus which has gained for the group of Hymenoptera the popular and appropriate name of saw-flies.

"At the extremity of the abdomen and on its under surface are placed two flat horny plates set side by side. These are the saws, and, like the well-known 'tenon-saw' of carpenters, have one edge toothed and the other strengthened by a flat thick plate. On examination with a tolerably powerful lens, the teeth are seen to be most elaborately constructed. Instead of being mere simple teeth, like those of a saw, each tooth is formed of a cone set in a footstalk, the cone being deeply cut into eight or ten deep grooves, having a sharp edge between each. This structure is wonderfully adapted to prevent the saw from clogging with the green wood in which it has to work, and might with advantage be copied by our tool-makers. The toothing of the saw differs in the various species of saw-fly, but the form which has been described is found in some of the insects with which our list commences.

"The strengthened backs of these saws are received into grooves or sheaths in which they slide backwards and forwards, and they are so contrived that while one saw is being thrust forward, the other is being drawn back. There is not the least difficulty in detecting these beautiful instruments under the microscope. They are of course best seen in the recent specimen, but even after the insect has been long dead and dry, the saw can be detached with a little careful manipulation. The object of the saw, which is indeed a modification of the ovipositor, is to prepare a resting-place for the eggs. By alternately working the saws, a groove is rapidly cut in a twig, or a leaf rib, and an egg is then passed between the saws and deposited in the groove, where it is fixed by a small drop of liquid secreted by the insect. The number of grooves and of the eggs deposited in them varies according to the different species of saw-fly. Even if the observer should fail to see a saw-fly in the act of depositing her eggs, he can always see the grooves and the eggs in them, by carefully examining the leaves and young twigs of various trees. The common Currant is often much damaged by saw-flies, and not a single shoot is there but will be scarcely a leaf in which the grooves cut by the saw-fly cannot be found. These grooves are made on the under side of the leaf, partly because the nervures are thicker, and partly because the eggs are sheltered from the rain.

"In process of time the eggs are hatched, and from them are produced larvæ which very much resemble those of moths. They can, however, be at once distinguished from them by the fact that they have more legs and 'pro-legs,' or false feet, than the true caterpillars. No caterpillar has more than sixteen of these members, whereas the larva of the saw-fly has from eighteen to twenty-two. One of these larvæ, that of Cimbex lutea, is shown in fig. 328, No. 2."

Florists' Flowers.

"This is not a Chrysanthemum year," remark the growers of this fine old florists' flower, who in a manner plead extenuating circumstances, and point to the trying nature of the past season as the cause of the poor quality of the generality of the flowers exhibited this year. The past summer, there is no doubt, was a most trying one to the horticulturist, and especially so to the Chrysanthemum grower, whose favourites are gross feeders, and which, to be done well, must not on any account be neglected in the matter of feeding in the summer time; so that it may easily be imagined what an enormous amount of labour in watering is necessary during a hot dry summer. Growers, too, have also experienced the vexations caused by their most promising flowers not expanding so well as they do in earlier seasons, the late frosts having put a stop to the growth of the plants in unheated houses, and committed sad havoc amongst those in the open borders. Though, as we stated before, the generality of the flowers we have seen this year are inferior in quality to those of the past few years, we have seen some highly creditable ones, and amongst them the collection which has been on view at the Brunswick Nursery, Stoke Newington, during the past week. Mr. Adam Forsyth has been a most successful grower and exhibitor for the last 15 years, and annually makes a display of this kind, which has almost become recognised as one of the chief attractions in the florists' calendar. This year he has not grown any specimen plants, but his show-house bears ample testimony to the fact that his love for a good bloom remains unabated, and we hope it will continue so, for since the retirement of the Messrs. Salter, the Brunswick Nursery is the only place that we know of in the neighbourhood of London where a display of so inte-

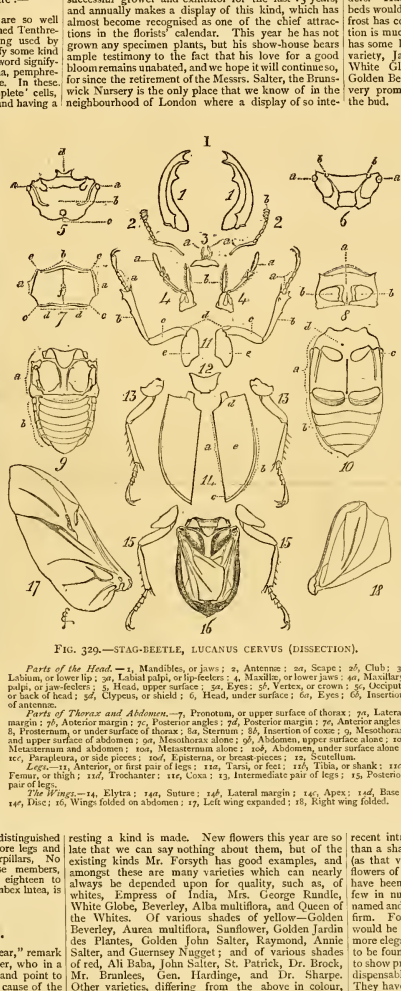

Fig. 329.—Stag-beetle, Lucanus cervus (dissection).

Parts of the Head.—1, Mandibles, or jaws; 2, Antennæ: 20, Scape; 26, Club; 3, Labium, or lower lip; 30, Labial palpi, or lip-feelers: 4, Maxillæ, or lower jaws: 40, Maxillary palpi, or jaw-feelers; 5, Head, upper surface; 50, Eyes; 56, Vertex, or crown; 5c, Occiput, or back of head; 5d, Clypeus, or shield; 6, Head, under surface; 60, Eyes; 6b, Insertion of antennæ.

Parts of Thorax and Abdomen.—7, Pronotum, or upper surface of thorax; 7a, Lateral margin; 7b, Anterior margin; 7c, Posterior angles; 7d, Posterior margin; 76, Anterior angles: 8, Prosternum, or under surface of thorax; 8a, Sternum; 8b, Insertion of coxæ; 9, Mesothorax and upper surface of abdomen; 9a, Mesothorax alone; 9b, Abdomen, upper surface alone; 10, Metasternum and abdomen: 10a, Metasternum alone; 10b, Abdomen, under surface alone; 11c, Paraplevræ, or side pieces; 10d, Episterna, or breast-pieces; 12, Scutellum.

Legs.—13, Anterior, or first pair of legs; 13a, Tarsi, or feet; 13b, Tibia, or shank; 13c, Femur, or thigh; 13d, Trochanter: 14c, Coxa: 13, Intermediate pair of legs; 15, Posterior pair of legs.

The Wings.—14, Elytra: 14a, Suture; 14b, Lateral margin; 14c, Apex; 14d, Base: 14e, Disc; 16, Wings folded on abdomen; 17, Left wing expanded; 18, Right wing folded.

resting a kind is made. New flowers this year are so late that we can say nothing about them, but of the existing kinds Mr. Forsyth has good examples, and amongst these are many varieties which can nearly always be depended upon for quality, such as, of whites, Empress of India, Mrs. George Rundle, White Globe, Beverley, Alba multiflora, and Queen of the Whites. Of various shades of yellow—Golden Beverley, Aurea multiflora, Sunflower, Golden Jardin des Plantes, Golden John Salter, Raymond, Annie Salter, and Guernsey Nugget; and of various shades of red, Ali Baba, John Salter, St. Patrick, Dr. Brock, Mr. Branlees, Gen. Hardinge, and Dr. Sharpe. Other varieties, differing from the above in colour, and well represented here, are Lady Talfourd, Prince of Wales, Alfred Salter, George Sand, Baron Beust, Marshal Duroc, Prince Alfred, Queen of England, Gluck, Miss Mary Morgan, Mr. W. H. Morgan, and Duchess of Roxburgh. The various but showy Japanese varieties are not quite so numerous as last year, but very fine; and the same must also be said about the Anemone-flowered and Pompon varieties.

In the Temple Gardens, Messrs. Dale and Newton have also maintained their reputation as successful growers and exhibitors of the Chrysanthemum, though the season has been very much against them. Mr. Newton, who, we are glad to see, bids fair to eclipse the doings of his predecessor, has, of course, the largest display, the temporary structure in front of Crown Office Row being about 110 feet in length. Here a very effective bank of large-flowered and Japanese varieties are neatly set off by a row of the dwarfer Pompon varieties, which latter are the most generally grown here in open beds and borders. Had the weather kept mild and open, these beds would have been a fine feature; but, as it is, the frost has completely spoiled them. Mr. Dale's collection is much smaller in extent than the above, but he has some handsome flowers, notably of the Japanese variety, James Salter, and of Prince of Anemones, White Globe, Lord Derby, Prince Alfred, and Golden Beverley. His beds of Pompon varieties were very promising, but King Frost has nipped them in the bud. Extensive alterations are going on in both the gardens of the Inner and Middle Temple, which we shall take an opportunity of alluding to at a future time.

Garden Memoranda.

The Stanstead Park Nursery, Forest Hill, S.E. — To the true florist, as well as the horticulturist proper, such establishments as Messrs. Downie, Laird & Laing are, and ever will be, of great interest, for "drop in" when one will for a "look round," there is always something fresh to be seen, something new to be learned by the practical horticulturist, whether it be in improving his acquaintance with, or gaining an introduction to, new or improved forms of flowers, which are ever appearing, or in gleaning seasonable hints on new or improved methods of culture, in which latter respect no one need go away empty from a well-ordered nursery. But it is as raisers and introducers of florists' flowers that the well-known reputation of Messrs. Downie, Laird & Laing has been gained, their productions in the way of Pansies, Hollyhocks, Bronze Zonal Pelargoniums, Phloxes, Pentstemons, &c., having for some time gained for them a position in the van of floricultural progress. There are one or two plants which this firm seem to have especially taken in hand with a view to improving them, such, for instance, as the Bronze Zonal Pelargoniums and the herbaceous Phloxes, and the immense strides which they have made in this direction must be apparent to all who saw the seedlings of the former shown by them at the last Pelargonium show of the Royal Horticultural Society, or the magnificent groups of Phloxes in pots which they exhibited at the supplementary Rose show held at the Crystal Palace in the beginning of August last. It was our good fortune a short time ago to visit the Stanstead Park Nursery, when we made the notes which are here strung together.

We will commence with the herbaceous Phloxes, firstly because they were then in great bloom, and secondly because the time is rapidly drawing near when the Phlox will essentially be classed as a gardeners' flower and take a leading position amongst summer decorative plants. The improvement which it has undergone in habit as well as in the form and colour of the flowers is something astonishing, the more recent introductions especially bearing but little more than a shade of a likeness to the "windmill" shaped (as that veteran florist, Mr. Gumpy, has it of them) flowers of a dozen years ago. Some very fine varieties have been received from the Continent, but these are few in number compared to the splendid batches of named and unnamed varieties raised by this enterprising firm. For the mixed border, as Mr. Laing says, it would be difficult to name a genus of herbaceous plants more elegant and possessed of so many excellencies as is to be found in a collection of Phloxes, and, as we hope to show presently, they must become invaluable, nay indispensable to the gardener for conservatory decoration. They have also the undoubted merit of being perfectly hardy, easy of propagation, and requiring but little attention during the growing season; indeed, so few are their requirements, and so simple their culture, that the whole sum and substance of their treatment may be summed up in the words, "Plant in a moderately rich, porous soil, and give them plenty of clear water when the flower-spike begins to form."

Coming now to the varieties, which we must state were all growing in pots, we have the following, all raised here, and which are to be distributed for the first

time next May. Of these flowers collectively we can safely assert that a finer lot was never sent out together:—Magnificent, dark rose, dark magenta eye, extra good in habit and spike; the segments peculiarly enough, being slightly reflexed, gives to the spike a most pleasing air of refinement. Forest Hill, bright rosy crimson, an exceedingly good trusser and a strong grower, but a little defective in the flower, which, though good in outline, is rather thin. Dr. Masters, crimson-purple, bright crimson eye, flowers very large, and fine in shape, very good in habit, though not equal to some of the others, but producing perhaps the finest spike of all, which constitutes it one of the very best varieties for exhibition and general decorative purposes. Mrs. Whitelaw, lilac, with a solid red-crimson eye, a beautifully shaped flower, produced in capital spikes; in habit it is dwarf and compact, and will become a general favourite for pot culture. Shirley Hibberd, rosy carmine, shaded with orange, and dark centre, excellent both in spike and habit; the flowers are large, of good substance, and fine form; a valuable acquisition amongst the dark kinds. Rosy Morn, rosy lilac, with the centre of a lighter shade, fine in spike, and growing only to the height of about 18 inches; the dwarfest and most compact variety we have yet seen. Philippa Penglase, clear rosy, shaded with lilac, and dark centre; flowers large and of excellent form, and producing good spikes; a showy and distinct variety. Mr. Balfour, rosy crimson, crimson eye; flowers very fine in size, and produced in very large and compact spikes; and Brian Wynne, deep crimson suffused with purple, and a dark crimson centre; the flowers are large, fine in shape and substance, but the plant is rather tall in habit, and must be planted in back rows. Of those sent out this year, the best to our thinking are A. F. Barron, rosy lilac, with a crimson eye, extra fine in spike and habit; Lothair, a splendid trusser, and pure in colour; it grows to the height of about 2 feet, and is a grand acquisition; Mrs. Laing, soft rosy lilac, flowers perfect in shape and slightly reflexed, produced in magnificent spikes, one of the very best for pot culture; Princess Louise, pure white, with a faint blush eye, and fine spike in truss and habit; Flora MacNab, rosy pink with magenta eye, flowers very large and produced in fine spikes; Lothair, light scarlet shaded with purplish violet, distinct and good in habit; and Miss MacRae, pure white, with dark purplish crimson eye, and nearly pencilled itself in habit, size, and habit. Of the older varieties the following will be found a good selection, repeated trials having proved their excellence and worthiness for a place in every collection:—Caillard, fiery salmon, crimson eye, fine in habit, and very distinct. Roi des Roses, rose suffused with vermilion, crimson eye, a good truss and free grower, a plant here, in little over an 8-inch pot, having 18 spikes—a showy object to be sure. Mons. Guilottеaux, rosy carmine, shaded with violet and crimson. M. Guldenschuch, rose-violet, with purple-scarlet centre, fine in habit, a good trusser, and very dwarf in habit, being less than 18 inches in height. William Bull, bright lilac, with lighter centre, neat in habit, and very distinct. Venus, silvery white, with bright violet-purple eye, a good trusser, but the flowers are rather small, though very distinct. Lord Derby, rose, striped with crimson, and striped variety of that colour. Madame Domage, white, slightly marked with purple, very large and extra fine, grows to the height of about 2 feet. Mons. Malet, lilac, bright centre, spike large and compact. Amabilis, rosy salmon, bright purple eye, a fine truss, and the best for pot culture on account of its neat dwarf habit. Mdlle. Christine Nillson, white ground, stained with rosy purple, a good trusser, and very distinct. James Veitch, grey slate, shaded with violet, stout in habit, and a good trusser. Mons. Rafarni, amaranth-red, bright scarlet centre, flowers of medium size produced on very large pyramidal-shaped spikes, and dwarf in habit. Etoile de Neuilly, white, with distinct purple eye. Souvenir de Berryer, crimson, with a purple centre; a grand flower, and good trusser, and most worthily indeed does it carry the name of one of the ablest lawyers of the Paris bar. Hollow, reddish purple, deeper in the edges, a good trusser, and neat in habit. Géant des Batailles, salmon-orange, very distinct, but rather a straggling grower. M. George Henderson, rose, shaded slate, purple eye, a fine trusser, and moderately dwarf. Madame Koempler, bright red, shaded with purple, and tinged with scarlet, tall in habit, but a nice trusser. Triomphe du Parc de Neuilly, brilliant carmine, with a bright crimson centre, very distinct. M. Linden, magenta-scarlet, flowers rather small, but produced in capital trusses, very pretty and distinct; and M. Marin Saison, red salmon-violet, very dwarf and compact. Most of the former belong to the P. decussata, or late-flowering section. Of the P. sufruticosa, or early-flowering section, which is readily distinguished from the former, by their longer and narrower leaves, and longer and more compact trusses, we can only a few in flower when we saw the collection; but as in any collection both sections must be represented, we may mention the following as possessing reliable merit:—Mrs. Thorn, white, dark crimson eye, flowers perfect in shape, and foliage of a deep bronze tint; Mr. M'Bain, tinted white, bright rosy eye; Thomas Forbes, rosy lilac, dark eye, very distinct; Miss A. Ballantyne, white, rosy pink eye, flowers large and of good substance; The Deacon, deep rosy purple, crimson eye, a good trusser; and The Queen, pure white, and excellent in habit.

As we said before, these truly showy flowers will ere long become indispensable to the gardener for conservatory and show-house decoration, for which purpose they must be grown in pots; and here let us state that we know of no other plants that give out such a delicate agreeable odour—like that of Violets—as is to be found in a house containing a collection of Phloxes in flower, the nearest approach to it being that found in a house of Verbenas. Supposing, then, that you wish to grow a collection in pots, you must propagate by cuttings, the side-shoots being the best for the purpose. The dark-flowered varieties, according to Mr. Laing's experience, are more difficult to propagate than the lighter ones, therefore these will require a little extra care. Put the cuttings in about the beginning of August, in a cool frame. Here they will strike freely, and must be potted off into 5-inch pots as soon as they are satisfactorily rooted, subsequently plunging them into a bed of ashes, old tan, or cocoa-nut refuse outside. Here they will remain until the following April, when they should be shifted into 8-inch pots, which are quite large enough for the first season, the shift in the following season being into 12-inch pots, in which size they undoubtedly do best. The soil selected for them should be light and porous, for they have a distaste to anything heavy; and they will require plenty of water during the growing season. Liquid manure, if given at all, must be applied cautiously; a better plan for affording a little nourishment consisting in top-dressing with sheep-dung when the spikes are forming. Such is the treatment adopted by Mr. Laing, and we know of no one who grows or shows them better.

Leaving these gorgeous Phloxes, we turned for a pleasant interval amongst some large beds of Pentstemons, a flower much in favour here, and grown in even larger quantities than the former. The past few years have witnessed a great improvement in this as well as many other garden flowers, Mr. Laing having led the onward march by annually raising and flowering a large batch of seedlings, from which only the very best are selected for naming and future distribution. As a border plant the Pentstemon has many advantages in its favour, not the least of which are that it will grow on almost any soil; and that bloom is of the showiest description, and it flowers in abundance from June to October. There is a rare amount of interest, too, in a bed of well selected varieties, if it is only in the varied and most beautiful tints of colour presented, to say nothing of a bed of seedlings like the one before mentioned, amongst which the plants from which only half a dozen or so will be selected for distribution. Up to the time of our visit Mr. Laing had selected the following five, but we have no doubt this number has been considerably added to, as a great deal of the best flower:—Rosy Morn, rich deep rose, throat pure white, broad and flat, a showy, refined flower, rendered even more attractive by having blue anthers. Minnie Denyer, dark rosy lilac, throat pure white, large, and well defined; a showy and attractive variety. Floribunda, white, shaded and margined with rose, throat white, broad and flat in outline, and the flowers well and evenly studded all up the spike; this, Mr. Laing considers the truest type of what a Penstemon should be that we have yet obtained. Gustave Lambert, 'slatish-purple, mouth broad, and throat clear; very refined. Madame Domage, tube carmine-crimson, with a crimson mouth, throat heavily stained with deep claret, and the lower lips spotted with white; a great novelty and a very decided gain. Amongst older sorts, the best yet sent out is Stanstead Rival, bright scarlet-crimson, pure; white throat, slightly pencilled with the same colour; though not nearly so highly of Polly King, rosy crimson, white throat, pencilled with brilliant crimson; Delicatissimum, pure white, tinted with bright pink; Rev. C. P. Peach, purplish crimson, with white-carmine pencilled throat; Regalia, rich purple, pure white throat, veined with rose; George Sinclair, dark purple, very fine; Stanstead Surprise, dark purple, white throat; and Mrs. Peter Cator, crimson, with white pencilled throat.

The improved varieties of Antirrhinums are as yet not so popular as they might be, or so much used for intermixing in the herbaceous or shrubbery borders as they will be when their merits are fully recognised. Grown as they are here, too, in beds, they present a gay and attractive appearance when in flower. Like the Pentstemon, their cultivation is very simple, being easily propagated by cuttings in the months of August and September, and requiring to be kept only in a cold frame during winter, their greatest enemies, damp and frost, being carefully guarded against. We have amongst these some first-class varieties, of which the following may be taken as the best:—Beda, white, lightly striped with crimson, a bold showy flower; Queen of Whites, a fine flower, of large size and perfect shape, fine for exhibition. George Gordon, deep glowing crimson, smooth, large and perfect in form; the greatest acquisition for exhibition purposes yet sent out. Europa, bright yellow, mottled with dark red, dwarf and compact. Orange Boven, bright crimson-scarlet, with deep orange lips; very showy. Striped Unique, greyish white, heavily striped with rosy crimson. Clio, yellow and buff, mottled and striped with red; very fine. Bronze Banner, yellow ground with deep chestnut zone; a good bedder. Pretty Polly, French-white, shaded with pure yellow, fine in form, and very distinct. Mathilde, rose, striped and mottled with dark purple. Beauty, white, mottled and striped rose. Yellow Queen, bright yellow, smooth and perfect in form.

In Gold and Bronze Pelargoniums Messrs. Downie, Laird & Laing have undoubtedly taken the lead since these showy and attractive plants came into fashion, annually exhibiting seedling forms, all more or less an advance on their predecessors, and in this matter they acted, we think, with a wise discretion, because—always, of course, excepting Mrs. Pollock, which, as a bedding Tricolor, has not been beaten—the Bronze Zonals are infinitely superior to the Golden Tricolors for bedding-out purposes; and we venture to predict that the former will hold their own when the latter are—well, forgotten. The Bronze Zonal, too, is a very effective plant for conservatory decoration, and again beats the Tricolor for freedom of growth. They are as a rule very strong growers, making very nice specimens the first season. To do them justice they must be grown in a nice fibrous loam, and if this is not attentive to its nature the addition of a little dry tolerably fresh horse-dung will keep it sufficiently open and porous. They require water plentifully and often when growing quickly, as they seem to become dry sooner than the green-leaved ones under the same conditions as to position, temperature, &c.; and when this is allowed to be the case too often the colour leaves them, and they soon turn to a sickly hue. There are of these, as of the Golden and Silver Tricolors, an immense number of varieties grown here, from which we made the following selection, as being in very many deserving of cultivation:—Herold, a fine-shaped leaf, with a small disc and a faint zone of chocolate-red. Rev. C. P. Peach, creamy yellow ground and margin, and chocolate-red zone, the leaves fine in outline; recommended as a good bedder. Emperor of Brazil, disc medium size, surrounded by a deep maroon zone and narrow yellow edge. Pretty Polly, golden disc and margin, with a band of chestnut-red, a free growing variety, with vandyked leaves. Black Douglas, leaves large, slightly convex, with a very broad band of dark chocolate, of a bronzy hue, and a narrow golden margin. In habit dwarf, bushy, and compact, and very showy as a bedding plant, its bright salmon-pink flowers contrasting most effectively with the sombre colour of the leaves. Reine Victoria, bright yellow disc, surrounded with a broad zone of brilliant chestnut, and a broad belt of deep golden-yellow at the margin. In habit very compact, the leaves being stout in texture, which enables it to stand a great amount of sun heat; these are perhaps the two best and most distinct bedding varieties yet sent out. Crown Prince, bright yellow leaves, with a deep zone of dark chestnut, compact in habit and a vigorous grower. Brilliancy, a dwarf useful border variety, also with yellow leaves and bright red zone. Mrs. George Gordon, a capital bedding variety, with nicely shaped leaves of a bronzy-gold colour, in which is a distinct and well defined zone of chestnut; and Vivid, leaves perfect in shape and of good substance, of a bright golden colour, and a bronze zone, an excellent pot plant, but not so good as a bedder.

Double-flowered Pelargoniums have increased materially of late, and amongst them are some very excellent things, chiefly of Continental origin. At the time of our visit, Messrs. Downie, Laird & Laing had a good sized span-roofed house devoted to them, and a nice lot of well grown plants they were. Out of the three dozen or more varieties in cultivation the following appeared to be the best and most distinct, though in saying this we do not condemn the others:—E. G. Henderson, carmine, dwarf in habit, and a free bloomer. C. Glijm, bright scarlet, flowers of good form, and in habit the dwarfest of the scarlet section; the best sent out last year. Sapeur Pompier, brilliant orange-scarlet, trusses large and of good shape, leaves of a bright green, with a bronze zone. Madame Lemoine, light rosy, individual flowers large in size, and produced in very large trusses; free flowering. Tom Pouce, cerise; flowers also very fine in size. Merveille de Lorraine, rose, tipped with white; first rate. Madame M. Buchner, bright salmon-rose, shaded with carmine, the trusses large, and the habit dwarf and vigorous. The greatest obstacle to the grower of these charming summer decorative plants has heretofore been their extraordinary vigour of growth, which we are pleased to see is gradually being overcome by the introduction of varieties whose habit more resembles that of our old favourite Tom Thumb, than which we have yet no better model of what a bedding Pelargonium should be.

In a large establishment like the one under notice, there are, of course, a great number of things deserving of comment, which, on this occasion, we are reluctantly compelled to pass over with the mere assertion that, in a walk over the grounds we found a very nice collection of ornamental trees and shrubs and some nice specimen Conifers; a large quantity of Roses, including a collection of very healthy and vigorous Teas in pots; an immense quantity of Hollyhocks and Gladiolus, not then in flower, and of which latter Mr. Laing annually sows a two-light frame, amongst which he obtains some fine flowers; a capital lot of pyramidal Pear trees, of good shape and fine health, followed by some very well-trained Apple trees; and

the best lot of Peaches and Nectarines—four years old from the bud—that we have seen for some time. In the matter of training it would, indeed, give some trouble to find a nicer lot. In the houses the principal features were the collections of Caladiums, of which there is an almost endless variety, to a certain extent, as indistinguishable as Tricolor Pelargoniums; a very large and rich collection of young Palms, amongst which are a great many seedlings of novelties, which must be examined when a little larger; a nice lot of Vines in pots, and the usual description of stock to be found in a good nursery.

Obituary.

On the 20th inst., JAMES WOODWARD, gardener at Garbrand House, Ewell, Surrey, age 36. Mr. Woodward was a pupil of Mr. Carson, Nonsuch Park, Cheam, and held his situation at Ewell for nine years, during which time he made himself known as a successful exhibitor.

Nov. 16.—Rain fell between 1 and 2 A.M. Nearly cloudless from 9 A.M. onwards. Very fine.

" 17.—A little snow fell occasionally in the morning. Very fine throughout. Small amounts of cloud prevalent.

" 18.—Cloudless throughout. Hoar-frost in morning and evening. Hazy and foggy.

" 19.—Generally cloudless throughout. Dense fog at times.

" 20.—A little light cloud present at times. Very fine. Lunar corona at night.

" 21.—Generally cloudless in morning; cloudy towards night. Lunar halo at night.

" 22.—Overcast throughout. Slight fog. Thin misty rain fell at night.

JAMES GLAISHER.

Miscellaneous.

EARLY OR FORCING PINKS.—To obtain fine strong plants for forcing, cuttings should be struck early in April, and when well rooted they should be planted out about 8 inches apart, and frequently watered during the summer months, so as to keep them in a growing state. Early in October they should be taken up with a good ball of earth, and potted into 6-inch pots, using rich soil consisting of three parts of good loam to one of well-rotted manure. They should then be placed on a bed in the open air, taking care not to let them suffer for want of water. After the plants have become well established, they may be placed in a little gentle heat, and brought on in succession as required. Some very fine varieties have recently been exhibited which are really great acquisitions to this class of Pinks, particularly Gibbon's Lady Blanche, a very fine pure white, a good, useful-sized flower, moderately full, and which has a good pod, so that it does not burst; it is of very free habit, and blooms very profusely, producing from 20 to 30 fine blooms on each plant. This is really a first-class variety, and will be found particularly useful for bouquets. Lee's Princess Louise is a fine bright scarlet and a large full flower. This blooms very profusely, and is of a very dwarf habit, growing only 10 inches high. I think it is a hybrid, as it has the perfume of the Carnation. Watson's Alba multiflora is a fine pure white flower, large and full without confusion; it has a good pod, not liable to burst, but the habit of the plant appears to be rather weakly. Clark's Lord Lyons is a deep, rosy purple, very fine, with large, smooth, full flowers; it is of good habit, very free, and quite distinct. The four varieties above named are of very fine quality, and will be found very superior to anything before sent out. *John Ball, Slough, in "Florist and Pomologist."*

THERE is in New York, on its way to a European museum, a solid section cut from one of the original "big trees" of Californin. Five men were employed 25 days in felling this huge tree; its height is 302 feet, and its largest diameter 32 feet. The specimen was cut at the height of 20 feet from the base. The stump is covered in, and is now used as a ball-room! It has been ascertained from counting the annular rings that the tree is more than 2500 years old. *New York Times.*

CINNAMON CULTURE.—The land under Cinnamon cultivation is about 15,000 acres. The best Cinnamon is thin, shining, and of a lightish yellow; it is slightly sweet, and has an aromatic flavour. It is cultivated by seeds, shoots, or layers, and old stumps are also transplanted; a quicker return is obtained by the last procedure, as shoots fit for peeling can be cut after they have been planted for eighteen months. The culture by seeds involves turning up about a foot square of ground at the rainy season (about the end of June or four) are then deposited, some ashes having been previously placed in the holes. The seeds germinate in about 22 days, but it is nearly seven years before shoots ready for peeling are produced. The seeds are also planted sometimes in nurseries, and the growing plants transplanted. The peeling commences about the end of April, and continues until the end of October. When a shoot has grown sufficiently large, the skilled labourer, or *chalia*, as he is called, inserts a sharp instrument, similar to a bill-hook, obliquely into it; the cut is then closely examined, to ascertain if the bark separates readily from the wood; if sinch be not the case, the shoot is left to be operated upon at some future time. The shoots that are cut are generally about ¾ inch in diameter, 4 feet in length; they are then stripped of all their leaves, and two incisions, running lengthwise, are made in the bark, when, in the generality of cases, a considerable portion of the latter comes off in one piece. The bark is kept for about thirty hours, and fermentation, to some extent, is thus provoked; the external covering of the bark is removed with a crooked knife. In about ten hours after this has been done the sections are put one into the other, and this is called piping; the pipes thus prepared are exposed to the influence of both air and sun for two or three days, and are then made up into bundles of about 28 lb. each, warehoused and shipped. *Food Journal.*

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

THOSE gayest of all our Christmas decorative plants, *Poinsettias*, both scarlet and white, should, now that their bracts are forming, receive very liberal and attentive treatment. Not unfrequently at this season, or rather at the time the flowers are about to form, these plants receive a check, either through being left too long in a cool place, where the heat is declining, or through inattention in the matter of watering when the pots become filled with roots, &c. The least inattention in these matters of detail invariably tends to reduce the size of the showy bracts. An occasional watering with liquid manure in conjunction with frequent syringings overhead, and a little bottom-heat, into which the pots should be plunged, will be of much benefit to them. In regard to *Cape Pelargoniums*, guard well against damp and spot upon the leaves, immunity from which is chiefly assured by keeping the foliage dry, and by affording an abundance of fresh air, so long as any draughts are permitted. On the other hand, during frosty weather or at such times as fires are required, care must be taken not to have more dry artificial heat than is absolutely necessary to keep out frost. Again, *Epacris* and *Ericas* have no greater enemy than a dry fire-heat. They thrive far better in a cool frame with its attendant damp, and when freely exposed to air, than in arid temperatures such as above mentioned. *Kalosanthuses, Rochæas, Cactuses*, &c., should all be kept dry now, in such a manner as to insure a perfect rest. Place *Lachenalias*, which are now growing, at the coolest end of the house they may be in, elevating them as near to the glass, and giving them as much air, as possible. Be careful that all *Cinerarias* which have filled their pots with roots are kept constantly supplied with water, as any neglect in this wise becomes injurious to them. Give another shift to such *Herbaceous Calceolarias* as may have again filled the soil moderately with roots, as no check must by any means be permitted there now. As with a few other plants I have mentioned, these also like the cooler end of any structure, or at least to be some distance from the heating medium.

FORCING HOUSES.

Strong young stock plants of *Pines*, intended for next year's fruiting, should now have a somewhat drier air maintained around them, and, comparatively speaking, a more abundant supply of fresh air. This for two reasons: whilst it reduces the extreme excitability of the plants, and tends to rest them, it also induces a better state of maturity in the parts already formed. These remarks in no wise apply to fruiting plants, which must have all the aid possible to further the end in view. Persistently maintain a very moderate temperature in *Pineries* now in process of starting; 55° will be the safest maximum until the buds break, and this only by day with artificial heat—a temperature of 4° or 5° less being ample by night, when aided by artificial heat also. Fires must be occasionally used in all vineries in which the Grapes still hang. This, however, must be in conjunction with a free circulation of air. To *Peach* and *Nectarine houses* started about this time I would afford less artificial heat at the starting than is given to the early vineries, by some 8° or 10° at the first. Keep the houses shut up, excepting for an hour or two early in the day, and with a slightly moist atmosphere. Be it understood, however, that except when air is afforded for a short time, the internal warmth may range higher if influenced by external temperatures, but not otherwise. *Cucumbers* to thrive well must still have a bottom-heat maintained of about 76° or 80°, and a day temperature of about 70°. Should the heat run up upon mild nights to 68° or 70° by the aid of external coverings, always give a little air at the apex of the structure. Be careful at this time not to cause the soil at the roots to become too wet, as to do so at this time is to cause the plants and their future fruiting prospects much injury.

HARDY FRUIT GARDEN.

With the leaves removed from wall trees, and the shreds, &c., taken from *Peach* and *Nectarine trees*, all wall borders should be neatly cleaned and carefully forked over. The shreds removed from the trees should be looked through, and any that are wholesome enough and will bear the test of a good pull with the two hands should be kept for use next time. Where the trees have been greatly pest-ridden, by red spider especially, it is well to destroy any eggs which may exist in the shreds by submitting them to a properly heated oven, as this may be like much else easily rendered innocuous. Independently of the larger pots and their contents, *Strawberries* for forcing should be made pefectly secure in this way, as the loss of the young roots and rootlets around the inner sides of the pots cannot be well estimated at the fruiting time. Persist in forking out the over-crowded suckers of orchard-trees, for the uninitiated may depend upon it that only by so doing are good crops of fruit of fine quality attainable. Where Moss exists upon fruit trees, as it does, not infrequently, upon damp soils and such as are calcareous in their nature, resort should be had to the Moss and fresh slaked lime, with which the parts infested should be dusted over. Prune *Outdoor Vines* at the first opportunity, nailing them neatly to the wall. I observe that, where Vines are grown against house walls, &c., they are almost invariably permitted to grow too thickly; indeed, so much so, that it would be an impossibility for a good crop of fruit to be carried of the quality expected. In pruning the rods, therefore, give each ample room to allow of its young shoots growing vigorously, and becoming properly developed when formed.

KITCHEN GARDEN.

Successional beds of *Asparagus* must be again formed where the demand is constant. In such cases these should be formed and planted by anticipation at this extremely dull time, as they seem to advance very slowly. Where it is contemplated to take up crowns of either *Asparagus* or *Seakale* in a month's time, more or less, to insure a supply at a definite time, it will be safer to have litter at hand ready to cover the crowns or stools over should a severe period set in. *Peas* should be sown about this time to stand the winter for the earlier spring supply. A dry quarter or border should be chosen, possessing a sunny aspect. It is advisable to sow moderately thickly to insure a crop

where they are likely to be attacked by insects, birds, &c. Often where gardens are in the vicinity of farmyards sparrows attack and eat them unmercifully when they get through the ground; hence, Pea protectors formed of galvanised wire are not unfrequently used. If, however, any kind of protection is afforded them, considering the cost of the above, it would be far better to purchase Rendle's plant protectors, which protect from the cold, and, besides, can be used for so many other different purposes. Attend to the sowing successionally of small salading, and tying *Endive* up in frames to blanch, &c. Do not neglect the forced herbs which the *chef de cuisine* may require shortly, such as *Sorrel*, *Tarragon*, *Mint*, &c., the possession of the requisite supply of which often saves the grower's credit. *W. E.*

TOWN GARDENING.

Bulbs may still be potted as well as planted out in the open borders, and *Hyacinths* and *Narcissi* may be placed in glasses and put away as previously directed. These will come on in succession to those put in earlier. The beautiful *Lilium auratum* and *L. lancifolium* may now be purchased for a mere trifle, and I strongly recommend them for town culture. They should be potted at once into 32-sized pots, in three-fourths loam and one of rotten dung and a little silver sand. Place them on ashes to keep the worms, and cover with 4 inches of ashes till spring, when they should be brought into the windows or be placed in the borders, where they bloom in perfection. As flowering plants suitable for the decoration of vestibules are now scarce, such places may be enlivened with a great variety of small bushy evergreen pots, mixed with Solanum Pseudo-Capsicum, with its beautiful coral berries, and the Acacia lophantha, with its graceful Fern-like foliage. Pot plants in frames should be turned round, have the soil stirred, and all dead leaves removed, and the lights should be kept off in fine weather. This will give them a constitution to stand against frost, with a little protection. *J. D.*

Notices to Correspondents.

ASPARAGUS : *Thorne*. Plant your bed with 1-year-old plants. They are very little, if any, distinction betwixt one Asparagus and another.

BOTANY FOR BEGINNERS : *C. E. F.* Yes.

LUDOVICA LANCIFOLIA : *M. M.* We do not know the plant you mention under this name.

NAMES OF PLANTS : *A Constant Reader*. Hartwegia comosa, Nees (Chlorophytum Sternbergianum, Stend.), from the Cape of Good Hope.—*C. W., Cornwall*. 1, Eccremocarpus scaber, var. aurantiacus; 2, Escallonia montevidensis; 4, Eheagnus japonicus; 6, Convolvulus Cneorum; 20, Adiantum setulosum; 40, Selaginella pubescens. We cannot name more than six specimens at one time.—*W. G. G.* 1, Adiantum pubescens; 2, Asplenium viviparum; 3, Asplenium bulbiferum; 4, Lomaria Patersoni; 5, not recognised : send fertile specimens.—*Correspondent*. 1, Oplismenus imbecillis fol. var.; 2, Irisine Herbstii; 3, Alternanthera reticulata; 3, Rivina humilis; 4, Epiphyllum truncatum.—*H. K.* Pelargonium crispum.

PARASITE ON SWEET WILLIAMS : *A. D.* The parasite is Puccinia Lychnidearum, which is not uncommon on Sweet Williams. *M. J. B.*

PEARS ON SOUTH WALL : *Thorne*. These answer exceedingly well; in fact, it is the best aspect for late Pears. They generally do not do to Peaches, &c., which do not succeed nearly so well elsewhere, whereas Pears are not so particular. Glou Morceau, Beurré Rance, and Doyenné du Comice are those we should recommend.

POINSETTIAS : *Eliza*. While growing these plants require the ordinary treatment of other stove plants as to air, syringing, watering, &c. They seldom flower till a later period than the present, unless specially forwarded. See articles on their cultivation at pp. 276, 353 (1870). The same remarks apply to the Bouvardias.

SEA-BUCKTHORN BERRIES : *H.* We never heard of these being injurious to cattle. They are eaten in some countries, although it is said in other books that they contain a narcotic poisonous principle. If so, it must be in very minute proportions; no mention of it is made in the standard books—such as Watts' "Dictionary of Chemistry."

SÉCATEUR : *L. & B.* We have no doubt that you have sold French *sécateurs*, but we do doubt whether you have sold them recently at any rate, the particular description figured last week, and which are, we believe, to be had at present only of the firm mentioned. We have nothing whatever to do with advertisements except in the columns specially devoted to them, on which account we decline to insert your letter.

CATALOGUES RECEIVED.—Jabez Jay Chater, General Descriptive and Wholesale Nursery Stock.—John Harrison, Descriptive Catalogue of Roses and Hollyhocks.—Maurice Young, Catalogue of New and Rare Plants, Conifers, Hardy Ornamental Trees and Shrubs, Rhododendrons, Roses, Fruit and Forest Trees, &c.—James Dickson & Sons, Catalogue of Forest Trees, Covert and Underwood Plants, Ornamental Trees, Shrubs, and Evergreens.

ERRATUM : At p. 1487, col. 2, line 37, for "would throw the onus," read, "it would be best to throw the onus," &c.

COMMUNICATIONS RECEIVED.—A. C.—J. S., Ripley.—J. H. C.—P. F.—W. P. A.—D. T. F.—J. McL.—H.—W.—L.—A. M.—J. G. B.—A. F.—F. C.—W. D. F.—A. Z.—R. Heath.—J. T. B.—W. R. McN.—E. Bennet—J. M. T.—D., Deal.—H. K.—Floors (your note shall be attended to).—Antoine (with thanks.—A. F. M.

Markets.

COVENT GARDEN.—Nov. 24.

Transactions generally have been limited during the week. Hothouse Pines and Grapes are well supplied, and some good American Newtown Pippins are in the market. Outdoor produce very plentiful and good, with the exception of dessert Apples. Pears comprise Chaumontele, Nelis d'Hiver, Glou Morceau, Beurré de Witte, Doyenné du Comice, and others. Peaches are over. In the Potato market prices are stationary, in consequence of the disappearance of the frost. The principal flowers in the market are, of course Chrysanthemums, but we have a few Hyacinths, Tulips, Primulas, and Poinsettias.

FRUIT.

	s.d.	s.d.
Apples, per ½ sieve	2 0 to 3 0

The Agricultural Gazette.

SATURDAY, NOVEMBER 25, 1871.

MEETING FOR THE ENSUING WEEK.

MONDAY, Nov. 27 } Midland Counties Cattle Show, at Bingley
THURSDAY, Nov. 30 } Hall, Birmingham.

FOOT-AND-MOUTH DISEASE has a wide range of affinities. Originally developed in the system of the ox, it is capable of being transmitted, through the medium of the diseased secretions, to other animals of the same family, and even to those which are remote from them in the natural scale.

Specific diseases generally confine their attacks to the individual, or, at most, to the members of the same family. Thus, sheep-pox affects only the sheep, typhus is found in the pig, pleuro-pneumonia belongs exclusively to cattle. Cattle plague, the most virulent of animal maladies,

extends to all the members of the ruminating family, but does not reach any creature outside of it; foot-and-mouth disease alone of all the specific affections of stock has a range far beyond the family among which it arose.

Next to cattle, sheep appear to be the most susceptible to the disease, which, however, in this case, principally affects the feet, commencing by the development of small vesicles on the skin of the heels and sides of the digits, immediately above the horny covering of the foot. A discharge of serous fluid at this part very soon takes place, rendering the hair moist and sticky; as the disease advances, the hoof-horn is separated from the secreting membrane, and loss of hoof is a very frequent result of the ravages of the affection. Many years ago, in the time of the old Smithfield Market, and during one of the great outbreaks of the foot-and-mouth complaint, sheep suffered so severely that it was necessary at the end of a market-day to sweep the cast-off hoofs into heaps, prior to removing them in baskets. In very few cases are vesicles developed in the mouth of the sheep, and it is not impossible that this is due to the manner of infection. Sheep would be most likely to bring their feet in contact with saliva or the manure of diseased cattle during a journey along the road, or in a railway truck, while they are less often in the way of feeding from the same pastures; no doubt, however, exists as to the fact that the disease is almost always confined to the feet, whatever the cause may be. Pigs stand next to sheep in the order of susceptibility, and these animals also suffer much from the effects of the disease in the feet, although it is not confined to those organs; numerous vesicles commonly appear on the muzzle, and in sows the udder is frequently affected. We have been recently asked if the complaint has been known to attack poultry, and we have no hesitation in giving an affirmative answer. Of late years we have not met with any cases of the malady in fowls and turkeys; but some 25 years ago, in one of the early outbreaks, the disease spread so extensively among poultry as to cause considerable loss. The feet were sometimes completely destroyed by ulceration, and the birds either pined away from the pain which they suffered, or were killed as useless. The habits of the birds are unfortunately calculated to increase the severity of the disease, by leading to the accumulation of particles of grit and dust in the cavities which are left when the vesicles burst; and nothing short of confining them to a room with a perfectly clean floor will prevent the exercise of the habit of scratching in the dirt.

It is asserted by some persons that ducks and geese have been attacked with foot-and-mouth complaint, but the evidence on this point is by no means satisfactory; in our experience they have always escaped, even when poultry have been severely attacked, and our impression is that web-footed birds are exempt. Horses are occasionally reported as affected with foot-and-mouth disease, but here again our own observations are opposed to the assumption of their liability to the affection; in hundreds of instances where horses have been in close association with diseased cattle, we have never met with a single case of communication of the disease. Horses are subject to slight abrasion of the mucous membrane of the mouth in simple febrile diseases, and it is quite possible that this circumstance may have led to an erroneous conclusion.

Communication of the disease to the human subject is just now a point which is attracting some attention. Several medical men have reported cases of eruptive disease, among children particularly, which they have traced to the use of milk from diseased cattle; but, judging from the accounts which have been given of the symptoms and progress of the disease, there is no very striking resemblance between it and the malady affecting cattle.

Two years ago the question was investigated by the Medical Department of the Privy Council, and Dr. THORNE, who is now, we believe, continuing the inquiry, found that in many instances eruptions occurred on the lips and gums of children, and even of adults, who drank diseased milk; but in a still greater number of instances the use of such milk was not followed by any ill effects.

There is no question that the fluid secreted by the mammary glands of a diseased cow is totally unfit for human consumption, but at present there is no positive evidence that human beings are liable to be attacked with foot-and-mouth disease; and we are in a position to assert positively that all the experiments which have been undertaken at various times, with a view to test the susceptibility of man to the infection, have had a negative result.

In another page will be found the address of Mr. SCOT SKIRVING, as the retiring chairman, at the recent annual meeting of the Scottish Chamber of Agriculture. It is only to his remarks on the subject of AGRICULTURAL EDUCATION on that occasion that we desire to refer just now. Mr. SKIRVING is the energetic advocate of the widest possible education of the lad who is to be a farmer. To any one who should parody the words of BURNS, and ask,—Can Turnips be grown "by dint o' Greek?" he replies that Yes is at least as true an answer as No. Let the mind receive the best training that the schools can give—such a training is what the farmer wants in the true interests, whether of the man or the profession. Such advice is indeed against the usual style of that which professional men are in the habit of giving, for, according to Mr. SKIRVING, whether it be to agricultural or the divinity student, the usual recommendation is, not that the general powers of the mind be cultivated, and the whole nature of the man enlarged, but that, after a sufficiency of school education has been received, a successful man in the particular profession be taken as a model or a guide, and his example and instructions carefully copied and received. In particular is this true of the farmer. He belongs to the best advised class in the three kingdoms, and is lectured at on all occasions by men whose chief qualification is "a total ignorance of the subject" about which they lecture. "One of these advisers," a gentleman who remained unnamed because he was not present to reply, had even obtained the ear of the Royal Agricultural Society "some time ago," and offered a series of recommendations of this kind on the subject of agricultural education which Mr. SCOT SKIRVING regretted to say had been received with favour by the Council, and to which he, therefore, then proceeded, after more than six years' interval, to offer a reply.

The reply in question, though founded somewhat on misquotation, is a very forcible assertion of a very important truth; and though, like all fighting men, Mr. SKIRVING cares only for his own side of the affray, we are certain that the "adviser" whom he disparaged is not only ready heartily to applaud his sentiments and adopt his views, but is even under the delusion, it may be, that the views and sentiments in question had been often expressed "some time ago" by himself. It is not, however, on personal grounds at all that we wish to revive a subject which has long been out of reach of controversy. The history of the discussion which preceded the Royal Agricultural Society's present treatment of the subject in question is useful, apart altogether from Mr. SCOT SKIRVING'S condemnation of any particular adviser or lecturer about it, and we therefore reproduce to a certain extent a *resumé* of that history, which appears to us to state with fairness the points which were under discussion at the time, to which attention may be usefully redirected now.

There was never, we believe, in the whole course of this discussion any difference of opinion whatever as to what is desirable for a thorough education, in order to good and successful agriculture. Universally was agreed that good schooling during boyhood is necessary in order to good manhood, to whatever occupation that manhood may be devoted. There was perfect agreement upon the all-importance of a good and sufficiently prolonged schooling for the boy, whether as a man he is to adopt a profession or to become a tradesman or a farmer. Mr. ACLAND—now Sir THOMAS ACLAND—may be said to have led the discussion on the one side and Mr. HOLLAND on the other. There was no difference whatever between these gentlemen on the importance of the primary education which the tenant-farmer as much as any other man of business needs in order to be respectable, influential, and successful in the station which he occupies. No doubt Mr. HOLLAND, equally with Sir THOMAS ACLAND, felt that the consideration accorded to agriculturists as a body, the position they occupy in public opinion, the influence they exert, must ever be in exact proportion to the intelligence, the self-reliance, and the power which their education has given them. And, still more, both of these authorities no doubt believed that the social position, the personal influence, and even the professional success of the individual farmer depend very much upon those qualities of head and heart for which he is indebted, not to his professional, but to his general and preliminary education during boyhood and youth.

It was not, therefore, in any degree whatever upon the relative importance in a complete agricultural education of this preliminary schooling on the one side, and of the subsequent professional studies and apprenticeship on the other, that any difference arose. The discussion lay simply upon what it was fit and proper for the Agricultural Society to do. One party believed that the Agricultural Society should confine itself to helping forward agricultural education; the other party believed that it might do what it could to help forward the preliminary education of farmers' sons. This latter was Sir THOMAS ACLAND'S opinion and advice. It was founded on his belief, first, that the preliminary and general education during boyhood and youth is the only foundation on which a good agricultural or any other good position during manhood is possible; and secondly, that this preliminary schooling for farmers' sons in England had been defective. It was also in some measure influenced by the impression that this preliminary and general education is the only part of the whole educational process which is capable of effective stimulant or guidance by any system of prizes or examination. Sir THOMAS ACLAND believed that more will be done towards the improvement of agricultural education by a well-directed schooling than in any other way; and he also believed that this, and only this, is capable of being tested and stimulated by examinations and by prizes. He accordingly induced the Society to vote a certain sum of money to be awarded as prizes to those sons of farmers or of members entering for this particular competition who shall have best acquitted themselves at the various local school examinations by the delegates of the Universities.

Mr. HOLLAND, office to the Society was, we believe, founded upon quite as enlarged a view of the whole subject as that of Sir THOMAS ACLAND. He equally with Sir THOMAS ACLAND believed in the absolute necessity of a good general education; he as much as any man urged the great importance of raising the standard of attainment as high as possible before young men set themselves to any special studies and the especial apprenticeship by which agriculture efficiency is obtained. But he believed, first, that the general standard of intelligence and of education amongst tenant-farmers had been rapidly rising during the past two generations, and that there is now a greater and more general anxiety on their part for the good education of their sons than there ever hitherto had been. He believed, secondly, that in the new modes of cultivation which have of late years been adopted, and in the new applications of scientific knowledge to farm practice which the last 20 years have witnessed, there is within the strictly professional part of an agricultural education an immense territory, as it were, of useful knowledge, open to the sons as farmers, which their fathers did not know, to the mastery of which they ought to be guided and incited. And he believed, lastly, that guidance and incitement can be offered to young men towards their attainment of professional studies, the practical and professional parts of an agricultural education, by prizes and examinations, just as everybody admits that spur and rein can by prizes and examinations be brought to bear upon their attainment of proficiency in the branches of a general and preliminary education.

There is less need than ever there was to urge upon the attention of agriculturists the importance of a good general education for those who are to succeed them—there is more need than ever there was to urge upon them the great value of special and professional instruction—and it is just as possible to promote by prizes and examinations the studies and the industry necessary to professional attainment as it is to promote by prizes and examinations the attainment of a high standard of general education.

These were the three propositions out of which it was thought that the Society ought, in accordance with its Charter, to have seen its way towards instituting annual examinations and prizes for agricultural students, so that professional attainment might have been encouraged and rewarded. The Society has, we know,

yielded to these considerations, and does now offer prizes to strictly agricultural students. They have at length directed their attention, which as an agricultural society they very properly might do, to the professional education of agricultural students. The education of the whole class of boys from amongst whom one and another step out to choose an agricultural career, was not their subject. That was of course a much higher subject than any that could come before the members of the Agricultural Society; but there was no reason on that account why an attempt should not be made to deal with the much humbler, but, though far inferior, yet important subject that did belong to the Agricultural Society, namely, how a well-educated boy should be made a good farmer. A clever writer in the *North British Agriculturist* at the time, with whom we entirely sympathize in the estimate he forms of the relative importance of the good education which a lad should have had for mere manhood's sake whatever be the profession he may adopt, and the special education which thereafter he requires, nevertheless imagined that the purpose of the lecture before the Agricultural Society to which Mr. SKIRVING has again referred, was to magnify the professional training as compared with the essential education on which it ought to be founded; and he exclaims to the editor:—

"You are at present writing articles on hypothec, Game Laws, and other farmers' grievances. Why do these things exist if farmers think them unjust? Why do they constantly take land, knowing that it is too dear? Why do they give their farmsteads, and their time, and their brains, and their capital for less remuneration than other people, and either occupy land by the year at the mercy of another, or sign leases with conditions such as those which have been quoted in the *North British Agriculturist*? Mainly, I maintain, because they are educated just as Mr. MORTON wants them to be educated."

In another place he says:—

"The object of Mr. MORTON seems to be that the lad should plough like a ploughman, stack like a stacker, shear sheep like a shepherd, and otherwise assist. He will do nothing of the kind. He will at first enjoy the liberty he has so early acquired; he will think himself a man; and after some years of a lazy life, he may be able to manage the practical work of a farm as well as the best; mainly because while better than if, as a well-educated youth, he had gone for a year in early manhood to study farming at a farm, carrying with him a disciplined mind, and the cultivated brain of a man."

We quote these passages, notwithstanding their personal injustice, because they express, as strongly as we believe we shall wish to express it, the feeling that after all it is an enlarged and liberal, and to the extent which time allows a thorough general education during boyhood and youth which, more than anything else, is needed in order to increase the power and raise the position of any profession whatever—agricultural or other. But though we do this no doubt as strongly as this writer does, that is no reason for putting things to improper uses. An agricultural society is a body in which men associate for a certain definite purpose. There are some good things which thus properly come under their consideration and patronage. But there are other good things, and even other better things, which do not belong to them; and the conviction that there are more important things connected with their proper objects must not hinder them from giving due attention to those purposes for which in particular they have banded themselves together. They will certainly be all the more likely to serve their generation usefully if they keep themselves or even *confine* themselves to the work which properly belongs to them. And thus it is that while they may individually believe the general education of their sons to be by far the most important purpose of their lives, yet, associated as they are in a society for agricultural improvement, they may feel bound to confine their attention there to that professional training by which after this preliminary education their sons are to be fitted for their career as farmers.

—— At Mark Lane, on Monday, English Wheat (a short supply) sold at 1*s.* per qr. advance on the prices of the previous Monday—and this advance was maintained on Wednesday.——At the Metropolitan Cattle Market on Monday, last week's quotations for beasts were largely realized; sheep the tendency was downwards. On Thursday the quotations of Monday for beasts were not reached: the same may be reported for sheep.——The upward tendency still continues in the wool market.

—— The Birmingham Cattle and Poultry Show opens to-day, when the judges are engaged in making their awards. We shall give a full report next week; meanwhile we are informed that the entries in all departments for this, the twenty-third annual exhibition, are highly satisfactory, showing an increase throughout, and necessitating the erection of an additional gallery, upwards of 200 feet in length, to accommodate the various exhibits. In the cattle classes, which contain 152 entries, the Scots and Scotch crosses are particularly strong, and the Devons, too, well maintain their position. The seekers after novelties will be rewarded in the sheep section, as Border Leicesters and Dorset Horned sheep will be represented in the hall for the first time on this occasion. The exhibition of pigs is very extensive, several classes numbering nearly 50 entries in each. The roots and corn are fully up to the mark: and the 200 dishes of Potatos make quite a show in themselves. The poultry department, as usual, is enormous, containing 2660 entries; some individual classes containing more pens than are to be found in the whole of many county and local shows?

—— We had the pleasure, on Saturday last, of inspecting the wonderful collection of Mangel Wurzel, Swedish and other Turnips, Kohl Rabi, Cabbages, Potatos, &c., which has this year been gathered in Messrs. Sutton's warehouses, Reading, to compete for the liberal series of prizes which they annually offer. The exhibitors are exclusively customers of this firm, and the roots exhibited are thus only of sorts and from seed supplied by Messrs. Sutton. The exhibition has not, therefore, the public interest which would belong to a perfectly open show. There is, however, no doubt, considerable public interest attaching to the Annual Exhibitions of Competing Seedsmen. It answers their purpose to adopt this plan of collecting the best specimens in the country, grown from seed which they have respectively supplied; and the Reading firm in particular, having such a widely spread connection, has brought together an extraordinary collection, which, as representing very excellent varieties of all our farm crops, well deserve the study and attention of the crowds of spectators who are thus attracted. The Mammoth Long Red Mangel especially was a very remarkable class. Among 23 entries of 12 roots each, Mr. J. Cave, of Piriesfield Farm, Rickmansworth, took the 1st prize with a collection averaging more than 40 lb. apiece. The same exhibitor took the 2d prize for Long Yellow Mangels, the 1st prize for Yellow Globe Mangels, the 2d prize for Yellow Intermediate Mangels, the 1st prize for Red Globe Mangels, the 1st prize for Green Kohl Rabi, the 1st prize for Purple Kohl Rabi, the 1st prize for Sugar-Beet, the 2d prize for Red Carrots, and the 1st prize for Reading Onions. He may therefore be pronounced to have achieved an unprecedented success. In the several classes we found the Long Red Mangel of astonishing size and excellence—the Long Yellows very good; the Red Globe Mangels not so good. The Swedes, "Sutton's Champion," included 57 entries of 2 roots each, and they were certainly a very remarkable collection. The 1st prize was taken by Mr. Allsop, of Hindlip Court, Worcestershire. The 24 roots in this case weighed 520 lb. The White Globe and other Turnips appeared to us rather whimsically judged—the prizes going to roots of very small size, which would, we suspect, be insufficient to justify a preference of a field of roots, however it might affect our choice of a specimen half-dozen. The Kohl Rabi, both green and purple, were very fine, especially the former. The 1st prize was taken by Mr. Cave, from the Bedford Sewage Farm, from which also some fine Drumhead Cabbages were exhibited. Mr. S. Robinson, of Melbourne, Derby, took the 1st prize for Cabbages. There was a very fine collection of Onions, Carrots, and Potatos; and altogether the display was of very extraordinary merit.

—— The Statistics of the Game Question in Aberdeenshire have been collected by a committee of proprietors and tenant-farmers, and an immense mass of facts has been collected. Of the 196 proprietors in the county to whom inquiries were addressed, 102 have replied. Of the 6664 tenant-farmers who were applied to, 4578 have replied. The total area of the land occupied by these is 1,344,000 acres, and of this 372,085 acres, of the value of £215,814, are represented by the replies. The nature of the answers that have been received is represented by a classification under nine different heads, and to some of these we may direct attention. Thus 4163 tenants, or 90·8 per cent. of those let, on 386 the tenants say they are injured by game, and 2267 of them have estimated their loss at (in all) £19,906 per annum, the individual estimates varying from a few shillings to £125 per annum. In addition to these 1549 tenants who complain make no estimate. Of all who complain only 846 have ever made direct complaint to their landowners, and only 414 have made direct claims, amounting in all to £683. These claims have been disposed of as follows:—One by legal proceedings, ten by compromise, eight were admitted and paid, and sixty-two remain unsettled. The ninth question asked for the number of tenants who say that the absolute and unrestricted right to kill, either by their own hands or by others employed by them, hares and rabbits on the lands they occupy, would enable them sufficiently to protect their interests. The answers show that 3106 would thus be satisfied, while 750 say such right would be insufficient, and 134 declare it to be unnecessary. Probably some explanation of these figures is afforded by the fact that, among the 3816 tenants who suffer from game, there are as many as 291 who are injured by deer, and no fewer than 1892 who suffer by rooks, wood-pigeons, and other vermin. Of 102 proprietors who have answered the questions of the committee, 69 reserve the right to hunt and kill game, and on the estates of 12 the tenants are bound to protect game and inform against poachers. On two estates the game is reserved to proprietor and tenant equally, and on 16 there is no special covenant or condition regarding game; 37 proprietors declare that they preserve game, so say that they do not preserve, 19 admit that they have received complaints, and 80 say that no complaints have reached them.

—— At the recent quarterly meeting of the Moray-shire Farmers' Club, the question—"Whether is it better to Board the Unmarried with the Married Servant, or keep them in the Bothy or Kitchen?" was discussed, and the remarks of the different speakers gave us very full and direct a picture of the Arrangements for Farm Labourers in the North of Scotland that we extract a few of them:—

Mr. Cruickshank, Meft, said he would keep the unmarried servants rather in the kitchen than in the bothy.—Mr. Ruxton, Inchbroom, had generally had four married servants in houses, and had a bothy. He was not sure that it would be desirable to have a cottage for every male servant on the farm; he would merely say that he was obliged to use the bothy. On his farm in the county of Banff he had about an equal number of servants, and he had tried the unmarried men in the bothy and in the farm kitchen. He continued them in the bothy for ten years; and for the last six or seven years he had them in the kitchen. Both the bothy and the kitchen suited very well. He never had the least difficulty, and he really could not say decidedly which was the best.—Mr. Walker, Lossiemouth, said that he had always had about an equal number of married and unmarried servants. The system in Fifeshire was to have a bothy for the unmarried servants, alongside one of the farm houses. The unmarried men got from 12 bolls of meal yearly, and a pint of sweet milk daily. The wife in the house next to the bothy kept boiling water for them twice a day, and the unmarried men made their own supper. The bothy was cleaned out by the wife of the married servant, and everything kept in order. With regard to keeping young men in the farm kitchen, they found in Fife that that would never do. It prohibited the mistress and her family from going into the kitchen. With regard to boarding young men with married men, that was out of the question altogether, there was no room for lodgers. If a bothy were kept, they could have it clean, and tidy, and comfortable; and that was by far the best way that young men could be kept.—Mr. Hay, Trochelhill, said he had no experience whatever of the bothy system. It seemed to him that it was a system that was passing away, and ought to do so. Nearly the whole of his servants had always been in the farm kitchen, except one or two of the principal, who were in houses. What he should like was to increase the home accommodation, to have more married servants, and, if possible to have the young men boarding with them.—Mr. Kay, Forres, thought the most objectionable plan of accommodating unmarried servants was to board them in the houses of the married servants. There were very few instances indeed in which the farm cottages contained more accommodation than was absolutely necessary for the several members of the family. If the family grew up, they required the most of the attention and care the mother could give them, without her having to attend to a boarder, while if the family were grown up, they could receive no benefit whatever from a boarder. The boarding of unmarried servants in the farm kitchen was also very objectionable. The best place for an unmarried servant was a well kept bothy, where the men were kept comfortable, their sleeping apartment kept clean, the furnishings and dishes for their food properly cared for, and everything done for them that could be done. They would never be so happy and well pleased as in that position.—Mr. Grant, Grange, said he was very sorry that the accommodation for married servants on his farm was limited. He would like more houses, and though he did get more of them, he certainly would not approve of young men being boarded with the families of married men. He did not think there was sufficient accommodation in cottages for boarders. His unmarried men were in a bothy, with the exception of one or two in the house. With regard to care in keeping the bothies clean, they would be exceedingly comfortable for the servants. The first desideratum was to get a good bothy. He thought it should go abroad that there are some places in the country used as bothies that are not fit for human beings to be in. There were one or two proprietors he could point to who were now building bothies upon an improved system, giving every facility and accommodation to the men in the shape of cooking apparatus, lavatories, &c., and he thought that should make the servants comfortable. As to living in the farm kitchen, that could not be approved of. It disturbed all their domestic arrangements in a way that is not at all desirable.—Mr. Tod, Ardivot, thought the result of this discussion would be simply to point out the great deficiency of accommodation both for married and unmarried men in the district. He could not disturbed all their domestic arrangements in a way that is not at all agreeable thing to have farm servants in a kitchen. It must be a discomfort; and what was a discomfort to the farmer, must be a discomfort to the servant who had a family, and who wished to have all the privacy that his house could afford. He thought their friends the farmers ought to provide better bothy accommodation for unmarried servants. There seemed to be no endeavour to make young men comfortable, by giving them cooking arrangements, and such other things as

would make their bothies fit places for people to live in. He had been in some of these bothies, and he was sure he had seen better dog-kennels.

OUR LIVE STOCK.

CATTLE.

FEW persons will have forgotten the price given by Mr. Cochrane for two Duchesses in 1870, or the still more extraordinary transaction in which Lord Dunmore purchased the two heifer calves of these animals for the same sum as was given for their dams—2500 gs. These calves arrived, in company with other six cows and heifers, at Liverpool last Tuesday week, on board the Sarmatian. They were all, thanks to the care of Mr. Simon Beattie, in excellent condition, although the passage had been rather rough. The young Duchesses are very promising, and had fair to equal, if not surpass, their dams, as Shorthorns. The Oxford cows are fine animals with highly creditable calves, and the two Red Roses are large, massive cows, full of symmetry, of excellent quality, and accompanied by two capital calves, much alike. The following is a list of the animals :—

Duchess 106th, white, calved November 30, 1870 : sire 8TH DUKE OF YORK, dam *Duchess 103d* by 4TH DUKE OF THORNDALE (17,750).

Duchess 107th, roan, calved December 16, 1870 : sire 8TH DUKE OF YORK, dam *Duchess 101st* by 4TH DUKE OF THORNDALE (17,750).

11th Lady of Oxford, roan, calved May 1, 1868 ; sire BARON OF OXFORD (23,371), dam *7th Lady of Oxford* by 6TH DUKE OF THORNDALE (23,754).

Oxford Duchess, red and white, calved July 2, 1871 ; sire 6TH DUKE OF GENEVA, dam *11th Lady of Oxford* by BARON OF OXFORD (23,371).

8th Maid of Oxford, roan, calved October 18, 1867 ; sire 2D DUKE OF GENEVA (23,752), dam *2d Maid of Oxford* by GRAND DUKE OF OXFORD (16,184).

Marchioness of Oxford, roan, calved January 21, 1871 : sire 4TH DUKE OF GENEVA, dam *8th Maid of Oxford* by 2D DUKE OF GENEVA (23,752).

Red Rose (late *Easterday 2d*), red and little white, calved April 12, 1867 : sire AIRDRIE, dam *Easterday* by PILOT.

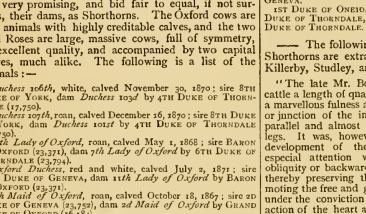
Red Rose 3d (late *Crocus 2d*), red, calved October 13, 1866 : sire DUKE FREDERICK, dam *Grace* by AIRDRIE.

Red Rose 3d, red and little white, calved FEBRUARY 15, 1871 : sire JOE JOHNSON, dam *Red Rose* by AIRDRIE.

Red Rose 4th, red and little white, calved July 3, 1871 : sire 4TH DUKE OF THORNDALE, dam *Red Rose 2d* by DUKE FREDERICK.

It should be stated that the *11th Lady of Oxford* and her heifer calf were imported with Colonel Kingscote's DUKE OF HILLHURST last April.

The pedigree of the two imported Duchesses, for which such "fabulous" prices have been given, is a matter of some interest, as showing the sires held in highest estimation by persons who value unsullied lineage. The following diagram illustrates their breeding :—



8TH DUKE OF YORK was sold at Mr. Bell's recent sale for 1065 gs., the highest price ever paid for a Shorthorn at a public sale. He is by 4TH DUKE OF THORNDALE, and from *Duchess 86th* by GRAND DUKE OF WETHERBY (17,997), out of *Duchess 67th* by USURER. 4TH DUKE OF THORNDALE, bred by Mr. Samuel Thorne, of Thorndale, New York, was by DUKE OF GLO'STER (11,382), great-grand-sire of 8TH DUKE OF YORK, and from *Duchess 64th* by 4TH DUKE OF YORK. 4TH DUKE OF OXFORD, bred by the late Earl Ducie, was by GRAND DUKE (10,284), and out of *Oxford 6th* by 2D DUKE OF NORTHUMBERLAND. GRAND DUKE was a son of 2D CLEVELAND LAD and *Duchess 55th*. ARCHDUKE was by DUKE OF CAMBRIDGE (12,742), a Duchess bull, and out of *Duchess 69th* by 4TH DUKE OF YORK (10,167), g.d. *Duchess 59th*, who appears in the pedigree of the two Duchesses just imported as 6th and 7th dam. USURER, bred by Mr. Hall, was by LORD WARDEN (7167), from Earl Spencer's *Gold* by ORONTES (4623). It is needless to pursue the pedigrees further. Were we to do so we should find the same system of breeding from near affinities carried out in the days of BELVEDERE and COMET. The above notes show sufficiently clear how systematically the best Duchesses have been in-bred, and their continued popularity is a strong argument in favour of the system.

—— We are glad to notice signs of revival in the live stock trade between France and England. Mons. Ste. Marie, of Paris, has purchased a Wild Eyes bull calf by 8TH DUKE OF GENEVA, out of *Lady Worcester 2d*, from Mr. Harward, of Winterfold : a roan Oxford bull calf, by 8TH DUKE OF GENEVA, out of *5th Maid of Oxford* ; ROYAL DUKE, a Booth yearling, from Mr. Aylmer, of West Dereham, and 3D DUKE OF WELLINGTON, a Waterloo bull, bred by Lord Penrhyn, from Mr. T. Morris, of Maisemore Court, Gloucester.

—— Mr. Cheney, of Gaddesby, has imported some Shorthorns from Messrs. Walcott & Campbell's herd, New York Mills, U.S. The animals came across in the New York, and were landed at Southampton, not, however, without a serious loss in the death of *9th Maid of Oxford*, who "dropped" on the voyage ; and, although landed safely, died a few days afterwards in the quarantine shed at Southampton. The following is a list of the animals imported :—

10th Lady of Oxford, red, calved March 23, 1867, by 10TH DUKE OF THORNDALE, dam *7th Lady of Oxford* by 6TH DUKE OF THORNDALE (23,754).

13th Lady of Oxford, roan, calved January 21, 1871, by BARON OF OXFORD, dam *7th Lady of Oxford* by 6TH DUKE OF THORNDALE.

9th Maid of Oxford, red and white, calved December 6, 1869, by 10TH DUKE OF THORNDALE, dam *3d Maid of Oxford* by GRAND DUKE OF OXFORD.

5TH LORD OXFORD, red, calved January 3, 1870, by 4TH DUKE OF GENEVA, dam *2d Countess of Oxford* by 2D DUKE OF GENEVA.

1ST DUKE OF ONEIDA, red, calved January 2, 1870, by 10TH DUKE OF THORNDALE, dam *12th Duchess of Thorndale* by 6TH DUKE OF THORNDALE.

—— The following particulars respecting the Booth Shorthorns are extracted from Carr's "History of the Killerby, Studley, and Warlaby Herds" (p. 118) :—

"The late Mr. Booth succeeded in imparting to his cattle a length of quarter such as no other herd can boast, a marvellous fulness and depth of thigh, and of the twist, or junction of the inside of the thighs, and a perfectly parallel and almost perpendicular position of the hind-legs. It was, however, to the ample and symmetrical development of the fore-quarters that Mr. Booth's especial attention was directed. He increased the obliquity or backward inclination of the shoulder blades, thereby preserving the level line of the back, and promoting the free and graceful carriage of the animal ; and whether correctly or not, that ample room for the vigorous action of the heart and lungs was an essential condition to the formation of good blood, and therefore of good beef, it was his aim to improve the form and enlarge the capacity of the chest. With this view he endeavoured to augment the prominence or circularity of the fore-rib, and the width of the sternum or floor of the chest, between and behind the fore-legs. It is to the success of Mr. Booth's efforts in this ample room for the vital action of surface which this improved formation of the chest affords for the accretion of flesh, that we are indebted for those valuable and almost peculiar characteristics of the Warlaby tribe, the extraordinary breadth of the chine even with the arm, the roundness of the barrel-shaped crops, and the width and massiveness of the projecting bosom. To this conformation also may probably be due the very remarkable immunity from pleuro-pneumonia and other chest affections which the Warlaby and its kindred herds have hitherto enjoyed. It may here be remarked that this development of the fore-quarters was mainly effected by the use of the male descendants of *Isabella* by PILOT. The necks of the Booth Shorthorns are worthy of note. Whilst displaying at their junction with the head much of that fineness and cleanness which characterise the dairy cow, they are remarkable for the bulky, yet symmetrical, development into which they gradually swell as they approach and blend with the shoulders and breast, completely hiding, even in the unfored animal, the shoulder points."

SHEEP.

M. DUTERTRE, of the Agricultural College, Grignon, has been purchasing sheep from some of our best breeders. He has secured 16 Shropshire ewes and one ram from Mr. Sandell, of Sudbury, Evesham, and ewes of the same breed from Mr. R. H. Masfen, of Pendeford ; 10 Leicester ewes and one ram from Mr. W. Torr, of Aylesby, and some Norfolk long-woolled sheep (Cotswold) from Mr. Hugh Aylmer, of West Dereham.

TOWN SEWAGE.

IRRIGATION *versus* "A B C."

IN view of the approaching experiment at Crossness with 500,000 gallons of London sewage, on the Native Guano Company's precipitation process, it would have been highly satisfactory could a similar one, on the principle of the disposal of sewage by irrigation, have been brought about ; but as that, either with irrigation or the other sewage schemes at present before the public, is unlikely to occur, as regards irrigation *v.* precipitation per the "A B C" process, I shall esteem it a favour to be allowed to make comparison of them, as to which is most applicable as "the model works for a town."

In setting up for both schemes, after fixing on the site is the purchase of it, and which, as regards precipitation, requires an extent of ground, in addition to the space for the engines and tanks, of half an acre for every 100,000 galls. of sewage treated, and which is not likely to be had at other than building land price. With all dry patent sewage-manure manufacturers, as well as for irrigation, the first business is to have their raw material laid on at or near the surface. Unless favoured by gravitation, the power to do so must be in duplicate ; otherwise the expense of receiving-tanks or reservoirs, for two days' supply at least, must be bargained for. The "A B C" Company provide only one engine for the experiment, a fact which, as well as their additional standing-ground, must be borne in mind in applying their costs.

For the medium of transmission a length of pipe is common to both, more especially for the precipitation process, to get it well away from the town to be less objectionable as a nuisance, and for land of less value as standing ground ; and the carriage of sewage, as an element of irrigation, in a through water-main, can well be put against the carriage attaching to the "A B C" stuff to its destination.

The one process is to be worked night and day, and so may the other ; but night sewage, which is small in volume, and almost clear water, is not worth the expense of dealing with it by night work.

So far the motive power for both, which, had it been by gravitation, irrigation would have had the whole of the "£7000," the stated cost of the Crossness experiment appliances, to act on ; as it is, there is only the price of a "15-horse power engine," as being common to both, to deduct, leaving, say, £6300 for the permanent work of the land for irrigation.

The subject for comparison is that of land in a farm, or farms, in the ordinary course of husbandry in the country, to which improved agriculture has proved that not only does it pay to drain the soil, but also that if a modicum of such drained water was brought over the land again as matter of irrigation, or if such an element as sewage were transmitted and laid on for that purpose, so much more would it be for the best cultural results.

£7000, the sum (less the price of a "15-horse power engine") for plant which the "A B C" Company expend to the point of the production of a dry manure, would be sufficient to provide for the permanent way—or the mains, chambers, sub-mains, and connections between fields, at £3 an acre ; and £3 an acre for extra underground drains for the additional rainfall (call it) in sewage, in the main distribution of sewage over 1000 acres. The cost of conducting water on the surface must be less than for underground drainage, and the main underground drainage of individual fields, to a depth of 4 to 5 feet, is accomplished for less than £3 an acre.

Again, the figures (which are considerably under-estimated) for labour all through the process of precipitation, are certainly in excess of those for the use of the smallest feeders, in the application of sewage, either on the ridge-and-furrow or the so-called catch-water system, to 1000 acres land, in the formation of elevated rows, such as for Potatos or Turnips, sufficient for the flow of water along, as well as for the passage of sewage in bulk. In a wet season the latter methods might arise whether to charge the furrowing up of the surface in the interest of dryness to the crop, or to the preparation for an element of irrigation to it.

As to the creditor side of the comparison, or as to yield, dry seasons are as favourable for dry sewage manure manufacturers as they are for sewage, or ordinary water, irrigated farms ; and dry sewage manure merchants during the dry season (or four or five months) of the year, may be said to be able to realise maximum results, according to their mode of production, while during the wet season, or the other seven months of the year, that they are not. Taking the maximum yield of the "A B C" process from the 500,000 galls. in the best season to be 3 tons a day of dry bagable manure, including precipitate, such would amount to a large quantity in the total for the five favourable months—450 tons in all—from May to October ; with, however, a steam-power to aid in the drying of that of the short day of winter, when the sewage is in double or triple volume of water, that it is one ton a day, or for the remaining seven months of the year 210 tons (a most excessive estimate as compared with the yield from the same quantity of sewage of much the same volume, and of as good, if not of better quality).

In the estimate of cost of appliances and labour for this Crossness experiment, given in the *Standard* of September 2 last, no mention is made of steam-drying, only that some wonderful transformation is to be performed on the precipitated mess, on being passed through a hot-air chamber : but as this has been tried at Leamington and found wanting, with complaints against it as a nuisance, it may be put aside with no alternative but erections with perforated iron floors, arranged for receiving the precipitate in a thin coat, of the vapour, however foul and noxious, from the drying mess to the air.

The steam-drying surface accommodation at Leamington was about 3500 square feet, but at the intrinsic value of the manure (although anything now that only gives an income will sell) the use of steam-drying is out of the question. It should be mentioned, that previous to steam-drying on perforated floors, the sludge requires to be of the consistency of nearly solid mud, and that, weather permitting, no better plan can be adopted to get it to that state than by exposure to the air in thin scatterings, and that, along with the maximum nuisance, the best result is obtained from steam-drying in hot midsummer weather. Farms of the ordinary description throughout the country provided with an element of irrigation, either as a fertiliser auxiliary, or moisture, with portions of them under such crops as Italian Rye-grass, roots, cereals for straw as fodder and litter, and having accommodation and stock to consume them, either for milk, meat, labour, or keep, it must be the farmers' own fault if they have not maximum results under the most exhaustive rotation of cropping. Grass for summer and roots for winter food—no two better crops for sewage—and, with a supply of it to cereals till they are able to cover the ground, and do for themselves ; an estimate of the yield from all such much under £35 an acre would not be the truth. Say £30 an acre.

Barking sewage farm, under Mr. Morton's management, averaged £44 15s. per acre; in 1870 it grossed £42 an acre; and Mr. Hope's farm, for the first nine months of its existence, and when not in full bearing, realised nearly £30 an acre. Allowing that the tenant gets £3 an acre out of the £30 for profit, and the balance charged over, preparation (permanent and temporary) of land, £7; labour, £5; seed and repairs, £2; rent and taxes, £4; there remain about £9 to £10 an acre to pay for sewage, equal to 10s. per head of the population per annum, or the sewage of 15 to 20 persons to an acre, or 200,000 gallons per acre.

The farmers of East Lothian, Scotland, expend £20 an acre on auxiliary manures alone, besides paying over £3 an acre for their land.

Thus the comparison to the point of precipitation and a dry manure is as under:—

"A B C" process.	Summer make	.. ..	450 tons
	Winter make	.. ..	210 ,,
			660

—at £3 10s. (not at 17s. 6d., the intrinsic value), and without deducting the cost of manufacture, which at Leamington was "£150 a month."

Against	.. ..	£2310
1000 acres, at £9	.. ..	9000
Deficiency by "A B C" process	..	£6690

If the Native Guano Company are to set up as purifiers of water as well as manure merchants, sufficient mention is not made of the process of filtration, and of the expensive grinding it, which are long and frequent. The filtering space at Leamington, for a fair-weather sewage of 550,000 galls., and a foul-weather flow of nearly three times that quantity, extended to nearly 2000 square yards, of which there were directly concerned with the clarifying nearly 480 square yards of subsidence canal, and close on 600 square yards of filtering surface. The filtering arrangement was composed of a winding canal fitted with wooden bearers, covered with wire netting, with layers of charcoal, gravel, sand, and charcoal again, and canvas cloths between each and over all. This filter on being cleansed, as might be for a particular visitation, for two days at most after the water which passed through it was apparently improved, but in less than a week, if the cleansing was not attended to, to remove the deposit, over the whole surface the sickly matter would bubble to the surface, bloating and floating about on it in unsightly masses. To have taken the full benefit of the filter, the whole 2000 square yards should have been in duplicate, and cleansed and aërated not less than every three days—otherwise, the effluent after precipitation might at best have been charged directly into the river. The cleansings from the top of the filter make the best testimonial manure, being richest in ammonia, and freest of sand; and the Metropolitan Board of Works should see to this notwithstanding the high manurial value ascribed to the general mess by the Company, but contradicted by chemistry, and not allow the cleansings from filtration after precipitation to be used as a fair sample of their guano on the 7 acres of proposed experimental ground; and attend also to several other facts for a fair trial of the concern for what it is worth.

It would be a poor concern indeed not to be able to cleanse a part of the sewage of London to a purity to suit an ebbing and flowing river, such as the Thames as far down as Crossness; but for sewage being so clarified by precipitation alone as to be continually admissible into a stream running always one way, is simply futile.

Whether filtration be tacked on to the process or not, it will be much the same thing, to set aside a sum for the periodical cleansing of the river, opposite and for some distance below the works, which being an outlay in the one case, in a strict matter of accounting should be reckoned with in the other.

But how is it to be credited to irrigation? Our country, like some of those more mountainous, does not abound in natural irrigating grounds to lay up winter's water supply for summer use; but the rain falls, and then by the means of much draining, both surface and underground, it is hastened on in rapid course to the river, and lost to us in the sea. Such rapid discharge of water may suit well the land, but not so the fish and crops in summer. Commissions of inquiry are appointed on behalf of the fish-producing interest to discover prohibitions and cures for the fouling of streams; and it must rejoice the heart of every true sportsman to see, not only the value of a pound of fish, but also that during the dry seasons it is in store for them to "get up,"—a most material provision besides the sweetening of the stream. The natural convergence, or the river, by the storage of water in winter for summer use over the land, whether by subterranean or surface channels, is sure to get its share.

The sum for the purchase of land, construction, maintenance, and cleansing of a filter (in duplicate at least) for the flow of half a million gallons of sewage previously treated by the "A B C" process, would materially assist in a storage system for 1000 acres. It would be a matter, if it were sufficient to provide gathering ground or reservoir accommodation, conveniently placed, to command the root and grass crop divisions of such an extent, at the rate of 30s. to 40s. per acre, including appliances, either for the gravitation of the water on to fields below, or for connections to transmit it to fields above, the power to do so being the portable steam engine, which all true agriculturists must long to see attached to homesteads, either singly or in combination, to perform the works of the farm, pumping its water of irrigation amongst the rest of them. Thus far to compare precipitation with irrigation, or with the experimenting on a set quantity of sewage, either at Crossness, Bolton, Leeds, or anywhere else, to afford data for the treatment of the whole sewage of a town, is any other than mere trifling. If the works at Crossness are on the scale for a quantity representing the maximum or storm-water flow of a town, and not a portion of it only, let it be understood 500,000 galls. of storm sewage represent 150,000 to 200,000 galls. of fair-weather flow, and a sewer-contributing population of 5000 to 7000 souls. But £7000 of outfit and £1500 to £2000 working expenses, look like £1 a head to begin with, and 5s. a head to carry on. The whole filter farm concern for the town of Warwick, with 11,000 inhabitants, cost £1 a head, with a current expense of 5d. a head, or about ½d. per 1000 galls.

In flat-lying towns, or in towns indifferently sewered, it is oftener in storm that their sewage accumulations are cleared—the solid matters brought down then are more in quantity than in the ordinary weather flow (see the analyses in the Royal Rivers Pollution Commissioners' report, March, 1870, of London sewage for suspended matters immediately after a storm), and more concentrated and frequent in winter when there is less drying power, and notwithstanding the shortcomings of any works the sewage must then be committed to the river, pure and simple.

The "A B C" process may do as an adjunct to irrigation, and on construction to allow the sewage to be passed on to the land in the degrees of purity—1st, as a fertiliser in place of the usual fold or other solid manure; 2d, as an auxiliary in place of the usual top-dressings of guano and the like; and 3d, as a moistener in place of rain.

With their process so adapted to irrigation, and under such a company of directors, the field is their own, and opposition from all quarters ceases. Failing their doing so, farmers in proximity to a through main will be found entering into combination for the interception of much of the solids of sewage, at certain times, at fixed depots, to suit it to their crops through all their stages. *J. M., Drainage and Sewage Engineer.*

THE SHEEP OF NEW SOUTH WALES.

(Concluded from p. 1490.)

Number of Sheep in the Colony.—New South Wales is at present only a fragment of the former self—the three prosperous colonies of Victoria, South Australia, and Queensland, having been carved out of its once ample domain. The last of these subductions was in 1861, when its northern territory was constituted into the separate colony of Queensland. Taking that year as a starting point, the official returns give the following as the number of sheep in the several years, though there is good reason for believing that during the earlier years the number was underrated:—

1861 ..	 6,170,163	1866 ..	 11,644,593
1862 ..	 6,502,852	1867 ..	 15,026,377
1863 ..	 7,169,926	1868 ..	 16,000,000
1864 ..	 9,082,463	1869 ..	 16,842,817
1865 ..	 9,653,302	1870 ..	 17,218,812

An observable increase is specially noticeable in the years 1866 and 1867. During these two years the seasons were good, and the cotton famine helped to make the price of wool high. Fencing was carried on to a great extent, especially on the large runs on Riverina, and the sheep being turned out unshepherded on these enclosed runs, the country was able to carry more to the acre. Many squatters from Victoria, crowded out by the growth of population and the extension of agriculture, migrated with their flocks into the south-western part of this colony; and the influx of gold to Victoria led them to make way for sheep. In the two following years the seasons were unfavourable. During the last year the numbers show an actual decrease of 629,392, and this is to be explained partly by the losses sustained during the severe drought which took place between the latter part of 1868 and the beginning of 1869, and partly by the very large consumption of sheep by the meat-preserving companies. The low price of wool having greatly diminished the profits of sheep-farming, the culling of flocks has proceeded much more vigorously than ever before, with no disposition to keep up large numbers, to take up new runs, or to overstock old runs. The tendency is all the other way, and the inferior stock has been sent remorselessly to the pots. The question is a wholesome one, and though the diminished number of sheep appears at first sight to indicate a retrograde movement, it is not so in reality. The inspectors of sheep estimated that the losses from drought were a million, but this must be an underestimate, considering that we have to account for the annual increase on a total of 15,000,000 sheep.

Stud Sheep.—Sheep from the best German, French, and American flocks have from time to time been introduced into the colony, and interbred with the Australian Merino, and some remarkably fine sheep have been thereby produced; but the conviction is now growing that Australia has little or nothing to gain by encouraging further importations of this kind, for not only is there natural deterioration due to the climate, which requires to be made good by the perpetual infusion of fresh blood, but, on the contrary, there is an improvement. Nothing that is important surpasses or even equals in its specialities the best specimens of the Australian Merino. By this last term is understood the produce of the imported Merino, carefully bred in the most favourable districts of Australia, and guarded from any injurious intermixture with imported blood. The full and special effect of the climate has been thereby obtained at its maximum, so far as the time that has elapsed has allowed. To intermix this special Australian strain with importations is only to undo the good effect of the Australian climate, *i. e.*, better result is to be obtained by careful culling and by close adherence to the best Australian breed. Under this conviction the importations from Europe have of late considerably fallen off. New South Wales, however, has drawn very largely on the stud flocks of Victoria, and would have done so still more but for the unfortunate prevalence of scab in that colony. The quarantine regulations prohibit sheep from crossing the Murray to the northwards; so that, instead of a short journey from Victoria to the runs of this colony, they have to be sent down to Melbourne, round by sea to Sydney, to perform quarantine and undergo ablutions in our coast districts, and then make a land journey up the country.

Previous to 1864 no record was kept of the importations of stud sheep. Since that time about 3500 have been introduced from Victoria, about one-half of which were ewes, and 500 from Tasmania, New Zealand, America, England, France, and Germany. Now that the importance of developing the Australian Merino is distinctly recognised, the formation of stud flocks is becoming more a matter of concern, and for those who have the requisite qualifications the employment is likely to be one of considerable profit, as for many years there must be a large demand for stud sheep before Australian flocks generally are brought up to their proper standard, and full justice is done to the virtues of the Merino.

The finest stud sheep in this colony are to be obtained at Mudgee—a district where Art and Nature have combined to produce a favourable result, and where the Messrs. Cox and Mr. N. P. Bayley have especially distinguished themselves. The climate is temperate, the soil moderately fertile, the grasses nutritious without being too rich, and some of the settlers there have had the good sense and the good fortune to pay unremitting attention to quality, and to follow out perseveringly sound rules of breeding. Over how large a period of time the celebrated flocks called "Mudgee results" are obtainable is at present undetermined, but there seems good reason to believe that equal skill and attention might produce equal results in the greater part of the rich west of that favoured land. Breeders favourably situated are now being stirred up to emulate the fame of Mudgee, and from this generous competition the best results may be anticipated.

Repeated attempts have been made of late years to try and combine the two requisites of large carcase and fine wool in the same animal, and for this purpose Merino ewes have been crossed with Leicester and Southdown rams; but the result has been uniformly a failure. The stock of the second generation has been comparatively worthless, and the first cross has simply been to spoil the Merino breed without any adequately compensating advantages. The practice is now nearly abandoned, and breeding for wool and breeding for carcase are regarded as separate undertakings. If in this colony the demand for the meat-preserving establishments should make it pay to produce large-framed sheep, then it would be better exclusively to cultivate the large breeds in those parts of the colony where the climate and pasture are suitable for them. But at present it seems very doubtful whether (except perhaps for the supply of lambs) there will be any need to bestow special attention on large sheep, as the Merinos will probably make up in number what they lack in size. There is still a very large proportion of the colony unstocked or only half-stocked, and the annual increase from the full number of sheep which the colony can maintain will yield an immense annual cast for slaughter.

Improvement in Flocks.—Nothing has done so much to stimulate improvement as the apparently disastrous fall in the price of wool. With a high and rising market, wool-growers were greedy of quantity. The effect of the glut has been to show that coarse and inferior wool can be produced in quantity in other parts of the world, and at least as cheaply as in Australia; and that low-class wool is the first to feel the falling price, and feels it the heaviest. A very general effort, therefore, is now being made at the production of superior wool, and though no amount of energy can undo in one season the errors of faulty breeding, or the neglect of a series of years, still such earnest attention is now being given to the careful selection of stud rams, to the classification of ewes, and to the culling of flocks, that every year may be expected to show perceptible improvement.

The fencing of runs is also indirectly tending to the improvement of the stock; and abundant experience has shown that when sheep are turned loose to graze in paddocks of moderate size, they not only get fatter, but throw finer fleeces than when they are driven by

shepherds and constantly rounded up by dogs. Now that the country is pretty well freed from the native dog, it is no longer necessary to shepherd the flocks by day or yard them at night.

Getting up the Clip.—During the prevalence of the gold mania, when rural labour was scarce and dear, and when very few stations had been much improved, most of the wool was shorn in the grease; but repeated intimations from the London brokers that the get-up of the wool was all-important as regarded price gradually led the more enterprising settlers to fit up apparatus for washing the wool on the sheep's back; and the use of hot water has also become pretty general. During the past few years very considerable sums have been expended in tanks, spouts, pumps, and other machinery and appliances. In some instances the hot-water process has been carried to an extreme,—and money has been spent which has not only not been returned but which has even injured the sale of the wool. Dry seasons have sometimes left stations short of water, and so neutralised all mechanical appliances; and on some thinly grassed and dusty runs it has been found difficult to keep the wool clean, though the washing process may have been satisfactory. Experience will show what are the profitable limits to the attempt to clean the wool on the sheep; but the satisfactory point is, that wool-growers generally are keenly alive to the importance of the question, and that as a rule there is now no want of enterprise to carry out what may seem to be the wisest policy.

Combing or Clothing.—There has been much discussion as to whether the wool-growers of this colony should aim at a combing or a clothing wool, and the former has undoubtedly been the ideal towards which the squatters have striven. But the conviction seems now growing, that it is impossible for this colony to compete successfully with Victoria and Tasmania for the production of a superior combing wool. At the same time, although unable to take the highest prize, New South Wales has a fair proportion of territory within which a good combing wool is producible; but there is always a large proportion of country, and especially that known as the salt-bush plains, within which it is certainly difficult to produce this description. In fighting against Nature; and the opinion, though by no means received, is gaining ground that it would be more profitable to strive after a good clothing than to achieve only an inferior combing wool; on this point further investigations are needed. The climate of each district requires to be separately studied in order to determine what description of wool is best adapted to it, and hitherto sufficient attention has not been given to this matter. Squatters have been too content to get good rams and to grow wool, and on no very definite plan, and the consequence has been a good deal of produce of a rather mongrel type, and not exactly either one thing or the other. Increasing attention, however, is now being bestowed to these points, and we are progressing towards a state in which our producers will seek to co-operate more intelligently with the forces of Nature, and in time this process will be of a more definite character and of superior quality.

Coarse-woolled Sheep.—Of these there are not very many in the colony, and they are principally confined to the coast districts, where they are kept for breeding lambs for the Sydney market. They consist chiefly of Leicesters and Southdowns, with a few Cotswolds and Cheviots; the latter, however, being principally in the New England district. The Leicester appears to be the favourite breed for fattening lambs, the ewes being excellent mothers; but a good many lambs are bred from Southdowns. For lamb-breeding purposes the coarse-woolled sheep would pay better than the Merinos in the coast districts, more especially if they are allowed to run at large in paddocks, as they do not thrive if knocked about by shepherds and by dogs. A flock of full-grown, pure-bred Leicesters will shear from 5 to 7 lb. of washed wool per head, which will sell at from 10*d.* to 1*s.* a lb., and lambs from three to four months old will cut from 3 to 4 lb. of washed wool. The wethers of this breed, when three years old, have been found to kill at from 160 lb. to 200 lb. each. The principal breeders of Leicesters are Messrs. Reynolds, Doyle, Christian, and Green, in the northern districts; and Messrs. Massey and Gibson in the southern. Of Southdowns the principal owners are His Excellency the Governor, and Messrs. Dangar, Loder, and Dight, in the northern districts. It is estimated that there are not more than 60,000 coarse-woolled sheep in the colony, the number being made up as follows:—

Pure Leicesters and Cotswolds	..	..	..	5,000
Well-bred do.	do.	..	..	10,000
Middling and inferior do.	..	..	..	25,000
Pure Southdowns	..	..	..	9,500
Well-bred do.	..	..	..	5,000
Middling and inferior do.	..	..	..	12,500
Total	..	..	..	60,000

The supply of fat lambs in Sydney is not superabundant, and there is plenty of room for better provision. For manuring land easily and cheaply by keeping sheep to eat off green crops, the coarse-woolled stock is better adapted than the Merino, and among the small farmers in the coast districts there will probably be a small but steady increase in the number of large-bodied sheep.

Value of Annual Produce from Sheep.—According to the Customs' returns in the "Statistical Register" the value of our wool export in 1869 was £3,164,442. But these figures are not to be depended on for minute accuracy. No completely separate account is kept of the relative amount of washed and greasy wool exported, although the returns of the border traffic show that about one-half of the wool from Riverina that crossed the Murray for shipment at Melbourne was greasy. The weights of the wool, as stated in the Customs' entries, are often loosely calculated, nor is there any check upon the valuations. Three different custom-houses, too, were concerned in the export of our wool, as a portion goes down the Murray to South Australia, and nearly two-fifths finds its way through Victoria, for shipment at Melbourne. A small portion, too, from the runs on the northern frontier passes through Queensland to Brisbane. On the other hand, a very large quantity of Queensland wool is brought down coastwise for shipment at Sydney.

The above calculation, however, may be roughly checked by another process. According to the sworn returns of owners, the number of sheep in 1869 was about 16,000,000. The weight of the fleece all round may be considered as averaging about 2½ lb. per sheep, and the average price of the wool in Sydney may be taken at 9*d.* per lb. The gross weight of the year's clip would, on this calculation, be about 40,000,000 lb.

THE GARDEN OF THE FARM.—IX.

THE FURNISHING OF THE GARDEN.—VEGETABLES.

I PURPOSE enumerating the best varieties of these, and offering a few observations upon the culture of a few that are seldom well cultivated in farm gardens. What are called permanent vegetables should be grown by themselves as near to the farmyard side or end of the garden as may be. There they will be near to the manure, as most of them are large or coarse, or need powerful stimulants to bring them to perfection or keep them there; this arrangement will facilitate their cleanly and handy cultivation. First among these perennials are Asparagus, Seakale, Rhubarb, however, is frequently exceedingly well done in farm gardens. The Giant is generally asked for, but it is doubtful if there is more than one variety. Liberal culture converts it all into giants, fat, sweet, and juicy; starve it and the best degenerates into small, tough, flavourless stuff.

Asparagus is commonly grown on beds, from 3 to 5 feet wide, and 2 feet alleys or vacant spaces between. On yard beds two rows are planted, 1 foot from the side; on 5 feet beds, three rows. The plants are generally planted 1 foot apart, or even 15 inches, on 2 feet, apart. Some prefer growing them in rows 3 feet asunder, with the plants 2 feet from each other. The point of most moment is that the soil should be rich, light, and deep. A tilth a yard deep, liberally enriched with some of the best and sweetest muck from the farmyard, is what Asparagus luxuriates in. During summer keep the surface clean, and give two or three sprinklings of salt, just enough to whiten the ground in showery weather. Should dry weather set in, soak the fast-growing plants with sewage or liquid manure. Every autumn remove the surface soil 3 or 4 inches deep, and replace with a dressing of good manure. Cut no grass till the third year after planting, and then cut all, big or little, till the end of May, and none after, and the beds will continue in first-rate condition for many years.

Artichoke.—Myatt's Victoria for the general crop, and Royal Albert for early cuttings. The former is very large, and of excellent quality. The roots should not be planted nearer than a yard apart, and the richer and deeper the soil the better it will grow. By covering the early sort with a pot or two, and surrounding it with leaves, it may be had in yard in February. Rhubarb may be cut all through the spring months. Another mode of getting an early supply is to take up a few roots and place them in a warm stable, cow-house, or cellar.

Celery.—This is one of the most useful of winter and spring vegetables. Its young stalks must be blanched before it is eatable. In that state it is brittle as the best Celery, and sweet as the choicest vegetable. It is easily raised from seed, or roots can be bought cheaply. A convenient mode of growing it is in double rows a foot apart, 4 or 5 inches between the plants, and 30 inches or 3 feet between these double rows; then cover the ground with boxes or pots at regular intervals from October to March, and place some warm dung round the same. In about a month the Seakale can be gathered. Or another way is to take up the roots and grow them in any warm place in the dark. Light is fatal to the tenderness of the Kale. After March, the last cuttings are gathered outside by simply excluding the light by a covering of pots or 6 inches of litter or earth. During the summer keep clean and give a light sprinkling or two of salt. A mat of manure to develope a full crop of large crowns for the next year. The flower-stems of Seakale as well as Rhubarb should be cut out as soon as they show themselves. I have been thus precise about Seakale, because it is so seldom seen in farm gardens. It is, nevertheless, one of the very best and most wholesome of vegetables, and its value is further enhanced by its coming in at a time when green sauces are scarce.

Globe Artichokes are another useful vegetable, almost wholly neglected by all but the aristocracy. They resemble downy Thistles in leaf and flower, and the part eaten in England is the half-grown flower pod. On the Continent they blanch the young stems as we do Celery, and delight in the stewed Chards. The base of the shell-like petals of the flower and its sweet bottom are stewed and eaten with white sauce or melted butter. A dozen plants will suffice, 3 feet apart, and protect their crowns with a 6-inch covering of litter in winter. Horse-radish should be grown against these rougher vegetables. If you want to match your joints of roast beef with Radish like your walking-sticks, give a rich soil, and plant the crowns 1 foot or more asunder.

The *Jerusalem Artichoke* is another vegetable seldom grown, but worthy of a few yards of soil in the vicinity of these rough crops. It is a tuber something like a very irregular Potato full of eyes, and the top runs up like a huge stalk of a Sunflower to a height of 6 to 10 feet on rich land. The tubers should be set closely round the stems, and are eaten boiled like Potatos, and converted into soup which is highly prized. They should be planted early in the spring, and may be taken up in November, or left in the ground till wanted. If the rows are apart set 3 feet, and 2 feet asunder in the rows, is close enough. The tops in a semi-ripe state have been recommended for stock.

Before dismissing permanent crops, it will be well to enumerate the different herbs that ought to find a place in the garden of the farm. Few things are more useful, but few are more generally neglected, than pot, savoury, bitter or sweet herbs. Even Rue, so highly prized for poultry, is often not to be found in a whole village or parish. The only sure way to preserve a good stock of herbs is to be always renewing them. This is accomplished by layering, root divisions, cuttings, and seeds. Each herb should have a patch of earth or a bed, or part of a row, wholly to itself, and be correctly named. If intermixed, the stronger will soon overrun and destroy the weaker,—the battle for life among herbs being assuredly with the strongest. The following plants of several, if not perennial, are apt to perish in the winter. Young plants of most sorts bear the cold best. The following should find a place in the garden of the farm if the kitchen department is to attain a perfect savour:—Mint, Peppermint, Golden Thyme, Lemon Thyme, Broad, Lavender, Fennel, Parsley, Winter Savory, Winter Marjoram, Pennyroyal, Rosemary, Tarragon, Sage, Balm, Pot Marigold, Sweet Basil, Summer Savory, Bush Marjoram, Borage (the latter five to be sown every year, being annuals). Amongst bitter or medical herbs,—Chamomile, Horehound, Tansy, Rue, Wormwood, should be grown; these, with plenty of Parsley, in the hands of a wise farmer's wife, will not only ensure the best flavoured food, but mitigate or cure most of the ills that the flesh of villagers is heir to. What wit is to conversation, herbs are to successful cooking; they stimulate jaded appetites into average briskness and avidity with their racy odours and piquant flavouring. They should be grown near to the kitchen, to tempt a liberal use of them.

Potatos.—For the earliest crop no sorts are better than the best varieties of Ashtop, which are Veitch's Improved Early and Rivers' Royal. Mona's Pride is a better bearer, but not so early. Berkshire Kidney, Fluke, and Milky White, are splendid later kidneys. Rounds: Daintree's Seedling, and Early Coldstream, for the earliest; Dalnahoy, Floertail, Reid's Improved do., Perthshire, Regent, and Paterson's Victoria, for later and general crops.

Peas.—To maintain a succession from May to November, sow the first crop in November, and successional crops every three weeks from February 1 to the last of July. It is good practice to sow again as soon as the preceding crop is an inch or two high. Earliest variety: Sutton's Kingleader, or Carter's First Crop; Laxton's Supreme, and Maclean's Advancer are not so early, but Peas of finer flavour.

Dwarf Early Peas, about a foot high, suitable for the earliest crops: Tom Thumb, earliest; and Maclean's Little Gem, a true marrow of high quality. Second or general crop, to be sown from February to June 1: Auvergne, Champion of England, Nonpareil, Wrinkled Marrow, Veitch's Perfection, and Maclean's Best of All. Dwarf: Bishop's Longpod, 1½ foot high. For later crops, to be sown from April to July (the last, however, to be sown at the end of July, to be early varieties): Ne Plus Ultra, one of the grandest Peas in cultivation; British Queen, Blue Scimetar, Victoria.

Broad Beans.—Earliest, to be planted in October or November: Early Mazagan and Early Longpod. For planting from February to June: Broad Windsor, Green Windsor, Johnson's Wonderful, and Royal Dwarf Cluster.

French or Kidney Beans.—From April to July 1: Speckled China, Dark Dun, and Negro Long-podded.

Runner Beans.—May 1: The Scarlet Runner is the best.

Onions.—Sow Tripoli in August, and James' Keeping, Brown Globe, Nuneham Park (an improved white Spanish), and Deptford, for general crop, in March. The two-bladed or silver-skinned are the best for pickling or drawing for green Onions; for these purposes sow thickly on poor soil.

Parsnips.—Hollow-crowned.

Parsley.—Carter's Champion Moss Curled; sow in February, May, and September.

Turnips.—Early Red American Stone, Early Snowball, White Stone, and Yellow Malta or Orange Jelly.

Spinach.—Every three weeks from March to September, round Spinach. October 1: Prickly or Flanders, to come in through the winter and early spring.

Savoy.—Dwarf Green Curled; for size, the Drumhead.

Radishes.—Every fortnight from July to September, French Breakfast, long scarlet, short-top, and red and white turnip. The last sowing in September: China Rose and Black Spanish, to stand the winter.

Cauliflower.—Sow every fortnight from March to June, and for winter, in September, Early London, Walcheren, large Asiatic.

Carrot.—Early Shorthorn, James' Intermediate Scarlet, Red Surrey.

Cabbage.—March to June, and August for winter and spring: Battersea, Enfield Market, Wheelers' Imperial, London Colewort.

Brussels Sprouts.—Sow the new imported seed in March. This is a splendid vegetable for winter and spring use.

Borecole, Scotch Kale.—Sow in February and May. The Dwarf Green for eating, and Melville's Superb Variegated for garnishing, and also for use.

Broccoli.—Make four sowings from March to June; the following in March and April: Early Purple and White Sprouting. The following should be sown in May and June for early autumn and winter use:—Early White Cape, Grange's Cauliflower, Snow's Superb White, and the Walcheren.

Beet.—Dell's Crimson. This is invaluable for salad, or sliced thin and served with vinegar or white sauce to cold meat. It should be washed clean, not scraped, and boiled whole for four hours. Peel, slice, and serve cold.

Lettuces.—Sow every three weeks from February to September, the last sowings, to stand through the winter, being of the black-seeded Brown Cos and the hardy Brown Bath Cabbage Lettuce. For summer use, Victoria and All the Year Round Cabbage Lettuce; and for size, the Drumhead, Cos, white-seeded Brown Cos, and Paris White Cos.

Endive.—One or two sowings may be made of the green curled from June to October. It makes a nice variety in salads, and must be tied up or blanched with an overlying slate or tile before use. It is only eatable in a pure white state.

Celery.—Cole's Superb, Crystal White, and Ivery's Nonsuch, pink.

Cucumbers.—For frame, Bluegown for length, and Telegraph for quantity and quality; for out-of-doors, Stockwood, Long Ridge and Short Prickly, the latter for pickling only.

Vegetable Marrow (for ridges).—Custard and Short-jointed Long Green.

Leeks.—Musselburgh or Giant.

Melons (for hot frames).—Queen Emma and Scarlet Gem.

Small Salading, such as Mustard and Cress, Corn Salad, American Cress, for cutting green to bread and butter, mixed salad, &c., every five or 14 days from March to September. The common white Mustard and extra curled Cress are the best for these purposes. The tall or dwarf-growing Nasturtiums are likewise often grown for the flowers for use in a similar manner, and the partially ripened seeds are an excellent substitute for, some prefer them to, capers for sauce with boiled mutton. They do best on a bit of rich soil, or trained up a wall, and they are beautiful as useful.

And now, having furnished the garden with good and substantial eatables, from Giant Asparagus, through various savoury salads and sauces, that now conclude with a few hints upon successful cropping, that is, the art of getting the most and best out of everything, from the smallest area, in the least time. Fortunately horticulturists are not bound by courses laid down by the wisdom or folly of our ancestors. And it is a singular fact, revealing a marvellous faith in our cultural capabilities, that those self-same landlords, who are so fearful of their farms being exhausted by over-cropping, never manifest the least anxiety about the same awful catastrophe of perpetual harvesting overtaking our gardens. On the contrary, only two rules prevail in regard to the latter: Get as much out of them, and put as little in, as possible. Keep on for evermore, the more crops in one year the better; but sow no manure—that is all needed for the land; as if in truth the garden were not land, but an inexhaustible mine of growing force. Farmers, as a rule, have been but too apt scholars in the same school, and hence to a great extent the low estate of many of their gardens. But many horticulturists, by impressing all waste into the service of production, have almost acquired the art of producing much from little or nothing. But such exceptional talent must always continue rare. If you seek to reap bountifully and continuously from your gardens, you must sow them liberally with manure. This done, the ground may be always at it. The only rest for the earth horticulturists believe in, is a change of crop. As for fallows in gardens, they are but a waste of time and growing force. They should seldom last more than a day, or part of one. Feed the earth well, and one crop may tread upon the heels of another for evermore, without overtaking exhaustion.

True, in old works on horticulture you may find four, six, and even eight course rotations. But these belong to the olden time, and can only be indulged in, if at all now, in ducal residences with 10-acre gardens—one half of them under root crops.

We shall give one, however, for example. The chief law of modern rotation in gardens is, that no two crops of the same thing should succeed each other on the same soil, neither in the same or the next year. And even this cannot always be adhered to in small gardens.

The following hints should be acted upon, as far as possible, and may easily be carried out strictly where several sorts of single cropping is practised. No two so-called exhausting crops should succeed each other, hence Peas and Onions should be succeeded by Spinach, Celery, and Lettuce.

Permanent crops should be succeeded by annuals—thus Strawberries by Broccoli, Cauliflowers, &c.; winter crops by summer, thus Savoys, Brussels Sprouts, &c., by Peas, French Beans. Crops of the same natural orders should not follow each other, as Onions, Leeks; Cauliflowers, Broccoli; nor Cabbage, Sea-kale. The following is an eight years' course of cropping:—1st year, Peas, Beans; 2d, Carrots, Parsnips, Beet; 3d, Onions, Cauliflowers, Tribe; 4th, Savoys, Broccoli, Winter Greens; 5th, Potatos; 6th, Cabbage, Broccoli; 7th, Celery; 8th Peas, Beans. Very few with small gardens get beyond the three-course system:—1st year; Cabbage, Broccoli, Cauliflower; 2d, Celery, with Spinach, Potatos, Lettuces between; 3d, Onions, Carrots, Parsnips, Beet; 4th, begin again. In this course the Strawberry crops are generally included, and used for winter Broccoli, Greens, Cabbage, to be followed by Peas, Beans, Celery, Onions, and Potatos.

But by far the greater number of kitchen gardens are cropped on what is called the system of catch crops. Such crops as Peas and Beans are all grown at wide distances among other crops. Potatos, Cauliflowers, French Beans, Celery, Broccoli, Brussels Sprouts, &c., are planted between, and thus the ground is always full. Thus, for instance, are sown 4 or 5 rows apart in February; in March, four or five rows of early Potatos are planted between the Peas; in June or July, Broccoli is planted between the Potatos; and when the two first crops are cleared off, the whole ground is covered with winter stuff. Celery ridges are made early in May, topped with a row of Peas, and Celery planted in May or June. The Peas are gathered before the earth is needed for blanching the Celery, and the lower ground on which they grew may be further utilised later in the autumn by a row of Cauliflowers.

By this system of cropping the earth is ever in harness. The crops are all more or less catch crops, racing against time, and occupying every available inch of space. With good feeding, the ground hoists no signal of distress, makes no sign of exhaustion, on the contrary, it improves under express cropping. Each crop prepares, I must not say enriches, the earth for another; and as they are being hurried forward to perfection, the stronger, that is the older, serve to shelter and nurture the younger and more tender into more rapid and vigorous growth. Partial shade to young vegetables is mostly a good thing from May to September, during which period the pressure of simultaneous cropping developes its full force. *D. T. Fish.*

Home Correspondence.

An Erratum Corrected.—In your excellent epitome of my address on the agricultural labourer (p. 1467), there is one mistake which I must at once correct. I am made to say, "If the labourer got 2*s.* a-day all the year round, winter and summer, he ought to be well contented." What I did say is thus correctly reported in *Bell's Messenger*:—"Correspondents of the newspapers are constantly asking us how the labourer can live on 2*s.* a-day. Now, in the first place, I contend that he does not live on 2*s.* a-day; in the next place, I maintain that if he get 2*s.* a-day in the winter, he ought to be well contented; for this reason, among others, that agriculture is the primitive industry, and depends more on unskilled labour than any other craft. It costs a great deal of time and money to make a skilled artisan." The only other inaccuracy that I need mention is this—I am supposed to argue that the agricultural labourer "lives nearer his work than the artisan." I meant it just the other way, and that being nearer his work was one advantage the poor artisan enjoyed over the rural labourer. *Cluny Sewell Read, Honingham Thorpe, Norwich, Nov.* 16.

Hop Cultivation.—Much has been written and spoken on the subject of Hop cultivation and management—a crop that I have been interested in for upwards of 30 years, having sojourned in the heart of the Hop district of Kent, and observed with interest the character of the various soils and different grounds that have had the reputation of producing good crops, both in quality and quantity, under the most skilful management. The crops on some of these, I observed, were this year very much blighted. Where 18 cwt. per acre was not uncommon in previous years, the produce this year has not been 3 cwt. The same remedies are applied by practical men, in some cases with good results, that are condemned by experienced Hop growers in their immediate neighbourhood. The plants in many gardens have been washed with soft soap and water three times over this year, and where done early the result has been most satisfactory in the majority of cases; but some of the most successful growers—one of them a gentleman who has grounds the produce from which this season was 20 cwt. per acre—repudiate washing, and consider it quite unnecessary. The remedy of the above-named gentleman has heretofore been successful, and the experience of 50 years lends weight to it. He carefully examines the physical characters of the soil and subsoil, especially the texture, depth, drainage, and the farming necessary for a crop, using farmyard manure, and avoiding as much as possible the application of artificial manures, or excessive stimulants that tend to weaken the constitution of the plant, and render it more susceptible to blight and mould Fungus. I find that the most successful Hop growers during a series of years are those farmers who have gone thoroughly into the drainage of the land, have made this their "first principle," who feed the largest number of cattle, and go deeply into artificial food, linseed cake, &c., for fattening stock. The various difficulties that were scarcely known 20 years ago appear to strike the most experienced now-a-days. It is difficult to find any Hop gardens which are not subject to blight, even considering the most favoured aspects as to wind or sudden change of temperature, cold or hot and wet or dry seasons; during the last season we have had examples that have never been experienced before. There are few exceptions to the fact, that the best growth of Hops are produced on lands whereon during the last half century farmyard manure the produce of fatting stock has been the main application, combined with strict attention to cultivation of the soil. On land that have not had farmyard manure applied—where the bine has been forced early by the application of artificial manures, nitrate of soda, ammoniacal salts, sulphate of ammonia, and even guano, or any other active stimulant, which are very soluble and powerful, causing the bine to make a most rapid or very vigorous growth—the result has been remarkable; a sudden check was observable during the last and the present year; the plant become weak and much blighted. As far as my experience goes, Hops cannot be successfully grown to produce quantity and quality for a series of years on any heavy lands, without farmyard manure. Many Hop growers who cannot apply T. Y. manure give a ton of rags to the acre, others 2 cwt. of blood manure, 8 to 10 cwt. of shoddy, 1 to 5 cwt. of guano, as a dressing. From 5 to 10 cwt. of rape cake and shoddy, 3 cwt. of rape cake and 3 cwt. of blood manure, are mixtures that have been satisfactory in many of the Hop gardens in Kent. Up to this time the falling-off in the plant has been marked in the same grounds and with the same variety of Hop. Experience has brought to light that when artificial manures have been exclusively applied, the constitution of the plant is weakened and rendered more liable to disease. *R. A. C., St. John's Wood.*

Reclamation of Waste Lands.—My recent communication to you on the reclamation of the waste lands of North Lancashire, appears to have excited some attention in the district, and is viewed with diverse feelings by the local press, though all agree as to the necessity for the work being speedily set about. Coleridge's "Ancient Mariner's" lament of "Water, water everywhere, yet not a drop to drink!" appears to have had an analogy in Furness, though with a slight difference. The mariner was unable to utilise the vast expanse of water, and render it subservient to his needs. The inhabitants of North Lancashire, owing to its increase of population, lack food-producing land to feed that population, and though they have the necessary land at their very doors, the idea of utilising seems never to have suggested itself. The *Ulverston Advertiser*, the oldest newspaper in the district, acknowledges the need of such reclamation, but is afraid that a long time would elapse before the sands could be brought into food-producing cultivation, and instances the shores of the Solway. The scheme which I propounded and the case of the Solway widely differ, inasmuch as the land attempted to be utilised in the latter case is regularly washed by the tide. Under such circumstances, vegetation is impossible. The surplus sands of North Lancashire can be embanked, and a rotation of crops could be commenced at once. It is well-known that the land is called "sandy land" produces both the heaviest and soundest crops of Potatos, and those grown on such land usually bring a halfpenny or a penny more per stone in the local markets than those from heavy lands. The lament of the *Barrow Daily Times* is in a poetic strain, inasmuch as the occasion which gave rise to numberless poems and pictures on the dangers of "crossing the sands" will be at an end. Had the editor of that journal experienced, as I have done, the discomforts and dangers of these sands, he would be thankful that steam has superseded horse locomotion. Fancy yourself mounted on the top of the Ulverston and Lancaster coach on a cold, wet, wintry morning, with the prospect of 20 miles of sands to be traversed, intersected by numerous channels, at each of which a man leaves the coach and wades through, in order that

the coach may avoid the quicksand beds. Fancy the coach in the middle of one of those channels, and you find it sinking slowly under you. There is no alternative; you must jump into the water as far clear of the coach as you can, to avoid the engulphing place; and then, if you are charitable, you must assist the driver to get out his horses, fasten ropes to the coach, and drag it out. By the time you have got your team again in harness, the tide is upon you, and you have to gallop for dear life. This is a fortunate sequence to such an episode, and the many who have found graves on those sands bear witness that not always was there so fortunate an ending. These sands may have afforded food for the painter and poet, but I think few will regret the change if they be made to afford life food for the million. Another reason why these sands should be reclaimed, and an important one, may be given. On each bank of the Duddon, and extending to the extreme ridges of the shores, valuable deposits of iron ore have been found, and there is strong reason to believe that these deposits extend underneath the whole of its bed. Assuming this to be correct—and the idea is strongly favoured by mining engineers—the cost of the work of embankment would speedily be cleared by the ore raised. Although I do not favour the idea expressed in some quarters that a few more years will see the exhaustion of the iron ore supplies of Furness, yet I think it is imperative that the ironmasters of Furness should strain every nerve to prevent such a calamity to the district, by using every exertion to discover new "finds." A falling off in the supplies of ore simply means district bankruptcy, and when we look at the immense amount of capital invested in the ironworks of North Lancashire, such a deplorable result must be avoided if human skill and enterprise can accomplish it. Again, let me instance the borough town of Barrow-in-Furness, with its rapidly increasing population. An excellent system of sewerage has been adopted, and the outfall is on the sands, close to the town. During every tide the action of the sewers is stopped, and as the town increases this will be more and more felt. An embankment from Barrow to Concle would reclaim 200 or 300 acres of land, and at very slight cost the sewage might be placed upon it. Coming eastward, to Ulverston, we have a town with a population of some 8000 inhabitants, and every prospect of increase. Recently an excellent system of town sewerage has been carried out, the outfall again being on the sands, but with this difference from that of Barrow: the outfall at Ulverston is one and a half miles from the town, and is carried there in underground pipes, so that the back-water from the effect of the tide is not experienced. But, as in the case of Barrow, the sewage is wasted. From Hammerside Hill to Conishead Bank stretches a long waste of beach and sands. Over this an embankment the tide is fast making inroads on the neighbouring property, and much grain, &c., is yearly spoiled by the high tides washing over the land. A sea wall from the two points named would enclose from, say, 400 to 500 acres, on to which the sewage of the town—the outfall being already there—could be easily poured. It may be objected that the river running from the town, and known as the "banking," might interfere with this project. This could be diverted and discharged at Conishead Point. The matter is well worthy the attention of the local boards of Ulverston and Barrow. As to the rivers Kent and Leven, there are many thousands of acres which might, the necessary outlay for embankments being provided, be utilized and made productive. No doubt there are many other places in the kingdom where land from the sea might be reclaimed, and sooner or later the matter must force itself upon the serious attention of the Government. *J. R. R.*

Beetroot Cultivation.—Two or three articles have appeared lately in your columns advocating the cultivation of Beetroot, and referring to the successful results on the Continent. None of your correspondents, however, seem to have adverted to one all-important question, viz., whether or no beetroot-sugar is on the Continent protected by discriminating duties against the competition of colonial sugar? Of course, such protecting duty could be expected in our own country. *P. P. C.*

Landlords and Tenants.—In your paper of last week I notice that at the South Hants Farmers' Club meeting, a discussion arose as to whether it would be more profitable to plough in the present root crop for manure than to buy stock to consume it. One speaker hinted that there were not sheep enough in the neighbourhood to eat up the crop, and "while the relations between landlord and tenant existed as they now were, that deficiency would never be made up. A tenant would not lay out his capital in the purchase and rearing of stock while the relations with his landlord were unsatisfactory." Hampshire is not alone in her complaint about bad relations between landlord and tenant. The bulk of the land in every county in England is held subject to the landlord's six months' notice to quit. It is therefore at the tenant's peril if he improves his farm. It speaks well for many landlords that they do not take advantage of their tenants' improvements to raise their rents in consequence of them; and it speaks well for many tenants that they improve their farms, in spite of the six months' notice hanging over most of their heads. But the land of our country cannot be properly tilled, nor the quantity of food raised from it that our increasing population demands, so long as the tenant's property in improvements is liable to be seized by the landlord. It is useless for Mr. Mechi or Mr. Smith to point out how we may increase our home growth of corn and meat, so long as a landlord can turn us out or pounce upon us periodically for a large rent as soon as we make the land grow more crops. Without security for our outlay it is simply impossible for us to cultivate the soil as we ought, and as we wish to do. Parliaments of the future may give security to English farmers, the same as Irish farmers now have. Parliaments of the past have done worse than nothing to promote English agriculture; if nothing else had been done, the police-helping gamekeepers' Act is alone sufficient to show this. All well-wishers of their country would rejoice to help us to raise such crops as would make us less dependent on foreigners for our daily bread. Parliament hitherto has not helped us a bit, and I do not think it ever will, until more farmers and fewer landowners are sent there. This is a question for tenant-farmers: combination will help farmers as well as engineers. Farmers can return more of their own class to Parliament. The labourers are as much interested in the welfare of employers as employers are of the man by those who raise its produce. If only 100 farmers, or men honest to the cultivators of the soil, were in the House of Commons, I think that such things as the six months' notice, the destruction of tenants' crops by landlords' game, or the employment of rate-paid policemen as gamekeepers, would not exist a year. With security of tenure, we dare lay out our money in steam cultivating machinery, in manures, labour, feed, and implements. The whole nation would then benefit. As it is, the whole nation suffers. *H. H. O.*

Societies.

SCOTTISH CHAMBER OF AGRICULTURE.

General Meeting.—At the annual general meeting of the members of the Scottish Chamber of Agriculture, held last week, there was a large attendance; and Mr. Scot Skirving, the retiring President, occupied the chair at the commencement of the meeting.

The CHAIRMAN delivered the customary closing address. He said:—

I fear I cannot escape, as my predecessor did, the formality of formally addressing you, and at the same time I am not so fortunate as to be able to refer to any marked progress we have made during the year that has passed as regards those measures affecting agriculture which the Chamber always takes so deep an interest. I do not think, however, that I am mistaken when I express the belief that the views of the Chamber regarding those measures are making such steady progress in the country that they must at no distant date command the attention of the Legislature, and that the special grievances against which we protest will be

The Game Laws and Hypothec.—It is not my intention on the present occasion to make more than a few observations upon those semi-political questions which have from time to time engaged our attention. The chief of these are the Game Laws and hypothec. With regard to the latter I have indeed no right to offer an opinion, as it is only within the last few years that I became connected with any portion of the property of one or two members of this Chamber, and perhaps still more by the weakness of the defence, that the law was not only unnecessary, but was often unjust. I saw from the opponents of hypothec that it frequently was the means of placing upon a farm capital which really belonged to neither the owner nor the occupier of the land; whilst from the other side I learned that there were hundreds of small farms all over Scotland which were (as the advocates of the law boasted) occupied by the same families for generations, through the agency of hypothec, who were yet too poor to pay a single half-year's rent in advance, and were often called upon by a change of circumstances to do so. It struck me that it was a very questionable benefit, a very doubtful kindness which resulted in families existing for generations, giving labour, and thought, and skill, with what capital they had, but no other result than that they should live from hand to mouth, and struggle on for ever, father and son and grandson barely keeping their lips above the bitter waters of poverty. Hypothec is, therefore, not a law of which I feel inclined to be conservative. Gentlemen, during the year that has passed I have not said a single word in reference to game or Game Laws. A supporter from the first moment that I read it of Mr. Loch's Bill, I knew at the same time that considerable difference of opinion existed in the Chamber as regard matters of detail, though of detail only; and, therefore, it considered it was not the part of the President to take any active share in your discussions. We are constantly twitted by our opponents with our want of unanimity in the matter; but it is my firm belief that, as regards not only this Chamber, but the whole of Scotland, the great bulk of the agricultural body—in fact, an overwhelming majority of their number—are at one in this, that they think a fair and just settlement of the question would be that while landlords retained the exclusive right to all winged game, they should share with the occupier the right to kill hares and rabbits. This privilege they think should be fixed and settled by law, and it is only as to the precise mode of doing so that there is some difference of opinion. On the other hand, I am equally convinced that it is only a small minority who wish to see the Game Laws abolished, or who imagine that, if they were abolished, their abolition would in any way redress the evils complained of. It is not by the Game Laws that deer are at present protected, and a trespass law would protect hares and rabbits quite as well as a Game Law. Few or no farmers object to a full, fair herd of game to be used for fair sporting purposes; it is the battue and market systems (these comparatively recent innovations) that cause all that bitterness of feeling which has so unfortunately set class against class. Masses of hares, which destroy ten times the amount of food which they actually consume, are on some estates preserved all the year round for a single day's slaughter, when they are driven with the other game in the coverts of Turnip fields, where they are frequently confined by netting, to be shot down wholesale by what may be called volley firing, gathered up, counted, boasted of in the local newspaper, and then sold in a very matter-of-fact fashion to the poulterer, who sometimes comes down with an advertisement that he has received 600 or 800 head of game, killed by a nobleman! The latest improvement I have heard of in battues was that a cart and horse was driven right across the Turnip fields, following the line of shooters. This bottling up of game for a whole season for the coarse amusement of a few days remaining at it is nothing so much as the poor sailor who sometimes hoards his daily allowance of rum that when he has got a bottle full he may have one glorious debauch. Goldsmith wrote:—

> "Yes, let the rich deride, the poor disdain
> The paltry pleasures of the lordly train"

From a sportsman's point of view, I hold that the battue system destroys half the sport of shooting, and very often puts an end to fox-hunting as well; but that is only a small part of the evil. It was objected to me, when you did me the honour to elect me President, that I was a Tory; but I trust you will pardon me if I make one passing observation on this game difficulty from a purely conservative point of view. That is, then, I would say, a very bitter thing for an earnest Conservative to see his party shot out from all share in the guidance of the country, and even its best members driven from the representation of almost every county in Scotland, chiefly because a small minority of the landed gentry, whose social position makes them conspicuous, prefer the killing of a hecatomb of hares to all that once made England so powerful and so glorious. These gentlemen seem to have deliberately made their choice, and to find a parallel to it we must go back to the day when Esau sold his birthright.

I think that the Chamber should seriously watch the present tendency to tax the animals and even the implements of the farm. The shepherds' dogs were first taxed, then the gun that scared a wood-pigeon, and then the cart that took a poor man and his family to church; and I have no doubt, if a firm resistance is not given, we shall very soon have every farm-horse taxed, while the whole steam horse-power of Manchester will go free.

There is another matter to which I think the Chamber might with propriety direct attention. I allude to many of the conditions inserted in leases, which are utterly out of keeping with the present position and circumstances of the agriculture of Scotland. I need not allude to them in detail, as they are only too well known. Most of them originated in bygone times, and were the creation of circumstances which have long since passed away, while others owe their more recent origin to mistaken ideas and to misdirected legal ingenuity. A great portion of the text of too many leases is a mere anachronism, and mars alike the interest of landlord and tenant, and forms at the same time a serious hindrance to the free and proper and progressive cultivation of the soil. How absurd, for example, to bind a man to farm now in accordance with the ideas of a century past. Is there any other science than agriculture (unless, perhaps, theology) in which it is attempted to force upon 1871 the principles and the practice of 1771? What would people think if doctors were bound before receiving their diplomas to do certain things and not to do certain other things in accordance with the teaching and knowledge of a hundred years ago? It is my conviction that in hundreds of cases these leases are only signed under the compulsion of irresistible circumstances, and that the tenant has a sense both of shame and indignation when he does sign them. Why, then, are they signed? Because, in the first place, the limited extent of land in this country makes it a virtual monopoly, and there are so many persons anxious to farm that in the struggle for existence they must either accept the conditions or give up all hope of farming in this country.

Education for Farmers' Sons.—Agriculture differs

from other professions in this, that the number of those who wish to practise it will always be swelled by new comers, who having succeeded or failed in some other profession, wish to invest their gains or hope to repair their losses in a business which most people think they understand and all believe to be much more remunerative than it really is. But I would ask, are the number of applicants for farms not unduly swelled from the ranks of the farmers themselves? I here venture to allude to what I think a too common mode in which the sons of farmers are reared and educated. Is it not very frequently the case that farmers, who know only too well how little margin of profit there is in farming at present rein in allow the early years of one or more of their sons to slip away without attempting to give them such an education as would enable them, when the proper age arrives, to seek admission into some other trade, business, or profession, and thus at the period of opening manhood hundreds of youths find it too late to think of anything else; they know how to farm, and they know nothing more, and hence, if they fail to find a farm they have the prospect of years of idleness before them. It is exceedingly difficult to suggest any general rules for the education of farmers' sons from the great diversity of their positions and situations in life. It has been remarked that when one talks of landed proprietors every rank of life is included, from a duke to a 40*s.* freeholder; and in like manner the word farmer may include many conditions of life, from the man who may have his sons educated at Eton and Oxford if he chooses, to the struggling tenant, who can sometimes barely afford to send theirs for a few years to the parish school. Farmers, however, have had no lack of advice as to how they ought to educate their sons; indeed, if advice would do us any good we should be perfect, as we have had the best advised persons in the world. Everybody, indeed, lectures or advises farmers, the chief qualification of most of the lecturers being a total ignorance of the subject they lecture about. I was much struck some time ago with the advice of one of these advisers on the subject of education. I shall not name the gentleman, as he is not known to fame to me, but I notice his advice because not only was it given in quite an *ex cathedra* style, but his sentiments were, I regret to say, adopted and applauded at a meeting of the Royal Agricultural Society of England. He said that no boy could turn out a good farmer if he did not devote himself to it from the age of the farm from the age of 14 or 15. He seemed to admit that he must go to school previous to that period, but from that age he ought to devote his whole time to learn the practical details of agriculture. He should be apprenticed to a careful farmer to be him as a pupil, and teach him to plough, and sow, and stack, and so on. Now, if the lad proposed to be a peasant farmer, who was to till his land with his own hand, the advice was good enough; but, on the contrary, the youth was supposed to offer some £5000 to stock a farm with, which, supposing he was one of an average large family, would imply that his father possessed a considerable amount of capital. There can be no doubt that, whatever were the professions for which that lad's brothers were destined, they would receive a fairly liberal education, and much better educated, and would consequently, when men, have a vast advantage over him. Why, I ask, should that son be placed all the days of his life in an inferior position to the rest of his family simply because he had been destined to become a farmer? The idea that a man would be better in any profession if he be schooled and instructed in it alone appears to me quite erroneous. I was filled with astonishment on reading the same advice as that which I have quoted addressed by a distinguished and strong-brained clergyman to the students of the Free Church. They were to study only divinity, and then take some successful preacher as a model. This advice was illustrated by an anecdote. A traveller on a Bristol coach asked the coachman a great many questions as to the places they passed. What mountain was that? At what was the name of that river? To all which John answered "Don't know." At length the gentleman, getting cross, said sharply, "Is there anything you do know?" "Yes," said the coachman; "I know how to drive the coach." But even that man might come to regret that he could do nothing but handle the reins and whip when the railway and the first screamed in his ear shrill notice that his occupation was in danger, and in like manner I think that the young farmer should possess as many weapons as possible with which to fight the battle of life. I would deprecate efforts to get up agricultural colleges, as we sometimes hear talk of, where a sort of technical education is proposed to be given. I would simply say, let each man get for his sons the best education which his means and his opportunities afford, and don't let it be the worse because the boy is to farm. If it should be said that by all existing methods much of a boy's time is occupied in learning Latin and Greek, or the higher mathematics, I would say so much the better. Don't be disturbed by any sneers as to Greek or Latin. Don't be moved by the thought that before he is 30 the man may have forgotten nearly all the classics that the boy was taught. The Professor of Humanity in the University here, in his opening address last week, painted to his students in glowing terms the inexpressible delights of those who could so master the classic authors as to make them the easy companions of their lives. But this pleasure, which falls to the lot of a mere fraction of those who study classics, forms no part of the reason I would give for having them taught. When a boy learns gymnastics and climbs up a pole, there is no intention of making him an acrobat—the design is to strengthen the muscles of his limbs; and so with the classics or mathematics. I would teach them to the many as the best means of exercising and strengthening the mental muscles, and I do not believe that modern languages, though *per se* much more useful and necessary, are able to educate the mind as the more difficult studies do. In fact, a man may, and indeed often does, speak several European languages with perfect fluency, and yet has no more education than a second-rate *valet de place*. If any one should be inclined to alter a line of Burns, and ask me contemptuously if "Turnips could be grown by dint of Greek?" I should say that "Yes" would at least be quite as good a reply as "No," because a brain properly trained and tutored and developed is placed upon a vantage ground, and can quickly adapt itself to altering circumstances, and can easily gather fruit in any new field of knowledge. The youth who has received a liberal education how farm, not because but farming for a livelihood, and is therefore often driven into taking land at a higher rent than he thinks it is prudent to undertake to pay; but his only alternative is idleness, or at best a forced emigration. On the other hand, as one of the great advantages of education, I have always the belief that were the agricultural community as a body as well educated as the members of most professions are, questions which have been agitated in this Chamber would receive a very speedy solution.

Conclusion.—In now quitting the office to which a year ago you did me the honour to elect me, let me again remind you that a farewell address is one of the implied conditions of accepting the Presidentship of the Chamber. Upon no other ground would I have presumed to address you in the manner I have done, knowing and feeling as I do that there are many members of this Chamber from whom it would become me to take counsel and to whom it would be presumption to offer the first hint of the youths who have been the subject of the latter portion of my discourse I would say—

> "May they better reck the *rede*
> Than ever did th' adviser!"

DEVONSHIRE.

The Steam Plough.—At the late quarterly meeting of the Devonshire Chamber of Agriculture, a paper was read on the "Progress of Agriculture resulting from the Steam-Engine," by Mr. JOHN DAW.

He expressed his astonishment at agriculture's unvarying progress during the last 50 years, and its increased rapidity during the last 20 years. Fifty years since there was nothing but wooden ploughs and harrows—no drills—few Turnips—Swedes a rarity—no Mangels—no artificial foods—no artificial manures, except lime, and that frequently brought from long distances, and 8 bushels to the land considered excellent if the produce were 20 bush. an acre. Small fields, enormous hedgerows, land undrained, pastures poor, small farmers often worse off than labourers, and rents badly paid. As to the hedges, a land-surveyor of the period had shown that in the rich and highly cultivated parish of Broadclyst, if extended in line, they would reach from that village to London, upwards of 160 miles. All that had been altered since, and after tracing the progress of the successive changes, and the effect of free-trade policy in developing both agriculture and manufactures, the lecturer set down steam cultivation as the cause of it all, and that the second, immediate subject—the effect of the steam-plough especially on the food-producing art, its probable effects on landlords, tenants, and the public.

The following points were taken up *seriatim*:—Its effect on the price of wheat—lessen the cost of cultivation—to decrease by nearly one-half the number of horses necessary for agricultural purposes, and the consequent unproductive consumption of food by them—it would tend to the consolidation and enlargement of farms as well as fields, and to make it more apparent that farms were not food factories, as there were woollen, cotton, and iron factories—it would tend to increase production—render necessary much increased capital—necessitate increased security to tenants—and increase manual labour.

1. It will lessen the cost of production. To enter fully into the details of the cost of steam cultivation would take a longer time than is allowed to me, but the question of expense is a matter already settled by experience. The steam-cultivator is used by the largest and best farmers, and it would not be so used, and when used, would be abandoned, if it were not the most economical system of cultivation. Doubtless our county is placed at a disadvantage with respect to coals. We have to pay 50 per cent. more than in coal districts, but this is not of primary importance. Coal is only one, and a small item in steam cultivation.

2. As to the decrease of horses, that is self-apparent. The great bulk of horse labour is in ploughing, and nearly all ploughing ought to be done in the autumn. To ensure a good seed-bed on average soils (even for Mangels or Turnips), land ought to be ploughed in the autumn, so that by the operation of the winter's frost a good seed-bed may be formed. A steam-cultivator can be used when horses cannot, and a 6-horse power traction-engine (or better two, one at each headland) will easily plough 500 or 600 acres of land in the estimated 60 to 80 days of autumnal fine weather. True there may be a scarcity of horses to draw all the crops to the homestead, but the simple remedy is to stack the crops in the fields where they are grown, as is now done in the great agricultural counties.

3. The steam-cultivator will tend to enlarge farms as well as fields, and herein is a fruitful subject for consideration. Many of our arable fields are too small for the most economic and beneficial cultivation, and for steam cultivation it will be even more necessary to square them. I believe there is no county in England in which the fields are so small and so ill-shaped, and none where there is so much hedgerow timber. The trees must be felled and the roots destroyed before steam cultivation can be exercised to the greatest advantage. And, as a consequence, it may be incidentally mentioned, that the more we do away with our small enclosures the more we shall increase the number of partridges to eat up the wireworm and grub, and the more will be increased the number of rabbits, which eat up our crops, and which in large numbers are, whether viewed in a light social or political, a serious nuisance. It will tend to increase production. It has been proved by experience that the use of the steam-plough increases the productive quality of the soil. It enables the land to be ploughed deeper and the subsoil brought to the surface, and exposed to the vivifying influence of the sun, the manuring deposit of the rain, and the disintegrating influence of the frost. It prevents the land being trodden by men and horses, and, when well ploughed and harrowed, leaves the land in a perfect seed-bed. By bringing the subsoil to the surface, &c., it brings into active use the mineral manures latent in the soil, and it is asserted by all having experience that the production is at least increased 20 per cent. The three principal requisites for plant growth are ammonia, phosphates, and water. The two first, contained in clay lands, but the clays are difficult to be penetrated by the roots. The soil has never been stirred. Some clay lands are so stiff as to render it at least doubtful whether the bringing the clay to the surface would not, by covering the vegetable mould, render the surface too stiff for permanent cultivation. But there is no occasion to plough deep. The steam-cultivator will keep the top soil on the top, but will break up the undisturbed subsoil as deep as may be desired. The present 12-horse power engine can be made to break up 14 inches, and doubtless there are engines now being built which are expected to cultivate 2 feet deep, and some think 3 feet. It is not the lack of food constituents, but how to get at and render them available, that is the problem to be solved. We cannot but admit our shortsightedness in not, having such a store of all that is requisite for the growth of our crops, we leave them unavailable for want of steam cultivation. It has been always remarked that the temper of the community depends in some measure on the price of food. In periods of abundance, although usually prosperous, discontent has usually followed close upon a rise in prices. Riots have always occurred during dearths. The squaring and enlarging our fields and the destruction of our hedge-row timber will be objected to by many as being destructive of the picturesque beauty of our country; but with educated minds there is no beauty like that of place. Devonshire is studded with parks and pleasure grounds, and they will be more appreciated and viewed with greater advantage in contrast with large square fields and their golden corn and their luxuriant green crops. That they could be created without infringing on its pleasure ground, can produce vastly more than is at present obtained from it, is undoubted, though the produce may have been doubled in the last half century. Lord Derby has no doubt this produce can be doubled, and Mr. Mechi thinks it can be trebled. In large farms, it is necessary there should be large landowners. It is disputed, but still I think it is a fact, at least in this county, that large estates are continually being increased in size. The old body of yeomen are decreasing, and their estates added to those of large landowners who have the means to purchase. Apart that the position of the yeoman is benefited by his selling his small estate, which yields him as rent three per cent. only, and with the proceeds renting a much larger farm, which brings a tenant's profit, instead of merely a three per cent. investment. Whether large landowners are wise in extending their boundaries on the terms they have frequently to do, merely for the pleasure of being larger landowners, is a question for their consideration; but the tenants are benefited. It is notorious that large landowners let their estates at much lower rents than small landowners, and are much more ready to invest money for those permanent improvements which are daily becoming more necessary, than are the smaller proprietors. With steam cultivation and large farms, increased capital will become necessary. It is well known that the farmer with ample capital makes more profit than he could do if deficient of capital, and I believe it will be found that only the best farmers have sufficient capital. There is too great an inclination to increase the acreages of farms without having the increased capital necessary

for it. When farming was only the obtaining as much as could be got out of the earth by the simple scratching of the ground and sowing the seed, leases were not of much consequence; but the great and increasing outlay necessary in farming in the highest degree of perfection now known necessitates security to tenants. It can no more be expected that tenants without leases will cultivate deeply, manure highly, and invest largely in feeding stuffs and manures, than that large manufacturers would build enormous factories on lands of which they were yearly tenants and liable to be ejected on six months' notice. Leases are more necessary in Devon than in those counties where there is a law of tenant right. Here it is that under great landowners good tenants are never ejected, and farms are allowed to continue in the same families for generations; but in the present state of agriculture this is not sufficient. The landowner may, for the purpose of consolidating his property, sell some estates, and death or other circumstances may occur which would deprive the tenant or his family of the farm. Leases are the only security for the repayment even of his outlay for permanent improvements. Increased manual labour: If we may judge from the past, every great improvement in agriculture must bring increased manual labour. While farming was primitive pastoral, few hands were necessary, but labour increases with production of crops and quantity of stock kept. It may be illustrated by reference to a fruit and vegetable garden near a city, where at least for every acre and half or two acres there is a hand employed. Some districts in Devonshire are specially adapted for large farms, and others for small ones; but probably there is no district which should contain exclusively large farms or small farms. In Devonshire there is great diversity of soil, of flat and open country, of hill and dale—the flat and open country fitted for large farms, and the steep and abrupt valleys, especially near our rivers, fitted for small farms. Viewed in another aspect, there ought to be a few small farms by which a struggling, persevering man might rise above the condition of a farm labourer, as very many farmers in Devon have already risen, most of them from the beginning as owners of cottages. These small farmers have risen because of their perseverance, toil, saving and intelligence. Each has done the work of two labourers, and lived at the expense of one. Moreover, there are some articles of produce which are particularly suited for small farms, such as milk, butter, eggs, and poultry, and, in my opinion, they can be produced cheaper and better upon small farms than upon large ones. If it be found expedient to keep numerous small farms—and during the transition from small farms to large farms, the steam cultivator may be obtained by hiring, as I suggested above with respect to the steam threshing-machine—of course there will be practical difficulties in steam cultivation in Devonshire, and more so than in other open counties. There is a 10-horse power engine and roundabout system suited for moderate-sized farms; and there is the direct system, with two larger engines and its economy of labour, and time, and money. For a farm of 300 or 400 acres, the former may be more advisable; for larger farms the direct system. The general rule was—never use a man if you can use a horse, for the latter costs no more to keep, and is eight times stronger. The new rule will be—Never use a horse when you can use a steam-engine.

Farmers' Clubs.

WISBEACH.

Freedom of Cultivation.—Mr. A. S. Ruston thus spoke, the other day, at Wisbeach:—

Perhaps there is no document extant which is regarded with so much real conservative veneration, and whose text has been so literally adhered to, as the old skeleton lease, which has been so scrupulously preserved and so jealously cared for in nearly every lawyer's office, and has been handed down as a kind of heirloom from generation to generation. Its formulæ and its covenants have been repeated with the most verbatim exactness decade after decade. It is a curious old document, heavy with age, and reverenced for its antiquity. Its style of composition drives one's thoughts back to the times of agricultural infancy, and its verbosity is a painfully wearying infliction. It contemplates no agricultural progression, its covenants of to-day are to be the settled, unalterable obligations of the future, as they have been the sure and binding terms of the past. There is an utter absence of the conception that science and practical agriculture can ever successfully combine in largely augmenting the capabilities of production, but there seems the implied idea that agriculture has reached its zenith, and that the cultivation of the soil must be held in with bit and bridle, lest unrestrained liberty should result in exhaustion, and landlord and tenant sink in one common ruin. Now we want to look at this subject for a few minutes, just to see how far these restrictions are wise, and how far they may be advantageously relaxed. It is not our intention to discuss the merits and demerits of leases, or the advantages or disadvantages of yearly tenancies, with sufficient and satisfactory tenant-rights. Both these systems of hiring have their advocates and their opponents, and both have in them that which is good and that which is evil; but in which the good, and in which the evil, most largely preponderates, I must leave to every man's individual judgment to decide.

My object is rather to plead for greater liberty in cultivation, whether the hiring be for a term of years, or only from year to year. We want to break the spell and charm of these old stereotyped covenants and conditions. They have long enough, as relics of antiquity, held in captivity minds otherwise strong and enterprising, and have placed hindrances innumerable in the way of agricultural progress and advancement. Let us blot from our minds all memories of the past, and starting *de novo*, and taking an intelligent and thoughtful view of the present and the probabilities of the future, seek to shape our farm agreements according thereunto. We shall then be confering a boon alike upon owners and occupiers, and upon the country at large. For increase of production without a corresponding exhaustion of the soil must be a national blessing. With a population daily increasing, it appears of the utmost importance that every possible effort should be made to increase production in order to meet the enlarged requirements of the community. The acreage under cultivation cannot be largely increased, and the yield per acre, in many instances, cannot be very considerably altered. It has been said that the man who makes two blades of grass grow where only one grew before is to be looked upon as a public benefactor. And so he is. And we may, regarding this as the enunciation of a principle, claim a rich meed of praise for the man who, by the judicious application of capital, and the skilful cultivation of the soil, makes it yield in can largely increase its produce. We don't wish to say hard things of those who place impediments in the way of the successful accomplishment of so desirable a result. We rather wish to invite their attention to the evils consequent upon the restrictions imposed, and to ask their co-operation in seeking their modification or removal. There is, doubtless, a growing conviction of the necessity of relaxing to some extent the stringency of existing covenants, and of giving more freedom and scope to enterprise and intelligent occupiers; hence, we now and then see a breach of covenant amongst the time-honoured tenants disregarded, and allowed to pass without remonstrance, or in a familiar phrase, "winked at." We would, however, prefer seeing the obnoxious covenants removed than their breach unheeded. It is neither wise in principle nor sound in morals to make laws and not enforce obedience to them. We never encourage conduct which, in the abstract, we are bound to condemn, and which, if manifested in all the business relations of life, would effectually destroy all confidence, and would consequently be an unmitigated evil.

The last quarter of a century has been fruitful of such mighty changes, and such rapid agricultural development (very unlike the slow development of the jelly-fish to the monkey, and the monkey to the man), that all the relations between landlord and tenant require revision, and claim serious and immediate attention. Steam cultivation, the enormous consumption of artificial food, and the almost incredible quantities of artificial manures supplied every year to the soil, necessitate fresh rotations of crops, and altogether altered modes of industry, and call for new forms of agreement, and new conditions of tenancy and of sale. This seems to us so self-evident a fact as to be patent to every one, and to require no argument to enforce it. As we have already intimated, the yield per acre of the cereal crops grown upon a farm which is highly and adequately cultivated cannot be very considerably increased. We already think, and rightly so, that any effort to produce larger crops will, in favourable seasons, be fraught with evil, and result in loss. The increase will be in the bulk of straw, but with this there will be a corresponding decrease in the yield of grain. We need only remind you of the harvest of 1868 in proof of the correctness of this assertion. One of the greatest fears experienced by the modern farmer who cultivates his land highly, is that the first thunder shower in June will prostrate his luxuriant crops, and seriously reduce their money value. And all this because he uses too much cake, and is too generous in his application of artificial manures. How can these be done? What is the remedy for this state of things? Is his style of cultivation to be lowered that he may with greater prospect of profit to himself manage his farm in harmony with those stringent and unalterable covenants under which he occupies? Or shall these covenants be modified, and the privilege of doing additional and varying crops be conceded, encouraging a more free and extended, instead of a diminished and restricted, use of all those fertilisers which enrich the soil, and when applied with judgment, under right and favourable circumstances, benefit alike the owner, the occupier, and the consumer? We say, encourage high farming, give greater freedom of cultivation, and let the land everywhere teem with plenty. Make more meat; meat is dear, animals must pay for feeding now, are all utterances with which our ears are quite familiar. But the practical question is, how can more meat be made? and if made, what will be the result? To make more meat implies the use of more oilcake and other feeding agents, and the extensive use of these implies greatly enriched manure, and this manure, to be a source of profit to the farmer, implies an increased acreage of money-paying cropping, which implies the removal of restrictions and increased liberty of cultivation.

Surely it has not come to this, that agriculture must quietly fold her arms—do as Lord Russell said a few years ago it was our privilege as a nation to do, "rest, and be thankful." Shall the rolling tide of agricultural progress be stayed and dammed back because antiquated covenants and deep-rooted prejudices render its onward flow unprofitable? Will this be wise? Shall progress? or shall the restraints to progress? Shall intelligence or prejudice triumph? These are questions thoughtful men are presenting, and are shrewdly observing what are the signs of the times, that they may try to puzzle out what the answer shall be. There was a time when the idea of additional cropping was the occasion of the gravest apprehensions; and the possible, yea the probable, exhaustion of the soils was a bugbear which terrified many. But these fears are gradually subsiding, and we should rejoice to pronounce their funeral oration; but they are not dead, only dying; every now and then we detect signs of life. But science is making rapid strides, and day by day disclosing the futility and groundlessness of such fears, and in companionship with practice (an alliance at one time deemed incompatible) is teaching us how possible it is to increase production, and yet not lessen the fertility of the soil. We need only refer to the experiments which are being made year after year by Mr. Lawes, of Rothamsted, as an evidence of the truthfulness of this. Probably some of you may have seen these, and others may have read or heard of these; but be this as it may, they disclose to us what may be done, and how the decided advantage of high cultivation, conducted under the guidance of practical and scientific knowledge, and how surely it results in profit to the occupier, without loss to the owner. Many land agents and many landowners are intelligently and thoughtfully weighing these matters, and are preparing to remove and facilitate agricultural progress. We commend the subject to the attention of all. To say there are no difficulties in the way of a liberal extension of privileges is to assert what is not true, and to say that these difficulties are insurmountable is, we conceive, not the less untrue. Let tenants gradually and carefully feel their lands bountifully, and cultivated them wisely and well, the great hindrance to increased liberty would be removed. But so long as estates are encumbered with slovenly and grasping tenants, who, regardless of consequences, are ever seeking to take from, and ever unwilling to add to the soil, allowing their sterility and avarice to control all their operations, vainly imagining that such a system is to their advantage, and deluding themselves with the notion that in proportion as they impoverish the soil they enrich themselves—we say that as long as this state of things continues, the happy will there be no argument to be employed in opposing concessions so urgently needed. But the argument, however skilfully it may be used, is not a sound one. It cannot be wise to punish the good and discourage all progress, and set aside all advancement, and crush all spirit of enterprise, on the ground that some are unworthy. We entertain far too high an opinion of the intelligence and ability of those who occupy a position between the owner and the occupier, a position so honourable and responsible, as to suppose that they cannot devise some way of encouraging good tenants and high cultivation, and of repressing and restraining the evil practices of bad ones. It is not for us to assert dogmatically how and in what way this shall be accomplished. Suffice it to say we believe in its practicability, and are deeply impressed with its necessity. To put the matter briefly, our position is this. It is of the utmost national importance that the land should be made to produce all that the discoveries of modern science and the most skilful practical cultivation can possibly make it yield, and that everything that prevents the realisation of this should be at once and for ever removed; that by liberal management largely increased produce may be secured without any corresponding exhaustion of the soil; that increased production consequent upon high cultivation implies better rents to the owner, larger profits to the occupier, cheaper food to the consumer, and increased wealth to the nation; that the most important employment of this universal good is the system on which lands are let, and the restrictions which are imposed. We therefore, in conclusion, plead for a full and intelligent re-consideration of the terms on which land is let, and their adaptation to the exigencies of the times. The speaker concluded by moving "That it is desirable that all lands should be made to yield a maximum amount of produce, having regard to the continued fertility of the soil, and that whatever hinders the realisation of this must be regarded as a national evil, and is opposed alike to the interests of both owner and occupier, and requires to be at once removed."

Notices of Books.

Report on the Cultivation, by means of Sewage Irrigation, of the Lodge Farm, Barking, *for the year ending August* 31, 1871. Metchim & Son, 32, Clement's Lane, E.C.

We recur to Mr. Morgan's report of his proceedings and their results on the sewage irrigated farm near Barking, to which we referred last week, in order that we may present some extracts to our readers:—

"*The principal crops which need notice* are—The

Wheat, which although looking very well up to a late period, and judged at 4½ to 5 qr. per acre, became partially laid upon plot H, where we have had the same 5 acres bearing Wheat five years in succession. This Wheat, on being threshed, only rendered 30 bush. per acre, with a good yield of straw, and was sold in Mark Lane at 58s. per qr. It is not expected that the Wheat in the remaining part of plot H, which followed grass, or that on L, will reach 5 qr. per acre, nor that the small bit of Talavera on P will do so. The last was also laid by gales, and many of the ears are deficient.—The crops generally all over the country have fallen short of expectation, but both the crops on L and that from H, which still remains to be threshed, are good enough in quality to command the best prices.—The yield of Oats on L was upwards of 9 qr. an acre, of good sample, with straw in abundance.—Our Mangel cannot be excelled. It is generally expected that that which is sown early on E will yield 40 tons out quite 50 tons an acre.* That which was sown on May 9 on plot C will make 30 to 35 tons an acre, and that on plot I, sown (after the removal of the Cabbage) from May 20 to June 2, will be about 25 tons an acre. The crop of early Cabbages on plot I was our best paying crop, and brought £37 an acre between the removal of the Wheat last year and the sowing of the Mangel this year.—All the Cabbage crops have been good, with the exception of some of the red Cabbages, which came to nothing, owing to the seed not being 'true,' and of the small bit of Drumheads, which all clubbed, and were pulled for cattle.—The Parsnips, on plot I, are specially favourable to this crop, are apparently as good as those which last year were sold for £50 an acre on the ground.—A bed of James' scarlet Carrots, having been attacked by fly, when just coming through the ground, had to be resown, and, when taken up, proved to be a very good sample both in size and colour.—The Potatos on plots I and P received no direct dressings of Sewage. The land is good, and had been irrigated for previous crops. These plots, together with plot O, which was lately broken up pasture to which no sewage had been ever applied, yielded very good crops of Potatos, but the unfavourable state of the soil on plot F, from the rainfall and the dressings of sewage, necessary to their fertilisation, prevented a full development of the crop.—Upon plot K, good land, we have a small bed of Bovinia Potatos, which also suffered from the wet setting together of the land.—The Scarlet Runners, so far as the unequal quality of the seed has allowed, are excellent specimens of their kind, and are of great size, but so many of the seed failed to germinate that on one time a yesterday's rose of ploughing up the whole crop. As the Runners, however, spread they have partially filled the gaps, although, of course, the yield has been much reduced.—The Sugar-Beet seed was kindly supplied by Mr. Duncan's order, and it was intended to make four experiments therewith, viz. :—Two beds under irrigation, but unequally treated. One bed dressed with superphosphate of lime only, and the rest of the crops had been sowing with sewage ever since the farm was taken, and one bed also dressed with superphosphate, and in which transplanted Beet were to be put out. The quantity of rain which fell, the evidence of abundant vigour, and a great tendency of the plants to 'run' or 'bolt,' prevented sewage from being applied after the starting dressings to the two first beds, and the extraordinary manner in which the transplanted Beet 'bolted,' has somewhat interfered with our purpose. We have, however, an excellent crop both on the sewaged and unsewaged beds. I think the unsewaged crop is, if anything, the better, because the plants have not run to so much, neither are the roots, as a rule, so large, which is, I am informed, an advantage for sugar-making purposes. Those, however, upon either bed which bordered upon the main sewage carrier have grown to the large as our Mangel. It will be instructive to learn the percentage of sugar they give, and whether more sugar an acre is not produced by growing a number of large roots than by growing the same number of small ones, though each of the former produces but only a smaller percentage of sugar than the latter. The tendency of Mangel and Sugar-Beet to 'bolt' has been very generally evinced. The experiment will be a fair one, for all the bulbs, were well ploughed, deeply subsoiled, hand and horse hoeing was concluded by the moulding up of the plants.†—Judging from last year's experience we hoped that the Onion crop would have been the most profitable on the farm; but the result does not justify our expectations. Our crops were very good, but they were later than they would have been had the dung-cart been used. We had the option of either launching them early when others were sending better to market, or of keeping them for the warm weather to fill and ripen, and so market them later when all the others had exhausted their stocks. We selected the latter course, but instead of there being any appearance of a decrease in the general supply, more and more were forced upon the market; and though our Onions improved by the delay, the price did not; whilst the labour, owing to the wet weather, was much increased.—The Strawberries, also, were not as fine as we have sometimes grown them, and they were moreover late, the first bloom having been destroyed by frosts. The general abundance of this fruit likewise reduced the prices.—Amongst the other crops grown on a small scale, in all cases with successful results, were broad Windsor Beans, Vegetable Marrows, Cucumbers, Kohl Rabi, Rocca Onions, and Red Salsafy Beet. The Rocca Onions were planted out this spring, without any previous preparation of the land with dung, and have done well under sewage treatment alone. The Windsor Beans were excellent, and even the Marrows and Kohl Rabi. The red Beet is still in the ground, and looks to be an improvement on former years. The Cucumbers have also shown that they will prosper under sewage treatment."

We add Mr. Morgan's general comparison of 1869-70 with 1870-71, giving the answers to most of the questions which the reader will be disposed to ask :—

General Comparison between the Years 1869-70 and 1870-71.

"Eggs preserved in this manner can also be used for hatching, as the fat easily melts away by the heat of the hen; and by this means the eggs of foreign fowls might be carried to a distance, hatched, and naturalised, in this and other countries. The French also find that a mixture of melted beeswax and olive-oil is an excellent preservative.

"Eggs may also be preserved for cooking by packing them in sawdust, in an earthen vessel, and covering the top with melted resin, or tar or pitch, so that it contains preserved. They are also said to keep well in salt, in a barrel arranged in layers of salt and eggs alternately. If the salt should become damp, it would penetrate through the pores of the shell and pickle them to a certain extent. M. Gagne says that eggs may be preserved in a mixture made of 1 bush. of quick-lime, 2 lb. of salt, and 8 oz. of cream of tartar, with sufficient water to make it into a paste of a consistency to receive the eggs, which, it is said, may be kept in it fresh for two years; but eggs become tasteless when preserved with lime. It may be as well to mention here that eggs are comparatively wasted when used in making rice pudding, as they render it too hard and dry, and the pudding without them, if properly made, will be just of the right consistency.

"'Another way to preserve eggs,' says Mr. Dickson, 'is to have them cooked in boiling water the same day they are laid. On taking them out of the water they are marked with red ink, to record their date, and put away in a cool place, where they will keep, it is said, for several months. When they are wanted for use, they are again put into hot water to warm them. The curdy part which is usually seen in new-laid eggs is so abundant, and the taste is said to be so well preserved, that the nicest people may be made to believe that they are new laid. At the end of three or four months, however, the membrane lining the shell becomes much thickened, and the eggs lose their flavour. Eggs so preserved have the advantage of not suffering from being carried about.'

"'It ought not to be overlooked,' says Mr. Dickson, 'with respect to the preservation of eggs, that they not only spoil by the transpiration of their moisture and the putrid fermentation of their contents, in consequence of air penetrating through the pores of the shell; but also by being moved about, and jostled when carried to a distance by sea or land. Any sort of rough motion, indeed, produces a commencement of this change, whilst the yolk, and the germ of the chick in their proper places, and upon these becoming mixed, putrefaction soon follows."

"If the eggs are to be kept for setting, place a box, divided by partitions into divisions for the eggs of the different breeds, in a dry corner of your kitchen, but not too near to the fire; fill the divisions with bran previously well dried in an oven, put the eggs in it upright, with the larger ends uppermost, as soon as they are laid, and cover them with the bran. Mark each egg in pencil with the date when laid, and description of breed or cross. They should be kept in a cool but dry place, and place according to the season. Air-tight jars, closed with air-tight stoppers, may be used if the eggs are intended to be kept for a very long time."

Profitable Ornamental Poultry. By Hugh Piper. Groombridge & Sons.

This is a practical guide to the choice, breeding, rearing, and management of all descriptions of fowls, turkeys, Guinea fowls, ducks, and geese, for profit and exhibition. So says the author on his title-page—and the book justifies his description. It is a very instructive little volume, beautifully illustrated and printed, and full of information. How far the statements here collected are the result of the authors' own experience, does not appear; but at any rate he acknowledges perpetually his indebtedness to his predecessors, and the result is, as we have said, an extremely well packed and serviceable little volume. We select here a page on the old problem, how to preserve eggs, which seems never to lose its interest :—

"An egg exposed to the air is continually losing a portion of its moisture, the place of which is filled by the entrance of air, and the egg consequently becomes stale, and after a time putrid. M. Réaumer made many experiments in preserving eggs, and found that, by coating them with varnish, it was impossible to distinguish those which had been kept for a year from those newly laid; but varnish, though not expensive, is not always to be had in country places, and it also rendered the eggs unfit for use under a hen and impeded the hatching, while in boiling them, the varnish, not being soluble in hot water, prevented them from being properly cooked. He tried other substances, and found that fat or grease, such as suet, lard, dripping, butter, and oil, were well adapted for the purpose, the best of these being a mixture of mutton and beef suet thoroughly melted together over a slow fire, and strained through a linen cloth into an earthen pan. It is only requisite, he says, to take a piece of the fat or butter about the size of a pea on the end of the finger, and rub it all over the shell, by passing and repassing the finger so that no part is left untouched; the transpiration of matter from the egg being as effectually stopped by the thinnest layer of fat or grease as by a thick coating, so that no part of the shell be left unrubbed; or the tip of the finger may be dipped into oil and passed over the shell in the same manner. If it is desired that the eggs should look clean, they may be afterwards wiped with a towel, for sufficient grease or oil enters the pores of the shell to prevent all transpiration, without its being necessary that any should be left to fill up the spaces between the pores. They can be boiled as usual without rubbing off the fat, as it will melt in the hot water, and when taken out of the water the little grease that is left upon the egg is easily wiped off with a napkin.

Farm Memoranda.

WESTER ROSS: *Nov.* 14.—During the last two summers our horses had so large an amount of extra work to accomplish in connection with building houses and improving land, that they very much required the harvest rest when it came round. The crops, on the farm mainly, our reaper was not used in cutting any of this or the previous year's crops. Besides, there is not great difficulty in securing, in this quarter, a sufficiency of hands, at moderate wages, to cut and secure the crops in good time; and, when these are close and sufficiently early, there is not much loss by cutting them with the scythe. Never was there a season more suitable for scythe cutting than this, for a few nights before we began, by a heavy gale, accompanied with rain, the crops were all admirably laid in one direction, and in the same direction the wind continued to blow nearly all the harvest. The favourable circumstances we began cutting, on August 24, with eight scythes, 150 acres of Wheat, Oats, and Barley, and in 12 working days the whole was in stook, each scytheman having cut a little over 1¼ acre per day. In six additional working days the crops were safe in the stackyard, the stacks, not of a large size, numbering 80. The last of the crop was brought to the stackyard on September 15, the harvest thus extending over three weeks and two days, including sabbaths and wet weather,—the whole outlay for cutting, gathering, binding, leading, and thatching, being £32, or something over 4*s.* 3*d.* per acre. It must be remembered, however, that all the half-year servants were engaged in harvest work, and that a large proportion of the more costly part of the work was performed by them, and their wages are not included in the above amount. The wages of the different kinds of hands are as follows: —scytheman, 3*s.*; binders, 2*s.* 6*d.*; gatherers and rakers, 1*s.* 9*d.* per day, without rations. The cost per acre is so small that it could not have been materially lessened by the substitution of the reaper, particularly as the crops were not laid so suitably for the reaper as for the scythe. In thin and light crops, however, the work of the scythe is not once to be compared with the orderly and regular laying by the reaper.

This is one of the most profitable seasons the farmers in the North have had for many years. The cereal crops are abundant, and the grain, generally, of good quality. Wheat, although not yielding quite so largely as it did for a few previous years, threshes fairly, while the grain is of fine quality, weighing in some instances 65 lb. per bush., and the price is very satisfactory.

* We referred to this crop last week.

† The following are two analyses of Sugar-Beet from land which for about five years grown heavy crops by means of sewage irrigation—the land from which the first was taken having been treated with 2 cwt. per acre of superphosphate of lime only, and the other with full dressings of sewage only :—

No. 1.—*Dressed with 2 cwt. of Superphosphate of Lime per acre.*

Weight of Roots.			Average Weight.	Percentage of Sugar in Roots.
lb.	oz.	lb. oz.	lb. oz.	
1	13	to 3 6	2 9	7.83
2	1	,, 4 11	3 2	6.03
6	11	,, 9 11	8 10	4.09

No. 2.—*Dressed with 308 tons of Sewage per acre.*

Weight of Roots.			Average Weight.	Percentage of Sugar in Roots.
lb.	oz.	lb. oz.	lb. oz.	
1	0	to 3 10	2 10	8.03
4	8	,, 5 7	4 15	7.13
9	2	,, 10 13	9 15	5.06

"The above analyses have been kindly made for us by Mr. Duncan from roots sent to him from the Lodge Farm. Mr. Duncan has just commenced operations at Lavenham, where the roots are fully 2 per cent. less rich in sugar this year than usual, owing to the unfavourable season.

"As the same complaint comes from Continental growers, the results which we have obtained must be regarded as very satisfactory, since a command of sewage can be made to assure, in all seasons, a very much larger crop of Beet than can be otherwise obtained, the amount of sugar in the root being, at the same time, of a full average percentage. I am informed that the large sized roots, giving, as they invariably do, a low percentage of sugar, will not pay the sugar maker, but are suitable for distilling purposes.

"There appears to be no difference in the weight generally between the experiments, and, after making a very full allowance for the adhering mould, our present year's crops will, it is expected, considerably exceed 30 tons an acre."

* The profit for year 1869-70 was reduced by loss of dairy stock amounting to £612 17*s.* 4*d.*

The colour of Barley is not so fair as we would like, but it also weighs well, and fetches from 34*s.* to 35*s.* per qr. Oats yield better than they have done for several years. Our Turnip crop was, perhaps, never better—Swedes, particularly, being unusually fine. Potatos are an abundant crop, of excellent quality, and generally free from disease. They are now finding their way in large quantities to the South, and the money is flowing into the farmers' pockets in a delightful stream. There is no agricultural community a good crop of which is more beneficial to the small holder of land than Potatos. He rarely grows Wheat, and consequently does not participate in the high price now and then got for it; but Potatos grow on poor land nearly as well as, and often healthier, than in richer soil, and consequently he has his full share of profit therefrom; and it was high time that such a season should visit him, as the series of dry years we had, adverse as they were to the growth of Oats, pressed heavily on him, his principal cereal crop being Oats. Foot-and-mouth disease has been pretty general, and still largely prevails, but sheep and cattle, on the whole, are doing well, favoured as they are with a fine season and abundant keep.

The Week's Work.

NOVEMBER 25.—*Draining Operations* should be prosecuted with vigour on arable farms, so as to get the work finished in time for the land being ploughed. There is still much land undrained, and large areas that have been only half drained—a drain between every two being necessary to remove heavy showers, and thus avoid flood-water. Again, some of the drains in the earliest drained land are beginning to give way, and the wider the drains are placed asunder, and the less perfectly the land is drained, the sooner the drains give way and require to be renewed by deepening. It must ever be borne in mind that the artificial drainage of land is rarely a permanent work. Moreover, the action of a drain during its existence is not always uniform; much, of course, depends upon the nature of the land and the way in which the work of drainage has been executed, together with the quality and durability of the draining pipes or materials used in draining. A bad pipe near the bottom of the field, by giving way, will destroy the drainage above it, hence the care with which pipes should be selected and put into the drain—all broken or improperly burnt ones being thrown aside. It follows, also, that drainage work at this season should be carefully examined, to see that the drains are all acting uniformly. Where they discharge their contents into main drains, as they always should do, it is not easy to determine whether they are discharging equal quantities of water; but when a drain "bursts," *i.e.*, becomes choked, and ceases to act, the rising of the water and the wetness of the land around can easily be seen. In bad cases, the drainage should be repaired immediately, and this is perhaps the best rule generally. But in young Wheat crops, if seeds it may, in exceptional cases, be advisable to mark the wet spots, and defer the opening of drains until after the next harvest; or a temporary repair may be made by opening a cut between the drain that has burst and the one nearest to it, so as to turn the water of two drains into the latter. This, however, is not a perfect mode, and should not be trusted beyond the end of the ensuing harvest. In some cases the failure is so easily seen that a cut can be dug down to the broken pipe, or series of pipes, where the ground has been washed away under (a very common mishap), and the repair effected at once. When draining is going on in a new manner, the best plan is to open a series of cross main drains, before the Wheat is sown or seeds, so as to relieve the others, and expedite repairs between the mains thus opened, where the parallel drains give way.

Steam Cultivators, under favourable circumstances, should be finished by this time, with the exceptions should be proceeded with as fast as the facts of the case will permit, such as drainage and the like. This is, perhaps, the best time for breaking up by steam poor wet pasture lands that have been badly drained; also wood land that has never previously been subject to the plough, in order to get it exposed to the winter frost and rain. Where the bottom is of a suspicious character, it is better to plough shallow and subsoil deep, so as to well ventilate the bottom. If this is thoroughly done, the alternate freezing and washing, with subsiding of the soil, will have a powerful effect in preparing the land for manure and the growth of crops. It often happens that inattention to the proper depth of ploughing and subsoiling is more than a season lost in the reclaiming of wet, clayey land, or land of any kind that has a bad bottom. Dry, calcareous, gravelly, and sandy soils form an exceptional class that may be cultivated by steam as successfully just now as at the close of harvest, so far as the mere work of ploughing is concerned, as they do not "squeeze" and "paste" like tenacious clays that have by this time absorbed their maximum of water; clayey soils of the latter class should be ploughed by steam when in a comparatively dry state, when, instead of "pasting," the furrow slice is left behind the implement broken into a thousand fragments.

Anthills cut and spread. Frost and cold rains both kill the ants, but when spread abroad in fine open weather they are apt to find a lodging for the winter. Dig out at the same time and remove Tussack-grass, Docks, Thistles, and other weeds in the pastures. If the land is to be top-dressed immediately, it is better to cart off anthills, Tussack-grass, &c., to a compost hill, and mix with lime or liquid manure, so as to destroy animal and vegetable life.

Fat Stock Exhibitions are now one of the chief attractions of the season. From the facilities which railways afford for travelling, the farmers of different counties enjoy the opportunity of seeing the fattening properties of different breeds, and of learning much that cannot be taught at home; and it is questionable if our Christmas meetings are so generally attended as they should be for educational purposes. No doubt the fattening process is too much in the extreme for many, but from an educational point of view the objection falls to the ground, for the fat ox, sheep, or pig can be sent to the shambles at any stage of the process.

Notices to Correspondents.

BOVINIA POTATOS: *H. M.* informs us that from 10 lb. of sets of the above Potato, Mr. Gill, Lodge Farm, Carthorpe, Bedale, has harvested 4 cwt. of fine sound Potatos, many of them nearly 12 inches in length, whilst the Victoria and Regent Potatos planted on each side of them were nearly all diseased.

COPROLITES: *Hussar* says—I have an estate in Cambridgeshire on which coprolites exist in great quantities and are being dug. I am anxious to learn all about them—their history, component parts, and the process of manufacturing them from the raw material into artificial manure. Is there a work on the subject, or how can I get the information I require? [We will procure the information for you.]

POULTRY AND FOOT-AND-MOUTH DISEASE: *A Subscriber from the Beginning* wishes to learn if, when the foot-and-mouth disease has prevailed amongst cattle, it has been known to extend to poultry—for instance, turkeys. [Poultry are certainly liable to foot-and-mouth disease. See the article on the subject at p. 1525.]

ROYAL AGRICULTURAL SOCIETY: *F. H.* Send your name and address to the secretary, 12, Hanover Square, W. £1 is the annual subscription.

Markets.

ENGLISH WOOL.

The upward tendency in wool still continues, and the stocks in the hands both of manufacturers and dealers are becoming much reduced, and those best able to judge consider that nothing some unforseen event should arise to check consumption a further advance of 1*d.* to 2*d.* between this and next clip is inevitable.

MARK LANE.

MONDAY, Nov. 20.

The supply of English Wheat to this morning's market was small, and was sold at an advance of 1*s.* per qr. upon the prices of this day se'nnight. The attendance was good, and a fair amount of business was transacted with Russian, in a similar improvement; other descriptions were unchanged in value. Malting Barley sold slowly at late rates; grinding Barley and Beans and Peas were unaltered in value. Oats were 1*s.* per qr. dearer. Flour remains as last quoted. Maize brought rather more money.

WEDNESDAY, Nov. 22.

A firmer feeling pervaded the Corn Exchange to-day. The supplies of English Wheat were short, but those from abroad were large. Transactions were not numerous, but the improved rates current on Monday were well maintained. Barley sold quietly on former terms. Malt was taken cautiously, at previous quotations. Large supplies of Oats were on the stands; the demand was fairly animated, and for all descriptions full prices were realised. Beans and Peas were steady, both in value and demand. Flour was quiet, but firm.

LIVERPOOL, Nov. 21.—Red winter and finer qualities of white American Wheat were readily sold, at prices rather higher than Friday's, but for other descriptions the demand was quiet. Flour was steady but slow. Beans and Peas unchanged. Indian Corn met a free sale, at a decline of fully 3*d.* per qr. on the market price.

METROPOLITAN CATTLE MARKET.

MONDAY, Nov. 20.

We have a larger number of foreign Beasts on offer than last Monday, of English there is no increase. There is great difficulty in effecting a clearance, and last week's quotations are barely reached. There are a few more Sheep, and the weight of mutton is considerably increased; our top quotation is only realised for choicest descriptions—the tendency is decidedly downwards for all kinds. The trade for Calves remains unaltered. Our foreign supply consists of 2600 Beasts, 10,600 Sheep, and 180 Calves; from Scotland there are 57 Beasts; from Ireland, 1200; and 1293 from the Midland and Home Counties.

Beasts, 5090; Sheep and Lambs, 19,000; Calves, 184; Pigs, 150.

THURSDAY, Nov. 23.

The number of Beasts is smaller than last Thursday, but the demand has equally decreased; on the average Monday's quotations are not reached, although some of the choicest qualities have made about the same. There is little business doing in the Sheep market. The supply is about the same as last week; the demand is, however, smaller, and a clearance cannot be effected, notwithstanding prices are rather lower. There is no alteration in the Calf trade. Our foreign supply consists of 340 Beasts, 5830 Sheep, and 108 Calves, and 15 Figs.

SEED MARKET.

We have to report increased activity in the seed trade. During the past week the demand for red Clover seed has been very brisk, and large quantities of seeds have changed hands, at enhanced currencies. New American red has been sold at 60*s.* per cwt.; in yearling parcels there has also been a good business doing. The crop in the south and west of Germany is described as being very deficient; in Silesia, however, the yield is said to be fair. For anything good in old English Clovers long prices are asked. White Clover and Alsike are exceedingly firm; the same may be said of Trefoil seed. French Italian has continued its upward movement, and must be noted 2*s.* per cwt. dearer on the week. Perennial Grasses are steady, at the high rates recently touched. Fine Lucerne seed is scarce and dear. For Mustard and Rape the trade is quiet. Feeding Linseed is in good request. Hemp and Canary are without alteration. The frosty weather has improved the trade for boiling Peas and Haricot Beans.

STEVENS'
"TRENTHAM" IMPROVED CORNISH BOILER.

The Advertisers have great pleasure in calling the attention of Gardeners, and all interested in Horticulture, to the above excellent Boilers. Being of the most simple construction, and in wrought iron, they are very durable, economical, and powerful; and, in the opinion of many competent judges, are superior to all other Boilers, even to the most approved form of Tubulars.

Appended are a few Testimonials :—

"ROYAL EXOTIC NURSERY, Chelsea, S.W.

"DEAR SIR,—Having now had your Boilers at work here for some months, we are very pleased to be able to report most favorably of them. They are certainly more powerful than the Tubulars they have replaced here, more economical as regards consumption of fuel, and they do not require so deep a stokehole.

"We shall be pleased for you to refer any one here who may wish to see the Boilers at work, and examine them. We have already recommended them to many people, and we are sure they will by degrees become largely used.—We are, dear Sir, yours, very truly,

"JAMES VEITCH & SONS."

"Combe Abbey Gardens, near Coventry.

"I feel that anything I can say in favour of Mr. Stevens' Boiler will come very far short of its real merits. The dilemma of choosing a Boiler has now been set at rest, by the advent of Mr. Stevens' Improved Cornish. Its introduction has made our heating a masterpiece, one Boiler heating 4000 feet of 4-inch pipe. It saves considerably both in time and labour, by comparison with the now discarded Tubular Boiler. "WM. MILLER."

"Ingestre Hall, Stafford."

"DEAR SIR,—I am delighted with your Improved Cornish Boiler. It is by far the simplest and most powerful Boiler I ever used, and economises my fuel and labour to an extent that I could not have believed possible, unless I had had ocular demonstration of the fact.

"W. PHIPPS."

"Huntroyde Park, Burnley.

"DEAR SIR,—We have had your Improved Cornish Boiler upwards of two years, heating more than 2000 feet of 4-inch piping, and I feel that I cannot speak too highly in its praise.

"I have worked a good many kinds of Boilers, but not one that requires so little fuel and labour to do so great an amount of work as yours, and when the Boiler becomes known it will be very generally used. "H. LINGSAY."

"Atherstone Grapery.

"DEAR SIR,—Your Boiler is the simplest and most powerful that I ever used, and I would back it to beat any boiler now in use, for economy of fuel and labour with thorough efficiency.

"It is a real *Gardeners'* Boiler, and will be as commonly used as the Old Saddle has been when it becomes known. "G. SAGE.

Agricultural Land Improvements.

DRAINAGE, IRRIGATION, FARM BUILDINGS, LABOURERS' COTTAGES, &c.

THE GENERAL LAND DRAINAGE and IMPROVEMENT COMPANY (Incorporated by Act of Parliament in 1849.)

DIRECTORS.

T. Chapman, Esq., F.R.S. George Thomas Clark, Esq. C. Cobbold, Esq. Henry William Currie, Esq. The Right Hon. Viscount Combermere. Edward John Hutchins, Esq. Sir William Tite, M.P., C.B. Principal Engineer, Mr. J. BAILEY DENTON.

Agricultural improvements of every kind are executed by the Company, or the outlay thereon repaid to Landowners who prefer carrying out the works for their own account.

Tenant Farmers may also, by agreement with their Landlords, procure the execution of such Improvements.

The outlay, with all official expenses, may be charged upon the Estate, and paid off by a Rent-charge of about 6 per cent., in 21 years, or at the option of the landowner, in a shorter term.

No investigation of title necessary, and no legal expenses incurred.

UTILISATION of SEWAGE.

Special arrangements will be made with Boards of Health, Sewer Authorities, and others, for undertaking Works of Sewage Irrigation, in connection with all Works incidental thereto. The outlay in respect thereof may be repaid either by a sum in gross, or by a terminable yearly payment, during a fixed period the Company may be entrusted with interest thereon.

Application to be made to ARTHUR MILMAN, Esq., the Secretary, at the Offices of the Company, 29, Whitehall Place, S.W.

THE LANDS IMPROVEMENT COMPANY.
(INCORPORATED BY SPECIAL ACTS OF PARLIAMENT.)

DRAINAGE, RECLAMATION, FARM BUILDINGS, LABOURERS' COTTAGES, TRAMWAYS, RAILWAYS, &c.

DIRECTORS.

John Clutton, Esq. Frederick L. Dashwood, Esq. Henry Farquhar, Esq. Lord Garlies, M.P. John Horatio Lloyd, Esq. Granville R. Ryder, Esq. Granville R.H. Somerset, Esq., Q.C. Henry W. Wentt, Esq., M.P. Charles Watkin Williams Wynn, Esq., M.P. (Chairman).

The Company advances money, unlimited in amount, for all purposes of Agricultural Improvement, including the Erection of Cottages and Farm Buildings, to Tenants duly entitled and desirous of the same by the Clergy in respect of their Glebe Lands.

Tenants may, with the consent of their Landlords, execute the necessary Improvements upon the Farms which they occupy, charging them with the cost.

UTILISATION of SEWAGE.—The Company also advances money for the purpose of Works of Sewage Irrigation.

The whole outlay and expenses are liquidated by a rent-charge upon the land, redeeming principle and interest, over 25 years.

No investigation of title is required.

For Forms and further information, apply to GRANVILLE R. RYDER, Esq., Managing Director, No. 1, Great George Street, Storey's Gate, Westminster, S.W.

Works on Botany, by Dr. Lindley.

SCHOOL BOTANY; OR, THE RUDIMENTS OF BOTANICAL SCIENCE. In One Volume, 8vo, half bound, with 400 Illustrations, price 5*s.* 6*d.*

DESCRIPTIVE BOTANY: OR, THE ART OF DESCRIBING PLANTS correctly, in Scientific Language, for Self Instruction and the Use of Schools. 12mo, 4*s.* Bound.

MEDICAL and ŒCONOMICAL BOTANY; or An Account of the Principal Plants employed in Medicine or Domestic Œconomy. In 1 vol. 8vo, with numerous Woodcuts, price 7*s.* 6*d.*

THE VEGETABLE KINGDOM; OR, THE STRUCTURE, CLASSIFICATION, AND USES OF PLANTS. Illustrated upon the Natural System. In One Volume, 8vo, cloth, price 36*s.*, with upwards of 500 Illustrations.

EXTRACT FROM THE AUTHOR'S PREFACE.

"The Vegetable Kingdom contains, upon a super quantity of plants of no known importance to man, various useful species employed in medicine, the arts, or the many branches of domestic economy. The principal part of those which only grow in botanic gardens in Europe under the notice of students, or which, from their great importance, deserve to be among the earliest subjects of study, are mentioned in the following pages, where they are arranged in the manner pointed out in my 'VEGETABLE KINGDOM' to which work the sequence of matter departed from in a few instances, when it was believed that the convenience of younger students would be consulted by doing so. The author trusts that this selection will be found to have been made in such a way that all teachers who possess reasonably extensive means of illustrating their Lectures, and all Botanic Gardens, may furnish the larger part of the species which are mentioned. A small selection was indispensable, but, otherwise, a greater work would have been beyond the reach of the majority of professors; and, on the other hand, a smaller one would be inadequate to those who have to study a science of observation, such as Botany, require to accompany it."—Preface, page 9, in the first instance, upon a limited number of objects."

LARCH for SALE.—One Hundred Thousand strong transplanted Larch, 2 to 3 feet.
S. BALE, Westerton Nursery, Burntisland.

LARCH for SALE.—A large quantity of fine transplanted Larch, from 2½ feet to 3½ feet; also some WELLINGTONIA GIGANTEA, ABIES DOUGLASII, Common SPRUCE, and ABIES MENZIESII, from 6 to 8 feet.
H. CARRIER, Dodington, Sittingbourne, Kent.

FOR SALE, a splendid PAIR of CAMELLIAS, to name, in tubs, 6 feet high, and as much through, in vigorous health, and well set with bud. Also FIVE large AZALEAS, 2½ to 3 feet high and through, in good condition, and well set.
GEORGE SELLEY, Kirkdale Nursery, Upper Sydenham, S.E.

NOTICE.—The GARDENERS' CHRONICLE and AGRICULTURAL GAZETTE for DECEMBER 9 will contain a FULL and ILLUSTRATED REPORT of the SMITHFIELD CLUB CATTLE SHOW.

Copies may be obtained on Friday morning, December 8, at STAND No. 88, Galleries, Agricultural Hall.

The Gardeners' Chronicle

SATURDAY, DECEMBER 2, 1871.

MEETING FOR THE ENSUING WEEK.

WEDNESDAY, Dec. 6	Royal Horticultural (Fruit and Floral Committees), at S. Kensington	11 A.M.
	Ditto (Scientific Committee)..	1 P.M.
	Ditto (General Meeting) ..	3 P.M.

IN another paragraph we have noted the days on which the next year's Meetings and Shows of the two principal London Societies, are announced to take place. The PRIZE SCHEDULES of the ROYAL HORTICULTURAL SOCIETY, which are in course of distribution, now lie before us, and we proceed to note some of the provisions made for the meetings at Kensington.

In the first place, we are glad to observe that the principle adopted some two or three years since, of offering encouragement to a variety of subjects which develope their beauties in succession throughout the year, and of not limiting the prizes to such as can be squeezed into the summer shows, has been adhered to. It is only by iteration that the invitation to grow other than the routine "show" plants, can be made to exert its proper influence on the contents of our gardens. The results are most unfortunate when radical changes in matters of this sort are too frequently made and unmade, since no one knows what to be about; and a single season is, in many instances, not sufficient to enable the grower to get up a set of unfamiliar plants, or even a specimen example.

Next, we note with approval the fact, that a show something more like the grand displays of former days, is to be attempted once in the course of the season, namely, on the first meeting in June—this to be a three-days' show. This will consequently be the Society's special *fête*; and it is to be hoped that the foreign horticulturists who come to take part in international contests, as well as those who may come only to see what English gardening is like, may find in it something of a more attractive character than was presented to them at the meetings of the past summer, when no special effort was made. This great show will also, we trust, be on a scale sufficient to satisfy the longings of those country horticulturists who complain that no London shows no longer offer them the same kind of attractions or inducements to visit them which they were wont to find in days gone by—a truism probably, but not wholly arising, as some would have it, from the inferiority of modern shows, either as regards display or culture, but partly, at least, attributable to the unsatisfied craving which is ever crying out for something beyond, and which, in fact, has already, step by step, led to the swallowing up of the space of our exhibitions by those elephantine specimens

which, whatever may be said in their disparagement, we cannot entirely dispense with, now that we have once had them.

For the behoof of our foreign friends, there are various competition prizes offered among new plants, which form the class of exhibits most freely brought from the "other side of the water." Thus, there are classes for—

6 new plants, in or out of flower, introduced by the exhibitor, and not in commerce. Open . .	} Gold Medal.
2 new plants, shown for the first time in flower. Open	} Gold Medal.
1 new plant in flower, introduced by the exhibitor, and not in commerce. Open . .	} Gold Medal.
1 new plant, not in flower, introduced by the exhibitor, and not in commerce. Open . .	} Gold Medal.
12 new plants, in or out of flower, sent out in 1870 and 1871. Open. . .	} Large Silver Medal.

Besides these, foreigners are specially invited to compete with Agaves and Cacti; they can, moreover, enter into competition with English growers in any of the classes of the schedules; and are further invited to contribute specimens or collections of plants or fruits not specified therein, as well as to make permanent exhibitions of such plants—Cycads, Pandanads, Palms, Arads, Ferns, for example—as may be suitable for that purpose.

Comparing the schedules with those of last year, we find that especial care has been taken to invite a set of new growers, in the shape of persons who have not taken the Society's prizes in the respective subjects on previous occasions. Small groups of stove and greenhouse plants, of Heaths, of Orchids, of Ferns, of Hyacinths, &c., are introduced with this object. The prizes for Azaleas in April have been considerably amplified, and should bring a better display than has usually been seen at the early shows; while at the great show in June (which, as already stated, is to last three days) the prizes are generally augmented for all the more important classes. Roses remain much as before, except that at the second meeting in May a grand prize of £20, with three other proportionate prizes, is offered for a group of 50 plants in 8-inch pots; and another of £12 for 12 specimen plants. The fruit schedule is extended at the great June show, by the multiplication of classes, but probably more might still be made of this element. An International Fruit Show, for which special schedules will be framed, is, however, announced for November. Dinner-table arrangement is revived—two classes, with first prizes of £30 and £10 respectively, being provided at the second meeting in May, the smaller one to be tested partly by economy of cost in the proposed arrangement. Delphiniums, Phloxes, Pentstemons, Lobelias, Hardy Perennials, &c.—all good subjects if well handled—are retained; and we really hope the growers will let us see something like good examples of them, equal in quality to the perennials which have been shown from Tooting, and the Phloxes from Stanstead Park.

The Florists have encouragement offered for Auriculas, Pansies, Ranunculuses, Roses, Pelargoniums, Fuchsias, Pinks, Carnations, Picotees, Phloxes, Gladioli, Verbenas, Hollyhocks, Dahlias, and Chrysanthemums; and Tulips would have been also, but for the fact that the meetings do not fall conveniently for them; so that the wants of this class of the horticultural body are fairly met. Of absolute novelty there is but little. Poinsettias form a class in November, Roman Hyacinths in December, and Rhododendrons, in baskets or pots, in May; all being subjects eminently suitable for exhibition.

The meetings of the Floral and Fruit Committees remain as before, certificates being offered on these occasions for deserving novelties.

Such, in the abstract, is the London programme of the Royal Horticultural Society; and it is only fair to the Council of the Society to add, that while its schedules are comprehensive and liberal, and such as should command the hearty co-operation and goodwill of the British section of exhibitors, it is understood that the arrangements in progress for setting out the exhibitions will show something at least of the improvement in this direction which has so long been desired. The details of the Provincial Show, and of the international department of the London Shows, remain to be adjusted.

—— We extract the following remarks on the London Parks and their surroundings from the admirable letters of M. Taine, translated in the *Daily News*. It will be seen how greatly the opinion of a cultivated Frenchman differs from that of some of our home detractors :—

"Enormous, enormous!—this is the word which always recurs. Moreover, all is rich and well ordered; consequently, they must think us neglected and poor. Paris is mediocre compared with these squares, these crescents, these circles and rows of monumental buildings of massive stone, with porticoes, with sculptured fronts, these spacious streets; there are 60 of them as vast as the Rue de Paix. Assuredly, Napoleon III. demolished and rebuilt Paris only because he had lived in London. In the Strand, in Piccadilly, in Regent Street, in the neighbourhood of London Bridge, in twenty places, there is a bustling crowd, a surging traffic, an amount of obstruction which our busiest and most frequented boulevard cannot parallel. Everything is on a large scale here; the clubs are palaces, the hotels are monuments; the river is an arm of the sea; the cabs go twice as fast; the boatmen and the omnibus conductors condense a sentence into a word; words and gestures are economised, actions and time are turned to the utmost possible account; the human being produces and expends twice as much as among us.

"From London Bridge to Hampton Court are eight miles, that is, nearly three leagues of buildings. After the streets and quarters crowded together, as one piece, by wholesale, like a hive after a model, come the countless pleasure retreats—cottages surrounded with verdure and trees, in all styles, Gothic, Grecian, Byzantine, Italian of the Middle Ages, or of the Revival, with every variation and every shade of style, generally in lines or clusters of 5, 10, 20 of the same sort, apparently the handiwork of the same builder, like so many specimens of the same vase or the same bronze. They deal in these as they deal in Parisian articles. What a multitude of well-to-do, comfortable, and rich existences! One divines accumulated gains, a wealthy and spending middle class quite different from ours, more active, so straitened, by no means vain, in brown brick, are pretty by dint of tidiness; the window-panes sparkle like mirrors; there is nearly always a green and flowery patch; the front is covered with Ivy, Honeysuckle, and Virginian.

"The entire circumference of Hyde Park is covered with houses of this sort, but finer, and these in the midst of London retain a country look; each stands detached in its square of grass and shrubs, has two doors, is in the most perfect order and condition, a portico, a bell for the tradespeople, a bell for the visitors, a basement for the kitchen and the servants, with a flight of steps for the service; two stories for habitation, with curtained or double sun shutters; large clear windows, which let in plenty of light; flowers on the sills and at the portico; stables in a mews apart, in order that their odours and sight may be kept at a distance. The external decoration is varied with white, shining, and varnished stucco; not a speck of mud or dust; the trees, the turf, the flowers, the servants prepared as if for an exhibition of prize products. How well one can picture the inhabitant of such a villa to himself! In the first place, it is the Teuton who loves Nature, and who needs a reminder of the country; next, it is the Englishman who wishes to be by himself in his staircase is the room, who detests the promiscuous existence of our huge Parisian cages, and who, even in London, plans his house as a small castle, independent and enclosed. Besides, he is simple, and does not waste his money; on this side of society it is exacting in the matter of condition and comfort, and separates his life from that of his inferiors. The number of such houses at the West End is astonishing! The rent is twenty £ 200 a-year, and five to seven servants are kept in the master expends from £1200 to £2400 a year. There are ten of these fortunes and these lives in England to every one in France.

"The impression is the same when visiting the parks; the taste, the area are quite different from what is the case among us. St. James's Park is a genuine piece of country, and of English country; huge old trees, real meadows, a large piece of water with ducks and waterfowl, and also sheep, in an enclosed space, feed on the grass, which is always fresh. There are even sheep in the narrow green border that surrounds Westminster Abbey; these people love the country in their hearts. It is sufficient to see their literature from Chaucer to Shakespeare, from Thompson to Wordsworth and Shelley, to find proofs of this. What a contrast to the Tuileries, the Champs Elysée, the Luxembourg! There, as a rule, the finest garden, that of Louis XIV., is a room or gallery in the open air, wherein to walk or converse in company; in the English garden, such as they have invented and propagated, one is by oneself alone; the sense of solitude is verse with natural things. We have arranged a park on this model in the Bois de Boulogne; but we have committed the blunder of placing therein a group of rocks and waterfalls, of which the artifice is discovered at a glance, and offends; English eyes would have felt it.

"Regent's Park is larger than the Jardin des Plantes and the Luxembourg together, and is so well contrived that our life seems to have cooped up, confined; they need air and space more than we do; Englishmen whom I knew in Paris left their windows open all night; thus is obtained the most pure motion, their breath passes in the country. Stendhal justly said that a young English girl walks a greater distance in a week than a young Roman girl in a year; the Northern man, of athletic temperament, has need of free respiration and of exercise. This park is in a retired neighbourhood; one hears no longer the rolling of carriages, and one forgets London; it is a solitude. The sun shines, but the air is always charged with damp clouds, ready to drop drop-pots, and twelve in rain every quarter of an hour. The vast watery meadows have a charming softness, and the green branches drip with monotonous sound upon the still water of the ponds. Enter a hothouse with three-pronged fork! Orchids, some having the rich velvet of the Iris, others a flesh colour of that inexpressible, delicious, mingled tint transfused with light, like palpitating living flesh, a woman's breast; the hand desires, yet dreads to press it; alongside, Palm trees raise their stems in a tepid atmosphere. A strange thing to us is that there are no keepers; admission is free, and no damage is done. I can understand that they must ridicule our establishments and public festivals, with their accompaniments of municipal guards. It is the same at the railway stations; every one is free to move about, to stand on the side of the line, to come and meet his friends at the carriage door. They are surprised and annoyed to see us caged in our waiting-rooms, enclosed, led like sheep, and always under the eye or the hand of an official."

—— Both the Royal Horticultural and the Royal Botanic Societies have now fixed and announced the days for their shows and meetings in 1872. Those of the Royal Horticultural Society take place on :—January 17, February 14, March 6 and 20, April 3 and 17, May 1 and 15—16, June 5—7 and 19, July 3 and 17, August 7 and 21, September 4 and 18, October 2, November 6, December 4. It will be seen that there is a two-days' show in May, and a three-days' show in June, the latter being the grand show of the season. The Royal Botanic Society announces spring shows on March 13, April 10, and May 8, and summer shows on May 22—23, June 19—20, and July 10—11, all the latter therefore being two-day meetings. It will also be seen that the June show is fixed for the same day as the meeting at Kensington, a blunder which will necessarily lead to a conflict of interests, and which, as the Royal Horticultural days are in regular sequence (first and third Wednesdays), and had been, moreover, publicly announced, should not have taken place.

—— By way of supplementing the remarks of Mr. Newton, in another column, on the Ornamental Water in Victoria Park, it may be worth while to show how much is made of it in addition to its pictorial effect. Two yacht clubs, we are informed, belong to it, one called the Victoria the other the Prince of Wales, each employing the lake for sailing matches, the prizes consisting of cups, &c. Each club is governed by a commodore, vice-commodore, secretary, treasurer, and committee. The yachts are divided into three classes, viz., third-class cutters, which are 4 feet 6 inches long; first-class schooners, 4 feet 6 inches long, all measurements being made at the water line. Each club is limited to a certain number of members, owning boats of 70 vessels. The lake is also much used for bathing purposes by the class of visitors who frequent this park; and to show how much this privilege is appreciated, we may mention that on the first Sunday morning in August in the year 1868 the number of persons who entered the gates leading to the water was 18,642; it was further calculated that 12,000 bathed that morning between 4 and 8 o'clock. About 80 acres of this park, too, consists of open grass space, to which as many as 82 cricket clubs are attached, for the purpose of practising and playing matches.

—— The Maximum Temperatures of the Air for the week ending November 25 ranged from 51° at Greenock to 44° at Hull, with a mean for the English stations of 43°·4, and for the Scottish of 48°·7. The Minimum Temperatures ranged from 34°.5 at Greenock to 19° at Leicester, the mean for the several English stations being 23°.7, and for the Scottish 28°.5. The highest Mean Temperature, 41°.2, was recorded at Greenock, and the lowest, 34°.6, at Hull; the mean for the English stations being 34°.6, and for the Scottish 37°.8. Thus the air during the past week has been warmer in the northern country than in the southern, both by day and by night. The cold weather that set in at the beginning of the month continued during the past week. On the 19th the mean daily temperature was 30°.1, being 11°.7 below the average, and on each of the other days generally less than 35°, all being in defect of the average, though to a less extent. Rain fell at all stations, but much less in quantity in England than in Scotland; the greatest fall in the southern country being 0.72 inch at Portsmouth; 2.30 inches fell at Greenock, and 2.15 inches at Dundee; all the other stations in Scotland, with the exception of Aberdeen, recording a fall of more than 1 inch. The mean fall for the English stations was 0.35 inch, and for the Scottish 1.69 inch. (See Mr. Glaisher's Tables, p. 1555.)

—— It might not unreasonably be supposed that we had Peas enough of all grades of earliness, and all degrees of excellence; but those who, like Mr. Laxton (one of our best and most careful hybridisers), are ever on the look-out for new and improved varieties, are not disposed to stand still; neither is the public at all more willing to stick to the old love, if we may judge from the prices asked for the new. Messrs. Hurst are the agents for Mr. Laxton, and it is certain that many of that gentleman's varieties, such as William the First, are of excellent quality; others, such as Superlative, are better adapted for the exhibition table. Whether they are worth the price asked, is for the consumer to consider.

—— We have before us the programme of a great Exhibition of flowers, fruit, vegetables, and horticultural subjects generally, to be held at Berlin in June next, in celebration of the 50th anniversary of the establishment of the Society for the Promotion of Horticulture in Prussia. The exhibition will be held from June 21 to June 30. Prizes to the extent of 2000 thalers (£300) are offered by the Society, in addition to special prizes offered by individuals for groups, Palms, Ferns, Roses, coniferous plants, and cut flowers, the details of which will be hereafter published. The schedule is divided into three classes—1, for

miscellaneous stove and greenhouse plants, including 46 classes; 2, for plants representing special orders or genera, *e.g.*, Orchids, Aroids, Lilies, Pelargoniums, &c., 62 classes; 3, fruit and vegetables, 9 classes.

—— From an advertisement in another column it will be seen that the valuable collection of BOTANICAL and HORTICULTURAL BOOKS of the late Mr. BAXTER is to be sold by anction at the Clarendon Hotel saleroom, Oxford, on Wednesday next, December 6.

—— At a meeting of the ROYAL BOTANIC SOCIETY, held last Saturday, the following Directors of Foreign and Colonial Botanic Gardens were elected Corresponding Members:—Dr. J. Anderson, M. J. Brasine, Mr. C. Moores, Dr. F. von Mueller, Dr. R. Schomburgk, and Mr. G. H. K. Thwaites, F.R.S. Among the donations reported was a fine plant of the Australian Chestnut, lately received from Queensland.

—— *Harper's Weekly* offers the following suggestion to those whose FRUIT and other TREES have been destroyed by the late FIRE in CHICAGO:—

"In many instances the vitality of the roots has not been impaired. By cutting off the trees close to the surface they will, before winter, and covering the wounds with a heavy coat of grafting-wax, the life will be preserved until next spring, when they will, in a majority of cases, send up strong shoots and grow rapidly. Some varieties of trees will not sprout, but Pear and trees, Grape Vines, berry bushes, and valuable shrubbery will sprout again if cut close to the ground before cold weather comes. The burned and heated portions of the wood should be cut until a live surface is laid bare, when a warm coating of grafting-wax should be applied. This should be covered with brown paper or cloth, and several inches of fine earth should overlay the whole. A suitable grafting-wax may be made of equal parts of resin and pitch and tallow, or one part of linseed oil and two of coarse resin. In the spring the soil should be removed, leaving only about an inch over the stump."

—— In a communication to our contemporary, the *Builder*, a correspondent thus writes upon the important question, HOW TO HEAT A SMALL CONSERVATORY TO CONSERVE COST:—

"A few years ago a friend of mine bought a house, one of a row; it contained two sitting-rooms on the ground-floor,—one to the front, the other to the back. In summer the back room was unfit for habitation, owing to the heat caused by a close range in the wall which separated it from the kitchen of the adjoining house. This suggested to me an idea which has been carried out successfully. In planning a new villa, I placed the kitchen fireplace in the west wall, and behind the range, and open to it, I built, and against this was built a conservatory, 14 feet by 8 feet. The open space behind the range is furnished with a wooden door, over which, in the thickness of the wall, is placed an air-flue, having a damper. By shutting the door and opening the damper, the heat from the range is carried off, and *vice versâ*. This contrivance may not suit those who wish to maintain a high state of temperature in the conservatory during the winter, but it is sufficient to protect plants from frost, and to cause some varieties to flower during that season, can be maintained free of cost."

—— The BULBIFEROUS CHARACTER of the STEMS of certain of the LILIES, *e. g.*, tigrinum and bulbiferum, is a well-known feature. It would seem, however, as if there were a strong tendency in this genus to develope these axillary separable buds, for the same phenomenon may sometimes be observed near the base of the stems of L. auratum and other species not usually bulbiferous; and we have lately seen in Mr. WILSON'S collection examples of the longiflorum section in which the stems were bulbiferous at every axil from base to apex, quite as much so indeed as in the Tiger Lily, though the plants in question are usually nonbulbiferous. Possibly all Lilies might be forced to produce axillary bulblets, and if so the propagation of rare species might be much expedited.

—— Referring to the wonderful increase in the TASTE for FLOWERS which has taken place IN AMERICA during the past 20 years, in the columns of that excellent Transatlantic monthly, the "American Agriculturist," Mr. PETER HENDERSON states that statistical investigations taken in the rough, extending in a radius of ten miles from the centre of New York Island, proved that the number of florists' establishments was above 500, and the capital used in stock and structures upwards of 6,000,000 dols. If the number of establishments, writes Mr. HENDERSON, is nearly correct, and there is no reason to doubt it, it is certain that the value is not overestimated, as there are at least half as many establishments where the capital used in stock and buildings must be nearly 100,000 dols. each; and this, too, in New York and its suburbs, where the taste is lower than it is in either Boston or Philadelphia.

—— Most works on Eastern travel tell us of the great UTILITY of the STEMS of the CLIMBING PALMS and Bamboos for the manufacture of baskets, hats, mats, and hosts of other equally common and useful articles. The most striking uses, however, of the slender stems of the Calami are for twisting into ropes and cables (such cables being used on many of the Indian coasting vessels), and in the manufacture of those fearfully dangerous-looking, net-like suspension bridges which are thrown across rivers in India, and about the construction of which Dr. Hooker in his "Himalayan Journal" tells us that "two parallel canes on the same horizontal plane were stretched across the stream, from these others hung in loops, and along the loops were laid one or two Bamboo stems for flooring; cross pieces below this flooring hung from the two upper canes, which they thus served to keep apart. The traveller grasps one of the canes in either hand, and walks along the loose Bamboos laid on the swinging loops." The stems of these Calami, of which many species grow in the eastern forests, are seldom more than an inch or two thick, usually they are much less, indeed quite slender, and they mostly grow to an enormous length, climbing and scrambling amongst the surrounding trees, in the branches of which they support and attach themselves by the hooked spines of their leafstalks. The stems are of a tolerably uniform thickness throughout their entire length, and to what an enormous length they grow may be judged from a stem lately received from Ceylon, and now exhibited in the No. 2 Museum at Kew. This stem, which is probably that of Calamus rudentum, measures 369 feet long, so that if it had grown perfectly upright, it would have been nearly as high as the dome of St. Paul's Cathedral. They are imported into this country as rattans in bundles, each bundle containing about 100 canes, and each cane averaging from 12 to 16 feet in length. The number of canes annually imported into this country amounts to about 7,500,000. These are used chiefly for splitting and making bottoms of chairs, bodies of gigs, perambulators, &c., and formerly were much used by schoolmasters, as many an old boy will remember; for "crinolines," for ribs of umbrellas, and, when split very fine, for stiffening for silk bonnets. Rattans are also largely imported for walking-sticks; these, however, are thicker than those just mentioned, and are distinguished by the peculiar knobs or joints. Sometimes they have, moreover, a small portion of the root remaining, to form the handle. The valuable walking-sticks known as Malacca canes are also the stems of a Calamus, probably C. Scipionum.

—— We hear that Parliament is to be applied to next session for the incorporation of a company to form a short RAILWAY from the ring line, or Metropolitan Railway, to Kensington, near the South Kensington Station, to the EXHIBITION BUILDINGS at ALBERT HALL. Application is also to be made for power to form a subway from the South Kensington Station to the Albert Hall.

PORTRAITS OF GARDEN PLANTS.

ACTINIOPTERIS RADIATA, *Flore des Serres*, t. 1852.

M. Van Houtte here gives a nice figure of this very elegant dwarf stove Fern, which in its general aspect somewhat calls to mind a miniature Palm. The small slender fronds grow up in a neat tuft, and the lamina, which are fan-shaped, and 1—2 inches across, are cut down into narrow segments, much in the way of the leaves of the Palms. It is a native of India and Ceylon. It was figured in the "Florist and Pomologist," in the volume for 1869, and in our own columns the following year.

ALLOPLECTUS VITTATUS, *Illust. Hort.* ser. 3, t. 13.

A stout-growing Gesneraceous plant, requiring stove temperature. It has erect fleshy stems, covering large short-stalked broadly-ovate leaves, 6—9 inches long, of a deep velvety green, having a broad greyish-green band down the centre, branching off along the course of the principal veins. The flowers are terminal and fascicular, and rounded by vivid red foliaceous bracts, and having a large crimson calyx, and a pale yellow corolla. It was collected by Mr. Wallis at Moyobamba, in Eastern Peru, and is in the hands of Messrs. Lucombe, Pince, & Co., of Exeter.

ALONSOA MATTHEWSII, *Regel. Bot.* t. 158.

A pretty little soft-wooded greenhouse shrub of the Scrophulariaceous order, with slender quadrangular stems, lanceolate toothed leaves about an inch long, and lax terminal racemes of scarlet flowers, of which, as in the more familiar species, the upper lobe is the smallest. It was obtained by W. Wilson Saunders, Esq., from seeds sent from Peru, and is said to produce its brilliant flowers in abundance.

ARALIA JAPONICA AUREO-RETICULATA, *Illust. Hort.* ser. 3, t. 22.

A variety of the well-known evergreen and nearly hardy shrub, often called A. Sieboldii in gardens, and referred by botanists to the genus Fatsia. It differs in having the greater part of the leaf-surface of a pale yellowish green, reticulately marked with yellow, the midribs being pale, almost white. It is a Japanese plant, and was imported by M. von Siebold.

BEGONIA MAGNIFICA, *Rev. Hort.* 1870, 271, with tab.

An ornamental stove perennial, of suffrutescent habit, with ovate unequal-sided finely toothed leaves, and terminal corymbose panicles; and the flowers are large, flattish, of a bright orange-yellow colour, the perianth being 2 inches long, with a very short tube. It is closely allied to H. minor of Miller (H. grandis of Andrews), but is a stronger plant, with leaves twice as broad, and shorter-tubed flowers. It is sometimes called H. rutilans and H. Sieboldii in gardens.

BIGNONIA PURPUREA, *Bot. Mag.* t. 5800.

This magnificent stove climber has long been cultivated at Kew. It is closely allied to B. speciosa, differing in the narrower tube of the corolla. The stem is slender; the leaves bifoliolate, sometimes ending in a tendril, with the leaflets obovate-lanceolate; and the flowers are large, funnel-shaped, with nearly equal rounded lobes, mauve-coloured, with a large white throat. Nothing is known of its history further than that it is considered to be the Bignonia purpurea of Loddiges' catalogue.

CERATOSTEMA SPECIOSUM, *Illust. Hort.* ser. 3, t. 9.

This Vaccinaceous shrub forms a splendid ornament for the greenhouse, being an evergreen, with the stem growing erect from a tubercular base. The leaves are leathery in texture, ovate-lanceolate, with a short twisted petiole; and the flowers, which grow in short, axillary, secund, drooping spikes, are cylindracco-coriate, about 1¼ inch long, bright orange-red, with a short and slightly spreading yellow limb. It was collected in Ecuador by Mr. Wallis, and is one of M. Linden's novelties.

CISSUS LINDENI, *Illust. Hort.* ser. 3, t. 2.

A smooth, shrubby, cool stove climber, of the Vine family, with terete tendrilled branches, and ovate-acordate bright green leaves, which are freely mottled with white between the veins. M. Linden has imported it from the Sierra Nevada of Santa Marta, in the temperate regions of the United States of Colombia.

CLEMATIS STANS, *Gartenflora*, t. 657.

A dwarf-growing half-shrubby plant, with erect stems, ternate leaves, having ovate toothed leaflets, and small terminal panicles of whitish flowers, tomentose on the outside. It is a native of Japan.

COTYLEDON ATROPURPUREA, *Refug. Bot.* t. 198.

The Echeveria atropurpurea of gardens, a well-marked showy plant, with short, stout, glabrous stems, and obovate-spathulate dark-purple leaves, covered with a glaucous bloom, and aggregated into a dense rosette at the top of the stem. The flower-stem is erect, bears much smaller leaves, and terminates in a long raceme of bright red pentagonal flowers, towards the base. It is supposed to be a native of Mexico, and is allied to C. canaliculata.

COTYLEDON GLAUCA, *Refug. Bot.* t. 61.

A very pretty dwarf greenhouse succulent, forming a dense rosette of obovate-cuneate mucronate farinosely glaucous leaves, under glass, and producing in spring a second raceme of 12 — 20 scarlet flowers tipped with yellow. It is better known in gardens under the name of Echeveria glauca, and is closely allied to C. (Echeveria) secunda, from which it differs in little besides its glaucous covering. A native of Mexico. Both it and C. secunda are much used in the modern system of planting flower gardens; and are remarkably neat and pretty subjects, totally distinct in their aspect from some of the other plants referred to the same genus.

COTYLEDON SALZMANNI, *Bot. Mag.* t. 5801.

A charmingly beautiful rock plant, of the Crassulaceous order, of annual duration, and forming literally a mass of brilliant golden star-shaped flowers, relieved by the red tips of the spreading corolla lobes. It has a stout ascending leafy stem, with fleshy, linear leaves, covered with short red streaks; and golden-yellow flowers, spotted with red, which form a broad compoundly corymbose head, and are between funnel and salver-shaped. It was gathered by J. MAWE in Tangiers in Spain, in aspect is as dissimilar as possible from the Echeverias which are now sometimes referred to Cotyledon, and bears much more resemblance to a Sedum.

CYPRIPEDIUM CANDIDUM, *Bot. Mag.* t. 5855.

A pretty hardy perennial Orchid, with leafy stems, the leaves lanceolate, plaited, the flowers small, white, with green sepals and petals marked with purple lines, and an inflated oblong white lip streaked with purple round the mouth. A rather rare native of bogs, from the Central and New York States of North America, to Virginia and Wisconsin, extending thence into Canada to the northward, and to the Platte Plains and Rocky Mountains to the westward. It is closely allied to C. pubescens and parviflorum. "It will be hoped that Cypripediums, this is easily cultivated in a bog soil, with a cool bottom, plenty of shade, and a copious littering of dead leaves."

DENDROBIUM SCHRŒDERI, *Floral Mag.* t. 502.

A handsome stove epiphyte, with the general aspect of D. densiflorum. It has clavate stems, oblong-acute leaves, and dense pendent racemes of flowers, in which the sepals and petals are pure white, and the bright yellow, with a strong orange tint along the upper margin. It is cultivated in the collection of the Messrs. Veitch.

DROSOPHYLLUM LUSITANICUM, *Bot. Mag.* t. 5796.

A very remarkable sub-shrubby species of Sun-dew, with a thick woody stem, 2—3 inches high, at the top of which are seated the elongate linear attenuated leaves, which are circinate and revolute in vernation. The whole plant is covered with stalked purple capitate glands. The large yellow flowers form a corymb at the top of a leafy stem, which grows a foot high. It is found in Spain, Portugal, and Mauritania, growing on sandy shores and dry rocks by the sea as well as inland. It has been flowered at Kew.

HEMEROCALLIS DUMORTIERI, *Refug. Bot.* t. 213.

A very pretty and little known hardy herbaceous perennial of the Liliaceous order, a native of Japan and Western Siberia. It has long narrow tapering leaves, 1—2½ foot long, and the flowers, borne on a scape, 2—3 feet, large orange-yellow flowers, the perianth being 2 inches long, with a very short tube. It is closely allied to H. minor of Miller (H. graminea of Andrews), but is a stronger plant, with leaves twice as broad, and shorter-tubed flowers. It is sometimes called H. rutilans and H. Sieboldii in gardens.

HOMALONEMA RUBESCENS, *Gartenflora*, t. 634.

A stout-growing stove perennial, belonging to the Araceæ. Its stem grows 1—2 feet high, and bears sagittate-cordate dark green leaves, having the under surface purplish, and the petiole of a deep red. The peduncle is also red, and is terminated by a sub-cylindrical convolute spathe, which is reddish-purple without, and whitish within. It is a native of India.

JUSTICIA LINDENI, *Rev. Hort.* 1870, 250, with tab.

An ornamental sub-shrubby stove plant, of the Acan-

thaceous family, having smooth stems, glabrous, oval-acuminate leaves, and terminal heads of showy orange-yellow flowers. It was imported from Mexico, to the Jardin du Muséum, Paris.

VICTORIA PARK.

At a time when paragraphs are going "the round of the papers" as to the ill-effects of encroaching upon the boundary lines of this park, it may not be uninteresting to direct attention to one or two of its chief features of internal beauty, viz., the lake, and what is not inaptly termed the Pagoda island. My object in placing before your readers the annexed illustration (fig. 330) is not only to furnish one of the best views to be found in this park, but to show how happily the materials employed have been associated and blended together, so as to make a beautiful picture, even on a small scale. In this case the water does not occupy more than about 6 acres, which are ornamented with three islands, the outlines of which are of a strikingly marked character, and which are applicable to any part of a country park, where water can be brought within view of the mansion. This park contains a fine collection of trees and shrubs, which, being young, are just in the best possible condition for transplanting for effect, a chance which should not be lost, inasmuch as if left much longer without removal they will be so thick as to injure one another. The islands are rich in Willows, of which, along with other things, many fine varieties were bought at the late Messrs. Loddiges' sale, and the fine Salix babylonica, or Weeping Willow, as shown in the illustration, explains how much real beauty can be exhibited by a tree when it happens to be placed in a situation suitable to its character. Amid the vegetation of these islands, the numerous water-fowl that ornament the lake find shelter, and a suitable home. The Chinese pagoda in the background is that which was shown in the great International Exhibition of 1851. It was presented to this park, in which it forms a feature of much interest. That considerate and kind lady, Baroness Burdett Coutts, presented this park with a magnificent drinking-fountain, by Derbyshire, the cost of which was about £9000. This is about the chief building of interest which the park contains.

Subtropical gardening has been tried here as well as in the other parks, and with considerable success. Unlike that in Hyde Park, it is less guarded from the public by means of iron protectors, a singular fact when the respective positions of the two parks are taken into consideration.

As a bit of boundary line, what a fine appearance the subject of the annexed woodcut would make, viewed from the windows of a mansion. At Hatton, near Hounslow, I at one time created a somewhat similar scene on a rather unpromising site. It consisted of water and rockwork, associated with planting and diversity of form in the groundwork, the whole space occupied in this manner being about half an acre. Trees and shrubs of a fastigiate character occupied the foreground and middle distance. These consisted of Irish Yews, Cupressus, Junipers, and Cedars; next in effect came vases of flowers, archways, and pillars, portions of ruins obtained from the Old Temple Church. As to the rockwork put up it was as much a matter of necessity as of choice, inasmuch as it surrounded a reservoir of water for the supply of the houses and other wants of the establishment, including ornamental water and fountains in other parts of the grounds; and as all the water had to be pumped from a well by means of a steam-engine, it also blocked out the objectionable appearance of the chimney shaft. Architectural effect was given to the scene by a clock tower, and the whole was bounded by a background of Elms and other large trees. I so contrived the outline of the water in the scene, that in passing round it a series of panoramic views occurred at short distances apart, each being so varied as to be distinct in character—a desideratum obtained by throwing up the material taken from the site of the water into banks and mounds of various shapes and sizes. These banks and mounds were margined with rockwork, made of concrete, and planted with a very complete collection of wild plants found in the district, all being carefully

FIG. 330.—VIEW OF LAKE AND PAGODA ISLAND, VICTORIA PARK, LONDON.

named and systematically arranged. A screen or boundary line of a very different character may be found at Fulham Palace. In this there is no water; the foreground is, however, richly ornamented with Rhododendrons, behind which is a thick mass of shrubs and low-growing trees, planted in front of the wall of the kitchen garden, which it is desirable to hide from view from the ornamental grounds. The entrance from the latter to the fruit and vegetable department is through an ancient Gothic archway, which is so charmingly overhung with Ivy as to form quite an enchanting feature in the scenery, which is strictly in the gardenesque style.

Beyond the kitchen garden, itself one of the oldest in England, is a belt of stately trees, which serves as a boundary line to the domain, and at the same time effectually shuts out the town of Fulham, whose antique church top is constantly brought into view of the Palace.

The situation being close to the banks of the Thames, is flat and comparatively uninteresting, were it not for the planting, which has not only been skilfully done at first, but by age has ripened into full development, showing to advantage the mature character of most of the materials employed in it. Vistas have of late years been cut through the boundary line, so as to bring in occasional peeps at the waters of the Thames, thus giving life and interest to a scene which previously was the reverse of animated. Thus, in addition to the pretty piece of ornamental scenery represented in the accompanying woodcut, two other examples have been adduced of the way in which our home surroundings may be improved, and they are of such a kind as hundreds might possess, but few do, simply because they lack the energy to make the attempt. If as much attention were paid to the improvement of features of a permanent character about a place as is bestowed on infusing colour into our flower-gardens, we should soon have backgrounds and boundary lines worthy of the often prettily designed mansions and villa residences which they enclose. *Joseph Newton, Oxford Terrace, Hyde Park.*

THE FORTHCOMING MEETING OF THE ROYAL HORTICULTURAL SOCIETY AT BIRMINGHAM.

As you invite suggestions in regard to the social and intellectual catering for this annual *réunion* of the craft, I am anxious to contribute something, however little, to the development of these most important features of the provincial shows. Fortunately for you and the object we have in view, though rather trying to us who may be expected to offer suggestions, you have in your two leaders pretty well exhausted the subject, and have hardly left us wind enough to bag our sails. A dinner, an assembly room, a congress, and a special committee or committees to arrange each or all—little more can be needful to develope the social and intellectual features of these gatherings to the fullest extent. And yet one thing more, and that the chief, is necessary to command success, and that hitherto has been conspicuous by its absence. I mean the thorough identification of the Council of the Royal Horticultural Society with each and all of these social and intellectual aspects of the meeting. For the future there must not only be no cold shoulder, but no condescending patronage manifested in regard to these features of the programme. The latter is most offensive, and has been most keenly felt by the most honourable working members of the craft. Two equally straightforward courses are open to the Council: the one is to ignore the social and intellectual side of the meetings wholly, the other is to adopt them as part—and one of the most important parts—of the official programme. Practical men could appreciate either course. We have our views about which of the two would tend most powerfully to the advancement of horticulture, but either way we could not justly blame the governing body of the Royal Horticultural Society. Its officers are bound to guard its honour and consider its prosperity first of all; and if it is thought that social fellowship and intellectual communion with practical horticulturists mars the one or hinders the other, the Council are bound to abstain from both, and we are equally bound to honour them for their abstention.

What we can neither understand nor appreciate are

the compromises between these two courses that have been from time to time adopted at these meetings—the Council now adopting, now ignoring, and again entrapped or dragged into a recognition of those important social and intellectual features of the provincial meetings. The dignity of the Society and the interests and self-respect of practical horticulturists alike demand that this policy of compromise should cease.

Thanks to your vigilance and zeal in the good cause, which has never faltered, the subject has been mooted early. The Society has ample time to consider it and announce its final decision. I trust it may heartily embrace these social and intellectual features, and permanently engraft them upon its provincial shows. But if not, I do think this should be the last time of asking. We owe much to the Royal Horticultural Society, but more still to our self-respect; and it is hardly consistent with the latter that we should go begging year after year of the Council to help us dine, or hold congresses or social *réunions*. Assuredly we are strong enough to do these things for ourselves; and if the Society chooses to stand aloof, why let it stand out in the cold in peace.

Hitherto the Society has concentrated, and seemingly exhausted, its energies on the show. It is of the first importance that the show should be successful. It must be made such as to draw company and pay. We are not so unreasonable as to wish the Royal Horticultural Society to visit the provinces at a pecuniary loss. It can do little or nothing for the advancement of horticulture without the sinews of war—vulgar money. The shows, also, give a powerful stimulus to the advancement of horticulture. They are object lessons for counties and districts, where new schools may be created by the thousand. They raise provincial horticulture at one bound to the highest level, and whet the appetite for novelties to the keenest edge. The Society has done good work by going into the provinces, but it has left equally good, and better, undone. How is the exhibition to be made to pay for the exhibition than the exhibitors, the products than the producers; and while smiling its sweetest official blandishments on the works of our hands, it has given the workers the cold shoulder, or worse. Such a course is as unwise as it is unremunerative. It is likewise mean, suicidal; for practical men, gainsay it who will, are the backbone of horticulture. Raise, refine, strengthen them, and you raise refine, strengthen horticulture. Indeed, the shortest cut by far to the advancement of horticulture is to instruct, not the practitioners. Grand opportunities are afforded for this at these annual gatherings; and the Society that permits such to run to waste misses a royal way of being true to its charter. Promote social intercourse, stimulate intellectual activity among horticulturists, and the result soon be seen and felt in the exhibition. More will add to their riches, and all will have more pleasure in bringing their best. In many cases now, money is the only power that draws forth superior excellence; sympathy with the objects, identity of interest with the Society, and a hearty desire to promote its prosperity, would prove far stronger motives. The Society has it in its power to call forth all these by simply taking the same interest in the human branch of horticultural progress as it now does in the cultural. Nay, we do not yet ask it to do so much as that, neither to reward our merits. It has but to identify itself with us in our social *réunions*, and share and help in and sympathise with our intellectual exertions. The attempt to divorce us from our works, to reward the latter while ignoring the former, is vain, and would only prove mischievous if possible. We are united for better or worse, and those who would reward our best doings had better begin or end, we care not greatly which, by giving the workers their just due, for the men upon the whole are better and more precious than their best doings.

Perhaps it may be well to add a sentence or two upon the Congress. First, as to time. The evening would probably be best. Most visitors have so much to see, and so little time to see it in, that all the day and every day is crowded with engagements. I merely throw out the suggestion, however, and am well aware that there may be strong objections urged on the other side. Again, as to the manner. There have been great complaints about haste and appearances of impatience. Doubtless this has been caused at times by an excess of papers, when 10 or 12 readers have raced against time for a hearing at a single sitting. But at other times, and without this excuse, presidents have looked bored, and practicals felt discouraged by an almost indescribable feeling that the whole thing was felt to be a bore. I blame no one, but only advert to an impression that was largely prevalent at one of those congresses. Then as to matter. It always seemed to me that the utmost freedom ought to be allowed at these meetings. There are social and pecuniary questions of the utmost moment to horticulture that have been carefully excluded from discussion. I believe horticulturists are the only class in the country who continue to meet, and remain dumb on their own peculiar grievances and prospects. I would be glad to learn who could be compromised or injured in any way by the thorough discussion of such a question as this at the Birmingham meeting—The *status* and rewards of horticulturists, and how both may be raised, in the interests of employers and employed, and to the further advancement of horticulture?

In addition to the dinner, assembly room, and congress or congresses, I would suggest a *soirée* and *conversazione* if possible. Also, if practicable, that ladies might be invited to the dinner, as suggested by Mr. Pearson, at Nottingham. Finally, might I, without presumption, propose that the Rev. Reynolds Hole, who I trust has been added to the Council of the Royal, be elected chairman of the committee for promoting the social friendship and intellectual fellowship of horticulturists at the Birmingham meeting of the Royal Horticultural Society? *D. T. Fish.*

THE MYSTICAL PLANTS OF BRITAIN.

"The plant of truth is not rooted in the earth."
Oracle of Zoroaster.

THE superstitions which, in olden time, connected themselves with certain trees and plants have been pretty fully dwelt upon of late," but, as we think, without exhausting the subject, or deriving from it all the materials for thought which it is capable of affording. The tendency of modern opinion is to suppose that wisdom dwells with the present age, and that the early races of mankind were as much inferior in power of mind as they certainly were in the means of testing their views of Nature, by subjecting them to the verifying process of experimental research. Those who have studied the Chaldean philosophy, in so far as it has been made to descend to us through the opinions of Pythagoras, or have seen how remarkably some of the choicest results of modern scientific thought were anticipated in other schools of Grecian lore—those who have looked into the charming poem of Lucretius, "On the Nature of Things," will not entertain these disparaging ideas of the capacities of our forefathers.

In this article we mean to explore but one branch of this wide subject, in the mystical properties ascribed to plants and trees. In order to comprehend these views of the Aryan nations, we turn first to the Bible, which is unquestionably the most ancient documentary evidence on the subject, reaching back probably to the times made familiar to us by the history of the Judges in Israel. In this work we find, especially in one passage not devoid of sublimity, the distinct recognition of the unknown life force, in fact "the breathing in me;" and to these early philosophers everything that was unknown was mystical, and the whole world was pervaded by subordinate deities. These were formed into shape by drawing largely on the resources of a fertile imagination. They were struck with the sudden manifestation of the electric force in lightning, as showing something peculiarly divine; and this they extended to fire, and to all the varied and subtle operations which we are accustomed to class under the heads of electricity and magnetism; and, penetrating still further into the unseen world, they associated also in the same category the vital principle in animals and in man. Thus the Parsees,† in a controversy which arose between them and the missionaries at Bombay, claimed the well-known lines, beginning—

"Vital spark of heavenly flame,"

as exactly expressing their opinions on this point; thence also (as we have been informed) the custom of placing frankincense on the forehead of a corpse which is about to undergo the process of incineration, as it is supposed that the vital spark escapes from that part of the body.

An intensely poetic appreciation of Nature appears everywhere. The clouds were the cows of heaven, from whose udders the fertility of the earth was replenished. They likened the sun a god, whose chariot was drawn by the horses of the dawn. The first rays shooting up from the horizon, before the emergence of the orb itself, were the horns of the hind or gazelle of the morning. Probably the imaginary hammer of the Scandinavian Thor, with always returned again to his hand after it had been launched against any object, was an illustration of the same accurate observation of the phenomena of a thunderstorm, as is well described by the Roman poet Lucan—

"Dat stragem late, sparsosque recolligit ignes."

These last illustrations do not belong (it is true) to the Rig-Veda, nor do we think that the Aryan nations can be segregated from the rest of mankind to the extent which is supposed. They generally have fixed on inworking powers, especially maleficient powers, at work in the storm and the tempest, and deities watching over the productions of the earth, and, as we shall see, requiring to be appeased ‡:—

"The demons that are found
In fire, earth, air, or underground."

The connection of all this apparatus of deities with mystical notions about trees is well illustrated by the following list of the deities of the Sanscrit-speaking race, which, whilst in the shape of a falcon rescuing the soma, or heavenly ambrosia, from the evil demon, lost, in the contest, a feather, which, falling to earth, and taking root, became the origin of a tree with feathered leaves, whilst a claw which came to earth in the same encounter became a thorn-bearing tree, the Mimosa Catechu. Bishop Heber was amazed and surprised to find that the same superstitions attached themselves to the Mimosa in India and to the Rowan tree in Scotland—superstitions connected with the promotion of fertility in animals. He inquires, "What nation has in this case been the imitator, or from what common centre are these common notions derived?" The answer probably leads us back to the very earliest period of the history of the sons of Adam on the first opening out of this well of tradition. The superstitions connected with the Ash, as mentioned by White in his "Natural History of Selborne," are probably from a different source, though scarcely less ancient. The Scandinavian tradition was, that the gods formed out of an ash tree the first man, who was thence called Aske. This was probably the first progenitor of the Teutonic race, well shown by Knobel in his "Volkertafel" to have been (almost certainly) Ashkenaz of Genesis x.,* so that the fabled Ash, Iggdrasil, with its roots directed towards heaven, towards Tartarus, and towards the region of frost, and overshadowing gods and men, looks like an enunciation beforehand of the preponderance of the German races. "Rhetoric turned into logic" has produced worse things than the Ash Iggdrasil. Then the passing of crippled children through the cleft Ash was simply an introduction into a new and, it was presumed, better life. As with the Brahmins, the twice-born of India, as with the masonically initiated Druids—for whom an analogous birth was provided,—so with these unfortunates, the reversion to the original stock was to be healing and good.

These things are not specially to our purpose, and therefore we turn to the Oak and the Mistleto, and enter upon the domain of Celtic superstition. More particularly (omitting the kindred Picts, Scots, and Irish) we look to the Welsh, the Cymri (descendants of Gomer), as representing our early British ancestry.

There can be no doubt that these have preserved the traditions of the past to a much greater extent than the more thoroughly English part of our population. Indeed we need scarcely class among things of the past some of the superstitions, especially about fairies, which are still prevalent in Wales. The physician of Llyddvai (whose lore was reputed to be derived from this source) are the subjects of a volume published at Llandovery in 1861; but we leave, for the present, these gentlemen to settle accounts with the regular practitioners, and pass on.

We ourselves have met among the kindred Bretons with an illustration of the still powerful belief in the fairies. When driving along near the celebrated Cymric Menhirs of Karnac, we alighted to gather the Dodder (Cuscuta europea) which, with its weird-looking, thread-like branches, covered abundantly the Gorse bushes of the neighbourhood. On returning to our vehicle the Breton driver most earnestly remonstrated, begging that we would throw away the perilous fruit of our botanical research. "*La reine des Fées vous blessera!*" he exclaimed; and if we understood him aright believed that if this were not done, we should all be dead before we reached our destination. He did not pay much regard to our dissent from his creed, so we thought it most prudent, all things considered, to throw the weed away, lest the nervousness of our driver should really bring us to grief.

There is no doubt that the Druids looked upon the Oak as a divine tree, and most intimately associated with, even identified it with, the god whom they worshipped. The feelings of religious horror with which the Gauls regarded a grove of ancient Oaks dedicated to the gloomy rites of Celtic superstition, are well described by Lucan, who exhibits for admiration the courage of Cæsar, in himself giving the first stroke of the axe, in order to break through the dread which swayed his legions and threatened to hinder his designs. Thus, in Tallessin's poems we find the following—

"A greater tree than the Taronwy there has not been to afford us a assembly round the ancient mystical circle."

The name of the Oak in Welsh is similar to its appellation in Greek, and has connection with the title of the Druids themselves.† "*Derwdd*, a Druid, is compounded of *gwydd*, a wise man, and *derw*, the Oak. The strict connection, both in Hellenic and Roman mythology, between the Oak and Jupiter as the god of the thunder and lightning, was drawn even closer among these Celtic nations, as the Gallic Jove was represented to the eye by an open stem and two lateral branches in the shape of the Greek π in its elementary form. *Derw*, an Oak, takes also the plural *dêr*, plural *dery*, but *daran*, a servile form of *taran*, means a thunderbolt, and *daron* and *daronwy* are synonymous with *taranon*; and *Taranwr*, the thunderer, is the same as *Taranis*, whom, according to the Romans, the British worshipped. *Dar* must therefore have once signified equally an Oak and the thunder; and that the thunder and the prophetic Oaks of Dodona had a like connection at the time when oracles were supposed to be delivered from their branches; and the *fulgura* and *fulmina*, the phenomena of lightning, were supposed to be the most trustworthy phenomena whence a knowledge of the future might be obtained. Whether this *dar* represents the

† An Johnson William's "Gomer," p. 13.

electric fluid or not, we have ample proofs that the tree was mythically confounded with that of which it was only a symbol." Thus, Taliesin :—

"The swift moving derw,
From his presence would shrink both heaven and earth."

It may lessen our surprise at such a confusion when we remember that our own select word electricity, in somewhat similar manner, identifies the whole range of these phenomena with the *electron*, or amber in which they were first noticed.

The Welsh word *Trydan*, "pervading fire," is in so far more philosophical, in that it is an attempt to give a definition in the very word itself.*

After all, we ask ourselves, whence came this strange idolatry of the Oak tree—from its height and grandeur as pre-eminent amongst the trees of the English forests? from the character of its bonghs reminding of the course of the lightning, or from its being more frequently struck than other trees? We cannot say; and though our Oak trees have been struck we do not know that they really attract the lightning, as it is commonly supposed, or are more subject than other trees to this visitation. It is a fair subject of inquiry as to the fact.

The worship of trees lingered much longer amongst the Continental nations than in our island. Keysler tells us of a sacred Oak (Quercus Jovis) cut down by St. Boniface, and tells the story of another Oak whose great age was owing to similar causes, and of so great a size that when it became hollow by age a mounted horseman could ride round within it, which feat was performed by Albert I., of Prussia, and by his son also. This Oak continued long an object of superstitious veneration. It grew between Wolavia and Oppen, and was 27 ells in circumference. Another (alike recorded by Hartknoch†) was horrid with the blood of sacrifices‡. Another, near Labiau, in Prussia, was so much worshipped by the people that the clergy thought it best to dedicate it to a saint (Jodocus), by which means it became a source of gain (at least of lucre) to the Church.

The dreadful deeds of *Frithsplottum* and *Ox ellenum* became as much the objects of solicitude to Popes, councils, and clergy, as the interpretation of the words to critics in a later age. Penitence of from one to ten years seems to have been decreed by Gregory III. Our author satisfies himself that the first was a kind of Dryolatry, or revival of the old worship. The second more clearly refers to the Alder, "which trees were held in such veneration, and according to Arnkiel still remained so in his day, that in many places it was not thought right by the stupid people to strike them with the axe, before they had, on bended knees and with prescedent prayers to the goddess of the Alder (as they vainly imagined), sought the wood as suppliants with promise of its return. This M. Torgillus Arnkiel reports that he has often seen and heard, in his work 'De Religione ethnica Cimbrorum.'" *H.*

(To be Continued.)

AMARANTHUS SALICIFOLIUS.

ONE of the most prominent features of the past exhibition season was undoubtedly the magnificent plant exhibited under the above name by Messrs. Veitch. We append a note concerning it from a practical gardener of high standing, and we can quite endorse all that he says as to the merits of the plant, removed, as we were told, from the open border for the purposes of the exhibition. One regret we may express, and that is, as to its name. It may be an Amaranthus; at present we have no means of telling what it is. Perhaps, like Iresine Lindeni of gardens, which is certainly not an Iresine, this may not be an Amaranthus. But then what to call it? that's the question. We object on principle to the custom of affixing scientific names to plants that are not known to scientific men, and which names in eight out of every ten cases are ultimately found to be inappropriate. Suppose, for want of a better name, the present plant had been called "Veitch's Amaranth," would it not have sold as well as it will now under an assumed name? The English word Amaranth is a general one, and has not the precise signification that Amaranthus has, and hence would not introduce the element of uncertainty, probably of error, which the present name does.

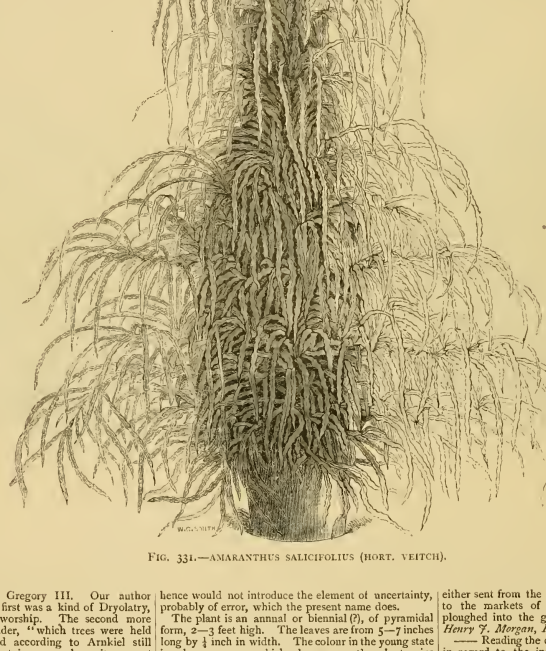

FIG. 331.—AMARANTHUS SALICIFOLIUS (HORT. VEITCH).

The plant is an annual or biennial (?), of pyramidal form, 2—3 feet high. The leaves are from 5—7 inches long by 1 inch in width. The colour in the young state is a bronzy green, which changes, as the plant gains age and vigour, into a bright orange-red colour. It was, we are informed, introduced from the Philippine Islands by the late Mr. J. G. Veitch.

"Permit me," writes our correspondent, "to add my testimony to the beauty and grace of this charming plant. I happened to drop in at South Kensington when it made its *début*, and it so fascinated me that I had eyes for little else at that gathering of good things. My first impression was—Well, Celosias must have progressed marvellously since I left off growing them on account of their inveterate tendency to hark back to tufted Cockscombs. With this stock, there is nothing to equal them. As I approached these plants, 'These never can be Celosias!' rose to my lips, before I had the pleasure of reading Amaranthus salicifolius. No cut or coloured plate, no, nor mere description, can do justice to the full merits of this plant. Whatever place it may take in the flower and sub-tropical garden—and that will be very high, if it proves sufficiently hardy for outdoor work—no plant can equal it for conservatory, table, room, or vase furnishing. It is no exaggeration to add that I believe those long drooping branches, so rich in colour and graceful in form, will mark a new era in the furnishing of tall stands, epergnes, &c., with cut flowers. I trust it may be offered at such prices that every garden in 1872 may be lightened up with the brilliance and dressed with the grace of this charming novelty."

Home Correspondence.

The Price of Vegetables.—I take it that your correspondent, "W. R. H." is a greengrocer, and therefore able to state (if he attends the Borough Market) whether the prices quoted by "A Market Gardener" in your last journal are a fair example of those which the retailers pay for the vegetables we send.

Prices of course vary each market day, but we have scarcely exceeded, and have sometimes fallen short of the prices quoted, within the hours named by "W. R. H.;" and I will add that the reason why such prices exist is to be found in the lack of buyers, and not in the fact, as he asserts, of salesmen overstanding the market. An injudicious salesman may occasionally sacrifice his goods to a desire to maintain prices, but to suppose that every salesman in the market would continually refuse the offers of the retail dealers, and eventually throw down his loads to be carted away to cows at a fodder price, is absurd. Having now responded to "W. R. H.," I hope he will in return tell me in what way he can justify the difference between the prices paid to the growers and those charged to the consumers? When the market prices were fairly remunerative to the producer the retail prices were as nearly as possible the same as they are at present. When the prices to the producer are positively ruinous, those to the public remain unaltered. If "W. R. H.' could by any possibility fairly explain this state of things, all inducement to high cultivation would vanish; but if, as I am confident, no such satisfactory explanation can be given, then such alteration in existing arrangements must inevitably be made as shall enable the people to profit by that which is now, in a prolific season, either sent from the neighbourhood of the metropolis to the markets of the manufacturing districts, or ploughed into the ground, or used for food for cattle. *Henry J. Morgan, Lodge Farm, Barking, Nov. 28.*

—— Reading the complaints of your correspondents, in regard to the inadequate returns received by the cultivators of garden produce, in comparison with the prices paid by consumers, I am tempted to send you an extract from Alphonse Karr's book, "Promenades hors de mon Jardin," on the subject of middle-men. Mons. Karr says, "It is a condition at once odd and illogical: the intervening person between the cultivator and consumer is a sort of parasite, whose business it is to buy at a very cheap rate of the grower, and to sell at a very dear one to the other. If the interested parties were to make an advance one to the other, to hold out the hand, and come to an understanding, both of them would make a good thing of it, in dividing the profit which is made out of them under the pretence of bringing them together." The difficulty of carrying out Mons. Karr's suggestion may be an insuperable one, but as the tendency of the state of things described by your correspondents is to restrict

* *Tyy* signifies aptness to pass through or over. Richard's Dict.
† In Rerum Prus. Diss., vi., m. 4 and 6; also Diss. xiv., m. 13.
‡ "Undique in trunco hærente."

production by making the cultivation of vegetables unprofitable, and so to inflict the hardship of high prices on the general consumer, any plan by which the evils complained of could be remedied would be welcomed by a large class of growers for the great markets of the country, and would confer a great boon on that class of consumers whose greatest deprivation, beyond the absolute staff of life, would be the loss or curtailment of their cheap supply of greens. *W. Ingram, Belvoir.*

Rochea falcata.—Though I have known this plant for many years, I have never been so struck with its beauty and utility as a flowering plant till this winter, having generally seen it among collections of succulents where it never had a chance of flowering. I had two plants planted out this summer among other succulents; they grew well, and when about 8 inches high each threw up a flower-truss. I took the plants up in October and potted them, put them in an intermediate house, and they have now been in bloom for a fortnight, and promise to last another month or more. The corymbs are something like those of the Sedum Fabaria, but broader and more rounded, and I cannot describe the colour better than by saying it is a combination of deep orange, scarlet, and pink. The plants are only about a foot high; the trusses inches across, and most conspicuous objects. The Rochea is a characteristic-looking plant when bedded out, and when taken up before the frost destroys the flower-buds and potted, it comes in for winter decoration, and in my opinion ought to rank high as a greenhouse plant, and be grown in batches. *J. Simpson, Wortley.*

Leptosiphon roseus.—It may interest your readers to hear that, so far, this beautiful little annual has passed through the recent severe frosts here in the open ground entirely uninjured. I have it growing from seed sown in June, the plants still putting forth a few blooms when the sun shines; and I have it also in the form of small seedling plants (looking just now like small Portulacas) that have come up where my earliest summer stock of it seeded. Whether it will pass as unscathed through the entire winter remains to be seen. I have just lifted some of these small ones, and pricked them into pots to stand the winter in a cold frame, so that I may be pretty sure of a display of it in the spring. It is a charming carpet plant, and would produce a lovely effect if mixed with Aubrietia Campbellii. *Alex. Dean, Bedford.*

Pruning Scissors.—The most useful of all instruments in a fruit garden is undoubtedly a good *sécateur*, or pruner, but, as in everything else, there are both silly and clever ones. The one you notice at p. 1483 is one of the clever-looking ones, but as the drawing fails to show it if the blade is longer than the handle (it is), or if it and the handle is all one piece, I am dubious as to its being really a clever acting instrument. There is no question that for a *sécateur* to be an efficient one the blade most be a piece of itself, thin and blade-like, as in a knife, and rivetted on to the handle, which should be strong, thick, and powerful for the work. I have had practical experience with a good number of these fruit-tree pruners, and every one has failed to please me except one. This is made by a working smith at Versailles. Prévost's *sécateur* is considered by most gardeners, in Seine-et-Oise at least, with M. Hardy and his assistants at all the fruit-tree growers in that department, the *sécateur*; and for my part I have no hesitation in saying that it is the best and most efficient pruner ever made. Of course, in those days nothing good came out of Versailles, and it was not patronised by the Paris centre of horticultural skill as it might have been. The price of this *sécateur* is 7 francs—rather dear, but it will last for years, since a blade can be put in when necessary, as I have had done with one or two of mine. M. Albert Truffaut, of the Rue des Chantier Nursery, Versailles, is sending me a price list, and I have forgotten Mr. Prévost's address. These *sécateurs* are made in two sizes; the smaller size will cut an inch Hazel stick in two—on the slant, of course—quite easily. *H. K., Floors Gardens.*

Old Garden Favourites.—In the "Botanical Magazine," plate 1622, there is a figure of a most singular variety of the Carnation, D. Caryophyllus, in which some of the flower-buds, by a most curious malformation, assume the appearance of a green Wheat-ear. This singular flower seems to have been well known to the past generation of gardeners, among whom it went by the name of the "Wheat-ear Carnation." Where is it gone to? It was so curious that it ought never to have been lost, and very possibly it still exists in some of those dear old-fashioned gardens whose owners have stood bravely out against the bedding mania, and have zealously propagated and zealously preserved these choice gems of floral antiquity. Who now grows the real old white Clove Carnation? I don't mean the poor thing commonly sold for it, but the true coarse grass and flat petal, and all the old crimson. I have often heard it talked of, but it has never gladdened my eyes. Does any one grow that fine old plant Malva campanulata, which, alas! I have lost, and know not how to recover? Where, too, is its congener, Malva purpurata (Bot. Mag. 3814)? Can any one tell me how to get Rosa microphylla (Bot. Mag. 3490) or Rosa Brunonii (Bot. Mag. 4030), and Primula amœna (Bot. Mag. 3252)?—and are Scilla villosa (Bot. Mag. 3211) and Fritillaria tenuifolia (Bot. Mag. 3083) now in cultivation? I have now before me in a pot, in full bloom, a clump of that beautiful autumnal Crocus, C. longiflorus. Can any one tell me where to get the white variety? *H. Harpur-Crewe, The Rectory, Drayton-Beauchamp, Tring, Nov.* 28.

Golden Champion Grape.—What I am about to state is my own practical experience of this Grape, and nothing could be more favourable. I planted it here in the spring of 1869, cropped it for the first time last year, and this year the bunches and berries astonished every one that saw them, and the flavour was exquisite. My employers were delighted with it, every berry was faultless. In a place not six miles from here I saw three very fine bunches of it this year, in the month of August, from a Vine on its own roots; not a single spot to be seen, in fact they were all that could be desired. I am aware that it has failed with some growers, but so have Black Humburghs, when they are red; White Muscats, when they are green and shrivelled; Lady Downe's, when the bunches are decimated with the spot it is subject to. The Golden Champion, as far as known to me, is the only one of the new Grapes that has been taking first prizes this year single-handed, and I believe the future will do so to a much greater extent. *J. Louza, Gr. to Sir H. S. Stewart, Bart., Zouch, Stirlingshire, Nov.* 29.

Hardiness of Draczena indivisa.—It may be worth mentioning, perhaps, that this plant will stand with ease many degrees of frost. In two large vases at one of our private entrances had been plunged a pair of very fine plants, with fully 100 leaves on each, that have stood from 4° to 12° of frost for several nights since October. They were only taken in yesterday during a fall of snow, and are none the worse for their cool ordeal. The aspect, where they have been standing, is east, and only in very early morning, during the summer time, do they get any sun. Vases of trees they would not risk to many degrees of frost with impunity. If this catches the eye of some of our French friends, who were sufferers last winter about Paris, one of them may be able to say what degree of frost this handsome decorative Draczena will stand. Elvirère, in a late number of the "Journal de la Société d'Horticulture de France," speaks of a Vanda teres flowering more profusely than ordinary after being exposed to frost some time last winter. M. Chantin, of the Rue de Châtillon, and many others, could a tale unfold, I have no doubt, regarding many indoor plants. I soon may be induced to give their experience. You may also allow me to say that some Echeveria secunda glauca are also yet in their summer quarters, and up till now are apparently as hardy as Sempervivum californicum; at all events, it is a much hardier thing than I had previously believed it to be. *H. Knight, Floors Gardens.*

Ferdinand de Lesseps Grape.—Tastes vary in fruits as in other matters; one person delights in the rich aroma of a perfumed Pear, another in the simple sweetness of a flavourless fruit. The merits of Grapes, in the opinions of some connoisseurs, consist very much in their possession of that flavour which distinguishes the Muscat of Alexandria: while the juicy sweetness of the Hamburgh commends it to others. In the "Gardeners' Chronicle," which has recently commented on certain matters connected with the cultivation of the Vine, employing the *nom de plume* of "Vitis," speaks in disparaging terms of a Grape raised at Chilwell, and called by Mr. Pearson Ferdinand de Lesseps. This opinion illustrates my remark that "tastes vary." Although "Vitis" ventures so far as to predict that this Grape will be consigned to the limbo of obscurity, many persons who have had the opportunity of tasting it have given it a good position in their vineries, so that obscurity will not be its fate; and I have forgotten Mr. Prevost's Christmas laughs in Dickens' "Christmas Carol," I regard Ferdinand de Lesseps as the first of a line of illustrious fruits and precious wines which will flow from the auspicious union of the Vines of Europe and America. The Grape has yet the dwarfed proportions of an undeveloped but pure stock, its merits consist in its intrinsic excellencies of flavour, and not in the meretricious advantages of size or colour. Like one of its parents, the Muscadine, it is comparatively small in size and bunch, but it has gifts beyond—being marvellous in quality. *W. Ingram, Belvoir.*

Hot-Water Circulation.—Your respected correspondent, Mr. Fish, thinks that I ought to have shown which takes the initiative in circulation, the hot or the cold. I hope to do so (and in a manner which shall not leave my reasoning open to such an objection as that contained in the last sentence of his letter) in those papers which you kindly approve of my sending for insertion in the *Gardeners' Chronicle*. I do not enter into the matter here, not wishing to intrude needlessly on your space; for the same reason I leave unanswered other remarks, not sufficiently understanding them. I apologise for having mistaken the purport of Mr. Fish's remark upon the "driving power of caloric," and now understand that he classes gravitation with it as a motive power of at least equal potency? But does he carry out this definition fully when he goes on to assign to gravitation as "its proper function" nothing more than "returning back the cold," while to caloric he assigns "the sending forth of the hot water?" I believe he does not, and I am confident that I shall not be alone in the belief that this is not a proper estimate of the function of gravitation. I have no other object in the task I have set myself than to elicit the truth, and when my papers have been published I shall be glad to have any point sifted or any error exposed by my respected friend, Mr. Fish, or others. I think that my criticism of Mr. Fish's statements would be more fairly described as a criticism of leading statements and defined conclusions rather than of "detached sentences" and of mere words. *J. M. Taylor, Seer Green Vicarage, Beaconsfield.*

The Cockspur Thorn.—Planters in search of the singular and the habitually beautiful combined should plant the Cockspur Thorn, Crategus coccinea Crus-Galli, an old North American species introduced nearly two centuries ago. Its peculiarity is that spines, spurs, or thorns are formed along its branches, many of them 3 inches in length, which makes them very conspicuous. It has large leaves and flowers, and belongs to the scarlet-fruited section, the berries being moderately large, and of a dark red colour. *William Earley.*

Supposed Influence of the Moon on the Flow of Sap.—That there are constant changes in the current of the sap in plants no one can deny, but that there is a periodicity in which is regulated by the influence of the moon I am not disposed to admit. It may at once be granted that Mr. Hutchison is correct in his observation, and that he actually observed that during certain days following the third day after new moon the sap was apparently more abundant. But are there any grounds for connecting the apparent increase of sap with the phase of the moon? I certainly think not. Mr. Hutchison has omitted all mention of the state of the weather and of the temperature. This is most unfortunate, because if a record of the temperature during the period of observation could be obtained, then the lunar theory would probably be shown to be untenable. During the winter months, when there is no flow of sap from the roots to the leaves to supply the water necessary for transpiration, the fluid in the stem always contains air-bubbles. The effects of the temperature on this mixture of air and sap are peculiar. If the temperature rises the air in the tree is heated, the air in the capillary tubes expands, and compresses the fluid or sap contained in the stem. As the fluid cannot move downwards it must move upwards and towards any cut surface, which will at once appear wet. In fact this is merely the process of bleeding so often seen in many trees—a phenomenon which ceases as soon as the leaves form, and the rapid ascending flow of sap is re-established. If Mr. Hutchison and others will again carefully observe the supposed lunar action, but in addition make records of the temperature of the air, he will probably be led to abandon his new theory. As the temperature of the trunks of trees does not correspond exactly with that of the surrounding air, it would be advisable to bore a couple of holes in the stem of the tree in a slanting (downward) direction. In each of these holes must be inserted a tube, one end of which dips into mercury is to be poured, and the bulbs of a registering maximum and minimum thermometer placed in the mercury. It will then most probably be found that the disturbed state of the sap corresponds with the rise of the temperature of the stem—a fact well known to vegetable physiologists—and not with the changes of the moon. *W. R. McNab.*

Nephrolepis tuberosa.—As a basket Fern this is, in my estimation, the best for either a conservatory, stove, or greenhouse. It seems to adapt itself to either of these structures better than any other exotic Fern that I am acquainted with. In a shaded position in the stove, if well attended to in watering, it will make fronds from 4 to 5 feet long, the numerous tuberous rootlets hanging about in all directions. In such a condition it is wonderfully effective; in the conservatory it looks equally as well, but does not produce such long fronds; and when grown in the greenhouse it has a more upright habit of growth, but it is very handsome. I need scarcely add that when grown in a greenhouse frost must be kept out, although it has stood a few degrees without any visible signs of injury. When about to put plants into baskets they ought to be potted in 4 or 6-inch pots, and be grown in the stove for a time, to get them well established, and the pots filled with roots. Then line the baskets with wet Moss, put in some leaf-mould, turfy peat, and charcoal, and turn the plant into this without breaking the ball, filling up all round the ball with the above compost, and covering the whole with Moss, the greenside up; run some small wire over the Moss, to make it firm, give a good watering all over, and the operation will be finished. *J. T. Burns, Tollesby Hall, Middlesborough-on-Tees.*

Artichoke Galls.—Pray give me three lines to assure Mr. Albert Müller that his criticism upon my remarks on this subject proceeds upon a mistaken assumption. In using the expression "better known as Cynips gemmæ," in relation to his having styled the insect in question Aphilothrix gemmæ, I by no means intended to say that the former was the better name, or should be generally adopted. It was only as if I had said, "which our readers will know better under

the name of Cynips gemmæ." I do indeed think it the better name for the pages of the *Gardeners' Chronicle*, for many of its readers would recognise it by the former who would not by the latter. At the same time I equally admit that where scientific entomologists are addressed, Aphilothrix is the proper name for the genus. The propriety of making such a distinction between one's hearers or readers is a vexed question, on which Mr. Müller and I would take opposite sides, but which, I agree with him, is not matter for discussion here. I do not, however, regret having used the expression (even although I should be in the wrong on this point), as it has drawn from Mr. Muller the very clear statement (in last *Gardeners' Chronicle*) regarding the nomenclature and what is known of the insect. I infer from his silence on it that he is not able to throw any additional light on the point which I suggested for his consideration, viz., whether the insect always selects flower-buds for the nidus of its eggs, or if the leaf-bud attacked undergoes metamorphosis into a half-developed acorn. There would appear, therefore, still to be something for entomologists to observe regarding this creature. I would like to observe further, that I find Mr. Müller's statement as to the scarcity of acorns this year confirmed by one of my correspondents. As I have already said, this is certainly not universal, but its occurrence in more than one quarter is curious and interesting. *Andrew Murray.*

The Brussels Sprout.—This excellent vegetable is only excelled by the Cauliflower as a general favourite for the dinner-table, and a few hints about its successful cultivation may be of interest to some gardeners. Having the advantage of a glass-covered wall, with a border inside, I have, for the last few years, sown the seed of the Brussels Sprout in the beginning of February, and had the plants strong enough to plant out early in April. By this early planting, and in well manured ground, the plants in the course of the summer and autumn get to a great size, and produce enormous quantities of sprouts at cutting time. As every gardener has not the means of growing the young Sprout plants early, a large piece of soil, sown and put into a cold frame or late Peach-house or vinery, and pushed on till the plants are ready for pricking or planting-out in the spring, would answer the same purpose; or a bed might be sown in the autumn, along with the Cabbage and Kale plants, and they would be ready to plant at the same time, if they stood the winter. When the Brussels Sprout seed is sown at the usual time of sowing the Broccoli and Kale in the spring, the plants are seldom ready for planting-out before May or June, and they never grow so tall and fine as the early planted ones. I find the seed of the Brussels Sprout imported from the Continent the best to be depended upon, and have discarded all the varieties in the nurserymen's catalogues, said to be new and good. The Roseberry variety of Sprout is an excellent dwarf late hardy kind, for it stood uninjured with me last winter, when there was such destruction amongst the Brassica tribe; and it will be the same the ensuing winter should the frost be severe, for all vegetables at the present time are in a very succulent state, although checked a little by the late frost. *William Tillery.*

The Thames Bank Peach—This Peach is not so generally known as it should be. As a late Peach it is decidedly one of the best we have, being a strong, robust grower, of good constitution, and a free setter. Dr. Hogg, in the "Gardeners' Year Book" for 1870, describes it as follows :—"A yellow-fleshed, or Apricot Peach, raised by Mr. Rust, gr. to L. Sullivan, Esq., Broom House, Fulham. It is about the size of Late Admirable, and rather more oblong in shape; the skin is deep orange-yellow, marked on the side next the sun with several broken streaks of crimson. The flesh is tender, melting, and juicy, and for a yellow-fleshed Peach is highly flavoured. This is certainly the best of yellow-fleshed Peaches we know, and is highly ornamental as a feature in the dessert." I can fully indorse this description of it, having seen it in different situations doing well. Of course there are others quite as good, but this one I can speak of with confidence. *G. Warren, Gr., Balcombe Place, Sussex.*

Figs—The treatment of this fruit seems to me to be little understood by gardeners in general. I believe that the knife should rarely be used. Such is the case in the Fig orchards in the South of England—Broadwater, to wit. You would do good service to Midland and Northern county gardeners were you, Figs on walls (matted up during winter) if you would favour them with the practical experience of others. I believe that the branches of Fig trees should be controlled, not by knife, but by bending them down in various shapes, so as to check growth and promote fruiting. I see them cut just as they cut Gooseberries. Apple trees, Peaches, &c. : the result is very little fruit. *S. W.*

Golden Variegated Cress.—Those who may desire to see a little liveliness in their flower beds during the winter months should get a packet of seed of this pretty Cress, and sow it in the open air next May; they will then have plenty of it for winter decoration. It is one of the very hardiest of ornamental foliaged biennials, and is not so disfigured by rain and frost as the Golden Feather too frequently is. The golden variegation is very marked and distinct, and the plant may be thoroughly relied upon. Gardeners who don't turn up their noses at the use of Beet for summer bedding, won't object to use this Cress for winter purposes. *A. D.*

Variegation, Transitory and Habitual.—Permit me to add two examples which I have met with. Just below the kitchen-garden at Digswell grows a robust young Horse Chestnut tree, which, though greatly shaded, assumes on many parts a slight variegation about midsummer, which it loses before the leaves change to a ripened hue. Not 20 yards from the above grows a large Spanish Chestnut tree, one of two twin branches of which has been broken off by the wind some 40 feet above the ground. From near this wound about a dozen branchlets have grown, which form a somewhat thick mass when in leaf, the leaves being of usual size, with the peculiarity that every one has, for the last 12 years, been of a pure and beautiful white, with no solitary exception; yet no sign of variegation exists on any other part of the tree. *William Earley.*

Foreign Correspondence.

To the Aspinwallians the BANANA TRADE is their all. The Banana is their only export; and the arrival of the American steamer is an event of great importance. Not a steamer leaves without taking from 5000 to 8000 bunches, and during the year something like 150,000 bunches of Bananas are exported to New York. It gives the name to the steamer; for to more than half the people it is only known by the name of "Banana boat," and the day of its arrival is called "Banana day." And when it does come it is a day of rejoicing; for the carrying of the Bananas gives employment to more than half the Aspinwall people. The Bananas are grown on the "farms" some seven or eight miles from the town. These farms are merely bush lands, partially cleared. The word "farm" to an English ear would give no idea of what an Aspinwallian means by it: there is no order—no fences or subdivisions—all is rude and rough.

On these farms many of the large trees remain standing. After the small bush is cut down, fire is run over the land, and the suckers are planted irregularly all through 6 feet or 7 feet apart. The Plantain is not exported, but is only used for home consumption. The Indians manufacture a kind of spirit from the Plantain. When the Plantain is fully ripe, the Indian gathers it, peels off the skin, and throws the fruit into a dish, where it remains for some days. After fermenting, he draws off the liquor and puts it in his homemade bottles for future use. The liquor (or, as the Indian terms it, *mina*) is said to be very strong, and very intoxicating. When drunk to excess the effects remain for two or three days. In Jamaica the Banana seldom comes to maturity in less than twelve or fourteen months; but in Aspinwall six or eight months are sufficient. In Jamaica, as I have before stated, it only comes up single, and bears but one bunch of fruit; but in Aspinwall a sucker comes up with several shoots, and these bear in succession one after another. As a general rule, the Banana plantations are kept in good order—persons constantly going through them and cutting away all dead leaves, &c.

In Aspinwall the Banana trade is principally confined to four merchants, and these export almost all the fruit sent to New York. These merchants contract with the growers to take their whole crop, at so much per bunch, large or small, deliverable at the side of the railroad. About a year since the contract price was 3*s.* per bunch. In the contract the merchant agrees to take all, and the grower agrees to sell to him, alone, all his crop. As soon as the Banana boat comes in sight, notice is sent to the farm to prepare. Then all is bustle, diligence, and activity. The merchant goes to the farm, and by a system of calculation he knows how much room he can obtain, for it is very seldom the steamer has sufficient space to meet all the wants of the Banana exporter.

As soon as this is ascertained, he sends his agents to the farms, informing those with whom he has contracts that he requires one, two, or three thousand bunches.

It is of great importance that the Bananas should come to the steamer uninjured, and to insure this, great care is taken in cutting and handling the bunches. It is of equal, if not greater importance, that the fruit should be quite fresh when shipped. Consequently the gathering, carrying, and shipping the bunches is crowded into as small a space of time as possible. When cut the fruit is carefully caught in the hands, and at once carried to the place where the horses can take it. There it is gently laid down, so as neither to bruise nor break the fruit. For much of the value of the bunch depends on its presenting a handsome appearance, without any of the "hands or fingers" being broken off. If a bunch has one or two of its "hands" broken off, it is at once rejected by the shippers.

The fruit is cut with as long a stalk as possible for the convenience of carrying, and it is always cut green, before it ever begins to turn ripe, or even half ripe; the Bananas would be of no good otherwise; they would rot long before New York was reached.

Having gathered all the bunches which are fit, and brought them to one spot, the grower hings up his horse to load. Two men stand, one on each side of the horse (on which is fastened a large piece of canvas), and the bunches of Bananas are handed to them, and held by them on each side of the animal. Five, seven, or nine bunches—always an uneven number, the odd bunch going on the back of the horse, according to size, compose the load. The ends of the canvas are then brought up and the bunches carefully collected to keep them from being bruised. The light of a rope (which must be so arranged as, when taut, to firmly hold the load) is next brought over the canvas, and one end of it passed through and carried back under the horse's belly over the side and tied to the remaining end. A "screw stick" is passed through the end, and the whole screwed up as tight as the horse will bear. Experience seems to have proved this mode of fastening the Bananas to be more secure than any other way; for the loads thus fixed are carried over and through tracts which seem scarcely possible for foot passengers—and scarcely does a line so fastened break loose. One man then takes charge of the beast, and leads him out to the railway track, when the line is very carefully untied and the Bananas gently laid on the ground. For the purpose of readily counting, each contractor places his Bananas in long rows of three tiers. A watchman is left in charge, and the man and horse go back for another load. At the "farm" is near, two or three trips suffice to make for each steamer. Early in the day, the merchant or his agent comes to the spot, and as soon as the last load from the contractor is put down, proceeds to count the whole number, which from the Bananas being arranged in a mass of three tiers is easily accomplished, and after pays for them at once or gives an order on his store. The Bananas being contracted for are taken as they come, large or small, as long as they are not bruised or broken, at one fixed price, somewhere about 3*s.* or 4*s.* per bunch. Meanwhile, a number of independent growers have also brought their Bananas down to the railway company's track, which for a few hours resembles a bustling market. These bunches are sold according to size and value — a large bunch bringing 8*s.* to 9*s.*, while the small ones are not worth more than 1*s.* 6*d.* to 2*s.* As each bunch is purchased, it is laid in the rows, of three tiers, by the side of the train. When the trains are made, the merchant, leaving a faithful watchman, gets into his "hand car" (a small railway carriage, propelled by two men by means of a crank), and proceeds to the depot, where he engages as many trucks as he has occasion for, which are instantly sent off to the Banana market. Everything is carried on with the utmost despatch, and as soon as the trucks arrive on the spot an animated scene commences. The long stem and end of the fruit which had been left on are now cut off, and the bunch is carried carefully and arranged in the truck. As soon as the loading is completed, the locomotive takes the cars to the dock, when, if the steamer is ready, the work of loading at once commences. Should the steamer not be ready, the doors of the truck are opened for the sake of admitting air, and a watchman placed at each end to prevent pilferage; for the theft of Bananas at the dock is something fearful, the petty officers and seamen of the steamer being at all times ready to purchase, and giving high prices, 3 dols. to 4 dols., for a bunch or so, to take to New York with them.

On board the steamer, large bins or bunks are constructed, into which the Bananas are carefully packed, being placed upright with their stems down. As far as possible, while being loaded, the Bananas are separated into two sorts, the choice and the common, and placed into separate bins. The choice kinds are not any distinctive fruit, but merely large ones—those having from 10 to 12 hands; but care is taken not to ship any fruit which is not green, or unripe. If a bunch seems turned (beginning to ripen), it is thrown away as useless. Even with all the care that is taken in handling the fruit, or rejecting all that are bruised, or that begin to turn yellow, a large proportion of the fruit is spoilt before it reaches New York. Yet the profits on this branch of commerce are so great that if only half of the whole quantity shipped reach New York in good condition, a large profit is made.

The retail prices of a single Banana in New York is 1*c.*, and 5*c* to 6*c.* is known to have been paid for a single bunch. *Trinidad Correspondent.*

Societies.

EDINBURGH BOTANICAL : *November* 9.—The first meeting of the 36th session of this Society was held at 5, St. Andrew Square, Edinburgh, on the evening date. Alexander Dickson, M.A., President, occupied the chair, and delivered an inaugural address, of which the following is an abstract :—

I purpose in this address to make some remarks on climate and weather relative to the geographical distribution of plants, having recently completed certain inquiries regarding prevailing winds and rainfall which are so intimately connected with the subject. In 1847, De Candolle made some researches which tended to limit vegetative species towards the North in Europe and similar regions, and arrived at the conclusion that every species having its limit in Central or Northern Europe advances as far as it finds a certain fixed amount of heat, calculated from that day of the year when a certain mean temperature commences, to the day when that mean terminates. This law he applied with great ingenuity in explanation of the northern limit of Alyssum calycinum, Euonymus europæus and Dianthus carthusianorum.

It is evident that this law can be best tested by applying it to the limits of Wheat, Barley, the Vine, and other cultivated species, since, owing to the care taken of them by man in their cultivation, it may be considered that it is climatic conditions alone which set the limits to their destination. According to Bonssingault, Wheat requires 8248° Fah., from the time it begins to grow in spring for the proper ripening of the crop; and, moreover, this heat must be so distributed as to secure a mean temperature of 58° during the period which the seed is ripening. This statement referred to the continent of Europe, to which his researches were confined. But we have found in Scotland that a mean temperature of 56° with the average amount of rain and sunshine is sufficient to ripen Wheat properly. Not only so, but the crops of 1864 ripened well with a temperature as low as 54°.4. In this year, however, the sunshine was much above the average, and the mean temperature of the day was high. Now, whatever be the cause, whether the longer day in Scotland, or the clear sky, or both combined, which brings about the above results, it is clear that in considering the influence of temperature on the ripening of plants, it is not merely mean temperature, but the manner in which this vital element is partitioned during the 24 hours, which must be taken into account.

Now, what most influences the mode in which temperature is distributed during the day is the amount of cloud and moisture in the atmosphere, to a knowledge of which the rainfall through the months of the year may be regarded as furnishing the best available key. Indeed, so great is the direct and indirect influence of moisture on plants, that we shall not be far wrong in supposing it to be co-ordinate with that of temperature.

De Candolle's researches applied to a region where the climates are determined rather by variations of temperature than of moisture. Not the least valuable of the results he arrived at in applying the latter to other regions is this, viz.:—"On the borders of the Mediterranean the limits appear to be so often determined by the humidity, or by causes still unknown, that the operations of temperature may elsewhere be examined." In the climates of this region the rainfall plays a conspicuous part, and hence, as was to have been expected, assumed a climatic limit to species, which did not include the rainfall, and turned out to be inapplicable to the facts of distribution.

Again, perennial species, especially trees and shrubs, are in many cases arrested, or limited, by the absolutely lowest temperatures that occur. The frost of last Christmas, 1860, brought us very valuable information bearing on that point. Those low temperatures depend to a great extent, no donbt, on the latitude, but they more particularly are determined by the state of the sky, and by local situation.

If the climate is characterised by a dry calm atmosphere, the loss of heat by radiation during the nights of winter is great, and the temperature falls comparatively low; and owing to the greater density, and consequently weight of cold air, it flows down the slopes of a country which is being cooled down, much in the same way as water, and settles in the low-lying districts. It is well known that it is in such situations where the destructive effects of frosts are the greatest on vegetative forms.

Now, what we wish to draw forcible attention to, is this:—That the two conditions, heat and moisture, we have in the distribution of rain a body of facts which will lead to a knowledge of the laws which regulate the distribution of temperature. It is not merely the daily and annual fluctuations of the temperature of a climate which may be inferred from a knowledge of its humidity; it is not merely the greater immediate results which accrue to plants, arising from a change in the humidity than rises from a change of temperature; but what especially concerns this question is this vital distinction between the two, viz., as regards temperature, climates merge into each other by comparatively nice gradations, whereas, on the contrary, the most diverse climates as respects moisture or dryness are frequently placed sharply side by side.

I have been long impressed with the importance of a knowledge of the rainfall viewed in these aspects; and have recently constructed 13 maps, one for each of the months, and for the year, the rainfall over the greater part of the land of the northern hemisphere. The result of the whole discussion, in its relation to climate, is very striking. It shows where the rainfall is greatest on the prevailing winds, and on the configuration of the earth's surface; and since the prevailing winds depend on the distribution of land and water over the globe with respect to the heat of the sun, it follows that temperature

class, of fine strong bushy habit; tube and sepals very stout in substance, bright coral-scarlet, the latter completely reflexed, and the corolla of the most perfect cup form. The best in this class for exhibition purposes.

Crown Prince of Prussia (E. G. Henderson).—This is certainly a most beautiful Fuchsia, with dark tube and sepals, the latter very broad and thick, of an intense scarlet, and finely reflexed, and the corolla violet-blue; of a fine but by pyramidal habit.

Will Sell (Banks).—Unquestionably one of the prettiest Fuchsias ever sent out; it is in the style of Killliecrankie and Glow-worm, both of which are well known to every admirer of the Fuchsia, on account of their peculiarly attractive satiny magenta-coloured corolla; tube and sepals coral-scarlet, the latter most beautifully reflexed, quite round, forming four perfect circles. A very free bloomer, and of a good free pyramidal habit, with small neat foliage.

Perfection (Banks).—The flowers of this variety are rather small, somewhat resembling the hardy varieties, but larger; the colour of the tube and sepals and their perfect shape render this perhaps the nearest approach to perfection of any Fuchsia we possess; unfortunately it is but a moderate grower, and so very free-blooming that it becomes rather difficult to grow.

Gazelle (E. G. Henderson).—This is one of the best habited of the dark Fuchsias for exhibition; scarlet tube and sepals, the latter immensely large, and boldly reflexed, while the blue corolla is exceedingly fine and graceful.

King of the Stripes (Banks).—This is a very distinct Fuchsia, producing fine bold flowers, having each petal distinctly striped with red on a violet-blue ground. It is very free blooming, and possesses a fine vigorous pyramidal habit.

Nabob (E. G. Henderson), *and Vesta* (Banks).—Both good new Fuchsias, and an advance upon older kinds, but scarcely wanted, as they so nearly approach some of those already described.

Sedan (Hock & Co.).—Strange to say, since obtaining that beautiful Fuchsia, Madame Cornelissen, we have had nothing from the Continent to approach it in excellence, but out of a quantity of new kinds imported this season the above promises to be a very attractive and distinct variety, although it is nearly a self-coloured flower, and is very similar to a good old kind called the Duke of Wellington, which used to be extensively grown about 20 years ago. The colour of this variety is very bright, and the corolla is remarkably attractive. It has short, thick-set, finely reflexed flowers, blooms very freely, and possesses a beautiful habit, so that it will undoubtedly become a favourite, especially for market and pot work.

FUCHSIAS WITH WHITE TUBE AND SEPALS, AND RED COROLLAS.

Arabella Improved (Lye).—Good varieties with light sepals and tube are always scarcer than the dark kinds. This, however, is really first-class, although perhaps rather coarse. It very much resembles Arabella, from which it is a seedling, in conjunction with Annie. Tube very large, sepals broad, of thick leathery substance, and well recurved. It is a quick grower, with a vigorous and graceful habit, and very free, and is certainly one of the best light Fuchsias ever sent out for exhibition purposes.

Leah (Weston).—This very much resembles a good old variety called Annie, but has more purple in the corolla; tube and sepals pure white, the latter well reflexed, very free blooming, with large flowers. It is a strong upright grower, and a good decorative Fuchsia.

Striata perfecta (B. S. Williams).—This is a Continental variety; its corolla is perfectly distinct; in fact, we have never had any of the light tube varieties with a striped corolla before. It is a strong-growing kind, of weeping habit, a free bloomer. Tube and sepals waxy white, the latter broad and well recurved; corolla bright carmine-scarlet, each petal distinctly striped, particularly on the inside. I had this exceedingly handsome all through the autumn.

FUCHSIA WITH WHITE COROLLA AND SCARLET TUBE AND SEPALS.

Mrs. Bland (Bland).—This class of Fuchsias have, from their very first introduction by Mr. Storey, about 19 years ago, generally assumed a long slender habit of growth, with foliage quite distinct from that of other classes, but this variety possesses a beautiful dwarf vigorous habit, and its foliage is broad and bold, and undistinguishable from that of the old kinds. Tube and corolla is very long and barrel-shaped, the sepals rather narrow but well reflexed. It is a very free bloomer, and the best in its class.

DOUBLE FUCHSIAS WITH WHITE COROLLAS.

Avalanche (G. Smith).—This is the most noble Fuchsia in its class yet sent out. The tube and sepals are of a light carmine-red, the latter of large size, and good substance and well recurved; the corolla is pure white, exceedingly large, and very closely set with petals. The plant is of free growth, although the wood is thin and wiry, and it is a most profuse bloomer for a double variety.

Princess of Wales (Bland).—Also a variety with double corolla, possessing splendid broad tube and sepals of a fine glossy coral-scarlet colour, the latter reflexed in the boldest form, almost equal to any of the dark varieties. It is of good free bushy growth, blooming most profusely.

Little Alice.—This is another of the same class, and of neat miniature growth, and a very valuable kind for small pots. It is of exceedingly dwarf growth, very free, with small foliage, and producing an abundance of pretty little perfect blooms, for which reason it is well adapted for market purposes.

DOUBLE FUCHSIAS WITH DARK COROLLAS.

Champion of the World (Bland).—This is by far the largest Fuchsia that we yet possess. The foot-stalk is of unusual length and strength, so that the flowers stand out boldly. The tube is short; the sepals are very broad and of great substance, well reflexed, and of a most beautiful coral-red. The corolla is of immense size, and as it expands forms two-thirds of a perfect ball, its colour being of the most intense bright dark purple. The plant is of free growth, tall, and blooming abundantly, so that for conservatory decoration it is one of the most valuable Fuchsias yet sent out.

Rose Bland (G. Henderson).—This is a very distinct double, on account of its peculiar and intensely dark corolla, beautifully flaked with red rose. The tube and sepals are dark red, the latter finely reflexed, the stamens long and showy. It is free blooming, and of fine graceful habit.

Albert Memorial (Bland).—A double dark Fuchsia, very attractive on account of its general free growth and free blooming qualities. It has a scarlet tube and sepals, the latter well reflexed, and a very broad large leathery corolla. One of the finest double Fuchsias for exhibition.

Purple Prince (G. Smith).—This is also a very good Fuchsia, with large blooms. The tube and sepals are waxy carmine-scarlet, the latter well reflexed; the corolla is much spread out, the outer petals arranged similarly to those of the single dark varieties, the centre being filled up with smaller ones of a light bright violet. The habit is strong and the foliage large. It is a free bloomer, and a fine exhibition Fuchsia. *H. Cannell, F.R.H.S.*

Garden Memoranda.

LOXFORD HALL, ILFORD, THE RESIDENCE OF FRANCIS WHITBOURNE, ESQ.—The editorial note at p. 1482, on the Chrysanthemums grown by Mr. Douglas, the gardener at this place, startled me across country to see, and I must admit, to greatly admire, the very superior display which he has. The plants are tastefully arranged in a very commodious span-roofed orchard-house, which in itself is fully in keeping with the many glass structures around it, which Mr. Whitbourne, as a great lover of the pursuit of gardening, has erected, and to which I hope to refer further on. Amongst the varieties grown for the size and beauty of their individual blooms I made a note of Princess of Teck, a beautifully incurved pure white flower; Her Majesty, a fine globular silvery bloom; and Mrs. Heale, a star incurved flower, both in size and form, the shape of the flower being exquisite—indeed too much cannot be said in favour of this variety as brought out here. Empress of India is perhaps too well known to require any comment, but the blooms which I saw here exceeded in size anything that I had seen before. The finely reflexed John Salter is a fitting representative of that worthy name, the orange shading upon its cinnamon-red broadly incurved florets being very striking. Faust, a variety of an intermediate habit, had very finely shaped flowers, in colour a dull bronze-purple, strikingly tinted with gold at the points of the slightly incurved florets. Mrs. Sharpe is another fine incurved bloom, deep rose in colour. Miss Hope, similar in build, is equally meritorious, but not of so dark a tint. Jardin des Plantes is a most lovely variety, of which blooms of cricket-ball size and build were prominent. Yellow Perfection comes second to it, and is superior to it in colour. Both these are pure white blooms, the latter, Nor should Golden Queen of England be forgotten, for when I say that some of its flowers measured 7 inches, by rule, enough will have been said to show the very superior manner in which these blooms are brought up. Venus is a finely incurved flower of a delicate tint of peach. Lady Hardinge, delicate rose, is well-known. Progne, with its amaranth colour and violet-like scent—even if somewhat straggling in habit—is worthy of cultivation. Prince of Wales is a dark violet and beautifully incurved variety, the blooms here being very large. Duchess of Wellington is a very classic rosy flower; and Lord Stanley is a large, finely incurved flower, of an amber-orange tint.

Turning to specimen plants suitable for exhibition—of which there were some very meritorious specimens of standards and dwarfs, averaging about 3 feet in height—I noticed that Bob possessed a remarkably bright colour, quite a shining scarlet in fact, similar to Julie Lagravière. Aurea multiflora is good of its colour for this work. Dr. Sharp is a decided acquisition to specimen growers on account of its good habit and darkish crimson, or red and crimson-coloured flowers. Amongst the Pompon section staged in another house I noticed Golden Aurore, the best white; Mdlle. Marthe, dwarf and free; the varieties of Cedo Nulli, four in number; and, what is grown very successfully here, the dark rosy violet Hélène. Of large-flowered Anemones, were Miss Margaret, white centre, which should not be confounded with Fair Margaret (rose-coloured peach); King of Anemones, crimson-purple; and Empress, lilac, and a large bloom. Amongst Pompon Anemones, Madame Monteth, Miss Nightingale, Madame Lemoine, Gracilis, Perle, Marie Stuart, and Miss Wyness, were conspicuous; whilst Queen of Anemones and Jean Hachette, respectively crimson and white, deserve a place in every collection.

Turning now to the quaint Japanese forms, we possess in Red Dragon an indispensable variety, the petals having strikingly numerous crinkles, for their narrowness and length to form a very pleasing bloom, whilst the spots, or mottlings of golden tint, give it a most novel and pleasing character. Other conspicuous kinds are—Meteor, with its yellow and orange twisted florets; Grandiflora, another yellow, and very properly named; Jane Salter, broad florets, possessing a white ground, striped with light lilac; Prince Satsuma, another telling yellow; Bronze Dragon, &c. James Salter is a fine large mauve, or lilac, and is perhaps the earliest flowerer in this section, whilst Mr. Masters is a most useful late variety, of a reddish tint tipped with gold. Yet one other form amongst the many—the best Chrysanthemum of all as a free grower and free bloomer combined, with purity of colour and form—I refer to Mrs. G. Rundle, of which the largest specimen I ever saw was at Loxford Hall. It measures, upon a 4-inch single stem be it understood, 6 feet across the head, or 18 feet in circumference. We have all heard of the man who built an article within his workshop which he was unable to get out at the door. This has absolutely occurred in this instance, for this single specimen has to remain in solitude within the structure wherein it was trained, because it could not be got out at the door.

As November days are but short we hurried through the other houses. In two Cucumber-houses Mr. Douglas had a grand display of Cyclamens in flower, with good examples of its long, neatly-shaped fruits. Seed it will not, however, hence it will not be propagated so freely as could be desired. In three neat and useful Pine-houses are a remarkably robust stock of Pines, in the various successional stages—the Queens, Charlotte Rothschilds, Enviables, &c., which will doubtless tell their own tale anon. Very fine examples of Lapageria rosea exist in the greenhouse, whilst fortunately for the owner, considering the mistake that has been made, the true white variety is in bloom, and growing strongly, in another house. Among repotted and other plants, &c., Acœd Yellow is a strong grower and free; Madame Adèle Calmito and Mons. Jacotot are two good Italian varieties. A good flower, too, is Prince of Orange. Turner's Bride has a fine bloom, and Queen of Whites is a true perpetual. Leviathan is a very useful scarlet, and quite extensively grown for market under a variety of synonymes. There is also the old Bride, which has fringed petals by way of contrast to Turner's Bride, possessing smooth petals. In this house I noticed a new variety of Thrift, with wider leaves than ordinary garden varieties, and the flowers are of a rosy pink colour.

In the late vineries were some excellent examples of late kinds of Grapes: Mrs. Pince, for instance, with bunches from 3 to 4 lb. in weight; Lady Downe's the same; whilst the red-foliaged Barbarossa had a heavy crop—notices of the latter, I remark, would weigh 3 lb.; and of Black Hamburghs there was a bunch amongst many that I think will likewise bring the scales down to the same weight, or more. Here were also examples of the Golden Champion grown along with Hamburghs, still firm, fresh, and of most delicious flavour. The bunches ever had been of fine size. The vineries were both large and good as I have described, whilst their hanging capacity, in contrast with the Hamburghs, was all that could be desired. As I must now consider myself encroaching upon your space, I will briefly add that collections of Masdevallias, Odontoglots, and other Orchidaceous Cypripedes were here, amongst which I noticed a remarkably healthy specimen of Phalænopsis grandiflora, a nice plant of Cattleya Warneri, various Vandas, &c. These were associated, more or less, with a valuable collection of stove plants, including Palms, conspicuous amongst which were Chamærops excelsa, C. humilis, and C. ritchii, each fine table plants; Areca lutescens, A. aurea, &c. Two species of Nepenthes, viz., N. Rafflesiana, and N. phyllamphora, served to show how infinitely superior is Sir Stamford Raffles' variety to the Chinese one which took possession of the technical specific name. The lesser Pitcher-plant has, indeed, one great merit, it will exist where the Singapore plant would not live at all, *i.e.*, in a temperature of about 55°. Amongst the stove plants Ixora coccinea bore fine heads of bloom, suggesting that the ancient Eastern nations were not far astray in regarding it their deities, must have possessed a very refined taste. There were good examples of Anthurium Lindeni and A. Scherzerianum, illustrative of a genus possessing very distinct and divergent characteristics; also of golden Ferns, and the new variety of Blechnum or Lomaria, which Mr. Douglas has turned out as distinct. It is a quaint Fern certainly, for whilst the fronds and the characteristic broad pinnæ of B. corcovadense are mainly conspicuous, narrow fertile fronds occasionally push, precisely like those upon Lomaria gibba. Nor should I pass by without notice a nice specimen of Lomaria gibba var. Bellii. One other incident which proved of interest to myself, and might perhaps to some readers, I may record. There is amongst the Coniferæ upon the lawn here an exceedingly beautiful specimen of Cupressus Lawsoniana of moderate size. I have generally planted this variety in conspicuous places in shrubberies only, it is, however, worthy of a position, as a single specimen, in even the most prominent situations. These hurried remarks prove how thoroughly I appreciated your hint regarding the merit of the Chrysanthemums at Loxford Hall, for I must add, that without expressing my hearty thanks to Mr. and Mrs. Whitbourne, who considerately and unrestrainedly

permit those who are interested in gardening to inspect the meritorious productions of their able gardener, Mr. Douglas. *Opus.*

Obituary.

We have to record with regret the death of Mr. Robert James, of the "Rochester Castle," Stoke Newington. Mr. James may be said to have been the founder of the Stoke Newington Chrysanthemum shows, which really gave the first impulse to the cultivation of that useful autumn flower. He was an enthusiastic florist, and an ardent supporter of horticulture, to which he devoted a large portion of his time. In private life his moral character was exemplified by the strictest integrity, kindness, and benevolence; his left hand, it may truly be said, never knew what his right hand did. He died rather suddenly, after three days' illness, on Tuesday, the 28th ult., universally respected and regretted.

Nov. 23.—Generally overcast. Very foggy.
— 24.—Overcast till noon, and again at night. Variable in the afternoon. Generally fine.
— 25.—Overcast throughout. Frozen rain fell about 9 A.M., and slun misty rain till 3 P.M. Very dull and foggy.
— 26.—Overcast. A little misty rain fell occasionally.
— 27.—Generally cloudy. A little rain fell at intervals.
— 28.—Cloudy till night; then variable and very fine.
— 29.—Fine, with small amounts of cloud at mid-day; cloudy at other times. A little thin rain fell occasionally. Slight fog.

JAMES GLAISHER.

Garden Operations.

(For the ensuing week.)

PLANT HOUSES.

Every gardener who takes a pride in his place will now be doing his best to make the plant-houses under his charge as gay and cheerful-looking as possible, whether these be stoves, greenhouses, or conservatories proper, all of which may be made more or less pleasing and attractive, according to the tact displayed in the arrangement of the subjects at command. Much may be done in creating variety even with a slender stock of plants, if the style of grouping is occasionally altered; but, in any case, every plant now in flower should occupy a front position. The best of the available specimen foliaged plants should be used for intersecting the former, and for occupying the most prominent and telling positions in the rear or above as the case may be, and it is with these that agreeable changes may be made by occasionally and judiciously transposing them. Fire-heat must be applied occasionally to all plant structures, even during moderately temperate weather, to dispel damp, and so save not only the blooms but also the more tender foliage from injury. These moderate fires should always, however, be lighted at such times that, by creating a little extra dry heat, the air may be made more buoyant during the time that it can be given with moderate freedom. Give now as much room as possible to *Pelargoniums* intended for early flowering. Stop the young shoots, and by keeping the air around them free and dry assist them to break well. Particularly bear in mind that a more limited regimen will tend to aid them more during this process than would a more liberal one. Tie out such as require it, and make preparations for potting them as soon as they have formed a sufficiency of young shoots. Place as many *Dutch Bulbs* in the forcing-pit as are likely to be wanted for successional display, as well as any of the many other desirable plants to hand, such as *Azaleas*, both Ghent and Indian, *Roses*, *Heliotropes*, *Mignonette*, *Pinks*, *Lilies of the Valley*, *Deutzias*, and Hyacinthus orientalis. Prevent drying off *Fuchsias*, so that they may be denuded of their foliage as quickly as possible, when, as before intimated, they may be stored away in any dark corner where immunity from frost is assured. Persist, also, in ripening off and resting all hard-wooded and other plants that require such treatment, by a sensible reduction, by keeping them somewhat short of water, and by maintaining them at the cool end of the house. Make the necessary selection, and mark off such of the stock of *Chrysanthemums* as it is intended to grow next season. Those who wish to grow large specimens during the ensuing year should put in cuttings now.

FORCING HOUSES.

Attend well to such *Vines* as are now in the act of breaking into growth. Keep up the heat in any fermenting materials placed in the house to soften the buds, and so induce them to break more freely, by adding more material where necessary, and by occasionally turning the main body over, and damping it, if it becomes too dry. As the operations of forcing advance, the atmospheric moisture must be increased, and the wood be damped over with the syringe. Care must also be taken to maintain a gentle warmth in all outside borders attached to such houses; proceed, however, with great moderation, as nothing is gained by excessive forcing in the early season. The temperature should not be allowed to rise above 60° by day, even on the most favourable occasions, whilst for a time 55° will be a suitable mean; this by day, of course with a relative decrease of from 8° to 12° by night. Do not omit to keep a slight warmth in the heating medium attached to the *Vinery* containing crops of late Grapes, and more particularly if these consist of Hamburghs, or other thin-skinned varieties. Keep the temperature around such *Pines* as are pushing up their blooms, or are already swelling, moderately brisk, to aid them onwards, if any have at this late time of the year beginning to maintain sufficient heat around Pine-pits, great care must be taken to prevent steam from entering, and to have an uninterrupted supply of fresh fermenting materials in readiness to renovate the heat as soon as it is found to be on the wane. In *Allotment-gardens* an abundance of moisture must be afforded when the young "buttons" begin to form and subsequently, especially where arid flue-heat only is afforded. The necessary successional beds should also be made, and a further supply of *Asparagus* and *Seakale* should be put for a like purpose.

HARDY FLOWER GARDEN.

Those who have delayed mulching such somewhat tender subjects as Pampas-grass (*Gynerium argenteum*), *Tritomas*, *Fuchsia* "stools" which stand out-of-doors during the winter, should do so no longer. In this department almost constant work will be found in sweeping, cleaning, rolling, &c., for the next week or two, as the fallen leaves incessantly supplied by the sward and gravel walks are brought through the ordeal with perfect order, neatness, and freedom from injury. This will be found a good time to re-label such outdoor plants as have their existing labels more or less injured, and the names more or less obliterated by the action of the weather. Be particular also at this season not to let fallen and decaying leaves collect and lie amongst beds, borders, or patches of tender annuals; for, even if they do not cause any to rot off, they do, to say the least, cause the plants to become drawn and unhealthy. Those who have not filled their flower-beds with annuals, bulbs, &c., should now have them manured with decayed leaves, and dug deeply, leaving the soil fully exposed to the action of the winter's air and frost. By thus manuring them at this season, the properties of the manure are absorbed by the soil, and so become divested of their original strength, which would only tend to grow leaves at the expense of a dwarf, freely-blooming habit.

KITCHEN GARDEN.

Cauliflowers, *Lettuces*, &c., grown under hand-lights or plant-protectors, should have as much air as possible at all times excepting during frosty weather, at which time, if the frost proves at all severe, a covering of some kind of waste litter would be beneficial. Watch the *Peas* and *Broad Beans* already sown, for doubtless the mice or birds will molest them greatly; where there are no Pea "rizzles" it will be well to soot and lime the surface of such Peas as are already through the ground, as a deterrent of both birds and mice. Have a few ordinary wooden hurdles neatly thatched with straw in readiness to place over beds of *Parsley*, *Endive*, &c., at the advent of snow, with its general accompaniment—frost. *Coleworts* and young *Cabbage plants* might, during a mild period, be earthed-up more permanently, in preparation for the severe frosts of winter. Take up and store away safely from frost a limited supply of *Jerusalem Artichokes*, *Horse-radish*, *Parsnips*, &c., to be in readiness, should a sharp period perchance visit us. Place also a good thickness of litter over the stools of *Seakale*, from which the supply of roots is got for forcing, and so prepare for all eventualities. *W. E.*

Notices to Correspondents.

Early Grapes and Peaches: *F.R.H.S.* Judging by the data which you furnish, and presuming that your Vines have already been pruned and prepared for forcing, our advice is, that you should start them early in the second week of December. Simply keep the house closed at the first week or ten days, and maintain only a temperature ranging from 42° at night to 46° by day, with occasional syringings. This will prepare the Vines for a gradual rise in the temperature, towards the end of the month, up to 50° by night and 55° by day. In this way they will be induced to break freely by the time the increased light of the lengthening days is felt, when forcing may be advanced rapidly. You do not say by what time you want your earlier Peaches ripe, but we would suggest that, if your earliest house is situated so unfavourably as regards the sun, you should start it about two months earlier, in the same manner as described for Vines.

Fungus on Grapes: *J. S.* Your Grapes are attacked by a mould or Penicillium, which lifts up the colourless cuticle, when the juice oozes out by capillary attraction, and causes the pretty dotted appearance. We have seen similar cases before. *M. C. B.*

Gardener's Luncheons. *Subscriber.* It would be better to have a definite understanding when the engagement is made. There is no established rule on the subject that we know of. If a proper sense of duty on the part of the employed, and a befitting confidence on the part of the employer exist, no harm to the master's interests, but often the reverse, may ensue from a good understanding between housekeeper, cook, and gardener. The harm is when such things are done "on the sly," or in contravention of direct orders. As a rule, we think it better that the gardener should keep out of the house.

Market Gardening: *J. M. & Sons, Aberdeen.* "Cuthill on Market Gardening" will perhaps meet your requirements.

Names of Plants: *J. M.* Polystichum aculeatum.

Orchid Leaves Spotted: *A. C.* It is the common case of Orchid spot, which so frequently attacks species of Phalænopsis. The cause is unknown, as is also the remedy. It is not the mere result of cultivation, as it occurs in specimens in their native country. It appears to be contagious. *M. J. B.*

Pear, Williams' Bon Chrétien d'Hiver: *W. D. F.* The merits of this Pear were stated by Mr. Scott at p. 203.

Primulas: *Fisher, Holmes & Co.* An excellent strain of crimson Chinese Primroses, the same as that grown in various quarters.

Sobralia Elizabethæ: *Orchidophilist, Dublin.* We have reason to believe that this Orchid, described by Schomburgk as having been found by him on the banks of the Orinoco, and as having flowers of "splendid configuration and exquisite scent," has not been introduced into any nursery at all events, as we do not see it advertised in any of the trade catalogues before us.

Veitch Memorial Prizes: *G. L.* We are informed that the trust deed, which has been for some time past in the lawyer's hands, now only requires the signatures of the trustees and the other contracting parties. When this is completed, the trustees will, of course, meet, and decide on what shall be done.

Errata: At p. 1516, col. *c*, first line of third paragraph from bottom, for "1 and 2" read "2 and 3." At p. 1518, col. *b*, line 41 from bottom, read "Hymenopteron;" line 24 from bottom, read "Mayr" for "Mayer;" line 7 from bottom strike out "Cynips glandis."

Markets.

COVENT GARDEN.—Dec. 1.

A moderate rate of business prevails, and the markets generally have a tendency to quietness, the supply being about equal to the demand, and there being no novelties to induce inquiries amongst us. Portugal Grapes prove generally very inferior on breaking the bulk. Hothouse

Grapes are sufficient for the trade. Good samples of American Newtown Pippins have made 60s. per barrel. In the Potato market prices have a slightly downward tendency.

FRUIT.	s.d.	s.d.
Apples, per ½ sieve	2 0	to 5 0

The Agricultural Gazette.

SATURDAY, DECEMBER 2, 1871.

MEETINGS FOR THE ENSUING WEEK.

MONDAY,	Dec. 4	London Farmers' Club (Mr. J. K. Fowler, on Breeding), at the Salisbury Hotel—6 P.M.
		Institute of Surveyors (Mr. I. Clutton, on Disafforesting), at 12, Great George Street, Westminster—8 P.M.
MONDAY,	Dec 4	Smithfield Club Show, at the Agricultural Hall, Islington.
FRIDAY,	Dec. 8	
TUESDAY,	Dec. 5	General Meeting of the Smithfield Club, at the Agricultural Hall—1 P.M.
		Royal Agricultural Soc. of England (Council Meeting), at Hanover Square—Noon.
WEDNESDAY,	Dec. 6	Central Chamber of Agriculture (General Meeting), at the Salisbury Hotel—3 P.M.
THURSDAY,	Dec. 7	Royal Agricultural Soc. of England (General Meeting) at Hanover Square—Noon.

NEXT WEEK will be full of agricultural interest. Many important subjects will engage the attention of the countrymen who are now arranging for a week in town. On Monday, at 6 P.M., in the Club room at Salisbury Square, Mr. J. K. FOWLER, of Aylesbury, will speak before the London Farmers' Club on the Principles of Live Stock Breeding, illustrating them by facts within his own experience. At 8 P.M. on the same day Mr. CLUTTON will read a paper before the Institution of Surveyors in Great George Street, on the Cost of Bringing Forest Land into Cultivation. On Wednesday evening, at 8 P.M., before the Society of Arts, Mr. BAILEY DENTON will read a paper on Land for Utilising and for Cleansing Town Sewage. The Central Chamber of Agriculture holds its annual meeting on Wednesday at 3 P.M., in Salisbury Square. The Royal Agricultural Society of England assembles, at a general meeting of members, on Thursday, at noon, in Hanover Square. But we have omitted all mention of the Smithfield Club, which more than any other gives its character to the week. On Monday morning their annual show of fat stock opens at the Agricultural Hall, Islington, and remains open during the week.

Including the best illustrations of our best breeds of stock, in the conditions in which they fulfil the purpose of all that the farmer does to

or for them, the show has for several generations of men held one of the highest positions in the agricultural exhibitions of the year. Once almost the only occasion of anything like a national agricultural meeting, it now, of course, takes a second rank after other shows where all the departments of agriculture are represented.

But here, too, there is much more than the bare fat stock display—machine makers, seedsmen, manure manufacturers, vie in their efforts which they make to attract the attention and supply the wants of the crowds who are drawn together chiefly by the cattle, sheep, and pigs; and the result is one of the completest agricultural shows of the year. We hope to give next week a full report of it in all its departments.

We read in MACAULAY'S history that "the golden age is a *mirage*, which, if we trace it backward, recedes before us into the regions of fabulous antiquity. Yet many in spite of evidence will still imagine to themselves the England of the STUARTS as a more pleasant country than the England in which we live." The brilliant historian gives a summary of the comparative advantages enjoyed by society now and in past times; contrasting the lumbering coach with the express train, and the luxury of modern civilisation with the plain simple life of the past. But when he attempts to make out a list of advantages enjoyed by the labouring classes he is obliged to rely on his inimitable power of word-painting, rather than on unvarnished facts. We read that the inclosure of wild land, common by law or fact, has diminished the physical comforts of a portion of the poorer classes. "Squatters and trespassers were tolerated to an extent now unknown." The peasant who dwelt on the common "could, at little or no charge, procure occasionally some palatable addition to his hard fare, and provide himself with fuel for the winter. He kept a flock of geese on what is now an orchard rich with blossoms. He snared wild fowl on the fen, which has since been drained and divided into corn fields and Turnip fields. He cut turf among the Furze bushes on the moor, which is now a meadow bright with Clover and renowned for cheese."

The progress of agriculture and the increase of population necessarily deprived him of his privileges, but he enjoys a long list of advantages, for "a large proportion of the blessings which civilisation and philosophy bring with them is common to all ranks." The historian proceeds to notice that the rustic and his cart can, in one hour, reach his market-place, which, 160 years ago, was a day's journey from him. "The street, which is now a secure, convenient, and brilliantly lighted walk, was, 160 years ago, so dark, that he might after sunset have broken his neck, or been knocked down and plundered of his small earnings." But now, every bricklayer who falls from his scaffold, every sweeper of a crossing who is run over may have his bones set and his wounds healed for a trifle, with more skill than a great lord could have purchased with all his wealth 160 years ago. These are great advantages, no doubt, to people who have occasion to go to market in a cart, and to bricklayers who break their legs; but, remembering our million and a half of paupers, and the misery of the poor in our great cities, we hope that some future historian will be able to claim certain more substantial advantages among the "blessings of civilisation and philosophy." Manners have, no doubt, greatly improved since the 17th century; we are less rude and rough now-a-days; our ancestors were less humane than their posterity, harsher in their families, severer to schoolboys, less kind to servants, rougher with their wives, and more cruel to their malefactors. Public opinion is in many respects far more enlightened than it was, in proof of which we may quote the same author:—

> "The practice of setting children prematurely to work, a practice which the State, the legitimate protector of those who cannot protect themselves, has in our time wisely and humanely interdicted, prevailed in the 17th century to an extent which, when compared with the extent of the manufacturing system, seems almost incredible. At Norwich, the chief seat of the clothing trade, a little creature of six years old was thought fit for labour. Several writers of that time, and among them some who were convinced as eminently benevolent, mention with exultation the fact, that in that single city boys and girls of very tender age created wealth exceeding what was necessary for their own subsistence by £12,000 a-year."

As "the State" now means public opinion, and Government has become the executive power for carrying into effect the will of the public, it is evident that the knowledge which guides public opinion must always be the measure of social progress. The "golden age" will approach in proportion as the public becomes more intelligent, enlightened, and virtuous, and when morals have improved in the same degree as manners.

It is unfortunate that at present the most active-minded of the working classes are more interested in watching the mere machinery of Government than in gaining knowledge of the means by which Government might aid society to improve the conditions of our social life. They suffer from political restlessness; they do not seem to recognise that we already have a Government from which the public can obtain any measures it thinks proper. They do not understand that our welfare does not depend on the improvement of the mechanism of government. There never was, and never will be, a perfect, patent, ruling machine; on the contrary, in good hands, a great deal may be done with an old machine, and in bad hands the best machine is useless. Questions relating to labour, food supply, shelter, sun, air to breathe and water to cleanse, or abounding pauperism, noisome crowded alleys, with circumstances of existence noxious and even murderous,—all such questions relating to the moral and material progress of society are more urgent than any others that can occupy public attention, and they require for their solution not mechanism of Government, but on the enlightenment of public opinion. We have few political grievances now-a-days; we no longer suffer from the injustice of Government, the ascendancy of the nobles, or the oppression of any class of the people. The country has its griefs and grievances, but they arise from social, not political causes, and their root is ignorance. The reform that is needed is such reform as shall better the condition of the millions, mending their manners and mending their souls. It must be confessed that in this age of progress the poor have fared badly. The concentration of capital has produced extremes of poverty and wealth. Let the cost of producing food be materially reduced by methods that have been often indicated, and a new channel will be opened for surplus labour. "Every step in advance made by agriculture serves to alleviate the sufferings and troubles of mankind." Agriculture would itself require a large increase of its labouring forces, other industries would be invigorated, and there would be an end of emigration and of an increasing poor-rate for many years to come. "Improvements in agriculture constitute the only solid foundation for further progress in all other branches of knowledge," but "observation and reflection are the fundamental conditions of all progress in natural science; and agriculture presents in this respect ample room for discoveries."*

Of these are hinted at from one whose works, beyond all others that have been written, reveal the special knowledge which is needed in order to understand the food question. They show the necessity for the co-operation of public opinion in the work of agricultural improvement. Farmers cannot prevent the continual increase in the cost of production, which is injurious alike to themselves and to the country. Legislation can alone deal with the modern evil of "town waste," and it is with the public that the great issue those commands to the executive without which it never ventures to act. The problem the public should set itself (not deputing the matter either to chemists or manure companies, for it is altogether too big for them to handle it effectually) is, to arrest the impoverishment and accomplish the enrichment of the soil. It would be easy to pile up authorities to prove that no subject can be more important. Much as the circumstances of the world have changed in these days of steam and progress, there are old rules which are as correct as ever they were, as, for instance, this of SWIFT'S:—"The first cause of a kingdom's thriving is the fruitfulness of the soil, to produce the necessaries and conveniences of life;" and likewise this other sentence of ADAM SMITH'S:—

> "Whatever increases the fertility of land, in producing food, increases not only the value of the land upon which the improvement is bestowed, but contributes likewise to increase that of many other lands by creating a new demand for this produce. That abundance of food, of which, in consequence of the improvement of land, many people have the disposal beyond what they themselves can consume, is the great cause for the demand both for the precious metals and the precious stones, as well as for every other conveniency and ornament of dress, lodging, household furniture and equipage. Food not only constitutes the greater part of the riches of the world, but it is the abundance of food which gives the principal part of their value to many other sorts of riches."

* "Modern Agriculture," Liebig.

The subject of the food supply, which has so often been brought under the notice of our readers, exceeds all other social subjects in importance, and is perhaps the one on which the public is least informed. Consequently we have "Land Leagues," meetings in Trafalgar Square, and impracticable schemes for increasing supplies by colonising the waste lands. These may be harmless, but the discontents, the misapprehensions and the hatred, bred of ignorance and want, are not harmless.

A MODERATE supply of English Wheat at Mark Lane on Monday sold at the prices of that day se'nnight. Wednesday's trade was inactive, and prices were in some instances lower.——Trade was active in beasts on Monday, at the Metropolitan Cattle Market, at an advance on the quotations of the previous Monday. In sheep, only choicest qualities made last week's prices. On Thursday trade in beasts was not brisk, but choice qualities were not affected. Sheep had to give way.

The report of an OUTBREAK of SMALL POX among SHEEP, in the East Riding of Yorkshire, naturally excited some alarm; but we are glad to be able to state that there was no foundation for the rumour. It appears that scab is prevalent in some flocks in one locality, and this circumstance seems to have given rise to a report which has happily been proved to be false.

The EXTENSION of the MEAT IMPORTATION is thus alluded to by the *Pall Mall Gazette*:—

> "The meat trade may, for statistical purposes, be roughly divided into four distinct categories. The first comprises live stock alone; the second, salted, fresh, and preserved meat; the third, animal produce—butter, lard, and cheese; and the fourth consists of vegetable food obviously intended for the fattening of cattle. To these it would probably be possible to add a fifth list, comprising game, eggs, fish, &c.; but we have thought it on the whole desirable to omit them from this article.
>
> "The increase which has taken place during the last four years (we have purposely extended the period embraced in the latest returns of the Board of Trade) is thus shown:—

1.—*Live Stock.*

	Ten Months ending October 31.

	Tons.	Tons.	Tons.	Tons.
Oilseed cakes ..	114,152	124,793	117,226	136,311

> "From these Tables it will be seen that, with the exception of last year, when the war created an unusual demand for meat abroad, there has been a progressive increase in the meat trade in the United Kingdom far exceeding, as we believe, the conceptions of most people. Since 1868 our trade in live stock has increased by more than 140 per cent.; in dead meat by more than 80 per cent.; in animal produce by more than 50 per cent.; and in oilseed cakes by more than 20 per cent.; while the population of the United Kingdom is not certainly more than 3 per cent. larger than it was at the commencement of the period. The supply of meat from abroad is, in

other words, rapidly overtaking the demand at home, and its price is consequently less and less dependent on our home produce. Whatever consequences may result from this circumstance to the landed interest, it is hardly possible to doubt that the vast body of our fellow countrymen must be deriving benefit from this branch of our import trade. There are already indications that the price of meat in this country is beginning to decline; and if our trade continue to expand at its present rate, it may at least be safely predicted that it cannot go on rising.'

— In an able discourse before the Cirencester Chamber of Agriculture last week, in which the Rev. J. Constable, Principal of the Royal Agricultural College, advocated the introduction of the Metric System of Weights and Measures into Great Britain, he thus referred to the confusion prevalent, especially among agriculturists, in the matter of weights and measures :—

"There are in this country alone no fewer than 20 different ideas of a bushel. We go to Saltash, perhaps, after learning in our tables that there are 8 bush. in a qr., and discover that in that part of the world there are 5 qr. A load of Wheat means in one part of the country 5 qr. ; in another, 5 bush. ; in another, 3 bush. If I buy Wheat at Swansea, I must order by the stack of 3 bush. ; if at Earnard Castle, by the boll of 2 bush., and must not, when I compare quantity and price, confuse this boll with the two other bolls—one of 140, the other of 280 lb. If I buy at Beccles, I must order by the coomb of 4 bush. ; if at Preston, by the windle of 220 lb. ; if at Wrexham, by the hobbet of 168 lb. But even if I do happen to know what a hobbet of Wheat means at Wrexham, that knowledge, good for Flint, is not good for Carnarvon, as Apothecaries. 6. Diamond weights and pearl weights, including carats. 7. Avoirdupois weights. 8. Weights for hay and straw. 9. Wool weights, using as factors, 2, 3, 7, 13, and 182 lb. 10. Coal weights. 11. Weights for millers. 8 Victoria, 1, .5, .2, .1, .05, .025. Practically everything in the way of weight and measure goes its own gait. A gallon is not a gallon. It is a wine gallon, or one of three different sorts—an ale gallon, or a corn gallon, or a gallon of oil—and the gallon of oil means 7½ lb. of train oil, and 8 of some other oils. If you buy a pipe of wine, how much do you get? Ninety-three galls. of Marsala, 92 of Madeira, 109 of Bucellas, 110 of Sherry, or 115 of Teneriffe. What is a stone? Fourteen pounds of a living man, 8 of a slaughtered bullock, 16 of cheese, 5 of glass, 32 of hemp. It is 14 lb. as sold by the growers, 15 as sold by the wholesale dealers to each other, as regards acres, there are seven measures to define an acre. Again, a man may live by selling coals at a less cost per ton than he paid for them at the pit-mouth. A ton of coals varies at the pit mouth from 22 to 28 cwt., or 2464 lb. each. Of cheese, 32 cloves (each 8 lb.), make a wey in Essex—42 in Suffolk. We walk by four sorts of miles, English, Scotch, Irish, and geographical. Our very sailors don't mean the same thing when they talk of fathoms as men-of-war: it means 6 feet, on a merchantman 4½ feet, and a fisherman means 5 feet. Not to weary you with any more details, I will simply read the names of the different measures that exist in this country (Mr. Young, in 1820, when he prepared a report on the subject for the use of Parliament.—The awn, bag, bale, basket, bat, bay, beatment, billet, bind, bing, boll, bolt, bolting, bottle, bout, box, bucket, bundle, bushel, butt, cade, calendar, cade, canter, caroteel, carriage, cart, cartload, case, cast, cheef, chest, clue, cord, corf, cran, cranock, cut, cyvar, cyvelin, daugh, dish, drop, dupper, erw, faggot, fall, fan, flask, fodder, fothmal, frazil, gad, gaun, gallon, gang, gathering, gwr, bank, head, heap, hide, hobed, hoop, hutch, hyle, inceat, ingrain, jar, jug, keel, kemple, kenning, kibin, kishon, kiver, knot, lay, leap, lispound, lith, llathen, gyvelin, lestraid, lug, mans, mass, mease, mast, mell, measure, meer, meiliard, merk, mount, mug, oxland, pack, packet, paladr, pared, peccaid, peget, piece, pig, ploughland, pocket, poke, pot, pwys, quintal, reel, reis, rhaw, rithe, rod, rope, rood, sack, saum, scantle, sieve, skain, skin, skron, sleek, spindle, square, stacca, staff, stank, stick, stimpart, stook, stoeed, sum, talk, talshide, tankard, teal, thrave, thread, threave, timber, topston, truss, tub, tunnel, vergis, vengna, waggon-load, wain, warp, web, weight, and windle ; in all, 154.

— The Annual Root Show of Messrs. Carter & Co. was held on Friday, the 24th ult., on the premises of their Horticultural Despatch Depot, High Holborn. Notwithstanding that this show has been instituted only a comparatively few years, it numbered this season upwards of 200 entries. The roots were all grown by Messrs. Carter's customers, under ordinary farm cultivation. The most striking feature of the show was a collection of enormous specimens of their Mammoth Long Red Mangel, weighing individually upwards of 50 lb. The 1st prize of 10 gs. or a silver cup, for 24 roots of their Imperial Swede brought a great number of competitors. Twenty-four roots in this class was a collection of over 4 cwt. There also a very handsome collection of Carter's Prize Intermediate Mangel, a variety which produces a great weight per acre, its form admitting of its being left closer in the rows than other kinds. The other most noticeable sorts were Imperial Green Globe, Pomeranian White Globe, Devonshire Grey Stone, and new Purple-top Mammoth Turnips ; the Imperial Green Kohl Rabi, White and Yellow Belgian Carrots, Ox Cabbages, &c. ; all evincing great care in the selection and cultivation of the various kinds. The following are some of the awards :—

For the best 24 roots of Carter's Imperial Hardy Swede.—1st, E. Lythall, Esq., Radford Hall, Leamington, a Silver Cup, value 10 gs. ; 2d, Mr. D. Tully, Bowes House, Fence Houses, £5 5s. ; 3d, C. Longden, Esq., High Chimneys, Hurst, £3 3s. ; 4th, R. W. Glendenning, Esq., Bromdykes, Chirnside, £2 2s.

For 16 roots of Pomeranian or other White Globe Turnip.—1st, J. Gosling, Esq., Sonning, near Twyford ; 2d, Mr. J. Cave, Surfleet.

For 6 roots of Mammoth or other Long Red Mangel.—1st, Mr. R. Beecher, bailiff to J. Beamish, Esq., Kilmaloods ; 2d, Dr. J. Buck, Leicester.

For 6 roots of Elvethorn or other Long Yellow Mangel.—1st, T. Hetling, Esq., Groundslow, Stone ; 2d, Mr. D. M'Vicar, Grimsthorpe.

For 6 roots of Warden or other Yellow Mangel.—1st, Mr. D. M'Vicar ; 2d, Mr. R. Beecher.

For 6 roots of Red Globe Mangel.—1st, W. Brooks, Esq., Weybridge ; 2d, S. Hindon, Esq.

For 6 roots of Intermediate Prize Mangel.—1st, Mr. D. M'Vicar ; 2d, J. Haws, Esq., Romford.

For 6 roots of Mammoth or other Purple Kohl Rabi.—J. Fleming, Esq.

For the finest Ox Cabbage.—S. Robinson, Esq., Melbourne, Derby.

— Mr. Mechi writes thus of the proceedings of a clever Scottish farmer in Essex, who had been "driven out" of his farm in Scotland by a still cleverer Scottish farmer as we must pronounce him to be, seeing that he had to pay the higher rent from which his predecessor ran away :—

"Scotch farmers are being driven out of Scotland by an enormous increase in their rents at the termination of their 19 years' leases, especially those who, as good and profitable farmers, improved their land at the commencement of their leases by draining, liming, and other means. The tenant-right of Scotland, purchased, the landowners get the benefit of these improvements at the termination of the leases ; and, where the demand for a new rent is excessive, the tenant seeks for cheaper and unimproved farms—often in Ireland. This is good for England, as I purpose to show by the following recent instance in our county of Essex. A Scotch farmer, whose lease was approaching termination, and who was paying £1600 a year rent for about 1000 acres of land, purchased, the landowners of 350 acres, with a good residence, &c., upon it, for £20 an acre. This was a good, honest, but very stiff tile earth or collapsing clay, untrained, which went begging at a rain fine for 18s.—25s. per acre. Unfortunately, there still exists in Essex a belief among farmers that it is of no use to drain these plastic or collapsing clays, although the hard chalky clays are frequently drained. Our Scotch farmer, having no such barbarian prejudice, drained all the land 18 feet apart and 3 feet deep, put the fields into proper shape, broke up the wretched pastures, using the steam-plough, thus reducing his number of horses nine instead of five, and now grows 150 acres of Wheat, 40 acres of winter Beans, fine crops of winter Tares, Clover, and Mangel. The farm being close to water carriage, all the crops and straw (except what is consumed by the farm horses and a few bullocks) are sold off the farm, and the barges that conveyed them to London bring back London manure. What a change in the scene! Poverty superseded by plenty ; employment for labour and capital greatly increased, food for the people multiplied, capital remunerated, and the manufacturer of farm machinery benefited. The land is all deeply steam-ploughed by a 10-horse power engine (a roundabout fixture), the iron breaking having teeth 12 inches long. No cultivator is used. This soil was in the first instance so adhesive and tenacious that three horses or more were required to plough it, and in its original unchained state was pierced with deep furrows and water furrows to carry off the water from the surface. Now, by deep steam cultivation, the land is all levelled and the water passes down readily to the subterranean drains. I have not a doubt that the present necessity for improvement when land so near the great food-requiring metropolis is to be had for £20 per acre? I have seen such land so sold within the last 12 months, and there is plenty to be had at prices ranging from £20 to £30 per acre. This would not be so if we had manufacturers in Essex.

"This Scotch farmer wisely adopted the crops suited to our Essex soil and climate, such as Beans, Wheat, Mangel, Clover, and Tares, and avoided the usual error made by Scotch farmers in attempting to grow Turnips here on the Scotch plan, or spring Wheat."

OUR LIVE STOCK.

CATTLE.

A very neat catalogue of the Dunmore herd, just published, already contains the names and pedigrees of the recent additions from different breeders to, at most, a few cows. This is, however, a fault (?) to be looked for in a young herd, and as time goes on we shall probably find certain tribes asserting themselves more emphatically, to the exclusion of others. This diversity constitutes our principal difficulty in reviewing the Dunmore catalogue, in which we find a list of 88 animals, and representing 33 families. Among these, *Duchesses 106th* and *107th* occupy the first place. Next follow four Oxfords—*11th Lady of Oxford*, and her calf by 6th Duke of Geneva, imported last April ; and *8th Maid of Oxford*, and her calf by 4th Duke of Geneva, imported during the present month. The four "Red Roses," also just landed from America, come next, after which we have a collection of eight Kirklevingtons, known also as Siddingtons, and at Dunmore as Marchioneesses. Lord Dunmore's three Kirklevington cows have been prolific since he obtained them at Didmarton and Siddington, having produced five heifer and two bull calves. There is one Waterloo cow, one Cherry Princess of the Cherry Duchess tribe, and *Lady Thorndale Bates* of the Lady Barrington tribe ; after which a considerable array of Wild Eyes cows and heifers concludes the Bates portion of the catalogue. Knightleys appear in considerable force, representing *Cathleen* by Candytuft, *Flourish* by Little John, and *Annette* by Little John ; *Sweetheart 5th* represents Milcote, and *Empress Oxford* and her daughter *Cygnet* the Southcott "Californias ;" *Red Bonnet*, by Mr. Peacock's Game Boy, bred by Earl de Grey, is the ancestress of the Revelry family, now boasting among them a *Revelry 9th* (late *Ruby*). Mason and Colling blood is also present, the latter descendant of *Portia* by *Lady Thorndale*, a direct descendant of *Portia* by Cato, and the latter by representatives of *Countess* by Cupid, and later of *Violet* by Henwood, and stock in turn possessed by the late Earl Ducie and Mr. Bowly, of Siddington. Musicals, of Siddington notoriety ; Cleopatras with a cross of Booth, through the famous Duke of Buckingham (14,428) ; animals from Didmarton, from Nunwick, from Kingscote, and from other famous herds, conclude a long list of well bred cattle. 2d Duke of Collingham, bred by Captain Gunter, and purchased on the Didmarton second sale, still heads the list of bulls, and the remaining young bulls are from cows now in the herd.

— The *Mark Lane Express* thus comments on a prevalence of white cattle among the prize-takers at Birmingham :—"If not quite fashionable, the white Shorthorns were altogether in the ascendant, as, where there was any competition, all the first-prize oxen and steers were of this colour. Thus beyond Mr. Stratton's ox, the best of the next class, who came from Scotland with a high character, was sent up to London, was white ; but though a really good steer, he had not much to beat, and the same may be said of Lord Exeter's white, a 1st prize at Oakham."—The prejudice against white Shorthorns is surely dying out, as it deserves to do. It is true that some love vexes sines a blood. Neither is the fact insignificant that not only our native wild cattle are nearly white, but that escaped cattle tend to the same colour. On the Ladrone Islands in the Pacific Ocean, immense herds of cattle, which were wild in the year 1741, are altogether of a milk-white, except their ears, which are generally black ("Anson's Voyage"). The Falkland Islands, situated far south, offer a more interesting case. Cattle have run wild there, during 80 or 90 years, and in the southern districts the animals are mostly white, with their feet, or black, or white and black (Darwin). Now, it is evident that, when animals are unrestrained, a kind of natural selection is constantly taking place ; the weakest go to the wall, the strongest bulls become the sires, and if any particular colour was correlated with constitutional weakness, it is hardly probable that it would at length predominate over other tints. We should not have any difficulty in naming famous bulls and cows among our most noted herds of a white colour ; and the results of sales show that the opinion of breeders is not averse to white.

— The 14th number of Thornton's Circular contains the prize lists of our principal shows, so far at least as Shorthorns are concerned ; the results of all the chief public sales from July 5 ; an account of cattle exported to Russia and Germany ; and lists of bulls for service and animals for sale. The present number derives an additional and sad interest from obituary notices of the eminent agriculturists and Shorthorn breeders, whose loss during the last few months we have had to deplore. We refer to the late Mr. J. C. Adkins, Mr. T. W. Bramston, Mr. John Clayden, Mr. Richard Eastwood, Sir John Rolt, and Mr. Richard Stratton. It is seldom that death has, in a single year, made such sad changes among us, and we may ask—Where is the agriculturist, of any note, who among these esteemed and lamented men has not lost a friend ?

SHEEP.

In the notice of the late Mr. J. C. Adkins' agricultural career (Thornton's Circular) the following passage occurs, relating to the origin of the Milcote Down sheep :—

"It is, however, as a breeder that his (Mr. Adkins) name is widely known ; sheep were the stock upon which he mostly depended, and he quietly succeeded in producing another variety of Downs. Cotswolds were originally kept, but there was difficulty in running them thickly ; they produced fat at the expense of lean, and this, with the preference of dark for white faces in the market, pre-

vented a good sale. The Cotswolds were crossed with Downs, the best sheep of each kind being procured. Pure-bred Cotswold sires were used on the darker faced ewes, and pure Down tups on those with the Cotswold character, but even with judicious selection and vigorous weeding he failed to secure uniformity. Nothing daunted, he pursued another system. The purchased rams were set aside, and cross or home-bred ones used; these were reared on two principles. From the finest Cotswold flocks a few of the finest ewes were occasionally selected, and mated with first-class Hampshire Down rams. A robust Cotswold or Down tup was paired with Hampshire or Wiltshire Down ewes, and from these alliances were reared cross-bred rams, of which the best alone were reserved for service. Carefully pursuing that system, with that fine judgment and care with which Mr. Adkins was so liberally endowed, the Milcote flock steadily became uniform; a large fall of lambs was regularly secured; the ewes were admirable nurses, and when the tegs were about a year old they went fat from Mangel and hay, weighing from score to 1b. per quarter. The weight of wool was scarcely sacrificed, and the screable yield decidedly increased. So compact, hardy, and thriving was the flock, and withal so uniform was its character, that no more demand has existed in the neighbourhood for rams. The type of the Milcote Down is somewhat as follows :—A dark mottled face, rather large broad head, tapering to a fine muzzle, a short stout neck, a good crescom, well clad with wool, the carcase long, cylindrical, and well ribbed up, with strong good loin, supported on rather short, brown-mottled legs, the wool partaking of the Down character, and averaging from the whole flock between 8 and 9 lb."

THE LEICESTER SHEEP.

YOUR review of Mr. Bell's history of the improved Shorthorns (August 26, 1871, p. 1112), relating to Leicester sheep, is not likely to add to the credit of his volume. As you ask the opinion of Leicester sheep breeders upon the following anecdote, I beg to offer a few observations :—

"Mr. Bates often mentioned a fact which showed Mr. Waistell's discernment. Mr. Bakewell, he said, had concealed from the world how he had produced that wonderful improvement in his flock, but if he (Mr. Bates) knew, he was sure that it would prove that he had done it by the use of a black tup. Seventeen years after Mr. Bates heard Mr. Waistell state this, he named it to a gentlemen who had visited Mr. Bakewell in his early career as a breeder, and he said that, 'While staying with Mr. Bakewell I observed that there was one part of his premises he did not show me, and I got up very early one morning and went and examined these premises, and there found a black tup, a most extraordinary animal; but as it was a liberty I had taken I did not mention it to any one,' which confirmed what Mr. Waistell had said. Mr. Bates further stated that he had learnt from good authority that Mr. Bakewell bought this black tup at Ashbourne market, in Derbyshire, and that the fact was well known by those who saw him buy the same black tup, and that he also had good authority for saying that of late years black lambs occasionally came from Leicester ewes, though none were ever seen in Mr. Bakewell's days, which is a strong proof that animals breed back even to remote ancestry."

As you justly observe, Mr. Bakewell's inquisitive friend would have found a mare's nest in his search, for any one at all cognisant of Mr. Bakewell's practices and habits will give him credit for being too good a general to be taken by surprise by any man, he had his staff so well regulated.

The history of the black ram is simply and easily told. The facts are these:—Mr. Bates, with Mr. John Clifford Elches, then of Barton Park, near Burton-on-Trent, afterwards of Hurley Thorne, near Stone, and another friend, came to Dishley, from the meeting of the Royal Agricultural Society at Derby, and spent a day and a night with me; and any one knowing the inquisitive mind of Mr. Bates, will readily imagine the theme of conversation on such an occasion: the three subjects discussed were Leicester sheep, Shorthorns, and manures. Mr. Bates was very anxious to copy some memoranda of mine on artificial manures, and when I came downstairs early in the morning, I found him hard at work at the subject. Whether the black ram had disturbed his rest, I cannot say; but now for its history.

The first that was heard of the black ram was related by Mr. Bakewell himself, and was not found out by any Pry. Messrs. J. P. and Thomas Stone, the former of Quordon, and the latter of Hanging Stour, sent ewes to Dishley to the ram, and Mr. John Stone sat up for a week with his favourite sheep, and at length she produced a black lamb, whereupon the brothers went to Dishley to complain to Mr. Bakewell that the shepherd had turned their ewes to "lane tup." Mr. Bakewell good-humouredly tapped Mr. John Stone on the shoulder, and said: "Young man, let this be a lesson to you through life; I can account to you for this black lamb. In my early improvements of my flock, I went to Ashbourne Fair, and the best ram I found there was a black one, which I bought, and used him, and that is how your black lamb came."

Now, with reference to what is stated by Mr. Bell or Mr. Bates, that he or they could add information as to Mr. Bakewell having been seen buying the sheep—it appears a fabrication; but I can easily imagine it from two such fertile minds. Now, Mr. Elches was a native of Ashbourne, and his father was an extensive butcher, and I knew them intimately, and believe I should have heard all about the black ram.

The fact is, there was a black lamb at Dishley about 1820, and at the June show of that year there was much conversation about it, and Mr. J. B. Stone related the anecdote. The lamb was killed for the show, and Mr. Turner, of Cadbury, near Tiverton, found fault with my father for killing it; that was the only black lamb that occurred in our flocks for nearly 50 years, and that fact was related to Mr. Bates and Mr. Elches at Dishley. Mr. Bates appears to be silent upon what passed about the Bolingbroke or Duchess blood in Shorthorns.

What must we say about the statements of Mr. Dixon's prize essay, "Rise and Progress of the Leicester Breed of Sheep," No. 8, 2d Series, Part II., 1868, of the Journal of the Royal Agricultural Society, which has only just come under my notice? He states that Leicestershire had good sheep before Bakewell's day. In searching some antiquated records of 200 years ago, he speaks of the famous Rothley plain as a rabbit warren and a sheep walk. Who ever heard of good sheep in the present sense of the word on a rabbit warren? He might as well have included Chunley Forest, which extends from near Ashby de la Zouch to Derby. Now, the first sheep were very small, with grey faces and legs, and fine wool.

Mr. Dixon limits the palm to Bakewell as the great improver of the Leicester; but not only are the Leicester sheep, Longhorns, and the heavy horse, indebted to Bakewell, but every other breed, for he set men to think of improving their breeds. Mr. Dixon states that there are pictures extant of the great breeder in his drab Quaker-cut coat, jack-boots, and periwig. On this subject, however, I am bound to take issue with Mr. Dixon, and say there never was a likeness of Bakewell taken from life, or painted from memory within 50 years of his death; what has been painted since I cannot tell. It was a constant object with my father to try to get a portrait of the great man. I have heard him talk to Mr. Walton, who was a pupil of, and many years with Bakewell, who was often represented as in the portraits of the Woburn and Holcombe sheep shearings, and with Mr. Vickers, of Loughborough, the surgeon, who was a constant guest at Bakewell's table; and also with Mr. Weaver, the artist, who he frequently asked and tried to persuade to paint Bakewell from memory. Now Weaver was a pupil of Mr. Boultby, who painted stock for Bakewell, so that had there been any portrait of Bakewell Weaver must have known it. Mr. Dixon then says, "dine who might with him, he would not break through his rule of having a small round table to himself in the corner of the room." This is not enough to constitute such a round table, but a sort of desk or rostrum, from which he held all conversation with his guests. Had Mr. Dixon been well informed upon this subject, he would have known that there is an anecdote told of Bakewell, at the time the Duke of Bedford and Sir John Sinclair were dining with him. Mr. Vickers, who was there, as the clock was nearly ten, asked permission to have his horse ordered, at which the Duke remonstrated with Mr. Vickers, hoping he would not break up the compaoy, but he replied, "I know Mr. Bakewell's rules, my lord: 'Nine o'clock well vouched for, and a quarter.'" If my servants do not go to bed at night, I cannot expect them to do their duty to me in the morning;" and no matter who was there, bed candlesticks were always brought in a little before ten o'clock, and no servant was expected to attend after that hour. Mr. Dixon then comments upon the black cart horse of the "old K sort," which was nearly as much Bakewell's delight as Longhorns and Longwools. "When Bakewell received a notice to show one of his horses in London to George III., his Majesty looked more at the man than at the horse." Mr. Dixon would wish to convey that the King was surprised at Bakewell's eccentric appearance, or was it that his Majesty was looking with interest on the man who had conferred such lasting benefits upon the kingdom and mankind? I should think the latter, for it must not be forgotten that it was by the improvements which Bakewell received assistance from the State. Such was the opinion of the Government of the benefits Bakewell had rendered to his country.

It may not be out of place here to mention an occurrence that took place at the "Warwick show," to which Mr. Bakewell was generally asked to preside. After his failure, some one asked Mr. Fowler, of Rowbright, to take the chair, and after dinner taunted Bakewell that Fowler's bull "Garrick" was the best bull in England. The old gentleman said, "Perhaps so." After the toast had been repeated, Bakewell replied, "it takes a great deal to constitute the best bull in England," and observed, "we have always in our discussions held that that bull, horse, or ram that got the best stock was the best animal. Now, I say Mr. Fowler's bull 'Garrick' is not the best bull in England, nor Mr. Dishley's bull 'Twopenny' is the best bull in all England, for he got 'Garrick.'" Mr. Dixon further states the memoirs of this old Leicestershire worthy have never been published, but that his sayings, such as "Money wears out three lives," "Consume half the corn you grow with beasts, or lay out half its price in cake;" "Rise with the lark and to bed with the lamb"—are still preserved in a MS. book at Dishley. I assert there never was such a book in Bakewell's days; if there had, it must have come to my knowledge, for Mrs. Honeybourne gave to my father everything of antiquity Bakewell left—principally samples of wool, specimens of sheeps' heads and bones! a large Flemish horse shoe, sea weeds, and the like. Had there been such a book, she would have been pleased to have given it to my father, to whom she felt she was under considerable obligations.

Mr. Dixon's informants seem to have very little knowledge of where Mr. Bakewell sought for crosses for his flock, for he never mentions one word about the "Derbyshire limestone sheep," or the "Teeswater," both of which, it is generally understood, were brought to Dishley; neither does he quote the "Romney Marsh" sheep as springing from Mr. Bakewell's flock, as there is no doubt they did, and their history traceable, which, however, would scarcely be required by any man who knew the true type of a "Leicester."

There is one more statement of Mr. Dixon's that I cannot pass over. Mr. Bakewell's flock, he says, went after its founder's death into the hands of Mr. Smith, of Dishley, and passed from him to Mr. Honeybourne (Bakewell's nephew). The fact is, my father succeeded Mr. Honeybourne, and felt that the flock had so much deteriorated in Mr. Honeybourne's hands that he did not buy a single lot, perhaps from the practice of "in-and-in" breeding, a fallacy long admitted.

I cannot close this letter without asking permission, as an admirer of Shorthorns, to thank Mr. Sanday for his valuable paper read at Newark upon the deterioration of that breed, in the main points of which I perfectly agree with him. *B. Smith, 37, Caledonian Road, London, N., late of Dishley.*

THE AGRICULTURAL LABOURER.

A FEW days since, Earl Nelson gave his annua audit dinner to his tenants at Whiteparish, Hants. His lordship spoke upon the position of the agricultural labourer, with especial reference to two questions of the day very nearly concerning their common interest, and their relations to each other. First, the demand pretty prominently put forth that if the rights of property were to be held sacred, the duties of property were as sacred and must be duly performed; secondly, the growing endeavour of the lower classes to rise in the social scale and to improve their condition physically and mentally. He was going to be very plain-spoken in stating what he considered to be the present relation between the tenant-farmer and his labourer. Might one not hear many a farmer say something as follows?—"We don't very much like this education movement, but we can't help it now. We wonder how people would not educate their boy we are in danger of having too small a supply of labour. The men must be looked sharply after, or they would chisel us out of a good deal at day-work; some are not above cheating even when we give them piece-work to help out their wages. When they get more wages we have no more hold than they will not squander than drink. They are pretty sure to come upon the poor-rates when ill, and when past work; we are so burdened by these rates that we can't give a good man higher wages, and yet they are getting so independent that the only way to get any power over them is to get hold of their cottages. It is the kind of property I like; I visit them when ill, draw their fuel, put them into a clothing club, and they ought to be contented." Now, he did not think this was a satisfactory state of things; it was ruling by making men feel their dependence; it was good for nothing mass that were to be put on now and then; and he thought this feeling of dependence had a direct tendency to destroy provident habits and increase pauperism. They ought to go right-about-face altogether and try a different system. He believed he could clearly show that the rate of wages was everywhere very much connected with the labour question, except that three good, provident, sober labourers at 15*s.* would be everywhere cheaper than four inferior, improvident, and drunken ones at 11*s.* It was manifest that their own Wiltshire labourer, though he had not got the benefit of good food or of continuous hard work to keep up the full efficiency of his physical powers, could and did do more at piece-work than he did at daily wages; therefore he could give more if he chose, and if they could gain his good-will they would get all the labourer could give, which was more than any supervision or any dread from a feeling of dependence could gain for them. First, there should be a hearty zeal for the real education of the people. A sham or half education brought all the evils and none of the good. Let them not wait for Parliament to compel them, but of their own free will refuse to employ a child until he had passed in the third standard, and oblige the children to go to school in the winter months till they had passed to the fourth or fifth. Secondly, their present system was altogether tending to drive out of our people all that spirit of independence and self-respect which used to keep them off the poor-rate. If they could only get rid of the drink and waste their money if they had nothing to save it for, and if their chance in old age or sickness was to share outdoor relief on the same terms as the profligate, the thief, and the drunkard, who had done nothing for his independence, and had been a burden on the rates all his life. Thirdly, a wholesome migration, by helping those who had saved something for the purpose, might be encouraged in overcrowded parishes, and everything that would give those that remained a greater interest in the

land they were required to till would tend to attach them to it, and encourage provident habits.

He would suggest the following practical points for their consideration :—1st. That with a general consent of all the tenant-farmers of the neighbourhood, 1*s.* per week should be added at once to the general wage rate of all who belonged to a duly registered provident society. This, whenever generally adopted, would benefit the tenant-farmer wherever he might be, as tending directly to reduce the poor-rate for sick pay or permanent relief.

2d. That they advise half-an-acre of ground being given at a fair rent as garden ground to every cottager on the farm, and that the tenant-farmer should plough it up for his labourer. That would enable any man to keep a pig without fear of the temptation to steal for its support, and would not take away from the work which the farmer might fairly require from a well-paid man. In the largest farm it would amount to little more than the ploughing up of five acres gratis, and would improve the position of the permanent labourer so much as to make the casual labourer anxious to fill any vacancy.

3d. He would give to every cottager at least a quarter of a year's notice, and secure to him full payment from his successor for any crops left in the ground at the time of his leaving his cottage.

4th. That the letter of neighbourly favours to the labourers there were various little things enumerated by his lordship which would be a great help to their endeavours for the good of the people.

With regard to the duties of the landlord, he would say that his first duties were to live on his property and among his people, to take a lead in supporting their church and school and provident and other societies, and where, unfortunately, non-resident, that he should visit his property from time to time, and give larger subscriptions for the support of those things, to make up for his enforced absence. These were truisms which were hardly now pretty generally accepted. But more than this was required of him. He must not allow his personal gratifications to hinder him from a careful performance of all parochial and county duties; he should not allow a large herd of game for his own amusement to interfere with the proper improvement and improvement of the land; he should be forward in encouraging such improvements, and must not be afraid, if required, to give long leases, at least to those whom he had found by experience to have the means and capacity for improving the land; he should be ready to give all things sufficient to keep them on his farms, and in good repair; and he should be willing to share in the payment of the poor-rate, as giving him, as well as his tenants, a direct interest in keeping them down. To complete the special work for improving the condition of the agricultural labourer, he might do two things to encourage provident habits among him—start a system of small cow-lands to be let to labourers of good character who had saved £10 to £20, and build or set apart a few houses on the property to be had rent-free by such labourerers or their widows who had worked long on the estate, and had secured for themselves sick or old age allowance from their provident society. He believed by the plans he had ventured to put before them they would obtain for themselves a contented and attached peasantry, who would be willing at all times to give an honest day's labour for an honest day's pay.

THE LAND QUESTION.

THIS great and grave question is at the present moment occupying a foremost place in many people's minds, and it behoves all to have some idea of to be met. It behoves all who are interested in the coming struggle to gird on their armour, bearing in mind that to be forewarned is to be forearmed. A small section of persons, with Professors Stuart Mill and Fawcett at their head, has for some time been busy promulgating the opinion that there is no private property in land, but that it belongs to the people, or rather to the State, for the public good, and that it is necessary for the good of the country, and even its safety, that we should adopt the French system of *morcellement*; in other words, that the land should be cut into slices, and that we should have small farms and a peasant proprietary. To this doctrine I demur. However this system may be adapted to France, it has been to a considerable extent tried in England and failed. The only way in which in this country a man can subsist on a bit of land is, as Mr. C. S. Read has so well expressed it, by doing the work of two labourers, and living at the expense of one. If we examine into the effect of the small farm system in Ireland, we can find nothing for congratulation. The landlords are dissatisfied, and would gladly change it. The tenants are dissatisfied with the landlords, the laws, and everything else, while at the same time the land is exceedingly fertile, and lower rented than in England.

If I look at the map of the parish in which I dwell, I find that at the time of the enclosure of the open and common lands there was a considerable number of small proprietors. These small properties have gradually become merged into the larger ones, until there is hardly one left. Why has this been so? Simply because the owners could not, or it did not answer their purpose to retain these small estates; and when a man has anything to dispose of, whether it be land or aught else, he does not generally seek a customer in a man more needy than himself, but, acting on the rules of common sense, he offers it to some one who can pay for it. It is the old story here, as it is all the world over: money begets money. Land as a rule pays less interest than any other form of security, and provided things are allowed to go on peaceably and quietly, which I trust they may, the ownership of land in this country will become a luxury in which only the wealthy can indulge. A millionnaire may obtain enough to satisfy his wants at 2 or 2½ per cent., and be content, but he is sacrificing the interest of the money which large landed possessions give. Not so John Green. He finds that he may toil on his few acres all his life and be in income no better, and in anxiety much greater, than a labourer. He wisely parts with his little freehold, and with the proceeds he can go into business on a larger scale, or, if he prefers it, he can invest in some other of the many kinds of security in the market, whereby his income may be doubled or trebled. This is no fancy sketch, it is what has been going on daily for the last century. And so long as it is open to every man to sell what he has, and the rich man to buy, I cannot see what anybody else has to do with it, provided it be not detrimental to the public good. I maintain that it is not. It is my belief that land in large parcels is beneficial rather than otherwise to the commonwealth. The large estate is usually country or generally the best managed. It is on these where improvements of a permanent character have been most extensively carried out. In fact, I can conceive no position in our social system where the elements of human happiness exist in so large a degree as they do on a large, well-ordered estate, when its wealthy owner fully recognises the privileges and duties of his exalted position. It is there that we generally find the most prosperous tenantry and the most thriving and contented peasantry. On such estates good schools have for years existed, when in the parishes owned by needy small proprietors there have been no schools at all, or none worthy of the name. The labourers and other retainers have had better homes with larger gardens or allotments at easier rents, the sanitary condition of the people has been better attended to, employment has been more regular all the year round, and in fact, the beneficial influence of the great house has been felt as widely as its sway extended.

If we turn for a moment to the poorer open parishes we find that little progress has been made as regards the permanent improvement of the land. Neither lords and needy tenants often co-exist. Here, however, the village tradesman or other small capitalist has had no difficulty in getting hold of a bit of land where small savings could be invested in running up a few breeding hutches for paupers. These have been built with the principle of having the smallest accommodation for the largest possible amount of rent, in other words to get as high a rate of interest for the outlay as possible. Into these places the labourers have from time to time congregated until their numbers were greatly disproportioned to the requirements of the cultivators of the land, and hence it has been here that labour has received its worst remuneration, and the poor-rate has been the heaviest. There are several parishes of this kind in this county, and I have no doubt in every county in England.

A word now as to the agricultural labourer. His condition has in my time considerably improved, and will continue to improve. A good deal of nonsensical twaddle has been written and talked during the last year or two, about rooting the labourer to the soil. I say we have no right to try to do so. The old Poor-law did it with a vengeance. Where the poor man was born there he must either live or starve. If he left the parish to which he belonged, and where he could obtain no work, and went to another where employment was to be had, he was hunted out by the parish officers as an unclean or excellent thing, and sent back whence he came. Happily for him a better state of things now exists. His shackles have been cut, and he is free to go where he pleases to sell his labour in the best market. This is as it should be. He has as much right, and in fact it is duty, to improve his position as any man in the community; provided always, as the lawyers say, he does so in a quiet, unobtrusive way; but strikes I regard as unmitigated curses. There has never yet been a conflict between labour and capital but has been productive of miseries and discomfort. From the parish of Ramsdell which I dwell there have, during the last year or two, as many as a hundred souls emigrated to Halifax in Yorkshire, where the children get employed at considerable wages. Now, if these people had all remained with us we should have done with them; as it is, we have somehow managed to do without them; and if they have gone there to earn a larger loaf, with perhaps a slice of beef or mutton to boot, it is an arrangement whereby all the parties are gainers, inasmuch as these people go where they become our customers instead of being a clog upon our industry by having to receive money for services with which we can dispense, or having to be supported out of the rate. Few persons have been inconvenienced more than I have at times owing to shortness of hands, but this is not an unmitigated evil. If we have less people, we have less wages to pay, and I prefer not having, as was the case in my youthful days, a dozen men and boys presenting themselves the first thing in the morning asking for work, which meant wages, when there was none to give.

Shortness of hands, too, has the effect of leading to stricter supervision on the part of the master; and as necessity is the mother of invention, it makes him set his wits to work so to manage the forces at his disposal as to make the most of them. Too great an abundance of cheap, or rather underpaid, labour often leads to laxity of discipline. Now that labour is allowed to flow freely, the labourer may be safely left to take care of himself, and practically he is doing it. The result will, ultimately, be a decent approximation of the wages as paid in town and country.

It would be better if three well-paid men would do three men's work, than that five underpaid men should do it. Unfortunately, I find in practice that when hands are scarce and wages higher, it leads to the belief on the part of the men that their services cannot be dispensed with, and is apt to make them both idle and impertinent.

It appears, however, that the friends of the working man are not satisfied with the intention of splitting up the land for his benefit, but the whole of the middle class, in the shape of tradesmen as well as farmers, is to be wiped out as with a sponge, and all his wants are to be supplied from huge co-operative stores. Now, let me ask who and what are the middle classes of this country? In our rural districts those belonging thereto have either themselves or their forefathers risen from the ranks to the positions they occupy by dint of superior intelligence, industry, thrift, frugality, and self-denial; and if any one of them ceases to practise these virtues, he very soon drops into the ranks again. If we go to the metropolis, or any of our large seats of manufacture or commerce, and inquire into the antecedents of the prosperous tradesmen or the merchant princes there, we shall generally find that either they or their fathers before them have begun life with barely a shilling. The same avenues to success are still open to the working man; the ranks are not multiplied, owing to our greater wealth; and, so long as he is content by fair and proper means to better his condition, and raise himself in the social scale, I for one wish him "god-speed;" but I have no patience with any set of men, whether philosophers or demagogues, who wish violently to break up the existing order of things, and build up a new social fabric on the ruins.

A word now about that long-suffering and much-abused animal the British farmer, the only person in the world who is popularly supposed to know nothing about his own business. Through good report and bad report he has somehow managed to hold his own. I have no fears for him yet, provided he is fairly dealt by. Give him long leases, or some well-devised scheme of tenant-right, and do not unduly eat him up with game, and he will compete, as he has competed, successfully with the whole world. I am satisfied that the only way in which the broad acres of England can be cultivated to the greatest advantage is by the manufacturers of bread and beef taking a lesson from their brethren, the manufacturers in other departments of industry; and by a liberal application of capital, and by judicious use of machinery, securing the largest result at the least cost. This is impossible on a small scale. No bank will pay a better interest for the investment of our savings than the bank on which we exist, provided that the bank in which we place our deposit should give us good security. It is easy to talk of the shortcomings of farmers, and their want of enterprize; but where on earth can any set of men be found ready to invest such large sums as they do in another person's property, with nothing better than a six months' notice, which hangs like the sword of Damocles suspended by a hair over their heads, and may any moment fall, through some slight bitch in conduct, some trifling breach of duty, or some unfortunate word spoken at a public meeting, as was lately the case with a tenant-farmer, who, for a speech made at Basingstoke, was turned adrift from the home where he and his forefathers had for generations dwelt. The connection between landlord and tenant is of too serious and important a character to be thus lightly broken. The cultivation of the soil is above all other interests paramount, inasmuch as it is impossible to do without it, and without it. If all the gold and silver and precious stones in the world, with all the subterranean treasures of the globe we inhabit were piled together in one huge heap, man could not subsist on it for a single week. It is that which is grown on the surface of the earth which sustains, not only the human race, but all animated Nature. Hence it is of vast consequence to every man, woman, and child in the world whether that surface be well or ill-cultivated. And in the common interest those who are engaged in this department of industry should have every encouragement and security offered to them. Even as things go, all writers on agriculture, whether English or foreign, concur in saying that the farming of this country is the best in the known world; and this is, in my opinion, sufficient proof that there is not much wrong in our system of land management, either as regards ownership or occupancy, and ought to be held as conclusive evidence against those who desire to effect radical changes. I look upon the English farmers as the braces which bind together the upper and lower strata of our agricultural system; and so long as the braces are kept sound the fabric will never fall. *F. W. Bignell, Loughton, Stony Stratford.*

Home Correspondence.

The Education of the Agricultural Labourer.—There can be very little doubt—if we take the tone of the last discussion at the London Farmers' Club as a guide, that the average farmer is opposed to the education of the labourer. There were no observations received with a more general murmur of assent than that of the chairman, Mr. Spearing, when he said, "It seems to me that the agricultural labourer is getting over-educated," "if he becomes much more educated we shall not be able to depend on his labour at all." When Mr. Clare Sewell Read objected to "the prohibition of boys working under 10 years of age," and "to the compulsory attendance of children up to 12 years of age in secular schools;" and when he said, "the man who is taught book-learning is not necessarily a better labourer"—"that our fathers were badly educated" in the ordinary sense, but were "better men than ourselves!"—that "whatever may be the result of improved education the farmers will derive less benefit than any other class"—that "the elementary education will not work well in the rural districts"—all this was highly approved; and if the audience had consisted of hundreds of farmers instead of dozens, it would have been enthusiastically applauded. What is the reason of this strong, so universal amongst farmers and shared by not a few old-fashioned squires? Does it not arise from the quality of the education hitherto imparted at considerable personal sacrifices by the rural clergy? How seldom is it that in a village school anything is taught, anything is read, having reference to the animals, the plants, the tools, or the occupations in which the children are to be interested when they go to work. I do not know one good text-book that gives an account of the live stock of the farm, written by a practical man, in the style that would interest children—I mean the style of which Anson Rabbit is such a master, and of which Mr. Knatchbull Hugessen has lately published an excellent example in fairy tales. Books of natural history there are in plenty, and pictures of all sorts of things to adorn school walls, that have nothing to do with practical rural life. Now these men and practical men, that the little labourer able to read more or less imperfectly, but not the least improved in intelligence as regards farm work. Why should not the cattle, according to their breeds,—Shorthorn, Hereford, Devon—and all the qualities, peculiarities of feeding and digestion of the milk cow form the subject of one thoroughly interesting handbook, written in a plain, clear, exact, yet amusing style, expressly for children? Why should not another be devoted to the sheep with its varieties, as suited to rich pastures, downs, and mountains? Why should not the modern implements of the farm and operations be made a subject of familiar reading? The child of ten hears of broadcast sowing in his Bible lessons, but not of the drill, and its appropriate manures, until he goes to work. A series of really practical handbooks for the use of rural schools do not exist at present. Those which have been published above the level of comprehension of children, and are usually too theoretical and too dry. This would be a proper subject for the education committee of the Council of the Royal Agricultural Society. Their last educational effort has not been crowned with very brilliant success —four competitors and one prizeman only, and £100 in prizes, at an expense to the Society of nearly £100. But I know it would be a waste of time to press anything so practical and plainly useful on a committee which is so entirely ruled by its chairman, and whose chairman considers his own style of didactic dulness the perfection of agricultural instruction. How many of the prize essays of the Royal Agricultural Society, which he admires so much, have ever been found worth separate publication? *S. Sidney, Nov.* 22.

Middle Class Schools.—The British public are yet in much perplexity relative to the final appropriation of the many charity school funds throughout the kingdom. It is manifest that every charity school fund for the especial purpose of educating poor children is superseded by the late Elementary Schools Act, which amply provides for their education from funds derivable from rateable property. This act of legislation has therefore set at liberty the funds of these schools for other purposes. To what purpose then can they be most beneficially and equitably applied? My reply is, in establishing middle-class schools wherever practicable. It would not be equitable or just to the country generally if they were applied to reduce the amounts paid in rates by the favoured parishes who possess one of those charity schools. All laws should be equal to all classes of the community; no particular parishes should derive exclusive benefits. These charity school funds then should be thrown open, and, as far as possible, be appropriated for universal service. This in a great measure may be effected by establishing schools of a higher order, *i. e.*, middle-class schools, in every convenient locality or district, to be open to all classes under proper and salutary regulations,—such schools to be under the superintendence of competent local authorities, and to be managed and taught by masters capable of teaching the higher branches of knowledge usually taught in our higher order of "grammar schools." These schools should be easily accessible, and by an amalgamation of the funds of several parochial charity schools may comprise a whole district; or, if more desirable, neighbouring parishes may form a more local school for these parishes only, and irrespective of every such parish being possessed of a charity school. In this way these funds may be made universally applicable for the general good, the local authorities to provide the school-rooms, elect the masters and teachers, and otherwise manage the affairs. The funds for building purposes to be borrowed of the Government Commissioners, as under the Elementary Schools Act, and to be charged upon the charity estates for the longest term permitted. Unquestionably these schools would ultimately be a great boon to the middle classes, and which they are fully entitled to, as some compensation for the unjust imposition upon them of the maintenance of the elementary schools from rateable property. It is quite superfluous to stipulate that these schools shall be unsectarian, no other can in these liberal and enlightened times for a moment be tolerated; but to banish from them the book of books, "the Bible," is still more untenable. It must be the School Book, and be read without denominational teaching. The difficulties attending the establishment of these schools is one, and should be promptly commenced as the various masters of the charity schools are superseded. *O. F.*

Milk—A Necessary Article of Food to the Children of Agricultural Labourers.—Mr. Mechi, in his article on the "Agricultural Labourer," in your last week's impression, says, "Skimmed milk is sold about here at 1*d.* per quart, when once skimmed, but only a halfpenny if twice skimmed; but there are so few cows kept that it is difficult to get any. It is generally soon to a fisherman's family of small children." Here, I think, Mr. Mechi only half states the case; it is not a great boon, but an absolute and urgent necessity. Living and practising for many years as a country doctor in an agricultural neighbourhood, I have had constant opportunities of seeing and lamenting the great scarcity of milk among the labouring population, many of whom are not able to obtain any. Fortunately and happily the poor and hard-working mother is most often able to supply her offspring with a fount of natural breast-milk that the high-bred and wealthy parent would give much, but in vain, to possess; and so for the first twelvemonths, or perhaps more, the children are plump and well-conditioned. If, however, the mother should fail in her supply of milk, the child falls off, and sooner or later finds its way to the surgery, with all the appearance and history of wasting and pining. The first question, "What is she feeding it on?" is asked. The mother is weakly, has no natural supply for it; the child is fed with sop, bread, water, sugar, tea, sometimes a little broth. Milk often not one drop; it cannot be procured. Thin and wasting as it is, we are told the little thing is never satisfied, and takes a great quantity of food. To the question generally given to represent the child's condition to the employer, and ask for a supply of good new milk for it,—"Please, sir, they only keeps one cow for the use of the house." It is not to be procured, and often does the poor little sickly thing have its belly rubbed with cod-liver oil instead of being filled with good milk. At the time the labourers' child leaves the breast its previously rapid growth generally becomes arrested, and its development for the next few years is really very slow. True, after a time, the natural changes in dentition and the whole digestive system fit it for digesting all and any kind of food; while the constant exposure to the atmospheric air causes a great demand for it in quantity; and so, out of much bread and Potatos, oatmeal and bacon, the growing boy appears to extract enough nutriment to make him grow up a tough and enduring man. (I speak now more of the boy than the girl, for girls rarely sooner get away from home to good food and comfortable homes as under nurses, &c.) But although he regains much lost ground as he grows up (and it is wonderful against what disadvantages Nature will fight in the great struggle for life) he seldom attains to the A 1 class among the human race. The agricultural labourers, as a class, are not nearly so fine a race as they should and would be if their progressive development were never checked. The registrars' report shows a sad amount of mortality among the children of the labouring class, and a comparison of it with the death-rate among the better classes would reveal a startling amount of something wrong. Not all, of course, but a very large proportion of the fault lies at the door of mal-nutrition. But does this state of things cast any reflection or reproach upon us as employers of the labouring population? I think so. How few fully is every intelligent farmer amongst us aware of the disastrous effect of checking the growth of any of his young stock by a want of that continuous supply of foods suited to its respective periods of age? Have we a flock of lambing ewes? How assiduously do we watch that there shall be a cow to calve just about the right time, to provide against the possible wants of the little strangers! Have we a sucking colt? How carefully do we look to its dam and her food, and if she appear not to be giving to him sufficiently, how we ransack the farm for a bit of rich Clover, a few green vetches, or, in winter, a mash of bran, Linseed, maltcombs, or other milk-giver. The same with our valuable Shorthorn calves; we would not have their early growth checked for pounds: before they cease sucking how we entice them and coax them with little niceties. The same, indeed, with all our valuable stock—all we breed or rear; while the young of man, the best and most useful and valuable and highest class of animal of all, born in the image of the Great Creator, grows or stunts, flourishes or pines as may be, without any special provision being made to ensure his progressive sustentation at this most important period of his life. I am far from saying that this state of things is universal; on the contrary, there are large numbers of benevolent farmers, and their wives, who conscientiously care for the families of their labourers, but coincident testimony from many parts of England at least show that this is a widely prevailing evil. There ought be no selling milk twice skimmed at 1*d.* per quart to genuine agricultural labourers. The order of things, viz., milk sold and beer given, ought rather to be reversed, viz., milk given and beer bought; the one is a necessary of life, the other is not. Let the poor have a claim to that which is necessary to their existence. The shrewd Scotch farmer knows and appreciates the importance of remunerating milk well as other stock well; and the conviction that children can no more be reared without milk than lambs has led, in Scotland, to the practice of giving the labourer the keep of a cow for his family. Such a system would not probably answer, or indeed be required, in this country; but I think, and do not hesitate to state my conviction, that it is the bounden duty of every farmer employing labourers with families, and occupying for his own profit the land which alone can produce the food which their children imperatively require, and the place of which the other can supply, to provide them with a sufficient supply of it. The land when tilled was intended to support the tiller and his family, and of the necessaries of life produced by the soil all should partake alike. So important a matter is this, that I think it ought to be made the subject of legal obligation. Employers of labour are obliged by some legal considerations for the welfare of their *employés*, why not by others? especially when so important. I have said that in many instances this matter is well cared for by the employer, and I believe would be much more generally so were its importance well impressed on the public mind; but, in justification of my suggestion to make the supply of milk to the labourer's family an obligation on the employer, I will repeat one of the saddest sayings ever said to me in my surgery some years ago. It will tell its own tale:—"Sir, it breaks my heart to have to give all that milk to the pigs, while my own child is starving for want of it." *M. W. Procter, Shifnal.*

Farm Accounts.—For the last six years I have lived as an agricultural pupil on farms in Sussex, Suffolk, Hants, and Surrey, and Berkshire, during which time I have not, I believe, wasted the opportunities that were afforded me to make myself proficient in all matters relating to the culture of land, the management and breeding of stock. But on one point I am not satisfied, that is as to the slovenly and unmethodical manner in which farm accounts are kept. Having served an apprenticeship in my father's office, carrying on a large mercantile business, you may imagine I have a very different idea of what accounts should be, and must say such as have been placed before me do not show the result in a concise and clear manner. As I now purpose starting on my own account on a farm of 340 acres, mostly arable, can you recommend to me a good farmers' account-book, whereby I may be able to ascertain the cost of my several crops, and expenses incidental to the stock. In fact, I wish to know how, and for what, moneys are expended. If you can find space for this in your well-read journal, you will oblige, and I may also obtain the opinion of some of your readers. *An Agricultural Pupil.* [Apply to Mr. Jemmett, Murrell Hill, Binfield, Berks].

Societies.

BIRMINGHAM CATTLE SHOW.

Bingley Hall.—The 23d exhibition of the Midland Counties Agricultural Society has come and gone, and the usual crowds have enjoyed the sight of a fair average show of live stock, a very remarkable display of farm crop produce, and poultry classes equal to any ever before seen.

The Hereford classes of cattle are not of that special merit which at Birmingham, so near their home, they ought to be. Several shabby-looking specimens are mixed in most of the classes, with those large symmetrical masses of beef by which the breed is best represented. The Shorthorns, too, are not as a whole so good as might be expected in a breed which is every where in this country close by its home, and which has long been at once the widest spread and best result of the breeder's art. Beside the best specimens, in most of the classes the animals exhibited in general look hardly "ripe" enough for a Christmas exhibition. The Devons stand best for general merit; the several classes of this breed are almost universally made up of well-bred, well-fed animals, and there is a considerable number of unusual size. The Scottish classes are pretty well filled, the

prize for the best animal in the yard going to a black Polled heifer from Aberdeenshire; and the West Highland, or Kyloe class, being of, we think, more than ordinary excellence.

In the sheep classes the late Lord Berners' flock takes its last sweep of the Leicester prizes. Lord Walsingham's name has at length disappeared from the Southdown classes, and the prizes, which used all to go to Merton, are now distributed chiefly between Lord Sondes and the Prince of Wales. The Shropshires, though outnumbering all the others, are not so large a class as usual. The Oxfordshire are fairly represented, the Cotswold are inadequately shown, the Lincoln breed still worse.

The pig classes are first-rate. Several disqualifications, owing to veterinary dissatisfaction with the terms of the entry, are posted—pigs stated to have been of one litter being pronounced by Professor Gamgee to be of different ages. The Berkshire breed is magnificently shown; the white breeds are in hardly such great perfection.

The poultry classes are very fine indeed. A multitude of the best bred Dorkings in the country, very large and perfect classes of Brahma Pootras, a breed of rapidly increasing popularity; smaller classes of Cochin Chinas, and very large collections of Hamburghs and game fowl, together with smaller classes of French and Spanish breeds, make up the bulk of the show.

The galleries are filled with a very extraordinary collection of roots and seeds, and the yard is surrounded on the floor with a fair representation of the agricultural implement manufacture.

THE CATTLE

first engage the attention. The *Herefords*, include 30 entries. The older oxen are a good class. Mr. Betteridge's 1st prize ox, which takes also the prize for the best Hereford in the yard, is a very deep-framed, heavy-fleshed animal, thickly covered over the loin and behind the shoulder. Mr. Heath's, standing No. 1, is wonderfully well ribbed up, and particularly good over loin and flank: altogether a beast of first-rate quality. The 3d prize goes to Mr. Bettridge again, for a rather flat-sided beast. Mr. Pike's ox, taking the 1st prize in a rather inferior class of younger oxen, is also rather flat-ribbed, particularly good, however, over loin and flank, and undoubtedly the best in rather a short class. Her Majesty the Queen shows a good stocky little beast in the class of steers. Mr. Baldwin's steer, commended, is not quite so ripe, and the other entries are very inferior. The cows and heifers we have from the Queen's herd, one of the old-fashioned monstrous, almost lobed Hereford backs which used to be more commonly seen. The 1st prize goes to Mr. Betteridge, for a very evenly and thickly fleshed animal, very heavy forward. In the two classes of Hereford heifers Her Majesty takes the 1st prize, with a very thick, wonderfully well made-up 3-year-old, extraordinarily fine over the loin, whose sister took the 1st prize in her class at both Birmingham and Smithfield last year.

The *Shorthorns* number 40 entries, viz., 9 older oxen, 7 younger, 7 cows, and 17 heifers. In the first class stands Mr. Stratton's white ox. He is an uncommonly well-fed specimen of a well-bred Shorthorn ox, with plenty of bone and constitution; good over back and loin, deep and heavy fleshed both in fore and hind quarters, perhaps a little light in flank. This beast was pitted against the 1st prize cattle in all the other classes for the prize which is given to the best animal in the yard. After easily disposing of the pretensions of Herefords and Devons, he yielded the palm to Mr. Bruce's black polled heifer. They will come together again at Smithfield next week, when we shall see whether there is anything in the idea which has found expression, that the Shorthorn, Hereford and Devon judges would more easily unite, when there is any room for doubt, in an award in favour of an altogether outside breed, than consent, any two of them, in decorating an animal of any of the three principal breeds at the expense of its rivals. It is a less disagreeable task for the three to confess they are all beaten than for any two of them to confess that they are beaten by the third. The white ox is certainly a very handsome animal, losing nothing when in the ring for lack of step and figure, but nevertheless the smaller black heifer is preferred. The prize ox girths 9 feet 6 inches, and is 5 feet 8 inches long, weighing 21¼ cwt. live weight. Several oxen in this class were hardly ripe for exhibition. The younger cattle are not so good a class. Mr. Bruce's 1st prize ox is a good thick beast, standing beside another Scotch animal, much larger, higher, gaunt, and lanky, exhibited by Messrs. Martin. In a class exclusively for tenant-farmers only one beast appears, and Mr. F. Wortley, of Ridlington, near Uppingham, worthily takes the prize with it. The cow class contains seven entries, none of remarkable merit. Sir W. C. Trevelyan, Bart., takes the 1st prize with a heavy, well-covered 6-year-old, which had had one calf only. The heifers are a much prettier class, the prizes going to Mr. Tidy, of Tamworth; Mr. Crawshay, of Newnham; and Mr. Ibbs, of Grinshill.

The *Devons* exhibited are the evenest and best filled classes in the yard. The 1st prize older ox, exhibited by Mr. Lee Senior, is a very heavy and thickly-covered beast. He receives also the prize for the best ox in any of the classes, bred and fed by the exhibitor, the white Shorthorn ox losing it by the death of its breeder, the late Mr. R. Stratton. There is a very good show of younger oxen, also of the Devon breed, Mr. Taylor, of Glynley, taking the 1st prize, and Mr. Smith, of Exeter, the 2d. The younger steers are a small class, the Queen taking the 1st prize with a pretty little beast, and Mr. Farthing being commended. Short classes of cows and heifers show Mr. Farthing, Mr. Lee Senior, and the Prince of Wales as prize-men. His Royal Highness shows the 2d prize animal in the younger class, hardly ripe, disfigured by a drooping rump, and not so good as a commended ox beside him from the same herd.

A few *Longhorns* still compete annually for the Society's prizes—there are no *Welsh* cattle shown—the *Scotch* classes are rather short. The Polled cow classes, though very short in numbers, contain one or two remarkably fine animals, and among them Mr. Bruce's heifer, which takes the prize as the best animal in the yard.

The following is the award of the judges in the cattle classes :—

Judges.—Mr. J. W. Baker, 48, Cambridge Terrace, Clapham Road, London; Mr. John Thompson, Bramdean, Hurstbourne, Mr. S. P. Newbery, 4, Baignton Villa, Plympton, Devon.

Reporter on the Classes of Short-horned Cattle.—Professor Gamgee, 1, Great Winchester Street Buildings, London, E.C.

Veterinary Surgeon.—Mr. E. Stanley, 35, Islington, Birmingham.

Herefords.

Class 1. Oxen or Steers, exceeding 3 years and 3 months old.—1st, £25 and Silver Medal as breeder, Mr. Betteridge, East Hanney, Wantage, Berks; 2d, £10, Mr. W. Heath, Ludham Hall, Norwich; 3d, £5, Mr. H. Bettridge, Wantage, Berks.

Class 2. Steers, not exceeding 3 years and 3 months old.—1st, £15, Mr. A. Pike, Mitton, near Tewkesbury; 2d, £10, Mr. H. Bettridge, East Hanney; 3d, £5, Mr. W. Groves, Brompton, Salop.

Class 3. Steers, not exceeding 2 years and 6 months old.—£10 (given by G. B. Lloyd, Esq., Mayor of Birmingham) and Silver Medal as breeder, Her Majesty the Queen. Commended: Mr. J. Fullelove, Ludlington, Stratford-on-Avon; Mr. J. Crane, Benthall, Shrewsbury.

Class 4. Cows.—1st, £15, Mr. H. Bettridge, East Hanney; 2d, £10, Mr. W. Heath, Ludham Hall, Norwich; 3d, £5, Mr. A. Pike, Mitton, near Tewkesbury. Commended: Mr. G. Pitt, Chadnor, Leominster.

Class 5. Heifers.—1st, £15, and Silver Medal as breeder, Her Majesty the Queen; 2d, £10, Mr. R. Shirley, Baucott, Salop; 3d, withheld.

Class 6. Heifers, not exceeding 2 years and 6 months old.—£10 (given by Joshua H. Dawes, Esq.), and Silver Medal as breeder. Mr. J. Crane, Benthall, Shrewsbury. Highly Commended: Mr. J. Codling, Whapload, Spalding.

Shorthorns.

Class 7. Oxen or Steers, exceeding 3 years and 3 months old.—1st, £15 (extra prize of £20 as best Shorthorn, and Gold Medal as best Ox or Steer in the Hall), Mr. J. Stratton, Alton, Wilts; breeder, the late Mr. R. Stratton. 2d, £10, Mr. W. Farthing, Stowey Court, Bridgewater, Somerset; 3d, £5, Mr. R. Nelson, Barton Hill House, York. Highly Commended: Mr. J. Bruce, Stanton Hindhope, near Jedburgh; Mr. McCombie, Esq., M.P., Tillyfour. Commended: Her Majesty.

Class 8. Steers, not exceeding 3 years and 3 months old.—1st, £15, and Silver Medal as breeder, Mr. R. Bruce, Newton-of-Struthers, Forres; 2d, £10, T. Walker, Esq., Berkswell Hall, Coventry; 3d, £5, Colonel Loyd-Lindsay, M.P., Lockinge Park, Wantage. Commended: F. J. S. Fullepen, Esq., M.P., Osberton, Worksop.

Class 9. Steers, not exceeding 2 years old, bred and fed by the exhibitor, a tenant-farmer.—£15 (given by G. B. Muntz, Esq.), and Silver Medal as breeder, Mr. F. Wortley, Ridlington, near Uppingham.

Class 10. Steers, not exceeding 2 years and 6 months old.—£10 (given by G. B. Lloyd, Esq., Mayor of Birmingham), and Silver Medal as breeder, the Marquis of Exeter, Burghley Park. Commended: Mr. J. Aylesford, Paddington Hall, Coventry.

Class 11. Cows.—1st, £15, and Silver Medal as breeder, Sir W. C. Trevelyan, Bart., Wallington, Northumberland; 2d, £10, Mr. R. Wellis, Hall House, Carperby, Bedale; 3d, £5, Mr. W. Faulkner, Rotherthorpe, Northampton. Highly Commended: Mr. J. W. Kirkham, Cadeby Hall, near Grimsby. Commended: Mr. T. Sidgewater.

Class 12. Heifers.—1st, £15, and Silver Medal as breeder, Mr. W. Tidy, Middleton, Tamworth; 2d, £10, Mr. J. Crawshay, Cop, Oakhanger, Newnham; 3d, £5, Mr. R. Ibbs, Wood stile, Grinshill, Salop. Highly Commended: Mr. W. How, Tottington, Thetford, Norfolk.

Devons.

Class 13. Oxen or Steers, exceeding 3 years and 3 months old.—1st, £15 (and extra prize of £20 as best Devon), Mr. T. L. Senior, Broughton House, near Aylesbury (2d, £20 as President's prize of £50, as best Ox or Steer bred and fed by the exhibitor), Mr. W. Smith, Hoopern, Exeter; 3d, £5, Mr. T. Bond Hardy, Hunstrete, Chelgwarter. Highly Commended: Her Majesty the Queen. Commended: the class.

Class 14. Steers, not exceeding 3 years and 3 months old.—1st, £15, and Silver Medal as breeder, Mr. W. Taylor, Glynley Easthourne, Sussex; 2d, £10, Mr. W. Smith, Hoopern, Exeter; 3d, £5, Mr. T. L. Senior, Broughton House, near Aylesbury. Highly Commended: Mr. W. Farthing, Stowey Court. Commended: the class.

Class 15. Steers, not exceeding 2 years and 6 months old.—£10, and Silver Medal as breeder, Her Majesty the Queen. Commended: Mr. W. Farthing.

Class 16. Cows.—1st, £15, Mr. W. Smith, Hoopern, Exeter; 2d, £10, Mr. T. L. Senior, Broughton House, near Aylesbury; 3d, £5, Mr. H. Hitchcock, George Nympton, South Molton.

Class 17. Heifers.—1st, £15, and Silver Medal as breeder, Mr. J. T. Senior, Broughton Pastures, near Aylesbury; 2d, £10, H.R.H. the Prince of Wales, Sandringham; 3d, £5, C. McNiven, Esq., Compton Durville, Ilminster. Commended: H.R.H. the Prince of Wales.

Class 18. Heifers, not exceeding 2 years and 6 months old.—£10 (given by William Lort, Esq.), and Silver Medal as breeder, Mr. W. Taylor, Glynley, Sussex.

Longhorns.

Class 19. Oxen or Steers, of any age.—1st, £10, and Silver Medal to the breeder, Mr. J. J. Burbery, The Crofts, Stratford-on-Avon; breeder, Mr. J. H. Burbery. The Chase, Kenilworth; 2d, £5, Sir J. H. Crewe, Bart., Calke Abbey, Derbyshire

Class 20. Cows or Heifers.—1st, £10, and Silver Medal as breeder, Mr. J. H. Burbery, Kenilworth; 2d, £5, W. T. Cox, Esq., Spondon Hall, Derby.

Scotch Breeds.

Class 21. Polled Oxen or Steers, of any age.—1st, £15, and Silver Medal as breeder, Mr. J. Stephen, Conglass, Inverurie; 2d, £10, Messrs. J. & W. Martin, Aberdeen.

Class 22. West Highland Oxen or Steers.—1st, £15, Mr. T. L. Senior, Broughton House; 2d, £10, Sir G. M. Grant, Bart., Ballindalloch, N.B.; 3d, £5, C. Morrison, Esq., Basildon Park, near Reading, Berks. Highly Commended: Sir W. C. Trevelyan, Bart. Commended: Mr. J. Mayo.

Class 23. Scotch Cows or Heifers.—1st, £15 extra prize of £20 as best Scot, Gold Medal as best Cow or Heifer, and Hotel and Innkeepers' Prize as best Animal in the Cattle Classes), Mr. James Bruce, Burnside, Fochabers, N.B.: breeder, Mr. Alexander Paterson, Mulben, Elgin; 2d, £5 (extra prize of £20 too, given by Mr. Ratcliff, Esq., as best Scot bred and fed by the exhibitor), W. McCombie, Esq., M.P., Tillyfour, Aberdeen.

Welsh Breeds.

Class 24. Welsh Oxen or Steers.—No entry.

For other Pure Breeds and Cross-Bred Animals.

Class 25. Fat Oxen or Steers, of any age.—1st, £15, Mr. A. Fike, Mitton, near Tewkesbury; 2d, £10, J. Coleman, Esq., M.P., Carrow House, Norwich; 3d, £5, Mr. J. Stephen, Conglass, Aberdeen. Highly Commended: Messrs. J. & W. Martin, Aberdeen. Commended: the Hon. Arthur Upton, Lord's Plain Farm, Westmoreland (2); F. Wright, Esq., Osmaston Manor, Derby; E. Cartwright, Esq., Kirkstead Abbey, Horncastle; Mr. J. Thompson, Ballederow, Kelso.

Class 26. Fat Cows or Heifers.—1st, £15, Messrs. J. & W. Martin, Aberdeen; 2d, £10, Mr. J. Reid, Greystone, Alford, Aberdeenshire; 3d, £5, Lord Fitzhardinge, Berkeley Castle, Gloucestershire. Commended: S. Carter, Esq., Quarry Hill, Battle, Sussex.

Extra Classes.

Class 27. Oxen or Steers (for animals not qualified to compete in any of the preceding classes).—No entry.

Class 28. Cows or Heifers, not qualified to compete in any of the preceding classes.—£5, Mr. R. Moss, Whisby, Lincoln. Highly Commended: Mr. R. Hudson, Sandall, near Forres; Captain R. E. Oliver, Sholebrook Lodge, Towcester.

THE SHEEP CLASSES

are generally satisfactory. A small class of *Leicesters*, to which three pens are contributed from the flock of the late Lord Berners, heads the list. These three pens take the 1st, 2d, and 3d prizes respectively, and are of the uniform fine quality and comparatively small size characteristic of the flock. The other pens, contributed by Mr. Herrick, of Beaumanor Park, Leicestershire, and Mr. Brown, of Holme-on-Spalding Moor, Yorkshire, are pens perhaps not remarkable for the scales, but in a frame capable of taking a greater weight with heavier fleece.

The *Lincolns* are represented by only three pens, Mr. Byron, of Sleaford, taking 1st and 2d prizes. A very liberal prize list has failed to attract the number that might have been expected.

We come next to the *Cotswolds*, to our mind by far the grandest breed in the island, and, as usual, imperfectly represented as regards numbers. Mr. Swanwick, of the Royal Agricultural College, is, however, persistently setting a good example to his brother breeders, and his pen is certainly well to the front. There is no reason whatever why the breed should not be abundantly represented at our fat stock shows. The objection to feeding breeding animals for show which interferes with an exhibition in July does not apply now. Mr. Hall, of Deddington, Oxford, takes the 1st prize with a very good pen of shearlings, but otherwise thoroughly characteristic of the breed in wool and form, handling, moreover, much firmer than the Lincoln sheep alongside of them. Messrs. Wheeler & Son, of Shipston, large exhibitors in other classes, are successful here; the 3d prize goes to the Agricultural College farm.

The *Southdown* breed is shown in two classes : Lord Walsingham's name and flock no longer appear. H.R.H. the Prince of Wales takes the 1st prize, and the 2d goes to Lord Sondes. The prize sheep are long, deep, and wide, and handle well. Colonel Kingscote shows a commended pen of rather smaller sheep, with finer wool and quality.

The *Shropshires* were not so large a show as usual. They are a much more even class than they used to be, with, however, still some difference in the character of the wool and head. Mr. Allsopp, of Hindlip Hall, Worcester, shows a sheep with a long and heavy fleece, of much coarser, looser wool than that, for example, of the sheep shown by Mr. Yates, of Shifnal, close by. The prizes go generally to the latter class of sheep, and Lord Chesham's sheep, which take the head prize, may be taken to represent the best type of the breed. The two styles are again contrasted in the class of single sheep. Mr. Allsopp's entries here compete with Lord Wenlock's, but the judges in this case have given the prize to Mr. Allsopp.

In another set of pens close by, *Ryelands*, *Dorsets* and *Hampshire Downs*, all very good of their kind, compete with one another. They are capital representatives of the several breeds : the prizes are given to the Downs.

A small class of *Oxford Downs* represents that short, stocky, heavy-fleeced, thick, upstanding breed—Messrs. Stilgoe, of Adderley, taking all the prizes. The *Cross-bred* sheep are a saddling lot, beginning with the produce of such an ill-assorted couple as a Cheviot and a Hampshire Down. Others, however, are better, as Cheviot and Leicester, Oxford Down and Long-woolled, &c.

The classes for single fat ewes are interesting specimens of the several breeds, and there is here, in a class all to itself, a single specimen of that useful sheep, the Border Leicester, a much heavier and larger sheep than any that is known as Leicesters in the Midlands,

The following is the list of the awards in the sheep classes :—

JUDGES.—Mr. John Wood, Harewood Hill, Darlington ; Mr. H. Overman, Weasenham, Brandon, Norfolk ; Mr. C. R. Keeling, Yew Tree Farm, Penkridge.

LEICESTERS.

Class 29. Fat Wethers, not exceeding 23 months old.—1st, £15 (extra prize of £10, given by the Linen and Woollen Drapers of Birmingham, and Silver Medal as breeder, the Executors of the late Lord Berners) ; 2d, £10 ; 3d, £5 ; Highly Commended : W. P. Herrick, Esq., Bourton-on-the-Water, Leicestershire.

LINCOLNS.

Class 30. Fat Wethers, not exceeding 23 months old.—1st, £15 (extra prize of £10, given by the Linen and Woollen Drapers of Birmingham), and Silver Medal, as breeder, Mr. J. Byron, Kirkby Green, Sleaford ; 2d, £10, do. ; 3d, £5. Mr. T. Gunnell, Milton, Cambridge.

COTSWOLDS.

Class 31. Fat Wethers, not exceeding 23 months old.—1st, £15 (extra prize of £10, given by the Linen and Woollen Drapers of Birmingham), and Silver Medal as breeder, Mr. R. Hall, Great Harford, Beddington ; 2d, £10, Messrs. J. Wheeler & Sons, Long Compton, Shipston-on-Stour ; 3d, £5, Mr. R. Swanwick, R.A. College Farm, Cirencester. Highly Commended : T. Jowitt, Esq., The Old Weir, near Hereford.

SOUTHDOWNS.

Class 32. Fat Wethers, not exceeding 23 months old.—1st, £15 (extra prize of £10 10s., given by W. Bromley Davenport, Esq., M.P.), and Silver Medal as breeder, H.R.H. the Prince of Wales ; 2d, £10, Lord Sondes, Elmham Hall, Thetford ; 3d, £5, do. Highly Commended : H. S. Waller, Esq., Farmington, Gloucestershire. Commended : J. J. Coleman, Esq., M.P., Carrow House, Norwich.

Class 33. Fat Wether, exceeding 23 and not exceeding 35 months old.—Silver Cup, value £5, given by Messrs. Mapplebeck & Lowe, and Silver Medal as breeder, H.R.H. the Prince of Wales. Commended : H. S. Waller, Esq., Farmington, Northleach.

SHROPSHIRES.

Class 34. Fat Wethers, not exceeding 23 months old.—1st, £15 (extra prize of £10 10s., given by C. N. Newdegate, Esq., M.P.), and Silver Medal as breeder, Lord Chesham, Latimer, Chesham, Bucks ; 2d, £10, Messrs. Beach & Hunman, Berwood, Stafford shire ; 3d, £5, Mr. T. Nock, Sutton Maddock, Shifnal. Highly Commended : Lord Chesham, Mrs. Beach. Commended : Mr. H. Mather, Moreford, Shifnal.

Class 35. Fat Wether, exceeding 23, but not exceeding 35 months old.—Silver Cup, value £5, given by Messrs. Mapplebeck & Lowe, and Silver Medal as breeder, H.R.H. the Prince of Wales. Commended : H. S. Waller, Esq., Farmington, Northleach.

SHROPSHIRES.

Class 34. Fat Wethers, not exceeding 23 months old.—1st, £15 (extra prize of £10 10s., given by C. N. Newdegate, Esq., M.P.), and Silver Medal as breeder, Lord Chesham, Latimer, Chesham, Bucks ; 2d, £10, Messrs. Beach & Hunman, Berwood, Stafford shire ; 3d, £5, Mr. T. Nock, Sutton Maddock, Shifnal. Highly Commended : Lord Chesham, Mrs. Beach. Commended : Mr. H. Mather, Moreford, Shifnal.

Class 35. Fat Wether, exceeding 23, but not exceeding 35 months old.—Silver Cup, value £5, given by Messrs. Mapplebeck & Lowe, and Silver Medal as breeder, H.R.H. the Prince of Wales. Commended : H. S. Waller, Esq., Farmington, Northleach.

OXFORDSHIRES.

Class 36. Fat Wethers, not exceeding 23 months old.—1st, £15 (extra prize of £10 given by the Linen and Woollen Drapers of Birmingham), and Silver Medal as breeder, Mr. N. Stilgoe, Adderbury Manor Farm, Oxon ; 2d, £10, do. ; 3d, £5, Mr. R. W. Sclgoe, Adderbury Grounds. Highly Commended : Mr. N. Stilgoe.

SHEEP NOT QUALIFIED TO COMPETE IN ANY OTHER CLASS.

Class 37. Fat Wethers, not exceeding 23 months old.—1st, £15, and Silver Medal as breeder, A. Morrison, Esq., Fonthill House, Tisbury ; 2d, £5, do. Highly Commended : Mr. H. Harding, Wether Stowey, Bridgewater. Commended : Mr. J. B. Downing, Holme Lacy, Hereford.

CROSS-BREDS.

Class 38. Fat Wethers, not exceeding 23 months old.—1st, £15, and Silver Medal as breeder, Mr. N. Stilgoe, Adderbury Manor Farm ; 2d, £10, Mr. W. F. Hobton, Adderbury House, Evesham. Highly Commended : Mr. Z. W. Stilgoe, Mr. W. F. Holton. Commended : J. J. Coleman, Esq., M.P., Norwich.

EWES.

Class 39. Fat Leicester Ewe, having bred one or more Lambs.—Silver Medal, value £2 2s., Mr E. Tindall, Knapton Hall, Rillington. Highly Commended : Mr. E. Tindall. Commended : W. P. Herrick, Esq., Bourton Park, Leicestershire.

Class 40. Fat Lincoln Ewe, having bred one or more Lambs.—Silver Medal, value £2 2s., Mr. J. Byron, Kirkby Green, Sleaford.

Class 41. Fat Cotswold Ewe, having bred one or more Lambs.—Silver Medal, value £2 2s., the Executors of the late Mr. J. Godwin, Cirencester, Gloucestershire. Highly Commended : H. S. Waller, Esq., Farmington, Northleach.

Class 42. Fat Southdown Ewe, having bred one or more Lambs.—Silver Medal, value £2 2s., H.R.H. the Prince of Wales. Highly Commended : Lord Sondes. Commended : J. J. Coleman, Esq., Oberton Hall, Worksop.

Class 43. Fat Shropshire Ewe, having bred one or more Lambs.—Silver Medal, value £2 2s., Lord Willoughby de Broke, Compton Verney, Warwick. Highly Commended : Mr. G. A. May, Elford Park, Tamworth.

Class 44. Fat Oxfordshire Ewe, having bred one or more Lambs.—Silver Medal, value £2 2s., Mr. N. Stilgoe, Oxon.

Class 45. Fat Ewe, of any other pure breed, having bred one or more Lambs.—Silver Medal, value £2 2s., Mr. R. H. Harris, Earnhill, Torres, N. B.

THE PIG CLASSES

are, as usual in Bingley Hall, of unrivalled excellence. The 1st class, of fat pigs under 10 months old, begins with Lord Aylesford's pen of three black Berkshires, which is followed by a Mr. Cartwright's three white pigs, of equal merit, and then by Berkshires —the 1st and 2d prizes going respectively to Lord Ailesbury and the Rev. H. Baily. Then follows a class under 15 months, and fully one-third bigger than the other. Here, too, white and black are interminglcd. The pen shown by Mr. Biggs, of Leighton Buzzard (Berkshire), takes the 1st prize, and an extra prize as the best fat pigs in the yard. There is a large class of single pigs over 15 months, the 1st prize going to one of extraordinary length and weight, shown by Mr. Eden, of Salford. In the classes of breeding pigs there is a most interesting and admirable illustration of the Berkshire breed ; from 269 to 287 in the catalogue we have a succession of pens of five pigs, each of really extraordinary beauty, which they owe not only to good breeding and feeding but to the mere art of getting up for show—the pigs shown by Mr. Smith, of Henley-in-Arden, in particular, showing the polished skin shining through the hair. The judges had a difficult task in these classes. The next class, of other large breeds, is of much more various quality—whites of all sizes and character competing with one another. The white pigs of a small breed, though poorly represented, are a much more even and respectable display.

The following is the prize list of the pigs :—

JUDGES.—Mr. C. Randell, Chadbury, Evesham ; Mr. A. F. Mr. Druce, Eynsham, Oxon ; Mr. H. Tait, Shaw Farm, Windsor.

Class 46. Three Fat Pigs of one litter, not exceeding 10 months old.—1st, £10, and Silver Medal as breeder, the Marquis of Ailesbury, Home Farm, Savernake Forest ; 2d, £5, Rev. H. G. Baily, Swindon ; 3d, £3, Mr. J. H. Clark, Lowood, Maidenhead.

Class 47. Three Fat Pigs of one litter, not exceeding 15 months old.—1st, £10, Silver Cup, value £5 5s., and Silver Medal as breeder, Mr. J. Biggs, Lushington, Leighton Buzzard ; 2d, £5, the Earl of Aylesford ; 3d, £3, Mr. J. H. Clark, Lowood, Maidenhead. Highly Commended, Messrs. R. E. Duckering & Sons, Commercial Street, Lincoln ; Commended : Mr. Eden, Cross Lane, Salford ; R. A. Davis, Esq., M.D., Burntwood Asylum, Lichfield.

Class 48. Fat Pigs, exceeding 15 months old.—1st, £6, and Silver Medal as breeder, Mr. P. Eden, Cross Lane, Salford ; 2d, £4, Mr. S. Deacon, Jun., Polebrooke Hall, Oundle ; 3d, £2, Messrs. R. E. Duckering & Sons. Highly Commended : Mr. P. Eden (2). Commended : C. R. N. Beswicke-Royds, Esq., Pyke House, Littleborough.

BREEDING PIGS—BERKSHIRE.

Class 49. Five Pigs of one litter, exceeding 3 and not exceeding 6 months old.—1st, £10, Silver Cup, value £5 5s., and Silver Medal as breeder, Mr. J. Smith, Henley-in-Arden ; 2d, £5, do. ; 3d, do. ; Extra prize (Silver Medal), Mr. R. Fowler, Broughton Farm, near Aylesbury ; and Mr. T. Radcliffe, Chiswell Green, near St. Albans.

PIGS OF OTHER LARGE BREEDS.

Class 50. Five Pigs of one litter, exceeding 3 and not exceeding 6 months old.—1st, £10, and Silver Medal as breeder, C. R. N. Beswicke-Royds, Esq., Littleborough ; 2d, £5, Messrs. J. Wheeler & Sons, Long Compton, Shipston-on-Stour ; 3d, £3, Mr. M. Walker, Stockley Park, Burton-on-Trent.

PIGS OF A SMALL BREED.

Class 51. Five pigs, of any pure breed, exceeding 3 and not exceeding 6 months old.—1st, £10, Silver Cup, value £5 5s., and Silver Medal as breeders, Messrs. J. Wheeler & Sons, Shipston-on-Stour ; 2d, £5, Mr. M. Walker, Stockley Park, Burton-on-Trent ; 3d, £3, Mr. P. Eden ; extra do. (Silver Medal), Mr. P. Eden.

THE ROOT SHOW.

The yard is surrounded by a gallery, in which is displayed, in capital light, and well arranged, a very interesting collection of roots of all kinds, and seeds and grasses of the same. The list is given below. There is, first, a class competing for a silver cup or other article of plate, of the value of five guineas, offered by Messrs. Proctor & Ryland, of Birmingham, as a prize for the best collection of the three following varieties, namely, Long Mangel Wurzel, Globe Mangel Wurzel, and Swedes, and open to the whole kingdom for this prize alone. Thirteen entries compete for this prize. Mr. Moore, of Long Itchington, Warwickshire, takes the 1st prize with roots of Messrs. Sutton & Sons, of Reading, and Messrs. Carter & Co., of Holborn, for some of his similar collections, and are well competed for. The Kohl Rabi and Mangel Wurzel are of extraordinary size. There are classes of Kohl Rabi, Mangels of various sorts, Swedes and common Turnips, Carrots, Bovinia Potatos, and Cabbages. We must refer to the prize list below for the enumeration of the most noteworthy exhibitors. It is a very extraordinary collection, and the awards, except, perhaps, in the case of the common Turnips, appear to us to have been fairly given—sufficient, but not excessive, regard being paid to quality as apart from weight, which after all determines for the most part the merit of a root of Kohl Rabi or Mangel. Cabbages are the most extraordinary display this year. We can only add that there is a very full and well-classified exhibition of Potatos, and an extremely interesting set of samples of Wheat, Barley, Oats, and Beans and Peas. The following list of weights is taken from the *Times* :—

"No such magnificent display of roots has ever been collected before, the 115 specimens of roots and Cabbage being of wonderful weight and quality throughout. The 5-guinea cup of Messrs. Proctor & Ryland for the best Long Mangel, Globe Mangel, and Swedes, six roots of each, in the Long Mangel, Purple-top Swedes, Globe Rabi, and Turnips, six roots of each, is won by Sir William Heathcote, the 30 specimens weighing 569 lb. The 5-guinea cup of Messrs. James Carter & Co., for a similar collection of roots, is won by Messrs. G. & J. Perry, the 36 specimens weighing 583 lb. Colonel North, M.P., is 1st and 2d for Kohl Rabi, averaging 12 lb. to 13 lb. per root. Mr. G. Baylis is 1st for Globe Mangels, averaging no less than 43 lb. per root. Sir F. Smythe is 1st for Globe Mangels, averaging 25 lb. per root; but quality, not weight alone, carries the honour, as Mr. G. Baylis' 2d prize Globes, averaging 22 lb., namely, 31 lb. per root. Mr. T. Algie is 1st for Swedes, averaging 20 lb. per root. Lord Willoughby de Broke's 1st prize Bovinia Potatos average over 2 lb. apiece. Mr. Samuel Robinson's 1st prize Cabbages weigh 64 lb., 72 lb., and 51 lb. apiece ; and his 2d prize Cabbages weigh 60 lb., 57 lb., and 49 lb. apiece. Of 139 lots of Potatos we can notice only the classifications adopted—namely, Ashleaf Kidney, Red Kidney, Ashleaf Kidney, Gloucestershire Kidney, King of Potatos, Milky White, Flukes, Dalmahoy, White Regent, Red Regent, Victoria, Redskinned Fourball, and classes for variety of early kidney, second earlies, white late or winter varieties, red or blue late varieties, early kidney, &c., and second early, &c. Some white Silesian Sugar-Beets are exhibited, but only 1st are of particularly good quality."

The following is the prize list under these heads :—

CORN.

JUDGES.—Mr. E. Davenport, Quadrant, Birmingham ; Mr. Joseph Guest, Ashted, Birmingham.

WHEAT.

Class 1. Talavera Wheat.—1st, £5, Mr. F. Lythall, The Spittall Farm, Banbury ; 2d, £3, Mr. S. Robinson, Shaw House, Melbourne, Derbyshire.

Class 2. White Wheat of any other variety.—1st, £5, Colonel Loyd-Lindsay, M.P., Wantage, Berks (Chidham) ; 2d, £3, Mr. H. Frampton, Watership Farm, Newbury, Berks (Victoria).

Class 3. Red Wheat.—1st, £5, Colonel Loyd-Lindsay, M.P. (Nursery) ; 2d, £1, Mr. F. Lythall (Nursery). Commended : Mr. H. Frampton (Nursery).

BARLEY.

Class 4.—1st, £2, Mr. S. Deacon, Eynsham, Oxford Hallett's Pedigree) ; 2d, £1, Mr. J. H. Clark, Lowood, Castle Hill, Maidenhead (Golden Melon).

OATS.

Class 5. White Oats.—1st, £2, Mr. F. Lythall, Banbury, (Canadian) ; 2d, £1, Mr. J. H. Clark, Maidenhead (Canadian).

Class 6. Black Oats.—1st, £2, Mr. F. Lythall (Poland) ; 2d, £1, Mr. H. Frampton, Watership, Berks (Tartarian).

BEANS.

Class 7. 1st, £2, Mr. F. Lythall (French Eyes) ; 2d, £1, Mr. J. H. Clark (White Eyes).

PEAS.

Class 8. White Peas.—1st, £2, Mr. G. Dunkley, Kingsthorpe, Northampton (Princess Royal) ; 2d, £1, Mr. Z. W. Stilgoe, Oxon (earliest in cultivation). Commended : Mr. Z. W. Stilgoe (Green Marrow).

Class 9. Blue or Grey Peas.—1st, £2, Mr. F. Lythall (Blue) ; 2d, £1, Mr. G. Dunkley, Northampton (Maple).

Silver Cup to the winner of the greatest number of Prizes for Corn : Mr. F. Lythall, Banbury.

ROOTS.

JUDGES.—Mr J. H. Burbery, The Chase, Kenilworth ; Mr. R. H. Masfen, Pendeford, Wolverhampton ; Mr. T. B. Wright, Quorndon Grange, Quorn Bear ; Mr. H. Thornley, Marston Hall, Elmdon.

Class 1. A Silver Cup, or other article of Plate, value 5 gs., offered by Messrs. Proctor & Ryland, of Birmingham, for the best Collection of Long Mangel Wurzel, Globe Mangel Wurzel, and Swedes—6 roots of each to be shown.—J. Moore, Esq., Long Itchington, Warwickshire. Highly Commended : Sir F. Smythe, Bart., Acton Burnell, near Shrewsbury ; Colonel North, M.P., Wroxton, Banbury ; Commended : the Marquis of Ailesbury, Burwood Farm, Marlborough, Wilts.

Class 2. A Silver Cup, value 5 gs., offered by Messrs. Sutton & Sons, Seedsmen to the Queen, Reading—Long Red Mangels, 6 Globe or Intermediate Mangels, 6 Purple-top Swedes, 6 Green Kohl Rabi, and 6 Turnips (Green, White, or Yellow).—Sir W. Heathcote, Bart., Hursley Park, Winchester. Highly Commended : the Marquis of Ailesbury, Colonel North, M.P. Commended : Colonel North, M.P.

Class 3. A Silver Cup, value 5 gs., offered by Messrs. James Carter & Co., London, for the best collection of 6 Purple-top Swedes, 6 Green Kohl Rabi, 6 Long Red Mangels, 6 Yellow Intermediate Mangels, 6 White-fleshed Turnips.—Messrs. G. & J. Perry, Acton Pigott, Condover, Salop. Highly Commended : Mr. J. Morth, M.P. ; the Marquis of Ailesbury, Home Farm, Savernake Forest.

Class 4. Kohl Rabi.—1st prize, £2, Col. North, M.P. ; 2d, £1, do. Commended : Col. Loyd-Lindsay, M.P. Commended : Sir F. Smythe, Bart.

Class 5. Long Mangel Wurzel.—1st £2, with 2 gs. added by Messrs. Proctor & Ryland—Mr. G. Baylis, Gayton Farm, near Ross ; 2d, £1, Sir F. Smythe, Bart. Highly Commended : Mr. J. Birch, Sefton, near Liverpool ; J. Moore, Esq., Long Itchington, Warwickshire. Commended : Mr. J. Dickinson, New Park, Hants ; Mr. S. Robinson, Shaw House, Melbourne, Derbyshire.

Class 6. Globe and Intermediate varieties of Mangel Wurzel.—1st £2, with 2 gs. added by Messrs. Proctor & Ryland, Sir F. Smythe, Bart. ; 2d, £1, Mr. G. Baylis. Highly Commended : Mr. W. B. Boxall, Strathfieldsaye, Winchfield.

Class 7. Swedes of any variety.—1st prize, £2, with 2 gs. added by Messrs. Proctor & Ryland, Mr. A. K. Algie, Togher House, County Mayo ; 2d, £1, do. Commended : the class.

Class 8. Long Purple-top Swedes.—1st, £2, Mr. T. Algie, Esq., Cloona Castle, County Mayo ; 2d, £1, Mr. G. A. May, Elford Park, Tamworth. Highly Commended : the Duke of Portland, Clumber. Commended : Lord Willoughby de Broke, the Duke of Portland ; T. L. M. Cartwright, Esq., Melville House, Lough Bank, Perth ; Sir F. Smythe, Bart.

Class 9. Common Turnips (yellow flesh).—1st, £2, Mr. H. D. Adamson, Balquhan, Alford, Aberdeen ; 2d, £1, W. McCombie, M.P. Highly Commended : Mr. J. Stephen, Conglass, Aberdeen. Commended : Mr. J. Stephen, W. McCombie, Esq., M.P.

Class 10. Turnips of any variety.—1st, £2, F. J. S. Foljambe, Esq., M.P., Osberton Hall ; 2d, £1, the Duke of Portland.

Class 11. Bovinia, or Cattle-feeding Potatos.—1st, £2, with Plate, 2d, £1, Mr. Parrington, Esq., Ingestre. Highly Commended : Lord Willoughby de Broke, Compton Verney, near Warwick ; 2d, £1, Mr. W. W. Pearce, Measham, Atherstone.

Class 12. Ashleaf Cabbage.—1st, £2, Mr. S. Robinson, Shaw House ; 2d, £1, do.

POTATOS.

Class 13.—Ashleaf Kidney.—1st, £1, Mr. J. Choyce, Pinwall Grange, near Atherstone ; 2d, £0 10s., do.

Class 14. Royal Ashleaf Kidney.—1st, £1, Mr. G. Dunkley, Kingsthorpe, Northampton ; 2d, 10s., Mr. D. Payne, Stoke Golding, Hinckley.

Class 15. Gloucestershire Kidney.—1st, £1, Mr. S. Evans, Arbury, Nuneaton, Warwickshire ; 2d, 10s., Mr. Z. W. Stilgoe.

Class 16. King of Potatos.—1st, £1, Mr. J. H. Clark, Lowood ; 2d, 10s., Mr. F. Lythall.

Class 17. Milky White.—1st, £1, Messrs. G. & J. Perry, Acton Pigott, Condover ; 2d, 10s., Sir F. Smythe, Bart.

Class 18. Flukes.—1st, £1, General the Hon. Arthur Upton, Lord's Plain Farm, Milnthorpe ; 2d, 10s., Messrs. G. & J. Perry.

Class 19. Dalmahoys.—1st, £1, Mr. J. Choyce ; 2d, 10s., Mr. A. Tustain, Great Barford, Oxon.

Class 20. White Regents.—1st, £1, Mr. F. Lythall.

Class 21. Red Regents.—1st, £1, Mr. F. Lythall ; 2d, 10s., Mr. J. Choyce.

Class 22. Victoria.—1st, £1, Mr. G. Mangles, Givendale, Yorkshire ; 2d, 10s., do.

Class 23. Red-skinned Flourball.—1st, £1, the Duke of Portland ; 2d, 10s., Mr. F. Lythall. Commended : the class.

Class 24. Twelve Early Kidney.—1st, £1, Mr. G. Dunkley, Kingsthorpe ; Early Conqueror ; 2d, 10s., Mr. D. Payne, Stoke Golding, Hinckley (Imperial Ashleaf). Highly Commended : Sir F. Smythe, Bart. (Early Rose). Commended : Mr. G. Mangles, Givendale, Ripon (Mona's Pride Ashtop) ; Mr. N. Stilgoe (White Blossoms).

Class 25. Second Early Varieties.—1st, £1, Mr. G. Dunkley (Giant Kingly) ; 2d, 10s., Mr. T. Bayliss (Breese's Peerless). Commended : Lord Willoughby de Broke (Bresee's Prolific) ; Sir F. Smythe, Bart (Lapstone Kidney); Mr. C. J. Perry, The

Cedars, Castle Bromwich (Early Emperor) ; the Duke of Portland (Largstone) ; Mr. George Dunklew (Johnson's Reliance).

Class 26. White Late or Winter Varieties.—1st, £1, Mr. F. Lythall (Bresee's Prolific); 2d, 10s., Mr. D. Payne, Stoke Golding, Hinckley (Bresee's Prolific).

Class 27. Red or Blue Late Varieties.—1st, £1, Mr. J. Choyce, Pinwall Grange, Atherstone (Red Flakes); 2d, 10s., Mr. W. Pearce, Measham, Atherstone (Albert's Blue). Highly Commended : Mr. C. J. Perry (Red Flukes) ; Messrs. Felton & Sons, 96, High Street, Birmingham (President Lincoln).

Class 28. Early Kidney, Second Early, and Late or Winter (collection of six dishes).—1st, £3, Mr. D. Payne ; 2d, £2, Mr. J. Choyce. Commended : Mr. F. Lythall.

Class 29. Second Early (two dishes).—1st, £1 5s., Mr. G. Mangles ; 2d, 15s., Mr. F. Lythall.

In addition to the articles attracted by the prize lists of the Society, there is a large collection unclassified but equally interesting, of which, not the judges, but the spectators, take account. Seedsmen are here with their wares, manure-makers exhibiting some roots which owe their size perhaps even more to their feeding than to their breeding; agricultural machine-makers, represented by all the leading firms, also help to fill the building. As, however, we hope next week to give a full report of the larger show under these heads which will be held in the Agricultural Hall, we postpone till then our remarks on the implements exhibited.

POULTRY.

Of this class we are unable to find room for a particular report. The following note is taken from the *Times* :—

"Dorkings, Cochins, Brahmas, game, and especially the favourite game Bantams, are exhibited in the highest state of perfection, with few inferior birds; and it is remarked that most of the varieties, including the Houdan, Crèvecœur, and other French breeds, surpass their demonstration of last year. It is still evident that, among fanciers in general, to win at Birmingham is considered a carrying off of the blue riband, and many a champion bird of other shows is here obliged to be content with honourable mention only. Mr. J. R. Fowler's 1st prize Aylesbury drake and duck weigh 17 lb. 12 oz., and his 2d prize Aylesbury drake and duck, 16 lb. 12 oz. Mr. Thomas Slatter's 1st prize Rouen drake and duck weigh 19 lb. 2 oz. ; and Mr. Dodson's 2d prize Rouen drake and duck weigh 19 lb. 1 oz. Mr. J. R. Fowler's 1st prize white gander and goose weigh 56 lb. 9 oz. ; and the Rev. G. Hostler's 2d prize white gander and goose weigh the same. Mr. J. R. Fowler's pair white geese were the only ones hatched in 1871, and only seven months old, weigh 48 lb. 6 oz. The same exhibitor's 1st prize grey gander and goose, hatched in 1871, and only seven months old, weigh 48 lb. 6 oz. Mr. F. Lythall's 1st prize American turkey cock weighs 36 lb. 4 oz. ; and his 2d prize Cambridge turkey cock 33 lb. 8 oz. The same exhibitor's 1st prize turkey cock, hatched in 1871, and only six months old, weighs 28 lb. 2 oz. Mr. E. Leech's 1st prize turkey hens weigh 38 lb. 12 oz. the pair, and his 1st prize turkey hens, hatched in 1871, weigh 28 lb. 10 oz. the pair. The pigeons present a most welcome increase of numbers over last year, and while improvement in quality is observable in many classes, the black carriers, pouter cocks, dragons, and birds of every other variety are especially excellent."

Notices of Books.

Handbook of Farm Labour. By John Chalmers Morton. New Edition. Cassell & Co.

A discussion of the amount of wages per acre ordinarily paid on arable land in this country, which has been recently carried on between two such unequal champions as the *Pall Mall Gazette* and Mr. C. S. Read, M.P., induces us to name this little book as containing information on this class of subjects. The *Pall Mall Gazette*, commenting with singular ignorance on an estimate by Mr. Read of the wages paid in farming, had put the cost of arable land at about 18s. an acre, and to the writer of the paragraph Mr. Read replied—

"In the first place, I did not say that 'the cost of labour averages 35s. per acre.' I was talking of arable land, and the amount is now frequently 35s.' Were I asked to strike an average, I should put it at about 30s. an acre on arable land.

"Now, allow me to have a word upon your statement. You say, 'Upon a farm of 600 acres it would be difficult to find employment for more than 20 hands, men and boys ; and if we allow £45. a week to all the labourers, irrespective of age, we have an actual expenditure of £728, or nearly 18s. per acre.'

"This farm contains 420 acres, 40 of which are in permanent pasture. November is not an over busy month of the agricultural year, but I have now at work 18 men, five boys, and two women, besides the bailiff, groom, and gardener. At present, I have no 'difficulty in finding them employment.'

"Indeed, to prepare the food and attend to the comfort of 60 or 70 cattle, and about 700 pigs—to say nothing of sheep and horses—needs so many hands that I employ as many labourers in summer as in winter. You have allotted 18s. per acre for the labour of arable land. Are you aware that upon every acre of corn we grow the simple act of harvesting the crop costs us about 12s. This is all done in one month, which, according to your calculation, would leave 6s. an acre for the other 11 months of the year. Fancy 6s. for the manual labour employed in ploughing, harrowing, drilling, hoeing, weeding, threshing, dressing, and delivering the grain! Upon 800 acres of arable land you would grow at least 400 acres of corn, and you would be lucky with your '20 men and boys' if you secured your crop by Michaelmas. In Norfolk we like to have the harvest ended in August, but then we should employ 40 hands instead of 20.

"P.S. My labour account for the last fortnight amounts to £31 5s. 10d. ; of this about two guineas is paid for taskwork, the rest for day labour ; but it does not include the standing wages of the carters, shepherd, &c."

To this we add the following Table, giving the ascertained particulars of wages on 14 different farms, extracted from the Handbook named above :—

Number.	Extent in Acres. Arable. Fallow Crops.	Corn.	Grain.	Clover.	Pasture.	Hands Employed. Men.	Women.	Boys and Girls.	Annual Labour Bill.	Average per Arable, Deducting 5s. for Pasture.	Acres to each Pair of Horses. Arable Land.	Ploughed Land.	Fallow Crops.

"The reader may be left to extract for himself what information the Table can convey. It will, however, be right to say, that our first instance of a medium-soil farm must be considered as altogether exceptional ; a very unusual proportion of the land was in laborious fallow crop, and not only was the quantity of hand labour unusually large, but the quantity of horse labour was unusually small. Taking those cases, of which the full particulars are given—viz., 13 out of the 14 farms described — we have the following gross results : — On 7824 acres of arable land, and 1650 acres of pasture, 240 horses are employed, and work is given to 359 men, 134 women, and 143 boys and girls, costing, on the whole, not less than £14,323. This, if we deduct £423 for the pastures, is equal to about 33s. per acre of arable land. The horse labour of these farms amounts, on the average, to one pair for every 65 acres of arable land, or for every 49 acres of actually ploughed land.

"It will be observed that more than the average wages are paid for manual labour on those farms where steam-power is employed as an auxiliary force. The interests of the labourer will be considered more fully in a subsequent chapter, and the possibility of his suffering by the employment of a cheaper force and more powerful machinery will be discussed. Meanwhile it is a fact, that on those farms of which the details are known, where steam-power is employed for cultivation, our clays, retaining their superior fertility, are made available for all kinds of fallow, labour-giving crops, such as Mangel Wurzel, Kohl Rabi, Cabbages, and other winter food for sheep and cattle.

"And there is, then, extra labour needed not only in their cultivation, but also in tendance of the live stock needed for the consumption of their produce."

Farm Memoranda.

HAMPSHIRE.—The close of the autumnal seed-time appears to be a fitting time to review and report upon agricultural operations. There can be no doubt that the past Wheat season has been better than in some previous years, having been favoured with copious rains during the month of October. The land has worked closer and heavier than during the dry seedtime of last year. We may, therefore, expect a better and more regular plant of Wheat for the coming season. All kinds of autumn seeding has been finished in capital style. Whether we speak of Rye, winter Barley, winter Beans, or Vetches, they are all equally well planted ; and, although not forward, are very regular and promising both on the hill and vale farms. Looking at the favourable seed-time and price of Wheat in our markets, it is fair to infer that at least an average area of land has been sown with this crop, and it is probable that more than the average extent on strong soils has been devoted to Wheat. The yield of Wheat by the further test of threshing is found to be quite as deficient as reported at harvest, and the weight and quality very light and various.

Barley proves about an average in quantity, but the samples are very thin, yet the best are found to work well and kindly in the vessels of the maltster.

Oats are, as first reported, a very large and yielding crop, of good quality. Beans a good average, and Peas an abundant produce.

Hay is very various in quality, the best having receded considerably in price, being about 30s. per ton lower than last year. The great abundance of grass in the meadows, with fine open weather for grazing, has, with a great root crop, tended to maintain a high price for sheep and cattle, the value of both being higher than at any time during the past 40 years, and a remarkable feature in the trade has been the uniformity of value, and absence of the usual fluctuations in price during the whole season.

On all sides the question is asked, What is to be done with the root crop? The natural reply is, Abide the spring season, and then decide. It is also asked, what is the cause of the high prices for sheep and cattle, and how can they pay for fatting? There is no doubt a great diminution of stock, occasioned by the scarcity of food in former years ; and the vale farmers are beginning to think that they ought to breed as well as feed their stock, the same as the hill flock-masters. The price of meat to the consumer is unusually high, and may be especially so for prime meat at Christmas. The importation of preserved meat from Australia is attracting attention, but can be compared only to a drop in the ocean, when it is considered that the total importations of live and dead meat amount to only 8½ per cent. of the consumption. If, therefore, the trade of the country continues satisfactory, the prices of meat must rule high until the flocks and herds can be replenished by favourable breeding seasons.

We cannot avoid alluding to the progress the Royal Agricultural Benevolent Institution has made in this country within the past few years, and it must be gratifying to all well-wishers to know that Hampshire is now placed in the foremost rank of counties in its support of the institution, through the exertions of the local secretaries and the numerous subscribers ; and it is worthy of special remark that 400 subscribers have lately testified their approbation of the zealous and disinterested exertions displayed by Mr. Alderman Naish, of Winchester, as hon. local secretary of the institution, by presenting him with a handsome testimonial and a purse of 235 sovereigns ; and let us hope that the attention of landowners and agriculturists generally will be called to the subject, and induce yet greater numbers to subscribe, and thus enable the institution to assist those who, through the vicissitudes of the farming business, may have fallen into adversity. *Joseph Blundell, Southampton, November 20.*

The Week's Work.

DECEMBER 2.—*Horse Ploughing* prosecute in open weather. Stubbles should have been finished before this, but in wet weather it is better to turn into lea fields until the stubbles dry than to poach the land. In late wet seasons in the North, stubbles liable to poach are not unfrequently left until spring for Beans, the Beans being sown in the stubbles and thinly covered by "ribbing," *i.e.*, stetches made by the common plough, each with one furrow. It is, however, only the heavier clay soils that are thus left to spring, and the practice is becoming less frequent as the land is thoroughly drained.

Clay, Chalk, Marl, and Compost are good tasks requiring them, in order that the coming frost and rains of winter may disintegrate and wash them in before the growth of spring commences. Some marly clays are sufficiently friable to be broken fine in the spreading for working in immediately by a chain-harrow ; others require frost to break them down. Composts generally may be thus applied and harrowed into grass land. But when from 200 to 400 cartloads per acre of clay are applied, to change the texture of poor, sandy, gravelly and peaty soils, seed-harrows or the common harrow may answer better than the chain-harrow or bush-harrow—frequent harrowings being sometimes necessary to effect the disintegration and washing in. Chalk is also found so broken, when dug from pits or drifted strata under clays, as to be easily applied and harrowed into clayey and peaty soils. On farms ploughed by steam, the carting of such applications forms profitable employment for the teams.

Claying Fen Land is extensively practised at this season. Sometimes the clay is carted, but over a large area of the Fen country the work is done by manual labour at from 30r. per acre and upwards. The clay or clayey marl is sometimes found only 2 or 3 feet below the surface of the peaty soil, but in other cases much deeper. It is not, however, so deep as it

* On the farms marked thus* much of the cultivation is done by the steam-plough.

formerly was, owing to the general waste of the vegetable matter forming the soil, and the consequent subsidence of the staple below the original surface level. Narrow trenches are opened down to the clay, which is next dug up, and spread across between the trenches with the spade, or spade and harrow, when the trenches are wide asunder, at the rate of from 50 to 200 cubic yards per acre and upwards. The trenches are then filled with the peat earth dug out above the clay. The work is heavy when the clay lies at a considerable depth, but remunerating; and, although much land is annually clayed, yet the practice is limited when it might with benefit be much more used, could steam-power and machinery be successfully brought to bear upon it, either by digging or warping. Trials both ways have been made; the former (digging by steam) proved a failure, but the latter is a successful practice, which merits greater patronage than it at present receives.

Water Meadows.—Attend to the alternate floodings; in a season like this the process requires close watching. Where there is a limited supply of water, provision should, if possible, be made for turning it on to a dry field, as the respective flooded ones are gone over, so as to use the whole supply at command. In this way a very small supply of water judiciously applied may enrich a much larger area than it can be generally imagined, and 1 cwt. of guano or artificial grass manure sprinkled over the meadow by a broadcast manure distributor, will greatly reduce the quantity needed to insure a heavy crop of hay.

Obituary.

WE regret to announce the death of Prof. SPOONER, of the Royal Veterinary College, on Friday of last week. Educated in the College of Prof. Coleman, he gave a course of lectures privately soon after he got his diploma. He afterwards entered the College as demonstrator, and at length became deputy professor under Prof. Sewell, on whose death, about 20 years ago, he became Principal of the College. He was a member of the Cattle Plague Commission in 1865, and may be said to have long been the chief authority in horse matters in this country. He died at the age of 66, on Friday, the 24th ult., after an illness of two days.

Notices to Correspondents.

BOOKS: *The Shepherd* can obtain a "Farmer's Diary" by applying to Mr. Jemmett, Munrell Hill Farm, Binfield, Berks.

MR. PEEK'S ONIONS.—"Abingdonicnsis" should have given his name. At present, his letter is a mere advertisement without authenticity.

RYE-STRAW: *The Earl of Essex* asks for information, through the *Agricultural Gazette*, as to the value per ton of Rye-straw, which is chiefly used by collar-makers. Will any reader give us his experience?

SMOKING HAMS: *A Correspondent* inquires if any reader will kindly give information where a Lambton's kiln, or a good substitute, for giving a smoke flavour to hams, bacon, &c., is to be procured.

TURNIP SEEDS.—Messrs. Sutton & Sons, of Reading, have sent us specimens of their Champion Purple-top Swede, and their "New All the Year Round Turnip," which they were putting out for seed at the time the frost set in, as "a fair sample of the roots put out for general sale, later being used for stock purposes." This is in reply to an article or two a short time since in our paper as to seed-growing, one writer having gone so far as to assert that a good deal of the seeds were saved from "stems like walking-sticks, and having no bulbs."

Markets.

MARK LANE.

MONDAY, Nov. 27.

The supply of English Wheat to this morning's market was moderate, and sold at the prices of this day se'nnight. There was a good attendance, but very little demand for foreign Wheat, in which scarcely any business was transacted, prices remaining nominally as on Monday last. Barley, Beans, and Peas were unaltered in value. The Oat trade was slow, and rather easier. There was no change in Maize. Flour sold slowly, at late rates.

WEDNESDAY, Nov. 29.

A quiet feeling pervaded the Corn Exchange to-day. The supplies of English Wheat were fair, and those from abroad were large. Trade was inactive, and in some instances lower. Fine Barley commanded previous rates, but other qualities were easier to purchase. Malt sold slowly, on former terms. The market was well supplied with Oats; the demand was limited, but prices were without material change. Beans and Peas were dealt in cautiously, at about late prices. Flour experienced a slow sale, at Monday's quotations.

LIVERPOOL, Nov. 28.—There was again a poor attendance of actual buyers at this morning's market, and the Wheat trade was without animation, sellers, in order to make progress with sales, having to allow some reduction on last Tuesday's prices. Flour quiet, but nominally unchanged. Beans quiet, at 33s. 6d. to 35s. 9d. Indian Corn in moderate request, at a decline of about 3d. per qr.; American mixed, 33s.

METROPOLITAN CATTLE MARKET.

MONDAY, Nov. 27.

We have a shorter supply both of English and foreign Beasts; trade is active, at an advance on last Monday's quotations. The supply of Sheep is larger; most of the choicest qualities are making about the same as last week, although our top figure is an extreme one. Heavy fat sheep are decidedly lower. There is no alteration in the Calf trade. The foreign supply consists of 1720 Beasts, 14,380 Sheep, and 230 Calves; from Scotland there are 65 Beasts; from Ireland, 900; and 1205 from the Midland and Home Counties.

		Pigs ..... 3 4—4 8

THURSDAY, Nov. 30.

We have a fair supply of English Beasts to-day as to numbers, but the average quality is not very good; with foreign we are but scantily supplied. Trade is not very brisk, yet choicest qualities, being scarce, are not cheaper. There are more Sheep, both English and foreign, and trade is exceedingly dull; prices are rather lower, and a clearance cannot be made. Choice Calves are still scarce and dear. Our foreign supply consists of 315 Beasts, 6240 Sheep, and 158 Calves.

	s. d.	s. d.

METROPOLITAN MEAT MARKET, Nov. 30.

Best Fresh Butter .. .. .. 18s. per dozen lb.
Second Do. do. .. .. .. 16s. „

Small Pork, 4s. 4d. to 4s. 8d.; Large Pork, 3s. 4d. to 3s. 10d. per 8 lb.

ENGLISH WOOL.

There has been a steady business doing, limited, however, somewhat by the poor assortment on offer and high prices asked. Those, however, who are running short of stocks will eventually be compelled not only to pay the prices now asked, but even higher ones, as it is becoming quite a difficult matter to see how present stocks can possibly keep machinery running till next clip day. The firm tone of the British market is further sustained by the advance of 1d. to 2d. per lb. realised in the colonial sales now being held in London.

HOPS.

BOROUGH MARKET, Nov. 29.

The tone of the market is firm; the demand is of the same retail character as during the past two or three weeks. The Alost market has fallen, and now stands at as low a point as at the commencement of the season. Only very few of the recent importations are Hops of fine flavour or quality, the bulk being Belgians, foreign Hops of inferior quality, or yearlings. Choice Bavarian and French Hops command a rise of 5s. to 10s. per cwt.

JOSHUA BAKER.

GRAY'S OVAL TUBULAR BOILER.

INTERNATIONAL EXHIBITION, CLASS IX., No. 2119.

MR. GRAY begs to call the attention of the Nobility, Gentry, Nurserymen, Gardeners, &c., to his

NEW OVAL TUBULAR BOILER.

Acknowledged by practical judges to be a great improvement on every form of Tubular Boiler yet introduced. It has proved itself superior to all other Boilers for quickness of action and economy of Fuel, doing its work with one-third less the amount required by any other.

Extract from Report in GARDENERS' CHRONICLE *of International Exhibition, May 24, 1862, page 476.*

"The upright form of Boiler is usually made on a circular plan, but the oval form given to Mr. GRAY's variety of it is said to be preferable in consequence of its bringing the tubes in closer contact with the fire. The usual form of a furnace being a parallelogram rather than a square, it seems feasible that the Boilers on the oval plan should bring the tubes more completely within range of the burning fuel; and this being so, the change, though a slight one, is no doubt an improvement."

☞ *They are made of all sizes, which, with prices, may be had on application.*

JAMES GRAY, HORTICULTURAL WORKS,
DANVERS STREET, PAULTON'S SQUARE, KING'S ROAD, CHELSEA, S.W.

Works on Botany, by Dr. Lindley.

DESCRIPTIVE BOTANY: OR, THE ART OF DESCRIBING PLANTS correctly, in Scientific Language, for Self Instruction and the Use of Schools. Price 12.

THE ELEMENTS of BOTANY, STRUCTURAL AND PHYSIOLOGICAL With a Glossary of Technical Terms, and numerous Illustrations. 12s. cloth.

This completes the series of Elementary Botanical Works by Professor LINDLEY, of which "School Botany," and "The Vegetable Kingdom," form the other parts.

The first two Parts of THE ELEMENTS OF BOTANY, comprising STRUCTURAL and PHYSIOLOGICAL BOTANY, and a Glossary of Technical Terms, are published in one octavo volume, price 12s.

These three parts form a complete manual of Botany for Medical and other Students who have made themselves acquainted with the Author's "School Botany."

N.B. The Glossary may be had separately, price 5s.

THE VEGETABLE KINGDOM; OR, THE STRUCTURE, CLASSIFICATION, AND USES OF PLANTS, Illustrated upon the Natural System. In One Volume, 8vo, cloth, price 36s., with upwards of 500 Illustrations.

EXTRACT FROM THE AUTHOR'S PREFACE.

"The Vegetable Kingdom contains, among a large quantity of plants of no known importance to man, various useful species employed in medicine, the arts, or in the many branches of domestic economy. The principal part of those which can be brought by teachers in Europe under the notice of students, or which, from their great importance, deserve to be among the earliest subjects of study, are mentioned in the following pages, where they are arranged in the manner proposed in the 'VEGETABLE KINGDOM' of the author, with the modifications which the separation of Ferns in a few instances has led me to believe that the convenience of younger students would be consulted by doing so. I have every reason to hope that this selection will be found to have been made in such a way that all teachers who possess reasonably extensive means of illustrating their lectures, and all Botanic Gardens, may furnish the larger part of the species which are mentioned. A work which, like the Vegetable Kingdom, is large because a greater work would have been beyond the reach of the majority of purchasers; unlikely, consequently, to become popular at a time when who have to study a science of observation, such as Botany, require to concentrate their attention, in the first instance, upon a limited number of objects."

London: BRADBURY, EVANS, AND CO., 10, Bouverie Street, E.C.

THE NEW METHOD of GROWING FRUIT and FLOWERS (by the Rev. JOHN FOUNTAINE, Southacre, Brandon), with Illustrations of Combination of Various Forms of House and Conservatory, as now worked in a New House erected for the purpose at Swinton, Yorkshire, and available for the Garden, Vine, or Greenhouse. Vol. 27 of the Third Series, 42s.

FLORAL MAGAZINE: 48 richly Coloured Plates, with Descriptions, of the choicest New Flowers for the Garden, Stove, or Conservatory. Vol. 10, 31s. 6d.

A NEW SERIES of the FLORAL MAGAZINE, enlarged to Monthly Parts, commences with the NUMBER for JANUARY, 1872, to be published Monthly, with Four Plates, Coloured in the first style. Price 3s. 6d. ; annual subscription, post paid, 42s.

L. REEVE AND CO., 5, Henrietta Street, Covent Garden.

Real Values of Feeding Stuffs.

A SECOND COLOURED SUPPLEMENT to the "AGRICULTURAL ECONOMIST."

It will Illustrate a New Method of Ascertaining Fattening and Flesh Forming qualities of nearly all the Feeding Substances in general use by Farmers. The Manurial Value of the Residue from such uses will also be shown.

It is requested that early Orders for Copies be given, as many orders for the last Supplement came too late.

Price 1s., or gratis to Annual Subscribers to the *Agricultural Economist*.

Address: Agricultural and Horticultural (Co-operative) Association, 35, King Street, Westminster, S.W.

STAND No. 54, at the Cattle Show, Agricultural Hall.

New Edition of Jukes' Geology.

Now ready, in crown 8vo, Price 12s. 6d., Illustrated, New Edition of

JUKES' MANUAL of GEOLOGY. Edited by ARCHIBALD GEIKIE, F.R.S., Regius Professor of Mineralogy and Geology in the University of Edinburgh.

Joyning's Nursery, Waltham Cross, N.

December 5, 1871.

J. AND M. WOOD, Nieces and Executrices of the late ROBERT JOYNING, beg leave to intimate that they have DISPOSED OF the above old-established BUSINESS to Mr. WM. RUMSEY, who for the last 21 years has been engaged with the Messrs. Paul, of Cheshunt, and Waltham Cross, and solicit for their Successor a continuance of the Patronage so many years afforded to their late Uncle.

Joyning's Nursery, Waltham Cross, N.

(ESTABLISHED UPWARDS of SIXTY YEARS.)

Ten minutes' walk from Waltham Station, Great Eastern Railway.

December 5, 1871.

WM. RUMSEY, late Manager at Paul's Nurseries, Waltham Cross and Cheshunt, begs most respectfully to inform all Patrons of Horticulture that he has taken the above Establishment, and intends carrying on the NURSERY and SEED BUSINESS in all its details, and hopes that his long practical experience, and strict personal attention to all Orders entrusted to him, will secure a share of that liberal support so long enjoyed by his predecessor.

Nursery and Seed Establishment, Romsey, Hants.

ELCOMBE AND SON have great pleasure in offering the following CHOICE SEEDS—price to the Trade on application :—

DWARF VICTORIA BEET.—This has been saved with the greatest care, and can be warranted true. Knowing what disappointments often occur from seed being saved in the neighbourhood of coarser kinds, they have been induced to pay particular attention to saving this superior kind, under their own care, so that they can confidently recommend this as the best Beet for all purposes that has been sent out. It has been used for the last three seasons as a ribbon and border plant in the flower garden, and no other sort has equalled it for that purpose. Leaves rich metallic crimson; growth true, even, and regular, surpassing the Perilla in the richness of its colouring. Its root is of a rich dark crimson colour, compact top, and of excellent quality. Numerous Testimonials have been received to confirm its superority. In packets, 6d. and 1s.

FRAME CUCUMBER, HORTON PROLIFIC.—Without doubt one of the finest Cucumbers in cultivation, being equally suitable for summer and winter forcing and the open ground culture; very prolific, and of excellent quality. 1s. per packet.

ELCOMBE'S IMPROVED PARSNIP.—Producing handsome shaped roots, free from fibres, and of fine flavour. Unquestionably the best Parsnip for table use. 4d. per oz.

KINGSHOLM COS LETTUCE.

THIS MAGNIFICENT LETTUCE made its appearance three years since in a piece of White Cos. It withstood the severe heat for a long time after all other varieties (with the exception of Wheeler's Tom Thumb) had run to seed, headed-in without tying, and formed one of the most perfect models of a Cos Lettuce ever seen. At length it ran to seed; owing to the late period of the season it had started, the produce was, however, small. The whole stock was carefully preserved for next season's seeding. The crop of seed was again very limited, but the Lettuces were magnificent, many of them weighing 7 lb. each. We are now enabled to offer seed at 1s. per packet, feeling confident it will give satisfaction to every one who grows it. It was seen last summer by a gentleman connected with Covent Garden Market, who remarked it was the finest Lettuce he had ever seen, and far superior to anything brought to the London Market. We recommend those who contemplate growing Lettuces for Exhibition to give this variety a trial. Get it sown in a frame, and planted out early in the season, on deeply dug and well-manured land, and we have but little fear such specimens will be produced that will defy competition.

Packets, 1s.; small packets, 6d. each, post free.

Trade price on application.

J. C. WHEELER AND SON,
SEED GROWERS,
Gloucester; and 59, Mark Lane, London, E.C.

To Planters.

J. SCOTT, Merriott, Somerset, advises Planters to send for his ORCHARDIST and its COMPANION, price 2s., before ordering their Fruit Trees. Ornamental planters, amateurs, and gardening folks generally, will find much useful information in J. S.'s GENERAL NURSERY, BULB, and SEED CATALOGUES; they are full of interesting matter suited for gardens and gardeners, gratis.

THE FRUIT TREES cover many acres, and are in perfect health; 1000 sorts of Apple, and 200 sorts of Pear are grown, and all other fruits in proportion.

THE FOREST TREES and ORNAMENTAL SHRUBS occupy a large space, more especially Alder, Ash, Birch, Beech, Chestnuts, Elms, Firs (Austrian, Larch, and Spruce), Hazel, Oak, Poplars, and at least one million of healthy Thorns, in all the usual sizes.

A NEW CATALOGUE, containing all the names enumerated in the "Orchardist," and many new sorts introduced since that work was printed, gratis on application.

New Wrinkled Marrow Pea.

"MCMILLAN'S" QUEEN of the MARROWS.—Every one who wishes a Pea of the first quality and an immense cropper, should sow this for a continuous summer crop. In the two most unpropitious Pea seasons of 1869 and 1870 it produced heavy crops of fine large Peas; while in the same ground, and treated the same, Advancer, No Plus Ultra, Supreme, and other similar kinds, gave very poor crops of inferior-sized Peas. In 1871 the haulm was literally covered with pods. I have now reduced the price to 2s. 6d. per quart.

It may be had of the Advertiser, and of the principal London and Provincial Seedsmen. Wholesale price on application to

H. McMILLAN, St. James' Road Nursery, Kingston-on-Thames.

SUTTON & SONS

BEG TO CALL ATTENTION TO THE SPLENDID

NEW WRINKLED PEA,

BEST OF ALL (McLean).

The best Wrinkled Marrow Pea ever introduced. It is a Main Crop variety. Height 3 feet. **5s.** per quart.

The forwarded PEA known is
SUTTONS' RINGLEADER,
Price **1s. 6d.** per quart.

SUTTON AND SONS,
SEEDSMEN BY SPECIAL APPOINTMENT TO H.M. THE QUEEN and H.R.H. THE PRINCE OF WALES,
READING.

Autumn Planting.

PETER LAWSON AND SON have respectfully to recommend the early planting of FOREST TREES and ORNAMENTAL TREES and SHRUBS, as producing more successful results than when deferred until late.

The large breadths of LARCHES, from 1 to 3½ feet, SCOTCH FIRS, SPRUCE, AUSTRIAN PINES, and other leading sorts of FOREST TREES, are unusually fine, and worthy of inspection. CATALOGUES and special offers will be furnished upon application. Edinburgh and London, October, 1871.

TO WILLOW GROWERS.—The Planting Season having commenced, WILLIAM SCALING, WILLOW NURSERYMAN, Basford, Notts, is now ready to execute orders for

WILLOW PLANTS and CUTTINGS for Timber Trees and Coppice Wood.

WILLOW PLANTS and CUTTINGS for Ornamental Trees and Shrubs.

WILLOW CUTTINGS for Basket Makers' purposes.

BITTER WILLOW PLANTS and CUTTINGS for Hedges and Game Covers.

WILLOW STOCKS for Budding and Grafting.

Descriptive CATALOGUES free upon application as above.

"THE SALIX, OR WILLOW," second edition, post free, 1s.; or of SIMPKIN, MARSHALL AND CO., London.

Transplanted Scotch Fir.

J. ROY, JUN., NURSERYMAN, Aberdeen, has a very extensive stock of transplanted SCOTCH FIR, of various growths; as the whole has to be cleared off this season he offers as under to the Trade :—

2-yr. SEEDLINGS, 2-yr. transplanted .. .. 5s. per 100.
3-yr. SEEDLINGS, 3-yr. transplanted .. .. 7s. 6d. per 1000.
Strong and fine do., 18 to 24 inches .. .. 10s. per 1000.
Large Specimens, 2 to 3 feet .. .. 1s. per 100.

OF RHODODENDRONS he has a very extensive stock, and to clear out he now offers his stock, which consists of upwards of 100,000 of PONTICUM, CATAWBIENSE, and other choice kinds, from 9 inches to 2 feet high, at 8s. to 30s. per 100.

LIMES.—Of these he has upwards of 100,000, from 3 feet to 9 feet. Prices will be forwarded on application: they are all clean-grown and fine straight stems.

Orchids.

JAMES BROOKE AND CO., Nurseries, Fairfield, near Manchester.—Our recent importations of choice ORCHIDS, especially of the best winter flowering kinds, having been extensive, and the plants being all in excellent condition, we are enabled to offer them on terms unusually advantageous. Where selections to a fixed value, say £20 to £50, are desired, and the choice is left to ourselves, the purchaser pays less than the catalogue prices, and is no loser in regard to merit and variety. The plants we have sent out in execution of such orders have, we are informed, given unmixed satisfaction. The following list, with prices annexed, will be some guide to intending purchasers :—

Dendrobium Falconeri, 21s. to 63s. each; D. Wardianum, 63s. to 105s.; D. chrysotis, 21s. to 63s.; D. McCarthiæ, 42s. to 84s.; D. heterocarpum, 5s. to 21s. D. moniliforme, 10s. 6d. to 21s.; D. transparens, 5s. to 21s.; D. Devonianum, 7s. 6d. to 21s.; D. nobile, 5s. to 10s.; Odontoglossum grande, 7s. 6d. to 10s. 6d.; O. Insleayi, 7s. 6d. to 10s. 6d.; O. citrosmum, 7s. 6d. to 10s. 6d.; O. luteo-purpureum, 25s.; O. glomerum, 25s.; O. Alexandræ (Humbertii), 21s. to 63s.; O. excavatum, 21s. to 63s.; O. Rossi superbum, 21s. to 31s. 6d.; O. crocidylerum, 42s.; O. platytænium, 31s. 6d.; O. ramulosum, 31s. 6d.; O. Bictoniense, 15s.; O. Uroskinneri, 10s. 6d. to 15s.; Vanda coerulea, 10s. 6d. to 105s.; Phalænopsis Wallichii, 5s. 6d. each, 30s. per dozen; P. Ingenaria, 5s. to 10s. 6d.; Cypripedium hirsutissimum, 7s. 6d. to 21s.; Cattleya Mossiæ, 7s. 6d. to 21s.; C. maxima, 31s. 6d.; C. Trianæ, 15s.; C. Warneri, 21s.; Barkeria Skinneri, 10s. 6d. to 63s.; B. spectabilis, 10s. 6d. to 63s.; Calanthe vestita, 5s. 6d. to 21s.; C. Veitchii, 10s. 6d. to 42s.; Cœlogyne cristata, 10s. 6d. to 63s.; Oncidium Papilio, 7s. 6d. to 10s. 6d.; O. Krameri, 21s.; O. Lanceanum, fine variety, 15s.

12 RHODODENDRON MADDENII, 12s.
50 Greenhouse PLANTS, of sorts, 25s.
12 LAPAGERIA ROSEA, strong, 24s.
12 ILLICIUM RELIGIOSUM, 12s.
100 fine double CAMELLIAS, without buds, own choice, strong plants, 2
2 fine stems of BALANTIUM ANTARCTICUM, £8.
100 CHAMÆROPS FORTUNEI, 42s. to 63s.
200 ,, HUMILIS, 20s.
100 CORYPHA AUSTRALIS, 63s.
6 LATANIA AUSTRALIS, fine strong plants, 18s.
6 ,, VEITCHII (SANGUINEA), fine strong plants, 30s.
100 GLOXINIA, in fine mixtures, 21s.
100 PANDANUS HUMILIS, small, 42s.
100 ,, larger, 63s. to 105s.
100 ACHIMENES, in sorts, 21s.
12 ANTHURIUM SCHERZERIANUM, flowering plants, 60s.
25 CALADIUMS, in varieties, 25s.
20 sorts of TROPICAL ORCHIDS, 60s.
25 sorts of PALMS, 30s.

ROYAL HORTICULTURAL SOCIETY, SOUTH KENSINGTON, W.

SHOW of LATE CHRYSANTHEMUMS, HARDY EVERGREENS, &c., DECEMBER 6, 1871.

AWARDS of the JUDGES.

CLASS 1.—12 TREE CARNATIONS, distinct, in 8-inch pots. (Open.)
CLASS 2.—6 TREE CARNATIONS, distinct, in 8-inch pots. (Amateurs.)
CLASS 3.—24 CHRYSANTHEMUMS, Japanese and late varieties, cut blooms. (Open.)
1st, Mr. E. Rowe, Gr. to Mrs. Lewis, The Rookery, Roehampton, 15s.
2d, Mr. J. Douglas, Gr. to F. Whitbourne, Esq., Loxford Hall, Ilford, 10s.
3d, Mr. J. Goddard, Gr. to H. Little, Esq., Cambridge Villa, Twickenham, 5s.
CLASS 4.—Collection of HARDY EVERGREENS, bearing berries (Hollies excluded). (Open.)
1st, Messrs. John Standish & Co., Royal Nurseries, Ascot, £2.
CLASS 5.—9 HOLLIES, in as many sorts.
CLASS 6.—6 BOX, distinct, in 12-inch pots.
CLASS 4.—9 HARDY EVERGREENS, of the New or Cypress type, in 12-inch pots.
1st, Messrs. John Standish & Co., £1 10s.
CLASS 8.—Collection of HERBACEOUS PLANTS, suitable for outdoor winter decoration. (Open.)
CLASS 9.—Collection of ENDIVE, and other SALADING. (Open.)

PRIZES OFFERED by MESSRS. JAMES CARTER AND CO.

CLASS 10.—Collection of VEGETABLES, to include Carter's Little Pixie Savoy, Scotch Kale, Brussels Sprouts, Carter's Garnishing Kale, Parsnips, Scorzonera, Salsafy, and Leek.
1st, Mr. G. Hall, Castle Gardens, Shaftesbury, Dorset, £2 2s.

MISCELLANEOUS—EXTRA PRIZE.

Mr. J. George, Gr. to Miss Nicholson, Putney Heath, for a Box of Cut Flowers.

Noteworthy Horticulturists and Botanists.

NOTICES of PORTRAITS of NOTEWORTHY HORTICULTURISTS and BOTANISTS is being published in the "GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE." The following have already appeared, and copies may be had on application to the Publisher, viz.:—

Dr. HOOKER, C.B., F.R.S.	Dr. HUTTON, Edinburgh
W. WILSON SAUNDERS, F.R.S.	Rev. S. R. HOLE, M.A.
Rev. M. J. BERKELEY, F.L.S.	F. J. LOWE, F.R.S.
M. DECAISNE	JAMES MCNAB, of Edinburgh.
G. F. WILSON, F.R.S.	ROBERT HOGG, LL.D.
Dr. MOORE, of Glasnevin	JOHN BATEMAN, F.R.S.

Published by WILLIAM RICHARDS, 41, Wellington Street, Covent Garden, W.C.

The Gardeners' Chronicle,

SATURDAY, DECEMBER 9, 1871.

ON more than one occasion it has been our duty to criticise the tasteless, uninstructive manner in which the fruit and vegetables at our great AUTUMN SHOWS are arranged, and to enter our protest against the continuance of a system so little creditable to our exhibition managers. There is the less excuse in the case of fruits and vegetables, as the articles are not so fugitive or perishable as flowers, and more time could be spent in arrangement and their subsequent exhibition than is always possible in the case of flowers. With a view of calling attention to this matter, we give a plan of the arrangement of the great fruit show held last month at Vienna, and we add a few particulars concerning the exhibition, from our special correspondent. The catalogue of the exhibition (which lasted from October 7 to 13) comprises no less than 55 closely printed pages, divided into four classes—fruit, vegetables, stove plants, horticultural seeds. There were about a hundred exhibitors, including most of the Vienna nurserymen, many Hungarian Vine growers, and private gentlemen. From one of the latter, Baron GAYMÜLLER, alone came 177 Apples and 77 varieties of Pears. Indeed the exhibition was one of great magnitude and completeness, and its tasteful arrangement may in some measure be inferred from the accompanying plan, and the remarks of our correspondent.

"The colour," writes our correspondent, "usually afforded by flowers and plants was also, on this occasion, with the exception of a splendid collection of cut flowers of Gladioli, supplied by quantities of beautifully-coloured Apples, Pears, and Grapes, by gigantic Gourds of many hues, by Tomatoes, striking in their splendid yellow and red tints, and by the large pure white Cauliflowers. Indeed, on looking down from the gallery of the building, the round tables, loaded with the fruits on dishes, bore a resemblance to large hand bouquets placed on a green carpet of turf.

"Pears and Apples were shown in great quantities, and of very fine quality. The shape of the fruits in general was very perfect and clean, but the size was often not quite up to the mark.

"Remarkable seeds appeared in general in quantities from 2 to 30 lb., there being no less than 754 exhibits in this class. We found amongst them a good collection of Potato seeds, and the well-known forcing Rape-cole of Vienna.

"The exhibition of vegetables was a very good one. It was not only richly supplied with good examples of the usual market vegetables, but was with several collections of splendid standards. MAYER & METZ, of Laibach, were unrivalled in their rich collection of these vegetables, not less than 134 kinds were exhibited by them, all remarkable in shape, and of great variety in colour.

"Among the collections of Beans and Peas were Laxton's Prolific, Alpha, Supreme, and Prolific Early Long-pod, Prince Albert, Victoria, and Maclean's Best-of-All, &c.

"Tomatos, from those of the largest size to those of the small cherry-like shape, made a great effect by

the brilliancy of their colour. From Baron SUTTNER'S estate we sent a good collection of Potatos, which included very fine and new sorts; the same was the case also with the Beans and Peas, Onions, &c.

"Entering at that part of the exhibition hall where the plants and flowers were arranged, it struck me that many hundreds of cut flowers of Gladioli, attracted the eye by their remarkable splendour and the beautiful colours. They were all seedlings of the last year, which Mr. ABEL HOOIBENK, of Hinterbrühl, near Vienna, raised from seeds collected from his own plants after artificial feecundation.

"The exhibition was decorated with plants taken from the Society's conservatories, and a very interesting collection of aquatic plants, for the use of the new fashionable aquariums, was also exhibited.

"The Botanic Garden of the University also contributed some very fine specimens, several Aroideæ, Gesneraceæ, and a few Orchidaceous plants in flower. Among the plants exhibited by Mr. ABEL, nurseryman, of Vienna, we observed, for the first time, the Ananassa Mordilona in fruit. The fruit was already pretty large, but not fully ripe. As this Pine-apple needs but little heat for cultivation, and its weight usually amounts to 10 lb., it will be a capital acquisition for our gardens.

"A remarkable series of plants was exhibited by North American Pines, 43 in number, was exhibited by Mr. F. ANTOINE, the gardener to the EMPEROR, comprising many species little known in England.

"Among the many objects used in gardening, we may mention a measuring wheel, an instrument very useful for measuring long lines (on a level) in a short time. A cast-iron wheel, the circumference of which is exactly 5 feet, is fixed on a handle in such a manner that we can push the wheel run before us if we intend to measure a distance. Close to the wheel is fixed a brass box, covered with a piece of glass. In that box every rotation of the wheel is marked, and when we have arrived at the end of the line which is to be measured, nothing has to be done but to look into the box and mark off how many feet have been marked in it. Another object worthy of mention consisted of water pipes composed of asphalted paper. They are very strong, keep the water perfectly clean through their smooth and highly surfaced walls, and are of a moderate price."

The illustration on p. 1579 shows the arrangement of the exhibition above referred to.

—— It will be remembered that in connection with the Horticultural Department of the International Exhibition of 1871, certain PERMANENT EXHIBITIONS of a horticultural character were arranged for, with the view to the decoration of the entrance to the Horticultural Gardens, and to the furnishing of certain portions of the space not otherwise occupied. These exhibitions have been incidentally alluded to in the course of the season, but now that the awards have been made we propose to offer a few brief notes on the whole exhibition. The assessors were the secretaries of the Horticultural Department of the International Show, aided by the principal judges who were present at the several meetings. These exhibitions, which were commenced with spirit, were well kept up during the season; the exhibitors being Messrs. KELWAY & SON, LANE & SON, W. PAUL, PAUL & SON, STANDISH & CO., and WILLS, and the following are the decisions arrived at, and the prizes awarded and earned thereon. In the early part of May he had a magnificent display of pot Roses, such as were probably never brought together before by one exhibitor. Their excellence has been marked by the special award of a gold medal. Later on Mr. PAUL kept up an excellent display of cut Roses, conspicuous for ornamental arrangement of various other interesting objects. Messrs. LANE & SON have been awarded the next place; their exhibition was of a more miscellaneous character, and mainly consisted of hardy evergreens, with Rhododendrons and Azaleas as the chief floral elements. Messrs. STANDISH & CO. also made a very effective exhibition, which was well kept up with objects of interest of a very varied character. These three were far ahead of the remaining competitors. Mr. WILLS kept up a display of what are known as furnishing plants, and introduced a very ingenious revolving stand, which was considered deserving special mention; the general arrangement, moreover, was very tasteful and effective. Messrs. PAUL & SON'S exhibition consisted chiefly of evergreens, set off by a supply of cut Roses throughout the season—but latterly this "feature" was neglected, and the general arrangement became an eyesore; and Messrs. KELWAY & SON'S consisted wholly of Gladioli, and was, therefore, necessarily more limited in duration. The sum of £250 was set apart by the Council for the remuneration of the exhibitors, and the awards were made according to marks recorded on a monthly inspection of the several exhibitions. They were, we understand, as follows:—

Mr. W. Paul	..	285 marks ..	£77 10 0	and Gold Medal.
Messrs. Lane & Son	..	243 ,, ..	62 0 0	
Messrs. Standish & Co.	..	228 ,, ..	58 0 0	
Mr. Wills	..	98 ,, ..	25 0 0	
Messrs. Paul & Son	..	61 ,, ..	15 10 0	
Messrs. Kelway & Son	..	40 ,, ..	10 0 0	and Silver Medal.

—— In connection with the subject of PROTECTIVE RESEMBLANCES, which has attracted so much attention, a note, extracted from the minute-book of the Linnean Society, dated April 7, 1801, may be referred to:—"An account was laid before the Society from Dr. MACCULLOCH, F.L.S., of an artifice used by the Cancer Phalangium to ensnare its prey. This contrivance consists in the insect (*sic*) dressing itself up, as it were, in fragments of a Fucus (the narrow-leaved variety of HUDSON'S ciliatus), which it seems to cut off, and to attach to the long hairs of its body and legs by means of a glutinous substance. It thus imitates a perfect plant of that Fucus so accurately as to have deceived Dr. MACCULLOCH." The plate illustrating this note, in the 6th volume of the *Linnean Transitions*, shows the clever nature of this disguise.

—— In a notice of Captain FORSYTH'S book on "The Highlands of Central India," the *Athenæum* has the following pertinent remarks on the management of INDIAN FORESTS, a subject which has frequently been adverted to in our pages:—

"One of the most important measures, as regards the well-being of the people, which has been adopted in India of late years, and one little understood, is the forest system of forest conservancy. The step was not taken a day too soon. In the Central Provinces, we are told by Captain FORSYTH that the hill tribes had for centuries devastated the forests by cutting and burning the best timber to form ashes to manure their crops, while the Teak had everywhere been mercilessly cut down for household purposes. But it would seem that there is some danger of the other extreme being reached by our forest administrators. In the anxiety to produce great timber, we have neglected the demand of the masses for small timber for their houses and other purposes. Captain FORSYTH points out that the payment of fees would have been to have reserved the best forests for timber purposes proper, and to have applied on the spot only such measures as would ensure the best and quickest production of wood for the requirements of the people. Vast expense is incurred in the attempt to conserve all the forests after a fashion, with a view to producing large timber; but he considers that the problem of clearly and efficiently management of these forests will never be satisfactorily worked out until the system is revised with the further aim of the continued reproduction of small timber for the use of the people. The Government is now under consideration of professors; and that its theories, based on the example of moist temperate regions, will be applied without sufficient caution to the very different conditions of tropical forests. One instance of such *doctrinaire* principles is mentioned by Capt. FORSYTH. The German system is to work forests in blocks by rotation, and, though the effect of stripping the soil of all trees in a hot country like India is to enhance in a ratio beyond belief the rainfall, this is still aimed at, and is the cause of much wasteful expenditure. Our author's warning, that the wisdom of the administrator must always be joined to the technical skill of the forester to secure the best results, is a timely one. It is a hopeful sign for the future that the forests of the Central Provinces have even now more than returned the outlay upon them, while their prospective value to future generations, both as a source of supply for the country's wants and in mere money, is wholly beyond estimation."

—— Mr. TILLERY strongly recommends FUCHSIA RICCARTONII as an autumn-flowering hardy shrub. In a long fruit-tree border at Welbeck, he says, there are about 20 plants of the Fuchsia Riccartoni. They were planted about 11 years ago, and some of the plants are from 6 to 8 feet in diameter of branches, and tall in proportion, every branch annually drooping with flowers down to the ground. He has never seen any show Fuchsias grown in pots or tubs that would stand any comparison with these specimens of Riccartoni grown in the open air, and therefore recommends the more extensive planting of this variety in shrubberies and mixed borders. The plants above referred to have never been protected in severe winters, being usually safe at the roots; but if old tan or litter is piled round the bottom of the plants in autumn, they break sooner in the spring, and flower earlier. This Fuchsia, he adds, is one of the grandest of all flowering shrubs in the autumn, especially when the plants get large.

—— According to M. CARRIÈRE, TAMARIX PLUMOSA is one of the prettiest of shrubs, the multiplicity and the fineness of its branches giving it a most graceful appearance, and gaining for it the common name of Maiden-hair, in allusion to its delicate character. The plant, he states, is more generally called Tamarix japonica by horticulturists, but he doubts its being of Japanese origin, and thinks it more probably originated from a sport of T. indica, which assumed a peculiar manner of growth, and has since retained it. It is as hardy as T. indica, and its culture and multiplication are identical; moreover, years before T. japonica was heard of, this T. plumosa was well known, branches of it having been cut from a stock found under some large trees, in the ancient nursery of Luxembourg, at Paris. After all, this question of origin is but secondary from a garden point of view, the important fact being, that the plant is specially meritorious.

—— We may remind young gardeners and those who are interested in the matter, that the Royal Horticultural Society's winter GARDENERS' EXAMINATION takes place on Tuesday next, the 12th inst., as announced in our advertising columns. The results of these examinations, as we stated in detail some time since (see p. 1003), are very encouraging, and should stimulate those young men who are really striving to win a place in the front ranks of the profession, to come forward and take part in them.

—— We extract the following particulars relating to a NEW GARDEN LABEL from the *Journal of Botany*. The introducer of this new label is Prof. A. CHURCH, Royal Agricultural College, Cirencester:—

"The indestructibility of solid paraffin suggested to me its use for the preservation of printed plant labels. The plan having proved successful, and the 'paraffined' labels having resisted the adverse atmospheric influences of two seasons, I cannot but hope that more extended trials will confirm my conviction that a permanent garden label, legible and inexpensive, has been attained. The following is a brief description of the mode of preparing the labels:—Print the names, &c., of the plants on thick, smooth, white paper of suitable dimensions and form. Prepare cast-iron label-holders with a flattened spike to keep them straight in the ground, and with the upper expanded portion so contrived as to have a sunk flat space about a quarter of an inch deep, and the right size for the reception of the printed label and its protective glass cover. Paint this sunk space with several coats of good white paint, and allow it to dry thoroughly. The next step is to unite the label to the glass plate with paraffin. The paper-label and the glass being cut to the same size, the latter is cleaned and kept hot,—almost as hot as boiling water,—while the label is being dipped into a bath of melted paraffin. The label is then quickly pressed on to the hot glass, a board and a weight being put upon both, to secure the glass with its adherent label is placed in the sunk space of the label-holder, and secured with good putty. Subsequently, a coat or two of paint on this putty will keep all secure. The above directions are more easier to carry out than they appear to be at first sight, while several contrivances and precautions will suggest themselves to any one who carries them out on a large scale. For instance, the glass plates may be kept hot in the oven, and instead of a pair of crucible tongs as wanted, while another pair of tongs or pincers will be useful to hold the labels during their immersion in the melted paraffin. Here it should be stated that the best paraffin is that which is purified from all kind of fat or grease, and melts at a temperature at least above 56° Centigrade. It might be found advisable to imbed the label and glass in paraffin, or to modify the plan of fixing the label to the glass by cutting it out in paraffin, between two sheets, but the principle of all these modifications is identical. The air and rain are excluded, and cannot give rise to the discoloration of the label."

—— The MAXIMUM TEMPERATURES of the AIR for the week ending December 2 ranged from 47° at Glasgow to 41°.5 at Sheffield, with a mean for the English stations of 43°.3, and for the Scottish of 44°.5. The MINIMUM TEMPERATURE of the Air ranged from 35° at Greenock to 27° at Edinburgh, with a mean for the several stations in England of 30°.2, and for those in Scotland of 30°.7. Thus we see that it has been slightly warmer in Scotland than in England, both by day and by night. The DAILY RANGE of Temperature, 39°, occurred at Newcastle-on-Tyne, and the lowest, 35°.3, at Wolverhampton, the mean for the English stations being 36°.9, and for the Scottish, 37°.6. In the south of England the weather during the past week has remained still very cold. At Blackheath the mean daily temperature has remained below the freezing point throughout. Rain or snow fell at all stations, with the exception of Greenock and Perth. The greatest falls were 1.22 inch at Newcastle-on-Tyne, 1.06 inch at Norwich, and 1 inch at Leith. The mean fall for the English stations was 0.27 inch, and for the Scottish 0.35 inch. (See Mr. GLAISHER'S Tables, p. 1589.)

—— Here is a hint which some of our practicals might do well to act on, if necessary; it refers to an expeditious method of destroying, in a few hours, MOSS. M. PAUL HANGUEL, in the *Revue Horticole*, calls attention to a self-acting, costless, and instantaneous remedy for this troublesome and, it may be, dangerous accident. The plan so confidently recommended consists in getting a quantity of horsedung (7—8 litres, say a gallon measure), steeping it in thorough it is completely dissolved, and then pouring the mixture into the boiler. If the leakage is not stopped by this proceeding, the plan may be repeated a second time. M. HANGUEL declares that he has repeatedly tried the plan, and always successfully. We should be glad to know if this method has been tried here.

—— We quote from the *Builder* the following letter, the subject-matter of which relates to a communication which appeared in our last issue (p. 1547) under the question, HOW TO HEAT A SMALL CONSERVATORY FREE OF COST:—

"Now, may I suggest that the great damage is done to plants by the occasional very cold mornings our climate is subjected to? On the plan referred to, in ordinary housekold the kitchen fire we may assume is extinguished by about 10 o'clock P.M. at latest. Allow an hour after that for the surrounding bricks to cool, and you have in your conservatory, by the following day at least, an even colder atmosphere by morning than if no heat had been diffused through it. May I suggest a really efficacious means for the same object, viz.:—Use the waste heat from the kitchen during the day to heat a reservoir of water, say 60 to 100 gallons. This can be raised to boiling point in about two hours, and all the ordinary kitchen operations going on just the same; then pass the air over the reservoir and out to the conservatory. The mass of water will retain its heat nearly intact until morning, and you will thus do effectually what, by the plan pointed out by 'S.,' must, I submit, be only very inefficiently attended. If 'S.' will pay a visit to Messrs.

COMYN CHING & Co.'s establishment, Castle Street, Long Acre, he will see there how this system can be efficiently applied."

—— What possible relation can there be between the ILLNESS of the PRINCE of WALES and the FIRE at WARWICK CASTLE? This much—both misfortunes are to a large extent preventible. Typhoid fever is a well-known resultant of dirt in the wrong place—bad drainage, sewage-sodden soil, contaminated water, foul dust bins, and the like. Who can say these are not to a great extent preventible? And yet we believe that many a country house is in a worse condition in these respects than a London alley or a Liverpool cellar. Typhus fever is a resultant of famine, typhoid of dirt. The more widely these facts are known, the less we shall hear of these disasters. As to the outbreak of fire it may be impossible to have anything like absolute security in the case of a building like Warwick Castle; but at least there should be every means and facility for extinguishing it, should a fire unhappily break out; and yet how often are the precautions taken either wholly inadequate, or the machinery out of gear when the time comes to use it.

New Garden Plants.

PLEUROTHALLIS AURICULIGERA, *n. sp.*

Apoda cæspitosa.) Caulibus secundariis brevissimis, vaginis basilaribus solutis; foliis lineari-lanceolatis acuto tridentatis, superne canaliculatis, transsectione crassis semilunatis, junioribus subpunctatis, adultis obscure atroviolaceo-guttatis; floribus fasciculatis hyrstrochromis, singulis; sepalo dorsali lanceo; sepalis lateralibus ab ovata basi cuspidatis, plica membranacea transversa intus ante basin; tepalis ligulatis acutis, superne minute, deorsum valde obtusangulo auriculatis, binervis; labelli ungue lineari subito in laminam cordatam serrulatam expanso; columna superne alata, ala postica triangula, alis lateralibus semiovatis acutis crenulatis.

A very small plant, of a cæspitose habit, with very narrow leaves, and bearing single, minute flowers of a yellowish tint, and having the general appearance of those of P. aviceps, but much smaller. There are decidedly two pollinia. The history is the same as that of P. aviceps. It came from Brazil in 1866, and has flowered since 1867 in the Saundersian collection, but as it appears not so freely as Pleurothallis aviceps. The discoverer was the late lamented Mr. Bowmann. *H. G. Rchb. fil.*

PLEUROTHALLIS AVICEPS, *n. sp.*

(Apoda cæspitosa.) Caulibus secundariis abbreviatis, vaginis emarcidis, lamina foliі cuneato oblongo-lanceolata acuta apice tridentata; floribus 1—2, bracteis ovariis pedicellatis brevioribus acutis; sepalis ima basi paulo coalitis, sepalo impari triangulo acuminato, sepalis lateralibus alte connatis bifidis; lacinis ovatis acuminatis; callo transverso oblique basin versus in utraque lacinia; tepalis a basi ligulata inæqualiter triangulis; labello sagittam supra unguem lineam oblongo, carina utrinque de sagitta crure in laminam descendente; columna androclinio membranaceo limbato utrinque alato descendente, serrulato, rostello truncato dependente.

A very gay, nice little plant, full of modest elegance. The leaves are crowded, lanceolate, purplish underneath. At their base there peep out many little flowers, showing a good deal of Masdevalliaceous appearance, whose buds are quite like the beaked heads of some birds. The upper sepal is green, the under ones are yellow, the former being full of numerous dark purplish blotches; the petals and lip are yellow. It is no little credit to Mr. Green's skill that this tiny little gem, an ornament *sui generis* of the Saundersian garden, has been kept in good spirits since October, 1866, when it came from Brazil, sent by the unfortunate Bowmann. I saw it in October, 1867, in beautiful flower, and have just now once more fresh flowering specimens and a Saundersian sketch at hand. *H. G. Rchb. fil.*

THE MYSTICAL PLANTS OF BRITAIN.

(*Concluded from p.* 1559).

WE now come to the Mistleto, which, from the mystery of its origin, might well attract the attention of the Druids. Perhaps they were aware that the seed must have been deposited upon the Oak by a bird, or, in their view, a heavenly messenger—possibly a god in disguise. According to Pliny the god of the Oak tree was concerned in the choice of this epiphyte. He says that the Druids had nothing more sacred than the Mistleto and the tree on which it originates. They chose the groves of Oaks where it is found, and they accomplished no mysteries without its boughs. Whatever grows upon them they thought to be sent from heaven, and a sign that they are chosen by the very god of the tree.

The Mistleto was called "the tree of pure gold," and it was gathered by the Arch-Druid with a golden hook or sickle. It was supposed to possess a fructifying quality, and to have potency in the affairs of love—without any intention, as it appears, of conveying the slightest imputation on the dispositions of his fellows, but figuratively enjoining caution in the face of the dominant Christian powers. In a similar manner we find the initiated represented as serpents, and, consequently, have been ready to question what was meant by the yearly association of that multitude of serpents, from whose hissing proceeded, according to Pliny, the celebrated *ovum anguinum*—one of the wonders of the world. Was this intended to represent an ancient British Association. There is more ground than appears at first for the inquiry, since it is certain that the serpent was a symbol of the Druid—it is said because of his casting his skin, and thus undergoing a sort of new birth; but more probably from the universally established idea of the connection (mystically) between the serpent and wisdom. However, as Pliny says he had seen this wonderful egg, we fear that we must give up the tempting explanation.

But we have almost forgotten the mystical lady in her moonlight wanderings in search of potent herbs for her cauldron. If, after all, her choice may seem somewhat capricious, we must not be too much surprised, considering all circumstances. We find then that "the placid cheerful Vervain" held a foremost place in her esteem. It is called "the enchanter's plant" and "the fiend's aversion." There seems to be no better reason for this dislike than for the lady's choice. Nevertheless, it was used in casting lots and in foretelling events. Anointing with a preparation of this was thought the readiest way to obtain all that the heart can desire. It was to be gathered at the rise of the Dog Star, without being looked upon either by the sun or the moon; the earth was to be propitiated by a libation of honey, and the left hand was to be used in digging it up. It was then to be waved aloft and dried in the air.

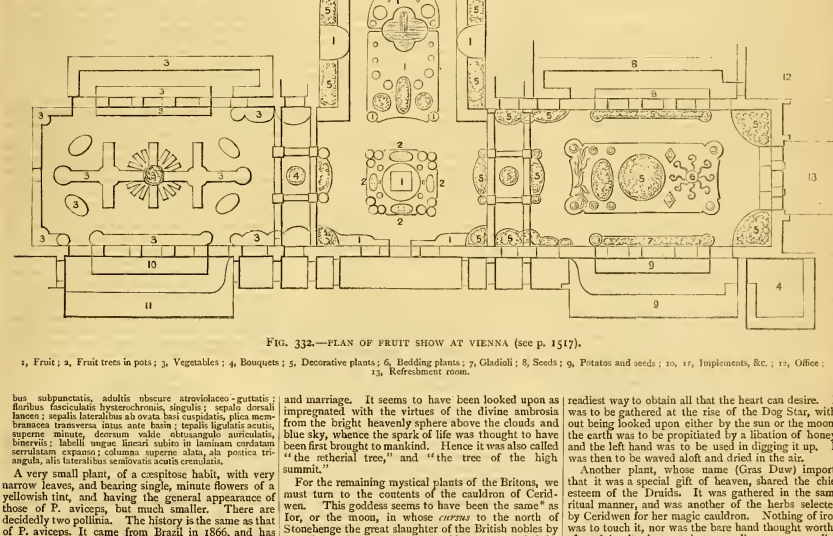

FIG. 332.—PLAN OF FRUIT SHOW AT VIENNA (see p. 1517).

1, Fruit; 2, Fruit trees in pots; 3, Vegetables; 4, Bouquets; 5, Decorative plants; 6, Bedding plants; 7, Gladioli; 8, Seeds; 9, Potatos and seeds; 10, 11, Implements, &c.; 12, Office; 13, Refreshment room.

Another plant, whose name (Gras Duw) imports that it was a special gift of heaven, shared the chief esteem of the Druids. It was gathered in the same ritual manner, and was another of the herbs selected by Ceridwen for her magic cauldron. Nothing of iron was to touch it, nor was the bare hand thought worthy of receiving it when cut, but a peculiar vesture, applied by means of the right hand. The vesture (called by Pliny *sagum*) must have been holy, and taken off from some sacred person privately, and with the left hand only. The gatherer was to be clothed in white, namely a Druid, whose garment was white, his feet naked, and washed in pure water. He was first to offer a sacrifice of bread and wine before he proceeded to gather the plant, which was carried from the place of its nativity in a clean new napkin. We need scarcely say that no vegetable production enjoys a place of such esteem amongst the modern Welsh. The Gras Duw above (as we are informed) is none other than the common Rue (Ruta graveolens).

The Samolus Valerandi, gathered in the same ritual manner, was another plant enjoying their special consideration.

Primroses also (and here at last we commend the lady's choice) claimed a special place of favour and a

And for the remaining mystical plants of the Britons, we must turn to the contents of the cauldron of Ceridwen. This goddess seems to have been the same* as Ior, or the moon, in whose *cerrus* to the north of Stonehenge the great slaughter of the British nobles by Hengist took place. The cauldron, surrounded by pearls, is represented on early British coins. It was boiled for a twelvemonth and a day, and this long period of concoction produced so potent a liquor, that three drops swallowed by an attendant conferred the gift of foreseeing future events. The ordinary effects of a draught were the *awen*, or bardic inspiration, and other celebrated endowments. We do not feel certain whether the favours of this mystical broth were extended to all the initiated, for it is not possible always to distinguish between the literal and the mystical signification. For instance, we find the bard Merddin thus addressing his fellows:—

> "Attend little pig, thou initiated pig,
> Burrow not with thy snout on the top of the hill,
> Burrow in a secret hiding place among the forests," &c.,

and marriage. It seems to have been looked upon as impregnated with the virtues of the divine ambrosia from the bright heavenly sphere above the clouds and blue sky, whence the spark of life was thought to have been first brought to mankind. Hence it was also called "the ætherial tree," and "the tree of the high summit."

* This may be doubtful, but it seems clear that she was the British Ceres, and this suggests the question whether her cauldron boiling for a twelvemonth and a day did not mean simply the full produce of the revolving year. The cromlechs dedicated to her were called *Maen Ketti*. Of these one probably remains as Kits Cotty House in Aylesford; probably a place of initiation for her worshippers *Coeddi*, Welsh, to purify.

name, perhaps from their golden hue, signifying dignity and power.

We close the list with the Trefoil (skilfully laid hold of by St. Patrick to illustrate to the Irish mind his explanation of Christian mysteries) which dates back its symbolic value far into the night of antiquity. We find the reason in the oracles of Zoroaster, who declares that "the mind of the Father said all things into three," together with much more about the Triad, which links together the notions of ancient Wales, of Persia, and of China. We do not stay to inquire what these ideas were, but it is easily to be conceived that the Trefoil was their natural symbol. Moreover the mark common on the leaves, resembling a crescent moon, associated the plant with all the notions embodied in the two-horned Astarte (Ashteroth-Karnaim)* much older, consequently, than the days of Abraham), the primitive queen of heaven.

We cannot fail to be struck with the grandeur of some of the conceptions of the universe entertained by the old unworshipping Aryan nations. They had their own way of explaining the relationship of the invisible world to those hidden forces, on whose operation they gazed as the manifestation of pervading fire. They saw in everything that was incomprehensible something divine, and their mystical plants were supposed to be in some sense interpenetrated with deity. When we reflect that the special manifestation of this divine force was to them the lightning, and that the same electric force is manifestly connected with the operations of the vegetable, and still more of the animal kingdom—once we think that certain plants are capable of producing the phenomena of heat and light, and of manifesting sensibility to the touch, we shall be the less surprised that these philosophers referred their disciples to the agency of the god of the lightning as explaining the mysteries of Nature.

There seems, indeed, to be at present a kind of eddy in the tide of human thought, reverting in measure to something very near the old doctrines. Thus we read amongst some of the latest "Scientific Results" the following speculations : —

"It is the conviction of [the author referred to] that of the two kinds of matter one exists in the elementary atomic state—simple, indivisible, impressible, and imponderable—constituting what is called the ether ; whilst the other is grouped into compound atoms, and constitutes the kind of matter with which we are familiar. Weight, according to this definition, is an accident of matter, and ponderable matter is merely imponderable ether, the atoms of which are grouped in a certain manner, which gives the property of gravitation. Ether constitutes the fourth state—the primordial state of matter. It pervades all the stars, penetrates into all solid, liquid, and gaseous bodies, and fills up the interstices between their molecules."

If this be correct it follows that the more important half of creation lies beyond our power of investigation, since it is the very accidents of matter which give us the opportunity of investigating its nature, and if the proximate causes of things are really hidden in an etherial and imponderable creation, we must simply confess our ignorance, for what more can we do to explore it ?†

We observe that the first impress of the lines of formative energy in the cell-formation of plants are of this inscrutable character, the visible originating from the invisible.

We are impressed with the same truth in regard to the animal creation. Thus, if we turn to the Amœba as an instance of one of the lowest forms of life, we find little else than an animated sac, which yet by virtue of the mysterious endowment of life is capable of acts of volition, of seizing and digesting its prey, and when the process of digestion is watched under the microscope nothing can be more wonderful than the sight—not a sign or trace of any interior organisation is found which could be supposed to direct the constant motion of the currents of assimilating food, all is as clear as crystal except the circulating particles, and they seem as if impelled by magic.‡ In a similar manner, if we regard the egg in the lower animals, we are unable to trace organisation ; but if we pursue the inquiry in reference to the same in the higher types, we are led to the conclusion that all the development is connected with electric action. The egg of a hen, for instance, may be defined to be a globular accretion of two kinds of fluids—albumen and oil—which are always situated at opposite sides or poles, or rather "we may look upon the egg as theoretically a bipolar aggregation of albuminas and oily substances, which eventually exhibits a more or less elevated degree of vitality."§ The further development of the animated creature shows how widely this differs from what takes place in the crystallisation of inorganic substances, and still more is this evident in the self conserving property, both of plants and animals, which in some unknown way operates upon the individual as a whole.

In the early notions of the Aryan nations, we can scarcely trace out with any distinctness the distinction between the Creator and the thing created. But in the reformed Zoroastrian religion, as indicated in the remaining oracles (λογια), or rather sayings, this comes out so clearly that we must presume that the traditionary connection between this celebrated man and the Jews must have had some foundation in fact—that he may have even seen, and like Longinus have been struck with admiration of, the declaration, "God said let there be light, and light was."

"The Creator who, operating by Himself, framed the world," is brought into prominence by Zoroaster as "the Eternal Father" who is to be comprehended only "by the flower of the mind of man ;" and a remarkable attempt is made to describe the intermediate agencies (αρχαι) by means of which the will of the Creator is supposed to be wrought out. "These (agencies), which have understood the intelligible works of the Father, disclosed them in sensible works as in types, being, as it were, the ferrynent between the Father and matter, and producing manifest images of unmanifest things, and inscribing the unmanifest in the manifest frame of the world." So that to them "the laws of Nature," "natural selection," and so forth were not mere expressions incapable of being logically interpreted. The "living" Father's intelligence to understand the mind of the Father and power to execute his superior will.

Throughout the whole of these oracular fragments there is a marked attempt to think out subjects, not only those within the bounds of thought but others entirely incomprehensible, forgetting that what is beyond the bounds of knowledge can never be logically defined. Bacon, in his "Novum Organum," has very well described what he calls the *idola tribus*, which, he says, have their foundation in the very nature of man, as springing from the tendency noted above. "For it is falsely asserted that human intelligence is the measure of things, whereas, on the contrary, all the perceptions both of our senses and of our mind are according to the analogy of man, and not to the analogy of the universe. For the human mind resembles an imperfect mirror, distorting and confusing the image of things."

The same author describes one kind of philosophers as resembling spiders, and weaving the webs of their speculations out of their own substance. We are at no loss for illustrations of this in the present day, and it would not be difficult to point out amidst their favourite theories a triad incomprehensibles more puzzling than those of the Druids.

We think that, from what precedes, we may fairly draw the inference that speculation is not science ; that any case which rests on imagination, rather than fact, must be accounted "not proven ;" and that every edifice of thought which rests on the false foundation, "I see no difficulty in believing," is destined to pass away, and, like the idolatry of our ancestors, "leave not a wrack behind."

Is it not well to consider that, if such theories were to become prevalent as those which derive the origin of man from the most unsightly forms of the brute creation, and which would reduce his faith and morality to the level of his supposed kindred, we *might* find a worse state of things resulting than that which existed in the days of the Druids, who confined their instructions to the initiated ; the cauldron of Communism *might* be worse than that of Ceridwen. *H.*

* Genesis xiv. 5.

† Another writer, Dr. F. J. Mills, endeavours, in the "Philosophical Magazine" for August, to account for the ether thus : "whilst on the other side arises the idea of motion, not of parts (for not an atom can be proved to exist), but of the whole universe." This appears like the conception of the Druids, who attributed the revolution of the spheres by a giddy dance, probably imagining that unsettlement of the brain rendered them peculiarly alive to the impulses of Nature. Our readers will pardon the quotation of our authority : "Drud awyrdwyth, amnwyth, amniver," which means (according to the author of "Celtic Researches"), "rapidly moving, in the course of the sky, in circles," and the Druids and Bards are represented as uniting in this exercise. The same notion is thus expressed in the Oracles of Zoroaster : "All things remain in a restless whirling"—παντα ρεοτ[illegible].

ARAUCARIA IMBRICATA.—No. II.

(Continued from p. 1516.)

SEEDS of this tree were again brought to Europe in 1822, and some of these are said to have vegetated, but few plants were raised, on account of the attempt made to grow them on hotbeds and in stoves. A large quantity of the seeds were brought to Europe between this and 1829, but few of them germinated, in consequence of their having been mostly collected by the natives, boiled, and then sent to market for food—very nice they are, too, roasted with a little butter, as I can testify from experience. Notwithstanding these failures, between 1822 and 1836 several lots of seed were brought over, and many plants were raised and distributed, so that they were to be seen of various sizes, planted out apparently in many of the best gardens throughout the United Kingdom, being greatly admired on account of their curious and uncommon appearance.

The memorable severe winter of 1837 killed many of these thriving trees, and during my subsequent spring and summer visits to neighbouring gardens I observed that the greatest destruction had taken place where the trees had been planted low, close to the surface. Those on close, cold, clayey and unkind soils, and in damp, low-lying localities, and particularly those which were open to the first rays of the morning sun, were almost entirely destroyed ; whilst almost every specimen that was planted high and dry on rubble, stone brash, in sandy loam, or on sloping banks or mounds, with rock and coarse gravel for subsoil, as well as those which were shaded from the rays of the morning sun, from being placed in a westerly aspect, withstood all the rigour of that severe winter. These are facts that many persons have no doubt observed, and have since acted on. Notwithstanding this, however, there are to be seen in every locality certain unhealthy, rusty, stunted plants, oozing gummy or resinous matter, which have been put in with very little preparation, and which are not likely to make useful or ornamental specimens.

The Araucaria does very well in plantations, along with a mixture of others, if the ground has been well trenched, in order to secure a free circulation of air and water. It does not flourish long when a mere hole is dug out a few feet in diameter, and the tree is planted on the level, and nothing is done to prevent the surrounding water from saturating the loose soil in which it is planted, as I have seen it flourishing in old-established woods and plantations with no other preparation than clearing and trenching a spot some few feet in diameter, casting up a mound with the surrounding surface soil, and planting the tree on the mound. Thus planted, and with the surrounding partial shelter and new soil, it is astonishing how this tree will flourish—progressing as fast as a Larch or any other free-growing Conifer.

Between 1837 and 1840 large quantities of seed were brought to this country, and numerous plants raised and distributed to all parts of the United Kingdom. Messrs. Loddiges, of Hackney, amongst others, raised a large number, and of these a batch was sent to Bicton in 1839-40—seedlings, in 60-sized pots. These I shifted into 32-sized pots, and placed them for the winter in a cold pit, fully exposing them to sun and air in early spring. They made a few healthy, short-jointed growth, and were again placed for a short time, in the dead of winter, in the cold pit, and then fully exposed in early spring, to prepare them for planting out. My employer proposed that they should be planted to form an avenue from lodge to lodge throughout the eastern park. In the year 1842 the late Mr. Veitch, grandfather of the present Messrs. Veitch, having men at Bicton, filling up the arboretum, was requested to see me respecting the Araucaria avenue, in order that we might discuss the matter as to the distance at which the trees should be planted, as well as the nature of the soil, and the obstruction from other trees. We accordingly met, and after consultation determined the distance at which the plants were to be placed, which was afterwards marked by taking out a sod at the place fixed upon for each tree.

Knowing as I well did, from being on the spot, the variation of the natural soil—the east end being a thick body of gravel, with but a few inches of surface soil, so that the grass was always burnt up after a few sunny days, while the middle part had a good depth of rich sandy loam, and the west end was shallow, the subsoil being a stiff red sand, fit for nothing, with a few inches only of light sandy loam over the surface—I contended that, to start this avenue fairly, so as to maintain afterwards something like uniformity of growth, there should be some uniformity in the way of preparation, otherwise the whole thing would prove a failure, and would result in stunted unsewn growth and a sickly hue. My own proposition was to turn off the turf from 30 to 40 feet diameter, trench the ground thus unturfed, and cart on any quantity of good soil which might be comeatable at an easy distance, so as to form neat, easy-looking mounds, to the height of about 4 feet in the centre, where the plant was to be placed. This, I calculated, would take about 50 cart-loads for each plant, and from the place whence I was about to have it carted it would have cost, at the most, something like 3*d.* per load. *James Barnes, Exmouth.*

(To be Continued.)

MORSUS DIABOLI.

"IN English, Deuel's Bit" (or, more correctly, bite) ; "in French, Mors du Diable ; in high Douch, Teuffels abbisz : in base Almaigne, Duyuels beet : of some late writers Succisa in Latine : in shoppes, Morsus diaboli : and it hath none other names where-by it is yet knowen." Thus Henry Lyte, "Esquyer," who wrote his "Nievve Herball, or Historie of Plantes," in 1578, nearly 300 years ago. At the present day we can call to mind almost a dozen other names by which Scabiosa succisa is known, some of them pretty and appropriate ; but the terribly ominous name quoted above seems to have been the only one in use at the time the herbals were written ; and, as we learn from the above old and "faithful" herborists, the name was by common consent adopted by several European nations.

Whether Morsus diaboli is a name originating with the old Latin physicians, which has been handed down and translated into these various languages, we cannot say ; or whether it was an original Germanic name that was thus rendered into Latin by the "high Douch," or "base Almaigne" herborists, or by the vendors of drugs, is equally obscure ; but of this there is no doubt, that a good many of our modern plant names are simply translations of the names given by the old Greek and Latin physicians, and that they have been adopted by the writers of herbals in many countries, and have thus been taken into common use ; and it is equally certain that in the course of time, partly on account of the imperfect knowledge possessed by the early herbarists, and partly by reason of their confused methods of arrangement, names have very

frequently been transferred from one plant to another; and this has rendered it very difficult, in many cases, to identify plants by their names alone. The plant in question, however, is certainly the original Morsus diaboli, because the name is descriptive of a remarkable peculiarity of growth, that would fix it at once.

There are a few plants, but notably the one called in Latin Scabiosa succisa, and still in English Devil's Bit Scabious, that have their root truncated in a very strange way. If a plant be pulled up, it will be seen that what was evidently once a long tap-root with lateral fibres has been eaten away or has decayed, leaving a stump, not nearly its original length, with a scar at the end. Such a root is called in scientific language "præmorse," and it is a very remarkable form of root; but it is described in any elementary book on botany, so we need say nothing more about its general appearance and structure.

To account satisfactorily, however, for this appearance it was necessary, in less enlightened times than the present, to invent a legend; and this recites that the Devil was jealous of a plant which, by possessing so many excellent medicinal qualities, was a great boon to suffering humanity, and so, in order to destroy its virtue, he bit off a part of the root. Of course, in those dark and superstitious ages, no one would venture to doubt the truth of the explanation; for did not the plant, even to that very day, bear in its root a confirmation of the astonishing fact? One is glad to find that the malevolence of Satan did not avail anything, for the plant was as useful as ever, if we may believe the "Nieve Herball" already quoted.

"The decoction of Denel's bit, with his roote, boyled in wine and dronken, is good against al the diseases that Scabious serueth for, and also against the Pestilence." . . . . "It doth clense the breast, and the lungs, and is good against an old cough, and the impostems of the breast, and all other inward parts, as in the clensing, riping, sodering, and healing of the same. It is also good against all itch and scurvinesse, to be found in hyde to the same, or to be mixte with oyles and oyntmentes fit for the same. It doth clense the heare from all bran or white scurffe, when the head and beare is washed therewithall." . . . "The same decoction doth clotted blond in the body, by means of any bruse or fall. Denel's bitte fressh an greene gathered, with his roote and floures pounde or stamped, and layde to carbonckles, pestilential sores and botches, doth ripe and heale the same."

There were other ailments which this plant was "good against;" and really, when we come to read over such a string of good qualities, which culminated in its being "good against all poyson," we can quite understand that an evil spirit, intent upon injuring mankind, should wish to curtail its virtues; nay, we can hardly help surmising that if it had not been bitten off, the catalogue might, perchance, like the root itself, have been twice as long. Whether Devil's Bit is in so great repute at the present day, I know not. In many of the rural parts of England, especially in the northern counties, where "yarbs" are in great demand amongst the manufacturing population of the large towns, the "yarb-doctor" still hold their own, and make a tolerable livelihood by collecting medicinal plants. I have never seen them gathering Devil's Bit; but as they consult the old herbals it is probable that the plant is still in use; though, as a rule, tonics and stomachics, like Buckbean and "Sanctuary," are the plants most in request. The latter plant (Erythræa Centaurium), and "Yellow Sanctuary" (Chlora perfoliata), are becoming quite scarce in many places, on account of the immense quantities that have been gathered for medicinal purposes; for being most efficient when in transplanting a number of seedlings of the garden Polyanthus a couple of years ago, I was struck with a very peculiar habit possessed by the young plants, which seemed to indicate the way in which roots really became præmorse. Further observation has shown me my surmises were correct, and as in all probability the præmorse habit of root is formed in all plants in the same way, I may use the Primrose seedlings to illustrate the phenomenon.

For some time after germination nothing peculiar is observed, unless it be a continued lengthening of the stem below the seed-leaves. Still there is nothing very remarkable in this, for the part never lengthens to the extent that is seen in Mustard, for instance, and many other plants. But after the first two or three rough leaves are formed, we note the following facts. The young plant begins to bend down towards the earth. Most likely it is the weight of the leaves that actually causes this to take place, for the stem is thin and threadlike, and the leaves somewhat thick and solid. This bending down often continues until the base of the little rosette of leaves actually touches the soil. Sometimes, when the stalk may perhaps not have grown so long, or may not be quite so thin, it scarcely reaches the ground, but in every case a white root now begins to push its way out from the base of the rough leaves just above the cotyledons (see fig. 333, B). This root is much thicker, and altogether stronger than the original radicle, and soon pushes its way into the earth, and sends out lateral fibres. A second root then appears at the opposite side of the plant; in fact, as the plant grows a new root is produced from the base of each rough leaf in succession, and the plant thus has a new set of much stronger roots, through which it is enabled to obtain food from the soil. For some time the original radicle continues to grow in some degree—probably until the new roots are fully established, and are able to supply sufficient nutriment to the young plant. Then, not being required, and because the elaborated sap now finds its way to the new roots instead of going to enlarge the radicle, that organ gradually dwindles, and at last decays entirely away, and we have thus the first indication of a scar, and the commencement of what eventually becomes a regular præmorse root; for the process of new roots being constantly formed above, and old roots becoming useless and dying away below, continues during the whole life of the plant. Thus we have, eventually, a rhizome or creeping underground stem, formed in precisely the same way as we observe in Ferns, in the Iris, the Wood Sorrel, and many other plants. There is another very curious resemblance in these little præmorse plants to the organ which is botanically called a "scion," of which a familiar example is the runner of a Strawberry. We have only to imagine the stalk of the seedling extending to a somewhat greater length before the rosette of leaves takes root, and we have a veritable "runner," with this peculiarity, that instead of growing from a parent plant, as it does in the Strawberry, it originates in itself; in fact, it was separated from the parent plant in the form of a seed, which in its germination echoes back the idea of an axillary bud shooting out into a new plant: and observation may show that it is only such plants as are in the habit of

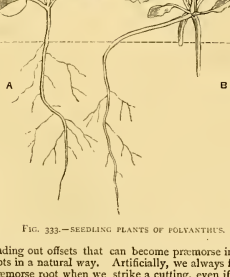

Fig. 333.—Seedling plants of Polyanthus.

sending out offsets that can become præmorse in their roots in a natural way. Artificially, we always form a præmorse root when we strike a cutting, even if it be from a plant which, in a natural state, grows with long tap-roots.

I have had no opportunity of watching the growth of seedlings of Devil's Bit Scabious, but I have little doubt that observation would reveal the same set of facts, and would serve, in a somewhat prosaic way, to explain the legend of "Morsus diaboli." *Robert Holland, M.R.A.C.*

MEDICINAL HERBS AND QUACKERY.

If there be any one sort of gullability more rampant than another in this city of Manchester, it is that of persons placing implicit reliance upon the quackery of the uneducated herb doctor—and not on him alone, for the engine-tenter in my own neighbourhood fills up his spare hours by salving all kinds of sores, and even goes so far as to lance finger-ends that have been mismanaged before he took them in hand.

"But O, what perils doth environ
The man that meddles with cold iron;"

for the cures thus effected are not always creditable to the practitioner. Still in the face of the fact of the Manchester Infirmary being one of the best-managed institutions in the kingdom, we constantly bear the old cuckoo cry that such and such an herb doctor cured scores of patients after all the leading men of the faculty had pronounced the case to be incurable. Burns laid the lash on most unmercifully when he painted Death and Dr. Hornbook discussing the merits of Buchan's "Domestic Medicine." With every new generation of men there arises a new crop of quacks. As, however, I am only cavilling with the herbalist, I would but remark in passing that there are apparently three classes of these unlawful practitioners of the healing art.

The first, by what Cobbett called "mere hardness of mouth," advertises himself as competent to do impossibilities—for nothing less would do, and of his "Materia Medica" the world knows nothing. He addresses himself to moneyed people, and it is for such only that his *ella podrida* is provided. The second belongs to the middle class, who consult herbals and doctor themselves and others by rule and order. The third has no literature, and his method of working consists in unwritten notions of old crones who have their "heal-all," and by means of a few herbs easily obtained at the right time of the year, they confidently assert the cure of almost all complaints, as the old ballad has it—

"O they say it's sure to do it, and it's sure to do it well.
But the first thing you must swallow is the vegetable pill."

Such parties visiting the poor are to be dreaded, for they give advice gratis, and push their opinions into practice regardless of the fearful consequences of powerful medicines misapplied. To persons struck down with disease, and so unable either to cope with them in argument or keep them at a distance, that which might have been like an angel's mission becomes an awful visitation.

But to return to the family herbals. Here before me lies Thornton's guide to the natures and properties of the various plants used in medicine, the plants drawn from Nature. The English and botanical names are given, the Linnean class and orders; the Latin and French languages are freely quoted; and what has been handed down from sire to son unchallenged is still to be seen figuring by way of information. I will just quote the author's remarks on one or two plants—such plants as the late Dr. Lindley said were of no known use to mankind. Many years ago I read in some religious book that persons sleeping under the shade of the Chaste tree became chaste. This Chaste tree should rather be called Chaste bush, for the Vitex Agnus-Castus grows only to the size of a broom bush on a common. Now, this good property in the Vitex would, to use a medical phrase, evidently be for "outward application only;" say, for a dose, a mere twig, like that of Mistleto, might be hung up where its services were required. But our author of the "Family Herbal" improves upon the doctrine of the Divine, and speaks of the four-seeded berry of the Vitex as Monk's Pepper, giving the Latin for the same, Piper monachorum, to confirm the respectability of the name—though Cobbett remarked that when nonsense was translated into Latin it looked as well but not more so still. So the doctor speaks of bachelors taking the Vitex berries—indeed, "flying to them;" this would amount to "taking them inwardly." Imagine a school-board in these days ordering a tiny besom made of Vitex twigs to be suspended in the class rooms, and a few pecks of the berries scattered about for the youngsters to nibble at, just as cage birds get Groundsel, Shepherd's Purse, and Chickweed! The doctor is seen to the greatest advantage when he comes to treat of the common field Orchis, O. mascula, where he quotes Sir John Hill's "Materia Medica" for the following:—"We believe known to Sir John once in every year brought before the magistrates to answer for his evil deeds, and he always excused himself by saying that Orchises were then plentiful, and he could not resist eating them." The doctor says that salep made of Orchis root is full of milk, and tells us in French that the root is a very remarkable one. He has gathered this plant often as well as most of the other beautiful native terrestrial Orchises, but never saw such a harvest as Sir John Hill's criminal must have met with, when he ran mad with his belly-full of Orchis tubers. French Orchis Potatoes would be worth the trouble to gather as medicine for the dull phlegmatic boys familiarly known by the *nomme de guerre*, "Want of devil," with no force of character, who would not be at the trouble to do any harm, and could not think of the self-denial required to do any good. Now, if a meal or two of such Orchis Potatoes would only rouse such boys into the region of vivacity, how it would delight their mothers' hearts to see them capering! But, joking apart, what faith could any sane person have in such writings as these? What I want to see in such books are the truthful opinions of practical men on things as they are, and not the transcribed nonsense of other days.

I could honestly name a very homely tree whose supple twigs have mended the manners of many boys, and could back my assertion with Scripture; for a birch rod seen in repose, as it hangs on the walls of a school, is a "terror to evil-doers;" but when it is put in motion, woe betide. This, indeed, were a rod worthy of all praise.

The third class of quacks consists of the old crones who have an idea that, if the medicine is only vegetable, it will be mild in its action and safe. I have gone into the herb market here, and bought herbs for the purpose of getting at the literature of the craft, to see what certain herbs were called, and for what complaints they were reputed to be a remedy. I found none of the herb vendors so well up in the business as to know the botanical name of any one article that they sold, and many of the English names were such as have not been heard out of Lancashire lately. When any plantsman looks over the stock, and sees deadly poisons sold by the handful, or even armful, and never by weight or measure, and with no reliable

instructions as to the dose for an adult, or for a child, the whole thing appears quite alarming. The business of the apothecary is regulated by law, and he qualifies for it, but the herbalist dispenses medicine in open market to all comers with impunity. I would not be severe upon the kindly old lady who sits by her herbs and roots all day long, and every market day, giving advice free, and charging very little for the medicinal herbs; but who can tell what fearful effects may be produced where excessive doses are given, and there is no duly qualified person ever called in to see the results? I have eaten the tubers of Wake Robin (Arum maculatum), and know it to be an excellent vegetable, the tubers being beautifully white when boiled, but if I had eaten as much as the size of a bean of the same roots in a raw state, I should have been poisoned. The whole secret of the Arum tubers is that the acrid principle is volatile, and goes off in boiling. In Thornton's "Herbal," above referred to, he speaks of doses of fresh Arum tubers of 10 grains taken inwardly, and that this very small dose (the 48th part of an ounce) makes the patient sweat. What a subject this fiery root would be for the herbalist to sell when fresh, while when dried or boiled it would be no better than a delicious porridge.

But strangers should come to Manchester at Whitsuntide to see the trade in Nettles. Of this plant it has been said that it has dogged the footsteps of man everywhere to hang him, as it contains a strong fibre, fit to make ropes of; but here it is made into beer, the Nettle sprouts in spring, at 4*d*. a bushel. When the scholars return from their yearly excursion to the country, they come home laden with Nettles, and were it not that every hair on the Nettle is a poisoned sting, the plant would have become extinct long ago—at least within 30 miles of Manchester. I have eaten the Nettle sprouts in spring, gathered before they got to be longer than one's finger, and they were very good plain boiled. If this practice were more common, it would lessen the crops of Nettles, and turn this unhandsome plant to some good account. The public have nothing to fear from the herbalist making a mistake in dispensing Nettles. The plant has a character; there is nothing mawkish about it, and it needs very little logic to explain to the dullest comprehension that it will excite (Dr. Thornton agrees with this); indeed I have seen lads dance with pain and without music when taking their first lessons on the nature and properties of a bunch of Nettles. The dulness of the ass, the thickness of his hide, and the power of his jaw-bones, are all proved by the fact that he can eat Nettles, green or dried, with impunity.

A lady lectured at Birmingham the other day on the education of women in the arts and sciences. Surely the botanical properties of the "Vegetable Medica" would be a lady-like business, as there are already many ladies who are good authorities on our native flowering plants and Ferns; and if the subject once got into a girl's school the pupils would collect the specimens, and when these were correctly named and described, the girls would ever after know the plants by name, and be able to turn them to account. Reliable information on the nature and properties of culinary and medicinal herbs might from time to time be given in the columns of your valuable paper. Large sums of money are paid to park-gatherers, and men may be seen fishing for the fleshy stems of Water Lilies (Nymphæas and Nuphars), and the Bog Hop, *alias* Buckbean, *alias* Water Trefoil (Menyanthes trifoliata); and women employ themselves profitably by gathering Wood Sage (Teucrium Scorodonia), Mugwort (Artemisia vulgaris), and Horehound (Marrubium vulgare); and as these parties pay no rent for the land on which the herbs grow, it is by no means an unprofitable speculation.

There is a large field open for useful service in collecting, drying, and preserving herbs. The herb teas are now-a-days sold in boxes properly dried and preserved in canisters for use.

It may not be always easy to draw a hard and fast line between the duties of the housewife and those of the herbalist, for we read of the Scottish lady of rank superintending the manipulation of Elder flowers when she was asked marrying the Laird of Cockpen—

"Lady Jane she was making the Elder-flower wine;"

and Solomon's ideal of a household matron, a priceless treasure, is largely made up of a lady that looks well to the ways of her household—a worker, or as the sacred penman has it, one that eateth not the bread of idleness. Such an one would soon know plants by sight, and how to manage them. *Alex. Forsyth.*

PREPARATIONS FOR DRY SEASONS.

DROUGHTS have come upon us of late years with alarming frequency, and abnormal force; for scarcely have trees and plants recouped themselves from the effects of one dry season, than another has come upon them, threatening to wither their sap and exhaust their energy. Vegetable growing has had to be prosecuted under difficulties. The fierce glare of the sun has arrested growth, while the little forced forth under such circumstances has run into wood rather than succulency. Toughness has taken the place of tenderness, dry woody fibre that of crisp, jelly-like cellular tissue. For water, essential to all plants, is the warp and woof, and mainly the bulk and substance of vegetables. If we would have their heads or produce tender, their feet must be kept within reach of water. Therefore the water supply of gardens is a matter of paramount importance; and the old proverb, "Waste not, want not," is peculiarly applicable.

The late Mr. Loudon had a theory upon this, as upon many other subjects; and experience has justified its wisdom and truth. His principle was that every dwelling collected enough water to supply its inmates, if it were properly stored. He held the same to be true of gardens, if I remember rightly. In most gardens there is a lamentable want of facilities for the storage of rain-water. The rain that falls on glass roofs is not infrequently run off into the main drains, and lost; and until the invention of the Chatsworth Conduit Tile, all the water that fell on gravel walks was wasted, or often worse, left as a source of weakness, wetness, and ruin to good paths. But it is not of such means of collecting or storing water that I wish to write now. Every garden ought to be well furnished with water-tanks, of sufficient capacity, and in handy positions for facile access and convenient use; but all such arrangements are costly. A cheaper and better storehouse of water is at hand, and often sadly neglected. I allude to the earth itself. It is common to see deep tanks excavated to hold water, while the earth would have held better, had it only been deepened and broken up. Shallow soils are most wasteful of water; they are too flat to hold it; it falls upon them, runs through, and so passes away. Take a piece of dry sponge, press it firmly together, and pour water over it; most of the water glides away, little is absorbed. Remove the hard pressure, gradually moisten the sponge, until it becomes expanded; then pour water upon it, and it will hold it like a vice, and only part with any at the bottom, after it is supersaturated.

These two states of the sponge are not inappropriate illustrations of the different conditions of shallow and deep soils in regard to water, and their varying ability to counteract drought. Shallow soils are like the hard dry sponge, and are soon baked into sterility. Deep friable soils are like the full sponge—nourishing the thirsty roots of plants with moisture, even through the longest droughts. The winter is the season for filling this great sponge, the earth, with water. Then we should set about digging, trenching, down, down to at least 30 inches or 3 feet. Then when the heavy rains or snowfalls fall, and February fill-ditch comes, all this depth will be charged with water, that will run instead of beating down the surface, and scouring away the richest and most soluble portions of the soil into the nearest ditch or stream, will sink into the earth with a fattening, fertilising thud. The entire tilth is thus converted into a storage tank, and a sieve also; for on deep tilths no water escapes by the surface, except that falls has to enter in, and abide. It is only after the land can hold no more, that any water escapes; and then, if the matter is properly arranged, the waste-pipe from the great tank, the earth, is placed at the bottom, and not at the top. The result is, that the whole of the water passes through the soil before any of it is discharged; and it parts with a good deal to the earth on its passage. It gives up heat, ammonia, carbonic acid gas, and probably many other things, all which are left as a toll tax within the land. But more than this, as the water filters through the earth rends and splits it into innumerable fragments. The result of the passage of so many watercourses, each cutting a way for itself, is that the whole mass of the earth, so far as the water is conveyed, is pulverized, comminuted, and broken down into the moist state of friability, as the latter follows the water, and deep tilths, so stored with water, are likewise stored with air—the one complementary, as it were, to the other.

Water, in the state in which I have here advocated its being stored within the earth, is partly dependent upon the air; whereas the air, again, could never have a thorough passage in the earth, but for the passage made for it by moving water. Again, all tanks should be furnished with a waste-pipe; otherwise, they may be filled to bursting, or till they run over, to their own injury and that of other property. The tank of our tilth is no exception to this law; without an outlet, the storage of water would soon become foul. The roots would be soured and soddened during rain, and baked into iron or rent into fragmentary fissures during drought; but by removing the excess of water through underground drains all these evils are rendered impossible. It is not so much that drainage removes, as that it opposes the natural tendency to stagnation of water. Deeply-cultivated, well pulverised, properly drained land holds sufficient water by capillary attraction, or suspension, to supply all the wants of plants. When the sun beats upon, penetrates, and bakes shallow, undrained tilths dry, it scarcely dries the surface of deep land as I have seen it dried, but it has deep cisterns to draw from, that the other land wots not of. It can therefore set all ordinary droughts at defiance. When the sun drains the surface, capillary attraction works on with increased energy, and sends up subterranean supplies. No sooner does the sun sink to rest, and dew begin to fall, than the whole surface begins to drink in water and hide it away in the roots or the ground, to fight the drought with on the coming morrow. This power of absorbing aqueous vapour, as well as the energy of capillary attraction, are greatest in those lands that are the most finely pulverised. The air, too, in such soils acts as a buffer against the fierce beating energy of the sun. The sun pursues the moisture of the earth with the thirst of a bloodhound after his prey; but at all points the air within the soil beats back its fiery energy, and thus arrests the loss of water.

With such tilths, stored with water in winter, drought may be set at defiance. We as a nation—and even some gardeners—only scratch the surface of the ground, and then expect it to carry good crops, and bear drought without flinching. Were we to carry to our own gardens the inquiries—How deep are your water-tanks, that is, tilths?—most of us would be astonished at the answer we should receive. We should find that our water storage ranged from 6 inches to 48 inches, so that while the crops on some soils are ruined by the first drought, others go safely through every trying season without apparent suffering. In every garden there is nearly the same demand for water: they are cropped alike, and the yield is expected to correspond; and yet the tilth varies from 4 inches to 40 inches or 50 inches. Now, this tilth is not only the feeding-ground, but the drinking-cistern of plants; and the first means of mastering drought is to deepen it, ready for the rains to fill. The highest success in vegetable culture will never be reached, nor severe droughts set at defiance, until our gardens average 3 feet of good, rich, moist root-run. The roots, drinking from such virtually inexhaustible fountains, will develop abundant produce, distinguished by size, succulency, tenderness, and sweetness. *D. T. Fish, in "Florist and Pomologist."*

THE ODOURS OF PLANTS.

THE subject of the phenomena of odour and colour in plants, and of the causes which induce or govern them, is considerably interesting; and the relations which exist between the two are sufficiently striking. Thus, it has been statistically ascertained, and a very little reflection will confirm the conclusion, that white flowers stand highest in number among fragrant species, next yellow, then red, and lastly, blue. And it is among white flowers that disagreeable odours are most seldom found, while orange and brown are frequently unpleasant in scent. In such calculations, however, it must be remembered that the appreciation of odours is by no means the same to different people: scents which are agreeable to one, are often the reverse to another. The strong odour of Tagetes patula and T. erecta is not objectionable to some; while others, besides the well-known fox-hunter, are of opinion that the Sweet Violet is a "stinking flower." There are even some unhappy beings—we trust they are but few—who cannot endure the scent of a Rose. The sense of sight, too, is much more acute in some persons than in others; and we have frequently remarked an analogy to colour-blindness in the want of perception of odours manifested by some among our friends.

A good summary and comparison of scents will be found in M. Lecoq's "Etudes sur la Geographie Botanique de l'Europe," from which some of the following details are borrowed. In almost every case, however, additional instances of similarity will suggest themselves to the reader, especially if he be gifted with a keen nose, and a good memory for smells. In the first place, it may be laid down as a general principle, that a larger proportion of white flowers are fragrant than those of any other colour; yellow come next, then red, and lastly blue; after which, and in the same order, may be reckoned violet, green, orange, brown, and black.

Among white flowers, certain types of scent are very prevalent. Thus many Umbelliferous plants have a strong odour of honey, which is very marked in Anthriscus sylvestris, and is found also in the aquatic Ranunculi: Eucalyptus glandulosa recalls the same scent; and in the Almond and Apricot we encounter a qualified form of prussic acid, from which is so perceptible in the Hawthorn when one does not inhale too closely the fragrance of its flowers. This scent is intensified in Spiræa Ulmaria; in S. Filipendula it is modified by a *soupçon* of the odour which is found also in the Privet and in Actæa spicata, and attains distinctness in Lilac and Ligustrum. Many Rubiaceæ have similar odours, and resemble certain Apocyneæ; and the Philadelphus coronarius has so much affinity in scent with the Orange, that it is often called the "mock Orange bloom." Other types of scent among white flowers are presented by the white Lily, the Jasmine, the Tuberose, and the Lily of the Valley. It is curious to observe, that among cultivated plants, white-flowered varieties are very often the most—if not the only—fragrant ones; this is the case with the white Petunia [?] and a commonly cultivated white-flowered Verbena [?]. It is also worthy of notice that many of the scents among white flowers are only pleasant when in very small quantity, and become absolutely disagreeable when intensified; this is the case, especially, with the Hawthorn and white Lily.

Among yellow flowers, the scent of the Orange is often found, we may note, in the common Broom, and in Biscutella sauvitis and other yellow Crucifers. The curious alcoholic odour which has earned for Nuphar lutea its English name of "Brandy-bottle" is found also in the yellow Brugmansia floribunda, as well as in the yellow catkins of Salix caprea. Hippocrepis comosa recalls the smell of cheese, and this

odour attains its maximum in the blossoms of Genista scorpius. The honey scent is found in several yellow and blossomed plants, notably in Galium verum and Mahonia intermedia.

Roses and Pinks occur to one at once, when sweet-scented red-flowered plants are referred to; but with these exceptions it is difficult to characterise the odours of plants belonging to this series. But among lilac flowers a great resemblance in scent may be traced; thus the sweet odour of Vanilla, which is so powerful in the garden Heliotrope, is found again in different degrees of intensity in Petasites fragrans, Valeriana officinalis, and the common Lilac; we meet with it also in Plantago media, which is exceptional among Plantains in its fragrance and in its coloured corolla.

Blue flowers are very rarely fragrant, and when so, only in a slight degree. The blue variety of Phyteuma spicata exhales a faint perfume, and one or two Campanulas are slightly scented. Francisca Hopeana has, however, deliciously fragrant blossoms, which recal at once the scent of the Orange and the Tuberose; but although at first blue, they soon lose their colour and become white.

Certain species, the flowers of which are of sombre hues, are very fragrant. Thus in the early flowering Calycanthus præcox, one finds a multitude of odours, such as Rose, Jasmine, and Tuberose, harmoniously blended. The night-flowering Stock (Matthiola tristis), Hesperis tristis, and one or two more, compensate by their fragrance for the absence of beauty of colour; while other dark-flowered plants, such as the Henbane, have an intensely disagreeable odour.

Thus we see that it is not the most brilliant flowers which are the most fragrant, indeed, many of the most brilliant in colour have no scent whatever. The beautiful Malvaceæ of equinoctial America, the Pelargoniums of the Cape, the Passion-flowers [?], the Gladioli, and some of the most striking Leguminosæ are destitute of perfume.

One or two conclusions as to the geographical distribution of sweet-scented plants may be arrived at from the preceding facts, united with many more which space will not permit us to cite. We have seen that a large proportion of pale and white blossoms are fragrant; and it is ascertained that these predominate in northern regions. We may therefore conclude that the relative number of odorous flowers is greater towards the poles than towards the equator. It would seem that the too powerful action of light and heat is opposed to the emanation of the odours of flowers; and we see many species, which are scarcely fragrant during the day, become so in the evening or at night. But if the odours emitted by the blossoms are more frequent in the North, the reverse is the case with the essences enclosed in the glands. Plants with fragrant leaves, aromatic fruits, and wood penetrated with essential oil, are scarcely found except in warm or tropical countries. *James Britten.*

Home Correspondence.

Theory of Lunar Influence on the Flow of Sap in Trees.—I have noticed in the *Gardeners' Chronicle* of November 11 an abstract of Mr. Hutchinson's address to the Scottish Arboricultural Society. It contains a most interesting renewal of a theory nearly 2000 years old, that there is a menstrual periodicity about the flow of sap in trees, and that, consequently, the quality of timber is influenced by the moon's age at the time when it is felled. The Romans, than whom no ancient people were more skilled in the theory and practice of working timber, appear to have kept the exact date of the felling of the timber used for important public works,* and may have deduced this belief from the traditions of long experience. To prove that the belief was general, I will translate passages from Macrobius, who lived more than 1500 years ago, from Pliny the elder, who was 300 years earlier, and from Cicero, who dates 100 years before Pliny. In his work called "Saturnalia," book vii., chap. 17, Macrobius says, "Timber felled when the moon is either full, or in the first or second quarter, is useless for building purposes, being rendered soft by the sap that contains enclosed in its pores." Pliny in his "Natural History," book xvi., chap. 74, discussing the best times for cutting timber, says, "The lunar theory, too, is of immense importance; builders will not use timber unless felled between the 20th and 30th days of the lunar month. All agree that the best time to fell is at the moon's conjunction, or the day called, by some Interlune, by others, Still Moon [new moon]. We know that it was specified in the contract made by the Emperor Tiberius, when the Naumachian Bridge had been destroyed by fire, that the Larch trees for rebuilding it should be cut in the Tyrol on that day. Some say that the moon ought to be in conjunction below the horizon, which can only happen at night. But if a conjunction of the moon should coincide with the winter solstice, timber cut on that day will last for ever." The passage in Cicero is found in his treatise on "Divination," book ii., chap. 14. He is speaking of sympathetic influences, as proving the unity of Nature, and says, "It is thought that trees in the winter continue to become seasoned for use whilst the moon is waning, because they are then drained of sap." In estimating the value of the above passages, it must not be forgotten that the Romans for the most part placed implicit faith in meteorological as well as judicial astrology. The Emperor Tiberius was especially notorious for this. On the other hand, Cicero most ably refutes belief in astrology, whilst he admits the truth of this "lunar theory." Indeed, astrology could never have obtained such hold on men's minds had not its supporters been able to adduce such indisputable proofs of lunar influence as the tides. We know, also, what importance one of the leading geniuses of our age attaches in a recent work to tracing of lunar periodicity observed in the human race. *C. Welley Dod, Eton, Dec.* 4.

* This appears from the sequel of the passage quoted from Pliny.

Artichoke Galls.—I will meet my friend, Mr. Murray, on his own ground, and tell him that, as a practical entomologist, he should abstain from perpetuating the use of the name, Cynips gemmæ, because this combination includes two distinct creatures, namely the maker of the gall and its parasite. It is almost as bad a plan as if some botanist were to call both the Oak and the Mistleto by the same name of Quercus! *Dixi! Alb. M.*

Certificating Grapes.—Perhaps my remarks on this subject were a little too strong, but I wrote under the feeling of irritation which always comes over me when I read observations which, in my opinion, the Fruit Committee give their time, and attend these meetings at their own charge, and I am sure there has always been a great anxiety to come to a correct conclusion when a new fruit has been brought before them. The reply of "Lynx Eye" is so courteous to me, that I feel sorry that I wrote anything calculated to annoy him; let him consider I was defending the body to which I belong, and not the credit of any of my own productions. I think we may gather from the remarks of "Lynx Eye," that the committee cannot give a reliable judgment upon a bunch of Grapes, or even from a single cut in the Vine which produced the Grape from which it was selected; indeed, he says several visits paid during two seasons would be necessary. This is, at any rate, a sufficient acknowledgment of the difficulties of coming to a correct judgment of the value of a new variety. I can only confirm the view of the case, but contend that even after such a trial a Grape may disappoint many persons. There are few, if any, Vines will please every one, or grow well in all places. Nay, a Vine may do well for years and afterwards do badly with the same grower, and *vice versâ*. For several years I have been afraid so well will the Vine be admired by every one; the last two seasons it has done so badly in all three houses where I have grown it that I have destroyed them all. What makes this the more remarkable, one was an orchard-house, where little heat is used, and one is a hot vinery. But surely lovers of new fruits will not consent to wait for as years till everything is known about a new Grape. What we want is as correct information as can be obtained as to their value, and that is all we can expect. The question is, how can we get this? My own opinion is that when the fruit is approved of, and the tree seen growing, it is as much as is likely to be afforded in the way of information; and I think we must be satisfied with the best opinion we can get in this manner. "Lynx Eye" thinks that the only way to come to a correct decision is to prove each new Grape at Chiswick, and with him, I think some persons would not choose to entrust their seedlings to any one's keeping, is a serious reflection on the officers of the Society. What right has any one to draw such an inference? I would trust all I have in the hands of our present superintendent; but who can say that during the next two or three years, which would be necessary to prove a new Grape, he would continue in his present position, or could be answerable for every one who might have access to the growing Vine? I think the objection "has a foundation in fact," whatever "Lynx Eye" may say. Cuttings, as I have done, do, who "Lynx Eye" is, I am surprised that the difficulties of proving new Grapes has not struck him. Is the Royal Horticultural Society to incur the expense of building new houses for the purpose? To prove new Grapes in pots would be very unsatisfactory, because it is well known that many good kinds are not adapted to this mode of culture; nor would they be properly proved by grafting, because a weak-rooted kind might be temporarily benefited, or by an unsuitable stock a good kind might be seriously injured. Whatever may be decided, this scheme will never be carried out. One objection raised by another writer has great force. Mr. Ayres says if a member of the committee is asked how he could have voted for a kind which has not proved good, he replies, or may reply, "I was not there, and had nothing to do with it." "Lynx Eye" asks if I voted for Golden Champion? My answer is the same, —I was not there; if I had been, probably I should have voted for it, *i. e.*, if it was shown in good condition. Only a day or two since I received a letter in its praise, and have seen several others, though my own experience of this variety was unfavourable; perhaps I wanted the necessary skill, or was in too great a hurry in discarding it—time will show. I think if the names of those members of the committee who vote for a certificate were in future attached to the document it would meet this objection, the feeling of responsibility would be increased, and certain names would carry great weight. To come to matters more personal, "Lynx Eye" wants me to give my own opinion of my own Grapes; rather hard, is it not? If I praise them, he may say every one's "geese are swans," and if I know of faults I must in candour state them. Well, trusting that he will believe the opinions expressed candid, and hoping he will take it as one person's opinion who may be mistaken, and who is besides the most interested party, I have no objection to put my own opinion on record, and we shall see in time if it be correct. Ferdinand de Lesseps, a small bunch, with berries of the size of a Frontignan; colour a beautiful yellow, having a strong scent of Strawberries; flavour, barley-sugar flavoured with Pine-apple; the Vine a vigorous grower, very early, being ripe first of a large collection. As tastes differ so much, opinions are sure to vary a great deal about this variety. Dr. Hogg is much superior to Duchess of Buccleuch in bunch and berry, and when just ripe is very delicious; it has another good quality, it never cracks: its fault is, the flavour soon goes after it is ripe, in this respect resembling my favourite Grape, the Muscat Hamburgh. I am not quite sure I did not make a great mistake with Chilwell White. As soon as it showed a tendency to separate from the stalk when ripe, I condemned it, and ordered some hundreds of young plants to be destroyed. Within a fortnight a plant of Muscat of Alexandria in the same house looked quite as badly, so I shall try it again. Now, if it prove that I have condemned a Vine, worth to me some hundreds of pounds, without sufficient cause, is it to be wondered at that others make mistakes as to the value of Vines they have never cultivated, but seen once or twice? I believe out of the hundreds of seedlings I have raised, I possess some of the finest new Grapes ever seen, but so nervously anxious am I not to have a bad sort sent out with my name attached, that I will not let out any more till the public are very anxious to possess them. *I. R. Pearson, Chilwell.*

Abies Douglasii variegata.—Herewith are sent twigs cut from two trees of Abies Douglasii, which for variegation cannot, I think, be excelled. Tree No 1 is a rare beauty; it stands exactly 9 feet in height, the spread of branches 3 feet. About three years ago it was shifted by one of "M'Glashan's Transplanters" from where it originally stood to its present position, the centre of a small pinetum, where it forms a very attractive object. The removal has done it good, it being somewhat more sheltered now. It has made a growth of 2 feet annual for 12 inches. The tree appears to be in perfect health; it had a large number of cones upon it last year. Tree No. 2 is of a different stamp, owing to its being planted in rather an exposed situation, though in soil of excellent quality—sandy loam. The tree is growing one-sided, and has a bushy appearance; otherwise, it is quite as showy as tree No. 1. When carefully examined it does not look so healthy as the other; still it cannot be said to be an unhealthy tree. The height of this one is 7 feet 9 inches. *John M'Donald, Forester, Dupplin Castle, Nov.* 31.

Transitory Variegation in Young Plants.—My attention has often been called to this in spontaneous seedlings of the common Horse Chestnut and Sycamore. I have had many of these collected and grown on; but, without exception, they have all ultimately lapsed to the dull or the green state. They have, however, varied much in the time taken to return to their natural colour. Some have gone back during the first season, others the second, and others, again, not till the third or fourth year. I have tried them in various soils—rich and poor, peat, loam, clay, sand, lime rubbish, and charcoal—but they have invariably become green at last. Such departures from the normal colour in seedlings have much less stability than branch sports, though these also frequently refuse to grow or run back. How comes this transitory variegation in the progeny of green parents, and from whence the difficulty of its propagation? *D. T. F.*

Price of Vegetables.—In answer to Mr. Morgan's letter, I beg to state that I do not attend the Borough, but have to say, and, as a rule, I think the prices are realised at Covent Garden. I am not a West-Ender, but my experience has been in poor neighbourhoods; therefore I leave the West-Enders to answer for themselves, as I think no one should answer unless from experience. Now, these were last week the average prices in poor neighbourhoods last Saturday night (December 2). I took the trouble to have a turn round to satisfy myself:—Collards, 2*d.* to 3*d.* per bundle; Celery, 1*d.*, 1½*d.*, and 2*d.*, according to size and quality; Brussels Sprouts, 2*d.* per lb.; Savoys, 1*d.* to 1½*d.* each for best; Onions, 3 lb. 2*d.* to 1*d.* per lb.; Carrots, 3 lb. 2*d.*: Altringhams (sacked, not bunched); Potatos, 3 lb. 2*d.* to 7 lb. 6*d.* for best, some places 4 lb. 2*d.*, but these were rough samples; and Turnips 2½*d.* a bunch. As to 4*d.* to 6*d.* a small dish of Scarlet Beans in the season, the first week they were 4*d.* per lb., then they were fetching 8*d.* to 10*d.* per bushel, but after that they were down all at once to 3 lb. 2*d.*, and 1*d.* per lb. Broad Beans, 4*d.* per peck; Peas, 4*d.* to 6*d.* per peck; Champions and Ne Plus, 8*d.*, and for a week or two they were as high as

12. Now, at the above prices you must not expect to see shops with fine plate-glass windows, get long credit, nor to have your articles done up so nicely in blue paper; but you generally get civility and good articles. I think these prices are lower than the wholesale ones last year, for at that time they were very dear; and when the producers were asked why, the general complaint was, we have nothing much to bring; and yet I see by Mr. Morgan's report the crops were as fine last year as this. I wish your journal were more widely read by greengrocers, as I think the *Gardeners' Chronicle* is as great a rarity in a poor neighbourhood as English Pine-apples or hothouse Grapes in May; then the subject would get more fully ventilated. I will just remark that greenstuff ruled higher in Covent Garden this morning, I suppose on account of the frost. The places I visited were Walker's Court, Berwick Street, Whitecross Street, New Cut, Caledonian Road, Hampstead Road, and Leather Lane. These are some of the poor people's favourite market places. *W. R. H., December* 6.

Pine-apple Growing in a Small Area.—The bed in which my fruiting Pines are grown is 17 feet long, and 5 feet wide, in a lean-to pit. The plunging material employed is tanner's bark. It will thus be observed that this noble fruit is grown here under circumstances and conditions exceptionally inexpensive and simple: that is, I am obliged to use plunging material for bottom-heat, and a flow and a return pipe running along the front only, to keep up the temperature. The pots I use and prefer for growing my fruiting plants in are of the sizes called 10-inch and 11-inch, and which I consider sufficiently large for all practical purposes. My successful and successional plants are grown in the vinery underneath the shade of Grapes and leaves, a practice I much object to, because the Vines not only shade the Pines too much, but it is difficult and tedious to get at the former for the purpose of training, thinning, pruning, &c. Some excellent Pine-growers affect a little shade occasionally, but I am decidedly opposed to the practice; indeed, my experience is, that Pines and Vines cannot be grown together satisfactorily. Nevertheless, with all these drawbacks, I have had a fair succession of Pine-apples, of tolerable size, all the year round, as will be gathered from the statement that out of an area of 85 superficial feet, or a little over 9 square yards, I have cut 15 Pine-apples in the present year, which weighed in the aggregate 61 lb. 10 oz. Perhaps in this fast-going age, to other cultivators who may fortunately possess modern appliances of the most approved description, this achievement may be of very extraordinary or sensational. Be it so. But what to me is far more pleasing, the produce has been pronounced by my estimable employer as possessing that desirable sterling quality, excellent flavour, without which the largest and heaviest Pine is perfectly worthless. The varieties referred here are the Montserrat and the Smooth-leaved Cayenne, which are considered to be of equal merit. *Wilson Boardman, Gr. to S. H. Norris, Esq., Altrincham.*

The Canon Hall Grape.—In the autumn I met with some examples of this Grape, of superior merit, grown by Mr. Dell, the gardener at Stoke Rochford, near Grantham. I confess it is a somewhat precarious Grape to grow and finish in first-class order, but it evidently appears that it is possible to grow it on a par with even the old Hamburgh. It possesses two rather indifferent qualities, viz., shy setting and bad keeping; the former can be overcome, and as it is so much earlier than the old Muscat, the latter is of small importance. I hope this noble Grape will yet be successfully and extensively grown. *John Edlington, Easton Gardens.*

Hardiness of Echeveria secunda glauca.—Allow me to caution those of your readers who think of wintering this plant out-doors, to plant it in open beds. It can resist neither the frost nor the damp of our climate in winter. I grudged the space that some thousands would occupy under glass last winter, and attempted to winter them on a raised bed in a warm corner, with the assistance of mats as an awning in severe weather, and came nigh losing the entire stock, and should have done so without doubt had I not lifted them just before Christmas and put them in a cool, dry frame, which saved the lives of most of them, but not the leaves, all of which fell off. I have, however, known the plant stand the winter about London under the wall of a dwelling-house, on a dry rockery; and I have a quantity along the bottom of a south wall this winter, where they are protected from rain and covered with dry leaves, which seem to get on well enough as yet. I shall be glad to hear the result of Mr. Knight's experience, however, in trying to winter them in open summer quarters, but I doubt its success. *J. Simpson, Wortley.*

Fruit Trees for Shrubberies.—It is a source of wonder to me that fruit trees have never been planted extensively for the ornamentation of shrubberies, at least never that I have heard of. Why this should not be done I know not, but there are several reasons why they should be grown for ornament. In the first place most kinds of fruit trees will grow in any situation, and in addition are perfectly hardy, even in our coldest winters. They might either be trained against walls, or as standards. Take the Apple, Pear, and Cherry, for instance, when they are in bloom; what shrub have we that has a more imposing effect, or is equal to them? Plant them in the shrubbery with other trees, and they will enliven the whole in the spring with their splendid blossom, and produce a grand effect with their golden fruit in the autumn. No doubt the greatest drawback to such a proceeding would be the cost of the trees, but then there are few nurserymen who have not a number of trees that would not do to send out for the fruit garden (I mean deformed trees), which they would be able to sell cheap for such a purpose, and which, when planted with other trees, would not show their deformity. The soil would have to be dug about 2 feet deep, and some manure incorporated with it, to give the trees a good start, and that would be all they would require for their first doing. There are other trees besides the Apple, Pear, and Cherry which I might mention, such as the Quince, Medlar, and Mulberry, all of which would help to adorn the shrubbery; and, if found necessary, the fruit could be gathered either for the kitchen or the dessert, and would no doubt come in useful both for the gardener and the cook. *G. Warren, Gr., Balcombe Place, Sussex.*

Pinus excelsa Coning.—Allow me to inform Mr. Chapman that I have just taken more than a bushel of cones from a specimen of Pinus excelsa. Many of them measure 8 inches in length, and contain a quantity of good seed. *G. Peckham, Beech House, Ringwood, November* 29.

Cutting Turves for Lawns, Bowling Greens, &c.—Would you allow me a corner in one of your columns, that I may call the attention of working gardeners to plain spade work? This is no high-flown theme, larded with hard names, but still every gardener seems in duty bound to maintain the honour of the spade, in all its various shapes and forms. The push-plough used for paring and burning I consider to be the legitimate division between the gardener's spade on the one hand and the farmer's plough on the other, for the paring spade or push-plough is necessarily made strong, and is therefore an unwieldy tool for a man to handle; the tools for draining; and lastly, we have the floating spade or turfing-iron, so essential in all new work for cutting the turves workman-like and of equal thickness throughout. On some of the London commons, in days gone by, piles of turf might be seen cut for sale, each turf 2 feet long and 9 inches wide, and as near as might be by the handy man as to be exactly 1 inch thick. With turves thus cut from a common where the grass was eaten down so close as to be little longer than the plush on the carter's waistcoat or the livery-servant's breeches, it is easy enough to make good work in laying the turf. On one occasion, where I laid down the turves and levelled the lawn in front of Syon House in what appears to be their last resting-place, for no one seems to have tampered with a sod there since 1836. I had no difficulty either about the cutting or the laying of the turves, for all hands knew how to do their work quite as well, if not better, than I could tell them; and when the level pegs had once been driven, about 40 hands could work without confusion. When, however, I had to lay down a great breadth of greensward in the country, it was very far otherwise; for, in conducting the work, I had to give way to the local system, and cut turves in squares of about 1 foot, because all hands understood how to do the work best in that way. When I had to put men in the way of cutting turves for a lawn who had never cut a turf in their lives for such a purpose, I found myself in the position of the love-lorn girl in the old ballad lamenting the loss of her lover—

> "They've ta'en awa Jamie
> That delved in the yaird;"

for my assistants could no doubt "plough and sow and reap and mow, and were good farmer's boys," but to cut a sound turf was out of the question. After getting a turfing-iron or floating-spade forged by the country blacksmith from a paper pattern, and a handle put to a new edging-iron, I had an inch board cut to the size of a turf, 36 inches long by 9 inches wide, and this is how we got to work:—The board, or pattern, was laid down upon the turf, and the man stood upon this board and kept it firm, and with the edging-iron cut all round the board, thus securing the exact size of each turf; the man with the floating-spade came next and raised the turf, and the boy rolled them up as they were cut. I could have set any number of men to work in this way with little expense, and with the certainty that every turf would be of the right size and workmanlike, which I never could accomplish before, because the men could never be trusted to keep the turves to the right size whilst working by the line. Now as others may be in the like predicament that I have been in, I thought it might save some trouble to tell them how well beginners can be got to cut turves neatly from a wooden pattern. *Alex. Forsyth.*

Orchid Cultivation.—I have read Mr. James MacPherson's letter in your journal, and though he puts me down as one of the 'Tweedle family, I venture again to trespass upon that space, as I am afraid, otherwise, his letter will go unanswered. He asks if Dr. Hooker gives a list of the Orchids found growing at Darjeeling. I have the Doctor's book, but cannot find any such list. As to his other questions, a long paper could be written on each; but as most of them are fully treated upon in the second volume of the "Himalayan Journals," I refer him to that work, as being much more to the point than anything I can write. Dr. Hooker says, "In our gardens we can neither imitate the conditions of an alpine climate, nor offer others suited to the plants of such climates." He does not think the change in regard to atmospheric pressure has much to do with it. Ground Orchids go to much higher altitudes than those that grow upon trees, I should think with Mr. MacPherson, as Dr. Hooker says he found the mean of the soil higher than the mean of the air all over India. At an elevation of 16,800 feet, he found the soil 12° above the mean of the two days he was there, at a depth of from 2 to 3 feet, that is, 43°; at 17,000 feet he found a lake of water with a temperature of 55°. The same plants go from the sea level up to from 14,000 and 15,000 feet; they accommodate themselves to the climatic changes as far as they can, but suffer in consequence—the seeds are produced with greater difficulty, and fewer germinate. In such altitudes, sun-heat and radiation are more important than mean temperature. Animal life is abundant in the dry, lofty provinces of Tibet from these reasons, and at Leh, at an elevation where subsistence is abundant, if the air is cold and moist when the air was at 4° the soil was 43°. Thus, the accumulated soil-heat saves plants and enables rodents to live. Vegetation is most backward also in moist and damp regions. In descending he found plants in seed at 14,000 to 15,000 feet; still green at 12,000 feet, and later again at 2000 feet. On another occasion he found fruit ripe at 13,000 feet, and still in flower at 9000 feet. Do ground Orchids require more heat than tree Orchids? In this question I take great interest, and I hope Mr. MacPherson will get some answers, though I have no faith on the subject myself. I think it will prove that the ground Orchids we have do not come from high elevations, and require more heat accordingly, because we cannot offer the conditions of alpine climates to those that do, and so lose them. Would bottom-heat, in conjunction with a cool atmosphere, suit them? Dr. Hooker gives an account of the Khasia hills, which, he says, are perennially humid:—rainfall from 500 to 600 inches; temperature, summer mean 90°, winter mean 66°; Geraniums refuse to grow, from the rarity of the sunshine; in winter hoar-frost is frequent, being produced by radiation. Now, the Orchids found in the Khasia hills—most of them tree Orchids—are tree Orchids found in any but the perennially humid climates, such as is here described, and in New Grenada? In the description of what he saw at Ghent, your correspondent, "D.,Deal," says that M. Verschaffelt grows his Orchids, which, he says, are chiefly sold us are, as a rule, small plants, at a moderate temperature, so that plants from there are the more likely to thrive than when grown in a higher temperature. If this means anything, I must take it as an unfinished sentence, implying that the plants are being prepared either for a cooler or better temperature. I think I may take it for granted that M. Verschaffelt intended it to mean that Orchids grown at less than an ordinary temperature are safer for amateurs to buy; to understand it, let us examine what an Orchid is. An Orchis is a plant that produces tubers in the soil, which tubers are the apparatus of nourishment prepared for the nourishment of the next growth. An Orchid is a plant having Orchis-like flowers, and producing pseudobulbs instead of tubers, which pseudobulbs are intended by Nature to act like tubers, as storehouses of nourishment for the future growth, and they are simply an adaptation of this principle, necessitated by their habit of growing above the soil instead of in the soil. If, therefore, the temperature these pseudobulbs had been grown in was under that required by the plant, its vigour of growth would have been impaired in like proportion, and these storehouses would have been proportion, and these storehouses would have been produced of a small size, and perforce contain a smaller stock of food for the use of the next year's growth. All Orchid growers know this fact, that a new growth is in direct proportion to the strength of the last, except some accident has happened. "What is worth doing at all is worth doing well," is still a good school maxim; but I prefer the Scripture language, "What thy hand findeth to do, do it with all thy heart," and your writers should not record without reflection what are only the economical ideas of the trade. There is also one other idea that I hear from time to time,—if an Orchid is out of health, it should be brought round gradually. Common sense practice can only be this: Has it been suffering through being out of its proper climate?—if so, the sooner you put it right the better. We have no substitute for climate, that is, the proper

combination of temperature, light, food, and moisture; if these are not in due proportion, no human hand can prevent death sooner or later, and Orchid cultivation simply means giving them these conditions. You do not say where Mr. John Scott's paper on Indian Orchids can be found; I read with great interest the letter of his you published in June last. *G. H.* [Mr. Scott's paper is published in the Journal of the Agri-Horticultural Society of India. Eds.]

The Slough Auriculas.—There is now collected in the nursery of Mr. Charles Turner what may without any contradiction be considered the finest "stud" (this was my dear old friend Mr. Graves' word for them, although what similarity there was between them and "'osses" I could not make out) of Auriculas that has ever been brought together. My memory goes back to the time of the Dicksons, in Acre Lane, Brixton. I have seen Dr. Plants' in olden time, and have had some knowledge of the collections in the North, but none of them can bear comparison with that which Mr. Turner's zeal and intelligence have brought together, and which Mr. Ball so well manages. Any one who has seen those which he has from time to time exhibited in London knows what a beautiful display he can make; any one who has seen his collection at Slough has had a treat, which might make a man a florist if he had a contempt for florists' flowers before; but this year he has added immensely to his already large stock. Early in the season he became the possessor of the fine collection of that veteran grower, Mr. R. Headley, of Stapleford, the raiser of the finest Auricula in cultivation, George Lightbody, and amongst these was a large number of very fine seedlings, especially in the green-edged section; and very lately he has also obtained possession of a very superior collection through the death of an amateur in the neighbourhood of Glasgow, comprising nearly 600 plants, so that he must have pretty nearly doubled his collection. And we must also bear in mind that we have now in growth flowers which are far in advance of those which used to be considered our best flowers. A green edges probably there has not been any great advance, but in grey edges we have such flowers as George Lightbody, Richard Headley, John Waterton; and in white, Surly Beauty; in selfs, Lord Clyde, Pegasus, &c., so that the quality of the collection is equal to its extent. *D., Deal.*

Crataegus coccinea maxima.—I cannot too highly recommend this beautiful scarlet-flowered and still more beautiful bright crimson-berried Crataegus, to be grown in the mixed shrubberies, even in prominent positions. At this season it is very showy, its berries, which are large, being produced in dense bunches. Crataegus coccinea minor should never be planted where the above can be had instead. *William Earley.*

On the Management of Boilers.—As a hot-water engineer I have always observed that after the first severe autumn frost those having the management of heating apparatus are more ready to listen to a little advice upon their management than at any other time; hence my now troubling you with a few remarks. Every heating apparatus that was not emptied in the spring or summer should have the water run off from them as quickly as possible, so as to carry off all sediment while it is dirty; water in an apparatus causes a slower circulation through the pipes, and increases the likelihood of steam being improperly formed in the boiler, causing an overflow at the cistern or expansion where used. Few people that have not seen inside the pipes of an apparatus that has been at work for a few years would believe the amount of mud and sediment they frequently contain. The boiler and pipes should be filled with rain-water, or, at the very least, whenever water be added it should be rain-water, for with its use boilers will last for years without furring, and this is of some importance where tubular and cast-iron boilers are employed in chalky districts. The importance of using rain-water for hot-water apparatus cannot be too much impressed on all who have the management of them. On the subject of stoking I shall make but one remark or suggestion, and that applies particularly to cast-iron tubular boilers. It is, that before opening the upper or furnace door the damper should be nearly closed, and the stoker should be careful not to leave the lid off whilst so doing. The object of this is to prevent the cracking of the bottom ring, which sometimes gives way in severe frosty weather by the rush of cold air across the underside of it when the furnace-door is open, and which, if the damper in the chimney is nearly closed before opening, cannot take place. In this way many a fine boiler may be saved from destruction. As cleanliness is said to be a virtue, all boilers and furnaces are the better for having the soot and dust cleaned out, a little every day. *Duval Campbell, Clapham Junction.* [Very important. Eds.]

Certificated Grapes.—Since writing my last note I have had an opportunity of tasting all the new Grapes in the garden of W. Newton, Esq., of this place. Madresfield Court is certainly the richest and most luscious in flavour, and Mrs. Pince's Black Muscat the second. They are quite distinct in character, the first-named being rich and juicy; the latter rich, crisp, and crackling. Neither, though the bunches are of more than average merit, shows any disposition to "crack." Alicante and Lady Downe's, compared with them, sink into perfect insignificance. Champion Muscat is also very fine, with berries of enormous size; and a three years planted Royal Ascot produced, the first year 12 bunches, the second year 30 bunches, and this year upwards of 50 bunches, averaging over half a pound each, and coloured to perfection. This, planted in the ordinary soil of the garden, without any special preparation, is a proof of the free-bearing properties of this variety. The flavour is fine and refreshing, and certainly less cloying upon the palate than some of its rivals in the market. Golden Champion has not behaved well; the berries, though very fine, damping almost before they were ripe, while now they are quite ripe, the flavour has lacked spirit. Mr. Newton's large orchard-house, which is not heated, I tasted some Frankenthals equal in flavour to the best I ever met with—certainly very superior to those in a properly heated vinery. *Wm. P. Ayres, Newark-upon-Trent.*

Chilian Beet is pretty well known about London as an outdoor decorative plant in more ways than one. One other way we may use it to advantage and profit, and that is, as an indoor decorative plant for winter. A packet of seed was given in May, and pricked out singly into the smallest pots when ready as seedlings, and potted into 6 or 7-inch pots in the course of a month or so after, will furnish a batch of brilliant foliage plants such as will astonish all who have the least love for fine-leaved plants. At this season, and during all the chill months, nothing is more attractive than this Beta chilensis when grown in pots. We have used it as a dinner-room plant, on the sideboards, in gold and silver vases. The bright yellow one and the magenta-coloured varieties, both alike, have been much admired. Many have hardly seen it before, thought it a wonderful plant, as I confess I did on seeing it at the late M. Lierval's of Paris several years ago, in the depth of winter. It was there, however, grown in hothouse heat, and the plants had a long, lanky look. Grow it and treat it like a Cineraria, and you have for winter a thing of beauty. *H. K.*

Cedar of Lebanon Seeding.—I took three cones in the month of February, 1870, from which I obtained a fully developed seedling, which I potted in three-inch pots, and placed in a cool vinery. All germinated, and very few damped off. I planted them out, but owing to the dry summer of 1870 they did not make much growth. This year, however, they have grown from 6 to 7 inches. I may also say that the trees here, which are considered old specimens, are in the present time loaded with cones and catkins. *J. McLean, Gr., Prestwold Hall, Loughborough.*

Grafting Vines on American Stocks, &c.—Some years ago a friend brought me from North America some native species of the Vine, knowing that Vine culture was my hobby. The great vigour of these Vines, together with the fact of their ripening early, induced me to use them as a hardy stock for other Vines, as I was well aware of the many and great advantages of this much neglected art in Grape growing; a few other stocks, as named, were also used. The Black Lady Downe's, grafted on an American stock, and on the true Frankenthal, is best on the American. A most remarkable vigorous growth is made, equal of the Vines, but at every break, after stopping, fruit was shown upon laterals from the green canes of the current year's wood, the Vines at the same time carrying a good crop, and had made new rods for the next year's fruiting of 20 feet and upwards, plenty of the canes being of the size of a man's thumb. This Vine, although generally looked upon as a late and keeping Grape, forces well, and as such does well in pots. Burchardt's Prince or Aramon: This very good Vine should be more grown, it keeps well, and is hardy and prolific on the American stock. West's St. Peter's does not like grafting on the Hamburgh; on the American stock it is best. Chavoush, the Turkish Sweetwater, is much grown about Constantinople, where it is prized. It is also a favourite with all my visitors, having fine oval berries (I like this shape best), noble bunches, and handsome foliage. It is remarkable that I have never fruited it on its own roots. Grafting, in this case, has improved the flavour. Foster's White Seedling, a twin sister of the Black Lady Downe's, very vigorous, fruitful, and good. This Grape is useful either early or late, and is hardy. Trebbiano is also good with like treatment. In some catalogues it is stated to require a high temperature; with me, grafted, I did not find such to be the case, but it is planted, as are all my Vines, totally inside. As to Gros Guillaume, or the Barbarossa, permit me to utter a brother's note to you, being grafted at the warmest end of the house. Bunches like Hamburghs, of 6 and 7 lb., will be the reward if so grown. After Christmas it is first-rate; it is one of the best of keepers, and so treated I may say that it never shanks. Black Tokay, or Alicante, a Vine with very downy leaves, if grafted Vine, very fine. Grafted on Hamburgh, pole-trained, with four bearing rods of 6 feet each, showed, in 1869, 83 bunches; but however fine looking the bunches of this Vine, my family prefer the Black Lady Downe's. Mrs. Pince's Black Muscat does best grafted. My Vines on their own roots I have destroyed. For late hanging it appears to stand damp better than most late keepers; it does well in a low temperature, and is useful in a greenhouse where pot plants cause damp. Golden Champion, on the Frankenthal, and Raisin de Calabre, and on some American stocks (three sorts), I have not yet proved by fruiting. Madresfield Court on the Syrian does well; on American stock it has not yet fruited, on its own roots it is a good grower, and produces fine fruit. It should be planted in some form by all Grape growers. Gros Colman: this noble Grape in bunch and berry is improved in flavour by grafting; I have it on the White Frontignan, Frankenthal, and two sorts of American Vines, but it has not fruited on the two last yet. The Royal Ascot is very good for pots on its own roots; the fact of its yielding a crop of Grapes from the green canes of the current year's wood, to ripen in the winter, makes it very useful. The Vine for this requires special, and the highest cultivation; it is not perpetual with me, and, as far as my judgment will allow, it is unwise to attempt to make it so. Vines of this sort for borders I prefer on the Frankenthal, and grown on my method, for which I refer the reader to your pages of November 12, 1870, p. 1508. If the Vine is for a second crop, I should then prefer an American stock, promoting as they do, hardy, vigorous fruitful Vines, also inducing the fruit to ripen early, which is a great point in these structures. I have other Vines grafted, including several Frontignans, the best of all Grapes to the refined taste, Black Damascus, etc.; and should these notes be acceptable, I will report progress after fruiting them. [Please do so. Eds.] I send for your inspection some of the leaves of the grafted Vines planted out. At the same time I must add that no costly borders, glass-houses, or other structures, helped to produce them, or the Grapes; for where the Vines are now growing, 16 months ago was a plantation of Gooseberries, and two standard Apples, which had existed several years. The ground was trenched 2 feet deep, making top and bottom well together, a small quantity of bones (chicken scraps), and the handlings of bone-knife handles was forked in the top, and the Vines planted. An iron stove, used at times, is all the means at command for heating. I also send a lateral from a Vine on its own roots, showing a bunch of Grapes strongly and well (it is common for my Vines to show 4 and 5 on a rod of West's St. Peter's, from a green cane of this year's produce. This Vine has a good crop, only a portion of the bunches that showed being left, and it has stout canes and over 20 feet in length for fruiting next year. I consider that this proves great fertility and great vigour, and which, I think, has been brought about in the following manner:—During the past nine years I have propagated my own Vines, always selecting the fruiting eyes only from Vines in the most healthy and vigorous condition, that had not at least with me been subjected to undue excitement, either by the Vines or producing the young Vines from eyes—which is, if I may use the expression, growing at "express speed," and which is, unfortunately, the general practice at the present time, and to be deplored, for amateurs especially. This I do know: curiosity some 20 years ago prompted me to select fruiting eyes and cuttings of the Vine known as the Malvasia (Grove End Sweetwater), from a gentleman who resided there, who I believe introduced it to England—in Sussex it is Lashmar's Seedling. Now the fruit eyes, as I term them, produced very fruitful Vines, and in all points 90 per cent. better than those from the wood eyes. My impression is, that the always using a careful selection to produce my young Vines during the space of nine years has produced the hardy, vigorous stock I now possess. At all events Vines I receive grown in high temperatures do not perform equal to my home-grown ones. Of the American hardy Vines I have possibly the only collection in the British Isles, some 16 species and hybrids—thanks, and many of them, to kind friends on the other side of the Atlantic, and may both nations always be cemented in friendship as close as the English-grown grafts I have joined with the North American species. [Bravo!] I have no doubt that they will prove valuable as stocks and for growing out-of-doors, being very robust, hardy, prolific, and not liable to disease. I send some of the leaves of these North Americans, produced from small plants, potted on this May, having now two and three canes of 6 and 7 feet long per plant; the wood is ripe, 3 to 4 weeks in advance of the Black Hamburgh grown in pots under the same conditions. I venture to write, no other Vines, as far as I know, would have produced such fine foliage in common garden soil and in pots of this small size, at least for Vine growing. Now, Messrs. Editors, permit me to request your opinion upon the foliage of the grafted Vines: the fact of the lateral with fruit from a Vine with crop, it not being a Royal Ascot; and last, though not least, the foliage of the North Americans. *R. M. W., Fir View, Walkley, Sheffield.* [The publication of this letter has been unavoidably delayed. The lateral with fruit did not come to hand. The foliage of both grafted and American kinds were particularly fine, vigorous, and healthy. Eds.]

The Cracking of the Madresfield Court Grape.—The cracking of this new Grape may be owing to the season, and not to any constitutional defect. I had the Gros Guillaume this year very badly cracked in a late vinery, and this happened just at the time of colouring; this was in the last week of September, when 3¼ inches of rain fell in five days, and this quantity of moisture on the outside border had the

effect of cracking the berries. In the same vinery the Black Damascus, a thin-skinned Grape, likewise cracked its berries, but not to the same extent as the Gros Guillaume. All firm-fleshed Grapes like the Madresfield Court are liable to cracking at their last swelling period, if the border, whether inside or out, are kept too moist; and this could not be guarded against in outside borders this year, from the heavy falls of rain in June, July, and September. With me the Madresfield Court, which ripened in an early vinery in June, showed no symptoms of cracking, and the colour of the berries and flavour were excellent. I think, therefore, your correspondent, James Smith (p. 1488), may safely plant as many Vines of the Madresfield Court as he has room for without fear of failure. *William Tillery.*

Potatos.—During the late bad season I had not one unsound tuber among my Sutton's Redskinned Flourball Potatos. I planted 8 lb. of each of the following sorts, side by side, treated them all in the same way—viz., manured them with horse-dung, and sowed at the rate of 6 cwt. of guano in the rows. The following is the result :—

1. Mona's Pride yielded 31 lb. sound tubers, 12 lb. unsound ; total, 43 lb.

2. Haigh's Seedling yielded 25 lb. sound tubers, 29 lb. unsound ; total, 54 lb.

3. Flukes yielded 23 lb. sound tubers, 14 lb. unsound ; total, 37 lb.

4. Butter Kidneys yielded 20 lb. sound tubers, 40 lb. unsound ; total, 60 lb.

5. Prince of Wales Kidney yielded 15 lb. sound tubers, 27 lb. unsound ; total, 42 lb.

6. Early Rose American, yielded 58 lb. sound tubers, 6 lb. unsound ; total, 64 lb.

7. Veitch's Early Ashleaf yielded 51 lb. sound tubers, 4 lb. unsound ; total, 55 lb.

8. Paterson's Victoria yielded 59½ lb. sound tubers, 9 lb. unsound ; total, 68½ lb.

9. Sutton's Redskinned Flourball yielded 96¾ lb. sound tubers, none unsound.

10. Pink-eye Regents yielded 15½ lb. sound tubers, 41 lb. unsound ; total, 56½ lb.

11. Myatt's Prolific yielded 49¾ lb. sound tubers, 3½ lb. unsound ; total, 53¼ lb.

12. Scotch Regents yielded 44 lb. sound tubers, 21 lb. unsound ; total, 65 lb.

I may add, that the above were planted 1 foot apart in a row, the rows being 2 feet 8 inches apart. *E. Varah, Manor Gardens, Braithwell, Rotherham.*

Foreign Correspondence.

MAURITIUS.—From the interest which is attached to the flora of Mauritius, and the group of small islands surrounding it, the following extracts from a letter from Mr. Horne, the Director of the Botanic Gardens, Mauritius, on the vegetation and general character of the Quoin Island, may be acceptable to our readers :—

This little island is about three-quarters of a mile long, and about the same broad, and lies above half-way between the mainland and Flat Island, being about three miles distant from Grand Bay, the nearest point of the mainland. The island rises abruptly from the sea, and in no place are its shores less than 30 feet, and almost perpendicular. Its greatest height is at the northern end, and here it rises to 450 feet ; a landing can be effected at but two places, and even at these only at such times as the sea is calm. These natural landing-places are projecting rocks two to three feet above the water-line, upon which one can step from a boat as upon a quay ; from these rocks one has to climb the face of the island, over steep, and slippery rocks upon which the sea breaks in stormy weather. On the top of these rocks the volcanic part comes into view ; volcanic boulders of all shapes and sizes are lying about in every direction, but they are not so numerous on the eastern as they are on the western side of the island. Here Pandanus Vandermerschii is very abundant. The ground is carpeted with Zoysia pungens, walking through which is somewhat dangerous, as it hides holes and stones alike. Over the boulders which this plant does not cover creeps the pretty little Tephrosia pumila in dense masses, its silver-coloured leaves forming a fine contrast with the blue volcanic stones. Here and there are plants of Tournefortia argentea, but it is not abundant. Neither on the Quoin, nor on Round Island, have the common oceanic plants, such as Suriana maritima, Pemphis acidula, Rhizophora, Scævola, &c., yet been found. This may be attributed, in a measure, to the abruptness with which these islands rise from the sea, and also to there being no quiet place for depositing soil or sand at the water's edge but what is swept by the waves. On Flat and Amber Islands, and also on the mainland, in every place where the shore is flat, sandy, or muddy, these oceanic plants abound, more especially at the parts that are protected by reefs from the force of the waves. Among the rocks near the sea, but about 25 feet above the water, two species of Portulaca were found. Even at that height, they were not beyond the height reached by the spray from the waves, which are broken in ordinary weather on the rocks below.

Passing on to the sandstone part of the island, the vegetation is more marked, and of a more arborescent nature. A species of Selaginella and Adiantum caudatum were the only Filices found ; these plants were growing in the crevices of the sandstone rock, on its windward side. The top, or plateau, of this rock is the highest part of the island, and is about 450 feet above the sea.

Among Monocotyledons, the most abundant were species of Aloe and Dracæna, Cymbopogon elegans, and Pandanus Vandermerschii. This latter, excepting on the volcanic part, is, with the Dracæna, chiefly confined to hollows at the bases of the precipices in the watercourse ravines. Cymbopogon elegans grew everywhere, so also did the Aloe, which served as a guide to point out where the sandstone part ended on the surface, and the volcanic part began. Few plants of it were seen where the surface is of volcanic origin, but their number gradually increased to that we passed over. Several plants of Latania glaucophylla were seen, but it is not numerous. The island is infested with rats, which devour the Latania seeds as soon as they are formed, and which will probably be the cause of this fine Palm becoming extinct on the Quoin de Mer. On the highest part of the island grew several plants of a very pretty Asparagus. The most common Dicotyledonous plants are Clitorea Ternatea var. alba, species of Cassia, Datura, and Rhamnus lucidus, which latter grows in a compact mass on the highest part of the island ; Eugenia (Jossitia) rotundifolia, with its delicious sweet-smelling flowers, is also common, as well as Gagnebina axillaris, a very pretty shrub, rare on the mainland.

There is a reddish-brown coloured grasshopper, which is said to be peculiar to the Quoin, and not found on the mainland. It is not numerous. The volcanic part of the island may be said to be a plain, interspersed on the surface with volcanic boulders, rising gently to where on the surface it meets the sandstone which it mostly overlays. The surface of the sandstone part of the island is well undulated, and broken by small ravines and small precipices. The watercourse at the bottom of the principal valley ; the stream is not perennial, and water is only found in it during what may be termed the rainy season, or for a short time after continued heavy rain ; it falls over a series of rocks before entering the sea. There are no springs on the island, consequently no water is the only fresh water to be obtained. The plateau on the top is about 150 yards one way by about 20 yards the other ; it is surrounded by small precipices, the deepest of which is a fall of about 20 feet on the south-eastern side. The greater part of the plateau is a bare rock, soft and crumbling on the surface from the sun's warmth. The sandstone strata of the top or plateau, lie almost horizontal, but generally they have a steep south-east declension. The sandstone appears to be same as that of which Round Island and part of Flat Island is composed ; numbers of shells and coral are embedded in it.

LA MORTOLA, ITALY : *Nov.* 20.—The observation of my friend, M. Naudin, in a recent number, that in his garden at Collioure Passiflora cœrulea fails to set its fruit, occasions me surprise. Here, as at Collioure, the plant grows half wild, spreading out by means of suckers ; it flowers profusely, produces an abundance of fruits having seeds which germinate freely. As the plant grows with vigour, it forms a good stock on which to graft other species, such as the more ornamental Tacsonia ignea (manicata ?). *Apropos* to Passion-flowers, I may remark that the Granadilla thrives well, and that a plant on a southern wall here produced, during the past summer, several hundred fruits, which, in spite of their numerous seeds, were by no means disagreeable eating.

Many Cape plants grow well here, but not those like the Heaths, that require a sandy soil. We are also able to cultivate successfully several species of Eucalyptus and Casuarina, innumerable Acacias, Banksia marcescens, and some Grevilleas. Dryandras are well worth trying, but seem difficult to procure. The beautiful Stenocarpus Cunninghamii does not thrive, nor have we had any success with Castanospermum australe. *Dan. Hanbury.*

SYDNEY, NEW SOUTH WALES : *September* 2.—I observed in the *Gardeners' Chronicle* of May 13, you had inquiries from Mr. Long as to the Fern with adventitious buds, and attached to it the name of Alsophila excelsa, but at that time you could not have received the letter I sent by the following mail correcting the error I made in the name of the Fern to Dicksonia squarrosa. I regret my error in nomenclature the more, as Dicksonia squarrosa is naturally disposed to throw out adventitious or rather axillary buds, without having received any injury to the stem. This has been observed in this Fern when growing in its natural state in New Zealand, as well as in the plants of all ages growing in the Sydney Botanic Gardens ; and on minutely examining the latter specimens, not the slightest injury could be detected in the stem from whence the adventitious buds emanated—indeed, whether in the wild or cultivated state, this Fern may be said to be seldom or never seen without them. This deviation is not seen in Alsophila excelsa or others of the Tree Ferns of New Zealand or Australia, with the exception, in the latter colony, of Dicksonia Youngiæ of C. Moore. This Fern has been mentioned in Hooker's "Synopsis Filicum" as identical with D. squarrosa of Swartz, whereas D. squarrosa is a native of New Zealand, and D. Youngiæ is only found in the warmest parts of New South Wales ; and when these Ferns are seen growing together (as they are in the Sydney Botanic Gardens), they have evidently a very distinctive character, for on the examination of plants of equal size, the pinnæ and the pinnules are much longer and not so rigid in D. Youngiæ as in D. squarrosa, as may be seen by the enclosed specimens, two of each species. (Quite distinct. EDS.) I observed in a plant of D. Youngiæ in a pot, which had grown about a foot in height, an adventitious bud had been developed a very short distance from the base of the stem, which was evidently not the result of injury. The pinnæ enclosed of each species were taken from plants grown of equal size. Moreover, D. Youngiæ has only as yet been found in one particular locality, viz., on the Richmond River, north of Sydney, New South Wales, occupying an area of about 10 acres. It is not a little remarkable that this latter species also throws out adventitious buds without having sustained any injury to the stem. Can this deviation be peculiar to Dicksonia ? *George Bennett, M.D., F.L.S., &c.*

AGRI-HORTICULTURAL SOCIETY'S GARDEN, MADRAS.—In your issue of October 7, I see a notice of variegation caused by grafting, in Mr. W. Paul's nursery, Waltham Cross. I have had the privilege of observing three cases of variegation of plants within the last 12 months. In one case the plant was Thespesia populnea, the other two are Calophyllum Inophyllum. The former was evidently caused by an injury to the stem of a young seedling, as under the part injured there was a branch perfectly green. In the latter two cases, as far as I can ascertain, there had been no injury, the plants having been picked from among a batch of healthy seedlings. One of them died through becoming too white, but the other is a healthy plant ; and should I succeed in rearing a stock, and in safely importing them to England, they will, with their beautiful dark glossy-green and creamy-white leaves, be a great acquisition to the many variegated-foliaged plants already in our stoves. *John M. Henry, Superintendent, Nov. 1.*

Societies.

ROYAL HORTICULTURAL ; *Dec.* 6.—James Bateman, Esq., F.R.S., in the chair. At the meeting, after the usual preliminary business, the chairman of the Fruit Committee announced the awards of that body, and subsequently stated that consequent upon the formation of the new garden at Chiswick there was plenty of very good wall accommodation which he had no doubt the Council, if requested, would place at the disposal of nurserymen for the exhibition of well trained trees. Mr. Marshall then commented upon some of the productions brought before the Floral Committee, and showed to the meeting some cut blooms of Scarlet Pelargoniums, of which he did not think gardeners, as a rule, made enough for winter decoration. All they had to do was to pot a few of the best of their earliest struck cuttings into 8-inch pots, and grow them on in a warm greenhouse, where in the dull months nothing would be more useful for display or more serviceable for cutting for bouquets, &c.

The Rev. M. J. Berkeley, referring to a beautiful cone-bearing spray of Picea nobilis before him, remarked that many Conifers which rarely fruited in this country were this year producing cones in abundance, a fact which he thought was due to the summer of 1870 being so warm that the wood had been better ripened than usual. He next showed to the meeting a specimen of Billbergia Moreliana, with a solitary drooping panicle, bearing purplish-crimson flowers, to show what a beautiful object it was, grown, as was the case in this instance, in a cool house. Referring to the fruit of the Osage Orange (Maclura aurantiaca), a specimen of which was exhibited by E. Hoyle, Esq., that had ripened on a tree 40 feet high, in the Botanic Garden at Parma, Mr. Berkeley stated that the fruit never came to perfection in this country. It had been recommended by the late Dr. Lindley as a good hedge plant, but though it was hardy at Margate and Folkstone, and a few other places, it was not so in all parts of England. The specimen, said the speaker, puts one in mind of the Breadfruit, though it belonged to the same order as the Mulberry (Moraceæ). Coming next to the subject of Hops, Mr. Berkeley said the question had recently been put to him, as to whether it was not to the same order as the Nettle on account of their becoming delicate in constitution ? On this he wished to state that Dr. Plomley, in his Hop garden at Maidstone, some years ago, used only to manure his plants with the ash, and no plants could be healthier, though he ought to state that the ground was good, and no doubt full of phosphates.

Mr. Bateman, after commenting upon the Osage Orange, said he had not yet succeeded to fruit it either in his garden in North Staffordshire, though he believed it was ripened some years ago in the neighbourhood of Falmouth, and upon the cones of the Picea nobilis, said that quite a trade was springing up in Scotland in cones, a friend of his having, but a short time ago, been offered £70 by an Edinburgh nurseryman for the cones upon a single tree of Picea nobilis. The Douglas Fir was, without doubt, the one for Scotland and Ireland and in the former country, especially, it was being planted in thousands. Commenting upon the Golden Yew, shown by Messrs. Standish & Co., he mentioned that many people would scarcely credit their value, but the late Lord Harrington collected at Elvaston enough to make a hedge, which was valued, shortly before his death, at £10,000. He then directed attention to a collection of models of tropical fruits which had been shown at the late International Exhibition by the India Office, who

had generously presented them to the Society, and to whom he proposed that an unanimous vote of thanks should be given. He remembered some 50 years ago having seen in Bullock's Museum a similar collection of the tropical fruits of America, and he was quite sure that if any gentleman possessing this collection would present it to the Society, their best thanks would be given to him.

In conclusion Mr. Bateman alluded to the losses which the Society had recently sustained in the death of Sir Roderick Murchison, Mr. William Baxter, and, more recently, of Mr. Bellenden Ker.

Scientific Committee.—A Grote, Esq., in the chair. The Secretary read the following letter from Mr. Anderson Henry, relating to a new hybrid Begonia :—

"I have this season flowered a seedling Begonia, the produce of Begonia Pearcei × B. boliviensis, again crossed with B. Veitchii, the seed having been fertilized by a hybrid of my own of 1869. Before operating upon it I divested the female flower of two of the three lobes of its stigma, securing it from all other influences save that of B. Veitchii, as well after as during. The produce of this double hybrid—double, at least, on one side—is a plant of almost specific distinctness, but bearing only female flowers—a dioecious plant, wholly unlike any of its parent species, which are all monoecious. I have succeeded in preserving only one plant of this cross.

"I have somewhat analogous experiments among the above tribes yet waiting to be tested.

"One other thing I wish to refer to is a singular tendency I have observed in some plants, creepers, to repel or withdraw from the contact of others, *e.g.*, I have an Ampelopsis Veitchii running up a tower, apparently to avoid a Pyracantha (Thorn) running up alongside of it. The natural tendeocy of the former (both on a west aspect) I thought should have been to the sun; whereas, as if to escape the latter, it tends to the north. I pointed it out to my neighbour, Colonel Rankeu, to-day, and he said he had heard something of the same kind as regards the Ash tree, and that certain other trees grew away from, as if repelled by, it. On the other hand, I have on a wall adjoining the tower I've running up, which, where originally apart, seem, as the shoots grow up, to attract each other. Has any such law as that of attraction and repulsion been observed among plants? Can there be any such law?"

Some conversation arose on the points mentioned in Mr. Henry's letter, Dr. Masters stating, on the authority of Dr. Hooker, that a similar change in sexuality had been observed in a new hybrid Begonia, raised in the South of France, and concerning which we shall have more to say on another occasion. In the meatime it may be mentioned that the origin of Begonia frigida, which bears hermaphrodite flowers, and which was the subject of much discussion in these columns in 1860, is not known. It is hence possible that the plant in question may be of hybrid origin.

Mr. Berkeley exhibited a leaf of Ficus reticulata, with supplementary leaves springing from the ribs on the under surface. This occurs constantly in, and other instances with the inferences drawn from them are to be found in, Dr. Masters' "Vegetable Teratology, pp. 31, 445. Mr. Berkeley also showed curious succulent stolons from Mimulus moschatus, which appeared never to have been observed before.

Leaves of a Beech with a peculiar gall thereon were shown, and which were referred to the entomologists for examination.

Mr. Blenkins exhibited a specimen of Cynomorium coccineum, in spirits, from a rock adjacent to the island of Gozo (Malta), and alluded to its parasitic habit, its empyreumat of old by the Knights of Malta as a styptic.

Mr. Murray showed specimens of a ladybird (Epilachna), which had been sent to Dr. Masters by M. Naudin, from Collioure, the larve of which are plant-eaters, instead of being, as other ladybirds are, aphis eaters. This subject will be treated of at greater length, and illustrated by Mr. Murray, in a future number of the *Gardeners' Chronicle*. Mr. Murray also showed a species of Coccus, from Guatemala—a large species, used to colour wood of a grey-rose colour.

A Teazel sent by Dr. Moore, of Glasnevin, remarkable for its spirally coiled stem, the leaves being in consequence arranged "alternate instead of "opposite".

Dr. Masters also laid on the table the report of the observations made on the growth of certain plants at Chiswick under the influence of different manures for the second season, 1870-71. This report is somewhat lengthy; its general conclusions tally pretty closely with those of the former year, and some of them, of importance to practical cultivators, will be alluded to in these columns on a future occasion. A vote of thanks was passed to Drs. Gilbert and Masters, as reporters of the sub-committee appointed to superintend the experiments now brought to a close by the curtailment of the Chiswick garden.

Fruit Committee.—G. F. Wilson, Esq., in the chair. The interest in this meeting was greatly enhanced by the exhibition on the part of Messrs. Lane & Son, Berkhampstead, of a basketful of excellent Cobham Pines; and a fine display of vegetables made by Mr. W. Pragnell, gr. to G. D. W. Digby, Esq., Sherborne Castle, Dorset. These were shown in competition for the prizes offered by Messrs. Carter & Co., and included capital samples of several varieties of Carrots, Parsnips, Cabbage, and Onions, and of Lettuce, Flanders Spinach, Radishes, Brussels Sprouts, &c. The 2st prize was awarded. In the collection of Grapes from Messrs. Lane 12 varieties were represented, amongst which the most noticeable were good shaped, capitally finished bunches of Alicante and Muscat Hamburgh, large bunches of Trebbiano and of Barbarossa, the latter being a little uneven in the size of the berries; and a remarkably well kept bunch of Muscat of Alexandria that was ripe in July, and still in a plump, fresh condition. A Special Certificate was awarded. A similar honour was so paid to Mr. G. Johnstone, gr., Glamis Castle, for two very fine smooth-leaved Cayenne Pines, weighing 16 lb. A good fruit of the same variety, weighing 7 lb., was also contributed by Mr. Peagnell. To Mr. William Robinson, 37, Southampton Street, Strand, a Certificate of the First Class was voted for a new winter Radish, the seed of which he brought from California. The specimens, of which the annexed illustration (fig. 334) gives a fair idea, were brought from the Chiswick Garden by Mr. Barron, from seed sown in the second week in August. They averaged from 8 to 12 inches in length, and about 2½ inches in diameter in the thickest part, the flesh being white, solid, and of very good flavour. The leaves are long and strap-shaped, and in general appearance the whole is not unlike the *sablons* Turnip. The Committee entertained a high opinion of its merits for winter use, and especially for cutting up for salads. From Mr. D. Piccirillo, Wigmore Street, came fine examples of the Naples Champion Cauliflower, which the Committee considered to be identical with Veitch's Autumn Giant; and from Messrs. Criscuolo, Kay & Co., Gracechurch Street, came good specimens of a new Italian Tripoli Onion, which they say are recommended for their quickness of growth and mildness of flavour. Mr. Trigg,

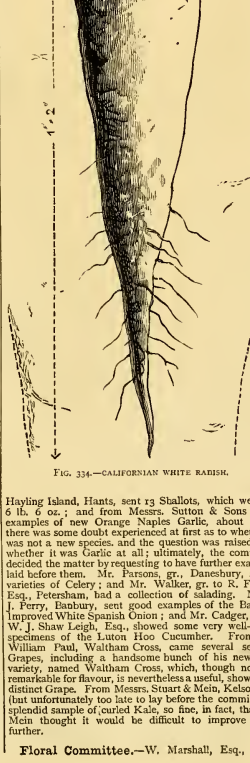

FIG. 334.—CALIFORNIAN WHITE RADISH.

Hayling Island, Hants, sent 13 Shallots, which weighed 6 lb. 6 oz.; and from Messrs. Sutton & Sons came examples of new Orange Naples Garlic, about which there was some doubt experienced at first as to whether it was not a new species, and the question was raised as to whether it was Garlic at all; ultimately, the committee decided the matter by requesting to have further examples laid before them. Mr. Parsons, gr., Danesbury, sent 6 varieties of Celery; and Mr. Walker, gr. to R. Fowler, Esq., Petersham, had a collection of salading. Mr. P. Berry, Banbury, sent good examples of the Banbury Improved White Spanish Onion; and Mr. Cadger, gr. to W. J. Shaw Leigh, Esq., showed some very well-grown specimens of the Luton Hoo Cucumber. From Mr. William Paul, Waltham Cross, came several seedling Grapes, including a handsome bunch of his new white variety, named Waltham Cross, which, though not very remarkable for flavour, is nevertheless a useful, showy, and distinct Grape. From Messrs. Smart & Mein, Kelso, came (but unfortunately too late to lay before the committee) a splendid sample of curled Kale, so fine, in fact, that Mr. Mein thought it would be difficult to improve it any further.

Floral Committee.—W. Marshall, Esq., in the chair. This, the last meeting for the year, was as usual in this season a small and comparatively uninteresting one. Two First-class Certificates only were awarded to a small specimen of Argyroxyphium Douglasii, a Composite plant recently introduced from the Sandwich Islands, shown by Mr. Green, gr. to W. W. Saunders, Esq. In habit of growth it somewhat resembles a small Littwa, having a swollen base, and narrow, slightly curved, silky leaves of silvery whiteness; it will, when it becomes larger, be a handsome decorative plant, and a welcome one for table decoration. The other Certificate was voted to Mr. Goddard, gr. to H. Little, Esq., Cambridge Villa, Twickenham, for Cyclamen persicum Queen of Crimson, a very velvety crimson, the darkest shade we have yet seen in Cyclamens. Prizes were offered for a collection of hardy evergreen plants, bearing berries (Hollies excluded), but there was only one group shown, that from Messrs. Standish & Noble, Bagshot, which had a 1st prize was given. It contained very nicely grown specimens, in pots, of Aucubas, Cotoneasters, Skimmia japonica, and Pernettya mucronata, with reddish crimson berries, and P. pulosa, with black berries, both very showy plants when well grown and closely studded with fruit. Messrs. Standish & Co. also took a 1st prize for "nine hardy evergreens of the Yew or Cypress type" with a very interesting group, which included, amongst others, a fine specimen of Taxus fastigiata aurea, a beautiful golden variegated (not striped) seedling, raised by Mr. Standish some 20 or 12 years ago, it having come up amongst a batch of seedlings of the Irish Yew. It has the merit of not becoming burnt, like the golden striped varieties, on the sandy soil at Ascot. These striped varieties do best on clay soil, and in positions where they do not get much sun. In habit it is as compact as the true Irish Yew, and for studding about on lawns it is one of the most valuable variegated plants yet sent out. Along with it was another plant, also a beautiful object, for the same purpose, Cupressus Lawsoniana fragrans, a very compact, glaucous, pyramidal-habited plant, one of a lot sent out some years ago by Mr. George Jackman under the name of C. fragrans, but which when it fruited proved to bear fruit similar to that of the true C. Lawsoniana, of which it is no doubt a distinct variety; also Retinospora lycopodioides, the most distinct of all the Retinosporas, and very hardy, the specimen shown being perhaps the largest in England; and Taxus coriacea, a Japanese form, with broadish, leathery, deep green leaves, and which is said to be exceedingly hardy, thriving at Dresden, and also at New York, where no other Yew will grow. Messrs. Standish & Co. also exhibited a nice specimen in flower of Asparagus decumbens, a native of the Cape, from whence it was introduced by Mr. Wilson Saunders, who exhibited here two or three years ago, but not in flower, this being the first time of its showing flowers, which are small, white, and rather strongly scented. It has a slender climbing habit of growth, and will prove invaluable for wreath work, and especially for cutting in bits for bouquets. From Mr. J. Freeman, gr. to Sir J. Schright, Bart., Beechwood, Dunstable, came a nice spray of Picea nobilis, on which were very fine cones, cut from a tree 58 feet high; and R. Keen, gr. to J. G. Shephard, Esq., Campsey Ash, Wickham Market, sent two tree-flowering Carnations, Miss Joliffe, pink, with a tinge of crimson in it, apparently a free-flowering variety, and nicely scented; and Monsieur Baldin, bright blood-red, and taller in habit of growth than the first named. Messrs. Downie Laird & Laing exhibited a new white form of Primula sinensis fimbriata, with white flowers, from 1½ to 2 inches across, with a prominent greenish-yellow eye; and Mr. J. Chambers, gr. to J. Lawrence, Esq., Beddington, Surrey, sent cut flowers of the delicate showy violet and white Ipomœa celestina. Mr. J. George, gr. to Miss Nicholson, Putney Heath, had a well merited extra prize for a beautiful box of cut flowers, which included white Camellias, Azaleas, Begonias, Poinsettias, Strelitzia reginæ, Cypripedium insigne, Heath, Primulas, and Rhododendron, attractive blue flower, which, however, does not stand travelling. To Mr. B. S. Williams a Special Certificate was voted for a nice group of improved hybrid Solanums. Messrs. Veitch & Sons exhibited Cyclamen Capaccum Yellow Gem, a very free-bearing and showy kind, the plants being tolerably bushy, on clean stems. The prizes for cut blooms of Japanese and late flowering Chrysanthemums came out a very nice display; the best 24 coming from Mr. E. Rowe, gr., The Rookery, Roehampton, and which included nice flowers of Dr. Masters, Red Dragon, John Salter, Mr. Brownlow, Lady Hardinge, Miss Mary Morgan, and Mrs. Haliburton. The 2d prize was taken by Mr. Douglas, gr. to Francis Whitbourne, Esq., Loxford Hall, who had some very nice flowers, especially of the Japanese forms, Grandiflora, Dr. Masters, Lang, and Eclipse. The other competitors were Mr. G. Goddard, Mr. J. George, and Mr. T. Hobbs, Lower Easton, Bristol. Very good stands also came from Messrs. Jackson & Son, Kingston, and J. Shrimpton, gr., to Mrs. A. Doxat, Putney Heath, the former receiving a Special Certificate. Messrs. Rendle & Burrows exhibited a model of a span-roofed frame, and also of a lean-to one, showing a new patent improved sash bar, by means of which the method of fixing glass is dispensed with. This is done by fixing the glass by means of cramps placed on the sash-bars, on either side of which are gutters to carry off water if any should enter. The following advantages are claimed for it by the patentees:—"Requires no putty, paint, indiarubber, felt, or the like. Is perfectly waterproof and can be made quite air-tight if necessary. Is very economical. Exceedingly simple, and can be repaired with great facility; requiring only to remove the screw in cramp to loosen four panes. It has great advantages over other inventions, the fastenings not being fixed tight down on the glass, which thus prevents breakage of the glass by expansion of the metal in hot weather. Is very portable, occupying little space when packed. If made in zinc or iron is indestructible. The sash-bars can be had either in zinc, wood, cast, sheet, or wrought iron, according to the size of the buildings." A model of a new hot-water circulator was also shown by Mr. W. Umpleby, gr. to Miss Rawson, Nydd Hall, near

Leeds, upon the merits of which the Committee expressed no opinion.

HORSHAM LITERARY INSTITUTION: *Nov.* 28.—The Rev. J. F. Hodgson, vicar, gave a lecture on the Natural History of British Fungi, with incidental notices of the esculent and poisonous varieties. The lecture was illustrated with large diagrams, affording a synopsis of the whole order, with its 2 cohorts, 6 families, 30 orders, 800 genera, and 5000 species. The distinctions between the several families were explained, but the entire field being so wide the lecturer drew special attention to the first family—that of the Agaricini, 9 gilled Fungi, of which he presented a complete synopsis. His friends had furnished him with large coloured drawings of the various species figured in the valuable plates of Dr. Badham, Mr. Cooke, and more especially Mr. W. G. Smith, and being arranged according to their genera, subgenera, and species—those esculents at the top and poisonous immediately below—he was enabled to illustrate the entire order, and this intricate matter was rendered comparatively perspicuous even to a general audience. The drawings of Amanita were really beautiful, having been executed by a first-rate lady artist of the neighbourhood. To the well-known Agaricus rubescens and the fir-cone Agaric was appended a splendid drawing of the celebrated Italian Agaricus Cæsarea, the "Boletus" of antiquity, the *facile princeps fungorum*, which a slave might not be entrusted with, according to Martial, for fear he should eat it on his way. This was the vehicle for the poison which settled the fate of the Emperor Claudius, sent him *in cælum* before his time, therefore called thenceforth *Deorum Cibus*, and to this day also called "Cæsarea." The lecturer dwelt particularly on Agaricus (Amanita) muscarius and its intoxicating qualities, leaving the impression that it was this which was inadvertently eaten by, and consequently sealed the fate of, the unfortunate Norfolk clergyman, the Rev. W. F. Welch; and at the same time remarked that this poison of A. verna was infinitely more virulent, four grains of the fresh plant being enough to kill a dog.

The merits of Agarics were next discussed, and A. procerus, A. gambosus, A. personatus, A. nebularis, A. deliciosus, A. georgianus, A. ostreatus, A. campestris, and A. arvensis (well pictured and described), obtained their full and well merited share of praise. It was shown how the sub-genera were distinguished by the colour of the spores, the arrangement of the gills, &c. The virulently poisonous species were also clearly drawn and dwelt upon, not that any of them would be found tempting except the "salmon-spored" A. (Entoloma) fretilis, a large fine Mushroom, growing in woods. Here the lecturer highly amused his audience by reading the experiences of Mr. W. G. Smith himself, who, when a novice, had very nearly succumbed to this "furiously" poisonous species. The lecturer was greatly indebted to this gentleman for a number of plates of spores of various strange shapes magnified to 10,000 diameters; and it was stated of the smallest variety that it would take 10,000,000 to cover a square inch, while Coprinus comatus, and Cortinarius violaceus, not one of which even a novice could mistake, were then noticed. The esculent varieties of Lactarius and Russula were next clearly distinguished from the rest; and, lastly, the Chantarelle and Champignon received their due encomium. Boletus edulis came in for its share of notice, with its natural ally, Ixtulina lapidea, also Polyporus repandum, a specimen of which was handed round.

The Stinkhorn was not forgotten, a dried specimen being forthcoming, about which there were some amusing recollections of its fetid odour in the fragrance it spread. The Giant Puff-ball was much commended, but not so the Lycoperdon cælatum, a tender-looking, encrusted, and smaller species. The genus Clavaria was greatly eulogised, especially commending to the "candy" taste the remaining orders of Hymenomycetous Fungi, viz., the leathery and gelatinous Fungi, having been then briefly noticed, and the four next families microscopically alluded to, the lecturer passing on to Ascomycetes. Amongst these, of course, the Truffle, the Morel, and Helvella crispa obtained their merited distinction; nor was the beautiful Peziza left out of consideration. On the whole, of the various orders of esculent Fungi, the palm was given to the Orange Lactarius, L. deliciosus, Agaricus prunulus, the Champignon, Boletus edulis, and the large Puff-ball when about the size of a croquet ball, and eaten the same day as gathered.

In the course of the lecture a largely spiced brewing of the Potato blight was exhibited, and the mode in which it destroys the plant described; also drawings of the "book" Fungus, the lecturer handing round some valuable books of his own which had been partially destroyed by its unwelcome ravages.

The lecture was interspersed with amusing anecdotes, not the least so being an account of a youth at Cirencester Agricultural College who one day brought home a Fungus, cooked it, and within half an hour found his uvula swollen up in his mouth as large as an orange, which occasioned "Smith's plates" to be introduced into the library, where the lecturer first saw them with the book of descriptions, whence his subsequent addiction to the pursuit, truly characterised as one which will "lead from joy to joy."

Notices of Books.

Spiritualism and Animal Magnetism, &c. By Prof. G. G. Zerffi. Hardwicke. 1871. Pp. 143.

The object of this volume is to supply a rational explanation of dreams, spectral visions, and spiritual manifestations. There is not even a ghost story, says the author, which cannot be explained from a natural point of view. Such phenomena are all subjective, and are referred by our author to the action of "the organ of dreams," an assumed organ, which is further assumed to have its seat in the ganglionic nerves, and to be acted on by many forces, of which the most effective is animal magnetism.

The spectral visions are the result of a disturbed balance between the positive and negative magnetism. Moreover, "persons in whom negative magnetism is predominant see, hear, smell, feel, taste, and even think whatever an individual charged with positive magnetism wills." The author condemns unsparingly the jugglery of so-called spiritualists, and the credulity of their followers, but it remains to be seen whether the explanations(?) given by Dr. Zerffi are one whit nearer the truth than those offered by the spiritualists. He classifies dreams as—*a*, dreams without reasoning; *b*, half dreams; *c*, theomantic dreams; *d*, allegorical dreams; *e*, somnambulic dreams; *f*, clairvoyant dreams; *g*, visionary dreams.

The author's work appears to us to fall best under the latter category.

Internationales Wortbuch der Pflanzen-namen, &c. (International Dictionary of Plants, in Latin, German, English, and French, for Botanists, and especially Horticulturists, Agriculturists, Students of Forestry and Pharmaceutics.) By Dr. William Ulrich. Leipsig. 8vo. Part I. (Williams & Norgate).

A polyglot dictionary of plant names, compiled by one sufficiently conversant with modern languages and with botany to be a great boon to botanists, and more especially to gardeners and nurserymen. Its philological value would also be considerable. How far the author of the Dictionary, of which the first part is now before us, is qualified for his task, is to us doubtful. Assuredly the English preface is not calculated to impress the reader with any high estimate of the author's knowledge of our language. His mode of spelling the Latin names is not a whit more reassuring. A few illustrations taken at random will show that our fears are not altogether groundless. Sibusa Lynapian, we are told, is called in English "Foot's Parsley, Garden Dog Poison." The "foot" is doubtless a mere misprint for "fool," but as to the second appellation we are left in doubt as to whether the poison is intended for dogs that commit trespass in gardens, or whether the word garden is introduced to distinguish it from some distinction to some wild plant used for poisoning dogs. A similar mystery environs the English equivalent for Amaranthus caudatus, which is rendered Love-his-bleeding. Whose bleeding? we feel tempted to ask, and why are we to love it? Amaryllis formosissima is given as the "very white Lily," and we no doubt it is, but the author's qualification is certainly not a nice rendering of the Latin term. Neither is a Bucramon at all a familiar word in English for the Snapdragon, Antirrhinum majus. Bunkin, as a name for the Aristolochia Serpentaria, assuredly not in common use in this country. In fine, so far as we can judge from the part before us, which extends from A to CE (in Latin), the work will be of little use to Germans or French wishing to become acquainted with English names. On the other hand an Englishman familiar with the Latin and English names of any particular plant may feel greater confidence in turning to the nomenclature for the German names. As a book of this character is much wanted, and Dr. Ulrich has no doubt accumulated his material and arranged his manuscripts, we earnestly advise him to submit the latter to the revision of competent French and English authorities before proceeding further with their publication, to withdraw the present part, and re-issue it in a revised form. As the author has probably never heard of Dr. Prior's work, it may be doing him a service to refer him to the pages of that useful publication for information as to English plant names and their equivalents.

We could hardly expect in such a work that the derivations should be given. The researches of philologists have, however, rendered a revision of the ordinarily accepted derivations absolutely essential. Thus Anacardium, generally derived from the Greek, and considered to be intended as an allusion to the heart-shaped form of the pedunole or of some other part of the plant, is now by Sanskrit scholars with more probability referred to the Sanskrit vrannakrta, the name applied to a plant, and itself derived from vrana = wound, and krt, to produce or create.

Florists' Flowers.

WHEN a raiser of the VERBENA exhibits some nine or ten seedlings in the course of a season, and succeeds in obtaining First-class Certificates for five of them, it must be assumed that the improvement of the Verbena goes on steadily and surely from year to year. Raisers are actively engaged in the production of new varieties, and nurserymen in their distribution; therefore the Verbena must be in demand. It is in demand for exhibition purposes much more largely than is imagined, and if any one wishes to see the Verbena exhibited well, other than by Mr. C. J. Perry, a visit should be paid to the summer exhibitions held at Sherborne, Taunton, Yeovil, Shepton Mallet, &c., where stands of Verbenas are set up that would fairly test the resources and mettle of even Mr. Perry.

It is Mr. Henry Eckford, of Coleshill, who has this season won five First-class Certificates for seedling Verbenas, and in a batch of seven varieties to be distributed by Mr. Keynes next spring four of these will be included; one named Lady Braybrooke being held over, probably for want of stock. The following are the certificated flowers:—Lady Edith, pure white, with a pale rosy purple ring round the eye, very large rounded pip, and fine truss; Lady Gertrude, very pale lilac, with a rosy mauve ring round a lemon eye,—novel and good, and of fine quality; Mauve Queen, pale lilac-mauve, with a large sulphur eye,—quite new in colour, distinct, and of good quality; and Pluto, orange-red, shaded with dark round a large and bold lemon eye; pip and truss of fine quality. The rest remainder of the batch consists of Grand Duke, cerise-crimson, large rounded pip, and splendid truss; Isa Brunton, plum-colour, tinted with blue, large white eye,—very distinct, and having an excellent habit, suited for bedding purposes; and Royalty, dark crimson-scarlet, considered by Mr. Eckford to be one of the most promising bedding varieties he has yet distributed, having a dwarf, compact, short-jointed habit, and being very profuse of bloom: the colour also is likely to stand exposure.

Mr. C. J. Perry confines himself to a batch of six new varieties, that will be distributed, as usual, by Mr. C. Turner. But one First-class Certificate fell to Mr. Perry's lot this year, viz., for Emma Weaver, a bold and handsome flower, colour blush-white, with a large and striking violet centre; habit excellent. The other varieties consist of Carnation, white ground, distinctly edged with scarlet and crimson, bright-looking, highly effective, and a good addition to the pretty striped varieties; Hero, bluish-grey, with dark centre, large pip, and of fine form; Queen of Pinks, delicate soft pink, with large white eye, very pretty and distinct; Sophia Dorothy, very deep crimson-carmine, novel and fine; and Sprite, delicate blush white, with small pink centre, of exquisite form, and very pretty.

Mr. H. Eckford recommends the early planting-out of Verbenas, if they have been sufficiently hardened off in cold frames. The Verbena has a somewhat wiry growth, and if this is made tender by heat and gradual hardening in cold frames, it is made capable of withstanding considerable exposure. Even if but little growth is made, owing to the weather being inclement, the degree of harm done to the plants will be small, and they will be drawing root, and as soon as warm weather opens, they burst into a rapid growth. Whatever be the habit of the variety, let it have a rich soil in which to grow; the starving process, to neutralise strength or redundancy of growth, is a mistake. If a variety grows freely and blooms sparingly in a rich soil, the result would scarcely be better in a poor one; and nothing looks worse than to see half-dead Verbenas in starved ground after a spell of hot dry weather in the month of August. Bedders-out are scarcely sufficiently alive to the value and effectiveness of mixed beds of Verbenas, nor will they, till the rage for masses of colour in the flower garden declines. Then, bold Phlox-like pips, and bright and delicate parti-coloured tints, that appear to rest on a dense undergrowth of foliage, make very pleasant pictures; and all that is required to keep them fresh and neat is the occasional picking off of the decaying trusses. Granted that a storm of rain or hail soon strips a bed of its beauty; but the gloom is only momentary—that singular fertility of bloom so remarkable in the Verbena soon supplies the place of the destroyed flowers; every joint of a branch appears to supply trusses of bloom, and the plants maintain this fertility of resource till quite late in the season. The Verbena cannot yet be spared as a bedding plant. *R. D.*

Nov. 30.—Snow fell occasionally during the morning, and rain in the afternoon and evening. Generally overcast.

Dec. 1.—Variable amount of cloud prevalent, increasing toward night. A little rain fell occasionally. Strong wind.

" 2.—A little light cloud present at times. Hazy and foggy. Hoar-frost.

" 3.—Overcast in morning; cloudless and very fine from noon onwards. Snow fell in early morning.

" 4.—A generally fine day, with variable amounts of cloud. Snow fell occasionally.

" 5.—Generally cloudless till night; then variable. A little snow fell at night.

" 6.—Generally overcast. Snow fell in the morning.

JAMES GLAISHER.

Obituary.

The death recently of one of our oldest contriburtors, Mr. Bellenden Ker, at Caunes, demands notice from us. Mr. Ker was known some 20 years since as an enthusiastic plant-grower. His articles in these columns, under the signature of "Dodman," were much esteemed for their pungency of expression and common sense. Mr. Ker was also for some time editor of the "Botanical Register," and though he did not bring to his task the botanical knowledge of his successor, Dr. Lindley, the accuracy of his descriptions of the specimens before him was quite unrivalled. For some years past, Mr. Ker had taken no active part either in horticulture or botany.

Miscellaneous.

The Common Cuckoo (Cuculus canorus) is a very common bird in the whole of N.E. Africa, which it traverses rapidly in spring and autumn, and seems to spend its winter in the equatorial regions. Heuglin never saw it in perfectly youthful plumage in N.E. Africa. In April it arrives from the south in March up to the beginning of May, and in August it returns to the south again. It takes its migratory flights singly; for, although tolerable numbers may be observed collecting in the small Acacia woods, avenues, and Palm groves, yet none of them concerns itself about its neighbour but pursues its journey alone. As to locality, the cuckoo in Africa is not particular. It is found in the plains round Alexandria, not unfrequently in low Date Palms. In Central Egypt more in gardens, especially in Olive plantations, on Lubach in Sycamore trees, Tamarisks, and Acacias, about dwellings and ruins. In the steppes it is often seen in quite low bushes; in Soudan in thick forests, either in marshy country, lowlands, or high mountains. It flies generally north to south, and it returns mostly following the Nile or the coast of the Red Sea; but it also wanders far into the arid wastes of the coral islands of the latter. Heuglin, during his several years' residence in N.E. Africa and Arabia, never heard the bird's well-known cry. The same is asserted by Jesse and Brehm; but Professor Hartman says he heard it in March at Der (Lower Nubia), in April at Old Dongolah, and in the first week in Jan. On the woods of North Sennaar, in September at New Dongolah, and in October at Siut. In all the African specimens Heuglin found the iris always of a more or less deep brown. The common cuckoo occurs in Algeria, St. Thomé Island in the Gulf of Guinea, Madeira, South Africa (?), Madagascar (?), Mauritius (?), over the greater part of Asia eastwards to Japan and Timor, in Europe northwards to 70° N. lat. *Field.*

The Californian Thistle.—The following Notes were read before the Royal Society of Tasmania by Mr. W. Archer, F.L.S.:—

"The genus Carduus, as established by Linnæus, consists of what are called 'true Thistles,' with a hairy pappus or calyx; and 'plume Thistles,' with a feathery pappus or calyx. Bentham, in his "Handbook of the British Flora," follows Linnæus, but some botanists class the 'true Thistle' under the genus Carduus, and the 'plume Thistles,' under the genus Cnicus or Cirsium. The Milk Thistle (Carduus Marianus) represents the true Thistle in Tasmania, and the Carduus lanceolatus, or Spear Thistle (Cnicus lanceolatus of the British Flora of Hooker and Arnott), the Plume Thistle. The Spear Thistle of England is what is called in Tasmania the Scotch Thistle; but it is not by any means peculiar to Scotland. (The Scotch heraldic Thistle is the Onopordon acanthium, which is a native of Central Europe and of Asia, but certainly not a native of Scotland, according to Bentham.) The Spear Thistle (Carduus or Cnicus lanceolatus) has a biennial root-stock, which sends up for two years (after which it dies) annual stems, winged and prickly, with broadish, pinnatifid, prickly-lobed leaves, and large, egg-shaped flower-heads, enveloped in involucral spreading bracts, with stiff, largish prickles. The Creeping Thistle (Carduus or Cnicus arvensis) has a perennial and creeping root-stock, which sends up perpetually, annual stems, with rather narrow, pinnatifid, very prickly-lobed leaves, and diccious flower-heads—the male flower-heads nearly globular, and the female flowerheads egg-shaped, enveloped in involucral appressed bracts, with small prickles. Both the Spear Thistle and the Creeping Thistle are found abundantly in Europe and Asia. The Spear Thistle is, of course, the more easily destroyed of the two; the Creeping Thistle seems to be quite ineradicable. The Creeping Thistle is mentioned by Prof. Johnston as being called in the United States of America the Canadian Thistle—probably because it travelled thither from Canada; and so, I suppose, the same Thistle is called here the Californian Thistle because it has come from California. It is nevertheless, the Creeping Thistle of Great Britain, and it never quits a country into which it has been introduced."

The Baobab or Monkey Bread (Adansonia digatata, L.) is popularly known on account of the immense diameter of its trunk, and the various notions that have been from time to time propounded as to its probable age. The great age of individuals speaks of the Baobab as "the oldest organic monument of our planet." The earliest account of the tree is given by a Venetian named Aloysius Cadamosto,' who, in 1454, discovered one growing in Senegal whose trunk measured 112 feet in circumference. Adanson, in whose honour the genus is named, and who, in 1794, likewise travelled in Senegal, speaks of a tree 29 feet in diameter and 70 feet high, its estimated age being over 5000 years. Whether or not the trees now standing are of the great age imputed to them is not so easy to determine, though it is beyond doubt that trees of enormous size are abundant in Africa, both on the East and West coasts, as well as across the country to Lake Ngami, and in other parts of East and West tropical and central Africa, so far as explorations have as yet been made. It has also become naturalised in many parts of the East Indies. The tree has a variety of uses, such for instance as the manufacture of cordage or rope from its tough fibrous bark, which the natives obtain in the following manner :—They make a horizontal cut in the bark of the living tree, low down upon the trunk, they then strip it up to the height required, usually a few feet, and cut off this process at the bottom to form a new bark forms, so that in some old trees there is a series of horizontal rings or scars round the trunk. After the bark is so obtained, it is manufactured in the usual way into ropes and cordage of different thicknesses. The leaves are used as a food, or kind of vegetable, and its hollowed trunks in the trees the natives deposit their dead, the bodies being, it is said, as well preserved as if they were properly embalmed; but besides these general applications, various medicinal properties are assigned to different parts of the tree—the fruits, which, when fully grown, are some 18 inches in length, and about 6 or 8 inches in diameter across the centre, are of an oval shape, and with a hard, woody rind, the inside being filled with a mass of agreeably sub-acid farinaceous pulp, in which the seeds are embedded; this pulp is used by the natives on the Zambezi for food, being mixed with water into a kind of thick paste and eaten by dipping the fingers into the dish and sucking them; it is also used in the preparation of a kind of sherbet, and has been brought to notice as a reputed remedy in dysentery—more, it is said, on account of its refrigerant and diuretic properties than for its astringency. From the flavour of the pulp the tree has been called, in some parts of Africa, the Cream-of-Tartar tree. The woody rind of the fruit, beaten up into a paste with the aid of a little water, has also been recommended for a similar purpose, while a decoction of the bark of the trunk itself has been used in India as a substitute for quinine in intermittent fevers. In Matabililand, South-eastern Africa, it is in great repute; the natives use it extensively in fevers, and as a tonic, and European travellers also frequently have recourse to it.

Garden Operations.

(For the ensuing week.)

Plant Houses.

The injury caused by the excess of moisture in the air at this dull season, extends equally to Orchidaceous or stove plants as well as to other subjects, and this, I think, may be explained by the fact that the density of the medium which surrounds them checks the natural exhalations from the leaves. I repeat my former suggestion, therefore, to give fresh air carefully with all possible freedom. Even this is at times of little use, so dense is the external atmosphere. Hence, as this external air, even in its driest state, is scarcely capable of expelling the moisture which abounds within our houses, it is highly judicious to light a fire upon drying days, and when air can be given most freely. The grower will not fail to perceive that this will insure to the inmates a much drier air for some days following, as well as aid a freer exhalation on the part of the plants during that particular day. Turn all plants round occasionally, to insure an equal amount of light to all sides alike. *Herbaceous Calceolarias*, which are now becoming good-sized plants, should have all decaying bottom leaves removed from them. Though these require an uniform root moisture, care must be taken not to water them to excess, or to cause the soil to become stagnant or waterlogged. Many *Cinerarias* will now push up their centre or bloom stalks freely, and should therefore have liberal waterings with liquid manure of tolerable strength. Greenfly must be assiduously watched for, and the usual antidote, fumigation, applied at the earliest sign of its existence. Many amateurs and others with too limited means endeavour to keep *Coleuses* and *Ivesine Lindeni* and such like bedding plants through the winter in greenhouses only, which is often found to be a difficult matter even by with practised hands. Maintain them at the warmest end of the structure, upon a dry base, and permit the soil to become, for the most, only giving them sufficient water at distant intervals to ensure to the balls a slight latent moisture. Keep them also free from cold draughts, and do not cut them back in any way.

Forcing Houses.

Where *Vines* which are being forced early have their roots in inside borders, the roots must receive equal consideration, and the same amount of practical attention as the growth aboveground. Indeed, as root action does not take precedence of leaf formation, as is often erroneously surmised, the food intended for them should be ready for their wants at the time when the young fibrils or spongioles are called into active existence. To this end give to the borders a moderate application of warm water every fourth day or so, from the commencement of shutting up the house in preliminary to actual forcing. By three or four such moderate waterings, the border will become moderately moistened, and each part will be in progress naturally together. The water given to these borders should be warmed up to 80° at least. Those who are now preparing *Vineries* for early work should bend the rods back and fasten them loosely together along the front of the structure, or in any position where the apices of the canes or rods are below the centre. In all instances where the Vines which are now being prepared for forcing have their roots out-of-doors, let the fermenting materials be got on the borders without further delay. *Peach* and *Nectarine trees* in the early house, which are now swelling their buds, must be syringed periodically, the atmosphere, too, must be well charged with moisture, and all the surroundings should be as clean and sweet as possible. It is often a very judicious procedure to sow a little *Cucumber seed* at this time, in all instances where any lack of vigour exhibits itself in bearing plants. By so doing, early seedling plants are often provided by the time they are actually wanted, though symptoms of waning health does not show thus early, the most trying time having yet to come.

Hardy Flower Garden.

Proceed with the pruning and nailing or tying-in of *Pear trees* during temperate intervals. The gross wood should be cut out of *Pyrus in Standard* trees where they have been permitted to run too greatly into growth. No better time can be chosen than the present to prune all kinds of *Orchard Trees*. We greatly neglect the pruning of standard *Plum trees* as a rule, even in the case of the common Damsons. The crop has become from this cause, in part, a very precarious one; the trees often grow to a degree exceeding the annual bearing strength, and hence we have generally one year a heavy crop, the succeeding year little or no bloom, and perhaps the following one such an excessive crop of bloom that the trees are compelled, from sheer exhaustion, to abandon the realisation of a satisfactory crop. A little judicious pruning will do good in this case as well as in others. *Strawberries* in pots used for early forcing should now be selected from the stock. Choose those with the most prominent crowns, and in the smallest-sized pots. Shake the pots well, place them in a temperature averaging about temperate for a few weeks, and if with a very slight bottom-heat, into which the pots can be plunged, so much the better. Continue until finished the transplanting of such *Pyramidal Fruit Trees* as are to be operated upon this season. The entire work operations is brought to a close now the better. Cut all strong rambling roots in somewhat severely, doing so always with a sharp-edged knife. In replanting them be very particular always to keep the base and roots well up; that is, not to plant too deeply. As no tree which has been uprooted or transplanted can succeed in the work of reconstructing its former mechanical hold of the ground whilst the least oscillation or wind-waving is possible, it is needless to dwell upon the importance of immediately staking all such as are so operated on, at the earliest possible moment afterwards.

KITCHEN GARDEN.

The past frost has somewhat delayed the germination of November-sown *Peas* and *Broad Beans*, which are now coming through the soil, though where unprotected at a sad sacrifice by reason of destructive bird agency. I referred last week to protecting them by means of "tirzles" wherever these are at hand, but who would think of purchasing them, in the face of the brick and glass appliances which we now possess? Plant protectors should be in the possession of every gardener who is expected to produce as early a dish of Peas as possible, as they afford protection at once against birds, and the inclemency of biting winds, which dash the tender tops against the hard frozen ground, as well as supply shelter from snow, by which they are weighed down. Even those who possess the means of sowing in turf or pots could not fail to accept their protective aid as a boon. Mould up the rows of young Peas, forming slight ridges on either side, an inch or so from them, so as to protect them from withering cold winds. *W. E.*

Notices to Correspondents.

*** CARRIAGE OF PARCELS.—We are at all times willing to render assistance in the matter of naming plants, fruits, fungi, &c., but our correspondents should remember that this entails, on our part, a very considerable expenditure of time, labour, and expense, and the least they can do is to pay the carriage of their parcels. In cases where this is not done, we shall rigidly adhere to our rule of not receiving such communications. We cannot undertake to name more than six varieties at one time.

BEETROOT CULTIVATION : *R. M. W.* We are unable to name any one conversant with Sugar-Beet growth and manufacture; but application should be made in the neighbourhood of Lavenham, Suffolk, and Faringdon, Berks, where the most extensive examples of the beet-sugar industry in this country exist at present. Probably Mr. Fish, of Bury St. Edmund's, could collect the Lavenham experience for you.

COLOUR OF GREENHOUSE STAGES : *Lady Subscriber.* This depends upon the surroundings, and on other circumstances. Stone colour we should think the safest to use.

CROSSING GRAPES : VINE POLLEN, &c. : *T. R., Wigan.* All that it is necessary to do is to keep the pollen in a dry place. We do not know how long the pollen so kept will retain its power, but in the case of the Aucuba it will do so for 12 to 18 months. What we require in new Grapes is constitution and flavour, combined with size. The Royal Edinburgh, Royal Horticultural, Muscat of Alexandria, possess most of these qualities. These, therefore, may be crossed with any others whose peculiarities you wish to secure.

GOOSEBERRIES : *T. H. M.* writes to say, that he would be obliged by any correspondent giving him the names of the 12 heaviest Gooseberries, three of each—red, green, white, and yellow.

NAMES OF FRUIT : *Skinner & Son. Pear :* Chaumontel.

NAMES OF PLANTS : *K. & S.* Picea grandis. *A. M.*—*T. S. Horner.* Ligustrum robustum, a native of the East Indies (Khasia, Nepal, the Neilgherries, &c.)—*Y. M.* Erica caffra; Cape of Good Hope.—*J. M., Southgate.* The variegated Cocksfoot grass, Dactylis glomerata variegata. Two forms of this are cultivated, one of them distinguished by gardeners as Dactylis glomerata var. elegantissima.—*J. C., Bromley.* Eupatorium glabratum, H. B. K. ; native of Central America.—*K. 1.* Begonia semperflorens Gaudichaudi, apparently a young scrap of Hypolepis distans ; 3, the leaf of some Orchid ; 4, Eranthemum sanguinolentum ; 5, Begonia Martiana ; 6, Begonia Griffithii. No. 3 probably suggests the usual treatment of Orchidaceous epiphytes ; try it potted high in turfy peat and sphagnum, with the pot nearly full of crocks beneath the soil.

STEPHANOTIS FLORIBUNDA : *J. M.* This does occasionally produce seed in this country.

TREE CARNATIONS : *J. W.* The following are recommended as some of the best of those which have the true perpetual-flowering habit : — Avalanche, white ; Maiden's Blush, tinted blush ; Vulcan, bright red ; Herbert, deep rose ; Garibaldi, rosy scarlet ; Miss Joliffe, flesh colour, very fragrant ; Jean Bart, scarlet ; Valiant, bright scarlet ; White Nun, white ; The Dragon, scarlet ; Congress, bright scarlet ; Vestal, white ; Lord Lansdowne, bright scarlet striped. *Constant Subscriber.* We know of no work devoted to these plants. There are some good articles on them in some of the numbers of the *Florist and Pomologist* for the present year.

COMMUNICATIONS RECEIVED :—A. M. R. H.—H. K.—Amateur. —W. A. H.—A. H.—D. J. N.—E. H.—R. G.—J. McP.—J. R. J.—X. Y.—J. P. C. (next week)—A. H. (next week)—W. E.—J. H.—J. M. T.—J. H. H.—Observer.—W. F., Jun. —T. H. M.—J. T. B.—W. H.—H. W. W.—W. E. H.—D. T. F.

Markets.

POTATOS.—Southwark, Dec. 4.

During the past week the arrivals coastwise and by rail have fallen in excess of the demand. Very large arrivals from France, many of which are being stored for want of sale. The following prices were barely maintained : —Yorkshire Flukes, per ton, 100*l.* to 130*l.* ; Yorkshire Regents, 60*l.* to 110*l.* ; Dunbar and East Lothian do., 110*l.* to 140*l.* ; Perth, Forfar, and Fifeshire do., 90*l.* to 110*l.* ; do. Rocks, 90*l.* to 95*l.* ; Kent and Essex Regents, 50*l.* to 100*l.* ; do. Rocks, 80*l.* to 90*l.* ; French Whites, 65*l.* to 80*l.*

COVENT GARDEN.—Dec. 8.

We have experienced a general dulness in the trade, business both wholesale and retail being influenced by the weather. The supply, however, is fairly kept up, and hothouse produce is comparatively abundant—Grapes, Black and White, and Pines being ample. Cucumbers, Seakale, and Asparagus is also sufficient both for the London and provincial demand. Amongst novelties we have a fair supply of truffles, and some nice specimens of the Prickly Pear are on sale. Some very good Bananas are also to hand.

FRUIT.

	s. d.	s. d.		s. d.	s. d.
Apples, per ½ sieve	2 0	5 0	Melons, each	2 0	5 0
Cobs, per 100 lb.	60	65	Oranges, per 100	6 0	10 0
Filberts, per lb.	1 0	1 0	Pears, per dozen	1 0	4 0
Grapes, per lb.	2 6	5 0	Pine-apples, per lb.	2 6	6 0
Lemons, per 100	7 0	10 0	Pomegranates, each	0 4	0 8

VEGETABLES.

	s. d.	s. d.		s. d.	s. d.
Asparagus, per 100	10 0	12 0	Horse Radish, per bundle	3 0	5 0
Beet, per doz.	1 0	2 0	Leeks, per bunch	0 2	0 4
Broccoli, per bundle, per bundle	1 0	1 3	Lettuces, per score	1 6	2 0
Brussels Sprouts, per half sieve	1 6	2 6	Mushrooms, per pottle	1 0	2 0
Cabbages, per doz.	1 0	1 3	Onions, per bunch	0 4	0 0
Capsicums, per 100	1 0	2 0	Parsley, per bunch	0 2	0 4
Carrots, per bunch	0 5	0 7	Radishes, per bunch	0 2	0 4
Cauliflowers, per doz.	2 0	6 0	Rhubarb, per bundle	2 0	2 6
Celery, per bundle	2 0	2 6	Salsafy, per bun.	0 9	1 3
Chilies, per 100	1 6	2 0	Scorzonera, per bun.	0 9	1 3
Cucumbers, each	0 6	1 0	Seakale, per punnet	2 6	3 0
French Beans, per 100	3 0	4 0	Shallots, per lb.	0 6	0 8
Herbs, per bunch	0 2	0 4	Spinach, per bushel	2 0	4 0
			Tomatos, per sieve	4 0	6 0
			Turnips, per bunch	0 2	0 4

Potatos, Regents, 100*l.* to 130*l.* ; Flukes, 120*l.* to 140*l.*

Flant Foreman

WANTED, for a Private Establishment, a first-class PLANT FOREMAN, to take charge of a large Fernery and an extensive and choice Collection of Stove Plants, Flowering and Foliage. He must also be capable of Managing Men, as he will have to under [illegible] Men, with house-work. Apply, stating if married or single, with references as to ability, &c., to JAMES VEITCH AND SONS, Royal Exotic Nursery, Chelsea, S.W.

To Propagators of Hardy Plants.

MESSRS. JAMES VEITCH AND SONS are in WANT of a PROPAGATOR for their Nursery at Coombe Wood. He must understand Propagation in all its branches, including that of all kinds of Ornamental shrubs, Conifers, Rhododendrons, &c. Likewise Layering. Also one for single Plants. Men fit for either to be on the spot.—Application to be made by letter, stating references as to ability, character, &c., to JAMES VEITCH AND SONS, as above.

WANTED, in a Nursery near London, a young MAN, who has been used to the general care of Plants and Houses where Plants are grown for Sale. Must be quick at Potting. Will have charge of Stock, and of Orders for Plants. Wages 16*s.* per week.—Apply, stating age and experience, to A. S., 15, St. Mary's Terrace, Paddington.

WANTED, as SECOND GARDENER, a respectable married Man, without family. Wages 18*s.* per week, with good apartments, milk, and vegetables.—Address, stating references, to apply to G. ASHBY, Head Gardener, Kidderpore Hall, New West End, Hampstead, N.W.

SECOND ASSISTANT in the Herbarium, Royal Gardens, Kew (age 18 to 30).—An Open Competition for this situation will be held in London, on JANUARY 16, and following days.—Application for the Regulations and Form of Entry should be made at once to The SECRETARY, Civil Service Commission, Cannon Row, S.W.

SECOND ASSISTANT in the Herbarium, Royal Gardens, Kew (age 18 to 30).—An Open Competition for this situation will be held in London, on JANUARY 16, and following days. Candidates must be familiar with the botanical nature of Gardens, and must show that they have had the necessary Technical Training.—Apply, at once, for the Regulations, and Form of Entry, to The SECRETARY, Civil Service Commission, Cannon Row, S.W.

WANTED, an INVOICE CLERK.—Must have a knowledge of Trees and Shrubs, and be of steady and regular situation.—Address, enclosing references, to JOHN CRANSTON, Nurseries, King's Acre, Hereford.

WANTED, a SHOPMAN.—Apply, stating full particulars, to G. AND W. YATES, Seed Merchants, Manchester.

WANTED, a SHOPMAN, capable of undertaking the Management of a Retail Seed business, and having some knowledge of Trees and Plants. The highest references required.—J. CRANSTON, King's Acre Nurseries, near Hereford.

WANTED, a SHOPMAN, having a thorough knowledge of the Garden and Farm Seed Departments. One with some experience in the Cut Flower Trade preferred.—Particulars as to age, salary required, &c., to DRUMMOND BROTHERS, 52, George Street, Edinburgh.

WANTED, an UNDER SHOPMAN.—One who has had experience in a similar business preferred.—Address, with full particulars, SEEDSMAN, Mr. John Maclaren, Stationer, 138, Princes Street, Edinburgh.

WANTED, a SHOPMAN or ASSISTANT.—Apply, per letter only, stating salary and last situation, to DICK RADCLYFFE AND CO., 139, High Holborn, W.C.

WANTED, an ASSISTANT SHOPMAN.—Messrs. HARRISON & SONS, Royal Midland Seed Warehouse, Leicester, require a young Man to fill the above situation.—Apply, stating age, experience, salary required, &c.

Seed Trade.

WANTED, a thoroughly experienced ASSISTANT, for the Counter and Warehouse, &c., to JAMES DICKSON AND SONS, 102, Eastgate Street, Chester.

WANT PLACES.—Letters to be Post Paid.

EXPERIENCED GARDENERS (or as GARDENER and BAILIFF), of various qualifications, recommended to Gentlemen Wanting Them, gives them gratuitously.—Apply to HENDERSON AND SON, Wellington Nursery, St. John's Wood, N.W.

Gardeners and Under Gardeners.

MR. CUTBUSH AND SON beg to state that they have at all times on their books MEN of various qualifications, whose characters will bear the strictest enquiry. Any Gentleman making application would save time by clearly stating the duties to be undertaken, wages offered, &c., so that suitable Men may be selected. —Highgate, near the Archway, N.

GARDENER (Head).—Has had extensive experience in Early and Late Forcing, the Cultivation of Stove and Greenhouse Plants, Vines, Pines, Cucumbers, &c. Age 35, single. Two years out of Land and Stock.—J. T., Pine-apple Nursery, Edgware Road, W.

GARDENER (Head).—Age 52, married, no family ; thoroughly understands the Growing of Vegetables ; also Stove and Greenhouse Plants, and Flower and Kitchen Gardening. Six years' character.—G. SMITH, Gardener, Westmill Road, Ware, Herts.

GARDENER (Head).—JOHN SAINSBURY, Gr. to Lady Vaughan of Leys, is at liberty to engage with any Noblemen or Gentleman requiring the services of a thorough practical Man. Has had experience in the Erection of Glass. Single-handed place preferred. Good character.—Lanelay Gardens, Fontypridd, Glamorganshire.

FOREMAN.—Age 25, single ; active and persevering. Understands Forcing in its various branches ; also Flower and Kitchen Gardening, &c. No objection to a small Premium. Good character.—W. H. L., 171, Maiden Road, Haverstock Hill, N.W.

FARM BAILIFF.—Married ; thoroughly understands the Cultivation of Light and Heavy Soils, the Breeding, Rearing, Feeding, and Selling of Cattle, Sheep and Pigs, and their general treatment in health and disease. Wife could undertake the Management of Poultry Yard and Dairy if required. Highest references.—Mr. S. M. HOLLINGHAM, Auctioneer and Valuer, Shifnal, Shropshire.

WOOD AND INGRAM wish to recommend a young Man as SHOPMAN, in a Retail Nursery and Seed Trade, who has been in their employ for some years.—WM. EARLOSS, The Nurseries, St. Neots.

SALES BY AUCTION.

SALE THIS DAY, at HALF-PAST TWELVE O'CLOCK.
Plants and Bulbs.
MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on SATURDAY, December 9, at half-past 12 o'clock precisely, First-class Standard ROSES; Dwarf-trained, Standard, and Pyramid FRUIT TREES; specimen CONIFERÆ, RHODODENDRONS, LAURELS, HOLLIES, CARNATIONS, PICOTEES, and PINKS, HERBACEOUS PLANTS, CLIMBERS, DECIDUOUS and EVERGREEN SHRUBS; also a consignment of choice Double and Single HYACINTHS, TULIPS, CROCUSES, NARCISSUS, IRIS, ANEMONES, LILIUMS, RANUNCULI, and other BULBS, just arrived from Holland.
On view the morning of Sale, and Catalogues had.

Bulbs from Holland.
MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on MONDAY, December 11, at half-past 12 o'clock precisely, a Portion of HYACINTHS, TULIPS, LILIUMS, IRIS, ANEMONES, RANUNCULI, GLADIOLI, CROCUSES, NARCISSUS, and other BULBS, just arrived from Holland.
On view the morning of Sale, and Catalogues had.

City Auction Rooms, 38, Gracechurch Street, E.C.
MESSRS. PROTHEROE AND MORRIS will SELL by AUCTION, without reserve, in the City Auction Rooms, as above, on TUESDAY, December 12, at half-past 12 o'Clock precisely, about 1000 DOUBLE GERANIUMS, 500 SALVIA INDICA, compact plants, 1 to 3 feet, beautifully furnished with bloom buds; one hundred standard Dwarf ROSES, of the best varieties; also selected FRUIT TREES; choice Hardy CONIFERÆ and EVERGREEN SHRUBS, and AMERICAN PLANTS, with a Collection of DUTCH BULBS, &c.
On view the morning of Sale. Catalogues may be had at the Rooms, as above; and of the Auctioneers, Leytonstone, E.

Hornsey, N.
IMPORTANT SALE OF VALUABLE NURSERY STOCK.
MESSRS. PROTHEROE AND MORRIS are instructed by Mr. M. Cleall to SELL by AUCTION, without reserve, on the Premises, the Hornsey Nursery, near the Church, Hornsey, on WEDNESDAY, December 20, at 12 o'Clock precisely, a large quantity of valuable NURSERY STOCK, including fine Common Laurels, 4 to 6 feet; Lygustrum ovalifolium, 4 to 8 feet; Euonymus, 200 Spruce Firs, 3 to 5 feet; 200 Cupressus Lawsoniana, &c.; 300 fine Standard and Dwarf ROSES; 200 POPLARS, of sorts; quantity of FRUIT TREES, 2000 GOOSEBERRIES and CURRANTS, 200 Double CAMELLIAS, 200 CHRYSANTHEMUMS, 200 Winter Blooming ERICAS, &c.
On view on the Sale. Catalogues may be had on the Premises, and of the Auctioneers, Leytonstone, E.

The Agricultural Gazette.
SATURDAY, DECEMBER 9, 1871.

MEETING FOR THE ENSUING WEEK.
SATURDAY, Dec. 16 { Norfolk Chamber of Agriculture, Norfolk Hotel, Norwich—11.30 P.M.

ON Wednesday evening Mr. H. S. THOMPSON presided over a meeting of the Society of Arts, before which the subject of SEWAGE DEFECATION and UTILISATION was discussed in a very elaborate paper by Mr. BAILEY DENTON. It was satisfactory to find the agricultural side of this subject so thoroughly recognised by the selection of a chairman standing in the front agricultural rank, and it was satisfactory to find the possible agricultural utilisation of a now mischievous waste material so recognised by a man of Mr. THOMPSON's good and sober judgment as that he should be disposed to take the chair on such an occasion. It is to that part of the paper which dealt with the subject of sewage irrigation that we must confine our attention just now. We have given an extract in another page, in which filtration and irrigation are discussed. They are virtually one and the same thing, or rather the latter includes and depends upon the former, irrigation being simply filtration *plus* plant growth—notwithstanding the broad line of distinction which Mr. DENTON tries to draw between them. He has, in fact, himself shown that there are some plants not generally considered aquatic which will prosper under the heaviest dressings of sewage which even a filter-bed has yet successfully dealt with. And, beyond the relation of the soil to plants, there is no difference at all between irrigation and filtration.

In all irrigation there is the passage of water through a certain quantity of the substance of the soil as well as over its surface, and in all irrigation there has, therefore, always been that intermixture of filtration which, as has been proved and explained in the laboratory of the Rivers Commission, is the only kind of filtration which will effectually deal with the filth of water laden with organic impurities. Mr. BAILEY DENTON's scheme of a large succession of beds—more than the "four equal plots" to which the Blue Book referred—on which the filthy stream may be poured at intervals of time which shall be regulated with strictest reference to the wants and powers of the plants growing on their surface than is possible in the case of a smaller number of beds, is just sewage irrigation—really nothing more nor less than sewage irrigation in the case of any farm which has to receive the whole daily sewage of a town. Moreover, even in the case of the filter-beds at Merthyr—which receive on every 5 acres or thereabouts (one quarter of their extent), six hours', or one quarter of the day's drainage of a district of 50,000 people, one-third of whom are connected with the sewers—the irrigation principle is complete. You have a channel carrying the water along the edge of a very wide bed, over which it trickles until: reaches the other end, feeding plants on its way. It is arranged with the view of giving the sewage as fair a distribution as possible, so that every square yard may have its share; and it succeeds in this—as in all comparatively flat, and therefore very slowly acting surfaces, it must succeed—in a much less degree than it does where the beds are steeper, and where you can take the tail-water away to mix with additional head-water, and run it on the land a second time elsewhere. We were for six or seven hours on the Merthyr ground, and saw in some places water running to the end of the bed, and ponding there, while in other places the water, sinking more rapidly near the carrier, never reached the end at all. If only a cross or catch-water surface drain or carrier had been drawn midway of the bed, so as to take up the stream in those places where it was more rapidly passing, and redistribute it evenly, the parallel would have been complete; and we should, by the use of the ordinary irrigation methods, have contributed to the more even application of that "filtration remedy," on which the merits of irrigation as a cleanser of town sewage so largely depend.

That, although we cannot go with Mr. DENTON in his attempt to draw a distinction between irrigation and filtration, which does not exist in any specimen of the latter process which is yet to be seen on the great scale, we must point out that it is to the great credit of that gentleman that this is so. He has himself, by his experience at Merthyr, shown that many of our vegetables will stand immensely heavier dressings of water than had before been supposed. Cauliflowers and Cabbages and Mangel Wurzels have been grown at Merthyr on land which has received the drainage of 17,000 or 18,000 people on 20 acres of land; and though this is not equal to the drainage of 3000 people per acre (of 9680 cubic yards), which was the utmost which, according to the experiments in the laboratory of the Rivers Commission, land could be expected to cleanse, yet, owing to the successful result of the Merthyr process notwithstanding the extreme unevenness of the distribution, we may declare that the work is there being successfully accomplished, notwithstanding its amount is three or four times as much in particular places as it is upon the average. The Merthyr experience does not yet quite prove that the Rivers Commissioners were wrong in supposing that the surface of a filter dealing with 3000 people per acre cannot grow profitable crops, but it certainly leads us to expect a greater possibility of growing crops under excessive dressings than they imagined possible. We earnestly hope, however, that the practice of using these excessive dressings on small areas will not be generally adopted; that, indeed, such excessive filtration will be adopted only where there is no alternative; that towns will take larger areas of land than this practice supposes, and try to utilise their waste water on a sufficient surface to yield more profitable results; and that if they should resolve that their duty is simply to destroy an enemy and abate a nuisance, they will at any rate take their filter-beds far enough away to enable the subsequent use of the sewage at a more moderate rate on lands lying between them and the town. This is what Birmingham has resolved to do. Taking this sewage to a comparatively small area of land, some 8 or 10 miles away, its conduit will command several thousand acres of land *en route*, and on these it will no doubt some day be utilised.

Let it be understood that, under the very best system known, an immense quantity of this fertilising matter is virtually destroyed. The nitrogenous matter is either absolutely decomposed and its nitrogen wasted in the air, or it is oxidised, and its nitrogen, as nitrites and nitrates, washed into the drains. It is but a modicum of the whole that is, under the best management, built up in plants. Mr. MORGAN's last report of Lodge Farm contains an analysis of effluent water, proving that two-thirds of the fertilising matter of London sewage runs through it unused. That farm is, in fact, a great intermittent filter, as all sewage farms are, and so

this unused sewage passes off no longer putrescible, and may be discharged into running streams without polluting them. This, of course, is a perfectly successful result so far as the question of river pollution is concerned; but it is an unfortunate result in an agricultural sense, and we trust that Mr. THOMPSON, and Mr. BAILEY DENTON, and other agriculturists who are now turning their attention to the sewage question, will keep the question of sewage defecation well subordinated to that of sewage utilisation, by which in an indirect and incidental way by far the best result, even for the rivers, will be obtained, at the same time that the agricultural result will be satisfactory.

THERE could not be a more appropriate subject for the week of the great cattle show than that discussed by Mr. J. K. FOWLER, of Aylesbury, before the London Farmers' Club on Monday evening last, viz., BREEDING—FACTS and PRINCIPLES. The paper, which will be found in another page, was exceedingly well received by a large and attentive audience, and the discussion which ensued was opened by Mr. G. SMYTHIES, who, in consequence of Mr. FOWLER having confined most of his remarks to that side of the subject embraced within the words "external form," wished to say a few words in favour of "quality," which term he applied to animals that would keep in good condition on poor land, or which, when put up to fatten, would quickly lay on flesh. He compared the weights of the prize animals in the three classes respectively for Herefords and Shorthorns at the last Smithfield Club Show, to prove that in point of flesh-producing power the former were the best, while they had also the advantage over the Shorthorn of being able to live harder, and to thrive on poorer land. As regards sheep, he considered the Southdowns—such as those bred by Lord WALSINGHAM—were heavier than Shropshires at the same age, and these, too, did the best on poor land. It was also his opinion that a cross between the Cotswolds and Shropshires would do good in bringing out increased flesh-producing qualities.—To him succeeded Mr. WARD, who was understood to say that in breeding sheep the second and third crosses were of no use; it was the first cross from which advantage—if any —was gained.

Mr. JAMES HOWARD, M.P., thought Mr. FOWLER's paper would disseminate a great deal of valuable information. Were the main principles of breeding more generally understood, we should not meet so many ill-shapen animals about the country as we did now. In reference to the idea that external form depended wholly on the male parent, he said that he had found that it was correct in horse breeding; and he gave instances to prove that it was also true in the case of pigs—in the breeding of which he had had some experience. Mr. HOWARD specially mentioned having some 18 years ago visited the Duke of BEDFORD'S farm, where he saw some young pigs, all of which were white, and the produce of black sows by a white boar, and he was informed that this had always been the case. He thought that if all the facts on the subject were gathered together and put into a tabulated form, they would have a very correct theory for future guidance in breeding, and this would tend in a great measure to reduce almost to a certainty what was now in most instances a mere matter of chance.

Mr. CONGREVE was sorry to say that, though since the Royal Agricultural Society was established, in 1838, a large amount of money has been given in prizes all over the country as an inducement to improve the breeds of cattle, the fact remains the same, that it is more difficult to buy a lot of good animals for grazing purposes now than it was 30 years ago, and what he could not understand was that the difficulty was increasing year by year. What graziers wanted were heifers that would put on flesh quickly when wanted. Mr. COUSSMAKER was of opinion that the great point which breeders should aim at producing was early maturity; and Mr. READWELL said the reason why Mr. CONGREVE experienced difficulty in getting good animals for grazing, was that farmers now liked themselves to feed the animals they bred. He began some years ago with a lot of common-bred cows, and since he had used a Shorthorn bull the improvement had been very great.

Mr. MECHI confessed that he was not much of a breeder, but he thought that the deterioration of cattle was due to the false economy practised by many farmers. What they wanted to impress upon the agricultural mind was the advantage of paying a little more in the first cost, and they would then obtain a better class of stock. He was a great believer in the effect of soil and climate upon animals, and instanced the big horses, big cattle, and big everything that came off the fat soils of Lincolnshire, and the smaller forms of the same from poor land, for which latter he recommended the use of covered yards.

Mr. H. M. JENKINS hoped that if any gentleman carried out the suggestion made by Mr. HOWARD, as to the tabulating of the facts on breeding, he would ascertain and give the value of them, especially in the case of well bred and, therefore, "prepotent" males. Mr. TEETHEWY believed that in some classes of animals the male exerts greater influence than in others, and said the fact much to be deplored was, as Mr. MECHI had said, that some farmers—he would not say all—continued to send their breeding stock to the cheapest instead of the best bred animals.

Mr. TATTERSALL thought Mr. FOWLER's paper would be of great service to scientific farmers, who he believed could breed animals almost to a certainty, and to any extent. Farmers should bear in mind that corn they may have cheaper, but meat they never would.

Mr. THOMAS remarked, that 40 years ago his county, Shropshire, was a good one for hackneys; but unfortunately the farmers had sold all the good mares, and had since bred from weeds. In his opinion a great deal depends upon the mare; but no matter what they bred, if the produce was brought up on good land they would be finer both in size and quality than those from off a poorer soil.

Mr. FOWLER, in reply, thought that all agreed that the facts and principles he had put together were as good as could be obtained from their present limited knowledge. He agreed with Mr. MECHI as to the ill effects caused through the practice on the part of farmers of false economy, and read a letter from Mr. C. S. READ, M.P., who was unable to attend the meeting through an attack of bronchitis from which he was suffering, but who wished Mr. FOWLER to impress upon those present the point that "the poorer the dam the greater was the necessity of a longer pedigreed sire."

—— A MODERATE supply of English Wheat at Mark Lane on Monday sold at about the prices of that day se'nnight. Wednesday's trade was quiet and steady.——At the Metropolitan Cattle Market on Monday, average quality of beasts being middling, there was a brisk demand for choice kinds, at fully late rates, and a fair clearance was effected. The trade in sheep was dull. Wednesday's trade in both kinds was slow, without change in price.——The seed trade is firm.

—— The show of the Smithfield Club has been favoured by good weather up till Thursday afternoon. About 800 people entered the Hall on Monday, nearly 23,000 on Tuesday, upwards of 38,000 on Wednesday. On the whole, several thousands more than appeared on the same days last year.

—— We learn, on the subject of CATTLE DISEASE, that of 38 cattle shown at Birmingham applying for admission to the Agricultural Hall, at Islington, 18 were rejected as suffering from foot-and-mouth disease. Notwithstanding all preventive care, at least 15 animals were suffering in the Hall towards the end of the week. The great confusion that arose last year on the occurrence of the disease will not, however, happen now, as all animals, themselves free from the disease, may be allowed to feed with on the conclusion of the show just as if no case of disease had taken place in the Hall.—By far the most serious announcement, however, to be made in this paragraph, is the occurrence of the Rinderpest, or Cattle Plague, in Belgium, just announced, which will immediately occasion a new Order in Council.

We have received, too late for publication this week, a copy of the REPORT of the SMITHFIELD CLUB, read at the General Meeting on Tuesday last. The only points which are now of material public interest in it are the resolutions to request from butchers a statement of the carcase weight of the exhibited cattle slaughtered by them, from which, when compared with the live weights published, very useful inferences may be drawn; and the resolution, in view of the prevalence of foot-and-mouth disease, to ascertain the opinions of members by inviting a discussion at the General Meeting on the following point, viz., whether animals exhibited elsewhere, within a limited period of time before the date of the cattle show, should or should not be admitted in future during the prevalence of the disease. The Right Hon. Lord PENRHYN, who was chosen as President-elect at the last General Meeting, has intimated to the Council his regret that advancing years would prevent his discharging the duties of President; but his lordship, by presenting the handsome donation of £100, has manifested the interest that he takes in the welfare of the Club. The Council voted their best thanks for the same; and they have elected the Right Hon. Lord TREDEGAR, V.P., to fill the office of President for the year 1872.

—— A prize, which had been offered by Earl POWIS through the Smithfield Club for any method whereby the slaughtering of animals might be effected with diminished suffering, resulted in virtually but one proposal. Mr. THOMAS KERR, of Paisley, appeared with a heavy cylindrical case carrying a stiff coiled spring acting on a sharpened bolt. The spring was pulled up tight, and on being released by a trigger, thrust forth the pointed shaft with force enough to penetrate bone. This instrument was intended to divide suddenly the spinal cord, and so destroy sensation. But neither Mr. KERR nor any other uninstructed man could say with certainty exactly where the spinal cord lay; and so in the case of the trial, after the poor beast had received three incisional stabs, it was despatched by the poleaxe. Clearly, Earl POWIS' humane idea has not resulted as yet in a success.

—— At the Council meeting on Wednesday last of the CENTRAL CHAMBER OF AGRICULTURE—Sir MASSEY LOPES in the chair—a resolution was adopted:—

"That Mr. GLADSTONE be requested to receive a deputation from the Central Chamber and the Associated Chambers of Agriculture in the afternoon of February 5 or 6."

The committee appointed to watch the local taxation question presented their report, chiefly on the Bill introduced by Sir CHARLES ADDERLEY last session, which embodied the recommendations of the Sanitary Commission. They found that its objects were:—(1). To consolidate all existing statutes on sanitary matters; (2), to make all existing provisions and regulations by means of the central authority in all rural as well as urban districts compulsory, whereas they were at present optional and permissive; (3), to enforce certain new recommendations of the Sanitary Commissioners. The proposed Bill would increase the burden of local taxation, because of its compulsory clauses for the carrying out of sanitary regulations.—The report was adopted. At the General Meeting, which followed, the sixth annual report of the Council, referring to the operations of the Society, under the several heads of the Consolidation, Increase of farming stock, uniformity of weights and measures, the Malt-tax, the Government Licensing Bill, occupation roads and highways, the Property-tax assessment, the Game Laws, Poor-law medical relief, and the Contagious Diseases (Animals) Act, was presented and adopted. It was stated that the Central Chamber, now in its sixth year, numbers 196 subscribers, and embraced 99 Chambers, having a total constituency of 18,000 members. Mr. HENEAGE will be President next year, and Sir M. E. HICKS-BEACH, M.P., is Vice-President for 1872.

—— A general meeting of the subscribers to the FRENCH PEASANT FARMERS' SEED FUND was held on Wednesday last, in the chair, Captain HELY had visited the districts relieved, for the purpose of reporting on the agricultural and economic effects of the operations of the Fund, and he had found that the Barley, Oats, Potatos, Vetches, and garden seeds sent had generally produced abundant crops, but that the Wheat had failed in most cases. The Wheat (Nursery) was for the most part sown during the month of March, but a little even so late as the beginning of April. Circumstances had in most cases not allowed of the due preparation of the land, and the seed-time was succeeded by three months of very unfavourable weather. The latest sown Wheat made by the Fund were of another description—the April Wheat—which yielded a satisfactory crop. The statement of receipts and expenditure showed that there remained an available balance in hand of about £1000, and the executive recommend that they be authorised to distribute this sum to the most necessitous peasant-farmers, in money, or in such other way as might be deemed most advisable.—The Chairman entered at some length into an explanation of the origin of the fund, and the work it had done since its establishment. He wished to remove an impression which had gained ground, that the French peasant-farmers were not grateful for the help afforded them. To this statement he desired to give a most unqualified denial. The committee had received from the French authorities and from the farmers numerous testimonials of their gratitude, and medals had also been sent from many districts. In conclusion, he paid a high compliment to Messrs. ODAMS and JENKINS, two members of the executive, who had rendered valuable assistance in the carrying out of the work. He also spoke in high terms of the hon. secretaries, and said he felt pain in parting, now that the object of the fund had been accomplished, with those with whom he had worked so harmoniously. A resolution was carried unanimously, "That the executive committee should be authorised to present a testimonial to Messrs. JENKINS and ODAMS as an acknowledgment of the great assistance they had

rendered to the committee." The proceedings closed with a cordial vote of thanks to the Chairman.

—— Mr. KAINS-JACKSON reports in his *Times* letter (Dec. 4) that there has been no important change to notice in the POSITION of the CORN TRADE for the last two months. So equally balanced have been supply and demand that value for English Wheat, which was 57*s.* 2*d.* on September 2, 56*s.* 3*d.* on October 7, 56*s.* 8*d.* on November 4, is at this date 55*s.* 10*d.*, a very trifling difference in the three months following harvest.

"Writing on October 7," he says, "I used the words, 'The wish is general that prices should keep where they are, as either a decline or advance would, almost equally, create future losses,' and the result has endorsed this view.

"I can only repeat, 'The grain stocks of the world appear fully equal to the world's wants.' If I stated this nearly two months ago I may more strongly affirm it now; for to our full granaries the last months of October and November have added large imports. For the nine weeks ended November 26 we have received of Wheat:—1871, 2,056,000 qr.; 1870, 1,243,000 qr.; an increase of three-quarters of a million that must not be overlooked.

"Indeed, while value appears evenly balanced—on one end, not to be under-estimated, a heavy winter demand, on the other end of the beam a bulk of supplies that overweighs regular consumption—the range of prices has already produced a result that more than answers expectation, and again the truth is demonstrated that production of bread-stuffs in the world increases more rapidly than population and consumption. The ratio of the first is multiplied by scientific agriculture, while the latter advances only by natural laws. The differences between peace and war in the sad year of 1870 I fixed at 10*s.* per qr. for Wheat, and thus, when the current quotations of English Wheat are referred to as only 4*s.* to 6*s.* above those of last year, we must add another 10*s.*, and say they are 14*s.* to 16*s.* above the level of the years of plenty; and surely this advance is ample for any admitted deficiency of the Wheat crop in England and France for the present season. Such would appear to be the case, since in France all the markets are dull, and Marseilles is reported to have a granary and floating stock of about three-quarters of a million quarters of Wheat, and all our English ports are well stored. Of the four or five million quarters of imported Wheat which I believe France will require, probably quite two-thirds are received or bought; and recent advices assure us that the winter wants of the French people are as well supplied by import and reserves of the home crop as we are in England."

—— At a meeting of the Landlords' Committee of the ABERDEENSHIRE GAME CONFERENCE, held in Aberdeen last week, the following motion, proposed by the Marquis of HUNTLY, was carried, viz.:—

"That this meeting recommends to the Conference that all agricultural tenants should be allowed to destroy hares and rabbits, subject to certain restrictions as to the mode of killing them on their respective arable farms, by themselves, or by a deputy, and subject also to the maintenance of a close time when the winged game is nesting.'

—— Mr. MORGAN reports from the Sewage Farm at Barking, that he has weighed off 39 rods of land, all that there was of the crop, 17 tons 14 cwt. of Long Red Mangel, which thus outweighed the Globe, being at the rate of 72 tons an acre!

—— We accidentally omitted, in our report last week of the Birmingham Show, to notice the very fine collection of Bovinia or Cattle Potatos, which competed for the handsome piece of plate presented by Mrs. PATERSON, of Dundee, to whose late husband we owe the introduction of this Potato. We find in our notes that some of these Potatos outweighed some of the Turnips exhibited in the galleries at Bingley Hall. Mrs. PATERSON'S prize was won by Lord WILLOUGHBY DE BROKE.

NOTEWORTHY AGRICULTURISTS.

MR. H. S. THOMPSON, OF KIRBY HALL, YORK.

MR. THOMPSON has long been known as an active public man, wielding great power most usefully in many walks of life. His agricultural career may be said to have commenced so long ago as 1836. When still a very young man, having been convinced of the utility of agricultural societies, he then started that of Yorkshire. Laying his plan before all the leading agriculturists of his county, getting meetings and committees held, and at length gratified by the general adoption of his proposals, he had the pleasure of seeing that great provincial society started on its useful career so long ago as 1837. In 1838, on the publication of Mr. Handley's letter to the late Earl Spencer, the Royal Agricultural Society of England was established; and of this too, as Mr. Thompson was an original member, so he has ever since taken a leading share in its management. As member of its Council from the very first, as frequent steward at its meetings, as an active member of many of its committees, especially of its Journal Committee, he has devoted a large portion of his life to its service. Having worked with Mr. Pusey during the early editorship of the Journal, he became chairman of the Journal Committee on his death. For some years, indeed, he was himself virtually editor of that publication, as Mr. Pusey's successor, bearing all the anxieties and difficulties of the office, and himself contributing largely to its pages.* Mr. Thompson had this special fitness for the office, that he is himself a practical and experienced agriculturist. Moreover, though not strictly a man of science, he has always fully appreciated its value, and he was one of the most active in persuading the Society to carry out its maxim, "Practice with Science," by the establishment of a chemical professorship. His own prosecution of this maxim has indeed borne most valuable fruit, and to his observations and experiments we owe the discovery of that principle of the "absorption, decomposition, and retention of ammoniacal salts by the soil," to which the researches of Professor Way were subsequently directed.

In 1849 the attention of Mr. Thompson was for a while diverted from agricultural to railway matters. In that year rumours began to be circulated that Hudson's railways were not as prosperous as they had been made out to be. Accordingly, though entirely unconnected with railways at the time, seeing that something ought to be done, and that no one seemed inclined to do it, he summoned a general meeting of the Derwick shareholders at York on his own responsibility, showed up the accounts, secured Hudson's deposition, and the appointment of a new board of directors, on which, however, he himself declined to sit. But after a few months, when the York and North Midland Company had reached the lowest point of depression, he was finally overpersuaded, and consented to become chairman of their board. The results of his management may be seen in the fact that that company has now expanded into the North-Eastern — the second largest, and one of the most prosperous of the large railways in the kingdom. As a proof of the estimation in which he is held in the railway world it may be added that he has been chairman of the United Railways Association since its foundation some years ago.

We refer to this portion of his career as a characteristic illustration of the courage and persistent resolution to which Mr. Thompson owes so much of his great influence. They have also served him in good stead during the agricultural career which we have sketched, and which culminated in his election to the Presidency of the Royal Agricultural Society of England in 1867.

Mr. Thompson sat in the House of Commons for Whitby between 1859 and 1865. He was High Sheriff of Yorkshire in 1851. He is still a laborious member of the English Agricultural Society, and chairman of its Journal Committee. And no later than last Wednesday he showed his interest in one of the leading agricultural questions of the day by presiding at the meeting of the Society of Arts, when Mr. Bailey Denton's paper on the sewage problem was discussed.

MR. H. S. THOMPSON,

Late President of the Royal Agricultural Society of England.

* Mr. Thompson's papers in the Journal include reports on implement shows, and essays on the absorbent powers of soils, on laying down grass lands, on road-making, agricultural progress, &c.

OUR LIVE STOCK.

CATTLE.

THE Hereford Circular, the fourth number of which we have just received, is intended to record all events of interest connected with Hereford cattle, just as Thornton's Circular supplies us with Shorthorn news. The present number gives a report of the prize lists at Guildford, Wolverhampton, and Hereford. Next we have a price list of the periodic sale of October 18, which was noticed as a pending event, but never until now heard the result of. BACHELOR (2941), the property of Mr. P. Turner, The Leen, was purchased at 60 gs. by Mr. Fen;

BANQUO, from the same herd, was bought for 48 gs. by Mr. J. Morris, and MERCURY went into the same hands at 40 gs.; Mr. W. Tudge's CORIOLANUS was purchased for 40 gs.; Mr. B. Roger's GROVE 3D made 57 gs.; Mr. J. Price sold FORESTER 2D to Mr. Gwynne Vaughan for 60 gs.; and Mr. H. Gibbon's GRATITUDE 2D was sold to Mr. Hall for 40 gs. The remainder of the cattle sold at from 20 gs. or less up to about 30 gs. Information as to the progress of Herefords in our colonies, and a list of pure-bred Herefords for private sale, concludes the Circular.

—— We take the following notice of the Shorthorn herd of the late Mr. Richard Stratton from "Thornton's Circular:"—

"More than 30 years ago Mr. Stratton had a herd of cattle in Wiltshire, which he kept in two parts: one numbering about 50 cows and heifers, as the ordinary dairy herd, the other about 40 head, as the selected herd. Expensive cattle were never bought, but the best heifers were purchased at different fairs, and put into the ordinary herd, where, if they proved good, and likely excellent milkers, their heifers were exalted to the selected herd; and if they in their turn became good milkers and breeders, and were worthy of the promotion, they were retained. In the selected herd of bulls, the cows were most particular, and his custom was to spend a month or six weeks in looking over various stocks for the male animal, selecting him not so much for his great beauty and symmetry as his character, blood, and the excellence of his sire and dam. PHŒNIX (6290), originally called Byron, was the first pedigree bull, and he was put to a neat but rather plain red and white heifer, supposed to be a pedigree Shorthorn, which Mr. Stratton had reared at one fair, and afterwards thought better of and purchased at Highworth. These animals produced *Moss Rose*, the best heifer calved that year; she afterwards became a good cow, and on being put to the same bull (1280) (who was bought of Mr. Adkins, of Milcote), gave birth to *Young Moss Rose*, and mother and daughter produced 30 calves between them. It is from these animals that the largest and best portion of Mr. Stratton's herd had been reared; and although one or two pedigree cows have been bought they have not been retained. Upon good bulls he has chiefly depended: Mr. Hayter's RED DUKE (8964), the Duke's BARON 60 or 2nd (1280), and Mr. Sanday's NOTTINGHAM (15,014), being among his most favourite sires. Of late years, however, he bred much from the Booth blood through Mr. Barnes' herd, but he never was a warm admirer of Mr. Wardell's love for fashionable pedigree, and it was rather by his friend Mr. Boyle's advice that he sent his prize cow *Maid of Honour* to 7TH DUKE OF YORK, and her son the 8TH DUKE OF YORK (23,668), with JANET 1ST (14,202), his prize winner by a Booth blood bull, out of *Queen Mary*, an own sister to *Maid of Honour*), have been the latest sires used. It is more particularly in the showyards, and especially at the Bath and West and Southern, that I think that his success as a breeder and exhibitor is so widely known. Since the modest 3 gs. were won at Devizes in 1837 for the best heifer in milk and for the best cow in milk, the amount has swollen to over £5000, and five gold medals have come from the Smithfield Club alone. At the Royal and local shows he has frequently sold his animals at high figures, chiefly to Australia, where they have been most highly esteemed; and many of his bulls have realised in the colony 400 gs., 470 gs., and 600 gs. respectively. Portions of his herd have, however, been brought into the sale ring, but no high prices obtained. At the sale in March last it was remarked that small and very large company scarcely half-a-dozen Herd Book breeders were present, yet for the general herd of 55 head, most of the best being retained, an average of £36 was realised. In fact, Mr. Stratton, a sound, good judge of animal life, studied and practised breeding for the animal's sake more than for fashionable tastes; he went for sound constitutions, good quality of flesh, and abundant milking properties, and looked at a pedigree, not for its long descent, but to assure himself that the immediate ancestors were good, and of a family of good animals. If he were particular to certain points, he would prefer a good back, full thighs, large mellow rump, a good chest, the chest, as his friend the late Mr. Adkins described it, scorning animals with 'no heart and long necks as good dairy cattle.' He did not very strongly object to in-and-in breeding, believing it rarely practised; the cross of LOTTERY on Lottery's daughter, *Young Moss Rose*, producing *Elegance*, 'a nice stylish cow, a great milker, but not so massive as her dam,' was by mistake of the herds man and not altogether an unsuccessful result, as she produced the *Duchess of Gloster*, who in their turn produced *Maid of Honour* and *Queen Mary*. Eminently successful as an agriculturist, and a great economist in management, he brought out animals that have ranked high in the showyards with the Booth, Towneley, and finest cattle of the day. Backward as some have considered him, and forward as others have remarked, in his generation he was nevertheless a man who commanded success, and who was looked up to by his brother farmers of the South as a man in advance of his time. He died on August 15, aged 62 years, and left a large family of five sons and six daughters, one only a minor. The sons, following their father's pursuits, are large occupiers, the four eldest having 6500 acres among them. Mr. Joseph Stratton, at Alton Prors, Wilts, and Mr. Richard Stratton, of The Jaffrey, Monmouthshire, divide their father's herd between them."

SHEEP.

AT Mr. Cochrane's sale of Cotswold sheep and Berkshire pigs, in Canada, on October 26, there was a large attendance, and the bidding was spirited. After lunch the sale commenced with the imported Cotswold ewes. The two first were knocked down for 75 dols. (£15 12*s.* 6*d.*) each; two more, same price; two at 50 dols. (£10 8*s.* 4*d.*); the next two were 1-year-olds, and fetched the top price of 100 dols. each (£20 16*s.* 8*d.*); two at 75 dols., three at 35 dols., 15 at an average of 42 dols. each (£8 15*s.*). The rest ranged from 35 to 40 dols. The Canadian, bred from imported ewes, came next; but even some of these ranged as high as 70 dols. Ewe lambs, bred from imported stock, were sold, nine for 324, three for 120, and three for 25 dols. each. Rams, from imported stock, brought 55, 60, and 75 dols. Twelve Berkshire sows were very strongly competed for, though they all fell to the same purchaser, who seemed determined to have them, though they stood him in 103 dols. apiece (£21 9*s.* 5*d.*). The lowest price was 75 dols. (£15 12*s.* 6*d.*); the highest 185 (£38 10*s.* 10*d.*).

—Last week additional testimony was contributed in another portion of the *Agricultural Gazette* as to the black tup which Mr. Bakewell is said to have used in his early improvement of the Leicester sheep. Our witnesses, however, do not agree, for Mr. B. Smith, while giving his own version of the transaction, does not hesitate to stigmatise a part at least of Mr. Bell's story as "a fabrication." After carefully reading Mr. Smith's very interesting remarks, we cannot take his story as evidence. He begins by telling us that Mr. Bates and Mr. Clifford Elches, and another friend, came to Dishley "after the meeting of the Royal, at Derby." What, we would ask, has this interesting little episode to do with the black ram? No mention seems to have been made of it, and Mr. Bates appears to have been thinking of artificial manures more than sheep. But now we come to the point. The first that was heard of the black ram was related by Mr. Smith's father, and was not found out by any Fry." The story then proceeds, and finally Mr. Bakewell is stated to have addressed Mr. John Stone as follows:—"* * * In my early improvements of my flock I went to Ashbourne Fair, and the best ram I found there was a black one, which I immediately used him, owing to how your black lamb came." As Mr. Smith relates this story, it appears to be entirely hearsay. Had Mr. Smith said, "This information I received direct from Mr. John Stone," we might have put some faith in it; but no such thing is said. So far as Mr. Smith's evidence goes, he has only contributed an addition to the gossiping story started by Mr. Bell. Lastly, on behalf of the late amiable and much respected Mr. Dixon, it does seem rather in bad taste to review his writings in the manner chosen by his critic, Mr. Smith. Unless Mr. Dixon in telling us that "When Bakewell received a notice to show one of his horses in London to George III., his Majesty looked more at the man than at the horse," intended the expression as complimentary to Mr. Bakewell. It was not meant to suggest that his Majesty was thinking, "What queer old soul is this, with his drab Quaker-cut coat, jack boots, and periwig?" No such thing; his Majesty was the very first man to thoroughly appreciate the talents and sterling character of the great stock breeder; and the late Mr. Dixon was too much embued with a similar appreciation for genius and manly worth to make remarks upon such a man as Bakewell, of a slighting character.

Now is the time for the "Friend of Dumb Animals" to see his long-tailed friends in perfection. We allude to the correspondent of the *Field*, who, under the above *sobriquet*, stigmatised the practice of docking lambs last August. He would now understand what was meant by his farming friends when they urged that the long-tailed sheep "would get so dirty." His innocent reply—"If getting dirty is the reason, the same argument would deprive them of their legs," falls to the ground. Alas! no. Cutting off their legs would have but little effect, and that little rather of a contrary sort. The long-tailed sheep appears to us, to say, "Pity a poor, ill-used, neglected, draggled, and altogether lost individual; my brethren are at least comfortable and also decent, while I—I am not only physically miserable, but must also be a loathsome object to even my dearest friends!" Such, or similar to them, must be, or ought to be the reflections of every long-tailed sheep.

BREEDING—FACTS AND PRINCIPLES.

[The following paper was read by Mr. J. K. Fowler, Prebendal Farm, Aylesbury, before the Central Farmers' Club, London, on Monday, December 4.]

SEVERAL years ago my friend, Mr. Jas. Howard, M.P. for Bedford, and late President of this Club, called my attention to a paper read by the late Mr. Reginald Orton, at the Newcastle Farmers' Club, on the "Physiology of Breeding," and sent me a copy for perusal. It made a great impression on me at the time, and having many advantages of testing several of his propositions therein enunciated, I commenced some experiments, and began to examine the truth of his premises. What I have found them in the main correct, viz., that the male gives the external organs, which are the skin, the muscle, and the bones, and the female the internal organs, which are the whole circulatory, respiratory, and digestive organs. Mr. Orton gives credit to Mr. Walker for first enunciating this theory, as far back as 1841, which is published in Stephens' "Book of the Farm." Mr. Howard suggested to me, when the committee was selecting subjects for discussion for the present year, that this subject should be taken up as one of great interest to the Club, and also to the public generally, and I hope my humble efforts will be the means of drawing special attention to the subject. The paramount importance of providing food for the people, especially animal food, is a serious problem to be solved, and anything which can increase, not only the number of animals, but their size and quality, must be read and studied by every agriculturist in the kingdom. If, therefore, some broad principles for our guidance can be established, it will make cattle breeding more certain in its results, and render that which is now treated almost as a matter of chance a comparative certainty. I would say, "What to breed, feed, and avoid" should be our standing motto; and, as my paper is on "Breeding—Facts and Principles," I will begin by stating such facts as have come to my own knowledge, and such as have been communicated to me by some of the most eminent breeders and others in England. I shall then state what principles I think would be desirable for perpetuating the best animals in general use as agricultural stock.

Mr. Orton, in his most valuable paper, read at Newcastle-on-Tyne, commences by stating the following facts with regard to the mule; and, as this is so plain, and so easy of comprehension, I adduce it here, that you may be able at once to comprehend the broad proposition with which I started. He says:—

You are doubtless aware that if the male ass is put to a mare, the produce is a mule; and you will find the produce is essentially a modified ass—the ears are long, the mane erect, the tail thin, the legs slender, the hoofs high and contracted—in fact, clearly taking after the male animal. But few people are perhaps aware that when a stallion is put to the ass, the produce is a "hinny"—and this is essentially a modified horse: the ears are short, but somewhat longer than a horse, the tail bushy, the skin fine, the legs stronger, and the hoofs flat, like the horse. You will, therefore, now clearly perceive that in appearance, follows the male. But now comes a very noticeable peculiarity. The body and barrel of the first named—the mule—are round and full, which resembles the mare; and those of the hinny are flat and narrow, like the ass; but the vital, or internal, organs of the mare belong to the hinny, while those of the ass require a longer cavity or barrel to carry them, and so the bones are moulded to fit the organs, not the organs to fit the bones; so also the smaller vital organs of the ass require a smaller and flatter cavity, and so also the bones are moulded to fit them.

Many of you have also heard of Lord Moreton's curious experiment with the quagga; he put a quagga stallion to a thoroughbred chestnut mare, and the produce was a quagga mule, with stripes, and many characteristics of the male. The next season he put the mare to a black Arab horse, and, to his astonishment and mine, she produced a foal bearing strong marks of the quagga, and this effect was visible for three generations from a blood stallion.

There is a similar case recorded in the Transactions of the Royal Society, where a mare of Sir George Ouseley's was put to a zebra, and the produce was striped like a zebra; the next year served by a blood horse, and the foal had zebra stripes, and again the same result followed the next year.

It therefore would appear that a female once impregnated retains certain traces of the male, which remained by her for an undefined period.

Now I have some pains to follow this out, and in the Zoological Gardens, from that most intelligent curator, Mr. Bartlett, I find this in the main correct. He showed me a white Spanish ass, with a few dark spots on him, and he had all the outward characteristics of that male ass in this respect as to colour, and they have put him to several clever ponies, and in every case the produce was a modified ass; but he seemed to have exercised but small influence as to colour. There is one very amusing fact with this asinine gentleman, viz., that since he has had mares he will have nothing whatever to do with his own tribe. Mr. Bartlett says they have tried mares with the male zebra in the establishment, and he is so ferocious and savage that he has nearly killed them, and they have ceased to try them. It is said, and I believe truly, that mules do not breed, but it may not be generally known that male and female mules do have sexual intercourse; Mr. Bartlett, however, thinks some day he shall find they will breed.

I have seen some extraordinary instances of external appearances, especially as to the locomotive powers following the male, and will give you one of my own experience. I once rode a very good hunting mare, got by a thoroughbred horse called Maple. He had a sort of club fore-foot, and was lame with it. My mare had upright coronets on her fore-feet, more like donkey's, and she eventually went lame with them some years afterwards. I saw a chestnut mare with a foal by her side going to the Baron Rothschild's horse, Hungerford; she was very lame, swinging her off fore-leg. I found she had a large "bumble foot," and on inquiring found she was got by Maple. I have since made inquiries, and find that most of his progeny had peculiarly formed fore-feet. I also remember a very good horse, called Uncommon, own brother to Jericho, belonging to Lord Lonsdale, who coursed in our neighbourhood; he had a peculiar

action of dishing or swinging his fore-feet outwards when going fast, either trotting or galloping, and nearly all his progeny, whatever mares were sent to him, did the same: it was well known to all our neighbourhood, who used to say, "Here comes an Uncommon."

Mr. Finlay Dun, who wrote one of the most interesting and able papers I ever perused, and read it at the Midland Farmers' Club last year, in that lucid and forcible style for which he is so noted, goes very fully into all these questions, and I shall have several times to quote him. He says—"That not only do the parents transmit to their offspring their own external configuration, they also mould the various internal organs, and implant the particular habits and temperaments. All are equally transmissible." He then goes on to state, with regard to horses—"How persistently does the blaze on the face, or white legs reappear in each generation," and mentions a case of a celebrated cart stallion in Leicestershire, where three-fourths of his stock have white leg-markings, and that in one of the best horse breeding counties in England "there is at the present time a yellow bay cart-horse, which has been repeatedly made up for showing, has gained various county premiums, and has thus acquired a local celebrity in spite of his narrow chest, his weak loins, and his round, rough, greasy legs. For several years this brute has procreated a large number of faulty foals; many are produced with deformed heads and crooked spines; from false presentations more than half of them die. Some of his colts when dropped are unable to stole or dung, and others their urachus is imperfectly closed; those that survive for a few weeks frequently have scrophulous abscesses about the joints, more than one-third of his foals die before they are six months old, the residue are rickety, delicate, ill-thriving, and will not pay for rearing." These are the eloquent and forcible remarks of Mr. Finlay Dun, and I am sure many of my hearers can assert pretty much the same of many stallions in their locality. But do not let us give the whole discredit to the stallions; look at the wretched animals constantly put to the shafts or travelling the country—any broken-down weed, or lame old cart-mare, is deemed in many cases good enough to breed from. Some of the most fertile sources of badly bred horses is to be found in the mistaken kindness of many landowners and gentlemen in a neighbourhood, who look more for the use of the surrounding tenants free of cost. Let them by all means keep the horses for use, but by making a charge for the mares I feel sure there would be fewer useless brutes sent to them to continue the flood of unsound animals generally to be found in the country.

This brings me to breeding of horned stock, and here my subject opens out so widely, that I fear I must somewhat trespass on your patience, and ask you to bear with me whilst I again call your attention to my first proposition as to the influence of the males. The great and distinguished lines of blood—the Bates, the Booth, and the Knightley, having each their followers, sometimes in their distinctive purity, sometimes in their judicious crossings, are each and all striving to attain perfection; and in that noble rivalry—I cannot call it a bloodless one—are all doing great service to the nation in their efforts to improve the meat-producing animals, not only of England and her colonies, but the world—for all come here for blood; whilst the colonies are hoping to add to their own pecuniary resources, they are all helping to swell the wealth of the nation. It is certainly remarkable to observe the external peculiarities of each of these tribes, and the noble carriage and grandeur of outline of the Bates tribe,—the heavy, thickly-fleshed, richly-haired character of the Booth, and the lovely sweetness of countenance, the fine shoulders and deep milking peculiarities of the Knightleys, are well known to all breeders.

There are many instances recorded as to horned stock, in which the influence of the male was felt through many generations—that of the bull Hubback (319), for instance, and that of Favourite (252), are striking peculiarities of quality and style are found to the present day. In our own time let us take Earl of Dublin (10,178). The late Mr. Adkins used him on his noted Milcote herd, where he did great service, and then sold him to Sir Charles Knightley, where he did even more distinguished service than in Mr. Adkins' herd. Here was an extraordinary instance of his impressing deep milking qualities on his stock, which was an internal organisation; but on looking to his pedigree, you will find he was over and over again Princess, Princess, and Princess, through almost every sire and dam, who were all noted milkers. And, again, being used on a herd of noted milking qualities, like the Fawsleys, it was not to be wondered at that his stock to this day are amongst the most prolific and deepest milkers we have.

In reference to this point, I must quote Mr. Darwin, who, in "Animals and Plants under Domestication," vol. ii., chap. 12, p. 2, on Inheritance, says:—

"What can be more wonderful than that some trifling peculiarity, not primordially attached to the species, should be transmitted through the male and female sexual cells, which are so minute as not to be visible to the naked eye, and afterwards through the incessant changes of a long course of development, undergone either in the womb or the eggs, and ultimately appear in the offspring when mature, or even when quite old, as in the case of certain diseases? Or, again, what can be more wonderful than the well-ascertained fact that the minute ovule of a good milking cow will produce a male, from whom a cell, in union with an ovule, will produce a female, and she, when mature, will have large mammary glands, yielding an abundant supply of milk, and even milk of a particular quality? Nevertheless, the real subject of surprise is, as Sir H. Holland has well remarked, not that a character should be inherited, but that it should fail of being inherited."

7th Duke of York (17,754) also has left his mark unmistakably on nearly everything he touched—and whether it was a pure Duchess, a Florentia, an Ursula, a Gazelle, or any others of the various tribes put to him, the progeny of one and all in external appearance were improved by him. The same thing, I am told, has been the case with Commander-in-Chief (21,451), Prince Alfred, and some others of the noted herds of Booth fame. On my visit to those extraordinary sales in the North of England, I was much struck with the old red friend, Mr. Strafford, when at Mr. J. P. Foster's, of Kilbow, I was much struck with the beauty of all the young stock, their grand style, fine touch, and rich hair and colour; and, on reference to my catalogue, I found they were all by his bull, Duke of Oxford 13th (23,504). It did not matter what he was used, they were all good; strains of blood the most opposite, and oftentimes freely mixed—yet all were good. When also at Colonel Gunter's, at Wetherby, some two years ago, the impress of 4th Duke of Thorndale (17,750) was remarkable. Duke comes up a very famous and interesting branch of the question—that of "prepotency," or the overpowering influence of one or other of the sexes. Mr. Finlay Dun says it is mostly developed in the males, and that amongst horses, "Some of the best thoroughbred families are remarkable for prepotency, and veterans with racing stock must admit the prepotency of Eclipse, and of Stockwell," and I would add King Tom.

He also says that the best Down sheep appear prepotent over the white-faced varieties. I myself used a bull, Hardicanute (2633), bred by the late Mr. Adkins, who was very strongly prepotent; Seraphinas and Knightleys were all fully impressed by him, and his fine touch and quality were perceptible in all.

There is a very remarkable instance of the theory of natural selection in the case of the noted wild cattle in Chillingham Park, which was communicated to me by Mr. Jacob Wilson. He says, "that at present the herd numbers 67 head, and that the herd has been kept up by in-and-in breeding for several centuries, of course the master bull always serving the cows." You will see here that the strongest male, continually asserting his prowess, keeps up the vigour of the herd; and when another stronger animal rises up amongst them, he in his turn becomes "lord paramount," and as old age comes on, gives way again to his successors. In the "St. James' Magazine" is an account given of a battle for the mastery of the bulls, which, from its graphic description I must give. It was written by a lady who had visited the cattle at Chillingham.

"There is always danger in meeting a 'sulky bull,' that is, a bull banished from the herd—literally sent to Coventry. The way this is effected: the younger bull, should he contemplate a hunt, and the wish to harass the comer. Then the older bull, stepping forth from his harem, answers the challenge, and advancing step by step, the rivals meet, and the battle rages furious and strong—I heard another lady seriously say that the two bulls are apparently acting as self-constituted umpires, are watching with heaving flanks and foam-stained lips, the chances of war. Thus the fight goes on, amidst growls of rage, clouds of dust, and the sward torn up, as beneath the thick foreheads meet. Presently one of the combatants falters; then the fight is decided, for upon the first symptom of weakness, the umpire, rushing in, bears down him, the proprietor

female in the internal organisation very great as to transmission of fecundity, milking powers, and constitution, to all her offspring. Some years ago I had a very favourite sow that had bred me six farrows of pigs, and most of them had taken prizes. She then refused to breed, after being sent to every Berkshire brawn I could get her to, then put her to her own son: the produce were half cripples, the hind feet being in the place of the fore ones, &c. She afterwards bred me six more farrows, the last one of 12 pigs the best she ever bred."

And Mr. Duckering, of Kirton Lindsey, the noted breeder of white pigs, writes to me thus,—"I have ever found symmetry depend much on the male animal; I should therefore have him as perfect in form as possible, displaying all the points of his race." And he also states,—"Occasionally my neighbours send a Berkshire sow to my white boar, and the produce has invariably been all white."

I have also an interesting letter from the Rev. Mr. Storer, of Hellidon, of Shorthorn notoriety, and he says, with regard to my broad proposition with which I started, that it is what the Scotch call "not proven"—of doubtful certainty,—"but that external peculiarities are often transmitted by the male through many successive generations, and where not strictly transmitted they have appeared after remaining in abeyance. But my experience does not lead me to but selected the best of the best every year, and produced a flock, which for evenness of character and perfection of shape has never been surpassed. So did Mr. Jonas Webb with his Southdowns. Mr. Darwin mentions the case of the Ancon sheep as a very curious instance. He says, "they were first raised in Massachusetts—a ram having been accidentally born with short, crooked legs, and a long back; it was soon multiplied and raised into a new stock, known by the name of the Ancon breed."

We therefore see, from the number of facts which have been produced, that the proposition I first laid down—that the male chiefly exercises the external and the female the internal organisation—is in the main correct. If I chose to carry on this paper farther, I should tire your patience, and could say no more than I have now. We have seen how this principle acts with the horse and the ass, in horned stock, with sheep and pigs, and also in numberless cases with poultry.

I admit there are many weak points in my armour, and which will probably be found out by the practical and scientific men I see around me; but let us see if we cannot apply these facts, and try to form principles to guide us in our attempts to improve the live stock of this country.

In our horses let us look well to the stallion—that he even the external surroundings must be attended to. Mr. McCombie, I am assured has all his buildings, his gates, his gateposts, and everything about his farm, black; so that no imagination shall disturb his black-polled stock. I have heard that a certain lady, of well deserved and well known Shorthorn fame, had wondered at the preponderance of white calves which were chiefly bred on her establishment, and that the roans, year by year, were getting lighter. It was suggested that her annual practice of lime white-washing her buildings should be discontinued; she did so, and very rapidly her ladyship's cows produced fewer white calves, and the roans got darker. Whether it was imagination or not I will not pretend to say, but I state the facts, and out of them, perhaps, principles may be determined. We have also seen how "prepotent" some animals are over others, and I am almost inclined to think that oftentimes the female is prepotent over the male, even in externals, but this has been inherited in former generations from the male. I have studiously avoided alluding to the human race, but I cannot forbear mentioning a well-known fact, as an illustration, that the thick lips of the Imperial house of Austria are said to have been inherited from the marriage of the Emperor Maximilian with Mary of Burgundy; and in a well-known ducal house of this country, the prominent finely-arched nose has been

FIG. 336.—MR. STRATTON'S SHORTHORN OX, WINNER OF THE SMITHFIELD CLUB CHAMPION PRIZE, 1871.

think that such power of external peculiarities is confined to the male animal. I conceive that all depends upon which of the two is the more prepotent." "As an example," he says, "I saw a few years since, at a farmer's in Notts, a Shorthorn roan heifer, with a large black spot on her thigh, and corresponding with it a black bar across the tail, and was informed that she was descended from a cow of Mr. Burgess', six generations back, which cow had an exactly similar blemish. This was a case of reversion or atavism." With regard to colour, "in many cases," he says, "the calf is more likely to derive its colour from one or other of its grandparents, than from either of its parents."

With regard to sheep, it is well known how a ram influences the external characteristics of a flock. The Oxfordshire Down, which now ranks as an established breed, was produced about the year 1830, by crossing Hampshire or Southdown ewes with the Cotswold ram, and despite the assertion to the contrary, I know the greatest difficulty is experienced in keeping up the great characteristics of the breed. Here we find the male leaving behind in his progeny size, wonderful external appearance, thickness of the lean and closeness of grain of the meat—being an internal production following the female. As an instance of remarkable careful selection, and thus keeping a breed of sheep pure, nothing can surpass Mr. Valentine Bayford's flock; for nearly 50 years he never bought a ram, has good carriage, fine action, speed, and good colour; that our mares have strong constitutions, free from constitutional blemishes, strong in wind, with great powers of endurance, and, above all, good tempers.

With sheep, that our tups shall have strong limbs, thick scrags, broad loins, length, and good heads and ears; that the ewes have good fleeces (whichever we go in for—long, short, or lustre wool), broad chests, showing strong internal structure, good milking powers, and disinclination to roam about in our southern districts, and good foraging powers on hill and mountain sides.

That our boars should be powerful, with good hair and plenty of it, short heads and good loins, straight and long, with short legs; our sows quiet, feminine-looking, great motherly instinct and great fecundity, with full milking powers and great aptitude to fatten.

That our bulls should be of noble bearing, with fine crests, good manes, and shaggy frontlets, grand carriage, strong hind legs, sweet yet masculine heads, and good tempers; the cows quiet, lazy, good-tempered creatures, with deep good bosoms, great milkers (the most essential of all), lovely heads, well expressed as "Knightley," &c.

These would be general characteristics, but we must be careful of association. I feel sure that a herd of valuable Shorthorns ought never to have a polled Scot, an Alderney, or any but their own breed with them; and, if we are to believe the statements we have heard, inherited for several centuries, in both the male and the female line.

There is one other circumstance that ought to receive consideration, that is, the influence of food and climate in modifying species. The Rev. Mr. Titcombe, in the reports of the Victoria Institute, in speaking of the origin of the negro, says—

"That the action of food and climate exercises great influence in modifying size, colour, and even structure; in food it is well known that Hemp seed given to birds of the Finch tribe will turn them black. Rich and plentiful food, when given to young swine, directly tends to make their heads broader and shorter, whereas poor food works a contrary result. Horses fed on fat marshy grounds, grow to a large size, while on strong soils or dry heath they remain small."

And I therefore think, if a man leaves the district to which he has been accustomed, and takes a farm in another county, he should fully study the class of animals indigenous to that district before he brings into operation his own pre-conceived ideas; and you may rely on it that, on the whole, the breeds which have become indigenous to a district are generally the most suitable. There are some notable examples. I believe the Shorthorns will adapt themselves to every part of the three kingdoms, and have proved themselves capable of living in almost every climate in the world. The Berkshire pig, too, seems to thrive everywhere. The Leicester sheep fail in many loca-

lities, and the Sussex Downs in many districts of England are comparative failures. I believe the Suffolk horses flourish nowhere but in the eastern counties. There are also many parts of England where the Dorking fowl cannot be reared to advantage, and there is no doubt that the early maturity and delicacy of colour of the Aylesbury duck rapidly deteriorates when removed from the neighbourhood of Aylesbury.

My subject has such a tendency to branch off into so many lines, that I must bring my remarks speedily to a close. But do not let it be imagined that I have been shown how easy breeding a good class of animals is. Successful breeding requires the greatest possible care, skill, and attention; and to obtain marked success every minutiæ must be attended to. Darwin says (p. 3, vol. ii.):—"Some writers, who have not attended to natural history, have attempted to show that the force of inheritance has been much exaggerated. The breeders of animals would smile at such simplicity, and, if they condescended to make any answer, might ask what would be the chance of winning a prize if two inferior animals were paired together? They might ask whether the half-wild Arabs were led by theoretical notions to keep pedigrees of their horses? Why have pedigrees been scrupulously kept and published of blood horses, of Shorthorn cattle, and more recently of the Hereford breed? Is it an illusion that these recently improved animals safely transmit their excellent qualities, even when crossed with inferior stock? Have the Shorthorns without good reason been purchased at immense prices, and exported to every quarter of the world, a thousand guineas having been given for a bull? With greyhounds pedigrees have been kept for generations, and the names of such dogs as Snowball, Major, &c., are as well known to sportsmen as those of Eclipse or Herod on the turf. Even with the game cock pedigrees of famous strains were formerly kept, and extended back for a century. With pigs, the Yorkshire and Cumberland breeders preserve and print pedigrees; and to show how such highly bred animals are valued, I may mention that Mr. Brown, who won all the 1st prizes for small breeds at Birmingham in 1850, sold a young sow and boar of his breed to Lord Ducie, for 43 gs.; the sow alone was afterwards sold to the Rev. F. Thursby for 65 gs., who writes: 'She paid me very well, having sold her produce for £300, and having now four breeding sows from her.' Hard cash paid down, over and over again, is an excellent test of inherited superiority. In fact the whole science and art of breeding, from which such great results have been obtained during the present century, depend on the inheritance of such like detail of structure. But inheritance is not certain, for if it were, the breeder's art would be reduced to a certainty, and there would be little scope left for all that skill and perseverance shown by the men who have left an enduring monument of their success in the present state of our domesticated animals."

Before I conclude I must say one word as to crossing. I have always observed a tendency to revert to one or both parents, which is very strong, and endures for many generations. In "Youatt on the Pig," Mr. Sidney states that, in a litter of Essex pigs, two young ones appeared which were the images of the Berkshire boar that had been used 28 years before in giving size and constitution to the breed; and Mr. Darwin also says that he observed, in a farmyard at Betley Hall, some fowls showing a strong likeness to the Malay breed, and was told by Mr. Tollet that he had got yearly before crossed his birds with Malays, and that he had often tried to get rid of this strain, but gave it up in despair, as the Malay character would reappear.

I have now tired myself, and perhaps exhausted your patience, and I trust that these disjointed opinions may open the campaign for the next session, and that in the next two or three years some more able writer will be enabled to lay before the country a statement of results showing that this paper has not been written in vain, and that the discussion of this evening may stimulate the farmers of England, and the nobility and gentry, who are amongst our most distinguished leaders in this most seductive art, to make experiments for enlarged exertions to provide food for our ever increasing population. And whilst I have given you the opinions of many of our leading farmers on this subject, and see around me so many of them distinguished by their zeal and success in the cause, let us not forget that not only we but many of the highest in the land are our competitors; and from the liberal yet judicious way in which they spend their money for breeding purposes, we may one and all congratulate ourselves that they are fully alive to the importance of this subject.

SMITHFIELD CLUB SHOW.

Agricultural Hall, Islington, December 4 to 8.—The large hall, with its galleries and off-set apartments, has been filled with the usual display of live stock and implements of the farm, and with more than the usual crush of sightseers during the week. The live stock department is short in some classes of cattle, and in the sheep classes as a whole, but fuller than usual in the classes of Devon cattle, and about as good as usual in the various breeds of pigs. Hereford cattle are poorly represented in respect of numbers, chiefly owing to the large number of animals which, though starting in sound health from Birmingham, were nevertheless found, before presenting themselves for admission at Islington, to be suffering from foot-and-mouth disease. Shorthorns are hardly so numerous as usual, but they include, we think, as good a set of illustrative specimens of the breed as is generally seen. The black polled heifer which received the champion prize at Birmingham as the best animal in the yard, is here again in competition with Mr. Stratton's white ox, and the decision of the Birmingham judges is overruled—the champion prize is here awarded to the Shorthorn. We give in another page a sketch of the winner, taken from a photograph, and therefore a trustworthy likeness. He stood a little awkward, but the engraving successfully represents his ripe and massive form, the beauty of his head, thickness of flesh over loin and back, depth of hind-quarter, and size and depth in front. The heifer against which he was pitted is also a perfect illustration of animal symmetry and quality, whether from the the butcher's or breeder's point of view. It is perhaps right that where so near an approach to equality exists, the palm should be given to the individual which belongs to the more generally useful breed.

THE CATTLE CLASSES.

The *Devon* breed stands first in the Smithfield Club lists. The younger class of steers includes seven entries, of which three were also shown at Birmingham, and the Queen's ox, 1st there, is also 1st here. The senior takes the 2d prize, and H.R.H. the Prince of Wales is placed 3d, with the largest ox in the class, carrying a capital top of thick flesh over loin and back. The older classes of Devon oxen are very good; no fewer than ten of the entries here had been previously shown at Birmingham, and the quality of the show absorbed, owing to the foot-and-mouth disease. Mr. Smith, of Exeter, takes the 1st prize in the younger class with a well-made ox, carrying a lot of useful flesh. Mr. Ford, of Rushton, takes the 2d prize with an animal which had not previously been shown, and the 3d prize goes to Mr. Farthing's Birmingham prize steer. In the older class, which has been generally commended by the judges, with three special high commendations in addition, Mr. Bond, of Huntworth, takes the 1st prize with an ox not previously shown. Mr. Overman is 2d with an ox, also new to the class, carrying a great weight of flesh, but somewhat disfigured by a drooping rump; and Mr. Taylor, of Glynley, is placed 3d with a very large and heavy ox, especially thick over loin and back. There is a very pretty class of Devon heifers—some of them of unusual weight. The 1st prize is taken by Mr. Farthing's Birmingham prize steer, a handsome heifer, fine in width and front, and carrying also a beautiful top, loin, and rib. The older cow class includes several of the Birmingham entries—the 1st prize goes, however, to Mr. Davy's old cow, not previously shown. The five weights here do not nearly reach the average attained by the younger class.

The *Hereford* class are sadly shorn of their beauty by the foot-and-mouth disease—24 entries of oxen have dwindled to 16. Two heifers are shown in place of five, and several in the cow class also have been unable to obtain admission. Mr. Baldwin takes the prize in the younger class of oxen with a fine ox, which we made beast; and Mr. Pike is 2d with a much heavier steer, two mouths older, rather flat-sided, but very deep and heavy. In the medium class of oxen, Mr. Groves takes the 1st prize with his very long and deep ox, shown at Birmingham. Mr. Wortley has a thick but rather short and lumpy 3-year-old, remarkably fine in front. The older class of oxen contains, among other fine animals, Mr. W. Heath's exceedingly well-fed and well-bred 1st prize ox—first-rate over top and hind-quarters, with also a wide and large bosom; Mr. Linen's prize ox, rather deficient in thigh and twist, is also well covered over back and ribs. These two oxen weigh close on 20 cwt. each. There are two very pretty Hereford heifers shown in their class, Her Majesty taking the 1st prize, and Mr. Allen, of Tisbury, taking the 2d with a heifer rather too fat. The cow class is rather more numerous; Mr. Wortley is 1st, and Mr. Bettridge 2d.

The younger class of *Shorthorn* oxen is not very good, the 1st prize goes, however, to a very well made steer, with a back straight to the very end, and well covered with useful flesh, though not fatter than we often see breeding animals shown at the meetings of the Royal Agricultural Society. The 2d class of oxen is very fair; most of the animals had been shown at Birmingham, Mr. Bruce, of Forres, again taking the 1st prize, Colonel Lindsay 2d, and Mr. Foljambe 3d. The older class of oxen includes a number of very fine beasts. Mr. Torr's grand ox figured in opposite number (fig. 336), taking the 1st prize in his class, as well as the champion prize of the meeting. We take the following description of him from the report in the *Mark Lane Express* of the Birmingham show:—

"Mr. Richard Stratton's 'walking advertisement' for the Burderop herd has gone on famously. He is a particularly handsome beast, and has continued to feed very level, as in fact for his weight and size it is not often that a better balanced ox has been brought out. He is very good to meet, has a neat, bloodlike head, and, a great point, is better out of than in his stall, so gay is his carriage and so smart his appearance. His touch is wealthy enough for that of a Hereford, or, as some superfine connoisseurs might call it, rather strong, but in our times this is a fault in the right direction. Moreover, the white steer is 'well connected,' for his grand-dam on the sire's side, *Diadem*, was a gold medal cow at the Smithfield Club, and his half-sister, *Village Rose*, is very nearly lengthy heifer, with every promise of growing into a handsome cow, was the 1st prize calf at the last All-Yorkshire meeting, where she beat the 2d prize calf from the Wolverhampton Royal. By Baron Lunedale's *April Rose* bull, this ox is a twin, but the other went wrong and died young. As is well known his breeder, Mr. Richard Stratton, died a few months since, and the ox was entered here by one of the sons, Mr. Ralph Stratton, so that he was ineligible for the combined fed-and-bred premium. Otherwise, up to a certain point, he won everything he could easily enough, as, beyond his class, when it came to the best of all the Shorthorns, the judges had the winners in the several classes paraded just for form's sake, and then arrived at an instantaneous decision. We quite expect to see the white ox do as well in London as he did in Birmingham, if not even better, for with three Shorthorn judges against a mixed bench, the Shorthorns have now always 'the pull' at the Smithfield Club when it comes to a comparison of breeds."

Mr. Farthing, of Bridgwater, a breeder of Devons, takes the 2d prize in this class with a deep and stocky, well-made beast, particularly well developed over loin. There are well-filled classes of heifers and cows, Messrs. Kennard, Mace, and How taking the 1st, 2d, and 3d prizes in the younger class, and Sir W. C. Trevelyan, Colonel Lindsay, and Mr. Kirkham standing 1st, 2d, and 3d in the older class.

Large entries of *Sussex* cattle are made, as usual, but there are several absentees. The prize animals are hardly to be distinguished from Devons, and in the older class of oxen, along with good quality there are a large number of very heavy weight, several animals standing over a ton upon the weighbridge. The class of Sussex cows and heifers contains some fine ones, them by judges of a general commendation. Mr. Brand, M.P., takes the 1st prize in this good class, Mr. Shoosmith the 2d, and Mr. G. C. Coote is highly commended.

There is a very poor show of the polled *Norfolk* breed, which is generally very well represented at the Smithfield Shows. The *Longhorns* hardly deserve their prizes by their number. Three in two classes are not enough to justify the continuance of the prize list. The West Highland breed is fairly represented, as also are the Scotch horned breeds. There is a fine display of polled cattle, including one or two very admirable specimens—among them Mr. Bruce's remarkable heifer, already named.

The prize list will give the names of the other successful exhibitors. There is no competition in Irish or Welsh cattle, and the cross-bred classes are as numerous, though hardly so interesting, as hitherto.

The following is the list of the judges and their awards:—

JUDGES.—Devons, Herefords, Sussex, Norfolk or Suffolk Polled, Scotch Cattle: H. M. Kerry, Bridgenorth; G. Smythies, Marlow, Leintwardine; Thomas Pope, Horningsham, Warminster, Wilts. Shorthorns, Scotch, Irish, Welsh, Cross, or Mixed: M. Scorer, Bourden Lodge Farm, Great Yeldon; William Torr, Aylesby Manor, Grimsby; T. W. Ruddock, Tweed House, Berwick-on-Tweed.

Class 1. Devon Steers, not exceeding 2 years and 6 months old.—1st, £25, Her Majesty the Queen; Silver Medal to breeder, Her Majesty the Queen; 2d, £15, T. L. Senior, Broughton House, Aylesbury; 3d, £10, H.R.H. the Prince of Wales.

Class 2. Devon Steers, not exceeding 3 years and 3 months old.—1st, £30, W. Smith, Hoopern, Exeter. Devon: Silver Medal to breeder, Mr. Bassett Passmore, Jun., Aller Farm, South Molton; 2d, £20, J. Ford, Rushton, Blandford, Dorset; 3d, £10, W. Farthing, Stowey Court, Bridgewater. Commended: H.H. the Prince of Wales.

Class 3. Devon Steers or Oxen, above 3 years and 3 months old.—1st, £30, T. Bond Park, Huntworth, Bridgewater: Silver Medal to breeder, T. Bond; 2d, £20, J. Overman, Burnham Sutton, Burnham Market; 3d, £10, W. Taylor, Glynley, Eastbourne. Highly Commended: the Queen, Mr. W. Smith, and Mr. J. Davy. Commended: H.R.H. the Prince of Wales.

Class 4. Devon Heifers, not exceeding 4 years old.—1st, £25, T. L. Senior, Aylesbury, Bucks; 2d, £15, Messrs. Kennard, J. D. Hancock, Hele, Taunton; 3d, £15, S. R. Jefferys, Maiden Bradley, Wilts; 3d, £10, J. C. Senior, Broughton Pastures, Aylesbury. Highly Commended: Mr. R. Silver Medal to breeder, J. Davy; 2d, £15, W. Smith, Hoopern, Exeter; 3d, £10, J. H. Buller, Downes, Crediton. Highly Commended: Mr. S. R. Jefferys. Commended: Mr. H. Hitchcock.

Class 6. Hereford Steers, not exceeding 2 years and 6 months old.—1st, £20, W. Baldwin, Luddington, Stratford-on-Avon; Silver Medal to breeder, J. Baldwin; 2d, £15, A. Pike, Mitton, Tewkesbury.

Class 7. Hereford Steers, not exceeding 3 years and 3 months old.—1st, £30, W. Groves, Brompton, Shrewsbury: Silver Medal to breeder, H. Linell, Eastrey; 2d, £20, T. Wortley, Stanley Hall, Aylsham; 3d, £10, C. Hall, Brockweir, Wilts, Croydon.

Class 8. Hereford Steers or Oxen, above 3 years and 3 months old.—1st, £30, W. Heath, Ladbrun Hall, Norwich: Silver Medal to breeder, J. Merry, Eyton-on-Severn; 2d, £20, L. Loyd, Monks Orchard, Addington Surrey; 3d, £10, J. Ford, Rushton, Blandford, Dorset. Highly Commended: the Countess Dowager Cowper, Earl of Darnley, and Mr. H. Betteridge. Commended: the class generally.

Class 9. Hereford Heifers, not exceeding 4 years old.—1st £25, Her Majesty the Queen: Silver Medal to breeder, Her Majesty; 2d, £15, J. D. Allen, Tisbury, Salisbury.

Class 10. Hereford Cows, above 4 years old.—1st, £25, R. Wortley, Sutfield, Aylsham: Silver Medal to breeder, J. Connop, Nookes Court, Leominster; 2d, £15, H. Bettridge, Wantage; 3d, £10, W. Groves, Brompton, Shrewsbury. Highly Commended: Mr. W. Heath.

Class 11. Shorthorned Steers, not exceeding 2 years and 6 months old.—1st, £20, Lieut.-Colonel Lloyd Lindsay, V.C., M.P., Lockinge Park, Wantage: Silver Medal to breeder, Lieut.-Colonel Lloyd Lindsay, V.C., M.P.; 2d, £15, J. S. Foljambe, M.P., Osberton Hall, Worksop; 3d, £10, J. J. Sharp, Broughton, Kettering.

Class 12. Shorthorned Steers, not exceeding 3 years and 3 months old.—1st, £10, R. Bruce, Newton-of-Struthers, Forres, Moray: Silver Medal to breeder, R. Bruce: 2d, £5, Lieut-Colonel Lloyd Lindsay, V.C., M.P.: 3d, £10, F. J. S. Foljambe, M.P.

Class 13. Shorthorned Steers or Oxen, above 3 years and 3 months old.—1st, £30, J. Stratton, Alton Priors, Marlborough: Silver Medal to breeder, the late R. Stratton, Burderop, Swindon: 2d, £20, W. Farthing, Stowey Court, Bridgewater: 3d, £10, W. Sissman, Buckworth Lodge, Kimbolton. Commended: Lieut.-Colonel Kerr, Yetholm: Mr. Mace.

Class 14. Shorthorned Heifers, not exceeding 4 years old.—1st, £25, Rev. R. B. Kennard, Marnhull Rectory, Blandford, Dorset: Silver Medal to breeder, Rev. R. B. Kennard: 2d, £15, Mr. Mace, Sherborne, Northleach: 3d, £10, W. How, Tottington, Thetford. Highly Commended: Rev. W. Sneyd.

Class 15. Shorthorned Heifers, above 4 years old.—1st, £25, Sir W. C. Trevelyan, Bart., Wallington, Newcastle-on-Tyne: Silver Medal to breeder, Sir W. C. Trevelyan, Bart.: 2d, £15, Lieut.-Colonel Lloyd Lindsay, V.C., M.P.: 3d, £10, J. W. Kirkham, Cadeby Hall, Grimsby.

Class 16. Devon Steers, not exceeding 3 years old.—1st, £20, Lee Steere, M.P., Sparks Park, Dorking: Silver Medal to breeder, Lee Steere: 2d, £10, G. C. Carew-Gibson, Sandgate, Sussex: 3d, £5, G. Coote, Longton, Alrewas, Burton.

Class 17. Sussex Steers or Oxen, above 3 years old.—1st, £25, Mary Coote, Climping, Littlehampton, Sussex: Silver Medal to breeder, the late T. Oliver, Sinfield, Horsham, Sussex: 2d, £15, J. M. Montefiore, Worth Park, Crawley: 3d, £10, J. Neale, Coldwatham, Pulborough. Highly Commended: Mr. J. Shoosmith. Commended: Mr. F. Gates.

Class 18. Sussex Heifers, not exceeding 4 years old.—1st, £20, H. Smith, Bolney, Cuckfield: Silver Medal to breeder, Arthur Smith: 2d, £15, Lee Steere, M.P., Dorking. Commended: Messrs. W. Neale and L. Huth.

Class 19. Sussex Heifers, above 4 years old.—1st, £20, the Right Hon. H. Brand, M.P., Glynde Place, Lewes: Silver Medal to breeder, Right Hon. H. Brand: 2d, £15, J. Shoosmith, Berwick, Lewes: 3d, £10, Mr. Mace. Highly Commended: G. Coote. Commended: the class generally.

Class 20. Norfolk or Suffolk Polled Steers or Oxen, of any age. —1st, £20, J. Colman, M.P., Carrow House, Norwich: Silver Medal to breeder, the late J. Savory: 2d, £10, W. Durrant, Thornstead Hall, Cromer.

Class 21. Norfolk or Suffolk Polled Heifers or Cows, of any age.—1st, £15, J. J. Colman, M.P.: Silver Medal to breeder. Sir E. Kerrison, Bart., M.P.: 2d, £5, J. S. Postle, Smallburgh Hall. Commended: Mr. S. Slipper.

Class 22. Longhorned Steers or Oxen, of any age.—£10, Sir J. H. Langham, Bart., Cottesbrooke Park, Daventry: Medal to breeder, Sir J. H. Crewe, Bart. Commended: Mr. W. T. Cox.

Class 23. Longhorned Heifers or Cows, of any age.—£10, W. T. Cox, Spondon-on-Stour: Silver Medal to breeder, W. T. Cox.

Class 24. Scotch West Highland Steers or Oxen, of any age.—1st, £20, G. Leigh, The Hoo, Luston: 2d, £15, W. McCombie, M.P., Tillyfour, Aberdeen, N.B. Commended: Mr. J. Tingey.

Class 25. Scotch West Highland Heifers or Cows, of any age. —1st, £15, Sir W. C. Trevelyan, Bart., Wallington, Newcastle-on-Tyne.

Class 26. Scotch Horned Steers or Oxen, of any age.—£10, G. and J. G. Smith, Glenlivat Distillery, Banff: Silver Medal to breeders, G. and J. G. Smith. Commended: Mr. R. Wortley.

Class 27. Scotch Horned Heifers or Cows, of any age.—Not sufficient merit.

Class 28. Scotch Polled Steers or Oxen, of any age.—1st, £30, J. S. Postle, Smallburgh Hall: Silver Medal to breeder, W. Salmon: 2d, £15, J. Stephen, Conglass, Inverurie. Commended: Mr. W. Scarth.

Class 29. Scotch Polled Heifers, not exceeding 4 years old.—1st, £15, J. Bruce, Kochabers, Elgin: Silver Medal to breeder, A. Paterson: 2nd, £10, W. Brown, Linkwood, Elgin.

Class 30. Scotch Polled Cows, above 4 years old.—£15, W. McCombie, M.P.: Silver Medal to breeder, W. McCombie, M.P.

Class 31. Irish Steers or Oxen, of any age.—£10, R. Wortley, Suffield, Aylsham, Norfolk.

Class 32. Irish Heifers or Cows, of any age.—No entry.

Class 33. Welsh Steers or Oxen (Runts), of any age.—£20, J. E. Parry, Glyn Hall, Harlech, Merioneth: Silver Medal to breeder, R. Parry.

Class 34. Welsh Heifers or Cows, of any age.—No entry.

Class 35. Cross or Mixed-bred Steers, not exceeding 3 years old.—1st, £15, Messrs. D. D. Martin, Aberdeen: Medal to breeder, J. Johnston, Ellon, Aberdeen: 2d, £15, W. Slatter, Stratton, Cirencester, Gloucester: 3d, £10, the Hon. Mathew R. Mathew, Llanwern, Cardiff. Commended: Messrs. Forres, Moray. Commended: Messrs. J. D. Allen, and W. Scott.

Class 36. Cross or Mixed-bred Steers or Oxen, above 3 years old.—1st, £15, W. Brown, Linkwood, Elgin, Moray: Silver Medal to breeder, W. Brown: 2d, £15, J. J. Colman, M.P.: 3d, £10, J. Overton, Hartlebury Station, Burnham Market. Highly Commended: J. Stratton and Sir W. Trevelyan. Commended: R. Skelton.

Class 37. Cross or Mixed-bred Heifers, not exceeding 4 years old.—1st, £20, W. Brown, Linkwood, Elgin: Silver Medal to breeder, W. Brown: 2d, £10, S. Goulder, Woodhastwick, Norwich.

SHEEP.

These animals are, as usual, a great show both for farmers and amateurs generally. The pens filled this year, however, are not so many by 38 as appeared last year; but there are ample for every purpose which can be answered by a Christmas fat stock show.

The *Leicesters* are not up to their usual standard, either in mutton or wool, some of the latter having very light, and of inferior quality. The value of this pure breed, however, now consists in the way in which the males produced are adapted for imparting form, quality, and a pre-disposition to fatten to other coaser breeds, as the Lincolns—the "Improved Lincolns" being, indeed, a judicious admixture of pure Leicesters and the heavier mutton and wool producing Lincolnshire sheep. The Keythorpe Hall flock still takes the lead, for the executors of the late Lord Berners take the 1st prize in each class in which they exhibit, while Colonel Lowther and Mr. Brown are also good exhibitors of pens of this valuable pure breed.

The *Cotswolds* follow the Leicesters as white-faced long-woolled sheep, but there are only four pens. This breed is well supported, though, by Messrs. Wheeler's, Mr. Hall's, and the late Mr. Gillett's sheep.

In the *Lincolns*, however, although they also number only four pens, there is the principal attraction in the sheep classes, for the piece of plate, value £50, for the best pen of sheep in the Hall is awarded to Mr. Byron for his pen of ewes, 45 months old. This is a great honour for the Lincolns, and on closer examination it appears to be deservedly won, for these ewes are very heavy, both in mutton and wool. As compared with the yearling wethers, the average live weight of the three pens is 7 cwt. 2 qr. 12 lb., while the three 3-year-old ewes weigh 9 cwt. 1 qr. 2 lb., or 186 lb. more. These ewes are, besides, the heaviest pen in the Hall. This is evidently fair evidence of the utility of recording the live weight of the animals, both for present purposes and for comparison in future years, for we have no hesitation in saying that the weight of these Lincoln ewes been presented to the judges, they would not, standing as a single pen of ewes as they did, have been brought out for competition for the plate for the best pen in the Hall. These sheep were bred from Mr. Thomas Kirkham's Bicesthorpe stock. The Lincoln wethers were only three pens, and they were only of middling appearance.

Turning to the short-woolled sheep, the *Southdowns*, of course, stand in first general interest. In these classes, however, we miss on this occasion the great size crammed with fine quality which used to be sent from Merton. The perfect trimming, too, which John Day, the late Lord Walsingham's shepherd, used to display, is also conspicuous by its absence. However, Mr. Rigden, whose flock has not been so very much "in luck" of late years, is 1st in the heavy weight pen, being with a weight and 2d in the class for sheep under 200 lb. live weight. His Royal Highness the Prince of Wales, Sir William Throckmorton, the Duke of Richmond, Mr. Foljambe, M.P., and Mr. Overman meritoriously support the prize-takers in this class. The 2-year-old pens are a great class, the Duke of Richmond's pen, 2d, being one of unusually particularly good, both for size and the quality to which they had been fed. Their respective weights were 6 cwt. 3 qr. 9 lb., and 6 cwt. 3 qr. 6 lb. Of these there are six pens. The pens of these Southdowns number altogether 31.

The pens of the *Wilts Downs* are as interesting as any breed in the Hall. These sheep are greatly improved, from the present breeders having studiously observed the advantages of selection. Not many years ago their coarseness was obvious, from their excessively large heads, but now, and in the comely to look at, and the excellence of the backs of the sheep corresponds to the improvements elsewhere. An indirect compliment is paid to this breed by the Smithfield Club offering no prizes for 2-year-old wethers. These sheep are too big, and they carry too much lean meat, to require to be kept beyond two years of age. The 3-year old they are generally heavier than the Shropshires are at two years of age. This, with the fine quality of the mutton they produce, has stopped the outcry which used to be made against them, and particularly by the Shropshire men. Their yield of wool is heavy, but as a rule it is very fine, and we find that the prizes in the Shropshire classes are generally awarded to such "close coated" sheep as Lord Chesham's, in preference to the much heavier sheep with "open" coats, as shown by Mr. Nock, of Sutton Maddock. To carry this comparison a little further, Lord Chesham's 1st prize pen of close-coated Shropshires weighed 5 cwt. 3 qr. 22 lb., while Mr. Nock's unnoticed pen of the same breed, which carried twice as much wool of nearly equal quality, weighed 6 cwt. 3 qr. 5 lb., or 95 lb. the pen of three more. The decision, which similarly occurred in the Hall, in Birmingham, is a very great encouragement to the combined growth of a large and fine quality of mutton and wool, which has long been a regular boast among Shropshire men.

The *Shropshires* are undoubtedly, however, a great show. They are not so numerous as they have been in late years, but the whole 31 all of them have dark faces, and they certainly display more than any other breed that which is so much coveted, viz., a large production of dark-fleshed mutton of fine grain, combined with a heavy growth of wool of fine quality. After what we have said, however, in our comparative remarks above in connection with the Hants and Wilts Downs, we need not further discuss these points, but we may add, that the popularity of these sheep is shown in the fact that of the 12 pens exhibited in the three classes, four of them only were from their native counties, the others come from Berkshire, Buckinghamshire, Cambridgeshire, Herefordshire, Northamptonshire, and Yorkshire.

The *Oxfordshire* pens are only five, but the sheep in them are of the great size which we have been in the habit of seeing from the flocks of this breed. Much improvement in the quality of their flesh is in some cases observable, which is indicated to the eye by the dark brown, whole-coloured faces of some of the specimens shown. As these sheep were originally a direct cross between the Hants Downs and Cotswolds, there is no doubt but that, by judicious care, a very fine quality of flesh could be produced in combination with a great weight of mutton and wool.

The miscellaneous breeds, as we may term them, as they appear at the Agricultural Hall, are various in numbers as well as form. There are the Kentish, or Romney Marsh sheep, with their dull, heavy white faces, and somewhat coarse straight wool, of medium length, growing on flatter sides than one would choose. These sheep, however, are very useful in their native place, as they are hardy, and thrive fairly on their not over-rich feed off the marsh whence they take their name! Then there are the Ryelands, Cheviots, and Dorsets, the former of which have a very circumscribed district, while the Cheviots are a famous breed for hardiness and fecundity, and are bred by hundreds of thousands on the hills of Northumberland, Cumberland, Roxburghshire, and other high grounds of the North. These sheep are not heavy individually, but they produce a good weight of meat to the acre; and when the wethers run to three and four years of age, as they are often allowed to do, they are much esteemed for their good size and fine flesh. The Dorsets are too well known for their white faces and curly horns, for their compact frames on short legs, and for the early lambs which they produce, to need any further reference.

Besides the above tribes there is the class for mountain breeds, which admits of a variety of hill sheep being shown. Accordingly Exmoors, Scotch Highlands, Scotch Horned (which appears to be a distinction without a difference), and Cheviots are here shown, a pen of the latter carrying off the 1st prize for the Duke of Roxburgh's stock. These sheep confirm our remarks above, so far as their age go, for they are four years and eight months of age, but they have had something more to eat than they could have found either on the Cheviots proper or the Roxburgh hills. Their weight at this advanced age is 4 cwt. 2 qr. 16 lb., or 173 lb. each. Mr. Stratton, of Alton Priors, sheep are notables, for producing a heavier weight of mutton and wool by numbers, and not in the form of one frame.

The following are the Awards:—

JUDGES.—Leicesters, Cotswolds, Kentish or Romney Marsh, Cross-bred Long-woolled, Oxford, Mountain, Cross-bred Long and Short Wools, Lincolns: James W. Mann, Spaldwick, Kimbolton, Hunts: John Bryan, Southleigh, Witney, Oxon: Shropshires, Church Farm, Stretton, Grantham. Southdowns, Hampshire or Wiltshire Downs, Shropshire, Ryeland, Cheviot, and Dorset: J. S. Turner, Eliwigan, Longford, Newtown: Thomas Horley, The Fosse, Leamington: Edward Little, Lanhill, Chippenham.

Class 38. Fat Wether Sheep of the Leicester breed, 1 year old (under 23 months).—1st, £20, the Executors of the late Lord Berners: 2d, £10, the same: Highly Commended: Lieut.-Colonel Lowther, M.P., Barleythorpe Hall, Oakham, Rutland: 3d, £5, W. Brown, Holme-on-Spalding Moor.

Class 39. Fat Wether Sheep of the Leicester breed, 1 year old, (under 23 months), each Sheep not to exceed 200 lb. live weight. —1st, £20, the Executors of the late Lord Berners: Silver Medal to breeder, the late Lord Berners: 2d, £10, W. Brown, Holme-on-Spalding Moor: 3d, £5, Colonel Lowther, M.P.

Class 40. Fat Ewe of the Leicester breed, above 3 years old (that must have had a lamb).—£10, Colonel Lowther, M.P.: Silver Medal to breeder, Colonel Lowther.

Class 41. Fat Ewes of the Cotswold breed, 1 year old (under 23 months).—1st, £20, J. Wheeler & Sons, Long Compton, Shipston-on-Stour: Silver Medal to breeders, J. Wheeler & Sons: 2d, £10, Lord Chesham, Latimer, Chesham.

Class 42. Fat Ewes of the Cotswold breed, above 3 years old (that must have had a lamb).—£10, the Executors of the late T. Gillett, Kingsey, Faringdon: Silver Medal to breeder, the late T. Gillett.

Class 43. Fat Wether Sheep of the Lincoln breed, 1 year old (under 23 months).—1st, £20, J. Byron, Kirkby Green, Sleaford: Silver Medal to breeder, J. Byron: 2d, £15, J. Pears, Mere, Lincoln: 3d, £5, J. Cunnell, Witham on the Hill, Lincoln.

Class 44. Fat Ewes of the Lincoln breed, above 3 years old (that must have had a lamb).—£10, J. Byron, Kirkby Green, Sleaford: Silver Medal to breeder, J. Byron.

Class 45. Fat Wether Sheep of the Kentish or Romney Marsh breed, 1 year old (under 23 months).—1st, £15, B. W. Tassell, Hode, Partridgebury, Camberham: 2d, £10, Thomas Gallipher, B. W. Tassell: 2d, £10, W. Burch, Rhode Court, Selling, Faversham.

Class 46. Fat Wether Cross-bred Longwoolled Sheep, 1 year old (under 23 months).—1st, £15, Sir W. de Capell Brooke, Bart., Geddington Grange, Kettering, Northampton: Silver Medal to breeder, Sir W. de Capell Brooke: 2d, £10, withheld.

Class 47. Fat Wether Sheep of the Southdown breed, 1 year old (under 23 months), each Sheep not to exceed 200 lb. live weight.—1st, £15, Sir W. Throckmorton, Bart., Buckland, Faringdon: Silver Medal to breeder, Sir W. Throckmorton, Bart.: 2d, £10, W. Rigden, Pyecombe: 3d, £5, H. H. Penfold, Selsey. Highly Commended: Duke of Richmond.

Class 49. Fat Wether Sheep of the Southdown breed, 2 years old (shorn), and under 35 months.—1st, £15, the Duke of Richmond, Goodwood: Silver Medal to breeder, the Duke of Richmond: 2d, £10, J. Overman, Burnham Sutton. Highly Commended: Mr. J. S. Foljambe.

Class 50. Fat Ewes of the Southdown breed, 2 years old (unshorn), each Sheep not to exceed 200 lb. live weight.—1st, £15, Sir W. Throckmorton, Bart., Buckland, Faringdon: Silver Medal to breeder, Sir W. Throckmorton, Bart.: 2d, £10, W. Rigden, Pyecombe: 3d, £5, H. H. Penfold, Selsey. Highly Commended: Duke of Richmond.

Class 49. Fat Wether Sheep of the Southdown breed, 2 years old (shorn), and under 35 months.—1st, £15, the Duke of Richmond, Goodwood: Silver Medal to breeder, the Duke of Richmond: 2d, £10, J. Overman, Burnham Sutton. Highly Commended: Mr. J. S. Foljambe.

Class 50. Fat Ewes of the Southdown breed, 2 years old (unshorn), each Sheep not to exceed 200 lb. live weight.—1st, £15, Sir W. Throckmorton, Bart., Buckland, Faringdon: Silver Medal to breeder, Sir W. Throckmorton, Bart.: 2d, £10, W. Rigden, Pyecombe: 3d, £5, H. H. Penfold, Selsey. Highly Commended: Duke of Richmond.

Class 51. Fat Wether Sheep of the Hampshire or Wiltshire Down breed, 1 year old (under 23 months).—1st, £15, A. Morrison, Fonthill House, Tisbury: Silver Medal to breeder, A. Morrison: 2d, £10, Henry Sutton-at-Hone, Dartford: 3d, £5, J. & M. Arnold, Westmeon, Petersfield. Commended: Messrs. Russell.

Class 52. Fat Ewes of the Hampshire or Wiltshire Down breed, above 3 years old (that must have had a lamb).—£10, J. Rawlence, Salisbury: Silver Medal to breeder, J. Rawlence. Commended: Mr. J. Barton.

Class 53. Fat Wether Sheep of the Shropshire breed, 1 year old (under 23 months).—1st, £15, Lord Chesham, Latimer, Chesham: Silver Medal to breeder, Lord Chesham: 2d, £10, Sarah Beach, The Hattons, Brewood, Penkridge: 3d, £5, Lord Wenlock, Dorrick Park. Highly Commended: Lord Sondes. Commended: Mr. G. Cooke.

Class 54. Fat Wether Sheep of the Shropshire breed, 2 years old (above 23 and under 35 months).—1st, £15, Lord Chesham: Silver Medal to breeder, Lord Chesham: 2d, £5, Lord Wenlock.

Class 55. Fat Ewes of the Shropshire breed, above 3 years old (that must have had a lamb).—£10, Lord Chesham: Silver Medal to breeder, Lord Chesham.

Class 56. Fat Wether Sheep of the Oxfordshire breed, 1 year old (under 23 months).—1st, £20, the Duke of Marlborough, K.G., Blenheim Palace: Silver Medal to breeder, the Duke of Marlborough: 2d, £15, N. Sidgee, Manor Farm, Adderbury: 3d, £5, S. Druce, Eynsham, Oxford. Highly Commended: Mr. Z. Tidgee.

Class 57. Fat Wether Sheep of the Oxfordshire breed, 2 years old (above 23 and under 35 months).—No entry.

Class 58. Fat Ewes of the Oxfordshire breed, above 3 years old (that must have had a lamb).—£10, the Duke of Mari-

borough, K.G.: Silver Medal to breeder, the Duke of Marlborough.

Class 59. Fat Wether Sheep, of the Ryeland, Cheviot, Dorset, or any other pure breed, not specified in any of the foregoing divisions, of any age.—1st, £15, H. Farthing, Nether Stowey, Bridgewater: Silver Medal to breeder, H. Farthing; 2d, £10, J. B. Downing, Holme Lacey, Hereford; 3d, £5, J. McGill, Ketchell, Dumfries.

Class 60. Fat Wether Sheep, of any Whitefaced Mountain breed, of any age.—1st, £15, J. Tapp, Twitchen, South Molton: Silver Medal to breeder, J. Tapp; 2d, £10, W. Smith, Hoopern.

Class 61. Fat Wether Sheep, of any Blackfaced or Speckled-faced Mountain breed, of any age.—1st, £15, the Duke of Roxburghe, Floors Castle, Kelso: Silver Medal to breeder, the Duke of Roxburghe; 2d, £10, T. Roy, Tullyhaird, Perth.

Class 69. Long and Short-woolled Cross-bred Fat Wether Sheep, 2 year old and under 23 months.—1st, £20, J. Overman, Burnham Sutton: Silver Medal to breeder, J. Overman; 2d, £15, N. Stiles, Addlerbury, Oxford; 3d, £5, D. Dunn, Brassey, M.P., Preston Hall, Aylesford, Kent. Highly Commended: Mr. J. Hine. Commended: Colonel Lowther.

PIGS.

The swine are a remarkably good collection, for although they are not so very numerous, there are none which, of course or otherwise, while all are ripe, and for the most part they have been fed till they are of the correct touch as regards firmness. This is the case, both as regards the softer Suffolk whites and Essex blacks, and the firmer Berkshires and Yorkshires, which shows that feeding generally have learned to use barley, or pea or bean meal, according as the swine need to be mellowed or made firmer. Pigs, however, appear to run in courses as regards the production of prize animals. For a few years one or two particular breeders take the leading prizes, when they appear to retire, and another herd of swine comes to the front. This is the case just now. Mr. John Biggs, of Cublington, Leighton Buzzard, Beds, has come upon the scene at the Agricultural Hall, and takes the 1st prize in three important classes with his Berkshires, and the Silver Cup, value £20, for the best pen in any of the classes. The hogs for which the latter honour is awarded in London, are the same which took a similar honour at Birmingham last week. The Suffolk whites and Essex blacks have seldom been better as a whole; in short, they are so good that our prize list learned readers will see the names of the several breeders who exhibit meritorious pens. The pens shown number 60, which are divided into 10 classes.

The following are the Awards :—

JUDGES.—John Angus, Whitefield, Morpeth; John Fisher Wood House, Cross Hills, York-shire; Joseph Smith, Henley-in-Arden.

Class 63. Pigs of any White Breed, not exceeding 9 months old.—1st, £10, Her Majesty the Queen: Silver Medal to breeder, Her Majesty; 2d, £5, Capt. R. P. Warren, Worting House, Basingstoke. Commended: Mr. T. Cartwright.

Class 64. Pigs of any White Breed, above 9 and not exceeding 12 months old.—1st, £10, J. and F. Howard, Britannia Farms, Bedford: Silver Medal to breeders, J. and F. Howard; 2d, £5, Her Majesty the Queen.

Class 65.—Pigs of any White Breed, above 12 and not exceeding 18 months old.—1st, £10, W. H. Dunn, Standen Manor, Hungerford: Silver Medal to breeder, W. H. Dunn; 2d, £5, R. E. Duckering & Son, Northorpe, Kirton Lindsey. Commended: H.R.H. the Prince of Wales.

Class 66. Pigs of any Black Breed, not exceeding 9 months old.—1st, £10, T. Chamberlayne, Cranbury Park, Winchester: Silver Medal to breeder, T. Chamberlayne; 2d, £5, C. McNiven, Perrysfield, Oxted, Godstone. Highly Commended: Mr. J. Coate.

Class 67. Pigs of any Black Breed, above 9 and not exceeding 12 months old.—1st, £10, T. Chamberlayne, Cranbury Park; 2d, £5, C. McNiven, Perrysfield, Oxted, Godstone. Highly Commended: Mr. J. Coate.

Class 68. Pigs of any Black Breed, above 12 and not exceeding 18 months old.—1st, £10, T. Chamberlayne, Cranbury Park: Silver Medal to breeder, T. Chamberlayne; 2d, £5, Mr. Benjafield, The Popkins, Stalbridge, Blandford. Highly Commended: Mr. J. Coates, Earl of Aylesford, Mr. H. G. Sturt, M.P.

Class 69. Pigs of any other breed, above 9 and not exceeding 12 months old.—1st, £10, J. Biggs, Cublington, Leighton Buzzard: Silver Medal to breeder, J. Biggs; 2d, £5, Mr. Benjafield, Silver Medal to breeder, J. Coate; 2d, £5, N. Benjafield, Short's Green Farm, Motcombe, Shaftesbury. Highly Commended: Mr. A. Benjafield.

Class 70. Pigs of any other breed, above 12 and not exceeding 18 months old.—1st, £10, J. Biggs, Cublington, Leighton Buzzard: Silver Medal to breeder, J. Biggs; 2d, £5, the Marquis of Aylesbury, Home Farm, Savernake Forest. Highly Commended: Mr. S. Druce. Commended: Mr. J. Treadwell.

Class 71. Pigs of any other breed, above 12 and not exceeding 18 months old.—1st, £10, and Silver Medal to breeder, J. Biggs, Cublington; 2d, £5, the Marquis of Aylesbury. Highly Commended: Mr. J. H. Clarke. Commended: the class generally.

EXTRA STOCK.

£10 and Silver Medal to the exhibitor, for the best Steer or Ox, J. Brown, Newcumbenland, Aberdeen. Commended: Mr. Jardine, M.P., Lord Penrhyn, Mr. J. G. Leigh.

£10 and Silver Medal to the exhibitor, for the best Heifer or Cow, R. H. Harris, of Earnhill, Yeovil. Commended: Mr. J. J. Colman, M.P.

Silver Cup to the exhibitor, for the best Wether Sheep, of the Leicester, Cotswold, Lincoln, and Kentish, or other Longwool breed; J. Pears, Mere, Lincoln. Highly Commended: the late Lord Hotham. Commended: Mr. R. Hall.

Silver Cup to the exhibitor, for the best Wether Sheep of the Southdown, and Hampshire or Wiltshire Down breed, A. Morrison, Fonthill House, Tisbury, Wilts. Highly Commended: Mr. Rigden, Sir W. Throckmorton. Commended: Duke of Richmond.

Silver Cup to the exhibitor, for the best Wether Sheep of the Shropshire, Oxfordshire, Cross-bred, or any other breed not specified above, Sarah Beach, The Hattons, Brewood, Penkridge, Stafford. Highly Commended: Mr. J. Overman. Commended: Mr. A. Stilgoe.

Silver Cup to the exhibitor, for the best single Pig, T. Chamberlayne, Cranbury Park, Winchester, Hants. Highly Commended: Messrs. Duckering.

SILVER CUPS.

Silver Cup, value £40, to the exhibitor, for the best Steer or Ox in any of the classes, J. Stratton, Alton Priors, Marlborough, Wilts. Gold Medal to Breeder, the late R. Stratton, Burderop, Swindon.

Silver Cup, value £40, to the exhibitor, for the best Heifer or Cow in any of the classes, J. Bruce, Fochabers, Elgin. Gold Medal to Breeder, A. Paterson, Mulben, Keith, Elgin.

Silver Cup, value £20, to the exhibitor, for the best pen of Leicesters, Cotswolds, Lincolns, Kentish, or other Longwooled breed, in any of the classes, J. Byron, Kirkby Green, Sleaford, Lincoln.

Silver Cup, value £20, to the exhibitor, for the best pen of 1-year-old Southdowns, Hampshire or Wiltshire Downs, W. Rigden, Hove, Brighton, Sussex.

Silver Cup, value £20, to the exhibitor, for the best pen of 1-year-old Shropshire, Oxfordshire, Cross-bred, or any other breed of Sheep (not specified in Prize List) in any of the classes, Lord Chesham, Latimer, Chesham, Bucks.

Silver Cup, value £20, to the exhibitor, for the best pen of Pigs in any of the classes, J. Biggs, Cublington, Leighton Buzzard, Beds.

CHAMPION PLATE.

A Piece of Plate, value £100, to the exhibitor of the best Beast in the Show (Extra Stock included), J. Stratton, Alton Priors, Marlborough, Wilts.

A Piece of Plate, value £50, to the exhibitor of the best pen of Sheep in the Show, J. Byron, Kirkby Green, Sleaford, Lincoln.

IMPLEMENT DEPARTMENT.

The implement department of the Smithfield Club's Christmas meeting this year is a complete success, both as to novelty and the number of articles exhibited. This is easily accounted for in the limited space, for, as soon as the space is filled, it is, we need hardly say, wholly inadequate to afford accommodation to a tithe of what the implement trade exhibited at Wolverhampton; hence, as exhibitors grow older they become wiser, and know how to more judiciously husband their room, and pack closer, so as by both full-sized articles and models to give the public the best sample they can of their manufactures. We never saw the Agricultural Hall at Islington so closely packed or better laid out for public inspection. But while we admit all this, there is one blank—a total failure—we mean the absence of a Smithfield Club catalogue! In point of fact, we hardly know how to refill it to readers in this age of printing by steam—or what it really means. The old proverb says, Necessity acknowledges

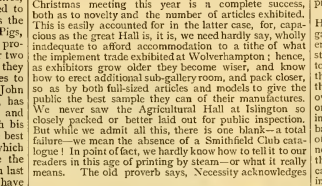

FIG. 337.—RANSOME'S CYLINDRICAL SCREENS.

no law—but we don't believe it applies to the case in question, for hitherto the public have paid 6*d*. for their penny-worth. At the Royal Agricultural Society's meeting we got a pennyworth for 1*d*., and the catalogue, with all its shortcomings, pays, and something over. Popular as the cattle department is, yet admitting this, the implement department has its increasing attractions; for it is now a well authenticated fact that before you can grow cattle in perfection you must first reclaim and cultivate the land by means of improved machinery, so as to grow food for your improved stock, and so on; all this will be understood by the practical reader.

Steam engines, &c., are not, perhaps, much above an average, at the same time the different classes of portable, traction, horizontal, and vertical fixed engines, are well represented. On entering the Hall from the Barford Street entrance, we meet with Tuxford, of Boston, the father of portable engines, on the right hand, and John Fowler & Co. on the left. The reader will readily perceive in this an instructive lesson in the march of improvement, for, say in Baker Street, the former always occupied a prominent position, limited as the space was for steam motors, whilst the latter, prominent as it now is, was nowhere then. This, however, is not all that the critical observer will perceive, for on the right hand he will see the great steam culture windlass of the Royal Agricultural Society of England at Wolverhampton, and on the left hand the friction drums and clip drums of Fowler & Co. giving way to the winding drum system of tillage. Between these there is a considerable difference between the winding drums of the Boston and Leeds firms, for the axes of the former are horizontal, whilst those of the latter are vertical. The two plans of winding may be termed rival ones, and up to the present time nothing very definite has been done to determine whether the advantages of this or that preponderate. Certainly the award at Wolverhampton is in favour of the Boston system of winding, whilst, so far as speaking, is that of Smith, of Woolston, at the Chelmsford meeting of the Royal, 1856, *versus* Fowler at the same trials, so that results must be weighed in the balance of the future.

In the absence of a catalogue (no great loss after all), we shall give our readers a running outline. Turning to the left, we have Fowler & Co's 12-horse steam ploughing engine and an 8-horse traction engine, a 4-furrow balance steam-plough, a turning cultivator, and two Pirie double-furrow ploughs; a better selection for the corner of the great hall could not be found. Clayton, Shuttleworth & Co., Lincoln and London, exhibit an 8-horse portable and a 10-horse traction engine, with safety differential movement; also a fixed engine, with improved bed-plate. But the greatest novelty, if novelty it can be called, is the reduction which this celebrated firm have recently made in the price of their engines. This is not the first reduction, and it is perhaps the most significant movement made in the march of improvement that calls for special notice in the present session, for whilst this firm have given their workmen the full benefit of "the nine hours' movement," they, at the same time, by means of advances in the manufacture of machinery by machinery, are enabled with profit to reduce the price to their customers. Facts of this kind never fail to speak for themselves, and in the case in question experience already proves they will not be silent. No doubt this reduction movement will meet with "trade opposition," and just so much the greater credit to those who triumphantly make it.

Humphries' threshing-machine, and Underhill's vertical engine and double furrow ploughs require no comment. Burrell's 8-horse Thomson traction engine calls for a more lengthened notice than our space and time will permit; suffice it to say, it is highly promising. The fixed engine and sawing tables of C. Bowles, Millwall, although common at the meetings of the Royal Agricultural Society of England, are novelties in their way here, and a relief to the eye of the agricultural student as he pushes his way onwards. The engine, boiler, and sawing table are fine specimens of workmanship, and practically equally successful.

We next come to one of the best stands the Messrs. Howard, Bedford, ever exhibited at this Christmas gathering, including details of their "safety steam-engine, steam and horse tillage implements, &c." Their steam-plough is interesting, inasmuch as it brings us back to the question between Fowler and Fisken's and Fowler's, the two sets balancing on a common fulcrum, whereas in the Messrs. Howards' plough each set balances on its own fulcrum; whilst at the same time the weight of the one set out-weighs that which brings the other set in work by means of the connecting chains. It was this balance connection that was found to be an infringement of Fowler's or rather of Fisken's patent implement. And now that Fowler and Fisken's patents are both expired, the return to such special mechanism has a very significant meaning, practically speaking; indeed, such facts in the march of steam-culture progress ought not to be overlooked. In the event of fog for the time of the race is another example exhibited in the stand of Amies & Barford, where each set of ploughs or cultivators has its own fulcrum, on which it balances by means of a connecting chain. This year Messrs. J. & F. Howard do not show either a portable or a traction engine, the space allotted to them being occupied with tillage implements, steam and horse power haymaking, reaping, and mowing machines. The general implements of the day. Are we, then, to conclude that the double-fulcrum balance-ploughs are to supersede the single-fulcrum balance-ploughs, and that the double-furrow horse-ploughs are gaining a triumph over steam? The principle is represented in our engraving (fig. 339), which shows the balance-plough of Messrs. Amies, Barford & Co.

The Messrs. J. & F. Howard have a splendid show of double-furrow, single-way, and ridge-way ploughs, cultivators, and harrows; their reaping and mowing machines involve considerable novelty by way of improvement since last Christmas meeting. Thus, the one-way double-furrow plough has two skeith coulters, and the two subsoilers or cultivating tines to the digging plough. The reaping-machine, although closely resembling that of last year, has been much improved in detail since the Wolverhampton meeting of the Royal Agricultural Society of England. Their new mower is both a novelty and a complete success, and would require an illustration to do it justice.

Passing the refreshment stall, we come to Aveling & Porter's 8-horse traction engine and 8-horse road roller, machines which have justly earned the highest merit at all the trials at which they have recently competed. In short, this firm has gained a world-wide celebrity with their traction engines and road rollers.

Holmes & Son exhibit a 9-horse engine with threshing-machine, also their celebrated clover-mashing, &c., machine. The Beverley patent cattle conveyance carts, common carts, waggons, clod-crusher, liquid manure carts, reapers with self-tipping platforms, &c.

Messrs. Ransomes, Sims & Jefferies show a fine show of engines, threshing machines, double-furrow ploughs, one-way ploughs, &c.; hay-harvesting machines, chaff-cutter, grinding and bruising mills, &c. They have this year erected a sub-gallery, which affords increased space for samples, and room is thus obtained for an unusually good illustration of their various manufactures. We give above an illustration (fig. 337) of their well-known cylindrical corn-screen.

Edington, Turner, Ashby, Jeffry & Lake, Woods & Cocksedge, we have noted "as usual."

The Reading Company have added something novel to their well-known manufactures, viz., a series of small fixed engines, of 2, 3, and 4-horse power, engines which are annually becoming more and more useful in the march of improvement. In this class of engines a very marked demand has recently sprung up, owing to their portability and their usefulness in chaff-cutting, corn and cake bruising, &c. The well-known firms of Marshall & Son, Nalder & Nalder, P. & H. Gibbons, Brown & May, are noted "as usual" in their several lines.

Davey, Paxman & Co., of Colchester, introduce a novelty that calls for a more detailed inspection, relative to the vertical boilers which have gained the approbation of the engineering public ever since the trials at Oxford, 1870, of the Royal Agricultural Society of England. We give an illustration (fig. 338), of their vertical steam-engine and a section of the boiler, showing the water-tubes within the fire-box, in which there is a constant current of water upwards, with a deflecting cap over each, sending the water downwards again through the outer boiler space.

At the stand of Messrs. Wallis, of Basingstoke, was shown an addition to the ordinary locomotive engine of a long chamber, into which the waste steam passes, it there condenses, and passes into the water supply for the boiler, which again is pumped back through pipes in the same chamber, made annular by cores, and therefore more efficient for receiving the heat of the outer steam. In another part of the gallery Mr. Perowne, of Great Snoring, Norfolk, shows a Banbury turnip-cutter, with an ingenious device for clipping in bits the last slice, which escapes the action of the barrel.

Robey & Co., Lincoln, also exhibit improvements in engines and threshing-machines introduced last year, whilst this year we have a new patent wheel for road and farm traction engines, the invention of a Mr. Mackindery. It would require an illustration to do justice to the merits of this new wheel. the tire of which consists of a series of segments, each supported by a spring, so that as the weight comes upon the spring it "gives," so as to enable the wheel to rotate without any further obstruction than the right-hand with a new steam-plough, illustrated elsewhere (fig. 339), in addition to their usual exhibit of cattle food steaming apparatus; and on the left Burgess & Key, with their reaping and mowing machines. We shall follow, as below-stairs, the left-hand course.

The Messrs. Burgess & Key, who may justly be termed the fathers of the modern reaping and mowing machines, have since 1851 been steadily and annually advancing in the march of improvement, on sound mechanical principles. What we have to notice since Wolverhampton are improvements in detail *i. e.*, the perfecting, as it were, of the progress previously made. In other words, they have added an undulating cam to their reel-raker, the latter to guide both reels and rakes across the platform, and deliver the sheaf at the side out of the way of the track of the team next turn. From the manner the rotating standard crosses centres with the knife and bearing wheels, they are enabled to do so with shorter reel and rake arms than would otherwise be the case, and hence with a saving of motive-power, tear and wear, &c. whose dairy utensils have long been something more than prominent in the Agricultural Hall.

The Messrs. Samuelson, of Banbury, the first who introduced the D'Orsay reel-raker into England, in 1861, have added a foot-gear movement for throwing their implement into and out of action by means of two chains with the necessary clutch-work and foot levers. We should prefer a single-link connection to that of a chain; but this is matter of detail, at the option of purchasers, for although chains are liable to stretch by a continuance of hard work, they actuate the clutches successfully *pro tempore*.

The eye here finds relief in a novelty, in the form of a small windmill for irrigation and other purposes, exhibited by Pollard, Jephson & Co., engineers, Southwark.

Priest & Woolnough have their usual selection of first-rate drills, &c., and Baker corn-dressing machines.

This brings us to Coleman & Morton's new Potato-digger, one, if not the only peculiar novelty of the Islington Hall for the current year. The principle is-

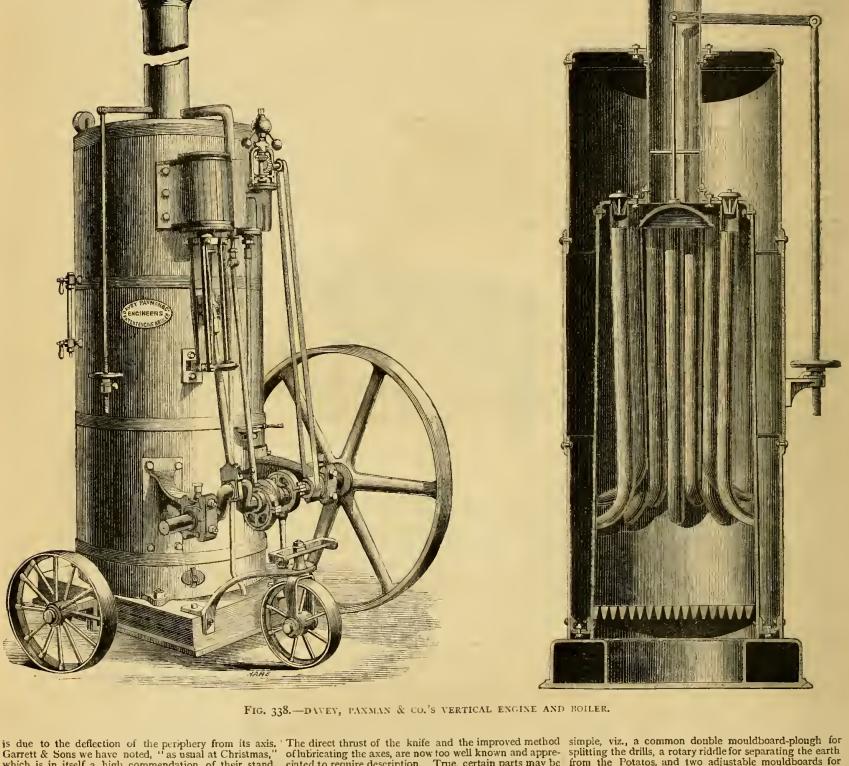

FIG. 338.—DAVEY, PAXMAN & CO.'S VERTICAL ENGINE AND BOILER.

is due to the deflection of the periphery from its axis. Garrett & Sons we have noted, "as usual at Christmas," which is in itself a high commendation of their stand. They exhibit very fine examples of threshing-machines and drills, &c.

Hornsby & Sons have made considerable improvement in their reapers, mowers, and double-furrow horse-ploughs, since the Wolverhampton meeting. At Manchester, this firm was *first* in reapers, and ever since it has maintained its elevated position. In the double-furrow plough trials it has been very successful this year, winning the 1st prize at the principal competitions in Norfolk, &c. Two improvements merit special notice, viz., the alteration of the seat in the reaper, so as to counterbalance the weight of the platform and pressure of the pole on the horses' necks, and at the same time increase the bite of the driving-wheel and cutting action of the knife; and the self-acting land-wheel of their double-plough. Barrows & Stewart, and Tasker & Sons are noted "as at Wolverhampton," which reads, "both are in advance of last year.'

This brings us to the gallery, where, on the right-hand from the principal staircase, we find Amies & Barford on the direct thrust of the knife and the improved method of lubricating the axes, are now too well known and appreciated to require description. True, certain parts may be subject to further improvement, but the advances made by this firm during the past year continue to keep them in advance of their rivals—the most successful of whom (Hornsby & Sons) are their licentiates.

Passing over Morton & Co.'s (London and Liverpool) mode of roofing, Hope's artificial food, and Hale's sheep-wash, we arrive at a very interesting and instructive stand, viz., average samples of the produce of Mr. Hope's sewage farm at Romford. This is a grand affair, and highly encouraging when seen, as it ought to be, from a practical point of view; for if Mr. Hope is not the father of successful sewage farming, he is undoubtedly the most advanced leader in the vanguard of progress, whose example sewage farmers in general would do well to emulate, as in every product of his farm a practical lesson is to be learned, both as to quality and weight of crops per acre, with the variety of crops grown. Smith, Kettering, and Nicholson, Navan, we noted "fine stands as heretofore;" and the same may be said of Alway & Sons, simple, viz., a common double mouldboard-plough for splitting the drills, a rotary riddle for separating the earth from the Potatos, and two adjustable mouldboards for filling the riddle. Thus, as the ridging-plough splits the drill, the earth and Potatos turned right and left are by means of two mouldboards turned inwards, or upon the herring-bone rotary riddle, which is said effectually to separate the earth from the tubers. An illustration is needed to do justice to this new implement—an American invention, reduced to practice to suit the requirements of English Potato-growers, the price of the machine being within the reach of all who grow a few acres of this all-important edible.

Hunt & Pickering exhibit their reaper, with a bell-crank movement of the knife between two connecting rods; also a new dry-earth closet, with a large and varied assortment of their usual articles. The two Balls have each, on opposite sides of the gallery, fine exhibits of their prize carts, &c. Dell, the great London house, comes in for millstones, and the various requirements of the miller; so do Bryan & Corcoran, with the other metropolitan firms in this branch of art. Grinding, kibbling, bruising and crushing mills for the preparation of food for cattle,

are well represented, but those for private family use are below an average. Thus we miss Pinfold of Rugby, and some other makers who have of late been introducing novelty in the improvement of family mills as well as of cattle mills. There is, however, no great reason to complain. The Bristol Waggon Company have, as usual, a select stand, C. Denning & Co., Chard, Somerset, exhibit Spenser's patent chain corn-drill, a first-rate implement, of which we present an illustration (fig. 341), in which it will be seen that the corn in the hopper is fed into the seed funnels by endless chains, passing through openings, which drag a constant stream of grain with them. Corbett & Son, of Wellington, show a new plough, the mould-board of which is serrated on the lower side, which is said by the exhibitor to have a more effective pulverising action than the American rotary mould-board, which won its laurels at Wolverhampton. These ploughs are being brought out in three classes, viz., single, double, and ridging ploughs; and at the recent tricunial trials of the Manchester and Liverpool Agricultural Societies easily beat six of their rotary mouldboard rivals. The pulveriser is followed by a subsoiler when necessary, and the autumnal reports speak very favourably of this new invention, which, in point of mechanism, is a very simple affair. Treen's dibbling-machine was noticed at Wolverhampton. T. W. Wedlake, of Hornchurch and Romford, exhibits his glandless steam-engine, in addition to his usual selection. James & Son, of Trindle, have added to their water-carts a chain-pump, by way of novelty, for irrigation and other purposes. In this department of the Hall there is a fine show by Owen & Co., Hayward, Tyler & Co., and others. The Messrs. Hayward & Co. show a pony gear for pumping apparatus, which, in numerous cases, is being usefully employed for irrigation. Thomas Baker, Compton, Berks, shows a tumbler or tip liquid-manure cart, which can be fitted with outlets and pipes for distributing liquid manure to drilled crops grown at different widths of drills; but the quantity of liquid calculated per acre is by far too small. Bentall, Robey, Carson & Toone, Penny & Co., Riches & Watts, Hayes & Son, Le Butt, are noted "as usual;" and so are the London firms of Lloyds, Whitmore, Pierce, Rollins, &c. On Messrs. Boby's stand we have, among other instances of their well-known corn screen, one in which the corn delivered from the hopper actuates by its weight an arrangement for working the oscillating discs by which the sloping screen is kept clean. It is, in fact, a self-acting screen of a very clever and efficient kind. John Gray & Co., of Uddingston, near Glasgow, exhibit two of their double furrow ploughs (Gray's and Firie's patents combined), which are well patronised. Walter A. Wood shows his new American reel-raker, which would require an illustration to do it justice. His common reapers and mowers have also been improved by the substitution of iron for wood, and tube mechanism for nuts, &c. C. F. Whitworth, of Lincoln, and Brigg, Lincolnshire, exhibits gates of a very ingenious construction of "midway catch and locking bar," which has recently gained the prize of the Liverpool Agricultural Society, in competition with other gates. E. Davis, of Rhuddlam, Flintshire, exhibits a chaff-cutter on an old principle, but with upward stroke instead of downward, as in the old machines of Salmon, &c., also a new axle. Cattle cribs, sheep racks, and other articles of this kind are as numerous as usual. Benjamin Reid & Co., Aberdeen, show their "patent drain-clearing rods," with other articles, as last year. G. D. Powell, of Lorraine Road, Holloway, a new exhibitor, shows rick-cloths, with the various articles of tarpaulin manufacture. In this department there is always a large show. Stands with "pure linseed-cakes" are on the increase.

The artificial manure trade is well represented in the galleries and in the arcade, as usual, by Mr. Stoffell (late Messrs. Whitworth & Co., Atlas Works, Rotherhithe), whose fish-manures are highly valued, more especially in our Hop-growing districts. H. J. Salmon, manure manufacturer, Bermondsey, is for the first time an exhibitor in the gallery, and also in the concert-hall. The general show in the bazaar baffles description, even granting that the passages had been less crowded than they were. What our country consins thought of this department it were hard to say, but some of them, by the time they had got halfway round, appeared as anxious to get out as they were to wedge their way in by 4 P.M. It was amusing to hear the jokes expressed in plain home-spun English, Scotch, and Irish. Even in this fancy fair one or two exceptions may be quoted. Thus we have Lawrence's "cooler," for milk or beer (wort), which is also adapted for heating milk at this season. It is largely used amongst brewers in cooling wort, but to what extent it has been applied in the dairy we are not informed. They are made of corrugated copper. The cold water flows upwards internally, the wort downwards externally, and the cooling power is said to "surpass belief."

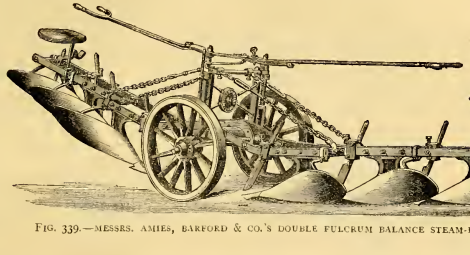

FIG. 339.—MESSRS. AMIES, HARFORD & CO.'S DOUBLE FULCRUM BALANCE STEAM-PLOUGH.

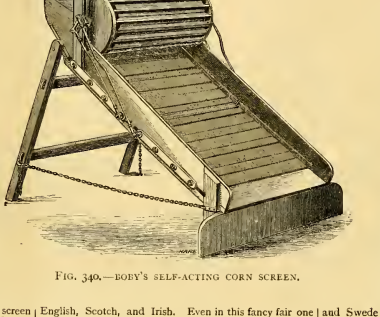

FIG. 340.—BOBY'S SELF-ACTING CORN SCREEN.

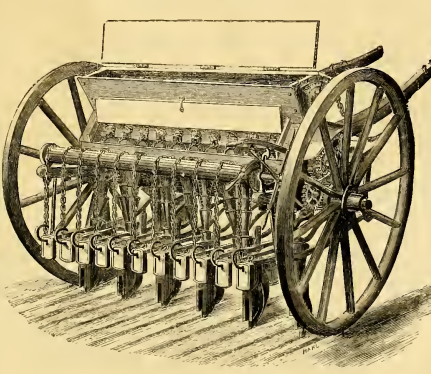

FIG. 341.—DENNING & CO.'S CHAIN CORN DRILL.

As usual the stands of the great seedsmen are one of the principal features in the galleries. Messrs. Gibbs & Co., the seedsmen to the Royal Agricultural Society, have a very good collection, flanked by enormous Cabbages of Mr. Robinson's growth, with a capital set of specimens of Mangel Wurzel, Swedes, Kohl Rabi, &c. Beyond this Messrs. George Gibbs & Co. exhibit roots and tubers, and seeds, in a large and well-arranged stand, including especially remarkably fine specimens of the White Belgian Carrot, besides Mangels, Swedes, and Turnips. Messrs. Raynbird, of Basingstoke, have a good collection of roots —their Globe Mangels, in particular, being very fine. In a corner of the gallery we have "average samples" of the results of sewage irrigation on Mr. Hope's poor gravel farm at Breton's, below Romford—capital Cabbages and Mangel Wurzel. Messrs. Carter, of 238, High Holborn, have an extraordinarily fine collection of Kohl Rabi, Long Red Mangel, probably the heaviest and largest in the hall; Cabbages, Swedes of very good quality, a large collection of Potatos, &c., graced with the silver cups which they offer as prizes at meetings of the Royal Horticultural Society. Beyond these you come to Messrs. Sutton's stand, in which are the largest and heaviest Swedes to be found in the Hall; some remarkably large Long Red Mangels, the largest Kohl Rabi we have ever seen, and a very fine collection of Potatos. Messrs. Wheeler, of Gloucester, have a very good stand; their Yellow Tankard Turnips are very fine, and their usual display of large roots of other kinds. Mr. King, of Coggeshall, shows a remarkably fine quality, combined with good size, of Globe Mangel Wurzel. Mr. Radclyffe, High Holborn, exhibits a good general collection of roots. Our woodcut (fig. 342, p. 1603) shows a collection of roots, measured and sketched on the scale of one-fifth, selected from the stands of Messrs. Sutton and Messrs. Carter, the roots to the right representing Messrs. Suttons' Mammoth Red and Long Yellow and Globe Yellow Mangel, their enormous Kohl Rabi and Swede; those to the left showing the largest Long Red Mangel on Messrs. Carter's stand—close on 60 lb., and there are here also Turnips and Swedes and Kohl Rabi. On the whole, the roots impress us with the idea that the season has been productive of large and coarse quality. If it is proper to single out any names as especially remarkable for the quality of the roots they have exhibited, we should be disposed to refer to Mr. King's Globe Mangels and Mr. Hall's (Westbury) Swedish Turnips.

Societies.

ROYAL AGRICULTURAL OF ENGLAND.

MONTHLY COUNCIL: *Wednesday, December* 6.—Present: Sir Watkin W. Wynn, Bart., M.P., President, in the chair; Viscount Bridport, Lord Chesham, Lord Tredegar, Lord Vernon, Sir A. K. Macdonald, Bart.; Mr. Baldwin, Mr. Barthropp, Mr. Booth, Mr. Bowly, Mr. Cantrell, Colonel Challoner, Mr. Clive, Mr. Davies, Mr. Dent, M.P.; Mr. Druce, Mr. Edmonds, Mr. Brandreth Gibbs, Mr. Hornsby, Mr. Bowen Jones, Colonel Kingscote, M.P.; Mr. Leeds, Mr. M'Intosh, Mr. Masfen, Mr. Milward, Mr. Pain, Mr. Randell, Mr. Rigden, Mr. Sanday, Mr. Shuttleworth, Mr. Stone, Mr. Thompson, Mr. Torr, Mr. G. Turner, Mr. Jabez Turner, Mr. Wakefield, Mr. Earle Welby, M.P.; Mr. Wells, M.P.; Mr. John

Wells, Mr. Whitehead, Mr. Jacob Wilson, and Dr. Voelcker.

The following new members were elected :—

Angas, George, Beeford Grange, Lowthorpe, Hull.
Baird, Alexander, Robeston Hall, Milford Haven.
Balston, Richard James, Boxley Abbey, Maidstone.
Bott, Joseph Fennell, Morrell Roothing, Dunmow.
Boucher, Charles, Caenby, Market Rasen.
Bradbury, G. E. Hobroyd, Longroyde, Rastrick, Yorkshire.
Cocks, Charles, Packington, Lichfield.
Eve, Frederick, Sherington, Newport Pagnell.
Fremlin, W. Alfred, Tovil, Maidstone.
Hack, Algernon, Buckminster, Grantham.
Heneage, Edward, Hainton Hall, Wragby.
Hilliard, Rev. J. A. Stafford, Little Wittenham, Abingdon.
Huntley, W. V., Welsh St. Donatts, Cowbridge.
Leighton, Stanley, Sweeney Hall, Oswestry.
Mackenzie, James, Camden Quay, Cork.
Paull, James W., Knott Oak House, Bminster.
Pogson, Frank M., Caxthorpe, Grantham.
Pratt, Frederick, Greatford, Stamford.
Price, Henry, Undy, Chepstow.
Pyms, John, Court Farm, Magor, Chepstow.
Rowcliffe, E. Lee, Hall Place, Cranleigh, Guildford.
Stratton, Rev. J. Y., Ditton Rectory, Maidstone.
White, George, Hunton, Maidstone.
Wright, William, Fiskerton, Newark.
Wright, W. Twaites, St. Nicholas, Cardiff.

FINANCES.—Major-General Viscount Bridport (chairman) presented the report, from which it appeared that the Secretary's receipts during the past month had been examined by the committee, and by Messrs. Quilter, Ball & Co., the Society's accountants, and found correct. The balance in the hands of the bankers on November 30 was £337 14s. 1d. The committee recommend that £500 be sold out of the reserve show fund to meet payments required. The committee recommend that the bye-law No. 76, relating to members compounding for their subscriptions, be extended to Governors of the Society. The committee have met nine times, and made nine reports.—This report was adopted.

JOURNAL.—Mr. Thompson (chairman) reported that 19 competitors* had entered their farms for the prizes offered by the President and the Society ; that Mr. Bowstead, of Eden Hall, Penrith, had accepted the office of reporting judge ; that the President had nominated Mr. Thomas Jenkins, of Plasyward, as one of the remaining judges ; and that the Secretary had been instructed to obtain the services of another judge on the list submitted by the committee. It was recommended that applications from the Viceroy of India for a complete set of the Journal, and from the Veterinary Department of the Privy Council for the numbers since 1864, should be acceded to. It was also recommended that the botanical report of Mr. Carruthers, F.R.S., be printed in the next number of the Journal, and that a Botanical Committee be appointed, as jointly recommended by the Journal and Chemical Committees. In reference to the protest of Messrs. Robertson and Richardson against the report of the judges of charms at the Oxford meeting, as published in the Journal, the committee, after consultation with the judges, see no reason to alter the report in question. This report having been adopted, Mr. Dent Dent, M.P., moved that the chairman of the French Peasant Farmers' Seed Fund (Lord Vernon) be requested to furnish, for publication in the Society's Journal, an account of the agricultural features of the work at that institution. This resolution having been seconded by Mr. Wakefield, was carried unanimously.

CHEMICAL.—[The reports of Dr. Voelcker and of the Chemical Committee must be postponed until next week.]

HOUSE.—Major-General Viscount Bridport (chairman) reported the recommendation of the committee, that a new arrangement be made with reference to the porter, and that in the meantime, pending such arrangement, the necessary temporary assistance in the house-work be procured.—This report was adopted.

LOCAL AND CENTRAL COMMITTEE ON RECEIPTS AND EXPENDITURE.—Lord Vernon (chairman) reported that the committee had arranged a schedule of questions to be referred to the several standing committees of the Council, and that it was recommended that comparative statistical tables in reference to these questions, concerning the receipts and expenditure for the last ten years, be printed for the use of the Council. —This report was adopted.

STOCK PRIZES.—Mr. Milward (chairman) reported the following recommendations of the committee : (1) That no second prize be given unless at least three animals be exhibited, except at the special recommendation of the judges, with the consent of the stewards ; (2) that sheep unfairly prepared for show, by oiling or colouring, may be disqualified on the recommendation of the inspectors of shearing ; and that (3) the conditions relating to cows and heifers producing living calves be modified in accordance with the resolution at the last Council meeting. This report having been adopted, it was moved by Mr. Jacob Wilson, seconded by Mr. Bowly, and carried unanimously, that the general rule No. 19 of the stock prize-sheet be amended to read as follows :—"No animal can be removed from its place without leave from the director or stewards, and any infringement of this or any other rule will render the exhibitor liable to a fine of £1 by the stewards, and to the forfeiture, by decision of the Council, of any prize he may be entitled to ; nor can any animal be taken out of the showyard without leave in writing from the director or stewards."

VETERINARY.—Mr. J. Dent Dent, M.P., reported that, in consequence of the death of Professor Spooner, the post of Principal of the Royal Veterinary College is now vacant ; and that it is possible that alterations may be made in the staff and course of study at the College. Under these circumstances it was recommended that the Council do postpone its decision on the relations of the Society to the College until the committee are able to make a further report.—This report wat adopted.

GENERAL, CARDIFF.—Lord Vernon (chairman) reported that the lists of prizes, proposed to be offered by the local committee of the Glamorganshire General Agricultural Society, had been revised, and were recommended for adoption ; that the offer of some additional prizes by the Marquis of Bute be gratefully accepted ; and that the following members of the local committee be added to the general Cardiff committee :—The Mayor of Cardiff ; W. Alexander, Esq. ; J. S. Corbett, Esq. ; G. C. Williams, Esq. ; Major Turberville. The committee had also considered the proposition of the local committee that they should have a separate yard, in which hunters exhibited should be allowed to jump, but they did not recommend this proposition to the Council. This report having been adopted, the stipulation attached to the prizes offered by the Glamorganshire Agricultural Society was taken into consideration, viz., that the subscribers to that society should be allowed to compete for those prizes on the same terms as the members of the Royal Agricultural Society. This proposal having been moved by Mr. Randell, and seconded by Mr. Jacob Wilson, was carried unanimously, after a few words from Mr. Dent, who pointed out that this was admitting a new principle, and doing away with one of the inducements which the Society had hitherto held out to attract new members.

SELECTION.—Mr. Thompson (chairman) reported the recommendation of the committee that Mr. Rawlence, of Bulbridge, Wilton, be elected a member of Council, to fill the vacancy caused by the election of Mr. Holland as a Vice-President. This report having been adopted, Mr. Rawlence's election was moved by Mr. Thompson, seconded by Mr. Randell, and carried unanimously. The first report of the Consulting Botanist, containing an account of his investigations for members of the Society since his appointment in August, was laid before the Council, and ordered to be printed in the next number of the Journal.

The Secretary was instructed to address letters relative to the country meeting of 1873 to the authorities of Darlington, Durham, Hull, Newcastle, and York.

The annual reports of the several standing committees were received, and the usual committees were appointed for the year 1872, with the addition of a Botanical Committee.

The report of the Council to the general meeting was prepared.

A communication from the Agricultural Society of New South Wales, in reference to a system of judging stock by points, was referred to the Stock Prizes Committee.

Letters from the Secretary of the Veterinary Department of the Privy Council, and from the Royal Agricultural Society of Ireland, in reference to the alleged diseased condition of Irish cattle imported into England, were laid before the Council, and the Secretary was instructed to forward a suitable reply to the latter communication.

At the GENERAL MEETING of the Royal Agricultural Society, held at noon on Thursday, Sir W. W. Wynn, Bart., M.P., President, in the chair, the annual report of the Council was read and adopted. It referred to the statistics of the Wolverhampton meeting —the prize farm competition—the forthcoming meeting at Cardiff—the chemical reports of Dr. Voelcker—the appointment of a botanical professor, and the prevalence of cattle disease. We are reluctantly forced to postpone it till next week.

SOCIETY OF ARTS.

Sewage as a Fertiliser of Land, and Land as a Purifier of Sewage.—On Wednesday evening Mr. J. Bailey Denton read a paper on this subject, of which, for the present, we can only present an extract, taking it from the Journal of the Society of Arts :—

Sewage Irrigation.—So much has been written and said recently on the practice of sewage irrigation, that I should be disposed to say very little on the subject, had not the special properties of the soil itself for appropriating the fertilising matter of sewage, and for cleansing the sewage itself, been, to a very great extent, omitted from consideration, and had not Boards of Health—the worst farmers in the world—been the principal cultivators up to the present time. Believing that, with a recognition that the soil will perform the functions accredited to vegetation as, or more, effectually than vegetation itself, and that the two in combination will obtain the best results, both as a means of profit and a sanitary agency, I regard all calculations that have hitherto been made as to the number of persons contributing sewage per acre, and the rules that have been laid down on that score, as worth very little as a guide for the future, when the principle shall be fully recognised that the surface of land must be rendered so absorbent that no sewage shall pass off into the river unseen.

In the application of sewage to land, the local features will, in future, decide the question whether the purification of the sewage and its profitable use should be treated as objects of equal importance, or whether the purification should be the principal object, and the profit a subsidiary one. If sufficient land for wide irrigation is not to be obtained, or, if obtained, only at a price that shall place the application of the sewage, by way of irrigation, beyond the possibility of profit, it is manifest that we must call to our aid the cleansing powers of an aerated soil, and regard the land more in the character of a filter than we have hitherto been disposed to do ; and by adopting intermittent application, that principle which has been so admirably explained by the Rivers Pollution Commissioners, realise all the advantages to be gained from it.

The two processes of irrigation and filtration are already viewed so differently from the way in which they were regarded in their first introduction, that it is necessary to state how we stand with regard to them at the present moment. It will be remembered that, up to very recently, an opinion prevailed with respect to irrigation that, "the object of getting sewage on to the land was, not to let it percolate into the ground, but to keep it on the surface," and that subsoil drainage would not do for sewage farms, as the sewage passed too rapidly to the roots of vegetation, and descended downwards.

Under-drainage as Essential to Irrigation as to Filtration.—Some members of this Society may remember, on the occasion of my reading a paper on "Water and Supply of the Metropolis, in relation to the Thames and its Tributaries," my friend Mr. Rawlinson, who has ever been the consistent and able advocate of the application of sewage to land, stated in this room, without giving any opinion himself, that some persons practically "acquainted with sewage irrigation would prefer, from their experience, to irrigate clay lands without underdrainage, if Italian Rye-grass, which was the most profitable crop, were to be sown ; and the little difference of effect that was to be noticed at Norwood, where the land was clay, and the manager had actually plugged the drains in order to keep the land in a state of impermeation, when compared with Croydon, where the land is free and is naturally drained, has often been quoted as a reason why sewage irrigated land should not be drained. I will not stop to condemn this view, which is repugnant alike to the principles of land drainage, and that may be already observed that, with very few exceptions indeed, operators now disclaim the opinion that under-drainage is unnecessary. So decided has the appreciation of drainage become with the majority of sewage farmers, that in the eagerness to secure rapid absorption, sewage farms have become filter beds of too rapid action, and by the adoption of inappropriate drains the purifying powers of the soil have been jeopardised. Short as the interval has been since intermittent downward filtration was first suggested by the Rivers Pollution Commissioners, that process has, like irrigation, undergone a change. The Rivers Pollution Commissioners stated—evidently under the impression that sewage would only be applied to a barren or fallow surface—"That with a properly constituted soil, well and deeply drained, nothing more would be necessary than to level the ground and divide it into four equal plots, each of which in succession would then receive the sewage for six hours. In this way the sewage of a water-closet town of 10,000 inhabitants would, at a moderate estimate, be cleansed upon 3 acres of land, if the latter were well drained to a depth of 6 feet." They then go on to state that, nevertheless, there are three formidable objections to the general adoption of the process, viz.) "It is entirely unremunerative." (2.) "The whole of the manurial ingredients of the sewage would be absolutely wasted." And (3) "The collection of solid fecal matters upon the surface of the soil, with no vegetation to make use of them, would probably give rise to formidable nuisance, especially in hot weather." The change to which I have referred has arisen on the proof which I have had the satisfaction myself of affording, that vegetation may be grown upon the surface of filtering areas, even when receiving sewage equal to the discharged refuse of 3000 persons to each acre ; thus adding, in the most apposite manner, to the cleansing powers of the soil the scavenging properties of vegetation. When speaking presently of land as a purifier of sewage, I shall give the particulars of the instance referred to, which, though the first and only case in which intermittent filtration has been tried and modified by the growth of crops, cannot fail to prove that the objections anticipated by the Rivers Pollution Commissioners may be avoided.

Technical Description of Irrigation and Filtration.—With the general admission that under-drainage is essential wherever sewage is applied to the surface of land, it must now be generally understood that irrigation means the distribution of sewage over as many acres as it will

wet without supersaturation, having in view a maximum growth of vegetation from the amount of sewage applied, and that any departure from this, resulting in excessive application, is a waste of fertilising matter. I think it may also be taken as proved that filtration through soil should not necessarily mean its application to a fallow or barren surface (as contemplated by the commissioners), but the concentration of the sewage, intermittently, on as few acres of land as will absorb and cleanse it, without excluding the production of vegetation at the same time.

Irrigation.—Having given the interpretation of irrigation as the application of sewage to as many acres as it will wet without supersaturation, I should point out that, owing to the absence of a proper apportionment of the sewage at command to a certain quantity of land, considerable waste has resulted in most instances of sewage farming. The Italian irrigators reckon that they lose half their water when carrying the other half forward for

FIG. 342.—SPECIMEN ROOTS SHOWN AT THE AGRICULTURAL HALL.

were applied during the year ending August 31, 1870, while the quantity used up to August 31 last was 3808 tons per acre. If we put ½*d.* a ton—which I have said sewer authorities ought to receive for their sewage—on each of these quantities, we find that the payment in the first year would have been £9 4*s.* 9*d.*, and in the last £7 18*s.* 8*d.* Turning again to Mr. Morgan's report, it will be seen that as much as 21,488 tons of sewage have been applied per acre in one field of Italian Rye-grass. This at ½*d.* a ton would amount to £44 15*s.* 4*d.* This is the extreme of the year, but taking the whole of the Italian Rye-grass produced, it will be seen that the average quantity of sewage applied from the date of sowing was 288 tons for every ton of Rye-grass produced and cut. At ½*d.* a ton the tenant would have to pay 12*s.* for this, which is the value of the grass when cut, so that he would suffer a loss of all outgoings in the shape of rent, rates, labour, seed, &c. The waste exhibited by these

us; and having the advantage of enormous quantities of water to deal with, and a power of regaining that which was absorbed by the soil, by tapping it at a lower level, they are indifferent to loss; but in England, where we reckon the value of sewage by the ton, and have taken its intrinsic value at 1*d.* per ton, we cannot be content to follow such an example. We must, in fact, in this country reject any mode of distributing sewage which does not aim at the utmost economy, and which I may here state would not be attained, in my opinion, if the average quantity of sewage applied to each acre per annum exceeded 2000 tons, which represents the sewage (proper) of 62 persons, with a water supply of 20 gallons a head.

Land may be too Porous.—To judge of the waste resulting from the present mode of applying sewage to the surface of land, we have only to look to the reports of the proceedings at the Lodge Farm, near Barking, published by Mr. Morgan, to whom the public are greatly indebted for the explicit way in which he has given the quantity of sewage applied and of vegetation grown, and we shall see that an average quantity of 4435 tons of sewage per acre figures is clearly due to the extreme porosity of the soil, and its unfitness for irrigation on that account.

A Proportion of Clay Desirable.—With the limited time at command I must not enlarge upon the advantages certain soils have over others for irrigation. It may be sufficient to state that, if we desire to make the most of sewage, it is necessary that a proportion of clay should exist in the soil, and that, although very stiff clays, from the difficulty attending their management, should be avoided, it is much more likely that soils may be too free than too stiff; I am now, of course, speaking of the retention of the fertilising matter of sewage by the soil, and not of the process of filtration as a means of purification. That is quite another matter. That clayey land is more grateful for sewage is very distinctly shown by Mr. Morgan's report, for the same quality of Italian Rye-grass was produced from clay lands as from free soils, though Mr. Morgan informs me the former did not absorb more than 4000 tons per acre, which is a little more than one-third of the sewage applied to the Italian Rye-grass grown on the free soils. I need hardly point out that the rapidity with which land will absorb sewage must depend, not only upon the nature of the soil—its density and porosity—but equally upon the inclination of the surface over which the sewage travels, and the character of under-drainage beneath, and that, therefore, it is the duty of the engineer, when laying out land for absorption, to regulate the inclination of the surface, and the number, position, and size of the under-drains upon which the effect mainly depends according to the degree of porosity of the soil, in order that a given quantity of sewage may go as far as possible.

Filtration.—Having dwelt upon the practice of irrigation, I ought now to explain the process of intermittent filtration as it may be carried into practice, but as I shall presently deal with it when considering "land as a purifier of sewage," I will only state that by adopting the process as technically described, the liquid refuse of from 1000 to 3000 persons—and probably more—may be cleansed by the soil of a single acre of land.

Return from Irrigation.—Up to this time, though sewage-farming has been practised for some years, we have not obtained sufficient data for the guidance of those who desire to follow it as a business. Although local boards and companies have had the farms in their own hands, no balance-sheets, showing the quantity of sewage applied to, and the money realised by the sale of, the various crops grown, have been published. Still, the occasional results that have been obtained afford us positive evidence of what will be done under the management of men practised in the cultivation of land.

The Table on the next page exhibits certain results obtained at various places at different dates.

From these instances sufficient proof is afforded that, with one crop per annum of a kind that will yield largely to the application of sewage, and command a certain and ready sale in the neighbourhood, a sufficient return may be gained to pay a full rent for the land and a half penny a ton for the sewage, besides affording a good profit after paying all outgoings in the shape of rates, taxes, hand and horse labour, repairs and restoration of implements, seeds, interest on capital, &c. It is true that crops as large,

and even larger, than those grown with sewage have been produced by good farming without sewage, and there would be nothing to say specially in favour of irrigation, were it not that the united advantages of manure and water ensure crops year after year under every vicissitude of season, and allow of two crops being taken from the same land occasionally. From the experience gained in the cultivation of Italian Rye-grass, it is found that it may readily be grown in excess of the demand for it in a green state, and that, as this description of grass is most difficult to convert into hay, it is desirable to limit its growth to a narrower space. It absorbs and appropriates, however, a larger proportion of sewage than any other description of crop, and it is only because it thus helps to swallow up sewage that it is continued to be grown by those who seek rather to get rid of the sewage than to make the most of it. That possibility leaves the force power in a fair value is put on the sewage, or when sewage is applied to land which is itself capable of absorbing and cleansing it, as in such case the manurial matter is stored in the soil for use by following crops. The following is the Table referred to :—

Return from Intermittent Filtration.—The acreage return for the cultivator from the growth of crops on land used for intermittent filtration will depend upon the extent to which the intermittent principle is extended. If several series of filtering beds are adopted, as I have advised in the case of several towns, among which I may mention Birmingham, where the Sewage Inquiry Committee have declared their intention to adopt it, the return will be found to be quite as great, if not greater, than that to be obtained from irrigation; for with the land rendered actively absorbent by drainage and deep cultivation, and laid up in bouts or ridges, crops may be grown while the sewage is being applied without suffering from excess of wetness. By extending the filtering process from one series, as suggested by the Rivers Pollution Commissioners, to several series of areas, so as to give two or three years' rest from filtration, such lands become available for the growth of the greatest amount of vegetation that can be produced from the land; for with the sewage at command, any amount of watering that the crops require can be obtained by diverting the sewage for a time from the filtering areas in use. At Merthyr, the money realised by the sale of crops, comprising various roots and Cabbages, grown between June 14 and August 31 last, amounted, on an average of a day's sale by auction, to £17 15s. per acre, while the crops which were sold afterwards realised upwards of £20 an acre. These figures will bear comparison with the returns from irrigation proper; and I may here state that although the works have been very costly, owing in a great measure to their being the first of the kind carried into execution, and in being themselves the result of Chancery proceedings, the chairman of the Board (Mr. William Jones, of Cyfarthfa), says in a letter to me that much as the land and works have cost, "the filtering areas may yet pay;" adding that "had we obtained the land at a fair agricultural value, and the works been executed at the cost they would now be executed at, without experience, we have no hesitation in saying they would be a source of great profit to the ratepayers of this district." These figures and the chairman's opinion are encouraging, and show a fair prospect of profit, if the authorities who have charge of such works abstain from growing the more refined kinds of gardeners' crops, which involve expensive hand-labour, and which are dependent on very fickle markets for sale.

Many considerations led to the conviction that it will seldom be within the power of the sewer authorities of towns to adopt the widest use of sewage, which would result in the provision of one acre for rather more than 40 persons, if we adapt the rate I have before stated, of 20 persons to 1 acre, with an allowance of 50 per cent. for increasing population. With constantly arising opposition based on a fear of a nuisance (which under proper management will not arise), the difficulty of obtaining land, and the high price to be paid for it, will always stand in the way of wide irrigation. To compensate for the limitation these obstacles will impose, it must not be forgotten that the produce of sewage farms loses much of its value directly it overreaches the home market, and with a large area used for irrigation in the neighbourhood of a town this may be easily done. Already we hear of the produce of the Warwick Sewage Farm being sent to Birmingham, and that of Romford to Liverpool, and various instances of a like kind might be mentioned. One great advantage in the adoption of intermittent filtration, in the shape of concentrated irrigation, is that a greater variety of crops may be grown, and the over-stocking of the market with vegetables avoided, inasmuch as by giving each series of filtering areas a rest of a year or two, crops such as cereals and other crops, which are not successfully grown by ordinary irrigation, would take their part in rotation, and thus dispose of those manurial elements which might otherwise be left in the soil.

It would be too sanguine a view to suppose that the ratepayers of a district adopting the filtration process in its narrowest form would receive as much for their sewage as when irrigation is carried on under advantageous circumstances, in its widest form, but it is more than likely that, in a majority of cases, a better return may be gained from a medium course of action than from any other, though it is our duty, in a national point of view, to aim at making the most we can of the valuable matter with which we have to deal.

Land as a Purifier of Sewage.—Having spoken of the general application of sewage by land, with reference to irrigation and filtration, it is only necessary to add a brief description of the process of intermittent filtration, as it has been carried out under my directions at Methyr-Tydfil. There are 2 acres of land have been laid out for the purification of the sewage of the district, of which the dry weather flow at the time when the works were commenced amounted to 870,430 gals. per diem, the least flow being 663,000 gals. per day (Sunday), and the greatest 663 gals., a minute. The population contributing this sewage exceeds 50,000, but at present less than half the houses are connected with the sewers, so that the sewage may be taken as equivalent to the discharge of about 30,000 people. The number of water-closets being few, the sewage may be considered to be weak. Upon occasions of rainfall (which is above the average), the flow of the sewers is much increased, the storm waters frequently raising the discharge at least 50 per cent. above the ordinary dry weather flow, and this excess finds its way to the filtering areas. The 20 acres of land were divided into four series of beds, and before forming the surface to receive the sewage the whole was drained from 2½ to 3 feet deep, and deeply cultivated. By this means 2 cubic yards of soil for every square yard of surface became serviceable as filtering material, there being but very few rods of ground in which the full depth of 6 feet was not obtained. The quantity of filtering material was fixed upon so that the maximum quantity of sewage which would at any time have to pass through each cubic yard of soil would not exceed 3 gals. per diem, while the mean quantity of dry weather sewage would pass through at the rate of 5 galls. per cubic yard. The under-drainage was so designed that no sewage could travel over the surface directly above the drain, which is the case in instances of irrigation of free soils in which the results have not been so favourable.

Here the result has been the most complete purification of the sewage up to this time, and the exclusion of the fact that the effluent water from the under-drains was as pure when the whole of the sewage was passing through half the filtering areas, *viz.*, 10 acres, as when it passed through 20 acres, the analyses showing that the latter number of acres than 20 acres would suffice for the purification of the quantity of sewage dealt with, and that therefore if the sewage had been double the strength or double the quantity, as it may be when the whole of the sewage of the 50,000 persons is discharged by the sewers, there will be a certainty of complete purification of the whole if the board manage the works efficiently when they are completed.

During the period when the existing sewage, increased at times by the rainfall, was discharged upon the 10 acres (half the areas), they were receiving as much as 3 inches per week, as it was found to be equal to a depth nearly 6½ inches, and never less than 72,000 per acre (equal to a depth of 3¼ inches).

Instead of following the mode of distribution usually adopted in sewage irrigation, when the fluid is either run over a regular surface, or along the ridge to flow over the slopes on either side, the surface of the Merthyr filtering areas was laid out in the ridge and furrow form, as before explained, the object being to allow of the use of the horse and hand hoe, and while growing crops on the ridge to allow the sewage to flow in the furrows, and rise up to the ridge sides with a certainty of being absorbed, and of feeding vegetation at the same time. This treatment has been so successful that, in spite of the deposit of the finer particles of floating matter in the furrow, the whole of the sewage has disappeared within four or five hours after application, and the land has acted as a purifier up to this time in such a way that the effluent water from the under-drains is pronounced by Dr. Benjamin Paul to be cleaner than the Thames water above the intakes of the metropolis water companies.

Notices of Books.

Easy Lessons in Rural Industry—Small Farms made Profitable.

Two little essays, written by Mr. Baldwin, Superintendent of the Agricultural Department of National Education in Ireland. These books are quite in character with the previous writings of the author. With a small compass they contain much valuable information, thoroughly trustworthy, and in a remarkably readable form. In the "Easy Lessons on Rural Industry," those subjects are treated which concern a large proportion of the Irish population, and it appears to us that this book might with advantage be placed in the hands of sons and daughters of farmers engaged in the cultivation of large as well as small farms. The rearing of cattle, management of pigs and poultry, are pretty fully discussed, whilst a very elaborate, almost exhaustive, treatise on dairy management is introduced. In giving prominence to this question, Mr. Baldwin does well. It is an important one for the Irish farmer, as the following extract will show :—

"The small farmers of Ireland own nearly a million of milch cows, and from a very considerable part of their income from these animals.

"For want of proper shelter in winter, and of proper care and skill in feeding throughout the year, the average return from these cows is upwards of £5 less than it should be.

"There are in Ireland a million and a half of milch cows, which produce annually about a million and a half cwt. of butter. From want of proper accommodation, and of skill and care, one third of this does not bring the top price in the market, the remainder ranging in quality from seconds to sixths.

"By a good system of dairy management, all the butter produced in the country might rank first or second, and never should be lower than third. It is difficult to arrive at an accurate measure of the improvement that might be effected in this branch of industry; but we are quite safe in saying that if the dairy were well managed in all parts of Ireland, it would increase the average value of the butter produced at least £1 a cwt., and add to the wealth of the country £1,500,000 a year."

Some pages are devoted to "cottage gardening," and we are made acquainted with the fact "that there are in Ireland upwards of 400,000 householders who have plots of ground set apart as gardens, but who do not grow any vegetables except Cabbage, and even this in inadequate supply, and often of the coarsest description." To remedy this, the author describes a simple system by which a good supply of vegetables might be produced, and if the classes for whom the book is intended could be induced to follow the directions, a vast improvement in home comforts would follow. If the Irish, and we might say English, cotter and small farmer could see how much palatable and economical food the Belgian derives from his plot of ground, a desire to follow the example would be engendered.

In "Small Farms made Profitable," Mr. Baldwin does not stand forth as the special champion for the small farm system. He "believes it is the interest of society that there should be a gradation of farms, from the smallest which will support a family, to the largest which a man is capable of directing," and knowing the defects of the present system of Irish agriculture, in his book he shows how many may be remedied. He is quite Mechian in his desire to see the inferior pastures broken up, as appears in the following extract :—

"The surface of Ireland contains upwards of 20 millions of acres; one-half of it is in permanent grass, one-fourth is under tillage, and the remaining fourth is under water and waste.

"The area under grass is far greater than in any country in Europe similarly circumstanced, and ought to be diminished. Many of the lands under grass, the high hills should be left in pasture; but there are four millions of acres of medium land now growing poor grass which would pay far better in tillage. If those four millions of acres were brought under cultivation, the wealth of the country could be increased to the extent of £3 an acre, or £12,000,000 a year, which would be available for distribution among labourers, farmers, manure and seed merchants, and shop-keepers of all kinds. In due time, too, the landlords would obtain an increase of rent.

"The average yield of the six millions of acres of grass land that would remain, could, by the application of correct knowledge, be increased to the extent of at least ros. an acre, or £3,000,000 a year.

"The present state of our grass lands arises from—1st, ignorance on the part of the farmer of the proper grasses to grow on given soils; 2d, want of care and skill in sowing them; 3d, want of care and attention in weeding the grass land, as well as of want of skill in topdressing it. There is not, perhaps, in Irish small farm management a greater defect than the mode of harvesting grass. Sometimes the farmer does not sow any grass seeds at all, but allows the land to cover itself with whatever herbage it throws up naturally. Again, thousands of small farmers put their land into grass when it is reduced by corn crops and bad management to such a state of poverty that it will no longer give even a middling crop of grain. Now, of all farm crops, the grasses luxuriate most in rich land. And, accordingly, good sward never put land into pasture unless it is in good condition."

Having noticed the chief defects in the management of small farms in Ireland, the author points out remedies under the following heads :—The crops to grow and how to grow them; suggestions for improving the condition of the more backward of our small farmers; cottier and school farms; details of the most profitable way of managing a farm of 5 or 6 acres of arable land; our horse farms.

The subject matter of these heads is treated in a masterly manner. Whilst perfect clearness is ensured the style is terse, and we are presented with a *multum in parvo*, as is evidenced by the following notes on haymaking :—

"As, however, all grasses do not flower at the same time, the following rules may be observed:—

"Italian Rye-grass should always be mown on the appearance of the flowers. Ordinary Rye-grass may be allowed to produce the flowers. Clover is best cut when the heads are in full blossom. Mixed meadows should be mown when the bulk of the herbage is in full flower; or when the seeds of the earliest grasses are fully formed, such as sweet-scented vernal grass and Meadow Foxtail; and the seed of the late grasses, such as Cocksfoot and Meadow Fescue, are just beginning to produce the floral organs. Timothy, Italian Rye-grass, perennial Rye-grass, and Cocksfoot, generally flower during the latter half of June, which is the proper time for mowing the cultivated grasses.

"The ruling idea in the saving of hay should be to allow it to remain in the field as short a time as is absolutely necessary, and to rick it as soon as it can be done with safety. The time within which this can be accomplished varies with the succulence of the grass. In the case of Rye-grass, and mixed grasses, from light or dry soils, for period may, by skilful management, be reduced to four days in dry weather; in rich low-land it takes, at least, a week or ten days.

"By delaying the process too long the hay is burnt up by the sun, and it is also liable to have its soluble constituents washed out of it by the rain.

"Well-made hay retains its green colour and possesses an agreeable odour. Hay exposed to too much sun and rain is of a whitish colour, without flavour, and looks dry and coarse, like straw."

A great deal of good might be done by making use of these little books for reading lessons in our rural schools. The sons and daughters of labourers and cottiers, into whose hands they might be put, would acquire information which in after-life might be very serviceable. The books are in use in one or two of our reformatories, where boys are trained in agriculture, and whence several boys are annually emigrated. With a desire to be of service to the community, the author offers a very liberal discount in the price of these books for such schools as come under the class of charitable or benevolent institutions.

Notices to Correspondents.

BEAN-MEAL FOR COWS: *W. H.* It is meant (p. 1184) that 4 lb. should be given a day, mixed with Turnips, &c.

BOOKS: *H. J.* "Handbook of Farm Labour," Cassell, Belle Sauvage Yard, Ludgate Hill, E.C.; M'Combie on Stock-feeding—we have not the exact title.

WEEDS: *G. H.* It is extremely unlikely that Couch-grass can be destroyed in a meadow, except by the destruction of all the other grasses in at least the patches where it prevails. Plough up, or pare and burn, and fallow the land. There is, however, a likely possibility that the growth of any particular grass may be so promoted by the use of special manures that its development may crush out others, and therefore, it may be, your problem may come within the scope of experiments with various manures. If by experiment or accident a manure could be found distasteful to the Couch-grass, and one favourable to the growth of some other grasses, the Couch-grass would have to go to the wall. Consult the reports of experiments at Chiswick and Rothamsted.

Markets.

SEED MARKET.

Our markets have been well attended during the past few days, owing to the pressure in London of a large number of agriculturists who have come to town for the cattle show. The seed trade maintains the same firm position noted in our last. Yearling parcels of English Clover command a ready sale, at high prices. White Clover and Alsike are both firm. In Rye-grasses and Italian there is a brisk business doing, at the recent advance. For Rape and Mustard seed the demand is quiet. Trefoil is steady. Feeding Linseed moves off freely, at late rates. Winter Tares meet with scarcely any inquiry. JOHN SHAW & SONS.

MARK LANE.

MONDAY, Dec. 4.

The moderate supply of English Wheat to this morning's market was sold at about the prices of this day se'nnight. The attendance was good, but foreign Wheat sold slowly at last week's rates. Barley was rather cheaper; Beans and Peas steady; Oats 6*d.* per qr. lower. There was no alteration in the value of Flour.

WEDNESDAY, Dec. 6.

The grain trade to-day was quiet but steady. There were fair supplies of English Wheat on sale, while the arrivals from abroad were on a liberal scale. Transactions were restricted, but prices were supported. Choice Barley was steady, but other sorts were cheaper. Malt sold slowly on former terms. The show of Oats on the stands was large, and trade was moderately active, and for sound corn extreme prices were obtained. Beans and Peas were purchased to a limited extent, at previous quotations. Flour was quiet, but unaltered in value.

METROPOLITAN CATTLE MARKET.

MONDAY, Dec. 4.

We have a much larger number of English Beasts, but fewer foreign than last week; the average quality is again very middling, and consequently the demand is brisk for choicest kinds, at fully late rates; a fair clearance is made of all descriptions. There is a considerable falling off in the supply of foreign Sheep, the English number about the same as of late. Trade is dull, and prices are scarcely as good. Choice Calves are still scarce and dear. Our foreign supply consists of 1380 Beasts, 8280 Sheep, and 105 Calves; from Scotland there are 100 Beasts; from Ireland, 1200; from Norfolk and Suffolk, 90; and 1400 from the Midland and Home Counties.

Beasts, 4180; Sheep and Lambs, 16,890; Calves, 109; Pigs, 60.			Pigs ..	3	4—5 0

THURSDAY, Dec. 7.

We have a considerable increase in the supply of English Beasts, but there are very few foreign. The average quality is not by any means choice; trade is slow, yet there is no change in prices. The Sheep market is very unimportant, both as regards supply and demand, either in English or foreign; quotations are unaltered. There are very few Calves on offer; choice qualities are still dear. Our foreign supply consists of 141 Beasts, 560 Sheep, and 52 Calves.

Improved and extra strong CAST-IRON TUBULAR BOILERS, with or without Water Bars, from 52s. 6d. each.

CAST and WROUGHT-IRON PORTABLE BOILERS, on Stand, for use without brickwork, from 60s. each.

Portable Boiler.

Patent THROTTLE and other VALVES; FURNACE DOORS, BARS, and FURNACE WORK of every description and size.

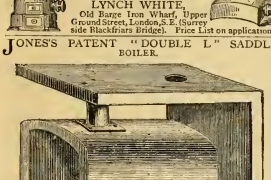
INDIA-RUBBER RINGS for Pipe Joints; Sockets require no other packing, and are perfectly water-tight.

Goods, of the very best manufacture, delivered at Railway or Wharf in London.

Elliptic Boiler.

LYNCH WHITE,
Old Barge Iron Wharf, Upper Ground Street, London, S.E. (Surrey side Blackfriars Bridge). Price List on application.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.



These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements, viz., the water-space at back and over top of saddle increases the heating surface to such an extent that a "Patent Double L Saddle Boiler" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and, being made of wrought iron, are not liable to crack. They are made of the following sizes:—

Sizes.			To heat of 4-in Pipe.	Price.
High.	Wide.	Long.	Feet.	£ s. d.
20 in.	18 in.	18 in.	300	5 0 0
20 "	18 "	24 "	450	6 0 0
20 "	18 "	30 "	600	7 0 0
24 "	24 "	24 "	700	8 0 0
24 "	24 "	30 "	850	10 0 0
30 "	24 "	30 "	1,000	12 0 0
24 "	24 "	48 "	1,400	15 0 0
30 "	30 "	60 "	1,800	20 0 0
36 "	30 "	72 "	2,500	30 0 0
36 "	36 "	96 "	4,500	50 0 0
48 "	48 "	108 "	7,000	75 0 0
48 "	48 "	144 "	10,000	100 0 0

And are kept in Stock and sold only by the Inventors and Patentees, J. JONES & SONS.

Price Lists of HOT-WATER PIPES and Connections, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES AND SONS, Iron Merchants, 6, Bankside, Southwark, London, S.E.

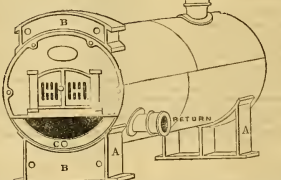
Architects' Designs carried out according to their details, or with his principles of Construction adapted to their Designs. The satisfactory completion of all work undertaken is guaranteed.

A richly Illustrated CATALOGUE forwarded Post Free for 33 Stamps.

PHOTOGRAPHS of HOUSES RECENTLY ERECTED SENT FREE for INSPECTION.

STEVENS'

"TRENTHAM" IMPROVED CORNISH BOILER.



The Advertisers have great pleasure in calling the attention of Gardeners, and all interested in Horticulture, to the above excellent Boilers. Being of the most simple construction, and in wrought iron, they are very durable, economical, and powerful; and, in the opinion of many competent judges, are superior to all other Boilers, even to the most approved form of Tubulars.

Appended are a few Testimonials:—

"Royal Exotic Nursery, Chelsea, S.W.

"DEAR SIR,—Having now had your Boilers at work here for some months, we are very pleased to be able to report most favourably of them. They are certainly more powerful than the Tubulars they have replaced here, more economical as regards consumption of fuel, and they do not require so deep a stokehole.

"We shall be pleased for you to refer any one here who may wish to see the Boilers at work, and examine them. We have already recommended them to many people, and we are sure they will by degrees become largely used.—We are, dear Sir, yours, very truly,

"JAMES VEITCH & SONS."

"Combe Abbey Gardens, near Coventry.

"I feel that anything I can say in favour of Mr. Stevens' Boiler will come very far short of its real merits. The dilemma of choosing a Boiler has now been set at rest, by the advent of Mr. Stevens' Improved Cornish. Its introduction has made our heating a masterpiece, one Boiler heating 4000 feet of 4-inch pipe. It saves considerably both in time and labour, by comparison with the now discarded Tubular Boiler. "WM. MILLER."

"Ingestre Hall, Stafford."

"DEAR SIR,—I am delighted with your Improved Cornish Boiler. It is by far the simplest and most powerful Boiler I ever used, and economises my fuel and labour to an extent that I could not have believed possible, unless I had had ocular demonstration of the fact.

"W. PHIPPS."

"Huntroyde Park, Burnley.

"DEAR SIR,—We have had your Improved Cornish Boiler upwards of two years, heating more than 2000 feet of 4-inch piping, and I feel that I cannot speak too highly in its praise.

"I have worked a good many kinds of Boilers, but not one that requires so little fuel and labour to do so great an amount of work as yours, and when the Boiler becomes known it will be very generally used. "H. LINDSAW."

"Atherstone Grapery.

"DEAR SIR,—Your Boiler is the simplest and most powerful that I ever used, and I would back it to beat any boiler now in use, for economy of fuel and labour with thorough efficiency.

"It is a real *Gardeners'* Boiler, and will be as commonly used as the Old Saddle has been when it becomes known. "G. SAGE.

ORCHIDS. — Gentlemen interested in this class of Plants would do well to inspect our Establishment at Fairfield, and to judge of our mode of growing for themselves. The House we have recently erected, in which the plan of supplying moisture by continued precipitation, without any disadvantage to neatness in appearance, has been the admiration of every visitor, and excites universal surprise that means so simple should have been so long neglected.

JAMES BROOKE AND CO., 16 and 18, Victoria Street, Manchester. Nurseries : Fairfield, near Manchester.

New Japanese Lilies, Orchids, Maples, Conifer Seed, &c.

MESSRS. TEUTSCHEL AND CO., Colchester, Agents for Messrs. KRAMER & CO., Seedsmen and Nurserymen, Yokohama, Japan.

Special Notice.

ROSES and VINES at Wholesale Prices. Fine Standard ROSES, best sorts, 10s. per dozen.
Fine Dwarf ROSES, best sorts, 7s. per dozen.
Fine fruiting VINES, of sorts, 5s. each ; 54s. per dozen.
Fine planting VINES, of sorts, 2s. each ; 24s. per doz.
LISTS free. Terms cash. Post Office orders payable at Huntingdon.
KIRK ALLEN, The Nurseries, Brampton, Huntingdon.

Bessie Johnson Rose.

HENRY CURTIS AND CO., Torquay, not having received a sufficient number of orders for this fine ROSE to justify them in sending it out in April, according to previous Advertisement, have considered it best to EXHIBIT the ROSE first, and send it out in NOVEMBER NEXT. Those who have kindly ordered them will be first supplied with strong Plants.

Elvaston Nurseries.

WILLIAM BARRON AND SON'S Priced Descriptive CATALOGUE of CONIFERÆ and other ORNAMENTAL PLANTS, ROSES, RHODODENDRONS, FRUIT TREES, &c., is now ready, and may be had, post free, on application.

A visit to the Nurseries from intending purchasers is respectfully solicited. Elvaston Nurseries, Borrowash, near Derby.

RICHARD SMITH'S LIST of EVERGREEN and DECIDUOUS SHRUBS, RHODODENDRONS, STANDARD ORNAMENTAL TREES, CLIMBING and TWINING PLANTS, with their genera, species, and English names, native country, height, time of flowering, colour, &c., and general remarks, free by post.

RICHARD SMITH, Nurseryman and Seedsman, Worcester.

SURPLUS STOCK of the following to be SOLD, cheap :—PRINCE ALBERT RASPBERRIES, old ASPARAGUS : SKIMMIA JAPONICA ; CLEMATIS LANUGINOSA ; CUPRESSUS LAWSONIANA PROSTRATA SPECIOSA, the berry-bearing variety : AUCUBA LIMBATA, bicolor and viridis ; SALIX BABYLONICA SAMONOIDES, the hardy Weeping Willow. Prices, &c., on application.

ISAAC DAVIES, Nurseryman, Ormskirk.

TWO HUNDRED THOUSAND extra fine 3-yr. transplanted QUICK, 3 to 4 feet.
100,000 2-yr. transplanted QUICK, 2 to 3½ feet.
500,000 2-yr. Seedling do., 1½ to 2 feet.
50,000 2-yr. transplanted ASH, 3 to 4 feet.
1,000,000 ENGLISH and CANADIAN FOREST PLANTS.
3 tons ASHTOP KIDNEY and EARLY ROSE POTATOS.
Samples and Prices forwarded per return.
W. COCKS, Old Nurseries, Donington, Spalding.

Autumn Planting.

PETER LAWSON AND SON have respectfully to recommend the early planting of FOREST TREES and ORNAMENTAL TREES and SHRUBS, as producing more successful results than when deferred until late.

The large breadths of LARCHES, from 1 to 3½ feet, SCOTCH FIRS, NORWAY SPRUCE, AUSTRIAN PINES, and other leading sorts of FOREST TREES, are unusually fine, and worthy of inspection. CATALOGUES and all information will be furnished upon application. Edinburgh and London, October, 1871.

Planting Season.

JAMES DICKSON AND SONS beg to draw attention to, and to solicit an inspection of, their almost unbounded stock of FOREST, FRUIT, and ORNAMENTAL TREES, SHRUBS, ROSES, and all other NURSERY STOCK.

The "Newton" Nurseries can now be reached on foot in 8 minutes from the Chester Passenger Station.

JAMES DICKSON AND SONS, "NEWTON" Nurseries, Chester.

Cologyne cristata.

R. S. YATES' Collection of the above have now matured their growth. He has Ten or Twelve PLANTS, with from ten bulbs each or 80 flower-spikes on each, part of which he offers (for cash only) at from 15 to 25 guineas each. Good plants from two guineas.

Sale, Cheshire ; or 14, Corporation Street, Manchester.

Celosia pyramidalis.

R. S. YATES will offer (early in the spring) packets of the finely-mixed selection of the above, grown himself. His stock will be very limited. The plants from whence the seeds are collected may be inspected at Sale, on application to Mr. PLANT, or Cut Blooms daily, at 14, Corporation Street, Manchester.

HOLLIES, RHODODENDRONS, CUPRESSUS, THUJA, PICEA, and other EVERGREENS.—To parties building, having land for intending to build mansions, and desirous of adding an approximate antiquity to their grounds, R. S. YATES invites them to inspect his unsurpassed and in some things unequalled STOCK of the above, many of which are upwards of half a century old. Their sale would be full of interest, and guaranteed. In Green Hollies he has the largest stock of large plants in the world, which can be removed with unerring safety. R. S. Y. received the commands of a gentleman to plant him a new avenue nearly a mile in length with specimen Hollies, to feet to 12 feet high, and 5 feet to 6 feet diameter. These were planted the first week in June last, and all have made a splendid growth. They may be transplanted with safety (if required), all the year round. Sale, Cheshire, December 5, 1871.

NEW CUCUMBERS.

HEATHERSIDE RIVAL.

Universally acknowledged to be a very superior kind, of the most perfect form, quite smooth, of a dark green colour, and scarcely any heel, also a great cropper,

2s. 6d. per packet.

DEAN'S EARLY PROLIFIC

(TRUE).

A great cropper, and excellent for winter work, smooth, and of good form ; average length about 15 inches.

1s. 6d. per packet.

PRICE TO THE TRADE ON APPLICATION.

THOMAS THORNTON,
HEATHERSIDE NURSERIES, BAGSHOT, SURREY.

CUCUMBER ARMITAGE'S SATISFACTION,

1s. per packet.

HAMMOND'S IMPERIAL HARDY WHITE BROCCOLI,

1s. per packet.

THE TRADE CAN NOW BE SUPPLIED.

WM. ARMITAGE & SON, SEED MERCHANTS, HUDDERSFIELD.
BUSINESS ESTABLISHED 1842.

Noteworthy Horticulturists and Botanists.

NOTICE.—A SERIES of PORTRAITS of NOTEWORTHY HORTICULTURISTS and BOTANISTS is being published in the "GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE." The following have already appeared, and copies may be had on application to the Publisher, viz.:—

Dr. HOOKER, C.B., F.R.S.
W. WILSON SAUNDERS, F.R.S.
Rev. M. J. BERKELEY, F.L.S.
M. DECAISNE
G. F. WILSON, F.R.S.
Dr. MOORE, of Glasnevin
Prof. REICHENBACH, Hamburgh
Rev. S. R. HOLE, M.A.
E. J. LOWE, F.R.S.
JAMES MCNAB, of Edinburgh.
ROBERT HOGG, LL.D.
JAMES BATEMAN, F.R.S.

Published by WILLIAM RICHARDS, 41, Wellington Street, Covent Garden, W.C.

The Gardeners' Chronicle

SATURDAY, DECEMBER 16, 1871.

AT the last meeting of the Scientific Committee of the Royal Horticultural Society, a report on the GROWTH of twelve DIFFERENT SPECIES of PLANTS, under five DIFFERENT CONDITIONS of MANURING, as observed during 1870-71, was presented by Dr. MASTERS. This report forms the complement to a former one recording the results of the previous year's experiments, and embodying also the results of the elaborate chemical analyses and calculations made by Dr. GILBERT. This first report, which is not yet in the hands of the public, has been previously alluded to in our columns (1870, p. 151), as also the circumstances which led to the establishment of the experiments, and the mode of conducting them.

The full details, which are necessarily somewhat lengthy, seeing that the observations were taken at intervals of a week or a fortnight during the greater part of two years, on 72 separate plots, will be published in future numbers of the Journal of the Royal Horticultural Society. Suffice it here to say that, making due allowances for the different, and in some respects improved, conditions under which the experiments were carried on during the second season, the results obtained presented a very general agreement with those obtained during the first year, except in the case of the root development of the several plants, which presented some singular discrepancies not easily to be accounted for. This is the more satisfactory as many circumstances concurred to throw a doubt over the trustworthiness of the first year's trials. But this uncertainty applied not so much to the physiological and structural questions involved, as to those connected with the chemical constitution of the plants acted on. We may here cite some of the general results deduced from the mass of facts now collected together:—

"At the conclusion of my remarks on the growth of the plants during the season of 1869," writes Dr. MASTERS, "I alluded to the 'habit' or special organisation of the plant as an element of the very highest importance in all questions concerning growth; and the result of the observations in 1870 does but increase my sense of the importance of this factor. In no single instance, either in 1869 or 1870, was any *absolute change* in habit observable. Changes in degree there were, a certain peculiarity being intensified, or the reverse, according to varying conditions of manuring; but there was nothing that would lead one to infer that by the agency of any manure, or the operation of any climatal vicissitudes, any change in the plant of a kind that a botanist would deem of 'specific' value could be artificially induced.

"All that the manures did in this direction was to enhance the vigour of growth or the reverse. The effect on the vegetative system (leaves, stem, &c.) was in all cases more pronounced and decided than it was on the flowers and seeds.

"That greater changes might have been induced by careful selection is of course not open to doubt, but that is not the point with which we are here concerned.

"It would seem from this, as indeed all evidence we have yet obtained shows, that 'specific' characters are not influenced by external conditions, at any rate within

short periods of time. The specific character is an innate quality transmitted by hereditary descent, and not materially altered by changes in external conditions. This was exemplified by the circumstance that in the case of the Plantain (Plantago lanceolata), numerous self-sown seedlings appeared in all the experimental boxes (five treated with as many different manures, one unmanured), and among these seedlings were many variations in shape and colour of leaf, pubescence, &c., variations which could not be attributed to the immediate operation of external conditions, seeing that they appeared in all the boxes indifferently, and in each box under the same conditions.

"The physiological characters, however, as we have seen, are materially influenced by these agencies, and it is quite conceivable that in course of time they might determine specific changes. These may seem large inferences to be drawn from such premises as are afforded by the Chiswick experiments, but the reader must judge of their value for himself, and he will recollect that so far as this matter goes few or no experiments have been made—always excepting the magnificent series of similar experiments carried on with a different object and under somewhat different conditions at Rothamsted for so many years—and few opportunities of examining for any length of time so large a number of plants grown under more than usually definite conditions. The reader, however, the opinion here expressed tally with those of most who have written on the subject.

"In reference to the main objects for which these experiments were carried on, the following considerations also seem to claim attention. They are not novel, but from that very circumstance, as also from the fact that they apply to the cultivation of all or any plants, they seem worth constant attention.

"To ensure the successful culture of any plant, and to gain the greatest possible advantage from it, its whole life-history, from germination to death, should be as thoroughly known as possible.

"Without such knowledge cultivation must be empirical; and although under one set of circumstances such cultivation may be as successful as could be desired, yet the grower would be at fault in the event of the occurrence of a lverse conditions. Possessed of such knowledge the c tivator can do much to remedy any evil which may rise, or make compensation for its effects. At the worst h knows its extent.

"Scarcely less important than a knowledge of the mode of life of the plant is an acquaintance with the circumstances causing modifications in it. Among these latter points may be mentioned the physical and chemical character of the soil, both important, the former specially so, always presuming there be no excess of hurtful ingredient in the soil and no absolute deficiency of essential elements therein. The effects of temperature and moisture have already been referred to. All that I would allude to now, in reference to climatal vicissitudes, is the i portance in such inquiries as those now under consideration of considering the time at which the changes take place, and the special work which the plant is doing, leaf, flower, or seed-making, at that particular period.

"Another point which strongly impresses itself in working out the results of the experiments is the advantage that is derived from an admixture of manures. In hardly any instance did mineral manures, or nitrate of soda, or ammonia salts when applied by themselves, produce anything like the same amount of vegetation as was produced by an admixture of mineral manures with a nmonia salts, or with nitrate of soda respectively. These are points which will probably be dealt with by the more experienced hands of Dr. GILBERT, who has charge of the c emical points concerned in these inquires.

"Lastly, may be mentioned the circumstance, which repeated observations seem to justify, viz., that certain plants prefer to grow in association with others rather than by themselves. This was noted, especially in the case of the vernal grass, Anthoxanthum, which made very unsatisfactory progress whenever grown by itself. A similar circumstance, though less marked, was observable in the case of the Dutch Clover, Trifolium repens."

Such are some among the conclusions arrived at from a physiological and cultural point of view. The chemical points involved will probably be dealt with by Dr. GILBERT on another occasion. In conclusion, it may be stated, that owing to the curtailment of the space, consequent on the new arrangements at Chiswick, the experiments are discontinued. It is hoped, however, that a similar series on a smaller scale will be carried out at Oxford under the superintendence of Prof. LAWSON. The experience gained in watching and noting these experiments at Chiswick has convinced us, that the number of species experimented on was too large for adequate supervision, and that, for the proper control of experiments of such magnitude and importance, the responsible observer should reside on the spot.

—— One of the greatest of the many benefits conferred by Mr. RIVERS on fruit growers and fruit lovers in this country, is the culture of ENGLISH DESSERT ORANGES, as carried on by him at Sawbridgeworth. Such a sight as the Orange-house presents would gladden the eyes and hearts of all lovers of gardening—so unique, so bright, so perfect is it! The house is 12 feet wide and 70 feet long, heated by eight 4-inch hot-water pipes—four above the flue and four on a level with it, covered with slates, so as to form a warm surface of slate, on which the pots stand. The temperature maintained now is about 64°. The former are heated all the year, except in hot weather, the latter when the Oranges commence to ripen in September. The path down the centre forms an avenue of green leaves and golden fruit, on a level with the countenance, and dipping into the mouth, seeming to say, Come, eat me! The Tangierines, or Mandarins of classic Covent Garden, are now fully ripe, and most abundant, some of the trees having from three to four dozen on each; the other kinds are the Maltese Blood and varieties of the St. Michael's, all nearly related, and differing only in form, colour, and delicacy of flesh. The first started was the Egg Orange, perfectly ripe, and seedless; then the Silver, with its delicate whitish rind, and the Long Orange, an oval fruit, said to be delicious, but not yet ripe; this tree is planted in the border, and is making prodigious growth. The Navel Orange is said to be of great excellence, as is the White Orange. The Maltese Blood, but not always red in its flesh, as one tree often produces two kinds—one with its flesh red, and the other with flesh of the usual colour—is always of the finest quality, its flesh crisp and very rich, differing much from those imported. Mr. RIVERS is now laying out a large Orange-house, 100 feet by 24; this will be heated by six or eight pipes on each side. The central border will be devoted to trees of the most vigorous kinds, and he hopes to live to see trees bearing half and even a bushel each of the dessert fruit. The side borders will be used for trees of humbler growth in pots, or the Tangierine planted out. And now arises the question, why are not these houses of real luxury found in our great gardens? The fruit and flowers of Orange trees are of the highest value. In January the trees commence to put forth their blossoms, and continue to do so till April, or even later. No feature in modern gardening can be more charming than the golden hues of the fruit, the silver tints of the flowers, and that most agreeable of all colours, the verdant green of their leaves.

—— At a recent meeting of the American Pomological Society, Dr. WYLIE exhibited some remarkable SEEDLING GRAPES, concerning which the "Gardeners' Monthly" thus reports:—

"But Dr. WYLIE has persevered year after year for now nearly 20 years, marking down exactly the parentage of each, and continually producing something valuable. Here, at this meeting, he had a large variety of seedlings, by which the Dr. has produced some most fine table eaters would consider superior even to the famed Grapes of Italy or the Rhine. Some of the scientific results are very curious. For instance, year after year he placed the pollen of the European Grape on the flowers of the Scuppernong, but it had no more effect than so much earth. The Scuppernong refused to be a parent to the European Grape, nor would it reproduce any better when the Scuppernong-American species were tried. So even our common Fox Grape has any effect on the reproductive organs. But when the Scuppernong was employed as a male parent, and its pollen introduced to the other species, a hundred-fold increase was produced, and the pollen of the mongrel race was introduced back again to the Scuppernong, then it was effective, and new varieties could be raised from the Scuppernong in this way. Thus, the native Scuppernong Grape will not reproduce with the male flowers of any other Grape, but it will do so with a mongrel male which is the progeny of a male of its own species."

—— The *Food Journal* for the present month calls attention to the economic value of the SUNFLOWER. Our contemporary is quite right in pointing to this as an instance of neglected opportunities. The leaves are said to be a fodder, the stalk yields abundance of fibre, or might be burnt for potash, and the seeds yield a large supply of oil. The culture is as simple, or simpler, than that of the Cabbage, and there are waste places all over the country that might be utilised in its cultivation, at the expenditure of wonderfully little time, labour, or manure. Our contemporary also alludes to the Jerusalem Artichoke, a plant we have before now called attention to, in the hope of getting some experimentalist to grow it in an orchard-house, or other structure, where seeds would be produced, and whence we could in due time obtain by selection an improved variety.

—— From the daily papers we learn that the CHANCELLOR of the EXCHEQUER recently received at Downing Street a deputation, introduced by Mr. C. REED, M.P., relative to the proposed building on the reserved land around the VICTORIA PARK. It is proposed to build upon some 35 acres on the confines of the park, and a very strong feeling has been aroused in the neighbourhood to spring up among the population of the East End. Victoria Park, it was urged, is situated in the midst of the borough of Hackney, and Bethnal Green, Bow, Stepney, and other densely-populated districts lay around.—Mr. HEATH said that the population abutting on the park had increased from 520,000 in 1841 to 831,000 in 1871, and that as many as 150,000 persons had visited the park in one day.—The CHANCELLOR of the EXCHEQUER said that the deputation had shown, what he never doubted, that it was desirable that their object should be attained. But he had to look upon the matter from a different point of view. The money for the park had been advanced by the Government to buy land, a certain portion of which was to be given to the Board of Works for a park, and another to the Woods for building. That land was therefore the property of the people of the whole country, but they asked him to give it to the people of the East End. He should deal with it as if it was money in bank, and they asked him for the cash to make an additional park. He granted it was desirable they should have the park, but why should the people of England, Ireland, and Scotland pay for a park for them? They were numerous, and perhaps poor, but they were not all poor. Some of those who owned property in the East End were very rich, and why should the whole people be taxed for their benefit? —Mr. REED said that the principle was admitted in the West End parks.—The CHANCELLOR of the EXCHEQUER: They are Royal parks, and we have them traditionally. Of course we should never dream of making them if we had to do so now.—Mr. HANSARD: If there be a prospect of getting the money to buy the land, will you suspend the building?—The CHANCELLOR of the EXCHEQUER: Yes, anything I can do in that way I will, if you try and buy the land.—Mr. HANSARD: It is a weak reed to lean on.—The CHANCELLOR of the EXCHEQUER: I hope you do not mean that for your representative (Mr. REED). This *has not* brought the interview to an end. We cannot pretend to discuss what is and what is not a proper thing for Government to do, as compared with what should be done by private effort; but we know that it is miserably false economy to neglect the interests of the poor and labouring classes, and it will ultimately prove most disastrous to the health, welfare, and social order of the community in general.

—— Parliament is to be applied to next session for power to construct MARKET HOUSES and other buildings, approaches, and streets, and a RAILWAY STATION, and other works, in LEICESTER SQUARE. The market will be for the sale of fruits, flowers, vegetables, meat, fish, poultry, butter, cheese, and other provisions. The station will be in connection with the Central, the North-Western, Midland, and South-Eastern Railways.

—— Londoners will learn with much satisfaction that the covenanted sum of £43,000 has been at length paid over by the Metropolitan Board of Works to Sir JOHN MARYON WILSON, as lord of the manor of HAMPSTEAD, in purchase of all his rights over the HEATH, and that the deed has been signed and sealed by which the open space has been permanently secured for the benefit of Londoners for ever. The Metropolitan Board of Works has also borne the legal and other incidental expenses of the transfer, amounting to £2000 more. In commemoration of this transaction a number of the inhabitants of Hampstead and the neighbourhood have lately raised by subscription a sum of £650 as a testimonial to Mr. PHILIP H. LE BRETON, barrister-at-law, chairman of the Hampstead Vestry, and representative of that parish at the Metropolitan Board, by whose exertions mainly the Heath was thus secured. The testimonial, consisting of a silver tea and coffee service, a gold watch, and a purse of £500, was formally presented last week to Mr. LE BRETON at a public meeting at the Hollybush Assembly Rooms.

—— From Belgium we learn that the Commission appointed to represent Belgian interests at the HORTICULTURAL DEPARTMENT of the INTERNATIONAL EXHIBITION of 1872, consists of MM. DE CANNART D'HAMALE, RONNBERG, LINDEN, A. VERSCHAFFELT, and E. MORREN.

—— BUXUS FORTUNEI is the name given by M. CARRIÈRE to a Chinese Box, cultivated under the name of B. longifolia, but not the plant of JACQUEMINOT so-called. It is a compact growing evergreen bush, with numerous erect branches, bearing long narrow subcuneiform leaves. This Box is extremely hardy, enduring the severest winters of the climate of Paris. JACQUEMINOT'S B. longifolia, on the other hand, is tender, has loose branches, long distant spreading leaves, attenuated at both ends, but is an elegant shrub, and is recommended by M. CARRIÈRE as an evergreen suitable for the decoration of apartments.

—— Few subjects are gayer in the spring months, or more useful for forcing purposes, than the DOUBLE-FLOWERED PEACHES—white, common, or striped. The French horticulturists have another striped-flowered variety, named STRIATA, which is said to be distinct from versicolor, although somewhat resembling it. It is a vigorous, abundant blooming plant, with freely expanded flowers, the greater number of which are flaked with bright red, others being partially, and some wholly, of the brilliant red colour. It is cultivated in the garden of the Paris Muséum.

—— The MAXIMUM TEMPERATURES of the AIR for the week ending December 9 ranged from 43° at Perth to 37°.5 at Leicester, the mean for the English stations being 39°.8, and for the Scottish 40°.5. The MINIMUM TEMPERATURES of the AIR ranged from 28°.2 at Leith to 9° at Norwich, the mean for the several places in England being 19°.2, and for those in Scotland 26°.4. By comparing the temperatures given above, it will be seen that the days have been warmer during the past week in Scotland than in England, in a slight degree, but at night the difference was much greater. The highest MEAN TEMPERATURE, 34°.8, occurred at Leith, and the lowest, 27°.7, at Manchester, the mean value for the English stations

being 31°, and for the Scottish 33°.6. During the past week the weather has remained very cold, and at Blackheath the mean daily values have been all greatly in excess of the average. On the 8th the mean temperature was but 22°.4, the departure from the average being 19°.3. The greatest fall of rain was 1.05 inch at Newcastle-on-Tyne, the mean fall for the several stations in England being 0.15 inch, and for those in Scotland 0.12 inch. (See Mr. GLAISHER's Tables, p. 1623.)

—— Dr. SYME contributes the following NOTE ON THE FERTILISATION OF CEREALS to the *Journal of Botany*:—

"I am not aware of any observations on the Fertilisation of Cereals. This year I turned my attention to the subject, from being at work on the grasses for the third edition of 'English Botany;' and as my residence is in the midst of cornfields, I had ample opportunities of investigating the subject. In Wheat and Barley the stigmas receive the pollen from the anthers before the latter are protruded, and the exserted anthers I found to be always empty. In the Oat most of the protruded anthers are empty, but occasionally anthers with pollen are to be found after protrusion, and stigmas exposed at the sides of the florets, which I have not been able to find in Wheat and Barley. All the British forms of the Agropyrum section of Triticum, and Hordeum murinum, maritimum, and bulbosum, protrude their stigmas and unemptied anthers in the manner usual among the Euryanthæ. My observations are confined to the county of Fife, and the case of the Oat seems to show that the mode of fertilisation is not always constant in the same species, so that observations are required in other places. The question is more important than it appears at first sight. I have noticed letters in the newspapers from farmers, predicting a bad Wheat harvest because the 'wind had blown off the flowers.' Now, if the anthers may be blown off without affecting the fertilisation no harm is done, and the belief of this may save a needless panic and uncalled-for rise in the price of corn."

—— In the French gardens SAMBUCUS FONTENAYSII, a variety obtained by M. BILLARD, nurseryman at Fontenay-aux-Roses, from seeds of S. glauca, is spoken of as a very desirable shrub, on account of its vigorous habit of growth, and the meritorious quality of being continually in flower from the month of June onwards. The leaves are large, and the yellowish flowers, which are arranged in very broad cymes, sometimes as much as 16 inches across, have a most agreeable odour. The plants present a peculiarity of growth which is not common, namely, the secondary or lower buds push more vigorously than the principal ones above them, this character inducing a proportionate lateral extension in its development. As the plant seldom fruits, it is chiefly multiplied by layers.

HARDY CLIMBERS.

In our rage for novelties we are too apt to overlook old favourites; in our addiction to one style or one feature of gardening we too often neglect others. Is there any good reason, for instance, for the prevalent neglect of hardy climbers? With the exception of climbing Roses, which we cannot do without, and of the Ivies, which, from their evergreen habit, their beauty, and variety, are sure to hold their ground, it is comparatively seldom that we meet with hardy climbers in any variety. In old-fashioned gardens we may find a Hop doing grand service, or perhaps a sweet-flowered Honeysuckle, but there is a wealth of hardy climbers which would answer admirably for covering arbors, concealing trellises, and other like purposes. Periploca græca, with its shining green leaves, and its oddly-shaped flowers, is one instance; Menispermum canadense is another; then there are various species of Smilax, some with spotted foliage, quite *à la mode*, as that is at present understood.

Those curious in such matters would do well to pay a visit to that treasure-house of all that is interesting in plant-culture—the garden of Mr. Wilson Saunders, at Reigate. There are gathered together scores of hardy climbers, placed side by side, with a view of testing their merits. It is curious to see how very many of our neglected wild plants come in grandly for this purpose, such as some of the Vetches, the Solanum Dulcamara, and of course the Bryonies, white and black. But it is among the Vines that we must chiefly look for fine plants of this character: the Parsley-leaved Vine, the claret Grape, and many others occur to us, beautiful in form and resplendent in colour in autumn; and then there is the history attaching to them, much of which would be *caviare* except to the professed botanist, but much of which also is of interest to any plant lover.

FIG. 343.—CISSUS ORIENTALIS.

These plants and their tendrils are alive in a sense hardly dreamt of by most gardeners. They show more method—we had almost said more reason—in their movements than many a mollusc, or even insect. How gently but surely they move towards their support; how sensitive they are to a touch; how particular they are sometimes in their selection; how firmly they grasp when they do lay hold; what manifold contrivances they have to secure their hold;—all this belongs to the poetry of science—the mere herbarium botanist can hardly appreciate it, the heedless gardener passes it by; and yet the grand charm of a garden is its life. However, we do not care to enter into such disquisitions just now, our main object being to recommend to the notice of our readers an old favourite in the form of Cissus orientalis (see fig. 343), which formed a splendid object in the nurseries of Messrs. Veitch last autumn, and which, we fear, is all but lost, though possibly still to be found in some of the old nurseries, where it languishes, neglected and unnoticed. Our drawing, though giving accurately enough the form of a single leaf, fails completely to realise the grace and beauty of the plant.

SEEDLING PEARS.

An elementary fact in the culture of the Pear is the circumstance that the seed produces as many varieties as individuals. The seeds, although belonging to improved varieties, produce seedlings which more or less resemble the original form of wild Pear. When by accident a variety is obtained sufficiently distinct as to the productiveness of the tree, the beauty of the fruit and the quality of its flesh, it is multiplied by means of grafting on the Pear stock or on the Quince. Many attempts have been made by raisers to increase the relatively small number of good varieties produced by seed. The Belgians especially have enriched pomology with a number of fine Pears, and have put on record a number of useful facts concerning their production. Van Mons was the first who occupied himself on a large scale with seedling fruit trees. He began in 1780, when 15 years of age, and continued his operations without interruption until his death in the 78th year of his age. A believer in the degeneration of cultivated varieties, he sowed the seeds and stones of recently obtained sorts. After from 12 to 20 years of experiments he obtained fruits which were for the most part rough, small, and bad in flavour. He waited, believing that the seeds of this first crop would give him in due time improved varieties and better fruit, and his patience was rewarded after the lapse of from 12 to 15 years. Van Mons sowed the seeds produced by this second crop, which was already superior to the first, and thus gradually, by means of successive sowings and careful selection, he succeeded in obtaining in almost all cases good varieties, some delicious in flavour and bearing early. Contemporaneously with and after Van Mons, Hardenpont, Esperen, Grégoire,—Nélis, and others increased the number of good varieties by similar means, a further explanation of which I now proceed to lay before the reader.

Selection of Seed.—Large well-formed pips are taken from the finest and best Pears amongst those which ripen in winter, preferably from a comparatively new not yet degenerated variety. The pips are placed one by one in a glass or other vessel protected from mice, and towards the end of January, when the severe frosts have abated, they are washed to remove the sticky mucilage which surrounds them, and then spread out to dry in a place where they are neither exposed to frost nor to injury from heat. Some days afterwards they are sown. Others put the pips into sand as soon as they are gathered.

Sowing the Seed, &c.—At the commencement of February the seeds are sown in pans filled with sandy soil, kept moist, but without excess of damp. If the weather be fine the pans are placed out-of-doors, if frosty they are put in a cellar or fruit room, but not in any place that is too much heated, and they are taken out when the thaw comes. Towards the middle of April the young plants are pricked out on to a well-prepared border, under a north-east wall, or under any other shelter which protects them from excessive heat. The plants are removed with a small trowel, and as soon as they have produced two leaves above the seed leaves: the end of the radicle is pinched off to prevent the formation of a tap-root. They are then replanted in lines an inch or two apart.

Transplantation of Seedlings.—After a year's growth the plant attains a height of from 4 to 12 inches. In the spring the more vigorous of them are taken up and

replanted at wider intervals than before. Those less developed are not transplanted until the succeeding year. In this manner, every year, while the plant is at rest, the most vigorous plants are taken up, their tap-roots cut, and themselves replanted at distances favourable to the full development of the branches. Every plant will thus be transplanted every two or three years, with the view of checking its growth, and of favouring the production of fruit-spurs. When they have attained a considerable size, and have only a scanty quantity of fibrous roots, their transplantation in a light soil may be a hazardous proceeding. In that case the soil is removed from around the stem of the tree, and some of the longer roots cut through.

Pruning.—During the first few years the seedlings generally make only spiny and unproductive wood, and they must not be headed back until they have produced strong, vigorous branches without spines, and provided with well-developed leaves. Where this happens the plants have attained the period of fructification, and the flowers will be produced on those branches which have lost the characters of the wildings. All that it is necessary, therefore, to do in the way of pruning is to shorten the laterals, so as to favour the development of the leader. The main object is, not to produce a symmetrical tree, but to obtain as early a production of fruit as possible.

Fructification.—The most precocious seedling Pears are those which begin to produce fruit at the age of five or six years. The latest are those which do not yield fruit till 20 years have elapsed. Can the period of fructification be hastened by grafting on the Quince, on another Pear? Experience has proved that this cannot be done. Moreover, it may be easily understood that the graft, taken from a seedling plant, not yet of age to produce fruit, will require as long a time as the parent, which, when it was taken, had arrive at adult age. The production of fruit, then, is not hastened, but the quantity of the first crop is doubled, and the merits of the new variety can be more quickly appreciated. The first fructification of a seedling is not sufficient to enable one to decide on its qualities; the size of the fruit is increased by grafting, and often the period of maturity is modified. Hence we never send out a new Pear before having tested it on its own roots, as well as grafted, for at least three or four years. *Ernest Baltet, Troyes, France.*

NEW PLANTS, &c., CERTIFICATED

AT THE ROYAL HORTICULTURAL SOCIETY'S MEETINGS, 1870—71.

** *The awards marked * were made by the International Jury, the remainder by the Floral Committee. F.C. indicates First-class Certificate,* S.C. *Second-class Certificate.*

(To be Continued.)

ON THE CULTURE OF TREE CARNATIONS.

THE reason why Tree Carnations are not to be seen more at this season of the year must be either that their culture is not properly understood, or that they are not sufficiently the possessors of gardens. The latter reason seems to be to me impossible, for who is there that doesn't love a Carnation flower at this, the dullest of all seasons? The unsightliness presented by their straggling habit of growth during the trim summer months may be supposed as another reason why they are not as they should be just now. In short, I think they are looked down upon in summer too much, and are apt to be shoved aside for some other showy, trim-looking plant, in the same way as early forced Roses are too often huddled into any out-of-the-way corner, to be chilled, parched, soddened, and tattered.

Tree Carnations, to be in perfection at this season,

require attentive summer care, and I have always found that indoor care is the safest, and with it more heat (dry heat), with plenty of air. To have Carnation flowers all the year round in quantity, one must have a quantity of plants. Of course we could cut them every day in the year, not from the same set of plants, but from sets of plants—plants of all ages, from the rooted cutting to those four years old. The best plants we rely upon chiefly for flowers at this season, and the younger at spring-tide. To keep up a stock of plants we put in a batch of cuttings at any time—every month, say—one cutting to the smallest pot, in sandy loam, or loamy sand rather, for the best are dominated by being added, and they are placed under a hand-light or bell-glass. Two hand-lights are kept going for the purpose. When a batch is rooted, others follow. They are potted on gradually from 2 to 12 inch pots; and while in sizes less than 6-inch they are stopped sufficiently to form a good bottom of from five to ten or more breaks. In this form and condition they are potted into the 10 or 12 inch pots in a pure loam, without any dung or any stimulating mixture whatever, further than a dash of sand. They get, when once the pots are full of roots, a liquid-manure watering every week from the manure tank.

Further than this, they get only that which common sense dictates, namely, staking and tying with care every growth that cannot support itself. Hazel stakes we find best for the larger plants, and Privet ones for the smaller ones; a neat stake should only be used where these are not to be got. Further, care must be used in putting long enough stakes after the second year, as the growths are sometimes over 3 and 4 feet long. We have many times seen people look critically on such long spindley-looking plants; and some practicals, who probably have been brought up in the faith, with stiff formal habits of turning plants to a shape and the evenest contour, have passed them by as beneath their notice. But ladies of taste here are the critics, and a dozen blooms at this season soon compensate for the want of symmetry in the plant's habit. Whoever, therefore, can't bend his ideas to the plant's natural requirements must leave Tree Carnations alone, and seek for plants of a more uniform mien.

The sorts we grow are the following, and to-day more than a dozen fine blooms have been cut, and as many more could have been furnished had they been wanted:—Henshaw's Scarlet, Remmant, Eclipse, Hector, Comte de Douy, Beauty, M. Valiant, Eugène Ducreux, Charles Baltet, Prince of Orange, The Bride, Jubilee, Belle Rose, Lady Stuart, and several seedlings of merit. Of course the summer-flowering variety, Souvenir de la Malmaison, finds a favourable place in the collection. Tree Carnations I regard as first-class flowers, ranking as high as the Gardenia, Camellia, and Daphne, and infinitely superior to Cinerarias and other kinds of flowers usually to be seen at this season. We grow our plants on the side stages of our Heath-house, where they have plenty of head room, which they really require, for some of the plants are fully 5 feet high and 2 or 3 feet through. I may remark further that we cut the flowers a day or two after they are opened, if likely to be wanted in numbers, and place them in damp sand in a cool room, as we do Cardenias and such-like flowers. In warmer, much warmer localities, I have grown Tree Carnations out-of-doors in summer, and lifted, as is done here in autumn; but never did I find them so satisfactory as when kept always in pots—for this reason, that I failed to lift them with sufficient root to winter them well, far less to flower them to my liking. *H. K.*

FIG CULTURE IN THE OPEN AIR.

I QUITE agree with "S. W.," p. 1552, that the less the knife is used the better. Plant the trees in poor soil, such as a mixture of lime rubbish, road sand, and loam, on a dry bottom. If they grow strongly at first, pinch the shoots into weakness, and let the trees grow into bold standards, and not up against the wall. Thus treated, they will form short-jointed wood, full of fruit, like the sample enclosed (fig. 344). As the fruit swells give two or three soakings of manure-water. From the time it approaches maturity the drier the roots can be kept the better. Except in the sunny South, only one crop can be ripened in the open air out-doors. This suggests the vital question, which crop? Upon the answer to this two courses of treatment depend. These may be called the covered and the exposed. Those who cover say, Why the largest of those fruit that show in the autumn (see fig. 344) shall be our crop for the succeeding summer. By excluding the frost from these they will begin growth next May at the point where they stopped in October, and we shall gather an early and a bountiful harvest. Well, they may or may not. There is little certainty about it. The rats may gnaw the fruit, or more likely, when the trees are uncovered next May or June, the transition from darkness to light will prove too much for the fruit, and down it will drop.

Thus it has happened that, taking an average of seasons, I have found the covering of outdoor Figs not worth the candle. My crop, which is mostly plentiful, comes forth from the ends of many shoots left. Beyond the green Figs on the shoots sent, you will observe Figlets, if I may so call them, in embryo. These and a few more that cluster around the terminal bud unseen, and develope themselves as it starts into growth, constitute our main crop. These have plenty of time to ripen, and hardly ever fail; but in mild weather, many of the larger ones also stand, and provide us with a longer succession.

Our out-of-door Figs are grown in a small stable or court yard, surrounded on all sides with buildings. They, therefore, grow on every aspect, and we gather ripe fruit off north walls. Of course the east, west, and south yield better. We intend to cover all the roofs with the trees, as I find they do well on the tiles. The trees have no borders, and the yard is paved throughout. Now the trees have got into full bearing, all the attention they have is to tie in the branches, and gather the fruit; and as they are strong and ripe for fruit-bearing, they have had no water but the rain that falls on them for some years. The buildings are troughed. We have several varieties, but the Brown Turkey is the best for this mode of treatment. This tree looks rough, and would offend the eye and taste of the slashing knife-men, and the straight-edge and chalk-line trainers. But they are clean, healthy, and, above all, fruitful to a degree that astonishes most visitors who have seen them. The branchlets sent are a fair specimen of the upper portion of the trees. They are literally studded closely with fruit. *D. T. Fish.*

—— The south of England is, of course, so far as this country is concerned, the place *par excellence* for Fig growing, and, as a general rule, they do not make so much wood as in the midland and northern counties. I remember what splendid crops of Brown Turkey I used to gather 15 years ago, when living on the south

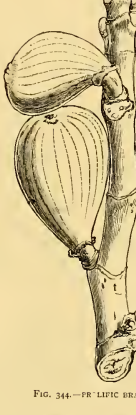

FIG. 344.—FRUITFUL BRANCH OF FIG.

coast. All the pruning required was done in the summer, and most of it with the finger and thumb, and there was no bother with covering up with mats in the winter. Is there not too much of that coddling done? I know it is generally recommended, but I much doubt the wisdom of indiscriminate covering. I believe in very exposed positions, where a little protection may be necessary, it is put on too early and kept on too long. In my opinion, the great thing to aim at is to get firm, short-jointed, and thoroughly well ripened wood. And I think the way to secure that is to pay more attention to the roots, by lifting and root-pruning, to check that gross and luxuriant habit which the Fig in the midland and northern counties too much assumes; and when, in addition, a close attention is paid during the summer to pinching and stopping, not much knife-work is required.

I remember some 20 years ago, when I was a pupil of the late Mr. Markham, of Hewell Grange, Worcestershire (a well known practical fruit grower), what fine crops used to be grown, both in the houses and on the open walls; and if my memory serves me rightly, most of the trees were trained horizontally, which had a tendency to equalise the flow of the sap. Great pains were also taken with the young wood to place it in such a position as to thoroughly expose every leaf and branch to the full influence of sun and air, and whenever symptoms of too much grossness of habit were perceptible, a trench was dug along the front of the tree and the roots pruned, and a little sound loam added, but no manure or any exciting stimulant.

To sum up in a few words, after an experience of upwards of 20 years in the southern, eastern, and midland counties, I would say—Let the border be well drained, and the bottom concreted; for soil, select the top 3 or 4 inches of an old pasture, with or without a few crushed bones, according to the quality of the soil, and if too heavy incorporate with it a proportion of old mortar rubbish from old buildings. Disbud early, leaving only sufficient shoots to form bearing wood, so that every leaf may have, as far as possible, the benefit of full exposure. Pinch with finger and thumb at the fourth or fifth leaf, and pinch persistently. If at any time too much luxuriance is apparent, check the supplies by root-pruning. Mulch in hot dry weather to save watering; and, if the cultivator is a protectionist, whenever severe weather is expected, stick a few feathery Yew or Spruce branches about the trees, and draw over all an old fishing-net, to prevent the wind moving them. *Edward Hobday, Ramsey Abbey, Hants.*

—— Your correspondent, "S. W.," at p. 1552, remarks that the knife should rarely be used in the culture of this fruit, and I quite agree with him in the case of large standard trees, if large fruit is not the object. In the summer of 1869 I had the opportunity of seeing several large trees (standards) of this fruit, growing at Scadbury Park (Viscount Sydney's home farm), Kent, all of which were carrying heavy crops; but, as might be expected, the fruits were small and large like those gathered from trees trained against a wall, otherwise the result was all that could be desired. I may here remark that from the appearance of the trees at Scadbury Park they cannot have had an application of "Swaine" for many years past. There are here several hundred feet of wall covered by Fig trees, one of which has a spread of branches of 60 feet, and they all receive a like treatment, which is similar to that of the Peach; the knife has been applied freely every year, and with very satisfactory results. "S. W." says that the treatment of Fig fruit seems, to him, to be little understood by gardeners in general. Now, allowing him to be an authority on the subject, will he be kind enough to give the readers of the *Gardeners' Chronicle* the benefit of his experience. *H. W. Ward, Longford Castle, Salisbury.*

—— I don't seem to like the knife. I would like to know what he would do bending down a branch 4 feet long, and as large as one's thumb. What good is a branch that size? perhaps he will say; you can't expect any fruit from it. But I do, and, moreover, I get it. What does S. W." want to check growth for? I say, give the trees every opportunity to make strong growth. "Check their growth, or you won't get any fruit," is, I believe, a mistaken idea. With me it is "the stronger the wood the better the fruit, and more of it." The grand secret (as most gardeners are already aware) is to have the wood well-ripened, and I think that if "S. W." takes good care to have his wood well-ripened by early autumn pruning—that is, pruning away all small and useless branches as soon as the crop is gathered, and exposing those intended for bearing to the direct influence of the sun's rays—he will be well satisfied with the result. *J. H. H., Twickenham.*

Home Correspondence.

Abies Douglasii.—In your report of my remarks at the last meeting of the Royal Horticultural Society, I am made to say that a friend of mine in Scotland was offered £70 for the cones on a single plant of Picea nobilis! Here there is a twofold error. It was for all the cones on his many specimens of Abies Douglasii, and not for those on a single specimen of the former species, that the liberal offer to which I adverted had been received. Indeed, I do not know—and should be much obliged to any of your correspondents who would tell me—whether living plants have ever been raised from cones of Picea nobilis grown in England. *J. B.*, 9, *Hyde Park Gate South.*

Scolopendrium vulgare crispum amplum.—In Lowe's "Native Ferns" mention is made of Scolopendrium vulgare crispum amplum, which is described as "a magnificent crispum, with fronds 18 inches long and 4 inches broad, deeply and densely frilled, and having a crenate margin; found by Mrs. Hole, of Parke, Bovey Tracey." I should feel greatly obliged if any of your correspondents would inform me where I could obtain a plant of this fine variety, as I cannot find it in any catalogue that has come under my notice. I am very much surprised at so few persons cultivating our native Ferns, as they require so little attention, and the numerous varieties are so beautiful. Cannot you do something to wake up the interest of your readers in this matter? *Fern Lover.* [Probably the variety has never been in the trade, but has remained in private hands, as many others have done. EDS.]

The Introduction of Araucaria imbricata into England.—In the notice of Araucaria imbricata by your esteemed correspondent, Mr. Barnes, I observe that he attributes its introduction to Sir Joseph Banks, and names 1795 as the date. I am sure he will excuse me for remarking that this is obviously an error, as Sir J. Banks returned to England in June, 1771, and did not make any other South Sea voyage. I believe the true history of the introduction is as follows, taken from Vancouver's Voyage, the narrative of which is most elaborate and valuable, though at this time I have not access to it. As far as memory will serve,

the case stands thus :—Somewhere about the year 1795, Menzies, surgeon and naturalist to the expedition, saw at the table of the Governor of Valdivia seeds from the cones of A. imbricata, placed as an article of dessert, and attracted by what he knew and heard of the forests of these trees on the slopes of the Andes, he brought a few to England. It is probable, therefore, that the well-known tree at Kew was raised from this source, and if so it must be about 80 years old. Seeds were again introduced to a large extent nearly 40 years ago. The name of Menzies, who was a man of much ability, is perpetuated in Abies Menziesii from the north-west of America. *G. Bath, Dec.* 12.

Cineraria acanthifolia.—I don't think this species can be too highly estimated, as a very distinct and showy white-foliaged hardy bedding plant. The frost of some days ago—very sharp indeed on our somewhat exposed position on the London clay—left it unscathed, while Echeveria secunda glauca, on a sheltered raised bed, was completely killed. C. acanthifolia is of an elegant and uniform habit, and when the sun shines on it, or a brisk air dries the leaves, it is nearly as silvery in appearance as Centaurea candidissima. Perhaps it is more capable of withstanding frost than damp, and while I believe winter and spring gardeners in the southern part of the kingdom will find it one of the most valuable additions to their lists they can receive, for we are very short indeed of hardy silvery-leaved plants—I do not go the length of advising spring gardeners in the midland districts, or the North, to plant it in the open air in autumn till they are fully assured of its capability to stand the winter. I would advise that it be kept in cold frames in pots through the winter, and planted out in the beginning of March, a process it would be a good plan to adopt with Myosotis dissitiflora in uncertain and inclement localities. *R. D.*

Blue Gown Cucumber.—I have always a jealous eye to new varieties of anything, more particularly in the shape of those kinds that have to be relied on for a supply. I look upon this Cucumber as the best, somest and finest of all Cucumbers, and also as prolific. We have fruit of it 20 to 24 inches long, even at this date. I find it is both a black and a white spine, both kinds being seen on one fruit. Mr. Parker, of Tooting, witnessed this with me some months ago. *H. K.*

Primula vulgaris auriculiflora.—I send herewith a few blooms of this Primrose, gathered from plants growing in a pan in a cold frame, to show its usefulness for winter work, as the plants in question were lifted from the open ground during October, being then in flower; they have continued to produce blooms ever since, and I have no doubt will still continue so to do until the spring. The Primrose, as its name implies, is akin in habit and appearance to the common variety, but is earlier to flower, and the individual blooms greatly surpass it in quality. The flower has good substance, is well rounded in form, and the colour is deep rich crimson, which is somewhat heightened by a bright lemon centre; it is also thrum-eyed. It is to me a matter of regret, that the plant should be overweighted by such an exceedingly mechanical name as Primrose, however beautiful, is but a Primrose after all, and the public are jealous of having an old favourite called by any other designation. I should be glad if the Editors could find a name for it, at once fitting and descriptive, yet simple. Flowers of this Primrose, if used in conjunction with a leaf of either Primula or Viola, make very natty "button-holes," and will endure exposure to cold with greater freedom than will flowers that have been raised in heat. Even for such a purpose I think it would pay well as a speculation for those who trade in that direction to plant up a large frame full of it. Established plants are best for such a purpose, as they flower much earlier and more abundantly than younger ones. A box of plants in flower was exhibited at South Kensington last March for the attention of the Floral Committee, when it failed to gain the notice it deserved; however, I propose to try the patience of that body yet again. *Aber. Dean, Ashford.* [We may call it Early Crimson Primrose? It is of a richly-tinted maroon-crimson, with large yellow eye, and altogether is of a very showy character. EDS.]

How to Heat a Small Conservatory.—Observing that you treat this as an important question, I beg to suggest a method, having thoroughly proved the principle. Having a register grate in a sitting-room, at the back of which is a small conservatory or plant-pit, let a hole, 9 inches long, and 4 or 5 inches deep, be cut through the iron back of the register, 3 inches or more below the level at which the register valve hinges. The conservatory flue is connected with this hole, which is, in fact, the entrance to it, the cover of the flue being anywhere above this hole, and below the level of the valve hinge. The return-flue must enter the chimney just above the level of the register valve. Light the fire with the register-valve open. When the chimney is warmed close the valve. The draught will now get in through the hole, and the hot air, &c., will travel through the flue before it enters the chimney. You will have the full comfort of the fire in the sitting-room, and see nothing about the grate beyond that which is commonly seen, viz., an orifice for the escape of smoke. The conservatory will have the benefit of the heat which is commonly wasted up the chimney, besides that at the back of the fire. The back of the register below the hole may form one side of the leading flue. Your readers may rest assured that the principles which govern draught are fully observed in this arrangement, and need not fear any failure on that ground. Moreover, it is of no importance whatever that the leading flue may have to descend. The proposed plan offers the peculiar advantage that the flues may be built at any level, or in any position, most convenient. Precautions : A register grate should be chosen which has the valve near the fire, so as to be well exposed to its heat. A flue may travel in any direction so long as the bottom of the chimney with which it is connected is well warmed; and the conducting property of iron will enable the valve to effect this all-important object. The valve must fit and close well. The joints of the flue in the conservatory should be well secured. The return flue should enter the chimney above and close to the valve. If more heat be required the hole must be nearer the fire. The back of the fireplace may be a strong grating, and the draught have to pass through the fire in order to get into the flue. This will involve of course the consumption of more fuel. If this grated back is used there ought to be a hole also, as before described, with a valve fitting loosely, and pivotted at each end. When this valve is closed the draught will be through the grating, but when open it will be through the hole. I gave a plan on this principle to a lady some years since. It worked most satisfactorily, although the workmen ridiculed it during the process of construction, because the fire was to be in the harness room, much higher than the level of the flues. If the leading flue has to descend care should be taken to so arrange the construction as that fuel and ashes should not be able to drop through and choke the mouth of the flue, or so as to remove such matters. This may be done by making a side brick of the flue movable ; but the joint should be well secured ; the draught must be from the sitting-room, not from the conservatory. A combustion of soot in the flue may be prevented by opening the register valve when fresh fuel is supplied to the fire and much smoke is given off, and closing it again when the fire is clear. *J. M. Taylor, Seer Green Vicarage, near Beaconsfield.*

Senecio argenteus, S. incanus, and S. uniflorus are all represented to be hardy, and, therefore, of great value for outdoor decoration. I saw them at the Hale Farm Nurseries, Tottenham, at the end of the summer, and was much pleased with them ; Mr. Ware spoke of the two former in the highest terms. The first-named has a habit of growth representing a "silvery-white compact rosette, 4 to 6 inches across," as Messrs. Backhouse & Son, who sent it out, correctly described it ; and Mr. Ware informed me it seemed to thrive best when planted in the borders in good loam, raised with plenty of stones. Respecting its hardihood, Messrs. Backhouse & Son state that they have "proved it for two or three winters, and can recommend it with the utmost confidence." S. incanus forms dense tufts of foliage, finely cut, and so-to-quite as effective as the former, but it grows more freely in the open border, and produces larger tufts. *R. D.*

Hardiness of Dracæna indivisa, Agaves, &c.—Having a reserve stock of this plant, I this season left about two dozen in their summer quarters in the flower garden, and although we have had on three different occasions as much as 16° of frost, they are not in the least degree injured. Should this fine plant prove to be perfectly hardy, it will be invaluable for "winter bedding," for although we have left out so few, their beauty and grace enliven the whole terrace garden. It must not be confounded with Cordyline indivisa, which is far more difficult to grow. Agave americana and A. americana variegata are also with stood all the frost we have yet had, apparently unscathed ; and though there are 40 fine plants, I have determined still to let them stay and risk them, as they are the admiration of all visitors. I may say that all the Agaves are planted on a carpet of medium grey-weed and sedum acre, encircled with Echeveria secunda glauca, which will withstand all the frost of an ordinary English winter. Why I say this is, that last winter, being a severe one, some of my neighbours lost all their stock ; and though I did not, like Mr. Simpson (p. 1584), I had a narrow escape. The winter previously they stood perfectly. I have this season got my reserve stock planted out under some of "Rendle's plant protectors," and which, I doubt not, would be ample protection in the severest winter. *W. Wildsmith, Heckfield.* [Our correspondent appears to refer to Dracæna or Cordyline australis. EDS.]

A Potato Trial.—During last winter I devoted a portion of my time to the successful growth of the Potato, in pursuance of which object I closely consulted the works of C. W. Johnson, Sibson and Voelcker, Shirley Hibberd, Thomas C. Fletcher, Macdonald, and others ; and thinking that the trial conducted during the past summer in accordance with a plan resulting from such study may be acceptable in your readers, I feel pleasure in forwarding the following statement. The trial ground was 1¾ acre, all manured, and treated in the same manner, the soil being of a loose sandy nature, very much like the Long Valley at Aldershot, from which it is distant five miles. Sixteen different sorts of Potatos were subjected to trial, side by side, the trial and result being given in a tabulated form. The ground was subjected to the following treatment :—In the autumn it was manured with ten tons of stable manure to the acre, and ploughed to a depth of 12 inches, thus it remained for the winter. In the early part of March it was again manured at the rate of 6 tons to the acre, and then cross-ploughed to a depth of 9 inches ; after that it was treated with a dressing of artificial manure sown broadcast in the following proportions :—

	Bush. per acre.
Soot	20
Salt	20
Guano	5
German calcined potash salts *	5
Superphosphate of lime	5
Dissolved bones	14
Gypsum	4

Sixteen sorts of Potatos were then planted in drills with the hoe ; early Potatos, 18 inches between the rows and 9 inches between the sets ; late Potatos, 24 inches and 12 inches. The Potatos were all planted together during the first week in April, and when the plants were about 2 inches high they were top-dressed with 1½ cwt. of sulphate of magnesia or Epsom salts, and 1½ cwt of nitrate of soda to the acre. And now for the Table, to see the results :—

Sorts planted.	Early, Medium, or Late.	Whole or Cut.	Bushels planted.	Produce per bushel planted.	Price per bushel for Seed.	Condition.
Myatt's Prolific ..	Early	Whole	4	22	5s.	8d.	Sound
Mona's Pride ..	,,	,,	4	23	3d.	10d.	,,
White Rock ..	Late	,,	3	33½	11s.	6d.	Very sound indeed
Fluke Kidney ..	,,	,,	3	10	3s.	7d.	Tolerably sound
Delmahoy ..	Med.	,,	2	10½	5s.	7d.	Sound
Webb's Imperial ..	,,	,,	3	28	6	9d.	,,
Walker's Improved Regent †	Late	,,	2	13	6s.	7d.	,,
York Regent ..	,,	,,	39	140	3s.	6d.	Much diseased
American Early Rose (Sutton) †	Early	,,	1	5¼	5s.	18d.	Tolerably sound
American Early Rose (Hooper, Covent Garden)	,,	,,	1	6¾	6s.	28d.	Sound ‡
Woodcock ..	Med.	,,	¼	2¼	4s.	18d.	,,
Early Goodrich ..	Early	,,	1	6¾	6s.	28d.	Slightly diseased
King of Potatos ..	Med.	,,	2	10	5s.	9d.	Sound
Bovinia	Late	Cut	12	124	12s.	10d.	,,
Reddika Flourball ..	,,	,,	2	13¾	6s.	18d.	,,
Paterson's Victoria ..	,,	Whole	4	24¾	6s.	8d.	,,
Suttons' Racehorse Kidney †	Early	,,	1	2¾	2s.	18d.	Diseased

Thus, for 8¼ bush. planted we have 455¾ bush. raised—or an average of 5½ bush. raised per bush. The Potatos were all dug together in the latter part of August. The previous year the sale of Potatos off this same piece of ground, 1¾ acre, was only 210 bush., from 30 bush. planted, ground only commonly manured. This was before I came to the place. The crop were all York Regents. It will thus be seen that by my mode of treatment I raised more than double the crop from the same ground. The artificial manures were supplied upon the principle of supplying what the Potato contains. According to Professor Anderson the ash of a Regent Potato contains :—

	Per cent.
Peroxide of iron	0.31
Lime	1.79
Magnesia	5.75
Potash	59.52
Chloride of potassium	5.39
Common salt	2.07
Phosphoric acid	12.49
Sulphuric acid	7.08
Silicic acid	0.88
Carbonic acid	11.30
Charcoal	3.65
	100.33

John P. Cheyne, Commander R.N., Penrice Villa, Fleet, Hants.

Successful Peach Culture.—I have two Peach-houses here, the united length of which is 80 feet, and they are 8 feet wide. They are heated by a common brick flue ; and I have Peach and Nectarine trees on the back wall, and also on a trellis in front. During the present year I gathered from these houses 764 fruit, or upwards of 63 dozen Peaches and Nectarines ; many of the Peaches weighing 8 oz. each, and some more. My trees not being large and strong, I cut away more than 300 fruit, for the purpose of giving them a partial rest, having the previous year (1870) gathered from them the prodigious number of 1728, or upwards of 142 dozen Peaches and Nectarines. In 1868 I gathered 1280, or more than 106 dozen. I may, therefore, I think, safely say that I have not laboured in vain. From my youth I have been a great admirer of this

* Sown on March 20, and then harrowed in. In making this mixture, the guano was first mixed with the gypsum, the dissolved bones with the salt.

† Planted on same ground the three years.

‡ Direct from America.

beautiful and luscious fruit, and earnestly devoted to its cultivation, in which I find that some amount of skill and assiduous attention is required to ensure success. But although the attention required is almost interminable, the successful cultivator is amply rewarded by such results. I once gathered from a Royal George Peach tree, on an outside wall, in one season, 600, or 50 dozen fine fruit. That tree never failed for seven successive years to produce excellent fruit in abundance. Indeed, the worst crop I ever had from it was 420, or 35 dozen Peaches. The tree was not at all diminished in health and vigour. *Wilton Boardman, Gr. to S. H. Norris, Esq., Altrincham.*

Pterocephalus Parnassi, a dwarf free-growing silvery-leaved tufted alpine, was seen very attractive at the Hale Farm Nurseries; it is allied to the Scabious, and bears flesh coloured flowers. I can't say whether it is hardy or not, but it seemed likely to prove a useful plant in the garden. I have called attention to this and other silvery-leaved plants, as Cineraria acanthifolia, Senecio argenteus, &c., for the sake of those who indulge in a little winter and spring gardening. Silvery-foliaged plants are peculiarly attractive when the skies of mid-winter; they serve to light up the garden in a very pleasant manner, and according to the brightness of the weather will be the measure of their effectiveness. As I write, a most welcome gleam of sunshine has just broken through the heavy clouds that all the morning have hung in the sky like a funeral pall, and the silvery tint of the Cineraria acanthifolia answers to it with a heightened brightness. It occupies the centre of a mass of Myosotis dissitiflora, as yet quite untouched by frost; round the Myosotis there is a band of white double Daisies, and Aubrietia grace, alternately with Bellis auriculæfolia, forms a margin to the bed, which is edged with a kind of wall of Sempervivum californicum, planted in a perpendicular fashion. *R. D., Ealing.*

American Early Rose Potato.—My trial of this having been on a very limited scale this season, I would feel obliged by any of the readers of the *Gardeners' Chronicle* who have made a comparative test of it under different conditions and on various soils, giving the results of their experience. It is certainly a good cropper, and very early ready for use, but with me the quality was not equal to Myatt's Prolific Kidney; and the reports from several who have tried it in the northern district of Scotland are so varied and conflicting, that I would like to know how it has done elsewhere. Some speak of it as just a thin skin with a globe of water; others as being waxy, and very inferior in flavour. *Amateur.*

Orchid Cultivation.—I am not about to enter into any controversy with your versatile correspondent, "G. H.," about his Orchids. He has mistaken my motives. I did not ask information, but made suggestions, more or less clear. I am obliged to him for referring me to the "Himalayan Journals;" I read them two or three times over some years ago, but had forgotten whether the Orchids were included in the valuable account of Darjeeling: hence my query. I quoted "Ex-Cantab," I remember, in the allusion to Tweeddlee: I think I have nothing further to explain, so now for a word about "ground Orchids," so called, to which Mr. Bentley and others mention which "G. H." tells me I asked. I once traced a road, passing over a rock (elevation about 6000 feet, and between 11° and 12° N. lat.), upon which grew Aerides Lindleyanum. I sat upon that rock in the sun, and broiled—well! This stewed me. I went home and took the thermometer from my verandah, then standing at 68°, and placed it upon a rock near my garden, and the glass—the mercury I mean, I must be careful—went up to 116° (nevertheless frost settles on these rocks during the night in moist places). I write more particularly because I think this was not "at a depth of from 2 to 3 feet," but on the surface of the rock, as nearly as may be, where the Orchids would grow. "G. H." further remarks—"the same plants (Orchids)? go from the sea level up to from 14,000 and 15,000 feet." I challenge such a statement, and if "G. H." is satisfied as to its correctness, then what in the name of fortune has he been arguing about so long? Your correspondent makes Dr. Hooker say—"In our gardens we can neither imitate the conditions of an alpine climate, nor offer others suited to the plants of such climates." Now what bearing can this possibly have upon Orchid cultivation? I am sure the Rhododendrons, introduced by Dr. Hooker himself, are from alpine climes, and I cannot help thinking that your worthy correspondent "G. H." had best give up all ideas of cool Orchid growing, if he believes it "will prove that the ground Orchids we have do not come from high elevations." *James Macpherson.*

Amaranthus salicifolius.—I was so struck with the appearance of Messrs. Veitch's Amaranth at the Edinburgh show, that I really thought, at a little distance away, it was a Croton angustifolium, with the elegant colour of foliage, and I little thought it was an Amaranth until Mr. Harry Veitch told me it was one. It is, so far as I know of that class of plants, one which will rank high in gardens, and, in fact, the whole tribe is not half grown as it should be. The variety I raised in France, elegantissimus so named, was between tricolor and caudatus: could we get A. caudatus with a tricolor elegantissimus leaf, it would be a splendid thing; but we have in Veitch's Amaranth one which is of equal or more value, not only as a pot plant but as a flower garden decorator, and at the same time a magnificent vase plant for conservatory or elsewhere. It will also, I have no doubt, make a chaste dining-room plant. *H. Knight, Floors.*

George's Patent Calorigen.—At the present moment the all-important subject with those who have small and unheated conservatories and greenhouses is—how they can most efficiently keep up the required temperature, with a due regard to economy. This being the case, we take the opportunity of directing the attention of those interested to the invention above named, and which, from an examination, we believe to be one of the most satisfactory yet introduced. For heating small conservatories, the Patent Gas Calorigen is well adapted, as the temperature can be regulated almost to a nicety, thus obviating the great injury done to the plants through over-heating. The annexed illustration, fig. 345, shows the general outline of the stove, and its working may be described thus:—In rooms or buildings where a chimney is not available, two holes are made in the wall to allow the pipes F and F to pass through. The cylinder E is attached to the ends of the pipes F and F, with the open end upwards. When the gas is lighted the action is as follows:—The product of combustion leaves the stove by the upper pipe F, and is discharged into the cylinder E, at the same time a current of air passes through the cylinder F, through the lower pipe F, to support com-

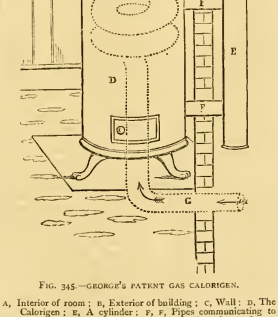

FIG. 345.—GEORGE'S PATENT GAS CALORIGEN.

A, Interior of room; B, Exterior of building; C, Wall: D, The Calorigen: E, A cylinder: F, F, Pipes communicating to supply air for combustion, and carry off products of combustion: G, Pipe for passage of cold air to Calorigen; H, Outlet for air into the apartment, after being made warm.

bustion. One end of the pipe G is inserted in the opening at the bottom of the stove, while the other end is carried either through the floor or wall, to communicate with the external atmosphere. When the gas is burning in the stove it will heat the coil contained therein, thereby causing the air to rush in through the pipe G, and out at the opening H, thus affording a constant supply of pure air warm to the apartment in which the stove is fitted up. The door of the stove is kept closed, and when not in use a cap is placed on the outlet H. Water being one of the results of combustion, the pipes F and F decline slightly from the stove, and so cause it to flow into the cylinder, where a small hole is provided for its escape. The manufacturers are Messrs. J. F. Farwig & Co., 36, Queen Street, Cheapside, E.C. [EDS.]

Judging Fruit.—At a provincial horticultural show, held in September last, a special prize was offered for the best three bunches of Grapes, of any variety. Two competitors entered the lists, one showing three well-finished bunches of the Black Hamburgh variety, large in berry, well coloured, perfectly ripe, and of excellent flavour; the other exhibitor showed three well-developed bunches of the Muscat of Alexandria, with berries of fair size, but quite green, and in an evidently unripe condition. The judges, however, awarded the prize to the Muscat Grapes. During the present season I attended as a judge at another provincial exhibition, and amongst other fruits exhibited was a very creditable display of table Plums of various sorts, amongst which was a rather ordinary dish of Green Gages. My coadjutor said the first prize must, of course, go to the Gages. This, however, I most decidedly failed to see, so an umpire was called, who at once said, "Oh, you can't get away from the 'Gages,'" so the Gages had to have it. I have not unfrequently heard a similar summary argument used with respect to Strawberries and other fruits, such as "You can't get away from the Queens," &c. But to return to the Black Hamburgh and Muscat Grapes, alluded to above. I must say that I could not by any means endorse the decision of the judges, as it was very evident that the former were much closer approximation to that degree of perfection which the particular variety may be supposed to be capable of attaining, than were the latter, *i.e.*, the Muscat of Alexandria; or, in other words, the Black Hamburghs were in all respects better Grapes, according to their kind, than were the Muscats, according to their kind, and on that account they ought, in my opinion, to have taken the prize. It appears to me it is only in instances where equality may be considered to exist that the acknowledged superiority of one variety over another should be taken into consideration; but your opinion, Messieurs Editors, or that of some of your experienced correspondents, upon the subject would be much valued by possibly many of your readers, as well as by *G.* [Grapes ought never to be rewarded unless fairly ripened. EDS.]

Water Required for Vines.—I have read your remarks upon Messrs. Lane's fine Grapes, and think they should be remembered by all Vine growers. If agreeable to you, I will write on the subject of preserving the great quantity of water which the grand Vines of America—mostly native species—thrive in, mounting the tops of the highest trees. I may add that I have been a rambler in nearly all parts, and have passed 14 months in North America. The Vine is my hobby; it was so when I was a schollyy, and in all parts of the world it has had my attention. I have a section of the Water Frost Vine, a native of Canada, 1¾ inch thick, 10¾ inch girt, which weighs over half a pound; it is perfectly solid, there being no pith. This was cut where it was growing, just out of the water at the river side. It was a grand Vine. *R. M. W.*

Hardiness of Cytisus racemosus.—I notice in a garden here (at Scarborough) a plant of Cytisus racemosus now in perfect health and vigour, with flowers upon it, perfectly uninjured by the severe weather which has prevailed more or less for the last month, and during which time there has certainly more than once been as much as 15° of frost. I learn from inquiry that the plant was grown in a greenhouse until last spring, when it was planted out in the open garden. It has had no protection whatever, and does not seem as if it would require any. What can you, or any of your correspondents say as to the hardiness of this well known and most valuable winter-flowering greenhouse plant? *C. W. Strickland, Dec.* 10.

Lawn Mowing, Daisies, &c.—Some short time since my attention was called to a singular circumstance, by a gentleman residing near Cork. He has for some years taken great pride in having a well-kept lawn, employing every season one or two persons to eradicate weeds of every description, so as to have nothing but the finest grasses and Clovers. Early in the spring his lawn was in splendid condition; being, however, fond of trying experiments, he used a lawn-mowing machine without the grass-box attached, and, so well pleased was he with the efficient manner and rapidity with which his lawn was mown, that he advised numerous friends to adopt the same plan. On my calling upon him early in November, he asked me my opinion respecting machines used without the grass-boxes. I could scarcely give him a decided opinion. Without expressing any himself, he asked me to look at his lawn, and to my astonishment it was one mass of Daisies; in fact so full, that little if any grass will be left in spring if some remedy is not applied at once. The question arises, How can this extraordinary crop of Daisies be accounted for? Both the gentleman and myself were of the opinion that the grass, Daisy flowers, &c., being only chopped in pieces, and allowed to remain on the grass, the seeds to a great extent matured themselves; and the result is, that in the moist, genial climate of the Cove of Cork, nearly every seed must be germinated, and thus undone the work of years. We may be wrong, and should any of your numerous readers be able to give their experience with machines used in the same manner, it may tend to elucidate the, at present, puzzling phenomena. I could not advise any remedy excepting digging the whole lawn, levelling, and sowing with the finest lawn mixtures. Before doing so, I asked him to try a small portion with Watson's lawn sand, and I hope he will be enabled to give you his experience in the use of it. *William Heale, Victoria Nurseries, Upper Holloway.*

Pinus excelsa Seeding.—With respect to the seeding of Pinus excelsa in England, I may say that I have many fine plants grown from seed gathered at High Elms, near Farnborough, in Kent. *C. W. Strickland, Dec.* 10.

Centaurea Clementei.—This is a charming addition to our stock of foliage bedding plants, and far outstrips older varieties for grace and beauty. Its value as a winter decorative plant for conservatory or greenhouse cannot be over-estimated. The rich silvery whiteness of its deeply cut and serrated leaves, which are of unusual size, have a most charming effect. This variety is not so liable to damp off when lifted from

the open ground as most others, and it also comes perfectly true from seed, which I consider the readiest mode of getting a stock. The propagation of the Centaurea by means of cuttings has hitherto been attended with much loss, on account of their liability to damp; this may be got over to a great extent by cutting each shoot about half way through, and slightly breaking it over about ten days before finally taking it off. By adopting this system, cuttings may be put in at almost any time when they can be had, with success. *J. Taylor, Rose Hill Lodge, Batcherby.*

Asphalte.—I should be glad to understand from any of your correspondents by what means I can hasten the stiffening process, consequent upon the dry formation of asphalte, as it, at this season of the year, is a long time setting firmly, with only plain gas-tar, dry lime, and Portland cement, with gravel in proportions, as directed. *W. B. Hurnard.*

The Twelve Heaviest Gooseberries.—We send you the following, in answer to your correspondent, "T. H. M.," who asks for the names of the 12 heaviest Gooseberries:—*Red:* Dan's Mistake, 30 dwt. 5 gr.; London, 31 dwt. 20 gr.; Rover, 29 dwt. 11 gr. *Yellow:* Leveller, 28 dwt.; Mount Pleasant, 28 dwt. 7 gr.; Kinger, 28 dwt. 9 gr. *Green:* Stockwell, 31 dwt.; Rough Green, 27 dwt. 14 gr.; Village Green, 28 dwt. 14 gr. *White:* Antagonist, 29 dwt. 18 gr.; Freedom, 28 dwt. 20 gr.; Overseas, 26 dwt. 13 gr. *E. Salsbury & Sons, Melbourne, near Derby.*

—— *Red:* London, Companion, Wonderful; *Yellow:* Catherine, Drill, Leader; *Green:* Thumper, General, Queen Victoria; *White:* Freedom, Queen of Trumps, Snowdrop. *Andrew Meikle.*

Horse Dung as a Remedy for Leaky Boilers.—This is nothing new. Horse-dung is not so good as cow-dung, and both are poor makeshifts. Besides, the construction of most heating apparatus is such as to render it difficult to get the dung inside the boiler. In some cases it will stanch a leakage for weeks, and in others it will either not act at all or not for more than a few days. But at the present day, when there is so much treacherous cast-iron used in the construction of boilers, where it can be applied it will sometimes answer—as a leakage takes place in severe weather, and it is not possible to replace the boiler without great injury to the inmates of the houses that are heated by the leaky boiler. *T. Baines, Southgate.*

—— I have used horse-dung for stopping a leak in a boiler on several occasions, and always with success when the aperture in the boiler was not very large. *J. Williamson, The Castle Gardens, Whitehaven.*

Witsenia corymbosa.—I have here a grand specimen of the above, measuring about 2 feet through. It has been one mass of flower from about the end of last July, and has still every appearance of giving me a good supply of flowers during the winter. Any one who has to keep up a constant supply of cut flowers for bouquet making, &c., at this time of year, would find this a valuable plant to add to their collection. Its flowers are of a purplish-blue, and answer admirably for nosegay and bouquet making. It is easy of cultivation, and only requires an ordinary greenhouse to grow it in. It delights in good, fibry loam, with a mixture of peat, and good drainage. *T. Carlton, Ashtead Park.*

Large Vegetable Marrow.—I have at present in my possession a Turk's Head Marrow of the extraordinary weight of 22 lb. 8 oz., which was grown in a cottage garden in the parish of Ockham, in Surrey. I would gladly show it to any of your readers who might happen to be coming this way. *W. R. Tate, 2, Strode Road, Crown Road, Fulham.*

On the Management of Boilers.—I would go much further than Mr. Campbell, who speaks of emptying all heating apparatus periodically. Every boiler ought to have an inch or an inch and a-half tap at its lowest point in the stokehole, and all warm water that is required for washing pots and other purposes of almost daily occurrence ought to be drawn from such tap, when the water is hot and in full circulation. By this means, if there is any sediment, it will come away as fast as it is made. On the subject of stoking I quite agree with your correspondent as to the necessity of checking the draught before opening the furnace when strong fires are used. At the same time I may observe that it is much easier to give directions than to get them implicitly carried out, and a far better remedy is to use wrought-iron instead of the treacherous cast-iron boilers. *T. Baines, Southgate.*

Amaranthus salicifolius and Celosia aurantiaca.—I have not yet had the pleasure of seeing this new Amaranth, but if the figure and description of it be correct (which there is no reason to doubt), a grand acquisition will undoubtedly be secured. Even if it should not prove sufficiently hardy for outdoor cultivation, it will nevertheless be eminently suited for the decoration of the conservatory and greenhouse, and as a dinner-table plant it must prove to be all that can be desired. I would also beg to take this opportunity of calling attention to a plant of kindred race, viz., the Celosia aurantiaca, which I think only requires to be better known to be more appreciated. I am unable to give any certain information as to the time of its introduction, although I believe it to have been introduced within the last few years. It is, strictly speaking, a tender annual, and, to succeed well, ought to be grown in a stove, or intermediate house, or warm greenhouse. It comes quite true from seed, that is, the plants do not vary in any degree from each other, and it has no tendency whatever to revert to the "tufted Cockscomb" style of growth; it is erect and pyramidal in its form of growth, attaining a height of from 18 inches to 2 feet; stem of a pale yellow colour, with pale green foliage, producing immense spikes, or rather plumes, of rich chrome-yellow, and it remains in full beauty for several months. It is an exceedingly suitable plant for dinner-table decoration, and has a very pleasing effect when mixed with Dracænas and other ornamental foliaged plants in the stove or intermediate house, where it will continue in beauty until Christmas, or later if desired. The seed should be sown in heat about the middle of March, and treated in all respects similar to Cockscombs, with the exception of using a soil less rich than is usually supplied to the last named plants. Over-potting ought also to be avoided, and the plants are somewhat impatient of over-watering. Very fine specimens can be produced in 6-inch pots, and this size of pot is found to be generally the most convenient for placing upon the dinner-table. *P. Grieve, Culford.*

Odours of Plants.—Mr. Britten (at p. 1583) says that "blue flowers are very rarely fragrant, and when so only in a slight degree." Allow me to observe that there is at any rate one exception to this rule, viz., the Primula viscosa (or P. rhætica ?—I am in doubt as to the correctness of my names). The plant I mean has the habit of *P. Cowslip*, with the flowers of a very rich deep blue, and have a deliciously sweet scent, which they in some degree retain for some years when dried and kept in paper. I apprehend it is not very common, as the only place where I remember to have seen it growing, though I have been much in the Alps, is in the Simplon Tavern, between Vallorbes and Wallnitz, in Carinthia. I should be very much obliged to any one who would put me in the way of obtaining plants or seeds of this charming little plant, which I am sure would be a great favourite if it can be got to grow on rockwork in our gardens. It grows high up on the mountains, I believe, but I do not recollect whether on granite or on limestone. *Alex. Nesbitt, Ashurst Lodge, East Grinstead.* [What about blue Violets? Eds.]

The Circulation of Hot Water.—It appears to me that the theory of hot-water circulation is a very simple one. An apparatus for heating by hot water may be compared to a wheel suspended on its axis: it will remain stationary if let alone, but put a pressure downwards on one side it will begin to revolve. The water in pipes remains stationary until one side is expanded by heat: this expansion can only take place vertically, for laterally the water is confined by the pipes, and as these were as full as they could be, the surplus caused by the expansion goes into the feed cistern or expansion pipe, thus leaving one side of the wheel lighter than the other, and the consequence is, the heavy side comes down, and the wheel begins to revolve, and as the process is continuous the revolutions are continuous also. I think the question to be considered is, not why the water circulates, but what is the best way to get the heat out of it. There are plenty of credence tables making the return-pipe the highest, but theoretically the water does not begin to return until it begins to fall, and that is not until it has passed the highest point in the pipes; for as water will find its own level, it is the vertical not the lateral direction that makes the length of the pipes (or rather the height) correct in the highest (or ascending) of an apparatus the return-pipe. The usual plan of horticultural engineers when putting in a heating apparatus is to get the boiler well below the place to be heated; they like a good rise from the boiler into the house, next they give the flow-pipes a gradual ascent to the furthest point to be heated, then the return-pipes descend to the bottom of the boiler. One great objection to this plan is, that if the houses are at different levels, the highest will get most heat; its demands are satisfied first, and it sometimes happens that the last heat enough left to bring the boiler to the lowest place. I cannot see the practical difference between this (which I call the usual plan) and Mr. Cannell's; they both have the pipes ascending. In my houses the pipes all descend thus:—From my boiler I have a vertical flow-pipe to a valve-box (containing a horizontal valve), 2 inches in diameter, 2 inches higher than any pipes; from this box the water flows downwards through the houses, the lowest heating as well, perhaps slightly better, than any other. I have never seen an apparatus work so rapidly; the water rushes downhill to the bottom of the boiler, there to recuperate. There are many advantages to this plan, and the least is, that it does away with the necessity for a deep stokehole, for the top of the boiler may be above the pipes. *William Foster, Jun., Stroud.*

The Provincial Visits of the Royal Horticultural Society.—These visits are nearly as far off from the goal of perfection, in a social point of view, as they were the first day the Society bore its banner away from Kensington. Truly it cannot be said that this is owing to the want of invitation to discuss the matter, for any one who has been a reader of the *Gardeners' Chronicle* since those visits were established well knows that that journal has always in the kindliest spirit invited the co-operation of gardeners and others who have the interests of horticulture at heart, by making known, either through its own columns or those of other gardening periodicals, any suggestions that would be likely to benefit the undertaking; and though those invitations have been accepted and acted upon, and certain good done, yet nothing definite has been the result. One year we had a congress, another we had a dinner, and now the question is, what are we to have next as a social companion to the great exhibition? We naturally look for something greater than those once annual visits than from local exhibitions, emanating, as they do, from the centre of intelligence and from a Society which has been the parent of other exhibitions. We look to that Society for greater things, but unless it has hearty outside support, we can hardly expect to see those great things realised. We should like to see the Royal Horticultural Society on these occasions hedged round by hosts of gardeners, not looking on with eye askance, but taking an active part, so that the exhibitions might be worthy the nation they represent, and that not only as an exhibition or a spectacular point of view, but also socially and intellectually. At one time it was evident that this latter part received good support both from within and without, and had favourable circumstances attended the other parts of the undertaking, the Congress at Old Trafford might have been made a pleasing event to future generations; but the rebuffs which were subsequently dealt out with liberal hand naturally led to some little coolness on the part of those who took part in the proceedings, and deterred them from entering again into a like movement. Diverse opinions may exist as to the desirability of these social meetings, and their utilities; but those who cannot see beyond the limits of fruits, flowers, or vegetable, are surely not awake to the interests of horticulture. No class of men have less opportunity for intercourse with their fellow-men than gardeners. Happy in the confidence of their employers, at least they cannot be otherwise than happy amongst their flowers; and it almost seems a pity to intrude upon their felicity, to drag them forth to fill up a niche in this Juggernaut of horticulture, and perhaps only to fall a sacrifice under its wheels. Again, in the main, a gardener has no social status. A political nonentity, for him social questions have little attraction. The nature of his calling absorbs nearly all his mental faculties. If he has time to plot, it is as to how he may annihilate the vermin which are constantly on his track. Sunday and Saturday, off work and on work, his mind is busy both with the present affairs of his garden, and with those locked in the womb of time. Then as to his isolation. Other craftsmen are continually rubbing up against some social question, but beyond a spasmodic lecture in the village school, gardeners have seldom the opportunity of that intercourse necessary to give them confidence to take a prominent part in any public assembly. With a little more intercourse with their fellow men perhaps the country would find "Odgers" of a different stamp rising from amongst the Roses—men more able to deal with scientific questions affecting their trade, and with social questions affecting their position. Education is becoming more and more horticultural in its character every year, and though we cannot see how every man is to have a "house and garden in the country," we are alive to the importance of horticulture; and whether it be to raise the social status of those employed in it or the profession, or the sympathy of those who embrace it as a pleasure, intercourse is necessary to raise and widen the intelligence of both. And what more fitting opportunity for this intercourse to take place than at those exhibitions? How can it be right, when so much requires to be done, when such opportunities be lost—to let things go without something to mark their advent beyond the mere recollection of the £ *s. d.* won in the encounter—without something which might grow with us and blossom and ripen into golden fruit? Fortunately, we have the benefit of past experience. We have seen how this rural horticultural assembly has been received. The ground was not fully prepared, the roots found no great depth of filth wherein to ramify, and when the droughty season came, the plant withered up almost to lifelessness, but, let us trust, not beyond the power of resuscitation. The cold shade which it has received imaginary than real, and we hope to see the affairs managed at Birmingham in a manner that will tend to corroborate that opinion. On the social question we would advise or suggest that it should partake more of an intellectual than of a convivial character. [Why not both?] True, the intelligence gained at convivial meetings is not of a durable character, for when the viands have tightened their belts, speakers and hearers are more humourisme, and however desirable it may be to have a little wit to help our digestion, this is not what I would recommend to raise the social status of gardeners. The same elements partly enter into the character of a *soirée*, but had I the choice, I would rather have genial after-dinner speeches than the somnolent lucubrations which float on the top of Mocha or cocoa. Beyond these everyday occurrences, the clash of knives or the clatter of Wedgewood, gardeners should be invited to a truly intellectual repast, such as a lecture given by some eminent professor, which might take place in the

evening and in the town; or take part in a congress, where the papers would be less in number and in length than was the case at Manchester. This might take place in a tent on the ground, but I would suggest that there be but one entrance to it, and that in front of the chair. I cannot but think, with fewer papers, and more discussion, the congress will yet play an important part at those great exhibitions. At least I think it capable, in a great measure, of raising the social status of gardeners. There are other means by which the social advancement of gardeners might be accomplished, but there is one in particular which, if not beneficial to gardeners in general, would at least be of great benefit to a certain branch of the profession, and one which is entirely within the province of the Royal Horticultural Society, and if brought into existence would form no mean feature of those annual exhibitions, and that is to have an exhibition of the competitive designs for such public parks or pleasure grounds as may have been advertised during the past year. That plan drawing—the style of execution—is at a low ebb even amongst landscape gardeners, is evident from the fact that the prize plans of public parks, &c., for the last two or three years, have always come from the office or table of the civil engineer; and if this be not looked into, the landscape gardener may sink lower and lower. That such an exhibition would be highly interesting to the rising generation of gardeners no one can doubt; nay, I have conversed with old gardeners, who have declared they had learned more from such a display than from all the flower shows they ever beheld. But how are we to have such a display? Easy enough. There are the designs sent by numerous competitors to Rochester, for the Castle gardens, and which would form an exhibition of themselves. There are the designs of the pleasure gardens at Bournemouth, and those of Raikes Hall, Lancashire, all within 8 months, and there may be more for anything I know. Beyond a stray advertisement, nothing more is heard of these designs. The plans are sent in, the prizes awarded, and then—exhibited, where? To whom? No critical remarks; no, not even the names of the successful competitors. Well, there are those plans. Let the assistant-secretary of the Society communicate the object to the authorities, and the names and abodes of those who furnished plans will be readily obtained; open communication with them, and the thing is done. There are no civil engineers, architects, landscape gardeners, and others, but what would willingly lend their productions to back an exhibition. In conclusion, I trust to see everything in connection with the great meeting duly arranged and carried into effect. The Council of the Society, if we are to have a Congress, should have the management of papers, as of yore; and in case some gardeners, who may treat on remunerative points, should have their papers rejected and feel disappointed, I beg distinctly to state that the Society should not be made a stepping-stone to the wages question. However magnanimous on the part of the Society to entertain the point, it would be more magnanimous on our part not to hamper the Society with the question. If we are to have any discussion on the remuneration of gardeners, let us have it under our own Veld and Fig tree. I feel sure from my heart to do so, but must have the countenance of the Royal Horticultural Society to enable us to discuss the rewards of horticultural merit, or, in plainer words, how to raise the wages of gardeners, then we are indeed a favoured class, for when those social questions have little attraction. *A. M. R. H.*

—— A few words as to the duration of the show and one or two other subjects I hope will not be wasted. Are five days actually necessary to make it successful? I am persuaded that four days is sufficiently long enough for any exhibition, and that Saturday must be included let the opening day be Wednesday. As great a success as the Nottingham show was, I think the same would have been achieved with four days. It must be well known that when exhibitions begin on Tuesday exhibitors from a distance have to prepare for packing on the Sunday previous, and if they extended to the Saturday following, the day of rest is again broken, and the greater portion of the plants have another day unnecessarily away from home, to say nothing of the extra expenses, which are always heavy enough. It may mention, for our exhibitors at Nottingham were placed to the expense of £35 10*s.* The conveyance of plants from the railway stations is another serious matter to exhibitors, more especially strangers, who have to run hither and thither for horses or conveyances, as the case may be. It is true something was attempted at Nottingham for the carriage of plants to and from the stations to the exhibitions, but at such a high rate of charges that that something would have been better left alone. We had two trucks loaded with plants, and for the cartage of these plants alone a charge of £2 2*s.* 6*d.* was made, besides 2*s.* for our own van. Some of the vans provided were not larger than a good-sized handcart, and yet they were called loads when full. On our return we employed the Midland Railway Company to take our plants to the station, and I must say their charges were very reasonable, being only 16*s.* Now could not the Royal Horticultural Society be as liberal as the Leeds and York societies are, and convey the plants from and to the different stations free, or if not free, at a rate that would not so seriously add to the expenses of exhibitors? Exhibitors could easily inform the secretary or manager what time and at which station they would arrive, stating what conveyance and horses would be required. Again, the staging of fruit at exhibitions, as at present carried out, is to me very objectionable. In the first place, there is scarcely any attempt at grouping for effect; next, the quantity that is spoilt by exposure to dust and decay is incredible, to say nothing of the losses by pilfering. I would suggest continuous frames (with nicely-made lights well glazed) to fit any length of tabling, of a suitable width, the height at back sufficient to admit Grapes and Pines, the lights on sliding hinges, and to open, with ventilation at the back, the fruit to be judged before the closing of the lights. I think this would prevent dust, fingering, and the spoliation of so much fine fruit; and then, instead of the meagre spreads we have now, we should have grand exhibits, and plenty of them. Vegetables, too, will bear some alterations in their arrangement on the exhibition-tables. I think it is not actually necessary to show vegetables on green baize. Could not trays for different classes (such as Mr. Chapman's), with perforated bottoms, be used instead of baize? We see a tray here and there, a few plates, a few dishes of diverse shapes and sizes, and a few boxes; and as many vegetables are now very artistically arranged on the baize. By using trays the articles could be sprinkled with water once or twice during the day, to keep them fresh, which would add to the effect. In conclusion, we want more unanimity between managers and exhibitors, more liberality, and not so many petty jealousies. What if we lose the contest, it is not disgrace; but, if we win, it is a credit. *J. Thorpe, Paddock Nurseries, Stratford-on-Avon.*

Foreign Correspondence.

ALLAHABAD.—We have received the following extracts from a letter written by Mr. G. Batcock, and dated October 18, 1871:—

When I first came out I was directed to proceed from Bombay to Nagpore, there to await orders from Mr. H. Rivett Carnac, the Cotton Commissioner for the Central Provinces and the Berars. As I passed along in the train I naturally took notice of the cultivation generally, and though Cotton fields were repeatedly passed, and in some cases large ones, I could really feel assured that the little bare sticks, about 18 inches high on the average, studded with little balls, were Cotton plants—they were so unlike what I had seen in Egypt, where, in August, the fields are one mass of foliage; and later on, when the leaves have dropped, one sees only cotton. The idea of Cotton a vigorous growth. I was ultimately posted to Sheagaum, in West Berar, where an experimental farm had been commenced and carried on during the preceding year. This is one of the leading districts for Cotton cultivation; the soil is "regur," averaging 4 to 6 feet in depth, resting on a very calcareous subsoil of variable depth; beneath this, again, is a stratum of broken and disintegrated trap lying on the solid trap. The underlying rock seems to be deposited in an undulating manner; here and there it crops out, forming low ridges, especially towards the south of the Berar valley. These ridges are, of course, bare of soil, while the solid rock is covered by a stratum of *debris*, known locally as "moorum," which is extensively used for making roads, and as ballast for railways. The proximity of the rock with its stratum of moorum to the soil must naturally be a marked effect upon the crops grown thereon. In the northern part of the Berar valley, where the regur is of great depth, a variety of Cotton known as "Jurree" is grown. Towards the south, where the soil becomes shallower and somewhat altered in character by an admixture of pulverized moorum, "Bunnee" Cotton is grown. "Jowarree" (Holcus Sorghum) is grown generally throughout Berar, though the crops in the southern parts have not the height and vigour of those in the north of the valley, where, from the great depth of the soil and consequent abundant supply of moisture, a vigorous growth is always the result, perhaps at the expense of the quality of the produce. On dry lands "Bajree" (Penicillaria spicata) is generally grown. This is, I believe, the staple grain of the Deccan, as Jowarree is of Berar.

The Jurree Cotton is a strong and vigorous growing kind; under fair cultivation it will give 70 to 80 lb. of clean Cotton per acre. The staple is strong, though somewhat harsh; the best will give 37 per cent. of clean from seed Cotton. The plant is characterised by a sturdy habit, varying in height according to circumstances; five-lobed leaves, of firm texture, with bright yellow flowers, the entire plant being densely pubescent. This kind is very susceptible as to the deficiency of regur or otherwise in its cultivation. In a deep soil of the former nature its growth is vigorous, averaging 6 to 8 feet high, but in shallow regur, or in soils of a somewhat loamy nature, its successful cultivation seems to be doubtful.

"Bunnee" differs considerably from "Jurree" Cotton; its habit is less sturdy, the branches longer and weaker, the lobes of the leaves are also less broad, and the degree of pubescence much less than in "Jurree." The Cotton of this kind is, however, much more silky, staple good and strong. In some places where the soil is a brown, friable loam, with less of regur, this kind has been improved in staple and altered in character. This is seen in the Wurdall valley, where the change has been so considerable, owing to the superior nature of the soil, that the Cotton produced there is known specially as "Hingunghat." The principal difference in this form from the original consist in the leaf lobes being much narrower, with rudimentary lobes occurring in one or more of the sinuses, the branches are longer and weaker, and the bolls more elongated and conical than in the usual form of Bunnee. From what experience I have had in Indian Cottons I believe that this kind, if cultivated in an open friable loam of good body, would sooner or later produce Cotton equal to ordinary American.

The regur, though a soil well adapted to the imperfect methods of agriculture adopted throughout the country, is not of a sufficiently fertile nature to produce extraordinary crops, it is light and sandy, and easily affected by climatic changes. Manure will produce better results, but one is needed at the application of manure, for the soil being devoid of that retentive power possessed by a good loam, any nutrition applied will soon pass away. I believe that a coating of 3 inches of good clayey marl would improve the soil naturally. A considerable degree of improvement, however, lies in the hands of the native cultivator, if he would but take advantage of it; this is principally in the picking, which, if carefully done, would cause the Cotton to realise higher prices than at present, as it is now allowed to hang till a large quantity has fallen on the ground, and then gathered up with any soil or rubbish that may adhere to the fibre.

In the North-west Provinces another variety of Cotton is grown peculiar to the country; it is evidently akin to the Berar varieties, though of more rambling habit: the development of the fibre is not so good as in the Berar kinds, the bolls are small and the staple short and harsh; it is, however, a prolific kind, and will, as a rule, produce a greater weight of Cotton per acre than the others. The want of development in the fibre may perhaps be due to the absence of decaying vegetable matters, and the consequent want of humus in the soil, which is a fine sandy loam. The best districts for cultivation in Berar and the Central Provinces during the dry, or winter months; the lands generally selected for this purpose being low-lying, and with a moist subsoil. In regur soils a good Wheat crop averages 700 to 800 lb. of grain per acre, and is 3½ months in coming to perfection. In the sandy soils of the Ganges valley in the North-west Provinces Wheat will yield from 1200 to 1600 lb. per acre, and is about six months coming to perfection.

A good deal of garden cultivation is carried on throughout Berar. Each plot so devoted is furnished with one or more wells for irrigation during the dry months. The crops principally cultivated in these plots are Capsicums, Egg plants, Sweet Potatos, Onions, Arachis hypogæa, Rice, Tobacco, and different kinds of vegetables. The fruits principally cultivated are Plantains, Limes, Custard Apples, Oranges, and Guavas. Zizyphus Jujuba is also preserved wherever it grows, though not cultivated as in the North-west Provinces, where orchards are planted, and some care bestowed on the cultivation of this plant, the fruits of which are in flavour something like an inferior Apple.

The general aspect of the Berar valley is that of an undulating plain, bounded on the north by the serrated ridge of the Sautpoorah hills, and on the south by the tabular Ajunta hills, which form the northern extremity of the Deccan plateau. The general lay of the valley is a gradual slope towards the Poornah river, a few miles from the base of the Sautpoorah. It being entirely an agricultural country, there are no forests; in fact, the amount of arborescent vegetation in Berar is comparatively small, and mainly found immediately around the villages. The kinds of trees principally grown are the Mango (usually grown in orchards or topes, as they are here called), Tamarind, Melia Azadirachta and M. sempervirens, Bassia latifolia, Acacia arabica (found everywhere), Ficus religiosa, and two or three other species of Ficus. Euphorbia Tirucalli is largely used for making hedges; trees of this with a stem diameter of from 8 to 10 inches may frequently be met with. Butea frondosa occurs plentifully, but is not often found beyond the size of low shrubs, as the natives dig up every season the largest plants for the sake of the liber of the root bark, out of which they make coarse but strong ropes. The Butea is a striking object when in flower, the brilliant scarlet of its blossoms making it conspicuous from a long distance. I have seen forests of this plant in the Central Provinces and the Punjab, averaging 12 to 20 feet high, looking like a scarlet sheet spread over the country.

Berar is very deficient in herbaceous vegetation possessed of any interest. The creeping plants belong principally to Convolvulaceæ and Cucurbitaceæ; a climbing Leea or Vitis is common, bearing corymbs of dark coloured berries, which are eaten by native children, the taste being nearly identical with that of the Celederry in England. A tuberous rooted Aristolochia is very common, and a plant of Compositæ—perhaps a Vernonia—is plentiful, from which the natives informed me a tonic drink is made.* Leguminosæ are largely represented in Berar, Hedysarum, Indigofera, Mimosa, and Phaseolus being the principal genera.

* Vernonia anthelmintica, Willd., and V. cinerea, Less., are both used in India as tonic medicines.

Notices of Books.

Contributions to Botany, &c. By John Miers, F.R.S. Vol. iii., containing a complete Monograph of the Menispermaceæ. 4to, pp. 402 ; tab. lith., 66. Williams & Norgate.

Some time since an eminent Continental botanist proposed a guage by means of which the benefits conferred on botanical science by different authors might be tested and their value estimated. This guage consisted in the number and excellence of the illustrations published by any given author. The test is a good one as far as it goes, but it must not be relied on too exclusively, or a Jussieu or a Robert Brown would have to yield precedence to a Jacquin. Accepting, however, the test, subject to the requisite modifications, and applying it to the works of the veteran botanist whose name stands at the head of this notice, it will be seen that there are very few to whom modern botanists are under greater obligations than to Mr. Miers. For many years he has laboured diligently to make known the structure and affinities of the plants collected by himself and others in Chili, Brazil, and other parts of South America. Readers of the Proceedings of the Royal Horticultural Society will also recall the fact that the plants collected by Weir were determined by Mr. Miers. In addition, certain groups, such as the Solanaceæ, Bignoniaceæ, Styracaceæ, &c., have been the subjects of Mr. Miers' special study, and he has conferred great benefit on science by the publication of his notes and illustrations on these plants.

The Menispermaceæ, the order to which the present volume is devoted, present great difficulties, from the circumstance that their flowers are unisexual, and there is the consequent difficulty of matching the sexes, from their variability, the frequent minuteness and occasional complexity of the structure of their fruit and seed.

We shall not presume to criticise Mr. Miers' work, as we believe no other botanist has studied the plants in question so profoundly, or knows them so well as he. If, therefore, we find that our author entertains different views as to the limitation of genera and species from those now prevalent in this country, we can but concede that he has acquired an indefeasible title to his own opinions. There can be only one opinion as to the importance of the facts he has accumulated with so much patient skill and keenness of observation ; the ultimate value of these facts is the same in whatever way they are made use of, whether in the construction of a few large genera, or in the formation of a great number of less densely peopled groups, the plan preferred by our author. Mr. Miers also merits the grateful recognition of every scientific naturalist for the manner in which he has, by precept and example, upheld the value of a full investigation into structural points. Too often the exigencies of the "system" necessitate the placing together in the same group of plants that really have little right to be so closely set together. This happens often, not from any wilful disregard of structure, but from the immense and constantly growing accumulation of unsorted material which requires to be thrown into some sort of order at once, so as not to obstruct progress, or delay the formation of descriptive catalogues—an urgent want—longer than can possibly be avoided.

Mr. Miers, however, has always subordinated system to facts, and there can be no possible doubt of the correctness of his principle, even on the part of those who may occasionally take exception to the way in which he applies it.

In the case of the Menisperms the peculiar structure of the wood, the simplicity of the floral structure, the arrangement of the several parts of the flower, the curious combinations of the stamens, the complex nature of the seed, &c., present points of very great interest to the structural botanist, who will find in Mr. Miers' pages a large series of carefully observed and well illustrated facts.

As illustrations of the simplicity of construction of the flower in some genera, we may allude to the flower of Antizoma, with its two sepals placed immediately over its two petals, or the even simpler flower of Cyclea, in which there is only one sepal, with one petal in front of it, and in the centre a single carpel.

Looked at from a horticultural point of view, Menisperms are not important, as their flowers are usually small. The old M. canadense is a graceful, hardy climber, too rarely met with, and there are many other species well worth growing as elegant climbing plants. The bitter tonic drug, Calumba, is the produce of an African plant of this family.

The Amateur's Flower Garden : *a Handy Guide to the Formation and Management of the Flower Garden, and the Cultivation of Garden Flowers.* By Shirley Hibberd. Illustrations. London : Groombridge & Sons.

The scope of this book may be learned from its second title, and the mention of the headings of some of its 19 chapters, such as Forming the Flower Garden, the Parterre, the Bedding System, Cultivation of Bedding Plants, Hardy Border Flowers, Selection of Hardy Herbaceous Plants, Rose Garden, American Garden, Subtropical Garden, &c. It is practical throughout, and the directions appear to be safe and sound, while the numerous woodcut illustrations serve to elucidate more completely the subjects treated on. What, however, the author can mean by his figure labelled "Glaxinia-leaved Foxglove," which looks far more like some hothouse Thunbergia, we cannot divine. There is a very good chapter on the making and management of lawns, a subject which it may be assumed the majority of amateur gardeners know comparatively little about. As to herbaceous plants, the author says :—

"Herbaceous plants are for the most part easily multiplied, and, generally speaking, may be increased by the very simple process of division ; but it is better to plant a small plot of ground in such a way as to ensure a good effect at once, than to lay out a great extent of border space with the intention of filling it 'some day' with home-grown stock. To enjoy herbaceous plants, they should be left undisturbed for years, to form great masses, or 'stools,' as they are called, for it is only when thoroughly established that many of the best of them present their flowers profusely, and show all their characters in full perfection. It is a strange thing that people who are always ready to expend money in the most liberal manner on bedding-plants, become ludicrously niggardly the instant they become convinced of a glimmering faith in herbaceous plants. *

"The Rose is not everybody's way. The furnishing of an extensive border by the purchase of sufficient of the very best herbaceous plants, will prove a more expensive business than every reader of this book may be prepared for. It follows, therefore, something should be said on the raising of plants by a cheap and simple method of procedure. Many good plants produce seed abundantly, and the careful cultivator may by this means increase the stock to any extent he may be desirous of. The best way is that saved at home, and the best way to deal with it is to sow it, as soon as it is ripe, in large shallow pans and boxes, and keep these in cool frames until the plants appear. Some kinds of seed remain a whole year in the soil before they germinate, and therefore it is only the patient who are well rewarded."

As amateurs sometimes find seed-saving a difficulty, they are recommended to place a lot of bell-glasses, mouth upwards, on a shelf in a sunny greenhouse, and when a seed-cluster is just beginning to ripen to cut it off. These glasses will hold a number, and a label inscribed with its name, when the ripening process will soon be finished, and the seeds become fit either for storing or sowing. There are half a dozen plates of popular flowers printed in colours, but we cannot say much for the artistic merits of these, nor are they of much utility, as the names of the varieties are not indicated. Still the book will be useful and acceptable to the class for whose use it is provided.

We have to announce the publication of Dr. Hogg's *Gardeners' Year Book* for 1872 (171, Fleet Street), a publication which has long been indispensable to gardeners.

The Apiary.

In reply to your correspondent, "A. H.," I can only answer the suggested alterations in his very ingenious sketch to be applied to the former bar-frame hive of September, 1870, in the *Gardeners' Chronicle*, by "remember cost of hinges," &c. The great thing is to contrive some simple, cheaply constructed box, which may become the bee-house—guarding the bees from the extremes of temperature, by leaving the space around the bar-frames (which carry the combs and bees) ; and by "internal ventilator" ventilation is not meant by "A. H.," which a Mr. Nutt attempted to suggest and carry out in his collateral boxes many years ago. The bees will never permit any such plan to succeed more than the Woodbury compound bar-frame, with straw around it, ever did, except to honour mothy, bygone, but the straw hives of old ; and "A. H." gives credit only for the bar-frame hives being free from moths or other enemies. The true bar-frame hive, we believe, contains within itself all the requirements of the most successful bee-keepers, unless they are of the class who are beguiled by the saper and nadir hiving systems, or greedy-of-gain bee-keepers, who have not the judgment to divide the summer gatherings with their bees.

Feeding below is better, because of the accidents of overflowing, and the slanting alighting board is best fixed without space for the bees to come under the bar-frames, which the bees will not do on the flat box. The top openings of the bar-frame will prevent all condensation of heated air, which the piece of carpet or flannel will absorb ; the broad pieces require no extra dividing slides, as in my experimental bar-frames with the glass frames, &c. *W. A. Munn.*

Garden Memoranda.

Castle Kennedy, the Seat of the Earl of Stair.—Thirty years ago Castle Kennedy was unknown to fame. No doubt it had the local celebrity due to a picturesque site, and that sort of traditional interest which is shared by scores of other border peels—little romances of its own, tales of private warfare waged between neighbouring chiefs, and also its own county distinction as the residence of a Scotch nobleman ; but extra-parochial fame it had none ; any connection with national progress or general science did not come within its dreams of the possible. But it has achieved it—thanks to the combination of the talent of an able and educated gardener and the support of its liberal and far-seeing owner. Silently and imperceptibly it has come to the front, as an object of general interest. Here, far to the North, are to be seen growing and thriving, in the open air, a multitude of the rare and costly trees and shrubs that have been imported from distant climes of late years. The climate of the district has proved favourable to many species that do not grow at all in Britain, except in a few similar localities. I know, indeed, of no other part of the kingdom, except at Bicton and some of the other mild localities of Devonshire and the South of Ireland, where the rare and tender Mexican and Himalayan Conifers have been found to stand the climate, nor where so much information is to be gathered as to what will or will not grow in favoured circumstances in Britain, or what will be the effect of successful growth, either singly or in masses. It is one thing to read a description of a plant or to look at a figure, or even to see a living plant in a nurseryman's pot, and another and a very different one to see the same plant growing of good dimensions in the open air, showing its natural habit, and the appearance that a full-grown tree may be expected to bear. For this purpose Castle Kennedy has already become an object of pilgrimage to the lovers of trees, and especially Conifers, and with every year that passes it will become more so as it becomes more worthy.

Castle Kennedy is at the extremity of Wigtonshire, three miles from Stranraer. In order to reach it the visitor from the south or east leaves the Caledonian or North-Western Railway at Carlisle for Dumfries, and thence proceeds by the Dumfries and Galloway line through Galloway, or "The Stuarty" as it is there called, and Wigtonshire, and Stranraer, and Castle Kennedy is the last station before reaching Stranraer, at either of which places the visitor can stop. The Castle Kennedy station, however, is that nearest to the Pinetum and also to the house of Mr. Fowler, the gardener, who professes—and I do not in the least doubt—that he will find a pleasant, hilly-wooded, and highly cultivated country. He had better dismiss any such expectations. After leaving Dumfries, he passes for many miles through a rich and smiling landscape almost as densely wooded as Kent or Surrey, while the surrounding scenery is still more beautiful. Kirkcudbrightshire, indeed, seems the natural country of the Oak. It grows like a weed. Much of the timber, although not so old, is as fine as any of its age that can be found in England. The contents of the great bogs go to show that the Oak was aboriginal to the district, and the beauty of it being there found. As the traveller pursues his way, however, he finds the railway gradually rising—the trees become fewer, the rich fields give place to moorland farms, and by the time he reaches Wigtonshire he is high up among heath clad mountains, from which the descent is gradually to Stranraer ; but although he leaves the heather and the mountains behind, he does not recover the rich arable fields or the hedges and trees. With the exception of Newton Stuart, which is a lovely oasis nestling in a nook at the base of the hills, bleakness and barenness is the character of the whole country to the very gates of Kennedy. Nor is there any appearance of improvement even there, until within the gates, and even then it must be understood that 30 years' growth of timber, however luxuriant, can do little to clothe the nakedness of a country side, especially when, as here, the planting has only been gradually extending, and the most important part of it is all concentred about the Castle—for 30 years ago there was no timber about the place except a bank of stunted Beeches and a few Ilexes, the remains of ancient hedges or wildernesses suffered to take their own way. These have acquired a certain celebrity, certainly not from their intrinsic excellence in the trees themselves—unshapely, straggling, leggy things, they are like Hollies drawn up in unthinned plantations. But they are Ilexes, and Ilexes are rare in Scotland ; and in a district where no trees at all existed the occurrence of Ilexes of considerable age and size must be the subject of interest. Then they were said to have been planted by a former owner and ancestor of the present family, a General (nay, I am not sure but that he was a Marshal), who had been present at the battle of Dettingen, or some of the other battles on the Continent of that date—and in memorial of that event it was said that he had caused his plantations to be laid out in plots representing the formation of his army on that occasion. Unhappily for the story, the formation and plans have been adhered to by his successors, and these show that the formation is what no army ever could have been

made to assume, but exactly such a plan as was common at that date for formal gardens laid out on the Italian style. Upon that plan, or rather upon an expansion of the principle of that plan, the grounds around Castle Kennedy have been laid out. Miles of smooth shaven grass terraces, with groves divided by radiating alleys, extend along the lake which surrounds the peninsula on which the Castle stands; and these groves now consist of different kinds of Conifers, and each radius has been made an avenue consecrated entirely to one particular species. On some future occasion I may note one or two of the more interesting of these. *A. M.*

Obituary.

A BRIEF notice in the *Times* of the 12th inst. announces the death of Dr. BERTHOLD SEEMANN, the managing director of the Javali Mina, Nicaragua. Dr. Seemann, the paragraph goes on to state, had "only recently reached the mine, and died of fever, caught in Colon, on his journey out." From our own correspondents we learn that this is only too true, his death having taken place on October 10. Dr. Seemann has long been known as an acute botanist, an intrepid traveller, and an accomplished man of science. Lately, Dr. Seemann had chiefly turned his attention to mining affairs in Central America, and his frequent visits to that country enabled him to send home many important novelties, in the form of ornamental plants. We propose on a future occasion to give a fuller account of the career of this distinguished naturalist, accompanied by a portrait.

Dec. 7.—Overcast till noon; variable amounts of cloud prevalent during the afternoon. Occasional snow.
— 8.—The sky was covered with clouds, and great gloom prevailed between 10 A.M. and noon; generally cloudless at other times. Hazy and foggy.
— 9.—Overcast throughout. Hour-frost in morning. Snow fell thinly during the day.
— 10.—Overcast, and at times very foggy throughout the day.
— 11.—Nearly cloudless and very fine till noon; overcast afterwards, and a little thin rain fell.
— 12.—Variable, but generally fine. Slight fog.
— 13.—Overcast throughout. Thin rain fell occasionally. Slight fog.

JAMES GLAISHER.

Miscellaneous.

THE DYAKS OF BORNEO ascend the trees by driving strong pegs of Bamboo into the trunk, which they connect with an upright Bamboo, and thus form a good ladder. The people of Timor literally walk up the trees by means of a long piece of creeper put round them and the extremities held in the hand. It is a wonderful sight to see a man thus ascend a vertical trunk, 100 feet high, and then creep out upon a horizontal branch and coolly brush away the myriads of bees from a comb a yard in diameter, and become immediately enveloped in a cloud of angry insects, while he cuts off the comb and lets it down to his companions below by a slender cord. In this manner, many tons of wax are annually collected. *A. R. Wallace,* "*Linnean Journal.*"

A PERPETUAL FLOWERING ACACIA.—The French gardens have yielded this, in the Robinia Pseud-Acacia semperflorens, which produces flowers from April or May onwards through the season. The new variety, which was raised in the Paris gardens, has the ordinary aspect and habit of the False Acacia, but the young plant was observed, three or four years since, to flower a second time during summer, after flowering at the usual season. The same habit was repeated in succeeding years, and in the present season the blooming has still been more abundant and continuous. We may, therefore, expect, in this perpetual-flowering Acacia, a really good acquisition amongst our ornamental deciduous trees.

KANGAROO RATS GOON THISTLE ERADICATORS.—This discovery has been made by several farmers on the Loddon River, in South Australia. "It has been found," says the *Bendigo Independent*, "that these animals dig down under the Thistles, and eat the roots of the same, which thus necessarily die. One farmer has issued orders that no kangaroo rats are to be killed on his land, in consequence of their having been of much service to him in destroying the obnoxious Thistles." The roots, and especially the stems, of Thistles have been used for food in time of famine. Evelyn recommends that they should be boiled, or baked in a pie.

CALIFORNIAN GRAPE CROP.—One of the leading wine-makers of California, who has extensive dealings with Grape growers, estimates that the crop of this year will produce from 6,000,000 to 7,000,000 gallons of "must," or raw wine. Alluding to this estimate, the *San Francisco Bulletin* of October 25, says :—

"This 'must' is worth about 30 cents a gallon, making an aggregate value of 2,100,000 dollars. Grapes for wine-making sell in bulk at about 1 cent per lb. There is, in addition, a large amount of table Grapes, raised for home consumption and for shipment. The choice varieties sell in the home markets at much higher rates than formerly. It will not be safe of the mark to estimate the cash value of the Grapes grown for other than wine purposes at 400,000 dollars. The aggregate value of the vintage for this year, in California, may be set down at 2,500,000 dollars. This estimate may be a low one, but there are data to support it. Moreover, there are a large number of Vines which are just coming into bearing, but which will not produce a full crop until next year. From all quarters we hear that the quality of Grapes was never better than this year. The dry weather has nowhere shortened the crop. In some vineyards noticed by us in Napa Valley, the yield of the better sorts of Grapes runs down at 500 gallons to the acre. The proprietor of one vineyard, containing about 20 acres of choice varieties, estimated that the nett returns would not be less than 10 cents per lb., the entire crop having been engaged for the home markets."

WINTERING ONIONS.—A few years ago we met a Western farmer who was growing 2000 or 3000 bushels of Onions yearly. They were sent chiefly to the Southern market. He wintered the Onions in pits as we do Potatoes. A moderate freezing, it is well known, does not injure the Onion, provided the frost is drawn gradually, and it is not allowed to freeze and thaw more than once. The best conditions for keeping them are a dry place and temperature just above the freezing point. We have covered with dirt only, using no straw, to the depth of 12 or 18 inches, according to the exposure of the pit, and the Onions came out crisp and sound in the spring. The danger to be avoided is heating. It should be remembered that some frost is safer than too much heat. If too much covering is used, the entire pile will rot. *Toronto Globe.*

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

"KEEP the frost out, and all will be right; hence I'll fire away well for additional safety." Such is now the mental soliloquy of the uninitiated. Add to this the fact that the plants look thrifty, are growing freely, and you have at once as good an illustration of what plants do *not* require, in regard to future success, as well can be. It cannot be too strongly urged that all growth of any account made at this season is injurious. The only result is, that a languid and impoverished vitality is framed, which, by the advent of summer, has so deteriorated the wonted robustness of the plant, that a strict period of rest should ensue. If I can convince the amateur or others of the importance of these facts, I shall perhaps do enough to induce them to fire less freely and more cautiously, though at the expense of some personal comfort and convenience. I would further add, rather let the temperature of your stove fall by the early hours of morning, down to even 53° or 54°, than risk engendering an excess of heat of even a few degrees only, and permit the temperature of your greenhouse to fall during a severe night down to a minimum of 40°, rather than endanger your plants by a higher degree of heat. Though I have before suggested the desirability of using external coverings, I would again revert to the subject, knowing what important economisers of the heat such coverings are, independently of the reduction of necessity of using excessive fire-heat. Some plants which are now assuming a period of rest, such as *Hoyas, Stephanotis, Rhynchospermums, Kennedyas, Allamandas, Asgapanthus, Stigmaphyllum ciliatum*, &c., might receive a moderate shift into a good fibrous compost suitable to their wants, and receive the necessary complement of new stakes, the requisite tying, &c. Some of the neat subjects, which form chaste edgings in front of the general flowering plants, such as *Isolepis gracilis*; *Lycopods* of the free growing recumbent forms, as *Selaginella denticulata*, &c.; *Tradescantias* and others, should also now be divided, and potted into small pots for early spring and summer decoration. Look sharply after *Camellias*, which are now swelling their buds and are about to bloom, and insure their having a sufficient supply of root moisture. Those planted out into the open borders, especially such as have their roots cramped for room in boxes or very shallow beds, or are growing in the vicinity of flues, &c., should be thoroughly well moistened at this time. A dearth of water at this time invariably causes their flower-buds to drop off.

FORCING HOUSES.

The general stock of *Pines* should now enjoy a mean artificial temperature of 60° to 62° by night and 64° to 65° by day, if dull, and fire-heat has to be relied on, allowing an advance of 5° or 6° by sun-heat only. Need I say that, in regard to *Pines*, the necessary acid heat reinforced must be met and neutralised by a slight expenditure of moisture, which, scattered upon the floors, and other cool surfaces, will give off a moderate vapour. If the tan upon the surface, however, is at all wet, an occasional stirring will afford the necessary supply. Those fruits which succeed the *Pines*, as Melons, should be examined occasionally to see whether the buds are swelling uniformly along the whole length of the rod. Those that are not doing this kindly should have their apices kept down persistently to the lowest level possible, thereby to encourage the buds which are nearest the base to advance more quickly to the stage which the others have arrived at. Syringe the Vines at this juncture very lightly with moderately warmed water, and by the customary means diffuse a nice wholesome humidity throughout the house. Do not forget also that every spell of fresh air, when not too harsh and ungenial, is an unqualified gain. Those in pots which are introduced about this time need only to have the pots plunged into a sweet bottom-heat of about 80°. Let the rods repose upon the surface around, without any kind of tying or restriction, and they will break more kindly. Introduce *Peach* or *Nectarine trees* in pots, if well established, plunging the pots into a nice bottom-heat. This will in all probability give a few dishes of early fruit, which will prove very acceptable. Those who force *Potato* early should introduce some "Ashleaf" in moderately small pots, and introduce them into a house having an intermediate temperature to make their preliminary growth. Where proper pits exist for the purpose, *Peas* of the dwarf Tom Thumb kind may now be sown; a dish or so should also be grown in pots with the necessary room and support. This dwarf sort does best when sown and grown like dwarf French Beans, about five or six plants only in 32-sized pots. A good batch of all kinds of flowering subjects that will force, may now be introduced into the forcing-pit.

HARDY FLOWER GARDEN.

All who know the value of decomposed leaves should now endeavour to collect as many as possible. Now that the frosty weather has gone, lawns and walks, &c., should have a thorough sweeping and rolling, to bring them back to their usual neat and cleanly appearance. Look over the store roots of *Dahlias*, to detect any that are showing symptoms of decay. Should the frost keep off, use every means to transplant trees, shrubs, &c., which always do better when left even a few weeks longer. Besides, it is very probable other frosts will follow.

HARDY FRUIT GARDEN.

The above remarks apply also to all kinds of *Fruit Trees* which are not already planted, as suggested at an earlier date. Loose no favourable opportunities in regard to the advancing of all pruning and nailing operations, as work multiplies so rapidly in the early spring months. Give attention at this dull time also to the re-naming of any kinds of fruit which have their labels more or less obliterated, whether from age or otherwise.

KITCHEN GARDEN.

The many kinds of vegetables maintained in cold pits or frames will need little other attention than keeping them from injury by frost. For this reason additional coverings must be placed over and around them. In regard to such subjects as *Salads*, *Cauliflowers*, *Carrots*, *Radishes*, &c., it will be advisable, should the frost penetrate sufficiently to freeze any, to keep the covering over them when a change sets in, so as to insure a gentle thaw, which in a great degree aids their perfect recovery. Where the repeated suggestions I have made, as to wheeling manure on to all vacant spaces, trenching up old soils, &c., have been carried out, little will remain for me to add at this time. *B.*

Notices to Correspondents.

APPLES FROM FRANCE: *E. A. O.* "The fine Calville Apples" which you have received from France, and which you say are only useful for cooking, are no doubt the variety Calville Blanc, upon which so much has been said during the last few years.

CELERY-LEAF FUNGUS: *W. D. F.* The Fungus on your Celery plants is Puccinia Apii, Corda. *M. J. B.*

ICE KEEPING: *A. V. A.* There is not a good place to keep ice in, unless properly prepared, in the way of draining and made moisture-proof above, in which case it will answer perfectly. At the same time there are many other simple methods, the best being a conical mass on the surface, in the shade if possible, and well thatched with wheat-straw. In this, if the heap be made of fair size to give body to the ice, it will keep the year round. In a cool place, and a mound of that size be unsightly, it can be faced to a walk with the cut of some summer-house or Russian log-hut; that gives a reason for the ridge of thatch. Any hole in the shade, old grave-pits, quarry, &c., facing the north, is best, but not a necessity. We have tried the Canadian system of straw walls—that is, straw packed between two rough wood fences, a foot or so apart, forming something like a small cow-house with rough thatched roof. In this it keeps well. *F.*

NAMES OF FRUITS: *A. G. Apple:* Egg, or White Paradise. *Pear:* Glou Morceau. *J. H., Lyndhurst. Pears:* 1, Crassane; 2, Beurré Defais; 62, Knight's Monarch.

NAMES OF PLANTS: *W. W.* Lapageria rosea, a greenhouse plant. *P. H. Gosse.* Oplismenus compositus. It is a very close allie of the variegated grass, now so much grown in bothouses under the name of the variegatum. This grass, or forms closely allied to it, is pretty universally distributed throughout the tropics.—*Cactus* sends several plants not in flower, and not easily recognised. *A.* may probably be Cereus peruvianus—the Carob; 2, is Rhodoclendron ciliatum; 3, very probably Olea excelsa; 4, Mammillaria, somewhat near to depressa, but not quite identical; 5, Kleinia tomentosa; 6, a Mesembryanthemum, united by the Post-office punches; 7, Bupleurum fruticosum.—*J. L.* Pteris serrulata cristata, Lastrea quinquangulare, Cheilanthes alabamensis. The Adiantum is not enough developed; probably A. æthiopicum, or A. formosum.—*E. H. S.* Oxalis versicolor, a beautiful little greenhouse bulb, now seldom met with.—*C. W. S.* It looks like a small variety of Burlingtonia granadensis, but you do not tell us whether it is scented.

PINE-APPLES BLACK AND DECAYED: *F.* This may arise from too much moisture overhead when ripening. There are, besides, a good many varieties that will not keep only a short time after being cut in the house. As the best Pines exhibited last season were grown on the old system of half manure, perhaps some of the successful exhibitors will oblige us with their experience.

SELECTION OF APPLES: *C. P., Stoneleigh Rectory.* For 6 of the best late kitchen Apples we would have:—1, Dumelow's Seedling; 2, Bessposol; 3, Norfolk Beaufin; 4, Rymer; 5, Northern Greening; 6, Yorkshire Greening. For three best stewing Pears:—1, Catillac; 2, Uvedale's St. Germain; 3, Verulam. Rivers' Prolific is the earliest Plum, succeeded by Gisborne's Autumn Compôte, and Sandall's, a very good late sort. We do not say which for dessert or cooking. We have given you a choice of the latter.

TREE TRANSPLANTER: *Subscriber.* Apply to Mr. Barron, Borrowash, Derby.

VILLAGE FETES: *T.* The Elm (Huntingdon), Horse Chestnut, Plane, Lime, with the Thorn and Mountain Ash as smaller growers if desired. In the churchyard, Cedar of Lebanon, Deodar, or Yew; but the latter is a slow grower. For stopping Wych Elm would be a characteristic deciduous tree.

VINE BORDERS: *X. Y.* A good Vine border is made thus:—Excavate a space 12 feet wide, 3 feet in depth. Put a drain at the bottom, then fill in 2 inches of broken bricks, &c., for drainage, and 2½ feet of soil—thus, good fresh turfy loam, mixed with about one-fourth of fresh rubbish, and a sprinkling of ground bones—say half a bushel to a rod in extent. Front and outside borders are all made on the same principle.

The borders may be of any width, from 4 to 20 feet.

WIRING WALLS: *Kildare.* We are not aware of any objection, only keep the wires close to the wall.

CATALOGUES RECEIVED:—Dick Radclyffe & Co., Spring Catalogue of Vegetable, Agricultural, and Flower Seeds, Garden Requisites, Horticultural Decorations, &c.—E. Salsbury & Sons, Trade List of Gooseberry and Currant Trees. J. Jones & Sons, Descriptive Catalogue of Roses, Fruit Trees, American Plants, Conifers, Deciduous and Evergreen Trees and Shrubs, &c.

ERRATUM. We are requested to state that in our report of the last meeting of the Floral Committee, we omitted to mention that a Special Certificate was awarded to Mr. J. Shrimpton, for a very good stand of Chrysanthemums. In remedying this omission, we beg to remind our readers that we do not undertake to mention all the awards made at flower shows, nor to notice all the objects there shown.

COMMUNICATIONS RECEIVED: C. W. S.—A. F.—F. W. B.—J. F.—H. R. S.—K. D.—I. L.—W. A.—W. P.—J. S.—J. K. J.—J. Weeks & Co.—W. E.—G. E.—W. T. (thanks).

Markets.

COVENT GARDEN.—Dec. 15.

Business generally, and especially the West End trade, is very depressed, in consequence of the illness of H.R.H. the Prince of Wales, so that our demand for choice goods is very limited. The country trade has not been so much influenced, though we have not had so many provincial dealers as usual at this season. Trade in the Potato market is rather better.

FRUIT.

	s.d.	s.d.
Apples, per ½ sieve	2 0	5 0

POTATOS.—Southwark, Dec. 11.

During the past week the arrivals coastwise have been quite equal to the demand. The consumption is limited, owing to a want of quality, and a deal of waste in the roots. Very large supplies, fine, and many of them stored for want of sale. Quotations as follow:—Yorkshire Flukes, per ton, 100s. to 130s.; Yorkshire Regents, 60s. to 110s.; Dunbrt and East Lothian do., 110s. to 140s.; Perth, Forfar, and Fifeshire do., 90s. to 110s.; do. Rocks, 90s. to 95s.; Kent and Essex Regents, 50s. to 90s.; do. Rocks, 80s. to 90s.; French Whites, 60s. to 80s.

WANT PLACES.—Letters to be Post Paid.

Gardeners and Under Gardeners.

WM. CUTBUSH AND SON beg to state that they have at all times on their books MEN of various qualifications, whose characters they have the greatest confidence in recommending, and making application would save time by clearly stating the duties to be undertaken, the wages, &c., so that suitable Men may be selected. —Highgate Nurseries, London, N.

EXPERIENCED GARDENERS (for as GARDENER and 2nd FOREMAN), of various qualifications, recommended to Gentlemen.—Further particulars given on application to Messrs. E. G. HENDERSON AND SON, Edrington Nurseries, St. John's Wood, N.W.

GARDENER (Head). Thoroughly understands the Management of Stove and Greenhouse Plants, Orchids, Ferns, &c., Early and Late Forcing, and Gardening generally.—T. M., Finnegan Nursery, Maida Vale, London, W.

GARDENER (Head).—Has had extensive experience in Early and Late Forcing, the Cultivation of Stove and Greenhouse Plants, Ferns, Orchids, Vines, Peaches, &c. Good Management of Land and Stock.—J. T., Pine-apple Nursery, Edgware Road, W.

GARDENER (Head).—JOHN SAINSBURY, Gr. to Mr. Jay Vanderpoel, Esq., Fairlawn, Yonkers, New York, is desirous of a Gentleman requiring the services of a thorough practical Man. Has had experience in the Erection of Houses, &c. No single-handed place accepted. Good character.—Lanelay Gardens, Pendennis, Falmouth, Cornwall.

GARDENER (Head), where three or four are kept.—Age 31, married, no family. Four years' good character, and other references.—W. M., Clayden House, Windsor.

GARDENER.—Age 28, married; has a thorough practical knowledge of the profession in every branch. Good references.—W. T., Rose Cottage, London Road, Staines, Middlesex.

PROPAGATOR or FOREMAN or ASSISTANT (under General).—Has had several years' experience of the same.—F. S., 12, Townfield Gate, Keighley, Yorkshire.

IMPROVER in Houses.—Age 22. Reference:—Wingfield, Esq., Tickencote Hall, Stamford.—S. BILLIALD, Ketton, Stamford.

To Wholesale Seedsmen, &c.

COMMISSION.—The Advertiser, who has a good connection amongst London Florists and Seedsmen, and a thorough knowledge of the business, is open to an engagement with a good House to Sell on Commission.—G. C., Mr. Haad, 38, Russell Street, Covent Garden, W.C.

CHIEF TRADE.—A young Man, age 28, single; 12 years' practical experience. Part knowledge of Plant and Fancy Trade. No objection to go abroad.—A. B. C., Adam Johnston, Nelson Street, Gateshead-on-Tyne.

SHOPMAN, or NURSERY MANAGER.—Many years' experience in the best London Houses.—A. F. D., Post Office, Carshalton, Surrey.

SALES BY AUCTION.

SALE THIS DAY, at HALF-PAST TWELVE O'CLOCK.

Plants and Bulbs.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on SATURDAY, December 16, at half-past 12 o'Clock precisely, First-class Standard and Dwarf ROSES; Pyramidal, Pillar, and Standard FRUIT TREES, SHRUBS, CARNATIONS, PICOTEES, and PINKS, HERBACEOUS PLANTS, CONIFERS, LAURELS, &c.; also an importation of choice HYACINTHS, TULIPS, CROCUSES, IRIS, NARCISSUS, NARCISSUS and RANUNCULI, LILIUMS, and other BULBS, just arrived from well-known farms in Holland.
On view the morning of Sale, and Catalogues had.

Bulbs from Holland.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on MONDAY, December 18, at half-past 12 o'Clock precisely, several importations of HYACINTHS, TULIPS, CROCUSES, NARCISSUS, IRIS, ANEMONES, LILIUM, RANUNCULI, GLADIOLI, and other BULBS, just arrived from Holland.
On view the morning of Sale, and Catalogues had.

Periodical Sale of Poultry and Pigeons.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on TUESDAY, December 19, at half-past 12 o'Clock precisely, first-class LIGHT SUSSEX FOWLS, the Property of Mr. Campbell, Esq., and a great variety of other choice POULTRY and PIGEONS, from the yards and lofts of well-known Breeders and Exhibitors.
On view the morning of Sale, and Catalogues had.

Choice Lilies and Seeds.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, December 28, at half-past 12 o'Clock precisely, 20 Lots of SEED of PRIMULA JAPONICA, in 6 varieties. Each Lot will contain about 8000 Seeds, and Coloured Illustrations of all the varieties, by native artists, will be exhibited on the day of Sale. A quantity of SEED of LILIUM AURATUM and ABIES FIRMA, and some BULBS of THUJOPSIS FALDUBOSA, &c., and some rare LILIES from Japan.
On view the morning of Sale, and Catalogues had.

The Agricultural Gazette.

SATURDAY, DECEMBER 16, 1871.

MOST people, we fear, still regard the drainage water of our towns rather as an enemy to be destroyed or a nuisance to be abated than as a power to be turned to good account, or a valuable property to be realised, and yet the latter is the truer view—and the sooner it is adopted, the better even for the achievement of the end contemplated in the former view of the subject.

The POWER of LAND to DEFECATE and PURIFY TOWN SEWAGE—in fact, to abate the nuisance and destroy the enemy—depends materially on the even distribution of the sewage over the square yards and through the cubic yards of the soil which is to act upon it; and the best way to ensure a tolerably even distribution of this kind is to cover those square yards with plants, and to put them in charge of a man who knows what plants need, leaving it to him to see that every plant shall have its share of the food it wants. In this way, then, and altogether irrespectively of the power of plants actually to consume and to convert the filth of sewage, it appears that the agricultural view of our subject is one which ought very early indeed to engage the attention. We are glad, therefore, that this aspect of the subject engaged the attention of Mr. DENTON in his recent lecture before the Society of Arts.

It is to this view of the subject that we wish to confine attention now. It is very obvious that it should be understood how much the success of sewage-farming, and therefore the satisfaction of the ratepayers of a town with any scheme of sewage irrigation which may be adopted for them, depends upon their land being properly *farmed*. Boards of Health, Mr. DENTON tells us, are the worst possible farmers. It is, therefore, very important that they should at once put their land in the hands of a man who understands soil and plants, who will not think that, because sewage contains the food of plants, therefore it is at all times and on all occasions a useful thing to apply to plants.

Speaking generally, the means employed on the sewage farms throughout the country are in all cases the same; yet there is the greatest possible difference in the condition of the land. In some cases everything looks in good order, and the soil is covered with a luxurious crop. In others everything is in a muddle, and sewage irrigation, so far as its balance-sheet is concerned, is a failure. Moreover, in some cases the effluent water is foul, in others it is clean. Let us add, too—and as a result of recent visits to many of these farms we are able to do so with the utmost confidence,—there is nothing in the various maxims of which we have heard in connection with sewage distribution to account for these differences. Two of the best farms, probably, of the number are those of Aldershot and Norwood; the former is a sand, draining easily, and *drained*, the water indeed sinking away almost as soon as it reaches the surface; the latter, over a considerable extent of it, is a clay soil, receiving the tail-water from one area over a second, and over a third, and *undrained*. In both of these cases the effluent water is beautifully clear; in both, and especially we may say the *latter*, the Italian Rye-grass is strong, and clean, and prosperous; in both the land is in the hands of a good man, who knows how to grow plants. Cases of this kind prove, we think, that while it is always true that land should be managed according to the rules of good farming, such maxims as we have heard on the subject of drainage, in connection with sewage irrigation, do not apply with anything like rigid necessity to the subject.

We must further say, that whether drained or not, and whether clay or sand, there is, in all cases of irrigation, that agency of intermittent filtration in operation of which we have heard so much. All water poured over a sloping surface of cultivated soil goes through it as well as over it more or less, and thus becomes subjected to those influences to which in intermittent filtration proper it is subjected. Mr DENTON specifies the intermittent filtration having been explained in the laboratory of the Rivers Pollution Commissioners: it is only fair to Dr. FRANKLAND to say that it was not merely explained but invented there. The idea of aërating a filter at regular intervals of time, in order to the maintenance of its power as an oxidating agency over any liquid passing through it containing organic impurities, originated, we believe, with him; and it is, no doubt, a great gratification to him to have seen his process so courageously adopted and carried out as it has been by Mr. BAILEY DENTON, at Merthyr, where he has not only succeeded in purifying sewage by this means, but in growing during the past summer heavy crops of Cabbages, and Mangels, and Broccoli.

Mr. DENTON calls attention very strongly to the fact that the Rivers Pollution Commissioners assumed that the surface of the land to be used as a filter, 6 feet deep, for cleansing the drainage of 3000 people per acre, would not be capable of growing plants. He has found, on the contrary, that the drainage-water of 1000 people per acre does not interfere with the growth of vegetables; in fact, promotes their growth in an extraordinary degree; but even if it should be found, as it probably will—for the water is most unevenly distributed at Merthyr, and some parts of the land have three or four times more to do than others—even if it should be found that the drainage-water of 3000 people per acre will not kill, but, indeed, promote the growth of plants, we fear that the contrast which the Commissioners drew between the filtration and the irrigation methods will remain virtually unshaken. The filter-beds at Merthyr may produce £20 or £30 worth of plants per acre, but this will be barely 2d. or 2½d. a head per annum for the people using or to use them; whereas, in a sewage irrigation farm, when only 50, 75, or 100 people contribute to the fertility of 1 acre, the yearly £15 or £20 worth of produce may amount to 8s., 5s. 4d., or 4s. a head. Filter-beds, therefore—*i. e.*, arrangements for cleansing anything like the drainage of thousands upon mere acres—must be looked upon as virtually a machinery for destroying not only an enemy, but a valuable property; and it is to be hoped that they will never be adopted where irrigation on a larger area is possible.

AN instrument which will inflict a swift and painless death on animals intended for human food, is doubtless a thing to be desired; but when Lord POWIS, as President of the Smithfield Club, offered a prize for a "pithing" instrument, to supersede the poleaxe, he failed to stimulate the inventive faculties of any who are skilled in the work of slaughtering, for the simple reason that these practical persons are aware that the poleaxe is itself a most effective "pithing" implement whenever the operator is minded to employ it for the purpose. The instrument which was brought forward, and tested on Thursday, December 7, at MARKHAM'S slaughter-house, in the Metropolitan Market, in the presence of the judges, Professor SIMONDS, Mr. ARNOLD, instrument-maker, and Mr. HIGGLEDON, butcher, failed completely, and therefore the question of how far it is capable of superseding the poleaxe does not present itself for discussion; but the really important question as to the ad-

vantage of pithing as a mode of slaughter remains open, although it should have been determined before any attempts were made to construct an apparatus for the effective performance of the operation. Most of our readers will understand the difference between "pithing" and "poleaxing," but for the benefit of the ignorant in such matters, we will attempt to make the distinction obvious. "Pith" is the butcher's term for the spinal cord or marrow—that mass of nerve matter which continues from the brain along the spinal canal nearly to its termination. As the brain is the seat of consciousness, and the place of origin of the nerves of special sense, as those of smell, sight, and taste, and also of common sensation and motion for parts in the vicinity of the cranium, so the spinal cord is the place of origin of nerves which supply other parts of the body generally with motion and sensation. All nervous function depends for its continuance on the integrity of the brain, and if that organ ceases to act, vitality is necessarily, if not immediately, destroyed. Division of the spinal cord, at a point near its origin from the brain, cuts off the communication with the principal centre of nerve force and consciousness, and the animal falls instantly in a state of apparent insensibility. This process of dividing the spinal cord, no matter how, is called "pithing;" its effect is to render the animal's body motionless for a time, but the spinal cord is a centre of nerve force as well as the brain, and a mere separation of the connection which normally subsists between the two does not at once destroy all the functions of either. The various organs, and parts of the head, will act under stimulation; and, as to the body, every slaughterman knows that the "pithed animal" cannot be touched with the knife without the immediate occurrence of violent muscular action, including, in plain terms, very decided kicking, and sometimes efforts to rise from the floor of the slaughterhouse. In such circumstances it is satisfactory to the looker-on to be told that the violent muscular movements are merely the results of reflex action, and do not depend upon conscious efforts; but there is the ugly fact, that certain nerves which arise low down in the neck are in intimate contact with the important nerves of the brain, and as this organ is in no way injured by the operation of pithing, it is at least possible that the animal may retain some sense of what is being done, and the attempt to convince oneself that it does not is only partially successful. At any rate, the assurance of the animal's being insensible is more complete when it is known that the brain itself has been destroyed, or mortally injured, by the blow of the axe or mallet, or the entrance of a bullet into the cranium.

"Pithing," however well done, being a less effectual means of destroying sensibility than either poleaxing or shooting, very little was to be hoped for the success of the instrument that Mr. CAIRD introduced, or the ordinary short dagger which the other competitor offered for trial, but which no one could be tempted to test.

Mr. CAIRD's weapon consists of an iron tube in which a short stilette moves under the influence of a strong double spiral spring; the instrument is set by pulling the stilette upwards against the spring until it reaches a catch, from which it is released by pulling a trigger; the stilette is then shot forward with great force. The theory was that, the instrument being placed at the back of the bullock's head, the stilette should be driven between the first bone of the neck and the skull, where there is an unprotected space, into the spinal marrow; the practice was quite the reverse. The first bullock was tied up for slaughter, and Mr. CAIRD placed the instrument behind the ridge of the head in the part which, in ourselves, would be called the nape of the neck, holding it at an angle of about 60°; he pulled the trigger, and sent the stilette against the bone, bending the instrument so as to render it useless. A second stilette was fitted, and a second attempt was made on the same animal, with a like result, a second stilette being spoiled. Another animal was brought forward, the first having been slaughtered in the usual way, and a third stilette was tried and bent out of shape as the others had been, after which the inventor retired from the field, leaving the poleaxe triumphant.

On no sentimental grounds do we object to the experiments which were carried out, at the cost of some unnecessary suffering to the animals that were selected for victims; the object was to find a way to lessen the suffering which must be inflicted, and if the means offered proved to be ineffectual, the failure may be deplored, but it cannot be made a subject of censure,—but we protest against any further blundering in the same direction. Division or puncture of the spinal marrow is not the best way of rendering a bullock insensible. If it were, the poleaxe can be used for the purpose with unerring effect; its point never bends, and if the bone comes in the way, it offers to the blow a resistance no greater than that of paper, but the result is nevertheless incomplete—the animal when struck falls as if shot, but a second blow on the forehead is always necessary in order to make an opening into which the cane is thrust for the purpose of breaking down the spinal cord, so as to destroy the power of motion before the beast is "stuck." Pithing is often resorted to by the slaughterman when an animal refuses to be tied up or to stand quietly to receive the blow in the forehead, but the frontal stroke is always inflicted afterwards, and had Mr. CAIRD's instrument succeeded, by penetrating the spinal marrow, the poleaxe would still have been necessary to finish the work.

—— The GREAT CHRISTMAS CATTLE MARKET at ISLINGTON on Monday last resulted in a rather smaller show than usual, but in a final on the whole fully the actual weight of meat on sale was, however, about an average. The condition of some of the stock excited well-deserved admiration, and testified to the excellency attained by English breeders of large stock. And a somewhat remarkable feature in the show was the decided improvement in the quality of the Scotch beef. The success which has hitherto attended the endeavours of foreign breeders to improve their stock, and to enable them to cope more successfully with their English brethren, has been very great, as any one conversant with the condition of the foreign beasts exhibited in the market during the last seven years ago will know. They have a long way to go before they attain the weight, symmetry, and, in fact, general excellence which have now become the established characteristics of home-bred stock. In point of excellence the Scots carried off the prize. North country graziers continue to keep up their reputation, as far as quality and purity are concerned. The show of stock on Monday was in every respect satisfactory, although it must be admitted that the abundance and cheapness of keep have enabled Scotch graziers to bring up their stock at less expense than during many previous seasons. Shorthorns, also, were powerfully represented, and were close rivals with the Scots. The number was good, and the condition on the whole satisfactory. Some choice Welsh Runts were offered, and generally experienced a quiet sale. Hereford cattle were not so well represented, and there were few Devon and Sussex animals at the stands. The Cross Breeds were different to what they did not call for special observation. The annexed return shows the number of beasts exhibited, and the prices realised for them on the "Great Days" during the last 30 years:—

Year.	Beasts shown.	s. d.	s. d.	Year.	Beasts shown.	s. d.	s. d.
1841 ..	4,944 .. 3	8 to 5	0	1856 ..	6,748 .. 3	4 to 5	0

1854 ..	6,181 .. 3	6 to 5	4	1869 ..	6,726 .. 3	6 to 6	2
1855 ..	5,990 .. 3	8 to 5	4	1870 ..	6,600 .. 3	6 to 6	0

The comparative absence of animation in the trade was doubtless attributable to the fact that the time between this and Christmas is too long to suit butchers, and they consequently exercised some caution in dealing. On the other hand the general excellence of no small proportion of the supply was the theme of universal comment, and imparted a firm tone to the quotations. The best Scots and crosses occasionally made 6*s.* 2*d.*, but 6*s.* per 8 lb. was the more general top quotation.—A change of weather and large supplies of beasts at Thursday's dead meat market caused a depression, and prices on the average were lower.

—— At MARK LANE on Monday trade in English Wheat was steady, at the previous Monday's prices; transactions on Wednesday were limited, Monday's prices being realised with some difficulty.—The SEED Market is very quiet; and a general advance has been realised in the WOOL Market.

—— The following is the substance of the new Order in Council, to which the appearance of the CATTLE PLAGUE in Belgium has given rise:—

At the Council Chamber, Whitehall, December 8, 1871. By the Lords of Her Majesty's Most Hon. Privy Council. Present: Mr. Secretary BRUCE and Mr. FORSTER.

The Lords and others of Her Majesty's Most Honourable Privy Council, by virtue and in exercise of the powers in them vested under the Contagious Diseases (Animals) Act, 1869 (in this Order referred to as the Act of 1869), and of every other power enabling them in this behalf, do order, and it is hereby ordered, as follows:—

1. This Order shall take effect from and immediately after December 8, 1871; and the words in this Order have the same meaning as in the Act of 1869.

2. Cattle brought from any place in Belgium or France shall not be landed at any port or place in Great Britain.

3. The following articles brought from any place in Belgium or France shall not be landed at any port or place in Great Britain:—Manure or hay.

4. The following articles brought from any place in Belgium or France shall not be landed at any port or place in Great Britain, except at the ports at which foreign animals may be landed, and shall not be removed from the landed quay without a certificate of an Inspector of the Privy Council, certifying that such articles are not likely to introduce any contagious or infectious diseases:—Meat, hides, fat, hoofs, or horns.

5. Subject to the provisions contained in the Orders of Council relating to the ports of Granton and Leith, dated August 10, 1869, and in the Order of Council relating to the port of Southampton, dated October 1, 1870, all the regulations in the 4th schedule to the Act of 1869 shall apply to sheep and goats brought to Great Britain from any place in Belgium or France, and landed in Great Britain, and all such sheep and goats shall be slaughtered immediately after the landing, and be exclusive of the day of landing. Provided, nevertheless, that cattle, sheep, or goats being, or having been on board any vessel at the same time with any cattle brought from any place in Belgium or France shall not be landed at any port or place in Great Britain.

6. Notwithstanding any Order of Council to the contrary, no sheep or goats brought from any place in Belgium or France shall be landed at the port of London, shall be moved alive out of any part of the port defined as a part within which foreign cattle may be landed for slaughter.

No further spread of the Cattle Plague has yet been reported from Belgium.

—— We desire to correct a mistake in our report of the show at the Agricultural Hall. Mr. H. J. SALMON, of Bermondsey, has long been an exhibitor at these annual shows; and it was not, therefore, by any means for the first time that he appeared there last week.

—— At a MEETING of AGRICULTURAL LABOURERS, held on Friday of last week at Brampton Bryan, Herefordshire, Mr. G. DIXON, M.P., in the chair, the first speaker, attired in a cleanly washed smock-frock, said the wages in the district (part of North Hereford and South Shropshire) were 9*s.*, four of 11*s.* per week, and the men wanted 15*s.* He combated the idea that the farm labourer was better off now than 20 years ago; if wages were higher, provisions were higher also. Other speakers pointed out that out of the 10*s.* per week 1*s.* had to go for rent, and where there was a family it took 5*s.*, or 6*s.* for bread, leaving only 3*s.* or 4*s.* for all the other necessaries of life. Flesh meat, the men declared, they seldom if ever taste, and one man said he had only had 3 lb. of butter in his house for 12 months. The masters, it was declared, did not as a rule give their men milk for their families. Many of the cottages are all in the hands of the farmer, who rents them to his labourers, and when a labourer leaves his "job" he has to leave his cottage also. The men all argued strongly in favour of being allowed "a little bit of land to keep a cow." One or two of the men had grievances of another character; earning 10*s.* and having a family to support, they had "to pay 1*s.* a-week to the Union to support their poor old parents, which they didn't care to do if the poor old folks got the benefit of it, but they didn't." This, one man declared, "was enough to make a fellow give up altogether, and not try to pay his way no more." Another was "puzzled how he got on at all, and when he went to bed at night he often wished he should wake up in the morning in America, or somewhere, where a man who liked to work hard could pay his way, and put something up for a rainy day." In default of any improvement at home, emigration seemed to be thought the natural remedy, and letters were read from emigrants who left the district a few years ago, and who are now in comparatively prosperous circumstances. Having heard the different speakers, the Chairman said he could not help thinking it would be deplorable, unjust, and wise, on the part of the farmers and landlords, if they were to take the condition of the men into their consideration and try to improve it. He thought they had made out a strong case for increased wages and for sufficient land to keep a pig and a cow. He believed the real cause of all their grievances was the fact that there were too many of them upon the ground, and he agreed with them that the great remedy was emigration.

—— The following RULES of CONSTRUCTION appear to us to deserve all the publication we can give them. They are from the pen of Mr. R. RAWLINSON, C.B. We abridge them for the Floors.

"With respect to house drains, many houses, both in town and country, have drains in the basements, usually square in section, porous, and just beneath the floors. The remedy here will be to break up the entire base-

ment, cleanse away all removable filth, fill up all cesspits and dumb wells with concrete, remove the old rotten sewers and drains entirely if practicable, lay in the old sewers and drains stoneware pipes, bedded in concrete and filled round and over with concrete, and connect closets and sinks with the new pipe sewers and drains.

"Ventilate all water-closet pipes, so that the water-trap shall not have any accumulation of gas.

"Ventilate all water-closets at or near the ceilings by air bricks, or by some one or other of the ventilators advertised in such publications as the *Builder*.

"Sink pipes should end outside the house wall, over a prepared chamber, at the end of the drain, which chamber is to be covered with a fine grate to let out any gas from the drain.

"Persons complain that foul smells arise from sewer and drain ventilators, and stop them up or cry out for this to be done, forgetting that the escape must be somewhere, and most probably into the house or houses of those who complain. That foul smells come from ventilators is the best proof that ventilation was and is required; the true remedy will be, not to stop up one, but to form a second, a third, and so on, until, by dilution and dispersion at several points (as far asunder as is practicable), concentration in a sewer or drain is prevented, and the sensation of smell ceases."

"Cesspools should not exist within the walls of any inhabited dwelling. If there are cesspools on any part of the premises, they should be abundantly ventilated to the external air, and no drain to the house should connect direct. But it is safer to abolish every cesspool on the premises, and if the sewage is to be used for garden or irrigation purposes, let any cesspool or tank be away from the house, in the garden, or on the land of the farm. Houses situate on elevated sites, if the sewers and drains have a steep gradient or fall, are most difficult to sewer and drain. As sewers and drains are also flues, and if refuse fluids flow rapidly down gases of decomposition flow rapidly up; and if the connection is complete from the sewers by drains, by water-closet stack-pipes, by sinks, by internal waste-water pipes, and by overflow-pipes from water-supply cisterns to the inside of the house, no form of trapping is of any avail. Let it be clearly understood that traps on drains and pipes from unventilated sewers, cesspools, and house drains are 'a delusion, and a snare.' The delivery end of sewers should be protected with a flap, to prevent the wind blowing into the open end, and so driving any gases back to the town or house with the force of the wind's velocity for the time. Every main sewer should have means for external air ventilation, not less than one such ventilator in each 100 yards. All drains should be permanently and fully ventilated outside the walls of the house. All sink pipes and waste-water (overflow) pipes from fresh-water cisterns should discharge above the trap of the drain, and not be sealed in with the drain. There should be ventilation at this point, so that any gas evaporated from the drain will pass outside to the open air and not to the inside of the house. Water-closet stack-pipes should be continuous, from the drain through the roof or above the battlements, so that an accumulation of sewer gas cannot rest against the closet-pan trap. Water-closets should have means for full and permanent ventilation at or near the ceiling, independent of windows. The arrangements for such ventilation should also be so contrived that they cannot be used, and that they may escape being tampered with. No water-closet should be within the body of the house, but should be against an external wall, and receive light direct, not a 'borrowed light.' The valve or pull-up handle of every closet should be capable of action with the lid down. This lid should always be down when the closet is not in use. House drains, stable drains, and yard drains should be flushed once each week; a clean-looking drain is no proof that it may not be very injurious. The purport of these remarks amounts to this: Isolate the house from the drains and sewers by full permanent external ventilation, and provide for permanent means of ventilation at or near the ceiling of every water-closet room. Arrange means to have all drains flushed not less than once each week, and order that they be so flushed. Every bed-room should have means for permanent ventilation at or near the ceiling.

"The philosophy of the question seems to be, that stinks in the open air do a *minimum* of injury, but that gases of decomposition within rooms and in stagnant air become dangerous to health."

NOTEWORTHY AGRICULTURISTS.

DR. J. H. GILBERT, F.R.S.

[We take the following note and portrait from the "Farmers' Almanac," published by Cassell & Co.

JOSEPH HENRY GILBERT, whose name, in conjunction with that of Mr. Lawes, is familiar to all students of agricultural chemistry, was born at Hull, August 1, 1817. His father was the Rev. Joseph Gilbert, the author of several theological works. Dr. Gilbert's monther (Ann Gilbert), who survived until 1866, also contributed to literature, writing originally with her sister, under the names of Ann and Jane Taylor.

DR. J. H. GILBERT, F.R.S.

After his school education, and the loss of several years by a gun-shot accident, which much impaired his health, and deprived him of the sight of one eye, Dr. Gilbert commenced his college courses at the University of Glasgow. Here, as elsewhere, he paid special attention to chemistry, devoting some time to analytical chemistry in the laboratory of the late Professor Thomas Thompson. He next studied at University College, London, attending the classes of Professor Graham and others, and working in the laboratory of the late Dr. Anthony Todd Thompson, then the Professor of Materia Medica, Therapeutics, and Toxicology. A short time was then spent in the laboratory of Professor Liebig, at Giessen, where he took the degree of Doctor of Philosophy. Returning to University College, London, Dr. Gilbert was class and laboratory assistant to Professor A. T. Thompson, in the winter and summer sessions of 1840-41, and attended other courses at the college at the same time. On leaving college he devoted himself for a time to the chemistry of calico printing, dyeing, &c., in the neighbourhood of Manchester.

In 1843 Dr. Gilbert became associated with Mr. J. B. Lawes, of Rothamsted, Hertfordshire; and from that time has continued to be engaged with him in a systematic series of researches in agricultural chemistry and physiology. The results of their investigations have been published from time to time in the Journal of the Royal Agricultural Society of England, the Reports of the British Association for the Advancement of Science, the Journal of the Chemical Society of London, the Proceedings and Transactions of the Royal Society of London, the Journal of the Society of Arts, the Journal of the Horticultural Society of London, the Journal of the Royal Dublin Society, the "Edinburgh Veterinary Review," the "Philosophical Magazine," in some Official Reports, and elsewhere. Dr. Gilbert was elected a Fellow of the Royal Society in 1860, and in 1867 the Council of the Society awarded to him, in conjunction with Mr. Lawes, one of the royal medals; he has been a Fellow of the Chemical Society of London since 1841, and is at the present time one of the Vice-Presidents of the Society. There is no single labourer in the field of agricultural research, nor indeed any society or association of labourers in that field, to whom agricultural progress owes so much as it does to Dr. Gilbert and to Mr. Lawes. The results of their investigations have been given in a series of papers, too long for enumeration here, which, as regards the agricultural history and literature of the past 20 years, are quite one of the glories of the English tongue.

OUR LIVE STOCK

CATTLE.

Our export trade in live stock yearly increases. Without giving minute particulars with reference to the animals, and the herds from which they were selected, we abstract the following from Thornton's Circular:—Four heifers were shipped on board the Erin, Aug. 19, for E. G. Bedford, Kentucky, U.S.; one bull (GLENSMAN) for Prince Edward's Island, on August 29; two heifers and one young bull on board the Germany, for R. Gibson, Minneapolis, U.S., on August 4; two heifers, on board the Austrian, for R. Gibson, August 26. Two heifers, on board the Paramatta, August 28, for D. Jenkins, Sydney, Australia; two heifers were sent to Mr. P. W. Anderson, Sydney, and two heifers, to Mr. E. King Cox, Sydney, by the same vessel; four young bulls were shipped in September for Mr. J. B. Watt, Sydney; two young bulls, per the Sobraon, from Grays, September 29, for Messrs. F. & W. Fanning; and four heifers and five bulls were consigned on board the same vessel to Messrs. Dangar, Gedye & Co., and to Mr. Vickery, Sydney; four bulls were shipped, in the Thomas Stephens and Kosciusko, to Messrs. Dalgaty, Ducroy & Co., Melbourne. The European took out a very considerable cargo of live stock to Canada on July 20, comprising twenty-five heifers and four bulls; BERKS were shipped to Mr. Snell, Edmunton, Ontario, on August 4; two heifers left Liverpool on board the Nova Scotian for the Messrs. Hunter, Sunnyside, Wellington, Canada; seven heifers and two bulls left Liverpool for Canada, consigned to Mr. T. S. Thompson, Mayfield, Whitby, in August. Five heifers and one bull were shipped from Liverpool in July for Messrs. Shaw & Dryden, Ontario; two heifers for Mr. Davidson, Canada; two heifers for Mr. G. Zoeppritz Ganterhof, Germany; and one bull for M. Olde, Germany; and three other bulls also found their way to Germany. Seventy-three females and 32 bulls, all pure-bred Shorthorns, have therefore been exported during the last half year, besides others which have probably escaped notice. Above 100 animals! And yet when we look at the requirements of the world the number appears unutterably insignificant. If the Shorthorn is to become the prevalent breed in America, Australia, and New Zealand, we see little prospect of the trade becoming overstocked, or prices sinking, for some years to come.

—— Breeders of stock appear to be unanimous upon the point once more brought forward by Mr. J. K. Fowler at the last meeting of the Farmers' Club, namely, that the external form of an animal is due to the influence of the sire, while the internal organs and constitution are transmitted by the dam. With this somewhat stale, but not the less true observation uppermost in our mind, thanks to Mr. J. K. Fowler, we took the following quite superficial survey of the cross-bred cattle at the late Islington exhibition, in the hope of detecting the "prepotency" of the male in transmitting his form to his offspring. This point having been so lately discussed, further preface is unnecessary, and we therefore proceed at once to chronicle our rough notes taken in the Islington Hall :—

In Classes 35 and 36 we noticed the following cases:—

Walter Scott, of Glendronach, Huntly, Aberdeen, showed a 2 years 10½ months steer (196); sire Shorthorn, dam a cross-polled cow, second cross. The pure form of this cross was polled, brindled red and black and white.

James D. Allen, of Tisbury, Salisbury, showed a 2 years 7 months steer (197); sire Hereford, dam Shorthorn. The produce was Hereford in colour and appearance, with face a little mottled, and back, with the exception of the shoulder-top, all red.

J. & W. Martin, of Aberdeen, showed a 2 years and 5 months steer (198); sire Shorthorn, dam Aberdeenshire, second cross. Colour and general appearance, Shorthorn.

Hon. M. Moreton (Mr. Bruce), of Newton-of-Struthers, Forres, Moray, showed a 2 years and 7 months steer (199); sire a Shorthorn, dam Scotch first cross Appearance, distinctly Shorthorn.

John Overman, of Burnham Sutton, showed a 2 years and 11 months steer (200); sire Shorthorn and Norfolk poll, dam Shorthorn, second cross. Produce polled, dark roan and white, and general contour scarcely characteristic of either breed.

Edmund Beck, of Oswick, Fakenham, Norfolk, a 2 years 9 months steer (201); sire Shorthorn, dam a Dutch cow, second cross. Appearance, that of a Shorthorn.

William Slatter, of Stratton, Cirencester, showed a 2 years 11 months steer (202); sire Hereford, dam Hereford and Shorthorn, second cross. Produce, Hereford in appearance.

Robert Skelton Senior, Gabriels Park, Edenbridge, Kent, showed a 4 years and 9 months steer (203); sire Shorthorn, dam Shorthorn and Sussex, first cross. Shorthorn in appearance.

William Taylor, of Glynley, Eastbourne, a 4 years 7 months steer (205); sire Devon, dam Kyloe cow, first cross. Of dubious appearance.

Sir W. Trevelyan, Bart., of Wallington, Newcastle-on-Tyne, a 3 years 7 months steer (206); sire Shorthorn, dam pure Galloway polled. Polled like a Galloway, red in colour.

William Scott, of Glendronach, Huntly, Aberdeen, a 3 years and 9 months steer (207); sire Shorthorn, dam a cross polled cow, third or fourth cross. Appearance, Shorthorn.

William Brown, of Linkwood, Elgin, Moray, a 5 years 7 months steer (208); sire Shorthorn, dam polled Aberdeenshire, first cross. Polled Aberdeen in outline, "pepper and salt" coloured.

Nos. 209 and 210 were withdrawn.

Joseph Straddy, of Manningford Bruce, Marlbro', Wilts, a 3 years and 4 months steer (211); sire pure Shorthorn, dam first cross from pure Brittany cow by pure Jersey bull. Very mixed appearance.

Robert Wortley, of Stanfield, Fakenham, Norfolk, a 3 years and 2 months steer (212); sire Hereford, dam Shorthorn, first cross. Hereford in appearance, face blotched, back and shoulders all red.

No. 213 not present.

John Overman, of Burnham Sutton, a 4 years and 4 months steer (214); sire Devon, dam Shorthorn first cross. Red in colour, Devon in character, although larger than a Devon.

J. J. Coleman, M.P., of Carrow House, Norwich, a 4 years 6 months steer (215); sire Shorthorn, dam Lincoln, firstcross. Appearance, Shorthorn.

216 not present.

Hugh Stratford Stratford, of Thorpe Lubbenham, Market Harborough, Leicester, a 3 years 3 months steer (217); sire Shorthorn, dam polled Scot, first cross. Colour black and white, but horned, resembling the Welsh cattle.

Gathering these observations into a form in which their meaning will be more or less easily perceived, we have the following list :—

196. Apparently took after cross polled dam.
197. Apparently took after Hereford sire.
198. Apparently took after Shorthorn sire.
199. Apparently took after Shorthorn sire.
200. Of dubious appearance.
201. Apparently took after Shorthorn sire.
202. Apparently took after Hereford sire.
203. Apparently took after Shorthorn sire.
204.
205. Of dubious appearance.
206. Apparently took after polled Galloway dam.
207. Apparently took after Shorthorn sire.
208. Apparently took after polled Aberdeen dam.
209 and 210. Absent.
211. Very dubious appearance.
212. Apparently took after Hereford sire.
213. Absent.
214. Apparently took after Devon sire.
215. Apparently took after Shorthorn sire.
216. Not present.
217. Dubious in appearance.

Thus, out of 17 animals examined, three took after their dams, and singularly in each case after black polled dams; ten took distinctly after their sires, whether Shorthorn, Devon, or Hereford, and four were of mixed or dubious appearance, two of these being mongrel (mixed) rather than cross-bred animals.

CHALKING AND LIMING LAND.

MR. F. EVERETT, touching on the above subject in his paper, read before the Newbury Club (p. 1405), remarked :—"I think the most practical man will allow that no amount of farmyard manure is an effective substitute for chalk when land requires it. So thoroughly convinced am I of the importance of supplying lime in one of its various forms of combination, when its application to the soil can be 'proved' to be necessary, that I have made the subject a special matter of inquiry." He at once proceeds in the right direction, by consulting with Professor Voelcker as to the real state of things. The reply he received from the Professor confirmed his suspicions : "It will be useless to go to any great expense in the purchase of any manures till your land has been either limed or chalked." The Professor's decision was formed after an analysis of the soil, enabling him thereby to ascertain correctly what constituents the soil was most deficient in. Having analysed the soil, the remedy, that is, a manure containing the largest amount of the constituents that are wanting, or their equivalent, having been applied—crops of a cereal or leguminous nature, Wheat or Beans, having been reaped—are we not in a position to say with accuracy, what has been added to the soil in the manures applied, or withdrawn therefrom by the crop harvested? This is like Baron Liebig's minimum law, repeating Mr. Everett's remark, "which, though for the present it may be scorned by practical men, is destined ere long to be acknowledged as lying at the root of all sound practice, and the guide to all who are not unwilling to confess, that the researches of scientific men materially assist us in working out our everyday practice." The inorganic or mineral constituents of the plant are taken from the soil, it is these we require to return; and to replenish Nature's storehouse must be our chief care. How is the deficiency or increase of any constituent of the soil to be ascertained? Need we analyse again? Let us see what information we can cull from our neighbours and friends.

Our soil has been analysed, disclosing to us its mineral constituents. It behoves us now to consider, knowing the weak or non-existent points therein, what crop we ought to grow. First, we must inquire what we can find to in, as to its mechanical condition. Have the processes of cultivation been guided by intelligence as to the proper time and seasons for executing them? If so, they cannot fail to be productive of much good. But let it be understood that the mechanical operations of cultivation, ploughing, harrowing, rolling, being well timed or performed, do not add anything to the soil—they, however, most certainly aid in bringing into activity certain constituents now dormant therein; the physical and chemical condition of the field will no doubt improve—the chemical store has not been increased, only made more comeatable, the power of the land to assimilate and convert to the use of the plants the elements of food supplied by the atmosphere is brought into greater activity; the rain percolates more freely, carrying with it, to be detained by the soil for the use of the plant, the carbonic and ammonia of the air; in other words, the repeated exposure of the soil to the action of the atmosphere, by means of ploughing, &c., causes a decomposition of mineral matter, while the carbonic acid and ammonia of the air unite with the various acids of the soil. It has been given on trustworthy authority that the atmosphere contains every organic constituent of the plant, in the form of ammonia, carbonic acid, water, &c., and of these it is considered there is a sufficiency for the proper growth of our crops, if we would but open up and loosen the pores of the earth by thorough cultivation, affording easy access to the roots of our plants, enabling them to ramify, spreading themselves in search of their natural food ;" or, as Jethro Tull would express it, "fit pastures for the young and tender rootlets." The organic constituents are provided by an All-wise Providence : it remains for us to utilise the store which we cannot do better than by thorough and deep cultivation, and returning to the soil the inorganic constituents derived therefrom by the crops we grow. Here is cheering encouragement to the deep cultivator. The productive power of the soil is increased, still he must not allow himself to be misled in this matter; he must endeavour to make himself acquainted with, and able to discriminate rightly between the appliances requisite to make effective the nutritive elements already in his fields and those which keep up the lasting productiveness of his land. Professor Voelcker, speaking of atmospheric influences, says "We may positively say that all soils that are not penetrated by air are unproductive, no matter how much food they may otherwise contain."

The soil being in a good mechanical condition, the next question that suggests itself is that of manuring, and it will be as well to keep the crop it is intended to grow in mind in determining the kind, quantity, and quality, as well as quantity, of manure, it may be considered requisite to apply. A crop having been taken since our analysis, we can note what mineral constituents have been withdrawn by it from the soil; by replacing those constituents which have been removed from it, we will restore it to its normal fertility. It may be questioned whether the mineral condition of the field has not been altered by the mechanical operation it has undergone, such as mineral constituents rendered more soluble by the action of the air on a subsoil thoroughly broken up, or by disintegration from loose stones or rocks beneath. Granted; still we are able to estimate this increased return, and are but debtors in a greater degree in reckoning with our fields. It is here we recognise the wisdom of a rotation. If we have by successive crops of Beans withdrawn to a damaging degree the potash, the lime, or the phosphates from the soil—and this fact we can determine by the ash constituents contained in the bulk grown by following Beans with Oats—very little pressure will be put on the lime resources of the field, and the potash and the phosphates will not be drawn upon in so great a degree by one-half. By a judicious application of manure on a suitable course of rotation, the deficiency can be rectified to such a degree as to enable us to draw from the soil the largest nett return, while the capabilities of the land are at the same time maintained and increased; also the agencies which improve the mechanical and physical condition of the soil are most important, for an actual increase in the majority of instances is less attributable to the addition made to the store of mineral constituents than to their distribution—to the fact that certain dormant substances have been rendered available; and it has been noted by the highest authority "that no plant can be cultivated upon a soil unless the mineral constituents of the soil are in proportion to the special requirements of that plant." By reference to "Morton's Encyclopedia," "Our Farm Crops" (Wilson), or "How Crops Grow" (Johnson), we are able to note the ash constituents withdrawn from the soil, and what have been added in the manure. With an analysis, say once during a rotation, to guide us, to point out our weakest part, a debtor and creditor account can be written in the field. The thorough disintegration of the soil renders the manures applied more effective; a knowledge of their constituents will enable us to apply them more in accordance with the requirements of the land.

Mr. Everett draws attention to the different chemical composition and mechanical structure of chalk; and Mr. Sibson, after analysis, points out that "it should be used in more moderate quantities than is customary in the district;" in other words, from want of the knowledge imparted by science, chalk had been wastefully applied. Does not this hold good in regard to the manures of the farm? Let the farmer reason thus :—My soil contains, by analysis, a very fair percentage of the constituents requisite for the profitable growth of the generality of farm crops, excepting one—lime. What quantity, and in what form of combination, can it be best applied? It must be laid in mind, that the chemical feeding which lime performs in the soil, though chiefly chemical, are also in part mechanical,—in the former, resulting in causing the materials of the soil to become more available to plants, aiding the plants themselves to draw more fully on what the soil contains; in the latter, consolidating the light and sandy soils, and, as a rule, opening such as are heavy and difficult to work. If some such reasoning were brought into action when considering the necessities of each field and crop, there cannot be a doubt but that the manures, as now applied, without such consideration, would be made to yield far more satisfactory results, in the same proportion as improving than diminishing the reproductive power of the soil. Those antiquated covenants, so stereotyped in leases, a slur alike to landlord, tenant, and English agriculture, would then be scouted; a mutual bond of good feeling and thorough confidence would be the result; and then we may be sure that honest benefactor of agriculture, Baron Liebig, would erase with feelings of noble pride and joy the last paragraph of the following sentence recorded in his "Natural Laws of Husbandry :"—"There is no profession which, for its successful practice, requires a knowledge of knowledge than agriculture; and none in which the actual ignorance is greater." *West Indian.*

ON MEAT-MAKING.

LAST year I tied up 23 Hereford bullocks; the year before, the same stalls were occupied almost together by blacks, or Castlemartin oxen. The year before I had a mixture, mainly of Shorthorns, with some cross-bred animals. I took those animals in one year, having bought them up at fairs or anywhere where I could get them during the months of September, October, or November. When I bought them I turned them out on grass, and tied them up about the middle of November. I, of course, endeavoured to get good animals, of prime quality, and tolerably fresh, as we say. I saw to that before I tied them up. The Herefords of last year I bought from a person living on the borders of Herefordshire, to whom I was recommended by my friend, Mr. Brodie. They were 2-year-olds, as they were called, but I think in the month of October, when I bought them, they were about two years and more old. I refer to them for the purposes 3-year-old oxen when I can get them; but I have sent to fairs and all about the country, and have found it impossible to collect a large number of oxen over two years old, for they all find their way out of the country at an earlier age. The graziers and butchers in England are so fond of our cattle that they carry them all away generally as 2-year-olds and often as yearlings.

Well, I will say of the Herefords of last year, and the blacks of the year before, and the Shorthorns and

mixtures of the year before that, that they were all tied up in the same stall and fed precisely in the same way. There were all tied up about the middle of November, and were sold out as the butchers required them. In fact, they were nearly all sold in Llanelly as they were wanted by the butchers. They came out in April, May, and June, and generally came out very ripe, and would be called superior butcher's meat. They were not so fat as those animals Mr. Brodie takes to the Swansea market at Christmas. They were not so fat as that; but he has, in a few instances bought of me a few of my animals when they were ready for our butchers in April or May, and has kept them on again to Christmas. But I do think this—I have heard the prices he has got for them—I do think that for my 25 weeks' keep I would have realised a larger profit than Mr. Brodie did.

The question is, how did I feed them? As I have said, upon an average they were tied up for about 25 weeks. Our friend has talked a good deal about hay. Now none of those animals had hay. They never tasted a bit of hay. Mind you, I have nothing to say against hay, but I have none to spare, inasmuch as I keep too many horses. The food I give to them is straw, the produce of the stackyard as it is threshed from the rick; it is then chaffed and mixed with pulped Swedes and Mangels, and carried to the animals five or six times a day, quite regularly, with about a quart measure of concentrated food, consisting of crushed Barley, Oats, and Beans or Peas, for each animal, which would be varied from time to time. I believe that the mixed food, as given by me, contains all the elements of flesh, muscle, bone, and fat. Therefore, having prepared all this by water-power, it is done quickly and with very little trouble. It is done in a sort of barn, which I built about four years ago, and in which I put up a 16 feet diameter water-wheel, and that has since done all the work of the farm. So that in a short time every day we prepare all this food, and there is nothing to do but to shovel it into tubs or buckets as it comes from the machine. There is no trouble, and besides it is more concentrated when done in this way. The food would consist of Barley crushed, Oats crushed, with a small quantity of Beans occasionally, or Peas. If you will use a small quantity of them you will produce more flesh, I think. I use a small quantity of cereals, but you use as a rule ten times the quantity of cereals that I do, and all these things must make a difference in the cost of feeding. I put a small quantity of cereals, as I have said, into this chaffed straw and roots, and it is very good when placed before the animals.

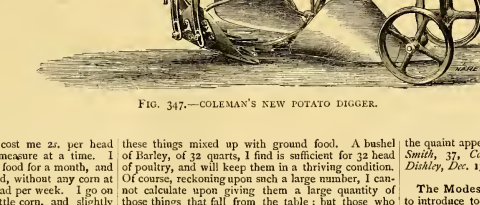

FIG. 347.—COLEMAN'S NEW POTATO DIGGER.

I would begin to feed my cattle with this concentrated food, and it would only cost me 2*s*. per head per week, giving them a quart measure at a time. I would continue that quantity of food for a month, and in that way the concentrated food, without any corn at first, would cost me 2*s*. per head per week. I go on in the next month adding a little corn, and slightly increasing the quantity of food, and I consider that the food during the second month costs 2*s*. 6*d*. per head per week. I proceed in the same way in the third month, increasing the quantity of corn a little, and also the quantity of food, which costs me in the third month about 3*s*. each per week. I then add a little oilcake, and give a larger quantity of corn, until in the fourth month the food costs me 4*s*. per head per week, and then I give a larger quantity of corn, and in the fifth month the cost is 5*s*. per head; and, then finishing off they cost me 6*s*. per head per week. Now, the average of that—I have been taking time about it; for I do not give the food too quickly, as the animals would not be able to assimilate it, but taking the average, the cost would be 4*s*. per head per week. In 20 weeks that would be £4, and five fours are 20. Therefore, at the end of 25 weeks my animals cost me £5 per head each. Well, if I paid for them £12 10*s*., and £13 10*s*.—those were the very prices—they did not cost me more, except the carriage. I bought 15 at £12 10*s*. each, and the other six at £13 10*s*.; and taking the carriage, they cost me about £13 each. Well, £13 and the cost of feeding them, £5 each; that would be £18 each. I ought to put down something for attendance. Say that they cost me £18 5*s*. per head. I will not go farther into numbers, only to say that last year in buying a lot of sheep—you all know how dry the summer was, and how the animals were, there being no roots—I bought them cheap in April, May, and June; and butchers' meat became very high, and I made a very handsome profit by them. And besides that, I had 250 cartloads of rich farmyard manure, not poor manure such as you have from dairy cows, where all the phosphates are consumed in the milk and cream. Where the animals are taken out fat the manure must be very rich.

I would merely say, comparing the three past years, that the Herefords were not so satisfactory to the butchers, after they killed them, as the blacks were, as they did not turn out so fat inside. That is a characteristic of the Herefords. They do not secrete fat inside. They look fatter outside than they are inside, whereas the black ox does not look so fat outside as he proves to be inside. I will say nothing against Shorthorns. They paid me very well; but they did not put on fat so readily as either of the other breeds upon the same food. The question with me is profit. I paid a good deal more for them than for the others, and I got more for them; but the profit was not so good, because they fed me more.

As to poultry, I am quite as much at home in the feeding and breeding of poultry as I am with the other animals. I would recommend any one who has even a good large yard to breed poultry. A small yard will not do to keep them in health, as they require a little liberty; and where there is a tolerable run they live and feed better. They live largely upon insects and on things they find in their rambles. Ducks feed upon such things as slugs and snails, and do a great deal of good in a garden without doing any mischief. As to feeding them, my poultry-maid comes to me once a week to know what food she is to have to feed the poultry. How do I ascertain that? In this way. I have generally several head of poultry. I lately, before I left home, had some of the poultry counted, and I found I had 46 turkeys, not quite so many geese, rather more ducks, and as to fowls of different kinds, I have Brahmas, Cochin Chinas, Spanish, Hamburghs, and so on, all of which I keep in separate walks. The number of these vary every week, and how do I ascertain how to keep them? This is how I manage it. I allot a bushel of Barley to every 32 fowls; that is, 32 quarts—a quart for each. Half the Barley is crushed, and half is given whole, and mixed with Potatos, and with the offals that fall from the table. I find that they feed well upon these things mixed up with ground food. A bushel of Barley, of 32 quarts, I find is sufficient for 32 head of poultry, and will keep them in a thriving condition. Of course, reckoning upon such a large number, I cannot calculate upon giving them a large quantity of those things that fall from the table; but those who keep a small number for the sake of eggs, can keep them entirely upon the offals from the table, and can get their new-laid eggs for the breakfast-table every morning. I should recommend those who have only a small yard to do that; but for myself, I cannot reckon upon that. I am obliged to cater for the whole of them, as I have got a large quantity. I reckon each of the turkeys and geese as two fowls, and give them 2 quarts each, and that really keeps them in a good thriving condition. Then comes the question—Does it pay? I say no. In keeping poultry on that large scale, I have never found it to pay, at the market price, mind. But I have this great advantage—I have always nice fat poultry for the table; and although a lean turkey is one of the driest things you can have, yet a nice fat turkey is one of the most acceptable things you can have on the table, and the same may be said of geese and fowls. I do not know that I have anything more to say. I have said that it does not pay to breed poultry—or rather, it would not pay me if I sent them to market; but I think it does about pay me, for this reason, I sell a good many to folks at a distance. I do not confine my poultry to the town of Llanelly, but send them to Glamorganshire and farther up very frequently. From this time up to the breeding time in the spring, people are continually writing to me. I had a letter a day or two ago. The writer says, "Have you any Dorkings?" To reply I say, "Oh yes; but mind the price is a guinea for a cock and two hens." So in that way I sell a great many, and I get those prices for them. Then, as you know, I take a great many prizes in the year. I take prizes here at Carmarthen, at Swansea, at Neath, and that makes it up. I don't want to get a shilling by keeping poultry, but of course I don't want to lose anything. I say, as long as poultry pay their way, I don't care, for I have all the pleasure of breeding them and looking at them. *Mr. Buckley, at a meeting of the Carmarthen Agricultural Society.*

THE NEW POTATO DIGGER.

FROM the following illustration (fig. 347), for the use of which we are indebted to Messrs. Coleman & Morton, of Chelmsford, it will be seen that the earth, first moved by the double mouldboard-plough, and afterwards thrown back again by the two side mouldboards facing each other, is thrown, the whole of it, in the inner rim of the revolving wheel, which lifts the stuff and shakes it, and leaves its contents on the surface.

Home Correspondence.

Leicester Sheep.—On reading an article which appeared in the *Agricultural Gazette*, dated December 9, commenting on my letter inserted in your issue of December 2 last, I felt that my letter was in some respects misunderstood. In the first place, allow me to explain that I was not aware of Mr. Dixon's demise, but even so, I submit that when an author, in writing on public topics, makes a mis-statement (no doubt through receiving erroneous information), it is better that the error should be pointed out. With reference to the misunderstanding about the history of the black ram, the article above referred to states as follows:—"After carefully reading Mr. Smith's interesting remarks, we cannot take his story as evidence. He begins by telling us that Mr. Bates and Mr. Elches and another friend came to Dishley after the meeting of the 'Royal' at Derby. What, we would ask, has this interesting little episode to do with the 'black ram?'" I answer that Mr. John Stone related at table at Dishley, in my presence, in the year 1820, the story of the black ram, when the conversation was upon the black lamb that was produced at Dishley in the same year, and which was related to Messrs. Bates and Elches by myself at Dishley; and, with reference to Bakewell standing in the presence of George III., with the black horse, and the implication to be drawn from Mr. Dixon's language, that the king looked more at the man than at the horse, I can only say that, having re-read Mr. Dixon's statement, I cannot see what implication or inference can be deduced therefrom other than that contained in my former letter. I have frequently heard my father (who knew Bakewell personally) speak of him as a most gentlemanly man, and there is no doubt that he did not present the quaint appearance represented to Mr. Dixon. *B. Smith*, 37, *Caledonian Road, London, N., late of Dishley, Dec.* 13.

The Modesty of Farmers.—I promised (p. 1466) to introduce to my readers a few gentlemen who had become successful farmers from observation, study, and reflection only, without having passed through any previous practical training. The number, however, as far as my knowledge of them has extended, has been but few; still they have been like lights shining in a gloomy atmosphere, guiding the travellers who have been wise enough to follow their leading, if not into a clear and brilliant light, yet into one that could be followed with perfect safety until the fog cleared away, and opened to them a safer road to travel. But since my letter was published, announcing my intention, I have received intimations from these gentlemen asking me not to publish their names, as my doing so would bring them into hostility with their farming neighbours, as raisers of their rents, and with whom they wished to live in friendship. Now, my respected readers, let us have a little reasoning together on the fear, among agriculturists, that the publishing of isolated systems of successful farming would be injurious to the farming community. That the opinion that it is so is pretty general I have ascertained by types, for the gentlemen I am referring to live very many miles apart, and, I believe, are strangers to each other; yet all fear to make known the successful system of farming they have been pursuing, lest the doing so should excite hostility against them as raisers of rents. But, I ask, do not farmers know, what all other men know, that the price of all the various kinds of productions depends upon the supply of them and the demand for them? Does not every market woman know that when in the spring eggs are plentiful the money price for them is low? and, on the contrary, when about Christmas they are scarce, the price for them is high? And is it not the same in everything that mankind really requires? If land were to become a drug, and

over plentiful, of course it would be of little money value, but in a country as thickly populated as our country is, land that can grow corn and support sheep and cattle, either for breeding or fattening them, or both, can never be so cheap, either to purchase or to rent, as it would where there are but few inhabitants and the land is poor and sterile, and not in demand. But who are the persons who have it in their power to raise rents, and do so? Are they not the farmers themselves? And is not one chief cause of this their great eagerness to obtain land, and to add farm to farm? I am by no means opposed to moderate-sized farms, but I am decidedly of opinion, and from long observation, that there ought to be farms of very few acres, as well as farms of hundreds of acres. No rule can be laid down as to how small farms should be, but I think the welfare of the country is opposed to arable farms being in any case larger than 500 or 600 acres, unless in peculiar cases. I will show that farmers themselves are the raisers of rents in their bidding for land against each other; but before I give proofs of this I will just observe that I believe low-rented farms are a reproach to the neighbourhood where they exist, and to the country generally at large. Farmers bid against each other for every bit of land and farm that becomes vacant and letable. And here I give one example of this:—A friend of mine, who possesses several farms, had a small one of 150 acres to let in consequence of the death of the tenant; and, as I knew the farm well, I asked the proprietor not to ask to ask my opinion as to the rent he should re-let the farm for, and I replied that £2 or 2 gs. an acre would be a fair price—the land, I observe, is very good. But what was the result? It was this, that the tenant of an adjoining farm, who occupied near 1500 acres, a two-thirds ring man, offered 3 gs. an acre for the farm. But I almost fancy I hear a hundred voices crying out, He could not pay that rent! My friends, he does pay it; and let me inform you, that to my knowledge he commenced farming a poor man, with a very little quantity of land, and that now 800 of the acres he occupies are, of course he is now a very old man, and his sons are stepping, or have stepped, into his shoes; but he had purchased his land while the whole of that land he occupies was in his own hands. Nor is this an isolated case, for many more of the same character might be adduced. But when a man can afford to give £470 a-year for a farm that other farmers would proclaim to be highly rented at £300 a-year, does not this prove that the land was by superior farming made to yield the additional produce, to enable the extra rent to be paid? No fear can be more senseless than that any class of men, and especially farmers, can be injured by the adopting, and then publishing, the results of superior farming. *George Wilkins.*

Southdowns at Bingley Hall.—You may think it worth your while to correct an error in your report of the Southdown Class 32 at the Birmingham show. You say, "Colonel Kingscote shows a commended pen of rather smaller sheep, with finer wool and quality." Colonel Kingscote showed three pens: neither of them were commended; and, if you will refer to the weights on p. 150 of the catalogue, Nos. 172 and 173 (his two best pens), you will see they are more weight than the 2d or 3d prize sheep. As regards your remark on their being finer wool and quality, there can be no doubt but you are correct; and, I may safely add, showed as much, if not more, of the pure Southdown type than any pen in their class. *Francis Burnett.*

Australian Meat. — The introduction into this country of preserved beef and mutton from Australia offers to effect a great and much-needed change in our meat trade. As the meat at present exists, and from what I can learn from the opinions of others, and my own experience, the decision seems likely to be a favourable one. Its introduction is viewed with varied feelings by those most interested—the breeder, the butcher, and the consumer. Owing to cattle plague, pleuro-pneumonia, foot-and-mouth disease, &c., which has recently prevailed in this country, the stocks of cattle and sheep, not only in this country but also in Continental nations, have been much thinned, and as our consumption has been on the increase, great difficulty has for the past few years been experienced in bringing to the market the number of cattle required. This has naturally led to an important rise in prices, which rise has induced breeders to prefer feeding to keeping for dairy purposes, another cause conducing materially to the diminution of the national stock. Thus, milk, butter, and cheese, from consequent scarcity, have also advanced in price, and the question has been more than once mooted, if these causes would not in the course of years lead to the gradual extirpation of cattle did not something arise to supplement the deficient supply. We have the authority of high-class medical journals that milk is simply impossible to be had in most of our large towns, and that its scarcity has led dealers to manufacture a spurious compound, which they sell under that name. To this cause the same journals attribute the high rate of infant mortality which prevails in cities and large towns. May we not, then, congratulate ourselves as a nation that the vast herds and flocks of Australia have come so opportunely to our relief? We never knew of a monopoly which long conduced to the benefit of any one interested, not even to those who for a period enjoyed that monopoly; for in a country like ours, where competition is so close, it must necessarily be short-lived. From all the counties in the United Kingdom we have accounts of surplus feeding stuffs—grass, roots, &c., simply because we have not stock to eat it. At the present time many farmers are leaving their Turnips in the fields to rot for manure. In the spring of this year a gentleman well acquainted with agricultural matters, who had been on a journey to the south of England, told me that it had pained him beyond expression to see thousands of acres of rich and luxuriant pasture land through which he had travelled almost tenantless of stock, and wasting, as, owing to the high prices asked for young cattle and sheep, the owners of the lands hesitated to speculate in grazing stock. Should the present supply of good Australian meat continue, it must, in a few years, have the effect of renewing our almost exhausted supplies of both cattle and sheep; and we may reasonably hope to see a reduction to fair limits of cheese, butter, and milk. In place of these articles becoming, as they have threatened to become, expensive luxuries, we may hope that they will again assume the shape of ordinary marketable produce, within the reach of all classes. There appears to be a morbid fear amongst some persons, who are not thoroughly acquainted with the question, that it is simply impossible that graziers can send good meat from the Australian farm with the prospect of a farmer to just purchase it, and that though the attempt has been previously made in Australia, the meat sent was not fit for human food. To this I reply, that in Australia the farms, or "runs," are not counted by the acre, but by miles, and that on some of these "runs" you may travel scores miles before you reach the "blasted tree" which marks one squatter's boundary. From this it will be readily inferred, looking at the sparse population of the country, that markets cannot there be found for the flesh of the countless herds of sheep and cattle which depasture upon these "runs." Then what to keep them? However, the land is cheap, vegetation so luxuriant and plentiful, that good profits can be made from hides, wool, and tallow, and that hitherto the flesh, after being boiled down to get the latter, has been used for manure. Some few years ago the idea of utilising this meat for the European market was entertained, but, as may be easily imagined, some time elapsed before the necessary experiments to that end were crowned with success; and when the first batches of the preserved meat reached this country it was found that it had not kept well over the voyage, although quite good when first shipped. This caused a prejudice in the public mind against it, until the recent shipments were landed, when, after fair trial in all imaginable ways, it has been found to be both cheap and nutritious. When we look at the unlimited supply of cattle in Australia, it dispels the idea that the meat monopoly can possibly have any interest in stopping anything but good and marketable stock, although, no doubt, as in our own markets, some of the preserved meat canisters will be better than others; for how seldom is it that we get joints of uniform quality? We look upon the importation of this meat as a great national good, and as such shall, I trust, wish it success, believing that it will benefit all members of the community, the farmers included; for it must be borne in mind that if their produce brings unusually high rates, the natural laws of supply and demand will enhance the prices of all other articles, and in the end they will be found to balance. I have tried the meat in a variety of ways, and find it good in all. As almost every cook has a different mode of treating dishes, according to the palates of those for whom they cater, it is useless to specify any set rules, but I can confidently set at rest one great objection which I have heard urged against it—cook it as you will, it has not the flavour of meat cooked a second time. In conclusion, I would urge butchers to lose no time in adopting the preserved meat as a part of their business, or they will speedily find it almost wholly in the hands of the grocers and provision dealers. *J. R. K., North Lancashire.*

Origin of Swedish Turnip.—In the *Agricultural Gazette* of November 18 I read a paper inquiring the "origin of the Swede Turnip." As it is not answered yet, if you think the following statement worthy of a place in your journal, you can publish it. My father has often told me when he was a young man, 70 or 80 years ago, a Mr. Cox, a gentleman who resided at Fair Oak, between Petersfield and Midhurst, in Sussex, brought a quantity of seed home with him from Sweden. Some he sowed himself, but the larger portion of it he gave to a Mr. D. Dennett, who at that time held Woolbeding Farm, about a mile from Midhurst. His (Mr. Dennett's) cattle liked it so well, he saved a large quantity of seed, which the neighbouring farmers gladly purchased of him, and he made a great deal of money from it. Hence the origin of the Swede Turnip in the South of England. Fair Oak is at present the seat of the Hon. J. J. Carnegie. *A. L. M. M., Hawkley.*

On Running to Seed.—As there have been several communications in your widely-circulated *Agricultural Gazette* on the subject of "bolting" or "running to seed" of Mangels and other annuals and biennials, I beg leave to state that I am of opinion that we are indebted, in a great measure, to the excessive heat of the previous summer for these untimely flowers. I therefore beg leave to ask the authorities at South Kensington, if it be not probable that the constant beating rays of the sun during the ripening of those seeds in July and August of last year did not develope the flowering matter so much as to charge the cotyledons of the seeds with more than the average quantity, and hence the "bolting" of the cross-petailed plants, and particularly Kohl Rabi. My seeds came from one of the "first houses" in London, and about one-half of my Kohl Rabi has "bolted." That annuals have this flowering matter more highly developed in their seeds than perennials may easily be conceived. Watch the common Gorse develope its seeds in tolerably good land: you will find that it is several years before it flowers much, and the year it makes its first grand display of yellow flowers, its whole bark is so deeply tinged with yellow, that he who runs may read that a display of flowers is nigh at hand. The difference in the length of time required by the fleshy-leaved American Aloe to charge itself with floral material is the same as that of the Turnip, is, according to tradition, 100 years. Hence, may we not assume that when a large bulb of Turnip is planted in "poor" land for "seeding," and a small bulb in "rich" land for the same purpose, the seeds of the latter may be equal to those of the former, though in a cold summer the seeds of the latter may be the best. As "bolting" is general both in the farm and the garden this season, it is hardly probable that all the seeds can have been reared from "bolting parents," or from what is called bad or indifferent bulbs for the production of seed. *C., on the banks of the Tern, near Shrewsbury.*

Steam Cultivation.—Recently I have had no end of letters asking for advice upon the question of steam cultivation. Here is an extract from one received this morning:—

"I am anxious to commence steam cultivation, but before I begin I should like all the best advice on the matter I can get. My farm consists of 1000 acres, 300 in grass, 700 arable, of which 600 are deep loam and 100 clay fields; are generally large, with few hedgerows. Now can you help me in the matter. What system am I to adopt—double-engine, single-engine, with clip-drum and anchors, or roundabout? and where am I to get the best? If you would kindly give me your advice, I should feel much obliged."

Now, sir, I beg that you will allow me to give this advice publicly, by publishing a copy of the letter that I have forwarded to the gentleman who asked for the advice, and thus let all the world know what to do:—

"Woolston, Bletchley Station, Nov. 29, 1871.

"Dear Sir,—I shall not be at the Smithfield show. It is utterly impossible for me to answer your question, for I cannot know from your notice of a four horse-power of steam-power is. This much I can tell you. All land intended for autumn sowing ought to be smashed. All land intended for spring seeding ought to be ridge-ploughed, and left exactly as it is now. Keep in intention to go upon your own hook, and play at steam cultivation as others have done after asking my advice? If so, you will buy a double-engine set, or perhaps a clip-drum, with all the implements recommended by the makers of those engines, and you will make but little progress, especially in damp autumns. If, on the other hand, you wish to be guided by me, you will buy a roundabout set, and work exactly as I do. Then you can send to Woolston to see the work with the results; that may guide you, if you are guidable. I write thus plainly, for no end who come to Woolston fancy they come to guide me instead of being guided by my 19 years' practice. Mind you, I have no interest in the matter, except that of showing how to work land clean, deep, and cheap—much cheaper and cleaner than double-engine or clip-drum sets can, and I am perfectly satisfied that I have not finished all that I get a greater produce than either of them can. It is my ridger and subsoiler that makes me their master upon the produce point as well as in cost.

"WILLIAM SMITH."

Woolston, Bletchley Station, Bucks, Nov. 29.

Mustard Seed in 1872.—Our Mustard markets being now over, I can furnish you with a tolerably correct estimate of the yield of the crop of this year. As I have, in former letters, brought to your notice the exclusive monopoly which exists among the Mustard-seed crushers, who are, of course, the only buyers of the seed, I will not now trespass to any great extent upon your space by dilating upon their iniquities, particularly as they this year have given us a fair price for our produce; but, at the same time, I do not for one moment suppose they would have done so had there been a full crop and as large an acreage grown as usual, but it was no generous motive that prompted the representatives of the manufacturers to start this year by giving 16*s.* per bushel, but really from the fear lest they might come down with a very little or none to be bought at any price; for, as I ventured to predict in my note last season, that farmers were tiring of growing Mustard to sell it at about 8*s.* 6*d.* per bushel; and the result this year has proved that I was correct, for the acreage this year under Mustard was considerably less than it has been for many years: besides the small area, the yield per acre was this year much less than an average, for the following reasons—the first month or two after the seed

was sown the weather was unfavourable to its growth, and many pieces that were drilled early lost plant a good deal, and notwithstanding the growing summer that followed, remained thin and patchy until harvest; in fact, on nearly all the lands which were not in very good condition, the crop was thin throughout. On "British land," as newly broken up pasture is called, however, the plant was very thick, too thick indeed, for many of the heads were rendered fruitless, being smothered by others above them, hanging over them, excluding light and warmth and air, and at harvest day these stems were found rotten and worthless, many of them having never flowered, and none having seeded. When I tell you that red Mustard frequently grows 7 and even 8 feet high, your readers will readily understand that with the plants thick on the land the results I have endeavoured to explain would naturally occur; under these circumstances it was not to be expected that the yield would be very large, but when the threshing machine was called into operation, "Oh what a falling off was there!" not more than 20 bushels per acre being the rule, many even less; and while some lucky men got 24 bush., yet these were like the visits of angels, "few and far between." It would just remark, in conclusion, that it was instructive to note the unanimity which existed among the buyers as to the maximum price to be given for the seed on the several market days; for instance, on the first Saturday the highest price offered was 8*s.*, but as the stock of growers were rather inclined to hold, and knowing that the supply was not so large as in former years, the following week they laid the rate at 17*s.*, and at the third market they gave 18*s.*; but though on each of these days scores of samples made the price I have named, not one was known to exceed it. The farmers, however, farmers are well satisfied with the crop this year; and in the hope of getting the same prices for the seed next year, I have no doubt many will become growers who this year grew none. *Nemesis, November* 18.

Sewage Irrigation.—The accompanying letter, relative to the Birmingham sewage question, is well worth the attention of professionals in sewage matters; and if the scheme, as at present proposed, is allowed to pass unchallenged by the agricultural and engineering professions it will be a great misfortune to them. The burgesses and Corporation are alike ignorant of the operation, and, though rich, are no doubt anxious to see accomplished that which will be a credit to them hereafter. But unless pressure is brought to bear on them they have no alternative, and the consequence will be that an ill-devised project will be widely spread against sewage irrigation, and by the first large town to adopt it. Connected with the difficulty are two admirable intercepting tanks, with steam-power attached, and a 100-acre sewage farm. There is wealth of water-power during the best part of the year, produced in the outfall; also much suitable land below it for the site of manure manufactories, alike convenient for water, road, or rail carriage, besides land to much purpose on both sides of the Tame valley (especially the south side), which can be commanded by gravitation, or pumping, or both. As to the sewage: on the moors it is sandy and smells like other sewage, but when at rest becomes of a red-rusty colour, so charged is it with the refuse of bard, ware manufacture. The engineer in his report proposes to transmit this along a gradient of 1 in 3520, hugging the Birmingham and Fazeley Canal for about 9 miles, and passing in and out of storage tanks on the way, at or about the starting-point of which he proposes to add sulphate of alumina, and, at distances in the course, milk of lime. It may well be asked, as did a workman who knows about the cleaning of the Birmingham sewers, "Does he mean to concrete the passage" for the sewage with three of the most binding substances in nature—iron, clay, and lime? Should the sewage get the length, it is to be received on to land, already "over head and ears" in water, and had it been proposed, it would have been no less a feat for engineering skill to have taken sewage to suspend land selected land some height in air, as then there would have been some hope of the water getting away from it, and of the air taking its place; but be it encompassed with embankments and filled with drains, it is only in the driest of seasons that either aeration, or any other action connected with agriculture, can happen on it. Of course, to be independent of wet, or weather other than of their own making, the whole 960 acres can be covered in with glass, and I daresay if any in their zeal told some of the good people of Birmingham so, they would believe it. Other than the importation of an amount of hot zeal—rushing into figures of hundreds of thousands of pounds—little else has been tried to grapple with the subject; but when it is scrutinised by the cool hand of experience, something more tangible and practical, and less extravagant, will be advanced, very much to the delight of the ratepayers, who are of the belief that feeing and feasting are about the most they have been able to make out from what has been done. *D. & S. E., Birmingham, Nov.* 28. [The following is an extract from the letter in question about the land to be irrigated, addressed to the *Birmingham Daily Post* :—

"Without wishing to be thought hostile or acrimonious to the gentlemen who are responsible for it, the selection may simply be said to be unfortunate. In the whole valley of the Tame a more unsuitable extent of land, in character and position, could scarcely be found; and supposing two-thirds of it to be presented to the Corporation, it would be no compliment for the purposes of purification, or any other irrigation. The area within the boundaries given amounts to 1250 to 1280 acres, which can be divided into three degrees of land :—(1), 320 acres of upland, well suited for irrigation, but at present, for ordinary culture, in need of draining; (2), 180 acres of flat land, generally good and reasonably suited, but also to surface-flooding from the river, but standing in the backwater of it—no outfall for drainage, and out of the question for irrigation—soil thin, an obdurate poorstone, and to put drains in it would all require to be poached; (3), 760 acres, situated in the old natural course of the River Tame, over which it spreads after three or four hours' rain in its upper parts. This land, when the water is off it, is used as autumn for steeplechasers, at other times is famous wild duck shooting. The floods remain for a week or so on it, frequently to the depth of 3 or 4 feet well up from the river's channel.

"The Improvement Committee, Birmingham should go and inspect the facts of this selected land for themselves. At the first glance of it from Kingsbury Bridge they cannot mistake concluding the whole land of the flat of it being subject to floods. They can inquire, or rather get in through it; and at a long distance inland they can observe and measure for themselves the height of the floods by the line [on the hedges] left by the wreck of grass and drift in the current of water rushing [when; and, without complaining its irrigation, they can satisfy themselves as to the advisability of a great engineering undertaking, with 6 feet draining; and they can see for themselves, but don't go away with the idea that for a few hours on its surface that it is free and gravelly throughout. As they traverse the 320 acres of upland, excepting its shape, they cannot but be struck with its suitableness for draining, and its complement—irrigation." *John Martin, Shore, Kincardine-on-Forth, Nov.* 20."]

Prices 300 Years ago.—The enclosed bill of fare (cut from an old newspaper) of an entertainment given by the Mayor of Norwich, in the year 1571, shows the astonishing difference in prices between that time and the present. *T. Taylor, Rose Hill Lodge, Botcherby.*

Tenancy at Will.—I heartily endorse the remarks of your correspondent, "H. H. O.," in reference to the unsatisfactory relations existing between landlords and tenants in other counties than Hampshire. If you will favour me, I shall send your readers a short sketch of my experience of the system of tenant-at-will. In 1850 I took a farm of 160 acres in the county of Durham; it was undrained, had bad roads, bad buildings, and was thoroughly out of condition, and none but those who have had such a farm can really understand the labour and expense of restoring it and bringing it into anything like a good state of cultivation. Believing in the solemn promise of the landlord, that so long as I treated the land well and paid my rent I should keep the farm, I set to work in earnest, made a good road nearly the length of the farm, carted materials for a quantity of new buildings from a considerable distance, had almost the entire farm furrow-drained, the landlord finding the pipes; and the land, which was covered with a carpet of Twitch, and almost every kind of noxious weed, I had thoroughly cleaned, very heavily manured, and well tilled and worked generally. Now, of course, the effect of all this outlay was very speedily seen in the luxuriance of the crops, and in the greatly improved general aspect of everything connected with the farm, and I naturally looked forward to getting a fair and reasonable return for what I had put into the land. But will it be believed, that when these improvements were all finished I received a six months' notice, that unless I would pay £100 per annum more rent I must quit, and that without a single farthing compensation? Yet such was the stubborn fact. Anxious to have some good of these years of labour and expense, I offered £50 a-year increase, but was told by my "honourable" landlord that some one else had offered him all he asked. Now, if this is not a case of downright robbery, I don't know where to find one. The man had no right in equity, whatever he had in law, to pocket the results of my hard labour. It is perfectly clear that if a fair system of compensation for unexhausted improvements had been in operation in the case above mentioned, I should have been a richer man by several hundreds of pounds. To put a finishing touch to this recital, I ought to add that my successor, who was acknowledged to be one of the very worst farmers in the district, allowed everything to go to wreck, bought no manure, and then, after reaping the benefit of my improvements, he left the farm completely impoverished. Let me strongly advise any young man who may contemplate taking a farm on mere words of promise, to take, instead, *Punch's* advice to those about to marry—Don't! I read the *Agricultural Gazette* every week, and have got several useful hints from it, which I am glad to tell you I have put into successful practice. *Anglo-Saxon.*

The Potato Crop.—The Potato crop is now harvested throughout the three kingdoms, and as these tubers have become a most important part of the consumption of the peoples of the kingdoms, it may not only be interesting, but highly necessary to ascertain the extent and produce of the crop, as by such acquired knowledge the trade and consumption may in a great measure be regulated. Ireland is generally the foremost in the product of Potatos. The acreage under this crop during the last five years is as follows :—1867, 1,001,781 acres; 1868, 1,034,681 acres; 1869, 1,041,902 acres; 1870, 1,043,583 acres; 1871, 1,058,287 acres; being a gradual but slow increase in the growth of Potatos, the present year showing the largest increase, *i. e.*, 14,704 acres. The total breadth planted is very large, but not being plied after the liberal manuring and costly expenditure of this country, the yield is far less abundant; and as the disease is very bad, and nearly universal, the crop is a seriously defective one. The consumption of Potatos in Ireland is enormous, and all other food being dear, the presumption is that it will be greatly increased, and so much so, that very few will be exported to this country. This will make a considerable difference to the supplies in our markets, which it is to be feared will not be compensated by the produce of our home crops, which are in all districts badly diseased, and in many districts almost worthless. The acreage under the Potato crop in this country is far below that of Ireland. The returns of the past five years for Great Britain are as follows :—1867, 492,217 acres; 1868, 541,543 acres; 1869, 585,211 acres; 1870, 587,661 acres; 1871, 628,287 acres; being an increase in breadth planted over 1870 of 40,626 acres, and over 1867 of 136,070 acres, or nearly 30 per cent. increase within the past five years. This is encouraging, and had not the disease been so prevalent, and the attack so early in the growth of the Potato, it would have done much to keep up our supplies; but unfortunately the reverse is the fact. In every district of the country the crop is a light one, and in some parts deplorably diseased. From a number of reliable reports before me I abstract the following, *i. e.*, Scotland only one-fourth of the crop will be saved; Northumberland, two-thirds; Cumberland good; Cambridge, one-third lost; Cumberland, two-thirds do.; Devonshire, one-fourth do.; Lincolnshire, one-fourth bad; Gloucestershire, much diseased; Leicestershire, do.; Yorkshire, one-half diseased; North of England, a bad crop—heavy lands very bad; Lancashire very virulent; Cheshire much rotted; Huntingdonshire, very bad; Kent, a light crop; Warwickshire, not an average, greatly diseased; Worcestershire, much diseased; and the like reports are general. The conclusion is, that Potatos must be scarce and dear, therefore the public must economise in every way; and as other vegetables and esculents are unusually plentiful, great resort should be had to them as substitutes for the Potato. *O. F.*

On Gravelling Clay Soils.—There is an old story of a man who, having a very stony field, determined to experiment on the value of these stones in the growth of his crops. With this view he divided his field into three equal parts; from No. 1 he gathered all the stones, which he spread upon No. 3, leaving No. 2 in its original condition. He then sowed Barley over the whole field, and carefully noted the results. The story ends by saying that No. 1 bore a miserably poor crop, No. 2 a tolerable one, and No. 3 a splendid one. I quote this story as a text on which I wish to speak, as to the advantage of gravelling heavy clay soils. Some weeks ago I saw a few days' work in the village of Milnthorpe, Westmoreland, and, driving one day with Mr. Hutton, the celebrated bone-setter, to look at his farm, I remarked that the land was very stony, being covered with stones (not pebbles) having very much the appearance of road metal. He replied that these stones were essential to the fertility of the soil, and said that some years before there was a great demand for such material in the neighbourhood of Preston, and the high prices stimulated the farmers to gather these stones from their land, and send them to Preston; but the consequences were so injurious to the growth of their crops, that they were compelled—at least, those who had the means of doing so—to load stones again upon their land before the crops would grow with the vigour which they had before the stones were abstracted. This brought to my mind what had occurred in my own farm practice. A church was built in the

neighbourhood, and the stones for it were hewed on the corner of a field which was afterwards sowed with Wheat, and I remarked that the straw was much brighter, the ripening was forwarded 10 days, and the sample was much better where the stones had been hewed than elsewhere in the field. (The stones of which the church was built were of ordinary sandstone, probably millstone grit.) Borrowing from this hint, I had them covered with about 1000 cubic yards of alluvial gravel to the acre, and the land was then ploughed two furrows deep, one plough following another. Previous to this gravelling the land was a stiff, obdurate clay nearly to the surface. The subsequent effect was the doubling or, more probably, trebling the value of the land, which has now become a nice friable soil. I was much amused with the criticisms of some of the neighbouring farmers (men of the old school), one of whom remarked to me that he had seen land tilled in various ways before my time, but until now he had never seen a field tilled with cobble stones. I said, "What is your objection to it, John?" "Why, ye see, it makes th' land so poor." I replied, "Making anything or anybody poor means robbing them of something. If you had twenty shillings in your pocket, and I filled up your pocket with these cobble stones, you would be poorer would you be? Of what have I robbed this field by putting the gravel into it?" "Why, of nothing; but it looks so queer?" I said, "John, did you never hear of a man gathering the stones off his field and then having to lead them back again?" "Yes, I have; but they were natural stones, and of soil." I said, "What does manuring land mean, but putting something into it of which it is short? You don't till a muck midden. If, in stony land, stones are essential for the vigorous growth of the crop, is it not exceedingly probable that they will be still more beneficial in the land, which has no stones in it?" This is a doctrine I tried many years ago to inculcate to our friend Mechi, and some of his land (I speak of its condition 20 years since) needed such a gravelling as much as any land I ever saw. Whether he adopted my suggestion, or his land remains in the same condition now as then, I don't know; but if it does I would just suggest to him, and to all landed proprietors who own stiff clay land, if they are near to gravel pits, to try a small portion by gravelling it freely, and let us hear the result. *T. G., Clitheroe, December 2.*

Societies.

ROYAL AGRICULTURAL OF ENGLAND.

GENERAL MEETING: *Dec.* 7.—The following is the report of the Council to the general meeting of the Royal Agricultural Society on Monday of last week, to which we were, in our last issue, only able to make a short reference:—

The Council of the Royal Agricultural Society of England, in presenting their half-yearly report, have to state that since the last General Meeting in May, 6 governors and 53 members have died, and the names of 33 members have been removed from the list; on the other hand, 2 governors and 232 members have been elected, so that the Society now consists of 69 life governors, 72 annual governors, 1622 life members, 4030 annual members, 14 honorary members, making a total of 5827, showing an increase of 198 members during the year 1871.

During the past half-year the Council has lost some of the oldest of its members, the ranks of the trustees having been thinned by the death of Sir Thomas Dyke Acland and Lord Berners; the list of Vice-Presidents by the decease of Mr. Samuel Jonas; and the general body of the Council by the death of Mr. John Clayden. These vacancies have been filled up by the following elections:—Mr. E. Holland as a trustee, in the place of Lord Berners; Sir A. K. Macdonald, Bart., as a trustee, in the room of Sir Thomas Dyke Acland, Bart.: and Mr. B. T. Brandreth Gibbs as a Vice-President, in the room of Mr. Samuel Jonas. Mr. M'Intosh, of Havering Park, Essex, has been elected to fill the vacancy in the Council caused by the death of Mr. John Clayden, and the vacancies caused by the previous elections have been filled by the elections of the Hon. Wilbraham Egerton, M.P., of Rostherne Manor, Knutsford.

The half-yearly statement of accounts to June 30, 1870, has been examined and approved by the Society's auditors and accountants, and has been published for the information of the members in the last number of the Journal. The permanent funded capital of the Society remains the same as at the last half-yearly meeting, namely, £20,000 New Three per Cents., but the Reserve Show Fund has been reduced by the sum of £500.

The financial results of the county meetings at Oxford and Wolverhampton having been a loss to the Society of about £4000, owing chiefly to the extensive and costly nature of the trials of implements, the Council have appointed a special committee to consider the whole question of the conduct and expenditure of the Society, and the possibility of securing equal results at less cost.

The extensive nature of these trials also presses with great severity on the local committees in years when land has specially to be hired for the purpose. The Council have therefore resolved that when the trials of implements at the country meetings are not held in the showyard, one-half of the expenses of providing trial-fields shall, in future years, be borne by the Society; but to enable the Council to know the extent of its engagements, it has been stipulated that the competing localities shall state the maximum cost of the land required for the trial of implements, the acreage wanted being furnished by the Society.

The Wolverhampton meeting was distinguished from previous exhibitions of the Society by the extensive trials of steam cultivating machinery and traction engines, full reports on which have been furnished to the readers of the last number of the Journal. Notwithstanding a long continuance of unfavourable weather, the Council are able to congratulate the Society on the practical results of these trials. The Council have pointed out the many communities the best combinations of machinery for the cultivation of the land by steam-power, not only by the medium of the most powerful sets of tackle, but also by means of the less expensive machinery within the reach of individual farmers in districts where no system of hiring is in force. The competition for Lord Vernon's Prize Cup, offered for a set of machinery not to exceed £700 in cost, and that for the Society's prizes for engines by which the weight of the engine was restricted, as well as for others to be driven by ordinary portable engines, produced results which will be practically useful to farmers of every class who may be desirous of cultivating their land by the aid of steam.

The trials of traction-engines were an entirely new feature, and the exhaustive report of the engineer judges has placed in permanent record the valuable additions which they made to our knowledge of the principles of steam-traction on common roads, and the inferences which they suggest to the practical engineer.

The competition for the prizes offered in the section of Hop machinery was not so extensive as the Council had hoped to excite, but this disappointment has been to a great extent overcome by the fact that the trials exposed the exhibitors to the fullest comment makers many striking defects in the existing machines.

The exhibition of live stock did not in some cases equal that of last year, but the show of Shropshire sheep was the largest that has ever been brought together on the this Society. The liberality of the local committee in offering prizes for numerous additional classes of horses did not meet with an encouraging response from exhibitors, but the Council trust that changes for conveyance by the railway companies have a very prejudicial effect on this department of the Society's show. Although the Council have frequently endeavoured, unsuccessfully, to obtain concessions from the railway companies for the conveyance of live stock, and more especially of horses, they have recently placed themselves once more in communication with the railway authorities with this object in view.

The farm-prize competition in connection with the Wolverhampton meeting excited great interest in the counties of Shropshire and Staffordshire, as well as in other parts of the kingdom. A full report on the successful farms, by Messrs. Wheatley and Mornington, has been published in the Society's Journal, and it is hoped that it may aid in producing results commensurate with the liberality of the landowners in the two counties in offering the prizes, the enterprise of the competing tenant-farmers, and the careful investigation of Mr. Wheatley and his colleagues.

The series of farm-prize competitions will be continued next year in Yorkshire, and the £100 having been offered by the President of the Society (Sir Watkin W. Wynn, Bart., M.P.), and a second prize of £50 by the Council. These prizes will be awarded to the two best managed farms in the West Riding and Monmouthshire which shall conform to the following conditions:—1. That they are not less than 100 acres in extent. 2. That not less than one-fourth of the land (not including sheepwalk) is in the occupation of the Competitor, and that the other farmer paying a *bonâ-fide* rent for not less than three-fourths of the land in his occupation, or (*b*) by a landowner occupying his own farm, the total extent of whose property in cultivated land (exclusive of sheepwalk) does not exceed 200 acres, and whose sole business is farming.

The implement prize-sheet for the ensuing country meeting to be held at Cardiff has received the careful attention of the Council, and will have been altered for portable steam-engines, threshing-machines, straw and hay elevators, corn screens, corn dressing machines, and seed drawers. The regulations of the trials and the instructions to the judges have been revised, especially in reference to the points representing perfection in threshing-machines, and further restrictions have been imposed on exhibitors with a view of keeping the exhibition of implements within the Council's limits.

The regulations affecting the awards of medals to miscellaneous articles have also been once more under the consideration of the Council, and such modifications of the rules have been introduced as appear to the Council as will ensure that the medals are awarded either to implements belonging to the classes to be tried at that meeting, or to those which have an entirely novel construction, and which are likely to prove of value to the public.

The Council have renewed the education grant for the year 1872, on the same conditions as were attached to the examinations this year, feeling that more time must elapse before the advantages arising from success at these examinations can be generally appreciated.

Since the commencement of the publication of the quarterly reports of the consulting chemist, the number of analyses made by Professor Voelcker have increased, during 1871, by 150 in excess of those made in 1870, and 265 over those of 1869; and the Council are satisfied that the publication of these quarterly reports has caused agriculturists more fully to appreciate the value of chemical research, and has aroused a spirit of inquiry in this department of agriculture which cannot fail to produce very satisfactory results. They trust, therefore, that the publication of the reports of the consulting chemist and the consulting chemist may be less advantageous to the members of the Society than they have hitherto been.

The Council have to announce that they have appointed Mr. W. Carruthers, F.R.S., chief of the national botanical collection at the British Museum, to be the consulting botanist to the Society. In making this appointment the Council have endeavoured to secure the services of a competent botanist, whose duty it will be to examine plants, seeds, &c., for the members of the Society; to report on the principal work performed by him during each year; and from time to time to furnish papers to the Journal on special subjects of botanical interest. The following schedule of charges has been provisionally fixed by the Council for the examination of plants and seeds for the use of members of the Society:—

No. 1. A general opinion as to the genuineness and age of a sample of Clover seed (each sample) ..	5*s.*
No. 2. A detailed report on a sample of dirty or impure Clover seed, with a report on its admixture with seeds of Dodder or other weeds (each sample)	10*s.*
No. 3. A test examination of Turnip or other Cruciferous seed, with a report on its germinating power, or its adulteration with oco seed (each sample) ..	10*s.*
No. 4. A test examination of any other kind of seed or corn, with a report on its germinating power (each sample)	10*s.*
No. 5. Determination of the species of any indigenous British plant parasitic), with a report on its habits (each species)	5*s.*
No. 6. Determination of the species of any epiphyte or vegetable parasite, on any farm crop grown by the member, with a report on its habits, and suggestions (where possible) as to its extermination or prevention (each species)	10*s.*
No. 7. Report on any other form of plant disease not caused by insects	10*s.*
No. 8. Determination of the species of a collection of natural grasses indigenous to any district on one inch collection	10*s.*

The prevalence of foot-and-mouth disease in English herds has induced the Council, on more than one occasion during the past half-year, to draw the attention of the Government to the existing regulations in reference to the importation of live stock, and Irish cattle, and to the restrictions which it is desirable to impose in order to diminish the risk of their conveying contagious or infectious diseases to English stock. The correspondence between the Veterinary Department of the Privy Council and the Secretary of the Society, together with a *précis* of the various Acts and Orders in Council relating to the importation of foreign animals, has been published in the last number of the Journal. In connection with Irish stock, the Council have received the assurance of the Government that measures are being taken which, it is hoped, will be found satisfactory.

The extensive prevalence of a wide-spread disease, of home origin, has been brought under the notice of the Council by the Lincolnshire Agricultural Society during the past half-year. The nature and origin of this disease have been previously described in the Journal of the Society, but in view of the great losses which it has this year caused to Lincolnshire flockmasters, the Council have requested Professor Simonds to make a thorough and immediate examination of the nature of the disease and the circumstances under which it most commonly occurs, and to give suggestions for its treatment and prevention.

The relations between the Royal Veterinary College and the Society are still under discussion by the governing bodies of the two institutions; but the Council are still hopeful that the result will be to extend the usefulness of the Veterinary Department of the Society in accordance with its increasing importance to the British agriculturist. In consequence of the death of Professor Spooner, the post of Principal of the Royal Veterinary College is now vacant, and it is possible that alterations may be made in the duties at that office on the part of College. Under these circumstances the Council have postponed its decision on the relations of the Society to the College.

—By Order of the Council,

H. M. JENKINS, Secretary.

The adoption of this report was moved by Mr. Botley, and seconded by Professor Coleman, who said, that although the loss which the Society had sustained through their annual shows was great, he believed that the advantages of these exhibitions to the country fully repaid them for the money that, he would say, had been admirably laid out.

Sir JOHN V. B. MAXWELL congratulated the Society on the great reduction that had taken place in the cases of adulteration of manures and feeding-stuffs since the publication of the chemical reports.

Mr. NIELD suggested that, to recoup the Society of the financial losses of the shows, they should show both agricultural and light horses in harness, as they did at Liverpool, which was the most successful show of the Society.

Mr. ARKELL was of opinion that the appointment of a botanist was a good step, and also that the precautions taken for the detection of adulteration in manures would effect much good. He thought that the names of the merchants who sold inferior manures should be communicated to the secretary, and furnished to tenant-farmers without prejudice. With regard to the disease in lambs he was of opinion that an entomologist should be appointed to investigate the nature and habits of the insects which caused the disease.—The report was unanimously adopted.

Mr. TORR referred to the losses the Society had sustained by the two last shows. They could not, he said, carry out trials of steam machinery at hundreds, but thousands of pounds must be spent. These thousands had been spent, but the result would be seen for a number of years to come. With respect to the disease in lambs, he mentioned that he had lost over 100 animals himself, which was very small in comparison with the general loss. Along with six or seven Lincolnshire farmers, he had had a consultation with Professor Simonds on the nature of the disease, and that gentleman had given them most elaborate information respecting the worms which were the cause of all the mischief. When he got home he intended to send grass to Professor Simonds, where it was thought they existed in a parasitic form. It was known that they

did exist in a parasitic form during the winter, re-appearing in the spring, and were then taken up by the lambs. The great object of the inquiry was to trace the insect, and with that end in view they intended to begin early next spring, and ascertain how and when the insect was transformed from a parasite into a worm. The Society had liberally granted funds, and he was engaged with a committee in Lincolnshire in collecting all the information on the subject they could.

The CHAIRMAN then asked if there was any member who wished to make any suggestions, whereupon,

Sir JOHN H. MAXWELL said that at a former meeting there had been a regret expressed that more tenant-farmers were not members of the Society, and he gave his opinion that there were more tenant-farmers members of the Highland Society than there were members of the Royal Society. With a view to obtaining positive information on the question, he wrote to Mr. Menzies, Secretary of the Highland Society, and received the following answer :—"In 1850 we had only 2700 members on our list, only 239 of these being tenant-farmers, nearly all of them life members. In that year it was resolved that tenant-farmers should be admitted on a subscription of 10*s.* per annum, or £5 5*s.* for life, instead of £1 5*s.* 6*d.* per annum, or £12 12*s.* for life—the ordinary rate. The number of tenant-farmers is steadily increasing : we have now 4033 members of all classes, and 1784 of these are tenant-farmers. In 1861, we had 1540 tenant-farmers ; in 1866, when I became secretary, we had 1684, and in 1871 we had 1784. I have no doubt it has benefited the Society as well as the country, reducing the subscription to tenant-farmers—so much so, that I have induced the Society to add a number of other classes to the same list." He asked if English tenant-farmers could not practically be admitted to the Royal Society under the same or similar conditions to those enjoyed by the Scotch tenants who entered the Highland Society.

The SECRETARY (Mr. H. M. Jenkins) said, although he had not gone into statistics, he thought there were do not contain the guaranteed percentage of soluble phosphates.

With respect to bones, they have become scarce and dear, and few manufacturers supply genuine dissolved bones ; nine-tenths of the bulk of what is sold as dissolved bones is a mixture of ordinary superphosphate with more or less of bone-dust. Such mixtures should be sold under a name which expresses more fairly the real character of the article.

Most of the samples of bone-dust analysed in 1871 were pure and of good quality.

Sulphate of ammonia has risen much in price this year, the present price being £21 to £22 per ton, and it is very necessary to have the percentage of ammonia guaranteed, which in the first quality should be 25 per cent., and in the second not less than 23 per cent.

The quality of the guano from the Guanape Islands has not improved ; three-fourths of the samples of guano analysed by Dr. Voelcker were from the Guanape Islands, and the majority were too wet and lumpy for direct application to the land. Many samples contained from 23 to 24 per cent. of water, and but few more than 10 per cent. of ammonia. In former years such guano would have been sold as 14-guano, varying according to the intrinsic value of the cargo. During the last season, Guanape Island guano has all been sold at one uniform price, and importers would not allow samples to be taken of the quality of the various cargoes, so that analyses might be made before purchase. The sales guano have, consequently, fallen off very much.

There is reason to believe that the Peruvian guano which will be offered in future, when the Government sales in this country are undertaken by the new contractor, will be of a superior character. The supply of good guano, Dr. Voelcker adds, is of the greater importance, because, whilst phosphatic fertilisers are being constantly discovered, and the supply from phosphatic rocks and minerals is practically inexhaustible, the sources from which ammonia can be obtained are limited. The supply, therefore, of guano from the Ballestas Islands, which may be looked for next year, many more tenant-farmers in the Highland Society than in the Royal ; but in the Scotch Society these tenant-farmer members were not entitled to the privileges of chemical analysis without extra payment.

Sir W. W. WYNN, as the close of the meeting, speaking of the prize farm competition, said, there was a large class of men in Wales who farmed their own land, which their families had done for each succeeding generation ; and he was, therefore, of opinion that they ought to be allowed to compete under the same conditions as *bond-fide* tenant-farmers, at the same time carefully eliminating all those who farmed more for amusement than for profit. He was glad to find that the course taken by the Society of exposing those people who had for years been robbing the farmers, had met with approval, as they knew farmers were a little too fond of trying to buy the cheapest stuffs ; and it was therefore the duty of the Society to endeavour to guard them from being cheated.

The meeting afterwards separated.

We now add the report of the Chemical Committee to the Council of the Society, read at the Wednesday meeting last week :—

CHEMICAL :—In his annual report, Professor Voelcker states that, whereas in the year 1870 the number of analyses furnished by him were 115 in excess of those for 1869, this year the unprecedented number of 730 analyses, or 150 more than in 1870, had been referred to him.

He calls attention to the further addition to his staff which this amount of work entails, and takes the opportunity of mentioning that his staff consists of only well-trained paid assistants, several of whom have been in his service for many years.

Dr. Voelcker states that several of the samples of manures sent were found all but worthless, and he reiterates his advice that purchasers of artificial manures should always obtain, if possible, a guarantee by analysis of their composition and fertilising qualities. The practice of buying superphosphate of a guaranteed strength is, he adds, gaining more and more ground, and he recommends the stipulation that a proportionate deduction be made if the bulk of manure on delivery and samples of which Professor Voelcker has already analysed, will be most welcome.

The accompanying Table shows the analysis of 17 different cargoes of Ballestas Islands guano, an abundant supply of which may be looked forward to for a good many years.

As respects feeding cakes, the Professor again calls attention to the adulteration of linseed cake with earth-nut cake ; and of rape cake, including green German rape cake, with Mustard seed.

Five or six cases have been brought under his notice, in which decorticated cotton cake was alleged to have caused the death of sheep and lambs ; as, however, some of these cakes were of a superior quality, and none of them contained any poisonous ingredients, it is Dr. Voelcker's opinion that the animals probably partook too freely of the cake, and could not digest the large proportion of nitrogenous compound contained in good cotton cake, and he suggests the admixture of Indian Corn or some similar starchy food.

Out of the 36 samples of water sent for examination, Dr. Voelcker found many largely contaminated with sewage, and he earnestly invites attention to the serious injury which may be produced to health by the use of such impure waters.

The following is a summary of analyses made for members of the Society from December 1870 to December 1871 :—

Guano	78
Superphosphate, dissolved bones, Wheat manures, and similar artificial manures	202
Bone-dust	36
Refuse manures	31
Nitrate of soda, sulphate of ammonia, and potash salts	21
Marls, limestones, breclays, and other minerals	20
Soils	44
Oilcakes	212
Feeding meals	24
Vegetable productions	12
Waters	36
Examinatioos for poisons	4
Total	730

The following are the papers contributed by Professor Voelcker to the February and August numbers of the Journal for 1871 :—

1. On Sugar-Beets and Beetroot Distillation.

2. On the best mode of Preparing Straw-chaff for Feeding Purposes.

3. On Field Experiments on Root Crops.

4. On the Composition and Nutritive Value of the Prickly Comfrey (Symphytum asperrimum).

5. Quarterly and Annual Reports.

The following is the quarterly report of the Chemical Committee :—

1. Dr. Voelcker reports the analyses of three samples of guano sent to him by Mr. H. W. Hollis, Estate Offices, Keele, near Newcastle, Staffordshire, in May, 1871.

These three guanos were found to have the following composition :—

	No. 1.	No. 2.	No. 3.
Moisture	7.56	7.02	15.55
*Organic matter and ammoniacal salts	21.67	21.91	42.25
Phosphate of lime	14.85	15.31	23.06
Carbonate of lime	9.67	10.31	..
Alkaline salts	8.08	7.20	6.05
Insoluble siliceous matter	38.17	38.22	13.08
	100.00	100.00	100.00
*Containing nitrogen	4.36	5.01	9.55
Equal to ammonia	5.54	6.07	11.59

The prices of the three samples were—No. 1, £14 ; No. 2, £12 15*s.* ; No. 3, £16.

The first and second samples are adulterated, for both contain as much as 38 per cent. of sand, and about 10 per cent. of carbonate of lime (chalk) ; and the one yields only 5½ per cent. of ammonia, and the other 6 per cent. of ammonia, in round numbers.

The composition of these two samples is pretty much the same, the second being slightly better than the first, although it was sold at 25*s.* less money per ton than No. 1. The third sample is genuine guano, but of an inferior character, inasmuch as it contained 15 per cent. of insoluble matter and yielded only 12½ per cent. of ammonia. Such guano, is not worth £16 a ton, and the adulterated samples, No. 1 and No. 2, sold respectively at £14 a ton and £12 15*s.*, were not worth more than £8 a ton.

Moisture	18.04	18.06	18 93	19.19	18.86	17.01	16.67	17.77	18.51	13 48	17.01	17.70	17.93	16.77	16.60	18.18	19.28
*Organic matter and ammonia salts..	49 22	46.81	47 97	48.19	45.57	50.35	49.61	49.04	49.11	45.56	51.01	49.10	48.73	50.71	48.03	48.83	48.05
Phosphates	22.18	23.20	21.05	20.69	23.29	22.01	21.26	21.69	21.97	25.37	22.65	21.76	20 63	21.74	22.97	22.68	21.72
**Alkaline salts, &c.	8.40	9.49	9.40	9.40	10.45	9.28	11.17	9.86	8.94	12.75	8.04	9.85	11.32	9.09	10.16	8.87	9.61
Silica	2.16	2.44	1.75	2.53	1.83	1.35	1.29	1.64	1.47	2.84	1.29	1.59	1.39	1.69	2.24	1.44	1 34
	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00
*Containing nitrogen	12.91	12.27	12.09	13.60	12.14	13.26	13.20	13 60	12.73	10.75	12.98	11.98	12.59	12.58	12.32	12.97	12.26
Equal to ammonia	15.67	14.89	15.77	16.51	14.74	16.10	16.03	16.51	15.46	13.05	15.76	14.54	15.29	15.51	15.20	15.75	14.88
**Containing phosphoric acid	2.82	2 70	2.49	2.47	3.07	2.74	2.95	2.31	2.26	3.25	2.90	2.39	2.06	2.10	2.32	2.36	2.42
Equal to tribasic phosphate of lime	6.16	5.89	5.43	5.39	6.70	5.98	6.44	5.04	4.93	7.09	6.33	5.21	6.46	4.58	5 06	5.15	5.28

Dr. Voelcker wrote for the names of the sellers of these guanos, but obtained no reply in answer to his inquiries.

2. A sample of artificial manure, sent by Mr. J. Reeve, Snetterton Hall, Thetford, on analysis was found to have the following composition :—

Moisture	13.53
*Organic matter	25.06
Oxide of iron and alumina	10.35
Phosphate of lime	7.70
Carbonate and sulphate of lime	16.74
Magnesia and alkaline salts	2.01
Insoluble siliceous matter (sand)	30.61
	100.00
*Containing nitrogen	.87
Equal to ammonia	1.05

This artificial manure, it will be seen, contained only 1⅞ per cent. of phosphate of lime, and yielded only 1 per cent. of ammonia. It contained 30½ per cent. of sand and a large proportion of oxide of iron, alumina, carbonate of lime, and similar worthless materials.

No information could be obtained respecting the names of the vendors or the price of the manure, which hardly deserves the name.

3. Mr. Edward Taylor, Whitton, Leintwardine, sent a sample of manure, which he purchased as genuine dissolved bones.

This manure on examination was found to contain no more than 10 per cent. of green loam at the most, and consequently was not genuine dissolved bones. The name of the dealer of these so-called dissolved bones could not be obtained.

4. Dr. Voelcker had previously reported on the composition of a sample of fish and bone manure sent by Mr. Nathaniel Baskett, Baines Hall, Wetheringset, Stonham, Suffolk, as follows :—

Moisture	11.98
*Organic matter	8.88
Phosphate of lime	3.43
Sulphate and carbonate of lime	51.00
Magnesia and alkaline salts	2.70
Insoluble siliceous matter (sand)	21.95
	100.00
*Containing nitrogen	.32
Equal to ammonia	.27

This manure was sold at £5 a ton, but is scarcely worth 10*s.* a ton, delivered free of cost on the farm.

In answer to the inquiry made as to the vendors, Mr. Baskett wrote on July 6 :—

"You applied to me for the name of the manufacturer of some fish and bone manure I sent you for analysis a short time since, and which you valued at the low sum of 10s. a ton. I beg to state that I had it from H. Marshall & Co., Wivenhoe, Essex: also from the same firm the guano sent to you at same time for analysis, and which you stated to be adulterated, and not worth more than £7 10s. a ton, and for which I paid £12 15s.—I am, yours faithfully, NATH. BASKETT."

6. Mr. Baskett sent again in July two samples of manure, marked No. 3 and No. 4, which were both sold to him at £5 a ton cash, delivered, by Messrs. H. Marshall & Co., Wivenhoe, Essex.

The two manures had the following composition :—

	No. 1.	No. 4.
Moisture	7.51	9.68
*Organic matter	16.26	11.85
Oxide of iron and alumina	1.40	.89
Phosphate of lime	2.42	5.72
Carbonate and sulphate of lime, &c. ..	67.15	63.46
Insoluble siliceous matter	5.23	8.40
	100.00	100.00
*Containing nitrogen	.44	.49
Equal to ammonia	.53	.59

No. 1 manure was scarcely better than the sample of fish and bone manure which Mr. Baskett sent me before, and which was valued at 10s. a ton in comparison with Peruvian guano.

This manure, it will be seen, contains but little phosphate of lime, and yields only ½ per cent. of ammonia.

No. 4 is very similar to No. 1, but somewhat richer in phosphate of lime, and worth about 7s. more per ton than No. 1. Both these manures consist principally of gypsum and carbonate of lime or chalk.

7. The next case is a sample of blood and bone manure, which was sent by Mr. T. H. Saunders, Watercombe Farm, near Dorchester, who states that it was manufactured by Messrs. Festing, Brothers, near Weymouth, and sold at £5 a ton. On analysis its composition was found to be as follows :—

Moisture	22.72
*Organic matter	29.07
*Phosphate of lime	1.81
Oxide of iron and alumina	11.59
Lime, carbon, and sulphate	8.85
Alkalies, &c.	7.73
Sand	29.32
	100.00
*Containing nitrogen	.88
Equal to ammonia	1.07
**Equal to tribasic phosphate of lime	3.97

This so-called blood and bone manure, it will be seen, contained only 4 per cent. of bone-phosphate, and only 1 per cent. of ammonia, and as much as 22½ per cent. of moisture, and 29 per cent. of sand. I reported it to be worth not more than £1 10s. a ton, but Mr. Saunders thinks 20s. a ton.

In the course of their inquiries, the Chemical Committee frequently find that the vendor agrees to abide by the analysis of Professor Voelcker, and so, the purchaser being satisfied, there is no opportunity for further investigation. Two samples of cake, for instance, were submitted to Professor Voelcker; one, stamped pure, contained seeds of some 20 different weeds, and was made of very dirty seed. Another contained Castor-oil Beans, but the purchaser wrote that he was in correspondence with the vendor, and did not wish to have any further analysis.

In presenting their annual report to the Council, the Chemical Committee beg to observe that they have had very little responsibility thrown upon them, in consequence of the publication of Dr. Voelcker's analyses in their quarterly reports. The committee offer their sincere thanks to the Council for the support they have received, and the confidence that has been reposed in them. They are thoroughly satisfied of the good that has been done by these publications, and they trust that, while continuing them as usual, the experience they have acquired may render the reports equally valuable to the public, and at the same time not provoke any legal proceedings.

SMITHFIELD CLUB.

WE make the following extracts from the report for 1871 :—

The Right Hon. Lord Penrhyn, who was chosen as President-Elect at the last general meeting, has intimated to the Council his regret that advancing years would prevent his discharging the duties of President, but his lordship, by presenting the handsome donation of £100, has manifested the interest that he takes in the welfare of the Club. The Council voted their best thanks for the same, and they have elected the Right Hon. Lord Tredegar, V.P., to fill the office of President for the year 1872.

The Council have to lament the loss by death of the Right Hon. Lord Berners, the Right Hon. Lord Walsingham, and the Right Hon. the Earl of Aylesford, Vice-Presidents of the Club; and also of Mr. John Clayden, the chairman of the Agricultural Hall Company; and Mr. Richard Stratton, both members of the Council. Mr. Clayden would have retired by rotation at this meeting, and therefore the Council have not filled the vacancy caused by his death. They have elected Mr. Joseph Stratton in the place of Mr. Richard Stratton.

The Council have revised the prize sheet for the present show, and the following alterations have been made :—

In the division for Scotch polled cattle, a new class has been established for cows, separate from the heifers. In the Irish division, the wording has been amended, so as to keep the classes exclusively for Irish breeds. The class for light-weight cross-bred sheep has been discontinued. The rule restricting any animal once exhibited at the Club's show from being again shown, except as extra stock, has been expunged, and in lieu thereof the following substituted :—"No animal exhibited at any previous show of the Club can again compete in the same class."

Several minor alterations and emendations have been made.

The Council have determined, that in addition to having every animal weighed, and its live weight published, the butcher purchasing each shall be invited to send in a return of the dead weight, and that the name and address of the purchaser shall be published in conjunction therewith, in recognition of the wishes of the Club having been complied with.

The Council having received a communication from the Agricultural Hall Company to the effect that the publication of an implement catalogue entailed a pecuniary loss, the Council resolved to accept the offer of the company to add to the stock catalogue a list of implement exhibitors, with the address and trade of each, in numbers to suit the stalls, and in front of the building, indicating the position of each stand.

The Council lay before the meeting printed copies of the annual balance-sheet, duly audited, showing balances in hand on December 1, £2863 11s. 10½d., and stock invested in the 3 per Cent. Consols, £4664 18s. 1d.

The Council having regard to the great importance of this subject as affecting the future exhibitions of the Club, and the necessity of all due precautions being taken for the protection of exhibitors' interests so long as the disease shall continue to be prevalent, have determined to endeavour to ascertain the feelings of the members of the Club generally by inviting a discussion at the general meeting on the following points, viz., "Whether animals exhibited elsewhere within a limited period before the date of the Club's Show should or should not be admitted in future during the prevalence of the foot-and-mouth disease."

The Council will take the opinions then expressed into final consideration at the February Council meeting. The Council will then discuss whether any, and if so, what modifications shall be sought to be obtained from the Privy Council in reference to the regulations affecting the foot-and-mouth disease generally. By order of the Council (Signed) *E. T. Brandreth Gibbs, with some few Secretary.*

CHESHIRE.

Education Adapted to Rural Districts.—At the annual meeting of this Chamber of Agriculture, held at Crewe on the 22d ult., Thomas Dibley in the chair—

Sir HARRY MAINWARING, Bart., introduced the subject of "education in the rural districts of the country," the consideration of which had been postponed from last meeting. He said this was a subject which appeared to be causing great contention now, and which would give infinite trouble to the next generation—a subject which had been discussed for and with by statesmen and learned persons of every station in life; by persons of every religion and religious persuasion; by infidels, a very large and numerous body at the present time; by enigmatical persons in female clothing; and by the great writer and poet of the day, who said—

> All you who write and talk on education,
> And all such themes of doughty disputation,
> For mercy's sake, do study condensation,
> Or sense in fewest words—consolidation.

He proposed to act on this writer's advice. The subject might be consolidated into these few words, "Train up children in the way they should go," or, in other words, "Give children an education such as would materially help them and push them on in the profession which they adopt or which is adopted for them." Our clergy were educated for the profession, so were soldiers, sailors, and others. Why, then, were not agriculturists children educated for their profession? Why was the one and the same system of education pursued in all our parochial schools? Whether it be a school at a seafaring place like Birkenhead, or a mechanic school as at Crewe, or a school at a manufacturing place like Staleybridge, or a school at a purely agricultural place like Over Peover, the system of education was the same. It was no matter of surprise, therefore, that, with some few exceptions perhaps, children educated at parochial schools in agricultural districts should be found to be grossly ignorant of the profession which they adopted. He was opposed to all compulsory education of children after they attained the age of eight years, and thought the State should not dictate to parents as to their management of their children after that age. In these days, when labour was so scarce and costly, children in agricultural districts were of great use to farmers, and of great advantage to their parents. In addition to this, he did not think that children should be kept at school after they were eleven years of age. He never yet knew a good farmer or a good cheesemaker kept at school after that age. If they remained any longer, boys were afraid of pulling off their coats and dirtying their hands, and all wanted to become excisemen or railway clerks, and girls wished to become milliners or something else. But why was one and the same system of education pursued at all parochial schools in the country? The children in agricultural districts were now taught things which could in no way profit them. Some years ago, when the inspectors first came, they asked one of them if he could give them a system of education adapted purely to an agricultural district, and the inspector replied that there was only one form of education, and that no other would be allowed in the schools which he inspected. Let them look for a moment at the "Book of questions proposed to candidates for admission into training schools" issued by the Education Department, for Christmas, 1870. In it the student was required to read, write, and parse the following passage :—

> Woods that wave o'er Delphi's steep,
> Isles that crown the Ægean deep,
> Fields that cool Ilissus laves,
> Or where Mæander's amber waves.

More consummate nonsense he never read. But that was not all. The student was requested to explain the following words :—"Many-twinkling feet, sympathetic, incense-breathing, azure." He was further asked to comment briefly on the subjoined lines from Gray's Ode :—

> Ye towers of Julius, London's lasting shame,
> Modred, whose magic song
> Made huge Plinlimmon bow his cloud-topped head.

At page 33 he was required to describe the struggle with the Danes in the reign of Ethelred II. The Lord only (said Sir Harry) knew when that man lived. He was then asked to describe the relations between France and England in the reign of Henry III. The next question must be a joke, if the Education Department were jocular. It was this—"Describe the union of England and Ireland, how it was accomplished; give the terms of the union." This was the book for the masters of schools in the agricultural districts of Cheshire. (Sir Harry) wished to know something about the state of the schools, so he made application to a person who, after visiting several of them reported that the children were extremely ignorant of subjects of importance to them. Sir Harry then read a little sketch of an examination of boys, which contained the following amongst other questions:—Do you intend to be a farmer? Yes. Can you measure land? No. Can you measure a tree? No. Can you measure a road? No. Can you map a road? No. What counties border on Cheshire? Don't know. What are the principal rivers of Cheshire? Don't know. What are the natural market towns of Cheshire? Don't know. They knew all about Plinlimmon and Ethelred, but nothing about the market towns and rivers of Cheshire. Where do coals come from? Station. Have you ever walked the boundary of the parish and then mapped it? No. Are there any banks upon Dunham parish? No. Is London in the north or south of England? Don't know. This appeared to show the system of education pursued. This wretched system ought to be altered, and he made three suggestions—1st, that they should have agricultural schools for boys from the ages of 8 to 14; 2nd, that the Chamber should intercede with the Board of Education, and request them to give a little more suitable education. He had, however, no confidence in boards, and as there was no elasticity in them, if they were asked to supply an education adapted to the farming business, the board would say one system must be adopted. His third suggestion was that trustees of schools in agricultural districts should supply schools with books on farming, and agricultural periodicals. It was their duty to supply suitable education for boys who were intended for farmers, and if they did not supply it they were neglecting their duty.

Major EDWARD LEIGH said there was no doubt that a mechanic required a different education from a person employed in agriculture, and he did not see why education suitable to such should not be given. They ought not to be satisfied with learning things they did not want. There was no use in knowing something about Plinlimmon, but there might be in knowing something about Penmaenmaur. He coincided with Sir Harry Mainwaring in thinking that agriculture ought to be taught in our schools. The simple A B C of education must be very much the same everywhere; but if there were to be specialities, they ought to diverge into the particular profession which the greatest number of boys in a district would eventually follow.

The Hon. W. EGERTON, M.P., thought Sir H. Mainwaring should have tried to suggest some remedy for what he complained of, but he had not suggested any definite scheme. He had laid down that nobody should attend school after they were 8 years old. But they must admit that before they could have special education they must have general education, and what chance was there of teaching the son of an agricultural labourer, or a farmer, special education before he was 8 years old? The proposal to teach such a one special education was either absurd, or they must continue the education after the boy was 8 years old. Then they must have compulsion if the scheme was to be carried out, but how could they compel sons of labourers to attend between 8 and 12 years of age,

between which ages of course some special education might be given? Between 8 and 12 years old there were many employments in which an agricultural labourer's son could be usefully engaged. He believed, from evidence given before Commissioners, it was undesirable that the children should be employed in agricultural operations before the age of 10, and therefore, between the age of 10 and 12, they came to a time when they might have a higher education, and when they might do some agricultural work. He believed that the question of compulsory powers would again come before Parliament, and he had no doubt they were given to school boards as an experiment. He thought the Factory Acts might be advantageously extended to agriculture.

SOCIAL SCIENCE CONGRESS, LEEDS.

Local Taxation.—Mr. E. R. FORDHAM read a paper on this subject. He said local taxation, unlike almost every other system in the country, remained just in the state in which it was originally organised. It started with the assumption that every one in the country should contribute to the exigencies of the State in proportion to his ability to do so. This was fairly secured in the then state of things, when the only income from property was that derived from houses and land, or nearly so. Now, the income from land and houses was only about one-third of the people's annual income, instead of constituting nearly the whole, as formerly. It seemed to be conceded that the onus of maintaining the pauper, of educating him, of making roads, and supporting a police force for the security of the population, ought to be thrown on the people generally. How is it, then, that all these charges, which were always increasing, should still remain almost the exclusive burden of a part of the State, the owners of real property? There were several ways of accounting for this. One was, that property in land had enjoyed a protective duty on corn, which probably enhanced its price by 6*s.* per quarter on all the produce of these islands, say 8,000,000 qr. of Wheat, and 2,000,000 qr. of other grain. This would give them little or nothing to the vast mass of pauperism created by such population. Then, again, see the enormous number of ships—floating houses—their lettable value immense, tenanted by seamen, earning countless millions for the shipowner, and leaving their pauper population, belonging to those employed in such vessels, a burden borne by real property only, from which these ships are exempt. Then there were the many millions of property in railways paying a very small proportion of income of the shareholders towards the rates. Why should railways be rated as they were? Why should not the rail owner contribute the same proportion of his income from rent, or estimated rent, of a railway as a landowner did from the rent of his land? The vast amount of wealth still untaxed for these purposes would bear some share of those charges, but there would be no additional burden cast by arresting the diminution of duties on such articles as tea and sugar, and slightly increasing those on alcohol. Let the Post-office charges remain as they were, and there would be a constantly increasing surplus from this source. The property and income tax also would yield a rapidly increasing sum. These sources would almost imperceptibly rectify the flagrant injustice of the present plan, now obsolete. With respect to the incidence of rates on houses, he contended that it was much more unjust than on land, and that it fell almost exclusively on the tenant. In the state of things had an important incidence, thus: £6 rental would be rated at £5, and a poundage rate of 4*s.* would thus deprive the tenant of £1 per annum. In the case of a labourer who earned 12*s.* per week, which would give him an annual income of £31 4*s.*, it would represent in his case a property tax of 8*d.* in the pound as his contribution towards the support of pauperism, &c., as occupier, while the owner of the house, much more able to contribute, would not, in respect of this property, pay a fraction. If this very unequal impost were removed, the house property would cost him only £6, instead of £7, as it did now; and he would have the £1 to pay for a house with a second or third bedroom, so essential to the interests of morality. With regard to land, exactly the reverse was the case. Every tax, such as land-tax, tithe, rates, is always paid by the owner, and its amount affects the value of the land to the owner, but in no way concerns the tenant.

Mr. BURHAM SAFFORD said, those burdens of local taxation of a purely local character should be separated from those that should be national. The spirit of the basis of the existing Poor-law, passed in the 43d Elizabeth, cap. 2, contemplated that personal as well as real property should support their mutual offspring, the poor. Since the rise of trading companies, the rising influence of commerce had, instead of relieving the land, enabled it to add to the burden of the land the maintenance of the vast number of paupers caused by commercial failures. He contended that many of the grievances of taxation arose from the existence of too great a variety of financial machinery, and said many desirable results would accrue by rendering the taxation of the country equitable by transferring to one machinery all those subjects which were of a national character. The nuisance of collectors calling for taxes, he considered, might be obviated, and, at the same time, economy be secured, by having certain days appointed by public notice when the taxes could be received by an officer on circuit. He suggested the establishment of new money-orders for small sums, payable on account of taxes, as Government receipts were free of stamp duty.

Mr. BOTLEY said land had increased very much in value by the great commercial operations of this country, and the fact was they were continually sending children from the agricultural districts into the manufacturing towns for occupation; therefore it would be seen that the manufacturing districts were employing the children of agriculturists. With respect to the question of keeping up the roads, he said, remembering the wear and tear of harness and other stock, there was nothing more profitable to the agriculturist than good roads; therefore he thought they should bear their share of maintaining the roads in repair. As to the income-tax, he thought it would be better to put it on to real property than to tax a man on half his income. Everything, he maintained, went to show that land did not bear an undue proportion of the taxes.

Mr. D. FORDHAM thought the argument that land was rising in value, and did not pay a fair proportion to the rates, was a mistake. The increase in the value of land was an accidental circumstance, and there were other kinds of property which had risen much more rapidly in value than land. He instanced railway property, and particularly the rapid rise in the shares of the Great Northern Railway Company. He did not see why landowners, because it was land which benefited by the population raised upon it. As the population accumulated, so should the landlord have an interest in improving his property. Thus, he thought, as the landlord was benefited by the population, he should pay for the roads. He agreed with the present unsatisfactory state of things was for the municipalities to become the proprietors of the property in the municipality, and they would thus regulate the amount of rates; therefore, no differences would ensue. They ought not to permit the increase of the rates by allowing landowners to appropriate land which was ripe for building purposes, thus engendering fever and disease, which meant an increase of rates.

Mr. E. CHADWICK said the whole of the evils of our present taxation were due to the early system upon which the Poor-law was established. He said the one principle which applied with respect to our taxation for many years past had been this—wherever the rates were high, the people in that district began to consider how the rates could be shifted. In those districts where manufacture was the most heavily rated they tried to put it upon agriculture, and *vice versâ*. This was come to this—that he saw it throughout the entire country—that one section of the community was trying to shift the onus of taxation upon the other. Even the Government, he was sorry to say, was following in that suit. Local municipalities assumed that nothing could be done except by their own administration. He found that in the towns the local rates were kept down to the lowest possible amount. In London the object was to stop outdoor relief in supplement of wages. The fact was that out of the entire sum given in relief, three and a-half millions was relief given in-house, and they would not get rid of abuse until they improved the administration. He maintained that if local administration was properly carried out there was no part of it which was not beneficial to landed property. One great cause of the present unsatisfactory state of things was central legislation. It was the penalty we were paying for centralisation.

The CHAIRMAN said the sum received in England for local taxation was £17,000,000. It was made up in the following general proportions:—Poor-rate, £8,000,000; county, hundred, borough, and police rate, £3,000,000; highway rate, £1,500,000: the rest being made up by property, watch, improvement, and other rates. As to the incidence of the taxation, the difference between the English, Scotch, and Irish systems was that in England the local taxes were wholly paid by the occupiers, and in Scotland and Ireland in proportion by both owners and occupiers. In England the rates were managed by the magistrates; in Scotland, by the owners entirely; and in Ireland, by bodies on which the occupiers were represented. The discussion, so far as it had gone, pointed very clearly to the imperfect nature—not to use a stronger word—of the English plan of assessing the whole of these rates from the occupier alone. A very considerable part of these rates was a charge on sound principles of economy. The occupier, of course, on all principles of right, and expediency, and economy, was fairly liable to provide out of his own resources a certain part of the local expenditure, such as lighting, police, and the poor-rate; but he should hardly be liable to what might be called permanent purposes. He should hardly be liable to take upon himself the cost of such great works as, for example, the cost, once for all, of extensive public works, drainage, or county or borough buildings. These clearly ought to be borne by the owner, and at the present time a considerable part was borne by the owner. What had been done of late years, especially in the metropolis, had pointed to a much more extensive division of those local burdens than had been made in England up to the present time—that was to say, the adoption in England of those principles which had been wrought out with more success in Scotland, and to a certain extent in Ireland, than perhaps they had been worked out anywhere else. Then there was the much larger question which was incidentally raised, whether, in regard to this local revenue, some other kind of property besides real property should be brought into account. They knew that in England, and also in Scotland and Ireland, and he might say in nearly every other country in Europe, whatever the theory, the only fact was that those local burdens were assessed almost entirely upon real property. It was fortunate for the purpose of that discussion that they were able to refer to what had been done in the State of New York with regard to this question of the mode of assessment. The result of inquiries was to prove that the attempt which had been in force in New York and contiguous States to raise the local revenue by assessment on real property, personal and that of property had been an entire failure; and it had been recommended that in future the assessment should be confined entirely to real property. For his part, he entirely agreed in that recommendation. The local taxation of Belgium, which might bear comparison with that of any other country, was placed entirely upon the basis of taxing only the visible, taugible, and real estate possessed by a man. When they went beyond that, they found themselves landed in a maze of difficulties, out of which there was no escape at all.

Notices of Books.

Twenty-seventh Annual Report of the Botley and South Hants Farmers' Club. *Hampshire Advertiser* Office, Southampton.

The annual issue of the proceedings of our local Farmers' Clubs is really one of the most serviceable agricultural publications of the year. A whole agricultural library might be very easily extracted from the excellent papers which are in the course of years communicated to the various Farmers' Clubs, Societies, and Chambers of Agriculture throughout the land. The work of selection, which would, no doubt, be advisable, those do good service who collect for each society by itself some record of its 12 months' work, for distribution to its members. The Botley Farmers' Club, which seems very well served by its office-bearers, has now more than a quarter of a century contributed in this way its annual report to its members, and the pamphlet just published gives its twenty-seventh year's transactions. They include papers on the Chemistry of Feeding-stuffs, the Employment of Agricultural Labour, the Impediments to Agricultural Progress, and the Four-course System: its Evils and Remedies,—four capital essays, to which we referred in our pages at the time they were read. We now extract the address of the committee to the members, by which these essays are introduced to their notice:—

"In presenting to our members the twenty-seventh annual report, the first point which strikes our attention is the wonderful contrast between this season and the last. Then, after a hot and dry summer, we had a large produce of Wheat wherever there was a sufficient plant; and but little besides. Now, after a moist season and a low temperature, the yield of Wheat is bad, with a good crop of spring corn and Pulse, but the straw in a damaged condition. The hay crop is considerably greater than in 1870, but in a great extent has been injured by rain; whilst instead of the poor root crop of last year, we have now one of the finest ever known. Unfortunately as regards the latter the average of the two seasons cannot be thrown together. The scanty crop of 1870 has produced its baneful results. It has caused three animals to be slaughtered instead of two, and thereby seriously reduced the number and consequently the value of the stock that we reared for this year to convert our roots into mutton and beef. Never were two seasons more unlike each other.

"Our discussions during the last year have by no means been deficient in interest, as the little volume before us will sufficiently testify.

"The relative value of feeding stuffs, at all times a useful subject, but particularly so in such a peculiar season as the last, was introduced, as his first paper, by Mr. Albert Spooner, and was well received.

"This was followed by a very practical paper by our President, on the 'Employment of Farm Labour,' and was fully and ably discussed.

"To which succeeded an able paper by Mr. Blundell, on 'The Impediments to Agricultural Progress.' The subject, although necessarily discursive, excited much attention, and elicited a good discussion.

"For our last subject, 'The Four-course System, its Evils and Remedies,' we are indebted to a gentleman from a distance, Mr. Hughes, of Market Harborough, who introduced it in a very elaborate paper; a good discussion succeeded.

"For the second time in our history we have to mourn the loss of our President. A good man and true has been taken from us, and one who, whether as chairman of our club, competitor at our shows, in active business, or in private life, performed his part honourably, and performed it well.

"In conclusion, we have to congratulate ourselves that this country has escaped the horrors of a European war, and the distant horizon happily exhibits no signs of disturbance. This favourable aspect may in a great measure be ascribed to the glorious constitution under which we live, to the sound common sense and moderation which, with some slight exceptions, pervade all classes, and which induce them to respect and revere, and if need be to defend our laws, our liberties, and our institutions, and the throne of a thousand years which knits them altogether."

Farm Memoranda.

A Prize Dairy Farm.—We extract the following, from the pen of the late Mr. Jackson, of Tattenhall Farm, describing in the official report of the second prize farm (Journal of the Royal Agricultural Society) the labours of the dairy :—

Mr. Walker has made on an average over 4 cwt. of 120 lb. of cheese per cow, even the last three bad years—the remainder cheese fetching 78s. and the summer-made more than 83s. per cwt. of 120 lb. He has also gained the three 1st prizes of the Staffordshire Agricultural Society, and the Society's three silver medals for the best cheese in both classes, thick and thin. Last year he took the 1st prize of A. Bass, Esq., M.P., open to all Staffordshire and 15 miles from the borders. He has taken two 1st prizes for cheese of the Derbyshire Agricultural Society, together with a number of local cheese prizes; and as the system of cheese-making practised by Mr. Walker has not been described or known, except in that important dairy district, a special visit was made with a view to record some of his more peculiar features of dairy management.

1st. Mr. Walker gives his cows through the summer two feeds of grains per day, viz., 17 stones, at 2d. per stone, and 8 stones of Indian meal, at 1s. per stone, costing 25s. per day, 8d. per day. This will explain the large quantity of cheese made per cow per year, and the exceptional richness of the milk, 90 lb. of which yielded 3 lb. 4 oz. of butter. It was remarkable, in the month of July, to see how eagerly the cows left their pastures and returned to their stalls; and Mr. Walker considers that the cheese and butter pay for the food, and leave him a profit in the increased fertility of his pastures.

2d. He, by rearing a large number of female calves, is enabled to draft off his worst milkers, and by putting them late in the season, they milk through the winter and part of the second summer, when they generally fetch high prices for winter milkers; and thus he makes cheese through the winter.

3d. The cows are milked by the men, Mr. Walker and his farm pupil assisting; and the importance of good milking may be illustrated by the fact of Mr. Brown, of Preston, one of the competitors, who thus writes :—

"I give high prices for my cows, I keep them on expensive food, and to hear and see them badly milked is a trouble I cannot bear. So well as my cows did the last year, considering the season, I am satisfied they would have done much more if my milkers had been up to their work. It is my determination to have only those that would go about their work in a way so as to give the cow an appearance of enjoying her meal, rather than hold it back, as she will do to an indifferent milker. Again, I strictly enforce habits of cleanliness, a vessel of clean water and a towel being kept in or near the shippon, in order that each milker should keep his hands perfectly clean. It is the want of proper attention to these matters of detail that is the cause of so much ill-flavoured cheese and butter being sent into the market."

We have no doubt that the milking is better done by males, and in Mr. Walker's case it has the advantage of giving those employed in the dairy extra three hours per day for their work, which they really need.

The milking commences at 5 o'clock, night and morning, and ends from 6.15 to 6.30 o'clock—one of the milkers carrying the milk, with a yoke and swing tins, crossing the farmyard, through the kitchen, and into the cheese-making room, where the night the milk is poured into four milk coolers. These coolers are placed in a trough made of Staffordshire bricks and cement, into which the dairy help has pumped spring water. After remaining in the water for about three-quarters of an hour, having been frequently stirred, the milk is poured into one of the two cheese tubs, such as are known in the district as "Travise's Patent," and for which Messrs. Mellard, of Rugeley, last year obtained a prize at the Oxford Show. These tubs or vats, made of block tin, stand on wooden stages about 10 inches high. One tub is 3 feet 4 inches, and the other 3 feet 1 inch in diameter, and both are 2 feet deep. Each tub has a perforated follower called a sinker; and for putting pressure on the sinker is a wooden frame with a contrivance above, resembling those of the lever cheese presses, but having a much heavier weight—say of 40 or 50 lb. In the front of the tubs are two vents, the one about 6 inches above the other, to each of which a screw plug is fitted, and withdrawn at pleasure to let out the whey. The first milk from the coolers being poured into the tubs or vats, the same coolers are refilled with milk, and replaced in the cooling trough, into which the help has again for about 10 minutes been pumping spring water. The milk, both in the coolers and the vats, gets a frequent stirring until bed-time, to keep the cream from rising.

The household consists of Mr. and Mrs. Walker, a farm pupil, three little children, a cowman, a pigman, waggoner, and two lads; the dairy help, vessel cleaner —who is also housemaid—and the nurse girl, Mrs. Walker acting as dairymaid.

The dairy duties begin in the morning at 5 o'clock—the vessel cleaner or housemaid lighting the cooking-range fire, and the dairy help the vessel-boiler fire. The dairy help is, fortunately, strong, active, and interested in her duties. She is intrusted to skim, scald, and put away "clean" the cans or coolers, a barrel churn being used, and in July about 30 lb. of butter per week was taken, or over half a pound per cow for 50 cows. But some cream is now being taken off the evening's milk, in consequence of the cheese being so rich and tender, for although one of the samples of cheese exhibited at Wolverhampton was commended, and the other highly commended, they were, as stated by the cheese judges, wanting only in firmness.

The morning's milk, when brought from the cows, is poured into the cheese-making tub by the milk carrier, in such proportions as directed by the help when she and the cowman take from the cooling-trough one of the milk-coolers of the evening's milk, and lift it on the side of the vessel-boiler; then both mount the boiler, and gently let down the milk-can into the boiling water, and when it is sufficiently heated they again bring it and pour it into the cheese-making tub; and this process is repeated until the new milk and the old in tub No. 1—for two cheeses—is raised to about 80°, and in No. 2 tub—for one cheese—to about 90°; there being in No. 1 tub double the quantity of milk, for two cheeses, it will retain more heat, so that by the time coagulation has taken place the milk in both will be nearly equal; and no further heat is applied in the process of cheese-making. Were heat applied as in the Cheddar, or slip-scalding process, there would, we apprehend, be no danger of excessive richness in the cheese, and much labour would be saved. When the temperatures already indicated have been obtained, an ordinary-sized teacup twice filled with rennet is put into No. 1 tub, and once filled into No. 2 tub; and a tablespoon twice filled with liquid annatto—prepared by Mr. Hodway, of Tutbury—is put into No. 1 tub, and once into No. 2. The contents have been gently stirred, the tubs are left uncovered; but previous to the stirring, about 2½ lb. of salt is put into No. 1 tub, and half the quantity into the other. This is done instead of salting the curd, and is a new feature; the small quantity of salt put in the milk is accounted for by the cheese being salted under press; and although it will be seen that the cheese are not Leicester cheese, it would not do for thick cheese like Cheddar or Cheshire.

The rennet and colour are added at 6.20 A.M. to No. 1 tub, and at 6.30 A.M. to No. 2; in the first coagulation was complete by 7.20, and in the other by 7.50 A.M., or extra 20 minutes in the second case may be taken as an indication that the smaller quantity of milk had cooled too rapidly, which could be avoided by the use of the steam or hot-water vat.

The mode of preparing the rennet is new, interesting, and cheap. A gallon of the greenest or poorest of the whey is put into a saucepan and gradually heated and skimmed until it has thrown up all the curds. A pint of strong brine is then added, and the whole boiled for 10 minutes and put to cool until, say, 85° temperature, when three dried veils or "bag skins," kept from the previous year's stock, are put into the whey and well rubbed in it. Then the three last bag-skins are taken from the former rennet, distinguished by being tied together, and these six are left in the rennet, which on the second day is fit for use, and serves for about two weeks.

When the men servants had breakfasted, they carried the whey tubs from the whey room to the kitchen, and poured their contents into a cast-iron head, and so the whey passed to the pigs' food-house. Putting the contents of each tub at 112 lb., a man on each side managed it, without much slopping, at ten journeys, the weight of the whey exceeding half a ton.

The rennet and colour having been added as described, breakfast intervened, while coagulation was taking place, up to 7.20 A.M. The help had hitherto acted as dairymaid, leaving Mrs. Walker free for domestic duties, and to scatter her bounty to a numerous and no doubt profitable progeny of poultry.

After breakfast I noted the following course of operations :—

The dairy-help commenced by lifting the presses and turning 18 cheeses, rubbing each on the edges and sides with salt, and pricking or stabbing with a thick skewer on each side of the three cheeses from the previous day, and putting clean dry cloths on them all. Mrs. Walker, at 7.20 A.M., proceeded to break up the curd or custard, with an ordinary tin curd-breaker (save that the handle was placed at an angle of 45° to enable it to be worked under the beam over the cheese tub, which supports the screw and lever, by which pressure is put on the sinker), by passing the breaker up and down, slowly at first, to prevent any loss of curd in the whey. When finishing, the breaker was used more freely. A great improvement on these breakers is the American frame, with a series of sharp thin steel knives, which cuts the tender curd instead of bruising it. When No. 1 tub was finished his part was also slowly let down on the curd to cut it more rapidly than by its own specific gravity. The same process was repeated on No. 2 tub; and at 8.10 A.M. the whey tubs, which had been carried out by the men to the vessel-shed, were brought cleaned by the house-maid. A hair-sieve—with a contrivance for hooking it inside the whey-tubs—was then placed under the vents of No. 1 tub, and the upper plug withdrawn, until the tub was sufficiently filled, so that Mrs. Walker and the help could carry it into the whey-room and pour its contents into larger tubs on the stage, which required considerable strength. When the whey from No. 1 tub had been drawn down to the upper vent, a strong wooden frame was placed on the sinker, and slight pressure applied by the contrivance from above. This done, the same operation was repeated on No. 2 tub. At 8.25 A.M. the frames and sinker from No. 1 tub were removed, and the whey drawn from the lower plug, and then Mrs. Walker and the help, each with a large knife, standing on the wooden stage and leaning on their breasts over the edge of the tub, proceeded first to cut the curd into cubes, and then into slices of from a quarter to half-an-inch thick, in order to set the whey at liberty. At 8.50 A.M. the tubs and sieves were returned, and increased pressure applied; next the curd in No. 2 tub was subjected to like treatment. At 10.20 A.M. No. 1 tub was in like manner cut up, and increased pressure applied; and for the third time at 11.20 A.M. No. 2 was thus treated for the third time at 12 o'clock, both were left to stand until after dinner. Having to stoop under the beam or frame, which passes over the tub, renders the position of the cheese-maker difficult, and, if she be a mother, perilous, as may be inferred from a neighbouring farmer stating that his wife advised him to give a wholesale order for busks, in the event of her many while cutting up the curd. At 2.15 P.M. the frame and sinkers were again removed from tub No. 1, and the curd cut into slices of about 2 inches thick, when the curd-mill, consisting of two wooden barrels or cylinders, thickly studded with wire spikes, was used; and, as the curd was firm and tough, considerable power was needed to turn it. Under the mill was placed a mould or cheese-vat 18 inches over, and about 4 inches deep; over this was spread a clean dry cheese-cloth, and the ends brought up to the sides of the mill to prevent any crumbs from falling, and when the curd from No. 1 tub was ground fine, cloth was folded over the cheese, and it was removed to the lever press. In like manner the curd was ground for the other cheese, and also for the one cheese from No. 2 tub. After remaining under the presses for four days, and turned daily, the cheeses will be removed to the store room, where they are about three weeks old, they will be daily rubbed with the hand and turned over; after this they will be turned alternate days until sold, when about two months old.

As I left before 4 o'clock, I give the following sketch of what remained to be done before bed-time, or 10 o'clock P.M. :—

The three newly-made cheeses had to be thrice taken from under the press and pricked with a skewer, the last time about 9 P.M. Both the cheese-tubs, with the sinker and wooden frame, and also the curd mill, had to be carefully cleansed and scalded; the whey room, cheese-making room, and kitchen floors to be well washed down; some 20 cheese-cloths to be washed and put to dry for morning; water pumped for this, and also to twice fill the milk-cooling trough; the evening's milk to be cooled, stirred, and treated as before described. The copper used for milk vessels had to be well-scalded and cleansed, the whole or part of the upstairs cheese to be turned and rubbed, and to what has already been described must be added the household duties of this weak staff — churning, butter-making, baking, cook-ing, washing, mangling, and a host of domestic duties in a family numbering seven males, four females, and three young children to be fed and cared for. It is not very wonderful that Mrs. Walker, the daughter of a successful and retired dairy-farmer, at one time resolved that she would not be the dairymaid; but the difficulty of getting hired servants to undertake milking was the only difficulty in dairy eventually broke down her resolution, and she now smiles at her work, though this round of duties knows no cessation, for the cheese-making here continues all through the winter. I therefore feel that I cannot better conclude than in the words of Mr. MacAdam in his admirable treatise on "Domestic Dairying :"—

"At present there is heard from many quarters a loud and earnest appeal for sufficient rest and leisure, and fewer hours of labour, and no class has better cause to turn this appeal into a demand than those employed in

cheese-making. It is no uncommon thing to find them engaged from 5 o'clock in the morning till after 8 at night, in milking, making, and turning cheese, or cleaning the dairy and utensils; and this Egyptian bondage is seldom lightened by the repose and sanctity of the Sabbath, for the thoughtlessness, or prejudice, of landlords and farmers, or a false motive of economy, often compel them to continue their drudgery on that day. Surely such a state of affairs is worse than a want of profit, and far more reprehensible than a lack of success. Must these have no leisure, no recreation, no culture, nothing save the protracted hours of labour and a stinted allowance of rest? Must all their energies of mind and body be directed to the accomplishment of such tasks as selfishness or apathy is pleased to impose, and which circumstances compel them to perform?"

When Mr. MacAdam penned the above, he was an advocate for "Domestic Dairying." He and his sons are now managing several American cheese factories, and he advocates their adoption in England with still greater prospects of success.

The Week's Work.

DECEMBER 16.—*Water Meadows*, in southern counties at low levels, attend to as in November, making due allowance for a fall of temperature; not unfrequently the close of this month is as good for watering as the close of the last, but generally the earth and atmosphere both become colder. In the North, frost and snow more frequently interfere with the operations. The thermometer requires close watching, even in open weather, and should a slight frost overtake, the opening of the sluices a little more, so as to supply an extra flow of water, may carry the waterman through, when otherwise his labours would be locked up in ice. Much depends upon the natural temperature of the water, and the land being irrigated, and the mode of irrigation. The temperature of the former (the water) will be influenced by that of the land over which, or through which, it flows in the carriers. With regard to the actual temperatures of the water and meadow, these should always be ascertained by a wet-bulb thermometer.

Irrigation Works.—This is a favourable time for execution of such, most rivers being sufficiently high to determine practically "the influx and efflux levels," *alias* "feed and tail levels;" springs are likewise open, and past experience ought to teach both landlord and tenant the propriety, not only of laying out works for immediate use, but for storing water for summer use, if it cannot be got direct from springs or rivers, for applying more especially to grass land, whether lying in permanent meadow or under alternate husbandry. No doubt strong prejudices still exist to the irrigation of land only lying one, two, or three years in grass, but such prejudices are based upon a bygone experience, for the thorough underdrainage and subsoiling of land, with the liberal use of artificial manures, have removed the practical objections of the olden time. Water can be successfully applied to corn and green crops of every kind, including Turnips and Potatoes, as well as to grass, during the early period of their growth in spring and summer; but the water must be brought to the land before it can be so applied, and an effort should be made at this season to provide the supply for next summer, when pipes and other underground modes of conveyance can be laid down without interfering with growing crops. As to the immediate application of the water to grass lands, the water levels and surface of the land will determine the nature of the work. When the water can be applied to a plain sloping surface of permanent meadow or pasture either on the right-or-left-hand or catch-water plan, at 1*l.* or so per acre, the gutters from the underground mains being opened by a plough, the rule is plain.

Warping, natural and artificial, should be carried out at this season, and the latter (artificial warping) to a much greater extent than has yet been done. A large area of poor peaty soil in North Lincolnshire and the West Riding of Yorkshire adjoining, has been successfully warped, and the whole of the Fen country and bogs of Ireland may be so warped in the same way. And besides fen and peat-bog there are immense tracts of sandy, gravelly, and chalky soil, capable of being warped at this season, when there is a command of water almost everywhere for the conveyance of the warp. As to the quality of the warp, it is not necessary that it should be "Nile mud," or Humber mud, or anything chemically like either. "Lay clay on sand and you buy land," is an old proverb, and the fertilising effects of clay is as well known on some Irish bogs as in the Bedford Level. And nothing would be more thankful for clay warp than poor chalky soils.

Chalking, Marling, &c., are sometimes done wholly by manual labour, as claying is done in the Fen country. Thus in places where chalk is covered with a few feet of drifted clay, parallel trenches are opened, and the chalk dug out and spread between the trenches. In other cases the chalk is drifted into large beds and covered with a subsequent layer of drifted clay. In this case, also, the chalk may in many places be dug up and spread by manual labour; but in examples of drifted chalk it is more common to open pits, and apply the chalk by carting. Marl, shell sand, and green sand are applied in the same way, not only to clayey soils, but to all soils differing in character from themselves. When applied to peaty or fen soils, clay and sand should be mixed with the chalk and marl, or applied separately. Pure sand, applied to peat earth, will greatly sharpen and improve its quality in growing corn-straw and roots.

Carting in frosty weather is an old rule, and where the ploughing is done by steam, and the strength of teams reduced to what is required for constant carting, the work should be kept well in advance, the road work being done in open weather, and the field work in frosty, and also in dry weather when the land will carry. Carting by steam has become an exceptional practice, but from the importance of getting the carting expeditiously done, it will no doubt with the progress of things very soon become the rule, and horse-carting the exception; or the two may be so combined that the bulk of the heavy work will be done by the former, leaving only the light work and the minor details of the heavy work for the latter.

Notices to Correspondents.

CLOVER: *W. H.* The best manure you can give it, under the circumstances, is either bone dust (10 bush. per acre, rotted in sand), or superphosphate of lime (3 cwt. per acre), 60 bush. of hot lime, made into a compost, and well slacked, with a lot of mould, roadside turf, &c., would be a good dressing per acre. Or, if you can get old gas-lime, and make a compost with it and similar stuff, you might put on 40 or 50 bush. per acre of it with advantage; only you must take care that the compost is turned over several times, so that its mischievous causticity is taken out of it.

Markets.

SEED MARKET.

As usual about Christmas our markets are just now very quiet, very few people caring to go into stock towards the close of the year. Values of all descriptions are, nevertheless, exceedingly firm, and a good business is anticipated early in January. Yearling parcels of homegrown Clovers are held for long prices. Alsike and white Clover show no alteration. The same can be said of Trefoil seed. Foreign Italian continues to advance in price. For feeding Linseed we have an improved demand. Hemp and Canary seed show off steadily, at late rates. Blue Peas are in slow request. Mustard and Rape are quiet. Sainfoin now meets with some attention.

JOHN SHAW & SONS, Seed Merchants,
37, Mark Lane, London, E.C.

MARK LANE.

MONDAY, Dec. 11.

The supply of English Wheat to this morning's market was small, and the trade steady at the prices of this day se'nnight. There was the usual attendance, and the few sales of foreign Wheat were of Russian and American, at late rates. Barley was very difficult of sale and rather easier. Beans were cheaper. Peas unchanged in value. Oats brought an advance of 6*d.* per qr. upon the prices of this day week. Maize was unchanged in value. Flour sold slowly at late rates.

WEDNESDAY, Dec. 13.

There were limited supplies of English Wheat on offer here to-day, and from abroad the arrivals were only moderate. Transactions in all descriptions were restricted, and some difficulty was experienced in realising Monday's currencies. Fine Barley was unaltered, but other qualities were easier to purchase. Malt sold slowly on former terms. The show of Oats was large. The demand was not animated, but prices were maintained. Beans and Peas were dull, and drooping in value. Flour met with a quiet sale, at about late rates.

METROPOLITAN CATTLE MARKET.

MONDAY, Dec. 11.

This being the annual "Great Market," the supply of Beasts is larger than on ordinary occasions, and about the same as on the corresponding day last year. The trade is not very brisk, yet choicest qualities make a high price. Some of the best Scots have reached 6*s.* 4*d.* per stone; the general quality is very good, yet there are not so many of the largest descriptions as we have sometimes seen. The restrictions on the removal of cattle have greatly interfered with the trade. Butchers living beyond the metropolitan district were loudly complaining that they could not purchase the animals they so much needed. The number of Sheep is not large, but enough for the demand, this being a day on which but little attention is paid to this department. Trade is dull, and late prices are with difficulty realised. Choice Calves are still scarce and dear. Our foreign supply consists of 970 Beasts, 6030 Sheep, 15 Calves, and 10 Pigs; from Scotland there are 1190 Beasts; from Ireland, 1000; from Norfolk and Suffolk, 600; from Western Counties, 380; and 2180 from the Midland and Home Counties.

			Pigs ..	..	3 4—5 4

THURSDAY, Dec. 14.

The number of Beasts is not excessive for the day, but the change of weather and large supplies at the dead market have caused a depression in the trade; prices on the average are lower, and a clearance cannot be effected. We have but a few Sheep on offer, but quite sufficient for the demand, which, for reasons stated above, is very limited. Calves are scarce, and consequently very dear. Our foreign supply consists of 330 Beasts, and 1150 Sheep.

JOSHUA BAKER.

ENGLISH WOOL.

There has been a good demand for English wool during the last week, and an almost general advance has been realised. Buyers begin to see that there is no chance of manufactured goods going cheaper, and consequently place their orders more freely.

HOPS.

BOROUGH MARKET, Dec. 14.

Messrs. Pattenden & Smith report that there is rather more inquiry for all descriptions of Hops, prices being very firm. The Continental markets, like our own, are almost cleared of Hops, and the tendency is upwards.

Rose Lane Works, Norwich.

COTTAM'S PATENT PORTABLE UNITED COW FITTINGS

Their advantages are—Portability, not fixtures, removable at pleasure; no Wood-work or Partitions to impede Ventilation or breed Vermin; Hay Rick dispensed with as unnecessary; increased width and depth of Feeding Troughs, Water Cistern, and Patent Drop Cover to prevent over-grazing. Cleanly, durable, and impervious to infection, being all of iron. Price of Fittings per Cow, £5s.

Prospectuses free of COTTAM AND CO., Iron Works, 9, Winsley Street (opposite the Pantheon), Oxford Street, London, W., where the above are exhibited, together with several important Improvements in Stable Fittings just secured by Patent.

The Royal Pottery, Weston-super-Mare.

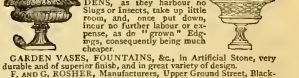
UNDER ROYAL PATRONAGE.

JOHN MATTHEWS (late C. PHILLIPS), Manufacturer of TERRA COTTA VASES, FOUNTAINS, ITALIAN BASKETS, RUSTIC FLORAL ARBORETTES, STATUARY, GARDEN POTS (from 4s. to 50 inches in diameter), of superior quality, withstand frost, and do not become green; EDGING TILES, &c. See specimens in the Royal Horticultural Gardens. Price List free Book of Drawings, 6d. each.

JOHN MATTHEWS, Royal Pottery, Weston-super-Mare.

Rosher's Garden Edging Tiles.

THE above and many other PATTERNS are made in materials of great durability. The plainer sorts are especially suited for KITCHEN GARDENS, as they harbour no bugs or insects, take up little room, and, once put down, incur no further labour or expense. They are of perfect edges, consequently being much cheaper.



GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, very durable and of superior finish, and in great variety of designs.

F. AND G. ROSHER, Manufacturers, Upper Ground Street, Blackfriars, S.E.; Queen's Road West, Chelsea, S.W.; Kingsland Road, E. Agents for LOVEGROVE'S PATENT ACME FRAME, PLANT COVERS and PROPAGATING BOXES; also for FOXLEY'S PATENT READY-MADE GARDEN WALL BRICKS.

Illustrated Price Lists free by post. The Trade supplied.

ORNAMENTAL PAVING TILES for Conservatories, Halls, Corridors, Balconies, &c., from 3s. per square yard upwards. Perfect fac-similes of ancient and more modern designs, with prices, sent for selection.

WHITE GLAZED TILES, for Lining Walls of Dairies, Larders, Kitchen Ranges, Baths, &c. Grooved and other Stable Paving of great durability. Wall Copings, Drain Pipes and Tiles of all kinds, Roofing Tiles in great variety, Slates, Cements, &c.

F. AND G. ROSHER, Brick and Tile Merchants.—See addresses above.

SILVER SAND, fine or coarse grain as desired. Fine 14s., Coarse 13s. per Ton. In Truck Loads 1s. per Ton less. Delivery by Cart within three miles, or to any London Railway or Wharf, 2s. per Ton extra. Samples of Sand free by post.

FLINTS and BRICK BURRS for Rockeries or Pineries. KENT PEAT or LOAM supplied at lowest rates in any quantities.

F. AND G. ROSHER.—Addresses see above.

N.B. Orders promptly executed by Rail or to Wharves. A liberal discount to the Trade.

GEORGE JACKMAN & SON,

THE "WOKING" NURSERIES, SURREY,

ESTABLISHED UPWARDS of **60** YEARS, and NOW OCCUPYING an AREA of **180** ACRES,

Respectfully call the attention of all who are interested in Planting to the resources of this Establishment.

Their DESCRIPTIVE PRICED NURSERY CATALOGUE of frequently TRANSPLANTED STOCK, can be had Free by Post on application, with Plan (Home portion) of Nursery.

Standard Fruit Trees.

For the Orchard:—Pyramid, Dwarf Maiden, Cutback, and Trained Fruit Trees. For the Garden:—Embracing all the finest and popular varieties of Apple, Pear, Plum, Cherry, Peach, Nectarine, Apricot, &c.

Miscellaneous Fruits.

Almonds, Chestnuts, Walnuts, Figs, Cobnuts, Currants, Gooseberries, Strawberries, Medlars, &c.

Standard and Dwarf Roses,

Of all the best new and old varieties of Provence, Moss, Hybrid Perpetual, Bourbon, Noisette, China, Tea, Climbing Roses, &c.

Climbing and Trailing Shrubs

(Including the Clematis).—Well adapted for covering Verandahs, Pillars, Festoons, Walls, Porticos, Trelliswork, &c.

Forest Trees (for Covert and Coppice Planting)—All carefully transplanted, free grown, and good rooted.

American Plants,

Including the Andromeda, Azalea, Erica, Kalmia, and Menziesia; also Rhododendrons of the best scarlets, whites, and other choice varieties, &c.

Hardy and Rare Conifers

(For Lawn and Pleasure Ground)—which embrace most of the fine hardy species and varieties in cultivation.

Ornamental Deciduous Trees

(For Park and General Planting)—including Trees with either remarkable growth or foliage, such as weeping, cut-leaved, or purple, variegated, &c.

Evergreen Trees and Shrubs

(Suitable for Clumps, Belts, Screens, &c.)—containing a choice collection of all shades of foliage.

N.B.—G. J. & SON, knowing that Nursery credited accounts are generally very long, compared with many other businesses, have, after due consideration, decided to offer advantageous cash terms (see cover of Catalogue). This old-established Firm being large Wholesale Growers, the Public (favouring them with orders) will also derive the benefit of obtaining their goods direct from the producers.

WOKING NURSERY, SURREY.

The Gardeners' Chronicle

SATURDAY, DECEMBER 23, 1871.

AS we write these lines, cartloads of Holly are passing our windows, Mistleto pours into our great metropolitan market by the ton, and Spruce Firs, in quantities sufficient to form a veritable Wood of Birnam, are carried by our doors. Away in the country shrubberies have been ruthlessly despoiled of their stores, the orchards of Somerset and Worcester, of Normandy and Brittany have yielded their stores of mystic Mistleto, and nimble fingers are gaily stitching and hooking and nailing the leafy devices which are to quicken our thankfulness, gladden our hearts, and testify that even in the gloomiest of midwinters hope and joy and good fellowship are to be found among us.

If we remember that there is nothing in the spelling of the words "holiday," and "holyday," to justify our pronouncing the former as if it were spelt holliday, and that this pronunciation is solely determined by custom, it will not be difficult to believe that what we now call the HOLLY TREE was by the earlier writers upon plants spoken of as the "Holy tree." But if we go back to the Saxon, we find "Holegn" is the Holly tree, while "halig" is holy. In Anglo-Saxon times, too, the Holly was, according to Dr. PRIOR, called "elebeam," or oil-tree, from its branches having been used for Olive branches and strewed before th Cemage of JESUS, in certain solemnities of the church that represented His entry to Jerusalem. It is indeed likely the fruiting branches of the tree have long been in use for religious festivals amongst many northern nations in Europe, since we find it called Christmas in England, Christdoan by the Germans, and Christoon by the Swedes and Danes. Doubtless its "thorny leaves, and berries like crimson drops," have been regarded by Christians in all times as symbolical of an event which they thankfully keep in remembrance.

We all know how extensively the branches of this tree are used for decoration at this season, both in houses and churches, both with berries and without berries, although there is no Scriptural authority or warrant for its use, since none of the kinds grow in Western Asia, and it is not one of the trees mentioned in the Bible. It is this extensive use of Holly that leads us to think that some account of its culture for decorative uses might be acceptable at this season.

In some parts of England Holly occurs in great abundance, and increases from seed; but in nurseries it is found a saving of time to strike cuttings of the ripened wood under glass in some sheltered situation, while the rarer sorts are usually grafted upon the common Holly. Seeds, that is, the berries, may be sown in October, and covered with about an inch of soil, but none of them begin to vegetate until 15 months afterwards, while some will remain dormant for more than three years.

Owing to this uncertainty about their germination, we cannot recommend raising plants from seed to those who have not a surplusage of land and labour to spare, to say nothing of the risks of loss by frost, if the seedlings should unfortunately be left unprotected. Besides, it cannot be worth while for any amateur to incur all this trouble and risk when he can buy seedlings 9 inches high for 50s. per 1000.

It next becomes a question, what sized plants it would be most economical in the end to buy. Our recommendation is to purchase Hollies about 3 feet high, which can be had in parcels of 50 at the rate of about 75s. per 100.

These should be planted 5 feet apart in rows 5 feet from each other, and the first plant of the second row should be put in 2½ feet from the end of the row, so that trees shall all have as much room and air as possible.

The plants should be obtained from some respectable nurseryman who is a large grower, for it is important to the speedy well-doing of the young trees that they should have been transplanted several times before they find their way into the purchaser's hands. Bushy plants should be selected, since good crops of leaves and berries are the main requirements.

The soil in which Hollies grow best is a deep sandy loam. They will grow in almost any soil that is well drained; but they have a decided objection to a wet subsoil, or to any situation where their roots are constantly damp. It cannot fail to have been noticed that the Holly trees on the top of the hedge-banks by the sides of roads have usually finer crops of berries than the trees in plantations or woods; and this fact indicates that a plantation of Hollies should be made upon a raised bank or an incline, and that a deep ditch or drain should run between the rows, if the soil should be at all retentive of moisture.

The time for planting is in April, when mild, open weather should be selected; or, better still, the middle of October, as there is perhaps less to fear from November frosts than from May sunshine, though protection from either extreme of temperature, and particularly from cold, dry winds, is imperatively necessary.

Cutting the branches for decorative purposes is not a matter which it is prudent to trust to the man who chances to have the sharpest knife or the thickest-skinned fingers. Much judgment and discretion are required, for upon the ability or ignorance exhibited depend to a great extent the future "crops." No branches ought to be cut from a young tree until it has been planted a year. Supposing there are 100 young trees from which a few branches might safely be cut, it will be better in the end to cut from the 25 strongest plants, and then leave them untouched for four years. By thus cutting at only 25 in each year, although more is taken out of each tree, the trees have a longer time to recover the pruning, and ultimately keep up a succession of berries, since by more frequent pruning the trees would be less to be depended upon for a regular crop. No doubt hard pruning had a tendency to make a tree produce a heavy crop of fruit; but this is an abnormal condition of affairs, which is by no means to be recommended, for although it might give a quantity of berries one year, there would probably be none the following Christmas.

Grafting and budding must not be forgotten, as it is by these means that the variegated kinds of Hollies are cultivated, the common green kind being the stock preferred. From the middle of July to the middle of August is the best season, care being taken to choose wet or damp weather for the operation, and to shade young buds from the sun, if the weather becomes hot and fine.

As, however, this sort of work requires an amount of practice and patience which amateurs might deem expensive if purchased by experience, we should not be surprised to find that many will prefer buying the variegated sorts ready grafted, since nice young plants can be had from 15s. to 40s. per dozen of all the best varieties.

We began this article with an allusion to the suggestive or sentimental uses of Holly. We passed on to a question of philology, quickly diverged into the regions of practical gardening; suppose, by way of wishing our readers a Happy Christmas, we conclude by singing them a verse or two of an old carol—here it is:—

Here comes Holly, that is so great,
To please all men is his intent.
Allelujah!

Whosoever against Holly do cry,
In a loop shall be hung full high.
Allelujah!

Whosoever against Holly do sing,
He may weep, and his hands wring.
Allelujah!

IT is often said of a certain personage, who shall be nameless, that he is not so black as he is painted; and, though we have had of late but too painful reminders of the wickedness and imperfection of human nature, there has been one redeeming feature amid all the horrors and miseries of which we have been the unwilling witnesses, and that feature is SYMPATHY—human sympathy. We all know the world is bad enough—most of us can at least see the faults of our neighbours—but we are tempted to ask, is human nature really so bad as it is sometimes stated to be? GOD knows there is no cause for vainglorious boasting or pharisaical self-complacency, but we may fairly, as a nation, feel that we did what we could to assuage the miseries of our neighbours across the Straits of Dover in the time of their direst need. When Chicago, all but burnt to the ground, but still undaunted, set to work to repair her losses with a degree of pluck that commanded the admiration of the British heart, our sympathy was not limited to words. Science has done for us, in fact, what ARIEL only hinted at in words empty as "airy nothings," and no more noble service has been done by the wire at the bottom of the Atlantic than that which conveyed from our shores the message of practical sympathy. Still more recently, in a case where no actual outlay has been required from us, there has been a genuine outburst of human sympathy, more valuable by far than many a costly offering, more valuable as indicative, in these oft-decried days of selfishness and hardness, of a real store of charity unsuspected by the GRADGRINDS and MAWWORMS of the world we live in. We look on these facts as valuable evidences of the intrinsic sound-heartedness of our fellow citizens. Appeal to their sympathies in a good cause, and see how ready and cheerful is the response. Cast but the shadow of a doubt as to the goodness of the cause, however, and all the commercial instinct and business prudence returns, and for the time substitutes the implacable columns of the ledger for the nobler impulses of the heart. Thus has it been to a great extent with the FRENCH HORTICULTURISTS' RELIEF FUND Started at a time when all Europe was ringing with the distress and miseries of the French in the invaded districts, the fund in question was fairly set going by and amongst our own horticulturists. Some five hundred pounds were subscribed, and then came the Commune. It is needless to dwell on its horrors; suffice it to say that the effect was to put an instant stop to the flow of charity. It was not quite logical to make the unoffending gardeners of Paris responsible for the frightful catastrophe that ensued; but now that that has passed, it may not be amiss to call attention to the subject once more, and to make public certain facts which have just come to our knowledge. The French Relief Commission, with which our own Committee has been in communication, have drawn up a list of the estimated losses sustained by the gardeners around Paris, detailing only those on whom the loss has fallen heaviest, and omitting altogether those who, from the possession of larger capital or other circumstances, were considered only less fitted to be recorded in such a list. The case stands thus:—In 20 districts or communes in the department of the Seine, *i.e.*, in the neighbourhood of Paris, 535 nurserymen are enumerated as worthy to be helped, from the extent of their losses or the poverty of their resources. In the commune of Montreuil 354 nurserymen are estimated to have lost by the destruction of their premises an amount equal to 238,338 f., and by the loss of their plants 151,667 f. In the district of Vitry the losses incurred by 123 gardeners and small nurserymen are estimated at 1,444,714 f. 30 c.

The sum total of this loss is estimated at 2,626,330 f., and (let us be precise) 52 centimes—equal in round numbers to upwards of £100,000.

Now, the sum to be set against this as our contribution towards our fellow horticulturists is

13,500 £ (£540), there or thereabouts. Surely it is sufficient to put the two sums in juxtaposition to awaken once more the slumbering sympathy of British horticulturists, and induce them, ere the subscription list is finally closed, to render the disparity a little less striking. We may also here state that we have been requested to ask that all subscriptions not yet paid, and all monies received by nurserymen or others for the fund, be paid in at once to the Treasurer, G. F. WILSON, Esq., Weybridge Heath; or to the Secretary, Rev. H. J. DOMBRAIN, Westwell, Ashford, Kent.

At home, fortunately, we have no tale of distress of such magnitude, but the list of candidates for the Gardeners' Royal Benevolent Institution, as well as other cases—one of which is mentioned in a communication in another column—are sufficient to show that there is enough for each and all of us to do in the matter of human sympathy and help for our fellows. We may surely ask those who have the social welfare of their *employés* at heart, to bestow some consideration on the social evils of which the best and most honourable among our gardeners complain, in the matter of scanty wages, long hours, inadequate house accommodation, and that horrible announcement in our advertisement columns, summed up in the two words, "no encumbrance." Our Christmas will be none the less merry, and our New Year none the less happy, if we each and all in our several degrees, and according to our several means, endeavour, in a practical, demonstrable, but not self-laudatory manner, to love our neighbours as ourselves.

—— On Saturday last an adjourned PUBLIC MEETING of the MARKET GARDENERS, NURSERYMEN, and FARMERS' ASSOCIATION, which was invited the shop-keepers, salesmen, and other persons renting stands or premises in Covent Garden, was held at the Bedford Head Hotel, Covent Garden, for the purpose of further discussing the great necessity of a roof being constructed over the uncovered area of the market. Mr. H. MYERS, who occupied the chair, stated the object of the meeting, and said they would be very pleased to hear any remarks or suggestions upon the subject. He had every reason to hope that the question would meet with a favourable reception at the Bedford Office, and although he had now been 40 years endeavouring to obtain this much-wanted protection, he did not despair. The principal objection raised by the shop-keepers was that the market gardeners would turn higglers, and stay late in the day to retail their goods to the public; but he believed if they would consent to an extra toll if they sold after a certain hour, that objection would be overcome. Mr. POCOCK called attention to the statement that the place would be unbearable for habitation if wholly covered in, and that currents of air were absolutely necessary for their health. One of the shop-keepers complained that they would have to inhale the noxious breath of the costermongers if the present arrangements were covered in. The Chairman said he believed another obstacle was, that the amount provided by the Act of 1828 for the covering was not considered sufficient to make a reasonable return. Several of the growers present objected to the proposed extra extra toll, as very often the morning-gathered Strawberries did not arrive until late, and others objected to it upon principle; but it was generally acknowledged that the present over-crowded state of the market could not long continue, as on a full market the growers' carts and waggons filled all the surrounding streets, toll being taken from them as if they were in the market; while a great portion of the available space was appropriated to the retailing of foreign produce. Mr. CLARKE said the market gardeners should follow the example of the flower growers, and purchase a market for themselves, and drew the attention of the meeting to the proposed new market in Leicester Square, and Newport Market, which offered a fine site, as shown on the plans. Mr. LOBJOIT moved that the memorial for the covering of the open parts of Covent Garden be presented to His Grace the Duke of BEDFORD, and said that although he was willing to make any reasonable concession, he could not agree to the proposed extra toll, as he could not see how it could be collected; if all present were to agree to it, others not present might disagree to it, and an Act of Parliament would have to be obtained. As to the statement which Mr. POCOCK had called their attention to, he believed the Act never intended that Covent Garden should be occupied by dwelling-houses, at least, not to the prejudice of those for whom it was originally granted, viz., the growers. In reference to the price fixed by the Act, he thought if 3*d.* per foot was considered sufficient 43 years ago, surely it was enough now, with our economical roofs of iron and glass. He was sorry the shopkeepers had not accepted their repeated invitations to the public meetings, as he felt sure a little friendly discussion would soon dispel all their fears as to the injurious effect of the coverings, and he hoped all present would, like their worthy Chairman, persevere in their efforts to obtain the long-sought protection. The resolution having been carried, a vote of thanks to the Chairman closed the proceedings.

—— The Council of the Royal Agricultural and Botanical Society of Ghent has issued a notice that it intends to hold, in the end of March, 1873, its usual quinquennial INTERNATIONAL HORTICULTURAL EXHIBITION. The programme of this exhibition will appear early in 1872, and it is presumed that the display will exceed in magnitude and importance that of 1868. M. DE CHELLINCK DE WAELS is President, and C. CHARLES LEIRENS, Secretary.

—— We learn that the opening of the PROVINCIAL SHOW of the ROYAL HORTICULTURAL SOCIETY, at Birmingham, has been fixed to take place on Tuesday, June 25. The show will close on Saturday, June 29.

—— We hear officially from MANCHESTER that the Botanical and Horticultural Society of that city, which has been for some time past in correspondence with some of the leading exhibitors, with the view of establishing there MONTHLY FLORAL and HORTICULTURAL MEETINGS similar to those held fortnightly at South Kensington, has determined upon holding six such meetings in the ensuing year, on the following Tuesdays, January 16, February 13, March 19, April 9, September 10, October 8, and November 19. The Annual National Horticultural Show, under the auspices of this Society, will be held in May, from the 18th to the 23d; the Rose and Fruit Show on July 5 and 6. The monthly meetings are to be held in the Botanical Gardens of the city, and it is intended that First-class and Second-class Certificates and Commendations shall be awarded according to merit, by a competent committee, to the novelties which may be exhibited on these occasions.

—— We are requested to state that the JOURNAL of BOTANY, lately under the Editorship of Dr. SEEMANN with the assistance of Mr. BAKER and Dr. TRIMEN, will in future be published under the direction of the latter gentleman.

—— In an early number we propose to give a Table of the DATES FIXED FOR EXHIBITIONS throughout the country, when these are sent to us officially, or are announced in our advertising columns. The Secretaries of Horticultural Societies and others concerned in the management of flower shows, are requested to afford us early information on this point. The Table will be repeated monthly for the convenience of persons requiring to consult it.

—— Last year the French journals called public attention to a DISEASE in AUCUBAS, which attacked the leaves, and destroyed them wholly or partially. The removal of the affected parts appeared to be an efficient remedy, as the plants pushed forth new leaves, but unfortunately, such has not proved to be the case, since the disease has again appeared this year in a form which has proved fatal to the plants. When attacked, the leaves show black spots and droop, the roots become rotten or ulcerated, and the pith blackened. Neither a cause nor remedy for this disease has been suggested.

—— The MAXIMUM TEMPERATURES of the AIR during the week ending December 16 ranged from 50°.9 at Hawick and 50°.5 at Paisley, with a mean from the several English stations of 48°.4, and for the Scottish of 47°.5. The MINIMUM TEMPERATURES of the AIR ranged from 35°.5 at Sheffield to 23° at Norwich, the mean for the places in England being 29°.4, and for those in Scotland 29°.7. Thus it will be seen that the days have been warmer and the nights colder in the southern country than in the northern during the past week. The highest MEAN TEMPERATURE, 44°, occurred at Bradford, and the lowest, 33°.1, at Paisley. The mean for the English stations was 40°.3, and for the Scottish 39°.5. The variation in temperature that set in on the 9th continued steadily till the end of the week. The mean daily temperatures passed above the average on the 13th, and have continued in excess since that day. The remarkable cold wave that preceded this rise had fallen from November 30, and reached its minimum on December 8, with a mean daily value of 22°.4. RAIN fell at all stations on one or more days during the past week, the fall being much greater at the Scottish stations than at the English. The maximum fall, 2.05 inches, occurred at Greenock. The mean for the English stations was 0.24 inch, and for the Scottish 0.81 inch. (See Mr. GLAISHER'S Tables, p. 1655.)

—— The colonists of New South Wales find a substitute for our Christmas Holly in the CERATOPETALUM GUMMIFERUM, which is named by them Christmas Tree. It is a very elegant tree, with a profusion of delicate branches, and attains a height of from 15 to 30 feet. Dr. BENNETT says, that in November it is covered with minute white blossoms, which, in the following month (about Christmas Day), assume a red colour, as if the flower had changed suddenly from white to red: most persons consider this appropriate to the time of year, and as ushering in the festive season. The change of colour is caused by the disappearance of the white corollas, while the persistent calyces remain, thus imparting to the tree the appearance of colour, which lasts until the end of February. It formerly grew in the vicinity of Sydney in abundance; but, owing to persons at Christmas cutting down entire trees, the owners of the land stopped the destruction. By enclosing and carefully tending those remaining, they have succeeded in preserving it. It is a common greenhouse plant here.

—— In Mr. BAKER's paper, at p. 1516, on the FRUIT of YUCCAS, it is inferred that HESPERALOE YUCCÆFOLIA had not been introduced into this country. This we now learn is an error, a young plant having been sent to Kew by Professor ASA GRAY.

—— The volume of the *Botanical Magazine* for the current year is dedicated by its Editor, Dr. HOOKER, to Mr. I. ANDERSON-HENRY. A gentleman more deserving such recognition it would be hard to find, as there are very few who have been the means of introducing more valuable plants, and still fewer who take up horticulture in a scientific spirit, increasing its bounds and its resources by carefully devised and well conducted experiments.

—— Professor BALFOUR has recently published, in the *Transactions of the Botanical Society of Edinburgh*, an account of a species of HIERACIUM, which alters its character entirely at different seasons of the year. In June the plant presents itself in two small-flowered forms, one with, the other without offshoots or stolons. Many of these stolons produce flower-heads in August, such flowers being considerably larger than those produced on the primary stem in June. Others of the stolons remain in their rosettes, and root-emitting independent plants. Some of these latter produce one or two large flower-heads in October and November; others do not produce flowers till the succeeding year, when they flower like the June form. The species referred to is considered to be *H. stoloniflorum*, but whatever it may be it affords an excellent example of variation in habit of the same individual species, apparently not dependent on the action of external conditions, and so far confirms what was stated at p. 1481.

—— A good instance of an ARMORIAL BEARING originating in a play upon the name of the family who bore it, may be found in the case of the family MALHERBE, of DEVONSHIRE, who bore three nettle-leaves proper. GWILLIM, in his *Display of Heraldrie*, figures this coat of arms, and says, "The Nettle is of so touchie nature toward a nature that no man may meddle with it, as many testy-natured people are. One writes that a little girle being stung by a Nettle, in her father's garden, complained to him that there was such a curst berbe in his garden, as that it was worse than a dogge, for it would bite them of their owne house. The father answered her, that it was the nature of it to be impartiall, and friend or foe were all alike to it. Yet this propertie it hath, that the harder you presse it, the lesse it will sting."

—— We extract the following passage relating to DR. MAYER's researches on the EFFECTS OF HEAT ON PLANTS, from an article of Prof. TYNDALL's in a recent number of *Nature*. Dr. MAYER, it may be remarked, recently received the Copley Medal from the Royal Society for his researches:—

"Having thus with a firm step passed through the powers of inorganic chemistry (Dr. MAYER's) next object is to bring his principles to bear upon the phenomena of vegetable and animal life. Wood and coal can burn; whence come their heat, and the work producible by that heat? From the immeasurable reservoir of the sun. Before this idea proposed to herself the task of storing up the light which streams earthward from the sun, and of casting into a permanent form the most fugitive of all powers. To this end she has overspread the earth with organisms which, while living, take in the solar light, and by its consumption generate forces of another kind. These organisms are plants. The vegetable world, indeed, constitutes the instrument whereby the mechanism of the sun is changed into the rigid form of chemical tension, and thus prepared for future use. With this provision, as shall subsequently be shown, the existence of the human race itself is inseparably connected. It is to be observed that MAYER's utterances are far from being anticipated by vague statements regarding the 'stimulus' of light, or regarding coal as 'bottled sunlight.' He first saw the full meaning of DAVY and LIEBIG's researches, and discovering power of the solar rays, and gave that observation its proper place in the doctrine of conservation. In the leaves of a tree, the carbon and oxygen of carbonic acid, and the hydrogen and oxygen of water, are first sundered at the expense of the sun, and the amount of power thus sacrificed is accurately restored by the combustion of the tree. The heat and work potential in our coal strata are in much stronger withdrawn from the sun at former ages. MAYER lays the axe to the root of many notions regarding the vital force which were prevalent when he wrote. With the plain fact before us that plants cannot perform the work of production, or generate chemical tensions, in the absence of the solar rays, it is, he contends, incredible that these tensions should be caused by the mystic play of the vital force. Such an hypothesis would cut off all inquiry, and leave the land to a host of unverified phantasy. 'I count,' he says, 'therefore, upon assent when I state as an axiomatic truth, that during vital processes the conversion only and never the creation of matter or force occurs.'

"Having cleared his way through the vegetable world, as he had previously done through inorganic nature, MAYER passes on to the other organic kingdom. The physical forces collected by plants become the property of animals. Animals consume vegetables, and cause them

to reunite with the atmospheric oxygen. Animal heat is thus produced, and not only animal heat but animal motion."

New Garden Plants.

CYPRIPEDIUM ASHBURTONIÆ, *hybr. nov.* (*Cypripedium barbatum* × *insigne.*)

Foliis ligulatis apice bidentatis haud ita conspicue obscure reticulatis; pedunculo pilosulo, bractea carinata acuta ovario pilosulo duplo brevior; sepalo dorsali magno cuneato ovato acuto, crassinervi reticulato; sepalo inferiori oblongo acuto ovarium non aequante; tepalis ligulatis obtuse acutis margine hinc undulatis hinc brevibus et raris pilis elongatis ciliatis, basi pilosulis, calcei ungue bene implicito in processum triangulum obtusum utrinque exeunte; canali aperto, sacco pandurato conico, labello bene developato paulo emarginato, utrinque extus acutangulo, staminodio semirotundo, basi bifido emarginato, antice forcipato, deute in medio abbreviato, superficie pilosulo.

The leaves are ligulate, with two teeth at the apex, of a very dark green, with some indications of dark netting (not represented in the engraving), a span long, between 1 and 2 inches broad. The peduncle is hairy, deeply violaceous or purplish (like the juice of the fruits of Sambucus nigra, the common Elder). The bract is greenish, with a violaceous base, and with five similar nerves, oblong, subacute, carinate on the back, half as long as the atrovioleaceous hairy ovary. The dorsal sepal is cuneate-oblong, acute, ciliate at the borders, puberulous outside, with numerous dark purplish nerves, becoming white and one-coloured over the whole upper part, with many purplish blotches on the nerves toward the inferior part; the numerous ascending transverse reticulations of the nerves are greenish; and there is a narrow purplish tint next to the nerves. The inferior sepal is triangular, acute, whitish, with greenish nerves, dotted with purple internally near the base over the nerves. The tepals are ligulate, transverse descending, with a few undulations, ciliate, greenish-white with purplish veins, the borders coloured totally with purple, and some purplish reticulations of transverse nerves. The claw of the lip is turned in, and bears an open channel; the sac is pandurate saccate, bearing an acute edge on each side; its colour is pale purplish, with yellow tints and numerous purplish blotches on the pallid nail. The column is wholly yellow. The staminode half circular, split on its base in two acute teeth, forcipate in front, with a shorter tooth in the centre of the sinus. There are numerous short purplish hairs on the surface.

The plant is a hybrid between the two species above-named, raised by Mr. Cross, at one time gardener to Lady Ashburton, at Melchet Park, in Hampshire. It is just intermediate between the two, though at first sight it looks much nearer *C. insigne*, notwithstanding the purplish tints of the flower. It has the circumscription of the leaves of *Cypripedium insigne*, but they are much shorter, darker, with some indications of reticulation. The peduncle and bract are more like those of *Cypripedium barbatum*. The superior sepal is nearly as in *C. barbatum*, but there are the undulations and some blotches of *C. insigne*. The inferior sepal is nearly as short as in *Cypripedium barbatum*. The petals have much more resemblance to those of *Cypripedium barbatum*, being not dilated at the apex, and narrow. There are some very indistinct reticulations, which I can only find in a very few of the number of flowers of *Cypripedium barbatum* at hand. The lip, too, is just intermediate, and in its emulation of an elegant lady's shoe reminds one a little of that organ in *Cypripedium Stonei*. It is much nearer in size to *Cypripedium insigne*. The staminode approaches that of the *Cypripedium barbatum*, but it is narrower, and longer, and hairy, thus approaching that of *Cypripedium insigne*.

It is quite a pleasure thus to observe how the parents contributed their gifts to their child, and it is satisfactory that our views on species and their limits get by-and-by enlightened by such experiments. This gay novelty is dedicated most respectfully to a zealous promoter of gardening, the Right Hon. the Lady Ashburton. I am indebted for a flower and two leaves, also for the history of the plant, to Messrs. Veitch & Sons, the happy possessors of the whole stock of the plant.

The accompanying woodcut (fig. 348) represents, at 1, the staminode of one plant; at 2, that of *Cypripedium barbatum*; at 3, that of *Cypripedium insigne*; and at 4, a side view of the lip. *H. G. Rchb. fil.*

ARAUCARIA IMBRICATA.—No. III.

(*Continued from p.* 1580.)

At the time referred to in my last letter, the main road was about to be diverted, so as to remove it further from the church, American garden, &c., and a common foot-path was also about to be diverted, and taken across an old grass field, a rich meadow, and the lower end of the park. In carrying out these improvements, I proposed to take as much of the surface soil—any amount might have been had

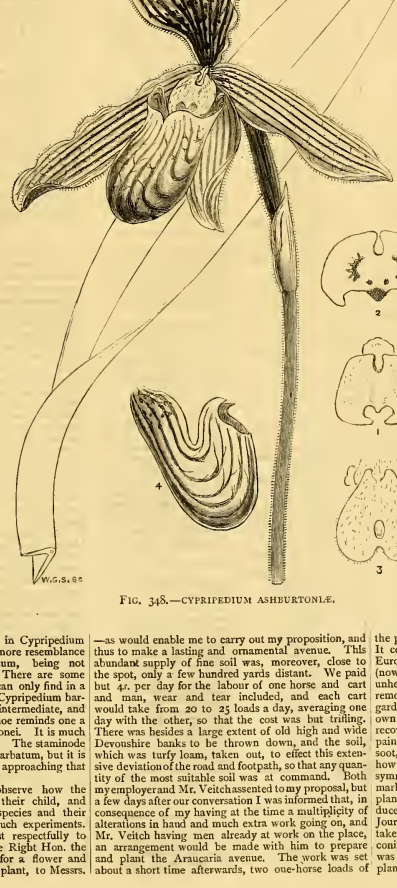

FIG. 348.—CYPRIPEDIUM ASHBURTONIÆ.

—as would enable me to carry out my proposition, and thus to make a lasting and ornamental avenue. This abundant supply of fine soil was, moreover, close to the spot, only a few hundred yards distant. We paid but 4*s.* per day for the labour of one horse and cart and man, wear and tear included, and each cart would take from 20 to 25 loads a day, averaging one day with the other, so that the cost was but trifling. There was besides a large extent of old high and wide Devonshire banks to be thrown down, and the soil, which was turfy loam, taken out, to effect this extensive deviation of the road and footpath, so that any quantity of the most suitable soil was at command. Both my employer and Mr. Veitch assented to my proposal, but a few days after our conversation I was informed that, in consequence of my having at the time a multiplicity of alterations in hand and much extra work going on, and Mr. Veitch having men already at work on the place, an arrangement would be made with him to prepare and plant the Araucaria avenue. The work was set about a short time afterwards, two one-horse loads of the soil I have referred to being placed in a steep hillock on the spot marked for each tree; but this not being approved, it was levelled down, and the avenue of Araucarias was then planted—that is, the little shrubby, healthy plants were simply turned out of 32-sized pots, and a little wire cage for protection was placed around each.

The large Araucaria standing in the flower garden, on a little circle of grass surrounded by a gravel walk, being in a stunted condition, getting brown, and having resinous matter oozing at the base of the stem, I set about renovating the soil, with the view to induce healthy growth. First, I had a trench taken out all round it 2 feet wide, and 4 feet deep, and the soil being a solid, natural sand, I had a foot of stones and rubble placed all round the bottom, and a thin turf to drain away the superfluous water from its roots. I then filled up the trench with turfy loam. It was astonishing what a splendid, vigorous growth the tree made after this, and continued to do so, regaining its beautiful dark green colour, and being no longer affected by the oozing of resin from the stem. The second year afterwards it showed some splendid cones.

There were two other smaller plants in the flower garden, near the Temple, which had got into the same stagnated condition. These I treated in the same manner. A specimen in the Arboretum, planted at the base of a slope, had quite given up growing, and was terribly browned, giving out from its bulged, carbuncled stem quantities of resin, which hung like bunches of snake's eggs, and as large. This tree was thought to be dying and incurable. The large female tree I proposed to remove to the Arboretum, the second year after making the preparation, which was assented to. I made a rare provision for it, as we were throwing down some old banks close by. I had the turf laid back to a diameter of 50 feet, trenched the space from 2 or 3 feet deep, and carted on as many loads of new soil; we then successfully removed this noble tree, with a ball of earth 8 feet across by 4 feet deep, wonderfully matted together by the mass of new roots made in the soil which had been placed around it. It was removed to its new position most successfully, although, with its many tons of earth, it had to travel a very awkward road up hill and down, and over a wall. It was placed with its huge ball on the trenched raised surface just referred to, and probably nearly 200 loads of old bank soil, turfy loam, &c., which we had close at hand, were placed round about it, to form an easy mound gently sloping away in the distance. Here it continued to bear annually heavy crops of cones, so that we were obliged to take off quantities in their young state. This tree did not seem to receive the least check in its removal; it grew but slowly in height, its head being immensely thick and healthy, and its branches sweeping down a good deal, which I think was caused at first by the weight of the cones. However, the stem increased very much in size and the head in diameter, and it is altogether a very fine tree, and likely to continue so for many years to come, since the preparation made for it was of a durable character. It certainly is a memorial tree, as being the first in Europe to produce perfect fruit, which plants (now several feet high) were raised. The poor unhealthy resin-oozing plant in the Arboretum, I removed to the new part of the American garden, making similar preparations for it, and to my own surprise, and that of many others, it soon began to recover. We scraped off the resinous matter, and painted over its stem with a paint made with chimney soot, clay, and cow-dung, and it is really wonderful how robust and healthy it became, and what a splendid symmetrical head it made. What is still more remarkable is, that in three years it proved itself a male plant, and was thus the first plant in Europe that produced catkins, a fact recorded at the time in this Journal and elsewhere. Some of the catkins were taken, when the pollen was ripe, to the old female coning plant. Had it been known previously that it was a male plant, it would no doubt have been retained in the Arboretum, with a good preparation for

its roots, and not have been removed to a distance. One of the other Araucarias, then in the flower garden, was, after due preparation, both of the tree and of the site, removed to a corner in the deer park, near the lake, where, like the rest, it grew vigorously, proving itself to be a female, and soon producing immense cones. In a few years this became the most vigorous free-growing and handsome plant on the estate. It is somewhat curious, but true, that the remaining Araucaria left in the flower garden, after having been removed to fill up a vacancy in the eastern park, proved also to be a male. Had this been previously known, it would probably have been placed in the Arboretum. *James Barnes, Exmouth.*

(To be Continued.)

NEW PLANTS, &c., CERTIFICATED

AT THE ROYAL HORTICULTURAL SOCIETY'S MEETINGS, 1870–71.

*** *The awards marked * were made by the International Jury, the remainder by the Floral Committee. F.C. indicates First-class Certificate, S.C. Second-class Certificate.*

THE GRAVITATION OF FLUIDS.

THE words "rise," "sink," and "float" are those commonly used to express the movements of bodies in air, water, and other fluids. Now these words all bear a neutral sense, and in their use simply make acknowledgment of the phenomena rather than comprehension of their nature and causes. Such a set of words afford by their use a singular proof of the extent to which the idea has spread, and of the hold it has obtained on men's minds, that bodies rise and float or sink in air or water "of themselves,"—for such terms imply that these actions have their immediate origin in the bodies themselves. They certainly imply that the fluids (air and water) have no more to do with these motions than to afford a field for their exercise. Modern nomenclature aims at giving instructive names. We follow God's rule if we make a name convey useful meaning. It should be not such as serves to cover ignorance, but to remove it.

Now the very fact that the ordinary terms applied in this case are at least vague, not to say misleading, should *à priori* incline us to hold the common theory which affects to account for these movements in suspicion.

The uninquiring mind is easily satisfied that light bodies float "of themselves," when the locality in which they are witnessed is the atmosphere, and not being visible, and not therefore forcing its presence upon the observation, is easily (to use an Irishism) lost sight of, and its agency in the matter wholly neglected and unacknowledged. But when we turn from air to water as the locality of these phenomena, popular language undergoes a change, which implies acknowledgment of the existence of the fluid, and an idea that it has something to do with the matter. Cork and wood do not float when taken out of the water. These things are not found, then, to "rise of themselves," or to possess "a tendency to rise." They are spoken of, therefore, as "floating in water," not as floating "of themselves."

And if the mind would take one step further from the spot thus reached, suspicion at least would be aroused as to the correctness of the language applied to the flotation of bodies in the invisible fluid, air. Air is a fluid having a very perceptible and appreciable existence. One need not rise from one's seat to find that out; but to own its existence when thinking of the flotation of bodies in it, would at once modify the terms used. We should use this form of language, that "while certain heavier bodies float in water, other lighter bodies float in air." The words "of themselves" would probably slip out of the sentence, and the next thought would be that the air in which the bodies are seen has something to do with their flotation.

Another step in advance is thus made, and the distrust (betrayed by the change of language) felt in regard to the popular theory invites us into the track of useful investigation which opens out here from the pathless waste of error.

It is necessary to attack the vague popular theory at the outset of such inquiry. That theory, however unsatisfying, is, in the absence of a better, too strongly held to allow true reasoning at once to assert its superiority. The mist of error must be cleared to some extent from the vision to make truth visible.

Akin with this misconception with respect to the floatation of bodies in fluids, were such old ideas as that the sun moves round the earth, that the earth is flat, and that the stars are in the blue "vault" of heaven. With the conviction that wide-spread, long-lasting and deeply rooted notions such as each of these three cases be distinctly traced to ocular deception and blind uninquiring submission to it, how much reason have we for suspicion that the common theory about floating bodies has no better foundation.

And while the three former errors are those of the past, the latter will appear to be an error of the present time also. Not only among the generality of educated persons will such views be still expressed in answer to inquiries, though perhaps not very confidently; but many (at least) of the books which affect to teach, speak of light bodies as having a tendency to rise and form a vacuum, and of the heavier fluids as flowing in to fill up the vacancy. Such words are still uttered, and especially with regard to atmospheric pressure and draughts. There is need, therefore, for investigation, and most useful results may flow from it.

And the most efficient way of contributing error, perhaps, is to invite men to look again a little more accurately at the facts, a hasty and partial view of which has misled them. Thus they teach themselves; the most pleasant and satisfactory of all teaching. The mind thus shapes itself by degrees to the mould of truth, in which it will finally fit accurately and contentedly. The rule in arithmetic, unintelligible and uninteresting as it appears at the head of the chapter, becomes far more intelligible to the learner after a few trials and examples, and interesting from the confidence with which it fills the mind. The great value and interest of the theory are found by looking upon it again and again from the track of experiment and illustration. Such, then, I propose as the most instructive and profitable course.

Something, then, being ascribed even in common correct observation to the fluids in which bodies float, in relation to their flotation, experiment will go to show what that something is, but first it will show—a very important matter too—that flotation is not due to any inherent property in the floating body.

All bodies have one property, which prevents them from rising and floating of themselves in that property is weight. Weight is well known to be due to the earth's attraction, and to the liability of all matter to be acted on by that attraction. And that attraction is well known to be exactly proportional to the amount of matter (regardless of size or dimensions) contained in the body acted on. Every body, therefore, is subject to this action. Every body, in other words, has weight; and weight results in nothing else than a falling to the earth. The lightest, moreover, of all bodies has weight, for lightness means truly and really nothing else than low weight, while heaviness means more weight. All bodies, therefore, have a natural tendency to fall.

Some bodies, indeed, could not be weighed in a scale, in the ordinary way, the scale being used in the atmosphere. It would be needful to weigh them in a vacuum. Floating substances are developed in a fluid atmosphere, which interfere and perplex. The atmosphere, therefore, must be removed. Then will the lightest gases lie in open vessels like water, and may be weighed in grains, or fractional parts of grains. A philosophical experimentalist could tell us the weight of a pint of carburetted hydrogen, show us the little metallic weight, and ask us if a piece of metal has any tendency to rise. He would thus teach us most conclusively that, however easily such a body of gas might be lifted, it would certainly fall "by itself," if weight could make it to do so.

The huge war steam-vessel, with all its cumbrance of armour plating, guns, shot, anchors, &c., weighing thousands of tons, has no tendency to rise. It rises, however, without the possibility of failure, by the letting in of water into the dry docks. Water running beneath, filling up the space below, insinuating itself between the wall and the vessel's side, though but a few inches intervene, lifts up the whole enormous mass, and never fails under the burden. "Lifts," I say, for who shall account for so stupendous a result, by finding out any inherent property of lightness in this monstrous mass which should account for this elevation of it? We can show that a fluid body does act, and from the condition in which it exists in a body must act, and that it can do so with ample power to lift such a mass as this, but we can find no other cause. We may conceive an ideal cause, and clothe it with a name, but the name will have more sound than sense, and serve but to shroud a deception and shelve a difficulty.

The bather can help our inquiry. A large stone laid hold upon and lifted from the bottom of the pool feels so light in the water that he can hardly believe it to be a stone. His eye corrects this thought, though the lightness seems anomalous. But lo! as he lifts the stone out of the water, the full weight due to its nature is perceived. It is perceptibly and materially increased. Why is this? The water has helped him in lifting it, and lifting the arm too which held it. It has a lifting power; in no other way can the matter be accounted for. The stone at any rate has no tendency to rise.

But again, his arm which should have suffer them to do so, will drop down to his side, will, as he steps into deeper water and leaves them free, be carried to the surface. Nay, not only will his arms be lifted up, but, if he is not careful, he will himself be lifted off his feet, so small now is the pressure with which he bears on the ground below that the smallest elastic action of the muscles of his feet would cause him to spring right away from his position. If he can plant his feet firmly on to a plastic clay bottom, excluding the water beneath them, he will stand somewhat more firmly; but the moment he withdraws a foot, he will feel the pressure of the water like a broad, soft, but powerful hand thrusting him upwards.

Now the very same course of experiments, though not so easily carried out, applies to the fluid, air, and with the same result. The stone which is found heavier in air than water will be found heavier still in a vacuum. Hence we know not only that water lifts or helps to lift the stone, but that the air also helps to lift it. If we are not mistaken in the teaching of the water experiment, we may strongly infer that we are not in error as to the lifting power of air.

If we would know ask ourselves why a toy balloon rises to the ceiling when let go from the hand, we should answer, "Why even a stone experiences the lifting power of the air. The stone does not give way to the power because it is too heavy to obey the amount of lifting force, but the balloon being light enough to obey it." This would be the lesson taught by the experiment.

Observe: the toy ballon rises because of the lifting force of air, and because it is light enough to obey the lifting force. It would do so if filled with hot air instead of gas. Is not the theory of draught contained in these words, and illustrated by this fact? I should not use the word draught if I knew of one more accordant with the lifting theory for which I contend. *J. M. Taylor, Seer Green Vicarage, Beaconsfield.*

(To be Continued.)

THE AMATEUR GARDENER.

Winter Work in the Kitchen Garden.—A good gardener may be known by his winter operations as well as by the more attractive work of the fine months of the year. Amateurs are apt to grow remiss when the cold weather arrives, and to leave the plot of ground devoted to fruit and vegetables in an untended and untidy conditinn till longer days and warmer suns imperatively call for exertion. But this is neither creditable to themselves nor advantageous to their gardens; indeed, it may be truly affirmed that the character of the whole of the whole coming season will be greatly influenced by what is now done. As regards the soil, not a foot of it unoccupied should remain unturned during the frosts, which act most beneficially upon it, and prepare it for the coming seedtime. It should be thrown up on the ridge and furrow system, so that every part may penetrated by, by which it will become well pulverised in the spring.

An early seed-time is very important for many crops, but it is often delayed by a fortnight or more when the soil has not been well exposed to the frosts in the winter. Observe the neighbouring gardens and you thus find themselves in very contrasted positions in the month of February; the one who has, so to speak, cultivated the ground in the winter, may be getting his Onions in in fine style, while the other is regarding his compartments despondingly as too damp to admit of anything being done.

Remembering the destructive effect of the frosts last spring among all the Brassica tribe, all possible protection must be given at the present time. We have laid down all our Broccolis with their heads towards the north or east, by taking out a good spadeful of earth on the side of the plant which is to be levelled, and placing it on the other side, so as to keep it down, spreading it at the same time over the crown of the stem as much as possible. In small gardens the stock can readily be protected by mats, boards, and other temporary appliances. A ridge of earth thrown up on the most exposed side of rows of young Cabbages will be of great service in saving them in a hard season. It may be useful to observe that laying down Broccolis with their heads towards the north or east is to preserve the coming flower-heads from bright sunshine, which is more destructive in frosty weather than could be imagined without experience. Turnips may be taken up and pitted like Potatos, and will be found good till February. Celery is very likely to be rotted in the trenches by hard weather, and therefore straw or leaves should be strewn thickly over the tops, to be removed whenever a thaw takes place. We always take up a few dozen roots in December, when frost seems imminent, and place them flat, one on the other, in a cellar or outhouse, with the roots all one way. It will grow in such a position, and be kept quite fresh and crisp by a watering to the roots now and then. Seakale can be forced at any time by the application of warm manure, but where that is not easily attainable the stools can be potted in large pots and put into a warm cellar. We always grow some roots especially for this purpose, and the same process applies to Rhubarb. The Seakale left in the rows for later use need not be earthed up till after Christmas. Frost does good to the plant, and a mass of earth upon it in mid-winter rather retards its growth than advances it. Seakale can be forced, but its growth cannot be retarded in the spring. We mention this because Asparagus beds in large garden has just asked us where he could procure a good stock of plants, as he wanted to have blanched Seakale in the summer! Asparagus beds should be slightly forked over, after being thoroughly weeded and receiving a dressing of rotten frame manure, to the depth of about 3 inches. Alterces should be all in their quarters by this time, but if they have been neglected the strongest plants can be taken up with balls of earth, and put in the warmest borders; these will be fit for use early, but the beds of young plants, as a rule, had better be undisturbed till the end of January.

The saving of Peas is a vexed subject with gardeners, some being very zealous to bring a crop through the winter, while others think the little time gained is not worth the trouble, and the great risk of failure. Where a gardener is not stingy of a little care and labour in bad weather, we would advise him to try a row or two of the early sorts, to be sown in a protected situation, and to be watched through the winter, earthed up when needed, and screened from severe frosts by some artificial light covering. In this way a dish of Peas may be ready a week or ten days before those are ready which are sown in March, and in very favourable seasons a fuller crop may be obtained. Broad Beans can be sown at any time when there is no frost in the ground.

All pruning is best done in November, or even earlier, but the large gardener is not practicable, and it must be got over gradually as the weather permits. Fine days should be taken advantage of for attending to wall trees, for it is cruel to set a man to this work in wet or frosty weather. Trees which do not need nailing can be done at any time, unless hard frosts do not prevail, for a man can keep himself warm at this work. Simultaneously with all these operations, the rake and broom should be kept going, to clear away all leaves and decayed vegetation with which the beds may be encumbered. *H. B.*

ON BOTTOM-HEAT AND COLD.

A WATER-BOTTLE of porous terra-cotta, of much the same consistency as an ordinary flower-pot, is called in the trade a water-cooler. Now, when this bottle made of burnt clay is used it produces its natural effect upon the water inside, for if the outside of the bottle is kept moist, it will assuredly evaporate moisture and cool the water. A well-watered plant in a flower-pot will likewise have the outside of the pot moist as well as the inside, and hence there will be evaporation from the surface of the pot, and the roots inside will be cooled just as the water is cooled of the water-cooler. This will explain the reason why plants in pots do best when plunged in earth, ashes, or the like; for as the bulk of the roots is generally at the sides of the pot they must suffer more or less from every change, because when the pot is exposed to the sun and wind, the roots applied to it will prove itself a root cooler. It must indeed be clear to every practical man that all plants in pots are more or less affected in this way.

The late Thos. Andrew Knight, full of the very sensible idea "that what is not to be had from the earth and not the earth that heated the air," saw no reason why bottom-heat should be needed in the culture of Pine-apples, nor indeed in the culture of anything else; therefore he mounted the Pine-apple plants on a shelf to grow, and so they did, but so slowly, that the Aloe, which is proverbial to flower once in 100 years, might have overtaken Mr. Knight's Pine plants before they ripened their fruit. He had unconsciously applied the cooler, so that the roots of his Pine-apple plants would be chilled even in the midst of a tropical heat, and would only make a little way in the moist clay, and that but slowly through half an inch of burnt clay. From that time Mr. Knight's "shelving" the Pine-apple plants has been set up as a beacon to beginners, and it has answered that end, for I have not heard of the experiment being repeated for 30 years past.

Many years ago I had suffered so much annoyance from the green scum and dirty character of common flower-pots—requiring so much labour to keep them clean—that I had a lot made of glazed ware, which could be easily washed at any time, and, when washed, would remain clean for years. Evaporation from such a surface was out of the question; besides I got rid of using crocks at the bottom of these pots, for my glazed pots had a colander kind of bottom, lull of small holes, to let out water, and had, moreover, a ledge to stand upon, like the chimb of a barrel. If the pots in which some of the species of Acacia have been grown should get broken and be eventually smashed up for crocks to drain some important plants, its best roots would at the earliest opportunitity be right in the midst of this poison. The vent hole in flower-pots is frequently so large as to need an oyster shell to cover it first, and then some 2 or 3 inches of sharp-edged

crocks, of no cultural use to the plant beyond drainage, and causing a wanton waste of room where room is so important a matter. I used less than half an inch deep of clean coarse sand in the glazed flower-pots, and as there were plenty of small holes all over the bottom of the pots, the drainage was perfect. Objections were raised at the time against glazed pots because the old brick pot was said to admit air to the roots, which the glazed pot could not. On this point I remark, that the radicle and plumule always take different directions, the root running away from the air with all its might, and enjoying the calm of the dark damp earth. Such objections only show that we have yet a deal to learn in our dealings with plant life.

The Melon plant is a short-lived subject, seldom living more than half a year from the time of sowing until it has ripened its seeds; and it has been grown to perfection for many years on a hotbed of prepared stable dung, but where is the plant that has ever had such a supply of bottom-heat as the Melon? In short, its treatment is altogether unequalled in modern horticulture. When did either Grapes or Pine-apples get such a supply of moist sweet heat to root and branch as does the Melon?

Cuttings of rare plants live a sluggish life in a pot of moist sand, and the evaporation is prevented by covering them with a bell-glass until the callosity is formed at the bottom of the cutting by the action of the descending sap, and when this stage has been reached the application of bottom-heat will soon begin to tell. I invented a system of striking cuttings by having a small potful of water inside the cutting-pot, so as to keep the cuttings moist without any other watering than what percolated through the pot-sides; and the system had many other advantages, for the cuttings did not damp off as before, and could be examined by lifting up the inner pot, without damaging the cuttings.

When I had seen the splendid specimens of Pine-apples, produced by a very strong bottom-heat, at Oak Hill, East Barnet—such a heat as I durst not until then have applied—I longed to try what bottom-heat could do for other plants. The early forced Vines there had a slight hotbed of leaves and dung over the Vine border, so that whilst the leaves were steaming in warm vapour, the roots were by no means left out in the cold; but how rarely do we see a bed of tanner's bark in a proper state of fermentation for plunging Pines in, and still more rare is it to see a Vine border protected properly from cold and wet, not to speak about bottom-heat for it. I had a fire-flue running under a bed of Pine plants planted out, and the soil rested on slates supported on iron bars, and we got a supply of useful fruit in this way with little trouble; and at a neighbouring place of great note I saw rows of hot-water pipes running under the Pine beds, and there also the plants were not in pots, and they seemed to be doing well.

When I lived in the botanical department at Syon, we borrowed a hothouse from the kitchen garden for the purpose of forcing flowers; and I was at great pains to get a good bottom-heat in order to give hardy plants a dose of that which suited exotics so well. My idea was to maintain a growing heat in the house, but to let the roots feel that they were wanted by keeping up a sharp bottom-heat, and with this treatment Moss Roses bloomed freely, and were not long-drawn and naked, as we so often see them when forced. When I was comparing notes the other day with a "market-trade," who was in the business 30 years ago, he stated that he too had successfully forced Moss Roses, and it will give our country cousins some idea of London extravagance when they are told that the wholesale price was 5*s.* each; and where high cultivation could raise even four marketable blooms from a pot they would pay for the extra allowance of bottom-heat.

There was at the late exhibition in the Manchester Botanic Garden a stand of coolers by evaporation—a large dish covers covered with jackets of bed tick, and when these were put over the dish covers with the meat, &c., on the dish was kept cool. Most people have seen butter coolers of porous earthenware on a similar principle. I have named these examples from ideas already reduced to practice, which, if not so brilliant as theory, may yet have more weight with those who would do likewise.

I applied bottom-heat to early Potatos by means of a long earthen flue under them, but without any covering over the plants, and I found the crop forwarded a good deal, and the quality excellent. I also grew tender annuals and forwarded spring flowers by what was called the "Killogie" system—a hotbed made after the fashion of a corn-kiln, where the space under is called the Killogie; and in places where brushwood is plentiful and manure scarce, a good bottom-heat can be got in this way at small cost beyond that of a little earth work.

The use of flued walls in gardens for the ripening of Peaches and Nectarines seems to have gone quite out of fashion, the heat was always irregular, and, moreover, unnatural, for heat applied to the face of the leaf is all right, but not so to the back. Had the same expense been gone to with bottom-heat the result would have been more satisfactory, for the orchard-houses have quite settled the extent of border—small indeed—that wall fruit trees require, and root pruning has clenched this practical lesson. Surely a cubic yard of soil (27 cubic feet) should do something when a cubic foot will grow a dozen Peaches from a plant in a pot.

Heat and cold are relative terms, and when deciduous trees cast their leaves at the first approach of sharp frost, their roots, only 1 foot under the surface, may certainly be said to have, comparatively speaking, bottom-heat; for the temperature in which the roots live will be very little altered by the weather overhead, and that little difference will be exceedingly gradual both as to its rise and fall.

We see in the *Transactions of the Horticultural Society* that the late T. A. Knight was a great experimenter, and made most laughable blunders, as in the case of the Pine-apples on the shelf above mentioned; yet this gentleman, born to wealth, complained that my namesake had got a grant from Government for his experiments with fruit trees. Mr. Knight could see the mote in the gardener's eye, but being his own master he could not see the beam in his own. Mr. Forsyth was as much entitled to his grant, as Marlborough was to Blenheim.

When trees or other plants are grafted, some kind of grafting wax or grafting clay is used to prevent evaporation from the wounds of the scion and the stock; and all other wounds or cuts, whether in root or branch, would, generally speaking, be benefited by "daubing." Hence in transplanting we use puddle to dip the roots in, for evaporation is the "roaring lion" of horticulture, constantly going about devouring. Yet this destroyer can be harnessed to the car of horticulture, for heated vapour is the very soul of indoor culture, and woe to the luckless wight that tries to grow "dry heat." His fortune may be foretold without any witchcraft, and he will see spiders elegantly attired in scarlet arrive in battalions,—

> "As if the mother earth to heaven
> A subterranean host had given."

In turning over a lining, or in taking a hotbed to pieces, we always see the heat accompanied with vapour. This in one word is bottom-heat as it ought to be; and whether got up by flues, pipes, or like it is always questionable, unless accompanied by sweet vapour. In the Melon "hill" we see the beautiful white roots shoot out into the moist medium, and yet live; this is, indeed, a lesson as to what heat roots will bear when there is moisture with it. I was amazed to see the gold fish in a tank at a silk mill enjoying life, and breeding freely in very hot water; and when I tried them with bread-crumbs I found that, though they did not suffer from cold, they might from hunger in such a place. Yet although I have had to keep gold fish for ornament in cold water these 30 years past, they neither increased in size nor in number. There is a limit of course to the heat of the water for fish, as well as to the heat of the vapour for plants above-ground, and for the roots of such as Pines, Melons, &c., under ground; but common sense is no guide in this matter, and it takes years of dearly bought experience to see how far we may go and be quite safe in the affair of bottom-heat. In renovating old Orange trees, Camellias, and the like, the power of bottom-heat must be felt, and a mild heat is but a mockery in such cases. What is the culture of epiphytal Orchids but an affair of well-managed bottom-heat for the pseudobulbs and the roots? In short, the whole plant has little else besides the vapour to thank for its existence. When Orchids are in bloom they will live longer in a dry room than any other plant, and suffer nothing, but they never would have got that length but for the hot vapour that puffed out the wrinkled pseudobulb, and made it push its fleshy roots downwards, and its gorgeous flowers in all sides, long, falling, hanging, trailing, against all rule and pattern in other plants. *Alex. Forsyth, Salford.*

RIVERS' ELIZA STRAWBERRY.

I WAS very much pleased the other day to see a long shelf full of pots of the above Strawberry, in what I call splendid fruiting condition, with Mr. Jefferson, Carlton House, Worksop. It is one of his favourite forcing sorts, both as regards quantity and quality; and without hesitation I may say, although I have never forced it myself, that it is a sure fruiter in his hands. To show its fruitfulness, I may mention that the above was a batch that was forced early this season, and when the fruit was gathered the plants were removed to a sheltered place outside, to harden them off for planting-out in the open ground, but, from pressure of other work, they remained in their summer quarters, with every attention as to watering until the autumn; and the result was a fine show of bloom, and with a little extra attention to feeding, they were kept until there was a good set of fruit. Ultimately the pots were removed to the shelves of a Cucumber-house to finish off their crop of very inviting fruit. *J. Miller, Worksop.*

A NEW SYNOPSIS OF ALL THE KNOWN LILIES.—X.

IN conclusion, I give a revised key to all the species at one view, and an index to all the names of Lilies, book or garden, with which I am acquainted, and another short list of garden names, which I am not able to refer to their proper places.

Sub-genus NOTHOLIRION.—Bulbs tunicated; stigma with three subulate hooked lobes.

Stem stout, with 20—30 leaves, crowded near the base.	1. L. ROSEUM, Wall.	(p. 302).
Stem slender, with 6—8 leaves, scattered up it.	2. L. HOOKERI, Baker	(p. 302).

Sub-genus LILIUM PROPER.—Bulbs squamose; stigma with three short blunt lobes.

Group 1: EULIRION. — Filaments sub-parallel. Flower segments broadest above the middle, turning back only towards the tip.

Leaves long-stalked cordate-ovate.	3. L. CORDIFOLIUM, Thunb.	(p. 479).
Leaves sessile, linear, or oblanceolate.		
Leaves always scattered on the stem, irregularly.		
Flower narrowed suddenly from the throat to the top of a long tube.	4. L. LONGIFLORUM, Thunb.	(p. 479).
Flower narrowed gradually from the throat to the base.		
Leaves 12—20; flowers 5—6 inches long, with divisions 1½—2 inches broad.	5. L. JAPONICUM, Thunb.	(p. 709).
Leaves 30—50; flowers 3—5 inches long, with divisions an inch or less broad.	6. L. NEPALENSE, Don	(p. 709).
Leaves 60—100; flowers 2—3 inches long, with divisions under an inch broad.	7. L. CANDIDUM, L.	(p. 709).
Leaves arranged on the stem in regular whorls	8. L. WASHINGTONIANUM, Kellogg	(p. 709).

Group 2: ARCHELIRION. — Filaments diverging very much. Flower segments not erect, ovate-lanceolate, turning back from very low down.

Leaves linear sessile, with bulblets in their axils.	9. L. TIGRINUM, Gawl,	(p. 903).
Leaves lanceolate, short stalked, without bulblets.		
Lower leaves 2½—2 inches broad, 9—9 ribbed.	10. L. SPECIOSUM, Thunb.	(p. 903).
Lower leaves 1—1½ inch broad, 5—7 ribbed.	11. L. AURATUM, Lindl.	(p. 903).

Group 3: ISOLIRION.—Filaments diverging moderately. Flower segments erect, broadest at the middle, spreading only in the upper half.

Leaves usually arranged on the stem in irregular whorls.		
Flower 2—3 inches deep, its segments with a very distinct claw.	12. L. PHILADELPHICUM, L.	(p. 1034).
Flower 1½ inch deep, its segments not clawed.	13. L. MEDEOLOIDES, A. Gray	(p. 1034).
Leaves never arranged in regular whorls.		
Flower red-yellow, the segments 2—4 inches long, distinctly clawed.	14. L. CATESBÆI; Walt.	(p. 1034).
Stem cottony, leaf-axils often bearing bulblets.	15. L. BULBIFERUM, L.	(p. 1034).
Flowers red-yellow, the segments 1—2 inches long, without claws.		
Leaves glabrous linear.	16. L. PULCHELLUM, F. and M.	(p. 1034).
Leaves pubescent lanceolate.	17. L. CONCOLOR, Saliab.	(p. 1034).
Flower white, under an inch long.	18. L. LANCIFOLIUM, Thunb.	(p. 1035).

Group 4: MARTAGON.—Filaments diverging very much; flower segments drooping, lanceolate, turning back from very low down.

Leaves usually arranged on the stem in irregular whorls.		
Flowers dull purplish-red, canary white.	19. L. MARTAGON, L.	(p. 1164).
Flowers bright red passing into yellow.		
Style ½ an inch long.	20. L. MACULATUM, Thunb.	(p. 1164).
Style 1—2 inches long.	21. L. CANADENSE, L.	(p. 1164).
Leaves never arranged on the stem in regular whorls.		
Leaves 1—1½ inch broad, 5—7 nerved.		
Flower 2½—3 inches long, reflexed only in the upper half.	22. L. MONADELPHUM, Bieb.	(p. 1303).
Flower 1½—2 inches long, reflexed from near the base.		
Leaves thick in texture, distinctly ciliated.		
Flower segments ½—¾ inch broad.	23. L. CARNIOLICUM, Bernh.	(p. 1305).
Flower segments about ¼ inch broad.	24. L. PONTICUM, C. Koch.	(p. 1305).
Leaves thin, not ciliated.	25. L. POLYPHYLLUM, Don	(p. 1305).
Leaves ½—1 inch broad, 3—5 nerved.		
Flower-segments ½—¼ inch broad.		
Leaves close, 50—80 to a stem.		
Flowers bright red, not dotted.	26. L. CHALCEDONICUM, L.	(p. 1402).
Flowers yellow, dotted.	27. L. PYRENAICUM, Gouan	(p. 1402).
Leaves lax, about 30 to a stem.		
Flower-segments ¾—1 inch broad.	28. L. CALLIBŒUM, S. and Z.	(p. 1402).
Leaves 60—100 to a stem.	29. L. TESTACEUM, Lindl.	(p. 1402).
Leaves 20—30 to a stem.	30. L. LEICHTLINII, Hook. fil.	(p. 1402).
Leaves ¼ inch broad, or less, 1-nerved.		
Stem 1½—3 feet high, with 80—200 leaves.	31. L. POMPONIUM, L.	(p. 1402).
Stem a foot high, with 30—50 leaves.	32. L. TENUIFOLIUM, Fisch.	(p. 1402).

Of any of the following, which I do not know where to place, I should be glad to have specimens or drawings sent :— abchasicum, alterıaans, californicum, Jeffersoni, lilacinum, pinifolium, punicum, pygmæum, and Sieboldii. *T. G. Baker.*

Home Correspondence.

Cleaning-out Boilers and Hot-water Pipes.—Few suggestions could be more seasonable and important than that of Mr. Duval Campbell at p. 1585. Every hot-water apparatus should be emptied once a year to get rid of sediment, and only fresh, clean water should be used for refilling. Fully half the irregularities of circulation and of boilers burnt out arise from sediment or incrustation. And even should these be avoided or mastered, deposits of dirt and carbonate of lime are coal wasters of the most inveterate type. They act like buffers between the fire and the water, and no heat can reach the latter without first passing through these more or less impervious strata. The dirt, too, in many instances has to be driven along the whole length of the line of motion, lifted here, driven round a sharp curve yonder, pushed through a half-shut valve at another place, everywhere and always hindering the free course of the water, and absorbing force that would otherwise have been expended on the diffusion of heat. And yet (it seems hardly credible, still it is true that) very few of the older boilers have any proper means for running off the water. More marvellous still, hardly any of the newer ones have a waste pipe of sufficient capacity to rinse the pipes and boiler clean. Nothing does this so effectually as the rapid outpouring of the water. This carries all before it. In old boilers I have often had the brick setting removed, and the lower part of the boiler bisected to let out the water. The hole can be safely enlarged with a steel augur for iron, and a threaded bolt fitted closely in. It is not safe to plug such boiler with an iron pin, tow, and red lead, like pipe joints. Now the weather is milder it would pay well in the reduction of coal consumed, and the ensuring of greater efficiency of heat, to have this matter attended to at once. There is no danger in the tapping of old boilers. Before doing so, however, see that your drainage is all right, or make provision for the removal of the water. Those without experience in such matters will receive a new lesson on the annoying capacity of long lengths of 4-inch pipes. I remember the first apparatus I ever saw emptied. It was that of a large span-roofed conservatory. A pipe gave way against the boiler, with 20° of frost beating down the temperature. Nothing astonished me through the dreary night, spent in covering the roof with rick-cloths, &c., like the rush of water. It ran all night, filling the stokehole, and engulphing even the top of the furnace and boiler. Next to the difficulty of keeping the frost from the plants was that of getting rid of the water. That lesson was not lost. I have planned many stokeholes since then ; deep or shallow, my first care has been to see them thoroughly drained. Prevention in this matter of boilers lessens the need of cure. See that nothing but clean water is used, and there will be little or no sediment, still there will be some ; the water eats the iron, and this should be run out. Above all things beware of hard water ; the lime forms a crust on the boiler which no mere rinsing will remove. If spring water must be used for hot-water apparatus it should first be exposed for a week to the air, when most of its mineral constituents will be precipitated or deposited, or a considerable proportion of common washing soda or wood ashes added to hard water will soften it. A weak solution of muriatic acid will also loosen calcareous deposits from boilers, and enable them to be rinsed out with the water. It is safest, however, not to allow them to form, as mechanical scrubbing or scraping, which is impracticable inside most boilers, is needful to get rid of these incrustations after they have grown to any great thickness. One caution more : beware of the frost touching either pipes or boilers ; it will at once strain or rust either or both by the expansion of the water in freezing. Empty unheated apparatuses for the winter or keep fire enough to prevent freezing. *D. T. Fish.*

Laxton's Alpha Pea.—This Pea I planted in good loamy soil, 6 inches apart, in single rows, 3½ feet between the rows. Even this sowing was too thick. The crop was enormous, pods well filled, the Peas very large, and of delicious flavour. I cannot speak too highly of it. *R. B. Read, Cooper, New South Wales, October* 12.

Lawn Mowers.—Mr. W. Heale (p. 1619) describes a lawn, in the county of Cork, that had become one mass of Daisies, from using (as is thought) a non-collecting lawn mower. Now, my experience has been just the reverse. Our soil is very dry—a portion of our flower garden occupying what was formerly (generations ago) the site of a part of the old abbey, portions of the foundations of which are frequently found in making alterations. As a consequence the turf in dry summers used to burn very much. Last spring we procured two of the Archimedian lawn mowers, as I was previously thoroughly impressed with their utility in dry situations, and the result has been so far very satisfactory—the turf is much finer and thicker, and the Daisies are not less numerous, they are certainly less conspicuous. Without wishing to detract from the merits of Green's machines, which I have used many years, I would advise all who have a lawn much subject to burning to give the Archimedian a trial. The advantages may not be so patent in warm genial moist climates like the south of Ireland, but on dry parched lawns I think the result will be satisfactory. We find it necessary sometimes in warm showery weather to mow twice a week, and sometimes to sweep up the grass if it is too thick, but it is astonishing how much this great pest disappears. A lawn very full of Daisies, if the time or labour at one's hand will not admit of their eradication, would require to be mown very frequently during the time the Daisies were in full bloom, and it might perhaps be advisable to use a machine with a collecting-box for two or three days at that time. Nine-inch machine is to the most suitable sized machine for manual labour. I think a 12-inch machine is quite large enough for one man. If there is much to do, two men, with a 12-inch machine each, will do more work than the same men with one machine of a larger size ; and there is also this advantage about it : a 12-inch machine will run into all the nooks and corners, thus doing away with the necessity for using the scythe. In the case of the lawn in question, I quite agree with Mr. Heale in recommending a trial of Watson's lawn seed. *Edward Hobday, Gr., Ramsey Abbey, Hunts.*

Goniophlebium appendiculatum.—It is well known that many Fern leaves, even when they are matured, will not stand long in water after being cut —one of the best tests as to the great well-known Fern beauty. Even the Maidenhair, though quite matured, will not stand more than three days. I may mention one kind which is a very beautiful Fern in any way we choose to look at it, whether in pot, basket, or Fern-case—Goniophlebium appendiculatum, fronds of which will continue three weeks in water in a perfect state. I look on this Fern as a most valuable one at this season of the year. It is a warm greenhouse kind, and like most of the valuable winter decorative Ferns, is most impatient of heat. It should never be allowed to get dry, and a saucer of water at the roots in summer will assist it very much to mature its numerous fronds for the winter months, when they are found really valuable. *H. K.*

Hardiness of Dracæna australis.—This must be the plant Mr. Wildsmith mentioned as enduring 16° of frost. If the dead leaves are allowed to remain around the stem, *i. e.*, allowing Nature to protect herself, it will stand even more cold. Even if the plants should be killed to the ground, they will again sprout up, and form nice plants in the following summer. The practice of pulling off the decayed leaves of Yuccas is often the cause of their death. The frost gets thoroughly through the stem, and when this takes place the plant falls to the ground. In many instances, however, I have found, that if immediately propped up, they will recover. *H. M.*

Cast Metal Flooring.—It is pretty generally acknowledged that there is no kind of greenhouse flooring so neat, clean, and serviceable as the cast-metal grating of different patterns ; but the great advantage of this kind of flooring is most seen when crossing an inside Vine or Peach border that requires to be pretty frequently forked over. It is so easily lifted and laid down, and, when down, is no hindrance to the border being equally watered, the water running quickly off, and soon drying again, admitting the heat and air freely to the border. Yet this kind of flooring is not perfection ; heat and the daily use of water cause the metal to rust, in spite of the different kinds of outward applications to keep this enemy in check, and few coatings stand for any length of time, owing to the continual treading there must necessarily be upon it. I have tried, with very good results, dipping the gratings after being heated into boiling coal or gas tar, and immediately they are taken out dusting them over freely with dry lime and sand, previously well mixed in about equal proportions ; this dusting not only hardens the surface, but prevents the smell when they are again laid down. The great secret in this permanent coating is the equal and sufficient dusting, which is quickly done with the hand or sieve. Tar applied without this addition soon perishes, and retains its smell for a length of time. *John Taylor, Rose Hill Lodge.*

Weather in Cornwall.—We have had, for us, an early beginning of winter. For nearly a month we have had frost more or less every night, the shifting of the wind causing variations of 5° to 10° of frost in a few hours. It is also remarkable that such difference in the temperature should exist in a distance of a mile or two —often of 8° or 10°. If a situation has no shelter, so to speak, for the cold mist to escape, the cold is the most intense. To-day it has broken up into mild, warm weather. *H. M., December* 14.

Picea nobilis.—Your correspondent "J. B." (p. 1617) says—"Indeed I do not know, and should be obliged to any of your correspondents who would tell me, whether living plants have ever been raised from cones of Picea nobilis grown in England." Your correspondent need be very careful reader of the *Gardeners' Chronicle*, or he would hardly have made such a request. Let me tell him, many thousand Picea nobilis have been for years past, and are yearly, raised in this country from cones ripened in this country. I have two Picea nobilis nearly 20 feet high, raised from seeds sown in England, I believe, at Preston Castle. If your correspondent doubts my word, let him inquire of any of our leading nurserymen. Why surely he must have seen the controversies that have been carried on in the *Gardeners' Chronicle* as to whether Picea nobilis, when raised from seeds grown in this country, was as robust as when raised from imported seeds. *C. F. P., The Grange, Kingston, near Taunton.*

Winter Cucumber Growing.—Those cultivators who wish to make the most of a limited space, and to be able to cut fine handsome Cucumbers at Christmas, I would earnestly advise to try a variety called Early Winter Prolific, a Cucumber which averages from 12 to 16 inches in length ; it is an abundant bearer, of excellent quality, and of a dark green colour. Having grown it this season with success, I can strongly recommend it before any of the Sion House section, which I had previously grown. The Telegraph is also an excellent Cucumber, but I find it requires more heat than I have at command. It is of the utmost importance to secure an excellent and productive variety for winter work, for it is no easy task to maintain a continuous supply of good Cucumbers through a long dreary winter, except the cultivator has a well constructed and powerfully heated house, in which case there is not much difficulty. My Cucumber-pit is merely a span-roofed lean-to, or perhaps it would be more correctly described as a division of my fruiting Pine-pit. The inside measurement is 7 feet 8 inches long and 4 feet 6 inches wide. The bed of soil in which the Cucumber plants are growing is 5 feet 3 inches wide, 3 feet 6 inches deep, and 2 feet depth of soil about 18 inches. I have been cutting Cucumbers from this pit since the end of September, and when the plants show signs of a little exhaustion I mulch with rotten manure, and encourage the shoots to extend inside the Pine-pit, both front and back. They thus become re-invigorated and more productive, proving that extension is better than restriction in the cultivation of the Cucumber. It has often struck me as being remarkable that although the Cucumber has been from time immemorial a cultivated and coveted esculent, I believe it is not known what, nor by whom, it was introduced into England. Probably the Romans may have done so, as they have enriched our gardens with many fruit trees, as the Vine, Apple, Peach, &c. Whether the Cucumber is a native of Egypt or not I do not know, but it appears that the Israelites more than 3000 years ago, when wandering in the Wilderness, remembered with regret the Cucumbers which

they enjoyed so abundantly when in Egypt. *Wilson Boardman, Gr. to S. H. Norris, Esq., Altrincham.*

Hardiness of Primula japonica.—Have any of your correspondents proved the hardiness of Primula japonica? In the autumn I had two splendid plants from Mr. Bull, which I repotted and plunged under a north wall; they grew away in fine style, and were pictures in bloom. When the cold weather came on the plants were covered with a hand-glass as a precaution. When the hard frost was on I examined the plants, and found they were suffering severely, and now the frost has disappeared all the outer leaves are dead, and I am not at all sure the plants will recover. This is a sad disappointment to me. *Jay Aye.*

Periodical Variation of Leaves (pp. 1517, 1552).—There is, doubtless, a great deal of interest attached to this subject; and, as stated in the leading article of November 18, it is a subject upon which we are all very ignorant. The first thing to be done, however, is to collect facts, and to record any circumstances which may tend, in any degree, to throw light upon the matter. But I think there has been some little misunderstanding of the meaning of that article. I take it that it referred to some, or, at any rate, especially, to the changes of colour which take place in certain leaves during the time they are growing upon the tree [Yes.], and not to those permanent variations or sports in which the same colour remains unchanged during the whole life of the leaf. Of course there is an intimate connection between the two, and many of the same laws will affect both phenomena; but instances of the former, or what the Editors aptly called "periodical variation," are those that are particularly asked for. As a remarkable case in point, I may draw attention to the following:—Three years ago some variegated seedlings of the common Sycamore were brought to me, which had been found in a small wood under trees of the ordinary colour. To begin with, it was strange that so many variegated seedlings should be found at the same time; scores of them were pulled up, and scores more might have been collected. There were no variegated trees near, and one could only account for the great number of variegated seedlings by supposing that some atmospheric influence had been at work with the flowers the year before. A number were planted out, but they were fully in leaf, and dry weather set in, and many died; those that were left one year or two turned out to be a curiosity. When first the leaves expand they are of a vivid pink colour, marked with white strokes and blotches, and the plant then is exceedingly pretty. In a few weeks one sees that the colour has faded considerably, causing the white to be very much more conspicuous. One also sees that a slight tinge of green has begun to mingle with the red, and this change gradually goes on until green has taken the place of pink. The green is never very brilliant, always a little dirty, so that the plant is not nearly as pretty in summer as in spring. The white, likewise, gradually becomes tinged with green, so that in the autumn, when other green leaves are turning red, or yellow, or brown, this seems to be almost reversing the order of things, by becoming green. The variegation evidently affects the plant in other respects, for it is of a branching habit, and grows very slowly; and although if it grows it seems to be anything but a shrub. I shall be anxious to see whether in a year or two it will become permanently green, like the seedling Horse Chestnut and Sycamore mentioned by "D. T. F." on p. 1583. *Robert Holland.*

Hoya bella.—This beautiful little plant is not met with so frequently as it should be, for it is one of the most charming of small stove plants. The essential points of its treatment are:—A strong moist heat while growing; a thorough moisture at the root; and a perfectly open well-drained soil. The latter may consist of a mixture of about equal parts of good fibrous peat, leaf-mould, and sand. When started in spring the temperature should be from 65° to 70°; when ripening in autumn from 55° to 60°,—the plant being then placed on a shelf near the glass and kept drier, though not so much so as to affect the foliage. It is a good stove basket plant. *W. H. O.*

The Introduction of Araucaria imbricata into England.—"The Spaniards, having settlements in the immediate vicinity of the country of the Araucanians, employed Don Francisco Dendariarena, in 1780, to examine the trees, with a view of discovering if any of them were suitable for ship-building. The result of his experiments was to select this species (the Pehuen of the natives), which was accordingly made use of to repair the Spanish squadron, then lying at anchor in the port of Talcaguano. The Abbate Molina, who was then writing his "Civil and Natural History of Chili" (published at Bologna in 1782), supposed the tree to be a Pinus, and he described it in his work under the name of Pinus araucana. In 1782 the Spanish Government commissioned Don Joseph Pavon to search for this tree; and he, finding both its flowers and fruit, ascertained that it was a distinct genus, and called it Araucaria imbricata. Don Joseph Pavon (who had previously visited Chili in company with Don Hippolito Ruiz and the French botanist Dombey, in 1777) sent specimens of Araucaria imbricata to France, to the care of Dombey, who showed them to MM. Lamarck and De Jussieu, in Paris—the former of whom called it Dombeya chilensis, while Jussieu retained the name of Araucaria. Don Joseph Pavon, however, complains, in his account of this tree, published in the first volume of the 'Memoirs of the Royal Academy of Sciences at Madrid,' that both Jussieu and Lamarck made several mistakes in their description of the botanical characteristics of the species, which had been avoided by both Molina and himself. In 1795, Captain Vancouver touched at the coast of Chili, and Mr. Menzies, who accompanied the expedition, procured cones, seeds from which he sowed on board ship, and brought home living plants, which he presented to Sir Joseph Banks, who planted one of them in his own garden at Spring Grove, and sent the others to Kew. From this circumstance, the tree was called at first, in England, Sir Joseph Banks's Pine. The tree at Kew was kept in the greenhouse till about 1806 or 1808, when it was planted out where it now stands by Mr. M'Nab [the father of the present superintendent], of the Edinburgh Botanic Garden. After it was planted out, not being considered quite hardy, it was protected during winter with a temporary frame covered with mats, and having become habituated to this mode of treatment it has been considered unsafe to leave it off. The species is, however, now found to be quite hardy at Dropmore and other places, and we have no doubt that as soon as plants can be procured from seed at a reasonable rate it will be as generally planted as the Cedar of Lebanon or the Deodar, and will be found to be quite as hardy as these trees." From vol. 4, second edition, of the "Arboretum Britannicum," pp. 2436-7. The above extract from Mr. Loudon's great work corroborates what "G., Bath," says of the introduction of the Araucaria imbricata into this country, p 1618. *C. F. P., The Grange, Kingston, near Taunton.*

—Observing a letter in your issue of Saturday, December 16, from "G. Bath," disputing the statement put forth by our esteemed friend in this respect, to put the date of the introduction of the above-named plant to this country, I would beg respectfully to refer him to Loudon's "Encyclopædia of Plants," which is one of the most valuable and correct works extant, and in which he states, at p. 846, that this Conifer was introduced by Sir J. Banks, from Chili, in 1796; this shows only a difference of one year as compared with Mr. Barnes' statement. *E. Wilson Serpell.*

The Odours of Plants.—Mr. Alex. Nesbitt, at p. 1620, referring to the odours of plants, mentions a sweet-scented blue alpine Primula, and the Editors justly remind their readers of the fragrance of blue Violets, yet Mr. Britten, at p. 1583, is not far out about blue flowers generally; and even amongst all the coloured flowers there is generally a large majority of sweet-scented kinds. Nature seems to have bestowed upon the white flowers an extra portion of odour, to compensate for the want of gaudy colouring. I will just dot down a few of the white beauties as they occur to my mind, and I think it will be difficult for any one to quote a flower from any country, that will not: we take the Lily of the Valley, the Woodruff, the white Violet, the white Hyacinths, the white Clematises, the white Roses, especially Lamarque, the white Verbenas, the white Petunias, the white Magnolias, the white Erica fragrans, odorata, &c.; the white Rhododendron, the white Azalea, the white Pinks, Carnations, at least six or eight sorts; the Gardenias (several kinds), Bouvardias, Carnations and Pinks, Crataegus, Daphne, Cytisus, Pittosporum, Rondeletia, Swainsona alba, Brugmansia grandiflora, Tuberose, Jack Orange, white Lilac, Phalenopsis, Citrus, Lilium, and the following climbers—Periandeville dulcis veolens, Stephanotis floribunda, Rhynchospermum jasminoides, Lapageria alba, Petræa volubilis, Richiea fragrans, Quisqualis volubilis, white inside. The same may be said of Lucuma gratissima and Clerodendron fragrans, they have a brownish tinge outside of the petals, but are nearly white within. I am sorry that my time does not allow me to go more minutely into this subject. I have long thought over it, but was led to consider it more closely about a year ago, on being applied to by a gentleman who required sweet-scented climbers, this conversation led to going into the matter, I found I could furnish very few climbers that had coloured flowers and at the same time were sweet-scented. It would, no doubt, be of considerable service to a great many of your readers if some one of your correspondents (Mr. Britten, for instance) would give a detailed list of odoriferous plants, arranging them in colours and in sections, showing whether they were hardy, greenhouse, or stove kinds. I would do the thing myself, but I have been so long out of harness amongst plants, and memory fails, that I think it must require many more able to perform the task in a satisfactory manner; and I trust that some one who has time and opportunity will take the subject up. *Y. Scott, Merriott, Somerset.*

On the Hardiness of Various Ferns.—We have here a specimen of Adiantum cuneatum, planted in the hardy fernery, which has been exposed to 12° of frost without showing the least signs of injury. A Capillus-Veneris planted near to the above, and protected with a mat, has some of its fronds blackened through the sharp weather. Asplenium marinum has not been the least injured. Pteris cretica albo-lineata, also planted with the above, but with a bell-glass placed over it, has been frozen several times without showing any ill effects from it. *G. Warren, Gr., Balcombe Place, Sussex.*

The Price of Potatos.—I hope some of your correspondents, acquainted with the facts, will tell us something of the retail price of Potatos as well as of market produce in general. I find the highest price of best York Regents, in your Saturday's issue, in the Southwark market, was 110s. per ton, or 8s. 1d. per sack of 168 lb., with quantities unsold. The same day, in the Borough market, I could get none under 12s. a sack, and they were quoted in the *Times* (retail) 15s. per sack, or nearly double the price in the latter case. Can it be explained to the unfortunate consumer? *A. R.*

Plea for Higher Wages.—Many such could be urged at the present time—such as the demand for higher services, and the fact that the same amount of money purchases much less than it used to do. In other words, we do much more work—and better—and get less for it than our fathers. For the value of money is not its absolute amount, but its purchasing capacity. Not what we get, but what we can buy for it, determines our absolute wages: judged thus, the wages of gardeners have retrograded of late years. But it is not such pleas as these that I would now use, but others, more simple, that can be appreciated and understood by all,—such, in fact, as are now being brought before us daily by the would-be pensioners of the Gardeners' Benevolent Institution; heartrending cases of men of spotless character and exemplary ability, toiling through life until disease, old age, or death overtakes them, without any provision for themselves or others dependent upon them. How is it that so many gardeners, of from 30, 40, or even 50 years standing, are left helplessly destitute at last? Making every allowance for other causes which may be called preventible, is it not a fact that the present wages of gardeners will not admit of the rearing, clothing, educating of a family as these primary duties ought to be performed, and as they are expected by employers to be done; and also the making of any provision for the future? To do one of these things strains ingenuity in economical spending to the utmost. To do both honestly with present wages is utterly impossible. There may be many ways of doing both, which I am happily ignorant of, and would scorn to learn; but the honest gardener, without other means or extraneous aid to money-making, must perforce leave his wife and family a burden to posterity, pensioners on the Benevolent Institution, or to literally starve. Surely the workman is worthy of his hire, and reason, and religion, and the well-being of society alike require that that hire should suffice for present needs, and likewise for the making of some provision for the certain necessities of the future. Then if gardeners failed to make provision for their wives and families it would be their own fault; now it is quite otherwise. And it cannot really be to the interest of any class that those who contribute so much to the wealth, happiness, and adornment of this country should be kept struggling for life in a hand-to-hand fight with poverty, and be forced to die and be buried with the pauper's wave of hopeless want engulphing all they held dear on earth. Familiarity with such scenes is apt to beget indifference to their enormity—for enormous evils they are, and the result of great wrong, if not absolute injustice somewhere. The proportion of these terrible evils of low wages originates from want of thought and reckless competition. Thought can only be called forth by discussion, and somehow it seems looked upon as a crime in most quarters to write of the wages question. And yet all other wrongs are dragged to the light that they may be righted. Why not this? If, for instance, my view of the matter is faulty, surely there are wage-payers that could set the matter right from their point of view. Here is a public case in point, that may help both sides to a just decision. In the *Gardeners' Chronicle* of last Saturday, the Public Parks Committee of Manchester advertise for a head gardener for Alexandra Park, wages 32s. a-week, with house, coals, gas, and water, that is, £83 4s. a year in money, or say, £100 gross income,—a fair average, but still a low wage for the place. I invite the members of the Corporation of Manchester to try this experiment: supply seven persons with food, clothing, and education out of this income, dressing, teaching, and educating all as they would expect their head gardener and park-keeper to do. Would any of them undertake it, or succeed if they did? It was done, it seems, by the late gardener, Mr. Macmillan, and let no one blame him that he could not do more. That this was impossible is proved by a circular received this day (December 18) from Manchester, from which it appears that his widow and five children (the oldest nine years and the youngest four months) are left destitute; that an influential committee is formed, of which Mr. Bruce Findlay, of the Botanic Garden, is secretary; and that a subscription list is opened, and subscriptions earnestly solicited. While I hope these will flow freely at this festive season of the year, I trust that the more serious question will be pondered—the prevention of such and similar cases for the future. I am positively sick at heart from reading of destitute gardeners, their widows, and orphans. One would need to be made of guineas to meet all the heart-

rending appeals made to them; and it is by no means creditable that the benevolent should be impoverished that rich corporations, or individuals, may save a few pounds out of the wages of those who serve them so faithfully and well. No one, who seriously looks into the subject, can doubt that higher wages would lessen the number of these wails of distress two-thirds at least, and mitigate the misery of the remainder. Prevention is better than cure, even when the latter is possible. Cure there hardly ever is for such cases as I have noted. The fall is irretrievable from a happy home in a public park or garden to the very door of the union workhouse, with nothing to keep one's family out but private or public charity. But this, and thousands of such cases, would be prevented by the addition of a few pounds per year to gardeners' salaries. They might then not only live and do their duty by their families in the present, but be able to make some provision, however small, for themselves when laid aside by the infirmities of age, and for those they leave behind them when called to a higher service. *A. T. Fish, Dec. 18.*

Scolopendrium vulgare var. crispum-amplum. —In answer to your correspondent, I beg to say that I believe Mr. James, of Vauvert, still retains this variety, and therefore it cannot be procured; there is, however, another variety, which I believe I named "crispum-magnificum," equally beautiful, and having a large tasselled apex, and which is at present distributed by Mr. Glave, nurseryman, Scarborough. If your correspondent will write to me I shall be glad to give him all the help in my power. *F. J. Lowe, Highfield House, Nottingham.*

Orchid Cultivation.—I sent you last year some notes upon Dendrobiums, and I purpose to again send you a few jottings by the way of the peculiarities I have noticed during the present autumn. As I think I may call seasonal, as the majority are now at rest, but it is more particularly so for the purpose that I have in view, which is, noticing those that are not at rest. I am quite aware that I am going contrary to many a good garden maxim, by dividing them into three classes, as, evergreen, deciduous, and I shall hardly know to which they belong; but you already know me to be one who does not see why I should be bound by rules I did not assist in making, and therefore cannot be much surprised if I should hesitate to force my Dendrobes to obey rules which I cannot comprehend. I should perhaps again repeat that we have always treated the Orchids that grow in our *omnium gatherum*, the Pine stove, as being interlopers; we did so at first when they were few, and as it suited them we do not see why we should change it now when they are many. Thus our plants have the chance of doing their own way if they wished, and I am not desiring to claim merit for a grand find—I am simply noting, for the benefit of those who while they run can read, what is the practice of certain Dendrobiums that are permitted to do as they like, and there may be nothing new in it to others. We have not found any that will grow during autumn and winter that are injured thereby. Thus it has become our practice to moss them up for a new growth whenever we see them commencing a fresh start, regardless of the time of the year. As far as flowering is concerned, it is of course necessary to moss them rest a certain time, to concentrate their strength for the effort; but as it is of advantage to us to lengthen this season as much as possible, the result becomes pretty much this: so many are taken from time to time; if the number wanted can be found among those that are at rest none else go, but if more are required some go with growths unfinished, but we know that such are practically lost. I have often been asked what I would do at the beginning of winter with a plant that had not made up its growths, as if we had a choice that is not what is called Orchids, for such know of no other than growing them till they have formed pseudobulbs, or losing them, for an incompletely formed bulb cannot live without leaves. We grow them in an atmosphere largely supplied with moisture all the year round, and when resting to flower some are taken out to a colder house; when resting without growth, but still engaged in perfecting bulbs, they remain in the house, the watering being diminished till they are wanted to flower, or they commence to grow again; many never go out of the house, and some even thus inhabit houses that are used to swell the Pines off as they come forward. Neither do I wish to be thought advocating a similar practice to our own. I am jotting down individualities, and not desiring the charge of other men's Orchids. I will begin with nobile, in which we have the most pliable subject of the lot—I mean the nobile intermedium, pendulum, cœrulescens, and Wallichianum. I think they will grow three times a-year, certainly twice, flower either with leaves or without, rest six months if required, delight in the full sunshine; moniliforme grows twice, likes the sunshine, deciduous; lituiflorum, deciduous, grows twice, and makes long pendulous bulbs; heterocarpum, deciduous, as easily forced or retarded as nobile, and as free a grower; albo-sanguineum, if grown in the sun, makes strong bulbs, and is deciduous; crassinode, deciduous, strong grower, either in or out of the sun, will grow twice if started early; luteolum, deciduous, but flowers from the new growth, as also does lasioglossum, they will both grow twice a-year; Falconeri, habit of growth peculiar, as also form of bulb, grows best in autumn and winter, should not be rested long, or grown in the sunshine; nodatum, habit of growth and form of bulb much like the last, but much stronger, enjoys sunshine, should not be rested long grows during winter: chrysotis refuses to grow if shaded, is evergreen, flowering from new growth, and never rests long: what little rest it makes is usually in autumn, its flowering season; taurinum, will, I think, be much like the last, the plants we bought are still growing, and look as if they meant it, —should like to hear of those that have been dried off; Wardianum, deciduous, grows best in autumn and winter, grows twice, does not like the sunshine; Parishii, deciduous, likes the sun, should not be rested too long or too cold or too dry, transcends little nobile; Devonianum should not be rested long, does not stand sunshine till very strong, grows late in the year; Bensoniæ and crystallinum, deciduous, can stand a rest better if started early, grow twice, enjoy full sunshine; chrysotoxum and Farmeri delight in sun, grow twice, are evergreen; fimbriatum, oculatum and Paxtoni, like to keep some leaves, enjoy sunshine, grow twice sometimes; Dalhousianum has a similar habit; formosum and infundibulum should be grown in sunshine, flower with their leaves; Lowii has a similar habit, sometimes grows twice; Pierardi, nearly evergreen, likes sunshine; M'Carthiæ grows in autumn and winter, hardly rests at all, certainly grows twice, and sometimes flowers twice, enjoys the full sunshine; bigibbum flowers in November, should be evergreen, grows twice, enjoys full sunshine. In these remarks I have purposely left out comparative merits for show purposes, quality and quantity of flowers produced, &c. I might also have added many more to the list, but I have given, I think, examples of each type. Who can tell me if these are following their native habit in thus dividing themselves into classes? *G. H.*

Foreign Correspondence.

BOTANIC GARDEN, REUNION. — The following description of the Botanic Garden at Reunion is from the pen of Mr. Horne, Director of the Botanic Gardens, Mauritius.

The garden is situated in the suburbs of St. Denis, the capital and seat of the Government of the island. At the time the garden was laid out the site in the vicinity of the town may have been well chosen, and perhaps the best and only available place. The town has now, I dare say, outgrown the expectations of the founders of the garden, and the consequence is that it is surrounded by buildings; the plants, enveloped in clouds of dust, breathe an impure air, and are badly supplied with water when they require it most. The situation, also, is excessively dry and, at the time of my visit, there was not a plant in the garden that was not suffering from want of water. To irrigate appears out of the question, as shrubs, as well as large trees, are watered by the watering-pot. Several years ago the Government of the colony gave the management of the garden to the Acclimatisation Society of Reunion, and it is now under the charge of M. Poitier, who has two assistants under him.

The entrance to the garden is at the top of the Rue du Paris, a street which leads straight from the landing place to the garden gate. The entrance is well shaded by Tamarind trees, and there is a remarkably fine plant of Ficus elastica on the right of the gate, the curator's house being a little to the left. The house is occupied by the late curator's (M. Ricard) widow. M. Ricard had worthily taken charge of the garden for about 40 years, and died a few years ago at the age of nearly 90, much beloved and respected. He made some 10 or 12 visits to Madagascar and the Comoro Islands, and enriched the garden and herbarium with specimens from these seldom visited islands: in fact, to such an extent that I may safely say that the Reunion Botanic Garden contains a greater number of living specimens from the above parts than any other garden in the world. Fronting the entrance is a small mound of natural history, which is fairly kept up. It contains no botanical specimens. Between the museum and the gate there is a wide promenade, well shaded from the sun by four rows of Mango trees; there the band plays on Sundays, and, judging from the number of seats, the garden must be crowded on those days by the inhabitants of St. Denis. To the right of the promenade an attempt at flower-gardening has been made by laying out with flower-beds the bottom of what, at one time, had been a small basin; the beds are raised above the level of the bottom of the basin, their sides turfed, and a Caladium or similar plant planted in the centre of each bed, and edged with a species of Portulaca. The extent of the garden is about 6 or 7 acres; over nearly the half of it the trees, shrubs, &c., are planted in the natural orders to which they belong, Branginiers being the one adopted. The plants are planted in rows, which are about 8 to 10 feet apart; between the rows are paths or al'eys about 3 feet in width, and the ground arrangement is not unlike beds in a nursery. The plants are very closely planted, and the consequence is that the hardy and fast-growing kinds overtop the weaker and slower growing ones, consequently there is a sort of struggle for existence, not only amongst the plants themselves, but also with the drought. Notwithstanding the crowded state of the plants, there are several noble specimens, especially Palms, which have suffered less from crowding than the others. All the plants have once been named, and zinc labels are still attached to some of them. Many of the plants from Madagascar and the Comoro Islands were new to me.

The other portion of the garden is kept as a nursery, and the ground in this portion is also well covered with trees; not a few of them, from Madagascar, were strangers to me. In the nursery there is a miscellaneous stock of young plants, but notably of Oranges and Coffee.

Notices of Books.

Poems and Songs. By the late John Palmer, Nurseryman, Annan. (Printed for private circulation.)

Mr. Palmer, we are told in the introduction to this volume, began his career as a "herd-laddie," subsequently became a "billyer,"* but not liking life in a cotton mill any better than tending cattle, occupied himself as book-canvasser for Messrs. Blackie & Fullarton, which prospered him at this employment that he was soon enabled to establish a small nursery near Annan. Fortune still smiled, the nurseryman became baillie, then provost, occupied himself much in local affairs and local politics, and took much interest in the progress of agriculture. Almost all these phases of his life are reflected in the poems, to whose composition he devoted his leisure hours. Some of the poems, inspired by all sorts of subjects, are in the English, others in the Scottish dialect; and these latter, are, to our thinking, infinitely the best, and have often a smack of Burns about them. Indeed, Mr. Palmer evidently was an enthusiastic admirer of Burns, and, consciously or unconsciously, has imitated him.

Many of Mr. Palmer's effusions are on agricultural topics, and give evidence that he was a staunch advocate of the "go-a-head-science-with-practice" school of farming. As a good sample we quote the following verses from a "Harvest Song for 1848," set to the tune of "There's nae luck about the house":—

I've heard them say a Spanish Don
A squire once did keep,
Wha pray'd for blessings on the man
That first invented sleep;
But I will bless the cunnin' chiel
That first invented drains;
And did he need our biggest stack
I'd gie't him for his pains.
The barn-yard's rinnin' o'er, guid-wife,
The barn-yard's rinnin' o'er;
A single stack would scarce be miss'd,
The barn-yard's riunin' o'er.

Ye ken the field ayont the craft,
It wasna worth a preen;
Rashes were the standing crap,
Wi' tails o' girse atween:
But since we've drain'd it deep an' wee',
And stir'd wi' Deanston's plough,
Nae mortal een e'er saw sic stooks,—
I'll brag Dumfriesshire through.

It's wouuerfu' to think, guid-wife,
How things tak' sic a turn:
Ye mind sin our deep maiden hole
Ran black into the burn;
But now we hoard each precious drap,
As misers hoard their store;
It's ae grand thing, among the rest,
That mak's the yard rin o'er.

There's many things were wasted then
That we think precious noo;
I look around and wonder aft
Hoo our forbears gat through:
Guano, tue, 's an unco help,
And sae is broken banes;
Our turnips stan' along the grun.
Like rows o' chairnel stanes.
The barn-yard's rinnin' o'er, guid-wife,
The barn-yard's rinnin' o'er;
The bairns they canna count the stacks;
The barn-yard's rinnin' o'er.

We regret that our limited space does not allow us to quote more of this fresh, spirited, and really valuable song. There are more like it in the little volume before us, which compensate for a good deal of very mediocre versification, of a kind that one might expect to find in the poet's corner of a country newspaper.

The Choice of a Dwelling: *A Practical Handbook of Useful Information on all points connected with the Hiring, Buying, or Building a House, &c.* By Gervase Wheeler. Murray. 8vo, pp. 299.

The illness of the heir-apparent to the British crown has already had one good effect—it has supplied the "one touch of Nature" which, we are told, "makes the whole world kin," and has banded together in one link of sympathy men of all classes, all creeds, all opinions—differing in almost every point save that they were citizens of the British empire and subjects of the British Queen. Such a manifestation of human sympathy, and such a display of patriotism, go far, very far, to counterbalance the evil which called them forth.

* This is explained as the last operation on the cotton before it passes to the spinner.

If the Prince's illness—now, happily, abating—should enforce attention to sundry sanitary defects in ordinary house building, and bring about some practical results, our successors may say, out of evil cometh good.

We own that we are not sanguine in this matter. Our nation has frequent spasms of alarm; tons of chloride of lime and other disinfectants are used, the ledge of this kind might be expected in every man and woman in the kingdom who is not absolutely idiotic; next a general acquaintance with the construction of the houses we inhabit, and of the means of rendering them wholesome, and of keeping them so.

If this latter description of knowledge were more general, the tricks of "scamping builders" would not any newly built houses to be occupied till they have being thoroughly inspected and reported as complete in their sanitary arrangements. We do not think it would be going too far, either, to enforce, so far as possible, a periodical inspection by some competent and disinterested person, of all houses, so far as their drains, dust-bins, closets, water supply, and the like are con-

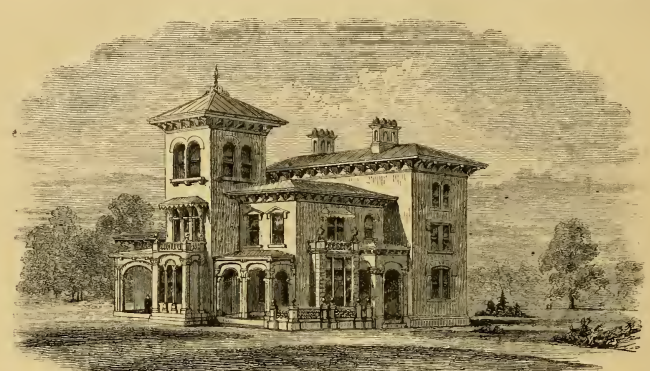

FIG. 349.—SYMMETRICAL VILLA RESIDENCE.

whitewash brush is in great request for a time, the attack subsides, and nothing is done in the way of prevention. This sort of thing occurs over and over again. People will not realise the fact that diseases, which might be almost entirely banished from our land if proper care were taken, kill annually their thousands and tens of thousands, and pauperise a still larger number. People will not realise the fact that the truest economy, like the best medicine, acts by prevention; but rather than make an immediate outlay they suffer their fellow-creatures to be prostrated with sickness, they paralyse the energies of the breadwinners, and too often force his family to become pensioners on "the rates," and thus ultimately entail an expenditure many times greater than that which would have been necessary in the first instance.

One main reason of this indifference arises from ignorance—ignorance of the mechanism and office of the human body and its component parts—ignorance or only shallow knowledge of the conditions necessary for healthy life—ignorance of the construction and arrangement of the houses we inhabit.

It is strange that, as reasonable beings, having faculties given us to be employed to the best advantage, having organs set apart for the performance of particular duties, the proper carrying on of which is essential to our health and comfort, we should know so little of our own bodies. This is a matter which nine people out of ten are content to leave in the hands of the doctors. This being so, it is not so surprising that the average master of a house is equally ignorant of the construction of the dwelling he inhabits—that, he thinks, is a matter for the builder or the architect. What is the consequence? From motives of trifling economy, often from sheer carelessness, want of supervision, or ignorance on the part of the labourers, a house is built in which the commonest sanitary precautions are deliberately ignored; and sooner or later disastrous results, in the shape of fever, rheumatism, diphtheria occur, while the minor evils of headaches, languor, indigestion, and the like, flourish without the cause of the evil being suspected till some manifestation more than usually striking makes it apparent.

It is of no use preaching a tirade unless we are prepared to suggest some remedy for these evils. We have already indicated what we think are the most potent remedies in the hands of individuals,—first a general knowledge of the structure and functions of the human body, and of the conditions likely to impair its action or to maintain it in a healthy condition. Some knowescape detection so often as they do. We should not have leaky drainpipes under our very floors, wastepipes which are mere conduits for sewer gases, and traps which are deceptive shams; we should have efficient ventilation without draughts, in fine we should have houses built for people to live in, not for builders to be rid of at the first available opportunity. Failing this kind of knowledge we do not think that it would be at all inconsistent with our individual freedom if district surveyors and nuisance-inspectors were compelled to perform their offices with far more rigour than they do now. The law, as we think, should forbid

FIG. 350.

PLAN.—1, Entrance Porch; 2, Inner Hall; 3, Staircase; 4, Drawing-room; 5, Bay Window, opening into, 6, Conservatory; 7, Library, forming the lower storey of the tower; 8, Verandah, terminating in, 10, Terrace; 9, Morning-room; 11, Dining-room; 12, Butler's Pantry; 13, Servants' Staircase and Closet; 14, Kitchen; 15, Scullery. Above there are six sleeping rooms, closets, bath-room, &c. Entire cost, well-built, with cellars, conservatory, hot-water apparatus, under £2000.

cerned, and to follow up such inspection by practical action whenever required.

We shall have to wait a long time for so revolutionary a programme as this to be carried out. "An Englishman's house is his castle," and therefore he is to be allowed without protest to poison himself, deteriorate the health of his family, and endanger the lives of his neighbours. In the meanwhile *paterfamilias*, just now suffering from one of his spasmodic attacks, will do well to consult the useful and unpretending little work whose title is given at the head of this notice. Existing circumstances have naturally led us to dwell on the construction of a house from a sanitary point of view, but we should be doing Mr. Wheeler an injustice, if we omitted to say that while his directions and explanations on the points we have referred to seem to us very judicious, his remarks on house building in general, or "the house as it should be," and on the various matters relating to buying or renting a house, are equally worthy of attention.

The illustration which we give shows a villa residence of varied elevation and convenient arrangement, permitting elegance without involving the necessity of a large establishment.

In conclusion, let us beg all about to erect houses, and all architects who may be employed for the purpose, to bestow a thought upon the entrance lodges, gardener's cottages, "bothies," and the like. How often do we see in close proximity to some mansion or villa, where comfort and convenience have been made the subject of anxious consideration, some structure erected for the dependents and retainers, absolutely unfit for human habitation, though it may be pictural—designed "to look well from the windows of the house," and so forth. For this evil we believe the architect is more generally to blame than the proprietor, though the latter is the more likely to secure faithful service in proportion to the consideration he manifests for the welfare of his *employés*.

The Young Collector's Handy-Book of Botany. By the Rev. H. P. Dunster, M.A. Small 8vo. Reeve & Co. Pp. 168.

We opened this little volume at an unfortunate page, whereon we are told that "albumen is a gummy substance surrounding certain seeds;" that the "calyx is the flower-cap or external fold of the floral leaves;" that the "capsule is a chest or dry seed vessel, as in the Poppy head;" that the "catkin . . . unisexual blossoms hanging like cats' tails." A little further on and we are told that the embryo is a leaf in an

immature state, that a gall is a humour in trees and plants produced by insects. Further experience shows us that the element of vagueness, and too often of incorrectness, is not confined to the explanations of the "hard words," but extends to the descriptions of the plants: for instance :—

"*Willow Herb.*—The flowers of this plant are curiously formed; petals ragged, stamens in two series, six long and six short, all within the tube of the calyx. It is a perennial. Its fine purple blossoms are seen on stems 3 or 4 feet high in July and August. It is sometimes called Purple Loose Strife."!

No greater end often no more correct information is given concerning the other plants mentioned in this volume, which is of value only for the clear woodcuts at the end, taken, as we believe, from the illustrated edition of Bentham's "British Flora."

Garden Memoranda.

NORWOOD NURSERY, BEVERLEY, YORKSHIRE.—In the East Riding of the great county of York, out of the usual traffic which seems to connect the mid-land route of railway communication, one would hardly expect to find anything in the form of a nursery, beyond a rough and half-cultivated place. In fact it is a very striking event for those who are in reality looking out for improvement and progress to find any horticultural and floricultural establishment in the provinces carried out in such a spirit, and in such taste, order, and skill, regardless of labour, cost, and complete detail of finish in every department, as must at once strike any visitor who enters, for inspection, this very remarkable nursery, of which we are about to give a very brief, and it is to be feared imperfect sketch. But where large sums have been expended for the advancement of civilisation and true progress, it is at least right to chronicle the spirit and honour of enterprising men.

In Orchids there is here a large collection, containing many fine plants and varieties of Cattleyas, Lælias, Aerides, Angræcums, Dendrobes, Cypripediums, &c., and in these houses are also probably the finest stock of Anthurium Scherzerianum in the country.

The New Holland house, a large structure, contains a grand collection of half-specimen and full-specimen Heaths, Azaleas, Genistellis, Pimeleas, and all the best varieties, in robust health. Three large stoves demand attention, containing a choice, extensive, and healthy stock of young, as well as specimen plants of Palms, Crotons, Marantas, Ixoras, Clerodendrons, Alamandas, Dipladenias, Stephanotis, and all the established favourites. And in order the fitter to accommodate many charming varieties, in all sizes; here may be seen probably the finest plants of Platycerium grande, Brainea insignis, and the Killarney Trichomanes, which can be found in any nursery. The large conservatory, a spacious building, 50 feet by 40 feet, contains grand specimens of Tree Ferns, magnificent Palms and Cycads, Dracænas, Phormiums tenax variegata and specimen Colensoi variegata, Yuccas, Aloes, Agaves, Camellias, Aucubas full of berries, Chrysanthemums, and others too numerous to particularise.

Besides the above are many smaller houses, filled with bedding-plants, such as young Pelargoniums, Ericas, Bouvardias, Coprosmas, Primulas, Cinerarias, &c.

The grounds are not extensive, but are kept up in first-class condition, and contain a very carefully selected assortment of fruit trees, Roses, ornamental plants, herbaceous plants, &c.

The nursery lies within 10 minutes' walk from the North-Eastern Railway, is easily reached from Hull, York, Scarborough, and will amply repay a visit. *W. F.*

THE WEATHER.

TEMPERATURE OF THE AIR AND FALL OF RAIN AT DIFFERENT STATIONS,

DURING THE WEEK ENDING SATURDAY, Dec. 16, 1871.

Dec. 14.—Generally overcast; thin rain fell occasionally.
" 15.—Overcast till noon; then variable. Slight fog. A little rain fell in morning.
" 16.—Overcast throughout and very gloomy about noon. Rain fell frequently.
" 17.—Rain fell between 12 and 2 A.M. Fine and cloudless at 9 A.M. Variable in afternoon; overcast at night.
" 18.—Overcast throughout. A little very thin rain fell occasionally.
" 19.—Generally overcast. Rain fell in the morning, and again very heavily between 10 P.M. and midnight.
" 20.—Generally cloudy all night: then cloudless. Rain fell during the early morning and occasionally during the day. Violent gale.

JAMES GLAISHER.

Miscellaneous.

CHRISTMAS itself has been the occasion of much diversity of opinion, for no less than 136 different days in the year have been fixed on for Christmas Day by Christian sects and learned men. These dates have ranged throughout every month in the year, and may be thus summarised :—The Egyptian Christians said it was in January. Wagenseil thought February or August, and inclined more strongly to the latter. Bochart was for March. Some, mentioned by Clemens Alexandrinus, placed it in April, and others in May. Epiphanius mentions two sects, the former fixing it in June, the latter in July. Wagenseil, we have seen, preferred August. Lightfoot says September 15. Scaliger, Casaubon, and Calvisius are for October. Several others put it in November; and the Latin Church on December 25, or that day now universally recognised by Christendom. This was decreed by Pope Julius I. to be fixed it on the same day that the ancient Romans celebrated the feast of their goddess Bruma, a festival much honoured by the heathen in the winter solstice, beginning on December 22. *People's Magazine.*

THE COPIQUE (Lapageria roses).—The plant winds over shrubs and low trees in a very elegant manner, and the flowers, shaped like those of a Lily, are often as much as 3 inches long, of a thick waxy consistence, and of a most splendid deep rose colour, minutely spotted with white in the interior, and marked at the base of each segment with a small blotch of dark purple. A white variety of the flower is also to be met with, but is of much rarer occurrence. The plant is a near ally of the beautiful Philesia buxifolia of the Strait (Magellan), but is much handsomer, and possesses a greatly more limited range, apparently only extending from the north of Valdivia to the north of Concepition, a space of between three and four degrees, while Philesia ranges over nearly fifteen. One interesting fact with regard to the Copique is its extreme hardiness, being almost the only plant that can exist in the area covered by the sulphurous smoke of the smelting furnaces. I found specimens in a flourishing condition winding around the skeletons of shrubs killed by the smoke. The Chilians sometimes make use of the flowers for poultices. *Cunninghame's Magellan* (p. 364).

THE RED SANDERS WOOD TREE (Pterocarpus Santalinus), which yields a valuable dye-wood, large quantities being annually exported from India, is, with other valuable Indian trees, receiving some attention in its cultivation under the Forest Conservancy of India. In the plantations at Codoor there are 10,000 Red Sanders trees planted out into pits. The seeds are collected in May and sown in June or July; if soaked in water for 24 hours they take about 25 days to germinate, but if unsoaked 30 to 40 days are required: they should be watered twice daily. The growth of these plants was very slow for the first three or four years, but during the last two years they have taken a great start, and many are now upwards of 20 feet high, with a girth of 12 inches. It is satisfactory to note the cultivation of this tree, for in some parts of India it is most wantonly destroyed, graziers cutting down the young saplings to any extent simply to feed their cattle upon the leaves.

WATERPROOF BOOT SOLES.—If hot tar is applied to boot soles, it will make them waterproof. Let it be as hot as leather will bear without injury, applied with a swab and drying in the fire. The operation may be repeated two or three times during the winter if necessary. It makes the surface of the leather quite hard, so that it wears longer as well as keeps the water out. It is a good plan to provide boots for winter in summer, and prepare the soles by tarring, as they will then become, before they are wanted to wear, almost as firm as horn, and wear twice as long as those unprepared. Ten years ago I met with a direction similar to the above, and with some hesitation I concluded to have it tried on the soles of a pair of field boots. By a piece of superorogance, a pair of thin-soled morocco boots was tarred with the others, the soles being saturated and the seaming too, all round, including the lower rim of the morocco all round the soles. As these boots are doing service yet, and have been much used every summer during the 10 years, I mention the fact because it furnishes what I then wished for, viz., a proof that the tar would not burn or otherwise hurt the leather. The soles remain like horn, and have never required any repair, and even the thin upper, apparently cracked in all directions from the first, has never torn but a little on one boot at the bend on the outer side of the foot. It has been oiled about once each summer, but the soles received only the one thorough tarring. Boot soles will take the tar best after having the grain worn off slightly. It soon dries in if exposed to the sun, and the odour even of gas-tar is quickly overcome by the all-conquering effects of dry earth. A short walk over a fallow field will remove it completely, and make it entirely unnecessary to inflict the custom of taking off the boots at the house entrance, unless there be some other reason for it than fresh tarred soles. *Correspondent of Country Gentleman.*

THE CULTIVATION OF COTTON IN SOUTH AFRICA.—During the past few years this is reported as very successful, so far as the growth and culture of the plants and the production of Cotton are concerned. At a recent Cotton show held at King William's Town upwards of 150 bales, amounting to nearly 70,000 lb., were shown, principally Sea Island Cotton. Some good samples of this variety, as well as of New Orleans, were exhibited for the prizes. Though it is clear Cotton can be grown successfully, the question still to be decided is whether it can be made a profitable crop.

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

THOUGH *Caladiums* are now for the most part at rest, they must nevertheless have so much attention paid to them as will insure their being wintered safely and with tolerable freedom from losses. I specially allude to this matter because I know that many of those who are not thoroughly versed in their culture invariably lose the larger part of their stock during this period of probation. The two main features to be observed in the treatment of the ginger-like roots of the Caladium when at rest I would mention as follows :—Do not dry them off thoroughly, on the contrary keep a slight amount of latent moisture constantly in the soil which surrounds them; also, do not keep them in a temperature below 55°, nor in one much above that heat. These remarks apply more especially to tubers of moderate size, and which have grown in moderate-sized pots only. The larger the size of the tubers the higher are their keeping properties, though under any circumstances, such as I have endeavored to warn the grower against, all may succumb to either wet or dry rot—the latter especially being injurious to them. *Gloxinias*, in like manner, cannot be placed in any out-of-the-way corner with impunity, though they may be kept off with immunity from injury, for these also suffer greatly from a too low temperature. During all mild periods in the weather let the utmost possible amount of air be afforded to *Calceolarias*, and especially such of the shrubby kinds as are grown in cool frames or other structures where other important subjects do not exist. It is only by inuring these thoroughly to the weather that thorough success can be looked for in the ensuing summer. Keep all valued subjects, such as *Ixoras*, *Burchellias*, *Boronias*, *Leschenaultias*, &c., in the full uninterrupted light, and well up to the glass. Be careful not to unduly water such plants as the following, even though they may be in flower, viz., *Tapinas*, *Sonerilas*, *Peperomias*, *Geneseas*, *Bertolonias*, &c., which are quickly injured by an excess of moisture at this dull period.

FORCING HOUSES.

Do not advance the night temperature much beyond 55° in connection with forced *Vines* at this time. I last week alluded to the amount of heat which should be afforded to *Pinories*, and would now add, keep them as dry as possible consistently with the requirements of the plants, atmospherically as well as at the root. Do not omit to give air on every favourable opportunity. In regard to the early *Peach* and *Nectarine* house, do not allow the

night temperature to exceed 45° to 47°. Keep up as much natural moisture as circumstances will admit, by sprinkling the trees over twice a day or so. Attend now to the thorough cleansing of the glass of the *Cucumber-house*, should any unwholesome greenness have become attached, as is not unfrequently the case. See also that each individual leaf is, if possible, so arranged that it can receive the full benefit of all the light possible. Keep up the bottom-heat to between 77° and 80°, if possible. Maintain a moderate temperature only during very dull days of, say, 75°; but should the sun shine, let the thermometer range upward to 95°, more or less, according to the brightness of the day or otherwise. Bear in mind, besides, that according to the heat—being artificial and extremely arid—so in proportion must be the expenditure of artificial humidity, without which these will not succeed. Do not overcrop the plants at this time, as this tends greatly to decrease their vigorous growth. As the gardener must operate in advance of time, let the necessary succession of *Strawberry plants*, *Asparagus*, *Seakale*, and *Rhubarb*, &c., be prepared.

HARDY FRUIT GARDEN.

Fruit trees, in orchards proper, are perhaps as much neglected in a general way as any trees planted in this country. I have repeatedly urged the need of thinning out the centre branches, to admit light and air more freely amongst the branches. This done, I would suggest a simple operation, which in the doing will not cost a tithe of the benefit to be derived. Pare up the turf as wide as you think proper, rolling it back under the branches, from the bole; just move the surface soil amongst the upper roots carefully with a fork, place a thick coat of good dung thereon, and put the turf back again as before. As we look for, and value annual crops, so should we by this and similar means aid and induce the trees to bear them, and not leave them to chance.

KITCHEN GARDEN.

Some definite arrangement should now be come to regarding the distribution of the crops in this department in the subsequent spring. If a new *Asparagus bed* is to be formed, the ground should be prepared by thoroughly trenching and manuring it to the necessary extent, some 3 feet deep, breaking up the bottom well, that the pulverising action of the air may exert its beneficial influences. During mild weather remove the glasses or lights entirely off *Cauliflowers*, *Lettuces*, *Endive*, &c., and so afford them all the fresh air possible. Attend to any hedges which may exist around any kitchen garden enclosure by weeding them thoroughly: if a Thorn hedge, cutting it back, &c., and so forward all such work at this season. Dust over the outer unprotected beds of *seedling Lettuces* with soot, lime, &c., to ward off destructive insects, which often commit havoc amongst them during mild periods. Clear all kinds of garden refuse, and convey it to the rubbish heap, and so make even the signs of decay a source of future productiveness. *W. E.*

Notices to Correspondents.

CHRYSANTHEMUMS: *F. L.* Your inquiry is not very definite. If you mean for cut blooms, suitable for staging at exhibitions, you may take—Queen of England, White Queen, Jardin des Plantes, Dr. Brock, Lord Lansdowne, Annedotum, Prince of Wales, Versailles Defiance, Prince Alfred, Plutus, Mrs. W. Holborn, Campestroni, Lady Harding. If plants for staging, take—Vesta, Christine, Chevalier Domage, Golden Christine, Her Majesty, Lucifer, Alfred Salter, Rifleman, Lord Palmerston, Prince Albert, Julie Lagravère, Lord Clyde. There are many others.

CRATÆGUS COCCINEA MAXIMA. Our correspondent, who lately referred to this fine berried plant, wishes to say that he was in error in stating that the flowers were red: they are white.

GRAPES: *W. W. S.* Some of the finest Black Hamburgh Grapes we have seen were grown under rough plate glass: we should, however, prefer glass of more transparency for White Muscats. We cannot tell exactly what spot you mean without seeing it. Have you kept up sufficient heat? It seems to us that what you speak of is caused through cold and damp.

INSECTICIDE: *J. H. C.* Experiments in progress: so far satisfactory.

NAMES OF PLANTS: *A. B.* 1. One of the forms of Selaginella Martensii; 2 and 5, apparently both Asplenium bulbiferum; 3, Asplenium flaccidum; 4, Pteris serrulata; 6, Adiantum cuneatum—all wretched scraps. —*W. R. G.* Anemidictyon Phyllitidis; 4, some Leguminous plant, quite unrecognisable without flowers; 5, Selaginella Martensii.—*T. A.* 1, 3, 5, all forms of Lastrea dilatata; 2, Lastrea Filix-mas; 3, may possibly be Lastrea spinulosa, but you have only sent the tip of a frond, which is insufficient. All hardy and native.

TREE FERNS: *A. B. C.* Re-pot as soon as growth recommences in spring. If you give them plenty of fresh soil well drained, the pot-bound roots will take care of themselves. The Cibotium, if well rooted, may be safely put into a rather larger tub, and if well cared for should be coloured larger before the end of the summer.

TRICOLOR PELARGONIUMS: *W. W. S.* Your Pelargonium shoots die off in the way you describe through sourness of the soil, or a cold atmosphere.

CATALOGUES RECEIVED.—James Carter & Co., Gardener's and Farmer's Vade Mecum for 1872.—Dicksons & Co.'s Catalogue of Forest and Ornamental Trees and Shrubs, Conifers, Rhododendrons, &c., and Descriptive List of Gladioli.—B. S. Williams, Descriptive Catalogue of Flower, Vegetable and Agricultural Seeds, &c.

COMMUNICATIONS RECEIVED:—E. L. (Your letter had no enclosure: the other questions next week.—A. R.—S. H.—T. Green & Son.—F. S. & Sons.—G. V. (next week).—D. S. G.—A. D.—W. F. C.—J. T. M.—J. May (next week).—J. Miller—W. P. A.—W. F. R.—D. T. F.—J. B.

Markets.

COVENT GARDEN.—Dec. 22.

The improvement we anticipated has hardly been realised; a few things have been in a little better demand, but the general tone of the market is not like the week before Christmas. We have a good supply of Pines, hothouse Grapes, and Pears. Apples of English growth continue more scarce, but good stocks have been strengthened by the arrival of Newtown Pippins, Baldwin, and others from the United States.

FRUIT.

	s. d.	s. d.
Apples, per ½ sieve	2 0 to 5 0	Melons, each	2 0 to 5 0

POTATOS.—Southwark, Dec. 18.

During the past week the arrivals coastwise, by rail, and from the docks have been considerable in excess of the demand, which continues very languid, and the following quotations have been barely maintained:—Yorkshire Flukes, per ton, 100s. to 130s.; Yorkshire Regents, 60s. to 100s.; Dunbar and East Lothian do., 110s. to 140s.; Perth, Forfar, and Fifeshire do., 90s. to 110s.; do. Rocks, 85s. to 90s.; Kent and Essex Regents, 50s. to 90s.; do. Rocks, 70s. to 80s.; French Whites, 60s. to 80s.

PARTNER WANTED, in an Established Market-Gardening, Florist, and Seed Business, in a very flourishing locality. To an energetic and persevering Man, with small capital, this is an opportunity of getting into a good business seldom met with.—Apply, by letter, to A. Z., *Gardeners' Chronicle* Office, W.C.

WANTED, an energetic young MAN, who understands the Cultivation and Propagation of Stove and Greenhouse Plants, Ferns, &c. To a deserving industrious Man, liberal wages will be given. For further particulars, address to Mr. BRUCE FINDLAY, Botanic Gardens, Manchester.

CLERK to the Curator, Royal Gardens, Kew (age 20 to 30).—An Open Competition for this situation will be held in London on JANUARY 16, and following days. Candidates must be familiar with Arithmetic and Book-keeping, and must show that they have had the necessary Technical Training.—Apply, at once, for the Regulations, and for the necessary Forms, to The SECRETARY, Civil Service Commission, Cannon Row, S.W.

SECOND ASSISTANT in the Herbarium, Royal Botanic Gardens, Kew (age 18 to 30).—An Open Competition for this situation will be held in London, on JANUARY 16, and following days.—Application for the Regulations and for the necessary Form should be made to the SECRETARY, Civil Service Commission, Cannon Row, S.W.

Seed Trade.

J. WHEELER AND SON, of Gloucester, have an OPENING for a JUNIOR ASSISTANT SHOPMAN.

WANTED, an ASSISTANT SHOPMAN.—Must be experienced, and be able to furnish first-rate references. Situation permanent.—Apply, stating where previously employed, and wages required, to Messrs. HENRY CLARKE and SONS, 39, King Street, Covent Garden, W.C.

Seed Trade.

WANTED, a young Man as SECOND SHOPMAN.—One who has had some experience, and accustomed to counter-work preferred. Address, stating wages required, with references, to Box 61, Post Office, Hull.

WANT PLACES.—Letters to be Post Paid.

EXPERIENCED GARDENERS (or as GARDENER and BAILIFF), of various qualifications, recommended to Gentlemen.—Further particulars given on application to Messrs. E. G. HENDERSON AND SON, Wellington Nursery, St. John's Wood, N.W.

Gardeners and Under Gardeners.

WM. CUTBUSH AND SON beg to state that they have at all times the best KEN of many qualifications, whose characters will bear the strictest inquiry. Any Gentleman making application would save time by first stating the duties to be undertaken, wages required, &c., so that suitable Men may be selected. —Highgate Nurseries, London, N.

GARDENER (Head).—Single; understands the profession in every department of Land. Can be well recommended.—Apply, first to W. MUIR, Oulton Park, Tarporley.

GARDENER (Head).—Thoroughly understands the Management of Stove and Greenhouse Plants, Orchids, Ferns, &c., Early and Late Forcing, and Gardening generally.—T. M., Pine-apple Nursery, Maida Vale, London, W.

GARDENER (Head).—Has a thorough practical knowledge in every branch of Gardening in all its character. —R. B., 26, Vernon Terrace, Havelock Road, Great Yarmouth, Norfolk.

GARDENER (Head).—Age 40; thoroughly understands the profession in every department of Gardening. Has lived in some of the best Noblemen's and Gentlemen's places. Particularly good at Ferns, Vines, Melons, and Cucumbers in frames, pits, or houses, Mushrooms, Stove and Greenhouse, and Flower and Kitchen Garden; also can manage a dairy-out, if required.—State particulars to A. B. C., Messrs. Rollinson & Sons, The Nurseries, Tooting, S.W.

GARDENER (Head).—An Englishman, age 40, married, two children (ages 13 and 9), begs to offer his services to any Nobleman or Gentleman requiring a thoroughly practical man in every department of his profession, and having had extensive practice in the improvement of Grounds, Buildings, &c. Is thoroughly competent to take charge of Trout-breeding Arrangements, &c. Has a character of 16 years, that will bear the strictest investigation. Present Residence has been at the above for 6 years.—G. WYATT, Shanbally, Clogheen, Ireland.

Gardener or Garden Bailiff.

GARDENER in a Gentleman's Establishment, or GARDENER and FARM BAILIFF.—Middle-aged, married, respectable. Nine years' thorough previous practice.—Address, stating wages, particulars, &c., to WILLIAM RAY, Everly Lodge, East Barnet, Herts.

To the Nursery Trade.

PROPAGATOR (Soft-wood), GROWER, or any other capacity.—A sober, steady, attentive Man; thoroughly practical in all branches of Nursery business; a Single Person moderate. Good reference.—P. J., 8, Dagmar Terrace, Hamilton Road, Lower Norwood, S.E.

PROPAGATOR (Under).—Age 21; four and a half years' experience.—C. F. O., 5, Weardale Road, High Road, Lee, S.E.

To Florists.

BOUQUET MAKER, and to fill his time up in Seed Shop or Glass Department.—Age 24; an abstainer. A permanent engagement required. Wages, £1 per week, &c.; 8s. per week, 20, Newton Street, St. John's Road, Hoxton, N.

MANAGER, or ASSISTANT MANAGER, to Gardens, Tea, Coffee, Sugar, or Cotton Plantations.—Age 28, single, English; has had ten years' practical experience in some of the largest gardens in Europe. Well educated. No objection to any part of the world. Highest references.—Z., Mr. H. SLATER, High Street, Uttoxeter, Staffordshire.

To Farmers.

STEWARD or BAILIFF.—A Farmer's Son, who for the last six years has acted as Overseer on a Farm in Aberdeenshire, wishes to meet with a similar situation being made to CARDNO and DARLING, Seedsmen, Aberdeen.

SALES BY AUCTION.

The Agricultural Gazette.

SATURDAY, DECEMBER 23, 1871.

SOME weeks ago a correspondent asked a question regarding THE COPROLITE BEDS of Cambridgeshire, and having before us the notes of a recent visit to these "diggings," we now proceed to answer it. These deposits are found generally at the bottom of the so-called "greensand" formation, lying in the last foot or perhaps two feet of it, above the "gault." They are not continuous, except for a few acres together; they are by no means equally full of the greenish-black nodules for which they are worked over; and they are at various depths beneath the surface. Similar beds are occasionally found below the gault, where they lie above the lower green-sand; and coprolites are also found in the "crag" of Suffolk and Norfolk, a much more recent formation. The Cambridgeshire coprolites in the upper green-sand are, however, the most valuable, containing a remarkably uniform (52 to 56) percentage of phosphate of lime, with much less mischievous ferruginous matter than is present in the crag and lower green-sand fossils. A recent Royal Commission has investigated the probable duration of the coal fields of this country. There is a useful field for a similar inquiry regarding coprolites. Beds are now being rapidly worked out, and though no doubt the area in which they may be found is large, and new discoveries are constantly being made, and the district is far from having been thoroughly "prospected," yet after all there is but a limited supply, and there are increasing annual demands upon it. Mr. LAWES alone digs 12,000 to 15,000 tons of coprolites each year, corresponding to probably an area of 60 acres, and the quantity dug out in the whole of England must be from eight to ten times as much.

It was to some of Mr. LAWES' workings that we paid a visit last week, and his experience may be quoted for the information of those who may believe that they have coprolites in their land. This belief may have arisen from some of the characteristic fossils having been found within the soil, or having been turned out when digging drains. The first step is to examine the field by borings. There is a tool for the purpose, a sort of taster, which bores a core through the subsoil to be brought up from any depth, of 2 or 20 feet. Such borings should be made at 10-yard intervals all over the suspected area, and if the existence of these coprolites is revealed by them, the layer must be uncovered here and there, perhaps in three or four places in a 10-acre field, and the quantity of the coprolites must be ascertained by washing a square yard or two of the layer, taking up its whole thickness for the purpose. Indeed, if the owner has ascertained the existence of a bed of sufficient richness, all this somewhat expensive process will be done for him by the purchaser. He will thus ascertain how many tons of coprolites he may expect per acre, and the depth from which they have to be dug.

The buyer will offer a price according to these two factors in the valuation. He will make a contract with the tenant also, engaging to complete the work of extraction in three or perhaps four years, undertaking to level the moved subsoil and replace the soil, leaving everything as he found it, and paying a certain sum per acre for the lost profits of the occupation. The contract with the landlord specifies the purchase-money, varying from £60 to £100 or more per acre, according to the ascertained productiveness of the bed, and the estimated cost of working it.

When these particulars are settled, the purchaser proceeds to work the field. He sinks and bores a well, getting through the gault into a water-bearing stratum. He sets up an 8 or 10-horse power engine in a shed near the well, and thence he pumps sufficient—say, 30 or 40 gallons. a minute—into a horizontal washing-mill, into which and out of which this water continually pours. The mill itself is a circular ring trough, perhaps of nearly 14 feet outer and 9 feet inner radius, thus providing a circular bed less than 5 feet wide and 3 or 4 feet deep, into which, it may be, 100 trucks of the dug-out coprolite stratum are tilted, one in every five or six minutes, throughout the day. A pair of heavy long tined iron drags within this trough are continually driven round and round, by proper mill gearing, worked by the steam-engine, and the muddy water, laden with the clayey matter thus discharged, is constantly pouring from it, leaving the hard nodules in the bottom of the trough. After 60 or 70 loads have been thus tilted in, the water is allowed to run clean, and the coprolites, roughly tumbled over by the spade, are at length thrown out clean. Three such washings, each of 4 tons weight or thereabouts, may be got out in two days. In one field at Shillington, near Hitchin, there were three such mills at work, and 100 tons a-week were being got—about 170 men and boys being at work. The diggings here are very deep, and the costs in this case probably are largely in excess of the average.

While the mill is being erected a party of men commence digging down to the bed, clearing, it may be, from 6 to 10 feet width, according to the depth of the layer, along one side of the area. We know of no workings more than 18 feet deep. If the stratum is deeper than that it does not pay to lift it, unless indeed it be unusually productive. The "rid" or waste top layer is in the first instance removed to a piece of land hired to receive it, the top soil being kept separate for replacement; but the next slice of land, yard by yard, is thrown forward into the trench dug out, the top soil for a width of perhaps 30 yards being put in barrows and wheeled into a ridge along the top of the first trenched slice of land. When 30 yards in width of the field has been dug over and the stratum dug out has accumulated in a heap beside the mill, the next 30 yards is skinned; and, the soil being placed in another ridge parallel with the first along the nearest line of moved subsoil, the interval of roughly turned over subsoil between the two ridges becomes a "pane," on which the washings of the mill can be poured. The washing then commences. Clean water is pumped into the mill, and the muddy stream is pumped from it, and by troughing is conveyed evenly over the surface of this interval until another space is ready, which in its turn receives its share. In this way then the whole field is cleared, dug over perhaps 5 feet, perhaps 15 feet deep. The coprolites, washed out and picked over, are weighed into the nearest railway trucks; the mud washed from them is evenly spread over the intervals between the parallel ridges of moved soil; and the whole, after a summer's drying, is ready to be levelled back again. This may cost from £8 to £14 an acre. The farmer gets his land restored to him with the subsoil deeply stirred, and the soil relaid evenly; the wells are filled up, and the machinery removed to other diggings, and the land is left better than it was before. The landlord has meanwhile had perhaps the double of its agricultural value put in his pocket; an army of labourers—and a capital set of fellows they looked, the Cambridgeshire quarrymen, or navvies, in Mr. WESTON's employment, under Mr. LAWES, at Shillington—have earned their 15s. a-week apiece during the winter months; and the tenant has had an easier earned farm profit (with his rent paid for him) than any other field has given him. Moreover, the land is improved without expense to him. We saw a large stubble field, on which manure was lying here and there on two portions, the rest remaining unmanured. This last was where the coprolites had been dug two or three years ago, and the other portions undug, needed the manure to bring about an even crop over the whole. It is plain that everybody is well served when a coprolite bed is found and worked; and the discovery of Professor HENSLOW has proved most fortunate for landlord, tenant, labourer, alike.

The whole workings at Shillington are conducted on the piece-work plan. The top soil is removed and wheeled into ridges and the first 3 feet deep of subsoil is thrown forward—the whole for, perhaps, 4*d.* a cubic yard. The remainder, thrown forward in great masses, and dug down afterwards to clear away the stratum, costs from 2*d.* to 3*d.* per cubic yard, till you reach the layer. This, which is rarely more than

18 inches thick, soon reveals itself by the rattle of the pickaxe among the nodules, and is thrown up on to the surface and loaded into trucks, which are drawn to the washing mill. The thinner the bed the richer generally it is, and a thin bed near the surface is thus a very valuable property, occasionally yielding upwards of 300 tons of coprolites per acre. Worth 50s., or rather more, per ton at the railway station, they are carried thence for grinding, and thereafter for the sulphuric acid treatment to manufactories over the island. And yielding, after skilful manufacture, a superphosphate rich in soluble phosphoric acid, they thus contribute to the current fertility of the whole island from stores of excrementitious matters deposited long ages before the present configuration of the earth's surface existed.

—— At Mark Lane, on Monday, the trade in English Wheat was dull, at the prices of that day se'nnight; increased depression characterised Wednesday's business.——Butchers having been largely busy last week, Monday's trade in beasts at the Metropolitan Cattle Market was very slow. Trade was bad for sheep. Thursday's was nearly a holiday market, purchases being made very sparingly—sheep scarcely inquired after.

—— Mr. W. H. Delano, C.E., the financial secretary of the French Peasant Farmers' Seed Fund, and manager for many years of the Continental business of Messrs. J. & F. Howard, Bedford, has accepted the post of manager to the French Asphalte Paving Company, 59, Rue de la Victoire, Paris. Mr. Delano retains his office at No. 4, Cheapside, E.C., where the agency of the Société des Agriculteurs de France will be carried on under the superintendence of his brothers.

—— The following is an extract from the Message of President Grant to the Congress of the United States of America, having possibly some significance for English politicians and agriculturists :—

"The Report of the Commissioner of Agriculture gives the operations of his department for the year. As agriculture is the groundwork of our prosperity, too much importance cannot be attached to the labours of this department. In the hands of an able head, with able assistants, all zealously devoted to introducing into the agricultural productions of the nation all useful products adapted to any of the various climates and soils of our vast territory, and to causing all useful information as to the method of cultivation, the plants, cereals, and other products adapted to particular localities. Quietly, but surely the Agricultural Bureau is working a great national good, and, if liberally supported, the more widely its influence will be extended, and the less dependent we shall be upon the products of foreign countries."

—— Mr. Hope, V.C., of Parsloes, contributes a useful letter to the recent discussion in the columns of the *Times* on the subject of Sewer Ventilation, pointing out—1. That the best and cheapest way of ventilating a house drain is to place a loose-hanging shutter, of tidal size, outside the sea wall of the house to permit the sewage to flow out, but to prevent the gas flowing in, and then just outside this to run up to the top of the house a pipe the sectional area of which is equal to not less than half that of the drain. 2. That if sewer gas produced fever as it escapes into the majority of houses, either continuously or intermittently the cases of enteric fever would be almost indefinitely multiplied, and the country would soon be depopulated. Here the germ theory of disease comes to the aid of common sense and chemistry, and affords a solution of the difficulty. No one ever heard of a chemist catching an infectious disease, experimenting with gaseous compounds in his laboratory. Mr. Hope prefers therefore to believe with Sir Thomas Watson that it is not the gas which produces infectious disease, but specific germs which are occasionally present in the gas, and of the danger of the possible presence of which the gas may always be taken as an indication. The gas is the warning, but the germ is the real danger; and this alone explains how the same arrangements of drains and traps may suddenly produce fever, which have existed harmlessly for years previously, or at most have only produced a little nausea. 3. Mr. Hope adds :—

"I would protest most earnestly for the thousandth time against the notion, still so complacently entertained, that if good sewers are constructed and good ventilators added the sewage difficulty is solved. It is only removed to a little the disease form changed. The sewage still has to go somewhere. At present, in the case of inland towns, it goes into the drinking water of the next town down the river, and in the case of seaside towns it goes into the sea in which the invalid visitors bathe. Until it is converted, by its application to land, into plant life, it will continue in obedience to the laws of Nature to produce animal death."

—— The following translation of a letter, reporting the Effects of Steam Cultivation, which lately appeared in the *Wiener Landwirthschaftliche Zeitung*, has been forwarded to us for publication by Messrs. Fowler & Co. :—

"In the following I have the honour of communicating to you the results of experiments with steam-ploughing, which took place near Wieselburg, end of June, 1871. The figures are taken from the official report of the administration of H.I.H. the Archduke Albrecht's estates at Frauche Altenburg.

"The Administration had orders to take the exact measurements with regard to quantities, and it reports about the effect of steam-ploughing as compared with ploughing by horses, as follows :—

"The plots (in one large field), which were partially ploughed by animal power, partially by steam, employing either plough or grubber, remained as a fallow from 28th/29th June, and were put into Beetroot in the spring of 1871.

"The harvest gave the following results on the different plots :—

	Cwt. of Beet.
Ordinary deep ploughing, with oxen or horses, to 12 inches depth, ...	143.77 per joch.
By steam cultivation, ploughing 12 inches deep	201.75 ,, ,,
Ditto, 14 inches deep	253.45 ,, ,,
Cultivating to 12 to 12 inches deep	174.51 ,, ,,

"This shows an increase of respectively 58, 109 and 30 cwt., or of 40, 76, and 24 per cent. in favour of steam-ploughing, compared with horse labour.

"The trial plots were close to each other. The nature of the alluvial soil was, therefore, of the same quality, and the difference in the results appears to be due solely to the superior quality of the cultivation.

"After the experiments at Altenburg, this steam-plough went to the estates at Bellge; similar experiments have been made on these estates, but the figures are not yet in the hands. According to order of H.I.H. the Archduke Albrecht, two more steam-ploughs were ordered, of which one is destined to work at Altenburg, where agricultural tourists of that district will be enabled to get personally acquainted with steam-ploughing and the steam cultivation.—(Signed) *Jesse, Vienna, December 1, 1871.*"

—— We quote from the *Times* portions of a description of the New Market for Imported Live Stock at Deptford which lately appeared in its columns. A visit to the place on Thursday gave one the impression that a great deal remains to be done before the old dockyard will have been completely converted to its new purpose. This, however, advertised to be opened for use on Thursday next :—

"The dockyard at Deptford, comprising an area of 22 acres, with a river frontage of 1012 feet, included a tidal basin of 13 acres in extent, with seven 'slips' or deep excavations for the reception of vessels now being covered by four great sheds, and nearly half the remainder of the area was occupied by ranges of buildings, houses, yards, and gardens. The arrangements for the conversion of these old dockyard premises into a new market were designed by Mr. Horace Jones, F.R.I.B.A., the City architect. By connecting together the three great sheds around the dock basin, the architect has formed the principal market-place area, in ground plan of a pentagonal horse-shoe form, with the basin in the centre, and the side next the river left uncovered. From the two ends of this horse-shoe range of lairs two separate piers or landing-stages, 350 feet apart, project into the river; and a third landing-stage, 400 feet from the east, is provided for a long shed, which stands apart from the other lairs. Each pier, consisting of timber work of very strong and superior character, projects 172 feet from the frontage, terminating in a landing-stage 60 feet in length, flanked by dolphin piers; and upper and lower fixed platforms, one 14 feet above the other, are being constructed for unloading at high or low tide. At low tide there is a depth of 18 feet or more of water, so that a steamer may lie alongside the pier head to discharge cargo at any state of the river, and three vessels may be unloading simultaneously. Should disease appear in any of the cargoes, one of the piers or landing-stages can be used for isolation. Cattle and sheep will walk off the ship along a gangway, just as passengers pass off a river steamboat; and Mr. Philcox, the clerk of the market, has contrived an arrangement of gates for the purpose of removable pens for receiving the animals at any part of the stage front and prevent accidents. A traversing steam crane, with a jib projecting 35 feet, will land in a sling any animal unable to take his own way from the ship, and the whole range of shed is divided by two brick walls into four large compartments for the better separation of healthy and suspected cargoes. The shed-roofs of the 'slips,' some 80 feet or 90 feet in height to the ridge, were open at the sides, but these have been converted into houses, with enclosures of wood-framing, the lower portion boarded, the upper part glazed, with a large aggregate area of opening panes and of glass surfaces under the roof-ridge. The pens are paved with brick on edge, and the roadways of 20 feet breadth passing down the centre of each building are of granite pitching. The new roofs uniting the original lofty arches are of wood scale, carried upon iron pillars, and are about 15 feet in height. Open pens have been fitted up a few iron pens, constructed of iron stanchions and round bars, while some sheep-pens, with their movable hurdle-racks, testify to the ingenuity of Mr. Rudkin, their designer. But nearly all the cattle and sheep pens are constructed of stout oak posts and bars, two different varieties of headstall for feeding and watering having been contrived according to the practical knowledge of Mr. Rudkin and Mr. Bevington, two active members of the City Markets Committee. Water-troughs of wood, connected together by short lengths of pipe, are fitted in most of the cattle pens, but some have smaller troughs of iron, and water is turned on by a cock at the end of each row of headstalls, the cast-iron water mains being filed by the Kent Waterworks Company from their artesian wells. Iron hay racks are hoisted in the sheep-pens. Each lair is well lighted at night by gas standards. The cattle pens are of 24 feet wide, and 60 feet to 90 feet long, according to the breadth of the building, the pens running transversely from the central roadway to the side walls, while 6-feet broad passages divide pen from pen. Each sheep-pen measures 27 feet in length by 10 feet wide, the fences consisting of wooden uprights, with iron round bar rails, and small iron drinking-troughs are placed upon the ground, and connected by pipes, so that water flows from one to another.—By a rough estimate there must be more than 5½ acres of these lairs under cover; and the exact calculation is that, with an allowance of 30 square feet per beast, there is accommodation for 3000; or, allowing 22 square feet per beast, there is space for 5300. At 5 square feet for sheep, there are pens for 11,500; or at 4 square feet for sheep, there are pens for 14,500. As a test of the sufficiency of this house accommodation, take the *maximum* importation arriving in readiness for a Monday market; this occurred on October 15, 1865, when 4074 beasts, 171 calves, 426 pigs, 14,500 sheep arrived in London from Harwich in the course of a Saturday and Sunday's traffic. Deptford, therefore, that the Deptford market is capable of warmly housing, feeding, and watering any number of foreign cargoes likely to arrive for any one market day. The animals will be sold alive in their pens, and then butchered in the abattoir.—These ranges of fine slaughter shops have been formed of the former arsenal and store-rooms, a pile of brick buildings standing midway between the two landing-stages, originally designed for very different use when they were erected in the last century, around the remains of an old monastery, which still stands, bearing the date A.D. 1513. The cattle slaughter houses, twenty-two parallel rows, with a court between, each row being divided into 10 shops, of which the dimensions are 43 feet in length by 23 feet in breadth, and each of these shops is parted into two bays by iron pillars supporting the roofing, the total length of which is about 22 feet. The partitions are of wood, the lower portion closed, the upper part consisting of open upright wood rails. The floor is asphalte, excepting that about one-third next the slaughtering end is flagged with large flagstones. A wooden pound outside the entrance receives each beast till his turn comes for the poleaxe. There are six separate slaughter-houses for sheep—namely, three measuring 42 feet by 24 feet each, and three measuring 28 feet by 24 feet each; and as 900 to 450 sheep can be hung up in one house, this amounts to an accommodation for killing 2200 sheep without removal. Hence it appears that ample accommodation for both buying and butchering is provided at the Deptford market; and, indeed, the smaller fittings, such as the 'crutch' and the 'fat-tray,' are now in perfect readiness for use. Every arrangement for drainage, cleansing, and ventilation has carefully attended to, and the long line of marine barracks and workshops has been furnished as stables and van houses for use by the salesmen and butchers, with stores for hay, offices, &c. ; while a tavern and coffee-house, with a limited number of beds, have not been forgotten.

—— At the Brentford Petty Sessions on Saturday last, Mr. Price Jones, a cattle dealer, of Abergele, North Wales, and John Thomas, his drover, were summoned for causing a herd of cattle to be driven along the road at Twickenham while several of the animals were infected with foot-and-mouth disease. Mr. W. Jarvis, local cattle plague inspector, stated that on Sunday, November 12 last, he overtook, on Twickenham Common, a drove of 125 Welsh cattle, under the charge of Thomas, and on getting among them he observed that about 50 of them bore symptoms of the foot-and-mouth disease. Thomas said they belonged to Mr. Jones, who was behind them on to Kingston. Information was sent to the latter and he came back to Twickenham, when witness served him with notice of the declaration of the disease in his herd. As he left Jones at the field his last words were, "Now, mind, Mr. Jones, those things must not be removed." Early next morning witness went to the field to see that the animals were fed and watered, and he then found all missing. He traced them to Kingston fair. Richard Lovell proved that the cattle were removed as soon as the inspector left. For the defence it was argued that none of the beasts had the disease when sold, and that Jones, when he left, thought had just recovered from it. The Bench fined Thomas £50, and Jones £100, including costs.

—— The Journal of the Agricultural Society of New South Wales, which is the consistent advocate of Judging by Points, publishes specimens of the award paper on a recent occasion, wherein the whole status of the beasts exhibited is distributed over 15 columns—the thousand marks, to which ideal perfection attains, being divided thus :—90 for colour and hair; 80 for hide and handle ; 60 for evenness of flesh and fat ; 70 for horn, eye, expression, face, and muzzle ; 60 for neck, throat, shoulder, and forearm ; 70 for breast, brisket, and chest ; 50 for chine and back ; 90 for fore and back ribs ; 50 for loin ; 60 for flank and belly ; 110 for rump, hip, quarter, tail, and set-on ; 60 for twist and thigh ; 40 for bone ; 60 for size ; and 100 for general symmetry. The estimate is given under each head in reference to any beast passing under judgment, and the totals vary from 220 up to the ideal 1000 in the 60 or 70 instances which are cited. It seems to us that the method is only wanted where there is a near approach to equality, and that it is just there where it will not safely apply. Take, for example, No. 168 and 171 on the published list : the former had achieved a total of no less than 925 marks, the latter only 915—the one accordingly took the first prize, the other the second. But now, on looking through the lists, we find that the latter of the two is the better in respect of "good symmetry" and of "size," in respect also of superiority in "twist and thigh," and "flank and belly," and

"horn, and eye, and expression," and "hide and handle," and "colour and hair." Of these several points the first, third, and sixth, would certainly be accounted very important. Moreover, it was equal to its competitor in "bone," "loin," and "chine and back." The first prize beast, on the other hand, was superior in "evenness of fat and flesh," "neck, throat, &c.," "breast, brisket, &c.," "chine and back," "fore and back ribs," and "rump, hips, quarter, &c." We doubt if arithmetic, to which the task of deciding merit is here remitted, is capable of performing it aright. Better let two such equal animals walk round the ring, and let the impression of vigour, health, and style, qualities of which it is impossible to make a numerical valuation, determine the award.

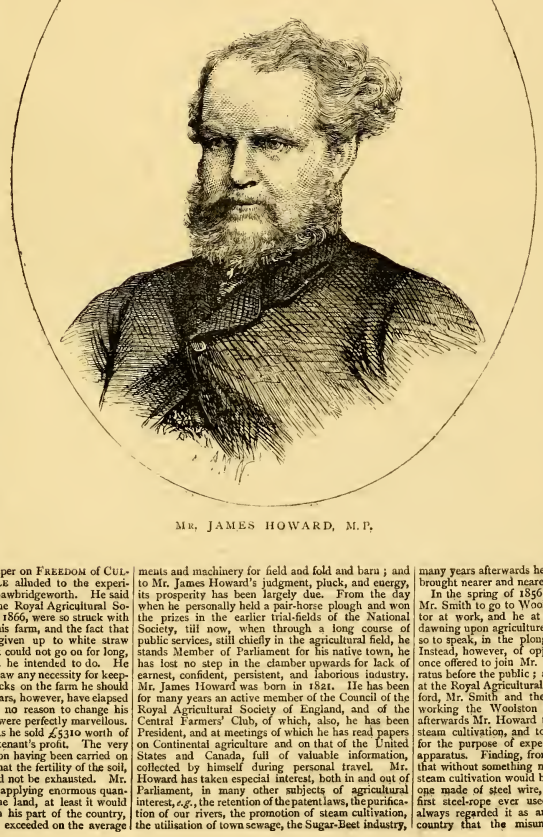
—— Mr. JEMMETT, of Murrell Hill Farm, Binfield, Berks, tells us, on the subject of FARM ACCOUNTS, that the majority of his correspondents speak of his "Annual Farm Account-Book" as satisfactory, but as requiring in the pocket-book additional space for the labourers' names. Provision is now made for 14 names. To meet, however, the case of larger farms, or for the use of stewards or bailiffs, the pocket-book form is now arranged anew, the object being twofold: 1st, to give the same room in a column of pay list as is given in the "Annual Farm Account-Book" — two columns (recording for a fortnight) meeting the requirements of the 200 to 600 acre farmer. On pp. 2 and 3 there is the same form for recording the work done as is given in the "Annual Farm Account-Book," also for a fortnight. Then follow notes of stock and corn, with cash account for the same period — lastly, a page for memoranda and engagements. In cases where the farmer requires to record the time and employment of 30 to 35 labourers, the second column of pay list must be taken into use. A bailiff can use the first column of pay list to note the time of the labourers employed on the farm proper, second column for those employed on account of gardens, home grounds, woodland, drainage, or any other permanent improvements, as the case may be, the work done being recorded on p. 4,— in these cases making the six pages a full record of one week; whereas the ordinary farmer, employing up to 20 hands, will find space for every entry for two weeks.

—— At an adjourned meeting of the members of the Wisbech Chamber of Agriculture, to continue the discussion on Mr. RUSTON'S paper on FREEDOM OF CULTIVATION, Mr. J. H. LITTLE alluded to the experiments of Mr. PROUT, near Sawbridgeworth. He said that the Commissioners of the Royal Agricultural Society, who visited his farm in 1866, were so struck with the amount of stock on his farm, and the fact that nearly the whole of it is given up to white straw cropping, that they thought it could not go on for long, and asked Mr. PROUT what he intended to do. He answered that as soon as he saw any necessity for keeping a stock of sheep or bullocks on the farm he should not hesitate to do so. Five years, however, have elapsed since then, and he has seen no reason to change his tactics. In 1870 his results were perfectly marvellous. Off 450 acres of strong lands he sold £5310 worth of corn, leaving £1880 as the tenant's profit. The very fact of that kind of cultivation having been carried on for nine or ten years proved that the fertility of the soil, if it was properly used, could not be exhausted. Mr. PROUT was in the habit of applying enormous quantities of artificial manure to the land, at least it would seem enormous to people in his part of the country, although he did not think he exceeded on the average 50s. an acre. He thought landlords and agents were in danger of forgetting the different circumstances of agriculture now to what they were 20 years ago. They had now an almost inexhaustible supply of different manures which they did not possess to any extent 40 or 50 years ago; and he thought some consideration should be shown to tenants who were willing to use those manures, and to take advantage of the other improvements in agriculture, and that they should be allowed almost perfect freedom in cultivation.

NOTEWORTHY AGRICULTURISTS.

MR. JAMES HOWARD, M.P.

THE leading member of the great Bedford firm of agricultural machine makers deserves a prominent place in the list of noteworthy agriculturists. The growth of little more than 30 years—not much older than the Royal Agricultural Society of England—this firm is now among the largest manufacturers of implements and machinery for field and fold and barn; and to Mr. James Howard's judgment, pluck, and energy, its prosperity has been largely due. From the day when he personally held a pair-horse plough and won the prizes in the earlier trial-fields of the National Society, till now, when through a long course of public services, still chiefly in the agricultural field, he stands Member of Parliament for his native town, he has lost no step in the clamber upwards for lack of earnest, confident, persistent, and laborious industry. Mr. James Howard was born in 1821. He has been for many years an active member of the Council of the Royal Agricultural Society of England, and of the Central Farmers' Club, of which, also, he has been President, and at meetings of which he has read papers on Continental agriculture and on that of the United States and Canada, full of valuable information, collected by himself during personal travel. Mr. Howard has taken especial interest, both in and out of Parliament, in many other subjects of agricultural interest, *e.g.*, the retention of the patent laws, the purification of our rivers, the promotion of steam cultivation, the utilisation of town sewage, the Sugar-Beet industry, &c. It is probably his work in the promotion of steam cultivation that most of the readers of this note will remember when thinking of his services to agricultural progress.—To him also was owing the origination last year of the Seed Fund for the benefit of French farmers, by which £50,000 worth of seed was sent, chiefly by English farmers, to meet the wants of the districts which had been ravaged by the war.



MR. JAMES HOWARD, M.P.

To this, taken from *Cassell's Farmers' Almanac*, we add further notes from another source:—

Mr. Howard possesses many other claims to the recognition and esteem of the public than those which are due to his connection with the great manufacturing firm at Bedford. For many years he has taken a deep interest in the advancement of agriculture and in the progress of agricultural societies. His management, too, of his own farms has been a useful example of successful strong land culture by steam-power.

Mr. James Howard was born October 16, 1821. He was educated at the great public schools of his native town, Bedford, where he very early distinguished himself. Before the age of 14 he had carried off three of the principal annual prizes, and upon the sudden dismissal of the head master of the lower school, he was placed, at this early age, in charge of it, and for some months discharged the duties of a schoolmaster, much to the satisfaction of the head master, who, to the day of his death, watched the career of his pupil with a lively interest.

For many years Mr. J. Howard's energies were almost entirely devoted to the management and extension of his own business. Naturally fond of mechanical pursuits, he turned his attention, soon after leaving school, to the improvement of the ploughs made by his father. In 1841, with a plough of his own design — the first iron-wheel plough of the present type ever exhibited—he went to the Royal Agricultural meeting, held at Liverpool, and, not finding a man who understood a wheel-plough, and having been accustomed to the handling of a plough, he determined to hold the implement himself, and at the conclusion of the trial found himself rewarded with a first prize. In the following year he went to the Bristol meeting of the Royal Agricultural Society, where he again carried off the chief honours. Having thus and so early gained a reputation in connection with the Royal Agricultural Society, his business rapidly expanded, and at every meeting for many years afterwards he was to be found with ploughs brought nearer and nearer to perfection.

In the spring of 1856 Mr. Howard was invited by Mr. Smith to go to Woolston to see his steam-cultivator at work, and he at once saw that a new era was dawning upon agriculture, and that his vested interest, so to speak, in the plough trade might be in danger. Instead, however, of opposing the new system, he at once offered to join Mr. Smith in bringing his apparatus before the public; accordingly, in the same year, at the Royal Agricultural Society's meeting at Chelmsford, Mr. Smith and the Bedford firm were allied in working the Woolston tackle. For several years afterwards Mr. Howard threw his whole energies into steam cultivation, and took a hilly, strong-land farm, for the purpose of experimenting and improving the apparatus. Finding, from the rapid wear of the rope, that without something more durable than iron wire, steam cultivation would be financially a failure, he had one made of steel wire, which, we believe, was the first steel-rope ever used in ploughing. We have always regarded it as an unfortunate event for the country that the misunderstanding which occurred

about 10 years ago should have separated two such energetic, although differently constituted men.

About the time of this separation, Messrs. Howard bought of Lord Ashburnham an estate near Bedford, upon which, on the testimony of the Royal Agricultural Society's Commission, and many others, steam cultivation has been most successfully carried out. Moreover, the records of our agricultural societies show how successful Mr. Howard has also been as an exhibitor of breeding stock. As these farms have been visited by thousands of English and foreign agriculturists, they have contributed in no small degree to the general advancement of agriculture, and particularly of steam cultivation.

Mr. J. Howard's grandfather lived for many years at the ancient Priory at Bedford. He farmed the Priory lands, which are now occupied by Mr. Charles Howard, of Biddenham. They adjoin those belonging to the firm of Messrs. J. & F. Howard; the brothers thus have in hand amongst them some 1600 acres of land, on which to try their implements, and carry on their experiments.

The Britannia Works were built upon a plan prepared by Mr. J. Howard. They are among the best-arranged manufactories in the kingdom: they occupy an area of upwards of 18 acres, and the extent of the business may be judged by the fact that some 600 railway trucks are laden with the implements to leave or arrive at the private station upon the works.

Notwithstanding the abundant occupation supplied by a rapidly growing business, Mr. Howard found leisure for much public work. In his own locality he was the founder, with a friend now deceased, of a working men's institute. To the members of which he has from time to time lectured on important subjects. His lecture on "Labour, Wages, and Machinery," may be mentioned as proving that he had made political economy the subject of careful study.

Another important institution of which he was the originator is the Bedfordshire Middle-class Schools. About seven years ago, in speaking at the county agricultural meeting, he remarked that although much had been done to raise the standard of education among the labouring classes, no corresponding effort had been made to bring a good liberal education within the reach of the sons of farmers; and he suggested a county school. The idea having been brought before the Duke of Bedford, he at once joined Mr. Howard and others, and the present splendid pile of buildings was erected, at which 300 lads are boarded, and receive a superior education, at a cost of about £30 a year.

Mr. J. Howard was elected Mayor of his native town in 1863, and at the end of the year was unanimously re-elected. In that official position he was enabled to carry into effect many local improvements which he had long advocated. Amongst other subjects, he turned his attention to that of town drainage and sewage utilisation. Before recommending a plan for Bedford, he went a tour through England and Scotland, to ascertain the results obtained in other towns. During his mayoralty, a comprehensive scheme of drainage, water supply, and sewage utilisation, was procured; and it is no little to the credit of his sagacity that Bedford was the first place to be sewered on what is now called "the separate system." In his report on the subject to the Corporation of Bedford, he recommended that the rain-water should be discharged separately into the river by the existing sewers, but that the proper mode of treating the rainfall from the sewage had come before the public, although the plan is now advocated by the leading sanitary engineers.

The electors of Bedford had, for some years before Mr. James Howard entered Parliament, urged him to become their representative, but he declined all overtures until the election of 1868, when, in view of the important public questions to be settled, he was prevailed upon to stand, and was returned at the head of the poll. During the first session, Mr. Howard spoke on the Endowed Schools' Bill, and was invited to act on the Select Committee on that Bill. The Cattle Diseases Bill was introduced about the same time by Mr. Forster, to whom Mr. Howard's practical knowledge and judgment on rural affairs were soon apparent, and were of no little service in framing the provisions of that difficult measure.

Mr. Edward Kerrison, M.P. for East Norfolk, has borne public testimony to the parliamentary services rendered by Mr. J. Howard to the agricultural interest, in a speech in which, after introducing Mr. Howard as President-elect to the London Farmers' Club, he said:—

"One evening last session, when there was a debate on the Patent-laws, and that great man, Sir Roundell Palmer, and that other great man, Lord Stanley, had denounced the Patent-laws, up got Mr. Howard and abolished the legal arguments of the one, and the philosophical notions of the other in the most charming and beautiful way. A gentleman who was sitting behind me said 'Well, the Liberal on the other side of the house seems to me to knock those great dons over just as if they were ninepins, and this he does while he is beaming with good nature.'"

After the session of 1869, Mr. Howard went a tour upon the Continent, and on his return read a paper to the London Farmers' Club on "Continental Farms and Peasantry," which was full of interest. Mr. Howard, believing it would counteract much misapprehension on questions connected with land, was subsequently induced to give a more lengthened account, and publish his paper. In this book he was one of the earliest to direct public attention in this country to the question of Beetroot sugar manufacture.

Mr. J. Howard's previous papers read at the Farmers' Club—on the "History of Steam Ploughing," "Things in America," being an account of his tour in that country—contain much valuable information, and had placed him quite in the front rank of the Club, of which he was subsequently elected Chairman. According to Mr. John Coleman's paper on "Cheese Factories," the first account published in this country of associated dairies and cheese factories is to be found in Mr. Howard's "Things in America."

Mr. Howard is also the author of letters and pamphlets on a variety of subjects. Some years ago, on the invitation of the principal agricultural implement manufacturers, he wrote a brief historical sketch of the implement trade, the effect of prizes upon that business, and suggestions for improved arrangements in the trials of agricultural machinery. He was also the author of the scheme for dividing the implement trials of the Royal Agricultural Society into triennial courses, and submitted to the Council a classification showing how the various machines should be arranged in the classes. A few months after the breaking out of the Franco-German war, Mr. Howard had the idea of aiding the French farmers with seed wherewith to crop the land, and at once put himself in communication with a French friend, His Excellency M. Drouyn de Lhuys. Owing, however, to an attack of illness, and the long continuance of the war, no steps were taken at the time, but subsequently Lord Vernon and Mr. Howard's assistance, when about £50,000 was raised, and in the spring the seed was distributed among the distressed peasant-farmers of France, Mr. J. Howard acting as treasurer to the Fund.

Mr. Howard's health, already weakened by an attack of sunstroke in Egypt, suffered much from the long hours of the House of Commons, during his first and second session. Owing to this he has not until recently been well enough to resume his numerous duties, and consequently has not taken so prominent a part in Parliament as he probably would have done. It is gratifying to know that a rest for several months has restored his former strength and vigour of mind. For two or three months past he has resumed the management of the Britannia Works, and has been busily engaged with his old pursuits of carrying on experiments in the field.

Prophets are said to be without honour in their own country. In Mr. Howard's this is far from being the case. The Bedfordshire Agricultural Society, which has for seventy years been presided over by a member of the aristocratic or hereditary landowners of the county, this year unanimously elected Mr. J. Howard to the presidency, an office which he fills at the present time. Indeed it may be affirmed that he not only stands well in his own district, but that his neighbours fully appreciate the laurels he has gained elsewhere.

MODEL FARMS IN IRELAND.

[Mr. Baldwin, of Glasnevin, Principal Inspector of Model Farms and Agricultural Schools under the Commissioners of National Education, lately addressed a meeting of the North-East Ireland Agricultural Society on this subject. The following is his speech, as reported in the *Dublin Farmers' Gazette*.]

MR. BALDWIN said he attended on the invitation of the secretary, and with the sanction of the Commissioners, to afford the members every information they might require. The system of agricultural education now in operation in this country under the direction of the Board was of comparatively recent date. It consisted of two branches, which were, to a great extent, independent of each other, but which were capable of acting and reacting on each other most beneficially. Much confusion has arisen from not viewing these two branches each on its own merits. The first branch consisted in blending, in ordinary rural national schools, instruction in the elements of agriculture with the ordinary course of literary education. The Commissioners have been pursuing this combined system of literary and agricultural education with varying success for upwards of 30 years. At first it was not well understood; but at last the efforts of the Commissioners were in a way of being crowned with success. The number of rural national schools in which agriculture is taught has been steadily increasing of late. In 1862 the number of boys who came within the influence of this species of instruction might be counted by hundreds. They are now more than ten times as many. The disposition of the gentry and clergy of all denominations is more strongly in favour of extending this branch of agricultural education, and the Commissioners were doing all in their power to meet the wants of the country. It was needless, in addressing a body of gentlemen of the importance of education at a meeting of enlightened gentlemen such as he had the privilege of addressing. The present time was favourable for its extension. The farmers evinced an increasing desire to receive it. The Board aimed at affording sound elementary notions of modern agriculture. The knowledge thus imparted would give the tenant-farmers a new power of developing the resources of their farms. The extension of improved implements and machines rendered it an imperative duty to afford elementary knowledge of agricultural mechanism to the rising labourers. He ventured to invite the co-operation of the gentry and clergy, in developing the simple and inexpensive system of agricultural education to which he had just referred.

The second branch or grade of the Board's system of agricultural education was afforded in the model farms, to which the meeting wished that he would, on this occasion, more particularly address himself. In the model farms, it may be said that their establishment was forced on the Commissioners; that is to say, the results convinced all classes that the state of agriculture which had prevailed should, as far as possible, be superseded by a new system; and many good and wise men advocated a system of model farms as one of the means of accomplishing that object. The Commissioners yielded to the demands made upon them, and established some twenty of these farms throughout the country. It was not in his province to offer any opinion on the policy of the course pursued; but he could state, for the information of the society and of the public, that the farms, as farms, are now, one with another, paying a satisfactory amount of profit, and exhibiting judicious modes of farming. The soil of the Belfast farm is, unfortunately, very stiff and plastic; but after the application of capital and energy, it has at last been brought to a state in which it will henceforward pay. There is a splendid building in it, capable of accommodating a large number of boarders. There is a first-rate staff—a clever, sensible agriculturist, who manages the farm, and affords systematic instruction to his pupils in the science and practice of agriculture. The literary education of the pupils is directed by one of the best masters in the empire, who has also charge of the general discipline. There is adequate assistance; so that at the school you have at present a staff competent to afford a sound, general literary, and agricultural education. They teach the elements of mensuration, of land, and other branches relating to farming; and the general education includes land surveying and mapping. The day is divided equally between practical agriculture, including outdoor business, and the cultivation of the mind. The head is stored with general knowledge, and the hand and eye are trained to skilled practice. With the view of placing this excellent general education and special training in improved ideas and practices within the range of all classes, the fee for paying pupils is only £2 a quarter, including board and education, the Commissioners contributing the additional amount required to provide suitable diet; and in order that young men of intelligence and promise, who evince a decided taste for farming, but whose parents or friends may find it inconvenient or impossible to pay £2 a quarter, the Commissioners take in four pupils without any fee. These free places are given away by competitive examination. Of course, those who seek admission to qualify themselves for farming a high standard of proficiency is not required. If they can read with intelligence, and write a fair hand, and do a little cyphering, they are admitted. A higher standard is required from those who intend to become land stewards, and from agricultural teachers. They must be persons who, by their intelligence and aptitude for agricultural pursuits, would, by promoting the public good, render the state an adequate return for the cost of their agricultural training. There is a central Agricultural Training Institute at Glasnevin, near Dublin, and to which the pupils who receive a preliminary agricultural training at the provincial agricultural schools are drafted from time to time. At present the great number of pupils at Glasnevin are free, admission being obtained half-yearly by competitive examination. Well educated persons from all parts of the country are allowed to compete; the most intelligent and promising are selected. It is competent for a boy who fails to obtain a free place to become a pupil on paying a fee of £5 per quarter. Paying pupils are also admitted at all periods of the year. Some of these intend to go to farm for themselves or for their parents; a large number seek employment as stewards, agriculturists, and agricultural teachers. For a long time a very well-founded objection was raised to them by the landed gentry on the ground of youth and inexperience. They are sent out as working stewards to the larger model farms, and, as opportunity offers, as assistants to clever stewards and successful farmers. A young man enters the Belfast farm, after his pupilage there he goes to Glasnevin, from Glasnevin he is sent as a working steward to the model farm at Kilkenny, Cork, or Athy. He often undergoes four or five years' training before he is recommended to a country gentleman. This arrangement has worked admirably. The demand is increasing, in proof of which this one fact may be mentioned, that while the course of training at Glasnevin is two years, there is not at present a pupil of 18 months' standing; and at the present moment nine persons are wanted to fill situations that require a good deal of agricultural knowledge, as well as intelligence and trustworthiness. An admirable arrangement has been commenced by Lord Clancarty, who has been good enough to encourage his steward, Mr. Nesbitt, himself a Glasnevin man, to take six Glasnevin men as apprentice pupils to finish their agricultural training on the home farm at Garbally. All he would say, in conclusion, was that it appeared

to him that no man who understood the state of Ireland could for a moment doubt the utility of such a system of agricultural training as he had now endeavoured to explain.

[It was then agreed that the secretary, Mr. Bingham, should open a list of candidates for admission to the Ulster Model Farm and School at Belfast, and place upon it the names of applicants recommended by members of the association, and that from that list vacancies could be filled from time to time, according as they might occur.]

OUR LIVE STOCK.

CATTLE.

THE results of the principal Shorthorn sales given in the accompanying Table show, when compared with those of previous years, the extraordinary increase in value of this kind of stock. We have been accustomed at the close of each year to place before our readers similar tabular summaries, and looking back at these we find the following average results over a large number of Shorthorns disposed of at public sales. The figures are not supposed to represent the entire number of Shorthorns sold, but the general results of the sales recorded in these columns during each year :—

In 1868, 1423 Shorthorns averaged	..	£35	7 0 each.
In 1869, 1565	,,	,,	35 15 6 ,,
In 1870, 1430	,,	,,	33 13 5 ,,
In 1871, 2254	,,	,,	53 3 6 ,,

A year ago, Mr. Thornton commented in his Circular No. 11 upon the "wonderful increase that is taking place" in the value of Shorthorns, and recorded an average increase in value of £2 per head over the sales of the previous year. The most extraordinary increase in average price during the last year may be, partially at least, accounted for by the general encouragement given to British breeders from abroad, and while we hear of such high prices in the colonies and United States for the best strains of English blood, we can hardly expect present prices to lower.

The number of good sales this year has been unprecedentedly large, and the general average has been swollen by such sales as Mr. Cheney's, when 56 animals made £91 13*s.* each; Mr. Jonathan Peel's sale, where 19 animals made £148 8*s.* 9*d.*; the late Mr. Eastwood's, where 15 animals averaged £161 8*s.* 0*d.*; Mr. Barnes' sale (Ireland), where 44 animals made £100 14*s.* 1*d.*; and the Duke of Devonshire's sale, where 43 animals made £240 13*s.* 10*d.* each. Such prices were unknown last season, when the highest average was £96, obtained at Mr. Saunders' sale; or in 1869 and 1868, when Mr. Bowly's average of £72 16*s.* stood unrivalled. The exportations of the season have been very considerable, and indicate the great favour with which the Shorthorn breed is viewed wherever it has been introduced.

CAPITAL AND LABOUR.

I HAVE oftentimes met of late in books or the public prints some expression of regret at the fact of such a vast amount of pauperism existing, side by side with immense wealth; and the writers, although they do not say so, seem to imply that the poverty of one class is attributable to the richness of the other. I am of a totally different opinion. I certainly fail to see that if our capitalists were only half as rich the very poor would be less poor. Now, what is capital? Political economists tell us it is accumulated labour. I agree with them. Money is only the standard by which the value of labour performed is measured, so that when a man takes his sovereign for wages at the end of the week, that represents a week's labour. Now if he contrive to lay up weekly a portion of this labour, in the course of time it becomes accumulated labour or capital, which will set other labour to work. I will try to illustrate this, after a very simple fashion. Tom Thrifty and Sam Spendall are both young men, working in the same shop; they are equally good workmen, and get the same wages, but they are of totally different characters. Tom has both heard of and known men who have risen from low estate to much higher positions, and he is determined to be one of this the same. So he is very diligent in business, loses no time, but if a chance offers makes overtime, and every week sets aside a portion of his earnings to go into the saving's bank, and what necessaries and comforts the remainder will not purchase, he wisely resolves to go without. He deteriminis that he will not marry until he can support a wife and family respectably. In the course of a few years he has saved a nice sum of money, and having made the acquaintance of a decent young woman after his own turn of mind, and with a little money, too, Tom marries, and sets up in business in a small way for himself, and soon remembers the saying that becomes an employer of labour. Such a man is sure to succeed. With perseverance and industry out of the house, and frugality and good management within, success is certain to be achieved.

Sam Spendall, on the contrary, likes to spend his money and treat himself as he goes. He spends his evenings chiefly at some place of amusement, or with a jolly set of fellows, like himself, at the public house; saves nothing for a rainy day, and after a while falls in love with, and marries, a little toy in the shape of a woman, and in consequence many of the wants of Spendalls appear on the scene. With bad management in the house and carelessness out of it, poverty begins to stare them in the face. Sam finds himself comfortless at home, and returns to his old haunts, goes from bad to worse, until he and his family become numbered among the very poor, for whom so much concern is manifested.

It is idle to ask which of the two men was the better citizen. Each of them had the same opportunities, but made a different use of them. Each of them earned the same wages, and in a free country had a right to spend them as he thought proper, and the man who wasted his opportunities has no right to turn round on his more prudent companion who has made the most of them, and become a capitalist, and is in this capacity probably employing, or being rated for the support of, the other's children. It is a fact which cannot be too strongly impressed on the minds of all young persons that future ease and comfort mean present self-denial.

Fortunes are generally saved, not made. It is true that the few—and the very few—may grow suddenly rich by successful speculation, but as a rule, the aggregate of the money which forms the capital of this country has been amassed by small savings, in the same way as the bridge is built brick by brick.

Capital, so far from being antagonistic to labour is, in my opinion, its best ally. It cannot increase while kept idle, and in these days men do not wrap their talents up in napkins, for every man is stranded to keep them in motion, and it is impossible to do this without the application of labour. Hence it follows that the greater the capital the more labour it requires for its profitable employment, and the greater the demand for labour the better will be its remuneration. It is when capital lies idle or stagnant, owing to there being no profitable field for its use, that labour suffers the most. If there were no capital there would be none to employ, and works of any magnitude could not be attempted.

A great Mr. Brassey is said to have died worth nine millions. Now I will venture to assert that in amassing this great capital he made no man poorer, but a great many richer. It is a positive fact that a man can hardly do anything to directly benefit himself without indirectly benefiting others. If Mr. Brassey invested money on his gold, or even had he hoarded it, it would have been mere selfish enjoyment, but so long as he kept employing his vast gains on reproductive enterprise he was benefiting the working man, and adding to the wealth of the nation, as well as to his private means.

It seems to me that undue prominence is at present given to what is called the working man, and by a certain party all the results of labour are credited to him. It seems to be fogotten that the horse is a great power, the steam-engine a still greater power, in the drudgery of the world. Surely this is not the property of the working man. Again, the power of brain appears to be utterly ignored, but where is the philosopher who will venture to assert that when the head fails any establishment can flourish. On the contrary, when that bit of brain which governs and directs has not properly fulfil its duty, no matter how skilful or how numerous the workmen, the concern will inevitably collapse.

The working man of the present time, about whom so much fuss is made, and in whose interest the interest of all the other classes is to fall, appears to me to be of a genus who is willing to render very light service for very heavy wages for one half of the week, and to employ the other half in spending them. Will any of our philosopher friends kindly explain how it is that persons who work for wages, no matter whether they be high or low, are so much less thrifty than persons who receive a similar income from any other department of industry. I know of many small village tradesmen or small shopkeepers in towns who would consider they had a princely income if their weekly profits were equal to the wages received by some of the skilled workmen in our factories; and yet they struggle manfully on regardless of the hour system, working all the day and ofttimes into the night, paying rates and taxes, they send out their children to service, live in the most frugal manner, and, in fact, do anything to keep themselves from pauperism, while the highly paid workman or those belonging to him are too often on the verge of it. Yet this is the class that is to be wiped out so that the working man can be supplied by co-operative stores. Surely our country cannot be so gone mad as to uproot the Oak, the growth of centuries, to make way for a Mushroom.

It is no uncommon thing at the Board of Guardians at which I have a seat, for a smartly dressed young widow in weeds to present herself. To the question of "What is your application?" the usual answer is given, "Out of work." "Where was your husband employed?" "In the works." "What were his wages?" The answer may be 30*s.*, 35*s.*, 40*s.*, or 45*s.*, as the case may be. "How long has your husband been dead?" "A month." "Well, you received £10 from the club?" (a compulsory one). "Yes, but the funeral expenses and sick bills that were due absorbed all the money." And so they have. Relief is given, and the little, comparatively indigent shopkeeper and tradesman have to aid in their support. It would be most unfair to suppose all skilled workmen equally reckless, but where all depends on one life, it seems a pity that something were not in all cases put by for emergency, or life insurance adopted.

Co-operation, we are told, is the grand panacea which is to cure all the ills to which the working man is subject. I don't believe it. A society of this kind was started near me a few years ago, which was to supply its members and customers from a miscellaneous store. A large flour mill was erected, with bakery, &c., and, apparently, private enterprise was to fall before it; but it did not last long. For the last two or three years a large, useful-looking building, fitted with expensive machinery, has remained a monument of brick and mortar. If the country were studded with these societies for the manufacture of goods as well as their distribution, some would be successes, others would be failures. In the latter case, those interested would be losers. Commend me to private enterprise. I cannot see the wisdom of the industrious man being chained to the lazy one, or the intelligent man to the stupid. In a country like our own, where every man is free, and has fair play, every atom of humanity will fall into its own proper place, and society will in such a case regulate itself far better than it can be done by any number of bricklayers or cobblers, with a few philosophers to boot.

I have seen a great deal of town and country life, but I have never yet met with an industrious, steady man, who could not obtain a tolerably comfortable livelihood if he practised ordinary prudence. I see nothing wrong in any number of young men co-operating and adding their savings together for the purpose of starting a factory, stocking a farm, or, following the example of the building societies, buying an estate and splitting it into small farms, if they choose; but I have a strong objection to their confiscating the savings or property of other people. The political economists tell us that the safety of the nation depends on a small peasant proprietary. I cannot see why, if a man to better his condition leaves the cultivation of the soil, it should make him less patriotic. How has it been with France and peasant proprietary against Prussia and feudalism. The peasants and small farmers were for peace at any price, so that they could be left quietly to pursue their callings.

The labour with which I am at present concerned is agricultural labour, and the wages of this class vary so much at different seasons, and there are so many advantages in lieu of wages, that it is difficult to institute a fair comparison between that and other unskilled labour. It is a false principle to give a man a cottage and garden worth 2*l.* or 3*l.* a week for 12*s.*, on the ground that the man cannot afford more. The same remark applies to gratuities of beer, milk, cider, &c., and numerous other extras. The correct principle would be to pay the man fuller wages, and make him

pay full value for what he receives. Although I could live more comfortably in a labourer's cottage as they are found at present, than in a cellar or attic in a town, I should be right glad if our landlords generally would provide enlarged and more decent homes for the labourers with at least a rood of ground adjoining, or as close as possible to them. Much has already been done in this respect, and it is to be hoped will, in the course of a few years, be generally carried out. *F. W. Bignell, Loughton, Stoney Stratford.*

CONDENSED MILK.

We believe that the credit of first condensing, or rather concentrating milk, is due to a Frenchman, named De Leignac, about 24 years ago, from whom the process was obtained soon afterwards by Mr. E. D. Moore, a medical man attached to the Court, who had manufactories in Staffordshire and Middlesex, making concentrated milk, and also a combination of it with cocoa. In 1857 Mr. House, now of 76, Minories, on the retirement of Mr. Moore, whose manager he had been, took up the business, and, on an "improved patent," has continued it ever since. It was from Mr. House, through a Captain Fletcher, that Mr. Gail Borden, of New York, got his idea of preserved or condensed milk; for, though Mr. House calls his "concentrated" milk, and says that the process differs little from that of producing "condensed" milk, the former being obtained by evaporation of the water from the milk in open pans; the latter by evaporation in closed vacuum-pans. We mention these facts to show that primarily to a Frenchman, though mainly to an Englishman, the credit of first producing concentrated or condensed milk is due, and not to Mr. Borden, or any other American who may have perfected the process and developed the trade, and seem inclined to take credit for the organisation of the whole matter. Mr. House has mainly confined his business to the supply of shipping, and has not "pushed" his article for home consumption. Of its merits we can bear witness, having lately tasted a tin of his concentrated milk, which was "put up" in the year 1858, and since then has made a voyage to Calcutta and back. It was the sweetened mixture, and out-tasted, and looked like as rich Italian sweetmange, but capable of being reduced, or rather expanded, into sweetened milk by the addition of water.

It was with Mr. Borden's process, and, perhaps, some improvement on it, that the originators of the Anglo-Swiss Company established themselves in Switzerland, at Cham, in the Canton of Zug, in 1866. Their works are on the banks of Lake Zug, opposite the Rigi range of mountains, on the lower parts of which, and on the adjacent villages, most of the cows from which the company get their milk are pastured. At their first commencing business they only took the milk of about 350 cows one day a week, for which they paid about 1*d.* per quart. The demand for the condensed milk has so increased that they now take the milk of between 1500 and 2000 cows daily (Sundays included), under contract with the neighbouring farmers, using in the process more than 30 tons of sugar per day. Preparations are being made for still more extended operations, and it is expected that next year they will be able to turn out about 10,000 tins daily. Of the total manufacture by this company, about one-half is consumed on the Continent, the other in England and its colonies, and other parts of the world.

The Aylesbury Company is an offshoot, or rather secession from the Anglo-Swiss, its manager, Mr. Merriam, having been one of the chief promoters and managers of the latter from its commencement, and other directors of the company are also connected with its English rival. It was established last year, and begun its business in September, taking the milk of about 400 or 500 cows, producing about 1200 galls. of milk daily, with the exception of Sundays, when the farmers sell their own the use the milk for butter and other purposes. The company have just erected further buildings to meet the increased demand for their milk, and when in full working order, which they will shortly be, they will take the milk of more than 1000 cows, and expect to make from 6000 to 10,000 tins per day, according to the season of the year. The factory, in which about 100 hands, old and young, are employed, is a few minutes walk from the town of Aylesbury, picturesquely situated on the banks of the canal which runs through the famous vale, and having a road on each side, forming the company's premises, which they rent under Baron Rothschild, into the shape of a triangle, pleasantly surrounded by trees, and measuring about 3 acres, including grass lands, yards, and out-buildings.

If for no other reasons, it would have been a happy thought to have fixed on Aylesbury for their *locale*, the very name being associated, like Canaan, with milk and the good things connected therewith; and the supply of excellent milk from some of the best pastures in England will doubtless commend the choice. Steam is got up in the factory at 6 in the morning, and the farmers, who live within from 1 to 10 miles of it, begin to deliver their milk about 7; but it is nearly 9 o'clock before the last arrives. We were on the scene during the delivery, and remained till the end of the process. The milk is emptied at once from the large tin cans generally used in the trade into a trough, which conducts it through sieves into a large tank holding about 800 galls., in the department where the first part of the process takes place. From this tank it is drawn into large open metal cylinders, which are slung up by a crane, and placed in a hot bath in large tanks, somewhat after the manner of the tins of meat in the preserving process; after remaining in this some time they are again lifted by the cranes and emptied into large open funnel-shaped vats, whence the hot milk is drawn up through a pipe in the centre into the condensing pans on the upper floor; the sugar having been mixed with it solely for the purpose of preserving it. It remains in these, subject to somewhat low heat, for two or three hours, while the evaporation of the water is taking place, and the milk gradually condensing. When this part of the process, which may be seen through the glass window of the condenser, is completed, the milk, then about the consistency of liquid honey, returns by a pipe into the lower room, and is received again into the open cylinders, which are swung into the central tanks; this time being filled with cold water for the purpose of cooling—the regulation of the temperature during the whole process being a matter of the greatest nicety. Thence it is taken to the filling-room and run into the 1 lb. tins, which are soldered up and packed in cases of four dozen each, ready for sale. The process is quite clean, and no tin leaves the establishment unless perfectly airtight; and to ensure this each one is closely examined by a lad, who, in addition to his regular wages, gets 1*d.* each for every tin he finds imperfect, and the solderer has to take and pay for its contents. The condensed milk in these tins gradually thickens, becoming slightly more consistent up to five or six months; after which it remains of the same consistency, and will continue good for years, perhaps as long as the tins themselves continue sound, and in all climates; and, even when opened, remains sweet for weeks.

It should be remarked, that the greatest cleanliness is observed throughout the whole process. Even the milk tins which the farmers deliver, immediately on their being emptied are, in the receiving room, placed in warm water and scrubbed inside with brushes. A strong jet of steam is turned into them, searching every chink and crevice; and then a similar very powerful jet of cold water completes the cleansing process, which is also applied continually to all cylinders and receptacles used in the factory. And, in addition to this, the floor of the lower room is constantly deluged with streams of water supplied by pipes from the Chiltern Hills by the waterworks. The milk received from the farmers, at about 2*d.* per quart, is tested in a variety of ways several times in the week, and some is stood in pans to test the rise of cream, a record of which is carefully kept. The contracts with the farmers are very stringent, and if anything is found wrong with the milk the company reserve to themselves the right of returning it, and at once throwing up the contract. They are careful also to examine the police records of the district, to see if any of the farmers whose milk they take have any cases of diseased cattle on their farms, which they are bound by Act of Parliament, under heavy penalties, to report at once to the police. The sugar used is of the best refined kind, some also from Beetroot, and we need hardly observe that no adulteration takes place at any part of the process; it would be impossible, and if attempted would at once defeat the main object, namely, the preservation of the milk; and as the article is sold only in the Company's tins, hermetically closed and labelled, it is impossible for retailers to tamper with it. The result is, that we have an article which is pure milk, not an article made from milk, for to the addition of sugar; all that is taken from the milk being the water, which in milk direct from the cow constitutes as much as 80 parts out of 100. Astounding as this statement may seem, there is no doubt about it, and the stream of colourless water which runs, as we saw it, condensed from the compounds give ample evidence of it, and its being almost tasteless further shows that by the process the milk loses nothing but its water, and this it does to the extent of about 55 parts out of the 80, leaving in the condensed milk from 20 to 25 parts of water, the rest being the caseine, butter, or fat, and other solid substances which remain intact. This is proved by the fact that when the proper quantity of water is again added to the condensed milk, it will, at a certain temperature, churn into butter. The analyses of the condensed milk produced by the Swiss and English companies made by Baron Liebig and many other eminent chemists leave no room for doubting the above facts.

We may here mention that the Aylesbury process is substantially the same as that used by the Anglo-Swiss Company; by Mr. Borden, in America; and by Mr. Newnham's Irish company, at Mallow; but the last-named company have not yet begun to make sugar. There are other companies on the Continent, one near Munich, one in the Canton St. Gall, and another in Holstein; but their business at present is somewhat limited. In America, also, there are several manufactories, but Mr. Borden takes the lead. He also produces the condensed milk without sugar, which will keep good for a week or ten days, and it is this form which a large portion of the population of New York and large American cities have used for some years past. The English company will probably offer some of this kind to the public, and we see no reason why it should not be very extensively used. Each household knows with tolerable exactness its weekly consumption of milk, and by taking a weekly supply in this form will be sure of getting a genuine article. We should not forget to mention that the English company make a preparation of condensed milk and cocoa, which is sold retail, at about 1*s.* for the 1 lb. tin. We witnessed the mixing, grinding, sifting, and general preparation of the cocoa, which is all done at the Aylesbury Works, and a most excellent combination is produced, the cocoa assisting as well as the sugar in the preservation of the milk. Two teaspoonfuls, equalling in value one penny, with boiling water, make as good a cup of cocoa, already sweetened, as can be desired. They contemplate also bringing out a mixture of the milk with essence of coffee.

But to return to the condensed and sweetened milk. The present retail price of the 1 lb. tin of both companies is about 8*d.*; and as this will bear at the very least as much water added to it as will make it equivalent to 2 quarts of pure milk, we have a genuine article at 4*d.* per quart, with the addition of nearly one pennyworth of sugar to each quart,—no slight consideration when estimating the price. Thus, it is considerably cheaper than any milk sold in towns, even if that could be obtained pure. The condensed milk can be used for any purpose for which ordinary milk and sugar are used—for puddings, custards, and other cooking purposes; less than a teaspoonful is sufficient for a cup of tea, sweetening it at the same time; two or three times the quantity will make a large basin of sweet bread and milk. *The Standard.*

Home Correspondence.

Sugar-Beet.—In consequence of numerous letters on the cultivation of Sugar-Beet, I determined to try some again, although I had not succeeded in doing any good with them some three years ago, being obliged to consume much more crop than I grew of Mangel in the same field. Also the difference in the Wheat crop after was most marked in favour of that part of the field which grew the Mangel. I selected 12 acres of deep friable Turnip land adjoining a railway siding, which I ploughed twice, subsoiling 16 inches deep with a double-furrow plough, one share removed replaced by a subsoiler. Sixteen loads of house-made dung and 6 cwt. phosphate-guano per acre were applied. The plants 12 inches apart made hand hoeing requisite to prevent injuring the roots, and to get them up nearly every root had to be dug. The best seed from Germany was used, at 2*s.* 6*d.* per lb. The year was very favourable, and no frost came, or the crop must have been resown, as frost causes the roots to seed, and renders them useless for sugar-making. No place missed, and the result was 372 loads of what have been allowed to be very superior roots. The account stands:—

	£	s.	d.
2 ploughings and 1 ploughing and subsoiling	2	8	0
2 grubbings, at 3*s.*	0	6	0
2 harrowings, at 2*s.*	0	4	0
1 rolling, at 2*s.*	0	2	0
Planting, 3*s.* 1*d.*	0	3	1
3 horse-hoeings, 6*s.* 2*d.*	0	6	2
Hand-hoeing, 25*s.*	1	5	0
Lifting and storing	0	15	0
15 loads of dung, at 3*s.*, two-thirds charged	2	5	1
6 cwt. phosphate-guano at 22*s.*, two-thirds charged ..	4	8	0
8 lb. seed, at 2*s.* 6*d.*	1	0	0
Rail, 1*s.* 6*d.* per ton	1	4	0
Rent, 40*s.*	2	0	0
Cost per acre	£14	13	7

The estimated produce is 16 tons per acre at 20*s.*, which only leaves £1 6*s.* 5*d.* profit in a good year. Now, I can grow 35 tons of Mangel at a cost of £11 11*s.* per acre, and for them I get most years 20*s.*; last year 30*s.*, but only 16*s.* this year, which leaves a profit of £3 6*s.*, against £1 6*s.* 5*d.*, showing a clear gain of £11 19*s.* 7*d.* in favour of Mangel. *Cincinnatus, Nov.* 21.

Utilisation of Sewage, &c.—Very much has lately been written, and spoken, relative to the utilisation of town sewage and all similar sewerage manurial deposits, and frankly closets, privies, cesspools, &c. Too much cannot be said to induce every family in the kingdom to take especial care to preserve for manurial purposes every kind of "refuse" that can be so utilised. The agriculture of the country requires every attention to be paid to these minor matters. The modern improvements cannot be fully realised, unless from a much larger application of manures for the many supernumerary crops now introduced in modern agriculture, as also the many additional crops introduced in the improved order of farm management, which can not only be carried out, but greatly increased by the liberal application of manures from one crop to another. It has become already one of the farmer's great difficulties how to supply himself with suitable manures. The chemical manures now manufactured are too high in price to be made generally appliceable, because so much is required to replenish the soil sufficiently to cause that fermentation of soil necessary for the full and rapid progress of the crop. It is now a matter of fact, that a slight dressing is of little avail—even good soils require dressings of from 7 cwt. to

10 cwt. per acre to cause effectual and beneficial results. The best Peruvian guano might prove beneficial in somewhat less quantity, but not so with others. Splendid results have followed from doubling the above applications, which of course would soon become general could such manures be provided at a greatly reduced cost. What surprising benefits would be derived, could all manurial substances and sewage be preserved and applied as a fertilising agency, and there really is no great difficulty in the way. It only requires attention, and the adoption of some of the many schemes and plans for such an object. Moule's earth closets are applicable instead of water-closets. Convenient cesspools might preserve the sewage; indeed, any of the thousand-and-one projects before the public might suffice, if only the requisite care and attention were given to utilise the whole. This could not fail to benefit the whole country greatly, by providing a much larger supply of food for its population. In small towns and country villages this mode of application could not profitably be adopted, but still all might be preserved and means provided for its conversion into home-made guanos, or other very useful manures or "mixens." The great loss of these almost invaluable manures lies with the towns. In the villages most of these deposits are brought into service. It is quite customary in the winter months to empty cesspools, privies, &c., and cart the contents into prepared receptacles in the fields, there to be mixed up with other manures, chemical or otherwise, soil, ashes, &c., by which a cheap and valuable manure for drilling is manufactured. The writer of these lines has practised this course for many years. A large circular vat is prepared by casting up the earth around to about 3 feet in height; into this vat is poured the contents of privies, cesspools, from breweries and private families, carted to it in the common scavengers' carts. This is covered up by straw or ditch-roadings for a time. As the season advances fresh substances are added, *i. e.*, good soil-ashes from turf, Twitch, &c., cinder-ashes, road-scrapings, soot, pig manure, and any suitable refuse likely to be beneficial. I avoid lime, and occasionally use superphosphate when mixing for drilling, the whole being previously prepared by repeated turnings till reduced to such a powdery state as to be applicable for drilling. I very confidently recommend this course as one means of obtaining a highly useful and cheap manure for drilling in with Mangel seed, Turnip seed, &c. It is also applicable as a dressing to be sown down ridges or furrows, where Potatos are to be planted. Its great value lies in forcing the young plants. In Turnip or Mangel culture this is important, to prevent injury from fly, &c. *O. F.*

The Six Months' Notice to Quit.—Your correspondent, "Anglo-Saxon," last week, is, I think, perfectly justified in calling "downright robbery" the conduct of a landlord who permits a farmer to improve his land at a great outlay and then refuses to let him to either the improving tenant or a successor, without first repaying the man who improved the land. But then this can be done in England according to law. Our Parliament has seen fit to grant justice to Irish tenants, and if farmers would combine and send the right sort of men into the House of Commons, many other just things besides tenant-right might be secured by farmers in England. A neighbour of mine told me a week or two ago, that during the last few years he had spent between £700 and £800 on permanent improvements on his farm. The farm had now just begun to repay him by increased crops when the landlord sold it. It made nearly £1800 more than it was worth before the tenant had it. The tenant's rent has been raised by the new landlord £70 a-year. This increase of rent is about 10 per cent. on the sum spent by the tenant. Was it not as though the latter, instead of spending his own money, had borrowed it of the landlord, or, as though the landlord had made the improvements. The tenant then asked the former landlord to return him a portion of the money thus spent in improvements, but could not get a farthing. The money is, therefore, wholly and solely confiscated by the laws of the country. Cannot farmers see what is the remedy for this injustice? It is this: at all elections take care to pledge candidates to vote for a good tenant-right. *H. H. O.*

Sunflower.—I notice some remarks on the above plant in your paper of the 16th inst. Thinking some further particulars may be interesting, I condense a few notes I have on the subject for insertion in the *Agricultural Gazette*. The Government of India made some inquiries in 1869, through Lord Lyons (Ambassador at Paris), as to the effect of the cultivation of the Sunflower plant in neutralising the injurious effect of marshy exhalations. These inquiries did not result in much of a definite nature, however, except that it was understood that Sunflower had been planted in Ireland for the above purpose, and that no one had occasion to fear intermittent fever who settled on the reclaimed land of the Lac de Haarlem, if he took care to plant Sunflower. Might not the experimental growth of the plant be tried on some of the irrigation farms? The Sunflower oil is said to be superior to either Olive or Almond oil for table use, and is also useful in the manufacture of soap, candles, and woollen goods. The flowers furnish a brilliant dye, which is said to stand well. I have also heard that the seed is splendid food for poultry, and I know that bees are exceedingly fond of the Sunflower. The leaves are reputed to have a pectoral value when smoked as cigars. The plant would thus seem to be useful in every part, like some Palms. Each bushel of seed yields on an average 1 gall. of oil, the average yield per acre being 50 bush. Lime rubbish is said to be a good dressing for the land, to be sown with this crop. The quantity of seed required is about 6 lb. per acre, and it is the practice, I believe, to leave about 15,000 plants or upwards to the acre of ground, probably a distance of 2½ feet between the rows, and 1½ foot between each plant would be better in this climate, looking to the necessity of a sufficient exposure to the sun. The quantity of seed is said to be increased by "dwarfing," *i. e.*, stopping the plants. I do not know the Continental plan of sowing, nor do I know the value per gallon of the oil. *James Mac-Pherson.*

The Root Show at Islington.—I send you my notes, that you may use them, if you please, as well as my own.

Roots and seeds are a fine show, but characterised with unusual diversity, a result, no doubt, mainly due to the season.

Thos. Gibbs & Co., Half-moon Street, Piccadilly, have a very uniform selection of roots, not over large but of fine quality; ox Cabbage, large, weighing 60 lb. There is as usual a fine exhibit of seeds, and the whole stand is tastefully laid out.

Sutton & Sons have an excellent stand. Their green Kohl Rabi is very superior, so are their Mangels and Swedes, and, as usual, they have a splendid exhibit of Potatos, grass seeds, &c.

The Messrs. George Gibbs & Co., of Down Street, Piccadilly, have some wonderful Cabbages, one heart weighing 66 lb. They exhibit 100 different sorts of Potatos, and some 20 of Onions. The Mangels and other roots, grown by Mr. Dickenson, Page, Dowling Forest, merit special notice, both for weight and quality.

Raynbird, Caldecott, Bawtree, Dowling & Co., also exhibit some of Mr. Dickenson's splendid New Forest roots. They have a fine show of seeds, cake, and manure.

Isaac Wright & Son, Great Bentley, Essex, have a small but select exhibit; so has Mr. Dixon, of Hull. Mr. Hipe's sewage produce has already been noticed.

Messrs. Webb & Co., Hatherop Castle, Fairford, have a splendid selection from their general show, reported in a previous *Agricultural Gazette*. The roots are large and of unusually fine quality, thus illustrating the high value of the seeds from which they are grown. Cabbage large, and their Potatos and Onions are remarkably fine samples.

J. K. King, Coggeshall, Essex, has a very fine selection of Mangel and Swede roots, finely grown, with single tap-root and small top, the bulbs being well shaped, with clean stem, indicating great hardihood. Samples of 2-year-old roots are shown in proof of their being as fresh and sound as they were last year. Seed fine and well dressed.

Sutton & Sons, Reading, have one of the best shows ever exhibited in the great hall. We do not recollect seeing its equal, and the artistic manner in which the different varieties are arranged displays their great value for symmetry and quality to the best advantage. The central bed of Potatos is a splendid show of itself. The almost incredible weight of the Mangels was given in previous reports. I have only to refer for the rest.

Alfred Hall, of Westbury Farm, Wilts, has as usual a very fine selection of his "Westbury Swede," Long Red and Globe Mangel, also a peculiar variety of Belgian Red Mangel grown and arranged display like a fine show of symmetry and quality to the best advantage. The central bed of Potatos is a splendid show of itself. The almost incredible weight of the Mangels was given in previous reports. I have only to refer for the rest.

[A known correspondent.]

Cattle Feeding.—A bullock two and a-half years old is estimated to consume 14 cwt. of Turnips in the 24 hours. Fed on Turnips, the increase of weight should be 1½ lb. By giving in addition to the above weight of Turnips 4 lb. of oilcake, the increase of weight will be brought up to 1¾ lb. daily. Under the heading "Odds and Ends of Farming Facts," the *Mark Lane Express* contains the above piece of information, upon which, with your permission, I will make a few remarks, with a view of gaining accurate information. If I am right in inferring from the above quotation that it will take 4 lb. of oilcake to produce ¼ lb. of beef, and that the writer of the article is right in his estimate, then it is plain that stall-feeding with oilcake at £12 per ton is not a profitable business, as I now propose to show. 4 lb. of oilcake, at £12 per ton, costs 5¼d.; its manurial value (taking Mr. Lawes' estimate of £4 12s. per ton) is 3½d.; to this add, say 2d. for value of ¼ lb. of beef; then by deducting the selling price of the beef, and the manure value of the cake from its cost, there is a loss on the 4 lb. of 1½d.; or, upon 1 ton, £2 14s. 8d. Would you or any of your correspondents give an opinion, based on experience, as to the profitableness of feeding with oilcake? *Short Grass.*

Societies.

HIGHLAND AND AGRICULTURAL.

Dec. 6.—At the monthly meeting of the directors of this Society, the Most Noble the Marquis of Tweeddale, K.T., president—

Chemical Department.—The board agreed, on the suggestion of the chemistry committee, to offer a premium of £50 for a report on "What has chemistry done for agriculture by improving or increasing the produce of the soil?" A suggestion originating from the chemical committee, that the Society should establish a model farm, was remitted to the committee, their proposals not being yet matured.

Transit of Animals.—The report by the committee on the transit of animals by railway was submitted. It narrates the whole proceedings of the Society, from the time the subject was first taken up by the directors in 1867, and proceeds as follows:—"After carefully considering the documents submitted, and the Act to which the Order of Council has reference, the committee beg to recommend that the board should again communicate with the Lords of the Privy Council, through Dr. Alexander Williams, specially pointing out,—1. That the Order of Council (3504) called 'The Transit of Animals Order of May, 1870,' for providing tracks with spring buffers, and supplying water to animals carried by railway, is not only systematically evaded, but is defective in respect that provision is not made for supplying animals with food; and that a new Order of Council is urgently called for. In the new Order it should be specially provided—(i.) That animals should be supplied with water when trucked and untrucked, and during the journey with both food and water; the necessary food to be provided by the owner of the animals, the water by the railway company. The Act says that if animals are allowed to be in trucks without water for a period between 12 and 30 hours (to be fixed by the Privy Council), the railway company will be guilty of an offence. A rule of the same kind should be adopted for food against the owners. (ii.) That in addition to the spring buffers stated in the Order of Council (300), it is absolutely necessary to provide covered waggons, closed at the ends, and 18 inches above the sides from each end, with an arrangement of troughs for the proper supply of the animals with water, and racks for supplying hay in the trucks during the journey. (iii.) That important railway stations, where animals are trucked and untrucked, are not included in the schedule attached to the order of Council (324), called 'The Transit of Animals (Water) Order of March, 1871.' (Here follow the list of additional stations suggested; but the committee consider that, should the Privy Council issue an Order that water be supplied in the trucks, it will not be necessary to have it at all the stations enumerated.)" The committee further suggest that, should the Privy Council not give effect to the representations proposed to be made to them, an influential deputation should be formed to wait on their lordships. The report was approved of by the directors.

Fisken's System of Steam Cultivating Machinery.—The following report upon the trial of Fisken's steam cultivating machinery, which took place on the Marquis of Tweeddale's home farm of Yester Mains, during the week ending November 11 last, prepared by Mr. Swinton, Holyn Bank, Gifford, was submitted to the board:—

Lord Tweeddale, being desirous to see this system of steam cultivation at work, and to give the agricultural community an opportunity of inspecting it, arranged with the Ravensthorpe Engineering Company of Mirfield, near Leeds, to send the patentee and the machinery to Yester; and hired from Mr. David Roughead, Myreside, a traction engine and balance-plough, made by John Fowler & Co., of Leeds. This engine is stated by Messrs. Fowler & Co. to be of seven horse power. Several practical engineers who saw the engine at work expressed doubts about the engine being of this power, and the price paid by Mr. Roughead for it (£420) indicates a smaller horse-power, although Mr. Roughead seems to get a good bargain of it. Mr. Roughead has used this engine for over three years, in working a set of round-about tackle on Howard's system. The only alteration which this engine required in order to adapt it to the Fisken tackle was the fixing of a grooved rim on the fly-wheel to receive the driving rope. The plough hired from Mr. Roughead was one of Fowler's ordinary balance 4-furrow ploughs, but with mouldboards made according to a pattern of Mr. Roughead's. This plough was only adapted for a furrow not exceeding 9 inches deep, and had to be considerably altered to enable it to turn a 14-inch furrow. Before the trial was very satisfactory, a trial was made to fit on mouldboards of the common horse-plough in use at Yester; but as the head of the plough and the mouldboard were not adapted to each other, the furrow was not so well turned as it might have been. The Fisken tackle is not, however, in any way answerable for deficiency in the quality of the ploughing, as this was wholly the fault of the plough.

The trial ploughed rather more than 2 acres, and had been under a crop of Oats in 1871, and was wished to be deep ploughed in preparation for a crop of Turnips in 1872. The part of the field operated on consisted of soil of various kinds, from stiff clay to sand and gravel, and a narrow hollow or glen passed through it, into which the plough had to descend and ascend at each turn across the field. This part of the field was chosen in order to test the working of the machinery on uneven land. The field had, during several previous rotations, been ploughed by horses to a depth of from 14 to 16 inches, and all the large stones removed. A full description of the Fisken method of steam cultivation is given in the pamphlets issued by the patentees and makers of the apparatus, and need not be here repeated. The Fisken tackle, consisting of two patent windlasses, six corner anchors, one tension anchor, 30 light rope porters, two claw anchors, two rope porters for steel rope, two wood levers, crowbars and tools, 1200 yards of hemp driving rope, 800 yards steel rope, 100 yards of steel rope for anchors, and weighing in

all about 8½ tons, arrived at Haddington station on Saturday, November 4, and required nine horses and two cents to convey it to Yester, 6 miles. The windlasses were set down in the field near their position for work, and a portion of the field, 400 yards long and 200 yards wide, and containing about 16 acres, was marked off, and the anchors and porters for the driving rope were set up round about it. The engine and plough arrived in the field on Monday, November 6, and the ploughing oc'clock on that afternoon of that day commenced to plough. Several hours were spent in getting the engine into position, in consequence of the wheels having sunk in the soft headland, which was very wet from the heavy rains on the previous days. Tuesday, November 7, was spent in making sundry alterations on the plough, and adjusting some parts of the Fisken tackle which had not been properly fitted.

Wednesday, November 8 : the tackle was fairly started this morning, and the number of people employed was as follows :—One engine-driver, two windlass men, one ploughmen, one and wire rope porter, one man and horse driving water to engine, one man and two horses driving coals (8 miles). Not long after starting the bearing of the pulley of the corner anchor, nearest to the engine on the right rope, became heated, and the anchor had to be removed to another one standing near. About three hours after starting the small pinion on the first motion of the patent windlass stuck fast on the shaft on which it runs loose when not in gear. The work had to be stopped, and part of the machine had to be sent to the blacksmith's shop to be adjusted, and the shaft ground, thereby causing a delay of three hours. Both of these stoppages occurred through sufficient provision not having been made for lubrication of the bearings, as all the bearings are vertical. Lord Tweeddale having required the land to be ploughed 14 inches deep, which is the depth ploughed by three horses at Yester, the balance-plough was altered accordingly, so as to plough that depth of the required breadth and depth ; and although the land was not so well turned as was desirable, still the soil was moved to the depth required, except where the land was light and there was a slope of the field to a hollow, where the tendency of the plough was to throw out of the ground. On several occasions, and in order to test the strength of the tackle, the plough was loaded with men, and found into the stiff clay, so as to try the engine. No breakages occurred. It was found that with three furrows 14 inches deep, one hour was required to plough an imperial acre, with the steam gauge of the engine showing 100 pounds pressure of steam per square inch.

On Saturday, November 11, the work was inspected by the directors of the Highland and Agricultural Society, the steam plough committee of the Society, and several other gentlemen. The engineering committee of the Society was in the field, but in consequence of the non-appearance of Mr. Slight till late in the afternoon there was not sufficient light properly to apply the dynamometer. This is much regretted, as there is no record of the power expended in dragging the plough, or the driving rope and windlasses without the plough. At the desire of the directors, the tackle was removed and set to work in a different part of the field. The engine moved into a new position. Three horses were required to move the windlasses, and two horses and carts to move the anchors, porters, and other apparatus. The time occupied in this removal was 1 hour and 35 minutes from the time of commencing the removal, when the plough was again at work. Some delay was caused by the coiling up of the hemp-driving rope on the reel, which, instead of being on the engine (its proper place), was temporarily fixed on a cart. The engine-driver, who has had charge of Mr. Roughead's engine for the last three years, states that the power required from the engine to drive the Fisken tackle is as near as possible the same, and certainly not less than is required to work Fowler's "double" tackle on Mr. Roughead's farm, and that the consumption of coal and water was also the same. The engine was found to consume 23 cwt. of coal and 16 cwt. of water per hour, and 2 gills of oil per day. The coal (got from Fountainhall colliery, and though not of the best quality of steam coal, is the coal commonly used for engines in this part of the country. The oil and tallow required after the inspection of the windlasses, anchors, and porters, after these got into proper working order, was 1 imperial pint of sperm oil per day, and about 1 lb. of tallow per week. The working strain on the hemp driving rope is said to be a fourth part of the strain on the wire rope which drags the plough, so that, supposing the strain on the wire rope with the plough turning three 14-inch furrows to be 28 cwt., the strain on the driving rope would be 7 cwt. The driving rope in new will stand a strain of 20 cwt., and the wire rope 14 tons. The working of the Fisken tackle during the week it was employed at Yester was very closely watched, and after the tackle was fairly started notes of everything that occurred were taken. The only defects observed in the tackle were those already mentioned. They were easily remedied, and with a little more care in manufacture would not have occurred. The management of the windlasses is apparently within the capacity of any ordinary workingman, and the facility with which these can be put into and thrown out of gear, and the plough thereby stopped, without communicating to the engine, seems to have reduced the danger of any accident almost to a minimum. The use of the friction clutch for setting the windlass in motion is also considered a great advantage, as the risk of breakage from the plough coming in contact with settled stones is much reduced. The tackle was examined by many practical agriculturists during the week, and they were unanimous in expressing their approbation of the apparent suitability of the tackle to perform the work required of it. It is to be hoped that the eminent consulting and practical engineers of the High land Society will express their opinion as to the mechanical arrangement adopted on this system, and as to the probable endurance of the windlasses and other parts of the machinery.

No statement of the cost of working the Fisken tackle has been given here, as this must vary much, according to the conditions laid down by the agent of the other system it was found to be beyond the means of a private individual to conduct such a trial as he insisted on, and Lord Tweeddale is of opinion that such a trial could only be carried on in Scotland by the Highland and Agricultural Society.

The board instructed the secretary to convey the thanks of the Society to Mr. Swinton for his able report, and to communicate with Professor Macquorn Rankine and Mr. Slight, with a view of getting a report from them of the mechanical arrangement, and of the probable endurance of the windlasses and other parts of the machinery adopted in Mr. Fisken's system.

Humanity to Animals.—A committee was named to read and report on the papers lodged for Lady Burdett Coutts' prizes for essays on the most efficient method of inculcating in primary schools the duty of humanity to the lower animals. Mr. Menzies reported that forty-three essays had been received.

SCOTTISH CHAMBER OF AGRICULTURE.

The Land Laws.—At a recent special general meeting of this Chamber Mr. M'Neal Caird delivered an address on this subject, from which we make the following extracts :—

1. The first point to which I shall ask attention is that apart from stipulation, and by mere force and presumption of law, an ordinary farm lease cannot be effectually transferred by the tenant unless he can obtain the landlord's consent. The lease is the tenant's property—very often, though his skill and expenditure, the most valuable property he can stand here to-day—but the tenant one of the essential rights of property—the right to dispose of it. Consider the case of a tenant-farmer who has his means locked up in the land, and whose health or circumstances disable him to remain in the management, though he may have many years of a valuable lease to run. What is the worth of his valuable property then? He cannot sell it—he cannot sublet it. But the rent is growing, the seasons for cropping are running on. He is unable to wait. He can do nothing but cast himself on the mercy of the landlord. He is constrained to renounce the lease, and the landlord enters to his laborers with such compensation, if any, as it is of his mere pleasure to give. Is it a righteous law which puts the tenant-farmer into that predicament? Take the case of a child, a few years old, succeeding to his father's lease. Fortune, indeed, will be in his favour if he is possessed of the courage and the ability and will to undertake the grave risk and responsibility of farming for a minor during 12, 15, or 18 years to come. For if they are not, his rights also must be placed at the landlord's mercy. And then consider what may be the position of a tenant-farmer who marries during the bulk of his means invested in his farm. The law does not permit him to regulate the succession to his own lease. How is he to secure a home for his widow? His eldest son may be settled abroad, or have no knowledge of farming ; he may be a spendthrift and a profligate. Unfortunate indeed is the law law no power to leave the lease to any other of his children. That is not the case with other property. Lord President Islay Campbell, when he was outvoted on this question on the bench, indignantly exclaimed, "It is not common sense" for the landlord to control the succession to a tenant's lease, "which is his own not common justice. It is a law expressly for the interest of the landlord ; which can be pleaded by nobody but the landlord ; which is, therefore, not available to the eldest son if the landlord chooses to accept the heir named by the tenant. And here is a climax to the intolerable wrong of this law. It puts both the eldest son and the selected heir at the mercy of the landlord. On the other hand, it would be unjust that the tenant should have the power by disposing of the lease to escape from his obligations to the landlord. I think it reasonable that in any alteration of the law the original tenant should remain responsible to the landlord along with the tenant to whom he transfers the lease.

2. I now come to the great question of tenants' improvements. When a man's lease is approaching its termination, every ton of purchased manure that he puts into the land is a premium to somebody else to offer a higher rent for his farm. Common prudence compels him to hold his hand, and to take out of the farm as much as he can get on a reduced expenditure, and the productive power of the farm is thus diminished at the end of the lease. This is a source of great national loss. It is hurtful also to the landlord, and hurtful to the incoming tenant, who incurs a heavy expenditure at the beginning of his lease to restore the fertility of the farm. The reduced production by which he suffers, and by which the landlord also suffers through him, commonly continues till he has at least gone over a full course of cropping. Neither is it for the advantage of the outgoing tenant if he were protected against the loss of his unexhausted manures and tillages. The true interest of all concerned is that he should have a right, by law, to have their value ascertained and allowed to him on his removal. You might then expect that farms in general would be kept in full fertility till the end of the lease, and the whole country would benefit by it. Reflect for a moment on the amount of wealth which is lost to the country through the want of reasonable arrangements on this subject. Have we any means of roughly estimating it? On a seven-course farm held on a 19 years' lease you may reckon that the last five years will be a period of reduced expenditure by the outgoing tenant, and of exhaustive cropping. Then the first seven years of the new lease will be a period of liberal expenditure and gradual restoration of productive power. The next seven years you may expect the farm to be in full fertility ; and then begins again the evil cycle of exhaustion. You will have on the individual farm seven years of Egyptian fatness alternating with periods of comparative leanness ; but the lean years will be in the proportion of 2 to 7. Now, if the leases and the compensations on removal—judging by the motives by which men are commonly influenced—the leanness will be apt to become chronic, unless in exceptional cases, or where the character of the landlord gives a tenant all the security which he could have from a lease. Then consider that this kind of thing is a constant action all over the country. And when you remember the enormous value of agricultural produce in Great Britain, even as things are, you may form some conception of the untold millions of wealth which might be poured into the coffers of the country through the pockets of farmers, if some legislation on the subject, based on the motives by which men are acted on, you could sustain the land in full fertility during the whole 19 years of a lease, instead of seven out of 19. I need hardly suggest that when the value of all that additional produce finds its way into the tenant's pocket, it is according to all experience to a considerable share of it will soon pass into the rent-roll of the landlord. If we could raise the average rate of acreable produce in Great Britain by only one-fourth, which is not an unreasonable expectation, the result in money could probably not be less than 40 millions a year. Again, if an enterprising farmer erects buildings for laborers' cottages, or executes drainage or other permanent improvements, the law is prompt to punish him for his rashness. The house is no sooner built—the moment the improvement is executed, the law takes the ownership of it from the man who built it, and transfers it without compensation to the landlord. The high priests of the law pronounce the formula, *inædificatum solo, solo cedit*, and every tenant must bow his head and submit, so potent is this mystic phrase to juggle away the just interest that every man has in the work of his own hands. It contains a dogma of the legal creed which we have generally received with unquestioning reverence. In plain English it just means, "What is built on the land belongs to the land." It is an assertion, not a principle or even an argument—an assertion not always supported by fact or reason. We are told in God's law, "The sea is His for He made it," but in man's law the ruling is reversed ; the house is the landlord's though he did not make it. That is the law of Scotland. Is it reasonable ? Is it just ? Is the law to cast the balance always, and irreversibly, against the tenant ? Our Yankee brothers have adopted the opposite principle for their unoccupied lands in the West. They call it the "squatter" law, and it is one main secret of the amazing growth of that great country. Its principle is, "Where a man builds his house and settles, the land shall be his." It is a wise and noble law for an unappropriated country. So, you see, the rules of law are capable of being adapted, and they ought to be adapted, to the circumstances and wants of society. We of this country had once vast, almost illimitable, tracts of unappropriated land in the colonies. And there never was a more gigantic blunder than was committed by our statesmen when they failed to make the unoccupied land available to every subject of the empire, before they abandoned the control of these lands. We have still large tracts of public land in this island—great commons, the birthright and property of the people, which are being encroached on and frittered away piecemeal year after year by the pressure of neighbouring proprietors. Their extent is immensely greater than is generally known. I would just ask, in a parenthesis, might it not be an appreciable relief to our crowded population if we had a wise and well-considered homestead law for these immense common lands, giving all reasonable priority to adjoining commoners ? I hope to see Parliament establish some such rule as this—What a tenant builds shall be his, and he may take it away unless he is paid for it.

3. I now pass from these great grievances to others which, though of less capital importance, are sufficiently galling. The legal warning of 40 days to leave a farm is quite inadequate. The exigencies of

modern agriculture require a farmer to look a long way ahead. When he manures his green crop, or folds sheep on his Turnips, it is in preparation for the grass crop which is to grow, not in that year, nor the next year, but the year after that. He prepares in summer the cattle that are to be fatted in winter. Whenever the corn is off the ground, the tillage for next year's crop should begin. He can hardly get his winter crops in too soon. Yet he may be kept in the most painful uncertainty whether he is to remove or not till he reaches the 40 days before Martinmas. The old law was more reasonable. It made a difference between removals in May and removals in November, in the very month of winter. Till 1853 a tenant could not be removed at the winter term without notice 40 days before May 15. That gave him six months besides the 40 days. But in 1853 there was a Bill in Parliament, a technical Bill, to regulate the business of Sheriff Courts. A clause was slipped into it that there should be no longer a distinction as to removings between one term and another—that 40 days before the actual term of removing should be sufficient in all cases. Away went the six months at a blow. That at least must be reversed. But since it brings under discussion the whole subject of warning to remove, I venture to say that, having regard to the expenditure which a man has now to make on his farm, and the necessity he is under of farming on plans which contemplate the future, no agricultural tenant ought to be removable on less than 12 months' notice at least.

Farmers' Clubs.

EAST LOTHIAN.

Double Ploughs.—The following paper was lately read before the East Lothian Farmers' Club, by Mr. James Wyllie, Innerwick :—

With regard to the comparative draughts of double-furrow and common ploughs, a great many trials at pubic competitions and elsewhere have been made, and the general result has been to show that the double-furrow is about one-half heavier to draw than the common single plough. I have, for my own satisfaction, tested the draught of both implements in various kinds of work, with very much the same results. As I carefully noted the results of the last trial, I will now, with your permission, give particulars. The land we were ploughing at the time was after Potatos, and had been harrowed and grubbed, so that it was loose for 4 or 4 inches deep, and nice and firm below. The furrows turned by both ploughs measured 7 inches deep by 9 wide. On applying the dynamometer to the common plough, I found it drawing, as nearly as I could judge, considering the variations of the instrument, about 31 stones. On trying the same plough without a furrow, I found it drew quite 10 stones, so that about one-third of the horse-power was exerted in moving the mere implement. On bringing the double-furrow plough to the same ground, and fixing it to the same size of furrow, I found it drew 62 stones. When trying the weight of the empty implement, we found the slight incline of the field made a great difference on the draught—much greater than that noted when testing the common plough without a furrow. Though very little uphill it drew 13 stones, while downhill it only drew 7 stones. The common plough was tested exactly in the same open furrow and on the surface. The double-furrow was, of course, only tested on the surface, which, as I mentioned before, was loose from being grubbed, so that the wheels sank somewhat into it. The average weight, then, of the empty double-furrow I put at 10 stones, being the same as that of the common single plough. From these results we find that to turn two furrows by the common single plough the total draught required of four horses amounted to 62 stones, or 15½ stones to each, while by the double-furrow the same amount of work was done at an exertion on the part of three horses of 43 stones, or 14⅓ stones to each; so that three horses, in the double-furrow, did the work of four in the single plough without being harder wrought. In this case three horses were somewhat easier in the double-furrow than two in the single; but in other cases I have found the draught about equal, and in one case somewhat in favour of the two in the single plough.

In trying to account for the evident saving of power effected by the use of the double-furrow, we find, on comparing the draughts of the empty implements, that to turn two furrows by the single plough 20 stones were required merely to move the empty implement, while in the case of the double-furrow under the same circumstances only 10 stones were required. This apparently gives us at once a saving of 10 stones in favour of the double-furrow; but, as to turn two furrows by the single plough required 62 stones, and by the double-furrow only 43, we have still 9 stones of evident saving to account for, or 4½ stones for each furrow. As I cannot show from actual experiment how this is effected, I can only state how I suppose it may be. In the first place, I believe part of this saving of draught is due to the great attention which has been paid to the construction and shape of the working parts of the double-furrow plough, and to the substituting of steel for cast-iron mouldboards. Then, I have already shown that to perform an equal amount of work, the double-furrow, on wheels, requires one-half the amount of draught to move the unloaded implement that the single plough, without wheels, requires. Although it did not occur to me at the time to try, we can easily suppose that had the implements been loaded with any equal weight, the implement on wheels would have shown to a still greater advantage. Now, when at work, a plough has to raise the furrow, turn it, and place it in another position. This lifting, and perhaps partly the turnings, will cause a certain amount of downward pressure, or, in fact, form a load on the implement, to what an extent I am unable to say; but at all events we may suppose the load to be equal in either case, and no one, I think, will doubt that a given load, whatever it may be, will be easier drawn upon wheels than without them, so that we may safely conclude that some part of the 4½ stones of saving to be accounted for is effected in consequence of the weight of the turning furrow being borne upon wheels. Still, another part of the saving may be effected by the side, or lateral pressure, being, in the case of the double-furrow, provided against by wheels set at an angle for this purpose, here again substituting a rolling for a sliding motion. I hold, however, that the front, or pilot wheel of the double-furrow plough, effects no saving in this respect, from the adjustment of the line of draught, or, rather, the proper adjustment of the plough to the line of draught, counterbalances this; and I cannot but think that had the eminent engineers who, in the late patent case, laid so much stress upon lateral thrust in front, been at the trouble of experimenting with a plough actually at work, they would have modified their opinions considerably upon this point. I cannot see how a case of lateral thrust in front can be made good, when it can be shown that a double-furrow plough which has no side or sole-plate to sustain such will work perfectly well with the wheel moving several inches away from the angle of the furrow; indeed, were it a fact that lateral thrust could not be overcome in front by the adjustment of the implement to the line of draught, then the common swing-plough would be useless without some appliance for preventing it being constantly drawn out of work by the wheel. But while holding that the proper adjustment of the plough to the line of draught overcomes the lateral pressure which might be worth providing against in front, were the implement pushed from behind, I believe the angular set trailing wheel of the double-furrow plough effects a considerable saving in this respect. It is a very common practice on the part of ploughmen, when setting double-furrow ploughs, to place the draught-chain too much on the right-hand side of the plough-bridle, thereby causing an undue pressure of the pilot-wheel against the edge of the unturned land; but this, instead of lateral thrust might be called lateral draught, as they virtually cause the horses to drag the wheel against the land, and I know from actual trial that when this is done to excess it adds considerably to the draught of the implement. When a ploughman finds his plough is properly set, the pilot-wheel should move easily on the angle of the furrow, neither pressing to, nor seeking away from, the unturned land, so that it may be either easily steered away, when a narrower furrow may be needed to straighten, or pressed somewhat closer to work a slightly wider furrow, though this latter may be done by merely drawing the horses a little more apart than ordinary: indeed, a good ploughman can, when once his work is properly begun, keep it quite straight and equal solely by the skilful management of his horses, at least where the soil is of uniform quality.

The advantages arising from the use of double-furrow ploughs, granting that they are only about one-half heavier to draw than the common single plough, are manifest. On an ordinary-sized farm the saving effected by them in horse-power must be very considerable, and I have no doubt that in some cases from their use a pair of horses might be altogether dispensed with, in which case a direct saving of about £100 a year would at once be effected. I would not, however, generally build much upon this idea, as ploughing is by no means the only operation requiring horses, and otherwise steam ploughing would have been more general ere this time. At the same time I am aware that in some cases a reduction of the number of horses has been effected. One of the chief advantages arising from their use is found in having work well forward at all times and in being able to get everything done in proper tid and season. This alone in many cases might be estimated at as much or even more than the saving of the keep of a horse or two. When working well, no common plough can compete against them, so far as equality of the work goes, and land ploughed by them in spring, where perhaps Turnips have been eaten on, will be found much more friable and easily harrowed down than when done by the common plough. This is caused, I think, by the hard surface cracking into comparatively small pieces, as it begins to rise, because of the wheels causing the implement at an uncompromising depth; whereas by the common plough the ploughman is constantly using the stilts by way of a lever, and by this up-and-down motion breaking up great solid clods which often afterwards require a tiresome amount of horse-power to reduce.

It is sometimes urged as an argument in favour of double-furrow ploughs that boys, or second-rate hands, will by them be able to make as good work as skilled ploughmen, but this is a mistake. Indeed, so far as my experience goes, I have reason to believe that we have more need than ever of clever, intelligent men. It often happens that, in changing from one sort of work to another, some difficulty is experienced in setting the plough to the best advantage, and it is often, especially until considerable experience is gained, only after an amount of trouble and patient thought that both furrows are got quite equal, and the implement to work otherwise in every way well. I have sometimes seen a very slight alteration effect all that was wanted after having been long puzzled. Should any one be thinking of investing in double-furrow ploughs, and not have his mind made up to bear with some petty annoyances, or not have one in authority under him who has energy and determination enough to make them succeed, I would caution him that he is not yet in a proper frame of mind to go in for them, as there is no denying the fact that a prejudice exists against them amongst many farm servants, who, if listened to, will soon find lots of excuses for throwing them aside. This same prejudice has already, I think, been a great means of consigning the double-furrow to oblivion. But, as the plough is perfection to which the implement is now brought, and the smart rents that farms are now fetching, might again succeed in accomplishing the same end.

DISCUSSION.

Mr. Gaukroger, Southfield, said he had used double-furrow ploughs for two years with the greatest satisfaction. When he first introduced them on his farm he had to put up with the objection that Mr. Wyllie stated, that farm servants had a prejudice against them. Now, however, the men who use them were highly pleased with them, and agreed with him entirely that they did the work very much better than the old single plough.

The Chairman said that the work done at the recent double-furrow trials at Hallow fair was very commendable.

Mr. Wilson, Crachil, noticed a double-furrow with a couple of handles, which he thought were very necessary, if it was for nothing else than keeping the ploughman in his place. The handle though referred to possessed an apparatus which enabled the ploughman to lift the plough 3 or 4 inches out of the ground and run it along. Double-furrow ploughs were very suitable for ordinary soils, but they were not adapted for hills.

Mr. Smith, Stevenson Mains, was convinced of the utility of the double-furrow plough, and of the saving of horse-power. Since introducing that implement on his farm he had reduced the number of his horses, and now wrought 350 Scotch acres with 4½ pair of horses.

Mr. Robertson said double-furrow ploughs were yet in their infancy. He had used one for two months, and he was not very strong in his favour. In reply to Mr. Wyllie's remarks, as to saving £16 a-year by the use of double-furrow ploughs, his (Mr. Robertson's) experience was that on a farm of 300 acres the saving might be set down at from £30 to £40 a-year.

Mr. Wyllie, Bolton, said it was two years past since he got a double-furrow plough. It was not long before he got another, and recently he had procured other two. He ploughed 80 Scotch acres of land with double-furrow ploughs, and calculated the saving at 5s. a-day by every one used. Moreover, the work was done better and quicker than any common swing-plough.

KINGSCOTE.

Farm Capital.—An excellent paper, on this subject, was lately read before the Kingscote (Gloucestershire) Farmers' Club, by Mr. F. Burnett, who said :—

First, Is it advisable to increase the working capital on the farm? We will confine the question to this immediate neighbourhood. The answer to the question would be Yes, and a very proper answer, too, under the present system of holding. There is no doubt but that the produce of the land can be much increased by an extra outlay of capital, especially in those parts where the soil is deep and wet. Few of us are in this position. But who would think of farming land under the law of landlords under a yearly tenancy? This being a rule and not an exception—not only in this neighbourhood, but throughout England—it is quite time it should be altered. I feel I cannot do better than quote the words of the Earl of Derby at the Liverpool meeting. The earl said :—

"Security is the first requisite, and I hold that any tenant good enough to be kept permanently, ought to have a lease if he wants one."

The Earl of Leicester at Docking said :—

"I will ask you whether we have in this description of soil, and in a favourable season, grown all that is possible to grow with profit? and is our grain crop and our root crop all that could be desired? I fear that these questions can hardly be answered in the affirmative; and as long as we are so cautious in deviating from the beaten track, and so slow in adopting the knowledge that is extending itself throughout the country, we shall be more dependent upon the seasons than we ought to be, and we shall obtain that success for our efforts which we otherwise should do. Since I last met you I have travelled much through England and Scotland, and I have cultivated, and am still cultivating the whole of the land that I have seen under cultivation, I think I may safely state that the produce of the land might be nearly doubled under a perfect system of agriculture."

This is strong language, remembering the quarter from which it comes. Here we have, not Mr. Mechi, but Lord Leicester, the best landlord, in one of the best cultivated counties in England,

saying in so many words that the land was scarcely half as well farmed as it should be—the produce might be doubled. But Lord Leicester went further, as he went practically into the merits of deep and shallow cultivation; and fortunately he went still further. Why is the land but half cultivated? Why do we not see more capital, skill, and energy brought to bear upon the business of farming? "Because," says Lord Leicester, "there is a want of proper security."

"Because," said Mr. James Howard, at the Lords' Congress, "what was needed was security of tenure. He had known many a man of capital and intelligence brought up to farming who, rather than embark his money in the cultivation and improvement of the land of another, without a title to compensation for improvements, had carried his capital and intelligence into other pursuits."

It is thus that we drive the best men away, and it is thus that Lord Leicester would bring them back again:—

"I have found that in the leases in use on my estate there were many restrictions, such restrictions as I should most like to be bound by were I a tenant of a farm. I have, therefore, with the assistance of my agent and my tenants, deviated from the beaten track, and endeavoured to frame a lease more in accordance with the spirit of the age, avoiding all interference with the capital of the tenant, removing all clauses that dictated as to the cropping of the soil or as to the sale of produce, and, as far as I can, giving him security for the capital invested. I have endeavoured to put my tenant in a similar position which I should like to hold as an occupier of land, and in doing so I am satisfied I have studied my own interest as well. That lease will be printed, and with as few legal phrases as is practicable, and I shall be happy to submit a copy of that lease to any of my friends who may like to see it, because I believe, with certain modifications, it may be adapted to many estates of this country, both for the advantage of the landlord and the tenant."

Let us believe that the good time is coming when every tenant-farmer will have in his possession a lease that will give him security of tenure, with fair and just protection for the interest of the community at large.

2. Comfortable accommodation for man, beast, and machinery. This is also a landlord's question; not that we would call upon the landlord for extensive accommodation, without repaying him interest for his capital invested. Before the farmer can lay out extra capital, he must have a prospect of doing it advantageously, which cannot be done in agriculture more than in any other branch of business without sufficient strength to carry it on; therefore, he must be of the greatest importance that there is sufficient house accommodation for his labourers—they must be comfortably housed and well fed. As with man so it is with beasts. We are all agreed that animals will do with much less food throughout the winter months if they have dry and comfortable lodgings—the less exposed to the weather the better; indeed, I believe that, on this high elevation on which we are situated, it would pay to have large covered-in sheds. Warmth and cleanliness are indispensable requisites to the well-being of all animals, and will repay extra care and attention. If the farmer is to increase his machinery, this must also entail an extra expenditure on the part of the landlord, as efficient covering ought to be provided for them when not out in the fields at work, else the machinery will depreciate more in value than any reasonable percentage for a covering. I fear we must not ask the landlord for much more; indeed, situate as most of you are, there is not much for more requests, although that is not one-tenth of the many needfuls absolutely necessary in the greater part of this country, such as draining, road-making, grubbing up hedges, and cutting timber, and that nevertheless unimproved, superabundance of game. I feel sure that all these requirements must be met before any great progressive revolution can take place in agriculture.

3. We will now fancy ourselves in the position of all our needs supplied so far as the landlord is concerned. In what way are we to set about increasing the capital per acre advantageously? Mr. Mechi tells us to break up the old pastures. Another tells us there is a mine of wealth in our old pastures if well manured, the moss dragged out, and where required fresh seed sown. Another says deep cultivation, and grow Wheat year after year, sell all the produce and keep no stock, but use a little artificial manure. Others are day after day saying, "Why think of growing any other root than Sugar-Beet?—sell it for distilling purposes, and have it back after the juice is taken out to mix with chaff for feeding purposes;" and many are the wonderful accounts we hear of cooked food, straw being made as good as hay by steam passing through it; and it is only to try any of the many cattle foods and condiments and your fortune is made. Then there are steam-engines—fixed, portable, and traction—from 40 to 1-horse power, the makers of which can supply any testimonials as to their efficiency. One thinks over all these and many other systems of money-making by farming, but when one thinks thoroughly over any one of them we find great difficulty in applying them to our circumstances. So to arrive at anything beneficial to us we must come home. Let us take our pastures in this district—Is it advisable to increase the capital in their restoration? I use this word because I believe that our pastures have not been fairly treated, and they are no better, if as good, as they were 20 years ago. The peculiar seasons we have had for some years past may have been the means of bringing me to this conclusion; but I fear all must not be laid to that. We all know that, however full our granary may be, if we were to take a peck a day it would get less; this is iu a great measure how we treat our grass land. Mow and carry away, or graze and take away in milk, beef, mutton, &c. The more my agricultural experience is, the more I am convinced that close and continual feeding off with sheep is the best system of cultivation, however good, and make it like a Wiltshire or Hampshire down. Sometimes we put a little on, but I believe it would repay far more liberal treatment. Worn-out pastures, which more properly might be called sheep-slight, would pay for an extra outlay in breaking: it was, if only for a few years; but I should not advise cropping it year after year without applying manure, but treat it as the rest of the arable land.

4. What is to be done with our arable land to increase the produce, so as to give a higher percentage if an extra capital is expended? Go 17 miles from home and ask the question, and nine out of ten you ask will tell you, deep cultivation. You may say, "I go near the rock now." The reply will be, "Go to the rock, and take a little of it, so as to increase your soil." Practical experience does not agree with this, and it would be far better to increase our capital in breaking up the rock which lies near the surface of the greater portion of the Cotswold hills. Where there is depth of soil, even if that soil is only what we call a cold or dead sand, an increase of capital would repay the outlay of subsoiling. This involves another question: whether it is more advantageous to use horses or steam? The answer would be horses, if this is the only cultivation that steam could be applied to; but I am of opinion there are many other uses, such as cultivating stubbles after harvest, cultivating across the fallows in the spring, and I am not sure whether it would not be advisable to have a traction engine to perform all our stationary operations on the farm, and also road work, such as hauling dung a long distance, taking out corn, bringing home coals and feed from the station; this would be increasing the capital. Now let us see whether we can make it anything like advisable to do so. I saw a 10-horse portable engine at work and tackle I saw working on Mr. Peacey's farm a short time ago, known by the name of Howard's roundabout system. The engine, Brown & May's double cylinder (which is preferable to a single cylinder), cultivator and windlass made by Howard. It was working on a stiff clay land, and I was informed that it had to do about 7 acres per day, which, in comparison with reports we hear of quantities done, is very small; but an average of 7 acres per day, we believe, is nearer the truth than 13 or 14. The work was done in a first-rate manner, much better than it would be possible to do it with any amount of horse-power, the cost 7s. per acre including every expense. Price of engine, cultivator, drags, rope-porters, pulleys, carriage, and a lot of extras, £556. Mr. Peacey said he was perfectly satisfied with the manner in which he had increased his capital. When he purchased it he sold off his 14 working horses, and believed the exchange to be to his advantage. This is his third year of working it, and had he to buy another set he would have the same sort, with the exception of a Smith's windlass instead of a Howard's. I said that I believed a double cylinder engine was preferable, but Messrs. Howard worked a 10-horse double cylinder portable engine and 5-tined cultivator at Wolverhampton, on a Clover lea, 7½ inches deep, and cultivated 3 acres in 2 hours 14 minutes, which in a day of 10 hours would be 13½ acres. Then there are Smith and Fowler, pioneers of steam cultivation; their doings are continually before the public, the latter at the Paris-take-and-be-forced, travelling on his own account and many others, is a practical steam agriculturist, and weekly—I may say daily—gives us account of all his operations. Therefore I need not allude to the system of working or cost, as most of you must be well acquainted with it. I must not forget or pass over the Fisken system, which I rather like the idea of, brought out by the Ravensthorpe Company, and which obtained a prize of £25 from the Royal Agricultural Society at Wolverhampton, and since the 1st prize of £150 at Breslau, in Germany. It has the advantage over all their roundabout sets of cultivating fields of extra size without moving the tackle. You may work to or from the engine, and it is of no consequence whether the man with the cultivator is in sight of the man with the engine or not. As it is not necessary to take the engine into the field that is to be cultivated, it can be placed at the side of a pond or stream, where it will supply itself with water. The cost of tackle is about £120 more than that of Mr. Peacy's mentioned, and I am doubtful whether to keep in repair so much Manilla rope would not be more than the maker's calculation, which is 6d. per acre. It would be unfair to expect you to listen to a very minute detail of this or any other system of cultivation. They are not very different in their performances or price, when the quantity done per day is taken into consideration. Their minor details or merits is not so much our question as is it advisable to have them? We have heard much of late about traction engines, and after what we saw of them at Wolverhampton they must be worthy of our consideration. To quote the words of the Royal Agricultural Society's Journal, "Whether considered in point of economy of fuel as a driver of machinery, or of efficiency for traction purposes upon a farm, Messrs. Aveling & Porter's 10-horse power engine was far ahead of any of its competitors." As regards using it solely as traction, drawing cultivator ploughs, &c., or any other agricultural implement behind them, I do not believe they will ever become general; the weight must be too great a pressure on the land, even with india-rubber tires, but it must be a great advantage to move of themselves and take the needful implements or machinery to accomplish their work without the aid of horses. I have often thought when we have a dry time after harvest how I should like a 10-horse traction-engine to draw a cultivator and drags behind it; if it even pressed the soil a little tight, and cracked the rock a little under, it could not do much harm. I doubt not the time is not far distant when the greater portion of the heavy road work will be performed by them. The expense of working a traction-engine for stationary purposes is no greater than a portable, with the exception of the first cost, which, for a 10-horse engine, is £320. I saw an account the other day of a traction-engine made by Messrs. Ransome, Sims & Head, of Ipswich, under R. Thompson's patent, built for the Indian Government, which ran from Ipswich to Edinburgh, a distance of 450 miles, in 77 hours. Now thus has sought for the use of steam cultivation before you, giving my opinion of quantity and quality of work done, cost of operation, and first cost of implements, I will leave it for you to draw comparisons, so that you may arrive at a most decided conclusion, whether it would be most advantageous to invest as much capital in steam cultivation. I need hardly state that it is an acknowledged fact that steam can be, and is, used most advantageously in threshing, grinding, chaff-cutting, and even root-pulping.

5. According to the heading of our subject, the next question for our consideration is machinery. I am sure you will all agree that there is no class of men more deserving of our thanks than the mechanic, for the perfection machinery is in at the present moment. The landlord, tenant-farmer, and labourer, all must hail machinery as a great boon. I know what it is to swing a scythe, hook and use a reaping-hook, and I can from the bottom of my heart welcome such machinery as will do these most laborious operations at less expense than they can be done by manual labour. To become the owner of a threshing, mowing, and reaping machine will increase the capital invested, but there can be no doubt that it will be an advantage. Then there are ploughs of a great variety. I doubt not all of you are in possession of sufficient ploughs now, but we are told by many that it would be a very wise investment to have double-furrow ploughs instead of single. Mr. James Ransome, one of the firm of Ransome, Sims & Head, at Norfolk ploughing match made a very interesting speech, and showed a very decided advantage in the use of double ploughs, but we must remember that they are the great firm which make them. I was anxious to have a thorough trial of them, and through the kindness of Mr. Ransome's at Boxwell, I asked Mr. Drew to lend it to me for a few days. I also borrowed one of Mr. Nicholls, which had been worked on Symondshall Farm for many years, and of course is of very old construction. The quality of the work done by the Messrs. Ransome's plough was quite accordant with its representation. I wish I could say as much regarding the draught. After working it several days I came to the conclusion that single ploughs can do as much work with the same horse-power. I believe if ever they are to come into general use in this neighbourhood, they must be lighter in draught, although I do not hold in all cases that the lighter the plough the easier the draught; yet, from experience, I can say the Messrs. Ransome's R.N.D. plough goes much lighter than the R.N.E., the lighter plough doing its work equally as efficient for all practical purposes as the other. Mr. Nicholls' plough had now been doing regular work of late, and was very rusty, therefore did not make anything like such good work as the other, and the draught was as great. There is an American invention of a revolving mouldboard-plough, which I have often been asked to purchase as a safe investment of extra capital. One of them being in the neighbourhood, I thought it would be well to try it, and the owner kindly allowed me to have it for a few days; but not being made expressly for our soil, it only went a few furrows when the share broke. But I could not see any real advantage in its work. It broke the furrow to pieces much more than our improved ploughs, but not more than our old wooden ploughs, with the short turn-furrows, would have done.

6. The next thing I will mention for your consideration—"Can we change our system of rotation with advantage, and, by an increased outlay of capital, increase our profits proportionately?" From my own experience, that on our light soil, the five-field system is the most advantageous. I have often tried what may be called catch crops, and the conclusion I have arrived at is, the less it is tried the better it is for one's pocket and the land. I do not wish you to understand by this that I would not sow Vetches on the Wheat stubbles, sufficient to have a good supply from May to the end of July, for the greater portion of the sheep and the

cart horses. As you are all aware, in most seasons, with a liberal supply of manure, a good crop of Turnips can be grown afterwards. If it is not advisable to change our system of rotation, can we expect a greater produce than the land now produces? Certainly not, unless there is a change in our system of cultivation. Let us try and find out what this change is to be. It is an acknowledged fact that on the Cotswold Hills deep cultivation does not produce beneficial results; therefore, so far as I can see, the only choice we have got with anything like a prospect of remuneration for an extra outlay is to increase the quantity of manure per acre. Grow larger breadths of green crops, so that we may increase our produce in beef and mutton, which, at present prices, must be more profitable than corn growing. Indeed, I believe if the capital on the farm is to be increased to any very great extent in this neighbourhood, the farmer must look to his stock in a great measure for his return, not only as producing beef and mutton for the market, but as manure manufacturers. I said the land must have a more liberal supply of manure, but should not for a moment advise the farmer to spend his capital in buying many of the worthless stuffs that are sold as manure, for it is only good manure that will produce good effects. The best of all manures can be manufactured by the farmer himself. I do not believe my ideas extravagant when I say that an extra capital can be employed to advantage, even on the land of this neighbourhood, for although poor, it is very grateful for what is done for it; and if the greater portion of the farm produce was consumed by cattle and sheep, the amount of sales would be much greater than they now are, the artificial manure bill would be saved, the land find the advantage of good manure, and the increase of crops would be much larger.

Lastly. The soiling system would add very much to an increase of expenditure, but I am not sure that if it was carried out in a proper manner it would not pay. I will quote the words used by Mr. Mechi the other day. I look up to him as an authority on many agricultural subjects, but when he lets us know what is his doings at Tiptree, and tells us to go and do likewise, regardless of soil and situation, it lowers one's estimation of his excellencies. He says:—

"The longer I farm the more I am convinced that the turning out and roaming-at-large system will come to an end, especially as land gets scarcer and dearer. It is cheaper and better to bring the food to the animal than the animal to the food; because in the latter case be is allowed to trample upon it, excrete upon it, and tie upon it. One of the largest and most successful farmers that I know has always folded his sheep and cut the grass for them—one man, a lad and a horse chaff-cutter being on the field there, feeding the sheep with green grass, chaff mixed with cake, &c. Although 77, he is, and always has been, among the best root and green crop growers among my acquaintances, on an area of 1500 acres. Green Tares, Clover, &c., are all passed through the chaff-cutter for my horses and cattle, the roots grated and the roots pulped. One trial will prove the fact, and put money into the pockets of my agricultural friends."

Although this system must be more advantageous on heavy soils than on light ones, where the treading is an acknowledged benefit, yet I know animals, even sheep, do much better in yards or sheds than out on the ground, exposed to the inclemency of the weather; and, although the expense is very much increased by haulage, yet I believe much more could be done profitably. We are aware that thousands of cattle are brought into market by people who have very little land; if they can be brought out by such men to advantage, how much more so by the farmer, who can grow the greater part of their food; and the manure instead of being a nuisance in their way, is just what the farmer wants. Mr. Leeds' farm at Castle Acre, Norfolk, consisting of 1200 acres, is nearly all under cultivation, and as much done by steam-power as possible:—

"Enriching the soil is an important part of the farm economy; everything that will help to increase the manure-heap or increase its quality is most carefully done. The manure is kept under shelter; enormous quantities of food for sheep and cattle are bought; artificial fertilisers are used largely; and only the sheep, cattle, Wheat, and Barley, are sold off the farm."

Mr. Leeds keeps 300 ewes, and feeds and fattens about 2000 sheep and 250 bullocks yearly. They are all Shorthorns, mostly 3-year-olds, but a few are 4-year-olds. They are bought at the markets, and are intended to be fattened in the shortest time possible. A judicious selection of these cattle, so as to get those which will make the most growth for the time and feed consumed, is the first element of success in this business. They are bought at prices from £20 to £30, and sold at from £28 to £48. The average increase in value while fattening is about £10 each. These bullocks are all kept in yards or boxes, and never turned out to graze. At each of the four sets of sheds there are boxes for 20 or 30 cattle, and these are occupied by the fattest animals; and the remaining ones are kept in the yards waiting their turns to enter those little boxes, from which they are never turned out till ready for the butcher. The boxes are not cleaned out from day to day, but are kept dry by throwing in a little straw; and as they fill up the feeding-troughs have to be raised. The manure accumulates in the boxes until they contain 8 or 9 tons each. The daily feed averages 2 bush. of roots, from 12 to 14 lb. of oilcake, and as much cut straw as they can eat. He fed out 300 tons of oilcake last year to his cattle and sheep. The expense for labour on the farm is usually said to be equal to the rent. The amount paid for labour was not far short of £1800. To carry out a system like this would much increase the capital; so much the better, if the farmer gets an equivalent for his money, it must be better for the community at large. I do not wish you to understand that I mention the soiling system as only applicable to fattening animals, but I believe farm horses and working oxen would be kept in to advantage till after Turnip sowing, and if calves were kept in all the summer the same food they consume would keep them in better condition, and there would be no loss from hausk, and not so susceptible to disease in the fall. I believe the dry soils of this and other land will be enriched by a better and more lasting quality of manure, and a much larger amount of capital pass through the farmer's hands in the course of the year with increased profit.

DISCUSSION.

Mr. H. HOLBOROW thought that as long as farms were let with a yearly tenancy the farmer would not be justified in laying out any extra capital. He had heard of a farm which had a fixed tenancy, raised his rent would make him farm better, but this was an exception and not a rule; and if a landlord tries to get what is called "tack" rent, the farmer must also rack his farm to enable him to pay it. As regarded superabundance of game, he did not believe anything could be done with it till all classes were brought to see that they were losers by it, for it was not only the farmer who lost the corn, but the cottager his all. I believe the

Mr. J. NICHOLLS thought a farmer ought to have compensation for unexhausted improvements—not but that there were good landlords, but for every good one there were bad ones. He thought the only thing that could be done would be to have an Act of Parliament to draw a line between the landlord and tenant. As regards sufficient buildings on the farm, many landlords would not put them up, and others were not in a position to do so. The way he had his put up was for the landlord and himself to share the expense equally. He thought it was a mistake for the law to acknowledge rabbits as game. He had no objection to

rally about 40 Irish acres in extent, or 65 statute measure.

Next to getting rid of superabundant water in a farm, providing suitable places for supplying cattle grazed on the farm with pure and wholesome water to drink is a matter of great importance. It is much to be regretted that this is not attended to as it ought to be; and hence we frequently find that the drinking pools become in summer mere receptacles of liquid filth and fruitful sources of disease. We have no doubt whatever that many cases of disease which appear among cattle on grass, and seem very mysterious, are owing solely to the horrible liquid the animals are compelled to drink.

Mr. Bomford has figured his watering places upon a plan which effectually prevents the evil of which we complain. An opening is left in the course of a main drain, one side of which is built up perpendicular, to above the level of the ground. The ground is sloped on the other side, and the slope is paved; hut instead of allowing the water to flow back on the slope, it is confined into a channel running along the foot of the perpendicular wall. This channel is 16 inches wide, and 12 inches deep. The bottom is paved with flags, and the paving is kept in its place by kerbstones, which rise 3 inches over the level of the lower part of the slope, and this prevents the cattle from slipping into the channel. The water flows down the slope slightly downwards behind the kerbstones, by which arrangement urine, &c., does not flow into the channel, but escapes at a separate opening on the lower side, and is carried off into the drain below the drinking place. The watering place is about 16 feet wide, and a retaining wall at each end prevents the cattle from getting into it by any other way than the right way. A slate or wooden sluice, placed at the lower end of the channel, raises the water, so that it is always a foot in depth. This is an excellent plan to adopt, especially when there exists any necessity for economising water, and keeping it clean at the same time.

In one part of the farm we noticed a very handy place for washing sheep, previous to their being shorn. The stream is dammed back by a sluice, and when the water rises to the top it runs over a spout into a lower division, the sides of which are lined with brick up to the level of the ground, except at the entrance on one side, where there is an opening left to allow egress to the sheep which have been washed. A sluice raises the water also in this lower basin, which looks like the lock of a canal on a small scale. The sheep are penned on the brink of the lower division, and when put into the water, they have no opportunity of turning round, but to a point where two men, one on each side, are stationed, in water-tight wooden boxes, which extend downwards to the bottom of the pool. These men swill the sheep about, and then pass it under the spout from which the water is discharged in a broad, thin sheet, and this finishes the operation in a most satisfactory manner. The use of the water-tight boxes is to keep the men dry, so that they do not require to be dosed with whisky to "keep the cold out of their hearts."

The gates used by Mr. Bomford at Drumlargan, and also at Oakley Park, are constructed of larch, and in order to prevent them from falling down at the lower point of the headpost, as is usually the case, he has adopted the following plan:—The upper hinge is prolonged so that it comes through the heel-post, and is there made into a screw having a large swivel on it. A piece of stout fencing wire is firmly tied round the lower part of the post—that part of the post on which usually drags on the ground—and is brought up in a diagonal line, and attached to the hook of the swivel. The wire is then brought a little under the upper horizontal bar to the upper part of the head-post, where it is also fastened. The swivel is then screwed home, and thus tightens the wire and braces the front part of the gate, so as entirely to prevent it from dragging.

The cattle kept at Drumlargan are, of course, chiefly purchased at different fairs; and, if any heifers, procured in this way, prove in calf, they are allowed to run on, and after suckling their calves, are stall-fed. The calves are well looked after by the dairy maid, when two years old, as much growth as many do when 12 months old. Mr. Bomford also keeps a Westland bull at Drumlargan, and the produce of such sires with common cows shows very clearly the improvement which good blood effects. He has also some pure-bred Shorthorn cows and heifers, bought at the Westland and Killynon sales. A number of cattle are fattening in the stalls on Turnips, cake, and crushed Oats, and will soon be ready for market. The flock consists of Leicester ewes, bred for several years from Mr. Torr's blood, and crossed latterly with Mr. Turner's rams. Flocks of breeding sheep are not, however, generally kept on grass farms in Meath which are capable of fattening cattle. In such cases Ballinasloe wethers are usually preferred.

Mr. Bomford's pigs are Berkshire, and crosses of Berkshire and Essex. He has gone somewhat zealously into poultry, particularly in Dorking and Spanish fowl, and Cambridge turkeys.

The drainage operations at Drumlargan gave a great deal of employment while they lasted, and there are still a number of persons kept regularly at work about the place; but in the district generally there is very little employment for labourers during winter. When men are employed, wages run about 9*s.* per week, and in summer and autumn from 10*s.* to 12*s.*, without food, &c. Irregular employment is a necessary consequence of almost universal grazing; but, although such is the case, it has become a common complaint that labourers are now not easily dealt with or managed, when employment is given to them.

Grazing farms let at from £2 to £3 12*s.* 6*d.* an Irish acre; and land held by small farmers, without leases, from 30*s.* to 35*s.* an acre. Among the last named class of farmers there is no improvement, nor any desire apparently to improve. The land is usually cropped by them until exhausted; but many of them are getting their farms into grass, not, however, as dairy farms, as might be supposed, but for grazing dry cattle. It is often difficult to get a pound of butter in the district. In a few instances, where land is let to small farmers, the course of cropping laid down in their leases, and where some encouragement is given, there are some signs of improvement; but it is a generally received opinion that the Land Act will ultimately have the effect of extinguishing this class of farmers. Most likely this was not anticipated by the framers of the Act; but such, there seems little reason to doubt, will ultimately be the result. *Dublin Farmers' Gazette.*

Miscellaneous.

EFFECT OF SCAMPED THATCHING.—A story of this kind appears in the *Chelmsford Chronicle*, which reports an action by a thatcher against a farmer, before the Maldon County Court. The action was brought by a thatcher named Appleton to recover the sum of £7 6*s.* 6*d.*, balance of wages for work done for Mr. J. F. Hutley, farmer, of Little Braxted, during last harvest.

Plaintiff said: I thatched "273 square" for the defendant, and the price agreed upon was £15 18*s.* The Wheat came from three farms, and there were about 25 stacks; it took

Much of this is owing, doubtless, to natural causes, but more, perhaps, to the manner this noble animal is tied up to the manger in a narrow sloping stall in a dark and badly ventilated stable during the long nights of December—treatment diametrically at variance with his natural requirements. The day, it is to be hoped, is not far distant when a roomy loose-box will be considered as absolutely necessary for the hard-working farm-horse as for any of his race. The normal habits of the horse require to be thoroughly understood in order to provide for his artificial position as to housing, food, and grooming at this season.

Milch Cows timed to calve about this time require careful attendance, both as to dietary and household management. A milch cow stands tenfold more in need of a loose box than a fattening bullock, and were milch cows thus housed and fed on wholesome food fewer mishaps would be experienced at calving time than are now complained of when tied up each to a stake in a narrow sloping stall. Cow-boxes should be cleaned out daily, the same as horse-boxes, and kept every bit as clean. They should also be roomy, well lighted and ventilated, and kept as nearly at a temperature of 60° as can be. The cold raw atmosphere of a damp house is as bad and unhealthy for a milch cow as it is for her owner, so that artificial heat is just as needful for the one as for the other; and few things will pay better, all things considered, than a small stove in the cow-house, whether the herd is kept for nursing or the pail, for it is now an established fact that a milch cow thus kept gives richer milk, and rich milk is just as good for the calf as for the butter and cheese manufactory, assuming the cows are properly fed. The influence of diet on milk must never be lost sight of, for although the best food will not compensate for cold, improper ventilation, &c., yet, however comfortable the cow be kept in a roomy box, bad food will make bad milk, and bad milk unhealthy calves, bad cream, and worse butter and cheese. If it is found impossible to keep farmhouses and labourers' cottages at a proper temperature, and free from damp and a polluted atmosphere, without artificial heat, how can it be otherwise with cow-houses and dairies in moist northern climates, where success depends so much upon a pure atmosphere of a proper temperature; and just now, when the health of live stock is the leading topic of the day, it becomes farmers to consider how the best treatment of milch cows with bad milk to calves is not laying the foundation of the predisposing cause of disease.

Notices to Correspondents.

BREEDS OF CATTLE, SHEEP, AND PIGS FOR EXPORTATION. *A Farmer* should consult Mr. Strafford, of 13, Euston Square, or Mr. Thornton, of 15, Langham Place. As to the characteristics of Booth and Bates cattle, we may in a week or two be able to give a fuller answer to your question.

Markets.

SEED MARKET.

The close of the year being so near at hand, our markets are now very quiet. All descriptions of seeds are, however, held with considerable firmness, and a brisk business is anticipated at the opening of the new year. English red Clover commands extreme currencies. Cable advices just to hand from New York describe the trade there as very firm. Alsike and white Clover are steady. Foreign Italian continues low quotations in prices. Feeding Linseed meets with fair inquiry. Other articles offer no subject for remark. JOHN SHAW & SONS, Seed Merchants, 37, Mark Lane, London, E.C.

MARK LANE.

MONDAY, Dec. 18.

There was a moderate supply of English Wheat to this morning's market, and the trade was dull, at the prices of this day se'nnight. The attendance was poor, and there was but little inquiry for foreign; prices remain as last week. Barley was unchanged in value; Beans and Peas were 1*s.* per qr. cheaper. The Oat trade was dull, at a decline of 6*d.* per qr. Maize was rather easier. There was no change in the value of Flour.

WEDNESDAY, Dec. 20.

An increased amount of depression was observable in the grain trade here to-day. There was a small show of English Wheat on offer, but from abroad a large quantity came to hand. Trade was inactive, and to effect sales lower rates had to be accepted. Barley sold slowly at drooping prices. Malt was dull, and occasionally easier. Oats, the supply of which was good, experienced a quiet sale, at barely Monday's currencies. Beans and Peas were difficult to sell, although a slight reduction was in some instances offered. Flour changed hands cautiously at about late rates.

LIVERPOOL, Dec. 19.—There was a fuller attendance, and Wheat was in improved demand, but the quotations of Friday last are unaltered. Flour slow, and 6*d.* per barrel and 1*s.* per sack lower on the week. Beans quiet, at a reduction of 3*d.* to 6*d.*; and Peas 6*d.* per qr. cheaper than on Tuesday last. Oats and Oatmeal quite neglected.

METROPOLITAN CATTLE MARKET.

MONDAY, Dec. 18.

The number of Beasts is small, but the butchers have bought largely in the past week, and consequently trade is slow to-day: prices are lower, and a clearance is with difficulty effected. The supply of Sheep is also small—about the same as the corresponding day last year; there are several of a prime character, but the trade is bad for them. Choice saleable half-breds are in request, at not much lower rates. Choice Calves are scarce and dear. Our foreign supply consists of 600 Beasts, 3900 Sheep, and 116 Calves from Scotland there are 450 Beasts; from Ireland, 500; from Norfolk and Suffolk, 370; and 1060 from the Midland and Home Counties.

Beasts, 2660; Sheep and Lambs, 12,640; Calves, 123; Pigs, 50.

THURSDAY, Dec. 21.

This is very nearly a holiday market, both as regards supply and demand; a few of the choicest beasts have been sold at Monday's rates, but the butchers having for the most part supplied their wants for Christmas, are buying very sparingly to-day, and only what is wanted for. The few Calves on offer make a good price. Our foreign supply consists of 95 Beasts, 990 Sheep, and 45 Calves.

JOSHUA BAKER.

ENGLISH WOOL.

For English wool there has been a good demand during the last week, and an almost general advance has been realised. Buyers begin to see that there is no chance of manufactured goods going cheaper, and consequently place their orders more freely.

HOPS.

BOROUGH MARKET, Dec. 21.

Messrs. Pattenden & Smith report but little business doing, as is usually the case at this time of year; still in all cases where sales are effected, prices are well sustained. Continental markets continue to rule very firm, owing to the limited supplies.

The Forwardest Pea known.

SUTTONS' RINGLEADER. Price 4s. 6d. per quart. May be sown in October.
SUTTON and SONS, Reading, Berks.

The Best Wrinkled Pea is

BEST OF ALL (DICKSON'S). Price 5s. per quart. Trade price on application
SUTTON and SONS, Reading, Berks.

To the Seed Trade.

FOR SALE, in large quantities, the following PEAS: NE PLUS ULTRA, CHAMPION OF ENGLAND, HAIRS' DWARF MARROWFAT.
All new seed and true stock. For price apply to
B. R. CANT, St. John's Street Nursery, Colchester.

MCLEAN'S ADVANCER, LAXTON'S PROLIFIC LONGPOD (improved stock), SUPREME, and ALPHA PEAS. Prices on application to
——— Seedsman, Stamford.

For Cash.

SCARLET RUNNERS, 1s.6d. per bushel; ADVANCER PEAS (hand-picked), 10s. per bushel. EARLY FRAME POTATOS (true); MYATT'S ASHLEAF POTATOS.—For further information apply to
JAMES TAPLIN, Seed Merchant, Uxbridge.

To the Trade.

SOOLY OUTDOOR CUCUMBER.
SUTTON and SONS have a limited quantity of SEED of the above to offer to the Trade. Price on application.
Royal Seed Berks Nurseries, Reading.

To the Trade.

CUCUMBER SEEDS.—Pearson's Long Gun, and Rollisson's Telegraph (true). Price, per 0z. or 100 seeds, on application to
E. COOLING, Mile Ash Nurseries, Derby.

BIRDS KING of the CUCUMBERS, 1s. 6d. per packet. The best for exhibition.
BIRD'S QUEEN of the MARKETS, 1s. per packet. The best green-fleshed variety. May be had of all the Seed Trade, and of
JAMES BIRD, Nurseryman and Seedsman, Dunnsham.

CONOVER'S COLOSSAL ASPARAGUS.—Strong 3-yr. old plants, 21s. per 100. Orders booked now for delivery in spring.
JAMES DICKSON and SONS, "NEWTON" Nurseries, and 102, Eastgate Street, Chester.

FORCING ASPARAGUS and SEAKALE. Extra strong, for immediate forcing.
JAMES DICKSON and SONS, "NEWTON" Nurseries, and 102, Eastgate Street, Chester.

RICHARD WALKER can supply the following, for cash:—Best SEAKALE for forcing, 10s. per 100; second size, 5s. per 100. ASPARAGUS for forcing, 1s. per 100. WHITE SPANISH ONION SEED, all new and genuine, 1s. 6d. per lb.
The Market Gardens, Barnham, Bognor.

Extra fine Forcing and Planting Seakale.

GEORGE CLARKE has many thousands, very fine 2 clean stuff, this season, which he begs to offer as under:—Planting size, 5s. per 100; forcing, 7s. per 100, and some superfine selected Crowns, 15s. per 100.
Nurseries: Tenison Road, London, S.W.; and Mottingham, Kent, S.E.

Turnip and Mangel Wurzel Seeds—1871 Crop.

JOHN SHARPE will on application furnish his LIST, with prices, of the Turnip Seeds he is growing this year.
Bardney Manor, Lincoln.—July 6.

Seed Potatos.

CHARLES SHARPE and CO., SEED GROWERS and SEED MERCHANTS, Sleaford, Lincolnshire, beg to intimate that their WHOLESALE CATALOGUE of SEED POTATOS is now ready, and will be forwarded, post free, upon application.

Seed Potatos.

H. AND F. SHARPE'S Wholesale LIST of SEED POTATOS is now ready, and may be had, post free, on application. It comprises all the best early and late varieties, also all the American sorts worthy of cultivation. The quality is excellent, and the prices very moderate.
Seed Growing Establishment, Wisbech.

The Gardeners' Chronicle
SATURDAY, DECEMBER 30, 1871.

"NINE hours' movement for gardeners"—"Observance of Saturday to Monday"—of "Boxing Day"—of the "Bank Holidays." How many of the people who make an outcry for these and similar concessions, some times reasonably at other times unreasonably, take into consideration the numbers of people, the due performance of whose avocations is quite inconsistent with such amenities as those above alluded to.

To be sure we do hear of the "frozen-out gardeners," and we have too often seen the labourers in a nursery chopping wood, or doing nothing, owing to a lock-out on the part of King Frost, but speaking generally, winter brings the gardener comparatively little cessation from toil, and if he have much glass to look after, or much forcing to manage, to say the least, his anxious forethought is not less at this season than at any other, and his enjoyment of short time and statute holidays pretty much a matter of observance in the breach rather than in the custom.

A retrospect of the work of the year has forcibly brought this subject to our notice, and the recollection of what happened last year in France calls attention to another cause which may—GOD forbid that it ever should—put a forcible stop here, as it did across the Channel, to all the pursuits of peace. It is as well now and then to remember, that in case of disaster, the evil time will make itself felt first in the garden. As we have seen in France, not alone those branches of horticulture which minister to the luxuries of mankind, but even those which supply his absolute needs, alike suffered. This remembrance may serve as a useful lesson now and then, and, at any rate, it may make one and all rejoice that this year we have not to point with a shudder to a fearful struggle, such as was then raging.

If we except the International Exhibition and its association with horticulture, there is little worthy of special comment in the progress of the craft during the year that is just closing. The period has been one of quiet progress. The exhibitions, already too numerous, have been increased in number; their general quality has been good, and some few objects of sterling merit, to which we shall hereafter allude, have made their appearance.

The horticultural department of the International Exhibition was not so successful as it might have been, owing, in the first instance, to the war, and next, to the difficulty of securing so frequently as every fortnight an adequate representation of Continental products. Next year we believe, while it will be open to foreign horticulturists to compete at any or all of the fortnightly exhibitions, a special effort will be made to secure a more important international contest at the great June show. We trust also that some effort will be made to illustrate more fully the practical bearing of gardening on the daily concerns of life, not as a mere luxury, but in relation to its food-producing importance, and its association with manufacturing interests, such as those devoted to cotton and paper. It would also add greatly to the educational value of the exhibition, if such of the gardening processes as are capable of being shown, were illustrated—such as the various modes of grafting, training, pruning, and so forth.

Among matters of public importance during the year that is passing away, the abolition of the sample post nuisance may be mentioned. It ought not to be forgotten, that the horticulturists and members of the seed trade took an active part in bringing about this reform, and no more perfect illustration of the absurdity of attempting to lay down a definition of what was and what was not a sample, was offered than that put forth by the seedsmen.

In our own columns we have endeavoured, as heretofore, to keep our readers well abreast of the times in all matters relating to gardening, whether in its practical, scientific, or social aspect. We have reason to believe, merit has not been lost sight of, and have not flinched from pointing out defects. At the same time, while not concealing our own opinions, we have tried to avoid dogmatism, and to allow all sides of a question to be fairly discussed.

We have largely increased the number of our illustrations during the past year, and have done our best, as chroniclers, to record matters of interest to horticulturists, not only in our own country, but also abroad. Our correspondents have kept us well furnished with garden gossip, or notes of travel, and botanical memoranda from the Continent, from our colonies, from India, and even from the recesses of Utah, and the still more unexplored districts of Morocco.

It has been our duty also—always a painful one—to record the loss from among our ranks of many votaries of gardening and kindred pursuits, among others, LEMAIRE, the scholar and the botanist, unrivalled in his knowledge of Cactæ of HARTWEG, a name known in all gardens; of WILSON, our foremost authority in Mosses; of DIX, the genial Chairman of the Floral Committee; of BELLENDEN KER, once so active in the horticultural world; of the veteran BAXTER; and, only the other day, of SEEMANN, to whose life and labours we devote an article in another column. What we have done in the past will be the best promise we can make for the future.

—— We extract the following additional remarks relating to our LONDON PARKS from M. TAINE'S "Notes on England," published in the *Daily News*:—

"The things which please me most are the trees. Every day, after leaving the Athenæum, I go and sit for an hour in St. James's Park; the lake shines softly beneath its misty covering, while the dense foliage bends over the still waters. The rounded trees, the great green domes, make a kind of architecture far more delicate than the others. They expose itself upon their flattened forms, upon these subdued tones. These are beauties, but tender and touching, those of foggy countries, of Holland. Yesterday, at 8 o'clock in the evening, although the weather was fine, everything was veiled. Suspension Bridge appeared vapoury; the last rays disappeared in whitish smoke; on the right, the remains of redness; over the Thames, and in the rest of the sky a pale slaty tint. These are tones like those of the landscapes of REMBRANDT, in the twilights of VAN DER NEER; the bathed light, the air charged with vapour, the insensible and continuous changes of the vast exhalations which float, imparts a blush like that which dims the contours, the whole producing the impression of a great life, vague, diffused, and melancholy—the life of a humid country.

"At Richmond, I felt this still better. From the terrace can be discerned several leagues of country; the Thames, which [here] is not larger than the Seine, winds through meadows, between clumps of large trees. All is green, of a soft green, almost effaced by the distance; one feels the freshness and the peace of the infinite vegetation; the grey sky extends over it a low and heavy dome; at the horizon are whitish mists in floating layers, here and there a darkened cloud, or the violet patch of a shower. From all the grounds a sluggish mist; one perceives it as if it were a piece of muslin drawn between the interstices of the trees, and gradually the floating gauze of the earth reunites with the uniform veil of the sky. How still is the park! And the deer feed in the moist bushes. They approach the fence, and gaze on the passer by without fear. Can a tract of country be better arranged for relaxing the nerves of the man who struggles and toils? The Oaks, the Lime trees, the spreading and huge Chestnut trees, are noble creatures which seem to speak in low tones with majesty and security; at their feet is thick and tall grass; the blades of grass, whereon the rain has left its tears, smile with a tender and sad grace. A sort of fond quietude emanates from the air, the sky, and all things; Nature welcomes the soul, weary and worn with striving. How one feels that their landscape suits them, and why they love it! Without doubt their climate befits trees, and, besides, they have had no invasion or popular rising to mutilate or cut them down; the national taste has favoured their preservation; olden things have been more respected and better preserved than in France, and among them must be numbered the trees.

"Those of Windsor and of Hampton Court are as beautiful. From Kew Gardens to Hampton Court [in Bushey Park] extends an alley of gigantic Horse Chestnut trees, of which the large pink and white bunches resemble girandoles. The foliage is so thick that underneath it is cool in the height of the sun. Upon the velvet of the grass [in Kew Gardens] established with rustic seats, bordered by Nasturtiums, stand forth clusters of Rhododendrons, as tall as two men, entirely covered with rose-coloured flowers, amid which bees are humming. There are so many of them, they are so magnificent, of so tender a tissue and of so fine a tone, they are grouped with such profusion in a single clump wholly impregnated with light, that one remains dazzled; it is delicious, intoxicating; almost beyond Nature. A little way further, in an enormous hothouse, Palms, as large as Oaks, spread their curious vegetation, and Bananas unfold leaves which would cover a child 12 years old. This is one of their talents; they admirably understand the architecture of trees, of grass, and of flowers; I have not seen even a classical palace or even a poor cottage where it was un comprehended. Sometimes, indeed, the effects is too strong; in the sun, it is sometimes dazzling. The inconsiderate thus assumes tones so rich and intense that they cannot be transferred to canvas; they would offend, they would be too raw; it is necessary to enjoy them with the mind, not with the eyes; they are a feast, and, as it were, an outburst of delight; in order to prepare and maintain them, swell and expand the tissues, moisture was required, excessive moisture, the caress and the guardianship of soft vapour; beneath a warmer sky such flowers would be stiffened and dried; they are not accustomed to bear the full sun; hence it is that they break forth to-day under his blaze. They have the tint of a beautiful lady; they, too, are patrician-like, embodied, dressed, embellished by all the refinements of art and of luxury; I have had the same impression at a full-dress morning party, before a staircase filled from top to bottom with young laughing ladies in swelling and sweeping dresses of tulle, of silk, the head covered with diamonds, the shoulders bare. This was a unique sensation, that of splendour and brilliancy carried to the highest pitch—all the flowers of civilisation and of Nature in a single bouquet and a single perfume.

"Hampton Court is a large garden in the French style, laid out in the time of William III. Our style was then the reigning one in Europe. Yet English taste is discoverable here also; the borders have been planted with standard Rose bushes, and these, closely trained along the slight espaliers, form columns of flowers. Ducks, swans swim in all the pieces of water; Water Lilies unfold their velvet stars. The old trees are propped up by iron rods. When they die, in order that they may not be wholly lost, the remainders of their trunks are converted into a kind of huge urn. Clearly, they are cared for, and they are loved. There are no notices. I noticed young charity-school girls walking and playing on the grass, but they never pluck a flower. The following notice suffices to protect the garden:—'It is hoped that the public will abstain from destroying that which is cultivated for the public gratification.' I have seen families of common people taking their dinners on the green sward of Hyde Park; they neither tore up nor spoilt anything. This is perfect; they feel every moment that each one should be always his own constable, and end by not having any other."

Mr. W. F. CHAPMAN, of Gloucester, has recently invented an ingenious contrivance for PROTECTING PLANTS AND FLOWERS from the inroads of snail, slug, earwig, frost, wind, and rain. These boxes are said to be so arranged that they answer the purpose of hand-glasses, one of their chief recommendations being that they are much cheaper, not so liable to breakage, and can be repaired by any gardener. The boxes are ventilated to prevent damping off; and they are so compact, they can be stowed away in a very small space when not in use. They are provided with excellently contrived slides, which enables them to be used to great advantage in preserving blooms on tall stems, such as Hollyhocks, &c., whilst growing, and intended for exhibition purposes. A contrivance of indiarubber is also provided, which makes the boxes impervious to insects, and does not injure the stem.

—— The ASTROCARYUM AYRI, a fine pinnate-leaved Palm, growing some 20 to 30 feet high, and remarkable for its numerous long black spines, has proved to be relatively hardy in the Palm-house of the *Fleuriste*, in Paris, it being the only one of numerous spiny species which bore the low temperature to which, in consequence of the want of fuel, it was exposed during the winter of 1870-71. This Palm has also fructified in the greenhouses of the same establishment.

—— Among the more remarkable features of YUCATAN may be mentioned the CENOTES, or WATER CAVERNS. These are in some places entirely subterranean, and are then without vegetation; in others more or less uncovered, in which case they become what may be styled subterranean oases, often of surpassing and singular beauty on account of the gorgeous development of vegetable life. Spots of this character abound especially through the southern and eastern portions of the peninsula, and to them the few Ferns

belonging to Yucatan are almost exclusively confined. Among the more remarkable Phanerogams which are almost peculiar to the Cenotes may be mentioned a species of Vanilla, the pod of which is brought to the market of Valladolid, where it may be bought for an almost nominal price.

— The Maximum Temperatures of the Air during the week ending December 23 ranged from 56° at Perth to 43° at Paisley, with a mean for the several English stations of 50°.9, and for the Scottish of 52°.8. The Minimum Temperatures of the Air ranged from 35°.3 at Blackheath to 16° at Perth. The mean for the several places in England being 30°.2, and for those in Scotland 25°. The highest Mean Temperature, 42°.7, was recorded at Liverpool, and the lowest, 33°.7, at Paisley. The mean value for the English stations was 40°.7, and for the Scottish 39°. As a mule, the weather has been warm over the country, but at several places in Scotland low night temperatures have been experienced. On the 20th a heavy S.W. gale swept over the country, doing much damage at places. At Blackheath, pressures exceeding 30 lb. on the square foot were recorded. Rain fell at each of the several stations, and at Greenock as much as 3.15 inches was registered. The mean fall for the English stations was 0.60 inch, but for the Scottish, 1.19 inch. (See Mr. Glaisher's Tables, p. 168.)

— We call the following from a monthly magazine published in Cape Town; it is interesting as affording a comparison of the Floral Seasons in widely Different Latitudes:—

"During September gardens begin to appear gay with flowers—Anemones, Ranunculuses, Stocks, Pansies, Azaleas, Petunias, and an innumerable host of annuals, are in flower during the month. Hyacinths, Crocuses, &c., are just going out. The greenhouses at the Botanical Garden are gay with Azaleas, Camellias, Cyclamens, Cinerarias, Begonias, Correas, Chinese Primroses: of these a very fine display, &c. A very curious and beautiful epiphytal Orchid, Angræcum sesquipedale, may be seen in one of the houses; it has been in flower for four or five weeks, and is now rather past its best."

— We are happy to hear that Mr. Leighton is bringing out a Conspectus of all the Lichens hitherto discovered throughout the world, with diagnoses. His work on the Lichen Flora of Great Britain, Ireland, and the Channel Islands, will be a guarantee to all Lichenologists that the work will be worthy of the subject. Of this he is preparing a second edition, which will comprise an introduction, glossary, and index, which it is hoped will be ready for the press early in 1872. The glossary will be printed separately, so as to enable possessors of the first edition to purchase separately.

New Garden Plants.

Epidendrum turialvæ, *n. sp.*

(Amphiglottium.) Caule erecto, polyphyllo: foliis papyraceis linearibus acutis basi cuneatis usque spathaneis vaginis pedunculi superioris arctis acutis, inflorescentia erecta, bracteis subpanicularia; bracteis squameeformibus minutis; sepalis a basi linear-oblongis acutis; tepalis linearibus acutis apice dilatatis; labelli lacinia postica abbreviata ovato-oblonga, obtusiusculis, isthmo lato, lacinia antica bicruri, cruribus omnino divaricatis linearibus extus retusis; carinis geminis a basi in apicem; calo utrinque in basi obtusangulo.—*Epidendrum*. n. sp. ? Rchb. fil., Beitr. Cent. Am. p. 85.

When I wrote the above-cited pamphlet, I did not dare to propose this as a new species, since the flowers and the interior part of the plant were not consistent. And yet they had been given me by that most learned observer, Dr. Hermann Wendland. I am not at all surprised to find that he was completely justified for having put the fragments together, since the plant has now reappeared in the Saundersian collection (N. 2124). Mr. W. Saunders also introduced it from Costa Rica. *H. G. Rchb. fil.*

Maxillaria Reichenheimiana, *Endr., Rchb. f.*

Affinis Maxillariæ crocææ. Pseudobulbis elliptici ancipitibus: foliis cuneato-oblongis obtuse acutis more Phalænopidis Schilleriance pallide puncticulatis; pedunculis plurimis, nonnis extinctoriformi: sepalis a basi triangula acuminatis; tepalis subæqualibus ima basi et ante basin inferne obtusangulis; labello cuneato dilatato apice trilobo, lobis lateralibus anticis lobulatis, lobo medio ligulato anticè valde carooso inferee carinato; calo lineari apice acuto a basi ascendente, lacinias carinis papillis quibusdam filiformibus brevibus circumspersis; columna brevi circa androclinium fimbriata, limbo stigmatico angulato porrecto.

Imagine a small Maxillaria with minute bulbs not larger than a threepenny piece, leaves just as long as one's middle finger, painted in the way of those of Phalænopsis Schilleriana, with pallid colour on dark green and then yellowish flowers, not much over an inch and a-half in length, on stalks 3 to 4 inches long. The lip is very remarkable, having a very thick, nearly triangular, anterior lobe, and bears some violet and purplish spots.

It was discovered by M. Endres, in 1867, at an altitude of 5500 feet, in Costa Rica, and was gathered later by Mr. Zahn, when one of the Centro-American collectors of Messrs. Veitch. M. Endres proposed its being named in honour of M. Moritz Reichenheim, of Berlin, now the possessor of one of the very best collections of showy Orchids in Germany.

Poor lovely plant! If it were an Anecochilus, a Hemaria, a Vandia, a Reinanthera, every Orchidophilist would be in ecstacies on account of its singular beauty. But since it happens to be a Maxillaria, what avails it that it possesses so much beauty and excellence? Is it not just the same with plants as with men? *H. G. Rchb. fil.*

Oncidium globuliferum, *H. B. K.*

Rhizomate scandente filiformi; pseudobulbis longe distantibus, laterisphæricis semi-oblongis; foliis ligulatis acutis; inflorescentiæ longiarticulatæ ramulis abbreviatis unifloris grandiflorisque; sepalis cuneato-oblongis acutis, lateralibus divaricatis; tepalis sublatioribus obtuse acutis supra basin hastatis; labello basi sagittato dein in isthmum angustum cuneatum, antice latissime reniforme bilobo; callo baso triangulo utrinque tricristato, dente adventitio solitario majusculo extroso utrinque in basi, parvulo utrinque autico; columnæ alis dolabriformibus crenulatis; tabula bistigmatico utrinque basi cristato.—*Oncidium ornatum*, Rchb. f., Linnæa, xxii. 844! Lindl. Folia Oncidium, N. 83. *Oncidium convolutulaceum*, Lindl. in Paxton's Fl. Garden, i., under tab. 21.

β. costaricense: gracilior, floribus minoribus, tepalis minus hastatis.

This has a peculiar manner of growth. The slender creeping filiform rhizome bears at long intervals little bulbs of a glaucous colour, and small oblong leaves. There are long or short axillary peduncles with showy golden-yellow flowers equalling those of Oncidium bicallosum, showing red spots at the bases of sepals and petals and lip. Heretofore we only knew that the plant grew in New Grenada, where it was gathered by Humboldt and Bonpland! Schlim! Funck and Schlim! Warscewicz! and Karsten! It is a new discovery that it occurs also in Costa Rica, where it has been found both by Endres and by the late M. Zahn, who sent it to Messrs. Veitch, with whom it has just flowered. There is, however, a slight difference, but I can only think it a local variety.

For a long time nobody knew what the Oncidium globuliferum of Humboldt was, and decidedly it could not be recognised from Kunth's description. Hence we are not to be blamed that we did not understand it. There is no vestige of it in the Berlin Museum, so rich in Humboldtian types. I was at length so fortunate as to find it in the Jardin des Plantes, at Paris, and I like to re-establish the oldest names since Kunth must be forgiven for his valueless description. It is by a *lapsus calami* that Lindley indicated "flowers red" (see Oncidium, fig. 58). Kunth says—"flores flavi, rubro maculati. *H. G. Rchb. fil.*

The late Dr. Seemann.

We mentioned in our issue of the 16th inst. the untimely decease of this distinguished naturalist, and we now redeem the promise then made of laying before our readers a biographical notice, and a portrait of our lamented friend. For the portrait we have availed ourselves of the photograph published by E. Edwards, B.A., in the series published some two or three years since under the title of "Photographic Portraits of Men of Eminence." We have also availed ourselves very largely of the accompanying biographical memoir, the facts for which were, we believe, furnished by Dr. Seemann himself. From this account we learn that Dr. Seemann was born at Hanover on the 20th of June 28, 1825; he received his education at the Lyceum of his native town, the head master at that time being the celebrated Grotefend, one of the earliest decipherers of cuneate writing; and that he graduated as Master of Arts and Doctor of Philosophy at the University of Göttingen.

The most ardent wish of Dr. Seemann, from his youth, was to see foreign countries, and he early commenced preparing himself, devoting much of his time to the study of the natural sciences, especially botany and anthropology. To this end he came to Kew in 1846 to perfect himself for a botanical museum collector, and there attracted the notice of the then curator, Mr. Smith, and of the late Sir W. Hooker, the Director of the Royal Gardens, who quickly recognised the talents of the young botanist, and in 1846 recommended him to the Admiralty as naturalist to H.M.S. Herald, at that time employed on a surveying expedition in the Pacific, the appointment having become vacant by the untimely death of Mr. Thomas Edmonston. Leaving England in August, 1846, he went to the Pacific, by way of Madeira and the West Indies, touching at several islands, and disembarking at Chagres, to cross the Isthmus of Panama, at that time not a journey of hours, but of days. When, in September, he reached the city of Panama, the surveying expedition, consisting of H.M. ships Herald and Pandora, had not yet returned from Vancouver's Island. Dr. Seemann profited by the delay to explore the greater part of the Isthmus of Panama, and collect the materials (augmented during subsequent visits), which enabled him to produce the most complete general description of that country ever published. His observations extended to almost every branch of science, and he returned not only a large number of new plants and animals, but also some curious hieroglyphics in Veraguas, on which he afterwards read a paper before the Archæological Institute of Great Britain.

When, in the beginning of 1847, H.M.S. Herald returned from the North, Dr. Seemann joined her, and remained with her until the completion of her voyage round the world, during which three cruises to the Arctic regions, *vid* Behring's Strait, were made. Dr. Seemann at this time had the opportunity of exploring nearly the whole west coast of America, frequently making long journeys inland. His explorations in Peru and Ecuador, when he was accompanied by Mr. (now Captain) Bedford Pim, R.N., led him from Payta through the Peruvian deserts, and across the Cordillers of the Andes to Loja, Cuenca, and Guayaquil, and familiarised him with the magnificent scenery, vegetation, and population of a large section of the former empire of the Incas. Subsequently, he traversed several of the western States of Mexico.

At that time the valuable Alpache Indians were very troublesome, and Dr. Seemann narrowly escaped with his life. In 1848, the fate of Sir John Franklin began to excite apprehension in England, and H.M.S. Herald, accompanied by the Plover, was directed to proceed to the Arctic regions, by way of Behring's Strait, to search for the missing voyagers. This gave an entirely new character to the surveying expedition under Captain Kellet, which, up to this time, had been used simply for making hydrographical studies of the west coast of America. Three times did the Herald proceed to the Arctic regions, the second year joined by the Enterprise and Investigator, making valuable discoveries at each visit; a new island was discovered between Asia and America, and the vessel attained a higher latitude than any other had previously accomplished on that side of America. Dr. Seemann availed himself of these opportunities to collect materials for a very complete Flora of the extreme north-west of Arctic America, and for the anthropology of the Eskimos. In her various voyages, the Herald visited repeatedly Kamchatka and the Sandwich or Hawaiian Islands; and in 1850 she began the homeward course, subsequently terminating for some time at Hong Kong, Singapore, Cape of Good Hope, St. Helena, and Ascension, and reaching England in June, 1851. Dr. Seemann was requested by the Admiralty to publish the result of this remarkable voyage, and he accordingly produced the "Narrative of the Voyage of H.M.S. Herald during a circumnavigation of the globe, and "Three Cruises to the Arctic Regions, in Search of Sir John Franklin," in two volumes, octavo, published by Messrs. Reeve & Co.—translated into German, partly by the late Edward Vogel, the celebrated African traveller; it passed rapidly through two editions on the Continent. The botany of the voyage, written by Dr. Seemann himself, appeared in a quarto form, with a hundred plates by Fitch, and comprises an account of the floras of Western Eskimo-land, north-western Mexico, the Isthmus of Panama, and the island of Hong Kong. During the time Dr. Seemann's scientific labours attracted the attention of the Imperial German Academy of Naturalists, and soon after he was made a member of the Academy, under the name of "Bonpland,"—the ancient usage of scientific men changing names, on becoming members before the public being still upheld. A few years later, after rendering some important services to the Academy, he was elected Adjunct or Vice-President for life.

In 1859 the Viti or Fiji Islands in the South Pacific Ocean were formally ceded by their king and chiefs to Great Britain; before the formally proffered cession, Colonel Smythe, R.A., and Dr. Seemann—the latter at the instance of Sir W. Hooker—were commissioned by our Government to draw up official reports on the state and condition of these islands. Leaving England in February, 1860, Dr. Seemann went, by way of Egypt and Mauritius, to Sydney, touching at King George's Sound and Melbourne, and thence proceeding, in the John Wesley missionary vessel, to Viti, where he arrived some months before Colonel Smythe, and at once commenced exploring this little-known group of islands, collecting information on all points of interest, and accumulating large collections of plants and other objects of natural history. During his stay of eight months he became familiar with the whole of the islanders, and addressed a series of letters to the *Athenæum* and to the *Gardeners' Chronicle* regarding them. They gave a vivid picture of Dr. Seemann's dealings and intercourse with the natives; his efforts, combined with those of Mr. W. T. Pritchard, in saving the lives of 500 people, who had been doomed to death, to commemorate the coming of age of the son of the Chief Kuruduadua; his ascent of Vo'mo and Buku Levu, two peaks never before climbed by any white man; of the scenery and vegetation, and also the customs and manners of the cannibal tribes amongst whom he found himself.

The letters in our own columns contain accounts of the vegetation of Malta, Egypt, Mauritius, parts of Australia, and the Fiji Isles. The substance of these letters, together with much fresh matter, and Dr. Seemann's official report on Fiji, was afterwards incorporated by their author in a separate work, published by Macmillan & Co., under the title of "Viti, an Account of a Government Mission to the Vitian or Fijian Islands." After doing full justice to the popular side of this subject, Dr. Seemann commenced a scientific quarto work, in Latin and English, on the vegetable products of Fiji—"Flora Vitiensis." This work is published by Messrs. Reeve & Co., and is now nearly completed—the final revision, index, as well as the elaboration of the Ferns, having been entrusted to Mr. Carruthers.

The "Flora of Viti" comprises not only the results of Dr. Seemann's own labours, but also all materials accumulated by other British expeditions to the South Seas, some of which have now been in the country for nearly a century without having been rendered useful to science. It comprises not only the scientific history of the plants observed, but also pleasantly written details as to their uses, &c. The articles on Cotton, Kava, Sandal-wood, and many others may be referred to in illustration.

In 1864, some French and Dutch capitalists availed themselves of Dr. Seemann's practical experience and intimate knowledge of tropical countries, to report on the resources and capabilities of a portion of the territory of Venezuela. He left Southampton on February 2, and reached Caracas towards the end of the same month; thence proceeded to Porto Cabello, Chichirividei, and Tocuyo, and returned to Europe, *viâ* Curaçoa and St. Thomas. During this expedition he had the good fortune to discover, on the banks of the Tocuyo, extensive coal-beds, the coal being smokeless, closely resembling Welsh steam coal in appearance, and being valued in London at 30*s.* per ton.

Dr. Seemann wrote English, German, and several other languages idiomatically, and with considerable power, and he published his first article when he was 17 years of age. Since then his pen has ever been busy, and his articles, literary, scientific, or political. Fifty-eight scientific papers relating to natural history and botany are catalogued in the Royal Society's Catalogue of Memoirs, the greater number being contributed to Hooker's "Journal of Botany," or the "Annals of Natural History." In 1853 he started the "Bonplandia," which, though published at Hanover, he edited in London, and to which many of the leading botanists of all nations contributed. The "Bonplandia," after the completion of the tenth volume, was metamorphosed into the "Journal of Botany, British and Foreign," Dr. Seemann retaining the editorship, but latterly delegating the chief portion of the task to Dr. Trimen and Mr. Baker. This continues to be the only journal devoted exclusively to botany in this country.

Besides the works incidentally mentioned in the foregoing account, Dr. Seemann has published several other independent ones, the principal being his "Popular History of Palms," and which, translated by Dr. Wolle into German, has already passed through two editions; "Paradisus Vindobonensis," a large folio work on botany, in Latin, English, and German, and illustrated by 84 plates, printed in colours; "The Popular Nomenclature of the America Flora," an attempt to collect all the native names of the American plants, arrange them alphabetically, and give their scientific equivalent, so that any practical man may at once know to what plant any given produce belongs, when the native name is mentioned; "An Enumeration of all the plants cultivated in our gardens," and "Hanoverian Customs and Manners, in their Relation to the Vegetable Kingdom." Amongst Dr. Seemann's literary labours should also be mentioned his translation of Kitlitz's "Twenty-four Views of the Coasts and Islands of the Pacific," and his introduction to Lindley and Moore's "Treasury of Botany," a companion volume to "Maunders' Treasuries," and his "Dottings on the Roadside in Panama," written in conjunction with Captain Bedford Pim.

Dr. Seemann was a frequent contributor to the pages of this journal, and in addition to the letters relating to Fiji, already referred to, contributed quite recently a series of articles on Palms, in which he reviewed all the genera of the order which have representatives in our gardens. In his recent frequent journeys to Nicaragua Dr. Seemann discovered many new and interesting plants, several of which were described for the first time in our columns, and many of which he introduced at various times to our gardens through the mediation of Mr. W. Bull. Among these plants may be mentioned the Cannibal Tomato, formerly eaten with human flesh by the natives of Viti, of which we gave a figure in 1864, copied from the "Botanical Magazine;" the colossal Arad, Godwinia gigas; Maranta Seemanni; the elegant creeper, Antigonon leptopus; the singular Parmentiera cerifera, the Candle Tree; Psychotria cyanococca; Vitis chontalensis; Agave Seemanni; Campsidium chilense (*Gard. Chron.* 1870, 1182, fig. 228); Bomarea chontalensis (*Gard. Chron.* 1871, 1387, fig. 305); and some good Palms, including Guilelma utilis, and Malorteia lacerata. Among his more strictly botanical papers, in addition to the separate works already mentioned, Dr. Seemann paid great attention to the Bignoniaceæ, Crescentiaceæ, Ternstromiaceæ, Hederaceæ, and other orders. His monographs on the last named order has been published separately.

BERTHOLD SEEMANN, Ph.D.

In 1865 Dr. Seemann was elected honorary secretary of the "International Botanical Congress," projected to meet in London, under the presidency of M. Alphonse de Candolle, in conjunction with the great International Horticultural Exhibition. But after devoting himself for a short time to the duties of this office he was reluctantly compelled to tender his resignation, in order to carry out an engagement made with his old fellow-traveller, Captain Bedford Pim, R.N., to explore New Segovia and other parts of Nicaragua, for the Central American Association. This led him a third time to the West Indies, and brought him once more to Panama, and other places and scenes with which his writings have made the public familiar.

Dr. Seemann was a Fellow of many of the botanical and horticultural societies of this country and the Continent, and took much interest in the Anthropological Society. Of late years he became connected as managing director with a gold mining company in Chontales, Nicaragua, and in its service made many voyages to that country. He died at his residence at the Javali mine, on October 10 last, after a short illness.

THE FOXGLOVE.

One of the most beautiful features about some of the French woods, especially in those connected with many of the old Royal residences, is the masses of gorgeous-coloured Foxgloves in all their natural beauty, associated with Bracken and Heather. One spot particularly calls for especial notice in the Versailles wood, through which the Chemin de Fer de l'Ouest passes to Rambouillet and on to Brest. This spot, I venture to say, is unequalled anywhere for such masses of this splendid, uncultivated flower. There may be places in this country where Foxgloves look and thrive as well, and, no doubt, there are hundreds of places where they would grow and flower in perfection were a few hundred plants planted in favourable spots at first, since it would perpetuate itself easily. This was done at one or two private places, to my knowledge, and was brought about by the sight of those above mentioned. I could mention a few places in France where the proprietors introduced them with effect near the flower gardens, in large masses, alongside the avenues that in all French châteaux run away right and left into the uncared-for woods. Foxgloves among masses of green, whether Bracken, or what not, have a grand and majestic look, such as is not easily forgotten when once seen; and I think, in places where we too often see such masses of Nettles, with a very small amount of trouble we might see in their stead the beautiful Foxgloves, as a rule, in perfection.

I purpose planting some hundreds next year about, here and there, among Rhododendrons—newly planted Rhododendrons, for where these thrive in the natural soil I have invariably seen the Foxglove do well. Many hundreds of plants can be raised from a good packet of seed, and, now-a-days, when we have such fine, spotted, improved strains, I think we may look forward to the time when all our woods, and shady, frequented nooks, will be beautified with this fine wild flower. To those who have had no experience with this plant I would further remark—procure a packet of seed and sow it in a pan, in a moist heat, in February. As soon as large enough to handle, prick out an inch apart or so in a frame or under a hand-light where there is a slight heat, and where no frost can enter. A month or so after they will be large enough to plant out into borders, to be lifted again in autumn to plant in permanent places anywhere and everywhere where suitable, to flower the following summer. They must be nearly two years old, and strong, ere they flower profusely. We had spikes of flower last year fully 4 feet long, from two year old plants. These were planted, however, in garden soil among large Rhododendrons, and had a fine effect. They continued to throw up spikes all the summer, and being a moist year, they, moreover, being situated on an east aspect shaded by a high wall, they continued to flower till September.

I can't say they are as brilliant as the Gladiolus, but one thing in their favour is, they can be grown among large evergreens in a dressed and formal way as well as in the shady woods. At the Château de Dampierre, the residence of the young Duc de Luyne—who was killed during the late war, under melancholy circumstances—about 20 miles from Versailles, I remember seeing, some years ago, on its being pointed out to me by M. Cide (the gardener there) an improved spotted form of Foxglove. It was amongst a lot, growing wild; and he kindly gave me a pod or two of seed, from

which I have grown the sort here and elsewhere. It is among Foxgloves, what the new spotted form of Gloxinia that came out at the French Exhibition in 1867, is among Gloxinias, and it varies in colour from pure white to dark pink and purple. The one I speak of as growing in the Versailles wood is a much darker variety, and shows at a distance, but is not spotted as is the sort which I grow. *H. K.*

NEW FRUITS, VEGETABLES, &c.,

CERTIFICATED AT THE ROYAL HORTICULTURAL SOCIETY'S MEETINGS, 1870–71.

First-class Certificates were awarded to the following:–

Apple, Galloway Pippin ..	J. Backhouse & Son, Feb. 15, 1871.	
Broccoli, Matchless	G. Cooling, April 20, 1870.	
Cauliflower, Veitch's Giant Autumn	Veitch & Sons, Nov. 2, 1870.	
Cherry, Bigarreau Noir de Schmidt	T. Rivers & Son, July 19, 1871.	
,, Burghley Park ..	R. Gilbert, July 20, 1870.	
Cucumber, Lamb Hoo ..	R. Gadger, April 20, 1870.	
,, Tender and True ..	J. Douglas, May 3, 1871.	
Fruit-gatherer, Bouckart's Patent	M. Verhulpen, Sept. 21, 1870.	
Grape, Ascot Citronelle ..	J. Standish, July 19, 1871.	
,, Dr. Hogg	J. R. Pearson, Sept. 6, 1871.	
,, Early Ascot Frontignan	J. Standish, May 17, 1871.	
,, Ferdinand de Lesseps	J. R. Pearson, Aug. 17, 1870.	
,, Waltham Cross ..	W. Paul, Dec. 7, 1870.	
Melon, Victory of Bath ..	R. Gilbert, June 29, 1870.	
Parsley, Covent Garden Garnishing	Carter & Co., Aug. 3, 1870.	
Pear, Brockworth Park ..	J. G. Wheeler, Sept. 21, 1870.	
Plum, Duke of Edinburgh ..	Dry & Son, Aug. 17, 1870.	
Radish, Californian Winter	W. Robinson, Dec. 6, 1871.	
Raffeau, or Reed-grass (for tying)	R. Wrench & Sons, July 5, 1871.	
Strawberry, The Amateur ..	S. Bradley, July 18, 1871.	
,, Royalty	J. Trotman, June 29, 1870.	

FOREST CULTURE.

[Extracts from a lecture delivered by Baron Ferd. von Mueller, C.M.G., M.D., Ph.D., F.R.S., Government Botanist for Victoria, and Director of the Botanic Gardens of Melbourne, on June 22, 1871.]

How to provide, in time, the wood necessary for our mines, railways, buildings, fences, as well as for the ordinary domestic and other purposes, becomes a question which from year to year presses with increased urgency upon the nations, the consideration of which we have already far too long deferred. It may certainly be argued that in the eastern portion, and some of the southern parts of the Victorian territory, abundance of forests still exist, enough to supply all wants for many years to come. This is perfectly true in the abstract; but how does this argument apply, when we well know that such timber occurs in secluded places, mostly on high and broken ranges, without roads? And even if the latter were constructed, which certainly will be required gradually, at what price can such timber be conveyed the required distance? Suppose, however, that all these difficulties be overcome, whence are we to obtain the deals of northern Pines, the boards of the red Cedar, and the almost endless kinds of other woods, which future artisans will require? For, assuredly, neither Europe nor North America can sustain the luxury of their indigenous and even planted forests for an indefinite period; and of tropical woods might for a time be brought from the jungles of three continents, but certainly not at a small cost. Besides, tropical trees, as a rule, are not gregarious; we cannot judge before hand in every instance of their utility and other qualities we cannot recognise their extraordinary variety of sorts specifically from mere inspection of the logs, and we should find ourselves soon surrounded by endless difficulties and perplexities were we to depend on such resources alone. Would it not be far wiser timely to create independent resources of our own, for which we have really such great facility? With equal earnestness another aspect of the timber question, as concerning our national economy, forces itself on our reflection. The inhabitable space of the globe is not likely to increase, except through forests which would initiate a new order of vegetation, or all events before the present phase in the world's history to a close; but while the area of land does not increase, mankind, in spite of deadly plagues, of the horrors of warfare, and of unaccountable oppressions and miseries, which more extended education and the highest standard of morals can only reduce or subdue—mankind, in spite of all this, increases numerically so rapidly, that before long more space must be gained for its very existence. Where can we look for the needful space? Is it in the tropic zones, with their humid heat and depressing action on our energies? Or is it in the frigid zone, which sustains but a limited number of forms of organism? Or is it rather in the temperate and particularly our warm temperate zone, that we have to offer the means of subsistence to our fellow-men, closely located as they in future must be? And this formation of dense and at the same time also thriving settlements, how will it be carried out, unless indeed we place not merely our soil at the disposal of our coming brethren, but offer with this soil also the indispensable requisities of a vigorous industrial life, among which requisites the easy and inexpensive access to a sufficiency of wood stands well-nigh foremost.

I may be met with the reply, that the singular rapidity of the growth of Australian trees is such as to bring within the scope of each generation all that is required, as far as wood is concerned; and as a corollary it would follow that each generation should take advantage of the facility thus brought locally within its reach. I can assure this audience that enlightened nations abroad do far more than this, and would not rest satisfied with the greater facilities here enjoyed; they provide, with keen foresight and with appreciation of their duty for their followers, that beforehand which cannot be called forth at any time at will. If we examine this part of the question more closely, we shall find much to think about, much to act upon. Not even all our Eucalypts are of rapid growth; they further belong to a tribe of trees with a hard kind of wood, which, though so valuable for a multitude of purposes, cannot supply all that the needs of life daily demand from us for our industrial work.

The quick-growing Eucalypts, among which the blue-gum tree of this colony and Tasmania stands preeminent, are comparatively few in number, nor are these few all of gigantic size. They are, moreover, restricted in their natural occurrence to limited tracts of country, from which they must be established by the hand of man in other soil for the necessities of other communities, to the gratification of other populations. Then, again, the Pines of foreign lands often impressing a splendour on their landscapes, must be brought to our shores—to our Alps—with an intention of utilising every square mile of ground, however unpromising in its sterility; for, after all, that square mile represents a portion of the vast area of the surface of the globe. See how the Norway Spruce (which gives us so much of our deals and tar) insinuates its massive roots through the fissures of disintegrating rocks, or, failing to penetrate the stony structure, sends its trailing roots over the surface and down the sides of the barest cliffs! Charlemagne—indeed with the commencement of agriculture and the settling of the nomadic hunter on fixed habitations. The forests thus discontinued to be common property, and in the 14th century there had commenced a forest economy. Full legislation, regular management and actual cultivation of trees on an extensive scale, date back 500 years. Venice formed its forest laws in the 15th century. Although the desire for ample hunting territory gave a great impulse to the restrictions placed on the encroachment of the Middle European forests, this at the same time saved them to the country.

Within the limits of ordinary culture may also be included that of subduing drift-sand, and solidifying the latter finally by plantations. For this purpose can be chosen the Aleppo Pine, Cluster Pine, Scotch Fir, or our own less arboreous so-called seashore Tea trees (Melaleuca parvifora and Leptospermum laevigatum); further, Acacia longifolia (the Sallow-leaved Wattle-tree), the coast Honeysuckle (Banksia integrifolia), and also our desert Cypress, or so-called Murray Pine. As not only in close vicinity to our fine city one wilderness of shifting sand exists, but as also in other places of our shores the sand is invading villages, farms, and perhaps harbours, and as, moreover, many a desert spot inland may be reclaimed, I would remark, that to arrest the waves of the sand some wickerwork or cover of brush is needed on the storm side. Large seaweeds help to form such covering. Sods of Mesembryanthemus, to which I have imported the name of "Pigface" is here given, and which abounds on our coast, should copiously be scattered over the sand ridges; wild Cabbage, Celery, Seakale, Samphire, New Zealand Spinach (Tetragonia), Chamomile and various Clovers and Broom plants should be sown, and creeping Sandgrass (Festuca littoralis, Triodium pinoeum), Bent-grass (Agrostis stolonifera), &c., should be planted, particularly also sand Sedges and sand Rushes, among the best of which are Carex arenaria, and here the Sword Rush (Lepidosperma gladiatum). Psoralea pinnata, also the tuberous-rooted maritime (the Canadian sea-coast Plum), and Ailantus glandulosa, prove also valuable in this respect. As eligible, I may add also the native Couch-grass (Cynodon Dactylon), the South African Ehrhartia gigantea, the European Psamma arenaria, Elymus arenarius (or Lyme), even the Live Oak (Quercus virens), also another American Oak (Quercus obtusiloba), and the Turkey Oak (Quercus Cerris), and perhaps Poplars, some Willows, and, among Firs, the Pinus insignis, Pinus edulis, P. rigida, P. australis. The common Brake Fern helps also much to conquer the sand. The New Zealand Flax on the coast stand naturally, within the very exposure of the spray.† It is needless to remark that exclusion of traffic from the sand is imperative, as also security against ingress of goats and domestic animals of any kind, otherwise the effort is hopeless. Fencing of the area and stringent municipal laws will help to however, any operations of this kind, even without great expense, a success, as, in consequence of my advice,

* It should be remembered that most of our forest ranges are naturally devoid of pine-wood, only one species of Callitris occurring in a few limited mountain districts, while our second Callitris is a decided shrub. Without coniferous trees, we shall finally experience difficulty of obtaining the required supply of deals, pitch, turpentine, and pine-resin. Doubtless for many wood structures iron is now substituted, but even a ship or a house cannot be built entirely of iron, and the very production of the iron is dependent on fuel. In the absence of coal, the use of iron, involving here an expenditure for heavy freight, must necessarily be limited.

† Dr. Jam. Hector calculated that in New Zealand an acre of good Flax land contained about 100,000 leaves of the Phormium tenax, and yields about 10 tons weight of dry leaves; or, if only the green leaves, 40 tons. The yield of clean fibre is about 23 per 100 of the green leaf.

to come from? The requirements in this direction must necessarily rise with the increase of the population and the augmented refinements of civilisation, yet the area of supply we see constantly decreasing. The loss on Wheat crops during four of the more recent years in the State of Michigan alone, for want of shelter against cutting winds, is estimated at £5,000,000, and this is regarded as the mere sequence of the removal of the forests, and not traceable to exhaustive culture. Cereal crops and Vines were destroyed in many parts of South Europe also, through the complete want of shelter.

To give some idea how long a time will elapse before actual timber, not merely firewood, is obtained from planted trees, I subjoin a brief list of the more common Middle European forest trees, together with notes of their age when eligible for various timber purposes :—

Beech	60–120 years.
Hornbeam	70–100 ,,
Oak	80–120 ,,
Alder	30–80 ,,
Birch	40–70 ,,
Silver Fir	60–150 ,,
Norway Spruce	60–150 ,,
Scotch Fir	30–60 ,,
Larch	40–80 ,,

That, however, in our winterless zone, such of these trees as will endure a warmer clime would advance with more quickness to maturity, must be readily manifest. The accurate Customs returns for the last year show an importation of foreign woods to the value of £223,769; there was scarcely any export. For one month the imported building wood sent to Sandhurst alone has cost £58,000. Some plum trees have not been altogether unmindful of the conservation of their forests. Germany, already much devastated at the time of the Romans, received its first forest laws as far back as Charlemagne—indeed coincident with the commencement of agriculture and the settling of the nomadic hunter on fixed habitations. The forests thus discontinued to be common property, and in the 14th century there had commenced a forest economy. Full legislation, regular management and actual cultivation of trees on an extensive scale, date back 500 years. Venice formed its forest laws in the 15th century. Although the desire for ample hunting territory gave a great impulse to the restrictions placed on the encroachment of the Middle European forests, this at the same time saved them to the country.

Within the limits of ordinary culture may also be included that of subduing drift-sand, and solidifying the latter finally by plantations. For this purpose can be chosen the Aleppo Pine, Cluster Pine, Scotch Fir, or our own less arboreous so-called seashore Tea trees (Melaleuca parvifora and Leptospermum laevigatum); further, Acacia longifolia (the Sallow-leaved Wattle-tree), the coast Honeysuckle (Banksia integrifolia), and also our desert Cypress, or so-called Murray Pine. As not only in close vicinity to our fine city one wilderness of shifting sand exists, but as also in other places of our shores the sand is invading villages, farms, and perhaps harbours, and as, moreover, many a desert spot inland may be reclaimed, I would remark, that to arrest the waves of the sand some wickerwork or cover of brush is needed on the storm side. Large seaweeds help to form such covering. Sods of Mesembryanthemus, to which I have imported the name of "Pigface" is here given, and which abounds on our coast, should copiously be scattered over the sand ridges; wild Cabbage, Celery, Seakale, Samphire, New Zealand Spinach (Tetragonia), Chamomile and various Clovers and Broom plants should be sown, and creeping Sandgrass (Festuca littoralis, Triodium pinoeum), Bent-grass (Agrostis stolonifera), &c., should be planted, particularly also sand Sedges and sand Rushes, among the best of which are Carex arenaria, and here the Sword Rush (Lepidosperma gladiatum). Psoralea pinnata, also the tuberous-rooted maritime (the Canadian sea-coast Plum), and Ailantus glandulosa, prove also valuable in this respect. As eligible, I may add also the native Couch-grass (Cynodon Dactylon), the South African Ehrhartia gigantea, the European Psamma arenaria, Elymus arenarius (or Lyme), even the Live Oak (Quercus virens), also another American Oak (Quercus obtusiloba), and the Turkey Oak (Quercus Cerris), and perhaps Poplars, some Willows, and, among Firs, the Pinus insignis, Pinus edulis, P. rigida, P. australis. The common Brake Fern helps also much to conquer the sand. The New Zealand Flax on the coast stand naturally, within the very exposure of the spray.† It is needless to remark that exclusion of traffic from the sand is imperative, as also security against ingress of goats and domestic animals of any kind, otherwise the effort is hopeless. Fencing of the area and stringent municipal laws will help to however, any operations of this kind, even without great expense, a success, as, in consequence of my advice,

has been shown at Queenscliff. Wood culture on drift-sand carries with it also the recommendation of providing the needful belt of shelter which each coast should possess. There are a few other Pines—for instance, Pinus Tæda, the Loblolly Pine of North America, and several other trees which grow fast in sand whenever it is no longer moving; they endure the sea storms, gradually consolidate the soil, and render it in course of time arable. In South Africa some Proteas and Leucospermums, the Virgilia, and Myrica, grow in coast sand. All these planting operations must be performed very early, and in the cool season. The grasses and herbs must precede the Pines and other trees. Technical industries will gain from these Pines in due time.

On the whole, of raising or renovating forests not much can be said on this occasion. For natural upgrowth, perfect clearing and fencing is recommendable. Subsequently, the removal of young crooked trees and the surplus of saplings is needed. Seedlings may be transferred from spots where they stand too densely, to more open or bare places. Suckers should be destroyed where the gain of good timber is an object. Periodic clearing of young trees is effected according to the rate of growth of the particular species; lopping of branches is advisable should they densely meet. For broadcast sowing, the ground should be completely turned over and burnt. By breaking the ground a great acceleration of growth of the trees is attained, even to a tenfold degree. Planting in rows affords the best access for subsequent thinning and successive removal of the timber; the quincunx system will give approach in three directions. Pines are planted in Germany only about 7 feet apart, as they require least room of all trees; but 15 feet is a fair distance at an age of 40 years. The New Hampshire Pine stands only 5 to 6 feet apart at an age of 50 years, and yet is not prevented by this crowded growth from being 100 to 120 feet high, with the stems very straight, and 18 inches in diameter at the base. If Pines and Oaks are promiscuously planted, then the former, which act as nurse-trees, are removed in 10 or 20 years, and the ground is left to the Oak, or any other deciduous tree, at distances at first 10 or 12 feet apart, and subsequently wider still. No decayed wood is left in planted forests, as it would harbour boring insects. Pines are considered not to increase much in value after 80 years, when most of them have attained full maturity; afterwards they grow but slowly. Sometimes as many as 1200 Pine trees are set out on an acre, with a view of early utilisation of a portion of the young trees. The rate of growth may be much accelerated in most trees by irrigation, hence mountain streamlets should be diverted into horizontal ditches where forests are encouraged on hill-sides. The best cultivated forests of Germany are worth from three to five times as much as native woods.

For shelter plantations, intended to yield ultimately also timber and fuel to farming populations, it is recommendable to adopt the American system, according to which belts of trees are regularly planted at about quarter-mile distance, the belts, according to circumstances, to be from 4 to 10 rods wide, and to be formed in such direction as to front the prevailing winds. These timber-belts are usually fenced. Such shelter-trees are likely to rise 30 feet in height, and have proved so advantageous as to double the farm crop, while judicious management of these tree-belts will supply the wood necessary for the farm. There are 1,400,000 square miles of treeless plains in the United States, which in due course of time will necessarily be converted to a great extent into agricultural land, on account of the generally excellent soil. The Locust tree is much chosen for shelter purposes. Denuded woodland of poor soil, left undisturbed to natural renovation, has become in some populous localities five times as valuable as the adjoining arable land, or pasture land. For the greatest profit in fuel the trees in some parts of North America are cut about every 16 years. We here, commanding Eucalypts, Acacias, and Casuarinas, would gain wood-harvests still sooner. The increased value of less fertile lands through spontaneous upgrowth of timber is estimated at 25s. per simple interest annually in woodless localities, no labour being expended on this method of wood-culture. Judicious management in thinning-out enhances the value of such forest land still more. Wet and undrained grounds can be made to yield a return in Elms, Willows, Cottonwood, swamp Cypresses and other swamp trees, or stony declivities in Pines and Encalypts, at a trifling cost. For details, the forest literature, which is in Germany particularly rich, should be studied. Capitalists would likely find it safer and more profitable to secure land for timber growth, than to invest in many another speculation. After the example set at Massachusetts, our agricultural societies might award premiums and medals for the best timber plantations raised in their districts. We have societies for the protection of domestic animals, and for introduced birds, young fish, &c.: why could not a strong and widely-spreading league be organised for the saving of the native forests? Might not every child in a school plant a memorial tree, to be entrusted to its care, to awaken thus an interest in objects of this kinds at an early age?

Reverting to the importance of shelter, let me remark that 50 years ago the Peach flourished in North Pennsylvania, in Ohio and New York, where it cannot any longer now be grown, in consequence of the now colder and far more changeable climate, since the forests have been extensively removed. Even ordinary orchards and cereal fields suffer there now. Yet poor land will yield a better return in wood than in corn crops, and it is not too much to say, that the favourable effect of a young forest on climate may be felt already after a dozen years. Even on ordinary sheep runs trees are of the greatest importance, both for shelter and shade.

(To be Continued.)

NYMPHÆA ODORATA.

In Nymphea odorata we have a perfect miniature of the N. alba. Its flowers are white, about the size of a florin, and highly fragrant, and they usually appear about July or August. When cultivated in the open air the leaves average about 2 inches across, but when grown in the stove or greenhouse (as it often is, though perfectly hardy) the flowers will be 2 inches and the leaves 4 inches across, the latter generally of a reddish-purple underneath.

It is of all others the plant for small tanks or basins, requiring only a depth of from 6 inches to 9 inches of water for its perfect development. If planted in a pond, it should be near the margin, and must not be planted more than a foot below the surface. It will also be advisable to introduce a few rough pieces of rock, so placed that the water can flow in and out, to separate it from the rest of the pond; and also to lay a few smooth pebbles over the surface of the soil, to keep it in its place.

The native habitat of this desirable aquatic is in ponds and slow-flowing streams from "Canada to Carolina." It is the most lovely of all the small-growing water plants, save and except that it has a rosy-red variety across the Atlantic, which, when introduced from the Canadian lakes, will become a formidable rival to it. Be it known, therefore, unto "Ye Englysshe" that the Nymphea odorata roses does exist in those lakes, and when we get the two to flower side by side, one rose and the other white, both equally beautiful in form and expansion in size, it will be a sight to see, and would almost justify us if we were to adopt the old name for these flowers, viz., Water Roses, for thus they were termed in this country about the time, now nearly three centuries ago, that Prosper Alpinus wrote his work on "Egyptian Plants," the 136 plates of which, containing the Nelumbium, Papyrus, &c., were cut in "brasse." The N. odorata occasionally ripens seed in the open air in this country, and young plants have been raised therefrom; still it is slow to increase, and is therefore comparatively rare. *W. Buckley, in Florist and Pomologist.*

Home Correspondence.

Holly Stealing.—For more than twenty years I have been a regular subscriber to and constant reader of your paper, and have learned to look upon it as the authority on all gardening matters, but notwithstanding this and the awful threats held out in the carol quoted in the article upon Holly in your last publication, I must cry out, and if I were musical would sing too against Holly, for the following reason. About 20 years ago when I took possession of my present residence, my orchard was divided from the public road, leading only to my residence and the adjoining farm, by an old shabby quickset hedge, which I grubbed up and replaced with young Hollies from a nursery, for which I was ridiculed by my neighbours and pronounced a thorough Cockney for expecting them to grow in our soil and situation; but, to their great surprise, they flourished to perfection, and with fair play would now be an object of perfect beauty: instead of which they are a perfect nuisance to me from the manner in which they are treated by passers-by of all classes and period of the year, notwithstanding the unfavourable weather of the past summer for most trees and shrubs, my hedge was fuller than ever of berries, but the consequence is that it is torn and cut to pieces by people of all classes. As there must be many other persons suffering from the same cause I think you could help us greatly by publishing in your widely circulated journal the risk such depredators run, which I think very few of them are at all aware of; for which purpose I enclose an extract of the Act of Parliament. *A Crier-out against Holly.*

Extract:—"An Act to consolidate and amend the Statute Law of England and Ireland relating to Malicious Injuries to Property. 24 & 25 Vict., cap. 97, August 6, 1861.—Sec. 20. Whosoever shall unlawfully and maliciously cut, break, bark, root up, or otherwise destroy or damage the whole or any part of any tree, sapling, or shrub, or any underwood growing in any park, pleasure-ground, garden, orchard, or avenue, or in any ground adjoining or belonging to any dwelling-house (in case the amount of the injury done shall exceed the sum of *5s.*) shall be guilty of felony, and being convicted thereof, shall be liable, at the discretion of the court, to be kept in penal servitude for the term of three years, or to be imprisoned for any term not exceeding two years, with or without hard labour, and with or without solitary confinement, and, if a male under the age of 16 years, with or without whipping."

[We think our correspondent should rather call police than cry out against Holly, as it is clearly the marauders—may their hands be well scratched!—that are to blame. Perhaps an announcement that any one found in the act would be held guilty of purloining "Ilex Aquifolium medio-picta-aurea-pallida-heterophylla," might create a wholesome terror. Seriously, we fully sympathise with our correspondent, and we cherish the same feelings of wrath against Holly stealers as against those who burden the poor bush with such appellations as the above. EDS.]

Practical Sympathy.—I have recently witnessed the sad destruction of the property of French horticulturists in various parts of France, and have seen with how much care they renursed what remained to them out of the wreck of what only a short time ago was the means of keeping them and their families, if not in a state of affluence, at least in competence sufficient for their modest wants; but now all is changed, and nothing but desolation is seen. No day seems too long for the hapless French horticulturist; at break of day you may see him, his wife, and children, commencing their daily toil—no nine hours' movement affecting in any way the aim and purpose of their lives—they work as much for the love of horticulture as for the profits derived from it. It was very distressing to see a class of people, who, from the nature of their profession, must be considered intelligent and who had no voice in bringing about or in preventing the folly which has desolated their homes, starved their children, reduced their horticultural buildings to heaps of ruins, and turned their own beautiful gardens into wildernesses of tangled weeds and rubbish. Your appeal to our human sympathy will not, I hope, be made in vain, and, for my own part, I have much pleasure in handing you a cheque for three guineas for the fund, and earnestly hope all horticulturists, whether amateur or professional, will aid in cause so full as to great a claim upon their generosity. *John Wills, F.R.H.S., December 25, 1871.*

French Horticulturists' Relief Fund.—I have read with much pleasure your appeal to the nation on behalf of the French horticulturists. Depend on it, there is no Communistic sympathy among them. Their occupation makes them a quiet, peace-loving people, content to live by the labour of their brains and hands, and never dreaming of snatching from others what they or their forefathers have for the most part acquired in the same way. I know by long intercourse with them that their instincts and interests are alike opposed to revolution in every shape. They know full well that their business thrives in time of peace, and fails in war, and they are too practical and thoughtful to indulge in any wild vagaries. Thus it would be hard if they should be made to suffer for the mad escapades and sins of their fellows. Last year's destruction of the stock of many, and the limited sales of all, have been a heavy blow to many an industrious and thriving family, and the early and severe frost of this autumn has further seriously reduced the value of their small properties. In a letter now before me, from one of my regular correspondents in the south of France, he says:—"We have just had a very severe winter at Lyons, the thermometer has shown 14° of frost (Fah.). The Roses are much injured, the wood of the Tea-scented is already cut down to the ground, and the hybrid perpetuals will, I expect, be the same. We have had scarcely any snow, and this helped to cause a great deal of the mischief done. Standard Roses and Grape Vines will also much damaged as they were last year." Let us then push on this movement, for I judge that by so doing we shall not be countenancing revolution, but rather discountenancing it, by holding out the hand of fellowship to those of our fellow labourers who are earnest, rational, and industrious. The desperadoes of the dark alleys and back slums of the large towns, if our efforts should reach their eyes or ears, will know well why Englishmen sympathise with and help those who labour industriously and orderly in the full free light of a cultivated garden. *William Paul, Waltham Cross, N.*

Manure for Conifers.—A few days ago a friend brought me a handful of one-year seedling Larch, the finest I have ever seen in Scotland; the smallest measures 4½ inches, the longest 8¾ inches in length, the strongest branched like two-year seedlings. The sample was pulled "without selection" from a breadth of about 2 acres, all of the same quality, in Messrs. Lawson & Sons nurseries, near Granton; and what makes this crop the more interesting is the fact that while the Larch crop is but very middling in general about Edinburgh, this lot is in all respects first-rate. The man who gave my friend the sample said the reason of their being so very fine was, that there was a large quantity of guano used when sowing. Now as I have grave doubts about using guano for Conifer seedlings, I ventured to hope that some of the readers of the *Gardeners' Chronicle* will give their experience in this matter. In the course of last summer I had a conversation with Mr. Coates, Messrs. Lawson & Son's late foreman, and he was then against the practice of using guano for such purposes, and preferred well rotted manure; but whatever manure he used or whatever system he followed with his Conifer seed, the Larch referred to does him great credit. I am much interested in the cultivation of the Larch and Scotch

Pine, and would like to see this subject handled by those able to do so. *J. M. B.*

Fuchsia Riccartoni.—I observe that attention has been called to this fine autumn shrub by Mr. Tillery. Too much can hardly be said in its praise. It has stood unprotected here for ten years; indeed when the old wood escapes the frost, it flowers early, from June to November. When cut down to the ground, either by frost or by the knife, it pushes strong shoots from below, and makes a bolder shrub, but does not flower so early. In either case the mass of rich crimson bloom it produces, which you have only to turn to see the purple gems within, are gorgeous in autumn. I know of no shrub, unless it is the Hibiscus (Althæa frutex), at all comparable to it at that season. *William Paul, Waltham Cross, N.*

Picea nobilis.—We have a number of healthy plants of different sizes, both of Picea nobilis and Abies Douglasi, raised from seed ripened north of the Grampians. So well does the Douglas Fir succeed, that there is some annual growth on the leaders of upwards of 3 feet in length. The Picea nobilis we have were raised from seeds grown in two different places in the North, both of which vegetated freely, and are growing healthy and strong, but none of them partake of the beautiful glaucous green of the parents. Their vigorous growth and thoroughly healthy state their cones were perfectly ripened. I may here remark that I saw in Ross-shire, about the end of June last, a fine healthy tree of Picea nobilis, somewhere about 50 feet in height, with its top branches well covered with large cones. This interesting specimen was growing in a sheltered situation in the pleasure-grounds and near the mansion house of Coull, the property of Sir Robert McKenzie, Bart., and is close to the south-west base of Ben Wyves, "the windy hill," or "hill of the storm." There was also growing in the same grounds a much larger specimen of Abies Douglasi, but unfortunately it had lost its top some years ago by the wind: it has now got a divided top of several leaders. These facts will serve to show that the climate of the far North is, after all, really not what those who have never frequented these parts, suppose it to be, as may be readily seen by referring to Mr. Glaisher's interesting weather tables, weekly recorded in these pages. It will also be seen observed that for three weeks' readings previous to the date of December 9, the average temperature of both day and night was higher in Scotland. It is also worthy of remark that at Norwich the temperature was 8° lower than any recorded station, thermometer being at 9°, or 23° of frost, while at this place the lowest temperature up to December 21 has only been 25°, or 7° of frost. Although it is not usual to have such a disparity, still as a rule we have less frost and a higher summer temperature along the southern shores of the Moray Firth and in Easter Ross than is to be found in many other places in Scotland and north of England. This is no doubt owing to the influence of the Gulf Stream washing our northern shores, and the narrow breadth of land between the Atlantic and German Oceans. I think Mr. Glaisher would do science some good by having another station somewhere along the Moray Frith. *J. Webster, Gordon Castle.*

Carrot Grubs.—Can any of your readers tell me of a preventive for the Carrot grub? I say preventive, because I am afraid nothing will destroy it but to put some of the larvæ into quicklime and soot, and they seem to exist for days, and ultimately perish from want of sustenance more than from the ill effects of the lime or soot. I have dug these into the ground until it has been black into the latter. Though our ground is not what is considered favorable for Carrots, we seldom fail to have good-sized ones—indeed, I think they have increased in size for the last three years; but our crops are of very little use to us after Christmas. Perhaps some of your entomological readers would give the history of this formidable enemy, and, if possible, drawings of it, with any hints as to the best means of getting rid of it. *W. P. R.* [Which of the several larvæ that attack the Carrot does "W. P. R." refer to? Eds.]

Orange Culture.—I am glad to see that Mr. Rivers is making such satisfactory progress in Orange growing; but, before he equals the culture of half a century ago, he will have to step considerably ahead of the pot system of growth. The following extract from a paper written by my late father, and read before the Horticultural Society, March 13, 1820, will show what was thought of Orange culture in those days. He says:—

"The fruit which I exhibited before the Society was part of the produce of 1818, which was particularly great in that year, of the older trees yielding 250 dozen of fruit, being an average of nearly 15 dozen to each tree. This quantity was thus produced:—The Citron tree in the greenhouse produced eight dozen of fruit, each Citron measuring from 14½ inches to 16½ inches in circumference; three China Orange trees, one in the greenhouse and two in the conservatory, had 60 dozen of fruit, some of which measured 13 inches round; six Seville Orange trees, one in the greenhouse, three in the conservatory, and two in tubs, bore 140 dozen of fruit; seven Lemon trees, three in the conservatory, three in the greenhouse, and one in a tub, had 60 dozen of fruit; and from two Lime trees, 20 dozen of fruit were produced."

I may mention that, for the growth of this crop, which was specially visited by Sir John Sinclair, Sir Abraham Hume, and Mr. Sabine, my father was made a practical Fellow of the Horticultural Society; and Mr. Donald Munro but a short time before his death stated in public company that the collection referred to was the best ever exhibited before the Society. Oranges at Shipley, where my father was gardener, were regarded as a specialty, a supply being required for the dessert just the same as of Peaches, Grapes, or Pine-apples. An Orange fully matured upon the tree is something very superior to those which we purchase, the best flavoured fruit being those which drop dead ripe from the tree. *W. P. Ayres, Newark-on-Trent.*

The Visit of the Royal Horticultural Society to Birmingham.—I witnessed some of the shortcomings at Nottingham. I think an arrangement may be made by which all articles relating to horticulture or floriculture should be concentrated, even from a watering-pot up to the most costly conservatory. The bazaar part should be distinct. The hints thrown out by Mr. Thorpe are worth consideration. I am also of his opinion, that there is very great improvement needed in the exhibition of vegetables, the most useful products of the garden. I can also bear testimony to the necessity of protecting choice fruit when staged. Some few weeks back I attended a three days' show in the West of England, held in a building the floor of which was paved with wood. The dust from it, I can assure you, did not improve the appearance of the fruit by the end of the third day, and there were instances of pilfering also. Now if the fruit had been protected by a case similar to those placed on shop counters, but made in a more portable and economical manner, both would have been prevented. Surely the Royal Horticultural Society has power to allow exhibits to be thus protected. I would suggest that all exhibitors should be allowed to cover their fruit after the judges have made their awards. Exhibitors would then be enabled to leave their exhibits for two or three days without fear of injury or pilfering. I enclose you a sketch (fig. 354) of what I would suggest; they can be made in pine or mahogany, varnished, and could be used for other

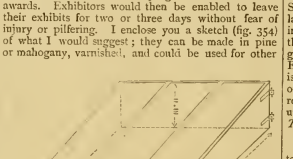

Fig. 353.—Fruit and Vegetable Protector.

purposes, which would be useful to gardeners. These fruit protectors can also be made continuous, or rather in sections, which fasten together in different compartments, to cover show tables of any length, and may be made with or without bottoms. *W. F. Chapman, Bristol Road, Gloucester.*

Plants in Bloom at Knowsley Garden, December 14, 1871.—In the stove: Poinsettia pulcherrima and its variety, albida; Pentas carnea, Plumbago rosea, Vinca rosea and alba; Epiphyllum truncatum, violaceum, and aurantiacum; Gesnera zebrina, Panicum variegatum, Begonia Ingramii, fuchsioides, rosea, odorata, hydrocotylifolia, and a free blooming white one, not known here; Eucharis amazonica, Sericographis Ghiesbreghtiana, Ardisia crenata (well berried), Orange, Gardenia citriodora. Cool house: Chrysanthemums of kinds, Primula chinensis of kinds, double Polyanthus Narcissus, Roman Hyacinth, Erica hiemalis, Lapageria rosea, Luculia gratissima, Tree Mignonette, Camellias of kinds, Azaleas splendens and amœna, Heliotropium peruvianum, Abutilon striatum, Pelargonium Rollisii's Unique. The Abutilons, Luculia, Lapageria and Heliotropium, are planted out. Foliage plants that look well to mix with stove plants named above: Dracæna terminalis, Cooperi, and ferrea; Croton pictum, variegatum, and angustifolium; Pandanus utilis, Sanderiæ, nobilis variegata, Maranta Veitchii, Cyanophyllum magnificum, Dieffenbachia picta, Alocasia metallica, Peperomia argyrea, Fittonia Pearcei and Verschaffeltii, Pothos argyrea, and Tradescantia discolor. *A. Z.*

Tomatos.—The Trophy Tomato I put as No. 1, for this reason, that among Tomatos it is as superior as is the Rock Potato coarse among Potatos. It is a round, smooth, large, handsome Tomato, entirely void of ridges and furrows, as in all other large sorts of Tomatos, and hence more useful in the kitchen, and less liable to damp and rot at this season. We have some very fine specimens just now, that were gathered partially green and ripened on shelves in the pineries. As the taste for Tomatos is gradually increasing in this country—now that it is pretty well known they are in any way a remedy for dyspepsia and indigestion—to know what sort is best to grow is not a small matter, and void of interest, but quite the contrary. We grow our Tomatos in pots (9-inch ones), under glass of course, and we have them from May to December. Amateurs, I have no doubt, would find they could get ripe fruit sooner by growing them in pots and training them against a wall than by planting them out and allowing the roots to go everywhere, the shoots also, and void of fruit—9-inch pots half plunged during the early season, and the roots wandering out of the bottom for a time, and severed by lifting the pot when the fruit was half-grown, would insure more ripe fruit than the ordinary common way of planting-out entirely. I was not aware till this year that the Currant Tomato was of much use in the kitchen. I have grown it as a pillar fruiting plant, and on trellises for ornament, and for the first time it has been used this autumn in many ways by our *chef de cuisine*. I have a notion it could be used as a winter fruit preserved in sugar syrup, as is done with all other ripe fruits so cleverly, by the French chiefly. It would form a very beautiful dish if the colour and the entire *grappe* could be preserved. The variety I allude to is the Solanum racemigerum, which must not be confounded with a variety sometimes called the Currant, of the size of a Cherry. This one is as small as a Black Currant, and with *grappes* a foot and more long. *H. K.*

Habits of Ants.—On the Riviera there are certain species of ants which habitually collect very large supplies of seeds of various kinds, those of wild species of grasses, leguminous plants, Amaranth, &c., forming the bulk of these collections; but cultivated plants are also put under contribution, and beds of Parsley and borders of dwarf Campion are not unfrequently robbed. Now I am aware that Huber, Gould, Kirby, and Spence have all stated that their experience of the habits of European ants was entirely opposed to the statements previously made as to their systematic harvesting of grain; but still I have remains, that in Southern Europe, India, and Texas ants do amass large quantities of grain; and I have met with a few intelligent, though not trained, observers who assert that they have repeatedly seen ants carrying away grains of Wheat at harvest time, even in Northern Europe. I shall feel much obliged by any person who is in the habit of cultivating plants for seed in England or on the Continent if he would furnish me with any reliable data as to robberies committed by ants upon the produce of his crops of grain or seed. *J. Traherne Moggridge.*

Outdoor Fig Culture.—Pruning the Fig or using too much of the knife has acted on our best cultivators rather like the paring of corns. Now all, I think, will agree with me that neither will Figs do long nor corns feel comfortable without a certain amount of the knife. The only difference between pruning corns and Figs is this—the corn you can prune until it nearly comes to the bleeding point; the Fig requires to be well thinned out with the knife in order to prevent the over-crowding of the shoots from the great exuberance of its foliage, and not duly attended to in proper time to give the wood a chance of ripening. It is needless for me to say the crop will in general be a failure, unless in very favoured localities. Unless the trees are kept thin of wood, whether trained horizontally or fan fashion, the chances of good crops will be indifferent. I remember I mentioned in the Journal last summer that summer thinning is of the most importance to the well ripening of the wood of the Fig out-of-doors. I must admit that I never gained much by pinching the Fig cultivated in the open air. As your able correspondent, Mr. Fish, truly observes, "except in the sunny South, only one crop can be ripened in the open out-of-doors;" and, as he further and justly observes, respecting his so-called Figlets, I thoroughly believe in a good show of them; thin, weakly wood will not produce them, neither under inside nor outside cultivation; so that, whatever system the cultivator may adopt, success will, as a general rule, follow in the shortening of matured wood, and with plenty of feeding at the proper time they will produce plenty of Figs. *J. Miller, Worksop Manor.*

American Early Rose Potato.—At p. 1619 "Amateur" ask for information on the above Potato in different soils, &c. In 1870 I planted a small quantity—1 lb. of seed—and had 33 lb. of good-sized tubers from it, and, owing, as I think, to the very dry summer, they were of very fair quality when cooked (boiled), but not equal by a long way to our best English varieties; when baked with their skins on in a brisk oven, they were very good, and looked very nice when dressed for table. In 1871 I planted a considerable quantity, thinking it might improve in quality, but was greatly disappointed, as it turned out to be one of the very worst in our whole collection, owing, probably, to some extent, to the wet summer we have had. They were planted in rows 2 feet 3 inches apart, and 15 inches from set to set, all planted whole, with all eyes but one cut out, on very heavy loam: the yield was very heavy, and fine, large, handsome Potatos, but of so little value, that I have for ever discarded it—and this is the verdict of nearly every one who has tried it in this neighbourhood. The same, to some extent, may be said of qualities of all the American varieties of which I have any experience. I have great pleasure in drawing attention to a Potato

of real sterling merit, namely, Veitch's Improved Ashleaf. Although not exactly a new one, it is not sufficiently known, or it would be much more extensively cultivated. It is quite a week earlier than Myatt's Ashleaf, Improved Walnutleaf, or Mona's Pride, and produces much larger and more even-sized Potatos than any of them. This for earliest, with White Blossom Kidney second, Webb's Imperial third, Flake fourth, and Paterson's Victoria latest, will give "Amateur" much more satisfaction than any of the American varieties yet offered, notwithstanding the extraordinary price asked for some of them. *John May, The Gardens, Westfield, Hayling's Island, Hants.*

Cucumbers.—At p. 1618, your correspondent, "H. K.," in speaking of Cucumbers, says, "I look upon Blue Gown as the handsomest and finest of all Cucumbers, also as prolific." Would he kindly inform us if he grows Rollisson's Telegraph (true)?—the general opinion being that this is by far the most prolific, although I have no desire whatever to deny the handsome appearance of the Blue Gown. *G. Simmonds, Sydenham.*

Notices of Books.

Elementary Treatise on Physics, etc. *Translated and Edited from Ganot's Elements de Physique.* By G. Atkinson, Ph.D. Fifth Edition. Longmans. 1872. Pp. 828; fig. 726.

This is an admirable text-book, clearly and accurately written and well illustrated. It occupies a middle place between rudimentary outlines and the more elaborate and complex works or monographs on particular subjects. The editor has evidently been careful in this new edition to incorporate the results of the most recent researches of Tyndal and other physicists. It might have been expected, perhaps, that the application of physics to vegetable and animal physiology would have received more attention at the hands of the author and editor than it has done, and we can but regret that the subject is passed over with such scanty reference. English literature is singularly deficient in this respect as compared with German, and we believe that one reason for the neglect on the part of our teachers and pupils of this most important subject, is the absence of a good text-book, setting forth clearly the agency of light, heat, gravity, and electricity on plant-life. That the author and editor of the present work are not disqualified for such a task, is shown by the following citation, which may serve as an illustration of the method employed in the work before us :—

"*Cold Produced by Nocturnal Radiation.*—During the day the ground receives from the sun more heat than radiates into space, and the temperature rises. The reverse is the case during night. The heat which the earth loses by radiation is no longer compensated for, and consequently a fall of temperature takes place, which is greater according as the sky is clearer, for clouds send towards the earth rays of greater intensity than those which come from the celestial spaces. In some winters it has been found that rivers have not frozen, the sky having been cloudy, although the thermometer has been for several days below 4° : while in other less severe winters the rivers freeze when the sky is clear. The emissive power exercises a great influence on the cold produced by radiation : the greater it is the greater is the cold. In Bengal, the nocturnal cooling is made a manufacturing ice. Large flat vessels containing water are placed on non-conducting substances, such as straw or dry leaves. In order, although the temperature be above 0°, that it may freeze, even when the temperature of the air is 12°. The same method can be applied in all cases with a clear sky.

"It is said that the Peruvians, in order to preserve the shoots of young plants from freezing, light great fires in their neighbourhood, the smoke of which, producing an artificial cloud, hinders the cooling produced by radiation."

Character. By Samuel Smiles. Murray. Small 8vo. Pp. 388.

Encouraged probably by the success of his former works, Mr. Smiles has here given us a long series of extracts, with his comments place book, tiresome to read from their multiplicity, and deficiency in cohesion. Each individual anecdote has its interest and its value, no doubt, but the reader becomes wearied by the incessant passage from one subject to another, with only an imperfect link to connect them together. In truth, Mr. Smiles has here accumulated materials for a dozen books, and has used them with much less literary skill than did Isaac Disraeli in his famous "Curiosities of Literature," and other works.

Nevertheless, Mr. Smiles' book may, with all confidence, be recommended to those who at this season are in search of a "nice book" for their elder children. As an illustration of Mr. Smiles' method of treating his subject, we may quote some of his remarks as to the cheerful frame of mind with which many naturalists have been blessed :—

"The study of natural history, more than that of any other branch of science, seems to be accompanied by unusual cheerfulness and equanimity of temper on the part of its votaries ; the result of which is, that the life of naturalists is, on the whole, more prolonged than that of any other class of men of science. A member of the Linnean Society has informed us that of 14 members who died in 1870, two were over 90, five were over 80, and two were over 70. The average age of all the members who died in that year was 75.

"Adanson, the French botanist, was about 70 years old when the Revolution broke out, and amidst the shock he lost everything—his fortune, his places, and his gardens. But his patience, courage, and resignation never forsook him. He became reduced to the greatest straits, and even wanted food and clothing ; yet his ardour of investigation remained the same. Once, when the Institute invited him, as being one of its oldest members, to assist at a *séance*, his answer was that he regretted he could not attend for want of shoes. 'It was a touching sight,' says Cuvier, 'to see the poor old man, bent over the embers of a decaying fire, trying to trace characters with a feeble hand on the little bit of paper which he held, forgetting all the pains of the present to indeed in natural history, which came to him like some beneficent fairy to cheer him in his loneliness.' The revolutionally gave him a small pension, which Napoleon doubled ; and at length easeful death came to his relief in his 79th year. A clause in his will, as to the manner of his funeral, illustrates the character of the man. He directed that a garland of flowers, provided by 58 families whom he had established in life, should be the only decoration of his coffin—a slight but touching image of the more durable monument which he had erected for himself in his works."

—— We have received from Messrs. J. Weeks & Co. a specimen of their annual *Pocket Book and Diary*, which contains, in addition to the diary, which can be removed to make way for fresh paper, a quantity of useful information, including a short account of the early history and development of the hot-water apparatus. It is well got up and nicely finished off, in good materials.

THE WEATHER.

Dec. 21.—Fine hoar-frost in morning ; overcast afterwards, and a little thin rain fell.
" 22.—Very fine till about 8.30 A.M., after which time the sky became overcast ; fog.
" 24.—Overcast throughout ; very dense gloom prevailed ; fog.
" 24.—A few light clouds prevalent ; a fine day. Lunar corona and halo at night.
" 25.—The amount of cloud was variable during the morning ; overcast afterwards ; rain fell throughout the evening.
" 25.—Overcast throughout ; heavy rain fell in the morning, thin rain occasionally afterwards.
" 27.—Variable and showery during the morning ; generally cloudless during the afternoon and evening.

JAMES GLAISHER.

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

CAMELLIAS, though they do not at this season give much outward indication of growth, are nevertheless very busily at work. As the development of the flower is being carried on very rapidly, to permit them to suffer from root drought at this particular time is to induce certain injury to the blooms, either by causing the buds to drop off, or to render the future blossoms of poor quality. The whole plant also suffers to a great extent. We must, therefore, give every possible attention to these plants, and more particularly to those that are planted out into open borders. We may easily learn what state the lower soil of such borders is actually in, and act accordingly. A good root-watering is, however, likely to aid them all at this time. These remarks are applicable to *Indian Azaleas*, and some other similar plants which we intend to force at an early date, that they also may have an opportunity of making some advance before we begin to force. It is not only advisable but also necessary at this dull, inactive period of the year to look over all kinds of plants periodically, and to remove at the earliest possible moment all dead leaves or other symptoms of decay that exist. This cannot be too much insisted on, as the symptoms increase with great rapidity. Amongst the many more or less hardy kinds of Orchids which may be somewhat advanced in flowering flower at this season, such as *Phaius grandifolius*, *Dendrobium nobile*, *D. chrysanthum*, *Cymbidium*, &c. ; these must be encouraged by an occasional supply of tepid water at the root, and by being maintained in a light and warm situation. The Cattleyas are the earliest possible moment all dead leaves or other symptoms of decay that exist. This cannot be too much insisted on, as the symptoms increase with great rapidity. Amongst the many more or less hardy kinds of Orchids which may be somewhat advanced in flowering flower at this season, such as *Phaius grandifolius*, *Dendrobium nobile*, *D. chrysanthum*, *Cymbidium*, &c. ; these must be encouraged by an occasional supply of tepid water at the root, and by being maintained in a light and warm situation. The Cattleyas are the earliest possible moment all dead leaves or other symptoms of decay that exist. This cannot be too much insisted on, as the symptoms increase with great rapidity. Amongst the many more or less hardy kinds of Orchids which may be somewhat advanced in flowering flower at this season, such as *Phaius grandifolius*, *Dendrobium nobile*, *D. chrysanthum*, *Cymbidium*, &c. ; these must be encouraged by an occasional supply of tepid water at the root, and by being maintained in a light and warm situation. The larger, later batch of *Cinerarias*, which it is necessary to keep growing on, will in all probability be much benefited by a shift at this time into pots one size larger, and into a good rich compost, somewhat more consistent than that in which they have previously been grown. The number and quality of their blooms will by this means be increased. Press the soil somewhat more firmly into the pots than before for a like purpose. These plants must still be kept in a cool temperature, and where a steady strong growth can be made. Others which are about to flower may be kept in a somewhat more warm and moist state, which will aid them greatly at this dull season in the development of their flowers. Be very careful not to over-water any kind of pot plants, bearing in mind the fact that we only should wish to keep the plants in pots of healthful a condition as to induce as little real growth as may be practicable.

FORCING HOUSES.

In regard to forcing operations generally, it may be said, now, when a certain though only moderate increase of daylight occurs, that the change is in favour of the forcing practitioner, and his operations may be carried on with greater success than heretofore. We must not, however, permit these facts to induce us to increase the artificial heat incautiously, as no amount of after care will retrieve the loss of vigour occasioned by over-forcing just now, whilst by "holding back" at this period such an amount of vigour will be retained for the benefit of the forced subjects, as will admit of a very high temperature being used by-and-by when a very rapid and safe advance will be possible. In regard to *Fruiting Vines*, permit the bottom-heat to range up to 82° or 84° with imbroken temperature ; a view of which have fresh tan ready, scatter a goodly thickness of it on the surface of the beds, and so stir the whole with a stiff stick as to mix them together without upsetting the pots. In all instances where, owing to the vicinity of pipes or flues, the old tan has become dry, endeavour to moisten it by the usual means. Do not by any means excite the successional plants to make any unseasonable growth at this season. Those *Forced Vines* which started in November, exhibit signs of "breaking" freely and uniformly, should now be tied up permanently in canes where the roots have loosened and bent down to aid them in making a start. Keep the night sprinklings, and afford on every possible occasion a nice amount of fresh air, taking care to avoid draught. Proceed with the dressing of successional houses with the usual mixture of soft soap, lime, and sulphur. In very early *Figs* and *Nectarine* houses increase the heat a little when the blooms show signs of final development previous to expanding. Do this by affording additional heat as gradually as possible, so that nothing like a fluctuation of temperature be experienced. Water the earliest *Figs* copiously at the root, and syringe them freely overhead as a preliminary to starting them into activity. Sow seeds of desirable sorts of *Cucumbers*, keeping the pots reared well up to the glass at the time germination takes place, and during the earlier stages of growth. The same remarks apply to *Melons* in case where very early fruit is in demand. Bring another batch of *Strawberry* plants into a cool house ; make also a sowing of *Dwarf French Beans* toward the end of the incoming week, placing them in a moderate temperature only, that the process of germination be not hurried. Sow in 60-sized pots.

HARDY FLOWER GARDEN.

At this period, when great vicissitudes often occur in the weather at short intervals, it will be necessary

to attend more particularly to *Auriculas*, *Polyanthuses* *Pansies*, &c., in cold frames than is necessary in settled weather. In regard to such subjects as the above, and indeed the general stock wintered in this place, it will be necessary to allow air with great freedom during all mild periods following a frost, as the condensed vapour bathes all internal surfaces in such a place with dripping moisture.

FRUIT ROOMS.

Look over and sort out Pears and Apples in the fruit room, and where it is possible to do so light a very moderate fire to move the stagnant air, and dispel its clammy dampness. Lay the fruit out singly if possible, running all straw or other material which has ceased to be of use, and only tends to increase the injurious internal dampness.

KITCHEN GARDEN.

Beds of fermenting materials should now be made up to sow *Radishes*, *Onions*, and similar salads, where a great demand exists. During a mild period take up also such plants of *Endive* as still exist under temporary shelter out-of-doors, and remove them to frames or other suitable situations, where a moderate growth can be made and the necessary blanching carried out. Another batch of *Chicory* should also be placed in the Mushroom-house or other similar position, to furnish the successional supply of blanched leaves. As the success of outdoor-sown *Peas* and *Broad Beans* already in the ground is somewhat questionable, owing to the early and untoward frosts, it will be advisable immediately they show through the ground, to place a layer of decomposed leaf-mould, or some similar light subject, not over retentive of moisture, over them. This will aid them vigorously if they are establishing their roots more permanently in the ground, especially should another harsh, cold period follow quickly. *W. E.*

Notices to Correspondents.

A Selection of Peas: *George Yordley*. Earliest Crop: Little Gem, Invicta, Advancer. Second or Main Crop: Premier, Veitch's Perfection. Late Crop: Advancer, Premier, Veitch's Perfection. These, sown at the proper seasons, and grown well, will give you all you can desire in the way of dwarf Peas with quality.

Asparagus and Artichokes: *E. L.* Your letter did not contain an inquiry. Asparagus you may plant at any time now, when the ground is in good condition. Artichokes should be planted in March.

Books: *M. G., Brixton.* Thompson's "Gardener's Assistant," and Shirley Hibberd's *Gardener's Oracle*. "Bréhaut on the Peach," "McEwen on the Strawberry."—*T. W.* Mrs. London's "Amateur Gardener's Calendar" (Warne & Co.), will suit you admirably. Reply to other question next week.

Lichen: *W. P., Shrewsbury.* The plant which persistently appears year after year, though a thick coat of paint on a garden rail, and referred by you to Pezizæ, is a Lichen, either Lecidea sanguinea, or very near to it.

Peaches, &c.: *A Subscriber. Six Best Peaches:* Early York, Grosse Mignonne, Bellegarde, Noblesse, Barrington, Walburton Admirable. *Two Nectarines:* Elruge, Victoria. *Three other Peaches:* Royal George, Lord Palmerston, Belle Beauce. *One Nectarine:* Pitmaston Orange.

Catalogues Received:—Wheeler & Son's Little Book, or Select Seed List for 1872.—James Cocker's Descriptive Catalogue of Gladioli and Pansies.—Sutton's Amateur's Guide and Spring Catalogue for 1872.

Errata.—In Mr. Baker's analytical key to the species of Lily, at p. 1650, owing to an oversight, the meaning of a portion of the Table is rendered obscure. The portion of the key referred to, is correctly set up as follows:—

Leaves ½–1 inch broad, 3—5 nerved.	
Flower-segments ½–1 inch broad.	
Leaves close, 50—80 to a stem.	
Flowers bright red, not yellow.	26. L. CHALCEDONICUM, Linn.
Flowers yellow, not dotted.	27. L. PYRENAICUM, Gouan.
Leaves lax, about 30 to a stem.	28. L. CALLOSUM, S. and Z.
Flower-segments 2—1 inch broad,	
Leaves 60—100 to a stem.	29. L. TESTACEUM, Lindl.
Leaves 20—30 to a stem.	30. L. LEICHTLINII, Hook. fil.

At p. 1651, col. 2, near to the end of first paragraph, for "rust," read "burst."

Markets.

COVENT GARDEN.—Dec. 29.

The markets have been very languid and dull since last week, the holidays intervening having a marked influence as usual. Supplies, however, have been well kept up, and the northern markets have much assisted us, in taking large quantities of rough produce. Asparagus and Sea-kale have much improved with the open weather, and Broccoli is excellent, though not large. A few new Peas are also to hand from France.

Fruit.

Potatos, Regents, 100s. to 130s.; Flukes, 120s. to 150s.; French Shaws, 60s. to 70s.

POTATOS.—Southwark, Dec. 27.

During the past week the arrivals have again been in excess of the demand, and many stored to save demurrage. The trade is very dull, and likely to be so till the Christmas holidays are over. The following are the quotations:—Yorkshire Flukes, per ton, 100s. to 130s.; Yorkshire Regents, 60s. to 100s.; Dunbar and East Lothian do., 110s. to 140s.; Perth, Forfar, and Fifeshire do., 90s. to 110s.; Jersey do. 80s. to 85s.; Cork, 50s.; and Essex Regents, 50s. to 90s.; do. Rocks, 70s. to 80s.; French Whites, 60s. to 70s.

WANT PLACES.—Letters to be Post Paid.

Gardeners and Under Gardeners.

WM. CUTBUSH AND SON beg to state that they have at all times on their books MEN of various qualifications, whose characters will bear the strictest inquiry. Any Gentleman making application would save time by clearly stating the duties to be undertaken, wages offered, &c., to that suitable Men may be selected. —Highgate Nurseries, London, N.

EXPERIENCED GARDENERS (for as GARDENER and BAILIFF), of various qualifications, recommended to Gentlemen requiring such by application given or personal, by G. HENDERSON AND SON, Wellington Nursery, St. John's Wood, N.W.

GARDENER (Head).—Single; understands the profession in every branch of Indoor and Outdoor Labour. Can be well recommended.—Apply, first to W. MUIR, Oulton Park, Tarporley.

GARDENER (Head).—Thoroughly understands the Management of Stove and Greenhouse Plants, Orchids, Ferns, &c.; Early and Late Forcing, Gardening generally, and Pleasure Ground Keeping. Fine-spite Nursery, Maida Vale, London, W.

GARDENER (Head).—Any Advertiser offers £5 to any Nurseryman, Florist, or Gardener who will procure him a situation as above, at not less than £90 per annum, with cottage. Had first-class character, and can give good references.—ALPHA, Post Office, Ryde, Isle of Wight.

GARDENER (Head).—Age 26; 12 years experience in the Management of Gardens. Thoroughly capable of Gardening in all its branches, including Orchids, Ferns, and Stove and Greenhouse Plants. First-class references from previous and present employers.—J. D., The Gardens, Foles, Ware, Herts.

GARDENER (Head).—Age 37, married, no family; has had a thorough practical knowledge of the profession, and can take charge of a Gentleman's Garden Land, if required; likewise Stock and Poultry. Good character and testimonials.—A. B., 16, College Street, Chelsea, S.W.

GARDENER (Head), age 37, married, one child (aged 9).—JOHN EASTER, Head Gardener to G. Nevill, Esq., Stubton Hall, Newark, Notts, is at liberty to recommend a steady Gardener to Gentleman requiring the services of a thorough practical Gardener, well versed in the Management of Vines, Peaches, Pines, Stove and Greenhouse Plants, including Orchids and Ferns, also Early and Late Forcing of Fruits and Vegetables, and good Kitchen and Flower Gardener.—Address as above.

GARDENER (Head), where three or four Men are kept.—A young Man, who has had good experience in several Noblemen's and Gentlemen's Establishments, can be well recommended for ability, sobriety, industry, and general good conduct.—J. C., Nursery Hotel, Thornbridge Road, Hanle.

FOREMAN, in a Nobleman's or Gentleman's Establishment.—Eleven years' experience in first-class places. Good references as to character and ability.—M. N., 49, Shalfburn Street, King's Road, Chelsea, S.W.

PROPAGATOR in general, or PROPAGATOR and GROWER.—Age 23; a good Salesman. Good character.—A. B., Post Office, Leytonstone, Essex.

PROPAGATOR (Soft-wood), and GROWER.—Married, no family; has a thorough knowledge of his profession. Can Grow for Exhibition or Market, if required. Nine years' good character.—A. B., 13, Hill Road, St. John's Wood, London, N.W.

IMPROVER.—In Fruit House.—Age and Reference: —Wingfield, Esq., Tickencote Hall, Stamford.—E. BILLIARD, Ketton, near Stamford, Lincolnshire.

To Farmers.

STEWARD or BAILIFF.—A Farmer's Son, who for the last six years has acted as Overseer on a Farm in Aberdeenshire, is desirous of being given an application being made to GARDNO AND DARLING, Seedsmen, Aberdeen.

LAND STEWARD or FACTOR.—The Advertiser is open for engagement at or before the 1st of May. Has had the charge of a large Estate for the last 13 years, where Draining and Improving have been extensively carried on; also a Home Farm of 400 Acres. He is a good Judge of Stock of all kinds, and only leaving in consequence of the Estate being transferred. England or the Continent preferred.—Mr. MULLEN, Gardener, Ballindalloch Castle, N.B.

FARM BAILIFF (no family).—The Advertiser is leaving his present situation, and will be glad to treat with any Nobleman in want of a thoroughly efficient Servant of a thoroughly competent Person. Wife can undertake the Management of Dairy and Poultry if required.—THOMAS POWLEY, Home Farm, Garnons, near Hereford.

TO AGRICULTURISTS.—An industrious young Man, in whom the strictest confidence may be put, wishes to place himself with a large Farmer for further Improvement, where his services would be considered equivalent to his board, or would make himself in a small way useful. Any Farmer is not a pleasure-seeker, but one who wants insight into Farm Work. Good references given.—D. F., Post Office, Hereford.

To Florists.

BOUQUET MAKER, and to fill his time up in Seed Shop or Glass Department.—Age 21; an abstainer. Writes a good hand. A permanent engagement required. Seven years good character.—Apply, stating wages, &c., to A. B. C., 19, Newton Street, St. John's Road, Hackney, N.E.

SHOPMAN.—Fifteen years' experience with all branches of the Seed Trade, and a good knowledge of the Nursery and Florist Business. Good reference.—C. D. E., 3, St. Andrews, Uxbridge.

SALES BY AUCTION.

The Agricultural Gazette.
SATURDAY, DECEMBER 30, 1871.

THE letter on SEWAGE IRRIGATION, by Mr. BLACKBURN, which we have given in another page, states the conclusions of an experienced and trustworthy man. We entirely agree with him in deprecating the destructive method of dealing with a valuable property, which is inevitable when the drainage of one or more thousand people is poured over a single acre of land. There is an immense destruction of fertilising matter under the most economical system of sewage irrigation yet in practice, and to convert land into a mere filter-bed—which is nearly all that we can expect it to be when it has to deal with so much filth per acre as is contained in the drainage of a thousand people per acre—is still more to aggravate this loss.

The drainage water of many a sewage farm is well worth redistributing for the use of another, and yet another, set of plants before it is finally dismissed. That of the Methyr filter-beds, and that of the Lodge Farm, Barking, alike show that two-thirds of the fertilising matter in the sewage has remained unused. It has been all completely defecated, and is admissible into running streams without risk of polluting them; but it still contains, though in an altered condition, more than half of the nitrogenous matter to which its original value as a manure is due. It is very desirable, therefore, that the urgency with which the "intermittent filtration" mode of dealing with the sewage difficulty is being advocated, be moderated, and that it be recommended only as a last resource, when the difficulties of adopting irrigation appear to be insuperable.

Let us most cordially acknowledge here the great services which Mr. BAILEY DENTON has rendered by his courageous adoption of the intermittent filter to meet the difficulties in which Merthyr found itself. Our remarks the other day upon this subject entirely failed to convey our meaning if any one has gathered from them that great credit is not due to the engineer to whom we owe the perfect success which has there attended the application of the great scale of a method which till then had depended for its justification upon mere laboratory experiments. Nor must we omit to acknowledge that in carrying out the works at Merthyr, to which this successful result is due, great care has been taken to ensure a perfectly even division of the stream of sewage over the several plots, to which it is directed in exact proportion to the extent of their several areas. The uneven distribution to which we referred (p. 1625), as occurring in spite of this perfectly proportionate apportionment of the sewage to the land, occurs when each particular bed has to deal with its separate share. That, as we said, sinks away in some places in fourfold quantity as compared with others; and we do not see how the difficulty can be avoided, except the sewage be made to fall as rain does, on each square foot alike. Wherever water is applied through a carrier over land, finding its way ultimately to a drain either on the surface, in which case it may be redistributed, or in the subsoil, from which it flows direct to the river, that portion of the land nearest to the carrier gets more than its share of fertilising matter—gets more, indeed, than its share of work to do. The reason why the crop is uniform in spite of this unevenness of distribution, is because the land which gets the least gets more than its plants can use, and thus the water which finally leaves the field is still full of manure. And the reason why the work of sewage defecation is complete, in spite of this uneven distribution, no doubt is that this method of destroying organic matter in water which we owe to Dr. FRANKLAND'S ingenuity and research, is of even greater power and effectiveness than has been imagined.

There is still a great deal to say on this subject before the discussion of it is exhausted; and we shall probably return to it, in order that the personal as well as the public sides of it may be properly presented; but these remarks will suffice for the present, both as an introduction to Mr. BLACKBURN'S useful letter, and as an addendum to the short memoir in another page, which we are very glad to give of the distinguished agricultural career of our friend, Mr. BAILEY DENTON.

IT is a very old saying, and there is a certain amount of truth in it, that "Experience holds the torch to Theory." We think that in the case of CLIMATE IN RELATION TO CROPS this saying may be applied with force. In Scotland, as in England and Ireland, the question where to grow Wheat has been settled by experience—that is to say, repeated failures have defined the exact situation of favourable localities, and of those to be avoided. Meteorologists have come to the assistance of agriculturists, and now we have mapped out for us the various climatal zones, and the "why and the wherefore" are thus jotted down. Perhaps no man has done better service in this generation in this direction than the President for the year of the Edinburgh Botanical Society, Mr. ALEXANDER BUCHAN, M.A., well known for his explorations in the field of meteorology. In his inaugural address for the session 1871-2, he referred to the subject of climate and weather, in relation to the geographical distribution of plants; and, from this address, we now give a few extracts, confirmatory of the experience of agriculturists, and therefore of value to them. He says:—

"1847 DE CANDOLLE made some researches into the causes which limit vegetative species towards the North in Europe and similar regions, and arrived at the conclusion [already determined by Experience] that every species having its limit in Central or Northern Europe advances as it finds a certain fixed amount of heat, calculated from that day of the year when a certain mean temperature commences, to the day when that mean terminates. . . . By this law this limit is to be tested by applying it to the limits of Wheat or Barley. . . . since, owing to the care taken of them by man in their cultivation, it may be considered that it is climatic conditions alone which set the limits to their destitution. According to BOUSSINGAULT, Wheat requires 8248° Fahr. from the time it begins to grow in spring for the proper ripening of the crop: and, moreover, this heat must be so distributed as to secure an average temperature of 58° during the period when the seed is ripening. This statement referred to the continent of Europe, to which his researches were confined; but we have found in Scotland that the same temperature is sufficient, our average amount of rain and sunshine, is sufficient to ripen grain properly. Not only so, but the crops of 1864 ripened well with a temperature as low as 54°.4. In that he

results which accrue to plants arising from a change in the humidity than arises from a change of temperature; but what especially concerns the question is this vital distinction between the two, viz., that climates merge into each other by comparatively nice gradations, as regards temperature, whereas, on the contrary, the most diverse climates, as respects moisture or dryness, are frequently placed sharply side by side.

"I have long been impressed with the importance of a knowledge of the rainfall viewed in these aspects, and have recently constructed 13 maps, showing for each of the months, and for the year, the rainfall over the greater part of the land of the northern hemisphere. The result of the whole discussion, in its relation to climate, is very striking. Everywhere the rainfall is dependent on the prevailing winds, and on the configuration of the earth's surface; and since the prevailing winds depend on the distribution of land and water over the globe with respect to the heat of the sun, it follows that the present climates are determined by the relative distribution of land and water."

There are laws general and laws particular—those adverted to by Mr. BUCHAN, and those modified by the absence or presence of woodlands. That these exert an immense influence on land, and therefore on crops, in their immediate vicinity no one can doubt—no one does doubt; and that thorough drainage and deep cultivation exercise a beneficent influence is also a proven fact. Drainage means to some extent a raising of the temperature of the soil. It is astonishing how much colder the head will stand, so long as the feet are kept warm; and no better proof of this can be found than in the experience of the agriculturist. Deep stirring of the soil is a wonderful aid to drainage, and where the two are co-existent, it is almost safe to say that they can afford to give away one or two degrees of temperature in the game of life, and still go in and win.

It would be interesting to all, when Mr. BUCHAN publishes the next edition of his Tables, if they could find notes appended giving localities where draining and deep ploughing are the rule, and the crop results compared with others in the same "zone," where neither draining nor deep stirring of the soil are the rule. *E.*

—— THERE was no Corn Market on Christmas day. On Wednesday in Mark Lane the grain trade ruled heavy, sales being effected with difficulty at previous rates.—The Metropolitan Cattle Market has been this week of an unimportant character; the very short supplies have, however, failed quite to supply the demand, and prices of both beef and mutton are higher than those of last week.

—— Mr. BLACKBURN, of the Aldershot sewage farm, has written a capital letter on SEWAGE IRRIGATION in the *Times*; and we make the following extracts from it:—

"The last new process which the authorities of town have been asked to sanction is intermittent filtration, originally invented and suggested by Dr. Frankland, as worthy of trial under certain conditions only, but now energetically recommended by some few engineers and others; nevertheless, I must say that if it is adopted in any locality where irrigation is practically available, it can but be viewed as so much loss in the shape of flow to the stream. We are told, from the experience, he it remembered, of a few months only, that the sewage of 3000 person can be filtered of its impurities through one acre of land, and also that edible vegetables can be produced on this intermittent filter at the same time; any estimate of which may be placed on the appropriating or scavengering power of such an infinitesimal amount of vegetable growth as can be raised under such conditions must be futile in the extreme; in fact, about as hopeless a task as two men attempting to scavenge the streets of London. Therefore, putting on this case most liberal almost slowly on the unaided resources of the soil itself; and my conviction is, that such vast accumulations of manure, coupled with the action caused by the solvent powers of sewage, will in time absolutely choke up its pores. I may say this opinion is based on many years' experience of the treatment of land under sewage, combining a variety of sources.

"Some of the advocates of intermittent filtration attempt to create what is purely an imaginary difference between irrigation and filtration, which, so far as the soil is concerned, really does not exist; irrigation —that is, utilisation—embraces filtration, the principle in both cases is the same; but the application of that principle involves the question of the production of food in the one case and waste in the other—in fact, irrigation does all that intermittent filtration is said to accomplish, with the valuable recommendation of producing food in addition, besides which the cleansing process of vegetable growth involves a constant abstraction of the fertilising matter deposited in the soil, and the almost continued conversion of the same into food maintains its filtering powers unimpaired. Sewage utilisation and purification must go hand in hand, and it will be a great national loss if the latter only is considered and rendered subservient to the former. I have myself made a filter of all parts of my farm since the year 1854, the extreme poverty of the land rendering it necessary that it should be supplied with large quantities of sewage matter before any vegetable growth could be obtained. This was accomplished by deep cultivation, with thorough soaking at short intervals for about a year, a few deep drains having been put into the land where found necessary. It has also been asserted as one of the drawbacks to sewage farming, that the experience said to be gained in the cultivation of Italian Rye-grass is that it may readily be grown in excess of the demand in a green state. But there can be no necessity to limit the culture of so valuable a crop that can account, and it is admirably adapted for the profitable conversion into that which is in ample and ever-increasing demand—viz., dairy produce or meat. As to the large quantity of sewage it is said to appropriate, I find that depends a good deal on the cultivation pursued. Under this management it yields a higher return per acre than most other crops, with the manure resulting from its consumption in addition. In support of this I know instances where cow-feeders pay from £25 to £40 per acre for grass which annually returns in milk or butter of something like from £80 to £100.—The late glut of vegetables in the market has to some suggested the the idea of growing cereals, and it has been seriously proposed that farmers having the command of sewage, with all its advantages, should grow that which can be obtained of much better quality and cheaper from America, Russia, and elsewhere. Moreover, there is no doubt that, under ordinary agriculture, the rest of the country could successfully compete with sewage farms in the growth of grain crops. And, cultivated, well-pulverised soil will retain in this climate a sufficiency of moisture for the perfecting of their growth without any additional supply from sewage or other artificial sources. All our leading men have long since agreed that the future success of our home agriculture must depend largely on dairy produce and meat, and I think it would show a want of sagacity in any sewage farmer to adopt so retrograde a step as a dependence on corn growing when he possesses such extraordinary facilities for raising green crops.

"A sewage farm should, I maintain, consist of such an area of land as will convert on the smallest space of ground the largest amount of sewage into vegetable growth without waste, thus recognising the economy of intensive as opposed to extensive farming, and to do this such plants must be grown as can build up the greatest quantity of fertilising matter into food in the shortest time.

"By all means put a stop to the nuisance arising from the pollution of our rivers; but instead of destroying that which occasions it as an enemy in an intermittent filter, convert it into a friend that will help to feed the British subject.

"The labouring class, and especially the children, are not much more than half nourished, and yet we find men recommending the waste of that which, if properly managed, should go some way towards feeding them; a plentiful supply of milk placed within reach of the rising generation of the poorer classes would improve them both mentally and physically. But, granting for a moment that intermittent filtration is to prove a success so far as purification is concerned, its general adoption would be a deplorable misfortune for this country."

—— At the close of the sessional examination at the ROYAL AGRICULTURAL COLLEGE last week, the Rev. JOHN CONSTABLE, the Principal, said it gave him great pleasure to present a satisfactory report on the intellectual condition of the College. There were now six diplomas and a number of certificates and prizes to be distributed. It was the wish of the Council that the College should maintain its place among the educational institutions of the country, and he was sure that when they came to hear the report they would be now making they would be satisfied. With regard to the moral tone of the College he could conscientiously remark that it would favourably compare with any college or institution in the country. Lord BATHURST presented the prizes to the successful students. Diplomas were awarded to—John Player Sturge, Tyndall's Park, Clifton, Bristol; Francis Wright Bourdillon, 2, St. John's Park, Blackheath, Kent, S.E.; John Dodson, Sheinton, Much Wenlock, Shropshire; Hugh Parker Holme, Mardale, Haweswater, Westmoreland; William Hall Pickering, Nottingham Place, London; and J. Charles Jones Monnington, Bitteswell Vicarage, Lutterworth, Leicestershire.

—— At a recent meeting of the CAMBRIDGESHIRE CHAMBER OF AGRICULTURE, assembled to discuss the policy of establishing a county school, available for the sons of farmers, the Rev. J. L. BRERETON gave the following account of the Devonshire County School:—

"This school has for several years been a centre of examination for Oxford as well as Cambridge, and it has, I believe, obtained more certificates and honours than any other school in the country. I do not mean that higher honours have not been obtained by other schools which have sent in a smaller number of candidates, but then it should be remembered that in the Devon County School no boys take up Greek, and only a small number Latin, while it has more than once been the good fortune of a pupil of this school to be in the English section of the examination—the first in all England. My object, however, is not to boast of their performances, but to give this Chamber some real assurance that the teaching which the Devonshire boys receive is, of its kind, 'excellent.' And now, what is the cost? 1. To the parents. 2. To the shareholders. Last year there were 111 boarders (on the average) in the school, and four day-boys. The total charges were—for board and tuition, £3033 7*s.* 8*d.*; for books, stationery and use of library, £229 6*s.* 4*d.*; for extra tuition in Latin, drawing, or music (an optional charge), £365 1*s.* 1*d.*; for examination fees to Oxford or Cambridge, £98 10*s.*: giving a gross average of £33 6*s.* per boy; and for necessary charges an average of £29 4*s.*—that is, for board and tuition £27 3*s.*, and for books and stationery £2 1*s.* Now these payments by the parents, added to some profit from garden, enabled the school to discharge all claims for salaries, for board, for rates and taxes, for books, advertisements, and sundries, and to hand over to the shareholders a balance of £725. Out of this balance the shareholders paid £90 interest for money borrowed on mortgage or advanced by the bank; they set £78 apart for doubtful debts, £97 for depreciation of furniture, £97 for depreciation of buildings, £69 for liquidation of preliminary expenses, and the remainder (£325) gave them a dividend of 4½ per cent. upon their shares. The shareholders are protected by limited liability, the nominal capital is £7000, in shares of £25. Of these 277 have been taken up, and 100 of them (£2500) have been presented by the subscribers to the school, and the dividend upon these is awarded in scholarships to the most deserving boys. In last year a sum of £172 10*s.* was placed at the head master's disposal, under certain regulations, for distribution in scholarships. I hope I have satisfied you by these figures that an 'excellent' education is given in the Devon County School at a 'moderate' cost, and without loss or great risk to the shareholders."

—— The following extract, from a recent address of Mr. JUSTICE LAWSON, at the opening meeting of the 25th session of the Statistical and Social Inquiry Society of Ireland, supplies a satisfactory index to the PROGRESS OF IRISH AGRICULTURE of late years:—

"The population attained its maximum of 8,000,000 in 1841. In 1871 it had fallen to 5,559,385, being a decrease of 20.5 per cent.; falling in the next decade to 10.30; and in the last to 6.83 per cent. The decrease of population in towns has been chiefly in west coast and central towns, which have been affected by emigration. The main cause of decrease of the population has been thus gradually diminishing, and caused by emigration. If the population had increased by the usual number of births above deaths at the same rate as in the former census, viz., 4 per cent., and if there had been no emigration, our population should have been 6,297,275, and, deducting from this the estimated number of emigrants, 846,957, it would give a present estimated population of 5,450,318, nearly with the number ascertained by the census, 5,402,759, showing that there has been no extraordinary decline of population, but that it has maintained an equable rate. In connection with this subject of population and emigration it is very interesting to observe the great increase in the use of agricultural machinery. I have not been able to procure any statistics on this subject which I could lay before the meeting; but it is highly interesting to note the part which these machines play in our social economy. They do not tend to reduce population or throw hands out of employment, which is the stock argument generally used against machinery. They did not with the spade, but followed it with a decrease of population. Their use benefits the farmers, by making them much less dependent upon the caprice of the seasons; because the operations can be performed so rapidly as to enable them, generally, to defy the weather in saving the crops. They render it unnecessary for a portion of the labouring population to be idle during the dead season, as they used to be with us. The farming classes have now something else. It is not the interest of their landlord to evict them as long as they pay their rent and use the land well. He suffers heavy penalties if he does so. I believe, never in the history of this country, were farmers so prosperous and well to do. Rents are well paid, land better tilled, houses and offices improved; food and dress have undergone a marvellous change, even within recent memory; and when lands are set up in lots to suit tenants, there is no lack of purchasers."

OUR LIVE STOCK.

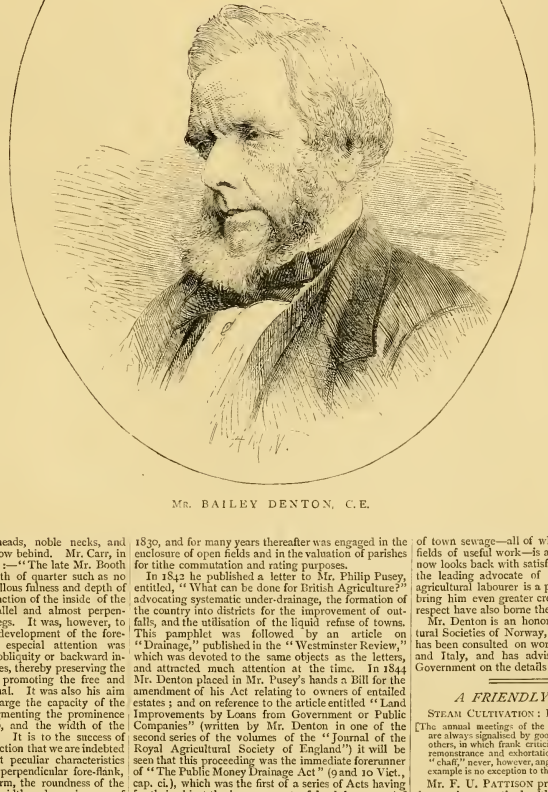
"A FARMER" inquires "what would be the best breeds of sheep and pigs to take out to America?" This is a very delicate, and difficult to answer. In the colder regions of North America, probably long-woolled sheep, such as Cotswolds and Lincolns, would prove the most profitable, and a considerable number of such sheep have already found their way into the States and Canada. That they succeed there to some extent is sufficiently indicated by the high prices very recently given at Mr. Cochrane's sale, on October 26, at Montreal, Canada, for Cotswold ewes. "The two first were knocked down for 75 dols. (£12 12*s.* 6*d.*) each; two more same price; two at 60 dols. (£10 8*s.* 4*d.*); the next two were shearlings, and fetched the top price of 100 dols. (£20 16*s.* 8*d.*) each." With reference to the best kind of pig for the States and Canada, we have no wish to place one variety before another, but no breed has lately been so much spoken of in connection with export trade as the Berkshire, and the high prices given for breeding animals fully attests the estimation in which they are held. Reverting to Mr. Cochrane's sale we find that:—"Twelve Berkshire sows were very strongly competed for, though they all fell to the same purchaser, who seemed determined to have them, though they stood

him in 103 dols. a-piece (£21 9s. 5d.). The lowest price was 75 dols. (£15 12s. 6d.); the highest, 185 dols. (£38 10s. 10d.)."

—— A correspondent wishes to know "the characteristic traits of the Booth and Bates' strains of Shorthorns." Judging from the extreme expressions made use of by some interested persons, an outsider would be led to believe that one section of the Shorthorn race was utterly worthless, while the other included every good quality. We must, however, remember that Booth and Bates blood maintain a very equal competition for public favour, and that Warlaby and Wetherby have been equally successful in producing notable animals. Pedigree is sufficiently important to demand a first place. Mr. Bates laid great stress upon the importation of HUBBACK blood. "No other breed of Shorthorns," he writes, "shows a family likeness except my own. Nor has any other breed of Shorthorns the same hair and handling as mine have; nor can it be obtained but through my strain of blood; for it runs in the blood, and none now can be found that have the old Hubback blood and that of his predecessors, and of Mr. James Brown's old RED BULL: and these two bulls were the last remains of those breeds which had been so long eminent as Shorthorns before the time when the Messrs. Colling began breeding." HUBBACK, KELTON, THE EARL (646), 2D HUBBACK, BELVEDERE, were the first bulls used in bringing out the Bates herd, and on the female side Mr. Bates informs us that it is to the union of Duchess tribe, Yarborough's dam, and *Princess* tribe that his cattle owed their superior excellence. Down to the present time breeders of Bates cattle have followed out the principles of in-breeding, and purity of blood is looked upon by them as all-important. Booth cattle, on the other hand, are sprung from stock contemporary with that of the Collings, and have been bred with a less slavish adherence to particular lines of blood. We venture to state our conviction, that while allowing due weight to pedigree, the Booth cattle breeders have bred with a greater regard to personal merit. These cattle are in the hands of a less wealthy but more thrifty class of men, and while, as a rule, commanding a lower price in the sale-ring, are more fortunate in the show-yard. The Bates cattle are unrivalled in "touch" or quality; the bulls have grand "Bates character" heads, noble necks, and upright shoulders, rather hollow behind. Mr. Carr, in speaking of Booth cattle, says:—"The late Mr. Booth succeeded in imparting a length of quarter such as no other herd can boast, a marvellous fulness and depth of thigh, and of the twist, or junction of the inside of the thighs, and a perfectly parallel and almost perpendicular position of the hind legs. It was, however, to the ample and symmetrical development of the forequarters that Mr. Booth's especial attention was directed. He increased the obliquity or backward inclination of the shoulder blades, thereby preserving the level line of the back, and promoting the free and graceful carriage of the animal. It was also his aim to improve the form and enlarge the capacity of the chest, which he did by augmenting the prominence or circularity of the fore-rib, and the width of the sternum or floor of the chest. It is to the success of Mr. Booth's efforts in this direction that we are indebted for those valuable and almost peculiar characteristics of the Warlaby cattle—the perpendicular fore-flank, which drops even with the arm, the roundness of the barrel-shaped crops, and the width and massiveness of the projecting bosom. To this conformation also may probably be due the very remarkable immunity from pleuro-pneumonia and other chest affections which the Warlaby and its kindred herds have hitherto enjoyed. It may be observed that this development of the forequarters was mainly effected by the use of the male descendants of *Isabella* by PILOT. The necks of the Booth Shorthorns are remarkable for the bulky, yet symmetrical development into which they gradually swell as they approach and blend with the shoulders and breast, completely hiding, even in the unforced animal, the shoulder-points."

NOTEWORTHY AGRICULTURISTS.

MR. BAILEY DENTON, C.E.



MR. BAILEY DENTON, C.E.

His name has long been familiar to agricultural readers as that of one of our most energetic agricultural engineers and most active agricultural writers. Mr. Denton was born in London in November, 1814. He was articled to the agent of the late Lord Dacre, in 1830, and for many years thereafter was engaged in the enclosure of open fields and in the valuation of parishes for tithe commutation and rating purposes.

In 1842 he published a letter to Mr. Philip Pusey, entitled, "What can be done for British Agriculture?" advocating systematic under-drainage, the formation of the country into districts for the improvement of outfalls, and the utilisation of the liquid refuse of towns. This pamphlet was followed by an article on "Drainage," published in the "Westminster Review," which was devoted to the same objects as the letters, and attracted much attention at the time. In 1844 Mr. Denton placed in Mr. Pusey's hands a Bill for the amendment of his Act relating to owners of entailed estates; and on reference to the article entitled "Land Improvements by Loans from Government or Public Companies" (written by Mr. Denton in one of the second series of the volumes of the "Journal of the Royal Agricultural Society of England") it will be seen that this proceeding was the immediate forerunner of "The Public Money Drainage Act" (9 and 10 Vict., cap. ci.), which was the first of a series of Acts having for their object the improvement of land by means of borrowed capital repayable by instalments. From that time to the present, Mr. Denton has been, as our readers know, extensively engaged in the conduct of works which those Acts were intended to promote.

In 1849 Mr. Denton sent in a design for the "main drainage of the metropolis," which was placed second in the list of 150 designs; that of Mr. McClean, M.P., and past President of the Institution of Civil Engineers, was placed first. But this design, in common with the rest of plans submitted to the Commissioners of Sewers in 1849, was shelved, although the Government referees (Messrs. Simpson, Blackwell, and Captain Douglas Galton, C.B.) stated in 1857, "that the principles upon which Mr. Denton's plan of 1849 was based are, in the main, those adopted by the Metropolitan Board of Works."

Mr. Denton has written many agricultural papers (including lectures delivered at the Royal Agricultural College, Cirencester) on land drainage, water supply, village sanitary economy, road-making, &c., but his principal work is the superb quarto volume entitled "The Farm Homesteads of England," which is quite our standard work on farm architecture. It has passed through two editions, and is now out of print.

A subject upon which Mr. Bailey Denton has shown by his writings that he feels the utmost interest, is the condition of the agricultural labourer—his conviction being that the best means to effect an improvement beneficial alike to employer and employed, will be by technical, *i.e.*, farm teaching, combined with the ordinary education, believing that thereby the farmer will get better work, and the labourer better wages. He read a paper on this subject before the Society of Arts in 1868, and another before the meeting of the British Association at Exeter in the following year.

Mr. Denton's views on the advantages to be gained by the storage of water, especially for rural populations and for villages, and his opinions upon the great questions of town sewerage and sewage utilisation, have been too recently expressed to require mention here.

It will be seen from this very bald enumeration of Mr. Denton's agricultural services, that a considerable share in the origination of some of the most important departments of modern agricultural progress must be attributed to him. To have advocated 30 years ago the under-drainage of land by borrowed capital repaid by instalments, the formation of districts for joint outfall drainage, and the utilisation of town sewage—all of which are now acknowledged fields of useful work—is a fact on which he no doubt now looks back with satisfaction; and to be at present the leading advocate of rational education for the agricultural labourer is a position which cannot fail to bring him even greater credit when his labours in this respect have also borne their fruit.

Mr. Denton is an honorary member of the Agricultural Societies of Norway, Sweden, and Hanover; he has been consulted on works of magnitude in France and Italy, and has advised nearly every European Government on the details of drainage legislation.

A FRIENDLY DISCUSSION.

STEAM CULTIVATION: LEASES: TENANT-RIGHT.

[The annual meetings of the Coggeshall Agricultural Society are always signalised by good speeches from Mr. Mechi and others, in which frank criticism takes the form, sometimes of remonstrance and exhortation, sometimes of banter or even "chaff," never, however, angry or ill-natured; and last week's example is no exception to the rule.]

Mr. F. U. FATTISON presided, and in the course of the evening gave the health of Mr. Mechi, saying: I am sure you will now join with me in drinking most hear-

tily the health of a gentleman on my left who has always favoured us with his company on this occasion, whose presence always gladdens us, and who always has a cheerful face, be the circumstances what they may. Even if you oppose him he doesn't mind it, but seizes the occasion to display his good and genial nature. I have been surprised, indeed, that Mr. Mechi, for it is to that gentleman I allude, has stood the blows he has. However, he does stand them, and no doubt he has gained a vast deal of influence by maintaining so amiable a disposition. We are always pleased to see him here whenever we have a meeting of this character, and I have the utmost pleasure in submitting, this evening, the toast of his health.

Mr. Mechi : I am much obliged to your excellent chairman, whom I am glad to see looking so well, for proposing my health, and also to you for the very kind manner in which you have received the toast. I have always had a great affection for Coggeshall, and for this institution in particular, because I have always received from the members of it, under every circumstance, the most marked indulgence, and when opposition, perhaps, might be expected, it has always been qualified by an excellent personal and kindly feeling ; and I look upon that as a very wise course of conduct, because if you exclude personalities from such institutions as this you are sure to prolong their existence. You cannot destroy an institution if this kind more quickly than by permitting personalities to be indulged in. We are met for a great and a good object. It is to encourage the labourer in good habits and in proficiency in his occupation, and altogether we must look upon these assemblages as tending very much to improve British agriculture. You know I am getting an old man. [No, no.] Well, I am 70 next May.

A Voice : You are only a chicken, sir.

Mr. Mechi : In my early days there were no Farmers' Clubs and no institutions of this character. But I believe I have had the pleasure of attending this meeting now for more than a quarter of a century, and I recollect perfectly well, when employment for the labourer was very difficult to obtain, I saw your prize given for digging. I estimated the time by my watch that it took to dig a rod of ground, and I went back to my farm and had 50 acres of land dug, as a means of employing the people and making profit for myself, at the small charge of £1 6s. 8d. per acre, or 2d. per rod. I found that the men, instead of going to the union-house in the months of November and December, were willing to earn those wages. Times have improved since then, or money has got cheaper. At all events I can say that wages are now not by one less than 50 per cent. increase. That was one good that was derived partially and principally from my visiting this institution. Now we come to a very important question—how can we make farming more profitable, more profitable for the tenant-farmer, for the labourer, for the landowner—because they must all go together—and more beneficial and profitable for the country at large. That question is receiving a solution, for the great and interesting feature of this year, agriculturally, has been the trial at Wolverhampton of the steam-plough and cultivator ; and if you could read attentively the voluminous report of the judges at those trials, it would convince you, as it has convinced me—if I had any doubt about it—that we must look to the employment of steam-power for the future increase and profit of agriculture. There are great impediments to that in the county of Essex. One of them is that farmers don't understand steam, and don't like to face the trouble of having it on their farms. I do not refer to threshing machines, brought to them to be hired, but to the very advantageous condition of having a fixed engine on the farm for the ordinary purposes of labour irrespective of cultivation. I have had one for 24 years, and our people on my little farm of 170 acres would say they would not know how to get on without it. What strikes me as very extraordinary is, that plenty of rich farmers—for there is plenty of money in Essex—Mr. Beaumont and Mr. Barnes, and other gentlemen of that kind, know all —what strikes me as extraordinary is, that these rich farmers don't try the experiment. But the explanation, I suppose, is, that the having a fixed steam-engine on the farm is a new event, because it entails a new arrangement of ideas—it is different from the shoeing your horses and having your blacksmith—and is thus different from the ordinary work of a farm as it has been hitherto carried out. I believe that is the reason that it is not more generally adopted. It ought to be adopted. I see farms of 400, 500, and 600 acres which ought not to be without their fixed steam-engine —that is, quite irrespective of steam cultivation.

Well, now we come to steam cultivation. Among the impediments are, the size of the fields, the incumbrance of trees, and the incumbrance of fences. It is impossible to come from London on this line of railway without being struck by this fact, that small as my fields were originally a vast number of them have been intersected by the railway and cut into halves or into thirds, what was a great evil before being thus rendered still greater. That is a question for the landowner principally; and next for the landowner and tenant combined. I hope and believe that the landlord will find it will be for his interest to give permission to abolish those fences, to do away with those trees, and put the land into such a condition that steam cultivation can be brought to bear upon it. Another thing too must be done—if the land be heavy and wet it must be drained before you attempt to steam cultivate it. There are some very interesting facts in connection with steam cultivation. Some companies have been formed in Yorkshire, in Northumberland, and in other parts, with capitals of from £20,000 to £40,000 invested in steam cultivation, to do the work by contract for the farmers. But you must bear in mind, gentlemen, that in the district in which they are working the fields are 20, 30, or 40 acres each. They could not profitably do it in certain parts of Essex on the same terms. But there is another very great obstruction in Essex—the engines could not cross your rivers, for on every bridge a notice is stuck up that no heavy machine is to go over it. No doubt that is proper, because, as was the case at Battles Bridge, the structure would fall in, and so would the engine ; and when I wrote to Mr. Eddington to say that I wanted some steam cultivation, he replied, "My machines are in Cambridgeshire. I should be willing to come to you, but I cannot. The bridges will not carry our engines." I must here appeal to our magistrates to feel the pulse of the county, and see whether it will be much longer permitted that one of the most interesting and profitable operations of a farm is to be rendered unavailable, simply because the bridges are not put in suitable repair for the passage of engines. I think a rate would not be objected to, and that the magistrates will find they can freely make the necessary alteration.

But, gentlemen, do you know what is doing in regard to steam cultivation ? I have taken great interest in this question. It is now 15 years ago—for it was in the year 1856—that Fowler's steam-plough was first brought on to my farm to plough the subsoil, and some of you gentlemen, I suppose, must have seen it. But look at what is taking place now. An acquaintance of mine in Berkshire has four steam-engines of 30-horse power each. Last year he subsoiled 1,000 acres, and he is going to do a great deal this year his cultivation is a yard deep. That is a very serious question. He is not a small farmer, for he has 4600 acres of land of his own which he farms. I believe he has been wise not suddenly to bring the bad soil to the top, but when I tell you that last year he grew 1000 acres of Sugar Beet for purpose of making brandy, it shows you, I think, that there is something going on in British agriculture. It is very clear from the facts that come before me that the cheaper class of engines are the most costly and the least powerful. I mean the bridge-and-wheel engine. I estimate 10-horse power by a 10-horse engine, although the price may be so much larger at first. I was told the other day that one of Mr. Fowler's first customers who bought an engine of him for £1500 some 14 years ago, as a practical farmer has now bought another for £1500, and it is not an uncommon thing for a man to have two engines at a thousand pounds each as the cheapest way of cultivating his land. I will give you an instance. The evidence we had in the course of the Wolverhampton trials showed that 1 lb. of coal in an engine moved 9 tons of earth. That will show you that steam power is infinitely cheaper than horse-flesh. A horse can lift another horse, or perhaps two, but a pound of coal will lift 9 tons of earth, or put in a pumping engine it will lift a million pounds weight of water and lift it a foot high. I say that if we as farmers do not make the change we must, in time, give up our prejudices in favour of our old customs, we are not quite sensible men of business. I am not quite so sanguine as to suppose the changes are to be very sudden. We know that in the Rochford country, where fields are large, Mr. Carey has several sets of implements that cost him several thousand pounds, and lets them out to the farmers.

But there is one point I would call the attention of our landowners to. Three years ago the Duke of Northumberland had a conference with his tenantry, through his steward, with the view of getting to know what they would do if he were to put a steam-cultivating machine on certain conditions. These conditions were that his lordship was to buy a 12-horse power engine of Fowler's, at £1500 ; they then calculated how much would be the wear and tear, and how much could be charged to each for the use of the machine. An agreement was made and this was the result, that the tenants had their land ploughed at 10s. an acre, it was then cultivated very deeply the next time at 5s. an acre. If it was cultivated a second time after the first cultivation and the ploughing the charge was 2s. 6d. an acre, and the harrowings were 1s. 6d. an acre, which the harrowings are we have with 3-inch teeth — but with machines of 12 and 15-inch teeth. That has been satisfactorily at work for three years. The Duke of Northumberland receives 5 per cent. interest on the money invested ; the machine is kept in order, with a reserve to buy a new one. There was a little difficulty as to who should have it first, and a very wise arrangement was come to : that was that the man who first cleared his 30-acre field and gave notice was to have it, and the next in rotation, and when it became an even question they should draw lots. In that way it has worked extremely satisfactorily ; it has been the means of largely increasing the farmers' profits, and I need not tell you has been a great benefit to the country at large. I am told there are in this country 10,000 locomotive engines running and 200,000 steam engines employed in making our clothes and other necessaries of life. I say that agriculture must take the lead a little more than it has done. We are all inclined to get a little more profit. I don't know a better farmer than our excellent friend, Mr. Catchpool. He has laid his fields open, and what I want to see is that his landlord should make him a covered yard in which to feed his cattle and charge him 5 per cent., and that he should have also a fixed engine for doing his work. I look upon Mr. Catchpool as one of our best farmers, for the reason that he maintains the fertility of the soil. Cow farming generally is a robber of the soil, but the way in which Mr. Catchpool treats his cows enables him while he is milking them to be also fattening them. He feeds them with cake and grains, and at one and the same time is finding milk and meat for the people, besides making the land grow plenty of corn. I have to apologise for taking up so much of your time. I can only say if every one of you gentlemen should procure a fixed engine, the comfort and the profit would be such that having once got it there would not be a man upon your farms who would say you ought to do without it. I thank you for drinking my health. I shall go on as long as it pleases God to spare me to point out our weaknesses. I believe we effect good by doing so, and it is therefore that I do it.

Mr. Catchpool said Mr. Mechi had spoken on the topic of steam cultivation. He, as a farmer, wished that gentleman could have said something about tenant-right ; for he held that it was of no use a man improving the land he occupied to a present extent if, at the expiration, perhaps, of a 14 years' lease, the landowner was to come down upon him and say, "Your land is of very much more value, and you must pay an advanced rent." The tenant, in that case, not only had to find the money for the improvements, but had also to pay a large rent upon it in the shape of increased rent. He quite agreed with Mr. Mechi, generally, that keeping a large number of cows impoverished land, but in the many years they must remember that from March to November people's yards were empty. Many of his farmers were in the habit of feeding their ox or grain per fortnight, which were imported on the farm, and he could not but think it must increase the value of the farm to some extent.

Mr. Dennis, the vice-chairman, quite agreed with Mr. Catchpool that the terms on which farmers held their farms ought to be such as to give a great stimulus from laying out so large a capital on the land as they otherwise would do. There was great insecurity of tenure even upon good estates, because life was very uncertain, and there were not always children to inherit the farms of their fathers. Farmers were never paid for what they laid out, and their children did not reap the benefit, and it was not altogether a matter of surprise, therefore, that there was not the money laid out in agriculture there ought to be. He felt convinced that if they farmed lands which they could occupy for a long series of years they could produce nearly double what they did at the present time. He was not going to bring any charge against landowners, because they had their interests and farmers had theirs. [A Voice : They ought to be identical.] He could not help thinking that farmers were very badly represented in the House of Commons. They had very good representatives so far as landlords were concerned, but what had been done for farmers in the House of Commons for many years past ? He was only aware of two important measures—one was to make rabbits game, and the other to do away with the last shilling on the corn, throwing a million of money away which might as well have been in their pockets now. The tendency of Parliament seemed to be to impose duties on foreigners, and put them all on the farms of the country. With regard to the malt duty, he was not an advocate of taking away it, because he thought the Government could not afford to give it up ; but whenever the malt duty had been brought forward, Parliament had always beat about the bush instead of going right to the heart of the question as they ought. Why did not Government reduce the malt duty, as they reduced the tea duty, in such a way that they could recoup themselves by increased consumption ? In reference to the insecurity of tenure, Mr. Gladstone gave Ireland a Land Bill. Why did he not give the farmers of England a Land Bill ? Had they not been as faithful to the throne, and as anxious for the welfare of this country ? He did not care what government we had, Mr. Disraeli's or Mr. Gladstone's. He was for doing justice to everybody, and he meant to say that the lands of this country would never be farmed in the way they ought until measures were passed to make the farmer's capital more secure on the land than it now is.

Mr. Mechi having added to his original observations a remark in favour of deep draining,

Mr. Barnes, referring to the observations of Mr. Dennis, said that, coming from a practical man, they had convinced him of what he had always thought was the case, that the land of this country had not been made to produce what it ought to produce. In that case the farmers surely had, to a considerable extent, the

remedy in their own hands, for if they could convince the landowners that by better cultivation they could make the land grow double what it now did, and were willing to increase the benefit of the owner to a fair extent, they would have no difficulty in getting long leases.

Mr. Hills said if Mr. Barnes would be kind enough to tell them how to lay their capital out it might be of some use. They knew the land would yield more, but Mr. Barnes' theory seemed to be that the tenant was to get the land in order, and then who was to have the benefit of it? If the country was to produce more that production must come from the tenants, and if the landlords declined to take advantage of the improvement in the land by the tenants, by raising their rents, &c., it would be done. But everybody was afraid to go on—they had to do it gently, and see if any move was made on the part of the landlords. As Mr. Catchpool had said, whenever a farmer got his land into a high state of cultivation the landlord took the benefit of it, and did not consider that the tenant had done it. It was well known that such was the case in this neighbourhood as well as in other parts. [Applause, and a voice, "Quite right."] What they wanted was combination, so that they could have some influence on their landlords, and say to them "Or shall I do it?"

Mr. Beaumont: If you could see the landlords at this end of the table you would be quite astonished.

Mr. Barnes was sorry Mr. Hills had mistaken him. What he intended to convey was this: Mr. Dennis had argued that if a tenant could have a longer lease and could be better protected, the land was capable of producing considerably more. He gathered from that if the tenant, by being secured in his tenancy, could produce more, he would be prepared to give a rent in proportion to the yield.

Mr. Skeridge: On whose capital?

Mr. Barnes said it might be on the tenant's capital, but they must bear in mind that land in this country would never decline in value, but would increase; and if they supposed for a moment that they were going to hire their farms at less rent than they now paid they were mistaken. He was not so stupid as to suppose that a farmer was going to lay out his capital unless he was guaranteed a fair return; but the landlord had his right—he had a right to an increase from the value of his land commensurate with the value of the capital of the country. He knew it might be laughed at and told that he was speaking on the part of the landlords, but he was not, but on the part of that which this great country showed must be the result of wealth and the accumulation of it. They had a right to some guarantee of a fair return upon the capital they expended, but they must expect that if they asked for a 28 instead of a 14 years' lease that they were to have it for the longer period at the same rent as they had for the shorter. The landlord would be justified in asking more, and they must be prepared to pay more. The value of the land would go up considerably in that 28 years, and they must, therefore, give the landlords some inducement for the fixture which they asked. There must be reciprocity in this respect. He was glad to hear what fell from Mr. Dennis as to farmers not being represented in the House of Commons. He wished every class in the country was represented, because then they would get better laws, the interests of all classes would be cared for and thought over, and they should not have the stupid and absurd Acts that were sometimes passed. As to Mr. Dennis' complaint that the farmers were not represented in the House, it was their own fault; they had sufficient power, and if they used it legitimately they might be represented, but if they stood still, and did not do that which all great classes were doing, they must not blame any one but themselves. Only let them show to their landlords that by having fixity of tenure they could improve the land, and afford to pay an extra 5s. an acre for it, and the landlords would be only too glad to grant it, for they desired to make as much of their land as they could; but, considering the accumulation of wealth in this country, they could not expect the landlords to tie down their land for a large number of years unless they had some inducement to do so.

Mr. Catchpool referred to the observation of Mr. Barnes as to the wealth of this country, and asked by whom it was brought about—the landlords or the tenant-farmers?

Mr. Barnes admitted that it was done by the tenant-farmers to a great extent; but they must consider also that the wealth of the tenant-farmer of the present day was very different to what it was some years ago. There were more agriculturists now who knew when the Three per Cents. became due. After some further observations, Mr. Barnes again urged upon the farmers the importance of their looking about them, and seeing after their own interests, and concluded with some exceedingly loyal sentiments with reference to the Queen and Constitution of the country, remarking that he did not think they could possibly have a better form of Government than "Queen, Lords, and Commons."

Mr. Mechi believed that the feeling of the meeting was that there should be a valuation of, and compensation for, unexhausted improvements made by the tenant.

The discussion, throughout carried on in a most friendly manner, having been continued by Mr. Mechi, Mr. Catchpool, and other gentlemen, was eventually diverted by

Mr. Beaumont, who proposed "The Town and Trade of Coggeshall," coupling with it the name of Mr. King, whom he congratulated on having this year established a root show in the town.

Mr. King suitably returned thanks, remarking that he hoped the establishment of his root show would have the effect of leading farmers to endeavour to improve their root crops. He argued against growing roots too large, and said it was much better to grow six moderate sized ones than two large ones. By adopting this plan they got a better quality and more weight per acre.

Home Correspondence.

Milk as a Necessary Article of Food, &c.—If the opinions which I ventured to express in your paper of December 9 fail to commend themselves to the consideration of employers of farm labour, the report of the Brampton Bryan meeting (with a Member of Parliament in the chair) in your last will probably help to convince them that the subject has not been introduced too soon—that its importance is already felt by the labouring class themselves, and that unless some reasonable concessions are made to them on the point, they will soon be knocking at the door, and that, persistently, and perhaps unreasonably, for concessions which many of us will think far from reasonable. Imagine the horror of many a farmer at having six or eight labourers, each demanding the keep of a cow, and not only demanding, but holding the power to enforce their demands. Let me ask, is it for a moment to be supposed that this class, who (in spite of much belief to the contrary, and, indeed, occasionally, appearances to support it) are really intelligent and reasoning beings, will long go on submitting to the privation entailed on their families by the want of this most useful, nay, invaluable article of food—necessary of life as it already, their eyes must soon become opened to its value as an article of diet. Seeing by the light of a superior intelligence and education, one of their first lessons will be the importance of a well arranged and economical diet, with those general principles of health preservation which are now "familiar as household words" in the mouths and minds of the educated and enlightened upper and middle classes; while the public press, teeming with its daily incidents of labour and capital conflicts, will teach them surely how to obtain what they demand. A real grievance is a standing danger; its redress is sure to come, and will probably be made the wedge wherewith to press home the demand for redress of a score more imaginary ones. Two quarts or so of once skimmed milk per day would not be a heavy payment in kind to the cottager, proportioned, as it may be regulated by number of family. I am aware that in many cases such a plan of selling milk to the labourers would be distasteful. The modern gentleman farmer of 500 or 1000 acres, in the magnitude of his capital, investments and returns, and his lady wife, who is, perhaps, ignorant of the value of milk as food and the profits of a small dairy insignificant, and not at all worth the trouble it would entail. Such considerations, however, would not prevail universally. I know a clergyman who is not given to the habit of indiscriminate charity so much in vogue, but who for years four or five days the milk of his cows, once skimmed, he has sold to the poor around him at a halfpenny per quart. I have seen it myself with a rich cream still on it—better than much of the new ordinarily sold in towns. Truly this is the essence of practical philanthropy, as compared with much of the pretentious beneficence that obtains. Try preaching to the poor as to what they ought to do, and lamenting over them that they will not be wise and well off. Most employers would, I think, willingly substitute the shilling a week which some already give for the usual 2 quarts of beer a day. If this milk is not sold, the labourer spend his shilling a week in milk, and contrast the result. At even double the Vicar's price, contrast 2 quarts of good skimmed milk with 2 quarts of such wash as is usually given and called beer. The one is the best of food and the other worth nothing. This is heresy, doubtless; but let us hear what an authority says whom few agriculturists will disregard, Liebig—"Supposing a man to consume daily 8 or 10 quarts of the best Bavarian beer, he will obtain from it in the course of 12 months no more than the same quantity of nutritive constituents contained in a 5 lb. loaf." If this is said of the "best Bavarian," what can be said of the beer usually given throughout the year (excluding the stronger harvest ale)? It is absolutely valueless. But let the substitute—2 or perhaps 3 quarts of milk (and here I would add that once skimmed milk is not so much less in value than new as is generally imagined—the price of the two presents no fair criterion of their value)—be boiled up with just oatmeal enough to thicken it, and then poured scalding over a good proportion of "whole meal," or entire wheaten bread, and the hearts of the poor breadwinning couple would be much more frequently gladdened than they now are by the sight of the "attack" of the young troop, ending in "defeat," the cheeks in the meantime becoming gradually broader, and the ribs less distinct, while the foundation would be laid of a sturdy lot of workmen, who, by their greater power and better constitution, would be well able to earn the extra money that they are even now beginning to claim, and which they will inevitably ere long have to be paid. *J. W. Procter.*

An Old Controversy Revived.—Your notice of "Mr. James Howard" at p. 1659 calls for a few words from me. I read thus:—"In the spring of 1856 Mr. Howard was invited by Mr. Smith to go to Woolston to see his steam cultivator at work." In the spring of 1856 Mr. Howard, having heard what I was at, asked by letter (I have the letter by me) to be permitted to see my cultivator at work. I used him the same as I have done every other man, by permitting him to do so. He then offered to render me any assistance that he could give. I did not need any then, for at that time my implements, &c., were all made. I then read on thus:—"He at once offered to join Mr. Smith in bringing his apparatus before the public. Accordingly, in the same year, at the Royal Agricultural Society's meeting at Chelmsford, Mr. Smith and the Bedford firm were alone in working the Woolston tackle." This is not correct, for I showed my tackle at Chelmsford on my own account, strictly by myself; p. 281, stand No. 131, of the Royal Agricultural Society's catalogue for 1856, will prove it. It is true that he stood by, and that I time to the presence of Mr. Amos a bit of his machinery for him, and that is all he had to do with me at Chelmsford. It was in the autumn following that I procured his aid as a maker of implements, to carry out an order that I had received from Lord Hatherton. Here is another extract:—"From the rapid wear of the rope, that without something more durable than iron wire steam cultivation would be financially a failure, he had one made of steel wire, which, we believe, was the first steel rope ever used in ploughing." This is giving to Mr. Howard more than is his due, for other ropes before he ever made them; besides all that, the credit for the introduction of the steel rope is due to the man who made the steel wire, the mere twisting the rope is but a secondary part of the matter. And here is another extract:—"We have always regarded it as an unfortunate event for the country that the misunderstanding, which occurred about 10 years ago, should have separated two such energetic, though differently constituted, men." For my own part I have no reason whatever to regret our separation; for I now see clearly—&c., &c. William Smith would not stand it, so he cut, and in time was overshadowed; since then Howard has stood upon his own merits—&c., &c. I have done without him, and my light shines clearer without his aid than it ever did with it, for now there is no mixed matter. My operations, costs, and results are known, and clearly before you, and there is no hint over the whole matter as to who aided me. I stand ready to farm 100 acres of clay land against him or anybody else, except those who use my implements, for £1000. *William Smith, Woolston, Bletchley Station, Bucks, Dec. 23.*

Farmers' Clubs.

HEXHAM.

The Relative Interests of the Landlord, the Tenant, and the People in the Soil.—A paper was lately read before this Club on this subject by Mr. Thomas Bell, of Hedley Hall, near Marley Hill, from which we make the following extracts:—The broad subject proposed for discussion is "The interest of the people in the soil." The people we propose to divide into three classes—1, landlords; 2, tenants; 3, the people who are neither proprietors nor cultivators of the soil.

Starting on the premise that all are interested in the soil to the extent of having food and raiment, it naturally follows that we are all deeply concerned whether the supplies of these products be scarce or abundant. Scarcity implies low rents to the landlord, empty pockets to the tenant, and dear food for everybody. It may therefore be safely assumed that the prosperity of any populous country will depend to a great extent on the products of its own soil. The country that imports these commodities must pay for them out of its own resources, and if able to produce them, must be impoverished unnecessarily to the extent that it imports. It must follow, then, until a country has fully developed its agricultural resources it has never attained to its highest possible condition. Taking this, then, as the *summum bonum* of the nation, how can it be best brought about without interfering with vested interests? We may now proceed to consider the interests of the three classes separately.

1. *The Landlord's Interest.*—To a landlord who lets his land, the main point of interest is its capital value. The proprietor has been aptly compared to a banker who lends out his capital to a customer at its market value. The land representing the capital, the tenant the customer, and the rent the interest. To this capital value all landlords in legal possession have an undoubted right, morally and legally. So long as the rights of any sort of private property whatever are mutually upheld and respected, so long will the right of the landlord to the capital value of his land be established. I must confess here that I have failed

to find any other interest in the soil to which the landlord can lay claim as an inalienable right, save this capital value, judging by precedent. Whatever portion of the soil can be proved to be absolutely required for certain public purposes—notably railways—the nation demands through Parliament that on payment of market value the owner must part with all interest in the portion required. The question not so easily settled is, for what public purposes may the nation demand a compulsory sale? Let us briefly glance at a few of the landlord's particular interests in the soil.

Mr. Bell proceeded to refer to the patriotic, political, and sporting interest of the landlord in his land. On the first he said:—Many of our old and noble families owe the possession of their estates to the prowess of their forefathers, who gained those estates either as a reward for gallant service in defence of king and country, or on condition that they would be ever ready when called upon to march at the head of an force they themselves should provide in the face of any enemy. This, as you all know, was part of the constitution of the old feudal system. It is unnecessary to say that the conditions under which these latter estates were held have vanished, leaving the descendants of these brave old warriors in possession, while they are only called upon to render such service as the State demands from their fellow-countrymen. I am not here to justify this state of things, but we will do well to keep the fact before us as we go along.

On the political interest of the landlord he said:—The passing of the Ballot Bill by the House of Commons proves that this power is held by a very uncertain tenure, and also goes to show that none of the other conventional interests at present possessed by the landlords in the soil will only exist so long as the classes under discussion mutually agree as to their possession.

On the sporting interest:—This interest cannot now be classed amongst the undisputed privileges of a landed estate let out to tenantry. It would be sheer the moral right to destroy the food of the nation without the consent of the people. It would easily be understood that were every landlord to convert his estate into a game preserve, the nation would have a perfect right to interfere.

Leading on to landlord's monopoly:—The present law for distraint for rent is one of the effects of this monopoly. What is know as the law of hypothec in Scotland has of late years been the subject of much discussion and inquiry. The Scotch law gives the landlord a much greater claim over the effects of a bankrupt tenant. In certain instances it empowers him to lay claim to the produce of the land after it has left the farm and been bought and paid for by other parties. So long as there was a difficulty in finding capital in the country this law might be advantageous. But now, when capital is everywhere seeking profitable employment, there can be no excuse for protecting the interests of one class at the expense of another.

2. *The Tenant's Interest.*—Assuming that the tenant is the customer of the landlord for his capital, the land, and the capital rent the interest paid for such capital this places us on the purely business relationship which exists between the two parties. Unfortunately this too often explains the whole relationship, it is a matter of money-getting. Although the mercantile aspect of the contract should be always definitely kept in view, yet the landlord and tenant ought to have a mutual interest in each other on account of the great interest they each have in the present and future treatment of the soil. It is only where this mutual interest exists that the highest fertility and greatest productiveness will be found.

The tenant-farmer's annual interest in the cultivated soil of Great Britain is much larger than the landlord's annual interest. We may suppose the average rent of arable land to be about 30*s.* per acre, but look over a highly cultivated farm about Midsummer and consider the interest of the tenant bound up in the soil at that time. It will be found to be from 5 to 10 times greater than the money value of the landlord's annual interest. Indeed, the products now raised cannot be said to be the natural produce of the soil. The old system of farming might be compared to a manufacturer with a natural water-power property, enabling him to set up a certain power of machinery, and produce a limited quantity of goods. The modern system might be likened to the same factory, having added to its natural water-power an additional imported power, multiplying almost indefinitely its capabilities of production. A second question is that if additional power brought to bear upon agriculture by the farmer, that needs the special attention of the nation. Is it desirable that it should be developed and extended? If so, what means would be likely to produce this effect? I would suggest, give the tenant security for his interest in the soil. The interest of the tenant in the soil is at present such that he would not be justified under any but the most favourable and exceptionable circumstances in maintaining the maximum fertility of the soil. Take a farm of 400 acres at a rent of 30*s.* per acre, fair market value, entered upon by an intelligent, practical farmer. It will be above the average of farms if it is not capable of improvement. What Dr. Chalmers has aptly described "The Margin of Cultivation," will not yield a rent if cultivated. It will not produce enough to pay its way. But by putting on additional capital much of the land outside this margin would pay the interest on such capital, yield a rent, leave a profit to the tenant, and a good produce to the nation. Supposing 100 acres of this farm to be lying in poor grass, wet, and valued at 7*s.* 6*d.* per acre. Suppose the proprietor judiciously expends £1000 in draining, fencing, clearing, &c.; this at 5 per cent. increases the rent to 17*s.* 6*d.* per acre. The production of this additional rent oftentimes requires considerable enterprise and energy on the part of the tenant. Such land left to Nature would be really worth little more for the draining for a few years, as a considerable amount of the grasses natural to wet land would die out, and not until the lapse of some years would the finer grasses fill the vacancies. The calculating tenant would say, "This land would pay for cultivation, but it would take a stiff outlay to do it justice. I am not sure of much return for the first few years, but it has a good subsoil, and I am sure it would pay eventually; but who knows whether either I or mine would reap the benefit of this outlay? I could perfectly trust my landlord and his agent. I am sure they would do me justice, but they are mortal. So a king may arise that knows not Joseph, and I may be turned out after I have put all this land into good condition. I certainly have an agreement for a proportion of the time being repaid, and so much for cakes, lones, &c., for the land will do so, and some other items, but that would be a poor return for all my outlay, labour, and anxiety. Why, I am sure in ten years I could make that land worth 27*s.* 6*d.* per acre; it is now dear at 17*s.* 6*d.* My landlord would then be entitled to raise the rent per acre, which, on 100 acres, is £50 per annum I or somebody will receive as the result of my attention. £50 per annum capitalised is worth to me £1000. If I had to leave I probably would not get £100." If the tenant acts on commercial principles, he would here say, "I shall be the gainer by my own investment, I must put no more in than I can take out." The consequence is, the land may never be worth more than 17*s.* 6*d.* per acre. The simple want of security here is permanent loss to all three classes. Suppose the tenant goes to work trusting to his landlord's honour, &c., for the land, and for ten years he has raised the annual value £100 per annum real value (making due allowance for any change in the value of money), which sum capitalised amounts to £2000. Owing to some combination of circumstances the tenant must quit. Now arises the all-important question, who shall be the gainer? The first would say "the landlord's, of course!" Justice would ask who made it? and equity would reply "the tenant." It will be said here, a lease under ordinary circumstances, gives a farmer security that he will be repaid any judicious investments. But we must fairly ask, does farming pay such a large percentage on capital, that the farmer can afford to give up a large proportion of its produce? Assuredly not! Yet that is what is yearly going on is apparent to every observant eye. If a tenant during his lease has expended all his real capital in improving, at the end of the lease he finds he has improved against himself, he is placed on the horns of a dilemma, for he must either buy over again what his own capital has produced, or part with it to another without payment. According to the present law, the tenant-farmer's position, with regard to it, is not equal to the capital in the corn that it produces, or the manufacturer's in that of its fleecy flocks. They are sure of obtaining their raw material at market value, and no matter how they invest their capital for producing food and clothing for the people, they can always command the market value of their goods. Not so with the producer of corn and wool. He may invest his capital to increase the production of food and wool, but what he invests in the soil has no market value to him. What he brings out he gets market value for, what he leaves he has no market for, therefore he is not justified in putting more in than he can take out. The country of Great Britain may be fairly allowed to ask the question, Why do you grant a tenant-right to Irish farmers and leave us out in the cold? This Irish story may help to illustrate the case. An Irish gentleman was residing with a friend, when he received a letter from a tenant requesting to stay overnight: there was a difficulty about accommodation. The good lady of the house said to her resident friend, "We'll have to do our best to make these strangers comfortable, so you, dear old friend, will just take the bed in the garret." "Shure and it's a mighty quare way to be showing your friendship entirely," to the friend; "better be a stranger than a friend here."

Granted that the Irish tenantry needed a tenant-right a little more, it cannot be said they deserved it better. Mr. Gladstone's definition of an unexhausted improvement was happy, and the correct one: "whatever increases the arable value." No details or scales of lime, bones, cakes, &c., used will ever do an enterprising, energetic tenant justice. They take no account of how a man uses his brains in their application. If farmers participated in the permanent improvement of the soil they create, it would give such an impetus to agriculture in England as would surprise the most sanguine. Capital would flow into the soil from the tenantry, when they knew security was given that they should have their share of what it produced. Landlords would have their estates improved with that capital, and participate in the increased value. The landlord's interest must increase with the tenant's improvements, therefore a definite proportion only of the permanent increase of value must be allotted to the tenant. The labour market would be greatly benefited. The produce of the soil would be immensely augmented. Importation of food would be proportionately lessened. Capital that must have left the country as payment of that importation will be left for trade purposes. In short it is capable of demonstration that it would be greatly to the benefit of all classes of society to bestow on the tenantry of Great Britain that interest in the soil which justice demands and an equitable tenant-right would bestow.

3. *The People's Interest.*—Mr. Bell proceeded to discuss this subject, observing in the course of his remarks, on the relations between agricultural and commercial industry:—Unfortunately the tides of commerce and trade have their ebb and flow. So long as they continue to flow all is well, but when the ebb comes then is the fiery ordeal experienced by a thickly populated country, and more especially by that portion who have left the slow but moderately sure pursuits of agriculture for the "glorious uncertainties" of trade and commerce. This tendency to leave agriculture and join the hives of industry is thought by many people to be a source of great evil to us as a nation. We have often pointed to the Swiss and French peasant proprietors with their small holdings as models of thrift, industry, and comfort. So far as I can make out it is not that the provinces of Switzerland and France offer greater returns to the agriculturist than the soil of England, but because manufactures and commerce do not there offer sufficient inducements to cause the peasantry to leave the soil and enter their ranks. It would not be difficult to show that in any country where manufactures and trade flourish, and where there is free trade in food supplies, that land must inevitably fall into the hands of the wealthy, and those who make it their business to add field to field. Banish the love of money from the hearts of men, and things might be different. Suppose a man to be the owner of 50 acres, worth a rent of £75 per annum; suppose him to be further possessed of additional capital to cultivate it, he would probably, on the Government mode of calculating a farmer's profits, add £32 10*s.* to his income by devoting his time and attention to the farming of his own land. A capitalist makes him an offer for his freehold at the rate of 30 years' purchase, which, with the stock in trade, would realise somewhere about £2500. An investment turns up for the money, offering 5 per cent. with good security. Here is a much larger income offered, with the additional value of whatever his time and talents might realize devoted to other pursuits. Trade or commerce might possibly hold out to him a prospect of 10 or 15 per cent. for his capital. No man who aspires after an increase of income would be content with little over £100 a year from his land, when its capital value dangles constantly before him an income of, it may be, several hundreds. This may account for the fact that the yeomanry class of England are gradually disappearing. The calculating, intelligent, small freeholder sells his land, the indolent and dissipated squander it. Under present circumstances the possession of the soil of England to any extent by small freeholders is, to say the least, highly improbable.

A tenant-right, such as we have proposed, would have a powerful tendency to increase the number of tenant-farmers in England. It is too much the custom of the tenantry of the present day to spread their capital over the greatest number of acres they can possibly obtain, and they are consequently obliged to allow Nature to be their principal agent. The experience of farmers urges them in this direction. They find that the men who best develope the resources of the soil do not always make most money, and the reason is not far to seek. Such men permanently improve their holdings with a large outlay, and nothing but the value of a permanent interest in such improvements will adequately repay them. It will be seen at a glance that if compensation were secured to the improving tenant, improvements would rapidly multiply, and instead of capital being spread over too many acres, as it is now, it would be concentrated on what is capable of improvement.

We may inquire if any plan can be devised to bring back to the healthy influences of agricultural labour that portion of society who, though able-bodied, seem either unable or unwilling to find employment. Let us take two facts and place them side by side. Thousands of acres of uncultivated land in England, capable of profitable cultivation, and 200,000 men and women and their families, able to work, yet professing to be out of sufficiently remunerative employment to keep body and soul together. The question is, Can there be no way devised to bring together these two material substances that seem naturally made for each other? Intimately connected with this part of the subject is the question of waste lands and how to deal with them. It is pretty confidently affirmed by many profound thinkers that in the enclosure and appropriation of common lands that have been going on these last 50 years a large proportion of the poor of the several districts have been robbed of their inheritance. It looks, to say the least, suspicious that 3000 or 4000 acres should be parcelled out amongst existing proprietors,

and perhaps 2 acres allotted to the poor. At the same time, the enclosure of commons and making them real property, either individual or corporate, is an undoubted benefit to the country. My experience in connection with an extensive unenclosed common led me to the conclusion that commons are one of the best nurseries for producing a thriftless, indolent, dishonest population —the most certain way of keeping land in its primitive condition, or of having its cultivated portions thoroughly impoverished. Some of that land which before the enclosure was not worth a rent of 5s. per acre has since been let for £3 per acre, and hills and valleys that were literally deserts have been converted into fruitful fields. Where they are conveniently situated, might not land allotments be provided where destitute persons might be able to earn money, and where vagrants would find that food, lodgings, and clothing could be had for working, but under no other conditions? The town of Hexham seems to have, at present, a peculiarly favourable opportunity for trying an experiment on a small scale. I see, from the papers, it is proposed to provide a scheme for disposing of Tyne Green for some public purpose for the advantage of the inhabitants of the town of Hexham. Now, what could be more to the advantage or credit of the inhabitants than their Local Board providing employment on Tyne Green for their destitute able-bodied poor, thereby giving those a chance who were willing to earn an honest wage, and would assuredly keep the town rid of those notorious scoundrels known as professional vagrants.

The North-Eastern Reformatory at Netherton, near Morpeth, affords a striking example of how productive employment may be found on poor land for one class of society that needs to be taken in charge by the nation, viz., juvenile criminals. There 150 lads may be seen drawn from the very scum of society, learning what in their class may be called the art of honest, productive labour. A large proportion of them wear the hue of health on their cheeks, and show well-developed muscles, affording a striking contrast to the pallid cheeks and flabby appearance of the corresponding class to be seen in our workhouses. The institution commenced with 40 acres of land, but a short experience warranted the committee in making considerable extensions, and two years ago they further enlarged their borders, and now farm 364 acres. It is no less a sum than 2,000 worth of this recently acquired land now in process of being broken up to say, that for agricultural purposes it is in its present condition valueless. No manipulation will make it produce a crop that will repay cultivation until the infusion of some powerful fertilising agency. The annual production of about £900 worth of farm material which the farm receives, in addition to the quantity made upon the farm by the extended system of feeding (38 head of cattle were at the time of our visit upon full feed, Turnips, cake, and meal), together with the trenching and system of spade husbandry carried out, is rapidly changing the whole aspect of the place. The farm accounts for the last year show a balance in favour of the institution. About 71 per cent. of the lads discharged are known to be doing well, which fact affords the best proof of the practical benefit the institution confers upon society. It is devoutly to be wished that the Reformatory at Netherton will prove the pioneer of many similar institutions. There the problem has been solved how to provide honest, productive labour on the soil for a class who would never either seek or find it anywhere but under compulsion. Society would rid itself of a great burden by extending this provision to other classes whose liberty of action has furnished proof that they mean to live by preying on their fellow-creatures. It is not beyond the bounds of probability that schemes will be hereafter carried out on a very extensive scale for the cultivation of unreclaimed lands by public companies, who, with Parliamentary powers and Government aid, will buy up such lands, build, plant, and cultivate, not solely for aggrandisement, but from commercial and philanthropic motives combined, composed of persons who will endeavour to make it impossible for any one to say in their hearing or district that they cannot find employment.

Notices of Books.

Elements of Agricultural Chemistry and Geology. By James F. W. Johnston, M.A., F.R.S.S.L. and E. Ninth Edition. Revised and Edited by G. T. Atkinson, B.A., F.C.S. W. Blackwood & Sons.

This little book is, as regards the main bulk of it, as it was when Professor Johnston left it. Of the corrections and additions which it seemed necessary, some are taken from notes left by the late Professor Johnston, others from various sources. An index has been added, and two or three woodcuts have been replaced by new ones.

It is hardly necessary that we take any pains to describe and characterise a work of which more than 10,000 copies have been already sold. That, perhaps, is best done by taking an extract from its pages, and we shall select one on a subject connected with which some controversy has already taken place, both as to the true theory involved, and as to the credit for originality due to the various writers, of whom Prof. Johnston was one of the earliest who wrote on this subject a quarter of a century ago :—

"*Land Drainage.*—"The first step to be taken in order to increase the fertility of nearly all the improvable lands of Great Britain, is to drain them. The advantages that result from draining are manifold.

"1°. The presence of too much water in the soil keeps it comparatively cold. The heat of the sun's rays, which is intended by Nature to warm the land, is expended in evaporating the water from its surface ; and thus the plants never experience that genial warmth about their roots which so much favours their rapid growth.

"The temperature which a dry soil will attain in the summer-time is often very great. Sir John Herschel observed, that at the Cape of Good Hope the soil attained a temperature of 130° Fahrenheit, when that of the air was only 120° ; and Humboldt says that the warmth of the soil between the tropics often rises to from 124° to 136°.

When the land is full of water, it is only after long droughts, and when it has been thoroughly baked by the sun, that it begins to attain the temperature which dry land under the same sun may have reached, day after day probably for weeks before.

"2°. Where too much water is present in the soil, also, that portion of the food of the plant which the soil supplies is so much diluted, that either a much greater quantity of fluid must be taken in by the roots—much more work done by them, that is—or the plant will be scantily nourished. The presence of so much water in the stem and leaves keeps down their temperature also, when the sunshine appears, and thus checks the supply it makes from their surfaces—a lower natural heat, in consequence, prevails in the interior of the plant, and the chemical changes, on which its growth depends, proceed with less rapidity.

"3°. By the removal of the water, the physical properties of the soil, also, are in a remarkable degree improved. The soil becomes more easily reduced to a fine powder, but it naturally, and of its own accord, runs together when water is poured upon it. So it is with the clays in the field. When wet, they are close, compact, and adhesive, and excellent for retaining the roots in growing plant. But remove the water and they gradually contract and crack in every direction, become thus open, friable, and mellow, more easily and cheaply worked, and pervious to the air and to rain-water.

4°. The access of this air is essential to the fertility of the soil, and to the healthy growth of most of our cultivated crops. The insertion of drains not only makes room for the water, and thus causes it to leave the soil, but actually compels the air to penetrate into the under parts of the soil, and renews it at every successive fall of rain. Open such outlets for the water below, and as this water sinks and trickles away, it will suck in fresh air after it, and draw it into the pores of the soil wherever itself has been.

"Vegetable matter becomes of double value in a soil thus dried and filled with atmospheric air. When ploughed in, and otherwise made to undergo its ways, it will thus to supply more rapidly what the several parts of the plant require. Hence, on dry land, manures containing organic matters (farmyard manure, &c.) go farther or are more powerful as to the farmer.

"5°. Nor is it only stiff and clayey soils to which draining can with advantage be applied. It will be obvious to every one, that when springs rise to the surface in sandy soils, the bottom of the pan made to carry off the water will also readily occur, that where a sandy soil rests upon a hard or clayey bottom, drains may likewise be necessary; but it is not unfrequently supposed, that where the subsoil is gravel or gravel, thorough draining can seldom be required.

"Every one, however, is familiar with the fact, that when water is applied to the bottom of a flower-pot full of soil, it will gradually rise its way through. In the garden, however light the soil may be. So it is in sandy soils or subsoils in the open field—all possess a certain power of sucking up water from beneath. If water abounds at the depth of a few feet, or if it so abounds certain seasons of the year, that water will rise towards the surface; and as the sun's heat dries it off by evaporation, more water will follow to supply its place. This attraction from beneath will always go on when the air is dry and warm, and thus a double evil will ensue—the soil will be kept moist and cold, and instead of a constant circulation of the downwards, there will be a constant current of water upwards. Thus will the roots, the under soil, and the organic matter it contains, be all deprived of the benefits which the access of the air is fitted to confer, and both the crops and the farmer will suffer in consequence.* The remedy for these evils is to be found in an efficient system of drainage.

"6°. It is a curious and apparently a paradoxical observation, that draining often improves soils on which the crops are liable to be burned up in seasons of drought. Yet, upon a little consideration, the fact becomes very intelligible. Let *a b* be the surface of the soil, and *c d* the level at which the water stagnates, or below which there is no outlet by drains or natural openings. The roots will readily penetrate to *c d* ; but they will in general refuse to descend farther, because of the unwholesome substances which usually collect in water that is stagnant. Let a dry season come, and their roots having little depth, the plants will be more or less speedily burnt up. And if water ascend from beneath the line *c d*, to moisten the upper soil, it will bring with it those noxious substances into which the roots have already refused to penetrate, and will cause the crop to droop and wither. But put in a drain, and lower the level of the water to *e f*, and the rains will wash out the noxious water from the subsoil, and the roots will descend deep into it ; so that it a drought again come, it may pass by the soil above *e d*, as before, without injuring the plants, since now they are watered and fed by the soil beneath, into which the roots have descended.

"7°. In many parts of the country, and especially in the red-sandstone districts, the oxide or rust of iron abounds so much in the soil, or in the springs which ascend into it, as gradually to collect in the subsoil, and form a more or less impervious layer on it, over which the roots cannot penetrate, and through which the surface-water refuses to pass. Such soils are benefited for a time by breaking up the pan where the plough can reach it ; but the pan gradually forms again at a greater depth, and the evils again recur. In such cases, the insertion of drains below the level of the pan is the most certain mode of permanently improving the soil. If the pan be now broken up, the rains sink through into the drains, and gradually wash out of the soil the iron which would otherwise have only sunk to a lower level, and have again consolidated into a solid cake.

"8°. It is now less common, even in rich and fertile districts, to see crops of Beans, or Oats, or Barley, come up strong and healthy, and shoot up even to the time of flowering, and then leaves and stalks wither, and at last they more or less completely die away. So it is rare in many places to see a second year's Clover crop come up strong and healthy. These facts indicate, in general, the presence of noxious matters in the subsoil, which are reached by the roots at an advanced stage of their growth, but into which they cannot penetrate without injury to the plant. The drain calls in the aid of the rains of heaven to wash away these noxious substances from the soil, and of the air to change their nature, and this is the most likely, as well as the cheapest, means by which these evils can be prevented.

"9°. Another of the great circumstances itself to the practical farmer. Saline substances are in certain quantity beneficial, nay, even necessary to the growth of plants. In excess, however, they are injurious, and kill many valuable crops. I have already referred to the existence of such saline substances in the soil, and to the fact of their rising in incrustations to the surface when droughts prevail.

In some countries, as in the plains of Athens, and near the city of Mexico, they come to the surface in such quantity as actually to kill the more tender herbage, and to permit only the stronger plants to grow. In the plains of Athens, when the rainy season ends, a rapid evaporation of water from the surface begins. The water, as it rises from beneath, brings much saline matter with it. This it leaves behind as it ascends in vapour, and at length so accumulates in the surface-soil that tender grass refuses to grow, though the stronger Wheat plant thrives well and comes to maturity.

"This result could scarcely happen if an outlet beneath were provided for the waters which fall during the rainy season. These would wash out and carry away the excess of saline matter which exists in the under soil, and would thus, when the dry weather comes, prevent it from ascending in such quantities as to injure the more tender herbage.

"It may be objected to this suggestion, that drains in such countries would render more dry a soil already too much parched by the hot suns of summer. It is doubtful, however, if this would really be the case. Deep drains, as in the case above explained (6°), would enable the roots to penetrate deeper, and would thus render them more independent of the moisture of the surface-soil.

"10°. On this subject I shall add one important practical remark, which will readily suggest itself to the geologist who has studied the action of air and water on the various clay-beds that occur here and there, as members of the series of stratified rocks. There are no clays which are not gradually softened under the influence of air, of frosts, and of running water. It is false economy, therefore, to lay down tiles of the common horse-shoe form without soles, however hard and stiff the clay subsoil may appear to be. In these cases the tiles of the first few years, the stiffest clays will generally soften so much as to allow the tile to sink to some extent—and many very much sooner. The passage for the water is thus gradually narrowed ; and when the tile has sunk a couple of inches, the whole may have to be taken up. Thousands of miles of drains have been thus laid down, both in the low country of Scotland and in the southern counties of England, which have now become nearly useless. The extending use of the pipe-tile will, it is to be hoped, gradually lessen the chances of pecuniary loss which the above practice involves."

* A few miles south of the town of Elgin, in Morayshire, I was shown a tract of land on which the crops were usually three weeks later than on another tract, separated from it by a small stream. Beneath the former was a pan at a depth of 3 feet, which prevented the surface-water from sinking beyond that level, and thus retarded the growth of the crop.

Farm Memoranda.

WEST SUSSEX : *December* 16.—We have now got to the dullest time of the year for the farm. Wheat is all sown, and coming up very slowly. The weather has been very sharp for some time : we have not had much snow, but a long continued dry frost, which has now given place to dull, mild weather. Our fat stock and root show has passed, and as usual is going down ; there were only eight or ten beasts, four or five pens of sheep, with two of pigs, but they were all good. It is remarked by the local papers as a strange thing that there should be one of the smallest shows connected with one of the largest markets in the south of England, but West Sussex is not over lively in any public matter. There is plenty of good land, and, as a

rule, it is well farmed, but everybody appears to mind their own business and leave national affairs to shift for themselves. Work is all well forward, and perhaps the labourer will not be so fully employed as he sometimes is.

By-the-by at this time we hear a good deal of talk about treating the agricultural labourer better in every way than he is at present. One party says give him a better cottage, a bit of land, a cow, and a pig. Well that is all right, and it is well that the labourer is so well cared for, but some of our advisers might turn their attention a little nearer home: some of them may have property in towns, and how about the accommodation there? Why, by the side of a hedge, without a cover, in the country is the better of the two, and that of many in towns. Now we have had plenty of advice from "men who live far off in large towns," and perhaps we needed it, but now it is time to say "Physician, heal thyself." Surely it is somebody's business to look after the habitations (?) in towns, and might we not recommend them not to waste as they do, and to see that their cottagers are properly housed, and have three bedrooms and two or three downstairs for each family? Would not this be a revolution? And if not, why not?

But this is hardly a report of West Sussex farming, only, as there is not much at this season to report, and as it is the time for wishing well to all, and as cottagers in West Sussex are pretty well provided for in the way of room, we can only wish everybody as well off in this respect.

When we are advised to farm better, we become debtors to that; but when it is pay and house your labourers better, we can return that advice, and pay off our score. Of course, "Our Own Correspondent" may come among us, and find many things not as they ought to be, and he can get about among us without fear; but in the districts east of the locality where the city cottages are built, certainly not unless the pair of policemen are near. And now we will promise to attend to the gratis advice that we have so often received for the next year, and let all our aristocratic and city monitors turn their attention to their own more urgent cases. *G. S.*

BANFFSHIRE, BOYNE DISTRICT: *December* 25.—We are enjoying excellent weather for the season of the year, consequently farm work is well forward. Late-ploughing is almost finished, and during last week many of the farmers having clay land in Turnips have ploughed all that was clear, as it was in excellent condition, and will get a chance of the frost to pulverise it before sowing time.

We can now boast of a steam-plough in Banffshire, and in the "Borgs," too. Tochineal, so long once famous for its whisky distillery, is now famous for its being the first in this county to have a steam-plough. The soil is a very stiff clay, but the fields are large and open, having water at almost every corner of them. The tackle was supplied by Amies & Barford, and is doing its work in good style, and is being visited daily by farmers from a great distance, who pronounce the work done to be very satisfactory; besides the plough there is a Smith's cultivator and harrows. Our neighbours, the Aberdonians, have taken the hint, and are taking the subject under consideration, and we believe, before another year goes, five or six sets will be in operation in that county. Two or three are ordered from the makers already; one, the same as the Tochineal set, is ordered for the farm of Mains of Towie, in Auchterless parish, and is to be forwarded for spring work. "The canny Scots are slow but sure."

The past two frosty winters have taught a useful lesson on the Turnip crop. The greater part of the crop in this district is all secured in many different ways. Like other counties we have a great many cases of foot-and-mouth disease, otherwise our live stock is doing well and paying; and although prices are now somewhat down, if not rack-rented, with beef and grain as it is, a living can be made. Draining is the principal improvement which is going on in this district, which creates a great deal of labour for the working class, who have been very fortunate, having had steady work since harvest, and good wages. So on this excellent Christmas day I wish you, Mr. Editor, and all the readers of the *Gardeners' Chronicle and Agricultural Gazette*, a Happy New Year. *William Foss.*

SANDRINGHAM.—[We abridge the following report by the Special Correspondent of the *Times*, which appeared in that journal of Wednesday last.]

The Sandringham estate consists of about 8000 acres, and includes the parishes of Babingley, West Newton, and Wolferton, with part of Deringham. It is rich marsh land where it joins the sea near Wolferton; black sand upon car-stone towards the middle of the estate, and light loam upon chalk, adapted for Barley and roots, at the east end, towards Anmer. The estate was purchased in the year 1862.

At Sandringham and West Newton, we find about 7 or 8 feet usually of the black sand upon car-stone. In 1861 this village contained, according to the *Diocesan Calendar*, a population of 300. The census of April, 1871, shows a population of 330, but an enumeration of the population which I was enabled to take on Saturday, the 23d current, showed a population on that day of 295. This points at once to what has evidently been a source of some of the troubles of the village—an influx of lodgers into a village not fitted to receive them, although it has since the Prince came into possession of the estate rapidly grown into more favourable residential conditions.

Attention has been prominently drawn to some ill-built and badly-arranged cottages. They do not present a fair sample of the present state of the village, but, as the whole facts are known, is it possible to draw a just deduction from that which has been said concerning them. The number of inhabited houses this day in West Newton is 62. In this village, however, there are two small freeholds belonging to small proprietors, and on which are erected in all 16 cottages, so that under the Prince's proprietorship 175 per cent. in the amount of sleeping room. The improvement in quality is even more marked than the increase in quantity. Of the new cottages in the village there is a row of eight, called the Alexandra Cottages, a group of nine called the Louise Cottages, four cottages designed for old people, and a group of four cottages not yet named.

Of these the Alexandra Cottages were first built, and a brief sketch of these will answer also for the Louise Cottages, which very much resemble them. They are all two-storied cottages, built in the rustic Gothic style, of passing elevation, provided with a porch and ample accommodation, built of car-stone, with white and red brick facings, having 14-inch walls, with concreted foundation. Each cottage has on the ground floor a front living room, about 12 by 14 feet, and 9 feet high, well lighted; a back kitchen provided with an excellent cooking stove, and a good larder, a pantry, and coal-house; above are three good bedrooms, two with fire-places. Detached from the house is a brick out-house, with kindling shed and sanitary conveniences. Each cottage has 30 perches of garden ground, and some of them have as much field allotment.

The water supply—and here we come to the weak place in the arrangements—is from a well 16 feet deep, cut through about 8 feet of sand, and then on the carstone; it is brick built, and within 20 feet of the cesspool, and is within 7 feet of a midden or kitchen heap. The purity of this water has been impugned; and, from the analysis which has been published, it would appear, not without good reason. The Louise cottages are built precisely on the same plan, except that here the Prince further advantage of having well spouted roofs, which collect the rain-water, and that each house is furnished with a pump connected with the sunken and covered rain-water tank. The well here is 23 feet deep, and on Saturday contained 7 feet of water. The garden houses are 100 feet from the bottom of the garden, and more better placed than at the Alexandra Cottages, where they are too near the houses. The cottages for old folks have the bedroom on the same floor as the living-room, and are altogether arranged for the comfort of the old people who are placed in residence. They afford evidence of the characteristic kindness and liberality which preside over all the arrangements of the estate. The rents of the Alexandra and Louise Cottages, with all their comforts and conveniences, and with their five rooms, garden ground and allotments, are not higher than were those of the two-roomed hut which they have superseded, and the improvements still existing in the village on the small freeholds to which I have referred.

In going through these new cottages it was pleasant to find them for the most part clean and well kept, and sometimes singularly neat. Many of the garden grounds, also, were evidently properly valued and carefully cultivated. But not all, and it is evident that some of the cottagers do not appreciate at its worth all that is done to help them and to enable them to help themselves. I was told, however, that a considerable improvement in this respect has been effected all over the estate by the influence of a Cottager's Garden and Flower Show for the estate, which is annually held in the Park in September, under the auspices of the Prince and Princess and the clergymen and leading tenantry. Prizes are given to the value of £40 for the three cleanest and neatest cottages and gardens in each parish on the estate.

The report then proceeds to discuss the vital statistics of the village. It appears that there has been no fewer than 10 deaths from typhoid and scarlet fever in 1871. I find that in 1869 there was only one death in the parish, and that from an accident. In 1868 there were eight deaths, of which three were from diphtheria. Moreover, there has not been any death either from typhoid or scarlet fever in any of the 25 new cottages which the Prince has built. No case of typhoid has occurred in them at all, and this is especially significant of good residential and sanitary conditions, although, unless the quality of the drinking water be carefully examined, no one can say that it might not occur. What is still more significant is, that although scarlatina was imported into the village and ran through all the Alexandra Cottages, no death occurred. The most excellent residential conditions and purity of air, soil, and water, will not afford immunity from "catching" diseases such as scarlatina, which can only be successfully dealt with by isolation; but cleanliness and purity of air and hygienic conditions greatly lessen their mortality, and this is the moral which may be drawn from the comparative immunity from death of the Prince's tenants in these cottages.

The black spots of the village are in the cramped and sometimes over-crowded portions, over the greater part of which the Prince's agent has no control. Thus one of these small properties contists of two blocks, one containing four and the other three cottages. Three out of the first four have only a single bedroom. In one of these cottages there have been living father and mother, an adult daughter with her two illegitimate children, and five of her brothers and sisters, from a lad aged 16 to a child aged five—in all ten. In a double cottage on this freehold—or, rather a cottage divided in two—there lived in one half-cottage, having a living room about 12 feet square, and a sleeping room over it, a family consisting of father and mother, eldest son of 21, married daughter and son-in-law, and five little children—in all five adults and five children. The two rooms thus crowded appear to have been poisoned with contiguous filthy nuisances, and in January, 1871, the eldest son, aged 21, was attacked with typhoid fever, and died; in March the mother, aged 43, and in April the married daughter, aged 20, died of the same disease—filth fever, as it is emphatically named by Dr. Murchison and Mr. Simon.

Experience teaches us to look for pollution of the wells and water supply in every outbreak of typhoid fever as the most common cause of the disease. Mr. Barrett, of Grimston, the Poor-law medical officer of the district, makes the following valuable observations on this subject:—

"As to the depth of the wells, there are at least two waterbearing strata, besides that supplying the surface water; for at the top of the hill the water is 15½ feet from the surface, while near the bottom of the hill it is 32 feet from the surface. Lower still, the water is only 2 feet from the surface. So the wells are not all shallow.

"There have been two epidemics of typhoid in the village, one beginning in 1860, the other in 1870, each in the month of September. In each outbreak of fever there were two different centres of the disease, each centre using a separate well. There were, therefore, four different well's open to question, which I will name after the people using them, giving the measurement from the ground to the top of the water:—Dye's, 15½ feet, shallow, near bottom of hill; Melton's, shallow, now replaced by a deeper one, top of hill; Boughen's, 2 feet, bottom of hill; Smith's, 9½ feet, on the fall of the hill.

"Smith's water has been analysed, but neither Boughen's nor Dye's; and if we are to look to the wells for the source of this disease, it would be interesting to know what their analysis would reveal, especially as each comes from a different stratum."

The circumstances connected with the supposed outbreak of diarrhœa and enteric fever among the visitors to Londesborough Lodge have directed public attention to the fertile source of disease in the pollution of air and water by sewer gas, from ill-ventilated drains, and from the ill-arranged inlets of sewers within dwelling houses. It is to be hoped that the present report on enteric fever in West Newton will serve an equally beneficial purpose by attracting equal attention to that well-known, but much neglected source of typhoid, diarrhœa, and cholera—the pollution of wells by penetration of foul matter through the soil.

Typhoid fever, it is known, is essentially the fever of the country as typhus is that of great cities. It attacks every year in this country about 100,000 people, of whom it kills from 20,000 to 25,000. They for the most part absorb the poison by drinking water polluted with sewage.

The report concludes with a reference to the great improvements effected in the estate since Sandringham became the property of the Prince of Wales. The large number of new cottages which he has built have every comfort and every provision for health and domestic propriety. They have been built at a considerable expense; they are let at very moderate rents. The rate of earnings has risen considerably meantime, from the increased demand for labour. Every inducement is held out to neatness, cleanliness, order, and good conduct. West Newton has been provided with a school, towards which the Prince and Princess of Wales contribute half the cost of maintenance, besides many little encouragements in the way of school feasts, at which they personally attend and take their share in making the little ones happy, as well as annual gifts of cloaks. The Princess, during her residence at the Hall, comes frequently to the schools and takes a class, and the little ones are well accustomed to her kindly and gracious presence. For the

sick there is an organised system, by which doctors and clergy alike can and do draw directly upon the Hall for every comfort which is needed, and for the minor luxuries which alleviate sickness and hasten cure. A spirit of intelligent thoughtfulness and kindness pervades the whole management of the estate. The schools of Sandringham parish are maintained not less liberally than that of Newton. Of the game which is shot upon the estate a large part is presented by the Prince's direction to the county and other hospitals. What is done is carried out merely by the efficient execution by General Knollys and Mr. Beck, and by the rectors of the parishes, of the Prince's general directions. It is done indeed in great measure under his own supervision, by his own wish, and according to his own plans, and the great improvements which have been made on the estate are due to his own active fulfilment of the highest duties of a landed proprietor.

The Week's Work.

DECEMBER 30: *Farm Accounts.*—With the close of the year tradesmen's bills are paid, new inventories made, and the books balanced. The increased expenditure in cake and manure bills, the amount of capital invested in implements and machinery, and the annual outgoings for repairs, as compared with former times, which the balance-sheets of some farmers show, would hardly be credited. The inventory for the ensuing year requires to be carefully made, otherwise the accounts and balance-sheets are worse than useless. The assumed calculations of farm capital actually invested too often lead astray as to the capital required per acre on farms of different sizes, qualities of land, and modes of farming, from a too hurriedly made out inventory. The productive state of the land from cultivation, the quantity of manure on the land, and the tear and wear on implements and machinery, including the tear and wear on the teams, are questions that require a careful solution before anything satisfactory can be arrived at. Two plans in use present an interesting contrast, viz., the fireside calculations of the amateur, and the off-hand estimate of the farmer who keeps no books at all, but who concludes that he is worth so much more or less than he was last year, or he may be worth about the same, and however that latter is not all of date, it, in nine cases out of ten, merits more confidence practically than the former. The contrast evidently shows that were the farmer's books properly kept the conclusion would be the other way.

Trenching and Planting, reclaiming waste land, and deepening shallow, rocky, and stony soils already under the plough, by trenching that cannot be done by steam or horse power, are works favourable for the close of the old year, and commencement of the new, weather permitting. In most places hands are more easily got now than earlier, and wherever such is the case, the works of trenching and deepening should be pressed forward with all the strength at command in places where not frozen out. Large areas of waste land are too full of stones and the like to be broken up by the plough, but may be profitably trenched, and what will not pay for being kept permanently under ordinary crop cultivation may be planted with young trees suitable to the soil and climate, or with Gorse, should such pay better. Shallow rocky soils are deepened, either by trenching out the rock or by carting on fresh soil, and not unfrequently both—the former (trenching) being necessary to expose portions of the rock that are not to the surface, and the latter (earth) carted on to level and supply soil sufficiently deep for tillage and the roots of plants. In some rocks the roots penetrate freely into crevices, but even in such cases the staple should not be less than from 15 to 18 inches in depth.

Thorn and Beech Hedges plant as soon as the thaw comes. The land, if wet, should have a drain on each side from 6 to 8 feet from the hedge—it should be trenched 2 feet deep, and be well manured with lime compost. The healthiest hedge grows on the flat, but banks and ditches are sometimes necessary to protect them. If planted on a bank between two open ditches, trenching may not be required unless there is moorband; but grown thus the young plants are more exposed, and stand more in need of manure. Some plant two rows vertically on the top, others level the bank when half made, lay two rows of plants horizontally, with the roots to each other, and cover when finishing the bank. The former is the more natural, as the roots will not grow horizontally; but the latter is best for soils that require the roots to spread over a greater surface.

Carting push forward at every opportunity.

Brood Mares.—What was said of *Farm Horses* on the 23d inst., and something more, applies to brood mares, for they often endure enough hardships at this season to kill them, and this happens as frequently to those not worked as to those daily in harness. The foetus now begins not only to draw largely upon the daily sustenance of the mare, but also to weigh heavily upon her physical energies in a twofold manner when she is in harness. Mares kept for breeding only generally suffer, not more from the changeable nature of the weather than improper food and household accommodation. Field grazing, with open yards and hovels to go under at night, are out of date; what the brood mare requires is rich but not bulky food, in a well-ventilated and lighted loose-box, with gentle grooming and moderate exercise daily.

Ewe Flocks always require careful attention at this time of the year, and both before and after lambing, in our southern counties. Those out-of-doors will require more hay and corn in the field. Lambing ewes should be fed indoors, and afterwards never allowed a run of the flushy green pastures with an empty stomach.

Obituary.

WE regret to announce the death of Mr. T. E. PAWLETT, of Beeston, Sandy, Beds, in his 72d year. He was a well-known breeder both of cattle and sheep; his Leicester flock not only stood very high in the showyards, but was much sought by breeders, and realised a high average when dispersed 12 years ago. The herd of Shorthorns for which he has since 1860 been well known both at the Royal and county meetings was started with some of Mr. Adkins' Charmers, and a dash of Duke blood from Mr. Phillips. These were sold off, and the present herd is bred entirely from two Booth families, the well-known "Mantalini" and "Fame" tribes. As Mr. Pawlett leaves no issue, it is understood his entire effects will come to the hammer during the spring, including, of course, his herd of Shorthorns, containing several prize winners and choice animals by Booth bulls.

Mr. Pawlett was an occasional contributor to our columns, and to the pages of other agricultural periodicals. He was an observant and considerate man, and his thoughtful and careful reports, whether of direct experiment or of past experience, belonged to the very highest class of such writings, being the result of patient and conscientious work by a most trustworthy and practical man.

Notices to Correspondents.

COWS: *Carry.* The cows have been probably already nine months at the pail, and being due to calve in April and May next they are naturally drying off their milk. Some cows will milk on to near calving, but it is not desirable they should. Perhaps if you were to give them Swedes or distillers' grains in place of a portion of the hay, and more Mangel, or other succulent food, they might be less prone to get prematurely dry.

FARMYARD MANURE: *F. W. Arundell.* Dr. Voelcker's writings have corrected the prevalent teaching on this subject. Farmers have always spread manure broadcast over grass land and over arable land without much hurry to cover it in in the better case, and they had always been advised by scientific men for the practice. Dr. Voelcker has, however, shown that the process of destruction and evaporation which goes on when manure is spread is very slow indeed, that there is very little loss of ammonia during it, and that the rain washes into the land anything soluble almost as rapidly as it is formed. The process of destruction will be almost entirely suspended during frost, and you may therefore lop-dress your land in winter without fear.

STABLE DUNG: *Cheltenham.* Five-fanged dung is very much injured. The best way to save the stable dung is to throw every day's portion on to the end of a ridge-formed heap standing on about 4 yards width of land, and piled as ridgewise as steep as it will lie, covering it up on both sides with earth as it daily lengthens. It keeps the manure of its full original goodness, and saves it from the injury of five-fanging, which is owing to excessive local fermentation.

Markets.

SEED MARKET.

Our markets are now quite of a holiday character, and the business passing is in consequence exceedingly limited. It is quite certain that of English Clover seed the crop is very small, and the quality for the most part unusually poor. From France little or no seed can be expected. Germany has also her deficiency for her large importations from the States. America will, without doubt, be the chief source of supply during the approaching season. Cable advices just to hand from New York describe the market there as very firm. Alsike, white Clover, and Trefoil seed are held at extreme rates. For winter Tares there is no demand whatever. Foreign Italian and perennial Rye-grasses are steady, and the high rates recently touched. For Hemp and Canary the trade is very quiet. Blue Peas are cheaper. Linseed is in good request. Rape and Mustard are dull.

JOHN SHARP & SONS, Seed Merchants,
37, Mark Lane, London, E.C.

MARK LANE.

WEDNESDAY, Dec. 27.

The grain trade to-day ruled heavy. There was a small show of English Wheat, and from abroad also the supplies were limited. In both red and white produce sales were effected slowly, at about previous currencies. Barley was purchased to a small extent at drooping prices. Malt was dull, and occasionally cheaper. The supplies of Oats on the stands were good. Trade was quiet, and prices in some instances were slightly reduced. Beans and Peas were difficult to dispose of on former terms. For Flour there was scarcely any inquiry, and prices remained nominal.

METROPOLITAN CATTLE MARKET.

TUESDAY, Dec. 26.

This being Christmas week, the market is held to-day instead of Monday; it is of a very unimportant character. The supply being very short, however, has caused a rise in price in many instances; our top quotations are in some cases exceeded. Our foreign supply consists of 200 Beasts, 500 Sheep, and 31 Calves; from Scotland there are 23 Beasts; from Ireland, 200; from Norfolk and Suffolk, 30; and 97 from the Midland and Home Counties.

Beasts, 550; Sheep and Lambs, 1320; Calves, 42; Pigs, 15.

THURSDAY, Dec. 28.

The supply is usually short on this day, but the numbers this year are smaller than for some years past. The demand for both Beasts and Sheep has exceeded the supply, and consequently prices are higher for all kinds of stock. Our foreign supply consists of 95 Beasts, 700 Sheep, and 27 Calves.
